

# Thermodynamically constrain a metabolic model

**Author: Ronan Fleming, Leiden University**

**Reviewers:**

## INTRODUCTION

In flux balance analysis of genome scale stoichiometric models of metabolism, the principal constraints are uptake or secretion rates, the steady state mass conservation assumption and reaction directionality. Von Bertalanffy [1,4] is a set of methods for (i) quantitative estimation of thermochemical parameters for metabolites and reactions using the component contribution method [3], (ii) quantitative assignment of reaction directionality in a multi-compartmental genome scale model based on an application of the second law of thermodynamics to each reaction [2], (iii) analysis of thermochemical parameters in a network context, and (iv) thermodynamically constrained flux balance analysis. The theoretical basis for each of these methods is detailed within the cited papers.

## PROCEDURE

### Configure the environment

All the installation instructions are in a separate .md file named vonBertalanffy.md in docs/source/installation

With all dependencies installed correctly, we configure our environment, verify all dependencies, and add required fields and directories to the matlab path.

```
initVonBertalanffy
```

### Select the model

This tutorial is tested for the E. coli model iAF1260 and the human metabolic model Recon3Dmodel. However, only the data for the former is provided within the COBRA Toolbox as it is used for testing von Bertalanffy. However, the figures generated below are most suited to plotting results for Recon3D, so they may not be so useful for iAF1260. The Recon3D example uses values from literature for input variables where they are available.

```
modelName = 'iAF1260';  
%modelName='Ec_iAF1260_flux1'; %uncomment this line and comment the line below if you w  
%modelName='Recon3DModel_Dec2017';
```

### Load a model

Load a model, and save it as the original model in the workspace, unless it is already loaded into the workspace.

```

clear model
global CBTDIR
modelName = [modelName '.mat']

modelName =
'IAF1260.mat'

end
end
end

```

Checking mass and charge balance.

Assuming biomass reaction is: BIOMASS\_Ec\_iAF1260\_core\_59p81M

ATP maintenance reaction is not considered an exchange reaction by default. It should be mass balanced:

ATPM    atp[c] + h2o[c]        ->        adp[c] + h[c] + pi[c]

There are mass imbalanced reactions, see </home/rfleming/work/sbgCloud/code/fork-COBRA.tutorials/analysis/>
