Background

Autism patients are known to have higher genetic susceptibility to cancer. However, cancer rates are lower in autism patients.¹

Cancer cells need folate for rapid growth. So they express more folate receptor alpha (FRA) proteins on their surface that helps transport folate. Thus treatments that target these FRA proteins with antibodies are an experimental cure for cancer.²

75% of autism patients test positive for folate receptor alpha antibodies (FRAA).³ This explains why autism patients have lower rates of cancer.

FRA proteins are present in cow's milk.⁴ Casein and casamino acids are cow's milk derived proteins used in the manufacture of vaccines. So numerous vaccines are contaminated with cow's milk proteins.⁵⁻⁷

Vaccines, Allergies, Autism and Cancer

Tetanus vaccine package insert⁸ from the World Health Organization site says:

"The vaccine has the appearance of a greyish-white suspension and does not contain any horse serum protein. Therefore it does not induce sensitization to sera of equine origin."

In other words, horse serum protein injection can cause the development of allergy to horse serum protein. Development of allergy is also known as sensitization and involves the induction of immunoglobulin E (IgE) antibodies against the protein. Due to this same process, cow's milk contaminated vaccines cause sensitization^{9,10}, resulting in the induction of antibodies against cow's milk proteins. The specific antibodies of interest in this case are the folate receptor alpha antibodies (FRAA).⁷ These FRAA tag cancer cells by binding to the FRA proteins on the surface of cancer cells. The immune system destroys the tagged cells thus preventing cancer. Unfortunately, FRA proteins are not unique to cancer cells. They are also present in the choroid plexus and transport folate to the brain.³ FRAA bind to these FRA proteins as well. This blocks folate uptake to the brain resulting in autism spectrum disorders (ASD)^{3,7,11,12} and cerebral folate deficiency (CFD)^{13,14} disorders.

So there is the possibility that one of the many cow's milk contaminated vaccines such as Tdap⁶ can be prescribed off-label to treat cancer. It may even be possible to subsequently control FRA antibody levels by modulating dietary milk intake.¹³ Folinic acid treatment¹² may provide further control over adverse effects.

In another cruel twist, women can develop FRAA due to cow's milk contaminated vaccines. Conveniently, a cow's milk contaminated Tdap vaccine is prescribed during pregnancy, intended to

protect the newborn against pertussis. The mother's FRAA block folate uptake in the fetus and cause autism. This newborn may not develop FRAA on its own. In that case you will have a child with autism but NO benefit of cancer protection.

Varicella vaccine

On the flip side, natural varicella infection prevents some types of cancer. So a varicella vaccine increases the rate of those cancers. Lee et al.¹⁵ wrote:

"In a comprehensive analysis of familial and personal medical histories in adults with glioma, we previously showed that history of chickenpox and/or shingles was inversely correlated with case status.³⁶"

Human papillomavirus vaccine

The HPV vaccine is contaminated with yeast proteins (*Saccharomyces cerevisiae*).¹⁶

Injecting yeast protein contaminated vaccines causes the development of antibodies against yeast – anti *saccharomyces cerevisiae* antibodies (ASCA). ASCA have been associated with many autoimmune diseases.¹⁷⁻²⁹

Wraith et al.³⁰ recommended autoimmune serology and bioinformatics analysis to evaluate risk of vaccine induced autoimmune diseases. The vaccine manufacturers have refused to perform such studies.¹⁶ So this vaccine intended to prevent cancer, causes numerous autoimmune disorders.

Most epidemiological studies investigating the role of vaccines in autoimmune diseases, ignore the mechanism of causation. Hypothesizing a mechanism allows for a study design that accounts for appropriate controls. By ignoring the mechanism, these studies have the wrong controls and the results are invalidated due to confounding factors. Relying on such invalid epidemiological studies have lead researchers down blind alleys for decades. Researchers must determine root cause by focusing on mechanisms of causation.

Conclusion

Vaccines induce numerous off-target immune responses that are being ignored. Poorly designed epidemiological studies are used to make unscientific vaccine safety claims.³¹

So when vaccines do prevent cancer, it comes at a cost of autoimmune diseases that cut your life short or ruin your life with autism.
