Citation: when reporting results obtained with P3DFFT, please cite the following:

D. Pekurovsky, “P3DFFT: a framework for parallel computations of Fourier transforms in three dimensions”, **SIAM Journal on Scientific Computing** 2012, Vol. 34, No. 4, pp. C192-C209.

1. Introduction

P3DFFT is a scalable software library implementing three-dimensional spectral transforms. It has been used in a variety of codes from many areas of computational science. It has been tested and used on many high-end computational system. It uses two-dimensional domain decomposition in order to overcome a scaling bottleneck of one-dimensional decomposition.

This allows the programs with this library to scale well on a large number of cores, consistent with bisection bandwidth scaling of interconnect of the underlying hardware system.

Below are the main features of P3DFFT v. 2.7.5:

- Real-to-complex and complex-to-real Fast Fourier Transforms (FFT) in 3D.
- Cosine, sine, and combined Fourier-Chebyshev transform (FFT in 2D and Chebyshev in the third dimension). Alternatively users can substitute their own transform in the third dimension, for example a compact scheme.
- Fortran and C interfaces
- Built for performance at all ranges of core counts
- Hybrid MPI/OpenMP implementation
- In-place and out-of-place transforms
- Pruned transforms
- Multivariable transforms

1. Directory Structure and Files

The following is a directory listing for what you should find in the p3dfft package:

Table 1: Directory structure of p3dfft package

Directory	Description
<i>toplevel</i>	The configure script is located here. Running the configure script is essential for properly building p3dfft. Please refer to section 2 of this guide for more information.
<i>build/</i>	The library files are contained here. Building the library is required before it can be used. In order to build the library, you must run <code>./configure</code> from the top level directory. Then type "make" and then "make install". For further details on building the library see section 2 of this guide.
<i>include/</i>	The library is provided as a Fortran module. After installation this directory will have <code>p3dfft.mod</code> (for Fortran interface), <code>p3dfft.h</code> (C wrapper/include file), and <code>config.h</code> (header that contains all arguments used when configure script was executed).
<i>sample/</i>	This directory has example programs in both FORTRAN and C, in separate subdirectories. Tests provided include out-of-place and in-place transforms 3D FFT, with error checking. Also provided is an example of power spectrum calculation. Example programs will be compiled automatically with the library during make.

IMPORTANT: *In order to use p3dfft with C programs, you must include the p3dfft.h header file in your program. This header file defines an interface that allows C programs to call Fortran functions from the p3dfft library.*

In addition to the library itself, the package includes several sample programs to illustrate how to use p3dfft. These sample programs can be found in the sample/ directory:

Table 2: Filename and description of samples

Source filename	Binary filename	Description
driver_inverse.c, driver_inverse.F90	test_inverse_c.x, test_inverse_f.x	This program initializes a 3D array of complex numbers with a 3D sine/cosine wave, then performs inverse FFT transform, and checks that the results are correct. This sample program also demonstrates how to work with complex arrays in wavenumber space, declared as real.
driver_rand.c, driver_rand.F90	test_rand_c.x, test_rand_f.x	This program initializes a 3D array with random numbers, then performs forward 3D Fourier transform, then backward transform, and checks that the results are correct, namely the same as in the start except for a normalization factor. It can be used both as a correctness test and for timing the library functions.
driver_sine.c, driver_sine_inplace.c, driver_sine.F90, driver_sine_inplace.F90	test_sine_c.x, test_sine_inplace_c.x, test_sine_f.x, test_sine_inplace_f.x	This program initializes a 3D array with a 3D sine wave, then performs 3D forward Fourier transform, then backward transform, and checks that the results are correct, namely the same as in the start except for a normalization factor. It can be used both as a correctness test and for timing the library functions.

driver_sine_many.F90 driver_sine_inplace_many.F90 driver_rand_many.F90	test_sine_many_f.x test_sine_inplace_many_f.x test_rand_many_f.x	Same as above, but these program tests the multivariable transform feature. There is an extra parameter in the input file specifying the number of variables to transform (nv).
driver_spec.c, driver_spec.F90	test_spec_c.x, test_spec_f.x	This program initializes a 3D array with a 3D sine wave, then performs 3D FFT forward transform, and computes power spectrum.
driver_cheby.F90	test_cheby_f.x	This program initializes a 3D array with a sine wave, employing a non-uniform grid in the Z dimension with coordinates given by $\cos(k/N)$. Then Chebyshev routine is called (p3dfft_cheby) which uses Fourier transform in X and Y and a cosine transform in Z (“ffc”), followed by computation of Chebyshev coefficients. Then backward “cff” transform is called and the results are compared with the expected output after Chebyshev differentiation in Z. This program can be used both as correctness and as a timing test.
driver_noop.c, driver_noop.F90	test_noop_c.x, test_noop_f.x	Similar to the above but instead of Chebyshev transform nothing is done; i.e. only 2D FFT is performed and then the data is laid out in a format suitable for a custom transform of the user’s choice in the third

		dimension (i.e. data is local for each processor in that dimension).
--	--	--

2. Installing p3dfft

In order to prepare the p3dfft for compiling and installation, you must run the included configure script. Here is a simple example on how to run the configure script:

```
$ ./configure --enable-pgi --enable-fftw --with-fftw=/usr/local/fftw/ LDFLAGS="-lmpi_f90 -lmpi_f77"
```

The above will prepare p3dfft to be compiled by the PGI compiler with FFTW support. There are more arguments included in the configure script that will allow you to customize p3dfft to your requirements:

Table 3: Arguments of configure script

Argument	Notes	Description	Example
--prefix=PREFIX	Mandatory for users without access to /usr/local	This argument will install p3dfft to PREFIX when you run make install. By default, configure will install to /usr/local	--prefix=\$HOME/local/
--enable-gnu, --enable-ibm, --enable-intel, --enable-pgi, --enable-cray	Mandatory	These arguments will prepare p3dfft to be built by a specific compiler. You must only choose one option.	--enable-pgi
--enable-fftw, --enable-essl	Mandatory	These arguments will prepare p3dfft to be used with either the FFTW or ESSL library. You must only choose one option.	--enable-fftw
--with-fftw=FFTWLOCATION	Mandatory if --enable-fftw is used	This argument specifies the path location for the FFTW library; it is mandatory if you are planning to use p3dfft with the FFTW library.	--enable-fftw --with-fftw=\$FFTW_HOME

--enable-openmp	Mandatory if using multithreaded version (OpenMP)	This argument adds the appropriate compiler flags to enable OpenMP	--enable-openmp
--enable-openmpi	Optional	This argument uses the OpenMPI implementation of MPI	--enable-openmpi
--enable-oned	Optional,	This argument is for 1D decomposition. The default is 2D decomposition but can be made to 1D by setting up a grid 1xn when running the code.	--enable-oned
--enable-estimate	Optional, use only with --enable-fftw	If this argument is passed, the FFTW library will not use run-time tuning to select the fastest algorithm for computing FFTs.	--enable-estimate
--enable-measure	Optional, enabled by default, use only with --enable-fftw	For search-once-for-the-fast algorithm (takes more time on p3dfft_setup()).	--enable-measure
--enable-patient	Optional, use only with --enable-fftw	For search-once-for-the-fastest-algorithm (takes much more time on p3dfft_setup()).	--enable-patient
--enable-dimsc	Optional	To assign processor rows and columns in the Cartesian processor grid according to C convention. The default is Fortran convention which is recommended. This option does not affect the order of storage of arrays in memory.	--enable-dimsc
--enable-useeven	Optional,	This argument is for	--enable-useeven

	recommended for Cray XT	using MPI_Alltoall instead of MPI_Alltotallv. This will pad the send buffers with zeros to make them of equal size; not needed on most architecture but may lead to better results on Cray XT.	
--enable-stride1	Optional, recommended	To enable stride-1 data structures on output (this may in some cases give some advantage in performance). You can define loop blocking factors NLBX and NBLY to experiment, otherwise they are set to default values.	--enable-stride1
--enable-nblx	Optional	To define loop blocking factor NBL_X	--enable-nblx=32
--enable-nbly1	Optional	To define loop blocking factor NBL_Y1	--enable-nbly1=32
--enable-nbly2	Optional	To define loop blocking factor NBL_Y2	--enable-nbly2=32
--enable-nblz	Optional	To define loop blocking factor NBL_Z	--enable-nblz=32
--enable-single	Optional	This argument will compile p3dfft in single-precision. By default, configure will setup p3dfft to be compiled in double-precision.	--enable-single
FC=<Fortran compiler>	Optional	Fortran compiler	FC=mpfort
FCFLAGS="<Fortran compiler flags>"	Optional, recommended	Fortran compiler flags	FCFLAGS="-Mextend"
CC=<C compiler>	Optional	C compiler	CC=mpcc
CFLAGS="<C compiler flags>"	Optional, recommended	C compiler flags	CFLAGS="-fastsse"

LDFLAGS="<linker flags>"	Mandatory (depending on platform)	Linker flags	LDFLAGS=-lmpi_f90 -lmpi_f77"
--------------------------	-----------------------------------	--------------	------------------------------

More information on how to customize the configure script can be found by calling:

```
$ ./configure --help
```

After you have successfully run the configure script, you are ready to compile and install p3dfft. Simply run:

```
$ make
```

```
$ make install
```

3. p3dfft module

The p3dfft module declares important variables. It should be included in any code that calls P3DFFT routines (via use p3dfft statement in Fortran).

The p3dfft module also specifies mytype, which is the type of real and complex numbers. You can choose precision at compile time through a preprocessor flag (see Installation Guide).

4. Initialization

Before using the library it is necessary to call an initialization routine 'p3dfft_setup'.

Usage: *p3dfft_setup(proc_dims,nx,ny,nz,mpi_comm_in,nx_cut,ny_cut,nz_cut,overwrite,memsize)*

Table 4: Arguments of p3dfft_setup

Argument	Intent	Description
<i>proc_dims</i>	Input	An array of two integers, specifying how the processor grid should be decomposed. Either 1D or 2D decomposition can be specified. For example, when running on 12 processors, (4,3) or (2,6) can be specified as <i>proc_dims</i> to indicate a 2D decomposition, or (1,12) can be specified for 1D decomposition. <i>proc_dims</i> values are used to initialize P_1 and P_2 .
<i>Nx, Ny, Nz</i>	Input	(Integer) Dimensions of the 3D transform (also the global grid dimensions)
<i>MPI_COMM_IN</i>	Input	(Integer) MPI Communicator containing all MPI tasks that participate in the partition (in most cases this will be

		MPI_COMM_WORLD).
<i>Nx_cut,Ny_cut,Nz_cut</i>	Input (optional)	(Integer) Pruned dimensions on output/input (default is same as Nx,Ny,Nz)
<i>overwrite</i>	Input (optional)	(Logical) When set to .true. (or 1 in C) this argument indicates that it is safe to overwrite the input of the btran (backward transform) routine. This may speed up performance of FFTW routines in some cases when non-stride-1 transforms are made.
<i>memsize</i>	Output (optional)	Optional argument (array of 3 integers). Memsize can be used to allocate arrays. It contains the dimensions of real-space array that are large enough to contain both input and output of an in-place 3D FFT real-to-complex transform defined by nx,ny,nz,nx_cut,ny_cut,nz_cut.

5. Array Decomposition

The p3dfft_setup routine sets up the two-dimensional (2D) array decomposition. P3DFFT employs 2D block decomposition whereby processors are arranged into a 2D grid $P_1 \times P_2$, based on their MPI rank. Two of the dimensions of the 3D grid are block-distributed across the processor grid, by assigning the blocks to tasks in the rank order. The third dimension of the grid remains undivided, i.e. contained entirely within local memory (see Fig. 1). This scheme is sometimes called pencils decomposition.

A block decomposition is defined by dimensions of the local portion of the array contained within each task, as well as the beginning and ending indices for each dimension defining the array's location within the global array. This information is returned by p3dfft_get_dims routine which should be called before setting up the data structures of your program (see sample/ subdirectory for example programs).

Figure 1: An example of 2D block(a.k.a. pencils) decomposition of a 3D grid.

In P3DFFT, the decompositions of the output and input arrays, while both being two-dimensional, differ from each other. The reason for this is as follows. In 3D Fourier Transform it is necessary to transpose the data a few times (two times for two-dimensional decomposition) in order to rearrange the data so as to always perform one-dimensional FFT on data local in memory of each processing element. It would be possible to transpose the data back to the original form after the 3D transform is done, however it often makes sense to save significant time by forgoing this final transpose. All the user has to do is to operate on the output array while keeping in mind that the data are in a transposed form. The backward (complex-to-real) transform takes the array in a transposed form and produces a real array in the original form. The rest of this section clarifies exactly the original and transposed form of the arrays.

Starting with v. 2.7.5 P3DFFT features optional hybrid MPI/OpenMP implementation. In this case the MPI decomposition is the same as above, and each MPI task now has N_{thr} threads. This essentially implements 3D decomposition, however the results are global arrays (in the OpenMP sense) so they can be used either with multi- or single-threaded program. The number of threads is specified through the environment variable `OMP_NUM_THREADS`.

Usage: `p3dfft_get_dims(start,end,size,ip)`

Table 5: Arguments of `p3dfft_get_dims()`

Argument	Intent	Description
<i>start</i>	Output	An array containing 3 integers, defining the beginning indices of the local array for the given task within the global grid.
<i>end</i>	Output	An array containing 3 integers, defining the ending indices of the local array within the global grid (these can be computed from start and size but are provided for convenience).
<i>size</i>	Output	An array containing 3 integers, defining the local array's dimensions.
<i>mypad</i>	Output/Optional	This argument is optional and is used in in-place transforms, to obtain the value of padding that should be used in the third dimension of the input array (since input and output arrays may not have the same memory size)
<i>ip</i>	Input	ip=1: "Original": a "physical space" array of real numbers, local in X, distributed among P_1 tasks in Y dimension and P_2 tasks in Z dimension, where P_1 and P_2 are processor grid dimensions defined in the call to <code>p3dfft_setup</code> . Usually this type of array is an input to real-to-complex (forward) transform and an output of complex-to-real (backward) transform. ip=2: "Transposed": a "wavenumber space" array of complex numbers, local in Z, distributed among P_1 tasks in X dimension, P_2 tasks in Y dimension. Usually this type of array is an output of real-to-complex (forward) transform and an input to

		complex-to-real, backward transform. ip=3: the routine returns three numbers corresponding to “padded” dimensions in the physical space, i.e. an array with these dimensions will be large enough both for physical and wavenumber space. Example of use of this feature can be found in driver_sine_inplace.F90 sample program.
--	--	--

IMPORTANT: the layout of the 2D processor grid on the physical network is dependent on the architecture and software of the particular system, and can have some impact on efficiency of communication. By default, rows have processors with adjacent task IDs (this corresponds to "FORTRAN" type ordering). This can be changed to "C" ordering (columns have adjacent task IDs) by building the library with -DDIMS_C preprocessor flag. The former way is recommended on most systems.

P3DFFT uses 2D block decomposition to assign local arrays for each task. In many cases decomposition will not be entirely even: some tasks will get more array elements than others. P3DFFT attempts to minimize load imbalance. For example if the grid dimensions are 128 x 256 and the processor grid is defined as 3x4, the original (ip=1) decomposition calls for splitting 256 elements in Y dimension into three processor rows. P3DFFT in this case will break it up into pieces of 86, 85 and 85 elements. The transposed (ip=2) decomposition will have local arrays with X dimensions 22, 22 and 21 respectively for processor rows 1 through 3 (the sum of these numbers is 65=(N_x+2)/2 since these are now complex numbers instead of reals, and an extra mode for Nyquist frequency is needed – see Section 5 for an explanation).

It should be clear that the user’s choice of P1 and P2 can make a difference on how balanced is the decomposition. Obviously the greater load imbalance, the less performance can be expected.

Note: the two array types are distributed among processors in a different way from each other, but this does not automatically imply anything about the ordering of the elements in memory. Memory layout of the original (ip=1) array uses the “Fortran” ordering. For example, for an array A(lx,ly,lz) the index corresponding to lx runs fastest. Memory layout for the transposed (ip=2) array type depends on how the P3DFFT library was built. By default, it preserves the ordering of the real array, i.e. (X,Y,Z). However, in many cases it is advisable to have Z dimension contiguous, i.e. a memory layout (Z,Y,X). This can speed up some computations in the wavenumber space by improving cache utilization through spatial locality in Z, and also often results in better performance of P3DFFT transforms themselves. The (Z,Y,X) layout can be triggered by building the library with -DSTRIDE1 preprocessor flag in the makefile. For more information, see performance section below.

Table 6. Mapping of the data array onto processor grid and memory layout

	Physical space	Fourier space
STRIDE1 defined	$N_x, N_y/M_1, N_z/M_2$	$N_z, N_y/M_2, (N_x+2)/(2M_1)$
STRIDE1 undefined	$N_x, N_y/M_1, N_z/M_2$	$(N_x+2)/(2M_1), N_y/M_2, N_z$

6. Forward (real-to-complex) and backward (complex-to-real) 3D Fourier transforms

P3DFFT versions 2.7.1 and higher implement transforms for one or more than one independent arrays/variables simultaneously. An example of this is 3 components of a velocity field. Multivariable transforms achieve greater speed than single-variable transforms, especially for grids of smaller size, due to buffer aggregation in inter-processor exchanges.

Forward transform is implemented by the p3dfft_ftran_r2c subroutine using the following format:

```
p3dfft_ftran_r2c(IN,OUT,op)
```

The input IN is an array of real numbers with dimensions defined by array type with ip=1 (see Table 2 above), with X dimension contained entirely within each task, and Y and Z dimensions distributed among P1 and P2 tasks correspondingly. The output OUT is an array of complex numbers with dimensions defined by array type with ip=2, i.e. Z dimension contained entirely, and X and Y dimensions distributed among P1 and P2 tasks respectively. The op argument is a 3-letter character string indicating the type of transform desired. Currently only Fourier transforms are supported in X and Y (denoted by symbol f) and the following transforms in Z:

Table 7. Supported types of transforms in Z

t or f	Fourier Transform
c	Cosine Transform
s	Sine Transform
n or 0	Empty transform (no operation takes place, output is the same as input)

Empty transform can be useful for someone implementing custom transform in Z dimension. Example: op='ffc' means Fourier transform in X and Y, and a cosine transform in Z. The DCT-I kind of transform is performed (DST-I for sine), the definition of which can be found here: http://en.wikipedia.org/wiki/Discrete_cosine_transform#DCT-I

Backward transform is implemented by the p3dfft_btran_c2r subroutine using the following format:

```
p3dfft_btran_c2r(IN,OUT,op)
```

The input IN is an array of complex numbers with dimensions defined by array type with ip=2 (see Table 2 above), i.e. Z dimension is contained entirely, and X and Y dimensions are distributed among P1 and P2 tasks correspondingly. The output OUT is an array of real numbers with dimensions defined by array type with ip=1, i.e. X dimension is contained entirely within each task, and Y and Z are dimensions distributed among P1 and P2 tasks respectively. The op argument is similar to forward transform, with the first character of the string being one of t,c,s,n

or 0, and the second and third being f. Example: op='nff' means no operation in Z, backward Fourier transforms in Y and X.

7. Complex array storage definition

Since Fourier transform of a real function has the property of conjugate symmetry, only about half of the complex Fourier coefficients need to be kept. To be precise, if the input array has n real elements, Fourier coefficients $F(k)$ for $k=n/2+1, \dots, n$ can be dropped as they can be easily restored from the rest of the coefficients. This saves both memory and time. In this version we do not attempt to further pack the complex data. Therefore the output array for the forward transform (and the input array of the backward transform) contains $(N_x/2+1)$ times N_y times N_z complex numbers, with the understanding that $N_x/2-1$ elements in X direction are missing and can be restored from the remaining elements. As mentioned above, the $N_x/2+1$ elements in the X direction are distributed among $P1$ tasks in the transposed layout.

8. Multivariable transforms

Sometime communication performance of transposes such as those included in P3DFFT can be improved by combining several transforms into a single operation. (This allows us to aggregate messages during interprocessor data exchange). This is especially important when transforming small grids and/or when using systems with high interconnect latencies. P3DFFT provides multivariable transforms to make use of this idea. Instead of an 3D array as input parameter these subroutines accept a 4D array, with the extra dimension being the index of independent variables to be transformed (for example this could be 3 velocity components). The following is the syntax for multivariable transforms:

```
p3dfft_ftran_many_r2c(IN,dim_in,OUT,dim_out,nv,op)
```

```
p3dfft_btran_many_c2r(IN,dim_in,OUT,dim_out,nv,op)
```

The multivariable transform routines for both forward and backward transforms have an additional argument *nv* (integer) representing the number of independent variables in the input/output arrays. The spacing between these independent variables is defined by *dim_in* and *dim_out* (integer) arguments for input/output arrays respectively. Both *dim_in* and *dim_out* should not be less than the size of the grid returned by *get_dims* routine. See sample program *driver_sine_many.F90*, *driver_sine_inplace_many.F90* or *driver_rand_many* for an example of such use.

9. Pruned transforms

Sometimes only a subset of output modes is needed to be retained (for forward transform), or a subset of input modes is used, the rest being zeros (for backward transform). Such transforms are called pruned transforms. Leaving off redundant modes can lead to significant savings of time and memory. The reduced dimensions *Nx_cut*, *Ny_cut* and *Nz_cut* are arguments to *p3dfft_setup*. By default they are equal to *Nx*, *Ny*, *Nz*. If they are different from the above (smaller) the output

of forward transforms will be reduced in size correspondingly. The input for backward transform will also be smaller in size. It will be automatically padded with zeros until it reaches N_x, N_y, N_z .

10. In-place transforms

In and Out arrays can occupy the same space in memory (in-place transform). In this case, it is necessary to make sure that they start in the same location, otherwise the results are unpredictable. Also it is important to remember that the sizes of input and output arrays in general are not equal. The complex array is usually bigger since it contains the Nyquist frequency mode in X direction, in addition to the $N_x/2$ modes that equal in space to N_x real numbers. However when decomposition is not even, sometimes the real array can be bigger than the complex one, depending on the task ID. Therefore to be safe one must make sure the common-space array is large enough for both input and output. This can be done by using memsize argument when calling p3dfft_setup. It returns the maximum array size for both input and output. Alternatively, one can call p3dfft_get_dims two times with ip=1 and 2.

In Fortran using in-place transforms is a bit tricky due to language restrictions on subroutine argument types (i.e., one of the arrays is expected to be real and the other complex). In order to overcome this problem wrapper routines are provided, named ftran_r2c and btran_c2r respectively for forward and backward transform (without p3dfft prefix). *There are examples for such in-place transform in the sample/ subdirectory. These wrappers can be also used for out-of-place transforms just as well.*

11. Memory requirements

Besides the input and output arrays (which can occupy the same space, as mentioned above) P3DFFT allocates temporary buffers roughly 3 times the size of the input or output array.

12. Performance considerations

P3DFFT was created to compute 3D FFT in parallel with high efficiency. In particular it is aimed for applications where the data volume is large. It is especially useful when running applications on ultra-scale parallel platforms where one-dimensional decomposition is not adequate. Since P3DFFT was designed to be portable, no effort is made to do architecture-specific optimization. However, the user is given some choices in setting up the library, mentioned below, that may affect performance on a given system. Current version of P3DFFT uses ESSL or FFTW library for its 1D FFT routines. ESSL [1] provides FFT routines highly optimized for IBM platforms it is built on. The FFTW [2], while being generic, also makes an effort to maximize performance on many kinds of architectures. Some performance data will be uploaded at the P3DFFT Web site. For more questions and comments please contact dmitry@sdsc.edu.

Optimal performance on many parallel platforms for a given number of cores and problem size will likely depend on the choice of processor decomposition. For example, given a processor grid $P_1 \times P_2$ (specified in the first argument to p3dfft_setup) performance will generally be better with smaller P_1 (with the product $P_1 \times P_2$ kept constant). Ideally P_1 will be equal or less than the

number of cores on an SMP node or a multi-core chip. In addition, the closer a decomposition is to being even, the better load balancing.

Beginning with v.2.7.5 P3DFFT is equipped with MPI/OpenMP capability. If use of this feature is needed simply set the desired number of threads through environment variable `OMP_NUM_THREADS`. The optimal number of threads, just like the processor grid, depends on specific platform and problem.

Performance is likely to be better when P3DFFT is built using `--enable-stride1` during configure. This implies stride-1 data ordering for FFTs. Note that using this argument changes the memory layout of the transposed array (see section 3 for explanation). To help tune performance further, two more arguments can be used: `-enable-dnblx=...` and `--enable-dnbly=...`, which define block sizes in X and Y when doing local array reordering. Choosing suitable block sizes allows the program to optimize cache performance, although by default P3DFFT chooses these values based on a good guess according to cache size.

Finally, performance will be better if `overwrite` parameter is set to `.true.` (or 1 in C) when initializing P3DFFT. This allows the library to overwrite the input array, which results in significantly faster execution when not using the `--enable-stride1` argument.
