List of Figures

- **Figure 1: How Stable Is the Quantum System?**
  A 3D surface plot shows how stable a quantum system is (its fidelity) depending on two settings: how time flows (α) and how fast it breaks down (γ). It reveals when the system starts to fall apart and when it can stay together.

- **Figure 2: How Long Before the System Collapses?**
  This figure predicts how long a quantum system can last before collapse, based on how much noise (γ) it experiences and how its internal clock (α) is tuned.

- **Figure 3: Lawrence vs Schrödinger (When There's Noise)**
  A comparison of Lawrence and traditional quantum evolution under noise. The Lawrence model retains coherence longer, resisting collapse more effectively.

- **Figure 4: Lawrence vs Schrödinger vs Lindblad**
  Comparison among three evolution approaches: Lawrence, Schrödinger, and Lindblad. Lawrence shows smoother breakdown and better control over decoherence.

- **Figure 5: Entropy and Fidelity Together**
  Entropy (disorder) increases while fidelity (stability) decreases over time. This dual plot helps explain the timing and nature of quantum collapse.

- **Figure 6: When Decoherence Happens in Space**
  Entropy growth over time from a spatially localized $\gamma(x)$ field. Confirms that targeted decoherence induces collapse in specific spatial zones.

- **Figure 7: Testing Alpha Alone (No Collapse)**
  A control experiment with $\gamma = 0$. Even extreme α values do not cause entropy growth, confirming that only γ drives collapse.
