Abstract

Pediciinae crane flies belonging to the genus *Dicranota* Zetterstedt, 1838 of the Korean Peninsula were studied beginning in 1933, but only seven species have been recorded from North Korea so far; the genus was unknown from South Korea. Seventeen species were found during our studies on the Peninsula, three of them described as new: *D. (Eudicranota) distincta* Podenas, **sp. nov.**, *D. (Rhaphidolabis) seoi* Podenas, **sp. nov.**, *D. (Rhaphidolabis) yeongokia* Podenas, **sp. nov.** Ten new species are added to the Korean species list, five of them new for North Korea with total number reaching twelve, and eleven species new for South Korea. Habitat, elevation range, and seasonality data is presented for each species. Images of taxonomically important morphological characters, distribution maps, and an identification key for all Korean species of the genus *Dicranota* are presented.

Key words: East Palaearctic, habitat, key, Pediciinae, taxonomy

Introduction

Research of Korean crane flies is on-going since 2012, when it was started together with researchers from the National Institute of Biological Resources. The aim of the study is to register, redescribe, illustrate, and prepare keys for all Korean species. We decided that redescrptions, illustrations, and keys should be based on Korean specimens, because variation of morphological features was noticed in crane flies belonging to same species but collected in different localities across the Palaearctic. Forested mountains cover more than two-thirds of South Korea's territory. Even though they are not very high, most of them are granitic with many beautiful small and fast running streams and springs. Larvae of Pediciidae (Pediciinae) crane flies belonging to the genus *Dicranota* Zetterstedt, 1838 develop on the bottom of these aquatic habitats. They prefer clean cold water and are predatory feeding on different small invertebrates. Adults fly nearby and hide in herbaceous vegetation during the day, becoming more active in the dusk, and some species are attracted to light. They are often met flying together with other Pediciidae crane flies, especially *Tricyphona* Zetterstedt, 1837 and could be separated from them based on wing venation, especially the short radial sector. The first *Dicranota* specimens from the Korean peninsula included

in this publication were collected more than 90 years ago, while the oldest specimens from neighbouring countries, especially Japan, were obtained more than 100 years ago. Despite intense work on Korean crane flies for many years, only seven *Dicranota* species had been recorded from North Korea, and the genus was unknown from South Korea (Oosterbroek 2025).

Materials and methods

Despite the many museum collections that were checked, *Dicranota* crane flies from the Korean Peninsula were found only at the National Institute of Biological Resources (**NIBR**), Incheon, South Korea; the Korea University Entomological Museum (**KUEM**), Seoul, South Korea; the Snow Entomological Museum, University of Kansas, Lawrence, KS, USA (**SMEK**); the National Museum of Natural History, Smithsonian Institution, Washington, DC, USA (**USNM**); the Hungarian Natural History Museum (**HNHM**) in Budapest, Hungary; and at the Nature Research Centre (**NRC**), Vilnius, Lithuania (Table 1). Comparative material from Mongolia was obtained from The Academy of Natural Sciences of Drexel University, Philadelphia, PA, USA (**ANSP**).

Together with entomologists from NIBR we started intense studies of Korean crane flies in 2012. Crane flies were collected every year, field work conducted from early spring to late fall in different localities throughout the country; thousands of specimens were collected and put on permanent storage at the NIBR collections. We managed to obtain 784 *Dicranota* specimens from Korea and 22 specimens from surrounding countries for our study. Some of them are new records and even new species.

Adults were collected in various ways, including insect nets, Malaise traps, Green-LED light traps, New Jersey (NJ) traps, and other light sources. The collected specimens were dry-mounted laterally on paper points. Wet specimens were preserved in 96% ethanol (EtOH). Some male wings were slide mounted in Euparal and photographed. Dissected terminalia were cleared in 10% KOH and preserved in microvials with glycerol.

Information on the examined material is given according to the journal requirements, thus altitudes are given in metric system regardless of the system on the label. For specimens collected by SP and his colleagues, the date on the label is followed by a number in brackets. Different localities where insects were collected on the same date were given separate numbers and all information from those localities, whether in the field notes and database, photographs, or other locality information, were marked with this specific number. Specimens are arranged according to the collecting date.

Specimens were examined with an Olympus SZX10 dissecting microscope and Nikon Eclipse Ti microscope. Photographs were taken with a Canon R5 camera through a Canon MP-E 65 mm macro lens and through Mitutoyo M Plan apo 10 × and 20 × lenses mounted on the same camera at NRC.

Total genomic DNA was extracted from the legs of *D. (Eudicranota) distincta* Podenas, sp. nov. and *D. (E.) perdistincta* specimens using a QIAamp DNA Micro Kit (Qiagen, Hilden, Germany). Standard PCR amplification and sequencing protocols were used to generate COI fragment sequences. The target fragment of COI was amplified in 20 µL reactions containing AccuPower PCR Pre-Mix (Bioneer Co., Daejeon, Korea), 1 U Top DNA polymerase, dNTPs (10 mM),

* Coordinates for old collecting sites are approximate.

Tris-HCl (pH 9.0), KCl (30 mM), MgCl₂ (1.5 mM), 3 µL (5–50 ng) template DNA, and 1 µL of each primer (LCO1490 and HCO2198; 10 pM each). Amplification was performed using the following thermal cycling program: 94 °C for 4 min; 35 cycles of 94 °C for 0.5 min; 48 °C for 0.5 min; 72 °C for 1 min; and a final extension at 72 °C for 10 min. PCR products were sequenced by Macrogen Inc. (Korea). Before further analysis, DNA sequences for each specimen were aligned in the BioEdit Sequence Alignment Editor. COI sequences were submitted to GenBank: *D. (E.) distincta* Podenas, sp. nov. has the accession numbers [PQ590791](#) (215 bp) and [PQ590791](#) (398 bp); The *D. (E.) perdistincta* accession number is [PQ590790](#). Genetic distances between examined species were calculated as proportion of differences (p-distances) as implemented in the program MEGA X.

The terminology of adult morphological features generally follows that of Cumming and Wood (2017), while terminology of wing venation follows de Jong (2017).

Taxonomy

Dicranota Zetterstedt, 1838

Dicranota Zetterstedt, 1838: 851; Edwards 1938: 51, 58; Ishida 1958: 37; Savchenko and Krivolutsкая 1976: 34; Savchenko 1983: 33; Savchenko 1986: 165; Savchenko 1989: 14, 15.

Type species. *Dicranota guerini* Zetterstedt, 1838 (by monotypy) (Western and Eastern Palaearctic).

Description. Small to medium-sized Pediciidae crane flies with body length 4.3–9.0 mm and wing length 5.0–11.5 mm. Body colouration varies from pale yellow to dark brown, dark grey, or even black.

Head. Rounded posteriorly, vertex with low but wide tubercle. Eyes with short erect setae between ommatidia. Antenna usually short, reaching approximately to frontal margin of prescutum, if bent backwards, sometimes longer in males and reaching posterior margin of first abdominal segment if bent backwards. Number of flagellomeres varies from 10 to 15, most usual number being 11–13. Flagellomeres slightly elongate or oval, covered with short pubescence, verticils variable, but usually not exceeding length of respective segments. Apical antennomere usually large, as long or longer than preceding segment.

Thorax. Pronotum rather big, covered with erect setae medially. Mesonotal prescutum without tubercular pits, pseudosutural fovea indistinct. Katepisternum often bare, bearing few setae in some species. Meron small. Middle and posterior coxae close to each other. Wing usually long and narrow, often $\sim 4 \times$ as long as wide, similar in both sexes, sometimes dimorphic: posterior margin of male wing extended, widest at tip of anal vein, or wing reduced, with some brachypterous females, sometimes brachypterous individuals occurring among both sexes. Some species, especially living in cold climate or at higher altitudes are all brachypterous. Wings of most species without any pattern, even stigma often is missing. Wings of only few species with smaller or larger dark spots, mostly surrounding cross-veins, base of *Rs* and cord. Venation: *arculus* present, vein *Sc* very long, reaching wing margin far beyond branching point of *Rs*, *sc-r* long distance before base of *Rs*, sometimes close to the middle between base of *Rs* and humeral vein, *R*₁ short, usually not exceeding *R*₂ in length. Radial sector short, $\leq 3 \times$ as long as *m-cu*, often shorter than that. Cell *r*₃ long with short stem or stem is missing completely. Cell *m*₁ usually short, much shorter than its stem. Discal cell missing due to reduction of vein *m-m*, rarely present, but even when present, *m-m* is weak. Cross-vein *m-cu* beyond branching point of *M*. Tip of anal vein far not reaches level of *Rs* base. Anal angle usually wide. Tibial spurs present on all legs. Claw usually simple, without spines.

Abdomen. Male terminalia not enlarged, approximately as wide as rest abdominal segments. Epandrium often with medial and lateral lobes, lateral lobes could be elongate and complicated. Gonocoxite simple or with larger or smaller dorsal lobe at apex. Usually this lobe covered with small dark spines. One or two pairs of gonostyli, outer gonostylus usually bearing lots of small spines, interbase large, often complicate. Aedeagus short and simple, paramere elongate. Ovipositor with long cercus and hypogynial valve, tip of cercus raised upwards, dorsal margin of hypogynial valve usually covered with long and strong setae. Most females with two spermathecae, some with three.

Remarks. The genus *Dicranota* is one of the largest not only among Pediciidae, but among all crane flies. It includes 256 species worldwide (Oosterbroek 2025), two of them with two subspecies each, and the subspecies of a third species raised to species level in this publication. The Palaearctic Region is the most species rich with 104 recognised species, 72 of them occurring in the Eastern and 39 in the Western Palaearctic. This publication adds three more species to the East Palaearctic fauna, now 75, the same number as the Oriental Region.

- corners of tergites. $R_s \sim 3 \times$ as long as $m-cu$, cell m_1 missing or very small (Figs 9–11). Outer gonostylus of male genitalia long and narrow, postero-dorsal lobe of gonocoxite rounded (Figs 12, 13), dorsal apodeme of aedeagus narrow and straight.....

- Wing without discal cell, cross-vein $m-m$ missing; radial sector branches into R_{2+3+4} and $R_{5'}$ or R_4 in direct alignment with R_s (Figs 39, 40, 45, 50, 54, 55, 59, 63, 66, 69, 72).....***Dicranota (Rhaphidolabis)* 10**
- 10** Darker areas surround cross-veins and tips of longitudinal veins (Figs 39, 40).....***Dicranota (Rhaphidolabis) gibbera* (Alexander, 1921)**
- No darker areas around cross-veins and tips of longitudinal veins (Figs 45, 50, 54, 55, 59, 63, 66, 69, 72).....**11**
- 11** Wing stigma distinct, brown; dark area extends along cubital vein, indistinct darkening around cord and at distal wing margin. Gonocoxite terminates in large curved spine (Fig. 64).....
-***Dicranota (Rhaphidolabis) polymera* Alexander, 1933**
- Wing stigma indistinct or missing, wing usually without any darker areas, sometimes indistinct darkening surrounds cubital vein. Apex of gonocox-

- ite without lobes, or lobe simple, round-apexed (Figs 46, 51, 56, 60, 67, 70, 73, 74, 75) **12**
- 12 Wing vein R_{2+3+4} (stem of cell r_3) long, approximately as long as cross-vein $m-cu$ **13**
- Wing vein R_{2+3+4} (stem of cell r_3) short, distinctly shorter than cross-vein $m-cu$ or totally missing **14**
- 13 Dark brown species. Posterior margin of epandrium with large median incision and large single rounded lateral lobe (Fig. 51) ***Dicranota (Rhaphidolabis) minuscula* Alexander, 1938**
- Pale yellow species. Posterior margin of epandrium with small median incision and two or three small tooth-shaped lateral lobes (Figs 73, 74) ***Dicranota (Rhaphidolabis) yeongokia* Podenas, sp. nov.**
- 14 Yellow species. Interbase with bifid apex (Fig. 46) ***Dicranota (Rhaphidolabis) luteola* Alexander, 1938**
- Dark species (brown, dark brown or grey, or at least abdomen and head dark brown). Apex of interbase not bifid (Figs 56, 60, 70) **15**
- 15 Pleuron obscure yellow ***Dicranota (Rhaphidolabis) neoconsors* Alexander, 1938**
- Pleuron grey to dark brown **16**
- 16 Legs obscure to brownish yellow. Posterior margin of epandrium with distinct median incision (Fig. 70) ***Dicranota (Rhaphidolabis) squarrosa* Savchenko, 1976**
- Legs brown. Posterior margin of epandrium straight or with median lobe (Figs 60, 67) **17**
- 17 Antenna 14-segmented. Wing with short vein R_{2+3+4} (Fig. 66). Posterior margin of epandrium nearly straight with small lateral lobe (Fig. 67) ***Dicranota (Rhaphidolabis) seoi* Podenas, sp. nov.**
- Antenna 13-segmented. Vein R_{2+3+4} missing (Fig. 59). Posterior margin of epandrium with rectangular median lobe and long curved lateral lobe (Fig. 60) ***Dicranota (Rhaphidolabis) ompoana* Alexander, 1945**

Descriptions

Dicranota (Dicranota) Zetterstedt, 1838

Dicranota (Dicranota): Edwards 1938: 51, 59; Alexander 1950: 18; Ishida 1958: 40; Tjeder 1959: 5; Brindle 1963: 235; Mendl 1972: 150; Savchenko and Krivolutska-ya 1976: 45; Savchenko 1983: 39; Savchenko 1986: 188; Savchenko 1989: 17.

Type species. *Dicranota guerini* Zetterstedt, 1838 (by monotypy) (Western and Eastern Palaearctic).

Description. Medium-sized to largest *Dicranota* crane flies with body length 6.3–9.0 mm and wing length 7.0–11.5 mm. Body colouration varies from brownish yellow to dark brown or dark grey.

Head. Antenna 12- or 13-segmented, longer than in most *Dicranota*, reaching at least to approximately middle of presutural scutum, sometimes well beyond base of abdomen, if bent backwards. Male antenna often comparatively longer than that of female. Flagellomeres elongate, verticils short, not exceeding length of respective segments. Apical antennomere usually small, shorter than preceding segment.

Thorax. Presutural scutum with three or four dark longitudinal stripes, medial stripe could have paler narrow line along middle. Wing with comparatively short radial sector, it is only $\sim 2.3 \times$ as long as vein *m-cu*. Cell r_2 with supernumerary cross-vein. Discal cell usually open due to atrophy of *m-m*, sometimes closed. Cell m_1 short to very short, distinctly shorter than its stem, sometimes missing.

Abdomen. Epandrium of male terminalia comparatively simple, posterior margin nearly straight or concave, without additional lobes at the middle, lateral lobe, if present, small and simple. Gonocoxite with blunt, densely setose dorso-apical lobe. Interbase elongate, species specific, often used for species delimitation. Two pairs of gonostyli. Outer gonostylus elongate, fleshy and setose, inner gonostylus pale, elongate, usually covered with small spines and often bearing subbasal lobe. Ovipositor with long cercus and hypogynial valve, tip of cercus raised upwards, dorsal margin of hypogynial valve setose at base, setae comparatively short.

Remarks. The subgenus *Dicranota* s. str. includes 38 species (subspecies of *D. yezoensis* are treated as separate species here) distributed in the Holarctic and Oriental regions (Oosterbroek 2025). Richest in species are the East Palearctic and Nearctic faunas, each with 14 species, the Oriental Region has eight, and the West Palearctic four species. Three species are known from both, West and East Palearctic.

***Dicranota (Dicranota) coreana* Alexander, 1940, stat. nov.**

Figs 1–6, 77

Dicranota (Dicranota) yezoensis coreana Alexander, 1940: 45–46.

Type material examined. NORTH KOREA • Holotype ♀ (pinned, antenna and wing slide mounted); Seren Mts.; alt. 853 m; 15 June 1938; A. M. Yankovsky leg.; USNM.

Yankovsky leg.; USNM • **1 ♀** (pinned); Pontani Paiktusan; alt. 1829–1942 m; 25 August 1940; A. M. Yankovsky leg.; USNM • **1 ♀** (pinned); Pontani Paiktusan; alt. 1829–1942 m; 27 August 1940; A. M. Yankovsky leg.; USNM.

Figures 1, 2. *Dicranota (Dicranota) coreana* Alexander, 1940, stat. nov. **1** female wing, holotype **2** variation of wing venation, female, right wing (left wing "typical"). Abbreviations: A₁ – first branch of anal vein; an lb – anal lobe; aux vn – auxiliary vein (supernumerary cross-vein in cell r₂); bm – basal medial cell; C – costal vein; CuA – anterior branch of cubital vein; CuP – posterior branch of cubital vein; h – humeral vein; M – medial vein, or media; M₁ – first branch of media; M₂ – second branch of media; M₃ – third branch of media; M₄ – fourth branch of media; m-cu – medial-cubital cross-vein; R – radius, or radial vein; R₁ – anterior branch of radius; R₂ – second branch of radius; R₂₊₃₊₄ – stem of radial branches R₂, R₃ and R₄; R₃ – lower branch of second branch of radius; R₄ – upper branch of third branch of radius; R₅ – lower branch of third branch of radius; r-m – radio-medial cross-vein; Rs – radial sector; Sc – subcostal vein; sc-r – subcostal-radial cross-vein.

Redescription. General body colouration dark brown, male sparsely dusted with grey, female more densely covered with bluish grey pruinosity. Body length of female 7.0–8.7 mm. Wing length of male 7.4–8.2 mm, of female 8.0–9.4 mm.

Head. Brown, light grey along eye margin, darker brown dorso-medially, covered with short yellowish setae dorsally. Eyes widely separated in both sexes, distance between them at base of antennae exceeds length of both basal antennomeres taken together. Antenna 1.1–1.3 mm long in male, reaching to approx. middle of presutural scutum if bent backwards, 1.3 mm in female. Whole antenna uniformly dark brown, scape elongate, nearly twice as long as wide, pedicel subglobular. Flagellum 11-segmented. Basal flagellomere elongate, subcylindrical, nearly twice as long as second. Remaining flagellomeres oval, decreasing in length towards apex of antenna. Flagellum covered with light grey pubescence. Verticils dark brown, not exceeding length of respective segment. Rostrum brown, palpus dark brown, labellum rusty brown.

Figures 3–6. *Dicranota (Dicranota) coreana* Alexander, 1940, stat. nov. **3** male genitalia, dorsal view **4** male genitalia, lateral view **5** aedeagal complex, dorsal view **6** ovipositor, lateral view. Abbreviations: aed – aedeagus; cerc – cercus; d ap – dorsal apodeme; ep – epandrium; gonx – gonocoxite; hyp vlv – hypogynial valve; i gonst – inner gonostylus; interb – interbase; pod lb – postero-dorsal lobe of gonocoxite; o gonst – outer gonostylus; spmth – spermatheca; st – sternite; tg – tergite; v ap – ventral apodeme.

Thorax. Dark brown, covered with grey pruinosity. Pronotum covered with erect straight pale yellow setae. Presutural scutum densely covered with greyish brown pruinosity, with four distinct dark brown stripes. Median stripes not reaching posterior margin of sclerite, narrowly separated along middle by very narrow light vitta. Lateral stripe short. Stripes without darker margins. Tubercular pits missing, pseudosutural fovea indistinct. Scutal lobe greyish brown

with longitudinal dark brown stripe along middle. Area between scutal lobes brownish grey. Scutellum bluish grey. Mediotergite brownish grey, paler grey anteriorly, darker posteriorly. Pleuron uniformly brownish grey, semi-polished brown where pruinosity has been denuded. Prothoracic spiracle surrounded by brownish yellow membrane. Wing (Figs 1, 2) widest before tip of vein *CuP*, translucent, strongly iridescent with greyish tinge. Stigma brown, elongate. Dark spot at base of R_5 and cross-vein *r-m* indistinct, no darkening at base of R_s . Veins brown, pale at wing base. Venation: *Sc* long, tip nearly reaching middle of stigma, *sc-r* far before base of R_s , beyond level of A_1 tip. R_s short, usually angulated, often with short spur. Free end of R_1 very short, distinctly shorter than R_2 . Vein R_2 transverse, at distal margin of stigma, supernumerary cross-vein in cell r_1 at frontal margin of stigma. Distal parts of R_3 , R_4 , and R_5 nearly parallel to each other. Cell r_3 with short stem. Cross-vein *r-m* distinct, discal cell open by atrophy of vein *m-m*. Cell m_1 distinct, rarely small, present in all studied specimens, length slightly varies individually. Cross-vein *m-cu* slightly beyond branching point of *M*, *CuP* straight, anal vein nearly straight. Anal angle widely rounded. Length of male halter 1.0–1.1 mm, of female 1.0 mm. Halter pale brown, knob slightly darker than stem. Coxae yellow, dusted with grey, covered with sparse yellowish setae. Fore and middle coxae darker brown at base, more darkened frontally. Trochanters obscure yellow. Femora brownish, paler at base, darker towards apex. Tibiae brown, slightly darker towards distal end, tarsomeres dark brown. Male femur I: 4.8 mm long, II: 5.0–5.6 mm, III: 5.2–5.4 mm, tibia I: 4.9 mm, II: 4.5–5.0 mm, III: 4.8–5.4 mm, tarsus I: 6.5 mm, II: 5.5–6.0 mm, III: 5.6 mm. Female femur I: 4.2–4.5 mm long, II: 4.4 mm, III: 5.0 mm, tibia I: 4.2–4.3 mm, II: 4.2 mm, III: 4.8 mm, tarsus I: 4.9–5.3 mm, II: 4.7 mm, III: 5.3 mm. Claw simple, without spines, rusty brown.

Abdomen. Male abdomen dark brown, sparsely dusted with grey, posterior margins of segments narrowly pale or greyish, lateral margins of tergites indistinctly rusty brown towards distal end of sclerite. Female abdomen with denser cover of grey or bluish grey pruinosity, posterior margins of sternites very narrowly pale.

Male terminalia (Figs 3–5) rusty brown to dark brown. Posterior margin of epandrium concave, postero-lateral angle rounded. Gonocoxite short and wide with elongate slightly arched round-apexed setose postero-dorsal lobe better discernible in lateral view (Fig. 4). Interbase long and narrow, rod-shaped. Outer gonostylus fleshy and setose, spindle-shaped. Inner gonostylus elongate, pale, mesal margin with small spines and darkened subbasal bump. Aedeagus (Fig. 5) with elongate distal part and with two pairs of lateral apodemes, dorsal apodemes wide, wing-shaped. Posterior segments of female abdomen concolorous with the rest of abdomen, base of ovipositor darker brown.

Female terminalia (Fig. 6). Cercus and hypogynial valve brownish yellow, cercus just slightly arched, blunt-apexed. Hypogynial valve straight, blackish at base, apex pale and acute. Spermatheca small, rounded.

Elevation range. From 850 m to ca 1900 m.

Period of activity. Adults fly from late April through to end of August.

Habitat. Unknown.

General distribution. Species endemic to northern Korea.

Remarks. Male was unknown, it is described for the first time herein. The taxon should be treated as a separate species because *D. yezoensis* Alexander,

1924 also occurs in northern Korea and they have differences in the male genitalia, like the shape of the gonocoxite and details of the aedeagus, especially the shape of the dorsal apodeme of the aedeagus. The male antenna of *D. coreana* is shorter than that of *D. yezoensis*.

***Dicranota (Dicranota) crassicauda* Tjeder, 1972**

Figs 7, 8, 78

Dicranota (Dicranota) crassicauda Tjeder, 1972: 223–228, figs 1–13.

Examined material (Fig. 78). NORTH KOREA • 1 ♂ (pinned, genitalia in microvial with glycerol on same pin); Pontani Paiktusan; alt. 1768–1942 m; 9 August 1940; A. M. Yankovsky leg.; USNM.

Redescription. General body colouration brownish yellow with grey thorax and yellowish wings. Male body length ~ 8.0 mm. Male wing length 7.0–10.5 mm, that of female 10.0–11.5 mm.

Head. Dark brown, narrowly whitish along eye margin, wider posteriorly. Vertex with large knob-shaped tubercle. Antenna dark brown, nearly black, ~ 2.5 mm long in male. Scape short, approximately as long as wide, pedicel slightly shorter and narrower than scape. Flagellum 11-segmented in male, 10-segmented in female. Basal flagellomere elongate, exceeding in length both basal antennomeres, subcylindrical. Remaining flagellomeres elongate, decreasing in length towards apex of antenna, segments 2–10 moderately swollen at both ends and slightly narrower at middle in male, segments 2–4 slightly elongate, 5–9 oval or subglobular in female, apical segment conus-shaped, larger in male, small in female. Flagellum covered with short dense pubescence. Verticils very

Figures 7, 8. Male genitalia of *Dicranota (Dicranota) crassicauda* Tjeder, 1972 **7** dorsal view **8** ventral view.

short, approximately as long as sparse trichia covering flagellomeres. Palpus yellowish brown, 4-segmented, basal palpomere small subglobular, second elongate, third palpomere distinctly swollen, apical segment small, rounded.

Thorax. Densely dusted with grey. Cervical sclerites brownish, pronotum dark brown with narrowly grey posterior margin, sparsely covered with short erect yellowish setae. Presutural scutum with four distinct dark brown stripes. Median stripes not reaching posterior margin of sclerite, narrowly separated along middle by very narrow light vitta. Lateral stripe short, reaching suture. Stripes without darker margins. Tubercular pits missing, pseudosutural fovea indistinct. Scutal lobe grey with large dark brown spot at middle. Area between scutal lobes whitish to pale grey. Scutellum because of denuded pruinosity dark brown. Mediotergite whitish to pale grey frontally, brownish grey posteriorly, fronto-lateral corner yellowish. Pleuron uniformly pale grey with yellowish anepisternum. Prothoracic spiracle surrounded by brownish yellow membrane, sparsely dusted with grey. Wing translucent with brownish tinge, yellowish at base, iridescent, widest at or slightly before tip of vein *CuP*. Stigma pale brown, elongate. Dark pattern includes pale brownish spots at base of *Rs* and along cord. Veins brown, yellowish at wing base. Venation: *Sc* long, tip reaching base of stigma, *sc-r* far before base of *Rs*, slightly beyond level of *A*₁ tip. *Rs* medium-long (similar to that of *D. guerini*), slightly arcuate at base. Free end of *R*₁ very short, distinctly shorter than *R*₂. Vein *R*₂ transverse, at distal margin of stigma, supernumerary cross-vein in cell *r*₁ at frontal margin of stigma. *R*₃, *R*₄, and *R*₅ parallel to each other. Cell *r*₃ with short stem. Cross-vein *r-m* distinct, discal cell open by atrophy of vein *m-m*. Cell *m*₁ small. Cross-vein *m-cu* slightly beyond branching point of *M*, veins *CuP* and *A*₁ slightly arched. Anal angle widely rounded. Length of male halter 1.2–1.5 mm. Stem of halter ochraceous, knob brownish. Fore coxa yellowish grey, mid-coxa greyish at base, yellowish distally, posterior coxa brownish yellow. Trochanters obscure to brownish yellow. Femora yellowish brown with paler base, tip without darkening. Tibiae brown, tarsi dark brown with paler base of basitarsus. Male femur II: 5.0 mm, III: 5.6 mm, tibia II: 5.1 mm, III: 5.1 mm, tarsus II: 6.6 mm. Claw simple, without spines, dark brown at base, pale at apex, slightly arched.

Abdomen. Tergites semi-polished, yellow to ochraceous, posterior margin indistinctly and narrowly greyish. Sternites pale brownish yellow. Two basal sternites with denser cover of greyish pruinosity.

Male terminalia (Figs 7, 8). Terminalia brown. Posterior margin of epandrium deeply and widely concave, postero-lateral angle rounded at tip in KOH cleared genitalia, rather acute in dry specimen. Gonocoxite short and wide with rounded setose postero-dorsal lobe. Interbase long and narrow with hook-shaped apical part. Outer gonostylus fleshy and setose, elongate, finger-shaped. Inner gonostylus elongate, pale, mesal margin with short spine-shaped setae and darkened subbasal angulate lobe. Distal part of aedeagus slightly elongate, directed upwards. Female with two spermathecae, ovipositor with short stout cercus and nearly straight hypogynial valve.

Elevation range. Circa 1800–1900 m in Korea.

Period of activity. Single specimen was captured at the beginning of August in northern Korea.

Habitat. Unknown in Korea. Scandinavian specimens were collected at margins of small cold lakes and streams at high altitudes above tree limit, on moist ground covered with willows and sedges (Tjeder 1972).

General distribution. Species occurs both in Eastern and Western Palaearctic, it is recorded from Armenia, Finland, eastern Kazakhstan, Norway, Sweden, and Tajikistan. Recorded from Korean Peninsula for the first time.

Remark. Female characters are based on Tjeder (1972). The finding of *D. crassicauda* in Korea was unexpected, because the distribution area of this species is much further west; the closest known locality is in eastern Kazakhstan.

Redescription. General body colouration greyish brown densely covered with grey pruinosity. Body length of male 7.0–7.5 mm, of female 7.6–9.0 mm. Wing length of male 7.1–8.5 mm, of female 9.3–9.5 mm.

Head. Densely dusted with greyish brown pruinosity, covered with short erect yellowish setae posteriorly, naked frontally. Eyes widely separated in both sexes, distance between them at base of antennae exceeds length of both basal antennomeres taken together. Antenna 2.7–3.3 mm long in male, reaching posterior margin of first abdominal segment if bent backwards, 1.5 mm in female, reaching slightly before middle of presutural scutum if bent backwards. Whole antenna uniformly dark brown, scape elongate, nearly twice as long as wide, pedicel subglobular. Flagellum 11-segmented in male, 10-segmented in female. Male flagellomeres elongate, nearly cylindrical, ~ 4 × as long as wide, decreasing in length towards apex of antenna, densely covered with short, dense and erect light grey pubescence. Basal female flagellomere elongate, remaining segments oval, pubescence very short. Verticils dark brown, short, ≤ 0.5 × as long as width of flagellomere in male, as long as width of flagellomere in female. Rostrum brown dusted with grey, palpus pale brown to brown in male, darker in female. Labellum pale brown.

Thorax. Cervical sclerites yellowish brown. Pronotum brownish grey covered with erect greyish setae. Presutural scutum densely covered with brownish grey pruinosity, with three distinct dark brown stripes. Median stripe wide, separated along middle by very narrow light vitta. Lateral stripe short. Stripes without darker margins. Tubercular pit and pseudosutural fovea indistinct. Scutal lobe dark brown laterally, grey medially. Area between scutal lobes pale grey posteriorly. Scutellum greyish frontally, brownish posteriorly. Mediotergite greyish with narrowly pale brown frontal margin and darker posterior part. Pleuron uniformly brownish grey, darker brown where pruinosity has been denuded. Prothoracic spiracle surrounded by pale brown membrane. Wing (Figs 9–11) long and narrow, widest at tip of vein *CuP*, translucent, strongly iridescent with light brownish

tinge. Stigma distinct, elongate, brown to dark brown. Distinct dark spot surrounds base of R_5 and cross-vein $r-m$. Indistinct darker area surrounds base of R_s . Veins dark brown, pale at wing base. Venation: Sc long, reaching level of stigma, $sc-r$ far before base of R_s , close to the level of tip of anal vein, but position slightly varies individually from before tip of A_1 (Fig. 9) to slightly beyond it (Figs 10, 11). R_s medium long, more often arched at base (Fig. 9), but it could be angulate and short-spurred (Figs 10, 11), or angulate without spur. Free end of R_1 longitudinal, as long or shorter than R_2 . Vein R_2 transverse, at distal margin of stigma, supernumerary cross-vein in cell r_1 at frontal margin of stigma. R_3 , R_4 , and R_5 nearly parallel to each other distally. Cell r_3 with short stem. Cross-vein $r-m$ distinct, discal cell open by atrophy of $m-m$ vein, closed in rare occasions. Cell m_1 usually missing or very small, length slightly varies, sometimes missing on one wing, but present on other. Cross-vein $m-cu$ slightly beyond branching point of M , CuP straight, anal vein slightly arched, nearly straight. Anal angle widely rounded. Length of male halter 0.9–1.1 mm, of female 1.1 mm. Stem of halter pale brownish grey with pale base, knob slightly infusate. Coxae greyish pale brown or brownish yellow, fore and middle coxae darker brown at base, more darkened frontally. Trochanters brownish yellow with slightly darkened distal margin. Femora brownish with pale base, distal margin not darker than remainder of femur. Tibiae and basal tarsomeres brown, distal tarsomeres dark brown. Male femur I: 4.4–5.0 mm long, II: 4.5–4.9 mm, III: 4.8–5.3 mm, tibia I: 4.3–4.8 mm, II: 4.2–4.7 mm, III: 4.9 mm, tarsus I: 6.3–7.3 mm, II: 6.3 mm, III: 6.4–6.6 mm. Female femur III: 4.9 mm long, tibia III: 4.9 mm. Claw simple, without spines.

Abdomen. Tergites of male abdomen dark brown with narrowly pale yellow posterior and lateral margins and widely yellow postero-lateral corners, leaving only narrow dark line between them along the middle of sclerite. Sternites with brown basal half and yellow posterior, narrowly pale grey along posterior margin. Female abdomen with less distinct pattern, tergites greyish brown, darker along middle, sternites yellowish brown. Posterior margins of segments narrowly pale.

Male terminalia (Figs 12–14) brown to dark brown, not distinctly darker than preceding segments. Posterior margin of epandrium slightly concave, postero-lateral angle with small bump. Gonocoxite short and wide with large rounded setose postero-dorsal lobe better discernible in lateral view (Fig. 13). Interbase long and narrow, widened subapically, tip spine-shaped. Outer gonostylus pale, unusually for the genus, long and narrow, fleshy and setose. Inner gonostylus sausage-shaped, slightly arched with bluntly rounded tip, mesal margin setose. Aedeagus (Fig. 14) short with two pairs of lateral apodemes, dorsal apodemes long and narrow, making together V-shaped structure. Posterior segments of female abdomen concolourous with the rest of abdomen.

Ovipositor (Fig. 15). Darkened at base. Cercus just slightly arched, blunt-apexed, distal part yellow. Hypogynial valve straight, blackish at base, distal part pale, dorsal margin with short arched setae at base. Spermatheca small and rounded.

Elevation range. From 1000 m to nearly 2000 m.

Period of activity. From late April through to end of August.

Habitat. Larvae develop in small springs, rivulets, streams, and fast running medium-sized rivers with sand or gravel on the bottom. Usually more abundant in small springs and rivulets. Larvae predacious.

General distribution. Wide-spread throughout the whole Palaearctic.

Remark. This species is recorded from the Korean Peninsula for the first time.

***Dicranota (Dicranota) yezoensis* Alexander, 1924**

Figs 16–18, 80

Dicranota yezoensis Alexander, 1924: 571.

Dicranota (Dicranota) yezoensis: Savchenko and Krivolutskaya 1976: 47, fig. 17b; Savchenko 1989: 18.

Type material examined. JAPAN • **Holotype** ♂ (pinned, wing and genitalia slide mounted); Hokkaido, Akan; 4 September 1922; T. Esaki leg.; USNM.

Other examined material (Fig. 80). NORTH KOREA • 1 ♂ (antenna, hind leg, wing and abdomen slide mounted); Kankyo Nando, Puksu Pyaksan; alt. 1219 m; 14 August 1939; A. M. Yankovsky leg.; C. P. Alexander det.; USNM.

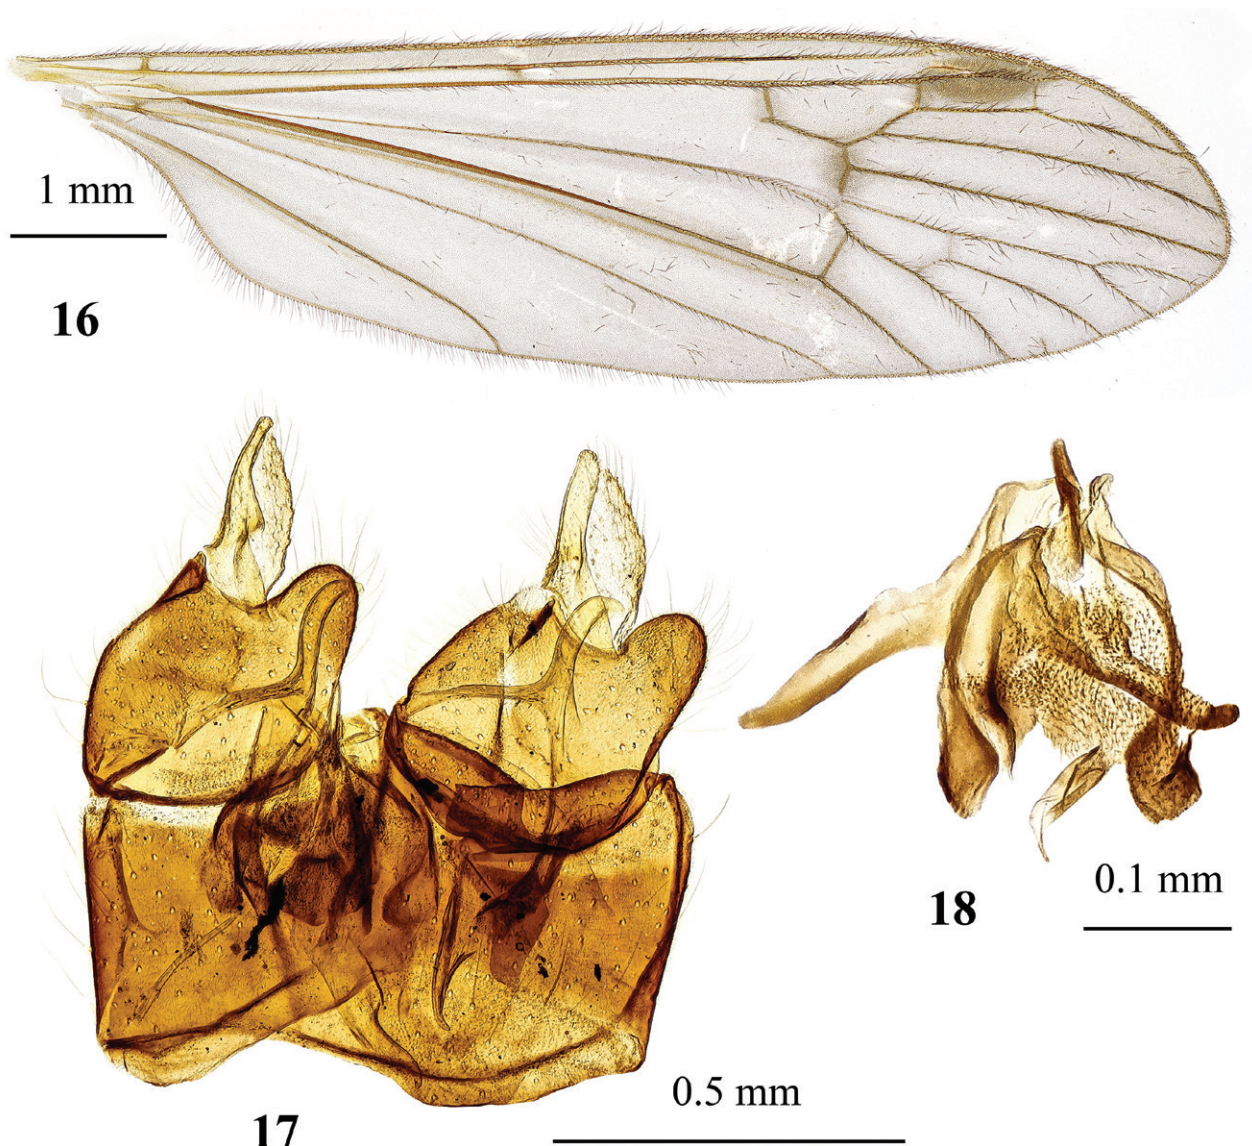

Redescription. General body colouration dark brownish grey. Body length of male 6.3 mm, wing length 7.0–8.1 mm.

Head. Brownish grey, narrowly pale grey along eye margin. Male antenna reaching to approx. middle between base of wing and halter if bent backwards. Antennal flagellum 10-segmented, uniformly shiny black, basal flagellomere elongate, succeeding flagellomeres oval, decreasing in length towards apex of antenna. Flagellum covered with white pubescence, apical segment very small.

Thorax. Dark brownish grey. Presutural scutum with three darker stripes. Median stripe with narrow light vitta along middle. Scutal lobe grey with pale brown spot. Scutellum and mediotergite light grey. Pleuron uniformly pale grey. Wing (Fig. 16) widest at tip of vein *CuP*, translucent, strongly iridescent, with brownish tinge. Stigma distinct, dark brown, elongate. Dark spot at base of *R*₅ and cross-vein *r-m* distinct, less distinct darkening at base of *Rs*. Veins brown, yellowish at wing base. Venation: *Sc* long, tip reaching wing margin beyond base of stigma, *sc-r* short distance beyond level of *A*₁ tip. *Rs* short, angulated and short-spurred. Free end of *R*₁ nearly as long as *R*₂. Vein *R*₂ transverse, at distal margin of stigma, supernumerary cross-vein in cell *r*₁ at frontal margin of stigma. *R*₃, *R*₄, and *R*₅ nearly parallel to each other distally. Cell *r*₃ with short stem. Cross-vein *r-m* distinct. Discal cell present in holotype, but cross-vein *m-m* very weak. Korean specimen has open discal cell with only part of *m-m* present. Cell *m*₁ large. Cross-vein *m-cu* 1/2–2/3 of its own length beyond branching point of *M*, *CuP* slightly sinuous, nearly straight, anal vein slightly arched. Anal angle widely rounded. Length of male halter 0.9 mm. Halter brown with paler stem. Coxae light grey with yellowish distal part. Trochanters dull yellow with blackened distal margin. Femora brown, paler at base, darker towards apex. Tibiae brown, slightly darker towards distal end, tarsomeres dark brown. Male femur I: 3.8 mm long, II: 3.5 mm, III: 4.3 mm, tibia I: 4.5 mm, II: 4.8 mm, III: 4.8 mm, tarsus I: 5.6 mm, II: 4.9 mm, III: 4.7 mm.

Abdomen. Dark brownish grey, tergites with narrowly pale caudal margin, sternites with yellowish grey caudal margin. Abdomen ventrally with indistinct broken median yellowish stripe.

Male terminalia (Figs 17, 18). Epandrium with caudal margin slightly sinuous, postero-lateral angle without additional structures. Gonocoxite short and wide with rounded setose postero-dorsal lobe. Interbase long and narrow, slightly arched. Outer gonostylus fleshy and setose, spindle-shaped. Inner gonostylus elongate, pale, with low wide lobule at ~ 1/3 of gonostylus length on mesal margin. Aedeagus (Fig. 18) with elongate distal part and with two pairs of lateral apodemes, dorsal apodeme narrow, similar to that of *D. guerini*, but with distinct shoulder.

Figures 16–18. *Dicranota (Dicranota) yezoensis* Alexander, 1924 16 male wing, holotype 17 male genitalia, dorsal view, holotype 18 aedeagal complex, dorsal view.

Elevation range. Korean specimen was taken slightly above 1200 m.

Period of activity. Adults fly from middle of August to beginning of September.

Habitat. Unknown.

General distribution. Species was recorded from Hokkaido Island (Japan), Sakhalin and Kuril Islands (Russia).

Remark. Species was recorded only on islands, it was unknown from the continent. Species recorded from the Korean Peninsula for the first time.

Dicranota (Eudicranota) Alexander, 1934

Dicranota (Eudicranota) Alexander in Curran 1934: 46; Alexander 1950: 17; Ishida 1958: 40; Savchenko and Krivolutsкая 1976: 35; Savchenko 1983: 39; Savchenko 1989: 18–20.

Dicranota (Dicranotella) Alexander 1950: 18.

Type species. *Dicranota notabilis* Alexander 1929 (original designation) (Nearctic).

Redescription. Small to medium-sized pale yellow or whitish yellow *Dicranota* crane flies with body length 5.0–8.7 mm and wing length 5.0–7.5 mm.

Head. Antenna 12–13-segmented, reaching to approx. or slightly beyond frontal margin of presutural scutum, if bent backwards. Antennal verticils long, at least as long as respective segments, usually longer.

Thorax. Presutural scutum could be uniformly coloured, without dark longitudinal stripes, sometimes just with indistinct medial stripe and sometimes with three indistinct stripes. Wing with at least narrow dark areas surrounding cross-veins and base of R_s , radial sector comparatively long, it is 4–5 × as long as vein $m-cu$. Cell r_2 with supernumerary cross-vein. Discal cell present, cell m_1 rather long, as long or longer as its stem.

Abdomen. Posterior margin of epandrium extended medially, lateral lobe long and narrow, slightly curved. Gonocoxite of male terminalia simple, or with distinct dorso-medial lobe. Interbase usually large, elongate. One or two pairs of gonostyli. Outer gonostylus or tip and outer margin of single gonostylus covered with small black spines. Ovipositor with long cercus and hypogynial valve, tip of cercus just slightly raised upwards, dorsal margin of hypogynial valve covered with long strong setae, tips of which reaching or nearly reaching apex of valve. Spermathecae three, small, drop-shaped.

Remarks. The subgenus *Dicranota* (*Eudicranota*) includes 16 species (one species is added in this publication, one species with two subspecies). Subgenus most diverse in the Eastern Palaearctic with nine species (one with two subspecies), four species recorded from the Nearctic, and three from the Oriental regions (Oosterbroek 2025).

Diagnosis. Pale yellow species with slightly darkened basal abdominal tergites. Wing translucent, milky with indistinct darker areas surrounding cross-veins, stigma missing. Gonocoxite of male terminalia with narrow subapical cone-shaped lobe on medio-dorsal surface, small subapical setose bump on dorso-lateral surface, small gonostylus and distinct strong darkened horn-shaped paramere.

Etymology. Species is named after that to which it is most closely related, *Dicranota perdistincta*, and because the most reliable character for its discrimination is the distinct horn- or spine-shaped paramere.

Figures 21–24. *Dicranota (Eudicranota) distincta* Podenas, sp. nov., paratypes **21** wing, male **22** wing, variation of venation, female **23** male genitalia, dorsal view **24** ovipositor, lateral view.

Description. General body colouration brownish to pale yellow (Figs 19, 20). Body length of male 5.8 mm, of female ~ 7.3–7.5 mm. Wing length of male 6.1–7.3 mm, of female 6.6–7.1 mm.

Head. Grey dorsally, paler grey along eye margin, yellowish grey posteriorly, obscure yellow ventrally, covered with sparse yellowish setae. Eyes widely separated, distance between them at base of antenna exceeds length of scape in both sexes. Antenna 0.9 mm long in male, reaching slightly beyond frontal margin of prescutum if bent backwards, 1.1 mm in female. Scape yellowish grey, elongate, pedicel oval, yellowish grey, covered with dark brown setae. Flagellum 12-segmented, light grey, slightly darker at distal end, basal flagellomere oval, 2–5 flagellomeres subglobular, remaining segments oval, decreasing in length towards apex, apical flagellomere approximately as long as preceding. Longest verticils slightly exceed length of respective flagellomeres. Rostrum obscure yellow, palpus greyish yellow covered with short dark brown setae. Labellum pale greyish yellow.

Thorax. Pale brownish yellow, covered with sparse greyish pruinosity. Cervical sclerites pale yellow. Pronotum pale, covered with few erect whitish setae. Presutural scutum pale greyish yellow with three indistinct stripes. Stripes not much darker than surrounding area, but they are semi-polished and not covered with pruinosity. Area around stripes covered with bluish grey pruinosity. Tubercular pit missing, pseudosutural fovea indistinct. Prothoracic spiracle surrounded by whitish membrane. Scutal lobe with pale yellow semi-polished area in the middle, margins covered with greyish pruinosity, area between scutal lobes and scutellum whitish. Mediotergite pale. Pleuron pale brownish yellow dorsally, turning totally pale ventrally. Wing (Figs 21, 22) elongate, length/width ratio 3.5, widest slightly before tip of vein *CuP*, milky, iridescent. Stigma missing. Narrow darker brown areas surround *sc-r*, tip of *Sc*, base of *Rs*, *R*₂ and supernumerary cross-vein in cell *r*₁, cross-veins *r-m* and *m-cu*, distal margin of discal cell. Veins greyish brown to slightly grey and pale at wing base. Venation: *Sc* long, reaching wing margin slightly before level of supernumerary cross-vein in cell *r*₁, *sc-r* far before the level of *Rs* base or tip of anal vein, approximately at the middle between humeral vein and base of radial sector. *Rs* long, slightly $> 4 \times$ as long as cross-vein *m-cu*, usually arcuate at base, but could be also angulate and short spurred. Free end of *R*₁ very short or missing, reaching wing margin together with *R*₂. Vein *R*₂ nearly transverse, supernumerary cross-vein in cell *r*₁ beyond or at the same level as branching point of *R*₄₊₅, *R*₃, *R*₄, and *R*₅ nearly parallel to each other. Cell *r*₃ without stem, *R*₂₊₃ starting slightly before or at same point as *r-m*, cell *r*₄ with short stem, cell itself $3.5\text{--}4.6 \times$ as long as its stem. Cross-vein *r-m* distinct, discal cell large, $\sim 2.4 \times$ as long as wide, in rare occasions open by atrophy of vein *m-m*. Cell *m*₁ short, its stem $\geq 1.3 \times$ as long as cell itself. Cross-vein *m-cu* at or slightly beyond branching point of *M*. Veins *CuP* and *A*₁ nearly straight just slightly arched before wing margin. Anal angle widely rounded. No brachypterous females were observed. Halter long, its length nearly reaches that of thorax. Length of male halter 1.1–1.2 mm, of female 1.0–1.2 mm. Stem of halter pale with yellowish base, basal half of knob milky, distal part slightly infusate. Coxae obscure yellow to pale yellow, depending on specimen. Trochanters of fore and middle legs pale greyish yellow, trochanter of hind leg pale or pale yellow. Femora pale greyish yellow with slightly infusate distal part. Tibiae greyish yellow with widely darkened distal margin. Basitarsi brownish

with darker brown distal end and pale base, remaining tarsomeres dark brown. Male femur I: 3.3–3.8 mm long, II: 4.0 mm, III: 4.0–4.4 mm, tibia I: 3.4–3.8 mm, II: 3.2–3.4 mm, III: 3.7–4.1 mm, tarsus I: 4.2–5.2 mm, II: 3.6–3.9 mm, III: 3.8–4.6 mm. Female femur I: 3.3–4.0 mm long, II: 3.8 mm, III: 4.0–4.5 mm, tibia I: 3.0 mm, II: 2.9 mm, III: 2.9–3.8 mm, tarsus I: 3.3 mm, II: 2.8 mm, III: 2.9–3.7 mm. Claw small and simple, without spines.

Abdomen. Obscure yellow. Three basal tergites dark grey medially, margins of darkening vague, lateral margins widely yellow. Remaining tergites and sternites pale yellow, but sclerites are so thin that blackish inner content of guts is visible through and gives dark appearance of the whole abdomen in museum specimens. Abdomen covered with sparse semierect yellowish setae. Male terminalia (Fig. 23) pale yellow, sometimes with weak greyish shade. Posterior margin of epandrium protuberant postero-medially, postero-lateral angle with long blade-shaped lobe, tip of which extended into narrow pale slightly curved caudal lobule. Whole posterior margin of epandrium widely covered with long setae. Gonocoxite elongate, slightly arched, $\sim 2.4 \times$ as long as wide, with narrow conical subapical lobe on medio-dorsal surface and small subapical rounded setose bump on dorso-lateral surface. One pair of gonostyli. Gonostylus subglobular with indistinctly protuberant dorsal part (rostrum) covered with long setae. Distal (caudal) part of gonostylus covered with numerous black peg-like spines. Aedeagus short, not visible in dorsal view. Paramere strong, horn-shaped, slightly curved, wider basally, brown to dark brown. Posterior segments of female abdomen generally yellow, concolourous with the rest of abdomen. Tenth tergite pale, cercus greyish yellow with pale yellow distal part, apex acute, slightly raised upwards. Hypogynial valve straight, pale yellow with brownish yellow base. Three spermathecae small, drop-shaped (Fig. 24).

Elevation. From circa 350 m to nearly 800 m.

Period of activity. From late April to middle of May.

Habitats. Larva unknown. Adults fly close to small fast-running springs, small and medium sized mountainous streams running through rocks, covered with mosses or algae. Usually these streams are surrounded by mixed forests or just pine grooves, with sparse grassy vegetation on the ground.

Distribution. Currently known only from South Korea.

Remarks. *Dichranota distincta* Podenas, sp. nov. is most similar and related to *D. perdistincta*. Both species occur in southern Korea. Calculated genetic distance of mt COI between *D. distincta* Podenas, sp. nov. and *D. perdistincta* is $> 5\%$. Presutural scutum of *D. distincta* Podenas, sp. nov. with three indistinct longitudinal stripes, when that of *D. perdistincta* with indistinct medial darkening, lateral stripe missing. Wing of *D. distincta* Podenas, sp. nov. is comparatively narrower with length/width ratio 3.5, when that of *D. perdistincta* is 3.1. Some females of *D. perdistincta* are brachypterous, but we never observed brachypterous females of *D. distincta* Podenas, sp. nov. Cell m_1 of *D. distincta* Podenas, sp. nov. is shorter than its stem, distinctly longer, except in brachypterous females, in *D. perdistincta*. Other wing venation characters are variable in both species and cannot be used for species discrimination, for example, R_s is usually arcuate in *D. distincta* Podenas, sp. nov. and angulate with short spur in *D. perdistincta*, but some specimens of *D. distincta* Podenas, sp. nov. could be with angulate R_s base, and some specimens of *D. perdistincta* arcuate. Despite some differences in body colouration, the most distinct characters for species identification are

found in male terminalia. Lobe on meso-dorsal surface of gonocoxite narrow, situated subapically in *D. distincta* Podenas, sp. nov., large and close to the middle in *D. perdistincta*. *D. distincta* Podenas, sp. nov. has small setose subapical bump on dorso-lateral surface, that area is covered with long dense setae, but bump is missing in *D. perdistincta*. Especially distinct is the strong horn-shaped, darkened paramere of *D. distincta* Podenas, sp. nov. while that of *D. perdistincta* is more graceful and terminating in a rod-shaped tip.

Podenas leg.; among fallen leaves on rock surface; net; Genbank No. [PQ590790](#); NIBR • 22 ♂, 1 ♀ (in ethanol); Jeollabuk-do, Namwon, Unbong-eup, Hwasu-ri; 35.45098°N, 127.57596°E; alt. 509 m; 6 May 2013 (1); S. Podenas leg.; net; NIBR • 13 ♂ (in ethanol); Jeollabuk-do, Namwon, Jucheon-myeon, Gogi-ri; 35.38131°N, 127.48412°E; alt. 450 m; 7 May 2013 (2); S. Podenas leg.; net; NIBR.

Redescription. General body colouration pale yellow. Body length of male 5.7–7.0 mm, of female ~ 5.5 mm. Wing length of male 6.0–7.5 mm, of female 5.0 mm.

Head. Grey dorsally, obscure yellow ventrally, covered with sparse pale setae. Eyes widely separated in both sexes, distance between them at base of antenna exceeds length of both basal antennomeres taken together. Antenna 1.0–1.2 mm long in male, reaching slightly beyond frontal margin of prescutum if bent backwards, pale brown, slightly darker at distal end. Scape brown, pedicel paler brown. Flagellum 10–12-segmented, two or three basal flagellomeres crowded, hardly distinguishable from one another, remaining segments oval. Length of apical flagellomere variable, from smaller to slightly longer than penultimate. Longest verticils $\leq 1.7 \times$ as long as respective flagellomere. Rostrum brownish yellow, palpus pale yellow with slightly infuscate distal palpomere, labellum pale yellow.

Thorax. Pale to dusky yellow, covered with pale or whitish pruinosity. Pronotum pale brownish yellow covered with setae. Presutural scutum pale yellow widely darker medially, dusted with whitish. Tubercular pit missing, pseudosutural fovea indistinct. Scutal lobe dusky yellow, area between scutal lobes paler. Scutellum pale frontally, obscure yellow posteriorly. Mediotergite pale

Figures 25–28. *Dicranota* (*Eudicranota*) *perdistincta* Alexander, 1940 25 wing, male 26 wing of brachypterous female 27 male genitalia, dorsal view 28 ovipositor, lateral view.

yellow, brownish yellow caudally. Pleuron uniformly pale yellow, semi-polished where pruinosity has been denuded. Prothoracic spiracle surrounded by whitish membrane. Wing (Fig. 25) comparatively wide, length/width ratio 3.1, widest slightly before tip of vein *CuP*, translucent, strongly iridescent. Stigma indistinct or completely missing. Narrow darker brown areas surround *sc-r*, base of *Rs*, *R*₂ and supernumerary cross-vein in cell *r*₁, branching point of *Rs* and cross-vein *r-m*, cross-vein *m-cu* surrounded by indistinct darker area. Veins dark brown to pale brown, or pale at wing base. Venation: *Sc* long, reaching level of supernumerary cross-vein in cell *r*₁, *sc-r* far before the level of *Rs* base or tip of anal vein, distinctly closer to humeral vein than to base of radial sector. *Rs* long, ~ 4 × as long as cross-vein *m-cu*, usually angulate and short spurred, but often arched at base. Free end of *R*₁ very short, nearly missing, much shorter than *R*₂. Vein *R*₂ nearly transverse, supernumerary cross-vein in cell *r*₁ at the same level as branching point of *R*₄₊₅, *R*₃, *R*₄, and *R*₅ slightly arched and nearly parallel to each other. Cell *r*₃ without stem, cell *r*₄ with short stem, cell itself ~ 4 × as long as its stem. Cross-vein *r-m* distinct, discal cell large, ~ 2.5 × as long as wide. Cell *m*₁ usually long, ≥ 1.5 × as long as its stem. Cross-vein *m-cu* slightly beyond branching point of *M*. Veins *CuP* and *A*₁ nearly straight just slightly arched before wing margin. Anal angle widely rounded. Usually, there is no difference between male and female wing shape and venation, but in some cases female wing is shorter than that of male when compared with body length, some females are brachypterous with wing strongly reduced and unsuitable for flight (Fig. 26). Such wing is much narrower than normal, length/width ratio nearly reaches 5, venation more or less preserved, but cells darker than in typical form. Halter long, its length exceeds length of thorax. Length of male halter 1.2–1.5 mm, of female 1.1 mm. Stem of halter pale, knob slightly infusate. Coxae obscure yellow to pale, trochanters pale with narrowly blackened distal rim. Femora pale yellow with pale base and slightly infusate distal part. Tibiae pale yellow with narrowly dark brown distal margin. Two basal tarsomeres brownish, paler basally, darker distally, remaining tarsomeres brown to dark brown. Male femur I: 3.8–4.1 mm long, II: 3.8–4.2 mm, III: 4.4–4.5 mm, tibia I: 4.1–4.2 mm, II: 3.7–4.3 mm, III: 4.2–4.6 mm, tarsus I: 5.2 mm, II: 4.4–4.7 mm, III: 4.6–4.9 mm. Female femur I: 2.5 mm long, II: 2.2 mm, III: 2.8 mm, tibia I: 2.6 mm, II: 2.5 mm, III: 2.5 mm, tarsus I: 2.7 mm, II: 2.6 mm, III: 3.4 mm. Claw small and simple, without spines.

Abdomen. Dusky yellow to brownish yellow. Tergites with narrowly pale posterior and lateral margins, basal sternite pale yellow, remaining sternites greyish yellow. Abdomen covered with erect pale yellow setae, denser on ventral side. Male terminalia (Fig. 27) concolourous with the rest of abdomen. Posterior margin of epandrium protuberant postero-medially, postero-lateral angle extended into long blade with finger-shaped apex. Whole posterior margin of epandrium covered with long setae. Gonocoxite nearly cylindrical, ~ 2.5 × as long as wide, slightly arched, with large conical outgrowth slightly beyond middle of meso-dorsal surface and densely setose area subapically on dorso-lateral surface. One pair of gonostyli. Indistinct rostral part of gonostylus in nearly dorsal position. Gonostylus truncate, distal part covered with numerous black peg-like spines. Aedeagus short, usually not visible in dorsal view. Paramere long, wider basally, distal part pale, rod-shaped, mesal margin finely setose ~ 1/3–1/2 from base. Posterior segments of female abdomen pale yellow, concolourous

with the rest of abdomen. Ovipositor (Fig. 28) yellow. Distal part of cercus just slightly raised upwards, yellow to brownish yellow. Hypogynial valve straight, blackish at base, distal part pale, dorsal margin at basal half with long setae parallel to margin, nearly reaching apex of valve, very tip with short single seta. Spermathecae three, they are small, drop-shaped.

Elevation range. From < 100 m to > 500 m.

Period of activity. From late April through to early July.

Habitat. Larva unknown. Adults fly close to springs, small mountainous streams and rivulets, shaded by mixed forests and shrubs with sparse grassy cover along the margins. Males could be abundant on the ground, crawling among fallen leaves on rocky surfaces in search for females. Some streams with muddy pools alongside.

General distribution. Species is endemic to Korean Peninsula.

Remark. It is the first record of brachypterous female. Species recorded from South Korea for the first time.

Redescription. General body colouration pale yellow to whitish yellow. Body length of male 5.0–6.9 mm, of female 5.2–8.7 mm. Wing length of male 6.1–7.1 mm, of female 5.4–7.1 mm.

Head. Brown, reddish along posterior margin, densely covered with pale grey pruinosity and sparse pale yellow setae. Antenna short, 0.9 mm long in male, hardly reaching frontal margin of prescutum if bent backwards, 0.7 mm long in female. Scape and pedicel reddish, flagellum 12-segmented, pale yellow with somewhat greyish distal flagellomeres. Basal flagellomeres short, oval, just slightly longer than wider, distal flagellomeres elongate, length of apical segment slightly exceeds penultimate. Longest verticils approximately as long as respective flagellomeres. Rostrum dark brown, densely dusted with grey, palpus pale yellow, labellum pale greyish brown.

Thorax. Generally pale yellow. Pronotum whitish. Presutural scutum pale yellow without darker stripes. Tubercular pit missing, pseudosutural fovea indistinct. Scutal lobe pale, area between scutal lobes whitish. Scutellum and mediotergite pale. Pleuron yellow to reddish yellow with blurred whitish areas. Membrane surrounding prothoracic spiracle concolourous with rest of pleuron. Wing milky, subhyaline, strongly iridescent, patterned with brown spots, sexually dimorphic. Male wing (Fig. 29) widened posteriorly at tip of anal vein, female wing (Fig. 30) without such widening, widely rounded along posterior margin. Patterning includes completely darkened costal cell from wing base to slightly beyond R_s base, subcostal cell also darkened but with clear window before $sc-r$; all cross-veins and branching points surrounded by dark areas, small greyish dots distributed along longitudinal veins, veins R_4 and R_5 with or without small dots (different from *D. (E.) nebulipennis* Alexander, 1936 which has at least one large spot in that area). Stigma indistinct. Veins brown or greyish brown, dark brown in darkened areas. Venation: Sc long, reaching to or slightly beyond level of supernumerary cross-vein in cell r_1 , $sc-r$ at $\sim 2/3$ between humeral vein and base of radial sector. R_s long, strongly arched or angulate and short spurred at base. Free end of R_1 distinctly shorter than R_2 . Vein R_2 transverse, supernumerary cross-vein in cell r_1 beyond branching point of R_{2+3+4} . R_4 and R_5 straight and parallel to each other. Cell r_3 with short stem, cross-vein $r-m$ distinct, discal cell large, $3.1\text{--}3.4 \times$ as long as wide. Cell m_1 long, slightly longer than its stem in male, slightly shorter in female. Cross-vein $m-cu$ beyond branching point of M . Vein CuP straight, A_1 slightly arched before wing margin. Anal angle widely rounded. Length of male halter 0.9–1.0 mm, of female 1.1 mm. Halter pale greyish, stem pale with whitish base, knob yellowish. Coxae from pale yellow in male to obscure yellow in female, fore coxa darker than posterior, mid-coxa darker at base. Femora whitish with narrowly and indistinctly infusate apices. Tibiae and basitarsi whitish, second

tarsomere slightly darkened distally, remaining tarsomeres brownish. Male femur I: 3.4–4.0 mm long, II: 3.6 mm, III: 3.5–4.8 mm, tibia I: 3.7–4.3 mm, II: 3.7 mm, III: 3.6–4.4 mm, tarsus I: 4.4–4.7 mm, II: 5.0–5.6 mm, III: 4.4–4.6 mm. Female femur I: 3.9 mm long, II: 3.9–4.3 mm, III: 3.4–4.9 mm, tibia I: 4.1 mm, II: 4.0–4.3 mm, III: 3.5–4.4 mm, tarsus I: 5.2 mm, II: 4.7–5.4 mm, III: 3.7–4.7 mm. Claw small and simple, without spines, dark brown.

Abdomen. Tergites weakly bicolorous, pale greyish brown with darker caudal margins, covered with sparse erect greyish setae. Basal sternite pale, second and third sternites pale with darkened posterior margins, remaining sternites greyish brown, paler at base. Sparse setae covering sternites pale. Female abdomen generally paler than that of male. Male terminalia (Figs 31, 32) dark brown. Posterior margin of epandrium extended into triangle-shaped medial lobe, shape of which can vary slightly: narrower in specimens from Korea, wider in specimens from Mongolia. Postero-lateral corner of epandrium with long and narrow, spine-shaped lobe, reaching to $\sim 2/3$ of gonocoxite. Whole posterior margin of epandrium covered with sparse long setae. Gonocoxite elongate, nearly twice as long as wide, widest at middle. Interbase with narrow stem and ball-shaped tip. Outer gonostylus dark brown and looks like extension of gonocoxite, wide and fleshy, outer and distal margin covered with numerous small blackened spines, mesal margin with three long pale setae. Inner gonostylus elongate, pale, outer margin with low blunt bump at middle, basal part of inner gonostylus encircled by outer gonostylus, tip rounded with few fine setulae. Proctiger divided longitudinally by deep narrow medial incision. Aedeagus short, round-apexed. Paramere long, blade-shaped. Ninth sternite widely concave at middle of posterior margin. Ovipositor (Fig. 33) dark brown with pale distal part of hypogynial valve. Cercus slightly arched, distal part raised upwards, blunt-apexed, hypogynial valve straight, blackish at base, narrowing distally, apex with short strong seta, dorsal margin with three long setae at approx. middle. Spermathecae two, small, subglobular.

Elevation range. From sea level to nearly 2000 m.

Period of activity. From early May through to middle of October.

Habitat. Adults were found among dense grassy vegetation along margins of water bodies and in marshy forest openings in South Primorye (Savchenko 1983), we found them flying along margins of small and medium-sized mountainous streams and rivers densely covered with trees and shrubs, in grassy vegetation surrounding springs and small pools in South Korea. Species is attracted to light.

General distribution. Species was recorded from the eastern Kazakhstan, Honshu Island of Japan, and the Far East of Russia.

Remark. Species recorded from the Korean Peninsula and Mongolia for the first time.

***Dicranota (Ludicia)* Hutson & Vane-Wright, 1969**

Pedicia (Ludicia) Hutson & Vane-Wright, 1969: 243.

Rhaphidolabis (Rhaphidolabina) Alexander, 1916: 540; Alexander 1950: 17; Savchenko and Krivolutskaya 1976: 35; Savchenko 1983: 39; Savchenko 1986: 168; Savchenko 1989: 25–26.

Dicranota (Ludicia) Starý 1996: 122.

Type species. *Tricyphona lucidipennis* Edwards 1921 (original designation) (West Palearctic).

Redescription. Medium-sized dark brown *Dicranota* crane flies.

Head. Antenna 15-segmented, reaching to frontal margin of presutural scutum, if bent backwards. Antennal verticils slightly exceeding length of respective segments.

Thorax. Presutural scutum with four distinct dark longitudinal stripes. Wing without any dark spots except indistinct stigma. *Rs* usually short, sometimes slightly elongate, branches into R_{2+3} and R_{4+5} . Discal cell present, but cross-vein *m-m* could be very weak.

Abdomen. Posterior margin of epandrium nearly straight or deeply concave, lateral lobe could be long, narrow and slightly curved or missing. Gonocoxite of male terminalia with dorso-apical lobe. Lobe covered with small black spines. Interbase small. Two pairs of gonostyli. Outer gonostylus covered with small black spines. Ovipositor with long and comparatively wide, slightly arched cercus and straight hypogynial valve reaching to approx. middle of cercus. Dorsal margin of valve covered with long setae at base, tips of them reaching to $\sim 2/3$ of valve.

The subgenus *Dicranota* (*Ludicia*) includes 19 species (Oosterbroek 2025), distributed in the Oriental Region (11 species) and Palearctic region (8 species), with four species in Eastern and four in Western Palearctic regions.

Yankovsky leg.; USNM • 1 ♂, 1 ♀ (pinned, male genitalia in microvial with glycerol on same pin); Ompo; alt. 305 m; 19 May 1938; A. M. Yankovsky leg.; USNM • 1 ♂ (pinned, genitalia in microvial with glycerol on same pin); Chonsani; alt. 1219 m; 13 June 1940; A. M. Yankovsky leg.; USNM.

Redescription. General body colouration dark brown with dense cover of silvery grey pruinosity. Body length of male 6.5 mm, of female 5.3–7.2 mm. Wing length of male 7.0–9.5 mm, of female 6.3–6.8 mm.

Head. Brownish grey because of dense pruinosity, sparsely covered with brownish semi-adjacent setae. Anterior vertex wide, eyes comparatively small, widely separated, distance between them $\sim 2 \times$ length of scape. Antenna short, 0.9–1.1 mm long in male, reaching to approx. frontal margin of prescutum if bent backwards. Scape and pedicel black, dusted with grey, flagellum of studied non-type specimens and specimens from the Far East of Russia (Savchenko

Figures 34–37. *Dicranota (Ludicia) emarginata* (Alexander, 1945) **34** wing, holotype **35** antennal flagellum, holotype **36** male genitalia, dorsal view **37** ovipositor, lateral view.

1983) 13-segmented, but original description mentions that flagellum of holotype male has only 11 segments (Alexander 1945). Re-examination of holotype reveals that it also has 13 segments. Basal flagellomere elongate, $> 2 \times$ longer

than wide, dark brown with yellowish base, remaining segments dark brown and short, nearly as long as wide (Fig. 35). Apical segment subequal in length to the penultimate. Longest verticils slightly exceed length of respective flagellomeres. Female antenna 0.7–0.9 mm long. Rostrum dark brown, densely dusted with grey, palpus dark brown to black, labellum dark brown.

Thorax. Generally dark brown with dense cover of greyish pruinosity. Pronotum brown with dense cover of brownish grey pruinosity and dense yellowish erect setae postero-dorsally. Presutural scutum brownish grey with four dark brown longitudinal stripes. Medial stripes separated by narrow grey vitta for nearly entire length, reaching each other only frontally, stripes not reaching suture posteriorly. Lateral stripe short, starting far beyond pseudosutural fovea frontally, but extending to suture caudally. Tubercular pit missing, pseudosutural fovea indistinct. Scutal lobe dark brown dusted with grey, lateral and mesal margins narrowly grey, area between scutal lobes grey. Scutellum uniformly brownish grey, mediotergite paler frontally. Pleuron dark brown, somewhat paler frontally, densely covered with silvery grey. Membrane surrounding prothoracic spiracle yellowish brown, sparsely dusted with grey. Wing (Fig. 34) subhyaline, brownish with yellowish basal area, iridescent, without darker pattern except elongate darker brown stigma. Veins brown to greyish brown, paler at wing base. Venation: Sc long, reaching far beyond branching point of Rs, at approx. same level as *m-cu*. Cross-vein *sc-r* nearly at the middle between humeral vein and base of radial sector. Rs long, arched at base. Free end of R_1 slightly exceeds R_2 in length. Vein R_2 transverse, distal portion of R_3 , R_4 , and R_5 straight and parallel to each other. Cell r_3 sessile. Cell r_4 with short but distinct stem R_{4+5} which is twice as long as cross-vein *r-m*. Discal cell long, nearly 4 × as long as wide, but cross-vein *m-m* very weak in holotype, it is also very weak or completely atrophied in other studied specimens, thus discal cell could be missing. Cell m_1 short, stem 1.7 × as long as cell itself. Cross-vein *m-cu* far beyond branching point of *M*, close to the middle of vein M_{3+4} . Vein *CuP* straight, A_1 slightly sinuous. Anal angle widely rounded. Length of male halter 1.2 mm, of female 1.2 mm. Stem of halter obscure yellow, knob pale yellow basally, darkened distally. Fore coxa dark brown with dense cover of grey pruinosity, slightly yellowish along distal margin, middle and posterior coxae dusky yellow with dark base. Femur from pale yellow at base, to obscure yellow at middle, to dark brown at tip. Tibia and tarsal segments dark brown, covered with short yellowish setae. Male femur I: 4.8–5.9 mm long, II: 5.3–5.6 mm, III: 5.0–5.8 mm, tibia I: 5.2–6.4 mm, II: 5.0–5.9 mm, III: 5.2–6.4 mm, tarsus I: 8.1 mm, II: 6.1–7.3 mm, III: 7.1 mm. Female femur I: 3.2–3.5 mm long, II: 3.5 mm, III: 3.8 mm, tibia I: 3.3–3.6 mm, II: 3.5 mm, III: 3.8–4.0 mm, tarsus I: 4.1–5.1 mm, II: 4.0 mm, III: 4.3–4.5 mm. Claw simple, without spines, dark brown.

Abdomen. Basal tergites of male abdomen yellowish brown with dark brown caudal and lateral margins, distal tergites darker brown, caudal margin narrowly light grey. Tergites covered with sparse erect golden setae. Sternites yellowish brown at base of abdomen, turning darker brown towards tip of abdomen. Male terminalia (Fig. 36) dark brown. Posterior margin of epandrium deeply and widely emarginate, lateral lobe wide, setose with rounded posterior margin which is densely covered with fine setulae. Lateral margin of epandrium with narrow lobule, tip of which extends slightly beyond bottom of emargination but far not reaches caudal margin of lateral

lobe. Gonocoxite short and wide, length just slightly exceeds width, with two unequal lobes near apex. Caudal lobe dark brown subglobular covered with short black spines, subapical lobe smaller, also blunt-apexed, covered with fine setae. Interbase reduced. Gonostylus pale, triangle-shaped, mesal margin covered with sparse erect setae, tip obtuse, rounded. Aedeagus short, bifid at apex. Paramere long, rod-shaped. Female abdomen uniformly brown with narrowly pale grey caudal margins of tergites and sternites. Caudal segments of female abdomen (9th and 10th tergites, 8th sternite) dark brown. Cercus (Fig. 37) yellow with raised distal part, apex blunt, rounded. Hypogynial valve straight, yellow with brown base and pale rounded tip, dorsal margin with few setae at middle far not reaching apex. Spermathecae three.

Elevation range. From sea level to nearly 1400 m.

Period of activity. From mid-May through to middle of July.

Habitat. Species was collected near small stream running through the hill covered with broad leaved forest in the Far East of Russia (Savchenko 1983).

General distribution. Species was recorded from northern Korea and the Far East of Russia close to the border with North Korea.

Remark. The female was previously unknown. The species is absent in South Korea.

Dicranota (*Rhaphidolabis*) *Osten Sacken, 1869*

Rhaphidolabis Osten Sacken, 1869: 284; Edwards 1938: 51, 61; Alexander 1950: 17; Ishida 1958: 40; Tjeder 1959: 5; Brindle 1963: 235; Mendl 1972: 150; Savchenko and Krivolutskaya 1976: 35; Savchenko 1983: 39; Savchenko 1986: 170; Savchenko 1989: 27.

Claduroides Brunetti, 1911: 284.

Type species. *Rhaphidolabis tenuipes* Osten Sacken, 1869 (original designation) (Nearctic).

Redescription. Small to medium-sized *Dicranota* crane flies with body length 4.3–9.0 mm and wing length 5.0–9.5 mm. Colour varies from pale yellow to brownish yellow, to pale brown, dark brown, or dark grey.

Head. Antenna 13–17-segmented, reaching to approx. or slightly beyond frontal margin of presutural scutum, if bent backwards. Length of apical antennomere varies depending on species, from shorter to nearly twice as long as preceding segment. Verticils usually short, from half the length to as long as the respective segment, longest reaching $\leq 1.5 \times$ as long as respective segment.

Thorax. Longitudinal stripes of presutural scutum vary depending on species, some species with uniformly coloured scutum and any stripes lacking, some species with medial darkening, and other with three distinct longitudinal stripes. Wing could have small dark spots, surrounding cross-veins or vein branching points, but usually without any darker areas besides stigma, stigma is often missing too. Venation: R_s usually short, sometimes longer; cell r_3 with short stem, or stem is missing, radial sector branches into R_{2+3+4} and $R_{5'}$ or R_4 in direct alignment with R_s ; discal cell open due to atrophy of $m-m$; cell m_1 always present. Due to individual variation in wing venation, most species cannot be reliably identified just based on wing characters. Wing squama often with few setae.

Abdomen. Posterior margin of epandrium species specific, often with medial and lateral lobes, sometimes concave at middle. Gonocoxite varies depending on species, sometimes simple, often with subapical dorsal lobe covered with small spines, interbase long, sometimes complicated. Two, sometimes one pair of gonostyli, outer gonostylus fleshy, covered with abundant small black spines, inner gonostylus usually paler, elongate, bearing just few small pale spines. If gonostylus single, then it has complicated structure, usually bearing outer and inner lobes. Aedeagus simple, paramere elongate, usually curved at apex. Ovipositor with long cercus and hypogynial valve. Two or three spermathecae.

The subgenus *Dicranota* (*Rhaphidolabis*) includes 112 species (Oosterbroek 2025) (two species are added in this publication). It is most diverse in the Oriental region, 45 species, then Eastern Palaearctic, 37 species (with one species also occurring in the Western Palaearctic, three species shared with Oriental fauna), Nearctic, 31 species. Two species are recorded from Neotropics.

Redescription. General body colouration: head dark brown, thorax yellow, abdomen brown. Body length of male 5.3–6.0 mm, of female 4.3–6.5 mm. Wing length of male 5.0–6.9 mm, of female 5.0–6.3 mm.

Head. Dark brown to black covered with sparse grey pruinosity, denser frontally and scattered yellowish setae. Anterior vertex wide, eyes widely separated, distance between them frontally slightly exceeds length of scape. Antenna (Fig. 38) short, 0.7–0.9 mm long in male, 0.7–0.9 mm in female, reaching to approx. frontal margin of prescutum in male if bent backwards. Scape elongate, nearly cylindrical, 1.7 × as long as pedicel, dark brown to black, sparsely dusted with grey and bearing few blackish setae dorsally. Pedicel oval, brown, sparsely dusted with grey. Flagellum 13-segmented, pale yellow with slightly infusate basal segment. Flagellomeres oval except elongate apical segment, which slightly exceeds penultimate in length. Longest verticils 1.5 × as long as respective flagellomeres. Rostrum dark brown, sparsely dusted with grey, palpus dark brown to black, labellum brown.

Thorax. Generally yellow. Cervical sclerites black. Pronotum black frontally and dorsally, pale yellowish grey laterally, covered with few erect blackish setae dorsally. Presutural scutum pale greyish yellow dorsally, pale laterally with longitudinal brownish medial stripe that does not reach suture posteriorly, some specimens with slightly darker narrow fronto-lateral margin. Stripe wider and more distinct frontally, turns narrower and less distinct caudally. Tubercular pits missing, pseudosutural fovea indistinct. Scutal lobe pale yellow with slightly darker brownish longitudinal line. Area between scutal lobes pale, whitish. Scutellum and mediotergite pale yellow to whitish. Pleuron pale yellow with

whitish area extending downwards at base of wing. Membrane surrounding prothoracic spiracle whitish. Wing subhyaline, milky with yellowish costal and basal areas, iridescent. Dark pattern includes narrow but distinct dark spots surrounding all cross-veins except at wing base, branching points and tips of all veins along wing margin, indistinct darker cloud in distal radial field. Stigma with darker margins and clear central area. Veins pale greyish yellow, darkened at branching points and at wing margin. Male wing (Fig. 39) with angulate posterior margin at tip of anal vein, thus anal cell long and narrow, female wing (Fig. 40) with evenly rounded posterior margin, anal cell wider than in male. Venation: Sc long, reaching far beyond branching point of R_{2+3+4} . Cross-vein $sc-r$ nearly at the middle between humeral vein and base of radial sector in male, closer to base of R_s in female. R_s long, angulate at base. Free end of R_1 varies from $\frac{1}{4}$ to as long as R_2 . Vein R_2 transverse. Distal portion of R_3 slightly arched, R_4 and R_5 straight and parallel to each other. Cell r_3 with short stem. Discal cell missing due to reduction of $m-m$. Cell m_1 medium-long, its stem $\sim 1.5 \times$ as long as cell itself. Cross-vein $m-cu$ at or very slightly beyond branching point of M . Vein CuP very slightly arched, A_1 arched before wing margin. Anal angle widely rounded in female, long and narrow in male. Length of male halter 0.9 mm, of female 0.7 mm. Stem of halter grey with yellow base, knob with pale base, yellow central area and dark grey distal margin. Coxae pale yellow, just fore coxa slightly darkened frontally. Trochanters pale with narrowly blackened ventral margin. Femur of fore and middle legs entirely black, that of posterior leg pale yellow with narrowly darkened tip. All tibiae and basitarsi snow white with indistinctly darker tips. Second tarsomere whitish with darker distal part, third tarsomere whitish at basal half, greyish at distal, two remaining tarsomeres grey. Male femur I: 3.1 mm long, II: 3.7 mm, III: 3.2–3.8 mm, tibia I: 2.9 mm, II: 3.2–3.6 mm, III: 2.8–3.4 mm, tarsus I: 3.0 mm, II: 3.1–3.4 mm, III: 2.7–3.4 mm. Female femur I: 3.1 mm long, II: 3.1–3.7 mm, III: 3.5–3.9 mm, tibia I: 2.9 mm, II: 2.9–3.4 mm, III: 3.0–3.6 mm, tarsus I: 3.2 mm, II: 2.6–2.9 mm, III: 3.1–3.2 mm. Claw simple, without spines, greyish.

Abdomen. Abdominal segments semi-polished. Basal tergite greyish, second and third tergites pale yellow with darkened distal margin, remaining tergites dark grey. Basal sternite pale yellow with darker distal margin, succeeding four sternites pale yellowish grey, pregenital sternites dark grey. Male terminalia (Figs 41, 42) dark grey with yellowish epandrium. Posterior margin of epandrium with small round-apexed bump at middle covered with long setae, postero-lateral angle extended into long and wide complicated lobe, bearing two branches: dorsal branch simple, extended, finger shaped in dorsal view, spine-shaped in lateral; ventral lobe distinctly longer, terminating in wider head, armed with two spines directed opposite to each other. Gonocoxite elongate with finger-shaped lobule dorso-apically. Interbase slightly arched spine-shaped, extending slightly beyond lobes of epandrium. One pair of complicated gonostyli. Gonostylus with narrow finger-shaped (in dorsal view) dorso-basal lobe that is wide and flat in lateral view, distal margin of which covered with small blackish spinules; ventral part resembles small head with long rostrum, head covered with small blackish spinules too, rostral appendage terminates in two strong setae (rostral appendage extends dorso-mesally thus looks rather short in dorsal view Fig. 42). Distal part of proctiger divided longitudinally by shallow medial incision. Aedeagus short and narrow. Paramere long and narrow, distinctly

arched. Ovipositor (Fig. 43) pale brown. Cercus brown, distal part slightly raised upwards, pale, blunt apexed. Hypogynial valve nearly straight, darker at base, apical part pale, dorsal margin basally with long setae reaching apex of valve, very tip with short single seta. Three small drop-shaped spermathecae.

Elevation range. From circa 150 m to 1400 m (probably up to 1800 m in Taiwan).

Period of activity. From late April through to late October.

Habitat. Adults fly along margins of small and medium-sized mountainous rivers and streams running through forested areas, above moss covered rocks and debris accumulated along margins on the slopes, wet areas with water seeping through rock surface, boggy areas surrounded by mixed forest. Males swarm under tree canopies before sunset. Both sexes are attracted to light.

General distribution. Japan, Far East of Russia, South Korea, Taiwan.

Remark. Species recorded from the Korean Peninsula for the first time.

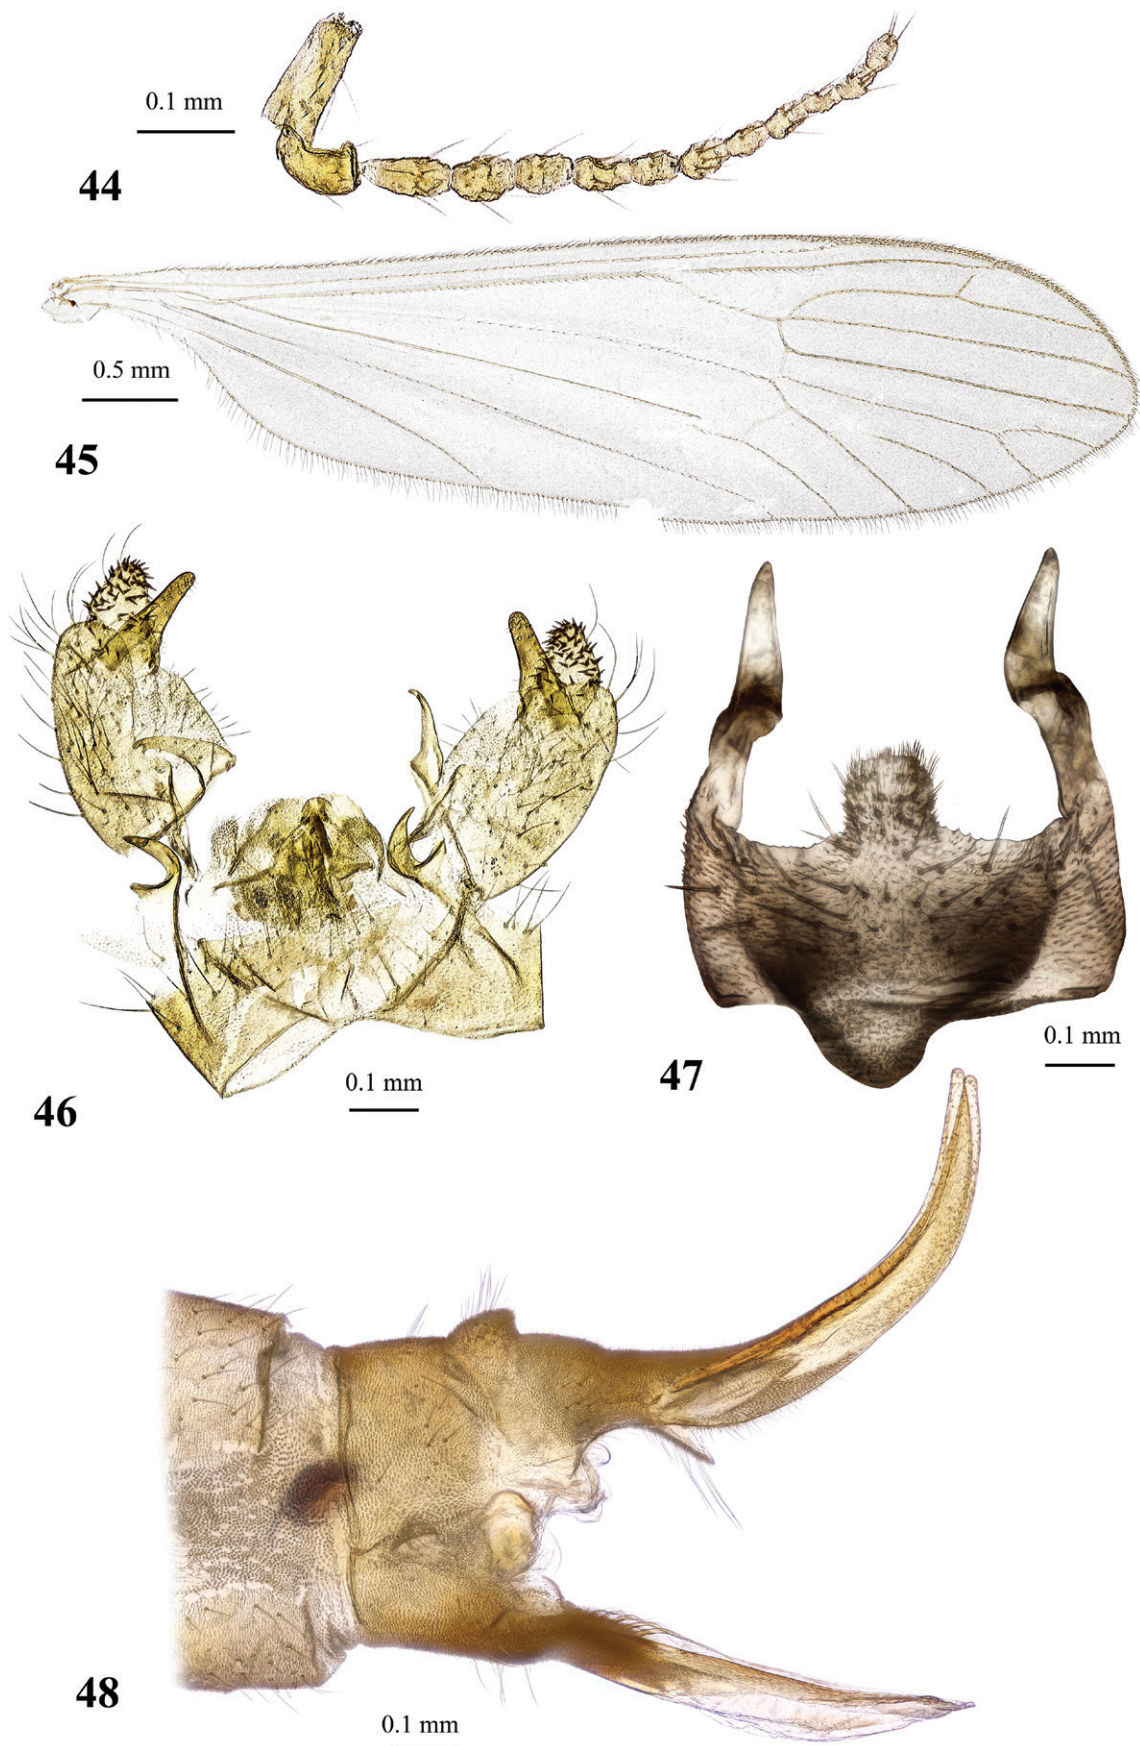

Dicranota (Rhaphidolabis) luteola Alexander, 1938

Figs 44–48, 86

Redescription. General body colouration yellow to brownish yellow. Body length of male ~ 4.5 mm, of female 5.2–6.0 mm. Wing length of male 5.8–6.0 mm, of female 5.3–7.0 mm.

Head. Brownish grey to light grey because of dense grey pruinosity. Antenna (Fig. 44) short and thick, hardly reaching frontal margin of prescutum if bent backwards in male, 0.6–0.8 mm long in female. Scape yellow to yellowish brown. Pedicel yellow in male, darker in female. Flagellum 11-segmented, dark brown or black. Flagellomeres compact, oval or barrel-shaped, covered with pale pubescence. Apical flagellomere large, at least as long as preceding segment. Longest verticils slightly shorter than respective flagellomeres. Rostrum yellow to brownish yellow, two basal palpomeres yellow, two terminal palpomeres black.

Thorax. Generally yellow, dorsum yellowish brown dusted with grey. Presutural scutum pale brown without longitudinal stripes, sometimes with dark medial darkening. Scutellum, mediotergite and pleuron yellow. Wing (Fig. 45) long and narrow both in male and female, nearly 4 × as long as wide, subhyaline, milky, slightly iridescent, without darker pattern, except cells beyond cord which are a trifle darker. Stigma missing. Veins pale brownish grey, a little darker beyond cord. Venation: Sc long, reaching far beyond branching point of R_{2+3+4} . Cross-vein $sc-r$ could be closer to base of R_s than to humeral vein, in the middle between base of R_s and humeral vein in holotype, it could be very weak or totally missing in some specimens. R_s ~2 × as long as $m-cu$, nearly straight, just slightly arched at base. Free end of R_1 very short, distinctly shorter than R_2 . Vein R_2 oblique. Distal portions of R_3 , R_4 , and R_5 straight and parallel to each other. Cell r_3 with very short stem, distinctly shorter than $r-m$, but length of stem varies individually. Discal cell missing due to reduction of $m-m$, but Savchenko (1983) mentions, that some specimens, both males and females have fully developed or reduced vein $m-m$. Cell m_1 short, its stem 2.6 × as long as cell itself. Cross-vein $m-cu$ distinctly beyond branching point of M . Vein CuP nearly straight, A_1 slightly arched. Anal angle widely rounded. Halter pale yellow with more intensely yellow knob. Length of male halter 0.8 mm, of female 0.9 mm. Coxae and trochanters yellow to pale yellow. Femora pale brown. Tibiae and basitarsi whitish to pale yellow with narrowly darkened tips. Second and third tarsomeres whitish yellow, terminal tarsomeres darkened. Male femur I: 3.8 mm long, II: 3.9 mm, III: 4.3 mm, tibia I: 4.6 mm, II: 3.8–3.9 mm, III: 3.8 mm, tarsus I: 5.5 mm, II: 4.3–4.4 mm, III: 3.8 mm. Female femur I: 3.7 mm long, II: 3.2–4.2 mm, III: 3.6–4.1 mm, tibia I: 3.4 mm, II: 3.1–3.8 mm, III: 3.4–4.1 mm, tarsus II: 3.0–4.5 mm, III: 3.7–4.4 mm. Claw simple, without spines, pale yellow.

Abdomen. Yellow to brownish yellow in male, somewhat darker in female. Tergites a little more infuscated than sternites, especially medially. Entire sixth segment dark brown in male, only posterior margin darkened in female. Seventh segment dark brown both in male and female. Male terminalia (Fig. 46) yellow. Posterior margin of epandrium nearly straight with distinct nearly parallel-sided medial plate and sickle-shaped lateral lobe (Fig. 47). Medial lobe nearly quadrangular, approximately as long as wide. Gonocoxite slightly longer than wider, simple, without additional lobes. Interbase long, wider at base, slightly arched, bifid at tip. Outer gonostylus short and wide, round-apexed, covered with dense blackish spinulae. Inner gonostylus long and narrow, finger-shaped. Aedeagus short and wide. Ninth sternite with very deep and wide membranous concavity postero-medially. Ovipositor (Fig. 48) brownish yellow. Cercus polished brown basally, brownish yellow distally.

Elevation range. From sea level to nearly 1800 m.

Period of activity. Adults fly the whole of both June and July.

Habitats. Small mountainous streams, partly disappearing underground, densely covered with broad leaved trees, shrubs, herbaceous vegetation in Korea. Southern slopes of rocky canyons of small streams surrounded by broad leaved forests in the Kedrovaya Padj sanctuary in the Far East of Russia (Savchenko 1983).

General distribution. North Korea and Far East of Russia.

Remarks. The species is recorded from South Korea for the first time. *Dicranota luteola* is similar to *D. complicata* Savchenko, 1979 from Sakhalin. *Dicranota complicata* was mistakenly identified as *D. luteola* by Savchenko and Krivolutskaya (1976), later described as new species. Judging from the illustration in Savchenko (1983: fig. 10) males from the Far East of Russia (Kedrovaya Padj sanctuary) and males from Korea identified as *D. luteola* by Ch. P. Alexander belong to different species. Especially, distinct differences exist in the structure of epandrium: the medial lobe of Korean males is much shorter than that of Savchenko's specimens, the lateral lobe of Korean males is distinctly larger and stronger. The interbase of Korean males has a subapical tooth resembling that of *D. complicata*, but the interbase of Savchenko's males has no subapical tooth. The original description of *D. luteola* was based on two females. Probably, at least three related species exist in the Eastern Palearctic, and Savchenko's males from the Far East of Russia belong to new undescribed species.

Redescription. General body colouration greyish dark brown with denser grey pruinosity covering thorax. Body length of male ~ 6.5 mm, of female 6.2–8.8 mm. Wing length of male 7.2 mm, of female 6.3–8.3 mm.

Head. Pale brownish grey because of dense pruinosity, ground colour dark brown. Ground colour more distinct in old specimens. Indistinct darker stripe or narrow line extends medially. Area along eye margin light grey. Sparse, brownish, semi-erect setae cover dorsal area. Eyes widely separated, distance between them at base of antennae approximately equals length of both basal antennomeres taken together. Vertex with distinct rounded tubercle. Antenna dark brown, short, reaching to approx. frontal margin of prescutum, if bent backwards, 0.6 mm long in male, 0.8 mm in female. Scape elongate, nearly cylindrical, ~ 2 × as long as pear-shaped pedicel. Flagellum 12-segmented, basal flagellomere short, barrel-shaped, approximately as long as wide, remaining flagellomeres oval, covered with short light pubescence (Fig. 49). Apical flagellomere large, 1.7 × as long as preceding segment. Longest verticils ~0.5 × as long as respective flagellomeres. Rostrum dark brown, covered with dense light grey pruinosity. Palpus short, dark brown, covered with sparse dark erect setae. Labellum brown.

Thorax. Generally light grey because of dense pruinosity that covers dark brown surface, dorsum brownish grey. Presutural scutum pale brownish grey with three distinct dark brown stripes. Medial stripe not reaching suture caudally, with interrupted pale longitudinal vitta along middle, more distinct posteriorly. Lateral stripe reaches pseudosutural fovea frontally and suture caudally. Scutal lobe lead grey with dark brown central area reaching lateral scutal stripe frontally. Area between scutal lobes pale grey with dark brown frontal margin. Scutellum pale grey with few erect yellowish setae. Mediotergite bluish grey. Pleuron pale grey, bluish dorsally, brownish ventrally. Wing (Fig. 50) long and narrow both in male and female, slightly > 4 × as long as wide, subhyaline, milky, with yellowish base and costal area, iridescent, without darker pattern, except indistinct pale brown stigma. Veins brown, yellowish at wing base. Venation: Sc long, reaching far beyond branching point of $R_{2+3+4'}$, nearly to the proximal margin of stigma. Cross-vein *sc-r* closer to base of R_s than to humeral vein. R_s 2.6 × as long as *m-cu*, arched. Free end of R_1 short, distinctly shorter than R_2 . Vein R_2 oblique. Distal portions of R_3 , $R_{4'}$ and R_5 straight and parallel to each other. Stem of cell r_3 long, longer than *m-cu*. Discal cell missing due to reduction of *m-m*. Cell m_1 short, its stem 2 × as long as cell itself. Cross-vein *m-cu* nearly its own length beyond branching point of *M*. Vein *CuP* slightly sinuous, A_1 slightly arched at distal part. Anal angle large, widely rounded. Halter brown with darker brown knob. Length of male halter 0.8 mm, of female 0.9–1.0 mm. Coxae grey, just fore coxa brownish postero-ventrally. Trochanters yellowish brown. Femora pale brown, slightly more infusate towards distal end. Tibiae and basal tarsomeres pale brown, distal tarsomeres brown. Male femur I: 4.8 mm long,

II: 5.6 mm, III: 5.3 mm, tibia I: 5.6 mm, II: 5.3 mm, III: 5.3 mm, tarsus I: 7.0 mm, II: 5.8 mm, III: 8.1 mm. Female femur I: 4.4–5.1 mm long, II: 4.6–5.4 mm, III: 4.3–5.5 mm, tibia I: 4.2–5.0 mm, II: 4.1–4.8 mm, III: 4.0–5.2 mm, tarsus I: 4.9–6.0 mm, II: 4.5–5.4 mm, III: 3.9–5.2 mm. Claw pale brown, without spines or teeth, basal half widened, distal narrow.

Abdomen. Tergites rusty brown, sternites somewhat paler, both covered with sparse yellowish setae. Pregenital segments dark brown. Membrane between tergites and sternites obscure yellow. Male terminalia (Fig. 51) yellow. Posterior margin of epandrium with deep and wide emargination, lateral lobe rounded, densely covered with long setae. Gonocoxite short and stout, simple, without additional lobes. Interbase wide at base, distal portion narrow and strongly arched. Outer gonostylus elongate, nearly parallel-sided, plate-shaped, distal portion covered with dense blackish spinulae, apex rounded. Inner gonostylus nearly as long as outer gonostylus, but narrower, mesal surface with few small spines apically. Aedeagus straight and narrow, extending beyond caudal end of paramere. Ovipositor (Fig. 52) brownish yellow with pale tips of cercus and hypogynial valve. Cercus arched with tip raised upwards, hypogynial valve straight.

Elevation range. From circa 100 m to nearly 2000 m.

Period of activity. Adults fly from late April through to late October. Probably two generations a year.

Habitat. Wet sparse alder grooves in South Kuriles (Savchenko and Krivoluts-kaya 1976), *Chosenia* and *Alnus* grooves on margins of deep pits permanently filled with water in river valleys in south Primorye (Savchenko 1983). Semi-natural margins of streams densely covered with shrubs near small villages; margins of small fast-running rocky streams surrounded by mixed forests, with moss densely covering rock surfaces and some sandy bottom areas in South Korea.

General distribution. Korean Peninsula and Far East of Russia.

Remark. This species is recorded from South Korea for the first time.

Podenas leg.; at light; NIBR.

Redescription. General body colouration: dark brown head, obscure yellow thorax with greyish dorsum, dark brown abdomen. Body length of male ~ 4.5 mm, of female 4.8–7.9 mm. Wing length of male 5.2 mm, of female 5.6–8.6 mm.

Head. Dark brown, paler posteriorly, narrowly light grey along eye margin, covered with dense grey pruinosity and sparse yellowish setae. Vertex with low, slightly darker, rounded tubercle. Eyes widely separated, distance between them at base of antennae slightly exceeds length of scape. Antenna (Fig. 53) short, 0.6 mm long in male, 0.7 mm in female, reaching slightly beyond frontal margin of prescutum, if bent backwards. Scape yellowish brown to brown in male, covered with grey pruinosity, nearly cylindrical, ~2 × as long as succeeding segment. Pedicel cup-shaped, yellowish brown to dark brown. Flagellum dark brown, flagellomeres elongate, basal flagellomere oval, remaining segments wider at base, tapering towards apex. Holotype flagellum 10-segmented, but many specimens of both sexes have 11-segmented flagellum. Apical flagellomere large, 1.6 × as long as preceding segment. Longest verticils nearly reaching length of respective flagellomeres. Rostrum testaceous yellow to pale greyish brown. Basal palpomeres pale, terminal segments dark brown. Labellum pale brown.

Thorax. Generally greyish yellow to brownish, densely covered with dense brownish grey pruinosity. Presutural scutum greyish yellow with yellow lateral margin, with three distinct dark brown stripes. Medial stripe darker than lateral, dark brown, wider frontally, not reaching suture caudally. Lateral stripe paler and more diffuse, extending from pseudosutural fovea frontally to suture caudally. Scutal lobe with diffuse dark area in the middle, lateral margin greyish yellow, area between scutal lobes obscure yellow. Scutellum weakly darkened. Mediotergite weakly darkened with more infusate ventral margin. Pleuron obscure yellow with darkened ventral area of katepisternum, less visible in older museum specimens. Wing (Figs 54, 55) long and narrow, nearly 4 × as long as wide, subhyaline, milky, with yellowish base, iridescent, without darker pattern, except indistinct pale brown stigma. Veins pale greyish brown, yellowish at wing base. Venation: Sc long, reaching far beyond branching point of $R_{2+3+4'}$ nearly to the proximal margin of stigma. Cross-vein *sc-r* closer to base of *Rs* than to humeral vein. *Rs* 2.3 × as long as *m-cu*, nearly straight. Free end of R_1 as long as R_2 . Vein R_2 transverse. Distal portions of R_3 , R_4 , and R_5 arched, tips of R_4 and R_5 converging. Stem of cell r_3 very short, shorter than *r-m*. Discal cell missing due to reduction of vein *m-m*. Cell m_1 short, its stem nearly 3 × as long as cell itself. Cross-vein *m-cu* approximately its own length beyond branching point of *M*. Vein *CuP* straight, A_1 slightly arched at distal part. Anal angle large, widely rounded. Halter pale with slightly darker brownish knob. Length of male halter 0.8 mm, of female 1.1 mm. Coxae brownish yellow. Trochanters yellow. Femora and tibiae pale brown, distal tarsomeres darker brown. Male femur I: 4.8 mm long, II: 5.6 mm, III: 5.3 mm, tibia I: 5.6 mm, II: 5.3 mm, III: 5.3 mm, tarsus I: 7.0 mm, II: 5.8 mm, III: 8.1 mm. Female femur I: 3.5 mm long, II: 4.0 mm, III: 3.7–5.6 mm, tibia I: 3.5 mm, II: 3.3 mm, III: 3.4–5.1 mm, tarsus I: 5.0 mm, II: 4.5 mm, III: 4.6–5.3 mm. Claw brownish yellow, without spines or teeth.

Abdomen. Brown to dark brown, covered with greyish pruinosity and sparse erect yellowish setae, basal sternites yellow in male, greyish brown in female. Pregenital segments concolourous with the rest of abdomen. Male terminalia (Fig. 56) yellowish brown. Posterior margin of epandrium with low and wide slightly serrate median lobe covered with dense short but strong setae, lateral lobe long and narrow, finger shaped. Gonocoxite slightly longer than wider, with tuft of long dense setae mesally at base and few small spines at apex, without additional lobes. Interbase large, elongate blade extending beyond apex of gonocoxite, distal half widened, terminating in an acute spine, basal part narrower and finely serrate. Outer gonostylus elongate, fleshy and setose, oval with concave mesal surface. Inner gonostylus nearly as long as outer gonostylus, distal part subglobular, without setae. Aedeagus short. Ovipositor (Fig. 57) yellow. Base of cercus narrowly dark brown, distal part pale yellow, raised upwards. Hypogynial valve nearly straight, yellow to pale yellow.

Elevation range. From 200 m to nearly 2000 m.

Period of activity. Adults fly from the end of April through to the middle of October.

Habitats. Southern slopes of rocky canyons of small streams surrounded by broad leaved forests in the Kedrovaya Padj sanctuary in the Far East of Russia (Savchenko 1983).

General distribution. North and South Korea, Far East of Russia.

Remark. This species is recorded from South Korea for the first time.

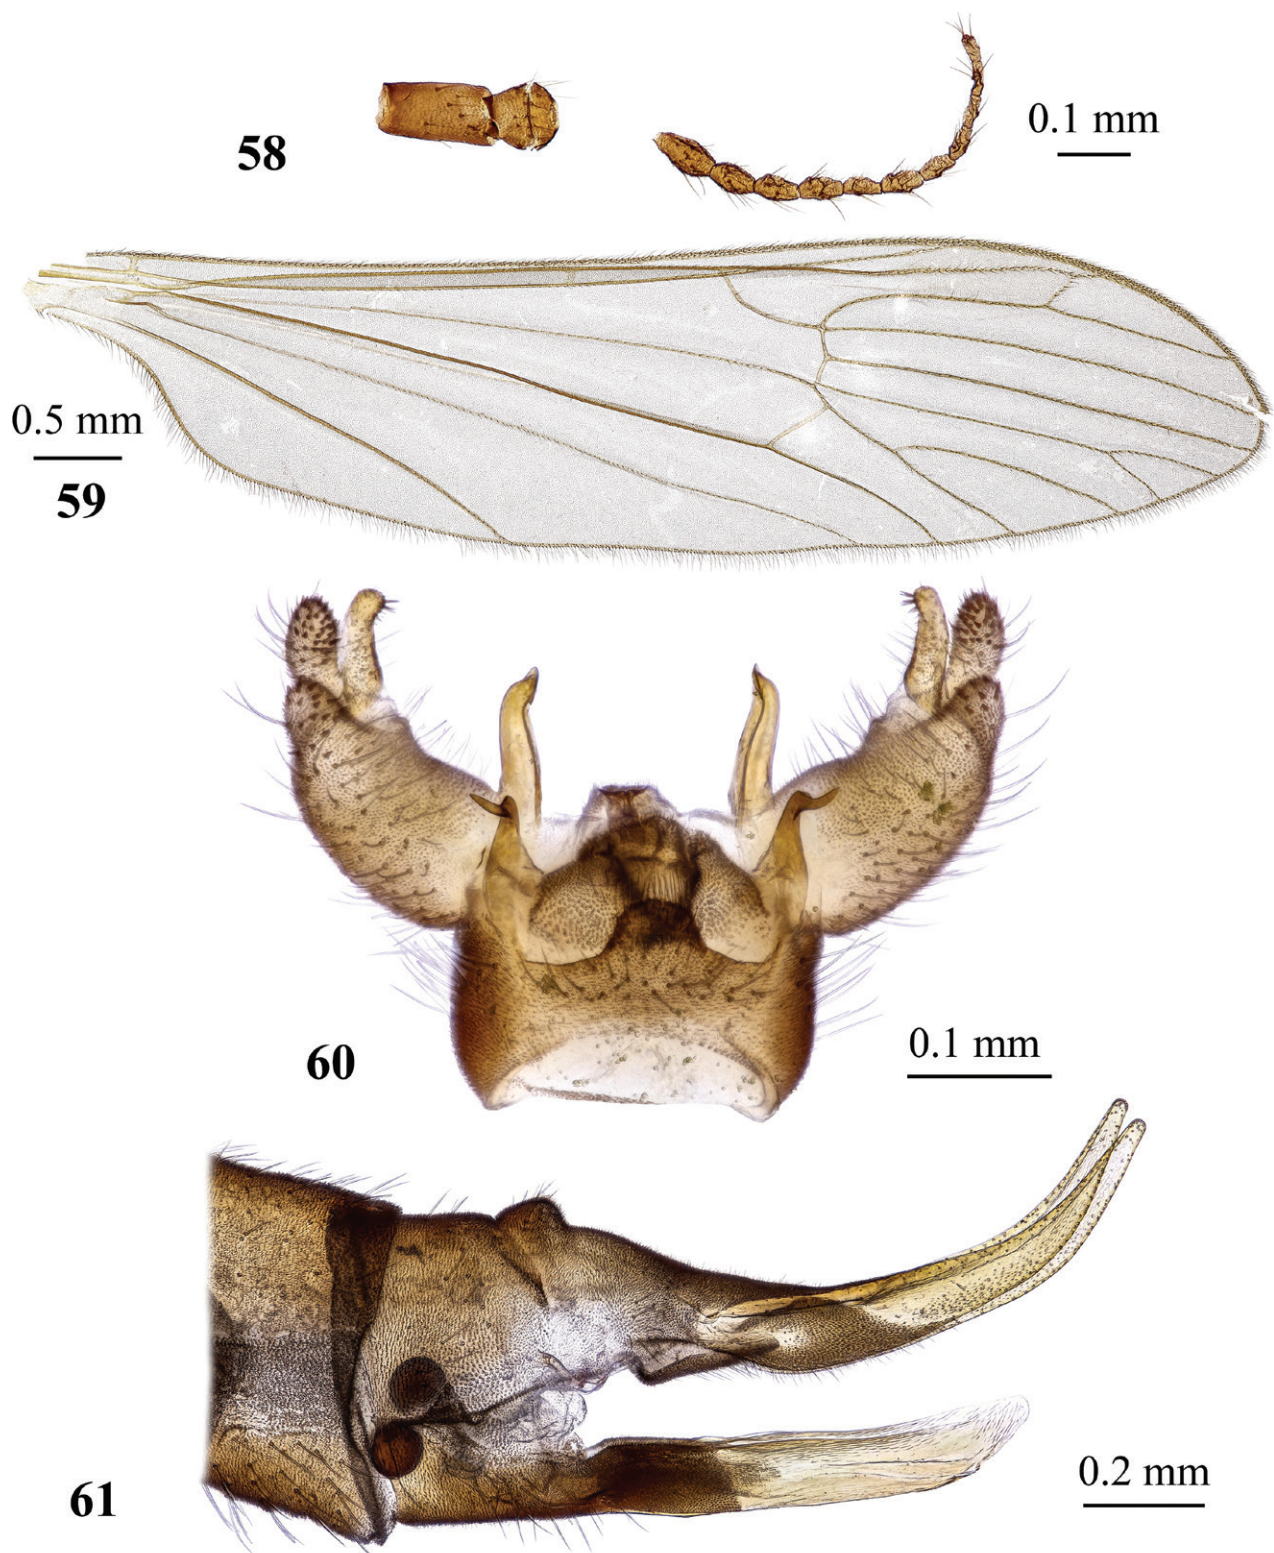

***Dicranota (Rhaphidolabis) ompoana* Alexander, 1945**

Figs 58–61, 89

Dicranota (Rhaphidolabis) ompoana Alexander, 1945: 246.

Type material examined. NORTH KOREA • Holotype ♂ (both antennae, fore leg, wing and abdomen slide mounted); Ompo; alt. 213 m; 8 May 1938; A. M. Yankovsky leg.; USNM.

Other examined material (Fig. 89). NORTH KOREA • 3 ♀ (pinned); Ompo; alt. 76 m; 7 May 1938; A. M. Yankovsky leg.; USNM • 3 ♀ (pinned); Ompo; alt. 91 m; 8 May 1938; A. M. Figures 58–61. *Dicranota (Rhaphidolabis) ompoana* Alexander, 1945 58 antenna, holotype 59 wing, holotype 60 male genitalia, dorsal view 61 ovipositor, lateral view.

Redescription. General body colouration grey. Body length of male ~ 6.0 mm, of female 5.1–7.6 mm. Wing length of male 5.3–7.0 mm, of female 6.4–9.2 mm.

Head. Black, densely covered with grey pruinosity and sparse semi-erect yellowish setae. Eyes widely separated, distance between them at base of anten-

nae slightly exceeds length of scape. Vertex with distinct tubercle, covered with yellowish grey pruinosity, top blackish. Antenna (Fig. 58) short, 0.5–0.7 mm long in male, 0.6 mm in female. Scape elongate, subcylindrical, $\sim 1.5 \times$ as long as pedicel, dark brown, covered with sparse greyish pruinosity and bearing few erect setae on dorsal surface. Pedicel wider distally, blackish, covered with few short dark setae. Flagellum black, 11-segmented, flagellomeres elongate, oval, basal flagellomere $1.5 \times$ as long as succeeding segment. Apical flagellomere relatively large, $0.9 \times$ as long as preceding segment. Longest verticils $0.7 \times$ as long as respective flagellomeres. Rostrum dark brown to black. Palpus black. Labellum large, obscure yellow with narrowly darkened margins.

Thorax. Pronotum grey laterally, greyish brown dorsally. Presutural scutum obscure brownish to bluish grey with three distinct dark brown stripes. Medial stripe without paler line along middle, or with very indistinct line posteriorly, darker frontally, less distinct caudally, not reaching suture. Lateral stripe short, nearly reaches pseudosutural fovea frontally and suture caudally, more distinct frontally, fading caudally. Scutal lobe with diffuse darker area extending lateral scutal stripe. Area between scutal lobes pale yellowish, greyish brown, colour varies depending on angle of light. Scutellum and mediotergite pale grey. Pleuron grey with darkened ventral area of katepisternum and meron. Dorsopleural membrane obscure yellow. Wing (Fig. 59) long and narrow, $4 \times$ as long as wide, subhyaline, milky, with yellowish base, iridescent, without darker pattern, except indistinct pale brown stigma. Veins pale greyish brown, yellowish at wing base. Venation: Sc long, reaching beyond level of cell m_3 base, to approx. proximal margin of stigma. Cross-vein $sc-r$ closer to base of R_s than to humeral vein. R_s $1.6 \times$ as long as $m-cu$, arched. Free end of R_1 very short, much shorter than R_2 . Vein R_2 oblique. Wing cell r_2 without supernumerary cross-vein, but one female from Ompo has this cross-vein on the left wing and missing on the right wing. Distal portions of R_3 , R_4 , and R_5 straight, parallel to each other. Cell r_3 without stem. Discal cell missing due to reduction of vein $m-m$. Cell m_1 short, its stem $3 \times$ as long as cell itself. Cross-vein $m-cu$ short distance beyond branching point of M . Vein CuP slightly sinuous, A_1 slightly arched. Anal angle large, widely rounded. Halter yellow with slightly darkened knob. Length of male halter 1.0 mm, of female 0.9–1.0 mm. Fore and middle coxae pale, densely covered with grey pruinosity, posterior coxae yellow. Trochanters yellow. Femora and tibiae pale brown to brown with slightly darkened apices, basal tarsomeres pale brown, distal tarsomeres darker brown. Male femur I: 3.9–4.8 mm long, II: 5.1 mm, III: 4.3–5.0 mm, tibia I: 3.7–4.7 mm, II: 4.6 mm, III: 4.1–4.8 mm, tarsus I: 4.9–6.8 mm, II: 5.5 mm, III: 4.7–5.3 mm. Female femur I: 3.5 mm long, II: 4.1–5.5 mm, III: 3.7–5.6 mm, tibia I: 3.5 mm, II: 3.6–4.9 mm, III: 3.4–5.1 mm, tarsus I: 5.0 mm, II: 3.7–4.9 mm, III: 4.6–5.3 mm. Claw dark brown, distinctly wider at base than distally.

Abdomen. Semi-polished, yellowish to greyish brown, covered with pale semi adjacent setae. Posterior margins of segments pale, wider on tergites. Basal sternite pale grey frontally. Pregenital segment darker brown. Male terminalia (Fig. 60) dark brown. Posterior margin of epandrium with low and wide rectangular median lobe covered with dense short setae, lateral lobe long and narrow, strongly curved. Gonocoxite short and wide, $\sim 1.5 \times$ as long as wide, with apex slightly produced and covered with scarce strong short spines. Interbase yellow, large, nearly as long as gonocoxite itself, tip slightly curved, distal margin finely

serrate. Outer gonostylus elongate, oval, fleshy and setose, distal part covered with short black strong spines. Inner gonostylus exceeds in length outer gonostylus, arched, fleshy and setose, distal half of mesal margin with few short spines. Aedeagus short, paramere slightly curved, extending well beyond tip of aedeagus. Ovipositor (Fig. 61) yellow with dark brown ninth and tenth tergites and eighth sternite. Basal half of cercus brownish, distal part paler. Hypogynial valve nearly straight, long and parallel-sided with pale rounded tip. Setae along dorsal margin of valve, common for most *Rhaphidolabis*, strongly reduced.

Elevation range. From < 100 m to nearly 2000 m.

Period of activity. Adults fly from late April through middle of October.

Habitats. Margins of small fast running streams with rocky bottom, densely covered with shrubs. Adults are sometimes found hiding under bridges.

General distribution. North and South Korea.

Remark. Species recorded from South Korea for the first time.

Redescription. General body colouration dark brown to dark grey (old museum specimens could be paler). Body length of male ~ 6.0, of female 6.8–9.0 mm. Wing length of male 7.0–7.9 mm, of female 7.7–9.5 mm.

Head. Dark grey, narrowly paler along eye margin, somewhat bluish caudally, silvery frontally, covered with semi-erect dark brown setae. Eyes widely separated, distance between them at base of antennae slightly exceeds length of scape. Tubercle on vertex low, with narrow darker line along middle. Antenna (Fig. 62) medium-long, reaching beyond frontal margin of prescutum, if bent backwards, 1.5 mm long both in male and female. Scape long, nearly cylindrical, 2.5 × as long as pedicel, dark brown, covered with sparse greyish pruinosity and bearing few erect setae on dorsal surface. Pedicel subglobular, brown, bearing few short dark setae. Flagellum black, 15-segmented. Basal flagellomere elongate, widening distally, 1.5 × as long as second segment, succeeding flagellomeres elongate, barrel-shaped. Apical flagellomere relatively large, approximately as long as preceding segment. Longest verticils nearly as long as respective flagellomeres. Rostrum black. Palpus dark brown with blackish setae. Labellum large, brown, sparsely dusted with grey.

Thorax. Pronotum dark brown dorsally and grey laterally, covered with erect brown setae medially. Presutural scutum dark bluish grey with three dark brown stripes. Medial stripe distinct, nearly reaching suture caudally, separated longitudinally by paler line along middle in Japanese specimens, such line is missing in Korean specimens. Lateral stripe less distinct, short, nearly reaches pseudosutural fovea frontally, extends to suture caudally. Scutal lobe grey with diffuse darker area in the middle, reaching caudal end of lateral scutal stripe. Area between scutal lobes brownish. Scutellum greyish brown with yellowish lateral margin, covered with erect setae. Mediotergite brown, greyish frontally, yellowish caudally. Pleuron bluish grey, semi-polished, with slightly darker ventral area of katepisternum. Dorsopleural membrane pale grey. Wing (Fig. 63) long and narrow, 3.9 × as long as wide, distinctly brownish, paler at base, iridescent. Stigma distinct, elongate, brown. Indistinct darker area surrounds origin of R_s , cord, cubital and anal veins, narrowly darkened also distal wing margin and base of anal angle. Veins brown, yellowish at wing base. Venation: Sc long, reaching proximal margin of stigma. Cross-vein $sc-r$ distinctly closer to base of R_s than to humeral vein, sometimes missing, like in Fig. 63. R_s longer than in most *Rhaphidolabis*, 3 × as long as $m-cu$, slightly arched. Free end of R_1 very short, shorter than R_2 . Vein R_2 transverse. Distal portions of R_3 , R_4 , R_5 and M_1 straight, parallel to each

other. Cell r_3 with short stem. Discal cell missing due to reduction of vein $m-m$. Cell m_1 rather long, its stem only $1.6 \times$ as long as cell itself. Cross-vein $m-cu$ less than its own length beyond branching point of M . Vein CuP straight, A_1 slightly arched before wing margin. Anal angle large, widely rounded. Stem of halter pale with yellowish base. Knob dark brown with pale base. Length of male and female halter 1.2 mm. Coxae obscure yellow, covered with erect yellow setae, denser on fore coxa. Trochanters yellow with narrowly blackened distal margin. Femora brown with yellowish bases and slightly darkened apices, tibiae yellowish brown with slightly darkened apices, basal tarsomeres brown, distal tarsomeres dark brown. Male femur I: 5.4 mm long, II: 5.5 mm, III: 5.9 mm, tibia I: 5.4 mm, II: 5.2 mm, III: 5.7 mm, tarsus I: 5.7 mm, II: 5.2 mm, III: 5.4 mm. Female femur I: 4.3–4.5 mm long, II: 5.2 mm, III: 5.2 mm, tibia I: 4.4–4.7 mm, II: 4.4 mm, III: 5.2 mm, tarsus I: 4.2–5.0 mm, II: 4.8 mm, III: 5.3 mm. Claw brown, just slightly arched.

Abdomen. Semi-polished, dark greyish brown, covered with sparse pale erect setae. Posterior margins of segments pale grey. Male terminalia (Fig. 64) yellowish brown. Posterior margin of epandrium widely concave and slightly serrate, densely setose; postero-lateral angle with long curved, rod-shaped lobe that narrows towards distal end. This lobe mistakenly was marked as interbase in original description (Alexander 1933), true interbase distinctly shorter straight blade with wider base. Gonocoxite short and wide, length just slightly exceeds width, mesal margin swollen at base, apex produced into large slightly curved spine-shaped lobe. Outer gonostylus pale, elongate, round-apexed, fleshy and setose, distal and mesal areas covered with short blackish spinules. Inner gonostylus exceeds in length outer gonostylus, arched, fleshy and setose, mesal surface with longer setae. Aedeagus short with bifid apex, paramere elongate. Ovipositor (Fig. 65) yellow with yellow tenth tergite. Base of cercus and hypogynial valve slightly infuscated. Cercus slightly arched, blunt apexed. Hypogynial valve straight, narrowing towards apex, dorsal margin with set of long strong setae.

Elevation range. From 100 m to nearly 800 m.

Period of activity. Adults fly from late April through to late October in South Korea; they are active from late March to mid-November in Japan.

Habitats. Adults fly close to springs, small mountainous streams and rivulets, shaded by mixed forests and shrubs with sparse grassy vegetation along the margins. Males sometimes seen fly around tree trunks even further from the water, probably in search of females. This species was not attracted to light even in places where it was collected with nets during the day.

General distribution. South Korea, Kyushu and Shikoku islands of Japan.

Remark. This species is recorded from the Korean Peninsula for the first time.

***Dicranota (Rhaphidolabis) seoi* Podenas, sp. nov.**

<https://zoobank.org/F2B18870-CEA7-49F9-871F-D4F616005023>

Figs 66–68, 91

Type material (Fig. 91). **SOUTH KOREA** • **Holotype** ♂ (in ethanol); Gangwon-do, Chuncheon-si, Namsan-myeon, Gongchon-ri; 37.81159°N, 127.64919°E; alt. 131 m; 7 October 2018; S. Podenas leg.; net; NIBR. **Paratypes** • 1 ♂, 1 ♀ (in ethanol); Jeollanam-do, Gurye-gun, Toji-myeon, Naeseo-ri, Jirisan National Park, Piagol valley; 35.26590°N, 127.58096°E; alt. 446 m; 24 April 2015; S. Podenas leg.; at light; NIBR.

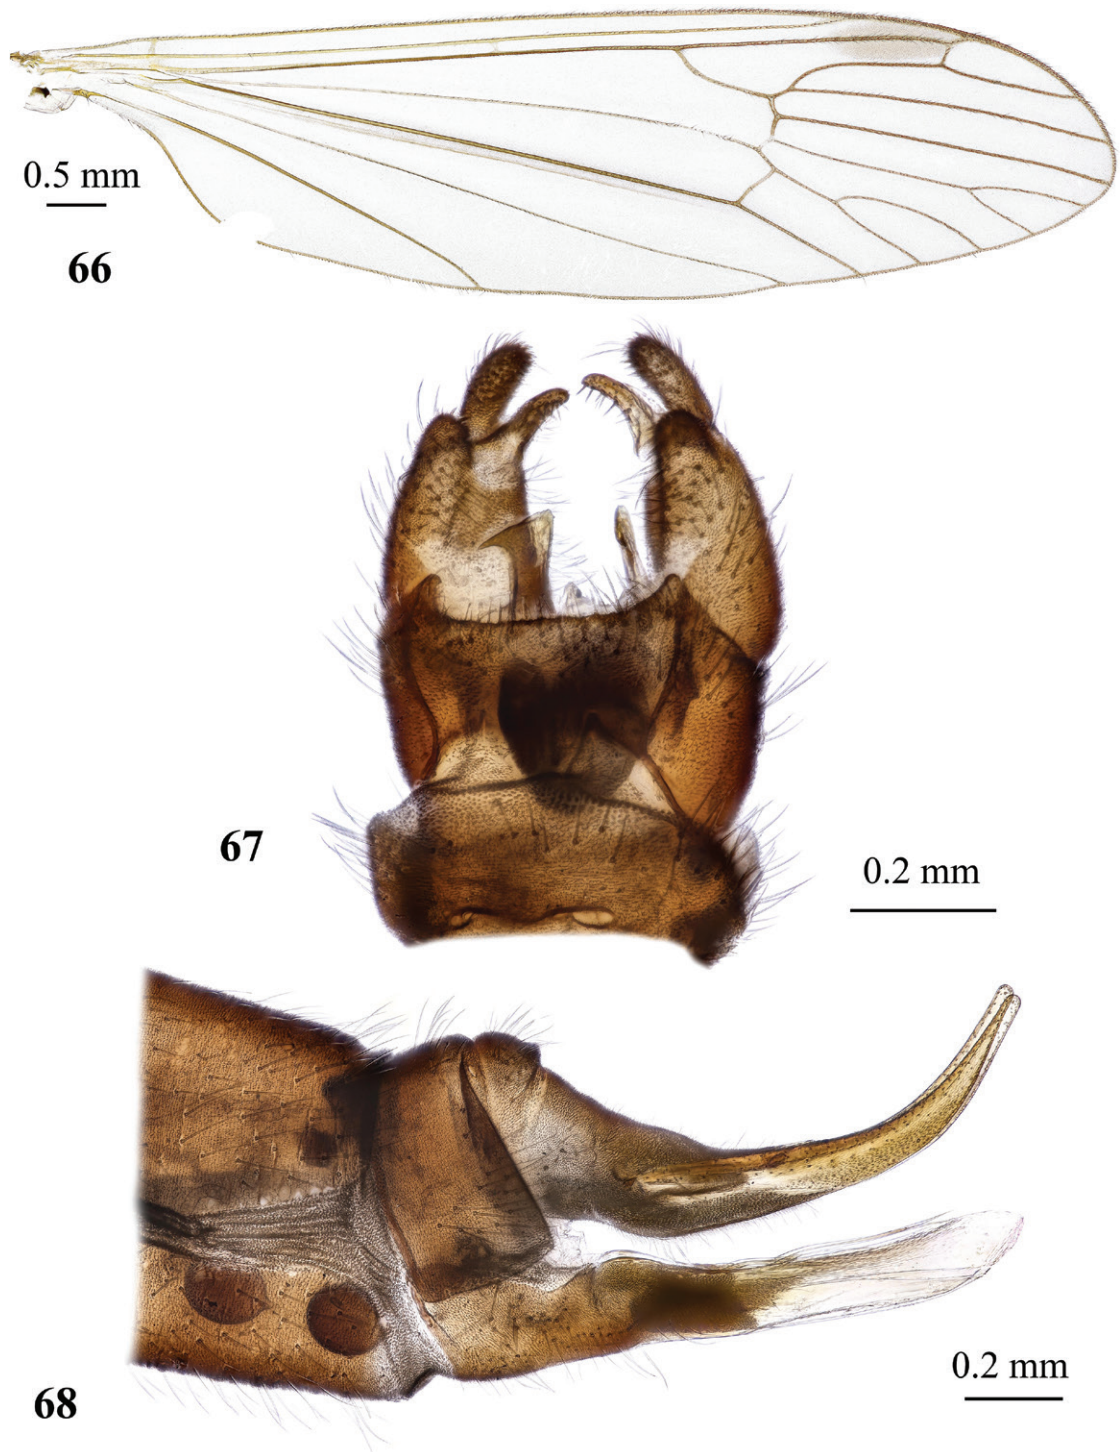

Diagnosis. Medium-sized dark brown species. Wing semi-translucent, milky without darker areas except brownish stigma. Antenna 14-segmented with large apical segment. Epandrium of male genitalia with straight caudal margin bordered with small lateral lobe. Gonocoxite with rounded dorso-apical lobe. Both gonostyli elongate. Gonostyli and gonocoxal lobe covered with short pale spines. Interbase large, flat, with strong spine dorso-caudally. Aedeagus short with blunt apex. Ovipositor yellow with arched cercus and straight hypogynial valve.

Etymology. The species is named after the Korean entomologist Dr Hong-Yul Seo, who not only studied Korean aphids, but did a lot for other groups of insects. He is a very warm person, our friend and colleague, and with whom we collected together on that cold October day when the holotype of this species was found.

Description. General body colouration dark brown. Male body length 10.0 mm, wing length 9.2 mm.

Head. Dark greyish brown, narrowly paler along eye margin, covered with sparse semi-erect dark setae dorsally, longer frontally, shorter caudally. Eyes widely separated, distance between them at base of antenna nearly equals length of scape. Male antenna 1.5 mm long, reaching to approx. frontal margin of prescutum if bent backwards, female antenna not reaching frontal margin of prescutum if bent backwards. Scape dark brown, subcylindrical, bearing few erect setae dorsally. Pedicel somewhat paler, slightly widening towards distal end. Flagellum 12-segmented in both sexes, brown, basal flagellomere slightly elongate, similar to pedicel, succeeding flagellomeres short, subglobular, distal flagellomeres slightly elongate, apical flagellomere large, distinctly longer than preceding segment, especially in female. Verticils short, not reaching length of respective flagellomeres. Rostrum and palpus brown, labellum pale.

Thorax. Uniformly dark brown. Cervical sclerites paler. Pronotum with yellowish lateral margin, bearing few erect whitish setae dorsally. Presutural scutum dark brown with three longitudinal stripes. Medial stripe very wide, not reaching suture caudally, area between caudal margin of stripe and suture yellowish. Stripes separated by grey area, covered with erect pale setae. Pseudosutural fovea indistinct. Prothoracic spiracle surrounded by yellowish membrane. Scutal lobe dark brown, area between lobes yellowish. Scutellum yellowish brown. Mediotergite dark brown. Pleuron uniformly dark brown, just ventral margin of katepisternum narrowly blackish. Wing (Fig. 66) elongate, length/width ratio 3.8, widest slightly before tip of vein *CuP*, semi-translucent, milky, yellowish at base, without any darker spots besides brownish stigma. Veins greyish to brownish, yellowish at wing base. Venation: *Sc* long, reaching wing margin slightly beyond frontal margin of stigma, far beyond of R_{2+3+4} branching point, *sc-r* closer to origin of radial sector than to humeral vein. *Rs* short, $2.3 \times$ as long as cross-vein *m-cu*, slightly arched. Free end of R_1 short, approximately as long as R_2 . Vein R_2 nearly transverse. R_3 , R_4 , and R_5 nearly straight and parallel to each other. Cell r_3 with distinct stem, which is as long as cross-vein *r-m*. Discal cell missing due to atrophy of vein *m-m*. Cell m_1 rather long, its stem $1.8 \times$ as long as cell itself. Cross-vein *m-cu* half of its own length beyond branching point of *M*. Vein *CuP* nearly straight, A_1 slightly arched before wing margin. Anal angle wide and rounded. Halter long, uniformly pale, knob not darker than stem in male, slightly infusate in female. Length of male halter 1.2 mm. Fore coxa dorsally brown, ventrally obscure yellow, brown area approximately equals yellow. Middle coxa brown with yellowish distal part, posterior coxa entirely brown. Trochanters obscure yellow with narrowly blackened distal

Figures 66–68. *Dicranota* (*Rhaphidolabis*) *seoi* Podenas, sp. nov., paratypes **66** wing **67** male genitalia, dorsal view **68** ovipositor, lateral view.

margin. Femora brown with widely pale base and darker distal part. Tibiae brown with indistinctly darker distal part. Tarsomeres brown, except dark brown last segment. Male femur I: 3.3–3.8 mm long, II: 4.0 mm, III: 4.0–4.4 mm, tibia I: 3.4–3.8 mm, II: 3.2–3.4 mm, III: 3.7–4.1 mm, tarsus I: 4.2–5.2 mm, II: 3.6–3.9 mm, III: 3.8–4.6 mm. Female femur I: 3.3–4.0 mm long, II: 3.8 mm, III: 4.0–4.5 mm, tibia I: 3.0 mm, II: 2.9 mm, III: 2.9–3.8 mm, tarsus I: 3.3 mm, II: 2.8 mm, III: 2.9–3.7 mm. Claw small, brownish, slightly arched, with subbasal spine.

Abdomen. Brown, slightly dusted with grey, basal sternite yellowish. Both tergites and sternites covered with very sparse short pale setae. Male terminalia (Fig. 67) brown with yellowish gonocoxites. Posterior margin of epandrium straight with small serration, covered with short pale setae, lateral margin with small simple, triangle-shaped lobe. Gonocoxite elongate, $\sim 2 \times$ as long as wide, with rounded lobe dorso-apically. Mesal margin of lobe covered with sparse short, spine-shaped setae. Two pairs of gonostyli. Outer gonostylus elongate, brown, fleshy and setose, round-apexed. Mesal and caudal margins covered with pale short spines. Inner gonostylus long and narrow, wider at base, slightly arched, pale brown, nearly as long as outer gonostylus. Mesal margin with few long pale spines. Interbase large, wide plate-shaped, dorso-caudal angle extended into large strong spine, ventral margin finely serrate. Aedeagus short, blunt-apexed. Paramere elongate, slightly curved. Ovipositor (Fig. 68) brownish yellow with pale distal part of hypogynial valve. Cercus uniformly brownish yellow, just tip paler. Distal part distinctly narrower, raised upwards, apex blunt. Hypogynial valve straight, brownish yellow at base. Dorsal margin with few short subbasal setae, reaching to $\sim 1/4$ of valve. Two spermathecae small, subglobular.

Habitat. Margins of fast running mountainous streams with rocky bottom. Slopes covered with mixed forest and sparse herbaceous vegetation. Preimaginal stages unknown. Both males and females attracted to light.

Elevation. From 100 m to 450 m.

Period of activity. Two generations per year, one flying early in spring at the end of April, the second late in the season at the beginning of October.

Distribution. Currently known only from South Korea, but probably has a wider distribution throughout the country, because both localities are far from each other.

Remarks. Generally *Dicranota* (R.) *seoi* Podenas, sp. nov. resembles *D. (R.) minuscula*: both are comparatively large dark species. The wings of both species are similar, without a dark pattern, just the stigma of *D. (R.) seoi* Podenas, sp. nov. is slightly darker, the stem of cell m_3 is slightly longer in *D. (R.) minuscula*, and the cross-vein R_2 slightly more oblique in *D. (R.) minuscula*. These characters are rather stable, but the best characters for species discrimination are found in the male terminalia. The easiest way to tell both species apart is through the caudal margin of the epandrium, that is straight with a small lateral lobe in *D. (R.) seoi* Podenas, sp. nov. and deeply concave with a large rounded lateral lobe in *D. (R.) minuscula*. The gonocoxite of *D. (R.) seoi* Podenas, sp. nov. bears a distinct dorso-apical lobe, while that of *D. (R.) minuscula* is simple, without such a lobe. Both gonostyli of *D. (R.) seoi* Podenas, sp. nov. approximately equal in length, outer gonostylus distinctly shorter than inner gonostylus in *D. (R.) minuscula*. Females of both species can be separated based on the structure of the cercus, the distal part of which is narrower in *D. (R.) seoi* Podenas, sp. nov. than in *D. (R.) minuscula*. A good external character separating *D. (R.) seoi* Podenas, sp. nov. from other Korean *Rhaphidolabis* and especially from the similar *D. (R.) ompoana* is the unique 14-segmented antenna. *Dicranota* (R.) *ompoana*, like most other Korean *Rhaphidolabis* have 13-segmented antenna.

We expect *D. (R.) seoi* Podenas, sp. nov. to be more abundant in Korea, but because adults fly only early in the spring and late in the fall, when most crane flies and other insects are inactive, few entomologists collect in the field; thus they are not well represented in entomological collections.

Yankovsky leg.; USNM • 3 ♂ (pinned, genitalia in microvials with glycerol on same pins), Pontani Paiktusan, alt. 1676–1890 m, 4 August 1940, A. M. Yankovsky leg.; USNM.

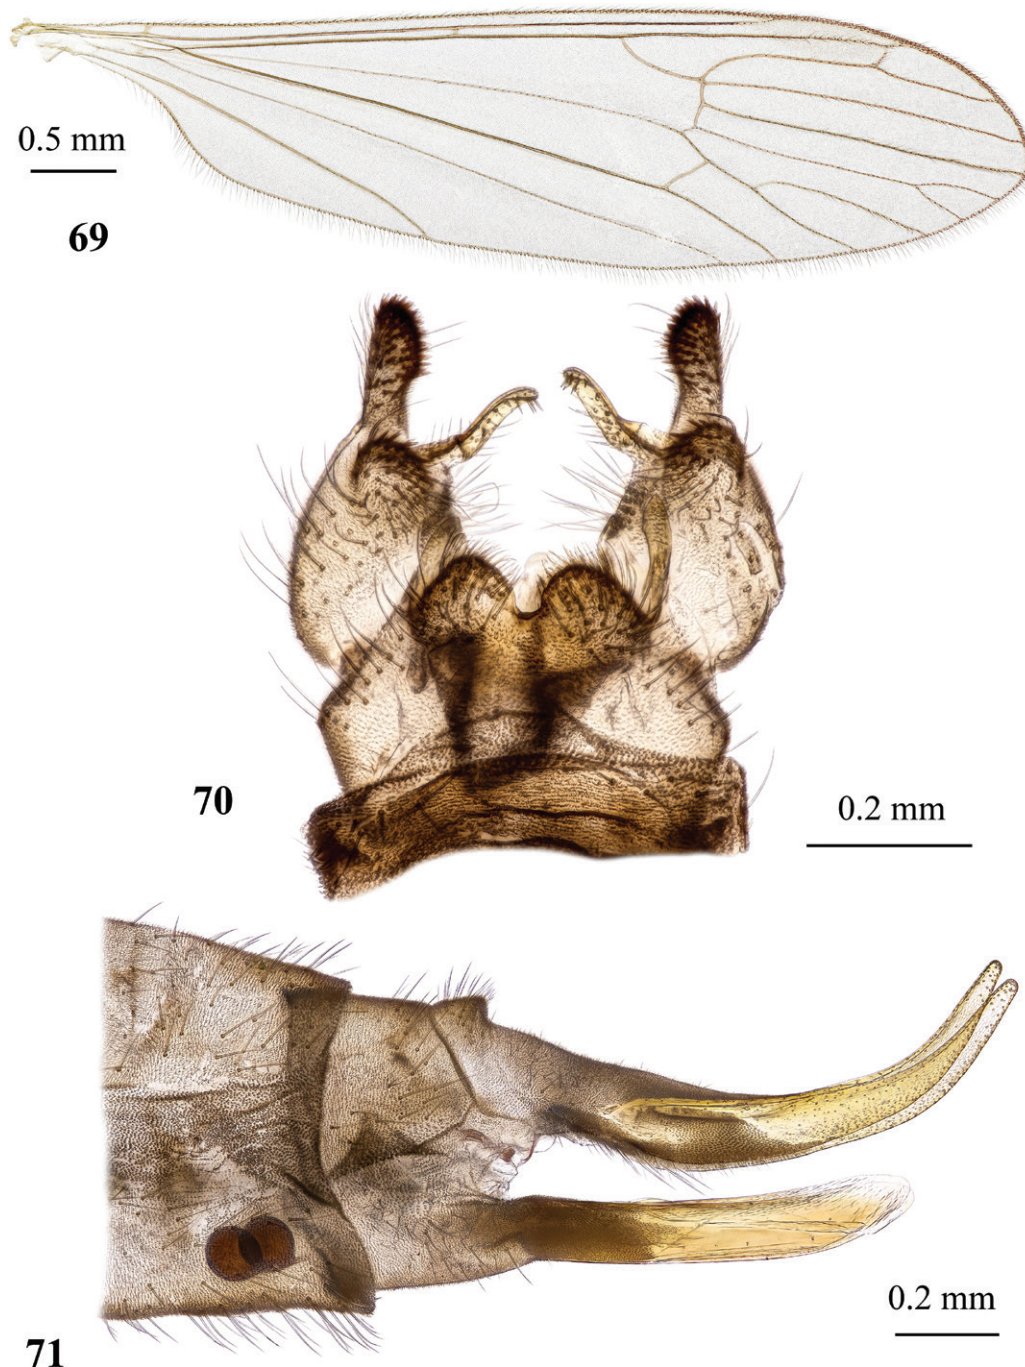

Redescription. General body colouration yellowish brown. Body length of male ~5.5 mm, of female ~6.0 mm. Wing length of male 5.5–6.0 mm, of female ~6.5 mm.

Head. Grey because of dense yellowish grey pruinosity, ground colour dark brown, covered with semi-erect setae, dark brown at base turning yellowish towards tips. Eyes widely separated, distance between them at base of antennae slightly exceeds length of scape. Tubercle on vertex low, indistinctly darkened along middle. Antenna medium-long, reaching frontal margin of prescutum at most, if bent backwards, 0.5 mm long in male, 0.7 mm in female. Scape long, nearly cylindrical, dark brownish grey because of dense grey pruinosity, bearing few short dark setae dorsally. Pedicel subglobular, concolourous with scape. Flagellum dark brown, 11-segmented. Basal flagellomere elongate, succeeding segments barrel-shaped. Apical flagellomere smaller than preceding segment. Longest verticils nearly as long as respective flagellomeres. Flagellum covered with short pale pubescence. Rostrum brown. Palpus dark brown. Labellum large, pale brown.

Thorax. Pronotum brown, dusted with yellowish grey, covered with erect pale setae medially. Presutural scutum brownish grey with three dark brown longitudinal stripes. Medial stripe distinct, dark brown with indistinct pale medial line, more distinct caudally, missing frontally. Lateral stripe less distinct, short, nearly reaches pseudosutural fovea frontally, extends to scutal lobe caudally. Area between medial and lateral stripe more rusty brown. Scutal lobe dark grey, nearly concolourous with lateral scutal stripe, only lateral and medial margins paler grey. Scutellum uniformly grey. Mediotergite yellowish brown with sparse cover of grey pruinosity. Pleuron uniformly brownish grey because of dense cover of grey pruinosity. Dorsopleural membrane yellowish grey. Wing (Fig. 69) long and narrow, 4 × as long as wide, translucent with slight greyish tinge, paler at base, iridescent. No dark areas besides indistinct stigma. Veins greyish, yellowish at wing base. Venation: Sc long, reaching proximal margin of stigma. Cross-vein *sc-r* closer to origin of *Rs* than to humeral vein. *Rs* short, 1.8 × as long as *m-cu*, slightly arched. Free end of *R*₁ very short, distinctly shorter than *R*₂. Vein *R*₂ slightly oblique. Distal portions of *R*₃, *R*₄, and *R*₅ straight, parallel to each other. Cell *r*₃ without stem. Discal cell missing due to reduction of vein *m-m*. Cell *m*₁ short, its stem nearly 3 × as long as cell itself. Cross-vein *m-cu* less than its own length beyond branching point of *M*. Vein *CuP* nearly straight, *A*₁ slightly arched at distal end. Anal angle large,

widely rounded. Stem of halter pale to greyish with yellowish base. Knob darker brownish grey. Length of male halter 0.5 mm. Coxae yellowish grey, covered with sparse erect yellowish setae, denser on fore coxa. Trochanters, especially fore and middle more intensely greyish. Femora obscure yellow with paler bases, tibiae and basal tarsomeres brownish yellow, distal tarsomeres brown to dark brown. Male femur I: 3.6–3.8 mm long, II: 3.2 mm, tibia I: 3.2–3.7 mm, II: 3.3 mm, tarsus I: 4.8–5.3 mm, II: 4.9 mm. Claw small, dark brown, simple, without spines.

Abdomen. Brown in male, yellowish in female, covered with sparse greyish pruinosity and short sparse pale setae. Posterior margins of segments narrowly

Figures 69–71. *Dicranota (Rhaphidolabis) squarrosa* Savchenko, 1976 **69** wing **70** male genitalia, dorsal view **71** ovipositor, lateral view.

pale greyish yellow in female, pale grey in male. Male terminalia (Fig. 70) obscure yellow. Posterior margin of epandrium with U-shaped concavity at middle, lateral lobe rounded, densely setose. Gonocoxite short and wide, length just slightly exceeds width, apex dorsally produced into large rounded lobe covered with small blackish spinules. Interbase extended into slightly arched blade. Outer gonostylus elongate, blunt-apexed, fleshy, covered with short blackish spinules. Inner gonostylus pale and narrow, slightly curved at middle, mesal surface bearing few spine-shaped setae distally, which are especially distinct at apex. Aedeagus short with slightly widened apex, paramere elongate. Ovipositor (Fig. 71) yellow. Base of cercus and hypogynial valve slightly infusate, brownish, tips pale. Cercus arched, apex blunt and raised upwards. Hypogynial valve nearly straight, parallel-sided, blunt-apexed. Dorsal margin with few short setae at $\sim 1/3$ of length.

Elevation range. From 1500 m to nearly 1900 m.

Period of activity. Adults fly briefly, from late July only to the beginning of August in Korea, but they are active in mid-September in southern Sakhalin (Savchenko and Krivolutskaya 1976).

Habitats. Adults hide among high grass along stream margins in wet mixed forests (Savchenko and Krivolutskaya 1976).

General distribution. North Korea, Sakhalin Island (Russia).

Remark. The species is recorded from the Korean Peninsula for the first time.

***Dicranota (Rhaphidolabis) yeongokia* Podenas, sp. nov.**

<https://zoobank.org/4790DDD3-FF3E-414E-8EE8-2D91EEEC2E1>

Figs 72–76, 93

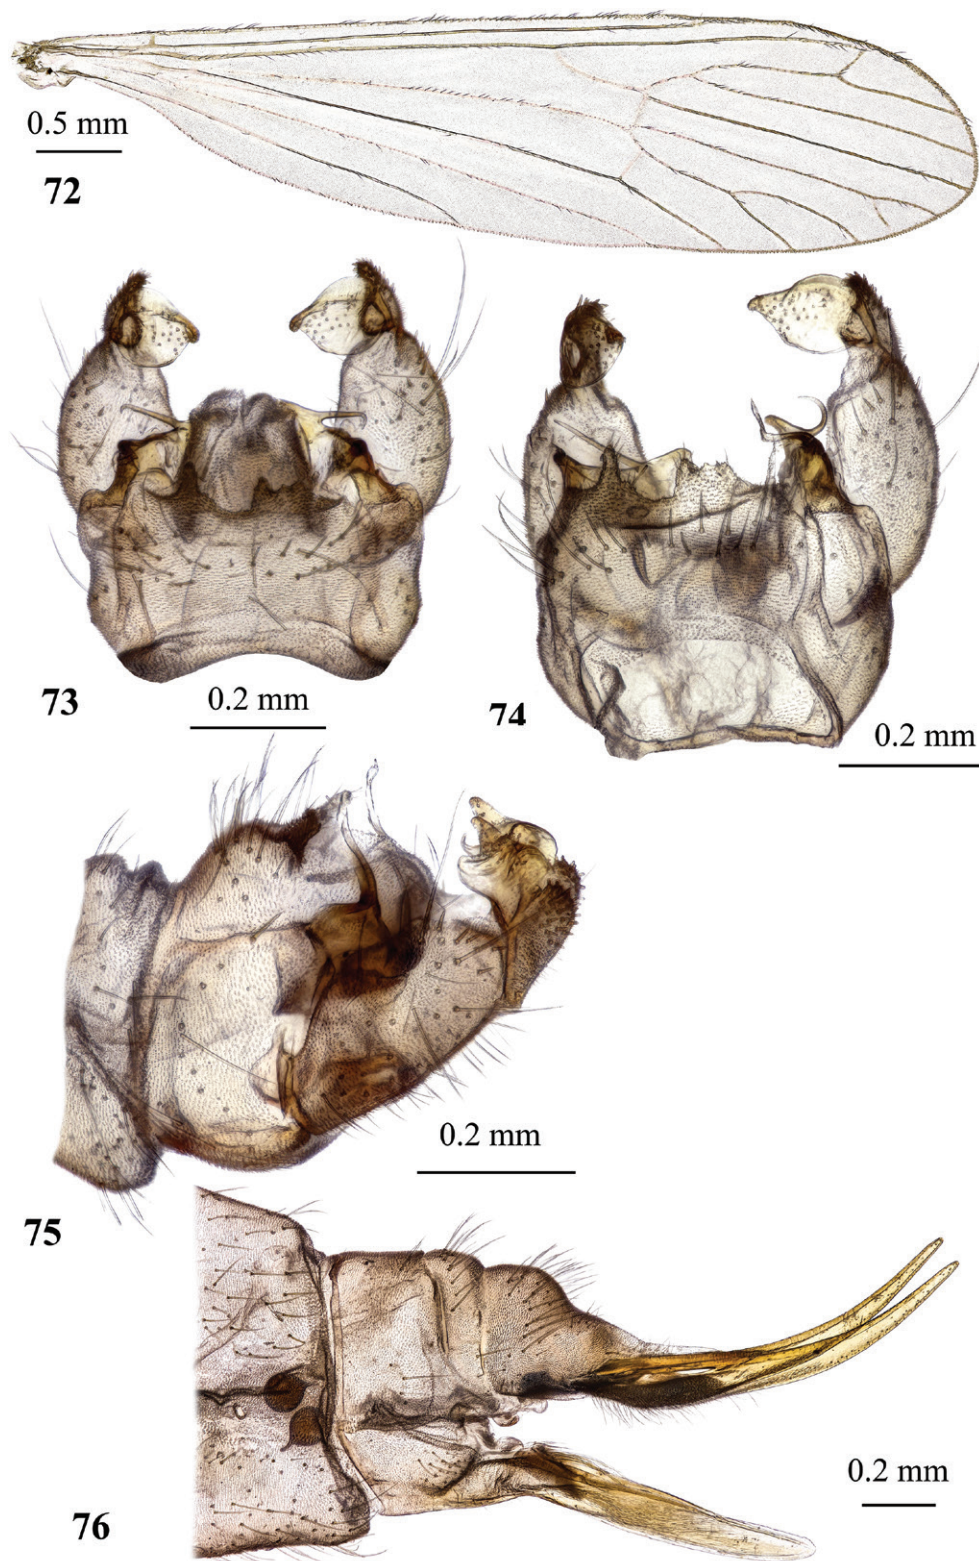

Type material examined (Fig. 93). **SOUTH KOREA** • **Holotype** ♂ (in ethanol); Gangwon-do, Gangneung, Yeongok-myeon, Samsan-ri, Odaesan National Park; 37.81161°N, 128.70116°E; alt. 280 m; 2 May 2012 (2); S. Podenas leg.; net; NIBR. **Paratypes** • 27 ♂, 5 ♀ (in ethanol, wing of 1 ♂ slide mounted, genitalia of 1 ♂ in microvial with glycerol); Gangwon-do, Gangneung, Yeongok-myeon, Samsan-ri, Odaesan National Park; 37.81161°N, 128.70116°E; alt. 280 m; 2 May 2012 (2); S. Podenas leg.; net; NIBR.

Diagnosis. Pale yellow species with contrastingly black eyes. Wing semi-translucent, milky without darker areas and without stigma. Male gonostylus with large mesal lobe, posterior margin of epandrium with U-shaped invagination, margins of which usually asymmetrical, interbase large with elongate postero-dorsal and postero-ventral angles, the latter with long curved spine. Female cercus just slightly arched with distinct black base of ventral margin.

Etymology. The species is named after the locality where it was collected, Yeongok-myeon.

Description. General body colouration pale yellow. Body length of male 5.0–5.7 mm, of female 7.3 mm. Wing length of male 5.0–6.2 mm, of female 5.9–6.4 mm.

Head. Greyish yellow, paler posteriorly, covered with sparse short pale setae. Eyes widely separated, distance between them at base of antenna nearly equals length of both basal antennomeres. Antenna 0.9–1.0 mm long in male, reaching slightly beyond frontal margin of prescutum if bent backwards, 1.1 mm in female. Scape pale, subcylindrical, $\sim 2 \times$ as long as second antennomere, bearing few setae dorsally. Pedicel pear-shaped, slightly darker than scape.

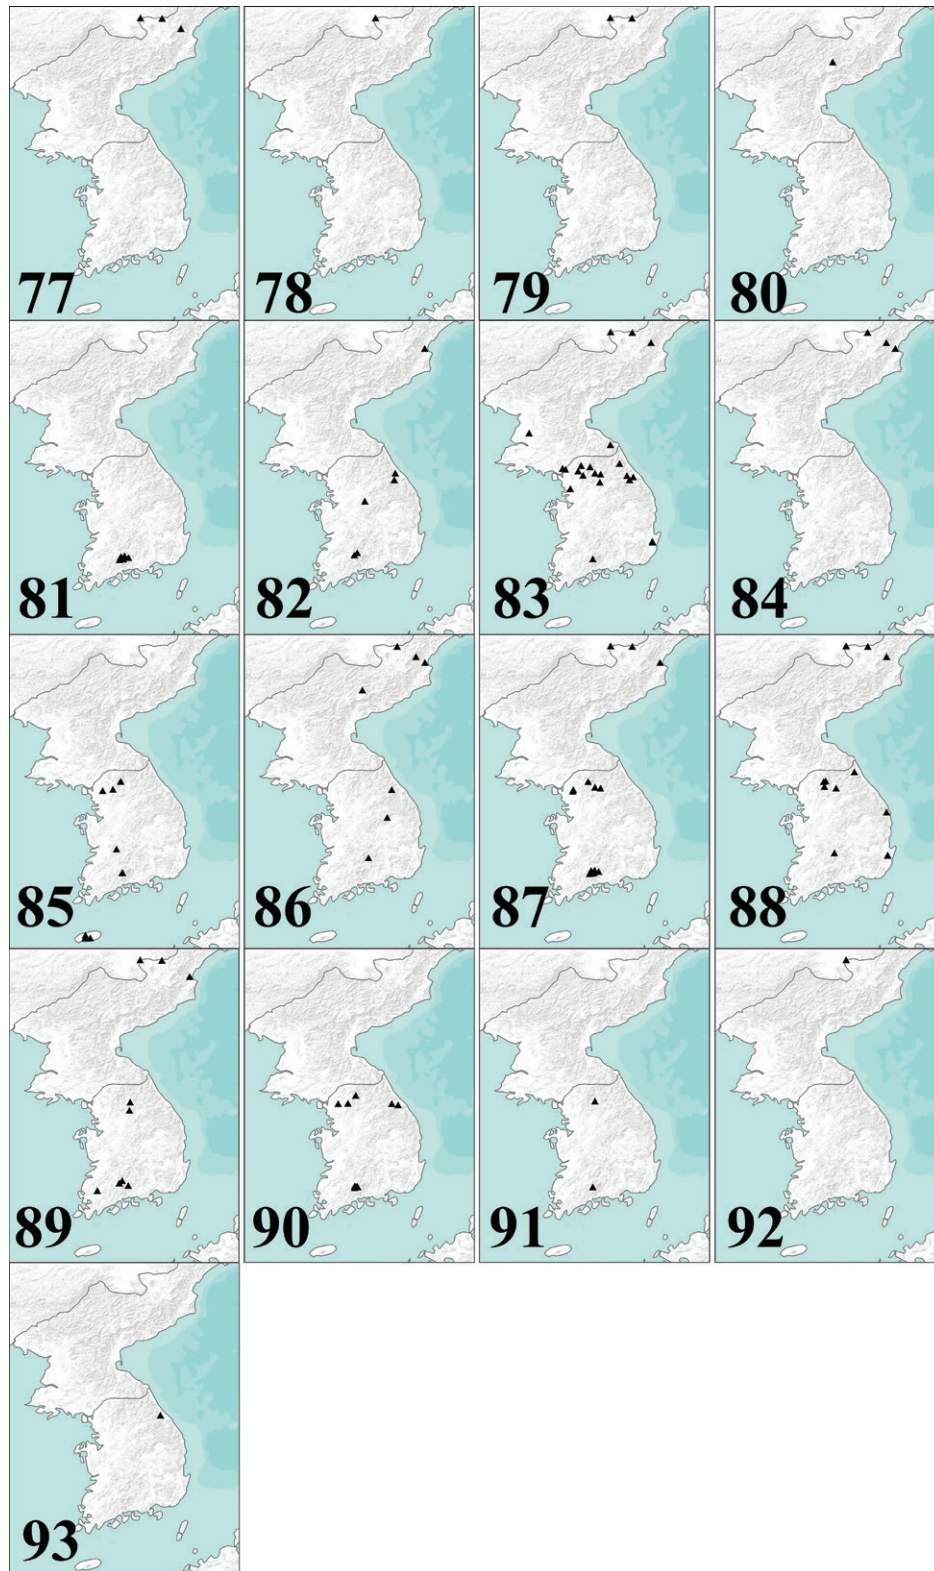

Figures 72–76. *Dicranota (Rhaphidolabis) yeongokia* Podenas, sp. nov., paratypes **72** wing **73** male genitalia, dorsal view **74** male genitalia, dorso-lateral view **75** male genitalia, lateral view **76** ovipositor, lateral view.

Flagellum 13–14-segmented, pale brown, basal flagellomeres oval, distal flagellomeres slightly elongate, apical flagellomere comparatively large, but shorter than preceding segment. Longest verticils nearly as long as respective flagellomeres. Rostrum and palpus yellow. Labellum pale.

Thorax. Pale brownish yellow. Cervical sclerites pale. Pronotum somewhat darker, bearing few erect setae dorsally. Presutural scutum uniformly pale brownish yellow, longitudinal stripes missing (stripes could be faded because of preservation in ethanol). Tubercular pit missing, pseudosutural fovea indistinct. Prothoracic spiracle surrounded by pale membrane. Scutal lobe concolourous with presutural scutum. Scutellum paler. Mediotergite pale brownish yellow. Pleuron paler than dorsum, darker areas missing. Wing (Fig. 72) elongate, length/width ratio 4.2, widest approximately at tip of vein *CuP*, semi-translucent, milky. Stigma and any darker areas missing. Veins greyish to brownish, paler at wing base. Venation: *Sc* long, reaching wing margin slightly beyond level of branching point of $R_{2+3+4'}$, *sc-r* slightly closer to humeral vein than to origin of radial sector. *Rs* short, $2.5 \times$ as long as cross-vein *m-cu*, slightly arched. Free end of R_1 nearly missing, reaching wing margin together with R_2 . Vein R_2 oblique. R_3 , R_4 , and R_5 parallel to each other. Cell r_3 with distinct stem. Cross-vein *r-m* also distinct. Discal cell missing due to atrophy of vein *m-m*. Cell m_1 very short, its stem $4 \times$ as long as cell itself. Cross-vein *m-cu* less than its own length beyond branching point of *M*. Vein *CuP* nearly straight, A_1 slightly sinuous. Anal angle long and narrow. Halter long, uniformly pale yellow. Length of male halter 0.8–0.9 mm, of female 0.8–0.9 mm. Coxae and trochanters pale yellow, distal margin of trochanter narrowly blackened. Femora pale brownish yellow. Tibiae pale yellow with slightly darkened apices. Basitarsi pale yellow at base, turning darker towards distal end, remaining tarsomeres brownish. Male femur I: 3.2 mm long, II: 3.8 mm, III: 3.6–4.0 mm, tibia I: 3.7 mm, II: 3.8 mm, III: 3.9–4.5 mm, tarsus II: 4.2 mm, III: 4.7–4.8 mm. Female femur I: 2.9 mm long, II: 3.4 mm, III: 3.5–3.7 mm, tibia I: 4.2 mm, II: 3.5 mm, III: 4.1 mm, tarsus I: 4.3 mm, II: 3.6 mm, III: 3.0–3.7 mm. Claw small and simple, nearly straight, without spines.

Abdomen. Pale, pregenital segments slightly infusate. Male terminalia (Figs 73–75) pale brownish yellow. Posterior margin of epandrium with U-shaped concavity at middle, bottom of which with few setae starting from small bumps. Setae often not symmetrically arranged on both sides. Margin of concavity extended into larger setose lobe, two or three much smaller lobules could be present further laterally. Often size of larger lobe is different on both sides, number of smaller lobules often varies too, and sometimes they are missing completely. Thus posterior margin of epandrium often, but not always, is asymmetrical. Gonocoxite slightly elongate, $1.4 \times$ as long as wide, approximately egg-shaped, without additional spiny lobe distally, but with few short spine-shaped setae subapically. One pair of gonostyli. Outer part of gonostylus darkened, elongate, basal half of mesal surface strongly swollen, rounded, with darker margin, lateral part elongated, darker brown, covered with small spines on distal two-thirds and apex. Middle of mesal margin with large pale, subglobular lobe bearing small brownish rostral appendage, lower, expanded part with scattered sensilla. Interbase extended into large flattened lobe, postero-dorsal angle of which extended into slightly arched spine. Postero-ventral angle extended into long rostrum, bearing long curved spine, turned backwards. Aedeagus short, not visible in dorsal view, tip shallowly bifid. Paramere elongate, slightly curved. Posterior segments of female abdomen generally yellow, concolourous with the rest of abdomen. Tenth tergite yellow. Cercus (Fig. 76) yellow, slightly arched, tip raised upwards, blunt-apexed with paler distal part and distinctly blackened basal part of ventral margin, dorsal margin slightly infusate.

(Rhaphidolabis) neoconsors* Alexander, 1938 **89** *D. (Rhaphidolabis) ompoana* Alexander, 1945 **90** *D. (Rhaphidolabis) polymera* Alexander, 1933 **91** *D. (Rhaphidolabis) seoi* Podenas, sp. nov. **92** *D. (Rhaphidolabis) squarrosa* Savchenko, 1976 **93** *D. (Rhaphidolabis) yeongokia* Podenas, sp. nov.

Hypogynial valve straight, obscure yellow with brownish base and pale distal part. Dorsal margin with few short subbasal setae, reaching to ~ 1/4 of valve. Two small subglobular spermathecae.

Habitat. Slopes to the fast running mountainous stream with waterfalls covered with mixed forest, sparse herbaceous vegetation. Collected during small rain. Preimaginal stages unknown.

Elevation. Near 300 m.

Period of activity. Beginning of May.

Distribution. Currently known only from Odaesan National Park, South Korea.

Remarks. *Dicranota* (R.) *yeongokia* Podenas, sp. nov. generally similar to *D. (R.) luteola*, both are small yellow species, but distinct differences are observed in many structures: antenna of *D. yeongokia* Podenas, sp. nov. has 15–16 segments, that of *D. luteola* 13-segmented; wing cell m_3 with distinct stem, anal angle long and narrow in *D. (R.) yeongokia* Podenas, sp. nov., stem of cell m_3 very short or missing, anal angle wide in *D. luteola*; big differences are observed in male genitalia, especially in structure of epandrium and gonostylus. Despite crane flies are intensively collected for more than a decade in many different localities throughout South Korea, *D. (R.) yeongokia* Podenas, sp. nov. was observed only once in Odaesan National Park. Probably it has very short flying period and very limited distribution.

Acknowledgements

Our warmest thanks to all Korean friends and colleagues who helped us during our visits to South Korea. We are very grateful for Dr F. Shockley and Dr T. Dikow (USNM), Dr J. K. Gelhaus (ANSP) for the use of specimens from the USNM and ANSP collections, J. C. Thomas for the help with Korean specimens from the University of Kansas, U. S. A., Dr T. A. Klein and Dr H.-C. Kim (Force Health Protection and Preventive Medicine, Medical Department Activity-Korea (MEDDAC-K)/65th Medical Brigade, Unit 15281, APO AP 96271) for the Pediciidae crane flies that they collected in 2017–2020, and two anonymous reviewers for their comments and improvement of the text. Special thanks are extended to colleagues from NRC Dr M. Dagys for his help on preparation of distribution maps and N. Nasevičienė for her help to arrange and measure specimens. We are also very grateful for the reviewers who helped us to improve our manuscript, and especially N. Yonov for her constant help with our crane fly papers.
