

## **Whole-genome comparison between the type strain of *Halobacterium salinarum* (DSM 3754<sup>T</sup>) and the laboratory strains R1 and NRC-1.**

Friedhelm Pfeiffer, Gerald Losensky, Anita Marchfelder, Bianca Habermann and Mike Dyall-Smith

MicrobiologyOpen (2019) 8: e974 (DOI: 10.1002/mbo3.974 ; PubMed: 31797576)

Note: This document contains Supplementary Tables for the above manuscript. The legends use some terms which are only defined in the context of that manuscript. Here is one paragraph from that manuscript which briefly describes the content of the tables.

*Correlation of protein-coding genes among Halobacterium salinarum strains 91-R6<sup>T</sup>, R1, and NRC-1.* As an annotation principle, every gene encoding a protein on a matching genome segment in one strain must have a correlated gene in the other strain. The gene sets of the three strains have been correlated in detail (for details see Methods of the associated manuscript and Appendix 4 and Appendix 5). Proteins are classified as strain-specific only after validation by tBLASTn that they are not mere missing gene calls. Correlated proteins, encoded on the chromosome of strains 91-R6 and R1 are listed in Table S1 (1986 proteins). The corresponding proteins from strain NRC-1 are also listed. In addition, there are regions of very high similarity between the plasmids from strains 91-R6 and R1, and the resulting plasmid encoded correlated proteins are listed in Table S2. Furthermore, Table S2 lists proteins which are encoded on a plasmid in strain R1 but in a strain-specific region of the chromosome from strain 91-R6. Chromosomally encoded proteins from strain-specific regions of 91-R6 are listed in Table S3. In several cases, a homolog exists in R1 but the genes are not positionally correlated. Such homologs are also listed in Table S3. Residual proteins which are specific for the chromosome of strain R1 are listed in Table S4. Plasmid encoded proteins specific for strain 91-R6 are listed in Table S5, while plasmid encoded proteins specific for strain R1 are listed in Table S6. A few protein-coding genes exist in strain NRC-1 but are absent in both strains 91-R6 and R1. These are listed in Table S7. Finally, Table S8 lists ORFs which are annotated in the current version of the NRC-1 genome (AE004437, AE004438, AF016485) but which are considered not to code for a protein (spurious ORFs; for definition see Appendix 4 in the associated manuscript).

**Table S1: Protein-coding genes on matchSEGs from the chromosomes of strains 91-R6 and R1.** As a basic rule, every protein-coding gene encoded on a matchSEG between strains 91-R6 and R1 has to be annotated in both strains. The locus tag of the corresponding strain is provided as code (**code**). For each gene, the protein name (**protein name**) and, if assigned, the gene (**gene**) is provided. Most of the genes can also be correlated with those from strain NRC-1. Missing gene calls in NRC-1 were resolved by post-

prediction. A hyphen indicates that the gene is absent from the NRC-1 chromosome. The protein sequence identity is reported (**seq id**). If the protein sequences are identical, it is indicated if the coding sequences are identical ("100d", identity at the DNA level) or if there are silent mutations ("100p", coding sequences differ but all mutations are silent so that the resulting proteins are identical). Sequences with less than 95% seq id are flagged in the comment column by "LowSim". Coding sequences are identical between strains R1 and NRC-1 with only few exceptions. These are flagged in the comment column by "seqdiff(R1/NRC-1)". The matchSEG serial number (**serial**) is indicated, preceded by "m". Genes which traverse the end of a matchSEG are flagged in the comment column by "traverse\_junction". If the gene traverses between matchSEGs (in case of indel with an insert in the other strain) the two serial numbers are separated by a slash ("/"). If the gene traverses from a matchSEG into an adjacent divSEG, the serial number of the divSEG is given, preceded by "d". Disrupted genes are flagged in the comment column by "pseudo()" with the affected strain(s) indicated within parentheses. If the gene has been targeted by a MGE (transposon or MITE), this is flagged by adding the term "split" within the parenthesis following pseudo. The targeted gene/gene set is indicated by square brackets around the code(s). In strain R1, only a single code is assigned, and the coding region is discontinuous. Even though biologically correct, EMBL/GenBank reject this annotation (as they forbid the resulting "join" feature for prokaryotic genomes). Therefore, it was decided to annotate the fragments of a targeted gene as independent ORFs in strains 91-R6 and NRC-1. Such ORF pairs are indicated as two codes within one square bracket. One protein-coding gene is disrupted in strains R1 and NRC-1 due to a large internal deletion. This is flagged in the comment column by "pseudo(R1;NRC-1;internal\_deletion)". The regular gene from strain 91-R6 traverses the end of more than one matchSEG. One protein-coding gene has a highly conserved 14aa tandem duplication only in strains R1 and NRC-1. This is flagged in the comment column as "insert(14aa;R1;NRC-1)".

**Table S2: Highly conserved protein-coding genes from strains 91-R6 and R1, at least one of which is encoded on a plasmid.** The 1<sup>st</sup> part of this table (up to HBSAL\_06290, column "code") lists proteins which are encoded on chromosomal divSEGs in strain 91-R6. The divSEG is indicated by "d" with a subsequent serial number in the "serial or plasmid" column. These proteins from strain 91-R6 match to a protein from one of the plasmids of strain R1 as indicated in the "serial or plasmid" column. It should be noted that the opposite, proteins from chromosomal divSEGs of strain R1 which match to plasmid proteins from strain 91-R6, has not been encountered. The 2<sup>nd</sup> part of this table (from HBSAL\_12005 onwards) lists proteins which are encoded on plasmids in both strains. Due to large-scale plasmid duplications, genes may be encoded on more than one plasmid (e.g. R1: pHS1+2 or 91-R6: pHSA1+2). In that case, both locus tags are shown, separated by a semicolon ("code"). This should not be mixed up with multiple locus tags for genes which have been targeted by a MGE. For these, the two codes are within square brackets and the comment column notes "pseudo(91-R6;split)". Other disrupted genes are flagged in the comment column by "pseudo()" (see the legend to Table S1 for details). Matching sequence pairs cover a range of sequence identity values. For proteins with identical sequence, it is indicated if the coding sequences are identical ("100d") or if there are silent mutations ("100p") (see also the legend to Table S1). Proteins with less than 95% seq\_id are flagged in the comment column (LowSim). If possible, R1 codes have been matched to NRC-1 codes. With few exceptions, R1 and NRC-1 genes are identical, differences being notes flagged as "seqdiff(R1/NRC-1)". Due to even further plasmid duplications in NRC-1, up to four copies of a gene may exists. All locus tags are shown, separated by semicolons. For proteins from R1 plasmid pHSA3 which correspond to a gene from strain NRC-1, a comment indicates if the NRC-1 gene is encoded on pNRC100 or on pNRC200. This table contains some special cases: (a) in some cases, a gene has been split but one fragment is very short and has not been annotated (flagged e.g. "N-term\_part\_unannotated"). (b) HBSAL\_04690: the R1 gene is split with a subsequent translocation due to a MGE-triggered genome inversion (OE\_5405F + OE\_5013R). (c) HBSAL\_05030; [HBSAL\_12805;HBSAL\_12815]; [HBSAL\_13495;HBSAL\_13505]: the gene has been targeted twice, more N-terminal by transposon ISH3B, more C-terminal by transposons ISHsa12. The N-terminal part upstream of ISH3B is encoded on the chromosome in divSEG12, while the C-terminal part, including its 2<sup>nd</sup> targeting MGE, has

been translocated to the plasmids, now being encoded on the duplicated part of pHSal1 and pHSal2. (d) OE\_5222A1F. This pseudogene is very short (15 codons) and has not been annotated in strains 91-R6 and NRC-1 ("very\_short\_pseudo").

**Table S3: Protein-coding genes on divSEGs from the chromosome of strain 91-R6.** Proteins encoded in divSEGs from strain 91-R6 are listed (**code**). The protein name (**protein name**) and, if assigned, the gene (**gene**) is given. If there is a paralog from strain R1, this is flagged in the comment column by "close\_paralog" and its code is given. If possible, the R1 gene is matched to a gene from strain NRC-1. The protein sequence identity is reported (**seq id**). The divSEG serial number (**serial**) is indicated, preceded by "d". This applies to the gene from strain 91-R6. If there is a paralog in strain R1, then the divSEG is a replacement and the R1 gene is found in the same divSEG. Disrupted genes are flagged in the comment column by "pseudo()" (see the legend to Table S1 for details). A special case is the *dmsA* gene which has been targeted by a transposon which was subsequently duplicated, associated with an insertion of >150 kb of DNA sequence. This is flagged in the comment column as "C-term\_far\_away(HBSAL\_05135)". Another

special case is the proS2 gene which traverses into the adjacent matchSEG on which the C-terminal heptapeptide is encoded. This is flagged in the comment column as "traverse\_junction (C-term\_7aa\_encoded\_on\_m32)".

**Table S4: Protein-coding genes on divSEGs from the chromosome of strain R1.** Proteins encoded in divSEGs from strain R1 are listed (**code**). The protein name (**protein name**) and, if assigned, the gene (**gene**) is given. The genes can be correlated with those from strain NRC-1 except for genes encoded on strain-specific MGEs, and for one very short pseudogene. In some cases, the comment indicates that a paralog is shared between strains R1 and 91-R6.

code (91-R6)	gene	protein name	comment

**Table S6: Strain-specific protein-coding genes from plasmids of strain R1.** Proteins encoded in strain specific plasmid regions of strain R1 are listed (code). The protein name (protein name) and, if assigned, the gene (gene) is given. If the plasmid region is also present strain NRC-1, the genes have been correlated except for genes encoded on R1 specific MGEs. Genes encoded on the 210 kb of plasmid unique to R1 and lacking in NRC-1 could not be correlated. Coding sequence differences are indicated in the comment column ("seqdiff(R1/NRC-1)"). Disrupted genes are flagged in the comment column by "pseudo()" (see the legend to Table S1 for details). In case of "split+trunc", the gene has been targeted in strains R1 and NRC-1 by the same MGE at an identical position, but the region on the other side of the MGE is lacking in the NRC-1 plasmid while it is present in the R1 plasmid unique regions. Up to four copies of NRC-1 genes are possible, due to large-scale duplications (four codes, separated by semicolons), because part of the region duplicated between pNRC100 and pNRC200 is further duplicated as an inverted repeat in each of the plasmids. The inverted repeat is longer in pNRC100 and thus some genes occur in three copies. In one such case, the copy on the inverted repeat is targeted by a MGE while the other two copies remained intact (indicated by "copy\_on\_pNRC100\_revDup\_isSplit").

**Table S7: Strain-specific protein-coding genes from strain NRC-1.** Besides strain specific copies of MGEs, there are only two short genome regions, totalling to 15 kb, which are specific to strain NRC-1 and are missing in strain R1 (ref\_R1genome). A 10007 bp insertion was identified in the chromosome (extending from VNG\_0207H to VNG\_0217H). Among the encoded genes is a XerC/D-like integrase family and a phage primase domain protein, two genes typically associated with prophages. The insertion has targeted the *pilB2* gene from a disrupted type IV pilus biogenesis complex. In this complex, the *pilC* gene carries an in-frame stop codon. Interestingly, this complex, including the disruption of the *pilC* gene, is strictly conserved between strains R1 and 91-R6. This type IV pilus biogenesis complex has been partially characterized in several *Halobacterium* strains (Losensky, G., Vidakovic, L., Klingl, A., Pfeifer, F. & Fröls, S. 2015. Novel pili-like surface structures of *Halobacterium salinarum* strain R1 are crucial for surface adhesion. *Front Microbiol*, 5, 755). A 4527 bp strain-specific region. coding for VNG\_6099H to VNG\_6105H is found in pNRC100 and pNRC200 between the MGEs ISH2 and ISH8. The first gene, VNG\_6099H, has been targeted by the MGE but the C-terminal region has been lost. In strain R1 plasmids pHs1 and pHs2 is a 19365 bp region between the same pair of MGEs in an identical genomic context. This region codes for OE6230R to OE6266R. Also in R1, the first gene has been targeted but the C-terminal part (corresponding to VNG\_6097C) is encoded on the other side of the ISH2, an element which has a TSD only in R1. Thus, the R1 sequence represents the original version over that MGE. There is no suitable protein-coding gene across the ISH8 element at the other end but as this MGE lacks a TSD in both strains, this MGE may have been affected by genome rearrangements in both strains.

**Table S8: Spurious ORFs from strain NRC-1.** This set of about 60 ORFs, which are annotated in strain NRC-1, are considered spurious and are named accordingly ("spurious ORF") in strain R1. Spurious ORFs are not represented in the R1 genome annotation but are retained in the TPA for strain NRC-1 to allow matching to the original annotation.
