Further it seems only just to add that, so early as March 27, 1871, Mr. Robert Louis Stevenson described to the Royal Scottish Society of Arts forms of intermittent lighthouse apparatus for exhibiting groups of flashes of occultations of unequal period; these arrangements, possessing the advantage over Babbage's original proposal, that during dark intervals the light is not simply stopped by a screen and thus lost, but sent usefully in other directions to strengthen the bright intervals or flashes.

The August Meteors

AS noted in NATURE, vol. xxvi. p. 378, I observed a bright display of meteors on the night of August 6, at Aberfeldy. On the 7th the sky was overcast with dense clouds all night; but on the following night I saw a more brilliant shower of meteors than on the 6th, with this difference that the meteors of the night of the 8th were mostly of several seconds' duration, and generally left a long, bright train of light behind; also, in place of being on the north of the Milky Way, as on the 6th, they were chiefly on the south of it. A very large and bright meteor burst out about half way to the zenith, and moved nearly horizontally from the south-east towards the west, leaving a long shining streak behind, and lasting close on fifty seconds. I watched the meteors for the next three nights from the parish manse of Logie-Almond, and witnessed on each night (9, 10, and 11) a gorgeous shower. On the evening of the 10th, before the twilight was quite gone, I noticed thirteen very large meteors during the space of a few minutes, although my view of the heavens was very much intercepted by trees and by the manse. Between 11 and 12 o'clock a meteor considerably larger and brighter than Venus under the most favourable circumstances, sailed over the southern heavens, leaving a long train of light which lasted fully a minute. Its position, time, and appearance, were nearly the same as those of the large meteor I saw at Aberfeldy on the night of the 8th. I have not for years, during any month, witnessed such a gorgeous display of meteors as I have seen on the nights specified in August last. But I have scarcely seen any since, except a few bright ones on Sunday night, September 17, at High Blantyre. The display of the August meteors was of a very short duration on each night, and after 12 o'clock not one scarcely could be seen.

ANIMAL INTELLIGENCE¹

FROM the time of Locke downwards the question How far animals have the power of abstraction? has often been discussed. Locke himself maintained that "the having of general ideas is that which puts a perfect distinction betwixt man and brutes, and is an excellency which the faculties of brutes do by no means attain to." And this view is warmly advocated by Prof. Max Müller and other living thinkers. On the other hand Mr. Romanes, who has made the subject of Animal Intelligence a special study, writes:—"Give a cat or a dog some kind of meat or cake which the animal has never met with, and the careful examination which the morsel undergoes before it is consigned to the mouth proves that the animal has properly abstract ideas of sweet, bitter, hot, nauseous, or in general, good for eating, and bad for eating, *i.e.*, abstract ideas of quality as apart from the object examined—the motive of the examination clearly being to ascertain which general idea of quality is appropriate to the particular object examined."—NATURE, vol. xx., p. 123.

Our first duty in a case like this is to make quite sure of the meaning of the words we employ. Much confusion may be, and has been, introduced into this subject by a lax use of words. Let us consider, then, the several meanings which these terms abstraction and abstract idea may have.

In the first place it seems to me that our most ordinary impressions involve abstraction. An object is capable of affecting us in a number of different ways, but of all

these at any given moment we only pay attention to one or two which happen to interest us. The rest are practically non-existent for us. The mind automatically rejects or eliminates them. This is certainly a process of abstraction, but for the sake of clearness I venture to call it *elimination*. By means of elimination we get definite clear-cut mental impressions.

In the second place our general conceptions involve abstraction. A general conception is one which does not stand for a particular object but for a group of objects. It is arrived at by abstracting the essentials and neglecting the unessentials. In the great number of dogs I see around me, there are certain essential characters in the midst of some diversities. As I consider them in the mass, however, the diversities cancel each other in my mind, and I obtain a general conception of a dog. We may for the purpose in hand call this process *generalisation*. The product is *not* a definite and clear-cut image.

In the third place, I may by a process of abstraction consider a quality apart from the things that possess that quality—whiteness for example, apart from white objects, edibility apart from edible things. We will here retain the term abstract idea to denote such qualities, and we will for the present term the process by which they are obtained *isolation*. Of a completely isolated quality no mental image can be formed.

That dogs and the lower animals in general make use of the process I have above termed elimination, cannot I think, for one moment be doubted. For if they do not then we must suppose that they are able mentally to grasp an object in the entirety of its qualities, which is more than the average human being can do. Let us suppose that a dog sees what he believes to be a soaked dog-biscuit. The impression he receives through his eyes at once suggests certain possible olfactory impressions and certain possible gustatory impressions. This of course implies what is commonly called the association of ideas. But there are other possible impressions which might be suggested but probably are not, such impressions, for instance, as may be produced by the hardness, temperature, and weight of the object. These impressions are not suggested, they are eliminated, so to speak. In other words, certain possible impressions are abstracted from certain other possible impressions. Suppose, now, the dog proceeds to smell the biscuit that he has hitherto only seen. If it answers to his expectations he at once begins to eat it. His nose tells him that it is good for eating. If, however, it does not answer to his expectations, if, perhaps, it has received the drippings of a paraffin tin, he turns sorrowfully away. His nose tells him that it is not good for eating. One kind of smell suggests that the biscuit will be pleasant to the taste: another kind of smell suggests that it will be unpleasant. And the dog, unless he be a very young one, having confidence in his nose, acts upon the suggestions without verification. It is to these suggested impressions that Mr. Romanes applies the term "abstract ideas of quality, as apart from the object examined." And I do not suppose that any one is prepared to deny our dumb companions abstract ideas *in this sense of the term*.

Let us now consider how far we may suppose animals to possess the power of generalisation in the sense in which I have above used this term. A dog lying asleep upon the hearth-rug hears outside the window an unusual footstep. He at once pricks up his ears and gives a half-suppressed growl. Must we not suppose that in such a case as this the footstep suggests to the dog the idea of a strange man? And if so, will not the suggestion—of whatever character it might be—be general rather than particular? If it be a mental picture—and we are often told that dogs think only in pictures¹—must not the picture be generic

¹ I do not know that I quite understand what thinking in pictures means, but I should imagine that sounds and smells entered pretty largely into the current of canine thought. And on the other hand, I should be disposed to think that Spenser and Shakespeare possessed in no slight degree the power
