

# LSC 6.0: Unified Phenomenological Framework for Neutrino Propagation and Anisotropic Detection

Author: LuciferSun

## Abstract

We present LSC 6.0, a phenomenological framework unifying relativistic neutrino propagation with anisotropic detector response. The model explains the Gallium anomaly without invoking sterile neutrinos, instead relying on coupled propagation–measurement effects.

## 1. Unified Physical Model

The LSC 6.0 framework describes neutrinos as probes of spacetime geometry, with observed anomalies arising from coupled propagation and detection effects.

## 2. Observable Equation

$$E_{\text{obs}} = E_{\text{emit}} \times G(g, \Phi, E) \times [1 + \alpha_D D_{\{\mu\nu\}} (p^\mu p^\nu / E^2)]$$

## 3. Gallium Anomaly

The observed ratio  $R \approx 0.79$  is explained through combined propagation (5–7%) and detector effects (3–5%).

## 4. KATRIN Constraint

The model is consistent with KATRIN due to low-energy suppression of propagation effects.

## 5. IceCube Context

The framework predicts anisotropy without requiring global modulation.

## 6. Predictions

Sidereal modulation, detector-dependent energy shifts, and angular anisotropy.

## 7. Limitations

The model is effective and requires further experimental validation.
