Chapter 4

IMPACTS OF INVASIVE ALIEN SPECIES ON NATURE, NATURE'S CONTRIBUTIONS TO PEOPLE, AND GOOD QUALITY OF LIFE

EXECUTIVE SUMMARY

1 Invasive alien species impact nature at all ecological levels, from native individuals, populations, species, to communities and ecosystems *(well established)* {4.3.1}. Although some invasive alien species can have both positive and negative impacts *(well established)* {4.3, 4.4, 4.5, 4.6}, the overall negative impacts of invasive alien species far exceed any positive impacts on nature and humans *(established but incomplete)* {4.3.1, 4.4.1, 4.5.1, 4.6.1, 4.6.3}. Almost three-quarters (71 per cent) of the documented impacts on nature adversely affect native species *(well established)* {4.3.1}. The magnitude of impacts of invasive alien species varies depending on the geographic and environmental context *(well established)* {4.3.1, 4.3.2, 4.3.3, 4.4.1, 4.4.2, 4.4.3, 4.5.1, 4.5.2, 4.5.3, 4.6.1, 4.6.2, 4.6.3, 4.6.4, 4.6.5}. The most commonly observed impacts on nature are changes in ecosystem properties, reductions in the performance of native species and declines in local populations of both plants and animals *(well established)* {4.3.1.3}. The most frequently observed mechanisms of impacts are competition, physical and chemical changes of the invaded ecosystems and trophic interactions through predation and herbivory *(well established)* {4.3.1.3}. In terrestrial ecosystems, most studies of impacts on nature are documented from plants and occur in forests, grasslands and human-dominated habitats *(well established)* {4.3.2.1}. Few impacts on nature are documented from very cold (tundra and high mountain habitats), very dry (deserts and xeric shrub lands) or flooded terrestrial habitats (wetlands – peatlands, mires, bogs) *(well established)* {4.3.1}. No impacts have been documented in the cryosphere and the deep-sea *(established but incomplete)* {4.3.1} **(Table 4.2)**. The magnitude of negative impacts of invasive alien species often varies with the invaded biomes and species, and impacts are sometimes exacerbated or attenuated by the interaction of invasive alien species with other drivers such as climate change, changes in land- and sea-use, or pollution *(established but incomplete)* {4.3.1} **(Box 4.5)**. The number of documented impacts of invasive alien species has risen in parallel with the documented number of alien species *(established but incomplete)* {4.3.1}. About 7 per cent of alien plants, 17 per cent of alien vertebrates, 23 per cent of alien invertebrates, and 12 per cent of alien microbes are known to be invasive, but their numbers are likely an underestimate *(established but incomplete)* {4.2}.

2 Invasive alien species have contributed to local or global extinctions of native species *(well established)* {4.3.1} (Box 4.4). Of all invasive alien species with documented impacts, 6 per cent (218 invasive alien species) have been associated with the local extinction of at least one native species *(established but incomplete)* {4.3.1}. Invasive alien species are a significant factor that directly or indirectly caused 60 per cent of documented global animal and plant extinctions *(established but incomplete)* **(Box 4.4)** and have caused 1,215 documented local extinctions of 255 native species across all taxa *(established but incomplete)* {4.3.1}. These local extinctions have been documented in marine (23.2 per cent) freshwater (14.5 per cent) and terrestrial realms (62.1 per cent) *(well established)* {4.3.1}. Invasive alien animals (vertebrates 51 per cent, invertebrates 32.5 per cent) are more often implicated in causing local extinctions than invasive alien plants (15.3 per cent) and microbes (1.2 per cent) *(well established)* {4.3.1}.

3 Impacts of invasive alien species are more harmful to isolated ecosystems, such as islands, than elsewhere *(established but incomplete)* {4.3.1.1}. Documented negative impacts on native species on islands are far more frequent than positive impacts (40.5 per cent vs. 4.5 per cent) *(well established)* {4.3.1.1}. Of the global extinctions caused by invasive alien species, the overwhelming majority occurred on islands and other isolated ecosystems *(established but incomplete)* {4.3.1} **(Box 4.4)**. Local extinctions are more frequently documented from islands than from non-island locations (9.2 per cent vs. 4.0 per cent) *(well established)* {4.3.1}. Of the top ten invasive alien species documented to have caused local extinctions on islands, five are domesticated or synanthropic species: *Rattus* spp. (rats), *Capra hircus* (goats), *Mus musculus* (house mouse), *Felis catus* (cat), but

also other vertebrates such as *Anas platyrhynchos* (mallard) *(well established)* {4.3.1.1}.

4 Invasive alien species pose a substantial threat to the conservation of native biodiversity, landscapes and seascapes in protected areas *(established but incomplete)* {4.3.1.2}. Invasive alien species impact areas protected for nature conservation, with impacts of similar magnitude and frequency occurring both inside and outside protected areas *(established but incomplete)* {4.3.1.2}. Impacts on nature in protected areas constitute 19.3 per cent of the total number of documented impacts on nature *(established but incomplete)* {4.3.1.2}. Reports of negative impacts on native species in protected areas are far more frequent than positive impacts (33.2 per cent vs. 6.3 per cent) *(established but incomplete)* {4.3.1.2}.

5 Invasive alien species cause impacts on all categories of nature's contributions to people *(well established)* {4.4}. A large majority (80 per cent) of documented impacts on nature's contribution to people are negative and harm people by decreasing ecosystem services *(well established)* {4.4.1}. The most commonly observed negative impact of invasive alien species to nature's contributions to people is a reduction of human food supply *(well established)* {4.4.1}, which is caused by all taxa, in all regions and realms *(well established)* {4.4.2, 4.4.3}. Other important impacts of invasive alien species on nature's contributions to people are on habitat maintenance (16 per cent records) and on the provision of materials, companionship and labour (14 per cent records). In terrestrial systems, the most common invasive alien species causing impacts are plants, particularly in cultivated areas and in temperate and boreal forests *(well established)* {4.4.2.1}. In inland waters, 70 per cent of the documented impacts on nature's contributions to people are from inland surface waters and water bodies/freshwater *(well established)* {4.4.2.2}, and most of them are caused by invasive alien vertebrates *(well established)* {4.4.2.2}. In marine systems, the impacts are mostly caused by invasive alien invertebrates and predominate in shelf ecosystems *(well established)* {4.4.2.3}.

6 Impacts of invasive alien species on human health vary from nuisance to poisoning, disease and death *(well established)* {4.5.1}. Zoonotic diseases transmitted by invasive mosquitos inflict misery, chronic disease and death *(well established)* {4.5.1.3}. Invasive alien plants can be highly allergenic or phytotoxic *(well established)* {4.5}. Several invasive ant species have been documented as causing serious allergic or toxic reactions *(well established)* {4.5.1.3}. Health impacts caused by venomous and poisonous invasive alien marine species have frequently been documented in the Mediterranean Sea *(well established)* {4.5.1.3}.

7 Global cumulative damages due to invasive alien species totalled more than US$ 1.738 trillion between 1970 and 2020 *(established but incomplete)* (Box 4.13). In 2017 alone, documented aggregate global costs of biological invasions were estimated to reach US$162.7 billion, exceeding the 2017 gross domestic product of 52 of the 54 countries on the African continent, and more than twenty times higher than the combined total funds available in 2017 for the World Health Organization and the United Nations *(established but incomplete)* **(Box 4.13)**. In 2019, global annual costs of biological invasions were estimated to exceed $423 billion, with variations across regions, but this is likely a gross underestimation *(established but incomplete)* **(Box 4.13)**. North America (53 per cent) and Asia (13 per cent) were associated with the highest documented costs, which is partly driven by cost data incompleteness for most taxa and regions of the world *(well established)* **(Box 4.13)**. Agriculture is the economic sector most frequently documented as affected by invasive alien species and specifically by insects which are often categorized as pests *(established but incomplete)* **(Box 4.13)**.

8 Invasive alien species cause impacts on good quality of life that affect the opportunities for people to live a fulfilled life *(established but incomplete)* {4.5}. The majority of the 3,783 documented impacts on good quality of life are documented as negative for people (about 85 per cent) *(established but incomplete)* {4.5.1}. Most negative impacts (56 per cent) on good quality of life are the result of changes to "material and immaterial assets" by invasive alien species *(established but incomplete)* {4.5.1, 4.5.2, 4.5.3}. Invertebrates are documented as causing the highest number of negative impacts on good quality of life (51 per cent of negative impacts) *(established but incomplete)* {4.5.3}. Conversely, plants (responsible for 42 per cent of positive impacts) are more likely to result in positive impacts on good quality of life *(established but incomplete)* {4.5.3}. Negative and positive impacts on society are most often documented in Asia-Pacific (41 per cent of negative impacts and 53 per cent of positive impacts), and in cultivated areas (29 per cent of negative impacts and 26 per cent of positive impacts) *(established but incomplete)* {4.5.2.1, 4.5.3}. Although there is very little systematic research on gender differences in impacts of invasive alien species, the available data suggest that some invasive alien species may cause gender-differentiated impacts *(established but incomplete)* {4.5.1}.

9 Indigenous Peoples and local communities report more negative than positive impacts caused by invasive alien species, especially on water resources, human health and health of livestock and access to traditional lands *(well established)* {4.6.1}. Indigenous Peoples and local communities report ten times more negative than positive impacts caused by invasive alien species on nature (92 per cent negative, 8 per cent positive) *(well established)* {4.6.1}. Impacts on nature, often affect the deep kinship connection that many Indigenous Peoples and local communities have with nature *(well established)* {4.6.3}. When considering nature's contributions to people, reports are more balanced (55 per cent negative to 45 per cent positive) *(well established)* {4.6.2}. Two-thirds (68 per cent) of the impacts on the good quality of life of Indigenous Peoples and local communities have been documented as negative, compared to one-third (32 per cent) that have been documented as positive *(well established)* {4.6.3}. Invasive alien species have frequently been documented to cause the loss of access to and mobility within traditional lands, leading to harder labour requirements *(well established)* {4.6.3}. Negative impacts on the health of Indigenous Peoples and local communities can be direct (e.g., injury) and indirect, including general feelings of despair and stress. Some invasive alien species can provide some benefits, including income and development of local industry *(well established)* {4.6.3, 4.6.4}, but Indigenous Peoples and local communities highlight that seemingly positive impacts are not often considered wholly positive by their communities, especially when communities had little agency or choice in responding to the invasive alien species *(well established)* {4.6.2, 4.6.3, 4.6.4}. There are many cases where Indigenous Peoples and local communities have adapted to the negative impacts of invasive alien species *(well established)* (4.6.3). Whilst more negative impacts have been documented on cultural values and practices, involvement of Indigenous Peoples and local communities in the use and management of invasive alien species is, in some cases, also documented as an opportunity for skills development and knowledge transfer *(established but incomplete)* {4.6.5}.

10 There are substantial geographic and taxonomic gaps in the documentation, quantification and understanding of impacts *(established but incomplete)* {4.7.2}. The quality and quantity of information available on impacts of invasive alien species for different taxa, units of analysis, regions and realms differ greatly, and research efforts are unevenly distributed across regions, temporal scales, and taxa *(well established)* {4.7.2}. These biases can be observed across all realms, especially in marine ecosystems, where the extent and timing of research efforts on marine invasive alien species lag behind terrestrial studies *(established but incomplete)* {4.7.2}. About 95 per cent of the sources listed in the dataset are in English, severely underrepresenting studies only available in non-anglophone sources *(well established)* {4.7.2}.

4.1 INTRODUCTION

> "The cardoon *(Cynara cardunculus)* has a far wider range: it now occurs in these latitudes on both sides of the Cordillera, across the continent. I saw it in unfrequented spots in Chile, Entre Rios, and Banda Oriental. In the latter country alone, very many (probably several hundred) square miles are covered with one mass of these prickly plants and are impenetrable by man or beast. Over the undulating plains, where these great beds occur, nothing else can live. Before their introduction, however, I apprehend the surface supported as in other parts a rank herbage. I doubt whether any case is on record, of an invasion of so grand a scale of one plant over the aborigines." (Darwin, 1839).

At the time Charles Darwin wrote this, European powers vied to import, grow and disseminate "exotic" plants and animals. The earliest "jardins d'acclimatation" were erected on the order of the King of France at the time, Louis XV, to accommodate edible, medicinal and decorative plants elsewhere; breadfruit from the South Pacific was shipped to French Guiana, and coffee plants to the Antilles and Brazil (Bailey, 2018). This was the continuation of a process rooted in prehistorical millennia. Zooarchaeological and archaeobotanical studies reveal the spread of the Near Eastern suite of domesticates, cultivated plants and synanthropic biota across Europe, Asia and Africa (Bortolus *et al.*, 2015; Colledge *et al.*, 2013; **Chapter 1**, **Figure 1.3**). Austronesian people transported their domesticated animals, including dogs, pigs, chickens and the synanthropic *Rattus exulans* (Pacific rat) to isolated archipelagos of Remote Oceania long before the sixteenth century (N. Amano *et al.*, 2021; Crabtree, 2016; Giovas, 2006). The direct and indirect impacts of these species on island ecosystems (**Glossary**), through agricultural deforestation and the introduction of mammalian predators, have only recently come to the fore: palaeoecological data reveal losses of many species (Drake & Hunt, 2009; Fillios *et al.*, 2012; Prebble & Wilmshurst, 2009).

Despite vast numbers of terrestrial, inland waters, and marine introductions over millennia, written documentation of their impacts was rare until the twentieth century. For example, *Sporobolus alterniflorus* (smooth cordgrass) occupying subtropical and temperate salt marshes along the Atlantic coast of South America may have been introduced in the eighteenth or early nineteenth century, but remained a "hidden invasion"; its impacts on coastal geomorphology and biodiversity have been overlooked and undocumented (Bortolus *et al.*, 2015). Studies that actually document impacts of invasive alien species have been limited to 3515 invasive alien species, about 10 per cent of all alien species (**Glossary**) according to the Global Register of Introduced and Invasive Species (GRIIS).

Charles Elton evinced great interest in biological invasions (**Glossary**) as early as the 1930s. Studying a bevy of introduced species in the United Kingdom, from *Ondatra zibethicus* (muskrat) to *Rattus norvegicus* (brown rat), he denounced them as a zoological catastrophe. Elton's seminal contribution (Elton, 1958) highlighted the impacts of invasive alien species – animals, plants, pathogens, terrestrial, aquatic and marine – and raised public awareness of biological invasions as a conservation issue (Simberloff, 2010). Still, it was not until the 1980s, when the Scientific Committee on Problems of the Environment (SCOPE) convened a series of workshops, that contemporary invasion biology was launched (Mooney & Drake, 1989; Simberloff *et al.*, 2013) and soon established that invasive alien species could have severe and lasting impacts on ecosystem functions, and that nearly every type of ecosystem had been affected (Lodge, 1993; **Chapter 1**, **Figure 1.2**). The mode, rate, order and crypticity of introduction, the inherent complexity in interactions between invasive alien species population and host community and ecosystem, and their interactions with the environment are each context-driven and difficult to assess (Jarić *et al.*, 2019; Parker *et al.*, 1999; Vanderhoeven *et al.*, 2017; **Chapter 1**, **section 1.5**).

Invasive alien species cause a wide array of economic damage, disrupting the production of goods and services. For example, invasive alien species can reduce timber and agricultural output (T. P. Holmes *et al.*, 2009; Paini *et al.*, 2016), damage infrastructure (Fritts, 2002), impact the operations of public utility companies (Elliott *et al.*, 2005; Magara *et al.*, 2001), and disrupt navigation (Ashe & Driscoll, 2013; Bryson *et al.*, 2008; Grewell *et al.*, 2016; Lindgren *et al.*, 2013; Mallison *et al.*, 2001). Invasive alien species are also notorious for altering nature's contributions to people and good quality of life (**Glossary**), which affects property values (Olden & Tamayo, 2014), tourism (Mejía & Brandt, 2015), and outdoor recreation (Lauber *et al.*, 2020). Human health can be profoundly affected, too (Juliano & Lounibos, 2005; Kemp *et al.*, 2000; World Health Organization & Convention on Biological Diversity, 2015). Significant costs are also associated with invasive alien species prevention and control efforts (**Glossary**), including clearing costs (Marais *et al.*, 2004) and increased costs of transportation (e.g., road-right-of-way maintenance costs, hull maintenance, inspection stations, ballast water treatment system costs, etc.). Invasive alien species are sometimes associated with economic benefits, having been deliberately introduced for aquaculture (De Silva *et al.*, 2009), forestry and landscaping (Knowler & Barbier, 2005; Richardson, 1998), cultural reasons (Pejchar & Mooney, 2009), or recreational pursuits such as sport fishing, yet there is general agreement that their net economic effect is overwhelmingly negative (Bradshaw *et al.*, 2016; Diagne, Leroy, *et al.*, 2021; Zenni *et al.*, 2021).

Though related literature has increased in recent years, research on the economic benefits and costs of invasive alien species is in its infancy. Perhaps more concerning, researchers are still trying to understand the links among biological invasions and economic activities, some of which are indirect and difficult to quantify (B. A. Jones & McDermott, 2018; B. A. Jones, 2016; Charles & Dukes, 2007). As a result, few long-term studies examine economic impacts over time (Essl *et al.*, 2011; Cuthbert, Pattison, *et al.*, 2021). As invasive alien species continue to spread and understanding about the economic implications of invasive alien species increases, it is safe to assume that the estimate of sustained damages will continue to rise. Perceptions of the costs and benefits of introduced species are varied (Jubase *et al.*, 2021; R. T. Shackleton, Richardson, *et al.*, 2019; Verbrugge *et al.*, 2013; **Chapter 1**, **section 1.5.2**). A limited number of invasive alien species are exploited commercially, though some of those have had substantial negative impacts in recipient ecosystems. In 1999, the International Union for the Conservation of Nature (IUCN), through its Invasive Species Specialist Group (ISSG), established the list of "100 of the world's worst invasive alien species" to increase public awareness (GISD, 2013). Geraldi *et al.* (2019), examined media attention to the aquatic and marine species on the IUCN list and concluded that coverage was low and short-lived; an important observation given the influence of media on societal environmental perceptions. Listed by the IUCN (but unexamined by Geraldi *et al.*, 2019) are *Oncorhynchus mykiss* (rainbow trout) and *Salmo trutta* (brown trout), which have been introduced worldwide for the main purpose of recreational fishing and have subsequently resulted in significant losses of biodiversity (Cambray, 2003). Yet, the growing popularity of sport fishing and angling delivers significant economic benefits to tourism, rending these and similarly introduced invasive fish "sacrosanct" amongst some stakeholders (J. E. Jackson *et al.*, 2004; Lewin *et al.*, 2006). Despite this inherent complexity, this chapter provides a global analysis and synthesis of the environmental, economic and social impacts of invasive alien species from available evidence (published peer-reviewed literature, grey literature, and information from Indigenous and local knowledge systems; **Glossary** and **Box 4.1**). This assessment only reflects documented impacts; however, the total impact of invasive alien species remains unknown.

The chapter flows from an unprecedented assessment of impacts, through which an impact database has been compiled. **Section 4.1** introduces the major concepts underpinning the analysis of impacts; **section 4.2** presents the methodology employed to record and analyse impacts in the chapter; **section 4.3** presents the analysis and synthesis of impacts on nature; **section 4.4** covers impacts on nature's contributions to people; and **section 4.5** describes impacts on good quality of life. For each section, the team of authors have presented general patterns, impacts by realm and units of analysis, impacts by region, and impacts by invasive alien species taxon. **Section 4.6** presents a

Box 4 1 **Rationale of the chapter.**

The chapter focuses on the impacts of invasive alien species on nature (**Glossary**) and nature's contributions to people and a good quality of life, as defined in the conceptual framework of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES; **Chapter 1**, **sections 1.6.1**), including non-economic values (e.g., cultural, social and shared, recreational, scientific, spiritual and aesthetic values).

Guiding questions:

- Which native taxa, nature's contributions to people and components of good quality of life are most negatively and positively impacted by invasive alien species?
- Which units of analysis and regions are most negatively and positively impacted by invasive alien species?
- Which invasive alien species caused local and global extinctions and which native species (**Glossary**) and taxonomic groups are affected?
- What are the global monetary costs of invasive alien species?
- How do people, including Indigenous Peoples and local communities, assess the magnitude of impacts of invasive alien species?
- What are our knowledge gaps and biases in the type and distribution of impacts across taxa, regions, units of analysis?

Keywords:
positive and negative impacts, invasive alien species, nature's contributions to people, good quality of life, native taxa, Indigenous Peoples and local communities, units of analysis.

summary of some impacts as perceived by Indigenous Peoples and local communities; and **section 4.7** discusses the future direction of impacts and their analysis, including the use of scenarios and modelling, and the knowledge gaps that can animate future improvements in methodology. Recording and analysing the impacts of invasive alien species will inform future efforts toward prevention and management (**Glossary**) of biological invasions.

4.1.1 Types of impacts: nature, nature's contributions to people, good quality of life

The impacts of invasive alien species on nature, nature's contributions to people, and good quality of life are all context-dependent, and range along a continuum from nearly indiscernible to region-wide changes (**Chapter 1**, **Figure 1.1** for definitions).

Impact on nature, formerly "ecological impact", is defined as a measurable change to the properties of an ecosystem (Ricciardi *et al.*, 2013), and implies that all introduced species can have an impact, even when not yet established or widespread (**Glossary**), which may vary in magnitude, simply by integration into the ecosystem. Impact can be measured at the level of an organism (e.g., effects on individual mortality and growth), a population (abundance), a community (species richness, evenness, composition, trophic structure), an ecosystem (physical habitat, nutrient cycling, contaminant cycling, energy flow), or a region (species richness, beta diversity). Individual, population and community-level impacts are most commonly studied (Jeschke *et al.*, 2014; Ricciardi *et al.*, 2013).

Impact on nature's contributions to people (**Chapter 1**, **Box 1.12**) comprises positive contributions as well as negative impacts, e.g., exacerbating fire hazards, soil erosion, allergenic pollen, zoonotic diseases, poisoning and envenomation (Vaz *et al.*, 2017). Regardless of taxon, ecosystem and region, invasive alien species alter nature's contributions to people by affecting populations, community dynamics, ecosystem processes, and abiotic variables. Yet, despite awareness of the susceptibility of nature's contributions to people to alteration by invasive alien species, research has lagged behind and impacts are often overlooked or underappreciated, leaving threats to people unquantified (Charles & Dukes, 2007).

Each constituent of good quality of life (**Chapter 1**, **Table 1.4**) is vulnerable to alteration by invasive alien species. Changes to the constituents of good quality of life such as material and immaterial assets (e.g., the provisioning of food and fuel), safety, health, economic and cultural practices, social relations, or freedom of choice and action can affect peoples' lives (**Box 4.9** in **section 4.3.2.1**, for example).

Appreciation of the extent and intensity of impacts is essential for prioritizing appropriate policy and governance (**Glossary**) responses to invasions. Attention of policymakers, stakeholders and the public is focused on a subset of introductions perceived as "harmful", having resulted in extinction or extirpation of native species and/or striking changes to ecosystem functioning, nature's contributions to people and good quality of life (Simberloff *et al.*, 2013).

4.1.2 Directionality of impacts: nature, nature's contributions to people, good quality of life

Impact directionality (i.e., whether impacts of invasive alien species are assessed as "negative" or "positive") is partly grounded in subjective perceptions embedded within economic, cultural and social contexts. Perception of impacts as positive or negative depends on value systems and values can vary even within the same economic, cultural and social context (R. T. Shackleton, Richardson, *et al.*, 2019). Thus, there are different ways of defining whether nature or its elements are harmed or benefit.

Nature and its elements have intrinsic value, and one could argue that this value can be damaged by invasive alien species. Extinctions and extirpations caused by the unintentional introductions of rats, snakes, gypsy moths, and chestnut blight, can be considered negative impacts (Czech & Krausman, 1999; Butchart *et al.*, 2006; Kochalski *et al.*, 2019). Local population losses and niche contraction of native species may not induce immediate extirpation, but they augur reduction of genetic diversity, loss of functions, processes, and habitat structure, increasing the risk of decline and extinction (**Glossary**; Galil, 2007). When studies document cases of rising species richness or abundance of native species following introductions of an invasive alien species (Irigoyen *et al.*, 2011; McQuaid & Griffiths, 2014; Thomsen, 2010), they can be considered as positive impacts on nature. However, this assessment recognises that the purported benefits can be predicated on provision of novel habitat (e.g., polychaete and oyster reefs in muddy habitats, algal meadows) by transforming entire habitats to the detriment of the pre-existing community. In many communities, some native species suffer from the introduction of invasive alien species while others may benefit.

In this assessment, impacts on nature are defined as negative when a native species suffers disadvantage,

Box 4 2 Environmental and Socio-Economic Impact Classification for Alien Taxa: EICAT and SEICAT.

The International Union for Conservation of Nature (IUCN) EICAT framework was developed to categorize and assess negative impacts caused by alien taxa on native taxa (IUCN, 2020). The framework assesses how much a native species is affected by an invasive alien species. Other types of environmental impacts such as changes caused by alien taxa to abiotic ecosystem properties (e.g., soil or water chemistry) are considered under the framework only if such changes lead to a decrease in attributes of native biodiversity.

The EICAT classifies impacts in a 5-step semi-quantitative scale based on the level of biological organization affected (individuals → populations → communities), and the magnitude and reversibility of these impacts (Blackburn *et al.*, 2014). The five steps reflect an increase in the order of magnitude of the particular impact so that a new level of biological organization is involved. **Minimal Concern** – negligible impacts, and no reduction in performance of a native taxon's individuals; **Minor** – performance of individuals reduced, but no decrease in population size; **Moderate** – native taxon population decline; **Major** – native taxon local extinction (i.e., change in community structure), which is naturally reversible; and **Massive** – naturally irreversible local or global extinction of a native taxon (**Figure 4.1**; IUCN, 2020; Volery *et al.*, 2020). Impacts of invasive alien species can be caused through 10 mechanisms **(Figure 4.1)**. The EICAT is conceptually and structurally related to the IUCN Red List of Threatened Species, with the Red List categorizing a focal native species based on its risk of extinction, and the EICAT categorizing a focal alien taxon based on the degree to which it has negatively impacted native taxa (Van der Colff *et al.*, 2020).

The SEICAT assesses negative impacts of invasive alien species on good quality of life (Bacher *et al.*, 2018). It follows an approach similar to the EICAT. In particular, it classifies changes in human activities caused by invasive alien species into one of 5 magnitudes. These are: **Minimal Concern** – negligible impacts, and no reduction in individual peoples' activities; **Minor** – normal activities are more difficult, but no decrease in activity size, i.e., all people still carry out the activity; **Moderate** – decline in activity size, i.e., fewer people participate in an activity; **Major** – local disappearance of an activity from all or part of the area invaded by the invasive alien species, which is naturally reversible; and **Massive** – local irreversible disappearance of an activity from all or part of the area invaded by the invasive alien species (Bacher *et al.*, 2018). Changes in human activities can be caused through impacts on five constituents of good quality of life **(Box 4.3)**. The framework is based on the capability approach of welfare economics (Robeyns, 2005; Sen, 1999) and thus avoids ambiguities in interpreting impacts based on monetary approaches (Hoagland & Jin, 2006).

The EICAT and the SEICAT have been used to compare impact magnitudes of alien taxa at various spatial scales, across geographic regions and taxonomic groups (e.g., Evans *et al.*, 2016, 2020; Canavan *et al.*, 2019; Galanidi *et al.*, 2018; Kesner & Kumschick, 2018; Volery *et al.*, 2021), and to facilitate evidence-based prioritization and other management decisions (Rockwell-Postel *et al.*, 2020). Widespread application of both schemes is expected to reduce data biases and data gaps on the impacts of invasive alien species on nature and good quality of life. Recently, the EICAT framework was expanded to include a classification for positive impacts of invasive alien species for nature (EICAT+; Vimercati *et al.*, 2022) but this was not available at the time when data for this chapter were gathered. EICAT+ might allow comparison of positive and negative environmental impacts in a common framework for a better understanding of the consequences of invasive alien species and to better inform conservation decisions. For a comprehensive understanding and efficient management, the reporting of both negative and positive impacts is critical (Vimercati *et al.*, 2020).

Box 4 2

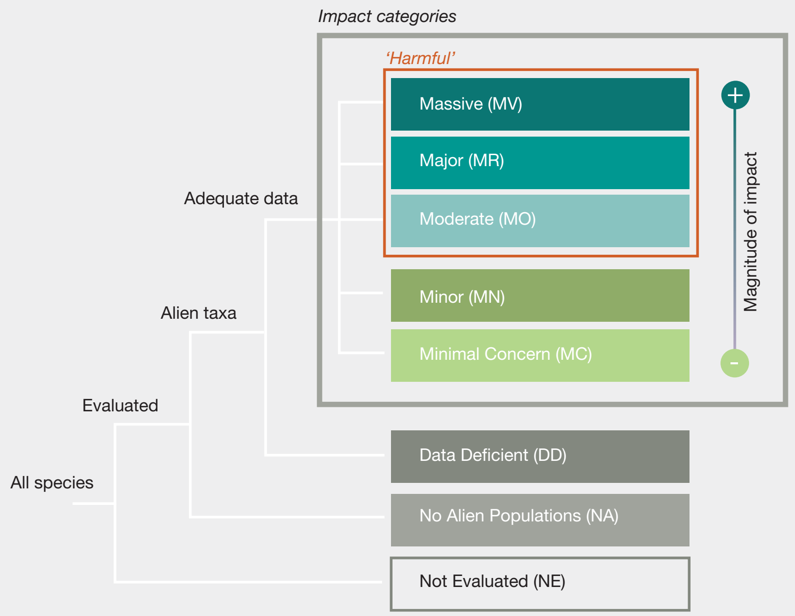

Figure 4 1 **EICAT and SEICAT categories and the relationship between them.**

The five impact categories (from minimal concern to massive) can be used to assess negative impacts caused by invasive alien species (which are a subset of alien species). Source: IUCN (2020), https://doi.org/10.2305/IUCN.CH.2020.05.en, under license CC BY-NC 4.0.

following the Environmental Impact Classification for Alien Taxa (EICAT, **Box 4.2**) approach developed by IUCN (2020), and as positive when a native species benefits from ecosystem changes due to the introduction of an invasive alien species (Vimercati *et al.*, 2022). However, not every ecosystem change can be assigned a unique directionality. For example, abiotic characteristics of ecosystems (e.g., changes in soil or water chemistry, structural complexity) can increase or decrease due to the impacts of an invasive alien species, but it is not straightforward to assign an impact direction (positive or negative) because these changes might have different consequences for different species. Moreover, abiotic ecosystem changes can sometimes be quantified as either an increase or a decrease of an indicator (e.g., an increase in the concentration of hydrogen ions (H^+) is equivalent to a decrease of the pH). Thus, in this report, impacts describing abiotic changes in ecosystem characteristics are classified as negative or positive only if the consequence of these changes is documented to harm or benefit a native species. Abiotic ecosystem changes are not assigned a directionality when it is unknown if a native species suffers or benefits from these changes. Invasive alien species can benefit or harm people, which determines the directionality of impacts on nature's contributions to people and good quality of life. Directional changes in nature's contributions to people (i.e., increases or decreases of the parameters that are measured, **Chapter 1**, **Box 1.12**) may be positively or negatively associated with changes in good quality of life. For this report, benefits in nature's contributions to people are documented as an increase in services and/or decrease in disservices, whereas deleterious changes would do the opposite (Vaz *et al.*, 2017). By contrast, in this report, directionality in good quality of life is assessed by changes in constituents of good quality of life (Bacher *et al.*, 2018; **Chapter 1**, **Table 1.4**) which are directly associated with humans profiting or suffering from the impacts of an invasive alien species. This follows the Socio-Economic Impact Classification for Alien Taxa (SEICAT; **Box 4.2**) approach, which recognizes that different people may perceive impacts by invasive alien species in different ways (Bacher *et al.*, 2018). Invasive alien species may cause a range of impacts with different directionality ("negative" and "positive") on native species of the resident community, on categories of nature's contributions to people, and on components of good quality of life. For example, a negative impact of an invasive alien species on a native predator may profit its native prey; an invasive alien species may increase food production at the expense of soil deterioration; or an invasive alien rangeland plant like *Echium plantagineum* (Paterson's curse) may profit bee keepers due to its proliferous nectar production, but be toxic to livestock and thus detrimental to farmers (Harris, 1984). Thus, impacts on nature can be at odds with impacts on nature's contributions to people and good quality of life. For instance, *Gambusia affinis* (western mosquitofish) has been widely introduced as a biological control agent (**Glossary**) to manage mosquito populations but also preys on rare indigenous fish, amphibians and invertebrates (Englund, 1999; Leyse *et al.*, 2004; Segev *et al.*, 2009; Rupp, 1996).

Occasionally, invasive alien species impact all three **(Table 4.1)** – nature, nature's contributions to people and good quality of life – as is the case with *Acacia mearnsii* (black wattle), in South Africa. This highly invasive alien species manifests significant negative impacts on water resources (losses estimated at 577 million m^3 annually), biodiversity, and the stability and integrity of riparian ecosystems, while supplying an industry of tanning agents and providing rural communities with firewood and building materials. Plantation owners, small growers and rural communities benefit economically from the products of invasive alien wattles, whereas most sectors of society bear the social and monetary costs of loss in water and biodiversity, and increase in fire risk and erosion (de Wit *et al.*, 2001).

When interpreting invasive alien species impacts, care should be taken to examine them in a comprehensive manner, addressing nature, nature's contributions to people, good quality of life, and their directionality. Reporting all types of impacts, positive and negative, separately allows a comprehensive picture of impacts by invasive alien species and avoids some impacts being masked by tallying or calculating "net impacts". For example, economic benefits are often gained by a few people or sectors while costs, often long-term ones, are borne by many others (Gozlan & Newton, 2009; Kelsch *et al.*, 2020).

The IPBES invasive alien species assessment acknowledges that the outcomes of assessments of the positive impacts of invasive alien species do not balance or offset their negative impacts, which may be irreversible (Lockwood *et al.*, 2023). Positive and negative stacked bar charts in this chapter do not imply that positive and negative impacts can be summed.

4.1.3 Impacts and Indigenous and local knowledge

Some Indigenous Peoples and local communities, because of their holistic and interconnected relationships with nature (M. C. C. Holmes & Jampijinpa, 2013) and close dependence on nature for livelihoods and support systems (Mungatana & Ahimbisibwe, 2012), experience impacts of invasive alien species that go beyond changes to distinct species or habitats, to include both negative and positive economic, social and cultural impacts, including on good quality of life (Vaarzon-Morel, 2010; Sundaram *et al.*, 2012; Jevon & Shackleton, 2015; K. Smith *et al.*, 2010; dos Santos *et al.*, 2014; Atyosi *et al.*, 2019; Martínez & Manzano-García, 2019; R. T. Shackleton, Shackleton, *et al.*, 2019). For some Indigenous Peoples and local communities, an impact of invasive alien species may change material assets, such as food and materials to sustain livelihoods (K. Smith *et al.*, 2010), as well as some immaterial values, including cultural practices (Monterroso *et al.*, 2011), opportunity for learning and teaching on traditional lands (Bach *et al.*, 2019), and persisting spiritual identities (Fischer, 2007), all of which underpin their health and well-being (Sangha *et al.*, 2015).

Reviews, such as the one conducted by Pfeiffer and Voeks (2008), highlight the importance of time scale in assessing impacts, and estimate that where an invasive alien species has been present for at least 3 generations (100 years plus), Indigenous Peoples and local communities may incorporate the invasive alien species into rituals, practices or as a resource. However, other studies (R. T. Shackleton *et al.*, 2017) and frameworks (C. M. Shackleton *et al.*, 2007) focused on sustainable livelihoods more broadly, suggest that if an invasive alien species is left unchecked over time, the negative impact on livelihoods and vulnerability of communities increases with longer exposure to the invasive alien species. For example, the Botswana San once embraced *Prosopis juliflora* (mesquite), planted by forestry officials in the 1980s, as a useful resource but, by the 1990s, its spread threatened animals, water sources and movement through the bush. Thus, the San people have since worked actively to eradicate (**Glossary**) it (Bach *et al.*, 2019; Fischer, 2007; Monterroso *et al.*, 2011; Mosweu *et al.*, 2013; Sangha *et al.*, 2015; K. Smith *et al.*, 2010).

The nature of research on impacts of invasive alien species for Indigenous Peoples and local communities has also developed over time. Early studies often documented the knowledge and use of invasive alien species by Indigenous Peoples and local communities (i.e., ethnobotanical studies looking at medicinal or food use of alien plants; Bye, 1981), while more complex impacts were not documented. As Indigenous and local knowledge has been elevated within mainstream arenas to inform global biodiversity policies (e.g., Local Biodiversity Outlooks; Forest Peoples Programme *et al.*, 2016, 2020), studies of Indigenous and local knowledge on broad ecological, social and cultural impacts have increased, including co-designed studies with Indigenous Peoples and local communities (e.g., Sloane *et al.*, 2021; S. Russell *et al.*, 2020). However, this recent rise in the number and complexity of studies does not mean that impacts have only recently been felt. For invasive alien species that arrived and spread centuries ago, the information about first impacts may not have been passed down through the generations of Indigenous Peoples or local communities, particularly if the introduced species is not part of ancestral or "Dreaming" stories and customs (Crowley, 2014; Salmón, 2000). Therefore, cultural stories and knowledge transferred in modern times may be more on how to use and adapt to invasive alien species, rather than documented negative impacts (e.g., rabbits in Australia, feral pigs in Hawaii, wild horses in North America, water hyacinth in waterways in Asia and Africa; Pfeiffer & Voeks, 2008; Collin, 2017).

Given the complexity of impacts considering time-scale and the diversity of Indigenous Peoples and local communities and their livelihoods, Pfeiffer and Voeks (2008) proposed a framework of invasive alien species impacts as either "impoverishing, augmenting, or facilitating" culture. Fitting within this framework, some studies recognize negative impacts of invasive alien species to the livelihoods of Indigenous Peoples and local communities (Kent & Dorward, 2015; Ngorima & Shackleton, 2019), others acknowledge the positive impacts such as facilitation of inter-generational culture retention (Maldonado Andrade, 2019), and some studies highlight the adaptation of some Indigenous Peoples and local communities to invasive alien species (P. L. Howard, 2019).

In this chapter, Indigenous and local knowledge sources have been included as data in the main impacts database (**section 4.2**) and, in addition, **section 4.6** includes a supplementary review of impacts directly documented by Indigenous Peoples and local communities from 124 peer-reviewed sources, which fills some information gaps in the mainstream database methods (**section 4.6**).[2]

4.2 METHODOLOGY

Authors of this chapter have systematically reviewed relevant available information to understand the impact of invasive alien species on nature, nature's contributions to people and good quality of life, at a global level for a large number of organisms and habitats.

Some regions of the world have notably more information in scientific publications than others (Nuñez *et al.*, 2019; Nuñez & Amano, 2021). Therefore, methods for reviewing literature varied within this chapter, with tailored criteria and systematic approaches for literature searches being adopted for different regions and taxa. The specific methodologies are presented in more detail in the data management report.[3] Reviewed information included scientific literature (papers, books) and grey literature (institutional reports, reports of agencies and other relevant sources), including from Indigenous and local knowledge, and databases of invasive alien species (e.g., Centre for Agriculture and Bioscience International (CABI)'s Invasive Species Compendium and the Global Invasive Species Database (GISD), the IUCN Red List of Threatened Species, or the InvaCost database).

From each analysed document, gathered data included:

- The geographical location of the impact.
- The corresponding IPBES unit of analysis (**Chapter 1**, **section 1.6.5** for a description of all 17 units of analysis), recording whether the impacted area was on an island or in a protected area.
- The name of the invasive alien species, and the name (if possible) and taxonomic group (plant, invertebrate, vertebrate, and microbe) of native species affected, as described in the document, and if the species was intensively used for multiple purposes by humans.
- The mechanism, magnitude (only for negative impacts) and direction of impacts on nature (**section 4.1.2**), at the local population level.
- The mechanism and direction of impacts on nature's contributions to people (**section 4.1.2**, **Box 4.3** and **Chapter 1**, **Box 1.12**). This doesn't include the magnitude of impacts on nature's contributions to people, as no standard methodology has been developed to date to assess it.
- The direction, magnitude (only for negative impacts) of impacts and affected constituents of good quality of life (**section 4.1.2**).
- The relation to Indigenous and local knowledge.

Authors did not collect data on the synergistic effects of other drivers of change in nature such as climate change (**Box 4.5**, in **section 4.3.1**), evolutionary aspects (**Box 4.8**, in **section 4.3.1.4**) or information on the interactions with other native or alien species (**Box 4.5**, in **section 4.3.1**).

The database of impacts developed through this chapter contains data on 24,129 reports of impacts caused by 3,515 invasive alien species, representing 10.9 per cent of all alien species (ranging from 5.5 per cent to 22.4 per cent, depending on the taxonomic groups, **Table 4.1**). There were no studies of impacts for many alien species and the real percentages of invasive alien species causing impacts is likely to be higher than documented in this chapter.
All numbers presented in this chapter are based on this single database compiled specifically for this chapter if not stated otherwise.

Box 4 3 Important terms and concepts used in this chapter.

Constituents of good quality of life are material and immaterial assets; safety; health; social and cultural relationships; freedom of choice and action (**Chapter 1**, **Table 1.4**).

Impacts on ecosystem properties are changes to (abiotic) ecosystem parameters e.g., soil variables, while it remains unknown how native species are affected by these changes (**section 4.1.1**).

Impacts on good quality of life (**Chapter 1**, **section 1.6.7.2**) can be positive or negative through changes in constituents of good quality of life; measured as changes in peoples' activities following the SEICAT approach (Bacher *et al.*, 2018).

Impact magnitudes:

- **Impact magnitudes on nature** follow the EICAT system from the IUCN (2020) namely impacts on performance of native individuals, population declines, local or global extinctions.
- **Impact magnitudes on good quality of life** are classified according to the SEICAT approach (Bacher *et al.*, 2018) namely human activities are more difficult, some people stop certain activities, and activity is locally abandoned.

Mechanisms include negative impacts on native species and follow the EICAT system from the IUCN (2020):

- **Competition** – the alien taxon competes with native taxa for resources (e.g., food, water, and space), leading to deleterious impact on native taxa.
- **Predation** – the alien taxon predates on native taxa, leading to deleterious impact on native taxa.
- **Hybridization** – the alien taxon hybridizes with native taxa, leading to deleterious impact on native taxa.
- **Transmission of disease** – the alien taxon transmits diseases (alien or native) to native taxa, leading to deleterious impact on native taxa.
- **Parasitism** – the alien taxon parasitizes native taxa, leading to deleterious impact on native taxa.
- **Poisoning/toxicity** – the alien taxon is toxic, or allergenic by ingestion, inhalation or contact, or allelopathic to plants, leading to deleterious impact on native taxa.
- **Bio-fouling** or other direct physical disturbance – the accumulation of individuals of the alien taxon on the surface of a native taxon (i.e., biofouling), or other direct physical disturbances not involved in a trophic interaction (e.g., trampling, rubbing, etc.) leads to deleterious impact on native taxa.
- **Grazing/herbivory/browsing** – grazing, herbivory or browsing by the alien taxon leads to deleterious impact on native taxa.
- **Chemical, physical, structural impact on ecosystem** – the alien taxon causes changes to the chemical characteristics of the native environment (e.g., pH; nutrient and/or water cycling), the physical characteristics of the native environment (e.g., disturbance or light regimes), or changes to the habitat structure (e.g., changes in architecture or complexity), leading to deleterious impact on native taxa.
- **Indirect impacts through interactions with other species** – the alien taxon interacts with other native or alien taxa (e.g., through any mechanism, including pollination, seed dispersal, apparent competition, mesopredator release), facilitating indirect deleterious impact on native taxa.

Nature's contributions to people are composed of 18 categories (**Chapter 1**, **Box 1.12**; Díaz *et al.*, 2018). Note that changes in nature's contributions to people do not always directly translate into positive or negative changes for people (e.g., if people do not use the increase in nature's contributions to people, then there is no actual contribution). Nature's contributions to people impacts are documented as positive or negative without assignment of magnitude, i.e., positive means an increase in nature's contributions to people, negative a decrease.

Positive impacts are assigned as positive when an entity profits from the change, i.e., a native species (impacts on nature) or humans (nature's contributions to people, good quality of life impacts).

Unit of analysis have been adopted by this assessment to classify "habitats" (**Chapter 1**, **section 1.6.5**).

Of the 3,515 invasive alien species that were found to cause impacts, 1,673 (48 per cent) cause impacts on nature, 1,530 (44 per cent) on nature's contributions to people, and 1,032 (29 per cent) on good quality of life. Invasive alien species frequently cause more than one type of impact: 556 invasive alien species (16 per cent) cause impacts on both nature and nature's contributions to people, 235 species (7 per cent) on both nature and good quality of life. About 5 per cent of all invasive alien species cause impacts on all three categories.

There are similar numbers of impacts documented from the Americas (8,163 reports), Europe and Central Asia (7,481), and Asia-Pacific (6,016), but considerably fewer reports from Africa (1,725) **(Figure 4.2)**. Of all the documented impacts, 4,679 are from islands, and 3,324 from protected areas. Most documented impacts are from the terrestrial realm (18,011, 74.6 per cent) with considerably fewer from aquatic realms (inland waters: 3,299, 13.7 per cent; marine: 2,352, 9.7 percent); 467 of the documented impacts were from studies that did not specify the realm **(Figure 4.2)**. Invasive alien species have been documented to cause impacts across all units of analysis, but most reports are from temperate and boreal forests and woodlands, inland waters and cultivated areas (including cropping, intensive livestock farming; **Table 4.2**). There are very few

Table 4 1 **Number of established alien species and invasive alien species identified in this assessment by taxonomic group.**

Data sources for the numbers of established alien species from different taxonomic groups: **Chapter 2**, **Table 2.3**). A subset of established alien species are known to cause adverse impacts; they are termed invasive alien species. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

	Taxonomic group				
	Plants	**Invertebrates**	**Vertebrates**	**Microbes**	**All taxa**
Number of established alien species	19,365	8,282	3,242	1,257	32,146
Number of established alien species with documented impacts	1,061	1,852	461	141	3,515
Percentage of invasive alien species	5.5%	22.4%	14.2%	11.2%	**10.9%**

Table 4 2 **Number of documented impacts across IPBES units of analysis.**

IPBES units of analysis	Number of impact records
Tropical and subtropical dry and humid forests	2,664
Temperate and boreal forests and woodlands	3,849
Mediterranean forests, woodlands and scrub	1,248
Tundra and high mountain habitats	205
Tropical and subtropical savannas and grasslands	1,106
Temperate grasslands	2,147
Deserts and xeric shrublands	579
Urban/semi-urban	1,480
Cultivated areas (incl. cropping, intensive livestock farming etc.)	3,032
Aquaculture areas	144
Wetlands – peatlands, mires, bogs	728
Inland surface waters and water bodies/freshwater	3,107
Shelf ecosystems (neritic and intertidal/littoral zone)	2,295
Open ocean pelagic systems (euphotic zone)	7
Coastal areas intensively used for multiple purposes by humans	649
Cryosphere	-
Deep-sea	-

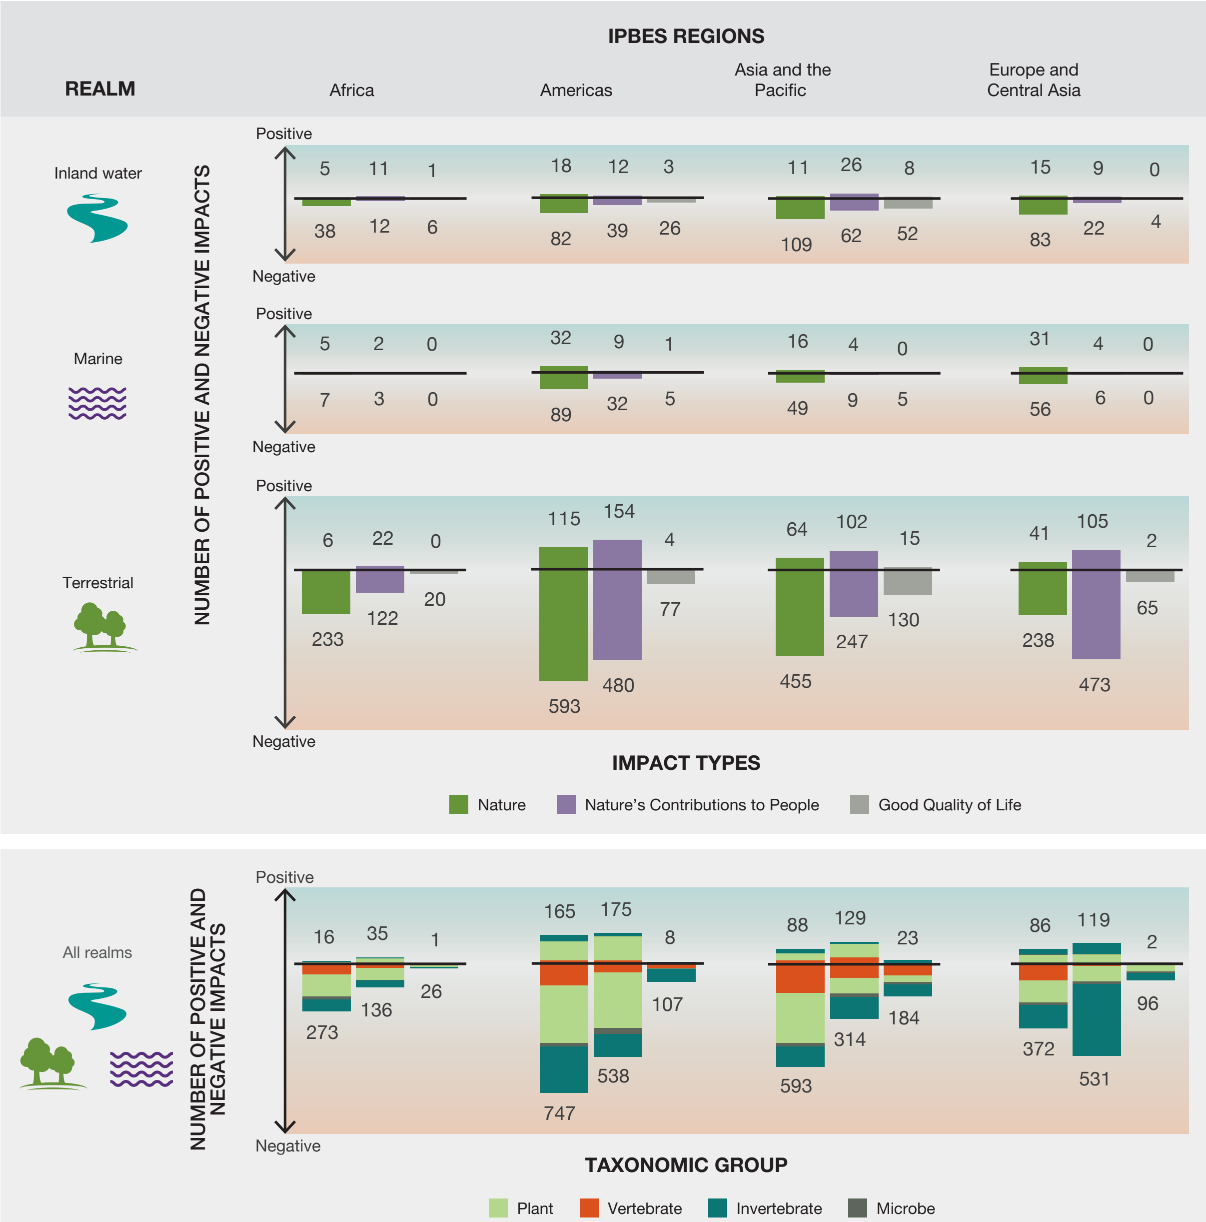

Figure 4 2 **Number of invasive alien species with documented negative and positive impacts on nature, nature's contribution to people and good quality of life, by taxonomic group, realm and IPBES region.**

Numbers and bars above indicate invasive alien species with positive impacts, numbers and bars below the x axes indicate species with negative impacts. Positive and negative stacked bar charts do not imply that positive and negative impacts can be summed. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

documented impacts from the open ocean, and no reports from the deep sea and the cryosphere were found. Twenty per cent of all impacts are reported from islands.

The most frequently documented impacts of invasive alien species are caused by plants (10,091 documented impacts), followed by invertebrates (8,180 documented impacts) and vertebrates (5,182 documented impacts), with invasive alien microbes having the lowest number of impact reports (676 documented impacts) **(Figure 4.2)**. These include all types of impacts (nature, nature's contributions to people, good quality of life) and all directions (positive, negative, and those that cannot be assigned a direction). Of the 13,898 documented impacts of invasive alien species on ecosystems properties, most affected native plants (6,376 documented impacts), followed by native invertebrates (4,629 documented impacts) and vertebrates (3,576 documented impacts), with impacts on native microbes being considerably less often documented (312).

4.3 IMPACTS OF INVASIVE ALIEN SPECIES ON NATURE

4.3.1 General patterns

Invasive alien species impact nature globally, and the majority of documented impacts are negative. This chapter documents more than 15,000 impacts on nature caused by 3,515 invasive alien species (**section 4.2**). Only a subset of these can be classified with a direction as being either negative, neutral or positive for native species (**section 4.1.2**). Of all the documented impacts with an assigned direction, 85 per cent (10,822) can be considered as negative impacts (caused by 1,623 species), and only 15 per cent (1,976) can be considered as positive impacts (caused by 361 species). Impact on ecosystem properties caused by 1,560 invasive alien species cannot be classified as either positive or negative impacts.

The vast majority of impacts were documented after the year 2000 **(Figure 4.3)**, which is likely to be a consequence of an increase in impacts correlated with the increase in number and occurrence of invasive alien species globally (**Chapter 2**, **section 2.2.1**), but is also due to an increase in research on the impact of invasive alien species. Negative impacts on nature have been documented since the beginning of the twentieth century with an almost exponential increase through time, while positive impacts of invasive alien species only started being documented in the 1970s **(Figure 4.3)**.

Invasive alien species most often documented causing impacts on nature

Invasive alien species with most records of negative impacts on nature include many vertebrates, e.g., terrestrial mammals such as *Rattus Rattus* (black rat), *Rattus exulans* (Pacific rat), *Felis catus* (cat), and *Vulpes vulpes* (red fox); *Rhinella marina* (cane toad); or marine and inland waters fishes such as *Pterois volitans* (red lionfish) and *Cyprinus carpio* (common carp). The ten most-often documented invasive alien species with negative impacts on nature include several ant species such as *Solenopsis invicta* (red imported fire ant), *Linepithema humile* (Argentine ant), and *Anoplolepis gracilipes* (yellow crazy ant); and *Procambarus clarkii* (red swamp crayfish). Examples of plants with many documented negative impacts on nature include *Reynoutria japonica* (Japanese knotweed) and *Lantana camara* (lantana).

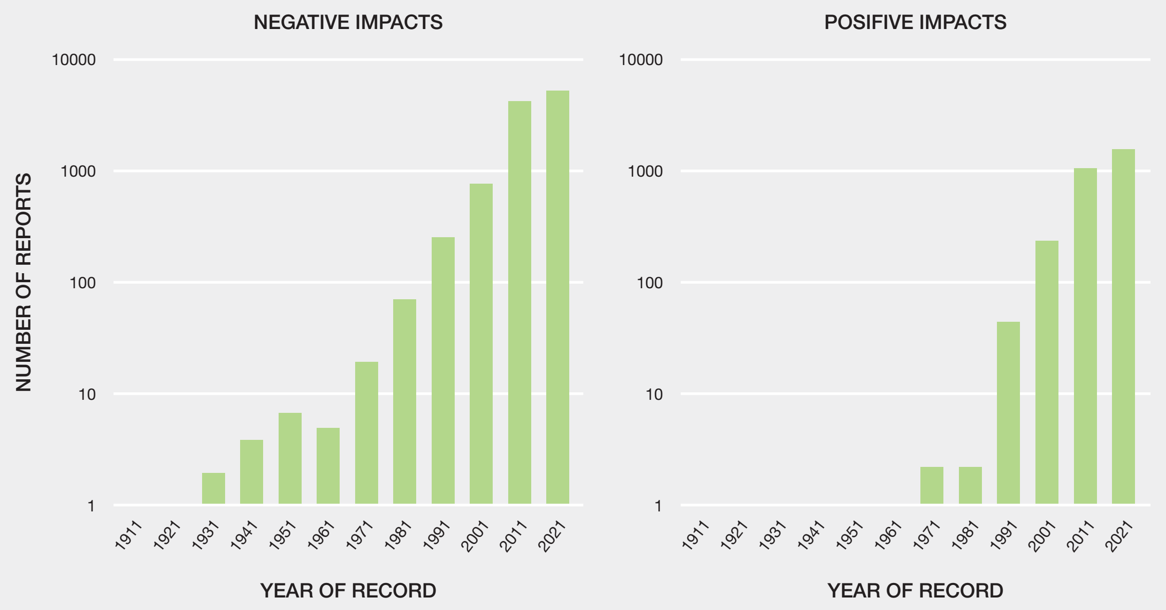

Figure 4 3 **Number of reported negative and positive impacts (y axes) on nature over time (x axis), from published literature since 1900 (note the logarithmic scale).**

A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

Most positive impacts on nature are caused by plants and invertebrates. Terrestrial plants, such as *Solidago gigantea* (giant goldenrod), *Reynoutria japonica* (Japanese knotweed), or *Carpobrotus* spp. (iceplant), and trees like *Acacia longifolia* (golden wattle) are abundant nectar sources for many native insect species. Marine species such as *Caulerpa cylindracea* (green algae) provide habitat for native species. Aquatic invertebrates such as *Magallana gigas* (Pacific oyster), *Dreissena* spp. (zebra and quagga mussels), *Ficopomatus enigmaticus* (tubeworm), or *Didemnum vexillum* (carpet seas quirt) also impact positively nature by creating habitat, and sometimes providing food, for native species. Although there are no vertebrates among the top ten invasive alien species with most records of positive impacts on nature, those with the most frequent documented positive impacts are *Neogobius melanostomus* (round goby), which provides food for native species (Hempel *et al.*, 2016; Rakauskas *et al.*, 2020), and *Rhinella marina* (cane toad), which indirectly favors native medium-sized predators by reducing populations of their competitors and/or top predators (Brown *et al.*, 2011; Doody *et al.*, 2013).

A total of 280 (8 per cent) invasive alien species have been documented to cause both negative and positive impacts on nature (**section 4.1.2**). Among these are many of the species that most often have been documented causing negative impacts, such as *Dreissena* spp. (zebra and quagga mussels), *Reynoutria japonica* (Japanese knotweed), or *Rhinella marina* (cane toad).

Local extinctions

Some invasive alien species cause local extinctions of native populations. Six per cent (218 species) of all invasive alien species with documented impacts have caused a total of 1,215 local extinctions of native populations. Local

Table 4 3 **Number of local extinctions caused by invasive alien species by taxonomic group and realm.**

Number of documented local extinctions caused by invasive alien species for invertebrates, microbes, plants and vertebrates in different realms. Two local extinctions (plant, microbe) could not be assigned to a realm. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

	Number of local extinctions in the marine realm	Number of local extinctions in the terrestrial realm	Number of local extinctions in the inland waters realm	Number of local extinctions in all realms
Local extinctions caused by invasive alien plants	98	53	35	187
Local extinctions caused by invasive alien invertebrates	134	210	50	394
Local extinctions caused by invasive alien vertebrates	48	480	91	619
Local extinctions caused by invasive alien microbes	2	12	0	15
All taxa	**282**	**755**	**176**	**1,215**

extinctions have occurred in all realms, but most extinctions have been documented in the terrestrial (62.1 per cent) realm, followed by the marine (23.2 per cent) and inland waters (14.5 per cent) realms **(Table 4.3)**. Overall, invasive alien animals have caused the most local extinctions of native species (vertebrates 51.0 per cent, invertebrates 32.5 per cent) in the terrestrial realm; whereas invasive alien plant species (15.3 per cent) and microbes (1.2 per cent) have caused fewer local extinctions **(Table 4.3)**. In contrast, in the marine realm, invasive alien invertebrates (47.5 per cent) and plants (34.8 per cent) are more often documented to be the cause for local extinctions than invasive alien vertebrates (17.0 per cent; **Table 4.3**).

Invasive alien vertebrates dominate the list of species causing local extinctions, e.g., *Felis catus* (cat), *Rattus Rattus* (black rat), *Rattus exulans* (Pacific rat), *Vulpes vulpes* (red fox), and *Capra hircus* (goats), but also the marine fish *Pterois volitans* (red lionfish). Ants also often lead to local extinctions, particularly species such as *Linepithema humile* (Argentine ant), *Anoplolepis gracilipes* (yellow crazy ant), and *Solenopsis invicta* (red imported fire ant). Plants that frequently lead to local extinctions are *Caulerpa cylindracea* (green algae) and *Pontederia crassipes* (water hyacinth). Microbes are less frequently implicated in local extinctions; pathogens that have caused local extinctions are *Batrachochytrium dendrobatidis* (chytrid fungus), *Austropuccinia psidii* (myrtle rust), *Ceratocystis platani* (canker stain of plane), *Cryphonectria parasitica* (blight of chestnut), the *Haplosporidium nelsoni* (MSX oyster pathogen), and *Morator aetatulas* (sacbrood virus) that affects honeybee larvae.

Global extinctions

Where invasive alien species caused global extinctions **(Box 4.4)**, the impacted native species often had a restricted spatial distribution with immutable borders. Thus, species endemic to islands, mountain ranges, or isolated lakes and river systems seem to be particularly at risk of global extinction caused by invasive alien species. Examples include *Boiga irregularis* (brown tree snake), which caused the local extinction and serious reduction of populations of most of the Guam's resident 25 bird species (Wiles *et al.*, 2003), leading to the global extinction of *Myiagra freycineti* (Guam flycatcher). Several global extinctions were attributed to the invasive alien *Euglandina rosea* (rosy predator snail), a predatory snail native to Central America and southern United States of America, introduced to many pacific islands to control *Lissachatina fulica* (giant African land snail) (Gerlach *et al.*, 2021). This terrestrial predatory snail led to the global extinction of several, mostly tree-inhabiting island-endemic snails of the genus *Partula* (Coote & Loève, 2003). The invasive alien *Rattus Rattus* (black rat) has been documented as the only cause of the global extinctions of *Nesoryzomys darwini* and *Nesoryzomys indefessus* (rice rats) endemic to the protected areas of the Galapagos Islands (Tirira & Weksler, 2017, 2019).

Box 4 4 Global extinctions caused by invasive alien species.

Invasive alien species have a range of impacts on nature which can ultimately lead to the global extinction of native species. The IUCN Red List synthesized information about species extinctions as well as their associated threats, which provides a basis to study the impact of invasive alien species in terms of extinctions. The IUCN Red List documented 327 animal and plant species as globally extinct or extinct in the wild with invasive alien species mentioned as one of the causes of extinctions, with an additional 205 species that are considered possibly extinct (average 50 years since the last specimen was seen). Invasive alien species are the only cause attributed to 16 per cent of all species extinctions documented in that database (K. G. Smith, 2020). Invasive alien species are also categorized as a significant contributing factor (i.e., having caused significant decline to the majority of the species' ranges) in nearly 60 per cent of extinctions, while in the remaining cases the role of invasive alien species as driver of extinctions is unknown and most likely minor compared to other drivers of change. By focusing on species extinctions in which the primary cause has been identified, invasive alien species are by far the most frequently mentioned driver. Note that most of the species that have gone extinct due to invasive alien species were also harmed by wildlife exploitation and/or cultivation and those threats are likely to act in combination on insular species (Leclerc *et al.*, 2018).

Among the extinctions in which invasive alien species are categorized as a significant cause (n=186), the overwhelming majority occurred on oceanic or continental islands (90 per cent). The risk of extinctions was greater on islands presumably because the species had reduced geographical range (**Glossary**), small population size, and reduced pressure from native predators compared to continental species (J. G. Cox & Lima, 2006; **Boxes 4.6**, **4.7**). For instance, naïve island birds, that have never encountered mammalian predators such as rodents and *Felis catus* (cat), are particularly vulnerable (Dueñas *et al.*, 2021; Medina *et al.*, 2011; Whitworth *et al.*, 2013; **Figure 4.4**). Extinction hotspots where invasive alien species are documented as the main cause are located in the Asia-Pacific region (73 per cent), followed by the Americas (15 per cent) and Africa (14 per cent). Vertebrates (62.4 per cent), invertebrates (26.3 per cent) and plants (11.3 per cent) suffered most extinctions as a consequence of invasive alien species, with birds (74 species) most vulnerable. (H. P. Jones *et al.*, 2008; Spatz *et al.*, 2014; Szabo *et al.*, 2012). This threat continues to the present (Butchart, 2008; Dueñas *et al.*, 2021).

Box 4 4

Figure 4 4 **Examples of extinct birds due to invasive alien cats on islands.**

On islands, *Felis catus* (cat) has caused the extinction of *Anthornis melanocephala* (Chatham bellbird; left), *Cyanoramphus novaezelandiae erythrotis* (Macquarie Island parakeet; middle), and *Microgoura meeki* (Choiseul pigeon; right). The number of mollusc extinctions documented by the IUCN Red List may underestimate the role of invasive alien species. A recent re-evaluation attributed at least 134 inland waters species extinctions exclusively to the introduction of the notorious predatory alien snail, *Euglandina rosea* (rosy predator snail; Régnier *et al.*, 2009). This species was intentionally introduced in the 1950s to the 1970s as a biological control agent for *Lissachatina fulica* (giant African land snail) in many Pacific islands. It also feeds on other snails and consequently a third of the species within the snail family Partulidae (Gastropoda) in the Pacific Islands are now extinct, the rest being at risk of extinction (Gerlach, 2016). Inland waters fish are also particularly affected by invasive alien species, with 8 native fish species documented as extinct worldwide due predominantly to interactions with various invasive alien fish and an additional 37 fish extinctions attributed to invasive alien species as one of several causes. Note that the same taxa are affected (i.e., birds, gastropods, fishes, mammals and angiosperms) when considering all the extinct species where invasive alien species are cited as one of the causes, but not necessarily the main one **(Figure 4.5)**.

Box 4 4

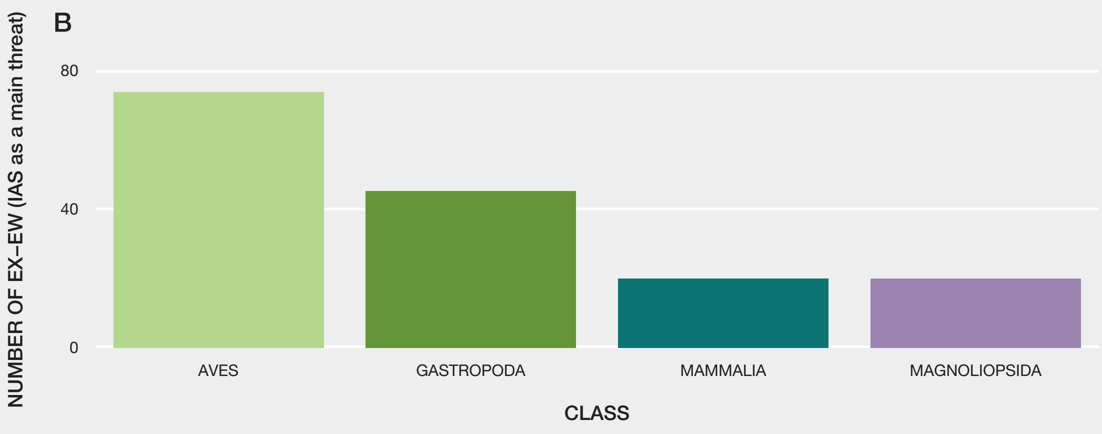

Figure 4 5 **Number of extinct species, including extinct in the wild (EX-EW), by classes.**

These bar plots only show classes represented by at least 10 extinct species, with A) all extinct species (EX-EW) where invasive alien species (IAS) are cited as one of several causes (but not necessarily the main one) and B) all extinct species (EX-EW) where invasive alien species (IAS) are considered as the main cause of extinction. A data management report is available at https://doi.org/10.5281/zenodo.5762737

At least 44 invasive alien species are implicated in the 186 extinctions documented by the IUCN as caused by invasive alien species, with rodents and *Felis catus* (cat) involved in more than a third of all extinctions. The large majority of the invasive alien species are represented by alien mammals that were responsible for the extinctions of native birds and mammals, while most of the amphibians are threatened by *Batrachochytrium dendrobatidis* (chytrid fungus; Pounds *et al.*, 2006).

Despite the fact that the IUCN Red List is recognized as the world's most comprehensive information source on the global conservation status of species, it should be emphasized that the attribution of factors driving extinctions relies on evidence from published literature (including peer review) in addition to expert opinion and thus is subject to data gaps in observations and to some level of uncertainty (IUCN, 2022; Salafsky *et al.*, 2008). The scientific literature frequently lacks specific

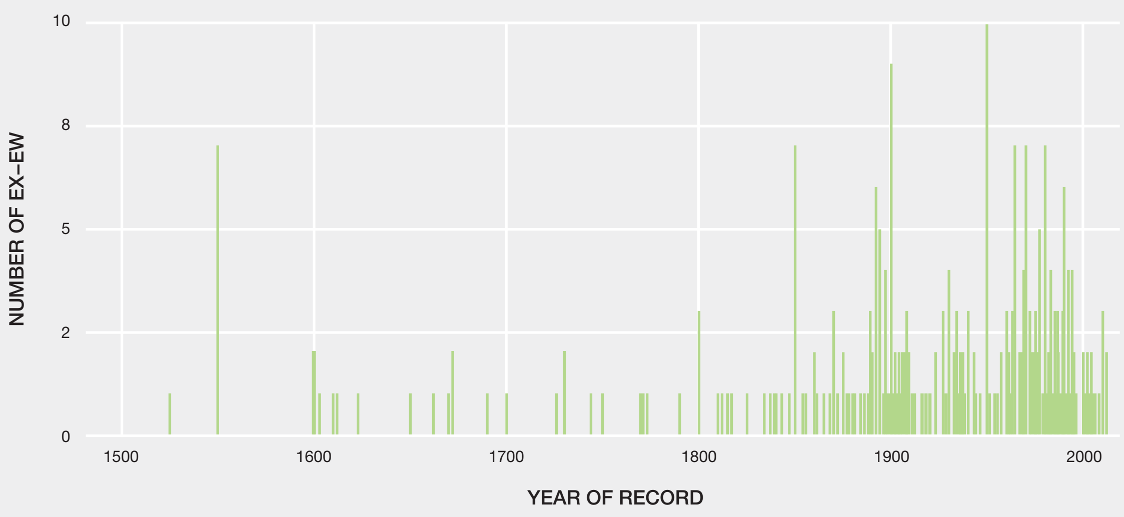

Figure 4 6 **Number of records of species extinct or extinct in the wild (EX-EW) since 1500, with their last seen date indicated.**

Information was available for 276 extinct species. Data source: IUCN (2021).

Box 4 4

information on already extinct species. This is particularly true for extinctions that occurred before the 1950s for which clear information is scarce (**Figure 4.6**; see also Sayol *et al.*, 2020). A recent systematic review, of manipulative experimental or comparative observational (before-after; control-invaded plots; BACI design; Kumschick *et al.*, 2015), on current extinction threat confirmed findings from the IUCN Red List on the strong impact of invasive alien species on threatened species (Dueñas *et al.*, 2021). Yet, the most prevalent threats across near-threatened and threatened species worldwide are overexploitation and agricultural activity (Maxwell *et al.*, 2016). It is thus crucial to emphasize that the number of extinctions or the number of species at risk of extinction are not the only reliable metrics to study the impacts of invasive alien species. The IPBES Global Assessment of Biodiversity and Ecosystem Services synthesized 11 biodiversity indicators including local species richness, mean body length and the IUCN Red List indices (Purvis *et al.*, 2019). Using those indices, the relative importance of invasive alien species may vary across ecosystems, taxa, and measure of biodiversity (Bellard *et al.*, 2022). As a consequence, the contribution of invasive alien species to explain the current biodiversity crisis should be carefully discussed considering the specific context, taxa, and metrics to avoid oversimplifications.

Global extinctions due to invasive alien species are not restricted to islands. *Batrachochytrium dendrobatidis* (chytrid fungus) is a pathogen of a wide range of amphibians and can be found in the Americas, Africa, Western Europe, South-East Asia and Australia (M. C. Fisher & Garner, 2020). Its origin is still disputed, but it has been widely transported and introduced by humans, initially probably with the global use of *Xenopus laevis* (African clawed frog) for medicinal purposes starting in the 1950s (Kay & Peng, 1992). *Batrachochytrium dendrobatidis* has contributed to the severe global decline of amphibians generally (M. C. Fisher & Garner, 2020), and has caused the global extinction of several native harlequin toads of the genus *Atelopus* from the mountains of Central America (La Marca *et al.*, 2005), most likely because climate warming increased the habitat suitability for the pathogen (Pounds *et al.*, 2006; **Box 4.5**).

Global extinctions due to invasive alien species have also occurred in aquatic realms. As an example, *Lates niloticus* (Nile perch) was introduced from its native range in Lake Albert to Lake Victoria to improve local fisheries but led to the global extinction of many cichlid fish species endemic to Lake Victoria (Goudswaard *et al.*, 2008). It remains controversial whether the introduction of *Lates niloticus* has profited local fishermen **(Box 4.10)**.

No global extinctions due to invasive alien species were documented in the marine realm; this might be partly because immutable dispersal borders are less frequent in the marine realm. Yet, one should also take into consideration that it is far more difficult to document impacts and their causality in marine environments due to accessibility challenges (Ojaveer *et al.*, 2015).

Box 4 5 **Invasive alien species impacts can worsen when interacting with other drivers of change.**

Invasive alien species occur in interaction with other major drivers of biodiversity change, such as climate change, land- and sea-use change, pollution and over exploitation of natural resources (IPBES, 2019a; **Chapter 3**, **section 3.5**). Interactions may be classified as additive, antagonistic or synergistic with examples of all outcomes evident from studies on the interactions between invasive alien species and other drivers. Research on multiple drivers of biodiversity change is challenging, with drivers operating at different temporal and spatial scales (Bonebrake *et al.*, 2019). Additionally, the interdisciplinary skills and resources required to study multiple drivers may not be available in all regions of the world. A recent metanalysis, assessing 458 cases from 95 published studies (with 74 of these being laboratory or mesocosm experiments) on individual and combined effects of drivers of change on invasive alien species, demonstrated that synergistic interactions were documented for more than 25 per cent of the studies (Lopez *et al.*, 2022). However, it is notable that in most cases the impacts of invasive alien species were not exacerbated by the other drivers, but the combined impacts of the other drivers with invasive alien species were typically no worse than the impacts from invasive alien species alone. Documented synergistic interactions mostly lead to the deterioration of ecosystems (Lopez *et al.*, 2022). There are several studies that have provided evidence on the synergistic effects of invasive alien species and other drivers of biodiversity change, here we highlight four examples of these phenomena **(Figure 4.7)**.

Climate change and invasive alien plants increase fire frequency and intensity

In a scenario of climate change, where vast areas of the Earth will not only be warmer but drier, and the number of lightning events is expected to increase, invasive alien plants may worsen the situation by adding additional highly flammable fuel (Aslan & Dickson, 2020; Turbelin & Catford, 2021). For example, *Pinus* spp. (pine) invading grasslands and forests

Box 4 5

of South America may increase fire intensity and frequency (Cóbar-Carranza *et al.*, 2014; Paritsis *et al.*, 2018; **Chapter 1**, **Box 1.4**). Similar effects have been documented in the South African fynbos (O'Connor & van Wilgen, 2020).

Climate change and alien mosquitoes threaten the health of humans and animals

For some vector-borne diseases, climate change may increase the range and the density of the invasive alien species vector (**Glossary**) with profound implications for human health. For example, *Anopheles* spp. (mosquitoes) that carry malaria have been documented to advance into higher latitudes of the Americas and Europe (Tjaden *et al.*, 2018; Brugueras *et al.*, 2020). Climate change has also been implicated in the rapid decline of amphibians as it interacts with the invasive pathogenic *Batrachochytrium dendrobatidis* (chytrid fungus), which may explain population reductions and even extinctions (J. M. Cohen *et al.*, 2019).

Pollution and invasive organisms can transform water bodies

Change in nutrient levels due to pollution can increase populations of aquatic invasive alien species in inland waters and marine ecosystems reducing native species diversity (Crooks *et al.*, 2011). Some aquatic invasive alien plants, such as *Pontederia crassipes* (water hyacinth), thrive in highly polluted eutrophicated habitats, worsening the consequences for local fisheries, infrastructure and transport (Villamagna & Murphy, 2010; Kleinschroth *et al.*, 2021).

Hunting and invasive alien vertebrates can bring populations of native species in islands or forests to extinction (steep population reductions)

A combined effect of hunting and invasive alien predators may cause faster local reductions in populations of endangered vertebrates such as birds, amphibians and mammals (e.g., New Zealand birds in Innes *et al.*, 2010). Furthermore, hunting can also be a source of new introductions of game animals (Carpio *et al.*, 2017), but in some cases, hunting may also be an effective tool to control invasive alien species (Jean Desbiez *et al.*, 2011).

Interactions amongst three or more drivers including invasive alien species

Conceptualization and quantification of impacts of the interaction of three or more drivers is a highly complicated endeavour (e.g., birds in Doherty *et al.*, 2015; bats in Frick *et al.*, 2020; deer and earthworms in Frelich *et al.*, 2006). However, evidence suggests that measures including research could address these complex interactions to concurrently reduce the threats of multiple drivers on biodiversity. Evidence suggests that while invasive alien species can exacerbate the impacts of other drivers of biodiversity change, the impacts of invasive alien species are generally no worse when acting in combination with other drivers of change such as climate change, pollution, over exploitation or land and sea use change (Lopez *et al.*, 2022). Indeed, managing biological invasions locally contributes to reducing the threat of multiple drivers of change (**Chapter 3**, **section 3.5**; **Chapter 5**, **section 5.6.1.3**).

Case study: Avian botulism, a probable synergistic impact of alien species and climate warming in the North American Great Lakes

In the North American Great Lakes, several alien species are considered to contribute to recurring mass die-offs of waterfowl by transmitting botulin toxin. Filtration activities of Ponto-Caspian dreissenid mussels (*Dreissena polymorpha* (zebra mussel) and *Dreissena rostriformis bugensis* (quagga mussel) introduced to the Great Lakes in the 1980s) increase light transparency in the water and consequently promote excessive summer growth of macrophytes and benthic macroalgae (Vanderploeg *et al.*, 2002). Later in the summer,

Box 4 5

the decomposing biomass of this vegetation, combined with elevated water temperatures resulting from climate change generated hypoxic conditions, favouring outbreaks of a rare cryptogenic (**Glossary**) strain of botulism bacteria, *Clostridium botulinum* Type-E (Chun *et al.*, 2013). The bacteria are then filtered by dreissenid mussels, which concentrate the toxic cells in their tissues. The mussels and other contaminated benthic invertebrates subsequently transfer the toxin to *Neogobius melanostomus* (round goby), a benthic predatory Ponto-Caspian fish introduced to the Great Lakes region, that is itself a common prey item for piscivorous native waterfowl such as loons and gulls (Essian *et al.*, 2016; **Figure 4.8**). Thus, the combination of alien species and increased temperatures through climate change promotes the proliferation and transfer of botulinum toxin to higher trophic levels, creating a new contaminant pathway (**Glossary**) that has caused the mortality of tens of thousands of waterfowls in the Great Lakes nearly every year over the past two decades (Essian *et al.*, 2016; Yule *et al.*, 2006).

Waterbirds mass die-off is attributed to botulism, which is considered to proliferate due to the presence of invasive alien species. Photo credit: Rogers Media Inc. – CC BY 4.0.

Reduction of population sizes

Many invasive alien species that are not documented to cause local extinctions can still reduce the population size of native species. The database of impacts developed through this chapter shows that 21.8 per cent (766) of the studied invasive alien species have caused a total of 4,282 local population declines in native species, which represents 36.6 per cent of the documented negative impacts on nature. While many invasive alien plants have not been documented causing local extinctions, they frequently cause declines in native species populations. Such invasive alien plants include the terrestrial forbs *Reynoutria japonica* (Japanese knotweed), *Impatiens glandulifera* (Himalayan balsam), *Carpobrotus* spp. (iceplant), *Eragrostis lehmanniana* (Lehmann lovegrass), or *Acacia longifolia* (golden wattle) and *Robinia pseudoacacia* (black locust). Other invasive alien species that have been documented as frequently causing at least local population declines are *Acridotheres tristis* (common myna) or *Bubalus bubalis* (Asian water buffalo), and *Phytophthora ramorum* (sudden oak death).

Invasive alien plants have the highest number of species causing impacts on nature, followed by invertebrates and vertebrates. Comparatively few invasive alien microbes are documented causing impacts on nature **(Figure 4.9A)**. By contrast, more invasive alien animals (vertebrates and invertebrates) cause high magnitude impacts, i.e., local extinctions, both in terms of the number of species causing impacts **(Figure 4.9A)** and the number of reports **(Figure 4.9B)**. Local extinctions are less frequently caused by plants, and microbes are rarely documented to have caused local extinctions. Invasive alien plants also have the highest number of species causing impacts on ecosystem properties, population declines and reductions in individual performance of native species.

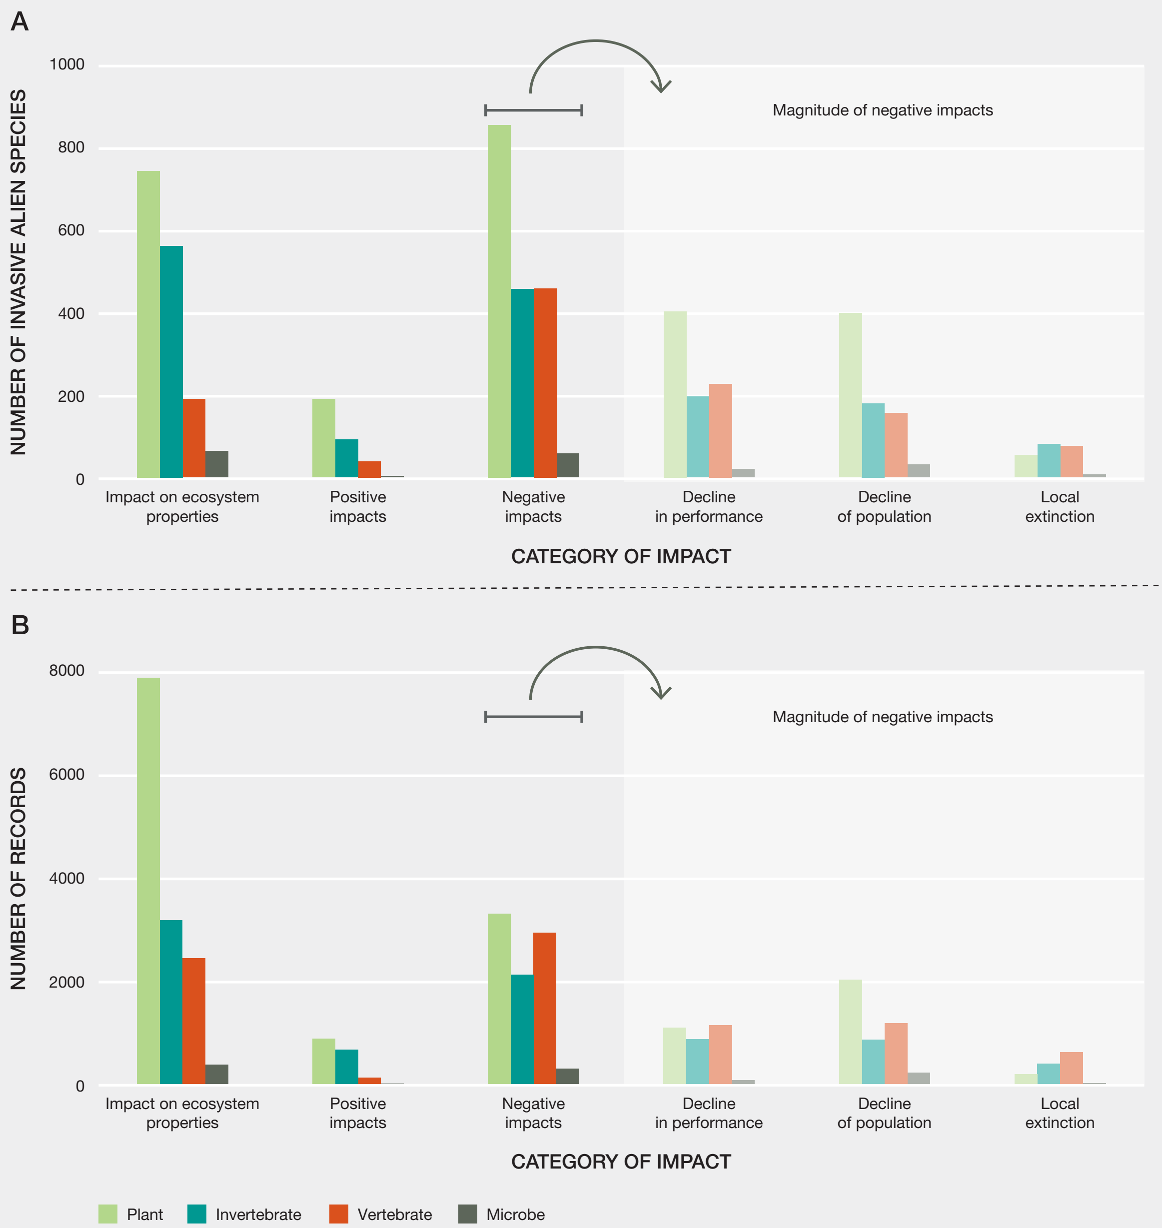

Figure 4 9 **Number of A) invasive alien species causing impacts on nature and B) number of impact records by direction, magnitude and taxonomic group.**

Negative and positive impacts relate to the consequences for native species, while impacts on ecosystem properties are not assigned a direction. Negative impacts are subdivided for each invasive alien species into the maximum documented negative impact on a native species globally (lighter box on the right). Note that the same invasive alien species could have a maximum negative impact on a native species, impacts on ecosystem properties and positive impacts on native species. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

Impacts on native species by invasive alien vertebrates are more frequent than impacts on ecosystem properties **(Figure 4.9A)**, while, in contrast, invasive alien invertebrates more frequently cause negative impacts on ecosystem properties (e.g., abiotic soil or water characteristics; **Box 4.3**) than on native species. Invasive alien plants and microbes have similar frequencies of negative impacts on ecosystem properties and native species.

Invasive alien plants have the highest numbers of species (both in absolute numbers and percentages; **Figure 4.9A**) and reports **(Figure 4.9B)** of positive impacts on nature globally. There are more invasive alien invertebrates than vertebrates causing positive impacts, but microbe species are very rarely documented in this respect.

4.3.1.1 Islands *versus* mainland

Islands, particularly smaller sized and more isolated islands, with higher rates of endemism, suffered greater impacts on nature than mainland regions. Following the introduction of various suites of alien predators and competitors through millennia of human settlement, the severity and rate of extinction has varied due to geomorphology, composition of the native biota and that of the introduced invasive alien species, and lifestyle and technology of human settlers (e.g., hunting-gatherering, husbandry, agriculture) (Wood *et al.*, 2017). Smaller islands which tend to support smaller native populations in easily accessible habitats, are more susceptible to impacts from invasive alien species through predation or habitat loss, leading to greater rates of extinction and other negative impacts (Duncan & Blackburn, 2007).

Impacts on islands represent 4,820 (19.9 per cent) of the total number of impacts on nature documented in published studies (**Boxes 4.6** and **4.7**). Negative impacts on native species on islands are far more frequent (40.5 per cent) than positive impacts (4.5 per cent; **Figure 4.10**).

There is no clear difference in the proportion of negative and positive impacts and impacts on ecosystem properties between island and non-island locations **(Figure 4.10)**. However, negative impacts of high magnitude, i.e., local extinctions, are more frequently documented from islands than from non-island locations (9.2 per cent vs. 4.0 per cent; **Figure 4.10**).

On islands, globally, 87 invasive alien species have caused 445 local extinctions. They are most often caused by mammals, such as *Rattus* spp. (rats), *Capra hircus* (goats), *Mus musculus* (house mouse), *Felis catus* (cat), but also other vertebrates such as *Anas platyrhynchos* (mallard) and *Boiga irregularis* (brown tree snake). Ants have also often led to local extinctions on islands, particularly from species such as *Anoplolepis gracilipes* (yellow crazy ant), *Wasmannia auropunctata* (little fire ant), *Linepithema humile* (Argentine ant), and *Pheidole megacephala* (big-headed ant). Invasive alien plants are much less often causing local extinctions on islands, but there are some reports, as for example from *Vachellia nilotica* (gum arabic tree).

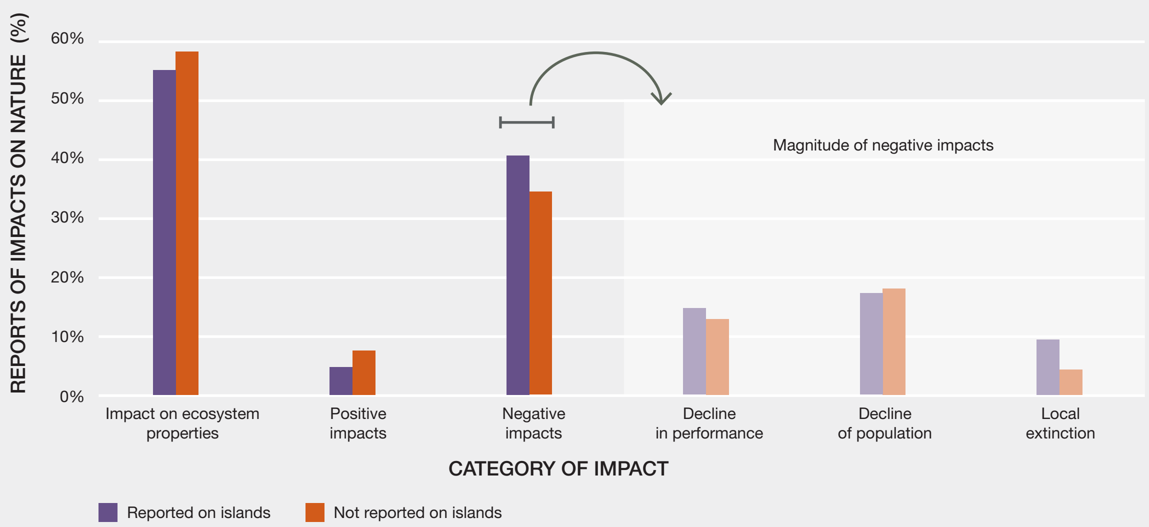

Figure 4 10 **Percentage of reports of impacts on nature on islands vs. locations that were either not on an island (mainland) or unknown.**

For each of the three impact categories, ecosystem properties, positive and negative impacts, the percentages sum to 1. Negative impacts are split into their impact magnitudes in the shaded box on the right-hand side. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

Box 4 6 Hawaiian extinctions – the birds and the bees and much else.

"The islands now contain more endangered species per square mile than anywhere else in the world" (Cabin, 2013).

Hawaii's isolation in remote Oceania resulted in a unique terrestrial biota, distinguished by the diversity of endemic forms derived from a small number of ancestral immigrations (Wagner *et al.*, 1990; Imada, 2012). Zooarchaeological and archaeobotanical studies reveal that the arrival of humans about 1500 years ago induced catastrophic ecosystem changes (Allen, 1984, 1989; Steadman, 1995). The Polynesian settlers transported their domesticates, including dogs, pigs, chickens, and the synanthropic *Rattus exulans* (Pacific rat; Crabtree, 2016). Their direct and indirect impacts, through habitat loss, fragmentation, and predation by the introduced mammals, caused losses of many species, and are continuing into the present (Vitousek & Walker, 1989; G. W. Cox, 1999; Staples *et al.*, 2000; Staples & Cowie, 2001; Vorsino *et al.*, 2014; MacLennan, 2017). Pollen analysis reveals that following Polynesian settlement Hawaii's lowland forests were reduced to a landscape dominated by opportunistic shrubs and grasses. Athens (1997, 2009) considers the Pacific rat as the underlying cause of lowland forest collapse. Only remnant populations sequestered in the least accessible habitats remain of the unique Hawaiian biota.

Olson and James (1982) estimate that the extinction of more than half the endemic avifauna of the Hawaiian Islands, including two thirds of endemic flightless, ground-nesting land birds and burrowing sea-birds, occurred between the initial human settlement and arrival of Europeans. At least 71 species or subspecies died out before the nineteenth century, and 24 have gone extinct since. The remaining populations are declining or are in danger of extinction (T. K. Pratt *et al.*, 2006). Cats, rodents, and mongoose have been the major extinction cause for ground nesting birds (G. W. Cox, 1999). Introduced avian diseases, such as *Avipoxvirus* spp. (avian pox virus) and *Plasmodium relictum* (avian malaria), have also led to the decline of the endemic Hawaiian avifauna (Warner, 1968; van Riper III *et al.*, 1986, 2002; Samuel *et al.*, 2015). Avian malaria is uniquely transmitted by *Culex quinquefasciatus* (southern house mosquito), introduced before 1830 (Fonseca *et al.*, 2000; LaPointe, 2000), the larvae of which are found in high densities in low- and mid-elevation forests, degraded by the foraging behaviour of *Sus scrofa* (feral pig; Lapointe, 2008).

Interactions amongst native pollinators and plants are considered to be important for long-term sustainability of natural island ecosystems (S. K. Walsh *et al.*, 2019). Loss of plant-pollinating birds has disrupted plant-pollinator relations and led to plant extinctions, e.g., 31 species of bird-pollinated bellflowers, Campanulaceae, have gone extinct. Introduced *Zosterops japonicus* (Japanese white-eye) outcompetes native birds for insects and nectar (G. W. Cox, 1999), providing a replacement pollinator for *Freycinetia arborea* (ie'ie vine), once pollinated by extinct or endangered native birds (P. A. Cox, 1983; P. A. Cox & Elmqvist, 2000). *Pheidole megacephala* (big-headed ant) and *Linepithema humile* (Argentine ant) threaten the once abundant native *Hylaeus* spp. (yellow-faced bees; Perkins, 1913; Lach, 2005; Magnacca & King, 2013; Sahli *et al.*, 2016; Plentovich *et al.*, 2021), of which half are now extinct, threatened, or extremely rare (Magnacca, 2007). These native bees exhibit high pollinator fidelity to native species, whereas *Apis mellifera* (European honeybee) also pollinates invasive alien plant species (E. E. Wilson *et al.*, 2010; Miller *et al.*, 2015; Aslan *et al.*, 2016). Endemic Hawaiian honeycreepers and insects are the most important pollinators of the iconic native tree *Metrosideros polymorpha* ('ōhi'a lehua) culturally important to the native Hawaiians (Kānaka Maoli), and a keystone species of the Hawaiian rainforest (Cortina *et al.*, 2019). 'Ohi'a lehua trees have been in rapid decline since the 1960s (Akashi & Mueller-Dombois, 1995; Gruner, 2004) from infection by introduced *Ceratocystis* fungi (Keith *et al.*, 2015; Barnes *et al.*, 2018; Heller *et al.*, 2019), likely transmitted by introduced *Xyleborus* spp. (ambrosia beetles; K. Roy *et al.*, 2020).

As many as 90 per cent of the 750 recognized species of land snails are extinct; the once speciose Amastridae, comprising more than 300 species endemic to Hawaii, are currently reduced to 10 species (Lydeard *et al.*, 2004). Many land snails were annihilated by *Euglandina rosea* (rosy predator snail) introduced in a failed attempt to control the previously introduced *Lissachatina fulica* (giant African land snail; G. W. Cox, 1999). The native freshwater gastropods, too are threatened with extinction or are much reduced in range (Christensen *et al.*, 2021).

Box 4 7 Impacts of invasive alien species on nature in Antarctica, Antarctic and sub-Antarctic Islands.

Few alien species have established on the Antarctic continent and its surrounding islands south of 60°S, within the Antarctic Treaty region, on land or in the many waterbodies on the continent, which vary greatly in salinity (Frenot *et al.*, 2005; Cavicchioli, 2015; Hughes *et al.*, 2015; McGeoch *et al.*, 2015; Bergstrom, 2021). Though alien crabs, mussels and tunicates have been documented from Antarctic coasts, none have established populations (López-Farrán *et al.*, 2021). Currently, alien taxa are limited to the Antarctic Peninsula and adjacent islands, mostly to areas under strong human pressure, such as the vicinity of research stations and sites attractive to tourists (Znój *et al.*, 2017). They include the recently documented

Box 4 7

mussel *Mytilus* cf. *platensis* (Cárdenas *et al.*, 2020), a chironomid midge *Eretmoptera murphyi*, for which direct evidence on impact on native species is lacking (J. C. Bartlett *et al.*, 2020), and the fly *Trichocera maculipennis* (winter crane fly), which is yet to be explicitly confirmed as established in the natural environment (Remedios-De León *et al.*, 2021).

Impact studies were conducted solely on the invasive alien grass *Poa annua* (annual meadowgrass) in Antarctica (Hughes *et al.*, 2015; Baird *et al.*, 2019; **Figure 4.11**). Experimental and modelling studies suggest that the invasive grass *Poa annua* could have impacts on the only two vascular plant species indigenous to the Antarctic: the grass *Deschampsia antarctica* (Antarctic hair grass) and the forb *Colobanthus quitensis* (Antarctic pearlwort) (Molina-Montenegro *et al.*, 2019). Observational and experimental data of co-occurrence of vascular plant species in the Antarctic Peninsula revealed that *Deschampsia antarctica* facilitates the presence of *Poa annua* and may impact its introduction and spread (Atala *et al.*, 2019).

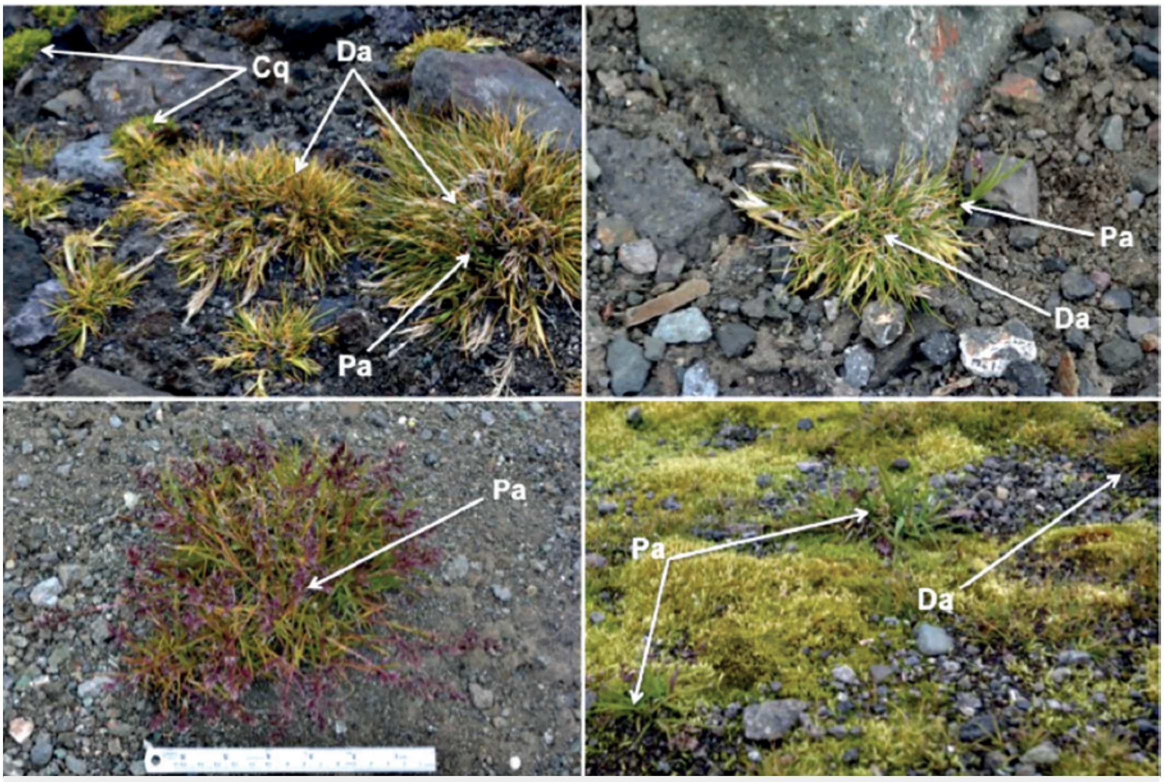

Figure 4 11 ***Poa annua* (annual meadowgrass), the only invasive alien species with documented impacts on the Antarctic continent.**

Da: *Deschampsia antarctica* (Antarctic hair grass)
Pa: *Poa annua* (annual meadowgrass)
Cq: *Colobanthus quitensis* (Antarctic pearlwort)

Due to their size and extreme isolation, the Southern Cold Temperate Islands (e.g., Tristan da Cunha, New Zealand Shelf Islands), and the sub-Antarctic Islands (e.g., South Georgia and the South Sandwich Islands, Crozet Islands, Heard Island), are taxonomically and functionally depauperate, and thus, vulnerable to synanthropic introductions (Dawson *et al.*, 2022; Frenot *et al.*, 2005; Hughes *et al.*, 2020).

Terrestrial mammals, absent prior to their introductions, have posed, and still pose, the most severe threats to the islands' biodiversity, ecosystem structure and landscape (McGeoch *et al.*, 2015). Introduced feral herbivores, such as *Bos taurus* (cattle), *Rangifer tarandus* (reindeer), *Ovis aries* (sheep), and *Oryctolagus cuniculus* (rabbits), have all had significant impacts on the vegetation of the islands to which they have been introduced (Vogel *et al.*, 1984; Chapuis *et al.*, 1994, 2004; Whinam *et al.*, 2014). In some cases, direct impacts led to indirect ones: on Macquarie Island, eradication of cats was followed by increasing rabbit population, resulting in island-wide ecosystem effects, altered vegetation structure, impacting burrow-nesting seabirds; on Ile Verte rabbit eradication enabled the rapid expansion of the invasive alien *Taraxacum officinale*

Box 4 7

(dandelion), and impacted both native, burrowing seabird prey populations and their predator, *Stercorarius skua* (great skua) (Chapuis *et al.*, 2004; Scott & Kirkpatrick, 2008; Bergstrom *et al.*, 2009; Whinam *et al.*, 2014; Brodier *et al.*, 2011; Houghton *et al.*, 2019). On South Georgia and the South Sandwich Islands, reindeer caused the replacement of indigenous grasses with the introduced grazing-tolerant *Poa annua*, a poor food for the indigenous *Hydromedion sparsutum* (tussac beetle), and thus indirectly contributed to its decline (Chown & Block, 1997). *Felis catus* (cat) has had major impacts on burrowing and other seabird populations on the islands to which they were introduced (Frenot *et al.*, 2005). Significant recovery of some populations followed their removal (Dilley *et al.*, 2017; Brooke *et al.*, 2018), and was tempered, in some cases, by the increase in populations and impacts impacts of *Felis catus*' invasive alien prey (e.g., *Oryctolagus cuniculus* (rabbits); Bergstrom *et al.*, 2009). Invasive alien rodents such as *Rattus Rattus* (black rat), *Rattus norvegicus* (brown rat), and *Mus musculus* (house mouse), have had significant impacts on invertebrate populations, to the point of extirpation in some cases (V. Le Roux *et al.*, 2002; McClelland *et al.*, 2018; J. C. Russell *et al.*, 2020). Rats have caused the near disappearance of terrestrial birds, such as *Anthus antarcticus* (South Georgia pipit; now recovering following rat eradication), and are also thought to be responsible for declines in the abundance of burrowing seabird species (Pye & Bonner, 1980; Jouventin *et al.*, 2003; H. P. Jones *et al.*, 2008; Dilley *et al.*, 2018). Mice were documented preying on naïve chicks and adults of several albatross and burrowing petrel species (M. G. W. Jones & Ryan, 2010; Dilley *et al.*, 2016, 2018; C. W. Jones *et al.*, 2019).

Invasive alien predatory beetles have led to substantial declines in the abundance of their preferred invertebrate prey on Kerguelen Island (Lebouvier *et al.*, 2011; Houghton *et al.*, 2019). Although many plant species have become invasive on the sub-Antarctic islands, impacts were only quantified for a few of them: *Agrostis stolonifera* (creeping bentgrass) reduces the abundance of indigenous plants and alters arthropod community structure on Marion Island (Gremmen *et al.*, 1998), and the widespread *Poa annua* outcompetes indigenous plants for space and resources, especially in coastal areas disturbed by seals and penguins (Haussmann *et al.*, 2013; L. K. Williams *et al.*, 2018).

4.3.1.2 Protected areas

Invasive alien species frequently impact protected areas around the world (Carlton *et al.*, 2019; Foxcroft, Richardson, *et al.*, 2013; Galil, 2017; Macdonald *et al.*, 1988). A report of the Working Group on Nature Reserves, associated with the SCOPE programme on the "Ecology of Biological Invasions" concluded that all nature reserves, except those in Antarctica, appear to have invasive species (Usher, 1988). Invasive alien species have reduced, or have the potential to reduce, the viability of protected areas to provide refugia for native species, habitats and the ecosystem services that they sustain (Foxcroft, Richardson, *et al.*, 2013). Impacts on nature in protected areas represent 19.3 per cent (4,673) of the total number of impacts on nature documented in published studies. Negative impacts on native species in protected areas are far more frequent (33.2 per cent) than positive impacts (6.3 per cent; **Figure 4.12**).

There is no clear difference in the proportion of negative and positive impacts and impacts on ecosystem properties inside and outside protected areas **(Figure 4.12)**, although declines of native populations seem to be higher inside protected areas than outside (20.3 per cent vs. 17.1 per cent; **Figure 4.12**). Thus, protected areas are not sheltered by their protection status from impacts of invasive alien species.

In protected areas, globally, 53 invasive alien species have caused 240 local extinctions of native species. *Rattus Rattus* (black rat) is by far the most frequent invasive alien species causing local extinctions in protected areas, but other mammals such as *Capra hircus* (goats), *Felis catus* (cat), or *Sus scrofa* (feral pig) have also been documented multiple times. Local extinctions of a native species have not only been restricted to the terrestrial realm, but have also occurred in the marine realm caused multiple times by invasive alien species such as *Sporobolus* spp. (cordgrass), *Caulerpa taxifolia* (killer algae), *Halophila stipulacea* (halophila seagrass), *Kappaphycus alvarezii* (elkhorn sea moss), or *Mytilus galloprovincialis* (Mediterranean mussel), and in inland waters caused by *Pontederia crassipes* (water hyacinth). The microbial pathogenic *Batrachochytrium dendrobatidis* (chytrid fungus) has also caused local amphibian extinctions in protected areas.

4.3.1.3 Mechanisms

The mechanisms through which invasive alien species can impact native species are classified according to the EICAT (IUCN, 2020; **Box 4.2**). They include competition; predation; hybridization; transmission of disease; parasitism; poisoning or toxicity; bio-fouling or other direct physical disturbance; grazing, herbivory or browsing; chemical, physical, structural impact on ecosystems; and indirect impacts through interactions with other species (**Box 4.3** for definitions). Note that standards for classification of impact mechanisms have only been defined for negative impacts at the time of developing this assessment report; thus, positive impacts are not discussed here with respect to their different mechanisms (but see Vimercati *et al.*, 2022).

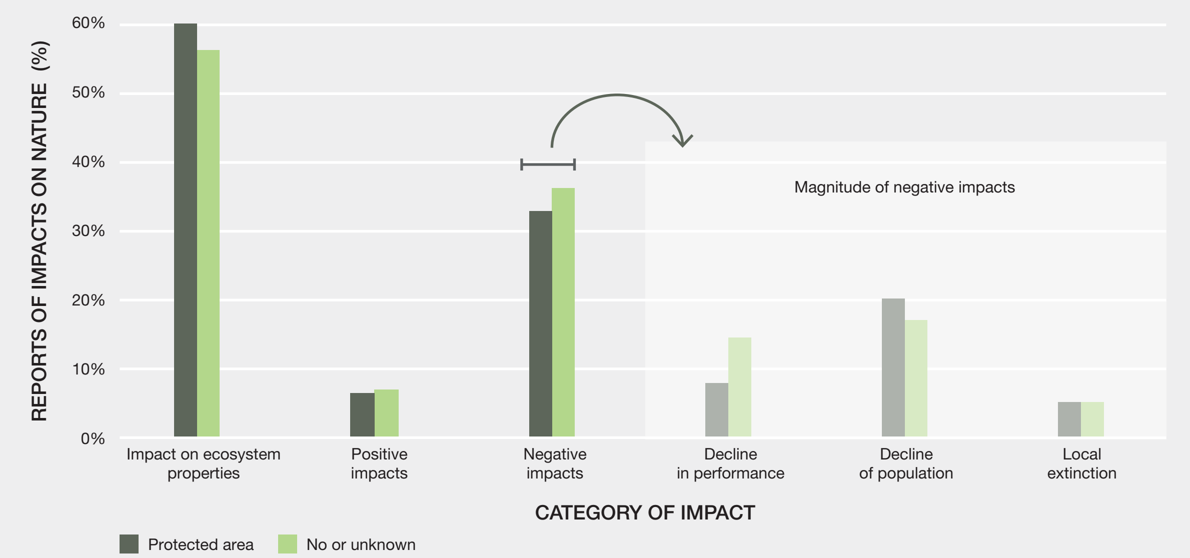

Figure 4 12 **Percentage of reports on impacts on nature in protected areas vs. locations that were either not in a protected area or unknown.**

For each of the three impact categories, ecosystem properties, positive and negative impacts, the percentages sum to 1. Negative impacts are split into their impact magnitudes in the shaded box on the right-hand side. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

Table 4 4 **Distribution of mechanisms across invasive alien species taxa and realms.**

Examples are not meant to be representative but highlight invasive alien species which have caused local extinctions of native populations.

Plants: Invertebrate: Vertebrate: Microorganisms: Inland waters: Marine: Terrestrial:

Mechanism	Main taxa	Realms	Examples of invasive alien species
Competition	Plants, Invertebrate	Inland waters, Marine, Terrestrial	*Linepithema humile* (Argentine ant), *Solenopsis invicta* (red imported fire ant), *Caulerpa cylindracea* (green algae)
Predation	Invertebrate, Vertebrate	Inland waters, Marine, Terrestrial	*Felis catus* (cat), *Vulpes vulpes* (red fox), *Pterois volitans* (red lionfish), *Lates niloticus* (Nile perch)
Hybridization	Plants, Vertebrate	Inland waters, Marine, Terrestrial	*Anas platyrhynchos* (mallard), *Ambystoma tigrinum* (tiger salamander), *Sporobolus densiflorus* (denseflower cordgrass)
Transmission of disease	Invertebrate, Vertebrate	Inland waters, Terrestrial	*Faxonius limosus* (spiny-cheek crayfish), *Canis lupus familiaris* (dogs)
Parasitism	Invertebrate, Microorganisms	Inland waters, Marine, Terrestrial	*Philornis downsi* (avian vampire fly), *Batrachochytrium dendrobatidis* (chytrid fungus), *Haplosporidium nelsoni* (MSX oyster pathogen)
Toxicity	Plants, Vertebrate	Marine, Terrestrial	*Caulerpa taxifolia* (killer algae), *Rhinella marina* (cane toad)
Biofouling	Plants, Invertebrate	Inland waters, Marine	*Kappaphycus alvarezii* (elkhorn sea moss), *Carijoa riisei* (branched pipe coral), *Dreissena polymorpha* (zebra mussel)
Herbivory	Invertebrate, Vertebrate	Inland waters, Marine, Terrestrial	*Capra hircus* (goats), *Carcinus maenas* (European shore crab), *Ctenopharyngodon idella* (grass carp)
Ecosystem	Plants, Invertebrate	Inland waters, Marine	*Pontederia crassipes* (water hyacinth), *Caulerpa cylindracea* (green algae), *Mytilus galloprovincialis* (Mediterranean mussel)
Indirect	Invertebrate, Vertebrate	Inland waters, Marine, Terrestrial	*Dreissena* spp. (zebra/quagga mussel), *Pterois volitans* (red lionfish), *Bromus tectorum* (downy brome)

Invasive alien species affect ecosystem properties and native species through all mechanisms leading to varying degrees of magnitude of impact. The occurrence of each mechanism is not evenly distributed across taxa and realms **(Table 4.4)**. While examples of most mechanisms can be found for all invasive alien species and across realms, some mechanisms are more commonly associated with some taxa and within specific realms. For example, most reports of hybridization of an alien species with a native species relate to invasive alien vertebrates and plants, while invasive alien invertebrates and microbes seem to hybridize much less frequently with native species **(Table 4.4)**. Likewise, transmission of diseases seems to be less frequent in the marine realm than in terrestrial and inland waters systems, and toxicity less frequent in the inland waters **(Table 4.4)**.

Impacts on nature by invasive alien species are most often caused by changes to ecosystem properties (26.8 per cent) and competition (23.7 per cent), followed by predation (18.4 per cent) and herbivory (12.3 per cent), i.e., direct trophic interactions. Indirect mechanisms (disease transmission and interactions with other species) only account for 8.7 per cent of all records, but this might be partly due to indirect interactions being less often studied or overlooked due to their complexity. Across all types of mechanism, changes to ecosystem properties alongside impacts of lower magnitude are more often documented than high magnitude impacts (**Box 4.2** for impact magnitudes).

Local extinctions are most often caused through hybridization (19.5 per cent), followed by impacts through predation (11.8 per cent) and direct physical interactions/ biofouling (7.2 per cent) **(Figure 4.13)**. Invasive alien species that are most commonly responsible for extinctions through hybridization are *Anas platyrhynchos* (mallard) and *Ambystoma tigrinum* (tiger salamander), followed by *Cervus nippon* (sika) and *Oreochromis niloticus* (Nile tilapia). Invasive alien species most frequently causing extinctions through predation are the terrestrial vertebrates *Vulpes vulpes* (red fox), *Felis catus* (cat), *Rattus* spp. (rats) and *Boiga irregularis* (brown tree snake). In the marine realm, *Pterois volitans* (red lionfish) and *Paralithodes camtschaticus* (red king crab) have caused frequent local extinctions through predation on native species. Terrestrial invertebrates are documented to have less frequently caused local extinctions through predation, and the most frequently documented species involved in local extinctions are *Anoplolepis gracilipes* (yellow crazy ant), *Pheidole megacephala* (big-headed ant), and *Euglandina rosea* (rosy predator snail).

4.3.1.4 Affected native species

Most documented impacts of invasive alien species are on native plants (8,472 reports), closely followed by native invertebrates (6,253 reports) and vertebrates (5,144 reports), but the number of invasive alien species affecting native plants is much higher than for the other taxa **(Figure 4.14A)**.

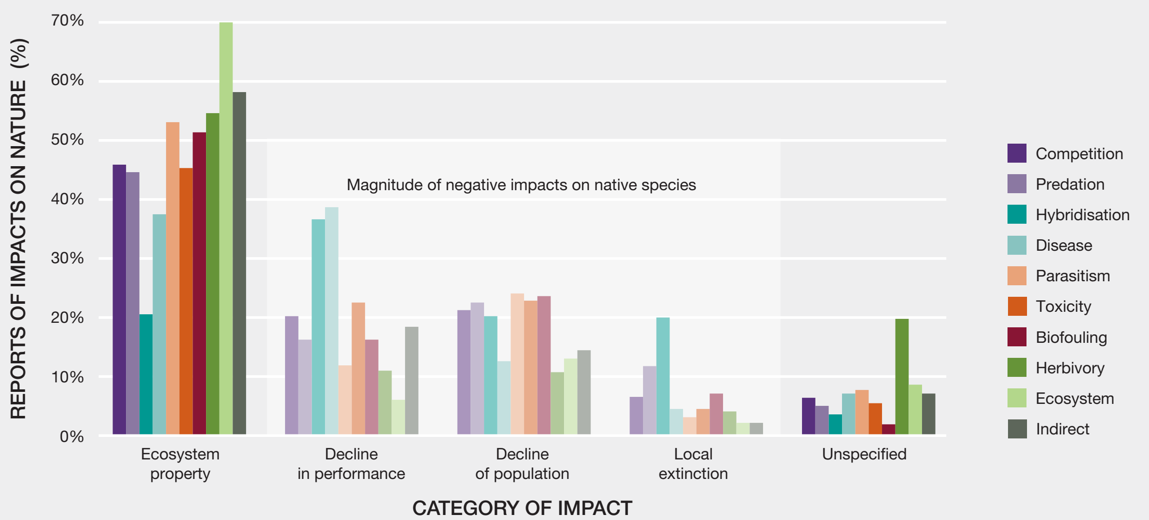

Figure 4 13 **Percentage of reports of impacts on nature through different mechanisms.**

Percentage of reports (y axis) for different categories of impact on nature: ecosystem property, native species and unspecified (x axis). For each mechanism, the percentages sum to 1. Negative impacts on native species at three different magnitudes are highlighted in the shaded inset box. No mechanisms are defined for positive impacts, and these are not considered here. Mechanisms are: competition, predation, hybridization, transmission of disease, parasitism, poisoning/toxicity, bio-fouling or other direct physical disturbance, grazing/herbivory/browsing, chemical, physical, structural impact on ecosystem, and indirect impacts through interactions with other species (IUCN, 2020). A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

Native microbes are rarely documented to be impacted by invasive alien species, which is most likely to be a research gap; only 1.2 per cent of documented impacts of invasive alien species relate to native microbes. There were 1,215 reports of local extinctions of native species due to 218 invasive alien species **(Table 4.5A; Figure 4.14A)**.

The number of invasive alien species positively affecting native species is less than 10 per cent for native plants, but increases to about 15 per cent for both vertebrates and invertebrates, and is highest for native microbes (over 25 per cent; **Figure 4.14A**), which can have higher abundance in soil communities dominated by invasive alien

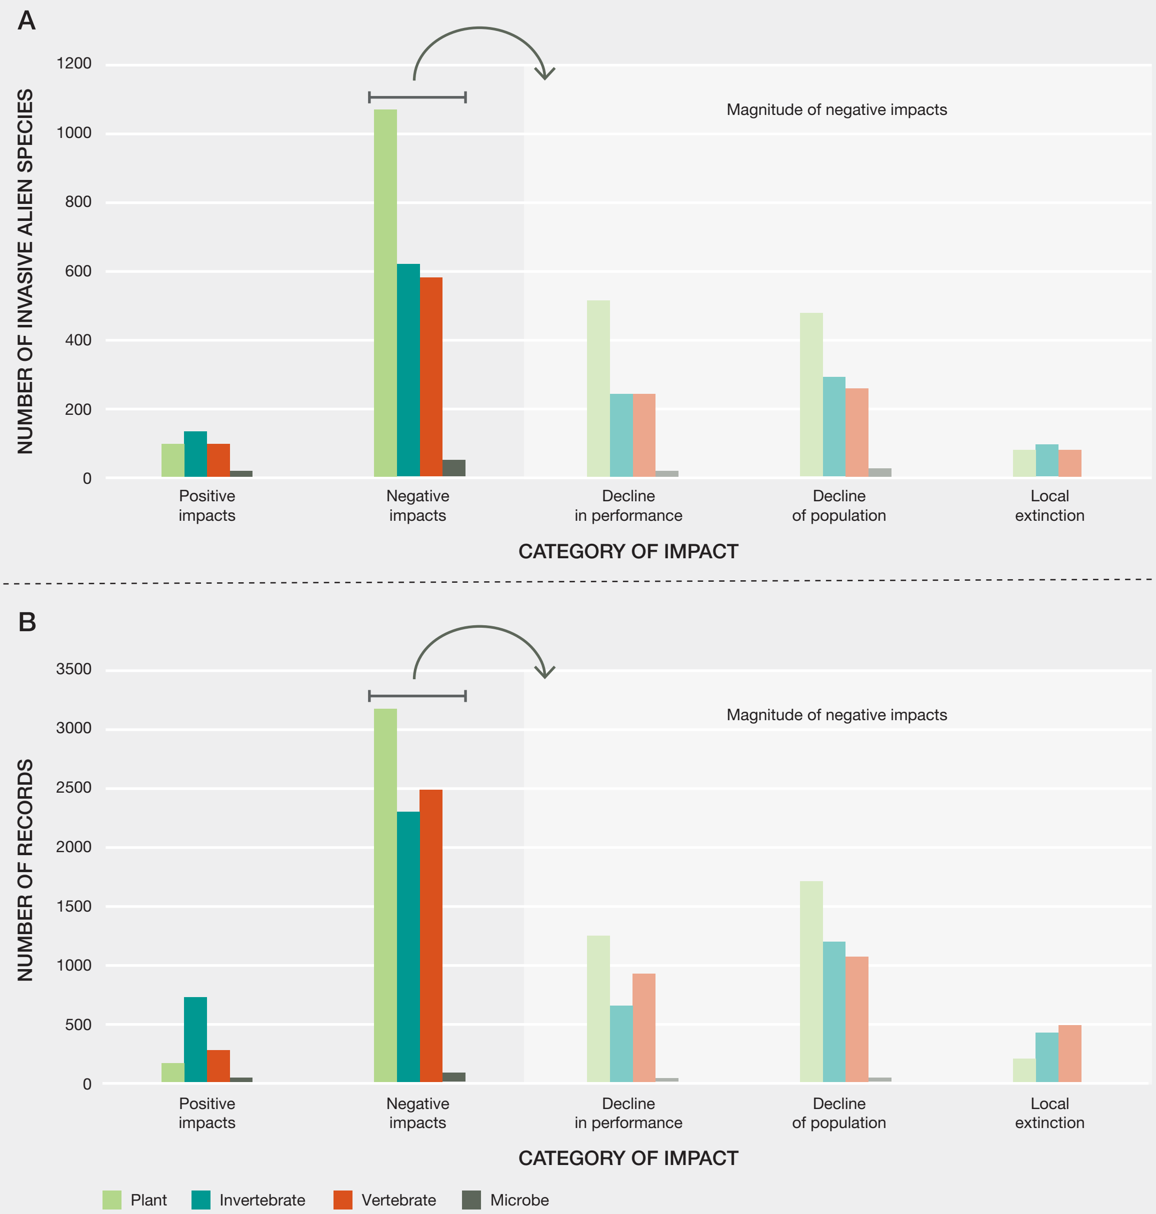

Figure 4 14 **Number of invasive alien species A) and number of impact records B) affecting native taxa by direction and magnitude.**

Number of records (y axis) for different categories of impacts (x axis). Negative and positive impacts relate to the consequences for native species, while ecosystem impacts are not assigned a direction. Negative impacts in A) are subdivided for each invasive alien species into the maximum documented negative impact on a native species globally (shaded boxes on the right-hand side). Note that the same invasive alien species could have a maximum negative impact on native species from different taxa, impacts on ecosystem properties and positive impacts on native species. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069 plants (de Souza *et al.*, 2018). The proportion of positive to negative impacts remains similar regarding the number of impacts documented except for invertebrates where the proportion of positive impacts rises to almost 25 per cent **(Figure 4.14B)**. Negative impacts of invasive alien species occur most often within the same taxonomic group **(Table 4.5A)**, i.e., invasive alien plants most often negatively impact native plants, and invasive alien vertebrates most often impact native vertebrates. However, this pattern does not hold for invasive alien microbes, which predominantly negatively impact plants (plant pathogens). The overall pattern is slightly different in positive impacts **(Table 4.5B)**, where invasive alien plants predominantly positively affect native invertebrates, either by providing a food source or habitat structure, while invasive alien invertebrates and vertebrates mostly positively affect native species in their own taxonomic group.

Documented local extinctions caused by invasive alien species mostly affect populations of native vertebrates, followed by native invertebrates and plants **(Figure 4.14B)**. Invasive alien species can also cause evolutionary responses in native species **(Box 4.8)**.

Table 4 5 **Records of negative and positive impacts of invasive alien species on native taxa.**

Number of negative A) and positive B) impacts on native taxa caused by invasive alien species, documented by the chapter impact database. Impacts within the same taxonomic groups in alien and native taxa are italicized. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

A) Negative impacts of invasive alien species on native taxa

Native taxa	Invasive alien species: Plants	Invertebrates	Vertebrates	Microorganisms
Plants	*2,542*	795	462	283
Invertebrates	701	*1,437*	399	38
Vertebrates	336	418	*2,027*	52
Microorganisms	84	12	5	*1*

B) Positive impacts of invasive alien species on native taxa

Native taxa	Invasive alien species: Plants	Invertebrates	Vertebrates	Microorganisms
Plants	*276*	29	20	1
Invertebrates	404	*452*	15	1
Vertebrates	99	129	*59*	--
Microorganisms	49	8	2	*--*

Box 4 8 Invasive alien species as drivers of rapid evolutionary change in native species.

Invasive alien species often dramatically alter habitat conditions for native species. As dominant community members, they may also act as novel resources (e.g., prey) for, or threats (e.g., predators) to, native species. These changes may lead to rapid evolutionary responses in native species (Carroll, 2007; G. W. Cox, 2004; J. J. Le Roux, 2021). Generally, changes caused by invasive alien species to host plants or food resources, the bio-physical environment, mortality and reproductive rates in native species, and competitive interactions, facilitate rapid adaptive evolution in native species (J. J. Le Roux, 2021). Non-adaptive shifts in the trait values of native species may also occur in response to invasive alien species, e.g., when they hybridize with invasive alien species (Todesco *et al.*, 2016). Alien species also often undergo rapid evolution throughout the biological invasion process which, in turn, may exacerbate their impacts (J. J. Le Roux, 2021).

The strength of selection pressure on native species brought about by invasive alien species, or vice versa, partly depends on how often these species interact and the levels of eco-evolutionary experience they share with one another (Saul *et al.*, 2013; Saul & Jeschke, 2015). Eco-evolutionary experience describes the historical exposure of species to biotic interactions, highlighting the role of preadapted traits in driving the biological invasion success of alien species (Saul *et al.*, 2013; Heger *et al.*, 2019). Therefore, the eco-evolutionary experience of alien species will determine how quickly their populations become widespread, as well as the form and strength of their interactions with native species (Carroll, 2007). Selection pressures on both alien and native species are expected to be strong when native species share moderate to high levels of eco-evolutionary experience with invasive alien species, e.g., when native invertebrates colonize invasive alien plants that are closely related to their native host plants (Carroll *et al.*, 2005). Native species lacking eco-evolutionary experience with experienced invasive alien species are also likely to experience strong selection, whereas alien species that share little eco-evolutionary experience with conditions in the new environment may fail to establish (J. J. Le Roux, 2021).

Direct impacts

Direct interactions between native and invasive alien species may cause rapid evolution in the native species for them to avoid, exploit, or co-exist with invasive alien species (J. J. Le Roux, 2021). Soapberry bugs in the subfamily Serinethinae provide classic examples of such impacts. As their name suggests, these bugs are herbivores of plants in the family Sapindaceae (Carroll & Loye, 2012). Given this eco-evolutionary experience, soapberry bugs have colonized various invasive Sapindaceae species in many parts of the world, often resulting in rapid evolutionary responses in these insects. For example, invasive balloon vines (genus *Cardiospermum*) have been repeatedly colonized by native *Leptocoris* soapberry bugs in Australia (Andres *et al.*, 2013; Carroll *et al.*, 2005) and South Africa (Foster *et al.*, 2019).

Balloon vines carry their seeds in inflated capsules, an adaptation to insect predators with piercing mouth parts. In Australia, the native soapberry bug *Leptocoris tagalicus* rapidly evolved longer proboscides (or "beaks") to increase its feeding efficiency on invasive *Cardiospermum grandiflorum* (Carroll *et al.*, 2005). Similarly, in South Africa host shifts by native *Leptocoris mutilatus* onto two invasive balloon vines (*Cardiospermum halicacabum* and *Cardiospermum grandiflorum*), not only led to the evolution of longer beaks, but also to the formation of genetically-distinct host races (Foster *et al.*, 2019). In the South-western United States, *Jadera haematoloma* (red-shouldered bug) shifted from its native *Cardiospermum* balloon vine host onto the invasive *Koelreuteria elegans* (goldenrain tree; Carroll & Boyd, 1992). In this instance, the bug was confronted with flatter seedpods on its new host plant, leading to the rapid evolution of shorter beaks (Carroll & Boyd, 1992; **Figure 4.15**).

Invasive alien species may also have significant evolutionary consequences when they act as novel resources for native species. On the one hand, native predators may experience strong selection to increase their ability to capture or consume palatable invasive prey or, conversely, to avoid toxic ones. Native Australian predators of invasive *Rhinella marina* (cane toad) illustrate how quickly such evolutionary impacts can happen. *Rhinella marina* produce a potent cocktail of defensive toxins that differs in its chemical constituents from the toxins produced by native Australian anurans (Daly *et al.*, 1987). Therefore, most Australian predators lack eco-evolutionary experience with cane toad toxins. Despite this, invasive cane toads are frequently attacked and consumed by native predators, presumably because of their superficial resemblance to Australian frogs. The amount of toxin produced by cane toads varies throughout their life cycle, with older and larger toads being more poisonous than younger and smaller ones (Hayes *et al.*, 2009). Snakes are gape-limited, and the size of their heads thus determines the size of prey they can consume. The evolution of smaller head (or gape) size is therefore likely to occur in toad-naïve predators, because those that can swallow larger toads would be removed from the breeding population. Morphological data from four Australian snake species, spanning a period of 80 years since the arrival of cane toads, partly support this hypothesis. As predicted, Phillips and Shine (2004) found two species, *Pseudechis porphyriacus* (red-bellied black snake) and *Dendrelaphis punctulatus* (common tree snake), to have evolved smaller heads since the arrival of cane toads in Australia. By contrast, *Hemiaspis signata* (swamp snake) and *Tropidonophis mairii* (common keelback snake) did not display any evolutionary responses to invasive *Rhinella marina*. *Hemiaspis signata* already have unusually small heads, making them incapable of ingesting toads large enough to kill them (Phillips *et al.*, 2003). While *Tropidonophis mairii* have normal-sized heads, their Asian ancestry, and thus historical exposure to poisonous toads, likely provided them with sufficient eco-evolutionary experience to tolerate their poisoning (Phillips & Shine, 2004).

Box 4 8

Figure 4 15 **Native species may experience strong selection when they utilize abundant invasive alien species as novel food sources.**

Invasive alien balloon vines in the genus *Cardiospermum* have been repeatedly colonized by native soapberry bugs. Shown here is the perennial balloon vine (*Cardiospermum grandiflorum*, main picture) in South Africa that has been colonized by the native bug *Leptocoris mutilatus* (inserted picture). In order to feed on balloon vine seeds more efficiently, some soapberry bug populations have rapidly evolved longer mouthparts. Photo credit: Johannes Le Roux – CC BY 4.0.

Invasive alien predators may also cause strong evolutionary responses in native species. In Lombardy, Italy, invasive alien *Procambarus clarkii* (red swamp crayfish) is established in waterbodies throughout the region (Ficetola *et al.*, 2011). Prior to its arrival, tadpoles of different populations of the native *Rana latastei* (Italian agile frog) exhibited pronounced variation in development time, depending on water temperature; this variation disappeared following the arrival of the red swamp crayfish (Melotto *et al.*, 2020). Within 14 years of the crayfish's introduction, tadpoles of the frog developed significantly faster in invaded ponds than in uninvaded ponds, irrespective of whether these were in foothill or lowland areas. These evolutionary responses likely occurred to reduce the frog's exposure to crayfish predation by allowing earlier metamorphosis and, remarkably, occurred over just 3-6 frog generations. Invasive alien species may also act as mutualists for native species (J. J. Le Roux *et al.*, 2020).

Indirect impacts

Invasive alien species may also create indirect evolutionary pressures on native species by changing abiotic and/or biotic conditions in ways that indirectly affect the fitness of native species (J. J. Le Roux, 2021). For example, along coasts of South-eastern Australia, the invasive seaweed *Caulerpa taxifolia* (killer algae), reduces water flow rates and causes anoxic sediment conditions, leading to increases in the abundance of large phytoplankton species (Gribben *et al.*, 2009; McKinnon *et al.*, 2009). These changes are thought to underlie the rapid evolution of longer and broader shells in the native mussel, *Anadara trapezia* (Sydney cockle), presumably for this mollusc to cope with altered sediment conditions and food resources (J. T. Wright *et al.*, 2012). While indirect evolutionary impacts are likely common, they are hard to predict and quantify (Berthon, 2015).

Hybridization between closely related native and invasive alien species is frequently documented. Genetic introgression, i.e., when hybrid offspring backcross to one or both parental species, can dilute native gene pools and purge them of locally adapted genotypes. This may ultimately lead to the extinction of native populations (Rhymer & Simberloff, 1996; Todesco *et al.*, 2016). A well-studied example is *Anas platyrhynchos* (mallard). This highly successful invasive alien species hybridizes with several native duck species around the world (Stephens *et al.*, 2020). Many of these hybrids are fertile and subsequent introgression has been documented in many instances (e.g., Rhymer *et al.*, 1994; Mank *et al.*, 2004; Stephens *et al.*, 2020). For example, in New Zealand, introgressive hybridization has led to the virtual elimination of *Anas superciliosa superciliosa* (New Zealand grey duck; Lavretsky, 2020).

The ecological consequences of the evolutionary impacts of invasive alien species

How biological invasions change and shape the evolutionary trajectories of native species is highly context-dependent and hard to predict, making inferences of long-term ecological

Box 4 8

and biodiversity impacts difficult. In the worst-case scenario, evolutionary impacts may lead to the extinction of native species. *Occidryas editha* (Edith's checkerspot butterfly) is a particularly dramatic example; it occurs in western United States and utilizes a narrow range of short-lived annual host plants. At Schneider's Meadow, Nevada, *Occidryas editha* rapidly demonstrated a rapid evolution of preference for invasive alien *Plantago lanceolata* (ribwort plantain; Singer & Parmesan, 2018). Selection for this host shift was strong, because, unlike the butterfly's native host plants, ribwort plantain provided its larvae with food year-round (Singer & Parmesan, 2018). Subsequent changes in land-use led to the recovery of grassland vegetation and the smothering of *Plantago lanceolata* plants, creating microclimatic conditions that were unsuitable for larval development. *Occidryas editha* was unable to switch back to their original native host plants at Schneider's Meadow and the local population died out (Singer & Parmesan, 2018). *Occidryas editha* is highly sedentary and therefore this local extinction likely led to the permanent loss of unique phylogenetic history.

Rapid evolution in native species may also reduce the impacts they experience from invasive alien species. For instance, in the United States, invasive *Alliaria petiolata* (garlic mustard) impacts native plants by interfering with their mycorrhizal fungal mutualists *via* strong allelopathy (Lankau, 2012). Invasive populations of *Alliaria petiolata* also rapidly evolved higher levels of allelopathy (Lankau *et al.*, 2009). Lankau (2012) found native *Pilea pumila* (clearweed) to have evolved tolerance to *Alliaria petiolata* and the ability to maintain high levels of mycorrhization in invaded areas. This suggests that co-evolutionary dynamics exist between the invasive alien species and native species.

Invasive alien species may facilitate speciation. A classic example is *Sporobolus anglicus* (common cordgrass), the descendant lineage of hybrids between invasive *Sporobolus alterniflorus* (smooth cordgrass) and native *Sporobolus maritimus* (small cordgrass) (Gray *et al.*, 1991). In another example, invasive *Lonicera* honeysuckles in North America acted as new host plants shared between two native tephritid fruit flies, *Rhagoletis mendax* (blueberry fruit fly) and *Rhagoletis zephyria* (snowberry fruit fly) (Schwarz *et al.*, 2005). These host shifts led to the breakdown of historical ecological barriers (i.e., utilization of distinct native host plants) between the two fly species and the establishment of a genetically-distinct hybrid fly lineage that is reproductively isolated from both parent species (Schwarz *et al.*, 2005).

The evolutionary responses of native species to invasive alien species likely ramify throughout entire communities and ecosystems, yet our understanding of such broad-scale impacts remains limited. For example, native insects may experience altered parasitoid loads when a native parasitoid evolves preference for a new and abundant invasive alien insect host. This may lead to community-wide changes in insect-host interactions.

4.3.2 Documented impacts of invasive alien species on nature by realm

4.3.2.1 Patterns of negative and positive impacts of invasive alien species on nature in the terrestrial realm

The database of impacts developed through this chapter includes more than 10,000 impacts on nature in the terrestrial realm, implicating 1,588 invasive alien species. Among these documented impacts, 76 per cent (6,638) can be considered as negative impacts, 17 per cent (1,498) as neutral and only 7 per cent (651) as positive impacts. Negative impacts in terrestrial habitats are caused by a total of 1,186 invasive alien vertebrates, invertebrates, plants or microbes.

The chapter impact database highlights that the vast majority of negative impacts caused by invasive alien species on nature are in terrestrial habitats (70 per cent). This bias towards terrestrial impacts is most likely a consequence of the rate at which humans have transported and introduced alien species through time (Seebens *et al.*, 2017), but may also reflect a bias in terrestrial research over inland waters and marine research.

Mechanisms and magnitude of negative impacts

Among all the species negatively impacting terrestrial habitats, more than half (52 per cent, 619 species) cause decline in the performance of native species, almost half (45 per cent, 530 species) cause decline of local native populations, and some (9 per cent, 105 species) cause local extinctions of native species. The magnitude of negative impacts is context-dependent; some invasive alien species have impacts of different magnitudes in different invaded habitats. The highest numbers of invasive alien species causing decline in the performance of native species are found in boreal forests and woodlands, cultivated areas and tropical and subtropical dry and humid forests but the highest numbers of invasive alien species causing impact of greater magnitude, that is, population decline of native species and local extinction, are found in tropical and subtropical dry and humid forests and temperate and boreal forests and woodlands **(Table 4.6)**. By contrast, tundra and high mountain habitats and deserts and xeric shrublands are the ecosystems with lowest records of negative impacts caused by invasive alien species on nature.

Table 4 6 **Number of negative impacts of invasive alien species on nature in the terrestrial realm, by unit of analysis.**

Number of invasive alien species (IAS) and records of negative impacts on nature in the terrestrial realm for each unit of analysis. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

Unit of analysis	Maximum impact on native species					
	Decline in performance		Decline of population		Local extinction	
	IAS	Records	IAS	Records	IAS	Records
Tropical and subtropical dry and humid forests	144	404	160	586	46	282
Temperate and boreal forests and woodlands	129	389	159	728	33	196
Mediterranean forests, woodlands and scrub	57	158	73	251	17	115
Tundra and high mountain habitats	8	22	31	60	4	5

Impacted units of analysis

Temperate and boreal forests and woodlands, and tropical and subtropical dry and humid forests are the most impacted units of analysis in the terrestrial realm, with, respectively, 1,313 and 1,272 negative impacts **(Table 4.6)**. Particularly, these are the habitats with the highest reports both of decline of native local populations and local extinctions caused by invasive alien species. For example, in the United States, *Lumbricus terrestris* (lob worm) can be found in temperate and boreal habitats and has caused the reduction of plant-species richness and changed plant communities in mature forests (Holdsworth *et al.*, 2007). Some vertebrates are also invading these forests, for example *Castor canadensis* (North American beaver; IPBES, 2018a) has invaded temperate forests, but also grasslands and peatlands in southern Argentina and Chile, causing several negative ecological and economic impacts (Duboscq-Carra *et al.*, 2021; Gaiarin & Durham, 2016; Valenzuela *et al.*, 2013). *Castor canadensis* is considered an ecosystem engineer due to the magnitude of the changes it produces in the riparian environments – it invades by building dams which affect nutrient cycling and soil properties, chemistry, biodiversity, morphology, flow and water dynamics of rivers and streams. *Castor canadensis* builds its dams by cutting down trees, degrading riparian forests. Associated with these modifications that it generates in the environment, *Castor canadensis* facilitates the invasions of other alien species, both aquatic and terrestrial (Gaiarin & Durham, 2016; Valenzuela *et al.*, 2013). The invasion of *Castor canadensis* has also economic impacts: the costs associated with the invasion of *Castor canadensis* in Argentina are estimated to be around 66.56 million United States dollars (US$; Duboscq-Carra *et al.*, 2021). Tropical and subtropical humid and dry forests are amongst the most extensive ecosystems in South America and are being impacted by several invasive alien species that mostly originated from tropical areas in Asia and Africa (IPBES, 2018a). Some examples of invasive alien plant species in these habitats are *Pinus patula* (Mexican weeping pine) in Colombia (GISP, 2005); *Artocarpus heterophyllus* (jackfruit) in Brazil (Fabricante *et al.*, 2012); *Ligustrum lucidum* (broad-leaf privet) in Argentina (Hoyos *et al.*, 2010), and *Acacia mangium* (brown salwood) in French Guiana (Delnatte & Meyer, 2012) and Brazil (Heringer *et al.*, 2019). According to published studies, tundra and high mountain habitats and deserts and xeric shrublands not only have the lowest number of invasive alien species causing negative impact but also have the lowest records of negative impacts among all terrestrial habitats **(Table 4.6)**. For example, *Ulex europaeus* (gorse), one of the most impactful invasive alien plant species in the world (Global Invasive Species Database, 2010), is invading several high Andean regions, altering the structure of plant communities which negatively affects the composition of birds (Amaya-Villarreal & Miguel Renjifo, 2010).

Invasive alien taxa most often documented causing negative impacts on nature in the terrestrial realm

Invasive alien plant species are responsible for almost half (45 per cent) of all the negative documented impacts on nature in the terrestrial realm (e.g., **Box 4.9**), followed by invasive alien vertebrates (27 per cent), invertebrates (23 per cent) and microbes (5 per cent). Several invasive alien plants cause negative impacts at different levels of ecological organization, from individual species populations to native plant and animal communities to ecosystems as a whole. For example, the shrub *Lantana camara* (lantana) has adverse impacts on native understorey shrubs and herbaceous plants diversity, and affects the vegetation community composition by reducing seedling recruitment of vertebrate-dispersed seeds (Dobhal *et al.*, 2010; Kohli *et al.*, 2006; Prasad, 2010; Raghubanshi & Tripathi, 2009; Sundaram *et al.*, 2012). It also increases soil nitrogen that may further favour its proliferation (Sharma, 2011). This shrub is unpalatable, and replaces native palatable herbs and reduces available forage for wild ungulates (Prasad, 2010; G. Wilson *et al.*, 2014). Physical changes of large extensions of invaded habitats by *Lantana camara* can change habitat use of large mammals such as elephants (G. Wilson *et al.*, 2013). In forests, increased density of this shrub is correlated with a decrease in bird diversity, with certain guilds (canopy and insectivorous birds) being more adversely affected than others (Aravind *et al.*, 2010). *Lantana camara* also alters fire regimes by increasing the fuel load of invaded forests, leading to more intense and severe fires (Hiremath & Sundaram, 2005; Kohli *et al.*, 2006; Sundaram *et al.*, 2012; Tireman, 1916). Furthermore, in temperate and boreal regions of north-western Europe, *Picea sitchensis* (Sitka spruce) is assessed to be among the highest-risk alien species in Norway (Norwegian Biodiversity Information Centre, 2018; Sandvik *et al.*, 2020) as well as in Great Britain and Ireland (Dehnen-Schmutz *et al.*, 2022). *Picea sitchensis* severely changes ecological conditions across a significant proportion of the habitat area of red-listed habitats such as coastal *Calluna*-heathlands and coastal mires, with knock-on impacts on red-listed plants, birds and other species linked to these habitats (Hinderaker & Nielsen, 2022; Norwegian Biodiversity Information Centre, 2018; Øyen & Nygaard, 2020; Saure *et al.*, 2013, 2014). These heathlands are now critically endangered throughout their range in western Europe, due to compound threats involving land-use change, nutrient pollution, and invasive alien species (IPBES, 2018b). Other examples of invasive alien plant species with multiple simultaneous impacts are species belonging to the Pinaceae family. Pinaceae comprises some of the most invasive tree species and at least 20 species of the genus *Pinus* are considered to be invasive in at least one region of the southern hemisphere (Richardson & Rejmanek, 2004). These invasive alien species affect the composition and structure of native plant, bird and soil arthropod communities, and displace endemic native species thereby promoting biological invasion by other alien species (León-Gamboa *et al.*, 2010; Pauchard *et al.*, 2015; Ziller *et al.*, 2005). *Pinus* spp. (pine) also have positive feedback with fire due to the accumulation of dry matter, this in turn results in greater intensity and frequency of fires (Cóbar-Carranza *et al.*, 2014; GISP, 2005; Paritsis *et al.*, 2018; Pauchard *et al.*, 2008, 2015; Raffaele *et al.*, 2016; Zalba *et al.*, 2008; **Chapter 1**, **Box 1.4**; **Chapter 3**, **sections 3.3.1.5.2** and **3.3.4.5**) and favours high *Pinus* spp. density post-fire (K. T. Taylor *et al.*, 2017). Other examples of invasive alien plant species with several records of negative impacts on different levels of ecological organization are *Prosopis juliflora* (mesquite; **Box 4.9**), *Impatiens glandulifera* (Himalayan balsam; e.g., Kiełtyk & Delimat, 2019), *Acacia longifolia* (golden wattle; e.g., Rascher *et al.*, 2011), *Cenchrus ciliaris* (buffel grass; e.g., Alves *et al.*, 2018; Bonney *et al.*, 2017), *Reynoutria japonica* (Japanese knotweed), *Robinia pseudoacacia* (black locust), and *Ailanthus altissima* (tree-of-heaven; e.g., Vilà *et al.*, 2010). Particularly, the latter three species are the invasive alien plants with the most widespread impacts across terrestrial habitats in European countries (Vilà *et al.*, 2010).

Box 4 9 ***Prosopis juliflora* (mesquite), an example of a high impact invasive alien plant.**

Prosopis juliflora (mesquite; **Figure 4.16**), a tree native to the Caribbean and tropical America, is considered one of the highest impact invasive alien trees (R. T. Shackleton *et al.*, 2014). It was deliberately introduced to 129 countries **(Figure 4.17)** to provide forage for livestock, for firewood, charcoal, as an ornamental, and to halt desertification and stabilize dunes in arid and semi-arid regions (Pasiecznik, 2001). However, this species has been documented to have negative impacts on native species, as well as on nature's contributions to people and good quality of life, throughout its introduced range (Patnaik *et al.*, 2017). Apart from its human-assisted spread, the species also spreads rapidly, aided by wild herbivores and livestock that feed on its pods and disperse its seeds. In the Afar region, Ethiopia, *Prosopis juliflora* is estimated to have invaded an area of about 1.17 million hectares (i.e., 12 per cent of the region) over a period of 35 years (Shiferaw, Schaffner, *et al.*, 2019).

Box 4 9

Impacts on nature

Negative impacts on nature mainly result from competition and habitat alteration. In the Brazilian Caatinga, *Prosopis juliflora* reduces the abundance of native species by more than 80 per cent, affecting seedling growth and mortality, and floristic composition, diversity, and structure of the native communities (Pegado *et al.*, 2006). It has had direct negative impacts on wildlife by altering natural grassland and wetland habitats (Mukherjee *et al.*, 2017; Sinha *et al.*, 2009).

Impacts on nature's contributions to people

One of the main negative impacts of *Prosopis juliflora* on nature's contributions to people, throughout its introduced range, is the loss of grazing lands, e.g., in East Africa (Bekele *et al.*, 2018; Mwangi & Swallow, 2008), and India (Duenn *et al.*, 2017; P. N. Joshi *et al.*, 2009). In Brazil and India, *Prosopis juliflora* has directly affected agriculture, competing with traditional short-cycle crops or encroaching tilled fields (Walter & Armstrong, 2014). It also affects agriculture indirectly due to increased crop raiding by wild herbivores as a result of reduction in wild forage availability (Sinha *et al.*, 2009). Furthermore, it has been shown that the water use of *Prosopis juliflora* impacts on water availability (Wise *et al.*, 2012). In the Afar Region, Ethiopia, the catchment water budget was estimated to be reduced by 3.1 to 3.3 billion m^3/year (Shiferaw *et al.*, 2021). The aggregated average social annual willingness to pay (**Glossary**) to manage the biological invasion in Afar, Ethiopia, and Baringo, Kenya, is estimated at US$6.1 million and US$4.2 million, respectively (Bekele *et al.*, 2018). *Prosopis juliflora* also provides benefits to people. For example, it is widely used by local communities in semi-arid regions of Brazil mainly for timber purposes (Guerra *et al.*, 2014), but also potentially as a natural pesticide and in the management of diseases in crop plants (Damasceno *et al.*, 2017). The fruits (pods) of *Prosopis juliflora* can be used to produce a number of food products; and they are extensively used for feeding livestock (Damasceno *et al.*, 2017; Duenn *et al.*, 2017). However, the livestock can only be fed up to a certain percentage by *Prosopis juliflora* pods, because exclusive feeding with these pods causes neurological disorders in the cattle (Patnaik *et al.*, 2017).

Impacts on good quality of life

Prosopis juliflora has more records of negative impacts than positive impacts on good quality of life. Reports from Africa demonstrate a negative effect of *Prosopis juliflora* on the occurrence of mosquito-borne human diseases. For example, in the Baringo area, Kenya, 40 to 60 per cent of local residents documented an increase in the incidence of malaria (Mwangi & Swallow, 2008). *Prosopis juliflora* flowers provide nectar for mosquito vectors of malaria, with higher numbers of female mosquitoes documented in Malian villages surrounded by *Prosopis juliflora* (Muller *et al.*, 2017). Further impacts include reduced access to grazing areas and water sources, resulting in conflicts among pastoralist communities due to resource scarcity; in India it has also been linked to conflicts between pastoralists and settled agriculturalists, due to livestock dispersing unwanted *Prosopis juliflora* into farmers' fields (Duenn *et al.*, 2017). In Ethiopia, reduction in grazing lands is leading to a breakdown of traditional customary laws as people seek new grazing areas disregarding the traditional users of these areas (Shiferaw, Bewket, *et al.*, 2019).

In heavily invaded areas, people have adapted to novel *Prosopis juliflora*-based livelihoods, especially making charcoal and harvesting the wood for sale; this livelihood diversification has enabled communities to cope better with losses of income from livestock or crops and respond to environmental shocks (Linders *et al.*, 2020; Sato, 2013; Walter & Armstrong, 2014). The longer term consequences of these adaptation processes seem to be context dependent: while studies in Africa found that utilization of the species was offsetting the losses, this was not expected to be sustainable in the future (Linders *et al.*, 2020; Wise *et al.*, 2012); whereas a study in India found that household incomes increased when the creation of small scale electricity generating facilities increased the demand for and prices of wood for energy generation following policy changes deregulating the electricity market (Sato, 2013).

Parts of the tree have traditionally been used for medicinal purposes, and people are adapting it for medicinal use in its introduced habitats (Damasceno *et al.*, 2017; Duenn *et al.*, 2017; Patnaik *et al.*, 2017).

Local extinctions caused by invasive alien species

A total of 105 alien species have been documented to have caused local extinctions of terrestrial native species, with a majority documented in tropical and subtropical dry and humid forests and Mediterranean forests, woodlands and scrub. Meanwhile, fewer local extinction caused by invasive alien species have been documented in tundra and high mountain habitats and urban/semi-urban habitats **(Table 4.7)**.

Invasive alien vertebrates are the main taxa responsible for local extinctions in terrestrial habitats (454 of 725 documented local extinctions have been caused by 36 invasive alien vertebrates). *Felis catus* (cat) has been documented as culpable in the greatest number of local extinctions, followed by *Vulpes vulpes* (red fox) and *Rattus Rattus* (black rat) **(Figure 4.18)**. These predatory invasive alien mammals have played a major role in the local extinction of native species in several terrestrial habitats (Doherty *et al.*, 2016; Radford *et al.*, 2018). Invasive alien invertebrates are the second taxa responsible for local extinctions of native species in terrestrial habitats (207 of 725 impacts with this magnitude have been caused by 33 invasive alien invertebrates), and most of these extinctions were registered on tropical and subtropical dry and humid forests, Mediterranean forests and temperate and boreal forests and woodlands. These invasive alien invertebrates include *Linepithema humile* (Argentine ant), *Solenopsis invicta* (red imported fire ant), *Anoplolepis gracilipes* (yellow crazy ant), and *Agrilus planipennis* (emerald ash borer). The emerald ash borer causes local extinctions of native plants through herbivory and is the focus of many studies because its larvae, feeding on ash trees, can kill the totality of ash varieties in tree stands, and, most recently, has been found to facilitate the spread of *Chionanthus* (fringetrees) in the northeast United States.

A similar number of invasive alien plants (31 species) have caused local extinctions of native species in terrestrial habitats. However, only 5 per cent (52 of 725 impacts) of all documented local extinctions have been caused by invasive alien plants. These invasive alien plant species include *Vachellia nilotica* (gum arabic tree), *Parthenium hysterophorus* (parthenium weed), and *Prosopis juliflora* (mesquite) that produced local extinctions of native species primarily due to competition (e.g., Duenn *et al.*, 2017) and poisoning or toxicity (e.g., Batish *et al.*, 2012).

In contrast, there are very few reports of local extinctions of native species (12 documented local extinctions) caused by only a few invasive alien microbes (5 invasive microbe species), which were documented on tropical and subtropical dry and humid forests and Mediterranean forests, woodlands and scrub. For example, the pathogenic *Batrachochytrium dendrobatidis* (chytrid fungus) has been associated with amphibian population declines, causing extinctions of frogs and salamanders in central and south America and Australia (Burrowes & De la Riva, 2017; Catenazzi *et al.*, 2011; Lampo *et al.*, 2008; Pounds *et al.*, 2006; Schloegel *et al.*, 2006).

Positive impacts caused by invasive alien species on nature in the terrestrial realm

In the terrestrial realm, documented positive impacts on nature are mostly caused by invasive alien plants (**section 4.1.2**; **Box 4.3**). Highest numbers of invasive alien species causing positive impacts to native species can be found in temperate boreal forests and woodlands and temperate grasslands. Invasive alien plants causing the most documented positive impacts on native species are *Reynoutria japonica* (Japanese knotweed), *Impatiens glandulifera* (Himalayan balsam), and *Robinia pseudoacacia* (black locust). For instance, invaded areas by *Reynoutria japonica* showed higher abundances of bumblebees, overall insect diversity and hoverfly diversity than uninvaded areas (Davis *et al.*, 2018). Nonetheless, *Reynoutria japonica*, *Impatiens glandulifera*, and *Robinia pseudoacacia* are also invasive alien plant species with high numbers of negative impacts on nature on terrestrial habitats (**section 4.3.1**).

4.3.2.2 Patterns of negative and positive impacts of invasive alien species on nature in inland waters

In inland waters ecosystems the impacts of invasive alien species often act in synergy with other pressures, including unsustainable water abstraction, widespread habitat loss and degradation, overexploitation of natural resources, climate change, and other drivers of biodiversity change (Darwall *et al.*, 2018). However, in some cases, invasive alien species are the main driver contributing to native species extinctions and population declines; for example, the precipitous decline of critically endangered amphibians has been caused by the pathogenic *Batrachochytrium dendrobatidis* (chytrid fungus) (Dueñas *et al.*, 2021).

Concerns about inland waters ecosystems' vulnerability to invasive alien species have contributed to an increase in the number of studies on invasive alien species in inland waters (Ricciardi & Macisaac, 2011). Negative impacts of invasive alien species on nature in inland waters represent about 20 per cent of the total number of documented negative impacts caused by invasive alien species (2,113 of 10,822 impacts). A total of 230 invasive alien species have been documented to cause these impacts in inland waters.

Mechanisms and magnitude of impacts

Ecological impacts associated with invasive alien fishes include biotic homogenization (**Glossary**) and replacement of endemic species, spread of new diseases, changes in behaviour and diet shifts of native species (Gherardi, 2010; **Table 4.8**).

Impacts of invasive alien species on native inland waters biota and ecosystems are often synergistic and the result of multiple mechanisms such as predation and competition (Olden *et al.*, 2021), and complex interactions. For example, invasive alien freshwater mussels require fish hosts to complete their life cycle (Modesto *et al.*, 2018), and, in Sweden, declines in native crayfish species have been driven by the combined effects of hybridization, the transmission of crayfish plague and competitive exclusion with introduced crayfishes (Lodge *et al.*, 2012). Other complex interactions include the facilitation by some invasive alien species of the establishment of other invasive alien species (Simberloff & Von Holle, 1999), or the contribution of some invasive alien species to multiple stressors in their introduced habitat (M. C. Jackson *et al.*, 2016; Reynolds & Aldridge, 2021). There are synergistic interactions between invading species and cascading food-webs that may affect ecosystems within and beyond water bodies (Ricciardi & Macisaac, 2011). In North America, for example, the introduction of *Mysis*

Table 4 8 **Number of invasive alien species causing negative impacts on nature in inland waters.**

The number of invasive alien species (IAS) adversely impacting nature in the freshwater realm, and the number of documented negative impact by unit of analysis in relation to the maximum impact on native species: decline in performance, decline in population, local extinction or unspecified. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

Unit of analysis	Maximum impact on native species							
	Decline in performance		Decline of population		Local extinction		Unspecified	
	IAS	Records	IAS	Records	IAS	Records	IAS	Records
Aquaculture areas	14	17	21	58	1	1	14	15
Wetlands	44	91	52	156	10	22	37	87
Inland surface waters and water bodies/ freshwater	132	613	125	636	54	168	94	249

relicta (opossum shrimp) to more than a hundred lakes, to stimulate the production of *Oncorhynchus nerka* (sockeye salmon), resulted in predation-driven declines of native zooplankton to such an extent that it led to the collapse of important planktivorous fish populations and to the decline of eagle and grizzly bear populations (C. N. Spencer *et al.*, 1991).

Decreases in native species' performance (34 per cent) or declines in local native populations (40 per cent) are the most commonly documented of all negative impacts on nature (2113 impacts) in inland waters. Local extinctions represent about 9 per cent of all documented impacts caused by invasive alien species in inland waters. For example, *Dikerogammarus villosus* (killer shrimp) caused the local extinction of the native amphipod *Gammarus duebeni* in Dutch water bodies through predation (Dick & Platvoet, 2000).

Impacted units of analysis

In inland waters, most documented impacts **(Table 4.8)** are from inland surface waters and water bodies (78.8 per cent), and fewer from wetlands (16.8 per cent) and areas used for aquaculture (4.3 per cent). Consequently, the documented number of invasive alien species causing impacts in the freshwater realm **(Table 4.8)** is larger for inland surface waters and water bodies (209) compared to wetlands (23) and areas used for aquaculture (28). Note that the same invasive alien species might be documented causing impacts in multiple units of analysis.

Invasive alien taxa most often documented causing negative impacts in inland waters

Some inland waters fish act as engineering species, profoundly affecting the environment. For example, *Cyprinus carpio* (common carp) and *Ctenopharyngodon idella* (grass carp) modify aquatic vegetation directly through uprooting or herbivory and indirectly through bioturbation and excretion, ultimately shifting the trophic status of water from clear to turbid (Matsuzaki *et al.*, 2009; Roberts *et al.*, 1995; Vilizzi *et al.*, 2015). *Salvelinus fontinalis* (brook trout), a widely introduced freshwater fish affecting food-webs and native diversity through various mechanisms (e.g., predation of various taxa including crustaceans, insects, amphibians and competition or hybridization with native fishes) is also causing high ecological impacts (Cucherousset *et al.*, 2007, 2008; Orizaola & Brana, 2006).

Despite not exceeding 2 per cent of total plant diversity, aquatic plants are vital in inland waters, shaping key processes such as primary production, oxygen release, and bank stabilization (Bolpagni, 2021). In Europe, more than half of the invasive alien species considered of concern according to the European Union Regulation 1143/2014, thus deemed highly impactful, are either aquatic or wetland plants. Dense mats of floating aquatic plants (e.g., *Pontederia crassipes* (water hyacinth)) can cause the complete cover of smaller water bodies and reduce the light available to submerged plants and phytoplankton, thus depleting dissolved oxygen and altering the composition of invertebrate communities (Hill *et al.*, 2020). Similar changes caused by thick underwater mats of *Myriophyllum spicatum* (spiked watermilfoil), leading to the decline of native macrophytes and invertebrates, have been observed in water bodies of North America (Boylen *et al.*, 1999; Kauffman *et al.*, 2018; S. J. Wilson & Ricciardi, 2009). Furthermore, *Myriophyllum spicatum* can affect native North American milfoils through hybridization; with the hybrid watermilfoil *Myriophyllum spicatum* x *Myriophyllum sibiricum* exhibiting an increase in reproductive potential and surface cover compared to its parental taxa (Glisson & Larkin, 2021).

The crayfish group causes many negative impacts in inland waters habitats. For instance, *Faxonius limosus* (spiny-cheek crayfish) and *Procambarus clarkii* (red swamp crayfish) interfere with water quality regulation, habitat maintenance and nutrient cycling through their burrowing activities, and decrease the abundance of macrophytes by feeding and stalk-cutting, reducing the availability of refuges for other species (Lodge *et al.*, 2012). In Portugal, the invasive *Pacifastacus leniusculus* (American signal crayfish) threatens the survival of *Margaritifera margaritifera* (freshwater pearl mussel), a critically endangered species in Europe, through predation (R. Sousa *et al.*, 2019). The translocation of live crayfish for aquaculture purposes has also facilitated the transmission of diseases that are potentially lethal to native crayfish (e.g., *Aphanomyces astaci* (crayfish plague); Martín-Torrijos *et al.*, 2018) and of ectosymbiotic branchiobdellidans (e.g., *Xironogiton victoriensis* carried by its host, *Pacifastacus leniusculus*; Gelder & Williams, 2015). This creates opportunities for novel associations between, for example, alien branchiobdellidans and native crayfish, *Xironogiton victoriensis* and the endangered native *Austropotamobius pallipes* (Atlantic stream crayfish) in Spain (Martín-Torrijos *et al.*, 2018), whose consequences are difficult to predict.

Python bivittatus (Burmese python) is another emerging invasive alien species, established in southern Florida. Free-ranging *Python bivittatus* have consumed a wide variety of birds, mammals, and one reptile, the *Alligator mississippiensis* (American alligator; Dove *et al.*, 2011; Guzy *et al.*, 2023; Rochford *et al.*, 2010; Snow *et al.*, 2007). Large species of mammals and birds are also vulnerable to predation by invasive pythons; *Lynx rufus* (bobcat), *Odocoileus virginianus* (white-tailed deer), and *Mycteria americana* (wood stork) have been consumed by *Python bivittatus* in the Everglades National Park (Dove *et al.*, 2011; Guzy *et al.*, 2023; Rochford *et al.*, 2010; Snow *et al.*, 2007). This large and voracious predator is directly responsible for the severe decline of several mammal populations (e.g., raccoons, opossums and rabbits; McCleery *et al.*, 2015). By reducing populations of their native predators, invasive alien pythons might have a potential indirect positive impact on non-prey species, for example by decreasing nest predation on native turtles (Willson, 2017).

Local extinctions caused by invasive alien species in the inland waters realm

Several invasive alien invertebrates cause local extinctions, including *Dreissena polymorpha* (zebra mussel) and *Faxonius limosus* (spiny-cheek crayfish) (**Figure 4.19**; **Table 4.9**). The introduction of invasive alien fishes, such as *Salvelinus fontinalis* (brook trout; Cucherousset *et al.*, 2007, 2008; Orizaola & Brana, 2006) and *Oreochromis niloticus* (Nile tilapia; Angienda *et al.*, 2011; Wise *et al.*, 2007), has caused local extinctions of native fishes and amphibians in all units of analysis of the inland waters realm (Cucherousset & Olden, 2011; Ellender & Weyl, 2014; **Table 4.9**). The best cited example of predation-induced extinction is the local extinction of about 200 species of endemic cichlid fish following the introduction of *Lates niloticus* (Nile perch) in Lake Victoria (Witte *et al.*, 1992; **Box 4.10**). *Clarias gariepinus* (North African catfish) has also been documented as causing local extinctions in areas used for aquaculture purposes. In India, *Clarias gariepinus* is considered responsible for the decrease of vertebrate species richness from several ponds during the post-monsoon season (Gopi & Radhakrishnan, 2002).

Plants such as *Pontederia crassipes* (water hyacinth) and *Pistia stratiotes* (water lettuce), have also caused local extinctions, mostly in wetlands **(Table 4.9)**. *Pistia stratiotes* causes changes in physiochemical properties of invaded water bodies, affecting water quality and altering macrophyte communities leading, in some cases, to the local extinction of native species such as several species of the pondweed *Potamogeton* in Slovenia (Jaklič *et al.*, 2020).

Inland waters molluscs represent one of the most diverse, but also highly threatened groups, in the inland realm (Böhm *et al.*, 2021). The diversity and the functions they provide (e.g., biofiltration, nutrient cycling and storage, substrate and trophic resources) are essential to aquatic ecosystems and susceptible to changes (Vaughn, 2018). Invasive alien molluscs can cause the decline of phytoplankton biomass or native mussels abundance. For instance, *Dreissena polymorpha* (zebra mussel) is responsible for the 10-fold increase in the rate of local extinction of native mussels in the Great Lakes region (Ricciardi *et al.*, 1998). *Pomacea canaliculata* (golden apple snail) is another example of an invasive alien mollusc responsible for the increase of phytoplankton biomass through the release of nutrients when grazing (Strayer, 2010), and outcompeting native apple snails in Indonesia (Marwoto *et al.*, 2020).

Conflict species causing both positive and negative impacts

Some invasive alien species can be referred to as conflict species (**Chapter 1**, **section 1.5.2**; **Chapter 5**, **section 5.6.1.2**), causing both positive and negative impacts, although this should be interpreted with caution as it is context-dependent **(Box 4.10)**. Such species are challenging to manage, as they affect stakeholders in different ways (**Chapter 5**, **section 5.6.1.2**). Examples of conflict species include invasive alien macrophytes providing refuge from predators to various native species or limiting bank erosion. Likewise, invasive alien crayfish provide food or shelter for other native species, are adequate for human consumption and can be appreciated for their aesthetic properties and cultural or spiritual values (Emery-Butcher *et al.*, 2020; Vaughn, 2018; **section 4.4.1**). Many crayfish species, like the North American *Faxonius immunis* (calico crayfish) and the parthenogenetic form of *Procambarus fallax* (slough crayfish), are kept as ornamental species in aquaria and ponds throughout Europe. This has led to a flourishing pet trade and to the inevitable escape or introduction of the crayfish in the wild with negative impacts on the native fauna (Faulkes, 2010; Holdich *et al.*, 2009; Martin *et al.*, 2010; Nonnis Marzano, 2009; **Chapter 3**, **section 3.2.3.2**) and on good quality of life, including cultural, social and ethical values, in many countries (Gherardi, 2011; Swahn, 2004).

Box 4 10 Fishes as examples of invasive alien species with both positive and negative impacts.

Invasive alien species may cause both positive and negative impacts on nature, nature's contributions to people and good quality of life (Zengeya *et al.*, 2017). Many fish have been intentionally introduced to enhance fisheries or as control agents, providing remarkable cautionary examples.

Lates niloticus (Nile perch), introduced in Lake Victoria, East Africa, to enhance the fishery, is a prime example (Balirwa *et al.*, 2003; **Figure 4.20**). Lake Victoria's fish fauna was comprised of about 500 endemic haplochromine cichlid species, two tilapiine species and 46 other species belonging to 12 families

Box 4 10

(Witte *et al.*, 2013). As increasing fishing pressure reduced the native tilapiine cichlids and other large fish species' populations, *Lates niloticus* and four tilapiine cichlids were introduced into the lake in the 1950s (Aloo *et al.*, 2017; Gichuru *et al.*, 2018; Luomba, 2016; Marshall, 2018). *Lates niloticus* biomass peaked at around 2.3 million tonnes in 1999, and accounted for 92 per cent of total fish biomass but fell to less than 300,000 tonnes in 2008, with average length declining from 51.7 cm to 26.6 cm, significantly below the required minimum size of 50 cm for export (Talma *et al.*, 2014). Dramatic changes ensued: *Lates niloticus* and *Oreochromis niloticus* (Nile tilapia) increased, as well as eutrophication of the lake, and the wetlands declined. The haplochromine cichlids were the most severely hit, with most species presumed extinct. These introductions were an economic success: the annual catch is estimated at US$544 million locally, in addition to US$243 million in exports in 2003 (Balirwa, 2017), at the price of the greatest documented extinction of vertebrates (Kaufman, 1992), with an estimated loss of 200 endemic fish species (Witte *et al.*, 1992).

Figure 4 20 ***Lates niloticus* (Nile perch).**

Photo credit: Fotogien, Shutterstock – Copyright.

The widely introduced *Oreochromis niloticus* and four species of carps – *Ctenopharyngodon idella* (grass carp), *Hypophthalmichthys molitrix* (silver carp; **Figure 4.21**), *Hypophthalmichthys nobilis* (bighead carp), and *Cyprinus carpio* (common carp), account for more than a third of the global freshwater fish production and contribute to global food security (FAO, 2020). These fish are listed among the world's worst invasive alien species (Lowe *et al.*, 2000). *Oreochromis niloticus* threatens native tilapia in Africa through hybridization and competition (Canonico *et al.*, 2005). *Cyprinus carpio* suspends sediments, increasing nutrient availability and turbidity, suppressing macrophyte growth (Vilizzi *et al.*, 2015). *Ctenopharyngodon idella* modifies aquatic vegetation through uprooting or herbivory and has transmitted parasites which threaten wild fish (Cucherousset & Olden, 2011).

Lakes and rivers worldwide were stocked with salmonids, including *Oncorhynchus mykiss* (rainbow trout), *Salmo trutta* (brown trout), and *Salvelinus fontinalis* (brook trout), for commercial and recreational exploitation. These top predators brought about profound ecological changes: predation on native fauna can reduce amphibian and reptile populations, led to changes in zooplankton and benthic macroinvertebrate species composition and size structure, alteration of nutrient cycling, competition for food and habitat, hybridization with native trout species, and disease transmission (Krueger & May, 1991; P. Jones & Closs, 2018; Miró & Ventura, 2013). Management of these and other conflict species depends on better balancing of competing goals and perspectives (Vigliano & Alonso, 2007; Ellender *et al.*, 2014; Zengeya *et al.*, 2017; Beever *et al.*, 2019).

4.3.2.3 Patterns of negative and positive impacts of invasive alien species on nature in the marine realm

The database of impacts developed through this chapter includes about 900 articles (2,350 reported impacts) documenting quantitative observational/experimental studies of impacts of invasive alien species in the marine realm. There are 159 documented invasive alien marine species causing 1,414 negative impacts on nature, and 72 invasive alien species causing 566 positive impacts. Some of the impacts could not be given a direction (**section 4.1.2**), for example impacts on abiotic ecosystem changes.

Impacted units of analysis

Most impacts of invasive alien species in the marine realm have been documented in shelf ecosystems (i.e., the shallow seafloor, between the shoreline and the shelf break, generally less than 200m in water depth; **Table 4.10**). The complex interactions among invasive alien populations and the host ecosystems (**Chapter 1**, **section 1.5**; **Boxes 4.3** and **4.5**), the functions they most often affect, the relationships between changes to ecosystems, communities, and populations, and the long-term responses of ecosystems to interactions with multiple anthropogenic activities, appear to offer insurmountable challenges in the marine realm, limiting the ability to assess the overall impact of invasive alien species on marine ecosystems (Fulton *et al.*, 2003).

Mechanisms of impacts

Marine invasive alien species have been shown to have differential impacts on native taxa within a biome, among different regions and ecosystems, from local extinction to food provision to rare and endangered species **(Box 4.11)**.

Table 4 10 **Number of impacts caused by invasive alien species in the marine realm.**

Box 4 11 ***Magallana gigas*** **(Pacific oyster) in European Seas.**

Magallana gigas (Pacific oyster; **Figure 4.22**) is the most widely cultivated and harvested shellfish species in Europe, with production totalling 142,000 tons, valued at 295 million euros (US$304 million) in 2007 (Miossec *et al.*, 2009). It is also a highly invasive ecosystem engineer, forming reefs on hard and soft bottoms, effecting large structural changes in littoral communities. In the Wadden Sea, *Magallana gigas* brought about a shift in dominance from mussels to oysters which entailed changes of associated organisms (Kochmann *et al.*, 2008). Yet, these complex structures provide habitat heterogeneity that can result in increased species richness, abundance, biomass, and diversity, and in the case of the Wadden Sea, replacing the ecological function of the native *Mytilus edulis* (common blue mussel) (Markert *et al.*, 2010). A field experiment revealed that epibenthic faunal abundance and biomass was higher on (dead) oyster shells than on live animals, both favouring fish and larger invertebrate species, likely to retain the changes to benthic community structure even in the case of mass mortalities (Norling *et al.*, 2015).

Figure 4 22 ***Magallana gigas*** **(Pacific oyster) reef, Sylt I., Germany, Wadden Sea.**

Photo credit: G. Nehls – CC BY 4.0.

Box 4 11

In the Bay of Mont-St.-Michel, France, extensive *Sabellaria alveolata* (honeycomb worm) reefs were damaged through trophic competition, increased silt deposition, and recreational oyster harvesting leading to trampling, breakage, and reef fragmentation (Desroy *et al.*, 2011). The proliferating *Magallana gigas* beds impacted on birds as well: Waser *et al.* (2016) found that the abundances of four bird species in the Dutch Wadden Sea, *Larus canus* (common gull), *Somateria mollissima* (common eider), *Haematopus ostralegus* (Eurasian oystercatcher), and *Calidris canutus* (red knot) were reduced where mussel beds were replaced with oyster beds, which the birds were unable to feed on. Herbert *et al.* (2018) noted that in southeast England, areas colonized by oysters were utilized by greater numbers of oystercatchers and *Numenius* spp. (curlews), but smaller numbers of smaller shorebirds. *Larus argentatus* (European herring gull), too were disadvantaged by the replacement of mussel beds with oyster beds (Markert *et al.*, 2013). Yet, *Larus argentatus* has soon adapted and adopted a shell-dropping behaviour utilizing pavements and parking lots (Cadée, 2001).

Magallana gigas have served as a major vector for introduction of algae, invertebrates and pathogens (Mineur *et al.*, 2007; Wolff & Reise, 2002). Mineur *et al.* (2014) list 48 species that have likely been introduced through the Pacific Northwest to Europe route, along with the oyster trade, including notorious invasive alien species such as *Codium fragile* (dead man's fingers), *Sargassum muticum* (wire weed), *Undaria pinnatifida* (Asian kelp), the sea squirts *Botrylloides violaceus* (violet tunicate), *Didemnum vexillum* (carpet seas quirt), and *Styela clava* (Asian tunicate). The intrahemocytic parasite *Bonamia ostreae*, protozoan parasite *Marteilia refringens*, the *Ostreid herpesvirus* (OsHV-1), and the two species of parasitic copepods *Mytilicola orientalis* (oyster redworm) and *Myicola ostreae* have all caused massive mortalities. Mineur *et al.* (2014) lay out a compelling case that the periodic disease outbreaks, affecting farmed *Magallana gigas* in Europe and causing major production disruptions and losses, originate in the massive imports of stock. Although providing relief to the industry in the immediate term, the translocations invariably introduce new disease agents.

Local extinctions caused by invasive alien species in the marine realm

Although the number of quantitative observational and experimental impact studies is limited, and most studies focus on sessile biota, shallow water and economically important species, marine invasive alien species have been documented as having significant impacts and causing local extinctions (**Table 4.11**; **Figure 4.23**). *Pterois volitans* (red lionfish) and *Caulerpa taxifolia* (killer algae) are listed among the top 10 invasive alien species that have been documented as causing most local extinctions globally (but see Albins, 2015; Bacheler *et al.*, 2022; Ballew *et al.*, 2016; Ingeman, 2016; Verlaque & Fritayre, 1994; **Table 4.11**).

In the marine realm, most documented local extinctions occur on the shallow shelf, and eight of the 10 invasive alien species causing them belong to the sessile biota: in descending order, *Caulerpa taxifolia* (killer algae), *Mytilus galloprovincialis* (Mediterranean mussel), *Caulerpa cylindracea* (green algae), *Pyura praeputialis* (cunjuvoi), *Halophila stipulacea* (halophila seagrass), *Womersleyella setacea* (red alga), *Carijoa riisei* (branched pipe coral), *Kappaphycus alvarezii* (elkhorn sea moss).

The sole exception in **Table 4.11** is *Pterois volitans* (red lionfish), a voracious piscivore denuding the vestigial reefs in the tropical west Atlantic, documented as causing significant reduction in density, biomass and species richness of small native reef fish (Albins, 2015).

Globally, in the marine realm, documented local extinctions through biofouling have been mostly caused by *Kappaphycus alvarezii* (elkhorn sea moss), *Carijoa riisei* (branched pipe coral), *Mytilopsis sallei* (Caribbean false mussel), *Polydora websteri* (mud blister worm), *Pyura praeputialis* (cunjuvoi), *Ciona intestinalis* (sea vase), *Didemnum* spp. (colonial tunicates), *Mytella strigata* (Charru mussel), and *Mytilus galloprovincialis* (Mediterranean mussel). Documented local extinctions through competition have been mostly caused by *Caulerpa cylindracea* (green algae), *Mytilus galloprovincialis* (Mediterranean mussel) and *Caulerpa taxifolia* (killer algae). Documented local extinctions through ecosystem change have been mostly caused by *Caulerpa cylindracea* (green algae), *Mytilus galloprovincialis* (Mediterranean mussel), *Pyura praeputialis* (cunjuvoi), *Eucheuma denticulatum* (eucheuma seaweed), *Womersleyella setacea* (red alga) and *Crepidula fornicata* (American slipper limpet). Documented local extinctions through herbivory have been mostly caused by *Carcinus maenas* (European shore crab), *Siganus* spp. (rabbitfish) and *Littorina littorea* (common periwinkle). Documented local extinctions through parasitism have been mostly caused by *Anguillicola crassus* (eel swimbladder nematode), *Haplosporidium nelsoni* (MSX oyster pathogen) and *Loxothylacus panopaei* (parasitic barnacle). Finally, documented local extinctions through toxicity have been mostly caused by *Caulerpa taxifolia* (killer algae) **(Figure 4.23)**.

eastern Asia, has been widely introduced with its native host *Anguilla japonica* (Japanese eel) for stocking and farming in Europe and North America. It is considered to have contributed to the collapse of the *Anguilla anguilla* (European eel) population. The parasite reduces endurance, while damage to the swimbladder impairs buoyancy control. High infection levels can reduce swimming performance, likely rendering the eels more susceptible to potting, predation, and hindering them from reaching their spawning grounds (Newbold *et al.*, 2015; Palstra *et al.*, 2007; Sjöberg *et al.*, 2009; Sprengel & Luchtenberg, 1991). Mass mortalities of wild eels infected with *Anguillicola crassus* in Lake Balaton, Hungary, as well as laboratory results, suggested that infected eels may have been more stressed than uninfected eels by the reduced oxygen levels under high water temperatures or increased concentrations of toxicants (Bálint *et al.*, 1997; Molnár, 1993; Molnár *et al.*, 1991).

Carcinus maenas (European shore crab), native to European and North African coasts, has invaded both coasts of North America, south-eastern America, southern Australia and South Africa. It has contributed to decline in native soft-shell clams, *Mya arenaria* (sand gaper), off north-eastern America, reducing its density, and inducing deeper burrowing (de Rivera *et al.*, 2011; Floyd & Williams, 2004; Whitlow, 2010). Mortality of small *Crassostrea virginica* (eastern oyster) was significantly higher in the presence of *Carcinus maenas* (Poirier *et al.*, 2017). Off central California, *Carcinus maenas* reduced the abundance of the native *Hemigrapsus oregonensis* (yellow shore crab), markedly decreased its body size and caused it to shift its habitat to the high intertidal zone (de Rivera *et al.*, 2011; Grosholz *et al.*, 2000). *Carcinus maenas*' predation on the Tasmanian *Katelysia scalarina* (sand cockle) reduced its population (Walton *et al.*, 2002). *Chondrus crispus* (carrageen), a unique strain of the red alga, found solely amongst clumps of *Mytilus edulis* (common blue mussel) in a coastal lagoon in Atlantic Canada, was wiped out coinciding with *Carcinus maenas* preying on the mussel (Yorio *et al.*, 2020). *Carcinus maenas* accounted for steep declines in in faunal organisms (Gregory & Quijón, 2011). *Zostera marina* (eelgrass) beds have been declining as a result of uprooting, grazing and cutting by *Carcinus maenas* (Garbary *et al.*, 2004; B. R. Howard *et al.*, 2019; Malyshev & Quijón, 2011; Matheson *et al.*, 2016).

Carijoa riisei (branched pipe coral), native to the Indo-Pacific, has spread to Hawaii and the western tropical Atlantic (Concepcion *et al.*, 2010; Grigg, 2003; Kahng & Grigg, 2005; Sánchez & Ballesteros, 2014). A large-scale survey (200 km^2) of Maui's black corals revealed that at depths between 75 and 110 m up to 90 per cent of the colonies of *Antipathes dichotoma* (black coral) and *Antipathes grandis* (Pine coral) are dead, having been overgrown by *Carijoa*

Figure 4 23 **Examples of marine invasive alien species causing local extinctions of native species.**

Pterois volitans (red lionfish, top left), *Caulerpa* sp. (top right), *Mytilus galloprovincialis* (Mediterranean mussel, bottom left), *Carcinus maenas* (European shore crab, bottom right). Photo credits: plus69, Adobe Stock – Copyright (top left) / Coughdrop12, WM Commons – CC BY-SA 4.0 (top right) / Peter Southwood, WM Commons – CC BY-SA 4.0 (bottom left) / Nicolás Battini – CC BY 4.0 (bottom right).

riisei (Grigg, 2003). It also fouls *Myriopathes* spp. (feathery black corals) and *Leptoseris* spp. (scleractinian plate corals) (Kahng, 2007; Kahng & Grigg, 2005). In the tropical eastern Pacific, *Carijoa riisei* overgrew *Pacifigorgia* seafans and *Leptogorgia* seawhips, caused community-wide octocoral mortalities, and the local extinction of some *Muricea* spp. (seafans; Sánchez & Ballesteros, 2014).

Caulerpa cylindracea (green algae), native to Australia, was first documented in the Mediterranean in the early 1990s, where it soon spread throughout the sea, forming dense meadows. The alga modifies habitat structure in terms of repartition of the available substrate (i.e., enhancing sediment accumulation, favours algal turfs over erect algal forms and enables them to monopolize space) (Bulleri *et al.*, 2010). Such changes affect the associated invertebrate assemblages, algae-native species richness, cover and diversity decreased (Baldacconi & Corriero, 2009; Bulleri & Piazzi, 2015; Klein & Verlaque, 2009; Piazzi, Balata, & Cinelli, 2007; Piazzi, Balata, Foresi, *et al.*, 2007; Piazzi *et al.*, 2001; Vázquez-Luis *et al.*, 2008). The effects of the colonization persist after the removal of the alga and the recovery of the assemblages appears to be quite slow: species numbers, total cover and erect perennial species cover were significantly lower than in the non-invaded plots 18 months after removal and exclusion of *Caulerpa cylindracea* (Klein & Verlaque, 2011; Piazzi & Ceccherelli, 2006).

Caulerpa taxifolia (killer algae) is a green alga native to tropical Australia. Since the 1980s, a cold-resistant clone has become notorious for high profile invasions in the Mediterranean, and in California, United States and Australia in the 2000s. The mat-forming invasive form of *Caulerpa taxifolia* grows rapidly, smothers seagrass beds and other benthos, replacing native macroalgal and seagrass communities. It causes a decrease in number, width, longevity of leaves, chlorosis and necrosis, and finally death of shoots of the native *Posidonia oceanica* (Neptune grass) in the Mediterranean. Furthermore, seagrass beds have never recovered their initial density, even after the decrease in *Caulerpa taxifolia* (de Villèle & Verlaque, 1995; Dumay *et al.*, 2002; Molenaar *et al.*, 2009). In Australia, canopy covers of *Posidonia australis* (fibreball weed) and *Zostera capricorni* (garweed) were significantly reduced (Glasby, 2013). Invertebrate assemblages (e.g., Anomura, Peracarida, Decapoda, Echinoidea, Bivalvia and Gastropoda) declined (Francour *et al.*, 2009), but *Caulerpa taxifolia* promotes an overall increase in nematode species richness by favouring species that were absent from the native environments (Gallucci *et al.*, 2012). The density of fish such as the commercially important *Mullus surmuletus* (red mullet) has declined, compared to native seagrass meadows (Harmelin-Vivien *et al.*, 1996; Levi & Francour, 2004).

Cercopagis pengoi (fishhook waterflea), a planktonic cladoceran crustacean native to the Ponto-Aralo-Caspian Basin, has spread to the Baltic Sea. It is a voracious predator that markedly reduces the density of its prey (cladocerans, copepods) (Lehtiniemi & Gorokhova, 2008; Ojaveer *et al.*, 2004; Põllumäe & Kotta, 2007). The population of the native cladoceran *Bosmina (Eubosmina) coregoni* (large long-nosed waterflea) has significantly declined after the invasion (Kotta *et al.*, 2006). The reduction in zooplankton abundance may result in higher concentrations of phytoplankton (owing to reduced grazing by zooplankton), and may ultimately aggravate problems of eutrophication. Yet, *Cercopagis pengoi* has become an important food item for the three-spined and nine-spined sticklebacks, herring, sprat, and smelt (Antsulevich & Välipakka, 2000; Gorokhova *et al.*, 2004; Ojaveer *et al.*, 2004; Ojaveer & Lumberg, 1995).

Crepidula fornicata (American slipper limpet), native to the Atlantic coast of North America, has unintentionally been introduced to the Pacific coast as well as to Europe with American oysters, and has spread throughout the Atlantic coast. *Crepidula fornicata* reduces growth and increases mortality of fouled commercially important *Mytilus edulis* (common blue mussel; Thieltges, 2005a; Thieltges & Buschbaum, 2007). Yet, it reduces the infection success of cercariae and thus their parasite load (Thieltges *et al.*, 2009), and reduces *Asterias rubens* (common starfish) predation (Thieltges, 2005b). Dense reef-like populations fundamentally alter the physical and chemical composition of the sediment when forming a novel substrate for sessile invertebrates (i.e., ascidians, tubicolous worms, bivalves) and shelters vagile invertebrates, at the loss of the infauna, deterred by the putrid biodeposits (Blanchard, 2009). Even at a moderate presence of *Crepidula fornicata*, species composition differs from the composition in its absence (de Montaudouin & Sauriau, 1999; Vallet *et al.*, 2001). Accumulated shell debris also reduces suitable habitat for commercially valuable native flatfish (Kostecki *et al.*, 2011; Le Pape *et al.*, 2004).

Didemnum vexillum (carpet sea squirt), native to Japan, is a colonial tunicate species, widely introduced in temperate cold seas. Its massive encrusting mats, over-growing sessile biota, natural and man-made hard substrates, outcompetes other tunicates, hydroids, seaweeds, sponges, bivalves, and reduces areas suitable for settlement (Bullard *et al.*, 2007; Lengyel, 2009; Valentine, Carman, *et al.*, 2007; Valentine, Collie, *et al.*, 2007). Fouled mussels and oysters have decreased growth rates and lower condition index; the swimming ability of fouled *Placopecten magellanicus* (Atlantic deep-sea scallop) is reduced, limiting their ability to escape predation and access food-rich habitats, thus affecting their survival (Dijkstra & Nolan, 2011; Kaplan *et al.*, 2017). *Didemnum vexillum* fouling result in economic losses due to direct impact on biomass of farmed species, equipment and trade restrictions (Fletcher *et al.*, 2013).

Eucheuma denticulatum (eucheuma seaweed), a red alga native to the tropical western Pacific, has been widely introduced for cultivation as one of the primary sources of carrageenan. *Eucheuma denticulatum* spread from farms into the surrounding ecosystems, overgrows and outcompetes reef-building corals, reduces seagrass beds, macroalgae, abundance and biomass of macrofauna, as well as on the benthic microbial processes and meiofauna populations. These modifications are apparent in the significant difference in the catch composition, trophic groups and diet of fish collected on coral, seagrass, sand and seaweed farms (Eggertsen *et al.*, 2021; Eklöf *et al.*, 2005, 2006; Johnstone & Olafsson, 1995; Kelly *et al.*, 2020; Ólafsson *et al.*, 1995; Tano *et al.*, 2015; Yahya *et al.*, 2020).

Halophila stipulacea (halophila seagrass), native to the Red Sea, Persian Gulf and Indian Ocean, has spread to the Mediterranean and Caribbean seas, where it forms extensive monospecific mat-forming meadows. It has displaced the native seagrasses *Syringodium filiforme* (manatee grass), *Halodule wrightii* (shoalweed), and *Halophila decipiens* (Caribbean seagrass) off Dominica, Lesser Antilles, and *Thalassia testudinum* (turtle grass) in Bonaire (Muthukrishnan *et al.*, 2020; Smulders *et al.*, 2017; Steiner & Willette, 2013, 2015). Continued invasion and subsequent loss of native seagrasses reduce key juvenile fish habitats in the Virgin Islands, United States (Olinger *et al.*, 2017). Fish, as well the native sea urchin, *Tripneustes ventricosus* (white urchin), were twice as abundant in meadows of *Thalassia testudinum* as in *Halophila stipulacea* in Bonaire and the Grenadines, respectively (Becking *et al.*, 2014; Scheibling *et al.*, 2018). Similarly, in the Mediterranean, *Halophila stipulacea* displaced the native *Cymodocea nodosa* (slender seagrass; Sghaier *et al.*, 2014), and the epiphytic assemblages on the latter were more abundant and more diversified (Mabrouk *et al.*, 2021).

Kappaphycus alvarezii (elkhorn sea moss), a red alga native to Southeast Asia, has been widely introduced for cultivation as one of the primary sources of carrageenan. In the Gulf of Manaar, India, it has been documented as shadowing and smothering corals, seagrass, sponges and thus affecting the diverse reef-associated fauna (Chandrasekaran *et al.*, 2008; Kamalakannan *et al.*, 2010, 2014; Patterson *et al.*, 2015; Patterson & Bhatt, 2012; Rameshkumar & Rajaram, 2017). Similar impacts have been noted in Venezuela and Panama (Barrios *et al.*, 2007; Sellers *et al.*, 2015). Studies in Hawaii suggest shading by thalli may result in coral death, but these thalli provide substrate for sessile invertebrates (ascidians, sponges) and shelter for holothurians and reef fishes (D. J. Russell, 1983).

Loxothylacus panopaei, a parasitic barnacle native to the Gulf of Mexico and Caribbean Sea, has spread along eastern North America, where it infects the native *Eurypanopeus depressus* (flatback mud crab). Prevalence of infection may reach upwards of 90 per cent in the invaded range (Hines *et al.*, 1997). The parasitic barnacle induces significant behavioural changes, such as reducing mud crab activity, influencing predator-prey relationships, enhancing hiding behaviours and changes in habitat usage in infected crabs. Moreover, infection results in castration of both male and female crabs (Belgrad & Griffen, 2015; Brothers & Blakeslee, 2021; Gehman & Byers, 2017; Toscano *et al.*, 2014).

Mnemiopsis leidyi (sea walnut), native to western Atlantic coastal waters, has spread to European waters (Black Sea, Caspian Sea, Mediterranean, North and Baltic Seas). The earliest records of *Mnemiopsis leidyi* in the Black Sea documented a decrease in mesozooplankton abundance and biomass, changes in diet composition of small pelagic fish, with concomitant reduction in planktivorous fishes (e.g., *Engraulis encrasicolus* (European anchovy)), their eggs and larvae (Finenko *et al.*, 2013, 2015, 2018; Petran & Moldoveanu, 1995; Shiganova, 1997, 1998; Shiganova *et al.*, 2003; Shiganova & Bulgakova, 2000), which were reversed, wholly or partially when *Beroe ovata* (ovate comb jelly), an invasive predator of *Mnemiopsis leidyi*, reduced its population (Finenko *et al.*, 2018; Kamburska *et al.*, 2003; Shiganova *et al.*, 2003). The single study conducted in the Mediterranean Sea documented significant differences in zooplankton abundance in the zooplankton community structure (Fiori *et al.*, 2019). Fearing an outbreak of *Mnemiopsis leidyi* similar to that which had occurred in the Black Sea motivated studies in the North and Baltic Seas (Riisgård *et al.*, 2007). Some studies documented it severely depressed mesozooplankton stocks and influenced bacterioplankton activity and community composition in the vicinity of the jellyfish (Dinasquet *et al.*, 2012; Riisgård *et al.*, 2012). Yet, subsequent studies concluded *Mnemiopsis leidyi* exerted low or no direct predatory pressure on the ecologically important mesozooplankton and ichthyoplankton species and posed no threat to eggs and larvae of commercially important fish such as *Gadus morhua* (Atlantic cod), *Clupea harengus* (Atlantic herring), and *Sprattus sprattus* (European sprat) (Hamer *et al.*, 2011; Jaspers *et al.*, 2011; Javidpour *et al.*, 2009; Kellnreitner *et al.*, 2013; Schaber *et al.*, 2011).

Mytilus galloprovincialis (Mediterranean mussel), native to the Mediterranean and the eastern Atlantic, has been widely introduced both intentionally for cultivation and unintentionally. It is an ecosystem engineer, and dominates wave-exposed rocky shores, increasing invertebrate density and species richness, and changing community composition (Branch *et al.*, 2010; Griffiths *et al.*, 1992; Hanekom & Nel, 2002; T. B. Robinson *et al.*, 2007; T. B. Robinson & Griffiths, 2002). *Mytilus galloprovincialis* has replaced open rocky habitat with complex mussel beds, displacing the native *Choromytilus meridionalis* (black mussel) and native *Scutellastra argenvillei* (Argenville's limpet), but increasing the abundance of *Aulacomya atra* (ribbed mussel) and *Scutellastra granularis* (granular limpet) that now occur within the *Mytilus* beds (Hanekom, 2008; Hanekom & Nel, 2002; Hockey & van Erkom Schurink, 1992; Sadchatheeswaran *et al.*, 2015; Sebastián *et al.*, 2002; Steffani & Branch, 2005). Settling on kelp fronds, *Mytilus galloprovincialis* reduces kelp buoyancy and increases hydrodynamic drag, facilitating uprooting (Lindberg *et al.*, 2020). Its extensive beds provide food for the rare and endangered *Haematopus moquini* (African oystercatcher; Branch & Steffani, 2004; Coleman & Hockey, 2008). In the northeast and northwest Pacific *Mytilus galloprovincialis* has extensively hybridized with *Mytilus trossulus* (northern bay mussel). On the west coast of the United States, hybrids are rare but more frequent near ports and mussel farms (Braby & Somero, 2006; Crego-Prieto *et al.*, 2015; Heath *et al.*, 1995; Rawson *et al.*, 1999; Shields *et al.*, 2010). The hybrid zone in the northwest Pacific runs from the Vladivostok area, Russia, to northern Japan (Brannock & Hilbish, 2010; Skurikhina *et al.*, 2001; Suchanek *et al.*, 1997). Hybridization has also been observed between native southern hemisphere *Mytilus galloprovincialis* and introduced Northeast Atlantic lineages near ports in New Zealand (Gardner *et al.*, 2016).

Pterois volitans (red lionfish), a voracious predator native to the Indo Pacific, has spread to the tropical and subtropical western Atlantic and Caribbean. Its invasion has had significant negative impacts on shallow coral reef fish populations, comprising severe reductions in recruitment, total density, biomass, and species richness of prey-sized fishes, both herbivorous and piscivores (Albins, 2015; Albins & Hixon, 2008; Ingeman, 2016). A shift to an algal dominated community occurred simultaneously with the loss of herbivores, resulting in a decline in corals and sponges at mesophotic depths (Kindinger & Albins, 2017; Lesser & Slattery, 2011). By foraging away from their patch reefs residence, *Pterois volitans* eliminate a spatial refuge from predation used by juveniles of many commercially and ecologically important reef fishes (Benkwitt, 2016; DeRoy *et al.*, 2020).

Pyura praeputialis (cunjuvoi), a solitary tunicate native to Australia, has spread to Chile where it monopolized the low and mid-low rocky intertidal and restricted the native mussel *Perumytilus purpuratus* (purple mussel) to the mid-upper fringe (Caro *et al.*, 2011; Castilla *et al.*, 2004).

Semimytilus patagonicus (bisexual mussel), a mytilid mussel native to the Pacific coast of South America, has spread to southwestern Africa (de Greef *et al.*, 2013; Ma *et al.*, 2020). On rocky, wave-exposed shores *Semimytilus patagonicus* competitively excluded co-occurring mussel species on the low-shore and native species (*Aulacomya atra* (ribbed mussel), *Choromytilus meridionalis* (black mussel)) in the mid-shore, displacing the latter to sublittoral and sand-inundated habitats (Sadchatheeswaran *et al.*, 2015; Skein *et al.*, 2018).

Womersleyella setacea is a turf-forming red alga introduced into the Mediterranean Sea. It has invaded areas where several turf species were absent or evinced lower cover values (Piazzi, Balata, & Cinelli, 2007), causing changes to biodiversity and cover of the epiphytic assemblage of *Posidonia oceanica* (Neptune grass), a species that is endemic to the Mediterranean Sea (Antolić *et al.*, 2008). Some sponge species overgrown by the *Womersleyella setacea* were unable to reproduce, others significantly reduced their reproductive effort (de Caralt & Cebrian, 2013). Following its introduction, colonies of the Mediterranean gorgonian *Paramuricea clavata* (chameleon sea fan), an important structural species in coralligenous assemblages, demonstrated lower survivorship of juvenile colonies, higher necrosis rates and lower biomass (Cebrian *et al.*, 2012).

4.3.3 Documented impacts of invasive alien species on nature by region and taxonomic group

The number of documented negative and positive impacts on nature by invasive alien species varies greatly across regions **(Table 4.12)**.

Negative impacts of invasive alien species across regions

In most regions, plants generally have the greatest number of invasive alien species causing negative impacts **(Table 4.12A)**, except in the Americas, where a large number of invasive alien invertebrates have caused local extinctions (**Table 4.12C**; 41 species), and in Asia-Pacific, where a large number of local extinctions have been caused by invasive alien vertebrates (**Table 4.12B**; 339 documented impacts). *Felis catus* (cat) is responsible for the greatest number of documented local extinctions across all regions (108 records), but mostly in the Asia-Pacific region **(Box 4.11)** and on the Galapagos Islands. Microbes generally have the lowest number of documented impacts across all regions, mostly causing population declines in Europe and Central Asia (**Table 4.12D**; 142 records). The microbe species with the greatest number of documented negative impacts is the oomycete plant pathogen, *Phytophthora ramorum* (38 records), which is known to cause the sudden oak death disease.

Positive impacts of invasive alien species across regions

Positive impacts have been documented in all regions, but the number of invasive alien species with positive impacts (361 species) is substantially lower than the number of species with negative impacts (1623 species). The number of invasive alien plants in the Americas have been documented to be the largest number of invasive alien species with positive impacts, globally (**Table 4.12A**; 109 species). Invasive alien plants in Europe and Central Asia have been documented to cause the greatest number of positive impacts, globally (**Table 4.12A**; 406 records).

The invasive alien plant with the greatest documented number of positive impacts on nature is *Robinia pseudoacacia* (black locust; 55 records), often resulting in increase in abundance and richness of native pollinators attracted to the abundant production of nectar by this alien plant. *Robinia pseudoacacia* (black locust) also has 44 documented negative impacts on nature (Vítková *et al.*, 2017).

Dreissena polymorpha (zebra mussel) is the invasive alien species with the greatest number of positive documented impacts on native species (143 impacts). *Dreissena polymorpha* has positive impacts on a wide range of native species, mostly invertebrates, through water filtering, thereby changing water chemistry and turbidity, which in turn favours littoral invertebrate communities, but disfavours planktonic communities (Strayer, 2009). *Dreissena polymorpha* is also in the top ten invasive alien invertebrate species causing negative impacts (85 records), and the nature of the invasion by the species (particularly in North America) and the conflicting interpretation of its impacts has been well documented (Strayer, 2009).

Native species impacted by invasive alien species across regions

Native plant species are generally the most often negatively affected taxa across all regions. However the large number of local extinctions of native vertebrates in Asia-Pacific (**Table 4.13B**; 284 records) and of native invertebrate species in the Americas and Asia-Pacific regions **(Table 4.13C)** constitute exceptions to this general pattern. *Linepithema humile* (Argentine ant) has been documented to cause the greatest number of local extinctions of

Table 4 12 **Number of invasive alien species causing positive and negative impacts on nature by region.**

The number of plants A), vertebrates B), invertebrates C), microbes D) causing negative and positive impacts by region and by taxa. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

A) Plants: Number of invasive alien species (number of impacts)

Region	Negative impacts caused by invasive alien plants				Positive impacts
	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	
Africa	131 (576)	83 (153)	65 (184)	8 (31)	10 (28)
Americas	408 (2494)	151 (393)	196 (727)	21 (48)	109 (337)
Asia-Pacific	246 (1034)	182 (364)	109 (307)	19 (52)	42 (103)
Europe and Central Asia	129 (3767)	47 (174)	103 (805)	12 (55)	46 (406)
Antarctica		1 (1)			

B) Vertebrates: Number of invasive alien species (number of impacts)

Region	Negative impacts caused by vertebrates				Positive impacts
	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	
Africa	37 (132)	37 (93)	31 (107)	13 (45)	2 (3)
Americas	49 (576)	101 (313)	60 (360)	30 (196)	17 (45)
Asia-Pacific	139 (1589)	117 (505)	92 (620)	37 (339)	21 (58)
Europe and Central Asia	31 (138)	76 (222)	39 (92)	22 (39)	5 (11)
Antarctica	1 (4)		1 (2)		1 (1)

C) Invertebrates: Number of invasive alien species (number of impacts)

Region	Negative impacts caused by vertebrates				Positive impacts
	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	
Africa	67 (397)	30 (58)	8 (45)	6 (39)	4 (37)
Americas	241 (1046)	81 (451)	86 (407)	41 (154)	37 (400)
Asia-Pacific	92 (522)	75 (212)	67 (176)	26 (117)	25 (57)
Europe and Central Asia	237 (1196)	43 (150)	45 (226)	25 (83)	34 (169)

D) Microbes: Number of invasive alien species (number of impacts)

Region	Negative impacts by microbes				Positive impacts
	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	
Africa	23 (45)	1 (1)			
Americas	26 (125)	4 (9)	17 (58)	4 (10)	2 (3)
Asia-Pacific	11 (18)	11 (15)	9 (17)	3 (4)	
Europe and Central Asia	16 (189)	7 (44)	12 (142)	1 (1)	1 (1)

native invertebrate species across all regions, mostly by outcompeting native ants, but also through predation on native invertebrates. Native microbes generally have the lowest number of documented impacts by invasive alien species across all regions, with the highest number of negative impacts being native microbe population declines in Europe and Central Asia (**Table 4.13D**; 24 records). The perennial woody shrub *Rosa rugosa* (rugosa rose) has caused the greatest number of documented population declines in native microbes (5 records), through changes in soil chemistry, particularly in coastal dune habitats (Stefanowicz *et al.*, 2019).

Table 4 13 **Number of invasive alien species causing impacts on native taxa by region.**

The number of invasive alien species impacting A) native plants, B) vertebrates, C) invertebrates and D) microbes and the number of documented impacts (in brackets) in each region. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

A) Number of invasive alien species impacting native plants (number of impacts)

Region	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	Positive impacts
Africa	203 (610)	103 (159)	68 (99)	8 (8)	1 (2)
Americas	496 (1554)	187 (397)	240 (675)	28 (81)	76 (130)
Asia-Pacific	287 (884)	232 (478)	134 (320)	27 (64)	16 (20)
Europe and Central Asia	269 (2030)	67 (216)	114 (620)	22 (58)	11 (30)

B) Number of invasive alien species impacting native vertebrates (number of impacts)

Region	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	Positive impacts
Africa	87 (209)	37 (67)	68 (112)	10 (38)	6 (19)
Americas	124 (679)	98 (310)	90 (383)	32 (142)	36 (93)
Asia-Pacific	169 (1189)	111 (356)	105 (469)	35 (284)	40 (89)
Europe and Central Asia	53 (293)	70 (188)	51 (114)	17 (28)	19 (71)
Antarctica	1(4)		1 (2)		1 (1)

C) Number of invasive alien species impacting native invertebrates (number of impacts)

Region	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	Positive impacts
Africa	55 (171)	24 (29)	38 (87)	10 (37)	12 (41)
Americas	225 (996)	109 (329)	110 (379)	44 (162)	58 (439)
Asia-Pacific	123 (532)	73 (161)	89 (257)	36 (154)	36 (81)
Europe and Central Asia	159 (1501)	64 (139)	90 (477)	24 (86)	34 (180)
Antarctica		1 (1)			

D) Number of invasive alien species impacting native microbes (number of impacts)

Region	Ecosystem impacts	Impacts on individuals	Population declines	Local extinction	Positive impacts
Africa	4 (4)	1 (1)			
Americas	37 (83)	12 (21)	12 (16)	2 (4)	8 (14)
Asia-Pacific	15 (27)	3 (4)	11 (13)	1 (1)	6 (9)
Europe and Central Asia	25 (140)		9 (24)		7 (10)

Box 4 12 Impacts of fox and cat predation in Australia.

Multiple studies have established that *Felis catus* (cat) and *Vulpes vulpes* (red fox) have had particularly significant impacts on, and continue to threaten, many native Australian vertebrate species (Doherty *et al.*, 2016; Hunter *et al.*, 2018; Radford *et al.*, 2018; Saunders *et al.*, 2010; Woinarski *et al.*, 2015). *Vulpes vulpes* has been shown to suppress populations of *Petrogale lateralis* (black-footed rock-wallaby; Kinnear *et al.*, 1988, 1998; **Figure 4.24**), *Dasyurus geoffroii* (western quoll; Morris *et al.*, 2003), ground-dwelling and arboreal mammals (Hunter *et al.*, 2018), medium-sized marsupials (Dexter & Murray, 2009), and even large species such as *Macropus giganteus* (eastern grey kangaroo; Banks *et al.*, 2000). When not controlled, *Vulpes vulpes* also reduce abundance of *Varanus gouldii* (sand goanna), diurnal scincid lizards (Olsson *et al.*, 2005), and *Varanus varius* (lace monitor; Hu *et al.*, 2019), and can destroy turtle nests, severely impacting their populations (R.-J. Spencer *et al.*, 2006; Limpus & Reimer, 1994). *Vulpes vulpes* have also been implicated in colonial seabird (Norman, 1971), *Leipoa ocellata* (malleefowl; Wheeler & Priddel, 2009; S. L. Williams, 1995), and ground-foraging passerine declines (Ford *et al.*, 2001).

Felis catus is currently considered the single most significant threat to Australian mammals (Frank *et al.*, 2014; Woinarski *et al.*, 2015). Indeed, *Felis catus* has been implicated in approximately two thirds of Australian native mammal extinctions, and another 54 native mammal taxa have suffered severe range contractions and are seriously threatened by cat predation. *Felis catus* caused local extirpation of a native rodent, *Rattus villosissimus* (long-haired rat) in a Northern Territory tropical savanna (Frank *et al.*, 2014), and has been identified as a factor contributing to northern Australian mammal declines (Woinarski *et al.*, 2011; D. O. Fisher *et al.*, 2014). Davies *et al.* (2017) demonstrated that *Felis catus* predation on threatened *Conilurus penicillatus* (brush-tailed rabbit-rat) is driving the remnant population to extinction on Melville Island, suggesting that predation has likely been a significant driver of *Conilurus penicillatus* decline throughout northern Australia **(Figure 4.24)**. Additionally, predation of juvenile *Dasyurus viverrinus* (eastern quoll) by *Felis catus* is likely inhibiting recovery of low-density quoll populations across Tasmania (Fancourt *et al.*, 2015).

Figure 4 24 **Examples of native species with serious population declines due to invasive alien species.**

Petrogale lateralis (black-footed rock-wallaby, left), *Leipoa ocellata* (malleefowl, middle), *Conilurus penicillatus* (brush-tailed rabbit rat, right). Photo credit: Kym Nicolson, WM Commons – CC BY 4.0 (left) / butupa, WM Commons – CC BY 2.0 (middle) / Hugh Davies – CC BY 4.0 (right).

There is clear evidence to implicate predation by *Felis catus* in the loss of wildlife populations at a local and regional scale, but the contribution of *Felis catus* predation to Australian extinctions or extirpations is hard to disentangle from confounding other threats such as habitat clearance, changing fire regimes, and other feral vertebrates. On offshore islands, where confounding factors are less severe, *Felis catus* have been shown to decimate native fauna (D. C. Duffy & Capece, 2012). Predation has caused the extinction of *Cyanoramphus novaezelandiae erythroti* (Macquarie Island Parakeet; R. H. Taylor, 1979), *Traversia lyalli* (Stephens Island wren; Galbreath, 2004), and the extirpation from Marion Island of *Pelecanoides urinatrix* (common diving petrel; Bloomer & Bester, 1991; Cooper *et al.*, 1995).

In addition to direct extinction of species, *Felis catus* predation can have significant knock-on effects at the ecosystem level, through alteration of ecosystem functioning. The local extinction of fossorial mammals (i.e., those that dig burrows underground), in Australian arid and semi-arid regions (Tuft *et al.*, 2021; Doherty *et al.*, 2017) has caused a loss of key soil-engineering processes, negatively impacting associated plant communities (James & Eldridge, 2007; Eldridge & James, 2009; James *et al.*, 2011).

4.4 IMPACTS OF BIOLOGICAL INVASIONS ON NATURE'S CONTRIBUTIONS TO PEOPLE

4.4.1 General patterns

Globally, the impact database collected through this chapter contains 6,211 impacts of invasive alien species on nature's contributions to people. The economic costs of invasive alien species are presented in **Box 4.13**. Impacts on nature's contributions to people can be negative or positive (**section 4.1.2**); they are considered negative when humans are harmed and positive when humans benefit from changes in nature's contributions to people by invasive alien species. In total, there is evidence of 4,905 negative impacts (78.9 per cent of all impacts on nature's contributions to people) caused by 1,337 invasive alien species on all nature's contributions to people categories, indicating the multiplicity of impacts that invasive alien species can have beyond nature (Vilà *et al.*, 2010). There are also 421 invasive alien species that have caused 1306 positive impacts (20.8% of all impacts on nature's contributions to people; **Figure 4.28**).

Box 4 13 The economic costs of biological invasions.

There are many case studies of economic costs of biological invasions worldwide (Dana *et al.*, 2014; Diagne, Leroy, *et al.*, 2020). As a result, these costs display a very high degree of heterogeneity (e.g., nature, origin, type, implementation, estimation approach, spatial and temporal scales) and lack standardized methods that would have allowed relevant compilations and comparisons, which in turn may provide key insights for management actions (Diagne, Catford, *et al.*, 2020). In addition, as costs are most often provided at the local scale, global estimations are very scarce while biological invasions still remain an increasingly planet-wide issue (Diagne, Catford, *et al.*, 2020; Diagne, Leroy, *et al.*, 2021; Latombe *et al.*, 2017; Pagad *et al.*, 2018). Consequently, the only global figures available up to recently were based on a handful of studies that used crude extrapolations from individual estimations (Kettunen *et al.*, 2009; Pimentel *et al.*, 2001), much criticized by ecologists and economists alike (e.g., Bradshaw *et al.*, 2016; Hoffmann & Broadhurst, 2016; T. P. Holmes *et al.*, 2009). Yet, these pioneer studies had the merit to suggest very high economic costs, and then trigger more robust assessments on many taxa or regions, as well as some more robust, global estimates, for example on a given economy sector (Paini *et al.*, 2016). Recently, the InvaCost project[4] has compiled a wealth of individual cost estimates in a public and updatable database and has devised a standardized method of calculating economic costs of biological invasions (Diagne, Leroy, *et al.*, 2020). This allows many comprehensive analyses of this particular dimension of impacts of biological invasions (Diagne, Catford, *et al.*, 2020).

The main results of these analyses (see Diagne, Leroy, *et al.*, 2021 for the very first analysis) are that (i) the global economic costs of biological invasions over the last 50 years (1970-2019) are massive, at least US$1,738 billion[5] if only the most robust data are taken into account **(Figure 4.26)**; (ii) these costs are increasing exponentially with a four-fold increase each decade[6] **(Figure 4.25)**; (iii) being based on already published and collated studies, the costs are massively underestimated (for example, currently occurring costs are not yet documented for most economically harmful invasive alien species and invaded countries) and (iv) management expenditures represent a very small fraction of the total costs, with damage cost recently shown to constitute 92 per cent of the total cost estimated (Cuthbert *et al.*, 2022). In 2017 alone, aggregate global invasive alien species invasion costs were estimated to reach until US$162.7 billion, exceeding the 2017 gross domestic product (GDP) of 52 of the 54 countries on the African continent, and more than twenty times higher than the combined total funds available in 2017 for the World Health Organization (WHO) and the United Nations (Diagne, Leroy, *et al.*, 2021). Applying a similar method (Leroy *et al.*, 2022) to the most up-to-date version of InvaCost (at the time of writing this report) has led to an upper prediction of US$423.3 billion for the year 2019.[7]

There are now a number of published analyses from this database. For now, they are mostly descriptive and synthesize economic costs of invasions in different regions of the world or from different invasive alien taxonomic groups. Studies with a geographical focus have shown that reported costs are more important in some regions, such as North America (Crystal-Ornelas *et al.*, 2021) and Asia (Liu *et al.*, 2021), and less so in regions such as Europe (Haubrock, Turbelin, *et al.*, 2021), Africa (Diagne, Turbelin, *et al.*, 2021) and South and Central America (Heringer *et al.*, 2021), most probably due to knowledge gaps. Studies have also been conducted at the country level: in Argentina (Duboscq-Carra *et al.*, 2021), Australia (Bradshaw *et al.*, 2021), Brazil (Adelino *et al.*, 2021), Canada (Vyn, 2022), Ecuador (Ballesteros-Mejia *et al.*, 2021), France (Renault *et al.*, 2021), Germany (Haubrock, Cuthbert, Sundermann, *et al.*, 2021), India (Bang *et al.*, 2022), Japan (Watari *et al.*, 2021),

Box 4 13

Mexico (Rico-Sánchez *et al.*, 2021), New Zealand (Bodey *et al.*, 2022), Russia (Kirichenko *et al.*, 2021), Singapore (Haubrock, Cuthbert, Yeo, *et al.*, 2021), Spain (Angulo, Ballesteros-Mejia, *et al.*, 2021) the United Kingdom (Cuthbert, Bartlett, *et al.*, 2021) and in the United States (Fantle-Lepczyk *et al.*, 2021). Interestingly, the large number of countries already surveyed show both commonalities (such as high, underestimated and increasing costs) and specificities (such as the costliest species, the most impacted sectors or the proportion of management expenditures *versus* damage costs).

Studies focusing on the economic impact of particular taxonomic groups are fewer for now, mostly due to a lack of reported costs in the literature, but the following have sufficiently high cost data to have warranted dedicated studies: fishes (Haubrock *et al.*, 2022), bivalves (Haubrock, Cuthberg, *et al.*, 2021), crayfishes and crabs (Kouba *et al.*, 2021), terrestrial invertebrates (Renault *et al.*, 2022), aquatic species (Cuthbert, Pattison, *et al.*, 2021), or ants (Angulo *et al.*, 2022). As cost data accumulate, other syntheses are being prepared.

Because InvaCost is a living database, it is regularly being updated, and published studies based on it may refer to earlier versions, with actual costs having increased since then. For this reason, a "living figure", directly linked to the latest version of the database and automatically updated, is available online (Leroy *et al.*, 2021). In addition, different studies have used different strategies regarding the filtering steps of their dataset processing. As a consequence, cost estimates highlighted in those studies may not necessarily be comparable. For example, most (but not all) studies focused on "observed" costs and those classified as "highly reliable" from a methodological point of view **(Figure 4.26)**. As a result, all the cost estimates provided should be considered as relative orders of magnitude, which remains a good indication of both the reported costs and the knowledge gaps.

From the living cost figure, in which all costs filters are identical, and which therefore allows meaningful comparisons, one can assess the costliest invasive alien species and the most impacted invaded regions, as they are currently reported in the literature **(Figure 4.27)**.

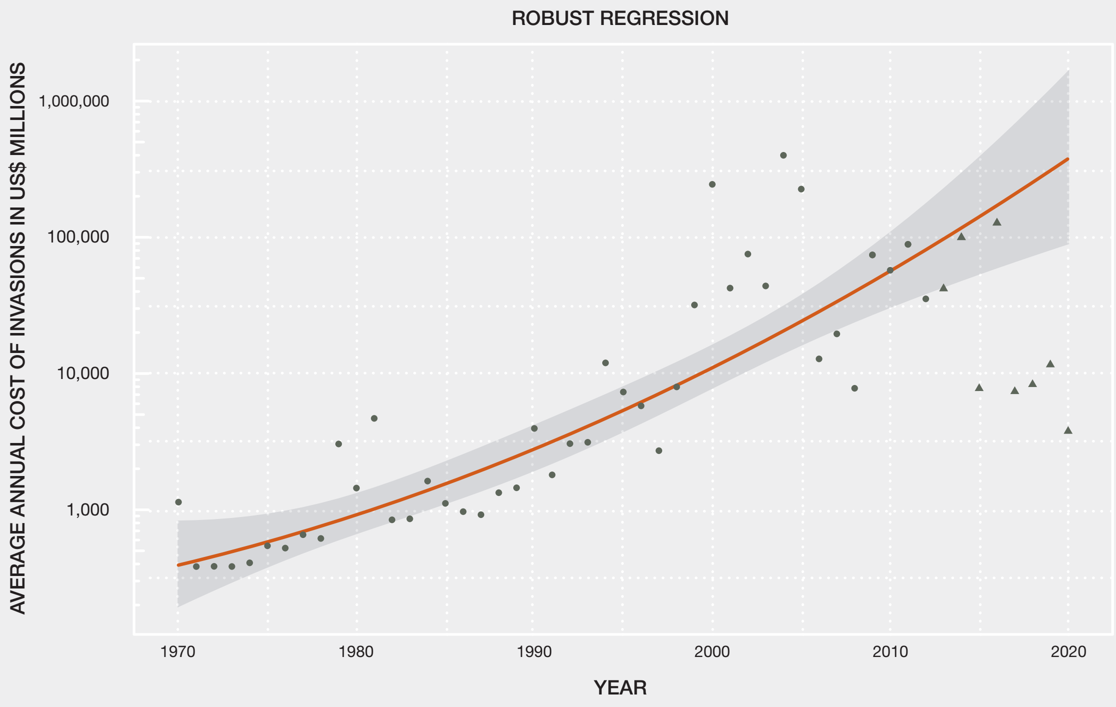

Figure 4 25 **Temporal trend of global invasion costs (in millions of 2017 US$) between 1970 and 2019.**

A model prediction approach based on an Ordinary Least Square (OLS) regression was used in order to take into account (i) the dynamic nature of costs, (ii) the time lags between the real occurrence of the costs and their reporting in the literature (called "publication delay" hereafter), (iii) the heteroscedastic and temporally auto-correlated nature of cost data, and (iv) the effects of potential outliers in the cost estimates. The model was calibrated and fitted with at least 75 per cent of cost data completeness. All methodological details necessary for the rationale behind model selection as well as for obtaining this figure are presented in Diagne, Leroy *et al.* (2021), Leroy *et al.* (2022). Data management report available at https://doi.org/10.5281/zenodo.7857828

Box 4 13

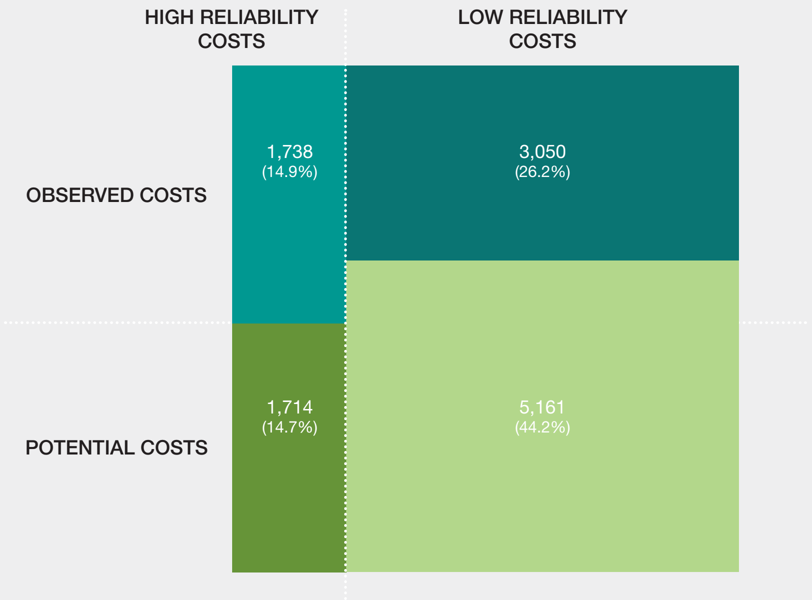

Figure 4 26 **The proportion of costs in the InvaCost database according to their implementation and reliability.**

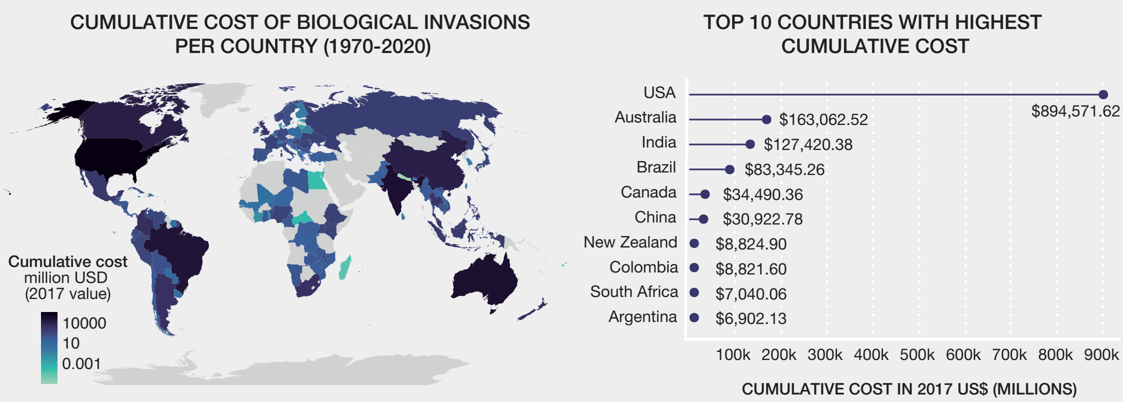
Numbers in the square represent the total cost in US$ billion, and the corresponding percentage of the whole in parentheses. All costs have been standardized in equivalent 2017 US$ (Diagne, Leroy, *et al.*, 2020 for methodological details). InvaCost displays over 13,000 individual costs (at the time of writing this report), each described with 64 variables characterizing the record, the study, the typology of the economic cost and the invasive alien species. Among these, two are of major importance: implementation, i.e., whether the costs are actually observed or extrapolated and predicted (called "potential") and whether the original methodology led to a classification into either high or low reliability. The choice of these two variables dictates the number of costs accounted for in different studies, the resulting final global estimate and its overall robustness. This chapter only considers the most robust subset of InvaCost, the costs that are simultaneously observed and of high reliability (upper left square, less than 15 per cent of all available data). Note that this figure represents data recorded in the latest version of the InvaCost database available at the time of writing this report, and the proportions displayed here are likely to evolve as the database is updated over time. All cost information are regularly updated (Leroy *et al.*, 2021).



Box 4 13

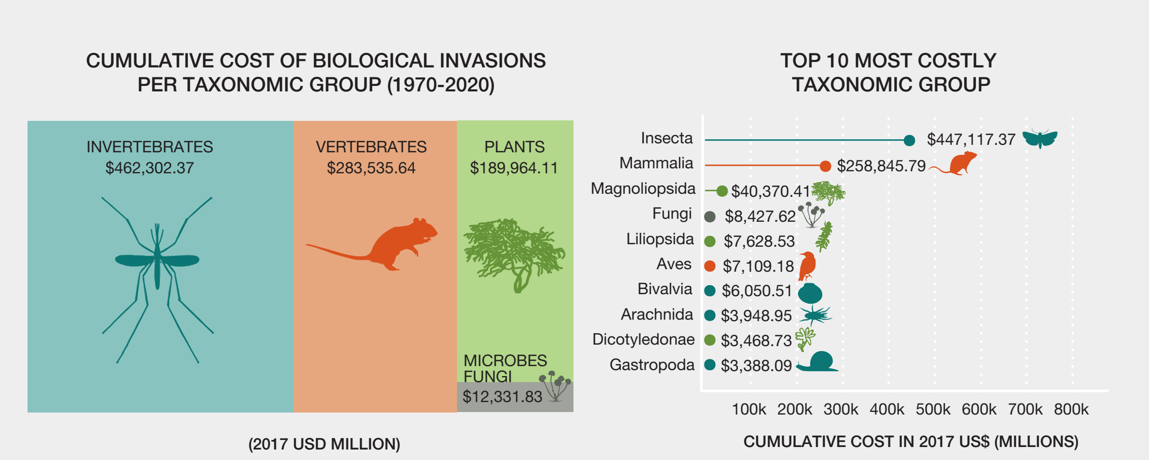


Figure 4 27 **Synthesis of cumulative economic costs of biological invasions.**[8]

As available in the literature and standardized in the InvaCost database (latest version 4.0 available at the time of writing this report): for all countries in the world (left on the previous page), the 10 countries with the highest cumulative costs (right on the previous page) and the four major taxonomic groups (left) as well as the ten costliest taxa (right). All costs have been standardized in equivalent 2017 US$ (Diagne, Leroy, *et al.* (2021) and Leroy *et al.* (2022) for methodological details) and only the most robust subset has been used here **(Figure 4.26)**. Note that this figure represents data recorded in the latest version of the InvaCost database available at the time of writing this report, and the proportions displayed here are likely to evolve as the database is updated over time. All cost information are regularly updated (Leroy *et al.*, 2021 for the most up-to-date figures).
Data management report available at https://doi.org/10.5281/zenodo.8231570

Most impacted categories of nature's contributions to people

More than 66 per cent of documented impacts on nature's contributions to people are on the provision of food and feed **(Figure 4.28)**. These include mainly decreases in crop and forest tree production caused by alien weeds, pests and pathogens (Fried *et al.*, 2017; Kenis *et al.*, 2017), but also the impact of invasive alien microbes on livestock (French, 2017) and the impact of invasive alien species on fisheries and aquaculture (Gozlan, 2017). Most invasive alien species cause negative impacts on provision of food and feed (748 species), on habitat creation and maintenance (255 species) and on provision of materials, companionship and labour (301 species). Invasive alien species also cause positive impacts on provision of food and feed (199 species), on medicinal, biochemical and genetic resources (83 species) and on the formation, protection and decontamination of soils and sediments (77 species).

8. The boundaries and names shown, and the designations used on the maps shown here do not imply official endorsement or acceptance by IPBES.

Conflict species causing both positive and negative impacts

There are some invasive alien species that cause both positive and negative impacts on nature's contributions to people, which causes conflicts among different socioeconomic sectors as, for instance, the farming and conservation sectors (Vilà & Hulme, 2017). This duality makes the quantification of nature's contributions to people a challenge. Conflicting values are prominently found with respect to invasive alien trees which are seen as positive because they provide wood and contribute to carbon sequestration and thus to climate regulation; however, at the same time, many alien trees increase fire hazards (Castro-Díez *et al.*, 2019) and decrease the recreational use of forests (Vaz *et al.*, 2018; **Chapter 5**, **section 5.6.1.2**).

Invasive alien species most often documented causing impacts on nature's contribution to people

The top ten species that are most often documented to have negative impacts on nature's contributions to people comprise four plants, five invertebrates and a fish **(Table 4.14A)**. *Pontederia crassipes* (water hyacinth) and many other aquatic plants have pervasive impacts on water

Figure 4 28 **Documented numbers of invasive alien species causing negative and positive impacts on categories of nature's contributions to people.**

Positive and negative stacked bar charts do not imply that positive and negative impacts can be summed. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

quality and quantity, clog irrigation and draining ditches, and thereby interfere with boating and fishing (Brundu, 2015; Ueki *et al.*, 1976). The plants *Reynoutria japonica* (Japanese knotweed) and *Impatiens glandulifera* (Himalayan balsam), and the tree *Robinia pseudoacacia* (black locust), which commonly invade central European habitats, cause impacts on soil quality and on pollination (Dassonville *et al.*, 2011; Nienhuis *et al.*, 2009). *Dreissena polymorpha* (zebra mussel), one of the most studied freshwater invertebrates, has negative impacts on nature's contributions to people by, for example, disrupting energy production (Ludyanskiy *et al.*, 1993; Karatayev *et al.*, 2005). Four invertebrates affect food and feed provision: *Solenopsis invicta* (red imported fire ant), *Bactrocera dorsalis* (Oriental fruit fly), *Chilo partellus* (spotted stem borer), and *Lissachatina fulica* (giant African land snail). *Cyprinus carpio* (common carp) is the invasive alien vertebrate with most documented impacts; it eats submerged vegetation and destroys hatching grounds for small native fishes, invertebrates, or other aquatic animals, changes the nutrient compositions in water through grubbing sediments (Matsuzaki *et al.*, 2009), and spreads Koi herpesvirus to native carp populations that show higher mortality than introduced populations (Uchii *et al.*, 2009).

The top ten invasive alien species that are most often documented to have positive impacts on nature's contributions to people are plants **(Table 4.14B)**, all of which also cause negative impacts. For example, *Acacia longifolia* (golden wattle) and *Acacia dealbata* (acacia bernier) are N-fixing species that have been introduced to restore degraded soils but at the same time, their invasion modifies the structure of the habitats to be both beneficial or detrimental to people depending on their socioeconomic and cultural context (Kull *et al.*, 2011). Similarly, *Prosopis juliflora* (mesquite) affects the availability of fodder for domestic livestock by reducing grassland area and grass cover (P. N. Joshi *et al.*, 2009; Kohli *et al.*, 2006; Timsina *et al.*, 2011), but at the same time constitutes an important source of fuelwood (Dayal, 2007; Duenn *et al.*, 2017), its stems can be used for fencing (D. Bartlett *et al.*, 2018; Duenn *et al.*, 2017), it can improve soil quality *via* biochar (D. Bartlett *et al.*, 2018), and there are reports of people adapting to the use of plant parts for medicinal purposes (Duenn *et al.*, 2017). The overwhelming negative impacts of *Prosopis juliflora* on nature's contributions to people are not offset by its positive impacts.

Table 4 14 **Top 10 invasive alien species with most documented negative and positive impacts on nature's contributions to people.**

The invasive alien species with most documented A) negative and B) positive impacts on nature's contributions to people. Note that this is not an indication of the global impact of these species, but of the number of cases found and analysed in this report. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

Plants: Invertebrate: Vertebrate: Microorganisms:

A) Negative impacts on nature's contributions to people

Species	Taxa	Nature's contributions people (number of documented impacts)
Pontederia crassipes (water hyacinth)		Energy (2); Food & feed (32); Freshwater quantity (19); Options (2); Physical experiences (4); Water quality (18)
Solenopsis invicta (red imported fire ant)		Biological processes (13); Energy (3); Food & feed (35); Learning (1); Materials (12); Options (4)
Dreissena polymorpha (zebra mussel)		Energy (17); Freshwater quantity (4); Materials (13); Medicinal (2); Ocean acidification (1); Options (8); Water quality (7)
Bactrocera dorsalis (Oriental fruit fly)		Food & feed (41)
Impatiens glandulifera (Himalayan balsam)		Biological processes (9); Freshwater quantity (4); Pollination & dispersal (5); Soils formation (22)
Robinia pseudoacacia (black locust)		Biological processes (13); Soils formation (27)
Chilo partellus (spotted stem borer)		Food & feed (37)
Lissachatina fulica (giant African land snail)		Food & feed (36)
Reynoutria japonica (Japanese knotweed)		Soils formation (33)
Cyprinus carpio (common carp)		Food & feed (28)

B) Positive impacts on nature's contributions to people

Species	Taxa	Nature's contributions people (number of documented impacts)
Solidago gigantea (giant goldenrod)		Climate (6); Soils formation (48)
Robinia pseudoacacia (black locust)		Energy (6); Food & feed (10); Materials (2); Physical experiences (8); Soils formation (26)
Acacia longifolia (golden wattle)		Climate (5); Freshwater quantity (3); Hazards (1); Soils formation (37)
Impatiens glandulifera (Himalayan balsam)		Biological processes (4); Freshwater quantity (5); Pollination & dispersal (8); Soils formation (23)
Reynoutria japonica (Japanese knotweed)		Climate (3); Pollination (3); Soils formation (32)
Rosa rugosa (rugosa rose)		Biological processes (6); Climate (2); Hazards (1); Physical experiences (3); Soils formation (21)
Prosopis juliflora (mesquite)		Energy (9); Food & feed (10); Habitat (2); Materials (6); Medicinal (3); Physical experiences (2)
Acacia dealbata (acacia bernier)		Climate (4); Soils formation (23)
Carpobrotus edulis (hottentot fig)		Air quality (1); Freshwater quantity (3); Hazards (2); Soils formation (15)
Pontederia crassipes (water hyacinth)		Biological processes (4); Food & feed (5); Hazards (1); Materials (2); Medicinal (3); Water quality (2)

4.4.1.1 Islands vs. mainland

Despite the seminal and substantial body of literature on the threats and impacts of invasive alien species in remote islands, such as Hawaii, the Galapagos or New Zealand, only 12 per cent of the impacts on nature's contributions to people are documented on islands. The vast majority (76.4 per cent) of impacts on islands are negative **(Figure 4.29)** which is similar to the proportion of negative impacts on mainlands (79.3 per cent). Also, the affected categories of nature's contributions to people for which there are the most documented impacts are similar between islands and mainlands: namely on provision of food and feed (caused by 139 invasive alien species), provision of materials, companionship and labour (51 invasive alien species), and on habitat creation and maintenance (44 invasive alien species). The proportion of documented positive impacts is more important on islands than on mainlands, noticeably on food and feed (44.8 per cent on islands against 22.2 per cent on mainlands) and pollination and propagule dispersal (10.4 per cent on islands against 3 per cent on mainlands). On the contrary, on islands, the proportion of impacts on the formation, protection and decontamination of soils and sediments (17.5 per cent on islands against 35.8 per cent on mainlands), medicinal, biochemical and genetic resources (2.2 per cent on islands against 9.8 per cent on mainlands) are smaller than on mainlands. Biogeographic comparative analysis between homologous habitats in islands and mainland invaded by the same invasive alien species are necessary to identify the consistency in direction and intensity of their impacts on nature's contributions to people (D'Antonio & Dudley, 1995).

4.4.1.2 Protected areas

The SCOPE international programme on biological invasions indicated the need for research, monitoring (**Glossary**) and management of the impacts of invasive alien species in

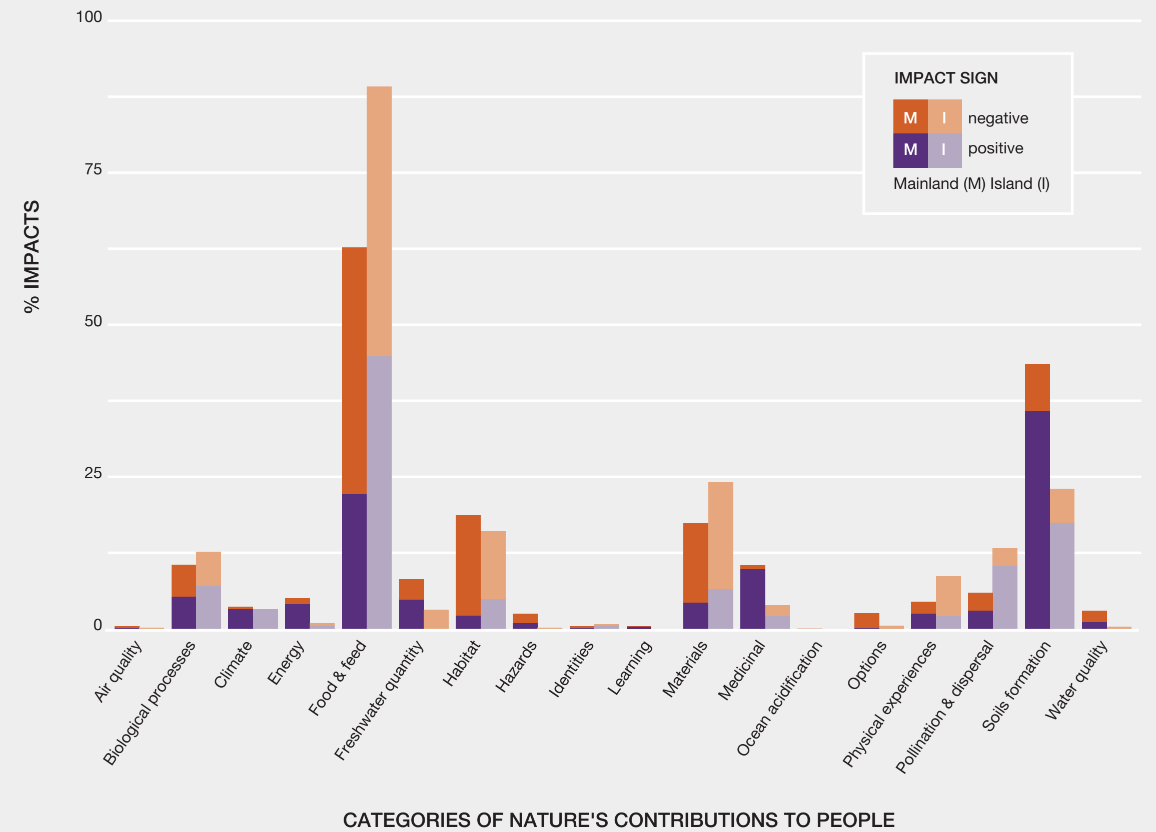

Figure 4 29 **Negative and positive impacts on nature's contributions to people on mainland and on islands.**

This figure shows the percentage (y axis) of positive (bottom half of bar) and negative impacts (top half of bar) on islands and on mainland or unknown territories for each category of nature's contributions to people (x axis). Positive and negative stacked bar charts do not imply that positive and negative impacts can be summed. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069 protected areas (Foxcroft, Pyšek, *et al.*, 2013). However, a recent analysis has shown that the perceived threat in protected areas has worsened over time especially for plants (Foxcroft, Pyšek, *et al.*, 2013; R. T. Shackleton *et al.*, 2020). Five per cent of the documented impacts on nature's contributions to people occur in protected areas, with more positive (54.7 per cent) than negative (45.3 per cent) impacts. More than 50 per cent of the documented impacts in protected areas concern changes of the formation, protection and decontamination of soils and sediments. Other important impacts are on the provision of food and feed (13.2 per cent of the impacts on nature's contributions to people in protected areas), the regulation of freshwater quantity, location and timing (8.4 per cent) and regulation of detrimental organisms and biological processes (8.4 per cent). Notwithstanding, the importance of protected areas for their cultural, sometimes sacred value, there are no documented impacts on non-material nature's contributions to people such as impacts on learning and inspiration, physical and psychological experiences and supporting identities.

4.4.2 Documented impacts of invasive alien species on nature's contributions to people by realm

4.4.2.1 Patterns of negative and positive impacts of invasive alien species on nature's contributions to people in the terrestrial realm

Impacted units of analysis in the terrestrial realm

There are many more documented negative impacts of invasive alien species on nature's contributions to people than positive impacts (3,424 against 1,103, respectively) in the terrestrial realm. Cultivated areas (approximately 33 per cent of impacts) and temperate and boreal forests (approximately 20 per cent of impacts) together account for more than half of all documented negative impacts of invasive alien species on nature's contributions to people. These are followed by urban/semi-urban areas, temperate grasslands, and tropical and subtropical dry and humid forests (8 to 10 per cent each). The remaining four units of analysis together constitute less than 20 per cent of all documented impacts. In the case of positive impacts, the largest proportion of documented impacts is from temperate and boreal forests (23 per cent), followed by temperate grassland (approximately 19 per cent). Cultivated areas, tropical and subtropical dry and humid forests, and Mediterranean woodlands, forests and scrub account for between 11 and 15 per cent each. The rest of the four terrestrial units of analysis together constitute less than one-fifth of all documented impacts. The predominance of certain units of analysis amongst documented impacts of invasive alien species on nature's contributions to people is more likely a reflection of information availability rather than actual impacts. For example, in a recent review of alien trees and their impacts on ecosystem services, Castro-Díez *et al.* (2019) found that the temperate and Mediterranean biomes were over-represented proportionate to their area, compared with other large regions of the world, such as Asia and Africa.

Impacted categories of nature's contributions to people in the terrestrial realm

Negative impacts of invasive alien species on nature's contributions to people are dominated by the categories of food and feed (40 per cent of documented impacts) followed by habitat creation and maintenance (approximately 20 per cent of documented impacts). Negative impacts on the category, formation, protection and decontamination of soils and sediments account for an additional 9 per cent of documented impacts, with all other categories together constituting less than 30 per cent of documented negative impacts **(Figure 4.30)**. Positive impacts are dominated by impacts on the categories, formation, protection and decontamination of soils and sediments (38 per cent), food and feed (21 per cent), and medicinal, biochemical and genetic resources (approximately 10 per cent). The remaining categories of nature's contributions to people together account for only 30 per cent of all documented positive impacts **(Figure 4.31)**.

Negative impacts on particular categories of nature's contributions to people predominate in certain units of analysis **(Figure 4.30)**. For example, negative impacts on food and feed are prominent in cultivated areas (76 per cent of documented impacts, caused by 321 species). Negative impacts on food and feed are also a large proportion of total documented negative impacts in tropical and subtropical dry and humid forests (45 per cent of documented impacts caused by 55 species), tropical and subtropical savannas and grasslands (32 per cent of documented impacts caused by 49 species) and urban/semi-urban areas (about 30 per cent of documented impacts caused by 42 species).

Impacts on habitat creation and maintenance account for about 40 to 50 per cent of all documented negative impacts in deserts and xeric shrublands (50 per cent of documented impacts, caused by 29 species), temperate grasslands (43 per cent of documented impacts caused by 74 species), and tropical and subtropical savannas and grasslands (36 per cent of documented impacts caused by 31 species). So also, impacts on formation, protection and decontamination of soils and sediments constitute between a fifth to a fourth of all negative impacts in Mediterranean woodlands forests and scrub (27 per cent of documented

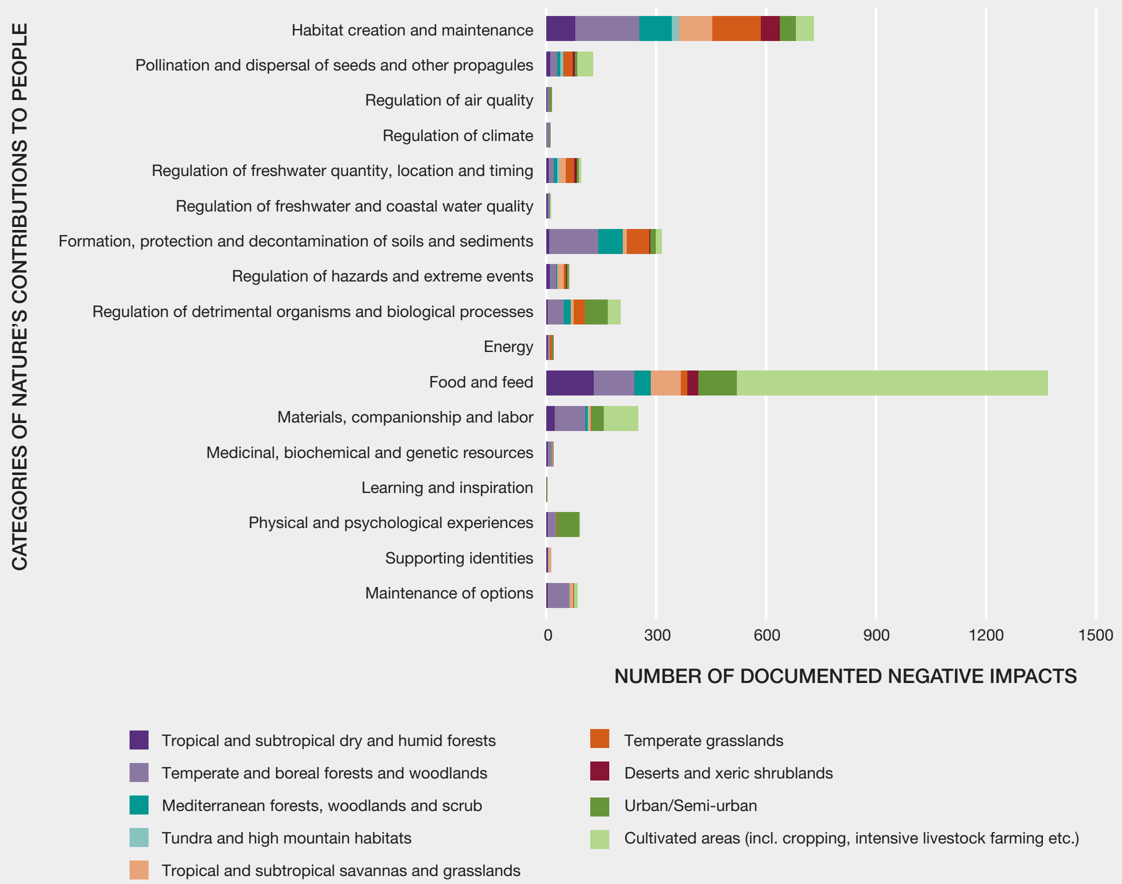

Figure 4 30 **Documented number of negative impacts of invasive alien species (x axis) on categories of nature's contributions to people (y axis) across different terrestrial units of analysis.**

There are 3,424 documented negative impacts across all categories of nature's contributions to people in the terrestrial realm. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

impacts caused by 22 species), followed by temperate grasslands (20 per cent of documented impacts caused by 19 species), and temperate and boreal forests (19 per cent of documented impacts caused by 25 species).

As with negative impacts of invasive alien species, certain types of positive impacts on nature's contributions to people also predominate in particular units of analysis **(Figure 4.31)**. Impacts on the category, formation, protection and decontamination of soils and sediments, outweigh positive impacts on all other categories of nature's contributions to people in Mediterranean woodlands forests and scrub (70 per cent of documented impacts; 14 species). Positive impacts on formation, protection and decontamination of soils and sediments also account for between a third to half of all documented impacts in temperate grassland (53 per cent of documented impacts, caused by 30 species), temperate and boreal forests (40 per cent of documented impacts, caused by 28 species), and in cultivated areas (34 per cent of documented impacts, caused by 23 species).

Impacts on the category food and feed, constitute around a quarter of all documented positive impacts in tropical and subtropical dry and humid forests (29 per cent of documented impacts, caused by 35 species), and temperate and boreal forests (24 per cent of documented impacts, caused by 32 species); they also account for almost a fifth of all documented positive impacts in temperate grasslands (18 per cent of documented impacts, caused by 21 species) and cultivated areas (18 per cent of documented impacts, caused by 18 species). Positive impacts on the category, medicinal, biochemical and genetic resources also make a sizeable contribution to documented positive impacts in tundra and high mountain

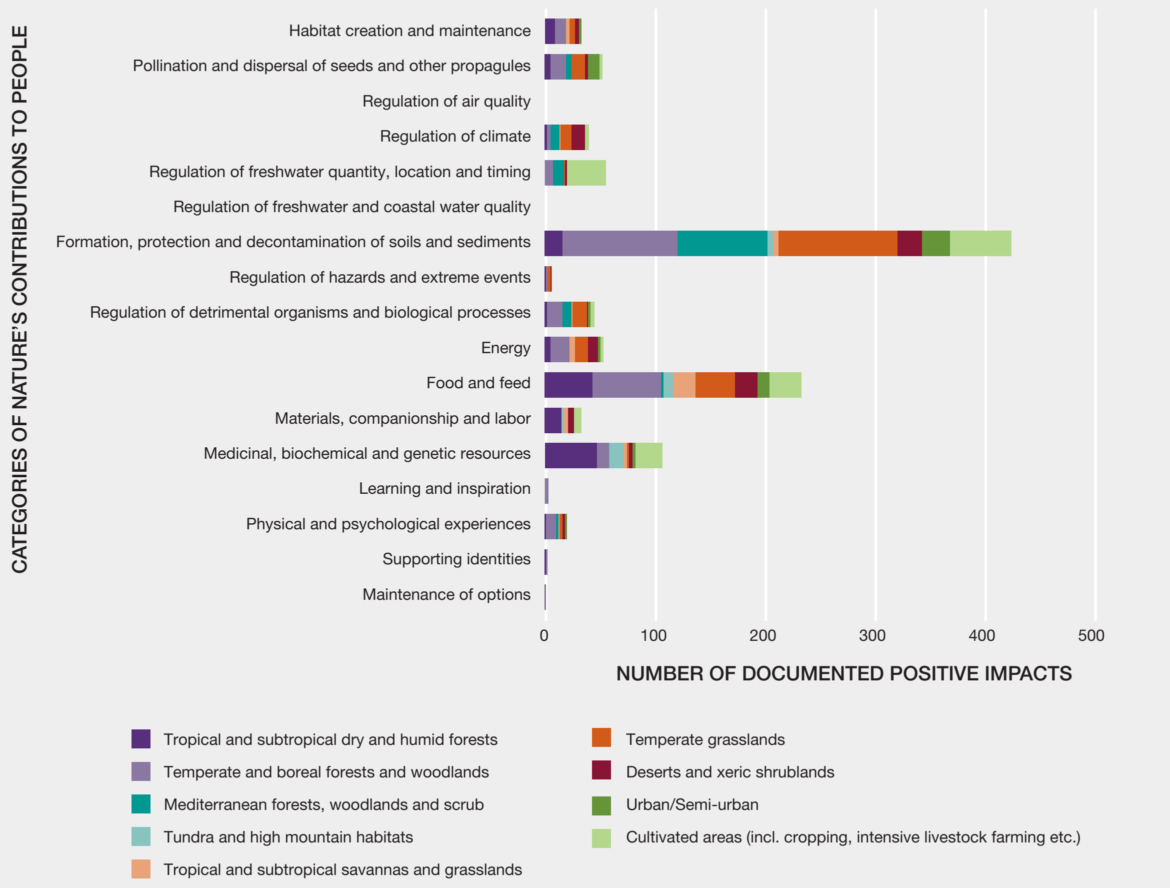

Figure 4 31 **Documented number of positive impacts (x axis) of invasive alien species on categories of nature's contributions to people (y axis) across different terrestrial units of analysis.**

There are 1,103 documented positive impacts across all categories of nature's contributions to people in the terrestrial realm. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

habitats (45 per cent; of documented impacts, caused by 13 species), tropical and subtropical dry and humid forests (32 per cent of documented impacts, caused by 43 species), and cultivated areas (15 per cent of documented impacts, caused by 22 species).

Invasive alien taxa most often documented causing impacts on nature's contributions to people in the terrestrial realm

Plants is generally the invasive alien species taxonomic group that causes the most impacts (both positive and negative) on nature's contributions to people across all units of analysis **(Table 4.15)**. Notable exceptions to this overall pattern occur in cultivated areas and in Mediterranean woodlands, forests and scrub. In cultivated areas, the top 10 species of invasive alien species causing negative impacts are invertebrate crop pests (the top five of which are *Spodoptera frugiperda* (fall armyworm), *Bactrocera dorsalis* (Oriental fruit fly), *Solenopsis invicta* (red imported fire ant), *Chilo partellus* (spotted stem borer), and *Phenacoccus manihoti* (cassava mealybug)). *Spodoptera frugiperda* alone accounts for four to six per cent of maize losses in North and South America and Sub-Saharan Africa (Savary *et al.*, 2019), though yield losses ranging from 10 per cent up to 58 per cent have been estimated across different countries in Africa (**Box 4.18**; **Table 4.26**). Globally, total crop losses (from all pests and pathogens combined) are estimated at 20 to 30 per cent, based on a global survey of crops that together account for about half of human calorie intake (Savary *et al.*, 2019). A large proportion of these total crop losses is due to insect and mite pests, 30 to 45 per cent of which are alien invasive arthropods, as estimated across several large crop-growing countries of the world (Pimentel *et al.*, 2001).

In Mediterranean woodlands, forests and scrub, seven of the top 10 invasive alien species are microbes and include five species of fungi, a bacterium (*Xylella fastidiosa* (Pierce's disease of grapevines)), and an oomycete (*Phytophthora cinnamomi* (Phytophthora dieback)). Negative impacts of these microbes on nature's contributions to people include, more specifically, impacts on habitat creation and maintenance. For example, *Ceratocystis platani* (canker stain of plane), a canker-causing fungus thought to have been accidentally introduced to Europe from North America in the first half of the twentieth century, damages the iconic *Platanus orientalis* (plane), especially in Greece (Tsopelas *et al.*, 2017). Other significant examples of negative impacts are impacts on the provision of food and feed. *Cryphonectria parasitica* (blight of chestnut), which has devastated native North American chestnut populations following its accidental introduction to the United States in the early twentieth century (Anagnostakis, 1987), is also a significant pest in Europe, where it threatens fruit and wood production from the European chestnut (EFSA PLH Panel (EFSA Panel on Plant Health), 2014). Likewise, recently discovered (in 2013) olive quick decline syndrome (OQDS), caused by *Xylella fastidiosa* has caused significant losses to the economically and culturally important olive crop in Italy's main olive growing region (White *et al.*, 2017).

Most invertebrates appearing in the top 10 invasive alien species by unit of analysis are associated with negative impacts on nature's contributions to people. However, exceptions are the positive impacts on pollination, and food and feed by *Apis mellifera* (European honeybee) in temperate and boreal forests, Mediterranean woodland forest and scrub, and cultivated areas. In the United States, for example, the pollination of crops by *Apis mellifera* is in the order of tens of billions of US$ annually (Pejchar & Mooney, 2009). *Apis mellifera* has also been observed to pollinate the culturally significant Hawaiian endemic tree, *Meterosideros polymorpha* (ʽOhi'a), and could play an important role in the future, as species assemblages increasingly change as a result of species invasions, habitat fragmentation, and climate change (Cortina *et al.*, 2019). However, in Latin America, *Apis mellifera* has hybridized with the aggressive Africanized honeybee, and threatens human health (Pejchar & Mooney, 2009). Another invertebrate that was introduced as a pollinator of cultivated plants to many regions of the globe is *Bombus terrestris* (bumble bee). Although it is now an invasive alien species, its use as a pollinator continues, though it is regulated (e.g., in Japan; Goka, 2010). In some cases, invasive alien plants also support pollination providing a reliable source of nectar and pollen at times of the year when agricultural landscapes are otherwise not providing sufficient resources to maintain pollinator populations (Hirsch *et al.*, 2020).

The regulation of detrimental organisms and biological processes is another category of nature's contributions to people that is positively impacted by an invertebrate, e.g., by *Nematus oligospilus* (willow sawfly) in urban/semiurban areas. This species was unintentionally introduced to Australia and New Zealand as a pest of introduced willows (Caron *et al.*, 2014). It is therefore perceived as a beneficial species, since willows are detrimental to riparian and aquatic ecosystems (Bruzzese & McFadyen, 2006).

Some species cause both negative and positive impacts on nature's contributions to people, even within the same unit of analysis. *Prosopis* spp. (mesquite) are an example of this in deserts and xeric shrublands. Positive impacts include the provision of fuelwood, shade, and fodder in the form of pods (S. E. Shackleton & Shackleton, 2018; **Box 4.9**); negative impacts include depletion of groundwater (Dzikiti *et al.*, 2013), a reduction in grazing resources, and damage caused to certain livestock from consumption of pods (Obiri, 2011; **Box 4.9**). *Prosopis juliflora*, *Prosopis pallida*, *Prosopis glandulosa*, *Prosopis chilensis*, and *Prosopis velutina* (collectively known as mesquite) have been introduced across the globe for the potential benefits they provide to people; however, with their spread in introduced regions, the negative impacts of *Prosopis* spp. come into conflict with their positive impacts, creating contradictions in how they are perceived by different stakeholders (R. T. Shackleton *et al.*, 2014; **Box 4.9**).

Some species or taxa cause impacts on nature's contributions to people across multiple units of analysis. One example is the genus, *Acacia*, with different species – *Acacia dealbata* (acacia bernier), *Acacia mearnsii* (black wattle), and *Acacia saligna* (coojong) – causing positive impacts on nature's contributions to people across several different units of analysis. These positive impacts (on formation, protection and decontamination of soils and sediments, climate regulation, energy, and materials, companionship and labour (Lorenzo *et al.*, 2010; Potgieter *et al.*, 2019; C. M. Shackleton *et al.*, 2007) align with a recent global review of the genus *Acacia* and its impacts, which found positive impacts on climate regulation, soil fertility and soil erosion control (Castro-Díez *et al.*, 2021). However, these findings are at odds with other work highlighting the negative impacts of *Acaciae* on various categories of nature's contributions to people, especially regulation of freshwater quantity, location and timing, and regulation of hazards and extreme events; (Le Maitre *et al.*, 2011). Although *Acaciae* are associated with negative impacts on nature's contributions to people in the impact database developed through this chapter[9] as well, their documented negative impacts do not rank amongst the top 10 species by units of analysis.

4.4.2.2 Patterns of negative and positive impacts of invasive alien species on nature's contributions to people in the inland waters realm

Impacted units of analysis in the inland waters realm

In inland waters, negative impacts of invasive alien species on nature's contributions to people outnumber positive impacts by a ratio of 4:1, with 600 documented negative impacts compared with only 145 documented positive impacts. About 70 per cent of all documented impacts, both negative and positive, on nature's contributions to people in inland waters are from inland surface waters and water bodies/freshwater; the remainder are found to almost equal measure in wetlands, and in aquaculture areas (**Figures 4.32** and **4.33**).

Impacted categories of nature's contributions to people in inland waters

In inland waters, invasive alien species' negative impacts on food and feed predominate, and constitute about 50 per cent of all documented negative impacts on nature's contributions to people in this realm **(Figure 4.32)**. In aquaculture areas, about 90 per cent of negative impacts are on food and feed (caused by 28 species); in inland surface waters/waterbodies 55 per cent of negative impacts are on food and feed (caused by 82 species). Other sizeable negative impacts of invasive alien species on nature's contributions to people are on habitat creation and maintenance in wetlands (44 per cent of documented impacts, 25 species), and on freshwater quantity (10 per cent of documented impacts; 16 species), and water quality (12 per cent; 18 species), in inland surface waters/waterbodies.

Impacts on the category food and feed also account for the majority (60 per cent) of all documented positive impacts in inland waters **(Figure 4.33)**. Impacts on food and feed constitute 95 per cent of all positive impacts in aquaculture areas (caused by 15 species) and about 60 per cent in inland surface waters/waterbodies (caused by 31 species). Positive impacts on the category formation, protection and decontamination of soils and sediments, constitute almost 50 per cent of all documented impacts in wetlands, caused by five species. Other documented positive impacts are on physical and psychological experiences, water quality, and regulation of biological processes (about 10 per cent of documented impacts each), in inland surface waters/ waterbodies.

Invasive alien taxa most often documented causing impacts on nature's contributions to people in the inland waters realm

In aquaculture areas, as well as in inland surface waters/ waterbodies, vertebrates are the invasive alien species causing the most impacts, both positive and negative, on nature's contributions to people **(Table 4.16)**. Species causing positive impacts include *Hypophthalmichthys nobilis* (bighead carp), *Hypophthalmichthys molitrix* (silver carp), *Oreochromis niloticus* (Nile tilapia), *Cirrhinus mrigala* (mrigal carp), several species of catfish such as *Clarias gariepinus* (North African catfish), and also a reptile, *Crocodylus rhombifer* (Cuban crocodile). These species positively impact the provision of food and feed, and reflect the growing contribution of aquaculture to food security, especially in the Asia-Pacific region (De Silva, 2012); fish constitutes the main dietary protein in many countries of the region (e.g., in Cambodia; Nuov *et al.*, 2005). However, many introduced fish species have also become associated with negative impacts on nature's contributions to people **(Box 4.10)**. These include species originally introduced for aquaculture such as *Cyprinus carpio* (common carp), *Oreochromis mossambicus* (Mozambique tilapia), *Oreochromis niloticus*, *Clarias gariepinus*, *Hypophthalmichthys nobili*, *Hypophthalmichthys molitrix*; species originally introduced for aquatic weed control such as *Ctenopharyngodon idella* (grass carp); *Gambusia affinis* (western mosquitofish) introduced to control malaria by feeding on mosquito larvae; and *Poecilia reticulata* (guppy), an ornamental species introduced for the aquarium trade. These species are linked to negative impacts on native fish (an impact on nature; **section 4.3.2**) *via* competition, predation, hybridization, and physical and chemical alteration of habitat (Ciruna *et al.*, 2004), which, in turn, negatively affect the category food and feed. For example, in the River Ganga, India, between 2004 and 2009, fish catch showed a 72 per cent decline of native

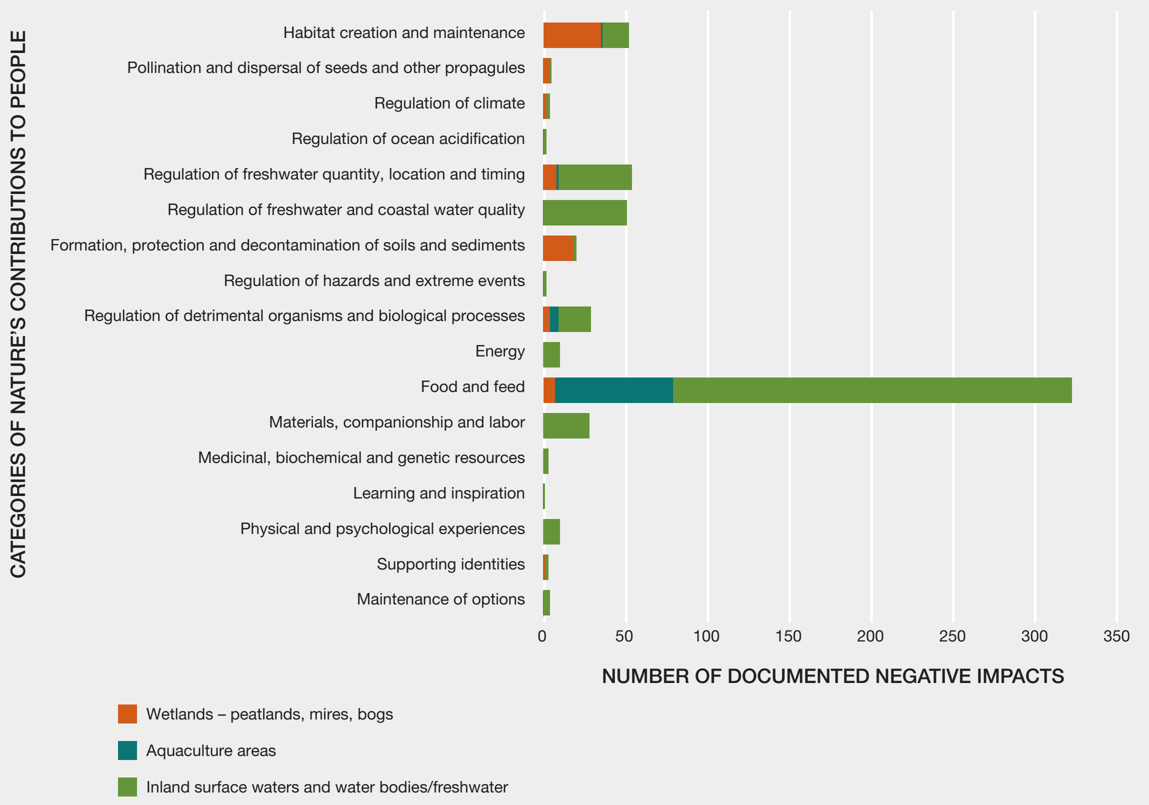

Figure 4 32 **Documented negative impacts (x axis) of invasive alien species on categories of nature's contributions to people (y axis) in the inland waters realm.**

There are 600 documented negative impacts across all categories of nature's contributions to people in the inland waters realm. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

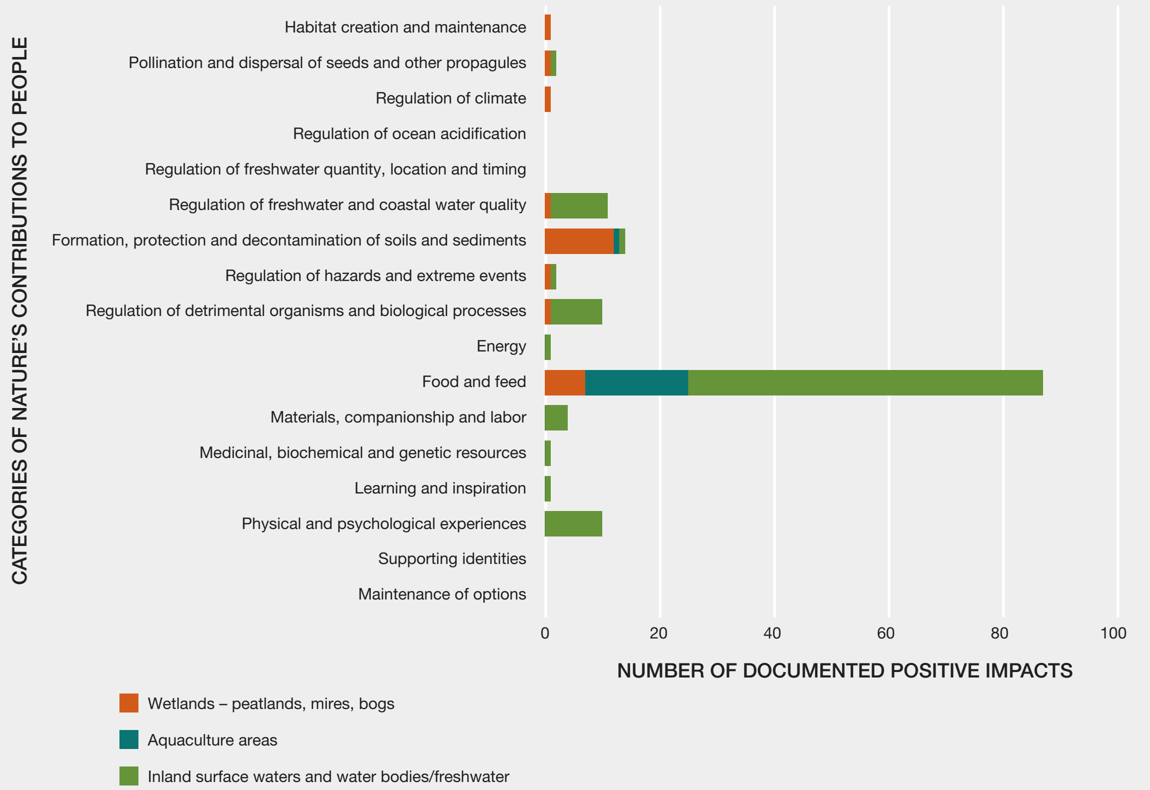

Figure 4 33 **Documented positive impacts (x axis) of invasive alien species on categories of nature's contributions to people (y axis) in the inland waters realm.**

There are 145 documented positive impacts across all categories of nature's contributions to people in the inland waters realm.

fish accompanied by a 237 per cent increase in introduced species (especially *Cyprinus carpio*, *Clarias gariepinus*, and the two species of tilapia (A. K. Singh & Lakra, 2011).

In inland surface waters/waterbodies, the other dominant taxonomic group associated with negative impacts on nature's contributions to people are invertebrates, e.g., *Dreissena polymorpha* (zebra mussel), *Corbicula fluminea* (Asian clam), and *Procambarus clarkii* (red swamp crayfish). Of these, *Dreissena polymorpha* and *Procambarus clarkii* are each responsible for a number of negative impacts on nature's contributions to people. The former affects food and feed, regulation of freshwater and coastal water quality, energy, provision of materials and companionship and labour (Colautti *et al.*, 2006; Strayer, 2009); the latter affects food and feed, habitat creation and maintenance, supporting identities, and learning and inspiration, leading to its evaluation as a high-risk species (Souty-Grosset *et al.*, 2016). Despite its multiple negative impacts, *Procambarus clarkii* also causes positive impacts (on food and feed, and harvested commercially), and live individuals are still bought and sold for the aquarium trade (Souty-Grosset *et al.*, 2016). Other examples of positive impacts by invertebrates are on the categories food and feed by *Pontastachus leptodactylus* (Danube crayfish) (Martinez-Cillero *et al.*, 2019), regulation of detrimental organisms and biological processes by *Gammarus pulex* (common freshwater amphipod) that feeds on mosquito larvae (Dalal *et al.*, 2020), and regulation of freshwater and coastal water quality by *Dreissena rostriformis bugensis* (quagga mussel), which increases water clarity (Verstijnen, 2019).

In wetlands, plants are the invasive alien species causing the most impacts, both negative and positive, on nature's contributions to people, with the exception of two vertebrate species. Negative impacts of plants are largely on the formation, protection and decontamination of soils and sediments. For instance, species such as *Reynoutria japonica* (Japanese knotweed) and *Heracleum pubescens* (Sosnowskyi's hogweed), affect soil food webs by negatively altering nematode communities (Čerevková *et al.*, 2019; Renčo *et al.*, 2019), and *Echinochloa pyramidalis* (limpopo grass) negatively impact habitat creation and maintenance in Mexico (López Rosas *et al.*, 2005). Positive impacts of plants in wetlands include regulation of hazards and extreme events, and regulation of freshwater and coastal water quality. For example, *Phragmites australis* (common reed) in North America can buffer wetlands against the effects of sea level rise, and removes nutrients from agriculture runoff (Kettenring *et al.*, 2012). The vertebrates among the top 10 invasive alien species in wetlands are *Rusa timorensis* (Sunda sambar deer), which has negative impacts on the regulation of freshwater quantity, location and timing due to grazing on vegetation that helps regulate water flows (Pallewatta *et al.*, 2003); and *Bubalus bubalis* (Asian water buffalo), which causes positive impacts on food and feed, according to Indigenous Peoples and local communities in Australia (e.g., Albrecht *et al.*, 2009; C. J. Robinson *et al.*, 2005).

4.4.2.3 Patterns of negative and positive impacts of invasive alien species on nature's contributions to people in the marine realm

Impacted units of analysis in the marine realm

In the marine realm, as with the terrestrial and inland waters realms, negative impacts of invasive alien species outweigh positive impacts on nature's contributions to people (85 and 24 documented impacts, respectively). Documented impacts of invasive alien species on nature's contributions to people are predominantly from shelf ecosystems (about 70 per cent of negative and over 85 per cent of documented positive impacts). The remainder of invasive alien species impacts are documented from coastal areas; there are no documented impacts from other marine units of analysis. There are far fewer documented impacts of invasive alien species impacts on nature's contributions to people from marine compared with terrestrial and inland waters units of analysis, which might largely be due to a bias in research efforts.

Impacted categories of nature's contributions to people in the marine realm

Negative impacts on the provision of food and feed predominate in shelf ecosystems and constitute 85 per cent of all documented impacts (caused by 23 species; **Figure 4.34**). Negative impacts in coastal areas are distributed across all categories of nature's contributions to people, though food and feed accounts for a large proportion of documented impacts (approximately 45 per cent, caused by 4 species); other categories of negative impacts in coastal areas include regulation of freshwater and coastal water quality (25 per cent documented impacts; 3 species), maintenance of options (17 per cent of documented impacts, 4 species), and materials, companionship and labour (12 per cent of documented impacts, 2 species).

Positive impacts (as with negative impacts) on the provision of food and feed predominate in both marine units of analysis **(Figure 4.35)**. In the case of shelf ecosystems, food and feed constitutes 76 per cent of all documented impacts (caused by 16 species), with impacts on medicinal, biochemical and genetic resources accounting for an additional 14 per cent of documented impacts (caused by 1 species). Positive impacts of invasive alien species in coastal areas are all on the provision of food and feed (100 per cent of the three documented impacts, caused by 3 species).

This predominance of invasive alien species impacts (both negative and positive) on food and feed in the marine realm documented in the chapter impacts database matches findings from a recent European review of marine invasive

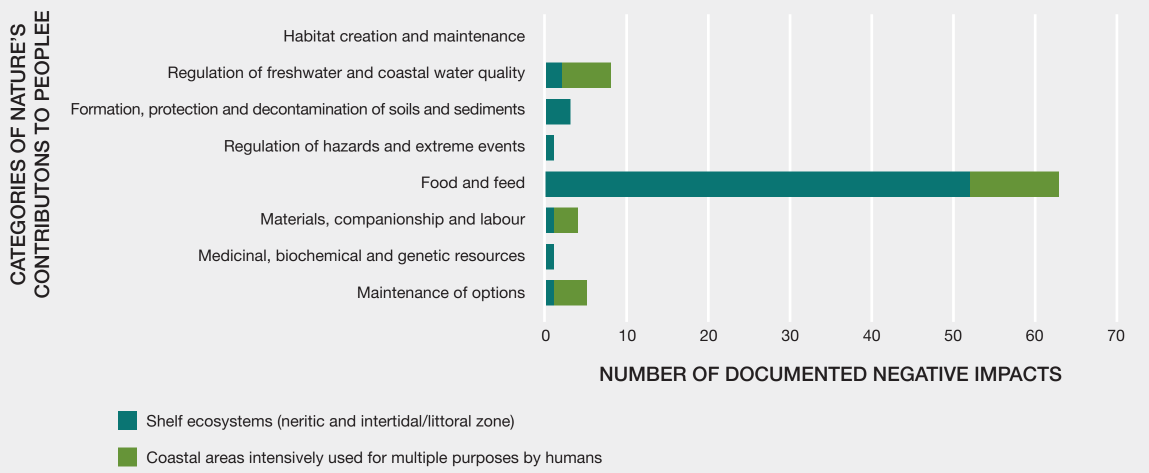

Figure 4 34 **Documented negative impacts (x axis) of invasive alien species on categories of nature's contributions to people (y axis) across different marine units of analysis.**

There are 85 documented negative impacts across all categories of nature's contributions to people in the marine realm. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

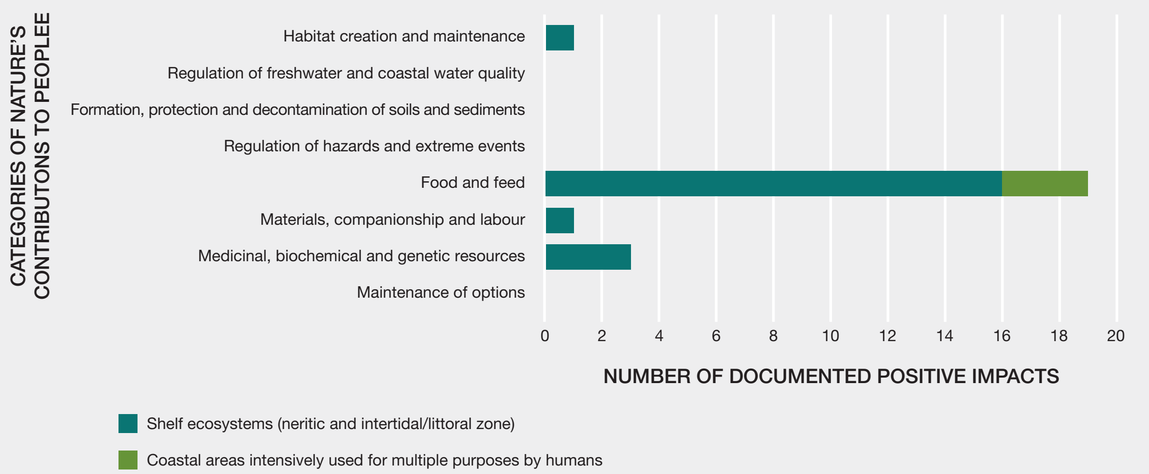

Figure 4 35 **Documented positive impacts (x axis) of invasive alien species on categories of nature's contributions to people (y axis) across different marine units of analysis.**

There are 24 documented positive impacts across all categories of nature's contributions to people in the marine realm. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

alien species and their impacts on marine ecosystem services (Katsanevakis *et al.*, 2014). Of all ecosystem services derived from marine ecosystems, Katsanevakis *et al.* (2014) found the highest number of documented invasive alien species with negative and positive impacts to be on food provisioning (fisheries, aquaculture); however, as suggested by the authors, this could reflect a study bias towards impacts on food, given its societal and economic relevance over other ecosystem services from marine ecosystems.

Invasive alien taxa most often documented causing impacts on nature's contributions to people in the marine realm

In coastal areas, the most documented invasive alien species causing both negative and positive impacts on nature's contributions to people are all invertebrates **(Table 4.17)**. The most documented negative impacts are on food and feed. Examples include impacts of *Carcinus maenas* (European green crab), which feeds on native oysters and crabs, and has decimated commercial shellfish beds in New England and Canada (Pimentel *et al.*, 2000), and the generalist predators, *Asterias amurensis* (northern Pacific seastar) and *Ciona intestinalis* (sea vase), which affect mariculture and fisheries along the Korean coast (Seo & Lee, 2009). Another example is *Mytilopsis sallei* (Caribbean false mussel), which competitively displaces native clams and oysters that are locally important fishery resources in India (Kumar, 2019). In coastal areas, the documented positive impacts on nature's contributions to people caused by invasive alien species are all related to food and feed. All three species, *Magallana gigas* (Pacific oyster), *Penaeus vannamei* (whiteleg shrimp), and *Ruditapes philippinarum* (Japanese carpet shell), are commercially harvested (A. N. Cohen & Carlton, 1995; U.S. Congress, Office of Technology Assessment, 1993).

In shelf ecosystems, invasive alien invertebrates are responsible for the majority of both negative and positive impacts on nature's contributions to people, mostly on food and feed. For example, *Carcinus maenas* (European green crab), through predation, and *Styela clava* (Asian tunicate), through competition for space, have led to a reduction in populations of native species in fisheries (Colautti *et al.*, 2006). Positive impacts of invertebrates are, likewise, associated with the provision of food and feed. For example, *Rapana venosa* (veined rapana whelk) in Turkey (Aydin *et al.*, 2016) and *Penaeus aztecus* (northern brown shrimp) in the Nile Delta of Egypt (Sadek *et al.*, 2018), are both harvested commercially. In addition to the documented invertebrate species, there are two plant species that feature in the list of top 10 invasive alien species: *Codium fragile* (dead man's fingers) and *Gracilaria vermiculophylla* (red alga). *Codium*

Table 4 17 **Main invasive alien species impacting nature's contributions to people in the marine realm.**

		Ascidiella aspersa (European sea squirt)	2		*Rapana venosa* (veined whelk)	2
		Ciona intestinalis (sea vase)	2		*Cercopagis pengoi* (fishhook waterflea)	1
		Ciona robusta (tunicate)	2		*Paralithodes camtschaticus* (red king crab)	1
		Tubastraea spp. (sun corals)	2		*Gracilaria vermiculophylla* (red alga)	1
		Codium fragile (dead man's fingers)	14		*Pterois volitans* (red lionfish)	2
		Pterois volitans (red lionfish)	2		*Megalops atlanticus* (Atlantic tarpon)	1

fragile has been associated with losses to commercial eel, lobster, and oyster fisheries in Canada (Colautti *et al.*, 2006). *Gracilaria vermiculophylla* is harvested for extraction of agar, which is used in the food industry (A. M. M. Sousa *et al.*, 2010). There are also two vertebrate species on this top 10 list, *Pterois volitans* (red lionfish) and *Megalops atlanticus* (Atlantic tarpon). *Pterois volitans*, a predator, has caused population declines of native fish on which local fisherfolk depend (Miguez Ruiz, 2013). Analogous to the much better documented introductions through the Suez canal that is regarded as an extremely significant route of introduction for marine invasions (Galil *et al.*, 2015), *Megalops atlanticus* is thought to have arrived in the eastern Pacific through the Panama Canal and was initially documented in the 1940s. It now extends on approximately 2600 km along the Pacific coastline of Central and South America (Castellanos-Galindo *et al.*, 2019). Its impacts are perceived as positive by different communities along the Colombian coast as it is used as a resource for food, crafts, and also for game fishing in the tourism industry (Neira & Acero P, 2016).

4.4.3 Documented impacts on nature's contributions to people by region and taxonomic group

Many invasive alien species are causing negative impacts on nature's contributions to people in all regions, with documented impacts from more than 500 species in the Americas and Europe and Central Asia (538 and 531, respectively), followed by 314 species in the Asia-Pacific region and 136 in Africa **(Figure 4.36)**. Across regions, some of these invasive alien species also have positive impacts on nature's contributions to people, and the percentage of species with documented positive impacts ranges from 22 per cent of species in Europe and Central Asia, 26 per cent in Africa, 32 per cent in the Americas, to 41 per cent in the Asia-Pacific region.

Most impacted categories of nature's contributions to people by region, and by taxon

Across all regions, food provisioning is the most impacted category of nature's contributions to people, both negatively and positively. Negative impacts on provisioning of food are found in all regions and for all taxa **(Figure 4.37)**. In Africa, most invasive alien species causing these impacts are plants (59 species), followed by invertebrates (36) and vertebrates (22), and with just one documented microbe species (Maize lethal necrosis disease). A similar pattern is observed for the Americas (131 plants, 76 invertebrates, 30 vertebrates, 22 microbes), whereas in the Asia-Pacific and Europe and Central Asia regions, invasive alien invertebrates are the largest taxonomic group causing impacts on food provisioning (81 and 217, respectively). The highest number of invasive alien vertebrates (74 species) causing impacts on food provisioning is found in the Asia-Pacific region.

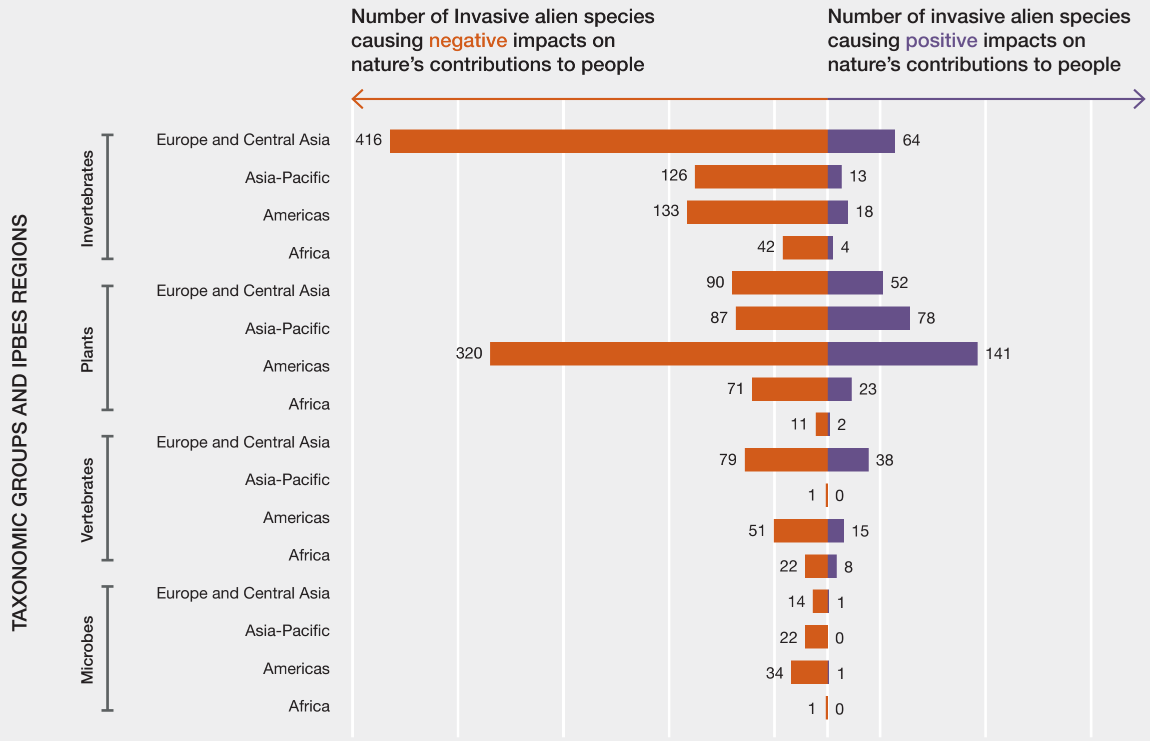

Figure 4 36 **Number of invasive alien species with documented negative and positive impacts on nature's contributions to people (x axis) per region and taxonomic group (y axis).**

Positive and negative stacked bar charts do not imply that positive and negative impacts can be summed. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

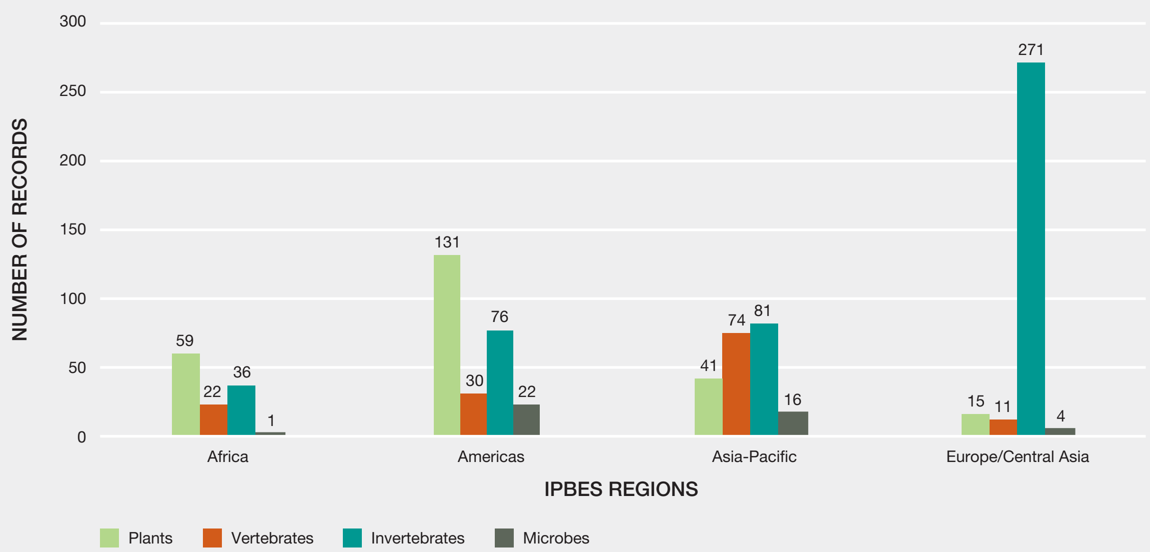

Figure 4 37 **Number of documented impacts (y axis) of invasive alien species on food provisioning by region (x axis).**

The number of invasive alien species involved is indicated above each column. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

Invasive alien taxa most often documented causing negative impacts by region

There are more impacts caused by plants in Africa, the Americas and the Asia-Pacific regions than in Europe and Central Asia **(Figure 4.37)**. In comparison to other regions, rangelands used for grazing livestock are less common in Europe and Central Asia than other regions of the world (Boone *et al.*, 2018), where high numbers of invasive alien species impact food provisioning through overgrowing rangelands or by harming livestock with poisonous or injurious parts **(Box 4.9)**. Impacts caused by invasive alien plants (as weeds in agricultural crops) are often not distinguished from impacts caused by native plants, especially when the impacts of the entire weed flora are assessed (Vilà *et al.*, 2004), and are therefore likely to be underrepresented in the impact database developed through this chapter.[10]

10. Data management report available at: https://doi.org/10.5281/zenodo.5766069

Pimentel *et al.* (2005) have estimated the impacts of invasive alien weeds in the United States by using the percentage of invasive alien agricultural weed species in the total weed flora to proportionate the crop losses caused by alien weeds. As a result, they estimated crop losses of US$24 billion annually based on the assumption of 12 per cent crop losses caused by weeds, of which 73 per cent were allocated to invasive alien weeds, corresponding to their share in the US agricultural weed flora.

A more comprehensive analysis of the impacts of plants across the four regions **(Table 4.18)** shows that in Europe and Central Asia, the highest number of different categories of nature's contributions to people is affected. In particular, impacts on soils by plants have been documented to be caused by 45 invasive alien species in this region, but there are also high numbers of plants impacting negatively on pollination (19) and biological processes (17). Across all regions, freshwater provision is the category of

nature's contributions to people that is more consistently negatively impacted by invasive alien plants. The number of documented impacts on material provisions by invasive alien invertebrates is very high in Europe and Central Asia (173 invasive alien species) and is also high in the Americas (37) and Asia-Pacific (39) regions, but there is only one record in Africa. In Africa in particular, impacts on forestry have not been as well documented (both in the literature and in the impact database developed through this chapter)[11] as, for example, in North America (e.g., Aukema *et al.*, 2011) or Europe and Central Asia. Europe also has a higher rate of documented new introductions of forest pests and diseases than other continents (Kenis *et al.*, 2017; Santini *et al.*, 2013).

Among immaterial nature's contributions to people, impacts on the maintenance of options by invasive alien plants have been documented in Africa (10) and Asia-Pacific (4), by vertebrates (34) and invertebrates (28) in the Americas, and for one microbe species in Asia-Pacific. Physical and psychological experiences have been impacted by 24 invasive alien plants in Europe and Central Asia, but also by invertebrates in the Americas, Asia-Pacific and Europe and Central Asia regions. There are eight plants with impacts on the "supporting identities" category, a further single record of one plant in this category for the Americas, of two invertebrates for Europe and Central Asia and of one microbe from the Asia-Pacific region.

Invasive alien taxa most often documented causing positive impacts by region

Many invasive alien species (mostly plants) also provide benefits to people, which, in many cases, have been the reason for their initial or continued introduction **(Table 4.19)**. Food provisioning can be improved by invasive alien plants

11. Data management report available at: https://doi.org/10.5281/zenodo.5766069

and vertebrates in all regions. In the Americas, 66 invasive alien plants have documented uses as food or feed, but numbers are lower in other regions, with 21 documented impacts in Asia-Pacific, 13 in Africa and 7 in Europe and Central Asia. Invasive alien vertebrate species are mostly used for food and feed in the Asia-Pacific region (34 species), whereas in the Europe and Central Asia region, invertebrates (41 species) are the largest invasive alien species taxa group providing this category of nature's contributions to people. Further benefits from plants are documented for soils in Europe and Central Asia (38 species) and Asia-Pacific (26 species). Invasive alien plants are used across all regions for medicinal reasons and for energy generation. Benefits for climate, for example through carbon sequestration in soils, have been documented for invasive alien plants in Europe and Central Asia (13 species), in Africa (9 species), mainly for micro-climate impacts of shade and windbreaks and in Asia-Pacific (2 species). Invasive alien plants also provide material benefits (e.g., as timber), and 14 species have been documented for this category of nature's contributions to people both in Asia-Pacific and the Americas, with fewer species in the other regions. Most documented impacts of the use of invasive alien plants for energy are from Africa, where 12 woody invasive alien species are documented as being used as firewood.

4.5 IMPACTS OF INVASIVE ALIEN SPECIES ON GOOD QUALITY OF LIFE

4.5.1 General patterns

Many of all documented impacts of invasive alien species are known to directly or indirectly affect good quality of life (15.7 per cent, 3,783 impacts), ranging from impacts on people's material and immaterial assets (e.g., food, housing), health (**section 4.5.1.3**), safety, relationships with people and nature, and maintaining opportunities for the future (i.e., the different constituents of good quality of life; **section 4.1.1**, **Box 4.3**). Globally, 1,032 invasive alien species have documented impacts on good quality of life, with 900 invasive alien species causing negative impacts and 236 causing positive impacts. Among those, 104 invasive alien species cause both positive and negative impacts, with both benefits and costs for good quality of life. These particular species can pose challenges for decision makers because they are differently perceived by different stakeholders (**Chapter 5**, **section 5.6.1.2**; **Figure 4.38**). The 796 invasive alien species causing only negative impacts is reflective of the higher number of negative impacts documented for good quality

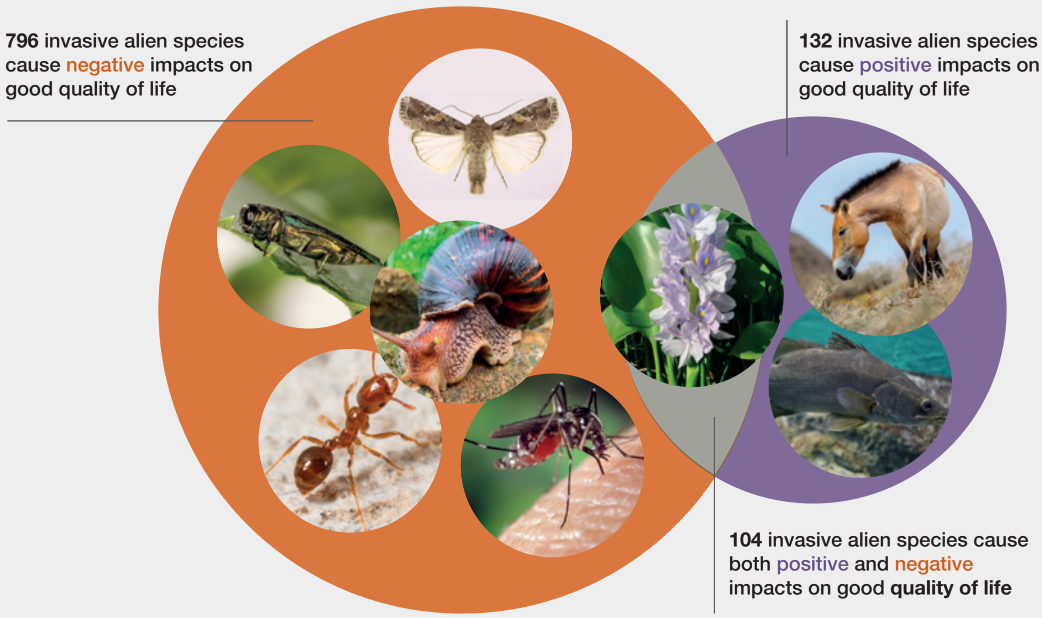

Figure 4 38 **Invasive alien species mostly cause negative impacts on good quality of life.**

Number of invasive alien species causing only negative impacts on good quality of life (left), negative and positive impacts (centre) and positive impacts only (right). Please note that the size of the segments is not proportional to the numbers. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069. of life, which is spread across all taxa, regions and units of analysis (**sections 4.5.2** and **4.5.3**).

Most impacted constituents of good quality of life

Globally, the most impacted constituents of good quality of life, both in terms of negative and positive impacts, are material and immaterial assets **(Table 4.20)**, which account for almost two-thirds (60.4 per cent, 2286 impacts) of the documented impacts. The number of negative documented impacts is approximately six times higher than that of the positive impacts, which is likely due to the fact that this constituent is directly related to livelihood of people, and is therefore documented more frequently. Positive impacts on material and immaterial assets have often resulted from the initial introduction of the invasive alien species for a specific purpose, for example food crops or plants delivering materials for fuel, which help people to improve their quality of life. However, if these species spread into natural areas, they can lead to negative impacts such as reduction in food gathered from nature, or yields from forestry and fisheries, therefore contributing to economic hardship, poverty and food insecurity for the same people or different stakeholders. Alternatively, invasive alien plants may cause initial negative impacts on material and immaterial assets, then people can adapt and find some benefits from the species. For example, after the intentional introduction of the tree *Prosopis juliflora* (mesquite) as forage for livestock and habitat stabilization, which led to widespread loss of native grassland, people have adapted to novel *Prosopis*-based livelihoods, especially by making charcoal and harvesting the wood for sale **(Box 4.9)**; this livelihood diversification and increased financial capital has enabled communities to cope better with environmental shocks (Sato, 2013; Walter & Armstrong, 2014). Parts of the tree have traditionally been used for medicinal purposes, and people are adapting it for medicinal use in its introduced habitats as well (Damasceno *et al.*, 2017; Duenn *et al.*, 2017). It is important to note that some communities do not voluntarily adapt to a species and its positive impact; they may not have had a choice, and their preferred option may still be the native species. Furthermore, adaptation does not necessarily increase the resilience (**Glossary**) of socioecological systems (**section 4.6**). Although some invasive alien species may be considered "useful" by particular groups of stakeholders, their presence is likely to have negative consequences for others, creating potential for conflict. In the Eastern Cape of South Africa, for example, *Opuntia ficus-indica* (prickly pear) provides a source of food and income for some local communities, but negatively impacts subsistence farmers by reducing the carrying capacity of land for livestock. The capacity to derive benefits such as food or energy from *Opuntia* spp. can even vary within local communities, whereby some women's groups are able to produce biogas and *Opuntia* jam and fruit juice, while others in the community do not have this capacity (IPBES, 2022).

Invasive alien species also greatly affect human health, which accounts for nearly one quarter of the impacts on good quality of life (22.2 per cent, 839 documented impacts), with 87 per cent of those impacts being negative (**Table 4.20**, **Boxes 4.15** and **4.16**). Together, the documented impacts on social, spiritual and cultural relations, safety and freedom of choice and action represent 14.2 per cent (536 documented impacts) of all the impacts on good quality of life and are also mainly negative impacts (77.8 per cent, **Table 4.20**). Many invasive alien species reduce access to grazing areas and water sources, resulting in food insecurity

Table 4 20 **Number of negative and positive impacts on constituents of good quality of life caused by invasive alien species.**

The number of impacts documented for each constituent of good quality of life. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

Constituent of good quality of life	Negative impacts	Positive impacts

Health	728	111
Social, spiritual and cultural relations	240	97
Safety	82	18
Freedom of choice and action	95	4
Unknown	58	64
Grand Total (%)	3208 (85%)	575 (15%)

and possible conflicts among pastoralist communities **(Box 4.9)**. The cultivation of *Acacia mangium* (brown salwood) has been documented to threaten the cultural and material continuity of the Wapichana and Macuxi in Brazil (Souza *et al.*, 2018). Invasive alien plants that form dense monocultures in semi-arid ecosystems, such as *Cenchrus ciliaris* (buffel grass), can physically block access to culturally important places, reducing socially valuable native species, and ultimately changing the opportunities for cultural knowledge transmission and well-being of future generations (Read *et al.*, 2020). Physical damage to ecosystems (e.g., changing water quality), can have a negative impact on people for whom water sources are sacred and central to their culture and well-being **(Box 4.14)**. Human safety is directly at risk from, for instance, falling branches due to dead or dying trees as a result of invasive alien species outbreaks, and indirectly impacted from, for instance, increased intensity of fires caused by more flammable invasive grasses (**Chapter 1**, **Box 1.4**). Impacts of invasive animals on personal safety are however more concerning, with, for instance, *Sturnus vulgaris* (common starling) nests near airports that put human lives and aviation equipment at risk regularly (Linz *et al.*, 2007). Larger invasive animals such as *Sus scrofa* (feral pig) or *Camelus dromedarius* (dromedary camel) are also known to directly scare or attack people or cause collisions and road accidents (Koichi *et al.*, 2012; Vaarzon-Morel, 2010). Invasive alien plants indirectly reduce people's safety as larger shrubs and trees have been documented to harbour wildlife that encroach on human settlements, increasing human-wildlife conflicts and impacting the safety of people; this has been especially documented by Indigenous Peoples and local communities (Puri, 2015; Sundaram *et al.*, 2012).

Ratio of positive and negative impacts on good quality of life

More than 6 out of 7 (3208 impacts, 85 per cent) documented impacts of invasive alien species on good quality of life are negative, and far fewer (575 impacts, 15 per cent) are positive for good quality of life. The ratio of negative to positive impacts on good quality of life caused by invasive alien species, is approximately 6 to 1. Other reviews of impacts of invasive alien species on human livelihoods have found higher proportions of beneficial impacts being documented. For instance, R. T. Shackleton, Shackleton, *et al.* (2019) have reviewed 51 case studies, in which 86 per cent of case studies documented detrimental impacts on human livelihoods and 79 per cent documented positive impacts on livelihoods. Similarly, in a review of 70 case studies, P. L. Howard (2019) has found that 90 percent of the case studies examined show evidence of harmful impacts on various ecosystem services and livelihood measures, while approximately 65 percent of the case studies document at least some positive effects. These reviews generally include groups of people with high dependence on nature for livelihoods, including, but not limited to, Indigenous Peoples and local communities. With a close proximity and reliance on natural resources, such communities may be the first to experience impacts of invasive alien species, but they also may be able to adapt and derive benefits when livelihoods are at stake (P. L. Howard, 2019; **section 4.6**). Therefore, the comparison of costs and benefits of invasive alien species will vary depending on the social-economic context, and some do not consider benefits as wholly "positive", and instead form part of trade-offs or more complex perspectives (IPBES, 2022).

Gender-differentiated impacts

Indigenous Peoples and local communities, ethnic minorities, migrants, poor rural and urban communities are disproportionately impacted by invasive alien vector-borne diseases (**section 4.5.1.4**; Bardosh *et al.*, 2017; Molyneux *et al.*, 2011). Gender bias is documented in some studies of invasive alien species impact upon people's livelihoods. Gender-differential impacts occur when invasive alien species limit or provide a resource which is gender-preferentially utilized. Male-dominated artisanal fisheries in Lake Victoria, dependent on tilapia for livelihood and food security, has declined due to the invasion of *Pontederia crassipes* (water hyacinth). The impact of *Pontederia crassipes* on the catchability was more important in the Kenyan section of Lake Victoria, where the tilapia population was reduced by 45 per cent (Kateregga & Sterner, 2009; Ongore *et al.*, 2018). In the gender-based division of labour among Rabari pastoralists in northwest India, men are responsible for the herd's health, access to water sources, fodder, camping sites, and face the negative impacts of *Prosopis juliflora* (mesquite; Duenn *et al.*, 2017). Similarly, women among the buffer zone community forest users of Chitwan National Park, Nepal, who are responsible for collecting grasses and fodder, reported that the invasive *Mikania micrantha* (bitter vine) makes collection of forest resources increasingly difficult (Rai & Scarborough, 2015; Sullivan *et al.*, 2017). The invasion of the forest reserve in Chamarajanagar, Karnataka, India, by *Lantana camara* (lantana) has been perceived by the neighbouring Lingayat women as contributing to the decline of a native palm. Palm-leaf broom making is one of the few income earning options available to them in the village (Kent & Dorward, 2015).

Some invasive alien species, such as *Acacia mearnsii* (black wattle), are widely used by Indigenous Peoples and local communities. In the Eastern Cape, South Africa, rural communities made widespread consumptive use, with 97 per cent of households in rural communities collecting wattle for fuelwood and building or fencing. While 53 per cent of the community members (men & women) prefer high densities of the shrub, 10 per cent fear criminals hiding in the *Acacia mearnsii* forests (C. M. Shackleton *et al.*, 2007).

Some invasive alien species provide food, fuel and income to women belonging to Indigenous Peoples and local communities, and help bring them into the mainstream economic activity. In most developing countries, the majority of marginalized coastal villagers impacted by invasive alien seaweed (e.g., *Kappaphycus, Eucheuma*) farming and small-scale processing are women. Economic gains from seaweed farming contributed to positive changes in the quality of life, in food, shelter, clothing, health care and social acceptance (Krishnan & Kumar, 2010; Msuya & Hurtado, 2017; Rameshkumar & Rajaram, 2019). In South Sulawesi, Indonesia, women documented seaweed farming as generating 50 per cent or more of their household income (Larson *et al.*, 2021; Rimmer *et al.*, 2021). In Kibuyuni, on the south coast of Kenya, women comprise 75 per cent of seaweed farmers. The income earned has empowered them to participate in societal issues and family decision-making processes (Mirera *et al.*, 2020).

There is very little systematic research on gender differences in impacts of invasive alien species beyond anecdotal evidence of direct impacts (for further examples see IPBES, 2022). The available data suggest that invasive alien species may, on occasion, cause impacts that are gender-biased, and gender-differentiated positive impacts may, in some cases, outweigh negative ones.

Invasive alien species most often documented causing negative impacts on good quality of life

The impact database developed through this chapter shows that there is a subset of invasive alien species that cause a disproportionate negative impact on good quality of life.[12] One-quarter of all negative impacts on good quality of life are caused by only 3 per cent (29 species) of all invasive alien species **(Table 4.21)**.

Six of the top 10 invasive alien species with the highest frequency of negative impacts on good quality of life **(Table 4.21)** are the same as those in the top 10 list of those invasive alien species that cause negative impacts on nature's contributions to people in the food and feed category (**section 4.4.1**; **Table 4.14**), which demonstrates

Cyprinus carpio (common carp)		24	0	0	0	0	24

how invasive alien species can harm good quality of life by negatively impacting the quality and availability of services and contributions from nature. *Spodoptera frugiperda* (fall armyworm; **Box 4.18**), *Bactrocera dorsalis* (Oriental fruit-fly), *Phenacoccus manihoti* (cassava mealybug), and *Lissachatina fulica* (giant African land snail) are serious pests of crops that affect the nature's contributions to people food and feed category, which then flows onto to affect people's access to material assets and support their livelihoods. Impacts of invasive alien species may also flow to other foundations underpinning good quality of life such as human health, for example, not only does *Lissachatina fulica* cause damage to crops, with Indigenous Peoples and local communities reporting that farmers have had to abandon their farms in Antigua and Barbuda after this damage, but they also affect human health by carrying a parasite that causes meningitis (IPBES, 2020).

In addition to serious crop pests, the top 10 most frequently documented invasive alien species with negative impacts on good quality of life **(Table 4.21)** include two microbial pathogens that cause dieback of plants, in this case important tree species such as *Fraxinus* spp. (ash) and *Quercus* spp. (oak), which are valued worldwide for amenity, climate regulation, and cultural traditions (Poland *et al.*, 2017). As a group, microbes causing tree dieback impact multiple constituents of good quality of life. For example, *Phytophthora cinnamoni* (Phytophthora dieback), *Phytophthora agathidicida* (kauri dieback), and *Austropuccinia psidii* (myrtle rust), which causes dieback of myrtaceous species such as the cultural keystone tree *Agathis australis* (kauri) in New Zealand, and *Eucalyptus* and *Melaleuca* (paperbarks) globally. *Eucalyptus* and *Melaleuca* support multiple livelihoods and major industries: where *Austropuccinia psidii* has caused a decline in tree health and subsequent yield losses of up to 70 per cent in *Melaleuca* oil plantations, fungicides needed to be applied, which limited the freedom of choice and action for growers, as they no longer had the option to be certified as organic producers (Carnegie & Pegg, 2018). Kauri trees are a key part of ancestral stories and spirituality for Māori in New Zealand (referred to as a taonga species), and the observed dieback of mature kauri trees in New Zealand has caused widespread concern about the potential impacts on spiritual

Table 4 22 **Main invasive alien species causing negative impacts on more than one constituent of good quality of life.**

The top 10 (by number of documented impacts) invasive alien species causing negative impacts on more than one constituent of good quality of life, representing invasive alien species with the broadest impacts on good quality of life. Dark shading represents species affecting 3 constituents, light shading those affecting 2 constituents. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

and cultural relationships, although more collaboration is needed between Māori knowledge and science knowledge systems to document how impacts on nature are also affecting good quality of life (Kauri Protection Governance Group, 2022).

Table 4.22 presents the top 10 invasive alien species causing negative impacts on more than one constituent of good quality of life, with a different ranking to the one based solely on the highest number of documented impacts for any category **(Table 4.21)**. It represents a broader range of impacts beyond material and immaterial assets. Some species appear on both tables: for example, Dengue virus causes damage to material and immaterial assets and health as well as freedom of choice and action and has a high number of reports across these categories. Other invasive viruses and human disease-causing microbes may well rank highly for impacts on good quality of life but have not been as well incorporated in the impact database developed through this chapter.[13] Some invasive alien species, whilst not documented as frequently as those in **Table 4.22**, were documented on a broader range of constituents of good quality of life, including *Dreissena polymorpha* (zebra mussel), *Lymantria dispar* (gypsy moth), *Ailanthus altissima* (tree-of-heaven), and *Agrilus planipennis* (emerald ash borer) **(Box 4.14)**. *Sus scrofa* (feral pig) affects human social and cultural relations and safety, and is probably representative of other invasive hard-hooved larger herbivores, whereby

Box 4 14 Impacts of emerald ash borer on Kanienkehá:ka (Mohawk) and W8banaki (Abénakis) Nations lands and the interaction with proposed policy responses.

Agrilus planipennis (emerald ash borer) is an invasive beetle from Asia whose lifecycle is dependent on ash trees. This invasive alien species was first discovered near the Great Lakes region of North America in 2002 and has since spread widely, killing millions of ash trees in North America (Haack *et al.*, 2002; Herms & McCullough, 2014). Many Indigenous nations have a special relationship to the ash tree, especially *Fraxinus nigra* (black ash – Maahlakws in Aln8ba8dwaw8gan (w8banaki language) and éhsa in Kanien'kéha (Mohawk language). Black ash is used in traditional arts such as basketry (Frey *et al.*, 2019; Poland *et al.*, 2017). In the past and still today, the loss of access to black ash due to land privatization, environmental pressures, and the emerald ash borer has had a significant impact on basket making (Blanchet *et al.*, 2022). In turn this results in a loss of traditional knowledge and language about this important cultural practice.

More than handicraft, basketry represents a symbol of cultural resilience for many nations, like the Kanienkehá:ka (Mohawk) and W8banaki (Abénakis) **(Figure 4.39)**. The practice survived despite all odds and the many obstacles that colonization and governmental restrictions have imposed over centuries. The art of basket making is embedded in Kanien'kehá:ka and W8banaki culture, identity, and spirituality. It has also been an important source of income for generations and continues today. According to the W8banakiak creation story, they come from black ash and their existence has always been interwoven. According to oral tradition, without the tree, W8banakiak (the -ak marks the plural) would not exist and if it would disappear, the Nation would as well. Furthermore, still today, many funeral urns are made of black ash. Thus, their identity "stems from the species", according to Martin Gill, Aln8ba from Odanak, (Blanchet *et al.*, 2022), and black ash is what holds the community together.

In 2018, the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) assessed the black ash tree as threatened (COSEWIC, 2018). This assessment prompted the Canadian government to consider listing the species under the federal *Species at Risk Act* (SARA). Listing the black ash in Canadian law would provide funding for recovery, but it would also impose restrictions such as a ban on selling ash baskets, and this would have devastating impacts on indigenous basketry, even though the practice of indigenous basketry is not causing the decline of black ash – the emerald ash borer is causing this decline. This approach also creates conflict between the Canadian view of conservation and Indigenous rights and relationship to the black ash. As an alternative approach, Indigenous Peoples have been actively researching and implementing measures to assure the protection and conservation of the black ash species, including monitoring, treatment, seed saving, and research collaborations (Poland *et al.*, 2017; Reo *et al.*, 2017) including W8banaki collaborations with University of Laval, Quebec. For example, sharing Indigenous and local knowledge, in this case about submerging black ash logs prior to harvest, has since been transferred to mainstream management as a suitable technique to reduce the survival of emerald ash borer (Poland *et al.*, 2017).

Banning the sale of baskets would significantly impact the ability to practice basketry, especially considering the existing pressures on the practice. This would then be a direct negative impact on the autonomy, rights and cultural identity of the Indigenous Peoples who practice this tradition and is counter-productive to the principal of self-determination.

"This would be the beginning of the end for basketry, teachings must continue so that the practice can be transmitted to future generations. We can't survive off love [and good faith] alone – we can't be giving them [baskets] away or keeping them for ourselves" Daniel G. Nolett, Aln8ba from Odanak (Blanchet *et al.*, 2022).

Box 4 14

"They would be taking a part of me. I cannot begin to conceive my existence without my relationship to black ash" Suzie O'Bomsawin, Aln8baskwa from Odanak (Blanchet *et al.*, 2022).

Women are likely to be particularly affected if there were a ban on the sale of baskets. For women, the sale of baskets is an incentive for not only their production and importance in household economies, but also for the intergenerational transmission of associated knowledge and skills. Long term impacts of this approach could see any entire generation lose access to basketry skills, and basketry practice and associated cultural identity would likely disappear.

Figure 4 39 **Basketry, a symbol of cultural resilience for the Kanienkehá:ka (Mohawk) and W8banaki (Abénakis).**

Black Ash trees and the process of basketmaking using prepared strips of Black Ash wood (right) has special cultural significance for many First Nations in North Amercia. Baskets (centre and left) are more than handicrafts, as they are symbols of cultural identity and resilience, the practice supports knowledge transfer between generations and they are integral to local economies, especially for women. Emerald Ash Borer has killed millions of Black Ash trees and policies to protect the Black Ash, such as banning the sale of baskets, may further threaten the cultural, social and economic livelihoods of First Nations people. Photo credit: Musée des Abénakis – Copyright.

they damage important cultural sites and species, and can attack people or cause road accidents (C. J. Robinson & Wallington, 2012; Vaarzon-Morel, 2010).

Invasive alien species most often documented causing positive impacts on good quality of life

In contrast to the top 10 invasive alien species causing negative impacts on good quality of life, which are mainly invertebrates and microbes, positive impacts on good quality of life are being derived primarily from invasive alien plants and vertebrates **(Table 4.23)**. These invasive alien plants have been introduced to multiple countries to either provide land and/or water rehabilitation, ornamental or shade purposes (*Robinia pseudoacacia* (black locust), *Pontederia crassipes* (water hyacinth), *Ailanthus altissima* (tree-of-heaven)), or livelihood resources (*Proposis juliflora* (mesquite)), from which people in multiple countries derive benefits that improve their quality of life (**section 4.6**). However, all of these four species in particular have negative impacts on nature, nature's contributions to people and good quality of life as well, with *Ailanthus altissima* also listed as one of the top 10 invasive alien species with negative impacts on more than one aspect of well-being. These four invasive alien plant species have been well-studied in the literature and thus, benefits to good quality of life are frequently documented alongside negative impacts.

Similarly, the three vertebrates in this top 10 listing of positive impacts also have negative impacts on nature, nature's contributions to people and good quality of life. *Cyprinus carpio* (common carp), *Oreochromis niloticus* (Nile tilapia), and *Oreochromis mossambicus* (Mozambique tilapia) are freshwater fish that have been introduced and adapted to as a food source and to support fishing industries and livelihoods, from which people derive material assets **(Box 4.10)**, although some of these adaptations may not have been the preferred option for some local communities (**section 4.6**). *Cyprius carpio* is also listed as a top 10 species causing negative impacts on good quality of life **(Table 4.21)**.

Three other invasive alien species that provide benefits to people are *Equus ferus* (wild horse), *Eucheuma denticulatum* (eucheuma seaweed), and *Columba livia* (pigeons). Wild horses are considered by some groups of people as a culturally-important species and thus benefit social and cultural relations (Collin, 2017), *Eucheuma denticulatum* contains medicinal properties, and *Columba livia* is used as a food source by local communities.

Table 4 23 **Main invasive alien species causing positive impacts on good quality of life.**

4.5.1.1 Invasive alien ants impact multiple constituents of good quality of life

Invasive alien ants are a group of invasive alien species with a high number of impacts documented across multiple constituents of good quality of life, particularly affecting human health, more so than material assets. Invasive ants have been well-studied in terms of socio-economic impacts (Gruber *et al.*, 2022). Using the SEICAT **(Box 4.2)**, 550 socio-economic impacts of invasive ants have been documented for 65 named species in 50 countries and territories, with most documented impacts from the United States (36 per cent), Brazil (22 per cent), Australia (5 per cent) and Malaysia (5 per cent). The most frequently identified socio-economic impacts are on health (60.6 per cent of documented impacts) and material assets (35.1 per cent). The remaining impacts are on social (4.7 per cent), spiritual (0.4 per cent), and cultural relations (2.4 per cent) and non-material assets (1.9 per cent). Health impacts (269/279 documented impacts) are predominantly from stings and bites, and some deaths have also been documented.

Vectoring of pathogens in hospitals and food preparation facilities have been considered minor health impacts. Effects on material assets are mostly electrical damage from ants nesting in appliances and infrastructure, and damage to crops and livestock that affected livelihoods, also usually to a minor degree (128 out of 153 documented impacts). Impacts on non-material assets and social, spiritual, and cultural relations include avoidance of outdoor activities and health effects on pets. Under the SEICAT methodology, which categorizes a species based on the highest magnitude of documented impact, *Wasmannia auropunctata* (little fire ant) poses the most serious socio-economic threat (massive impact as determined by permanent disappearance of an activity), followed by *Solenopsis invicta* (red imported fire ant) and *Anoplolepis gracilipes* (yellow crazy ant). However, these highest categorizations were each based on a single record only. Of these three species, *Anoplolepis gracilipes* is the most widespread having a pan-tropical distribution. The introduced range of *Wasmannia auropunctata* is predominantly in the Caribbean, but also includes some islands in the Pacific, eastern Australia, western Africa, southern United States, and in Europe and northern America. *Solenopsis invicta* has been introduced to the southern United States, the Caribbean, China, Japan, and Australia. All other species are ranked as having, at most, moderate impacts (changes in activity size, switching or moving activities) or minor impacts (difficult to carry out normal activities).

4.5.1.2 Small island states and the impact of invasive alien species on good quality of life

One fifth of the documented impacts (20.5 per cent, 776 impacts) of invasive alien species on good quality of life are found in island states. Among these, 76.5 per cent (594) are negative impacts, and 23.5 per cent (182) are positive impacts **(Figure 4.40)**. While the proportion of negative to positive impact cases in the islands is about 3.3 (594/182), this figure for the mainlands is about 6.7 (2614/394), suggesting positive impacts on good quality of life are proportionally higher in islands than on mainland. These numbers suggest that island ecosystems and good quality of life in islands are vulnerable to invasive alien species and their impacts (D'Antonio & Dudley, 1995; **section 4.3.1.1**). Both positive and negative impacts are primarily documented on material and immaterial assets, such as food production in agriculture, followed by health and relations. About half of the positive impacts of good quality of life in health and relations (52 of 111 cases, and 52 of 97 cases, respectively) are documented from island states. Islands tend to lack some of the species that can be beneficial for human uses, and thus inhabitants introduced alien species to improve their good quality of life. This could explain why positive impacts on good quality of life are documented at a higher rate from islands. For the same reason, agriculture introductions are the major pathway of invasive alien species introduction in island states (Driscoll *et al.*, 2014). This probably leads to the proportionally larger number of documented cases in cultivated lands. Documented impact across units of analysis in islands are disproportionally distributed: while the number of documented negative impact cases from dry land in islands is equal to the mainlands (201 and 214), there are only 4 cases from boreal forest as opposed to 292 cases in mainlands. This is probably because studied islands are predominantly biased to the tropics in the Asia-Pacific region. Indeed, 70.2 per cent of the documented impacts on good quality of life in islands are found in Asia-Pacific, although Asia-Pacific represents 40.9 per cent of all documented impacts on good quality of life. Invertebrates have caused 55.4 per cent of negative and 46.7 per cent positive impacts on the good quality of life in islands, while this figure is 50 per cent and 28.9 per cent in mainlands. While plants are the largest group with positive impacts in mainlands, invertebrates are the largest group with positive impacts in islands.

Figure 4 40 **Number of impacts (y axis) of invasive alien species on constituents of good quality of life (x axis) in islands and in mainlands.**

This figure shows the number of negative (-) and positive (+) impacts on good quality of life in islands and in other locations globally, and for each constituent of good quality of life. A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

In islands, two aquatic plant species, *Pontederia crassipes* (water hyacinth) and *Salvinia × molesta* (kariba weed), are the major species that reduce good quality of life through compromising assets and health constituents, followed by *Lissachatina fulica* (giant African land snail), Dengue virus, and *Laevicaulis alte* (tropical leatherleaf slug). Among invertebrates, molluscs are the major invasive alien species groups that provide positive impacts on good quality of life in islands. *Lissachatina fulica* and *Laevicaulis alte* are the two most documented invasive alien species from islands causing both positive and negative impacts. They are major agriculture pests (Cowie *et al.*, 2009) as well as intermediate hosts for various parasites, such as *Angiostrongylus cantonensis* (rat lungworms; Barratt *et al.*, 2016). At the same time, those molluscs were documented to positively impact assets and health through predating invasive alien molluscs or transmitting parasites to their final hosts, such as invasive alien rats (Nurinsiyah & Hausdorf, 2019). Studies on the positive impacts of invasive alien species on good quality of life are still limited, and information on the positive impacts caused by molluscs is based on a single study (Nurinsiyah & Hausdorf, 2019).

4.5.1.3 Direct and indirect impacts on human health

Invasive alien species negatively impact human health, from nuisance to allergies, poisoning, disease and death (Martinou & Roy, 2018; **Figure 4.41**; **Box 4.15**).

The widely dispersed agricultural and garden pest *Lissachatina fulica* (giant African land snail; **Figure 4.42**) serves as the intermediate host of a parasitic nematode, *Angiostrongylus cantonensis* (rat lungworm). Human infection with its larvae, through handling or consumption, causes eosinophilic meningitis, which may result in cranial nerve abnormalities, ataxia, encephalitis, coma, and, rarely, death (Kwon *et al.*, 2013; Malvy *et al.*, 2008; Thiengo *et al.*, 2010; Tsai *et al.*, 2001). The aggressive and venomous invasive alien ant *Solenopsis invicta* (red imported fire ant; **Figure 4.42**), introduced from Brazil to the southern United States, Caribbean, East Asia, and Australia, represents a significant health hazard. Its venom induces an immediate, severe burning sensation; subsequent reactions may range from local pustules and rash to life-threatening anaphylaxis (deShazo *et al.*, 1990, 1999; deShazo & Banks, 1994; Stafford, 1996; Xu *et al.*, 2012; Zhang *et al.*, 2007). Incidence of fatalities attributed to fire ant-induced anaphylaxis have been rare to none in the southeastern United States (Prahlow & Barnard, 1998; Rhoades *et al.*, 1989). Between 30 and 60 per cent of the population in urban areas infested by imported fire ants are stung every year (deShazo *et al.*, 1990).

Many vector-borne pathogens have appeared in the past few decades in new regions as result of introductions, some causing explosive epidemics (Kilpatrick & Randolph, 2012; **Box 4.16**). Zoonotic diseases transmitted by invasive mosquito genera (e.g., *Aedes*, *Anopheles*, *Culex*) include

Box 4 15 Direct and indirect impacts of invasive alien species on human health.

Invasive alien species occasionally have deleterious impacts on human health, presenting serious challenges to the good quality of life (**Chapter 1**, **section 1.6.7.2**). They can affect physical as well as psychological health (Martinou & Roy, 2018), directly (e.g., injury to people) or indirectly (e.g., through a reduction in food security). Their role as disease vectors is discussed in **Box 4.16**.

In the terrestrial realm, biological invasions are directly affecting people. There are many invasive alien terrestrial plants with highly allergenic pollen, including *Ambrosia artemisiifolia* (common ragweed), native to Central and Northern America but now found throughout the world, and the dermatitis-causing *Heracleum mantegazzianum* (giant hogweed), native to southern Russia and Georgia but now spread through northern Europe (Jakubska-Busse *et al.*, 2013; Klimaszyk *et al.*, 2014; Lim *et al.*, 2021). *Solenopsis invicta* (red imported fire ant), invasive in North America since the 1930s, inflicts severe stings and has killed people with allergies to its venom (Jemal & Hugh-Jones, 1993). Invasive alien snakes were introduced in Guatemalan oil palm plantations to limit rodent populations, and have bitten local children living nearby, forcing families to relocate (IPBES, 2020). Invasive agricultural pests can also indirectly affect human health by reducing food security; for example, the income and nutrition of small holder farmers and their families involved in mixed maize farming in east Africa is hampered by several major invasive alien species, including *Chilo partellus* (spotted stem borer) and viruses causing Maize Lethal Necrosis Disease (C. F. Pratt *et al.*, 2017). *Spodoptera frugiperda* (fall armyworm) has been described as an "emerging food security global threat" by the Food and Agricultural Organization of the United Nations (FAO) and International Plant Protection Convention; its impact has been painfully evident in countries facing other severe challenges to public health and governance, such as the Democratic Republic of the Congo, Sudan, and Yemen (FAO, 2018). Food security is tightly linked to invasive alien species management in China (McBeath & McBeath, 2010) and wheat-producing countries such as the United States and Canada need to protect against a variety of pernicious invasive alien species such as *Trogoderma granarium* (khapra beetle), one of the world's worst storage pests (Athanassiou *et al.*, 2019).

In inland waters, the shells of *Dreissena polymorpha* (zebra mussel) can cause skin injuries to recreational swimmers and commercial fishers. *Pontederia crassipes* (water hyacinth)

Box 4 15

can make small-scale freshwater fishing next to impossible, indirectly lowering income, food security, and nutrition levels for local communities. Moreover, its introduction has been implicated in the spread of malaria in Lake Victoria due to the creation of habitat for the mosquitoes that harbour *Plasmodium* parasites (Kasulo & Perrings, 2000).

In the marine realm, venomous and poisonous invasive alien species include *Plotosus lineatus* (striped eel catfish) and *Lagocephalus sceleratus* (silver-cheeked toadfish), urchins and jellyfish (Galanidi *et al.*, 2018; Galil, 2018; **Figure 4.41**).

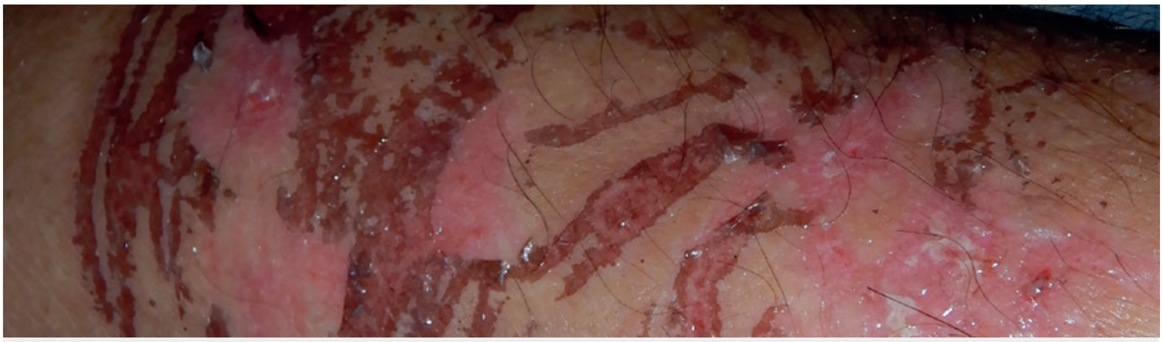

Figure 4 41 **Injuries inflicted by the invasive jellyfish *Rhopilema nomadica* (nomad jellyfish).**

Rhopilema nomadica are invasive alien species found in the Mediterranean Sea. Their stings impact good quality of life in this area. Photo credit: Moti Mendelson – CC BY 4.0.

Combined with other threats to good quality of life described elsewhere in this assessment, invasive alien species directly and indirectly present formidable challenges to human health, in the midst of climate change (Schindler *et al.*, 2018). Awareness of the extent of the threat posed to human health by invasive alien species is still limited. Studies on the impacts of invasive alien species on mental health impacts are also emerging. For example, a participant in an IPBES Indigenous and local knowledge workshop and a formal study both suggest there has been a noticeable decrease in "subjective well-being" due to the impacts of the invasive *Agrilus planipennis* (emerald ash borer) in North America (IPBES, 2020; B. A. Jones, 2017; **Box 4.18**).

malaria, dengue fever, chikungunya, Zika, yellow fever, and West Nile fever, and inflict misery, chronic symptoms, and occasionally death (M. R. Duffy *et al.*, 2009; Effler *et al.*, 2005; Enserink, 2006; Fares *et al.*, 2015; Heukelbach *et al.*, 2016; Kilpatrick, 2011; Laras *et al.*, 2005; Nash *et al.*, 2001; Polwiang, 2020; Rezza *et al.*, 2007; N. Singh *et al.*, 2015). Several widely dispersed plant species (e.g., *Prosopis juliflora* (mesquite), *Parthenium hysterophorus* (parthenium weed)) significantly contribute to *Anopheles* mosquito longevity, and thereby enhance malaria transmission potential (Muller *et al.*, 2017; Nyasembe *et al.*, 2015; Tyagi *et al.*, 2015).

Some of the most widely dispersed invasive alien plants cause direct or indirect adverse effects. *Hedera helix* (ivy), native to Europe, is established in Australia, New Zealand, Hawaii, Brazil, and North America, where it causes allergic contact dermatitis (Bregnbak *et al.*, 2015; J. M. Jones *et al.*, 2009). The pollen of *Ambrosia artemisiifolia* (common ragweed), a native plant to Central and Northern America that has spread widely, is a common seasonal source of aeroallergens, and a major concern for public health, causing allergic rhinitis, fever, or dermatitis (Déchamp, 1999; Möller *et al.*, 2002). A single *Ambrosia artemisiifolia* plant can indeed release up to one billion pollen grains per season, and as low as 10 pollen grains per cubic meter of air can trigger an allergic reaction (DellaValle *et al.*, 2012; Emberlin, 1994; Fumanal *et al.*, 2007). High pollen exposure or volume may lead to increases in sensitization rate (Gabrio *et al.*, 2010; Jäger, 2000). *Prosopis juliflora* (mesquite) pollen also elicits highly allergenic reactions (Al-Frayh *et al.*, 1999; Ezeamuzie *et al.*, 2000; Kathuria & Rai, 2021; Killian & McMichael, 2004). *Heracleum mantegazzianum* (giant hogweed), native to southern Russia and Georgia but now spread throughout northern Europe, poses threats to human health due to its photoallergic properties, resulting from the intensely toxic furanocoumarin in its sap **(Figure 4.42)**. Contact with the plant, followed by sun exposure, may lead to the development of blisters and symptoms of burns (Carlsen & Weismann, 2007; Jakubska-Busse *et al.*, 2013; Klimaszyk *et al.*, 2014; Lim *et al.*, 2021).

Health impacts caused by invasive alien marine species have been amply documented. In the Mediterranean Sea, for example, the venomous *Rhopilema nomadica* (nomad jellyfish; **Figure 4.42**), *Pterois miles* (lionfish), and the lethally poisonous *Lagocephalus sceleratus* (silver-cheeked toadfish)

Box 4 16 Invasive alien species as disease vectors or reservoir hosts.

Beyond the health impacts discussed in **Box 4.15**, many invasive alien species can act as disease vectors (i.e., introducing parasites and pathogens to new regions along with their host, passing diseases directly to humans), reservoir hosts (where a disease can survive before a vector passes it onward), or facilitators (i.e., helping the occurrence of pathogen or vector).

Global trade in livestock, wildlife and plants is a key driver facilitating both intended and unintended introductions of pathogens, hosts, and vectors to new land areas, increasing the rate of disease emergence and health impacts on human populations (Bezerra-Santos *et al.*, 2021; Chinchio *et al.*, 2020; Fèvre *et al.*, 2006; Lounibos, 2002; Vilà *et al.*, 2021).

Diseases such as the bubonic plague, caused by the flea- and rat-borne bacterium *Yersinia pestis* (black death), have caused traumatic social and political upheavals (Athni *et al.*, 2021; Kosoy & Bai, 2019; Wells *et al.*, 2015). Mosquito species such as *Aedes aegypti* (yellow fever mosquito) and *Aedes albopictus* (Asian tiger mosquito) have spread since the fifteenth century, largely due to shipping, air and road transport and trade (Lounibos, 2002). These species have exacerbated the spread of the lethal yellow fever, dengue fever, chikungunya and Zika viruses, and other infectious diseases, throughout the Americas, Asia and, more recently Europe (Juliano & Lounibos, 2005; LaPointe, 2021; Romi *et al.*, 2018). *Culex quinquefasciatus* (southern house mosquito), a vector for lymphatic filariasis, St. Louis Encephalitis virus, and West Nile virus, has spread from West Africa, killing over a million people a year (LaPointe, 2021; Lounibos, 2002; Romi *et al.*, 2018). Invasive mammals and birds can alter the epidemiology of resident pathogens and become reservoir hosts, increasing disease risk for humans (Capizzi *et al.*, 2018). Most zoonotic human diseases are known to originate from mammals: rodents and bats are vectors for a high number of pathogens (Han *et al.*, 2016), and so are *Nyctereutes procyonoides* (raccoon dog), implicated in rabies and tapeworm transmission, and *Procyon lotor* (raccoon), implicated in roundworm transmission (Lojkić *et al.*, 2021; Page *et al.*, 2016). Introduced bird species, in particular psittaciform (parrots), columbiform (pigeons) and anseriform (duck) species, represent a hazard to good quality of life. Main zoonoses include psittacosis, cryptococcosis, listeriosis and salmonellosis, transmitted by direct contact or *via* insect vectors (fleas, lice, ticks and mites). Some galliform species, introduced for hunting, can cause salmonellosis and other gastroenteric diseases (Mori *et al.*, 2018).

The magnitude of risks and impacts arising from co-invasive pathogens is difficult to discern because few data exist on the links among invasive alien species, their parasites or pathogen load and zoonotic diseases (Hulme, 2014). Robust documentation of the prevalence and abundance of parasites, pathogens, and vectors of human diseases associated with high-risk alien hosts would be needed to initiate effective management.

Figure 4 42 Examples of invasive alien species causing serious health problems.

present well-known dangers (Galil, 2018). With rising seawater temperature, it is likely these thermophilic species will expand their range. Though published records attest to the increasing spread and abundance of these species in the Mediterranean Sea, only fragmentary information is available concerning the spatial and temporal trends (**Glossary**) of their impacts (Bédry *et al.*, 2021; Galil, 2018). Even for common, wide-spread species with acute symptoms such as *Lagocephalus sceleratus* and *Rhopilema nomadica*, incidents are poorly documented. Öztürk and İşinibilir (2010) reported that in summer 2009, nomad jellyfish envenomation caused 815 hospitalizations in Turkey, but no data is available for other years and other locations. A similar pattern emerges from the records of toadfish poisoning, reported mainly in local journals and digital media (Ben Souissi *et al.*, 2014). The lack of region-wide, quantitative data on medically-treated health impacts could lead on one hand to medical errors (Beköz *et al.*, 2013), and on the other, prejudice risk analyses undertaken by management. Incidents involving large numbers of patients may be expected to become more frequent with changing environmental conditions, unless this becomes a public health priority (Glatstein *et al.*, 2018).

4.5.1.4 Impacts on human health: links with impacts on other constituents of good quality of life

Constituents of good quality of life are often linked, and impacts on human health are one type of impacts on other constituents of good quality of life. Many Indigenous Peoples and local communities experience these connections acutely due to their close physical and spiritual interactions with the environment **(Box 4.17)**. Many invasive alien species impact Indigenous Peoples and local communities' lifestyles, by restricting access to lands and participation in traditional activities (IPBES, 2020). For example, in Australia, *Anoplolepis gracilipes* (yellow crazy ant) and *Solenopsis invicta* (red imported fire ant), which can bite people, have prevented some Indigenous Peoples and local communities from taking part in traditional activities. *Pastinaca sativa* (parsnip), an invasive alien plant in Canada, has been documented by Indigenous Peoples and local communities to cause skin to become sensitive to sunlight, burning the skin, which is a problem for hunters of that community (IPBES, 2020). The increase of Lyme disease-bearing *Ixodes scapularis* (blacklegged or deer ticks) populations in Canada is indirectly impacting knowledge transmission as Indigenous Peoples and local communities are concerned about taking children out on the land, where the majority of Indigenous and local knowledge learning takes place (IPBES, 2020). Indigenous Peoples and local communities in Siberia have known that *Heracleum pubescens* (Sosnowskyi's hogweed or Borshchievik in Russian) has been a problem for them since the 1980s (IPBES, 2020); they report that it is highly poisonous when over 60cm high and seeding, with stems and leaves causing allergic reactions, severe dermatitis and may cause cancerous tumours, congenital malformations and even fatalities in humans and animals (IPBES, 2020). Indigenous Peoples and local communities often try to maintain access to land and carry out traditional activities, particularly passing knowledge onto the next generation. When invasive alien species impact upon these activities, this can lead to "cultural erosion" (Pfeiffer & Voeks, 2008), whereby knowledge, particularly names of native species, their habitats, and their cultural values and stories are not passed down to younger people, which can have negative implications for the good quality of life of future generations (Robin *et al.*, 2022; **Box 4.17**).

Box 4 17 The impacts on cultural species, cultural sites, cultural relationships and health of Indgenous Peoples and local communities, revealed through Indigenous and local knowledge and cross-cultural research in Australia's Northern Territory.

Cross-cultural research (using methodologies from different knowledge systems), was used in Arnhem Land, at the northeast corner of Australia's Northern Territory, to investigate invasive ungulates (buffalo, donkeys, pigs, cattle and horses) trampling and grazing on traditional bush food resources and impacting water quality at several culturally significant wetlands.

Wetlands provide Indigenous Peoples with drinking water, medicines and bush foods, including *Eleocharis dulcis* (Chinese water chestnut) and *Nymphaea* spp. (water lilies), and is host to aquatic fauna, including *Chelodina rugosa* (northern snake-necked turtle), which is an important seasonal source of protein (Fordham *et al.*, 2006; Ens, Fisher, *et al.*, 2015). The Indigenous People of Ngukurr, Arnhem Land, have raised concerns about drinking water from wetlands due to potential microbial contamination from feral invasive ungulates, yet deoxyribonucleic acid (DNA) analysis for the waterborne pathogens *Cryptosporidium* and *Giardia* revealed the latter was only detected in the late dry season and former was not detected at all (S. Russell *et al.*, 2021). The presence of invasive ungulates negatively impacts on indigenous access to bush food, medicine and freshwater resources which then reduces opportunities for cultural and spiritual practices (S. Russell *et al.*, 2020, 2021). For example, hooved ungulates damage *Chelodina rugosa* aestivating over the dry season (S. Russell *et al.*, 2021), and feral pig predation depletes turtle stocks immediately before Aboriginal harvesting (Fordham *et al.*, 2006). An Indigenous knowledge holder described an eco-cultural regime shift of a wetland ecosystem from a water lily (*Nymphaea violacea* and *Nymphaea macrosperma*) dominated

Box 4 17

system to a turbid, sediment dominated system. This was attributed to human depopulation of traditional lands and waters and the subsequent invasion by feral ungulates. Evidence for this "regime shift" is based on Indigenous ecological knowledge (S. Russell *et al.*, 2021). Transformation of this ecosystem has had implications for access to bush food resources; *Nymphaea* spp. Roots, stems, and bulbs that were a staple food for local Indigenous Peoples.

Although invasive ungulates are impacting ecological condition, indigenous cultural practice, and potentially human health, these animals present a significant food source and potential source of income to remote living Indigenous Peoples and local communities who have low socio-economic status (C. J. Robinson *et al.*, 2005). The conflicting impacts and benefits of these invasive alien species has meant that widespread and sustained control has not occurred across northern Australia. To accommodate the multiple values of these invasive alien species, at present, members of the Ngukurr community prefer maintenance of multi-functional landscapes where the multiple values of these species can be supported (Ens, Fisher, *et al.*, 2015). However, with economic development of this region, support of invasive ungulate management may increase **(Figure 4.43)**.

Figure 4 43 **Invasive ungulates pollute wetlands in Australia's Northern Territory; and indigenous rangers document the impacts on water quality and cultural species, including *Nymphaea* spp. (water lilies).**

4.5.2 Documented impacts of invasive alien species on good quality of life by realm

Impacts of invasive alien species on good quality of life vary by realm and unit of analysis. As a general pattern, the impact database developed through this chapter reveals that impacts are most often experienced through changes to material and immaterial assets, followed by impacts on health and social and cultural relationships.[14] Impacts on safety and freedom of choice and action are the two least documented components of good quality of life.

Notably, a small number of the units of analysis account for most of the impacts on good quality of life (**sections 4.5.2.1** and **4.5.2.2**). Among the documented negative impacts, 74 per cent occur in cultivated areas (including cropping, intensive livestock farming, etc.; 935 negative impacts caused by 332 invasive alien species), urban/ semi-urban (606 negative impacts caused by 245 invasive alien species), inland surface water and water bodies/ freshwater (411 negative impacts caused by 151 invasive alien species), and tropical and subtropical dry and humid forests (415 negative impacts caused by 136 invasive alien species). Similarly, 74 per cent of all positive impacts occur in cultivated areas (151 positive impacts caused by 79 invasive alien species), tropical and subtropical dry and humid forests (118 positive impacts caused by 70 invasive alien species), temperate and boreal forests and woodlands (82 positive impacts caused by 40 invasive alien species), and inland surface water and water bodies/freshwater (80 positive impacts caused by 49 invasive alien species). Examining positive impacts helps put these percentages

14. Data management report available at: https://doi.org/10.5281/zenodo.5766069

into perspective. The three least affected units of analysis with positive impacts, tundra and high mountain habitats (5 positive impacts, caused by 2 invasive alien species), Mediterranean forests, woodlands and scrub (2 positive impacts caused by 2 invasive alien species), and open ocean pelagic systems (1 positive impact caused by 1 invasive alien species), make up less than 2 per cent of all positive documented impacts. **Table 4.24** presents the main invasive alien species causing impacts on good quality of life in each unit of analysis.

Table 4 24 **Invasive alien species most frequently documented to cause negative or positive impacts on good quality of life by unit of analysis.**

A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

4.5.2.1 Patterns of negative and positive impacts of invasive alien species on good quality of life in the terrestrial realm

The terrestrial realm accounts for most of the documented impacts on good quality of life compared to aquatic realms; with 82 per cent (2,629 impacts) of all negative impacts and 81 per cent (467 impacts) of positive impacts. This is consistent with the literature on impacts of invasive alien species on livelihood, which indicates that a greater proportion of studies focused on terrestrial ecosystems have been conducted in savanna and woodland environments compared to freshwater ecosystems (R. T. Shackleton, Shackleton, *et al.*, 2019).

Most impacted units of analysis in the terrestrial realm

Cultivated areas have the highest number of documented invasive alien species (332) and negative impacts (935) **(Table 4.25)**. This pattern may be attributed in part to the greater attention paid to cultivated areas in research, given the critical role of food security in meeting basic human needs. Additionally, the ease of measuring human access to food in cultivated areas may make them a more accessible unit of analysis than other ecosystems (P. L. Howard, 2019; Pimentel *et al.*, 2005). Large numbers of invasive alien species have also been documented in urban/semi-urban areas (245 invasive alien species), tropical and subtropical dry and humid forests (136 invasive alien species), and temperate and boreal forests and woodlands (101 invasive alien species), which, together, round out the top four affected units of analysis, accounting for 83 per cent of all documented negative impacts in the terrestrial realm. Tundra and high mountain habitats and deserts and xeric shrublands are the least affected units of analysis, and only host 5 per cent of the documented invasive alien species causing negative impacts on good quality of life in the terrestrial realm.

Material and immaterial assets are the most impacted constituent of good quality of life across units of analysis. However, in deserts and xeric shrublands, health is the dominant constituent negatively impacted by invasive alien species. There are very few documented impacts on safety across most units of analysis.

Invasive alien taxa most often documented causing negative impacts on good quality of life in the terrestrial realm

The most prominent taxa negatively impacting good quality of life differ across units of analysis **(Table 4.24)**. For example, cultivated areas, temperate grasslands, and urban/semi-urban areas are mainly affected by invasive alien animals such as *Spodoptera frugiperda* (fall armyworm) that causes significant damage to agriculture and rice crops (Kumela *et al.*, 2019; **Box 4.18**). These species can create additional pressures for farmers in Africa or native American lands where the agricultural sector struggles to support farmers' livelihoods because of the lack of ownership, low or no financial capital, and increasing risks due to climate change (Gautam *et al.*, 2013; P. L. Howard, 2019). Temperate grasslands contended with *Acridotheres tristis* (common myna) whose droppings can irritate

Table 4 25 **Negative impacts on good quality of life in the terrestrial realm.**

Darker colours indicate higher documented numbers of invasive alien species or impacts. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

Unit of analysis	Material and immaterial assets		Freedom of choice and action		Health		Social and cultural relationships		Safety	
	species	impacts	species	impacts	species	impacts	species	impacts	species	impacts
Tropical and subtropical dry and humid forests	66	213	7	14	41	143	17	37	5	8
Temperate and boreal forests and woodlands	48	183	7	10	24	54	15	34	7	15
Mediterranean forests, woodlands and scrub	11	77	0	0	3	3	0	0	1	1

people's skin and lungs (Peacock *et al.*, 2007). Urban and semi-urban areas are most impacted by the aggressive *Solenopsis invicta* (red imported fire ant), whose powerful sting can cause injury and death to people, wildlife, and pets (Gutrich *et al.*, 2007). Their ability to tunnel also impacts infrastructure, such as roads, power distribution systems, and irrigation systems (Gutrich *et al.*, 2007). Impacts on good quality of life in Mediterranean forests, woodlands and scrub are mostly caused by microbes, such as *Xylella fastidiosa* (Pierce's disease of grapevines), known for killing olive trees (Schneider *et al.*, 2020), reiterating that material and immaterial assets are the most affected component of good quality of life.

The remaining units of analysis experience impacts from several taxa. Tropical and subtropical dry and humid forests and temperate and boreal forests and woodlands are negatively affected by microbes and animals. Deserts and xeric shrublands, tropical and subtropical savannas and grasslands, tundra and high mountain, and wetland habitats contend with both plants and animals. In the deserts and xeric shrublands in Africa, *Prosopis* spp. (mesquite) threatens safety through impacts on personal safety and secure resource access as the invasion has forced large predators like lions to move closer to villages, leading to livestock and human deaths (P. L. Howard, 2019). There are no units of analysis exclusively impacted by plant species.

Box 4 18 ***Spodoptera frugiperda*** **(fall armyworm) – how impacts on nature's contributions to people and impacts of management affect good quality of life for Indigenous Peoples and local communities.**

Impacts on nature's contributions to people: crop losses

A majority (61 per cent) of the studies reviewed[15] have documented that Indigenous Peoples and local communities suffer yield losses due to the invasion of *Spodoptera frugiperda* (fall armyworm). The crop yield loss estimates due to *Spodoptera frugiperda* range from 10 per cent in Malawi (Murray *et al.*, 2019) to as high as 58 per cent in Zimbabwe (Chimweta *et al.*, 2020; **Table 4.26**). Most of the yield loss estimates are related to maize production, but the FAO also

15. Data management report available at: https://doi.org/10.5281/zenodo.5760266

Box 4 18

found that *Spodoptera frugiperda* has caused 6 per cent and 2 per cent millet and sorghum production losses, respectively, at the national level in Namibia (FAO, 2018). There is also evidence suggesting that the yield loss estimates were higher in the early years of the *Spodoptera frugiperda* invasion. For instance, Day *et al.* (2017) found maize yield losses of 45 per cent and 40 per cent in Ghana and Zambia respectively (or 8.3 to 20.6 million tonnes annually in 12 African countries), but a follow-up study a year later by Rwomushana *et al.* (2018) showed maize yield losses of 26 per cent and 35 per cent in the two respective countries (or 4.1 to 17.7 million tonnes annually in 12 African countries). As noted by Rwomushana *et al.* (2018), this decline in yield losses could be due to build-up of natural enemies, climatic factors, improved management or the possibility that farmers are getting better at estimating *Spodoptera frugiperda*-induced yield loss. It should be mentioned that most of the yield loss estimates were based on farmers' perceptions, which may have overestimated true losses (Baudron *et al.*, 2019) even when controlling for potential confounding factors in a regression framework, documented *Spodoptera frugiperda*-induced yield losses are nearly 12 per cent (Baudron *et al.*, 2019; Kassie *et al.*, 2020).

Table 4 26 **Yield loss estimates due to *Spodoptera frugiperda* (fall armyworm) invasion.**

A data management report for the literature review underpinning this table is available at https://doi.org/10.5281/zenodo.5760266

Study	Country	Yield loss estimates
Asare-Nuamah (2022)	Ghana	Massive (no exact estimate)
Bariw *et al.* (2020)	Ghana	17.2 per cent
Baudron *et al.* (2019)	Zimbabwe	11.6 per cent
Chimweta *et al.* (2020)	Zimbabwe	58 per cent
Day *et al.* (2017)	Ghana and Zimbabwe	45 per cent in Ghana; 40 per cent in Zambia (extrapolated to up to 20.6 million tonnes annually in 12 Africa countries)
De Groote *et al.* (2020)	Kenya	33 per cent or 1 million tonnes
FAO (2018)	Namibia	14 per cent of maize (8 per cent in communal areas and 6 per cent in commercial farms); 6 per cent of millet; 2 per cent of sorghum
Turot *et al.* (2019)	Tanzania	10.8 per cent at area level; 15.8 per cent at farm level
Girsang *et al.* (2020)	Indonesia	26.6 per cent
Houngbo *et al.* (2020)	Benin	49 per cent
Kansiime *et al.* (2019)	Zambia	28 per cent
Kassie *et al.* (2020)	Ethiopia	11.5 per cent
Koffi *et al.* (2020)	Ghana	132,450 tons in 2016; 180,000 tons in 2017; 36,000 tons in 2018
Kumela *et al.* (2019)	Ethiopia and Kenya	46.5 per cent in Ethiopia; 38.8 per cent in Kenya
Mayee *et al.* (2021)	India	Decline in maize area from 9.2 million ha in 2018 to 8.2 million ha in 2019 (no exact estimate)
Murray *et al.* (2021)	Kenya	Up to 50 per cent
Murray *et al.* (2019)	Malawi	10 per cent
Nyangau *et al.* (2020)	Kenya and Uganda	No exact estimate
Rwomushana *et al.* (2018)	Ghana and Zambia	26 per cent in Ghana; 35 per cent in Zambia) extrapolated to up to 17.7 million tonnes annually in 12 African countries)
van Loon *et al.* (2019)	Ghana	Severe (no exact estimate)

Box 4 18

Impacts on good quality of life

Spodoptera frugiperda caused crop yield loss in invaded systems and has consequently resulted in increased production costs, decline in farmers' income, hunger and worsened food insecurity **(Figure 4.44)**. For example, Girsang *et al.* (2020) found that *Spodoptera frugiperda* led to 50 per cent and 71.4 per cent per cent increase in labour and pesticide costs in 2019, respectively, in North Sumatra province of Indonesia. Similarly, it is estimated that farmer's expenditure on pesticides has increased by US$195 per hectare (241 per cent) due to the *Spodoptera frugiperda* invasion in China's Yunnan province (Yang *et al.*, 2021). Moreover, Kassie *et al.* (2020) found that *Spodoptera frugiperda* invasion was associated with a 25 per cent reduction in maize sales in southern Ethiopia, while Tambo *et al.* (2021) documented a reduction in per capita household income by 44 per cent and a 17 per cent higher likelihood of hunger in Zimbabwe due to severe levels of *Spodoptera frugiperda* infestation.

The *Spodoptera frugiperda* outbreak is also having negative impacts on the livestock sector in terms of reduced availability of livestock feed, such as stover, grains, straw and pasture land (FAO, 2018; Mayee *et al.*, 2021). The Indian government imported 130,000 tonnes of maize in 2019 for the poultry industry as a result of a reduction in maize production (Mayee *et al.*, 2021).

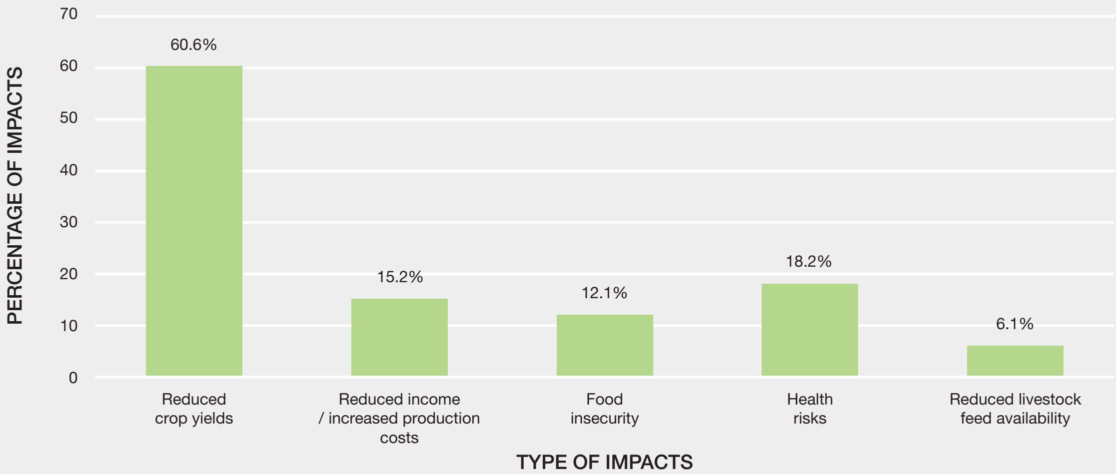

Figure 4 44 **Percentage of documented impacts (y axis) of *Spodoptera frugiperda* (fall armyworm) on good quality of life of Indigenous Peoples and local communities.**

Spodoptera frugiperda negatively impacts crop yields, income and production costs, food security, health and livestock feed availability (x axis). The results are presented in percentages of the 33 case studies reviewed. A data management report for the literature review underpinning this figure is available at https://doi.org/10.5281/zenodo.5760266

The synthetic pesticides used by smallholders for *Spodoptera frugiperda* control have been shown to pose high risks to human health (Murray *et al.*, 2019, 2021; Kumela *et al.*, 2019). Several studies have shown that farmers who used pesticide to control *Spodoptera frugiperda* experience pesticide-related illness, such as dizziness, headache, skin and eye irritation and stomach ache (Kansiime *et al.*, 2019; Rwomushana *et al.*, 2018; Tambo *et al.*, 2020). The use of pesticides also has been shown to affect native species (Kumela *et al.*, 2019).

Positive impacts caused by invasive alien species on good quality of life in the terrestrial realm

As with negative impacts, positive impacts in the terrestrial realm are clustered within a few units of analysis **(Table 4.27)**. Cultivated areas are most positively impacted, with 79 invasive alien species causing 151 documented impacts. Tropical and subtropical dry and humid forests (70 invasive alien species causing 118 impacts) and temperate and boreal forests and woodlands (40 species causing 82 impacts) round out the top three positively impacted units of analysis. Taken together, these three units of analysis account for 75 per cent of documented terrestrial positive documented impacts. Meanwhile, the three least affected terrestrial units of analysis, Mediterranean forests, woodlands and scrub, tundra and high mountain habitats, and wetlands (peatlands, mires, bogs), account for only three per cent of positive terrestrial documented impacts.

Material and immaterial assets account for the most positively documented component of good quality of life across most units of analysis, followed by health, showing a similar pattern than for negative impacts. However, the order differs for tundra and high mountain habitats, tropical and subtropical savannas and grasslands, and temperate grasslands that are mainly impacted through positive changes to social and cultural relationships, followed by positive changes to material and immaterial assets. Safety is the least documented positively impacted component of good quality of life, accounting for only three per cent of positive terrestrial impacts.

Examining the positive impacts highlights the different ways invasive alien species interact with people across landscapes. Plants are one of the most documented taxa affecting Mediterranean forests, woodlands and scrubs (e.g., *Agave americana* (century plant)), deserts and xeric shrublands (e.g., *Prosopis juliflora* (mesquite)), and tropical and subtropical savannas and grasslands (e.g., *Acacia mearnsii* (black wattle)). This result mirrors findings from R. T. Shackleton, Shackleton, *et al.* (2019), who documented that most case studies on positive impacts on livelihoods involve invasive alien plants, often intentionally introduced. These plant species affect different components of good quality of life, which widely differ across units of analysis. For example, as a source of fuelwood, *Prosopis juliflora* is an important source of energy for cooking and heating, along with a possible source of income for those who sell the wood, which can cause significant positive impacts on assets. Human health is positively affected by species such as *Acacia mearnsii*, known for its antibacterial properties and effectiveness in treating illnesses as shigellosis (Olajuyigbe & Afolayan, 2012). Sociocultural relationships benefit from species such as *Agave americana* (century plant).

Tropical and subtropical dry and humid forests, temperate and boreal forests and woodlands, urban/semi-urban, cultivated areas, and wetlands (peatlands, mires, bogs), are mainly positively impacted by animals. Many of these species impact good quality of life either through material and immaterial assets, by providing a new way of creating or enhancing livelihood or through improvements to human health outcomes. *Equus ferus* (wild horse) in temperate and boreal forests and woodlands (and tundra and high mountain habitats) illustrates the prominent role some invasive alien species play in maintaining cultural identities, especially among Indigenous peoples and local communities (Bhattacharyya *et al.*, 2011; Bhattacharyya & Larson, 2014). The remaining units of analysis, tundra and high mountain habitats, temperate grasslands, benefit from a several invasive alien plants and animals. Importantly, there are no documented cases of microbes producing positive terrestrial impacts on good quality of life.

Table 4 27 **Positive impacts on good quality of life in the terrestrial realm.**

Darker colours indicate higher documented numbers of invasive alien species or impacts. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

4.5.2.2 Patterns of negative and positive impacts of invasive alien species on good quality of life in the marine and inland waters realms

There are 575 documented negative impacts on good quality of life affecting the marine and inland waters realms.

Negative impact caused by invasive alien species on good quality of life across units of analysis in the marine and inland waters realms

Inland surface waters and water bodies are the most impaired of all aquatic units of analysis (151 invasive alien species causing 411 negative impacts), accounting for 71 per cent of all negative aquatic impacts **(Table 4.25)**. The least affected unit of analysis, open ocean pelagic systems, has only one documented invasive alien species, generating three negative impacts on material and immaterial assets, which accounts for less than one per cent of negative aquatic impacts.

The top two components of good quality of life most negatively affected across all aquatic domains are material and immaterial assets, followed by health **(Table 4.28)**. In shelf ecosystems (neritic, intertidal and littoral zone), health dominates followed by material and immaterial assets.

The top documented invasive alien species causing negative impacts on good quality of life in the aquatic realm are attributed solely to animals. Inland surface waters and water bodies are subject to impacts by invasive alien animals such as *Dreissena polymorpha* (zebra mussel) and *Cyprinus carpio* (common carp). For example, *Dreissena polymorpha*, which also impacts coastal areas intensively used for multiple purposes by humans, is known for its impacts on livelihoods and access to goods by clogging pipes used in water treatment plants, irrigation, and power generation stations (Elliott *et al.*, 2005). *Cyprinus carpio* limits access to nutritious food and adequate livelihoods by quickly dominating native fish species, negatively affecting fishing and recreation opportunities (Beardmore, 2015; A. K. Singh *et al.*, 2010). These two species highlight the numerous ways invasive alien species can negatively impact a single unit of analysis. Aquaculture areas are impacted by species such as *Oreochromis niloticus* (Nile tilapia) that negatively affect native fish and harms local fishermen's livelihoods (Ogutu-Ohwayo, 1990). Open ocean pelagic systems can be invaded by *Pterois* spp. (lionfish), which negatively affects commercially important native species (Johnston *et al.*, 2017). Health is the most impacted component of good quality of life in shelf ecosystems, with, for instance, *Rhopilema nomadica* (nomad jellyfish), known for its venomous stings (Öztürk & İşinibilir, 2010).

Positive impacts caused by invasive alien species on good quality of life across units of analysis in the marine and inland waters realm

The aquatic realm had 117 positive documented impacts caused by 73 invasive alien species. Inland surface waters and water bodies (49 invasive alien species, causing

Table 4 28 **Negative impacts on good quality of life in the marine and inland waters realms.**

Table 4 29 **Positive impacts on good quality of life in the marine and inland waters realms.**

Darker colours indicate higher documented numbers of invasive alien species or impacts. A data management report for the database of impacts developed through this chapter is available at https://doi.org/10.5281/zenodo.5766069

Unit of analysis	Material and immaterial assets		Freedom of choice and action		Health		Social and cultural relationships		Safety	
	species	impacts	species	impacts	species	impacts	species	impacts	species	impacts
Aquaculture areas	5	7	0	0	0	0	0	0	0	0
Inland surface waters and water bodies/freshwater	32	59	1	1	6	10	7	7	3	3
Shelf ecosystems (neritic and intertidal/littoral zone)	5	13	0	0	1	1	0	0	0	0
Open ocean pelagic systems (euphotic zone)	1	1	0	0	0	0	0	0	0	0
Coastal areas intensively used for multiple purposes by humans	6	8	0	0	0	0	6	7	0	0

80 impacts) and Coastal areas intensively used for multiple purposes by humans (12 invasive alien species, causing 15 impacts) account for 81 per cent of aquatic realm positive impacts **(Table 4.29)**. Open ocean pelagic systems are the least impacted unit of analysis, with only one documented invasive alien species, *Pterois* spp. (lionfish). Material and immaterial assets, social/cultural relationships, and health are documented to be the most affected components of good quality of life. Impacts on safety are the least documented component, and only observed in inland surface waters and water bodies where, for instance, *Pontederia crassipes* (water hyacinth) assist with creating resilient communities by removing heavy and toxic metals from waterways (Dixit & Dhote, 2010).

While invasive alien plants are documented to cause more positive impacts than negative impacts (R. T. Shackleton, Shackleton, *et al.*, 2019), positive impacts are mostly caused by invasive alien animals in inland surface waters and water bodies/freshwater (e.g., *Oreochromis niloticus* (Nile tilapia)), in coastal areas intensively used for multiple purposes by people (e.g., *Corbicula fluminea* (Asian clam)), and in open ocean pelagic systems (e.g., *Pterois* spp. (lionfish)). Many of these positive impacts are due to changes in material and immaterial assets, such as creating new opportunities for income and recreation. Postive impacts on good quality of life in aquaculture and shelf ecosystems are mostly caused by invasive alien plants and animals. As with positive terrestrial impacts, there are no documented microbes causing positive impacts on good quality of life in the aquatic realm.

4.5.3 Documented impacts on good quality of life by region and taxonomic group

4.5.3.1 General patterns

Invasive alien species affect good quality of life in all regions. Several patterns of documented impacts emerge when examining the positive and negative impacts across regions. In particular, for both negative and positive impacts, the Asia-Pacific region has the most documented impacts, followed by Europe and Central Asia, the Americas, Africa, and Antarctica. The database of impacts developed through this chapter mirrors previous reports, showing that most impacts of invasive alien species on livelihoods are documented in the developing world, particularly southeast Asia (R. T. Shackleton, Shackleton, *et al.*, 2019). Negative impacts on good quality of life are mostly documented for material and immaterial assets and health. Safety is the least documented component of good quality of life. This result differs for positive impacts, where material and immaterial assets and social and cultural relationships are the most impacted components of good quality of life, while freedom of choice and action is least affected.

However, there are few consistent patterns when comparing the taxa that cause impacts across regions. For example, even though invertebrates cause the majority of negative impacts for most regions, the second, third, and fourth most prominent species vary for each region. The order of impacts by region is as follows, Africa: invertebrates, plants, vertebrates, microbes; Europe and Central Asia:

invertebrates, microbes, plants, vertebrates; Americas: invertebrates, vertebrates, plants, microbes; Asia-Pacific: invertebrates, plants, vertebrates, microbes; Antarctica: vertebrate only. In terms of positive impacts, plants generally have the most significant number of impacts documented for all regions, except for the Asia-Pacific region, where invertebrates have the highest number of invasive alien species with documented positive impacts. Finally, negative impacts tend to be more evenly distributed across regions when looking beyond the most impacted taxonomic group (i.e., the second, third or fourth most dominant taxonomic group). In contrast, positive impacts vary widely among taxa. This result follows (R. T. Shackleton, Shackleton, *et al.*, 2019), where the positive impacts of invasive alien species varied substantially between case studies and different species.

4.5.3.2 Patterns of negative impacts on good quality of life by taxonomic group and region

A total of 484 documented invasive alien species have caused negative impacts on good quality of life in Asia-Pacific, 347 in Europe and Central Asia, 296 in the Americas, 90 in Africa, and one in Antarctica **(Figure 4.45)**. Across almost all regions, change to material and immaterial assets is the most frequently documented negative impact on good quality of life. The highest number of documented negative impacts is found in Asia-Pacific (853 impacts), followed by Europe and Central Asia (598 impacts), Africa (286 impacts), and the Americas (265 impacts) **(Figure 4.46)**. Antarctica only has one documented impact on good quality of life, through health changes. Health impacts are the second most commonly documented impact on good quality of life for all other regions, with the highest number of impacts documented in Asia-Pacific (290 impacts). There are 223 documented negative impacts on health in the Americas, 139 in Europe and Central Asia, and 69 in Africa. Social and cultural relationships, such as environmental equity and social infrastructure, is the third most impacted component of good quality of life, which is relatively evenly distributed across Asia-Pacific (89 impacts), the Americas (81 impacts), and Europe and Central Asia (62 impacts). Impacts on safety, such as risks to personal safety and security from disasters, have been less documented, where the top two impacted regions are the Americas (42 impacts) and Asia-Pacific (27 impacts).

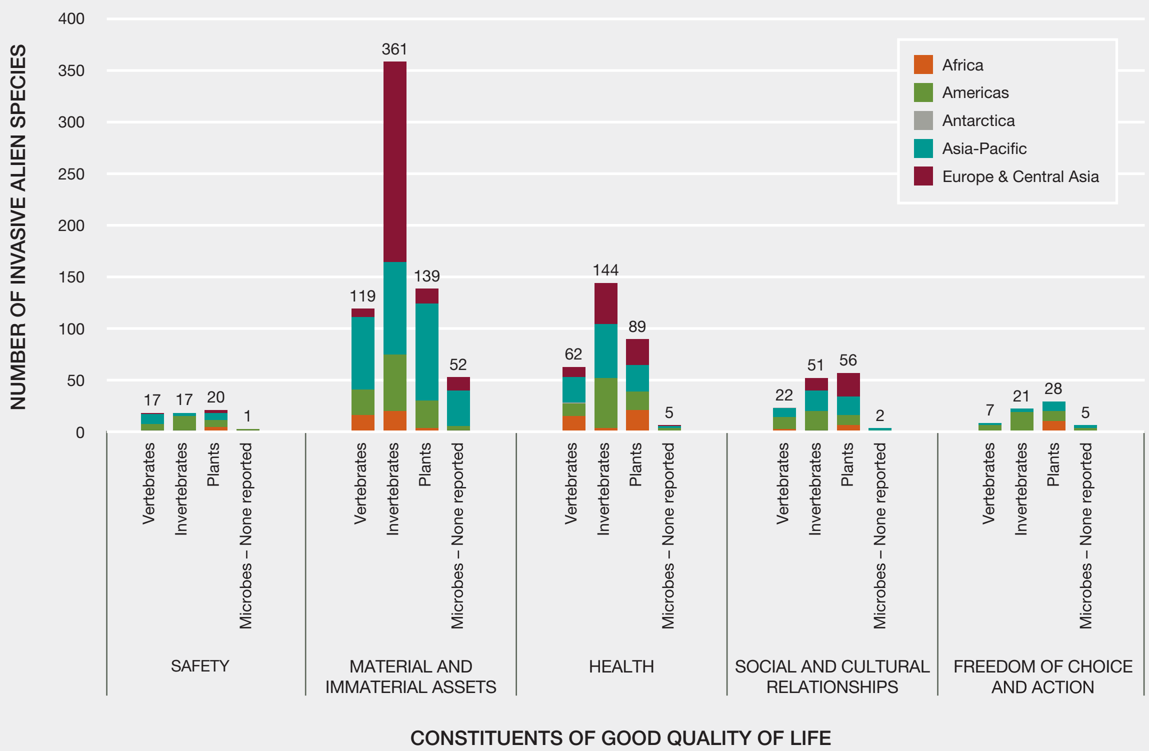

Figure 4 45 **Number of invasive alien species (y axis) causing negative impacts on constituents of good quality of life by taxonomic group and IPBES region (x axis).**

A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

The number of documented negative impacts on good quality of life for specific taxa varies by region, but some patterns do emerge (**Figures 4.45** and **4.46**). Invasive alien invertebrates are the main taxonomic group causing negative impacts on good quality of life across regions, with 594 species (51 per cent of all invasive alien species causing negative impacts on good quality of life). Negative impacts caused by invertebrates are relatively evenly distributed across regions: they have caused 494 negative impacts (31 per cent) in Europe and Central Asia, 457 in the Asia-Pacific region (30 per cent), 365 in the Americas (23 per cent), 258 in Africa (16 per cent), and none in Antarctica. Plants account for 21 per cent of all negative impacts across regions and are the second most documented taxonomic group affecting good quality of life in Asia-Pacific and Africa. More than half of negative impacts caused by plants on good quality of life are heavily concentrated in Asia-Pacific (391 impacts; 58 per cent of all impacts caused by plants on good quality of life). The remaining share of negative impacts are spread evenly across Europe and Central Asia (108 impacts; 16 per cent), the Americas (92 impacts; 14 per cent), and Africa (78 impacts; 12 per cent). There are no observed impacts of invasive alien plants in Antarctica **(Figure 4.46)**. Vertebrates cause 17 per cent of documented negative impacts on good quality of life across all regions, where documented impacts are heavily concentrated in the Asia-Pacific region (347 impacts; 64 per cent of all negative impacts caused by vertebrates). There are 116 impacts (21 per cent) caused by invasive alien vertebrates on good quality of life in the Americas, 49 in Africa (9 per cent), and 30 in Europe and Central Asia (6 per cent). Vertebrates are the least documented taxonomic group in Europe and Central Asia, and there is only one impact caused by a vertebrate documented in Antarctica **(Figure 4.46)**. Finally, microbes are the least documented taxonomic group to negatively impact good quality of life in most regions, accounting for 10 per cent of impacts across taxa **(Figure 4.46)**.

Europe and Central Asia record the majority of impacts caused by microbes across all regions (177 impacts; 52 per cent of all impacts caused by microbes). The Americas have the second-highest share of negative impacts caused by microbes (87 impacts; 26 per cent), closely followed by the Asia-Pacific region (74 impacts; 22 per cent). There are no documented microbes affecting good quality of life in Africa or Antarctica.

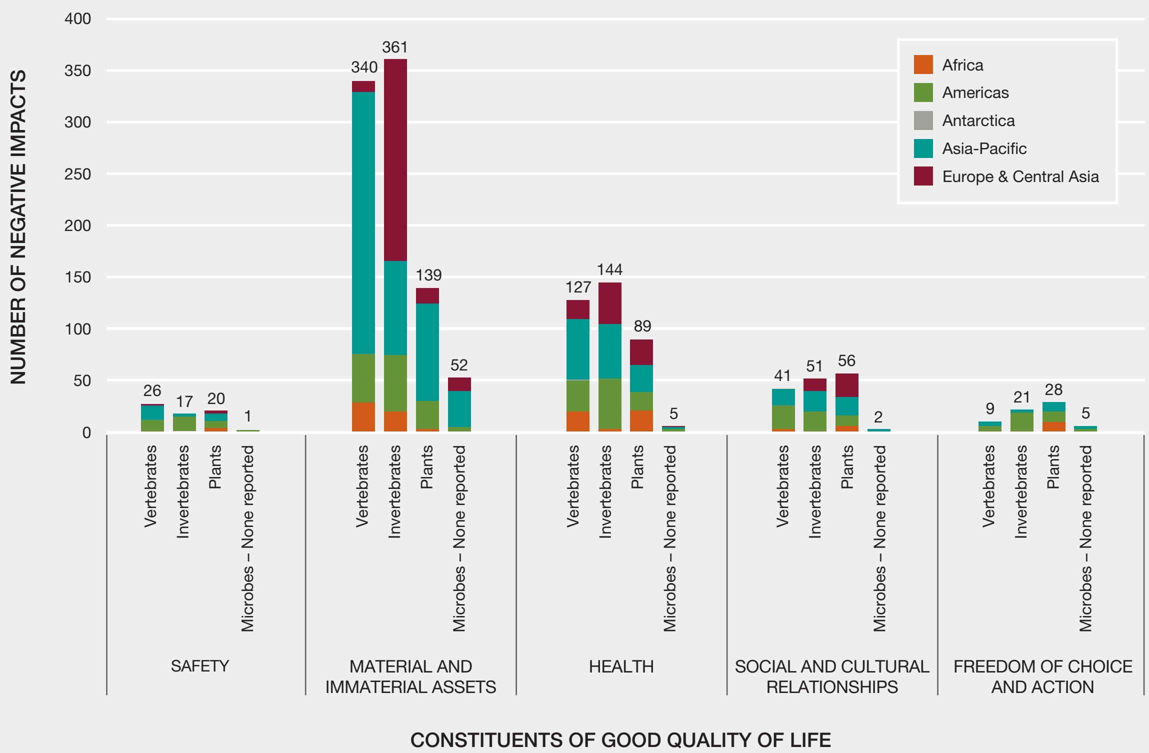

Figure 4 46 **Number of negative impacts (y axis) on constituents of good quality of life by taxonomic group and region (x axis).**

A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

4.5.3.3 Patterns of positive impacts on good quality of life by taxonomic group and region

There are 236 documented species that cause positive impacts on good quality of life, including 156 in the Asia-Pacific region, 56 in Europe and Central Asia, 61 in the Americas, and 26 species in Africa **(Figure 4.47)**. There are no documented species causing positive impacts on good quality of life in Antarctica. This pattern translates to the number of documented impacts, with 46 per cent (241 impacts) of the positive impacts on good quality of life documented in Asia-Pacific, 21.6 per cent (113 impacts) in Europe and Central Asia, 15.6 per cent (82) in the Americas, and 8.4 per cent (44) in Africa **(Figure 4.48)**. Across all regions, good quality of life is mostly positively impacted through changes to material and immaterial assets (180 impacts). Health (111 impacts) is the second most positively impacted component of good quality of life across regions. There are 92 impacts on health in the Asia-Pacific region, 11 impacts in Africa, 6 impacts in Europe and Central Asia, and 2 impacts in the Americas. Social and cultural relationships is the second most impacted component to good quality of life, with 52 positive impacts in Asia-Pacific, 20 in the Americas, and 18 in Europe and Central Asia. Safety and freedom of choice and action are the two least positively impacted components of good quality of life across all regions.

Compared to negative impacts, fewer patterns emerge with positive impacts by taxonomic group and region. Plants are the dominant taxonomic group causing 37 per cent (213 impacts) of all positive impacts on good quality of life across most regions, including Europe and Central Asia, the Americas, and Africa. Of all documented positive impacts caused by invasive alien plants, 40 per cent are in the Asia-Pacific region (86 impacts). The remaining share of positive impacts occur in Europe and Central Asia (71 impacts; 33 per cent), the Americas (34 impacts; 16 per cent), and Africa (22 impacts; 10 per cent).

Invertebrates are responsible for 170 positive impacts, or 29.6 per cent of all positive impacts on good quality of life across regions. Invertebrates are the dominant taxonomic group positively affecting the Asia-Pacific region (108 impacts), accounting for 64 per cent of all invertebrate

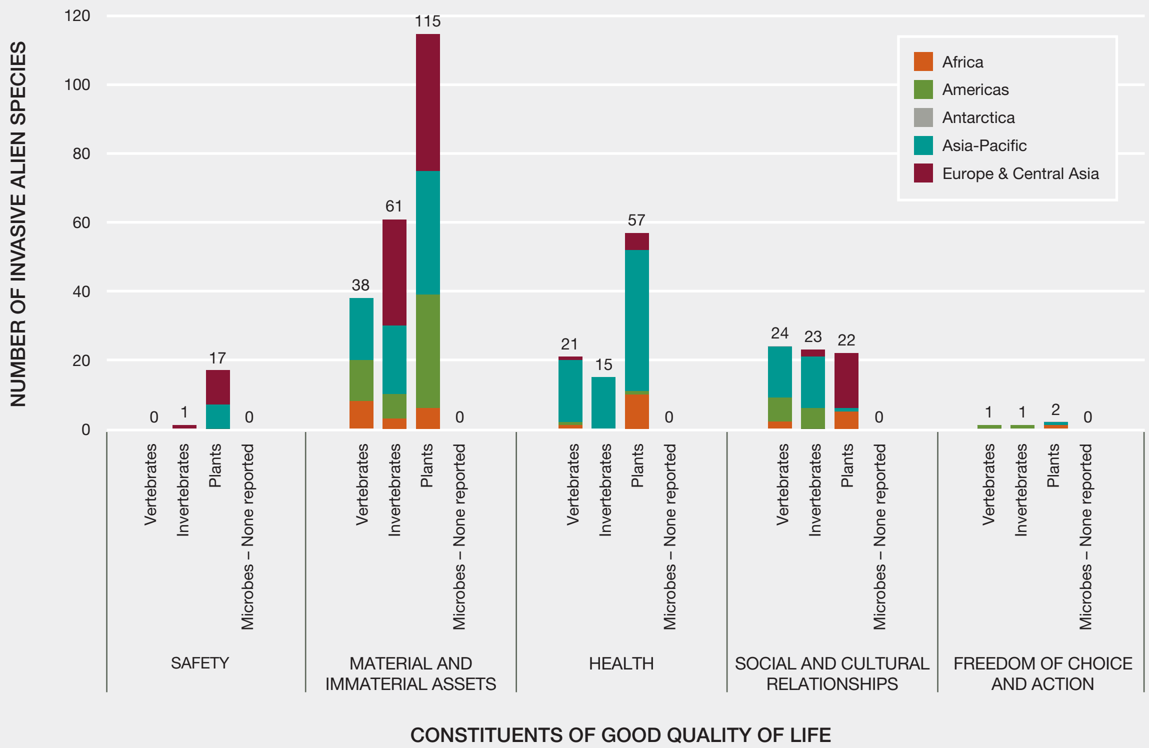

Figure 4 47 **Number of invasive alien species (y axis) causing positive impacts on constituents of good quality of life by taxonomic group and region (x axis).**

A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

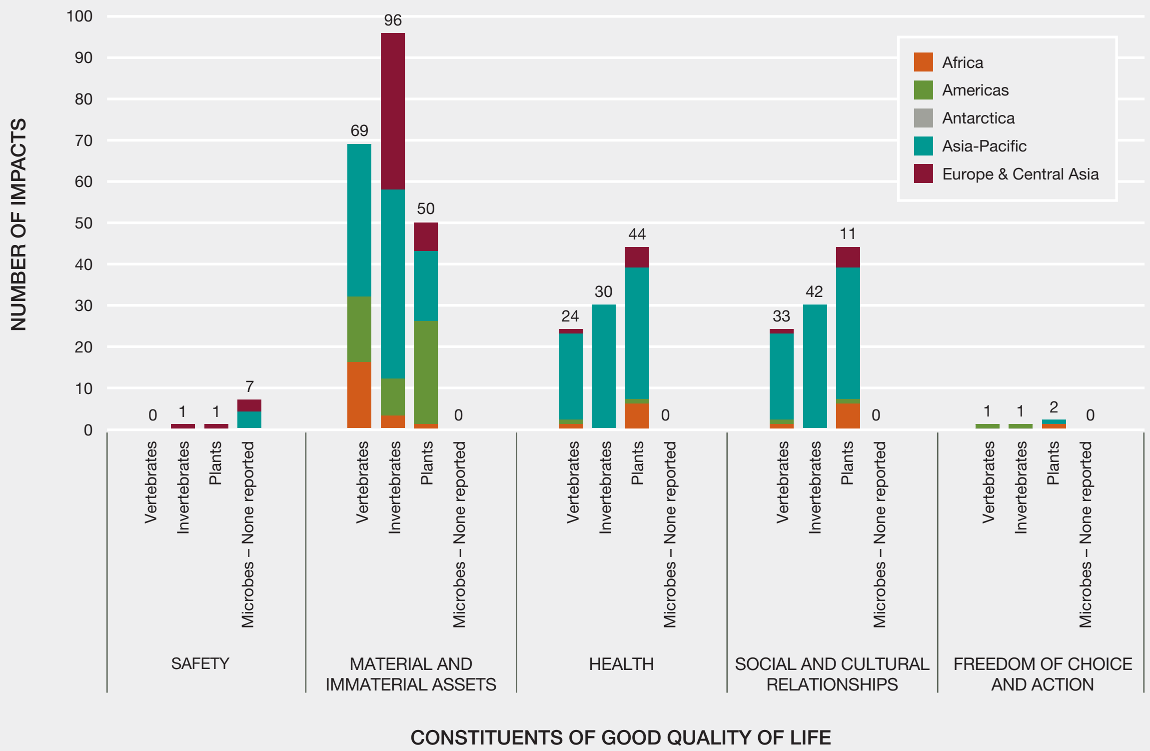

Figure 4 48 **Number of positive impacts (y axis) on constituents of good quality of life by taxonomic group and region (x axis).**

A data management report for the database of impacts developed through this chapter, with underlying data for this figure is available at https://doi.org/10.5281/zenodo.5766069

impacts. Europe and Central Asia account for 24 per cent of invertebrate impacts (41 impacts). The Americas (18 impacts; 10 per cent) and Africa (3 impacts; 2 per cent) are the regions with the fewest documented positive impacts from invertebrates.

Aside from microbes that do not have any documented positive impacts (**section 4.7.2**), vertebrates are the least documented taxonomic group causing positive impacts on good quality of life, accounting for 24 per cent of impacts by taxon. As with negative impacts, positive impacts caused by vertebrates are heavily concentrated in the Asia-Pacific region (77 impacts; 61 per cent of all positive impacts caused by vertebrates). The Americas document 30 positive impacts (24 per cent), Africa records 19 impacts (15 per cent) and Europe and Central Asia document only 1 impact (1 per cent) caused by invasive alien vertebrates on good quality of life.

4.6 REVIEW OF IMPACTS OF INVASIVE ALIEN SPECIES FOR INDIGENOUS PEOPLES AND LOCAL COMMUNITIES

This section presents the results of a systematic cross-chapter review on Indigenous Peoples and local communities and invasive alien species,[16] which supplements the chapter impact database. Of the 131 sources reviewed, a total of 124 sources provided evidence of impacts of invasive alien species on, or as perceived by Indigenous Peoples and local communities, with 79 sources containing direct information (e.g., from survey data, interviews and quotations) from Indigenous Peoples and local communities.

Overall, this review has revealed a total of 368 impacts on nature, nature's contributions to people and good quality of life, as documented by Indigenous Peoples and local communities. Indigenous Peoples and local communities

16. Data management report available at: https://doi.org/10.5281/zenodo.5760266

have identified a varied range of invasive alien species, with nearly two-thirds of the sources reviewed being associated with invasive alien plants. Additionally, they have documented the presence of invasive alien vertebrates and invertebrates, as well as a single microbe **(Table 4.30)**. This may represent a research bias towards invasive alien plants in rural communities, but all taxonomic groups are represented in this analysis.

Impacts are presented as they were described by Indigenous Peoples and local communities, but authors have assigned directions of impact following the classification used throughout this chapter (**section 4.1.2**). While it may seem straightforward to identify negative and positive impacts of alien species invasions on nature and native species (i.e., a native species suffers or is advantaged by the an invasive alien species) or on good quality of life (i.e., people derive a benefit from an invasive alien species), Indigenous Peoples and local communities have emphasized that a positive impact on nature's contribution to people or good quality of life may not be considered as wholly positive for their communities, and instead may represent the "least-worst" option (IPBES, 2022). For example, while the capture and sale invasive of alien fish species introduced into traditional fishing grounds may be considered as positive for some (Riedmiller, 1994; K. Smith *et al.*, 2010; Cid-Aguayo *et al.*, 2021), it may not be the case for Indigenous Peoples and local communities, especially when they have not had agency or choice in the initial introduction of the invasive alien species (K. Smith *et al.*, 2010; Broderstad & Eythórsson, 2014), and/or if their preference still is for the native species that have been displaced (IPBES, 2022). Therefore, when interpreting the findings of this review, it is important to consider the options available to Indigenous Peoples and local communities and whether their use of and adaptation to invasive alien species has been freely determined by choice. Some Indigenous Peoples and local communities lack resources, funding and capacity to voice and implement their preferences regarding management of biological invasions, and may have chosen eradication instead of adaptation if they had access to more resources (IPBES, 2022). However, it is also important to note that some Indigenous Peoples and local communities have shown considerable capacity for adaptation using their detailed and intimate knowledge and skills connected with their environment as well as partnerships with emerging technologies, and can be a model for resilience to future impacts (**Chapter 5**, **section 5.7**, Africa Uncensored, 2022; P. L. Howard, 2019). Overall, positive impacts documented on nature's contribution to people and good quality of life refer to where humans have derived a benefit, and yet they are often part of a more complex trade-off between positive and negative impacts inherent in socio-cultural-ecological systems.

4.6.1 Impacts on nature as documented by Indigenous Peoples and local communities

Indigenous Peoples and local communities report that approximately 92 per cent of impacts on nature caused by invasive alien species are negative, and only 8 per cent are positive impacts **(Table 4.31)**. They have observed an overall reduction in specific native species (31 per cent),

Table 4 30 **The number of Indigenous and local knowledge sources reviewed with information about the impacts of invasive alien plants, vertebrates, invertebrates and microbes.**

A data management report for this cross-chapter literature review on Indigenous Peoples and invasive alien species is available at: https://doi.org/10.5281/zenodo.5760266

Taxonomic group	Number and percentage of Indigenous and local knowledge sources reviewed	
Plants	80	65%
Invertebrates	14	11%
Vertebrates	19	15%
Microbe	1	1%
Multiple Taxa	10	8%
Total	**124**	**100%**

and a loss in vegetation cover and diversity due to invasive alien species (19 per cent), as well as negative impacts on native animals, including displacement, reduction in animal food and habitat and predation (7 per cent combined). Indigenous Peoples and local communities note that ecosystem processes, including fire regimes and regeneration, have also been disrupted by invasive alien species (e.g., Jevon & Shackleton, 2015), and that some invasive alien species are increasing the abundance of other invasive alien species. For example, local rice farmers in Cambodia report that the invasive shrub, *Mimosa pigra* (giant sensitive plant), has increased other invasive pests such as nematodes and rodents, which are more problematic for Indigenous Peoples and local communities in their rice fields (Rijal & Cochard, 2016).

Almost one-third of the reviewed sources highlight that invasive alien species have caused the reduction in specific native animal and plant species, with impacts occurring to species of similar niche or taxon (e.g., plants outcompeting other plants) or across different taxa (e.g., plants displacing fauna). For example, the Ifugao farmers in the Philippines have noted that *Pomacea canaliculata* (golden apple snail or "batikor" in local language) outcompetes native snails (R. C. Joshi *et al.*, 2001) and Aboriginal people in north-eastern Australia have reported that the invasion by *Rhinella marina* (cane toad) led to the disappearance of native frogs (Boll, 2006). The impact of invasive alien species on native species of a different taxon was highlighted by local communities in Nepal, who documented that the invasive vine, *Mikania micrantha* (bitter vine), limits food sources for

Table 4 31 **Number and type of impacts on nature caused by invasive alien species, as documented directly by Indigenous Peoples and local communities.**

A data management report for the systematic cross-chapter review on Indigenous Peoples and local communities and invasive alien species is available at: https://doi.org/10.5281/zenodo.5760266

Types of negative and positive impacts of invasive alien species on nature, as documented by Indigenous Peoples and local communities	Number of reports	Percentage of total reports
Total negative reports	57	92%
Reduced specific species	19	31%
Reduced vegetation diversity/abundance	12	19%
Limits regeneration	5	8%
Negative impact on biodiversity	4	6%
Altered fire regimes	3	5%

Increased abundance of other invasive alien species	3	5%
Kills trees	3	5%
Displaces animals	2	3%
Kills fish	1	2%
Predation	1	2%
Reduced animal habitat/food	1	2%
Total positive reports	5	8%
Provided animal habitat/food	2	3%
Increased animals	1	2%
Assist regeneration by limiting grazing	1	2%
Increased vegetation abundance	1	2%

wildlife, resulting in large and potentially dangerous fauna (tigers, rhinos, boar) increasingly leaving the forest in search of food (Sullivan *et al.*, 2017). Indigenous Peoples and local communities value specific species that may be important to livelihoods, be totem or culturally important species, and indicator species for seasonal or environmental changes (Curran *et al.*, 2019; C. J. Robinson & Wallington, 2012).

Aside from specific species and ecological properties, Indigenous Peoples and local communities also report an overall negative impact on biodiversity (8 per cent of reports; **Table 4.31**) which reflects their understanding of the impacts on nature as a whole. Invasive alien species causing declines in biodiversity are seen as a degradation of the overall habitat (Sundaram *et al.*, 2012), or a reduction in the condition of the forest (Jevon & Shackleton, 2015), leading to a decline in the health of landscapes. For example, weeds have caused "significant upheaval to their Aboriginal ancestral landscapes" (Bach *et al.*, 2019).

Positive impacts of invasive alien species on nature represent less than 10 per cent of impacts reported by Indigenous Peoples and local communities. Most of the reported positive impacts concern the increases in vegetation structure and cover provided by larger invasive alien shrubs and trees **(Table 4.31)**. For example, in open grasslands or previously degraded landscapes, some invasive alien species have provided habitat structure or additional food for animals (Bach *et al.*, 2019), or assisted regeneration of native seedlings underneath spiky canopies as seedlings were protected from browsing by animals (R. T. Shackleton *et al.*, 2017).

Brazil provides an example of how Indigenous Peoples and local communities can experience a range of impacts on nature, including connections with different taxa and with ecosystem properties such as water regulation.

> "We live on an island surrounded by [invasive alien] acacia plants! Before, we hunted and fished, now we have bees that attack us and acacia plants that invade our farm plots as soon as we clear (burn) them, and they grow even stronger. I've killed rattlesnakes there that are attracted by the rats, and there have been more foxes and opossums, which damage the buriti palms. There are no more electric eels, and the water is rusty. You can't drink the water in the Manoá igarapé, and even our wells are drying up. The ingá trees have stopped producing fruit since the acacia appeared. Parrots used to make nests in São Domingo, but now the bees have taken over. Rolinha doves used to wake us up and tell us when it was going to rain; now those birds don't exist here anymore" (Souza *et al.*, 2018, p. 6)

4.6.2 Impacts on nature's contributions to people as documented by Indigenous Peoples and local communities

Of the 368 documented impacts of invasive alien species,[17] over 50 per cent are on nature's contributions to people, which reflects the direct connection and dependence of many Indigenous Peoples and local communities on nature's contributions to people for their livelihoods (R. T. Shackleton, Shackleton, *et al.*, 2019) and reveals they have valuable knowledge on more complex ecosystem processes and services (F. Walsh *et al.*, 2013; Ens, Pert, *et al.*, 2015). Traditional and customary practices have often been developed over a long period of time to respectfully derive services from nature (Sangha *et al.*, 2018). Although the number of documented impacts on nature's contributions to people were relatively balanced between negative (55 per cent) and positive (45 per cent) **(Table 4.32)**, the incidence of these impacts varied across categories. There are more negative than positive documented impacts on the provision of food and feed, on the availability and quality of water, and on cultural identities; whereas Indigenous Peoples and local communities report more positive than negative impacts on materials, labour and transport, energy, medicines, soil processes, physical and psychological experiences, and climate, with the last two categories mostly related to the provision of shade and ornamental aesthetics from plants **(Table 4.32)**.

For Indigenous Peoples and local communities, the provision of food and feed is the most negatively impacted (31 per cent) category of nature's contributions to people **(Table 4.32)**. This broad category includes the abundance and condition of wild food or crops for people, wild food and fodder for domestic animals and wildlife, as well as broader scale impacts such as a reduction in the size of land or interaction with other invasive alien species that cause crop damage. Impacts upon crops alone lead to various impacts on good quality of life, as local swidden farmers in West Africa documented in interviews that:

> "in decreasing order of importance, [*Imperata cylindrica* (cogon grass)], reduces crop yield, limits field size that family labour can handle, increases labour requirements for weeding, causes physical injury to the skin, reduces quality of tuber crops, increases the occurrence of bush fires in perennial crops, and increases the incidence of insects and pathogens of economic crops" (Chikoye *et al.*, 2000; Table 4, p. 485).

Many Indigenous Peoples and local communities highlighted the negative impact of invasive alien species on livestock

Hazards	1	1%

health (7 per cent of reports), as a specific element within food and feed **(Table 4.32)**. These negative impacts subsequently affected their good quality of life, as poorer condition livestock need more labour to be looked after, and livestock have inherent cultural value. For example, Puri (2015) described how for local people from southern Karnataka, India, cattle are a cultural keystone species, and yet "*Lantana camara* [lantana] causes difficulties feeding cattle as it covers up and suppresses fodder grasses. This has led to underfed and malnourished animals, which has weakened them and led to increased vulnerability to disease, injury due to accidents, and attack by wild animals, such as leopards. People in these communities fear for their own safety – having to take cattle further into the forest, on to steeper and more marginal terrain, and having to stay longer every day." (Puri, 2015, p. 259).

Indigenous Peoples and local communities have reported significant impacts of invasive alien species on water resources, including water availability and security (5 per cent of reports) and water quality (3 per cent of reports). Their level of concern about these impacts was as high as that for impacts on livestock health **(Table 4.32)**. Indigenous Peoples and local communities have also documented negative impacts of invasive alien species on soils (4 per cent of reports), which include impacts on soil fertility, erosion, microbiological processes, and overall land degradation. In a similar holistic perspective to impacts on nature, Indigenous Peoples and local communities view soil health as connected to other ecosystem processes such as regulation of water and the provision of food and feed, health, and the land (Koichi *et al.*, 2012).

Indigenous Peoples and local communities have documented positive impacts of invasive alien species across multiple categories of nature's contributions to people, mostly on food and feed (12 per cent of reports), followed by energy (7 per cent), materials (6 per cent), soil processes (6 per cent), medicinal purposes (5 per cent), and physical/psychological experiences (2 per cent) and climate regulation (2 per cent), mostly related to shade and aesthetics from invasive trees **(Table 4.32)**. Positive impacts can generally be observed by Indigenous Peoples and local communities in two situations: where invasive alien species are introduced, recognized and used for a particular purpose, and where they have adapted to the invasive alien species in a way that is different or supplementary to the original purpose of introduction or unintentional introductions. Indigenous Peoples and local communities have however highlighted that the use of or adaptation to an invasive alien species may not always be their preferred option, while other Indigenous Peoples and local communities have shown capacity for adaptation (**section 4.6**).

There are many examples where Indigenous Peoples and local communities can derive food, energy, materials and recognize land rehabilitation from invasive alien species, in line with the original purpose of introduction. Invasive alien fish species including *Oncorhynchus tshawytscha* (Chinook salmon), *Lates niloticus* (Nile perch), *Cyprinus carpio* (common carp), and Tilapia species have been introduced to traditional waterways as a food resource, and several Indigenous Peoples and local communities use the invasive alien species in this way to sustain their livelihoods (Riedmiller, 1994; K. Smith *et al.*, 2010; Cid-Aguayo *et al.*, 2021). However, Indigenous Peoples and local communities are often not the agency in charge of such introductions (K. Smith *et al.*, 2010; Broderstad & Eythórsson, 2014), and, alongside use of the invasive alien species, they report negative impacts on the original food supply, such as native fish in this case (Macnaughton *et al.*, 2015; Santos & Nóbrega Alves, 2016; Cid-Aguayo *et al.*, 2021). Similarly, many invasive trees have been introduced for timber supply (e.g., *Acacia mearnsii* (black wattle)), as a fuel source for household energy (e.g., *Prosopis juliflora* (mesquite)), and for erosion control and land rehabilitation (e.g., *Grevillea banksii* (Banks' grevillea), *Prosopis juliflora*), and these species are used and recognized by Indigenous Peoples and local communities for these particular purposes (Duenn *et al.*, 2017; Kull *et al.*, 2019; C. M. Shackleton *et al.*, 2007). However, Indigenous Peoples and local communities report that whilst invasive alien species are used for these purposes, the materials or energy source may be of lower quality to the original native species that they have replaced (Kull *et al.*, 2019).

More commonly, Indigenous Peoples and local communities documented positive impacts where they adapted to the invasive alien species in new ways with additional or supplementary uses. For example, *Grevillea banksii* (Banks' grevillea) was introduced to Madagascar for erosion control but Indigenous Peoples and local communities now value this plant for honey production, as well as for charcoal and fuel, fencing, and as habitat for birds (Kull *et al.*, 2019). Branches of the invasive shrub, *Lantana camara* (lantana), are now used to make baskets for transporting goods, and supports basketry industry for local communities in southern India (Kannan *et al.*, 2014). Other adaptive uses for invasive alien plants include making manures and fertilizer, soaps, oils and glues, and in particular, adapting to use invasive alien plants as medicines (5 per cent of reports). Adaptation can lead to improvements in good quality of life, such as facilitating cultural knowledge transfer.

4.6.3 Impacts on good quality of life of Indigenous Peoples and local communities

Indigenous Peoples and local communities also experience impacts of invasive alien species on their good quality of life.[18] The systematic cross-chapter review on Indigenous

18. Data management report available at: https://doi.org/10.5281/zenodo.5760266

Peoples and local communities and invasive alien species highlights that over two-thirds of impacts on their good quality of life are negative (68 per cent), and less than one-third are positive (32 per cent) **(Table 4.33)**.

4.6.3.1 Affected constituents of good quality of life

When considering the different constituents of good quality of life (**Chapter 1**, **Table 1.4**; **section 4.1.2**; **Box 4.3**), Indigenous Peoples and local communities are experiencing both negative and positive impacts on material and immaterial assets, in a similar proportion, with 28 per cent and 24 per cent of all reports, respectively **(Table 4.33)**. However, when considering all the remaining elements of good quality of life, there are far more documented negative impacts than positive impacts of invasive alien species on human health (13 per cent negative, 1 per cent positive), safety (10 per cent negative, 1 per cent positive), and freedom of choice and action (8 per cent negative, no positive reports), and slightly more negative than positive reports for social, cultural and spiritual relationships (10 per cent negative and 7 per cent positive). Spiritual impacts may have been under-documented as, for many Indigenous Peoples and local communities, spirituality is a foundational consideration for all aspects of daily living and worldview, that is interconnected with more than one constituent of good quality of life (Robin *et al.*, 2022). However, spirituality may be private knowledge that is not shared in public research, or may be all encompassing and taken as an obvious component of everyday life that is therefore not singled out during interview questions (IPBES, 2022).

4.6.3.2 Themes directly documented from Indigenous Peoples and local communities

Indigenous Peoples and local communities have consistently identified themes within the literature that reviews how invasive alien species impact the five main constituents of their good quality of life **(Table 4.34)**. Some of these themes feed into multiple constituents of good quality of life, for example, maintaining access and mobility is considered by Indigenous Peoples and local communities in access to resources (material/immaterial assets, Adams *et al.*, 2018; Kent & Dorward, 2015), cultural sites (social/spiritual/cultural relationships; C. M. Shackleton *et al.*, 2007; Bach *et al.*, 2019) and the freedom to move as they have always done (freedom of choice or action, (Rettberg, 2010). This accounts for slightly different numbers of reports in **Table 4.33**, compared to **Table 4.34**.

Table 4 33 **Number of impacts of invasive alien species on the five constituents of good quality of life for Indigenous Peoples and local communities.**

Relaxation	1	1%		■			

Impacts of invasive alien species on material and immaterial assets have been documented as negative and positive in similar proportions **(Table 4.33)**, but breaking this down into themes from Indigenous Peoples and local communities, it appears that positive impacts derive from gaining income or developing an industry (10 per cent of reports combined), and negative impacts translate into increased labour, reduced mobility and access, and less availability of traditional lands (28 per cent of reports combined) **(Table 4.34)**.

Some invasive alien species provide income streams and support Indigenous Peoples and local communities to engage in or develop an industry such as honey production, basketry, *Melaleuca* oil distilleries, sports fishing, hunting, or tourism (Kannan *et al.*, 2014; Aigo & Ladio, 2016; Ens, Fisher, *et al.*, 2015; Kull *et al.*, 2019; Maldonado Andrade, 2019; Fache, 2021). In some cases, local industries supports employment that maintains cultural connections, with long-lasting and broad benefits to health and good quality of life for Indigenous Peoples and local communities (A. Wright *et al.*, 2021). Industries based on invasive alien species can also provide a more stable income stream, such as charcoal-making, which is more reliable and as economically beneficial as rain-fed rice cultivation (Chandrasekaran & Swamy, 2016). Industries specialized on a single invasive alien species can however become a more susceptible income stream for people, and reduce the diversity of earlier income stream made before invasion, for example from a wide variety of non-timber forest products (Kannan *et al.*, 2014). A study on *Lantana camara* (lantana) in Karnataka, India, showed little difference in household income derived from invasive alien species compared to original forest resources (Kannan *et al.*, 2014). As noted before, while Indigenous Peoples and local communities can adapt to an invasive alien species and derived benefits, they may have preferred to maintain and protect the original native species, had this option been available (IPBES, 2022)

The positive reports of income from invasive alien species are contrasted with reports of harder labour, reduced access and mobility, abandoned traditional activities or abandoned/reduced land area **(Table 4.34)**. Reduced access and mobility, and increases in labour requirements due to invasive alien species were both equally documented by Indigenous Peoples and local communities (11 per cent of reports each). Invasive alien species can indeed reduce access to traditional lands, cultural sites or access to basic resources such as to clean water by physically blocking travelling routes, limiting mobility of people and making it more time consuming to reach resources, and even leading to the thought of traditional lands being "blocked" by invasive alien species (R. T. Shackleton *et al.*, 2017; Witt *et al.*, 2019). There were no reports of invasive alien species improving access and mobility for Indigenous Peoples and local communities, nor increasing the size of available land, and only one mention of an invasive forb, *Chromolaena odorata* (Siam weed), which made labour easier for some local rice farmers in Laos (Roder *et al.*, 1995). Ensuring the rights of Indigenous Peoples to maintain, use, and control their traditional lands (Article 26 of the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP)) is important for Indigenous Peoples and local communities to maintain their cultural identity and self-determination as well as be able to better respond to and manage biological invasions. Loss of access and rights to traditional lands has been highlighted as a driver of the establishment and spread of invasive alien species (IPBES, 2022; **Chapter 3**, **section 3.2.5**), which facilitates further negative impacts.

Health of Indigenous Peoples and local communities has been documented to be more negatively impacted (13 per cent of reports) than positively (1 per cent) **(Table 4.34)**. Negative health impacts include injury, allergies, toxicity, lack of access to clean water, but they have also been documented when the lands of Indigenous Peoples and local communities and nature were affected by invasive alien species (Sloane *et al.*, 2019), inducing stress and sadness from working on "sick country" (Maclean *et al.*, 2022), or feeling despair at the influence of humans in environmental change (Aigo & Ladio, 2016). Indirect impacts on health have also been documented such as from charcoal production derived from invasive alien species (Kull *et al.*, 2019), and there may be more indirect health effects that have not yet been documented in the literature. There are multiple ways by which health of Indigenous Peoples and local communities can be affected. For example, Rogers *et al.* (2017) document that for traditional Afar pastoralists in Ethiopia, *Prosopis* (mesquite) has indirectly reduced the availability of milk for domestic consumption and/or market, resulting in a lack of cash resources for education and healthcare. Afar pastoralists also observed that their economic status, social health, and community well-being are negatively affected, leading to reduced capacity to adapt to change and cope with environmental risks, as well as contributing to a widespread feeling of despair and uncertainty regarding their overall quality of life (Rogers *et al.*, 2017). Invasive alien species can also impact the safety and security of Afar pastoralists, as dense invasive alien plants can provide a hiding place for larger wildlife or criminals, causing violent conflict with Issa pastoralists over resources (Rogers *et al.*, 2017).

Impacts on society-wide good quality of life

There are 66 documented examples where invasive alien species have impacted the well-being of communities and societies at a higher level **(Table 4.35)**. More research with input from Indigenous Peoples and local communities is required on this topic as these society-level impacts

Table 4 35 **Number and type of impacts on society-wide good quality of life for Indigenous Peoples and local communities.**

A data management report for the systematic cross-chapter review on Indigenous Peoples and local communities and invasive alien species is available at https://doi.org/10.5281/zenodo.5760266

Negative and positive impacts of invasive alien species on society-wide good quality of life for Indigenous Peoples and local communities	Number of reports	Percentage of total reports

have often been interpreted solely by authors of the publications. A vast majority (over 80 per cent) of these society-level impacts are negative, they include conflicts between groups, major changes in land use and resource tenure, and disruptions or other harms to ancestral cultural identities, laws and relationships (Amanor, 1991; Bekele *et al.*, 2018; Pretty Paint-Small, 2013; Costanza *et al.*, 2017; Sloane *et al.*, 2019). Some positive impacts have also been documented, highlighting that adaptation to invasive alien species can contribute, in some cases, to maintain cultural institutions and knowledge, and language transfer between generations, especially when Indigenous Peoples and local communities still have access to their traditional lands (Maldonado Andrade, 2019; Bach *et al.*, 2019). In some cases, invasive alien species have become part of the cultural identity of Indigenous Peoples and local communities (e.g., feral cattle in Hawaii, Fischer, 2007).

4.6.4 Indigenous Peoples and local communities: comparing positive and negative impacts of invasive alien species

The lack of data on the magnitude of impacts of invasive alien species on nature, nature's contributions to people and good quality of life, as assessed by Indigenous Peoples and local communities (**section 4.7.2**), poses a challenge in comparing impacts between studies, regions or communities. The magnitude of impacts of invasive alien species may not be simply categorized as either wholly positive or negative, as there are often trade-offs to be considered. In some cases, the positive impacts may be the "least-worst" option, while still having some negative effects (IPBES, 2022). In 12 of the reviewed sources,

Table 4 36 **Examples of invasive alien species with conflicting values.**

Sources retrieved from a systematic cross-chapter review on Indigenous Peoples and local communities and invasive alien species. Data management report available at https://doi.org/10.5281/zenodo.5760266

Comparison of beneficial and detrimental impacts within the text	Invasive alien species
"Only 37% of respondents said that mimosa could be (and sometimes was) used as firewood; 63% saw no plant uses" (Rijal & Cochard, 2016)	*Mimosa pigra* (giant sensitive plant)
"A fifth (20%) of respondents reported eating *O. stricta* fruit, with the remaining 80% saying they ate it only rarely or never. Significantly, more men reported eating *O. stricta* than women … Respondents mentioned that a lot of time and effort is needed to remove the small barbs (glochids) from the fruit and that it could only be eaten in moderation otherwise it would result in stomach 'irritation'" (R. T. Shackleton et al., 2017, p. 2433)	*Opuntia* stricta (erect prickly pear)
"Some people use the plant's milky latex sap as a livestock insecticide, applying it to insects that are attached to cattle. However, this is not widely practiced because, as a number of participants explained, the sap is also a skin irritant and will burn a person if any touches exposed skin." (Luizza et al., 2016)	*Cryptostegia grandiflora* (rubber vine)
"Respondents reported that they have other trees superior to *S. spectabilis* in their compounds that serve as shade, flower and fence provision, and wind brakes." (Mungatana & Ahimbisibwe, 2012, p. 189)	*Senna spectabilis* (whitebark senna)
"Health problems include animal teeth falling out from eating too many *P. juliflora* pods, as a pastoralist suggested, 'For two months of the year, the pods are good so animals can eat something; if they eat it every two days it creates no problems, but too much makes the teeth fall'" (Duenn et al., 2017, p. 571)	*Prosopis* ssp.
"Some farmers say Acheampong [*Chromolaena odoratum*] is bad. But if you are strong and can cut out its roots it is not bad. Maize grows well where Acheampong has been. It has some moisture in its roots and this is good. But if you can't cut out its roots it is trouble. It will grow back very quickly and spoil your crops" (Amanor, 1991, p. 9)	*Chromolaena odorata* (Siam weed)

Indigenous Peoples and local communities have conducted a comparison of the negative *versus* positive effects within the same study, considering these trade-offs. In 11 out of the 12 cases, invasive alien species were found to have more negative than positive impacts overall.

Particularly, Indigenous Peoples and local communities reported an equal number of negative and positive impacts on material and immaterial assets. Studies on the perspectives and experiences of Indigenous Peoples and local communities with invasive alien species have therefore sought further qualitative and contextual analysis through survey data to better understand these impacts **(Table 4.36)**.

4.6.5 Interactions between impacts and trends, drivers, management documented by Indigenous Peoples and local communities

Interaction of invasive alien species trends and impacts

Indigenous Peoples and local communities report changes in the impacts of invasive alien species depending on the trend in abundance over time. In this review, some impacts increased with time, whilst other impacts decreased depending on the interaction with livelihoods.[19] For example, *Paralithodes camtschaticus* (red king crab) was initially seen as a pest by the Saami fisher people in Norway, but was later viewed as a major economic resource (Broderstad & Eythórsson, 2014). In contrast, in Botswana, local people initially "embraced" *Prosopis juliflora* (mesquite), but as rates of spread increased in the 1990s, its negative impacts on livelihoods started to become a serious concern (Mosweu *et al.*, 2013).

Interactions of invasive alien species and other drivers of change amplify impacts for Indigenous Peoples and local communities

Other drivers were identified by Indigenous Peoples and local communities to interact with invasive alien species and amplify impacts. Climate-related drivers, including drought, rainfall and temperature variability were documented as reducing the resilience of livestock and crops to invasive alien species and diseases (Rettberg, 2010; Upadhyay *et al.*, 2020; Fenetahun *et al.*, 2020). A lack of resources, such as limited access to irrigation equipment or tools in the context of increased labour

19. Data management report available at: https://doi.org/10.5281/zenodo.5760266

demands, further put strain on Indigenous Peoples and local communities and their ability to cope with impacts of both invasive alien species and climate change (Rijal & Cochard, 2016). For some Indigenous Peoples and local communities, the introduction of invasive alien species to traditional lands and water is representative of human intervention by non-indigenous people at sacred landscapes, which causes additional distress on well-being due to historical and ongoing disempowerment (Aigo & Ladio, 2016; Bach *et al.*, 2019).

Impacts of interactions between management of invasive alien species by Indigenous Peoples and local communities

For Indigenous Peoples and local communities, positive impacts of invasive alien species can include opportunities for skills development, knowledge sharing and employment when managing biological invasions and controlling invasive alien species. For example, invasive weed management provided opportunities for elders to teach young Aboriginal peoples about culture, and to experiment with traditional burning regimes as a form of weed control (Bach & Larson, 2017). In North America, traditional methods to locate and harvest ash trees are being documented by Indigenous Nations in response to the spread of *Agrilus planipennis* (emerald ash borer), responsible for the death of culturally significant *Fraxinus nigra* (black ash). Family and tribal stories associated with traditional gathering areas are also being documented as part of this effort (Poland *et al.*, 2017; Reo *et al.*, 2017; **Box 4.14**).

Some reports have emphasized that the management of biological invasions can divert resources, such as time and money from other important priorities, or even cause harm itself. For instance, forest management committees in Nepal have been allocating a portion of their annual income for the management of *Mikania micrantha* (bitter vine), which would be otherwise spent on infrastructure development and social services (Sullivan & York, 2021). Additionally, they have reported an increase in the amount of labour and time required for controlling invasive alien species **(Table 4.34)**. As mentioned in previous sections, Indigenous Peoples and local communities have also reported experiencing health problems when controlling invasive alien species, particularly through the excessive or unsafe use of pesticides (Head & Atchison, 2015; Machekano *et al.*, 2017).

4.7 DISCUSSION AND FUTURE DIRECTIONS

4.7.1 Models and scenarios of impacts

Authors have conducted a systematic literature review of 778 papers on models and scenarios involving biological invasions, of which 171 papers address the impacts of invasive alien species.[20] Most studies consider the impacts of invasive alien species to native species or native ecosystems, and 18 per cent (31 papers) consider the impacts of invasive alien species on nature's contributions to people, 8 per cent (14 papers) on good quality of life, and 1.8 per cent (3 papers) on Indigenous and local knowledge **(Table 4.37)**. Material contributions (assets) are the most well-studied, both in nature's contributions to people and good quality of life. Most model and scenario studies on impacts of invasive alien species are conducted in the Americas, followed by Europe and Central Asia, and Asia and the Pacific **(Table 4.38)**. The United States has been the most extensively modelled country, followed by Australia, New Zealand, and Canada **(Table 4.39)**. Modelling studies in Europe often include more than one country and these studies are covered under the "several" category in **Table 4.39**. Process-based models are the most frequently used (81 papers) to study the impacts of invasive alien species, followed by correlative models (68 papers), hybrids (19 papers) and expert-based system (3 papers). The largest proportion of studies used exploratory scenario (138 papers), followed by policy-screening scenario (17 papers) and target-seeking scenario (16 papers). Climate change is the largest scenario type (60 papers), followed by invasive alien species managements. The most modelled taxonomic group for impact assessment is invertebrates (63 papers), followed by plants (54 papers), mammals (23 papers), and fish (22 papers). Terrestrial realm is the most frequently modelled realm (126 papers) followed by inland waters and marine.

Models quantifying the impacts of invasive alien species can be a helpful tool to inform decision-makers and stakeholders as they evaluate management options. The systematic review showed that a large proportion of model and scenarios studies focus on predicting the potential distribution ranges of invasive alien species (61 per cent), often using climate change scenarios (48 per cent), but the efforts to evaluate their impacts on nature's contributions to people, good quality of life and Indigenous local knowledge are limited. Building such models faces numerous challenges (Venette, 2015; Leung *et al.*, 2012) because the impacts of invasive alien species on nature, nature's

20. Data management report available at https://doi.org/10.5281/zenodo.5706520

contributions to people, and good quality of life are complex and highly context-dependent, and differ among invaded regions (Essl *et al.*, 2020; Kumschick *et al.*, 2015). Moreover, predicting future trajectories of the impacts of invasive alien species depends on the development of reliable scenarios for the introduction, time lags, and spread of the invasive alien species, but such attempts are still limited (Corrales *et al.*, 2018; Essl *et al.*, 2019). Currently, predicted trajectories of invasive alien species are primarily based on experts' knowledge and opinions from western regions, and inputs from other regions are rare (Essl *et al.*, 2020). Recently, however, conceptual frameworks for building alien species scenarios are emerging (Lenzner *et al.*, 2019), and future predictions of invasive alien species incursions and spread have been evaluated at the continental scale (Seebens *et al.*, 2021). Those studies will help to develop scenario-based assessments, such as climate change (IPCC, 2014) or biodiversity loss (IPBES, 2016), for biological invasions in the near future. Moreover, standardized global impact assessment schemes (Bacher *et al.*, 2018; IUCN, 2020; Vimercati *et al.*, 2022) and databases, such as InvaCost for the economic costs of biological invasions on a global scale (Diagne, Leroy, *et al.*, 2020), are available. A recent InvaCost study showed rising economic costs of biological invasions both in management and damage caused by invasive alien species (Diagne, Leroy, *et al.*, 2020; Diagne, Turbelin, *et al.*, 2021). Although there is no such global database nor study for the impacts of invasive alien species on native species or native ecosystems (but see **section 4.3.1**), it is most likely that those impacts are also increasing, since the number of invasive alien species establishments is still increasing globally (Seebens *et al.*, 2017; **Chapter 2**, **section 2.2.1**). Combining the predicted distribution of invasive alien species with those studies will provide an excellent opportunity to estimate the impacts of invasive alien species in a changing world.

The systematic literature review on scenarios and models completed for this assessment only focused on studies published in English, resulting in a potential bias towards western countries, especially English-speaking countries. Indeed, the United States is by far the most represented country in the dataset (23 per cent), followed by Australia (8 per cent), New Zealand (3 per cent) and Canada (3 per cent). Countries in other regions, especially Africa, are much less prevalent or missing altogether A recent study showed that non-English studies can contribute to improve our knowledge in conservation biology (T. Amano *et al.*, 2021), as well as estimation of the costs of biological invasions (Angulo, Diagne, *et al.*, 2021).

4.7.2 Challenges for future studies of impacts (based on knowledge gaps)

Chapter 4 identifies a number of challenges that may limit the understating of impacts of invasive alien species. This section highlights the main challenges that have been identified in the hope that future research will help close these important knowledge gaps. Aiming for a more complete and global understanding of the impact of invasions will contribute to their successful management and governance (Nuñez *et al.*, 2020; **Chapters 5** and **6**).

The data and information presented in this chapter reveal substantial geographical and taxonomical gaps on the documentation, quantification and understanding of impacts, with lesser-studied regions potentially more affected, and lesser-studied taxa potentially more impactful (e.g., invasive alien viruses, bacteria, protists, fungi). The quality and quantity of impact information available for different taxa, units of analysis, regions and realms differ greatly, and research efforts for invasive alien species impacts are unevenly distributed geographically, temporally, and taxonomically.

The impact database developed through this chapter highlights the incompleteness of information on impacts of invasive alien species in Central Asia (mainly due to language barriers) and Africa. There are also discernible biases within regions. For example, in Africa, most impacts are documented from South Africa; eastern and northern Africa being much less covered.

These biases are observed across all realms, but especially in marine ecosystems, where the extent and timing of research efforts lag behind terrestrial studies (Ojaveer *et al.*, 2015). Quantitative data on ecological impacts are generally scarce, even in well-studied regions. Although research on marine invasive alien species is relatively recent (initiated in the 1960s and 1970s), there are already distinct geographic and taxonomic knowledge biases on impacts of marine invasive alien species. Impacts for the vast majority of marine alien species have not been quantitatively or experimentally studied over sufficiently long temporal and spatial scales, and their cumulative and synergetic connections with other drivers of change affecting the marine environment are largely unknown. A literature survey on alien marine macroalgae revealed information on impacts for only 30 species globally (Davidson *et al.*, 2015). Evidence for most of the documented ecosystem impacts in European seas is based on expert judgement or correlations, with only 13 per cent of the documented impacts inferred from manipulative or natural experiments. A similar paucity of impact data is apparent in North America. A recent synthesis of global ecological impacts[21] comprises 76 species, about 4 per cent of documented marine alien species, and the ecological impacts of 49 of the species were quantified in only one study each.

This chapter also highlights biases in the study of impacts of invasive alien species across units of analysis: in the marine realm, most studies were confined to intertidal/shallow subtidal areas, and in the terrestrial realm few impacts have been documented in deserts, tundra and high elevation mountainous habitats.

The impact database developed through this chapter also reveals a lack of understanding and synthesis of impacts of invasive alien microbes across all regions of the world. Some microbes are pathogens of plants, animals or humans, and due to their small size and parasitic lifestyle, many microbes can frequently be transported, introduced and established. While microbes can be considered as invasive alien organisms (Nuñez *et al.*, 2020; H. E. Roy *et al.*, 2017), they have been long ignored in the field of ecology, and this could be a reason for their small representation.

Similar to trends in publications in other disciplines (Nuñez *et al.*, 2021), many of the publications reviewed in this chapter focus on impacts occurring in a narrow set of wealthy countries. Although references in other languages could drastically improve the understanding of impacts of invasive alien species, about 95 per cent of the publications listed in the impact databased developed through this chapter are in English, severely underrepresenting studies in non-English scientific journals (Angulo, Diagne, *et al.*, 2021; Nuñez & Amano, 2021).

The intrusion of geopolitical boundaries in biological invasion science constitutes another information-related challenge, as invasive alien species are often transported from one region to another within the same country. Subsequently, a species native to one region may, under certain definitions, be considered invasive in another region in the same country, especially in large countries (Nelufule *et al.*, 2022). In the impact database developed through this chapter, geopolitical boundaries have been considered, i.e., species were only defined alien if they crossed national borders.

Context dependency presents a fundamental challenge (Sapsford *et al.*, 2020) when determining whether impacts are deemed detrimental or beneficial. Assessing the directionality of impact can be influenced by subjective human perceptions and values, resulting in potential disagreement among different stakeholders. Some invasive alien species have conflicting values associated with them, whereby they may cause negative impacts for some, but may be treasured by others. They may negatively affect some native taxa, but create conditions that favour other native taxa (Vitule *et al.*, 2012) or have economic benefits to some sectors **(Box 4.10)**. Impacts may also change over time, with some species having very low negative

21. https://www.marinespecies.org/introduced/

impacts for long periods of time, before they become highly problematic (**Chapter 1**, **section 1.4.4**; **Chapter 2**, **section 2.2.2**; Essl *et al.*, 2012). Furthermore, the same invasive alien species can also have a large impact in one area but no impact in another (Zenni & Nuñez, 2013). A deeper understanding on the socioecological context of conflict species and time lags will contribute to more successful management programmes (**Chapter 5**, **section 5.6.1.2**).

This chapter highlights several other research and knowledge gaps that impede a comprehensive understanding of impacts of invasive alien species. Compared to the information available on impacts on nature, there is incomplete data on impacts on nature's contributions to people and good quality of life. Furthermore, there is very little systematic research on gender differences in impacts of invasive alien species beyond anecdotal evidence of direct impacts (for further examples see IPBES, 2022). Most studies on impacts of marine invasive alien species relate to impacts on nature, including ecosystem health. The number of marine invasive alien species with sufficient data to satisfy the criteria for "significant negative impact" is small, as the understanding of marine ecosystem functions is constrained. Unless impacts are conspicuous, induce direct economic cost, or impinge on human health, they fail to elicit public awareness, attract funding, or result in scientific analysis (Katsanevakis *et al.*, 2014; Ruiz *et al.*, 1999). Improving the data and understanding on the extent and variety of the impacts marine invasive alien species create, singly and cumulatively, will contribute to providing timely and efficient management and policy instruments.

Finally, impacts resulting from interactions amongst invasive alien species and with other drivers of change, are largely misunderstood. Interactions among co-occurring invasive alien species ("invasional meltdown"; **Glossary**; **Chapter 1**, **section 1.3.4**; **Chapter 3**, **section 3.3.5.1**; Simberloff & Von Holle, 1999) or with other drivers of change can exacerbate their impacts and facilitate additional invasive alien species, increasing competition with native species, and creating new challenges for restoration (**Glossary**) of native habitats (Kuebbing & Nuñez, 2016). For instance, global extinctions **(Box 4.4)** are often caused by multiple factors, including invasive alien species. Understanding the interactions of invasive alien species with other drivers of change such as land- and sea-use change, climate change, pollution and sociocultural drivers (e.g., hunting of wildlife), will improve the understanding of impacts of invasive alien species and inform future predictions of the impact of invasive alien species.

Chapter **5**

MANAGEMENT; CHALLENGES, OPPORTUNITIES AND LESSONS LEARNED

EXECUTIVE SUMMARY

1 **Substantial knowledge, options and experience in management of biological invasions exist at the regional, national and local levels *(well established)* {5.2, 5.3, 5.4, 5.5, 5.6}.** Key challenges for the effective implementation of biological invasion management include developing appropriate policies and regulations to support management {5.6.2.1}, building management capability and capacity {5.6.2.4} **(Table 5.11)**, fostering collaborative governance to assist stakeholder engagement within cultural contexts {5.2.1} and developing and implementing processes to manage cross-jurisdictional and transboundary issues **(Table 5.11)**. Addressing these challenges can ensure effective implementation of management strategies *(well established)* {5.6.2}.

2 **Options for management of biological invasions include pathway, species-based and site- or ecosystem-based approaches *(well established)* {5.1.1}. When implemented, these approaches will help mitigate impacts of invasive alien species and enhance ecosystem resilience *(well established)* {5.3, 5.5}.** Pathway management is a major component of prevention *(well established)* {5.5.1}. Species-based management, which includes surveillance, detection, eradication, containment and control, has been effective in many contexts *(well established)* {5.5.2, 5.5.3, 5.5.4, 5.5.5} **(Figure 5.1)**. Species-based and site-based approaches, such as species removal through adaptive management and ecosystem restoration, are likely to enhance cost-effective improvement of nature, nature's contributions to people and good quality of life *(well established)* {5.5.1, 5.3.2, 5.5.3, 5.5.6}. Integrated pathway, species-based and site-based management through engagement of stakeholders and Indigenous Peoples and local communities, can optimize management outcomes *(established but incomplete)* {5.2.1, 5.6.2.1}.

3 **Prevention, where possible, together with preparedness through surveillance and rapid intervention, is a cost-effective long-term biosecurity approach *(well established)* {5.5.1, 5.5.2}.** Preventive actions early in the biological invasion process decrease new species' arrivals and interception rates at the border and post-border *(well established)* {5.5.1}. Pre-border biosecurity planning and the implementation of prevention strategies through anthropogenic pathways is cost-effective in reducing biological invasions *(well established)* {5.5.2, 5.6.3.3}. Prevention is particularly effective for managing biological invasions in marine and connected water systems (e.g., ballast water and biofouling management) *(well established)* {5.5.1}. Safe trade that avoids biological invasions is supported by international sanitary, phytosanitary and animal health standards *(well established)* {5.3.1.1}. Preparedness based on surveillance, early detection and rapid response systems can quickly support cost-effective delimitation and eradication of newly established alien species when possible *(well established)* {5.5.1, 5.5.2, 5.5.3}. General surveillance systems for new alien species (e.g., through citizen science) are the most cost-effective approach to preparedness *(established but incomplete)* {5.4.2.2}. Many policies exist to support prevention of movement of invasive alien species pre-border, at the border and post-border *(well established)* {5.6.3.3}.

4 **Eradicating invasive alien species can be highly cost-effective on small islands or similar biogeographically isolated habitats of high biodiversity value and for localized and easily delimited invasive alien species *(established but incomplete)* {5.5.3}.** Eradication methods for invasive alien species on islands and similar isolated habitats are well developed, particularly for animals, and provide good examples of successful management *(well established)* {5.5.3}. Eradication other than on relatively small islands is typically only effective for highly localized incursions that spread slowly and/or where detection of invasive alien species' presence and delimitation is easy, where re-introductions are unlikely, and where effective removal techniques are available {5.5.3}. For invasive alien plant eradication, tested decision support tools exist *(well established)* {5.5.3}. Eradication programmes with community support on inhabited islands can become more challenging as island size increases *(established but incomplete)* {5.5.3}. Successful eradication of invasive alien species directly benefits good quality of life *(well established)* {5.5.3}.

5 **Effective management tools and technologies have been developed for prevention, preparedness and intervention *(well established)* {5.4}. New technologies are also being developed to improve**

complementary management approaches including ecosystem restoration *(well established)* {5.4}. Many platform-based tools exist or are under development including a) surveillance tools using remote sensing, sensory and genetic data capture and analytics, b) lab-based and in field diagnostics, c) robotic detection and intervention, d) biological control and e) adaptive management and ecosystem restoration *(well established)* {5.4.4} **(Table 5.6, Table 5.7)**. Smartphone-based data capture and analysis have game-changed affordability and adoption of digital invasive alien species management tools *(well established)* {5.4.4}. Developing novel technologies using a transparent precautionary approach in consultation with stakeholders, Indigenous Peoples and local communities, and regulators builds social licence and avoids unintended consequences *(well established)* {5.4.3.2}.

6 Many decision-support approaches, tools and methods exist to assist choice of management actions *(well established)* {5.2}. Decision-support approaches, tools and methods include scenarios and modelling, evidence-based tools that can identify hazards, prioritize pathways, species and sites for action *(well established)* {5.2.2.1}. Decision-support systems support transparency, adaptability and repeatability, through broad stakeholder community engagement, learning and endorsement of actions *(well established)* {5.2.2, 5.6.3.2}. Evidence- and consultation-based, quantitative and qualitative decision-support tools exist as standards and frameworks, and are supported by scenario and modelling platforms *(well established)* {5.2.2, 5.2.2.1, 5.6.3.2}.

7 Adaptive management, wherever possible led by stakeholders and Indigenous Peoples and local communities, promotes wide acceptance and capacity-building, and optimization of management success *(well established)* {5.2, 5.3, 5.6}. Failure to engage with Indigenous Peoples and local communities, especially those who are adapted to and use invasive alien species, in planning and implementing management actions can reduce good quality of life through loss of livelihoods, marginalization and/or gender inequity *(well established)* {5.2.1, 5.3.1.3, 5.4.4.2, 5.6.1.1, 5.6.1.2}. Broad and inclusive engagement improves planning, decision-making and undertaking management actions *(established but incomplete)* {5.2.1, 5.5.1.2}. This engagement is best achieved through partnerships around co-design, co-development and co-implementation and social learning *(established but incomplete)* {5.2.1, 5.4.4.3, 5.6.2.1}. Management programmes are most successful when their goal stretches beyond invasive alien species suppression to include restoring ecosystem resilience and nature's contributions to people *(established but incomplete)* {5.5.6}.

8 Though gaps exist in knowledge, data and management implementation, collective management actions can still proceed supported by stakeholders and Indigenous and local knowledge under a precautionary approach *(well established)* {5.2.2.1, 5.2.2.3, 5.2.2.4, 5.3.3, 5.4.4} (Box 5.13). Many sources of open-access data and analytical tools already exist to support capacity-building, priority setting, monitoring and management. However, there are many knowledge and data gaps which impede the development and implementation of pathway, species-based and site/ecosystem-based management approaches *(well established)* {5.6.2.1, 5.6.2.2, 5.6.2.3}. Despite this, effective decision-making and adaptive management programmes can still lead to successful outcomes if supported by stakeholders and Indigenous and local knowledge *(well established)* {5.2, 5.4, 5.6}. Addressing these knowledge and data gaps and uncertainty (e.g., on global change impacts) will improve management decisions and outcomes *(established but incomplete)* {5.2, 5.4, 5.6}. Improvements can be achieved by better capturing, sharing, integrating and analysing data in a manner that supports decision-making *(well established)* {5.2., 5.4}.

9 International and cross-sectoral collaboration through capacity-building networks and research and management partnerships improves transboundary management of biological invasions *(well established)* {5.6.3.1, 5.3.1}. The establishment of international networks between governments, scientists, non-governmental organizations, industries, relevant stakeholders, and Indigenous Peoples and local communities can help in the implementation of transboundary and cross-sectoral management of biological invasions *(well established)* {5.6.3.1}. International networks and partnerships help collective action, which may lead to societally acceptable and feasible management strategies and outcomes *(well established)* {5.6.3.1, 5.3.1}.

10 Failure to effectively manage biological invasions can result from data gaps, lack of awareness and societal, capacity, capability, resource and policy-related constraints especially in developing countries *(well established)* {5.3.1, 5.6.2.1, 5.6.2.2, 5.6.2.4}. Goals for the management of biological invasions are often not achieved even after considerable efforts. Gaps in data and knowledge on the distribution and spread of invasive alien species and lack of information on direct and indirect drivers of change facilitating biological invasions impede management in certain regions (e.g., parts of Asia, Africa and America) *(well established)* {5.6.2.1, 6.6.1.4}. Failures in management success can also be attributed to conflicting interests and values, lack of public awareness and understanding of impacts *(well established)* {5.6.2.1, 5.6.2.4}, inadequate policies and governance, poor capability and capacity, lack of resources, poor knowledge on modern tools and techniques and inefficiency to utilize them, and divergent public perspectives on individual species *(well established)* {5.3.1, 5.6.2.1, 5.6.2.2, 5.6.2.4}. Policy generally fails to address collective management for conflict species, for which there are positive and negative impacts of the invasive alien species on different stakeholders or sectors *(well established)* {5.6.1.2}.

11 Management of biological invasions that takes into account global change can also improve climate change resilience in ecosystems impacted by invasive alien species *(established but incomplete)* {5.6.1.3}. Effective management of invasive alien species can increase the long-term functional resilience of threatened ecosystems and habitats to climate change. Conversely, extreme climate events increase ecosystem susceptibility to invasive alien species. In such situations, rapid response through targeted adaptive management practices and ecosystem restoration supported by monitoring and collective decision-making can maintain benefits from existing management programmes *(established but incomplete)* {5.6.1.3}.

12 Long-term monitoring effectively supports management actions and sustains beneficial outcomes *(well established)* {5.4.4.2, 5.4.4.3, 5.5.3}. Long-term monitoring can be used to assess efficacy and outcomes of management actions and ensure sustained control of invasive alien species and ecosystem restoration *(well established)* {5.5.6, 5.5.7}. Long-term monitoring is also important for early detection of reinvasion *(well established)* {5.5.3}. These long-term efforts and strategies are best supported by cost-benefit, cost-effectiveness and risk analyses {5.2.2.1, 5.5.3} that consider benefits to Indigenous Peoples and local communities *(established but incomplete)* {5.4.4.2}.

5.1 INTRODUCTION

"Management" of biological invasions is conceptualized in at least two ways in different parts of the world. In the context of the invasive alien species assessment of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES), this term encompasses any activity or action undertaken to directly or indirectly prevent or mitigate negative impacts of invasive alien species. This includes pathway, species-based and site- or ecosystem-based management activities (**Glossary**).

Management of biological invasions is a global concern, and thus was an explicit element of Aichi Target 9 of the Strategic Plan for Biodiversity 2011-2020, and is a main focus of Target 6 of the Kunming-Montreal Global Biodiversity Framework (CBD, 2022a; **Chapter 1**, **section 1.1**, **Box 1.2**) and Target 15.8 of the 2030 Agenda for Sustainable Development. In this context, this chapter provides policymakers and practitioners with a range of options and scenarios where management actions can be optimally applied **(Box 5.1)**.

Chapter 5 has been written based on a comprehensive literature and technical review of tools, strategies, challenges and key outcomes of management of biological invasions. It reflects the current state of management of biological invasions and its implications as covered in existing peer-reviewed and grey literature available to the assessment team.

Section 5.1 provides an overview of the invasion continuum, the management objectives and approaches applicable at

Box 5 1 **Rationale of the chapter.**

Chapter 5 assesses the efficacy of past and current programmes and tools for the local, national and global prevention (**Glossary**) and management of biological invasions and the impacts of invasive alien species. In particular, the chapter reviews past experience with: (a) preventing the spread of invasive alien species including the role of trade and economic development; (b) the precautionary approach (**Glossary**) in preventing and managing biological invasions and the efficacy of risk assessment as a tool for their management; (c) the adoption of biosecurity approaches (**Glossary**); (d) managing complexity and intersectoral conflicts, including on the use of an invasive alien species depending on contexts and values; (e) uses of social media and citizen science (**Glossary**) for the detection of invasive alien species and prevention and management of biological invasions; (f) eradicating or managing invasive alien species, including control options such as precision application of pesticides, baits, biological control and "gene drive" technology (**Glossary**); (g) capacities of different countries to manage biological invasions, and barriers to the uptake of tools; (h) managing biological invasions in protected areas, including wetlands and biosphere reserves; (i) managing biological communities invaded by alien species, considering co-existence, including direct and indirect interspecific interactions; and (j) managing biological invasions in the context of the complex interactions between alien species, their invasion status and climate change.

Guiding questions:

- What are the decision-support processes, tools and frameworks available for prevention and management of invasive alien species? (**section 5.2**)
- How best to target invasive alien species management through pathway, species-based and site-based or ecosystem-based management options under different scenarios such as management goals, status of invasion and the socio-economic context? (**section 5.3**)

Box 5 1

- How to use databases, modern tools, emerging technologies and scenarios and modelling more effectively in detecting, preventing and managing invasive alien species? (**section 5.4**)
- How effective are the various management options at various steps in the invasion process? (**section 5.5**)
- How can international networks assist in the prevention and management of invasive alien species? What role can regional partnerships play? (**section 5.6**)
- How critical is stakeholder participation including of Indigenous Peoples and local communities in management success? (**section 5.5**)
- What are the obstacles to the uptake of invasive alien species prevention and management implementation? (**section 5.6**)
- What methods are available for managing invasive alien species on islands and similar habitats (**Glossary**) of high biodiversity value? (**sections 5.5** and **5.6**)

Keywords:
Biological control, containment, eradication, invasion stages, monitoring, pathway, prevention, surveillance, site-based management, species-based management.

different phases of invasion and suited to different biomes. It discusses the challenges and opportunities of management.

Section 5.2 focuses on decision-making frameworks for identifying and prioritizing targets and options in pathway, species-based and site-based management. It reviews methodologies and tools available, how these can be used to prioritize targets and addresses uncertainty considerations in decision-making.

Section 5.3 assesses what pathway, species-based and site-based management strategies are and when to implement each, and integrates these for application at local to regional scales. Practical examples of these approaches are nested within a sociological and socio-economic context to enhance good quality of life, with a focus on protected areas and islands.

Section 5.4 presents a summary of management approaches, frameworks, platforms, scenarios and models, tools and technologies for current and potential application of management actions. It explores how new technologies are deployed and the efficacy of various tools and their future potential to improve management actions.

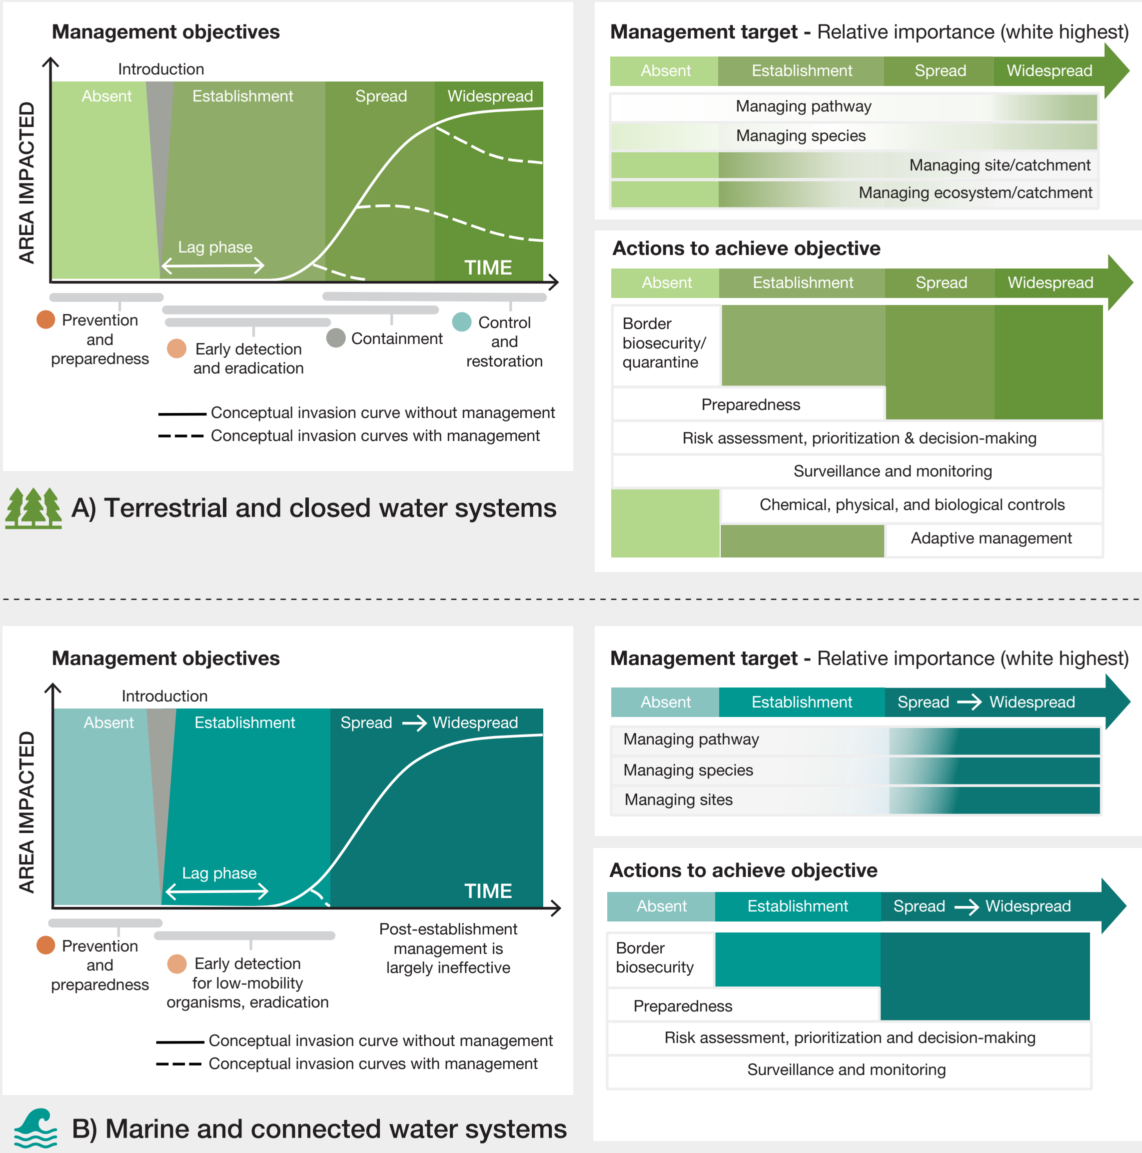
Section 5.5 assesses examples of successful and unsuccessful management approaches and examines how evidence-based decision-making and modern tools and technologies have brought successful management outcomes. It also provides evidence on management costs.

Section 5.6 summarizes the challenges in achieving effective management of biological invasions. It emphasizes context dependency and perspectives of various stakeholders and Indigenous Peoples and local communities on invasive alien species and related social conflict and discusses the knowledge gaps, lack of expertise and uncertainty which constrain effective management.

Section 5.7 provides a short conclusion.

5.1.1 Biological invasion management continuum

This chapter explores solutions to mitigate the impacts of invasive alien species (**Glossary**; **Chapter 1**, **Figure 1.1**) across biomes, species and regions. Any successful management action to prevent spread and ameliorate current or future potential impacts of an invasive alien species is built on a co-developed overarching management objective that goes beyond targeting one or more of the invasive alien species. The progression of a biological invasion by a species is generally divided into four stages, with a range of optimal management strategies which vary along this biological invasion continuum (**Figure 5.1**; **Chapter 1**, **Figure 1.8**). The management-invasion continuum (often called the "Invasion Curve", see **Glossary**) can be visually conceptualized to show the changes in management objectives and focus through each of the stages of the biological invasion process **(Figure 5.1)**. "Introduction" refers to the many introductions from intermittent or continuous propagule pressure (**Glossary**). Management approaches and responses may vary depending on whether the affected ecosystem is terrestrial or closed water systems, such as catchment basins, coastal systems and salt marshes, or an open water system (e.g., marine, brackish and water connected systems). Therefore, management-invasion continuum is presented here for these two scenarios; one for terrestrial and closed water ecosystems **(Figure 5.1A)** and another for an open water system **(Figure 5.1B)**. The management-invasion continuum presented here can support decision-making at multiple spatial scales, for example the entry and spread of an alien species into a new region/country, or into a defined space such as a protected area or an island. Also, it can help decision-making from a temporal dimension by identifying management actions suited for each stage of invasion. The management-invasion continuum can also be used to identify how management approaches targeting pathways, species, sites and ecosystems are inter-connected with each management objective and action.



EXAMPLES OF SUCCESS

Prevention

Zero tolerance biosecurity in Barrow Island, Australia
A risk analysis of all material and passenger pathways and a quarantine system prevent the entry of alien species to the island and surrounding marine habitats *(Box 5.2)*.

Eradication

***Ceroplastes cirripediformis* (barnacle scale)**
Eradicated by burning the infested plant stems soon after its detection in 2021 in India *(Box 5.16)*.

***Caulerpa taxifolia* (killer algae)**
A rapid response using liquid chlorine achieved the eradication in a lagoon in the United States of America *(5.5.3)*.

Containment

***Ageratina adenophora* (Croftonweed)**
National containment lines were proposed to prevent spread while a biological control program is under development in China *(5.3.1.2)*.

***Lymantria dispar* (gypsy moth)**
Using pheromone traps, spread of the species was slowed in North America *(5.5.4)*.

Control & retoration

***Sus scrofa* (feral pig)**
In the El Palmar National Park in Argentina, wild boar damaged Butia yatay (yatai palm tree). Through a controlled shooting program, abundance of wild boar was reduced to levels causing minimal damage to soil and the yatai palm tree recruitment *(Box 5.6)*.

Figure 5 1 **Conceptual diagram of the management-invasion continuum.**

The generalized invasion curve without management and the expected changes in the invasion curve with appropriate management actions in **A)** terrestrial and closed water systems (including coastal systems and salt marshes) and in **B)** marine and connected water systems. Boxes indicate the optimal management objectives at each invasion stage (**Glossary**). Colour gradient of managing

Figure 5 1

pathway, species, site and ecosystem boxes show how the relative focus generally changes as invasion progresses. Boxes below indicate typical management actions necessary to achieve each management objective. Post-establishment management actions are not shown under panel B since these are generally not achievable in these systems. In a management context, the first detection (introduction point), the lag phase and the exponential spread phases are important points to design an early detection and rapid response management plan. This figure is conceptual, and the curves do not represent actual population dynamics of invasive alien species.

For biological invasions in terrestrial and closed water ecosystems, there are generic management objectives such as prevention, early detection, eradication, containment and control and restoration associated with the status of the invasive alien species (absent, established, spread and widespread; Robertson *et al.*, 2020; **Glossary**; **Chapter 1**, **section 1.4**). Adaptive management and long-term monitoring need to be part of all modes of management (**Glossary**). Prevention is implemented by jurisdictions in the pre-entry phase and points of entry for intercepting new alien species, and by definition has to target arrivals of all alien species, not just those that may become invasive. Although context dependent, in the ensuing lag-phase (**Glossary**; **Chapter 2**, **section 2.2.1**) during establishment, opportunities may exist for eradication and the potential to flatten the invasion curve **(Figure 5.1)**. Early detection enables a rapid response to eradicate or contain an alien species before it spreads. The likelihood of eradication generally decreases during the rapid dispersal phase. Long-term species-based or site-based adaptive management approaches of invasive alien species that can no longer be eradicated or for which containment alone is not viable, can then effectively minimize biophysical and/or socioecological and socio-economic impacts.

In terrestrial and closed water ecosystems, effective management involves a series of actions, including objective decision-making (**section 5.2**), surveillance (**Glossary**) and monitoring (particularly at ports of entry; **section 5.5**) and chemical, physical and biological controls (**section 5.5.5**), all supported by a range of platforms, tools and technologies (**section 5.4**). Decision-making includes agreeing on clearly defined objectives ("why manage?") and carrying out evidence-based risk assessment and prioritization to undertake the most effective actions, responding to the questions: "what actions?", "where to take actions?" and "how to take actions?". Management programmes can focus on the following three management options, namely the pathways of introduction, the invasive alien species and the invaded sites/ecosystems singly or in combination (**section 5.3**).

Pathway, species-based and site-based strategies for the management of biological invasions are alternative or complementary approaches given particular socioecological contexts. The approach taken is dependent on the management goal, the status of invasion of an alien species along the introduction-invasion continuum **(Figure 5.1)** and the socio-economic situation. Pathway management, which aims to prevent the introduction of a species into new sites, functions across the biological invasion continuum (**Figure 5.1**; **section 5.3.1.1**), where efforts are generally aimed to prevent introduction into a new region/country, but also to manage the wider spread during the rapid expansion phase. Species-based management either proactively minimizes future impact risks (**Glossary**) through interventions to eradicate or contain new incursions of a species or targets suppression of a priority single species (e.g., through landscape level control such as classical biological control – **sections 5.4.3.2f** and **5.5.5**, or lethal control programmes – **section 5.4.3.2d**), or multiple established alien species (**Glossary**) through localized extirpation (McGeoch, Genovesi, *et al.*, 2016; Simberloff, 2013). Site-based or ecosystem-based management focuses on a specific area or ecosystem defined by its inherent value (e.g., biosphere reserves, heritage sites or protected areas; **section 5.3.2**) and the threat that invasive alien species pose to biodiversity conservation value and management objectives of that site (Owen & Sheldon, 1996). These objectives and ecosystems include the broader socioecological context (Stokols, 1996).

In marine and water connected systems, post-entry management of invasive alien species is generally ineffective (Booy *et al.*, 2020; Lehtiniemi *et al.*, 2015). Therefore, prevention at the pre-entry phase and surveillance and early detection before the establishment stage are the most effective management options in these ecosystems. In the marine context, site-based activities mainly consist of surveillance (e.g., in ports, harbours, mariculture facilities and marine protected areas). Eradication of established invasive alien species is rarely achieved in these ecosystems and may be possible only for sessile or low mobility organisms (Lehtiniemi *et al.*, 2015), with few examples of chemical control (**section 5.5.3**) in small bays or enclosed waters. Nonetheless, prevention is the optimal viable option to avoid negative consequences of invasive alien species (Galil, Danovaro, *et al.*, 2019) in marine systems given the complex nature (**Glossary**) and vastness of these environments for implementing management procedures. Early detection is important, even if eradication is not achievable, to explore the possibility of mitigation (Lehtiniemi *et al.*, 2015). In any case, all management actions would need resourcing for the costs of stakeholder engagement and communication, implementation of techniques and tools, restoration and long-term evaluation.

5.1.2 Scope of the chapter

Chapter 5, which covers all the key elements of management of biological invasions along the management-invasion continuum **(Figure 5.1)**, consists of an introduction section (**section 5.1**) and five theme-specific sections (**sections 5.2** to **5.6**), with the relationships between each shown in **Figure 5.2**. This solution-focused chapter has strong links to other chapters of the assessment, since management and decision-making are intrinsically dependent on knowledge of the impacts of invasive alien species (**Chapter 4**), their status and trends (**Chapter 2**; **Glossary**) and how to manage direct and indirect drivers of change that impact invasion (**Chapter 3**). Collective community management decisions are also supported by good understanding of Indigenous and local knowledge and how invasive alien species impact good quality of life (**Glossary**; **Chapter 4**, **sections 4.5**, **4.6**; **Chapter 1**, **section 1.6.7.1**). Lessons that can be learned from previous and current management efforts and control options presented in this chapter can inform and improve future policy options (**Glossary**; **Chapter 6**).

5.1.3 Management: challenges and opportunities

Throughout **sections 5.2** to **5.6** **(Box 5.1)**, various challenges, case studies and future opportunities have been identified and distilled as lessons to be learned.

Challenges that managers of biological invasions face are jurisdictional boundaries (Flueck, 2010; Stokes *et al.*, 2006), inadequacy of regulations (Burgiel *et al.*, 2006; Garcia-de-Lomas & Vilà, 2015), lack of expertise (Shine, 2005), poor stakeholder engagement (Driscoll *et al.*, 2014; Simberloff *et al.*, 2005; **Chapter 6**, **section 6.4**) and uncertainty on where to allocate limited resources (Prior *et al.*, 2018; **section 5.6**). Some decision makers are hesitant to attempt prevention given only a small proportion of alien species arriving may ultimately become invasive (**Chapter 1**, **Figure 1.1**), so in some cases it is perceived as best to wait until the impacts of the alien species are understood (Finnoff *et al.*, 2007; **Chapter 4**, **section 4.2**) but this can result in delays rendering subsequent management costly or even impractical. Additionally, implementing some of the management approaches may not be acceptable to all the stakeholders and Indigenous Peoples and local

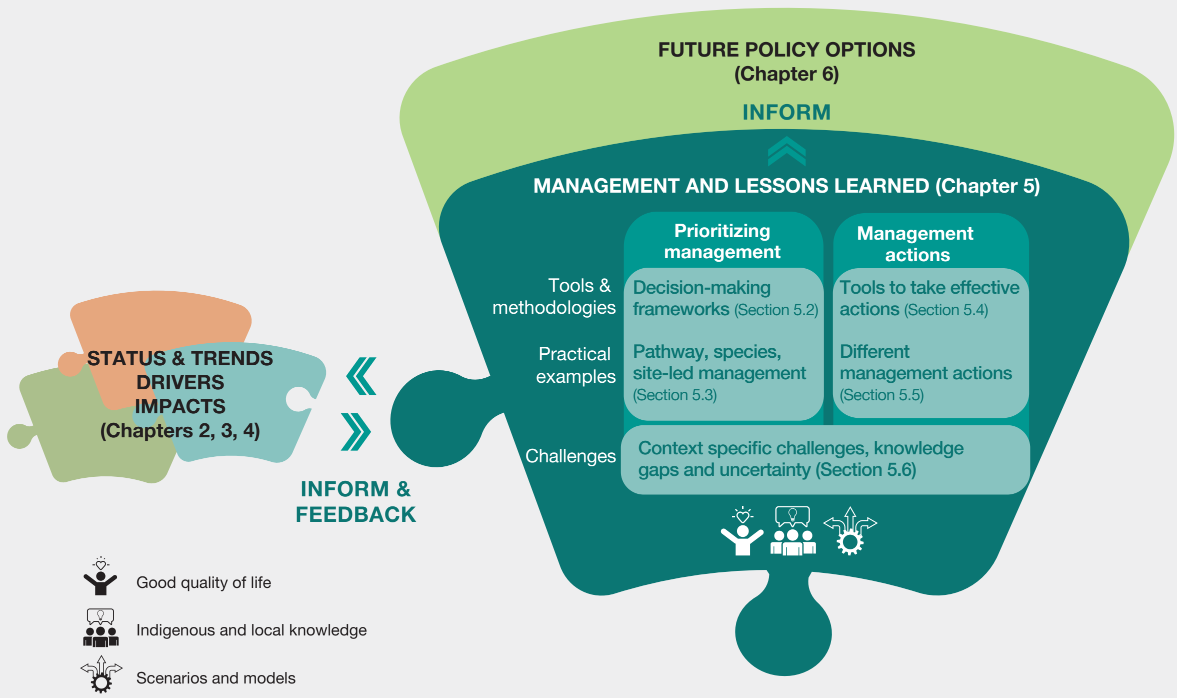


Figure 5 2 **Content of sections in this chapter and their linkages with the other chapters of the assessment.**

This figure shows the structure of **Chapter 5**, and how it connects to **Chapter 2** (status and trends of biological invasions), **Chapter 3** (direct and indirect drivers affecting biological invasions), **Chapter 4** (impacts of invasive alien species) and **Chapter 6** (future policy options to manage biological invasions). It also informs and provides feedback and clarity to all these chapters.

communities. For example, there is increasing opposition to some control methods, e.g., use of chemical pesticides or lethal control of alien vertebrates using toxins (Genovesi & Bertolino, 2001; Longcore *et al.*, 2009); concern about the non-target effects of certain methods (e.g., biological control, genetic control options), high costs of management and the paucity of funds for continuous management and monitoring (Wittenberg & Cock, 2003). Some invasive alien species are also considered by some stakeholders as beneficial (Niemiera & Holle, 2009; Scasta *et al.*, 2015; **section 5.6**; **Chapter 4**, **sections 4.3**, **4.4**, **4.5**). Removal of invasive alien species which have commercial or cultural values can deprive people who utilize these for livelihood and other adapted uses (Grechi *et al.*, 2014; N. A. Marshall *et al.*, 2011; van Wilgen, 2012), though other benefits through management of invasive alien species can also contribute to nature's contributions to people and to good quality of life. As the concept of an invasive alien species is a human construct, interests and perceptions of invasive alien species for different stakeholders and Indigenous Peoples and local communities may differ and the management of some invasive alien species may result in conflicting values (**Chapter 1**, **section 1.5.2**).

There are many opportunities for the successful prevention and management of biological invasions. Modern tools and techniques, combined with long-standing proven management methods, often involving Indigenous and local knowledge, can reduce the impacts of invasive alien species in many instances. There is an increasing global willingness and desire among stakeholders to cooperate on management, undertake collaborative research and build awareness on the impacts of invasive alien species. Promoting such collective efforts to address issues are important in the management process (**sections 5.4**, **5.5**). Scientific information and databases (**section 5.4**) and decision-making tools (**section 5.2**) are being made openly available to policymakers and resource managers to enable informed decision-making. Collaboration among governments, agricultural industries, the general public, including Indigenous Peoples and local communities, non-government institutions and land users, and concerted actions by all parties will assist in addressing the challenge in a strategic, holistic and timely manner (Reaser, 2003) at the most appropriate scales (Glen *et al.*, 2017). There is evidence to suggest that even less extensive cooperation and coordination among independent landowners can have a profound positive effect on managing invasive alien species (Epanchin-Niell & Wilen, 2015). Clear objective-driven invasive alien species management involving, and agreed upon by relevant stakeholders can bring substantial ecological and social benefits, and can eventually open new opportunities for improving good quality of life (Chikoye *et al.*, 2006; H. P. Jones *et al.*, 2016; Samways *et al.*, 2010; **Chapter 6**, **section 6.4**).

5.2 EVIDENCE BASED DECISION-MAKING

Attaining good community collaboration, co-development and governance of any form of environmental management has many challenges (Margerum & Robinson, 2016). Invasive alien species are the result of human activities, situations or events that are subject to human experiences, concerns and values (**Chapter 3**, **section 3.2.1**). Thus, the management of their threats and impacts implies effective multiway stakeholder community engagement in communication, knowledge sharing and co-development around goal setting, decision-making and intervention through action (**Chapter 6**, **section 6.4.2**). As for many environmental issues, there are also a wide variety of actions to address invasive alien species, for example, technical, legal, economic, social, behavioural, cultural or knowledge based. Whatever the action is, decisions are taken by representatives of societies, communities and individuals confronted with invasive alien species using a precautionary approach. Decision makers may be public or private, including policymakers, land and waterway managers, Indigenous Peoples and local communities, volunteers working on public land, private tenants, non-governmental organizations or community groups (IPBES, 2020). Decision-making can also be differential between communities and gender. For example, in many parts of the world women are action takers while men make most of the decisions (e.g., in smallholder crop management; Fish *et al.*, 2010; Upadhyay *et al.*, 2020). Decision-making relies on available evidence, respective values, interest and responsibilities of stakeholders, available management resources (D. L. Larson *et al.*, 2011; Piria *et al.*, 2017), and likely trade-offs.

A variety of frameworks and decision-support tools and systems have been developed to facilitate the decision-making process, linking science, policy and management (Matthies *et al.*, 2007; J. R. U. Wilson *et al.*, 2020). These can help choose between particular strategies and treatment options for management of biological invasions (Kriticos *et al.*, 2018) and can support adaptive management "learn as you go" systems (**section 5.4.3.3**). When direct management actions are required, these tools can assist in evaluating the progress or success of management (Garner & Beckett, 2005). This section describes stakeholder community engagement and knowledge-sharing frameworks, prioritization processes and available methodologies and tools for management decision-making to combat invasive alien species.

5.2.1 Stakeholder community engagement and knowledge-sharing frameworks for developing communities of practice

Approaches involving collaborative governance networks of stakeholder communities to mitigate the impacts of different invasive alien species will vary depending on context (**Chapter 1**, **section 1.5.1**; **Chapter 6**, **section 6.4.4**), with each community having different a) perspectives and engagement reasons (directly and indirectly affected communities), b) knowledge bases (understanding of drivers, processes, trends and impacts of invasive alien species) and c) roles in the response (resourcing, governing and implementing; **Chapter 1**, **section 1.5**). Effective environmental, social and cultural knowledge and governance (**Glossary**; **Chapter 6**) supports effective stakeholder community engagement and collaboration. The foundation of community engagement is building trust and understanding through knowledge sharing. For invasive alien species, this concerns knowledge of impacts on nature, good quality of life and nature's contributions to people (**Glossary**); and the likelihood that impacts can be mitigated with high benefit-cost and cost-effective management actions and that long-term system resilience (**Glossary**) benefits can result from these actions. Stakeholder engagement systems need to address the challenges of community collaboration (McAllister *et al.*, 2017), be cost-effective (S. Liu *et al.*, 2019), and grow social resilience to invasive alien species (Maclean *et al.*, 2018). Indigenous Peoples and local communities often have different motives for engagement than other stakeholders (**Supplementary material 5.1**), and manage biological invasions for multiple purposes which are closely related to each other (IPBES, 2022b). It may be noted that spirituality is an overarching motivation for Indigenous Peoples and local communities to protect their land and assets from invasive alien species, even though this is often underreported (IPBES, 2022b; **Chapter 4**, **section 4.6**). Therefore, they can provide unique knowledge and management response capacity (Bach *et al.*, 2019; Kannan *et al.*, 2016; Madegowda & Rao, 2014). These stakeholder community engagement systems can be highly context specific (e.g., low vs. high income countries, peri-urban vs. rural situations, terrestrial vs. marine environments, public vs. private, etc.) but are vital to create co-developed communities of practice around effective community-led responses that support prevention, preparedness (**Glossary**; **section 5.4.2**), rapid response and widespread control.

Collaboration and knowledge sharing among stakeholder communities (governments, scientists and non-governmental organizations) and Indigenous Peoples and local communities also help management of, or if needed adaptation to, new invasive alien species in localities and regions (IPBES, 2020). For example, the volunteering programme at the Horus Institute for Environmental Conservation and Development of Brazil with the Federal University of Santa Catarina engages university students and the local community to do hands on work controlling invasive alien pines and restoring coastal areas in the Dunas da Lagoa da Conceição Natural Municipal Park (Florianópolis, Santa Catarina state, Brazil), one of the most impacted ecosystems in the Atlantic Forest Biome in Brazil where some 470 thousand pines have been eliminated. Without the programme, invasive alien pine trees would have degraded half of the total area of the park in two decades (Dechoum *et al.*, 2019). In another example, by organizing tournaments or derbies since 2009, volunteers from Colombia, Bahamas and Florida (United States of America) helped raise awareness of *Pterois volitans* (red lionfish) and *Pterois miles* (lionfish), an Indo-Pacific invasive alien species widespread in the Caribbean region (Green *et al.*, 2017). There are two other similar initiatives described by Anderson *et al.* (2017) and Kleitou *et al.* (2021).

Community-based management of biological invasions often happens through profit-making activities such as harvesting for sale in new markets or by encouraging recreational hunters to act as management agents, however this can create conflicts (**section 5.6.1.2**). *Paralithodes camtschaticus* (red king crab) was introduced in the Barents Sea affecting local fisheries. The Saami community and other coastal fishermen communities of Norway played an important role adapting to this invasive alien species and participating in management actions with financial return and changing the fishing system (Broderstad & Eythórsson, 2014). Stakeholder communities can collectively plan options and select management interventions and evaluate and transparently communicate outcomes, recognizing potential negative and positive impacts. Societal and political support for management decision-making and engagement with Indigenous Peoples and local communities can be achieved through participatory decision-making to ensure a common understanding of the pros and cons of decisions and actions (S. Liu *et al.*, 2019). It is important that these participatory mechanisms respect social structures, intellectual property, land rights and self-determination through free, prior and informed consent, respect spiritual values and processes, including prayers, ceremonies and other ways through which relationships between humans and nature are balanced (Bajwa *et al.*, 2019; IPBES, 2020; Pretty Paint-Small, 2013). Once action has been decided, adaptive management involves observation, experimentation and collective learning to optimize outcomes (Alexander *et al.*, 2017). Communication activities imply consultation to understand and respect Indigenous Peoples and local community perspectives (IPBES, 2020). Without such engagement, conflicts may result leading potentially to loss of livelihoods, threats to cultural systems, displacement from lands, marginalization and gender inequity (e.g., as occurred with the Il Chamus in Ng'ambo pastoralists in Kenya; Mwangi & Swallow, 2005).

Standardized frameworks can support stakeholder community engagement, but still need improvement (Novoa *et al.*, 2018; R. T. Shackleton, Larson, *et al.*, 2019). Context-specific frameworks have been developed and analysed (Lansink *et al.*, 2018; McAllister *et al.*, 2015). There are a number of approaches that have been developed and applied to management of biological invasions which also support effective decision-making across multiple management options (Firn *et al.*, 2015; Carwardine *et al.*, 2019). Shackleton *et al.* (2019) argue that "to make stakeholder involvement more useful, we encourage more integrative and collaborative engagement to (1) improve co-design, co-creation and co-implementation of research and management actions; (2) promote social learning and provide feedback to stakeholders; (3) enhance collaboration and partnerships beyond the natural sciences and academia (interdisciplinary and transdisciplinary collaboration); and (4) discuss some practical and policy suggestions for improving stakeholder engagement in [biological] invasion science research and management".

5.2.2 Evidence based decision-making framework vs. *ad hoc* decision-making

How decision-making is undertaken with regards to what, where and how to manage biological invasions is rarely explicitly stated in most management contexts. Many management action decisions are done in an *ad hoc* way as a flexible emergency response to new incursions, a belated observed impact, or as a political imperative (Sheail, 2003). Often decisions on actions need to be made under a degree of uncertainty, such as when containing new incursion to avoid spread. Sometimes the science lags behind the operational tools required. Less often is there a formal community or government framework in place for decision-making.

Preparedness is improved through adopting a systems-based adaptive management approach allowing learning to lead to improvements. Explicitly addressing the rationale behind decision-making allows for transparency, repeatability, learning as well as endorsement and support for the actions resulting from the decision-making process (De Fine Licht, 2014; Estévez *et al.*, 2013; Moon *et al.*, 2015, 2017; Vanderhoeven *et al.*, 2017). This practice is the basis of some international standards such as the International Standards for Phytosanitary Measures (ISPM) of the International Plant Protection Convention (IPPC; IPPC, 2019; **Supplementary material 5.8**) and World Organisation for Animal Health (WOAH, founded as OIE) standards (World Organisation for Animal Health, 2020).

Conceptually, actions are often categorized into three main approaches **(Figure 5.3)** all of which are underpinned

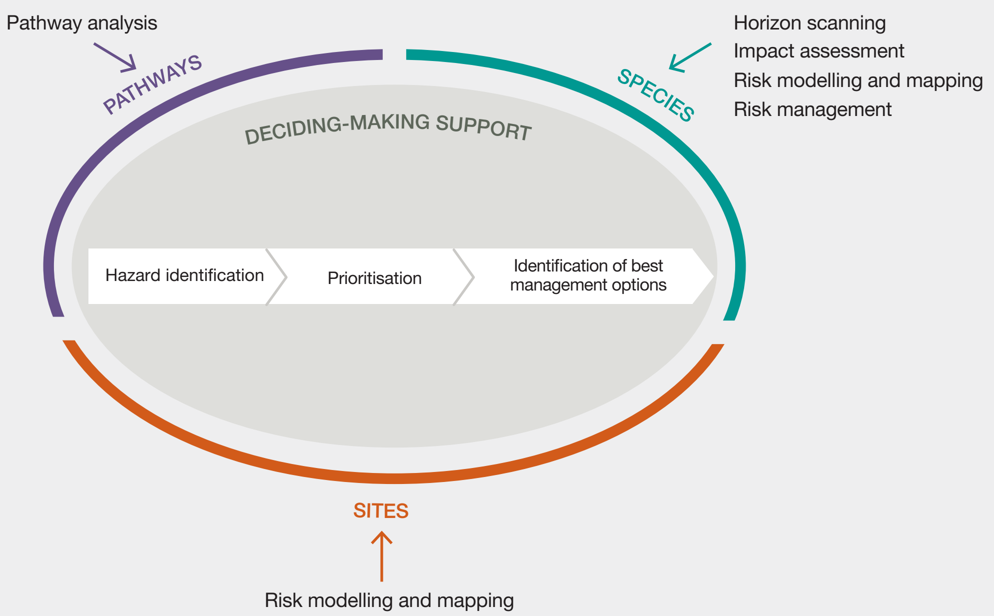

Figure 5 3 **The three main approaches to support decision-making actions on management of biological invasions and examples of contributing tools.**

Decision-making relies on a sequence of steps consisting of the hazard identification, the prioritization of threats and the identification of the best management options. This applies whether the decision deals with pathways, species, or sites.

by decision-making to identify and prioritize targets and management actions:

- Focusing on the pathways of introduction of alien/invasive alien species: this approach aims to answer questions such as "Is pathway 'X' a major source of supply of alien species for a given area?"; "Which are the most high-risk pathways for the arrival of invasive alien species?"; and "What is likely the most effective way to reduce the introduction of species *via* this pathway?"

- Focusing on the alien and/or invasive alien species of interest: this approach aims to answer questions such as "Is species 'X' impacting a given region?"; "Which species is most at risk of entry and establishment in a given jurisdiction?"; "Which species is most impactful?"; "How established or spread is this species?"; "Can it be contained or eradicated?"; "What is likely to be the most effective management action?"; or "How much will it cost?"

- Focusing on invaded sites: this approach aims to answer questions such as "What sites harbour the most sensitive habitats prone to invasive alien species establishment?"; "Does this site similarly include site Y which provides important ecosystem services to livelihoods?"; "Which sites are a high priority for management based on the level of invasion or the value of the biodiversity and ecological assets at that site?"; and "What are the best actions to manage high priority sites?"

A "site" here is a clearly defined land/freshwater/marine area including the sociological system (i.e., the social, institutional and cultural contexts of the relationship between people and the environment; Stokols, 1996). Management of biological invasions is also considered holistically in decision-making frameworks for ecosystem-based management, increasingly applied (Espinosa-Romero *et al.*, 2011; Lampert *et al.*, 2014; Tanentzap *et al.*, 2009).

5.2.2.1 Analytical approaches, methods and tools for decision-making support

Many analytical approaches, methods and tools are available to address the types of decisions under species, pathways and site management approaches, aimed at mobilizing existing knowledge around the three analytical elements. These are hazard identification, prioritization and

Table 5 1 **Analytical approaches, tools and methods available to making decisions about biological invasions.**

This table shows the different analytical approaches, tools and methods available to decision makers to tackle biological invasions as well as their respective utility and different levels of governance to which they apply.

Tools and Methods	Utility

identification of best management options (**Figure 5.3**; **Table 5.1**). Approaches, methods and tools may be used in isolation or in a complementary manner for answering common questions across the different approaches. The analytical approaches, methods and tools presented below align with the conceptual biological invasion process (**Chapter 1**, **Figure 1.6**; **Figure 5.4**). Several tools rely on information in previous chapters, including up to date knowledge of species distribution and abundance (**Chapter 2**), direct and indirect drivers facilitating biological invasions across the invasion continuum (**Chapter 3**) and invasive alien species impacts (**Chapter 4**). This highlights the importance of knowledge and data for evidence-based decision-making on management.

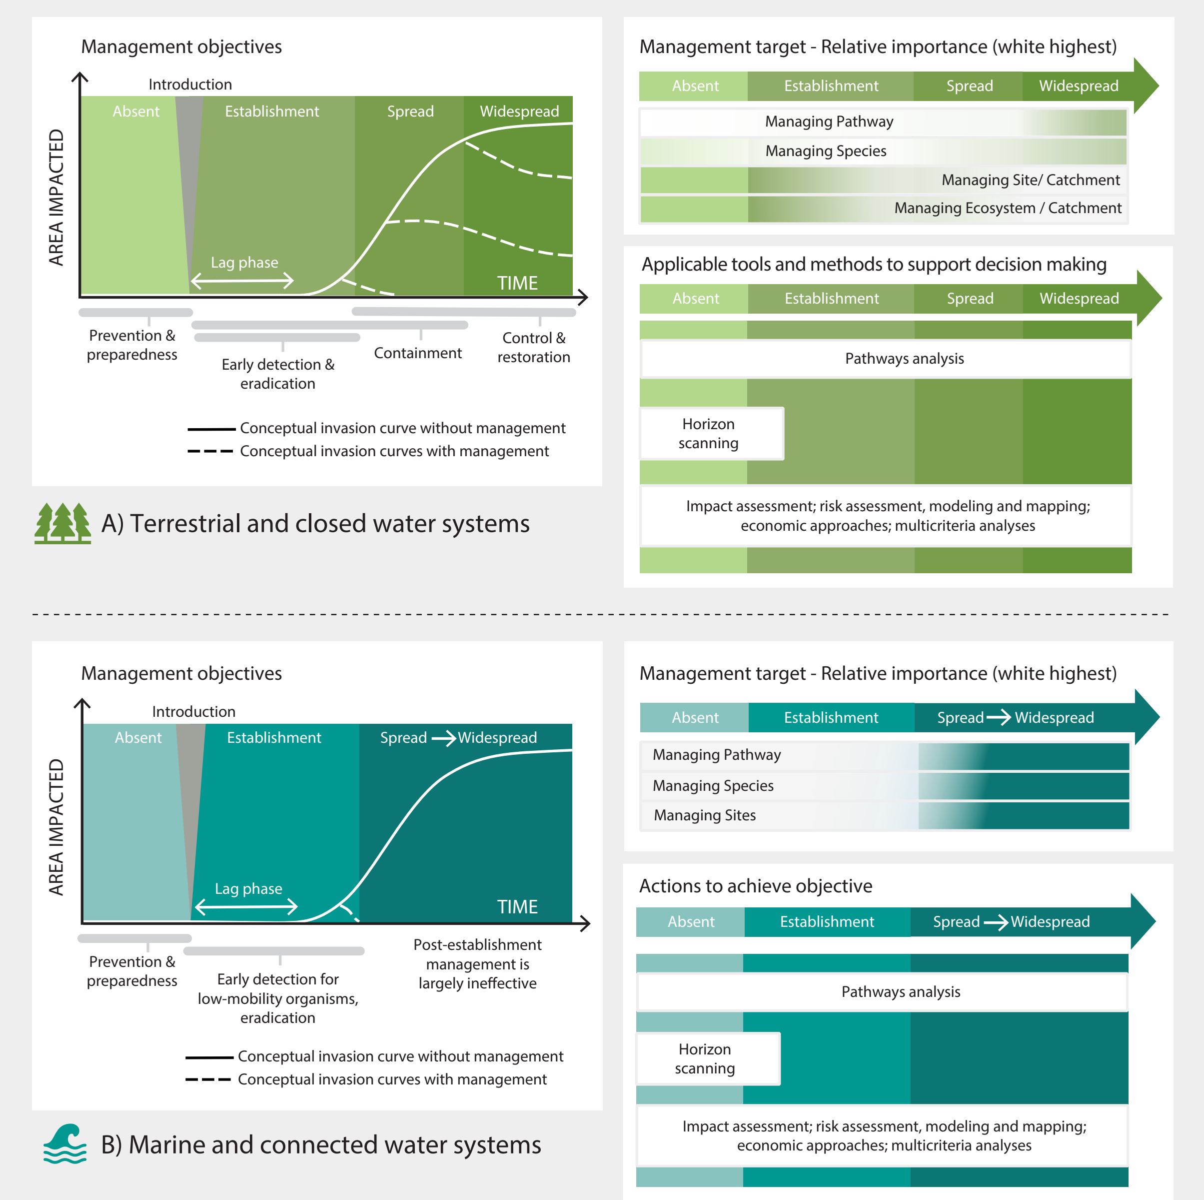

Figure 5 4 **Applicability of different tools and methods along the conceptual diagram of management along the invasion curve which provides a continuum for management interventions.**

This shows how tools and methods support decision-making in relation to the management targets for A) terrestrial and closed water systems (including coastal systems and salt marshes) and B) in marine and connected water systems. Gradients indicate the management target and the associated tools and methods necessary to support management decision-making, as well as their relative focus changing as invasion progresses. This figure is conceptual, and the curves do not represent actual population dynamics of invasive alien species.

The range of tools presented below is not intended to be exhaustive but to illustrate the diversity of tools available to meet different decision-making objectives.

a) Horizon scanning

Horizon scanning is the systematic examination of emerging and future potential threats and opportunities within a given context (Food Standard Agency, 2018) and has been used to prioritize potentially new alien species threats in jurisdictions supporting prevention and preparedness (Copp *et al.*, 2007; H. E. Roy *et al.*, 2014). Horizon scanning has been considered for discrete taxonomic groups, such as plants (Andreu & Vilà, 2010) or animals (Parrot *et al.*, 2009), and specific environments such as freshwater (Gallardo & Aldridge, 2013), at the national level (Lucy *et al.*, 2020; Peyton *et al.*, 2019) or for a wider region (H. E. Roy, Bacher, *et al.*, 2018) and globally (Dawson *et al.*, 2022). Horizon scanning usually follows a structured process based on some form of impact or risk assessment, often involving expert elicitation, to reduce and simplify a long list of potential invasive alien species to a prioritized subset. The inherent lack of evidence for horizon scanning, compared to risk assessment of established species, results in uncertainty but this can be documented through the process (H. E. Roy *et al.*, 2020). This has been applied in the United Kingdom (H. E. Roy *et al.*, 2014), where predictions subsequently supported future arrivals of eight out of the top ten species, including *Dreissena rostriformis bugensis* (quagga mussel; Aldridge *et al.*, 2014) and *Vespa velutina* (Asian hornet; Keeling *et al.*, 2017). The Centre for Agriculture and Bioscience International (CABI) has developed an online Horizon Scanning Tool quickly allowing identification and categorization of species that might enter one geographic area from another (CABI, 2021). Improvements to the process to quantify the likelihoods of economic, environmental and social impacts of species with no prior history of introduction outside their native range (**Glossary**) are now starting to be included (Peyton *et al.*, 2019, 2020).

b) Pathway risk analysis

Introduction pathway (**Glossary**) risk assessment, supported by standardized pathway categorization (IUCN, 2017), is needed to support pathway management decision-making, regardless of the geographical context or the many potential taxon–pathway combinations (A. P. Robinson *et al.*, 2017). The use of standard pathway categories allows to readily collate and compare introductions to prioritize pathways (Faulkner *et al.*, 2020; McGrannachan *et al.*, 2021; Saul *et al.*, 2017).

Analysis and prioritization of pathways supports regulatory approaches likely to also use and compare pathway data on commodities and vectors (McGeoch, Genovesi, *et al.*, 2016; **Chapter 3**, **section 3.1.1**; **Glossary**). Quantitative pathway risk analysis requires a set of key variables (Essl *et al.*, 2015; Hulme, 2009):

- Historical strength of the association between the species threat and the commodity, vector or pathway at the point of departure;
- Origin, volume and type of commodities or vector introduced for each pathway;
- Frequency of introduction;
- Species survivorship and population growth during transport/storage;
- Environmental suitability in the region of introduction for species establishment (e.g., climate matching);
- Time of year relevant for species establishment following introduction;
- Ease of species detection and identification;
- Effectiveness of management measures;
- Movement of the commodity or vector in the region following introduction;
- Likelihood of transfer from port of entry to a suitable habitat.

As such parameters are only known for very few alien species and only for specific pathways, pathway risk analysis (and management) remains challenging, requiring inferences based on statistical aggregates across species, but have been undertaken in different contexts (Leung *et al.*, 2014; Nunes *et al.*, 2015). Costello *et al.* (2007) developed an analytical model linking alien species introductions to trade volumes. In practice, pathway risk analyses often rely on information on the range of vectors and routes by which alien propagules are introduced, and their respective propagule loads (McGeoch, Genovesi, *et al.*, 2016). For example, a pathway risk analysis performed for the Antarctic identified high propagule loads linked with the importation of fresh produce (Hughes *et al.*, 2011), infrastructure development activities, and entrainment on the clothing of visiting tourists and scientists (Chown *et al.*, 2012). A similar pathway analysis for Barrow Island introductions provided details on the type of organism detected (classification and state; e.g., seed) attributed to specific pathways at and post-border (**Box 5.2** in **section 5.3.1.1**; Scott *et al.*, 2017).

The temporally dynamic nature of the introduction pathways for alien species makes pathway risk analysis particularly difficult to perform (Piel *et al.*, 2007), but is helped by increasing, harmonizing and consolidating pathway information across multiple sources and explicitly using border interception (Trouvé & Robinson, 2021) and post-border detection data (Essl *et al.*, 2015; Saul *et al.*, 2017) to strengthen pathway risk analyses. Postal mail is an explicit pathway risk for invasive alien species and understanding how mail inspections avoid biosecurity risks helps manage this pathway (S. Clarke *et al.*, 2018). Most attempts to model pathways have focused on describing the likelihood of species introduction and establishment (Bradie & Leung, 2015; Paini *et al.*, 2016) and rather few have attempted to address explicit strategies for the management of biological invasions(Hulme, 2009). García-Diaz *et al.* (2017) demonstrated that biosecurity activities implemented in Australia have decreased introduction probability of alien amphibian stowaways, in turn reducing the likelihood of a virus-infected animal entering the country. For pathway risk analysis the number of amphibian interceptions across six Australian States were more positively related to the amount of shipping than air transport. Risk assessment has also been recently applied to understand the pathways of introduction for marine invasive alien species incursions (K. R. Hayes *et al.*, 2019) and guidelines on pathways risk analysis application have been developed for the attention of sectors such as aquaculture (FAO, 2008).

c) Species impact assessment

Understanding and predicting the magnitude of actual or potential impacts of invasive alien species is key to deciding whether management actions are required (**Chapter 4**, **section 4.7**). Alien species impact assessments often differ in purpose, taxonomic scope, spatial scale and methods; often with bespoke ways of characterizing and assessing uncertainty. Some consider only environmental impacts (Van der Colff *et al.*, 2020; Vanderhoeven *et al.*, 2015) whereas others also include socio-economic impacts (Bacher *et al.*, 2018; **Chapter 4**, **Box 4.13**). Some protocols were designed to be taxonomically generic (Sandvik *et al.*, 2019) whereas others were developed for specific environments (Olenin *et al.*, 2007) or specific taxonomic groups. Some evaluation procedures rely on a panel of assessors to participate in the assessment (Kumschick, Bacher, *et al.*, 2020; Volery *et al.*, 2020), others are based on assessments performed by single experts or do not clarify this (Vanderhoeven *et al.*, 2017). Impact assessment systems have also been standardized, such as the Environmental Impact Classification for Alien Taxa (EICAT; IUCN, 2020b) and the Socio-Economic Impact Classification of Alien Taxa (SEICAT; Bacher *et al.*, 2018; **Chapter 4**). EICAT has been developed by the International Union for Conservation of Nature (IUCN; IUCN, 2020b; Van der Colff *et al.*, 2020). Unlike risk assessment, impact assessment does not consider the likelihood of establishment or spread following introduction.

d) Risk analysis

Risk analysis is a process of three complementary components: 1) risk assessment, supported by risk modelling and mapping; 2) risk management and 3) risk communication (EFSA Scientific Committee & Scientific Opinion on Risk Assessment Terminology, 2012; Geering & Lubroth, 2002; IPPC, 2019; Lanzoni *et al.*, 2019). These components are often undertaken independently and are described hereafter. Risk communication is often not explicit or even absent from decision-making processes.

As expressed by Liu *et al.* (2011), "the separation of risk assessment and management disrupts essential connections between the social values at stake in risk management and the scientific research involved in gauging the likely impacts of management actions, leaving the (…) decisions to be made in the wake of political pressures that reflect competing views on the proper trade-offs among competing values."

In order to improve the reliability of expert-based risk analysis, Vanderhoeven *et al.* (2017) provided the following eight recommendations:

1. Clearly define the scope and objective of any risk analysis;
2. Select an appropriate risk analysis/assessment approach;
3. Gather all baseline data and available information;
4. Identify missing data and information;
5. Define clear and transparent quality control procedures such as a peer-reviewing or consensus building;
6. Explicitly address feasibility of management;
7. Explicitly consider uncertainty in the analysis (assess level of confidence, quantify level of agreement among experts and highlight context-dependent variability); and
8. Explicitly consider uncertainty in risk communication.

Risk analysis requires mechanisms for acquiring expert information and opinion through an unbiased expert elicitation process (Burgman, 2005).

Detailed risk analyses are based on probability analyses and are complicated quantitative expert elicitation processes based on Bayesian belief networks and probability distributions. Although they have been applied in some invasion contexts such as the proposed release of genetically modified organisms (K. R. Hayes, Hosack, Dana, *et al.*, 2018), they are generally too costly for the assessment of most invasive alien species risks.

e) Risk assessment

The notion of "risk" is the chance that a particular hazardous event may actually cause harm, and is regarded as a product of three factors: *exposure x likelihood x consequence* (Kinney & Wiruth, 1976; A. P. Robinson *et al.*, 2017). For invasive alien species, *exposure* results from the successive introductions, establishments and spread of an alien organism, whereas *likelihood* and *consequence* underpin the impact assessment referred to in section c (D'hondt *et al.*, 2015). *Likelihood* is the probability that an invasive alien species impact affects nature, nature's contributions to people and good quality of life; and *consequence* is the magnitude of impact if it occurs.

Most commonly risk assessment is a relatively straightforward semi-quantitative approach based on a scoring system where different components of risk are assessed and scored, and a total score is obtained in some manner to define the overall level of risk. This was initially developed for assessing import risks of alien plants ("Weed Risk Assessment"; Bomford & Hart, 1999; Pheloung *et al.*, 1999). This approach is relatively quick and incurs only low cost per species and therefore is most favored by policy makers (e.g., Bomford & Hart, 1999; Pheloung *et al.*, 1999) and such approaches have been adopted as international standards (Devorshak, 2012; IPPC, 2019). Risk assessment tools have been established for particular types of invasive alien species in different parts of the world (Essl *et al.*, 2011; Groves *et al.*, 2001), including Australia (Pheloung *et al.*, 1999; Scott & Panetta, 1993), North America (Hiebert & Stubbendieck, 1993; Kolar & Lodge, 2002; Reichard & Hamilton, 1997), South Africa (Tucker & Richardson, 1995), Brazil (Ziller *et al.*, 2019) and Japan (Nishida *et al.*, 2009). In Europe a diversity of risk assessment systems have been developed (Baker *et al.*, 2008; Copp *et al.*, 2005; D'hondt *et al.*, 2015; Essl *et al.*, 2011; Gollasch & Nehring, 2006), including for specific use in sectorial activities such as aquaculture (Copp *et al.*, 2016). Each system has its own characteristics and decision-making contexts including taxonomic focus, geographical scope, type of environment, type of impact considered, scoring of impact, uncertainty consideration and expert contribution to the assessment (H. E. Roy, Rabitsch, *et al.*, 2018). Nonetheless, all systems follow the three factor standard premise and synthesize information based on formalized criteria to determine the overall risk. While risk assessment approaches based on scoring systems are relatively quick and easy, their effectiveness is rarely evaluated and there remain many shortcomings (Hulme, 2012).

Some initiatives have established repositories or databases giving access to available species risk assessments existing for a given territory, like the Canadian Invasive Species Center[2] or region, like the European Commission (CIRCABC, 2021). A comprehensive review of more than 1,000 risk assessment results is available for species that are invasive in Brazil from the National Invasive Species Database.[3] The database is open access and available in English, Portuguese and Spanish. Such an initiative does not currently exist on a global scale.

f) Risk modelling and mapping

Risk assessments are often supported by projection models to help evaluate species pathways, entry, establishment, spread and/or impact within an area of interest (Beaumont *et al.*, 2009, 2014; Elith, 2017; A. P. Robinson *et al.*, 2017; Stevenson, 2004; Venette *et al.*, 2010). Spatially modelling potential alien species distribution is a common practice for species either not present or of limited distribution (**Chapter 1**, **section 1.6.7.3**). Simple models generally based on species distribution data and climate matching software are often crude and can exaggerate the risks. Considering additional environmental data is one way to fine tune spread and distribution. Such models can also project likely future distributions under climate change (Kriticos *et al.*, 2005; Venette *et al.*, 2010). More complex process-based models can incorporate physiological limits of the target invasive alien species to better define habitat suitability (Kriticos *et al.*, 2020). Similar approaches have been applied for predicting and mapping habitat suitability and distribution of invasive alien vertebrate species, invasive alien arthropods, invasive alien plant pests and pathogens and biological control agents released to manage invasive alien plants (Haye *et al.*, 2018; Kriticos *et al.*, 2009, 2013). The maps generated can be used to guide decisions regarding the implementation of geographically targeted monitoring which allows early warning and rapid response (T. P. Robinson *et al.*, 2010). Creating accurate risk maps relies on available spatial data of species distribution, areas of interest, and climate, species physiological tolerances and environmental data layers. This is nowadays facilitated by geographic information systems (GIS) and facilities such as Global Biodiversity Information Facility (GBIF), having the capacity to process and give access to spatial data sets worldwide (McGeoch, Groom, *et al.*, 2016). Models are selected, calibrated, and verified to satisfy underlying assumptions and validated where possible against independent data. Results are depicted on maps and interpreted relative to uncertainty in the models (Yemshanov *et al.*, 2015).

Although these methods are not unchallenged, and despite a continuing debate on the accuracy of the different modelling algorithms, on the relevance and reliability of environmental data sources and on transferability of models (Capinha *et al.*, 2018; Datta *et al.*, 2020; Liu *et al.*, 2020), methodologies are still improving (Chapman *et al.*, 2019; Mainali *et al.*, 2015). Maps are commonly produced to

2. https://www.invasivespeciescentre.ca/invasive-species/what-is-at-risk/invasive-species-risk-assessment/

3. http://bd.institutohorus.org.br

illustrate potential risks from invasive alien species under different climate change scenarios (Venette, 2015; Venette *et al.*, 2010; **sections 5.6.1.3**, **5.6.3.2**), and validated in their successful prediction of invasive alien species establishment and spread (Barbet-Massin *et al.*, 2018). For example, the Tool for Assessing Pest and Pathogen Aerial Spread (TAPPAS) is an online platform for modelling the dispersal and impact of pests and diseases (Durr *et al.*, 2017). It can be used to assess the likelihood that a given pest or pathogen will be wind transported from a location where it is established, using global air current data in support of ongoing eradication or control programmes. Non-expert users can run climate-based scenarios for the spread of a given pest or pathogen in near-real-time, with downloadable data and visualization of results as risk-maps. Baysian regression models are also being used to create frameworks that can anticipate the likelihood of illegal wildlife trade of particular pet species of global popularity through wildlife smuggling pathways (Stringham *et al.*, 2021).

g) Risk management

Risk management is an extension of risk assessment to help prioritize species for management. It evaluates the implementation (feasibility and likelihood of success) of management options to reduce the known risks from invasive alien species (FAO, 1995; A. P. Robinson *et al.*, 2017). Very few risk management schemes specifically dedicated to invasive alien species exist. However, elaborate taxonomic or sector specific schemes are available for invasive alien plants (Auld & Johnson, 2014; Downey *et al.*, 2010), plant health (EFSA Panel on Plant Health (PLH), 2010) and the release of alien organisms as biological control agents (A. W. Sheppard *et al.*, 2003; van Klinken *et al.*, 2016). Governments are adopting risk management systems for some groups of invasive alien species to assist decision-making (e.g., in Australia; Department of Primary Industries, New South Wales, 2017; IUCN, 2020a). The “Non-Native Risk management scheme” is a protocol developed in the United Kingdom to assess a wide range of taxa from different environments and compare them directly according to the overall feasibility of eradication (Booy *et al.*, 2017). The management objective is first defined based on semi-quantitative response and associated confidence scores to evaluate key criteria: effectiveness, practicality, cost, impact of management, acceptability, window of opportunity and likelihood of re-invasion. Scores are obtained using expert judgement, based on available evidence, supported by consensus-building methods. This scheme has been used at different geographical scales (Booy *et al.*, 2020; Osunkoya *et al.*, 2019) and adapted in Belgium to evaluate alternative management strategies to eradication, in particular “spread limitation” (containment) and to support national management objectives (Adriaens *et al.*, 2019). Risk management systems and processes are also used to manage importation pathways to minimize the risk of alien species importations (van Klinken *et al.*, 2020).

h) Risk communication

Risk communication is the interactive process of exchange of information and opinions among individuals, groups and institutions concerning a risk or potential risk (A. P. Robinson *et al.*, 2017; Lundgren & McMakin, 2018). Communicating risks is often challenging given inherent levels of uncertainty. Ignoring uncertainty results in over-confident decisions or exaggerating uncertainty can lead to inaction in the face of mounting impacts (S. Liu *et al.*, 2011; McGeoch *et al.*, 2012). High stakeholder engagement throughout the risk analysis process, if transparent, promotes trust and confidence in decision makers (Estévez *et al.*, 2015; Groom, Strubbe, *et al.*, 2019; van der Bles, 2019; Vanderhoeven *et al.*, 2017; e.g., the TrIAScycle, **Figure 5.5**).

i) Cost-benefit, cost-effectiveness analyses and other economic approaches

Economic analysis for biological invasions generally consists of a) the actual or potential economic damages caused and b) costs of one or multiple management options optimized to minimize the combined impact and management costs (Hoagland & Jin, 2006; **Chapter 4**, **Box 4.12**). Cost-benefit analysis (**Glossary**) has been a standard approach for over 100 years and is widely applied to support decision-making for management of biological invasions (Courtois *et al.*, 2018; Naidoo & Ricketts, 2006; A. P. Robinson *et al.*, 2017) to generate a benefit-cost ratio (Naidoo & Ricketts, 2006). Socioecological systems generate inherent challenges and uncertainties associated with these approaches. When economic data are poor or lacking (Donlan & Wilcox, 2007) inclusion of even broad cost and benefit estimates have proven valuable for deciding conservation actions (Boyd *et al.*, 2015). Cost-benefit analysis can also inform the appropriate choice of biosecurity interventions across pathway, species-based (**Chapter 4**, **section 4.2**), or site-based, management responses. Portfolio theory-based decision-making or return on investment analysis (Boyd *et al.*, 2015) is another approach seeking the strategy with the best return on investment while taking into account uncertainties (Akter *et al.*, 2015; Finnoff *et al.*, 2007). Economic analysis can also support and supplement risk management where the costs of management are a component of this (Fernandes *et al.*, 2016). Economic analysis is less relevant for understanding impacts to environmental assets as the costs are hard to estimate (i.e., are intangible costs). Studies that attempt to put a value on ecosystem services are one way to address this, but generally in these contexts other approaches are used which are collectively termed cost-effectiveness analysis (**Glossary**). This aims to identify the most cost-effective management option to achieve a particular desirable

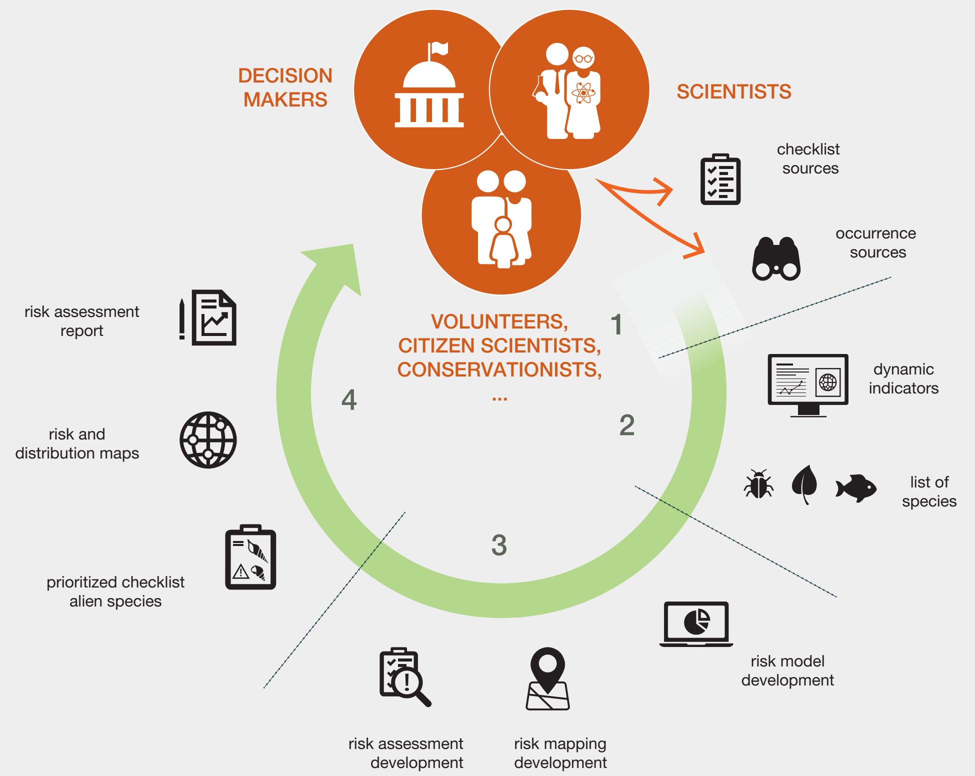

Figure 5 5 **The TrIAScycle – an example of knowledge flow allowing for transparency and promoting trust and confidence between stakeholders and decision makers.**

In this workflow, data and knowledge generated by all stakeholders (visualized in the circles at the top, i.e., scientists, public authorities, field managers and citizens involved in citizen science initiatives) are used to build a series of databases, indicators, risk assessments and communication tools to inform these stakeholders and take informed action. Source: Groom, Strubbe, *et al.* (2019), https://doi.org/10.5334/cstp.238, under license CC BY 4.0.

outcome (Drechsler *et al.*, 2016; Laycock *et al.*, 2009). Cost-effectiveness analysis generally requires unbiased expert-elicitation using a recognized transparent and documentable process. All such analyses can include economic, biodiversity, environmental, social and good quality of life considerations (Bithas *et al.*, 2018; IUCN, 2018; Rai & Scarborough, 2013). These can include tangible costs, such as costs of removing an invasive alien species from a particular location, or intangible costs or impacts such as lost biodiversity. Intangible costs can be estimated using approximations and mathematical simulations (Leung Brian *et al.*, 2002), or through monetarization approaches such as hedonic pricing (Horsch & Lewis, 2009), the travel-cost approach (Du Preez *et al.*, 2012) or contingent valuation where the stakeholder's willingness to pay (**Glossary**) for the invasive alien species impacts such as a lost ecosystem service is used to balance the benefits against the management costs (B. Provencher *et al.*, 2012). The IPBES Methodological Assessment of the Diverse Values and Valuation of Nature (IPBES, 2022a) presents diverse valuation methodologies and approaches that acknowledge, bridge and integrate the diverse values and valuation methodologies for policy and decision-making support.

j) Multi-criteria analyses

Decision-making for management of biological invasions frequently involves trade-offs between complex and conflicting environmental, social and economic objectives, potentially resulting in positive or negative consequences for different stakeholder groups (R. Gregory *et al.*, 2006).

Multi-criteria analysis evaluates multiple objectives against multiple criteria that represent competing values (Lahdelma *et al.*, 2000) and is sometimes coupled with species distribution modelling (T. P. Robinson *et al.*, 2010; **Chapter 1**, **section 1.6.7.3**). Expert elicitation is also used when available information is incomplete or imprecise. A multi-criteria analysis approach is often used to support or conducted in unison with risk management, impact or risk assessments and has proven useful for evaluating alien species threats and impacts and deciding on management options (D. Cook & Proctor, 2007; G. G. Forsyth *et al.*, 2012; Monterroso *et al.*, 2011). A simple form of multi-criteria analysis is risk-cost-benefit analysis applied to the selection of biocontrol agents proposed for the management of invasive alien plants, where all potential agent risks and benefits are identified followed by exposure analysis (likelihood of each risk or benefit occurring and the likely magnitude of the impact should it occur; Sheppard *et al.*, 2003). Deliberative multi-criteria analysis combined with participatory stakeholder engagement (Proctor & Drechsler, 2006) and facilitates consensus building and social learning (S. Liu *et al.*, 2010, 2011) and can take account of trade-offs. For example, in a case study in Western Australia, a jury was asked to prioritize a set of plant pests and diseases with different agricultural, social or environmental impacts (D. Cook & Proctor, 2007) when provided with relevant biological, ecological and economic knowledge based on perceived significance to the State's biosecurity system. The recommendations from the evaluation contrasted with the allocation of resources to the management of these species at the time.

k) Documenting successes and failures in biological invasions decision-making

Reviews of reports of successful or failed management actions, approaches or programmes available in peer-reviewed scientific studies, databases, books and published and unpublished reports across all taxonomic groups, environments or geographical areas can be used to inform future decisions for the management of biological invasions. Sutherland (2022) has promoted the value of this approach for biodiversity conservation more generally. Such information sources can inform and potentially inspire managers confronted with the same invasive alien species or a similar environmental context. Such repositories are, however, rarely developed, compiled or presented to support decision-making (Matzek *et al.*, 2014; McNie, 2007). Duplicating a successful approach often seems to be an easy decision but each context will have specific differences and challenges, so compiling many similar case studies can assist understanding when a management decision is more likely to be successful across multiple contexts.

l) Evidence synthesis

Evidence synthesis compiles individual studies within the context of global knowledge on a specific issue. It is often the basis of both evidence-based policy and practice (Dicks *et al.*, 2014). The resulting syntheses can provide rigorous knowledge for translating research into decision-support. Evidence synthesis requires an explicit and transparent question-based methodology targeting the identification, selection, appraisal and analysis of evidence from all available studies. The advantage of this approach is that all studies in a given context are assessed collectively. An example is the *Conservation Evidence* initiative, which is a collated free authoritative information resource designed to support decision-making to maintain and restore global biodiversity (Sutherland *et al.*, 2019). In 2017, the synopsis of this initiative published in print and as an open access online resource is a directory of 161 evidence-based interventions for managing freshwater taxa which were considered of high risk to Great Britain's ecosystems or economy (Aldridge *et al.*, 2015).[4] Of the 161 actions identified in this particular case, 62 per cent were not tested in any study, 20 per cent were considered "likely beneficial", 8 per cent were "unlikely to be beneficial", 5 per cent were "beneficial", 4 per cent showed "unknown effectiveness", and four studies reported "trade-off between benefit and harms" for one single action. While evidence synthesis has not yet been applied explicitly globally, it has been applied in some contexts and it is widely recognized that this approach could provide significant benefit for management of biological invasions (P. A. Martin *et al.*, 2020).

m) Best management practice approach

The best management practice approach brings together techniques and methods that have proven most effective. Such information is generally compiled through a context-specific evidence synthesis approach into a guide for addressing the management of an individual invasive alien species or a set of species generally in a particular ecological or biogeographic context. For example, the Prefectura Naval Argentina has a best practice manual for cleaning and maintaining maritime infrastructure to avoid dispersal and new introductions of marine invasive alien species (Argentine Naval Prefecture, 2021). As with case studies and evidence synthesis, similar management efforts are compared and analysed from which best practice collectively emerges. Guidelines exist for developing best practice for the management of biological invasions, including preventive strategies, eradication, containment and control (Adriaens *et al.*, 2018). Best practice management guides are being developed around the world and are generally designed for use within particular jurisdictions, based on local regulatory contexts (e.g., for use of chemicals) for management. Best practice guides can also target specific audiences (government agencies, hunters, anglers, reserve managers, or the general public). For example, the Invasive Species Council of Ontario (Canada) has developed 15 best management practice guides for invasive alien plants that also provide a historical background and taxonomic characteristics of each species (Ontario Invasive Plant Council, 2021). The series promotes the use of integrated pest management (**Glossary**) to achieve effective control and is updated on a regular basis.

5.2.2.2 How to prioritize management actions?

Management decision-making usually requires some form of prioritization. Management prioritization, whether it be in the context of pathways, species-based and site- or ecosystem-based approaches, often combines approaches, tools and methodologies presented in the previous section **(Figure 5.6)**. Species prioritization activities are the most common (Heikkilä, 2011) including being used early on in the analytical process to select species for risk assessment to optimize limited resources (Brunel *et al.*, 2010). Holistic, transparent and easy to use prioritization frameworks exist to help allocate limited resources to management actions which are expected to provide the greatest environmental and societal benefits (Bottrill *et al.*, 2008; K. A. Wilson *et al.*, 2007). Such frameworks can ensure prioritization replicable in different geographical or temporal contexts (Heikkilä, 2011). Prioritization ensures efficient resource allocation, increased transparency in collective decision-making (Kumschick *et al.*, 2012) and quantitative support to decision-making when there are conflicting objectives or measurable outcomes (Heikkilä, 2011). Prioritization for management of biological invasions is generally undertaken by public organizations, where scientific evidence may only be part of the decision-making process. Lobbying, public opinion and politics also influence prioritized decision-making around ranking invasive alien species for management. Aichi Target 9 of the Strategic Plan for Biodiversity 2011-2020 included prioritization of pathways and invasive alien species (UNEP, 2011), however McGeoch, Genovesi, *et al.* (2016) argued that any comprehensive and strategic approach to priority setting should include prioritization of pathways, species and sites. Prioritization can support prevention and preparedness along the invasion curve by ranking the high-risk introduction pathways for particular invasive alien species through to determining which sites are at greatest risk of invasion to help optimize surveillance. Prioritization can also help site selection for containment and management of established widespread invasive alien species.

Spatially explicit prioritization for the establishment of management strategies has also been proposed for example by Januchowski-Hartley *et al.* (2011) aiming at minimizing costs and the likelihood of reinvasion using the invasive tropical macrophyte *Hymenachne amplexicaulis* (hymenachne) affecting freshwater water quality, biodiversity and fisheries as a case study.

Defining overarching management objectives is important before undertaking prioritization-based invasive alien species

Figure 5 6 **Pathways, species and sites: three foci for a comprehensive approach to prioritization of management actions in biological invasions.**

This approach follows McGeoch *et al.* (2016). Combining these foci allows to 1. prioritize sites exposed to species introduced through priority pathways; 2. prioritize high-risk species introduced through priority pathways; 3. prioritize sites exposed to a set of high-risk species; 4. prioritize sites exposed to a set of high-risk species introduced through priority pathways.

management decision-making (**Box 5.10** in **section 5.3.3**). Below are some case studies.

a) Pathway prioritization, a case study from Great Britain (United Kingdom)

A method for prioritizing pathways was developed in Great Britain using established species that arrived *via* different pathways (following the classification of the Convention on Biological Diversity (CBD; CBD, 2014) and their impacts (Booy, 2019; DEFRA, 2019)). An existing dataset of the negative impacts on biodiversity of all established alien species was rated on a five-point semi- quantitative logarithmic scale (minimal = 0.0001, massive = 1) using criteria adapted from the EICAT (**Chapter 4**; Volery *et al.*, 2020b). The sum of impact scores for species introduced by

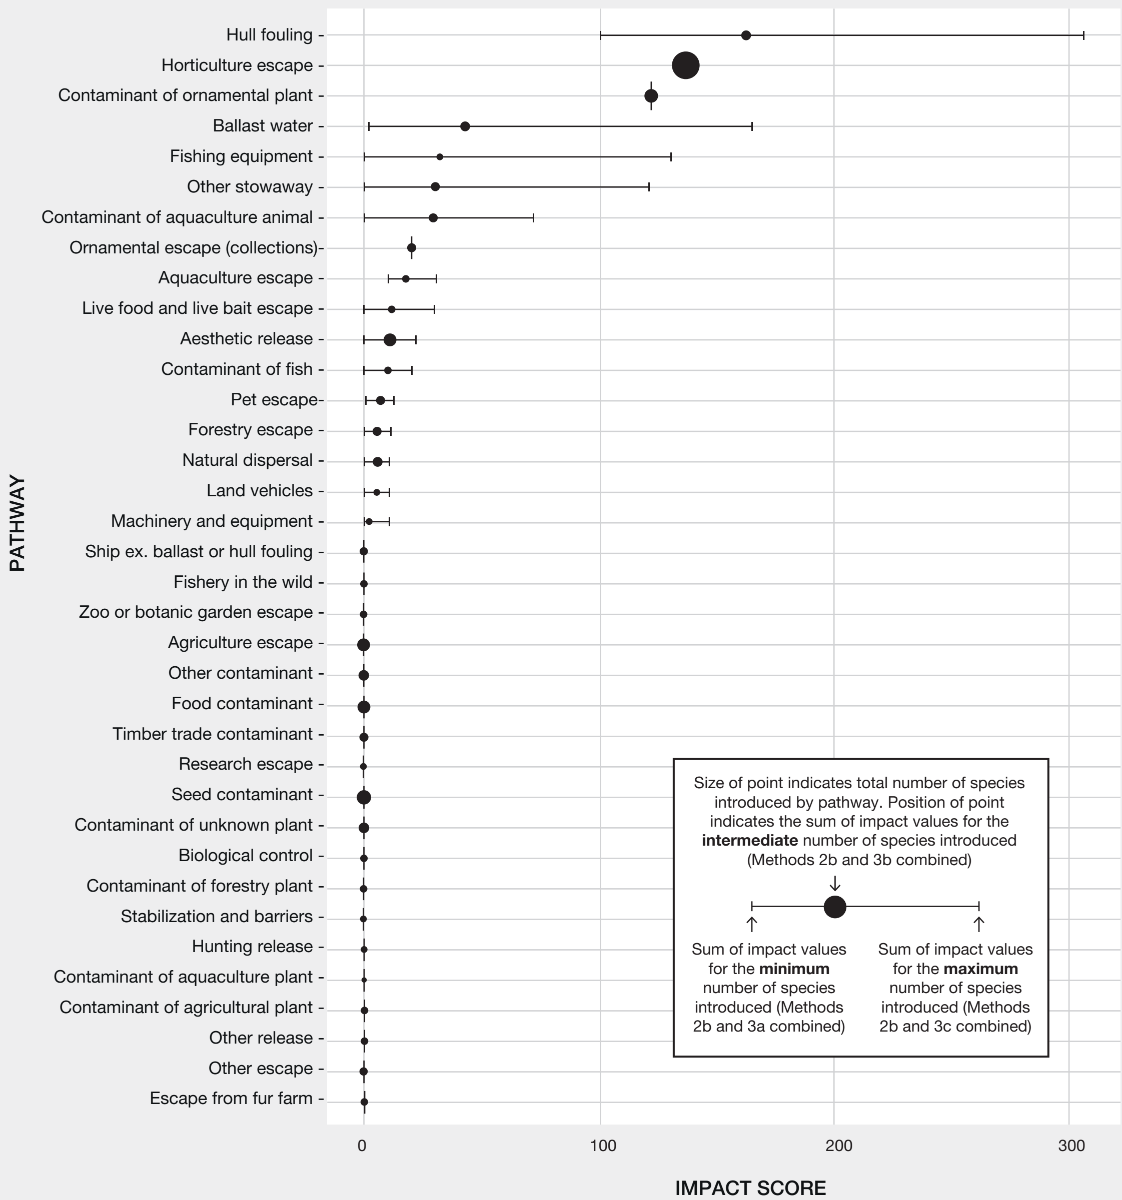

Figure 5 7 **Example of a pathway prioritization with a case study from Great Britain (United Kingdom).**

Pathway ranks using weighted impact scores for all established alien species in Great Britain. Point size indicates total number of species introduced since 1950, while position of points with error bars indicates the sum of impact values for the minimum, intermediate and maximum number of species introduced by each pathway since 1950. Source: Booy (2019), https://theses.ncl.ac.uk/jspui/handle/10443/4926, under license CC BY 4.0.

each pathway provided a pathway prioritization **(Figure 5.7)**. This was considered a more rigorous prioritization process than just using numbers of alien species per pathway, because pathway management is about reducing the risk of future arrivals and impacts.

b) Species prioritization

Caceres-Escobar *et al.* (2019) assessed the cost-effectiveness of six management scenarios for *Vulpes vulpes* (red fox) and *Felis catus* (cat) that were co-developed with local land managers and community groups on Minjerribah-North Stradbroke Island in Australia. Community prioritization of invasive alien plants was also undertaken in Chitwan-Annapurna Landscape of central Nepal using community memory of their arrival often due to a lack of knowledge of their impact status (Shrestha *et al.*, 2019).

Prioritization through horizon scanning is a prerequisite for deciding which species to consider for risk analyses. The European Union used horizon scanning to prioritize a list of alien species not yet present in Europe to inform selection of alien species for risk assessment and potentially future listing (H. E. Roy, Bacher, *et al.*, 2018). The list, published in 2018 partly (coupled with risk assessment) informed the list of invasive alien species of European Concern that underpins the Regulation on invasive alien species (European Union, 2014). Experts prioritized species based on likelihoods of i) arrival, ii) establishment, iii) spread and iv) magnitude of the potential negative impact on biodiversity and ecosystems over the next decade, within species thematic groups. From the 329 species initially considered, a final prioritized list was made of 66 species including eight species considered very high risk, forty species as high risk and 18 species as medium risk. A similar process was

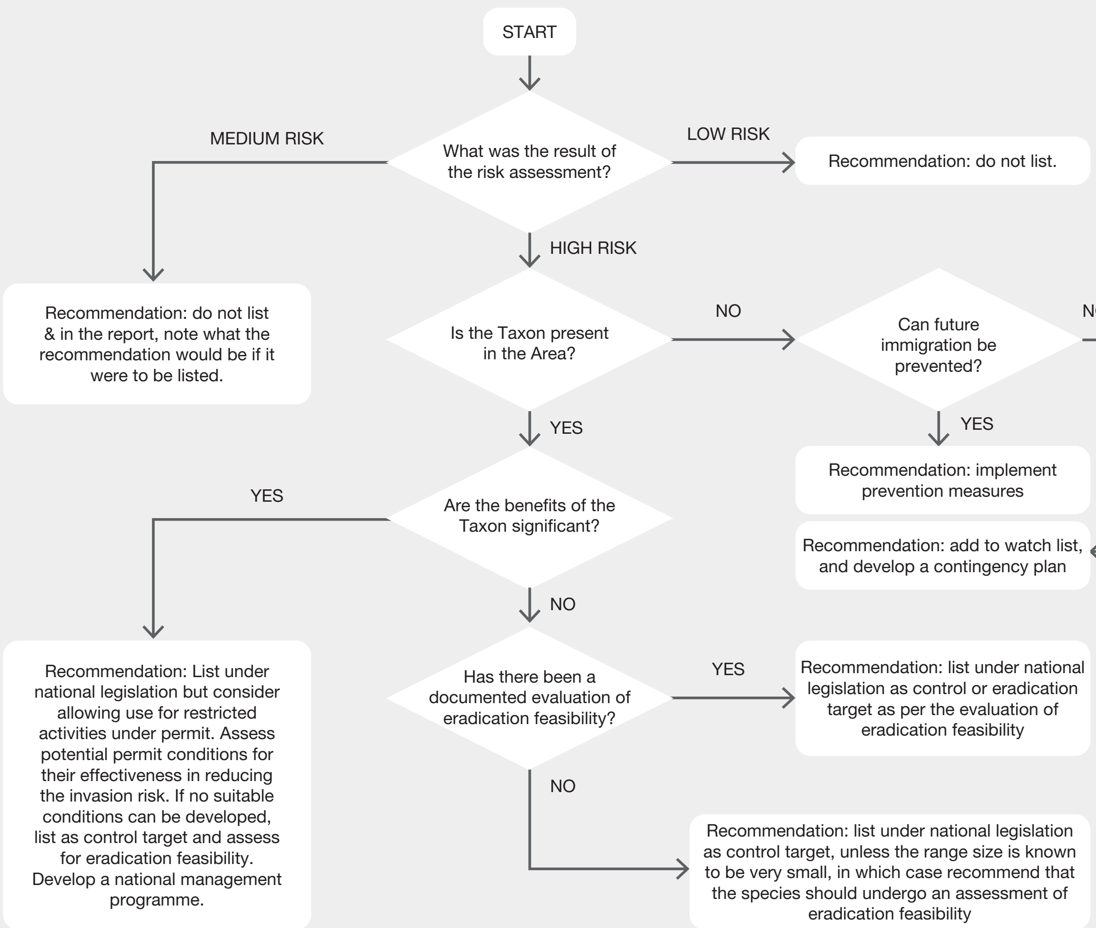

Figure 5 8 **Risk Analysis for Alien Taxa (RAAT) framework developed in South Africa as a standardized and transparent approach to prioritizing and regulating alien species based on evidence.**

The figure shows the process leading to the development of recommendations for the listing of alien taxa. Adapted from Kumschick, Foxcroft, *et al.* (2020), https://doi.org/10.1007/978-3-030-32394-3_20, under license CC BY 4.0.

undertaken in Australia where the task was to generate a National Priority List of Exotic Environmental Pests, Weeds and Diseases from which the top five to six species (from 168 initially identified) were classed as posing the greatest threat to the environment in each of eight biological groups including marine, freshwater and terrestrial ecosystems (ABARES, 2021).

Risk assessment: The Risk Analysis for Alien Taxa (RAAT) framework was developed in South Africa as a standardized and transparent approach to prioritizing and regulating alien species based on evidence (Kumschick, Foxcroft, *et al.*, 2020; Kumschick, Wilson, *et al.*, 2020; **Figure 5.8**). The aim was to increase capacity through expert and stakeholder workshops to prioritize species for regulation and management plan development. The framework has since been used retrospectively on species already regulated to confirm whether these should continue to be listed. Of 650 regulated species, 62 have been assessed, several of these now have a recommendation to change their regulatory status as they are not present in the country (delist) or can no longer be eradicated (move to widespread list). The regulators are now processing these recommendations *via* a committee and stakeholder consultation and are considering giving the framework legal force.

Risk management: On Viti Levu in Fiji, Daigneault and Brown (2013) undertook cost-benefit analyses of the management of five established species: *Spathodea campanulata* (African tulip tree), *Herpestes javanicus auropunctatus* (small Indian mongoose), *Papuana huebneri* (taro beetle), *Pycnonotus cafer* (red-vented bulbul) and *Decalobanthus peltatus* (Merremia). These analyses used survey data, impacts due to the species and management options. The cost-benefit analysis showed that benefits from management far outweigh the costs supporting the need to better manage invasive alien species in the Pacific, but that the most cost-effective management option varied between species.

c) Site prioritization

Prioritization of sites for invasive alien species management is built on the individual contexts of national environmental legislations (e.g., threatened species or ecosystem recovery and/or creating protected area networks), local knowledge, resources and management capacity and the cost-effectiveness of available management options. Managing invasive alien species in protected areas will also be prioritized based on the degree to which key ecosystems are invaded or at threat from invasion (Foxcroft, Pyšek, *et al.*, 2013; Giakoumi, Pey, *et al.*, 2019; X. Liu *et al.*, 2020). A combined site and species prioritization framework was developed and implemented in the Brazilian tropical and subtropical dry and humid forest in the Itatiaia National Park (Ziller *et al.*, 2020) assessing the level of biological invasion across four locations by 50 alien species. High priority was given to sites with high risk or in the early stages of biological invasion and low invasive alien species frequency. Krug *et al.* (2009) developed a prioritization scheme for the management of invasive alien plants in the Cape Floristic Region (South Africa). The identification of priority areas was based on weighted decision criteria, but the influence of the weighting on the outputs requires evaluation.

d) Management prioritization for species

Prioritization of management options for species rather than prioritizing species for management is also commonly undertaken for single or multiple species. A participatory decision-support software "Zonation" developed for this purpose on Reunion Island uses available spatial data on native species (**Glossary**) and invaded habitats to define conservation targets and provide projections at management-relevant scale, which helps to prioritize invasive alien plant management actions (Fenouillas *et al.*, 2020). Management priorities are defined based on three criteria: area accessibility; site history and likely intervention effectiveness.

Helmstedt *et al.* (2016) prioritized all eradication strategy options for invasive alien mammals across all Australian islands taking into account the complex decisions faced by managers. The optimal strategy was to eradicate a subset of invasive alien mammals, intentionally leaving some where either eradication costs were too high or removal might lead to complex ecological responses (e.g., trophic cascades). This eradication strategy was the most cost-effective generating 27 per cent greater ecological benefit across all islands compared to eradicating all invasive alien species on an island.

For marine invasive alien species where eradication is very unlikely, managing abundance to below ecologically defined impact thresholds is a better strategy (Usseglio *et al.*, 2017). Giakoumi *et al.* (2019) used experts to prioritize 11 management actions for 12 invasive alien species with different distributions and dispersal capacity. Each action was assessed using five criteria (effectiveness, feasibility, acceptability, impacts on native communities and cost) combined into an "applicability" metric. Rapid removal early in the biological invasion process and seeking commercial value from remaining species were ranked the highest management actions, while application of biological control ranked the lowest.

5.2.2.3 Dealing with uncertainty in decision-making

Decision-making, including for management of biological invasions, is weakened by multiple forms of uncertainty, bias and knowledge gaps (Moon *et al.*, 2017). Key gaps include future threats, likely-establishment patterns and the interactions with climate change (Leung *et al.*, 2012). Regan *et al.* (2002) developed a typology of uncertainty in conservation decision-making taking these gaps into account. This typology includes epistemic uncertainty associated with the knowledge of the system, and the linguistic uncertainty associated with communication between culturally different stakeholders. It has been used to evaluate the degree of uncertainty associated with prioritization approaches by McGeoch *et al.* (2012) **(Table 5.2)**. The majority of uncertainty sources are epistemic, and are caused by quantitative inaccuracies and knowledge gaps.

Decision-support tools generally explicitly assess the uncertainties around assumptions or knowledge (González-Moreno *et al.*, 2019; Leung *et al.*, 2012; Probert *et al.*, 2020), but not always (Caton *et al.*, 2018). Understanding bias and documenting and explaining uncertainty to decision makers and other stakeholders are critical in risk communication (Lundgren & McMakin, 2018; Probert *et al.*, 2022; WHO, 2013) and management decision-making (D. A. Clarke *et al.*, 2021; S. Liu *et al.*, 2011; Vanderhoeven *et al.*, 2017; A. I. Ward *et al.*, 2020). This allows a degree of confidence to be associated with decisions, increasing their legitimacy and providing transparency for managers (Estévez *et al.*, 2015; van der Bles, 2019).

5.2.2.4 Quantitative decision- support tools for implementing management options

Many quantitative decision-support models and platforms have been developed to support management implementation. Some generic modelling platforms have already been discussed (e.g., Tools for assessing pest and pathogen aerial spread (TAPPAS); Durr *et al.*, 2017; **section 5.2.2.1**). Their utility is broad and, when validated, can be cost-effective (M. E. Wilson & Coulson, 2016). Such platforms can be tailored to different manager perceptions or risk, types of invasive alien species and policy options (Lodge *et al.*, 2016; Perrings, 2016) and other management types such as pathway management (Leung *et al.*, 2014).

Such modelling platforms can help answering a wide range of risk-based management-related questions important to all stakeholder communities involved in a response to control an invasive alien species. Dynamic modelling platforms can be deployed during a management response to influence real-time decision-making. These tools have been applied, for example, for the eradication of foot-and-mouth disease (Garner & Beckett, 2005), pandemic influenza (Beckett, 2008), *Vulpes vulpes* (red fox), *Sus scrofa* (feral pig), *Felis catus* (cat; Ramsey *et al.*, 2011), *Trachemys scripta*

Table 5.2 **Dealing with uncertainty in decision-making for management of biological invasions.**

Types of knowledge (epistemic) and linguistic uncertainty, and errors associated with invasive alien species listing during the decision-making process that can be considered and documented when relevant. Adapted from McGeoch *et al.* (2012).

Type of uncertainty	Errors associated with alien species listing	
Epistemic uncertainty	Measurement error	Human error
		Incomplete information searches
	Systematic error	Species identification incorrect as a result of taxonomic uncertainty
		Survey information on presence, extent and population dynamics
		Resolution and scaling of invasive alien species range
		Data and knowledge not documented
		Documented data and knowledge not readily or widely accessible
	Stochasticity and natural variation	Survey information on presence, extent and population dynamics
	Subjective judgement	Baseline information on indigenous range
		Species designation as invasive
	Model uncertainty	Adequacy of research on impacts on biodiversity
Linguistic uncertainty	Vagueness	Species designation as invasive
	Context dependence	Resolution and scaling of alien range

elegans (red-eared sliders) (García-Díaz, Ramsey, *et al.*, 2017) and various weedy plant species (Panetta, 2012; T. J. Regan *et al.*, 2006; J. R. U. Wilson *et al.*, 2016). Publicly available tools are also under development for cost-effective decisions when eradicating invasive alien species (Centre for Invasive Species Solutions, 2021). Eradication programmes can have rule-of-thumb-based models or be dynamically assessed for likelihood of success (Panetta *et al.*, 2011; Panetta & Cacho, 2014). These help to ensure eradication programmes are neither terminated too early (Rout *et al.*, 2014) nor run beyond any real strong likelihood of success. Decision-making in the context of eradication programmes can also be assisted by Bayesian statistical methods (J. M. Keith & Spring, 2013; Solow *et al.*, 2008). Other methods include scenario tree analysis (Dominiak *et al.*, 2011) and Epitools (Sergeant, ESG, 2018). Predator-Free New Zealand has recently generated a rapid eradication assessment tool for invasive alien mammals (J. H. K. Kim *et al.*, 2020).

Pest risk maps are commonly used for strategic and tactical decision-support in managing biological invasions. However, such maps rarely measure spatial risk and are generally only used to estimate risk in one component of the invasion curve (general introduction or establishment risks – **Figure 5.1**), and can be improved to understand risks and consequences across the invasion steps and interdependencies (Camac *et al.*, 2020). More complex population-based modelling platforms can combine ecological distribution and climate data with process-based models to model pest establishment and spread, density and include impact risk analysis (e.g., Kriticos *et al.*, 2017; Z. Li *et al.*, 2016). These types of models can be made scalable from region down to farm level and provide risk-maps in near-real-time. Similar modelling tools also support decision-making around long-term management of invasive alien species and evaluating control programmes (Bourdôt *et al.*, 2018; Shephard *et al.*, 2016) as well as supporting ecosystem restoration to build resilience to prevent reinvasion. Most modern tools will have a mapping capability, and most will also use spatial information as a component of their evaluation (Beckett & Garner, 2007). Such tools can include individual-based (or agent-based) simulation models (e.g., Beckett, 2008), stochastic and deterministic mathematical models (e.g., Buckley *et al.*, 2005; Tildesley *et al.*, 2012) or, a combination of individual-based and mathematical approaches (e.g., Bradhurst *et al.*, 2015). High power computing helps draw inferences on invasive alien population change in space and time. Other model types include bioeconomic modelling, option value models, endogenous risk theory models, and other economic models. Many of these types of tools can also benefit from artificial intelligence to assist optimizing dynamic response approaches. Collectively, there are no fixed impediments to any of these forms of modelling, other than the availability of the relevant data, including spatial data and the time and investment required to design, implement and validate a model (**Chapter 1**, **section 1.6.7.3**).

5.3 TARGETING PATHWAYS, SPECIES AND SITES IN PRACTICE

5.3.1 When to implement pathway, species-based and site-based management strategies

As discussed in **section 5.1**, there are three main approaches for the management of invasive alien species: management of the pathways of biological invasion, management of the invasive alien species itself and site-based or ecosystem-based management. Pathway management approaches use methods to prevent incursions at the point of entry/border and post-border dispersal within jurisdictions (**sections 5.2.2.2**, **5.4**). Eradication, containment, or suppression of invasive alien species (control) are the main means of species-based management. The likelihood of successful species-based management usually declines with increasing distribution and density of the target invasive alien species **(Figure 5.1)**, except for classical biological control. Where the ability of a species-based programme to eradicate, contain or control the target invasive alien species is limited or where the emphasis may be on maintaining natural assets (e.g., threatened and endangered species or ecosystems), or on the maintenance of a site-based approach may be most likely to achieve long-term conservation outcomes, especially in terrestrial and closed water systems. This is particularly relevant for sites of high biodiversity and ecosystem significance in the context of nature's contributions to people and good quality of life conservation. Site-based approaches also aim to manage sites at risk from, or impacted by, multiple invasive alien species.

Site-based approaches are focused on delineated areas based on the values, objectives and environmental assets of the site. These delineated areas may include islands, protected areas, Indigenous sacred sites or other designated areas that contribute to good quality of life. Following site identification and prioritization, site-based management strategies generally include invasive alien species removal combined with site restoration in terrestrial ecosystems. At the ecosystem level, this is often described as ecosystem-based management. All three types of management approaches play key roles in management of biological invasions and are not mutually exclusive, therefore strategies and decision-making frameworks are needed to determine the context of when each management approach is best applied (Downey & Sheppard, 2006). Selection of the most appropriate approach depends on the outcomes sought and the available resources.

5.3.1.1 Implementing pathway management strategies

Pathway management can be applied to international pathways, which facilitate long-distance global invasive alien species dispersal (e.g., postal mail, trade, human travel, transport vessels, inland and marine canals; Hulme, 2009) and post-border domestic pathways (e.g., spread *via* agriculture or domestic trade, local travel and transport). Commodity-related drivers such as manufacturing, agricultural and pet trade shipping routes (including e-commerce; **Glossary**) and human-travel networks such as tourism and airline travel create invasion pathways (**Chapter 3**, **section 3.2.3.4**). Key components of pathway management include phytosanitary treatment of imported commodities and a combination of both active and general surveillance methods for early detection of invasive alien species to enable management outcomes to be achievable **(Figure 5.1)**.

Comparisons of general patterns of species introductions globally indicate that the commercial animal-trade (livestock, aquaculture introductions, companion animals and illegal pet trade), plant-trade (agricultural and horticultural commodities and trade in wood, seeds and ornamental and nursery stock), wood packaging and hitchhiker or contaminating pests and diseases arriving on other freight are the most significant pathways for terrestrial and freshwater species, whereas ballast water and hull biofouling are important invasion pathways for marine species (Downey & Sheppard, 2006; Hulme, 2009). International cooperation helps to understand pathway risks and manage long-distance pathways, through legislation, regulation, international guidelines and agreements (e.g., IPPC, WOAH), risk analysis, risk mapping, control of invasive alien species and mitigation of impacts (CBD, 2014; Hulme, 2009; Paini *et al.*, 2016). The IPPC has defined trade pathways of invasive alien species movement and provides standards on most plant trade pathways with respect to alien species movements through a range of ISPM for example the adoption of ISPM-15 in 2002 to manage wood boring insects in wood packaging material such as pallets has seen a reduction in incidence of invasive wood borers (Haack *et al.*, 2014). The exceptions are pathways of "contaminating pests" (i.e., "hitchhikers"), which spread through trade *via* movement of sea and air containers but are not associated with any specific commodities (IPPC-CPM, 2020) and e-commerce (Stringham *et al.*, 2021), but these are being

Table 5 3 **Management challenges and information needed when addressing invasive alien species risk associated with e-commerce.**

E-commerce is a rapidly increasing means of invasive alien species spread. Adapted from: CBD (2022c).

Management challenges	Information needed and implementation options
Risk	Improving information on the risks posed by e-commerce (including illegal e-commerce). Establish an international invasive alien species risk-based labelling system for shipments potentially containing invasive alien species as environmentally hazardous living organisms.
Commodities and invasive alien species	Identify commodities related to soils and growing media and living organisms. Create lists that specify which alien species may possibly be imported, including plants (and plant related), aquatic organisms, pet-trade.
Tools	Use autonomous internet tools to identify and locate e-commerce traders and other stakeholders. Gather data to monitor compliance and to evaluate the efficacy of risk mitigation measures. Apply non-intrusive inspection technologies and disseminate good practices and risk-based interventions using data analytics. Improve tools to support efficient international collaboration to link existing security initiatives with invasive alien species risk management and targeted (risk-based) inspections (databases and advanced digital supply chain management systems).
Communication and training	Better inform and communicate with all stakeholders and Indigenous Peoples and local communities in the early detection of incursion or spread of e-commerce derived invasive alien species in natural and managed ecosystems across traditional lands and waters. Develop voluntary codes of practices and standards to regulate cross-border e-commerce. Develop and implement training programmes and tools to facilitate appropriate levels of monitoring and inspection in e-commerce markets.
Management	Develop and apply improved management measures to minimize the risks of introduction of invasive alien species through e-commerce, consistent with international obligations.
Hazard identification	A substantial challenge is posed by living organisms currently being traded through e-commerce and whose risks have not yet been assessed.

addressed. While e-commerce is a key driver and pathway of international concern due to the increasing global volumes of parcel mail (**Chapter 3**, **section 3.2.3.1**), international efforts are underway to address this pathway (CBD, 2020b). **Table 5.3** illustrates options for implementing a coordinated e-commerce management programme.

Six categories of pathways of invasion have been recognized: release, escape, transport – containment, transport – stowaway, corridors and unaided (**Chapter 1**, **section 1.4.1**; **Chapter 2**, **section 2.1.2**, **Table 2.1**; **Chapter 3**, **section 3.1.1**). Deliberate releases, escape from confinement, containment of propagules (e.g., sanitary and phytosanitary control), prevention of stowaways and early detection and rapid response to combat natural spread from neighbouring regions need effective regulations at the jurisdictional level. Where jurisdictions do not have pathway management protocols in place invasive alien species will continue to establish (**section 5.5**), but where they are used effectively excellent pathway management can be achieved (e.g., **Box 5.2**). Various codes of conduct have been endorsed by the European Union for the

Box 5 2 **Case study: A successful pathway management programme from Barrow Island, Australia.**

One of the most ambitious and successful programmes of pathway management was the zero-tolerance biosecurity programme applied to protecting a class A nature reserve – Barrow Island, Australia (**Figure 5.9**; Merwe, 2015; Moro *et al.*, 2018; Scott *et al.*, 2017). The construction of a large liquefied natural gas plant required the transfer of material and personnel through marine vessels and aircraft to the island (**Chapter 3**, **section 3.3.2**). Since higher traffic brings a higher risk of introductions of invasive alien species (**Chapter 3**, **section 3.2.3.1**; **Chapter 2**, **Box 2.5**), a condition for the construction and operation of this project was that no alien species establish in the reserve. To date the Chevron pathway management programme for Barrow Island has been a success. The success of this biosecurity programme resulted from a risk analysis of all material and passenger pathways; identifying decontamination points and marine loading facilities; and all cargo undergoing pre-border cleaning, treatment, packaging and inspection of all transports and cargo (including a purpose-built low biosecurity risk container design) prior to transportation to the island. A quarantine system including behavioural incentives such as performance credits for all island personnel was established to prevent the establishment of terrestrial and marine alien species to the island and surrounding marine habitats. Marine invasions were the most challenging (e.g., Dias *et al.*, 2021). Seventy five percent of invasive alien species were detected pre-border (the majority on transport equipment or materials) which were invertebrates or seeds and 61 per cent detected post-border were *via* human assisted pathways on personnel and in luggage.

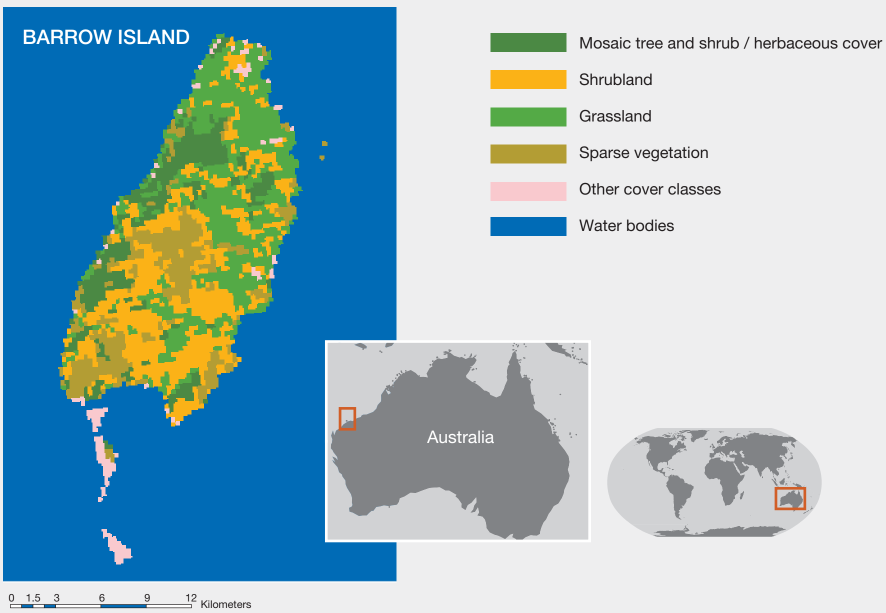

Figure 5 9 **Map of Barrow Island in north-western Australia which is dominated by grasslands and has an area of 202 km².**

pathway management of invasive alien species (Council of Europe, 2021).

Managing intentional introduction pathways helps preventing alien species that have been profiled through import risk analysis and that have high potential ecological impacts, reducing future unintentional spread and ecosystem impact risks (Pergl *et al.*, 2017). Understanding pathway risks through analyses of levels of trade between ecologically compatible countries and numbers of high-risk invasive alien species they do not yet share can help to better target pathway management. Risk can be quantified based on likelihood of arrival and establishment of whole complexes of invasive alien species (Banks *et al.*, 2015). An analysis of almost 1,300 known invasive alien insect pests and pathogens, based on total potential cost of these species invading each of 124 countries showed apparently climatically similar countries varying markedly in risk profile, depending on specifics of agricultural commodities and trade patterns (Paini *et al.*, 2016). According to the same study, the biggest agricultural producers were the greatest potential sources of invasive alien species but could also experience the greatest cost from future biological invasions. Similarly, data from border interceptions, trade volumes, country pest occurrence records and climate suitability models can be used to develop models to estimate the exposure risk of potential and current trading partners leading to an established population of a new high threat pest or disease (Camac *et al.*, 2021). A pathway-centred conceptual model has also been used to determine the role of pathways in invasive alien species establishment and design early detection and rapid response programmes (Colunga-Garcia *et al.*, 2013).

In several regions, control actions have reduced numbers of species deliberately released and to some extent escapes, although species continue to be introduced unintentionally as contaminants and stowaways (Hulme *et al.*, 2008). For example, more than 400 metazoan introductions were reported to have spread through the Suez Canal (Galil *et al.*, 2021), and of 1,257 alien marine species in Europe, shipping (Katsanevakis *et al.*, 2013) and the Suez Canal (Galil *et al.*, 2021) were likely responsible for increasing introductions. The freshwater fish *Pseudorasbora parva* (topmouth gudgeon), spread across Europe, was a contaminant of commercially-exported fish consignments (Gozlan *et al.*, 2010; **Chapter 3**, **section 3.2.3.2**).

5.3.1.2 Implementing species-based surveillance and management

Surveillance aims to detect new invasive alien species incursions early enough to allow for an effective rapid response towards eradication (**section 5.4.2**). Active surveillance is designed to detect priority invasive alien species to inform pathway risk assessment and to provide prevalence information on a trade pathway or a delimited area containing a suspected incursion (IPCC, 2018; **Supplementary material 5.8** for more details on surveillance guidelines). Terrestrial, aquatic and animal disease surveillance (IPPC, 2018; World Organisation for Animal Health, 2019) is generally focussed on specific threats and aims to demonstrate absence (i.e., supporting trade) or to detect prevalence at low levels to ensure rapid response and eliminate the disease or pest outbreak. Surveillance programmes are underpinned by a well-developed sampling methodology and statistical design, which provide transparency around confidence and detection thresholds (Kalaris *et al.*, 2014; FAO, 2018a; World Organisation for Animal Health, 2019). Stochastic scenario tree models can be used to describe each component of the surveillance system to demonstrate that a zone or country is free from a particular disease (P. A. J. Martin *et al.*, 2007). Online calculators such as Epitools assist the design of animal surveillance programmes demonstrating disease freedom (P. A. J. Martin, 2008; Sergeant, ESG, 2018). Stochastic scenario tree modelling of each of the surveillance system components can be used to estimate the probability of disease freedom (Sergeant, ESG, 2018) and to test the sensitivity of the surveillance system. For example, scenario tree modelling was used to assess the sensitivity of Ecuador's national surveillance system to human leptospirosis by conducting probabilistic modelling for each component of the surveillance system. The model assessed the programme's sensitivity as an output so that an economic assessment of the system could be made (Calero & Monti, 2022). Another example of use of stochastic scenario tree modelling is in helping planning a surveillance programme to demonstrate disease freedom for *Mycoplasma bovis* in cattle after an extensive and costly eradication programme in New Zealand (Cowled *et al.*, 2022).

Integrated evaluation frameworks and tools also help evaluate surveillance systems (Peyre *et al.*, 2019). The Food and Agriculture Organization (FAO) Surveillance Evaluation tool is part of the Emergency Prevention System for Animal Health providing countries with comprehensive and standardized methods to evaluate animal disease surveillance including zoonoses and action plans to track diseases that affect animals and people (Aguanno *et al.*, 2019).

Following detection of a new priority invasive alien species, rapid response can only be achieved with immediate access to resources, as the time it takes to mount an effective response is generally of limited duration. In most jurisdictions there is a lack of legislation, policy, protocols or plans to guide rapid management responses to new incursions. Many countries are still establishing such systems, but these are currently seldom implemented or require support from donor agencies (Boy & Witt, 2013). There are good working policies in some countries where pre-negotiated rapid-response plans are agreed at a species-level before each incursion is detected (**section 5.2.2.3**). Such plans pre-negotiate roles and identify funding and responsibilities around species prioritized as key future threats. Where the chance of invasive alien species eradication is lost, management can be done through site-based management, but it is more costly (e.g., *Sciurus carolinensis* (grey squirrel) in Europe; Bertolino & Genovesi, 2003).

Large scale species-based removal and eradication programmes have produced successful results, for example, on islands and for mammalian invasive alien species in northern Europe (Robertson *et al.*, 2017). Species-based management is more likely to achieve impact if relevant stakeholders collectively agree and clearly define overarching management objectives beyond species suppression (a reduction in the abundance of an invasive alien species population). These overarching management objectives could include objectives to measure benefits in biodiversity and ecosystem services or the reduction of threats to threatened and endangered species and communities. Managing invasive alien species in marine environments is particularly challenging, and some species-based management approaches were attempted on sun corals but only reduced localized colonies at small scales in the short term **(Box 5.3)**. Managing freshwater biological invasions is also challenging. In Indonesia, the main invasive alien freshwater fish include species of *Pygocentrus nattereri* (red piranha), *Tetraodontidae* spp. (pufferfish), *Trichomycteridae* spp. (parasitic catfish) and *Electrophorus electricus* (electric eel; Francis, 2011). They were brought in as part of a very large ornamental fish farming sector, and then escaped in rivers on many of the Indonesian islands, causing significant impacts on native freshwater communities. Indonesia has now taken a species-based approach which actively regulates the movement of these alien species within the Indonesian archipelago, and has banned 30 alien fish species from importation (Priono & Satyani, 2010). In Arizona, United States, successful invasive alien fish management has been achieved (e.g., *Salmo trutta* (brown trout)) through long-term collaboration between government agencies and the Indigenous White Mountain Apache tribe using cultural beliefs and habitat restoration practices leading to increases in the native *Oncorhynchus apache* (apache trout) populations (Pfeiffer & Voeks, 2008). In the People's Republic of China, while a biological control programme is under development, national containment lines with 30 km buffer zones were proposed for *Ageratina adenophora* (Croftonweed), to prevent spread from Yunnan province in the south west to other provinces to the north and east (Wan *et al.*, 2009).

Some widely established invasive alien species **(Figure 5.1)** can be targeted using classical biological control (**sections 5.4**, **5.5**) aimed at suppressing populations (number of individuals) at local and landscape levels. There have been over one hundred successful programmes using biological control against invasive alien plants (Schwarzländer *et al.*, 2018). For example, a survey with local communities in Eastern Africa showed *Opuntia stricta* (erect prickly pear) contributed to the loss of grazing land and health impacts (e.g., mouth sores, weight loss and death) of livestock but only 20 per cent of respondents could attempt manual control (R. T. Shackleton *et al.*, 2017). The subsequent release of the *Opuntia stricta* specific genotype of *Dactylopius Opuntiae* (prickly pear cochineal) as a biocontrol agent led to very effective management. In Tahiti, biological control using the fungus *Colletotrichum gloeosporioides* f. sp. *miconiae* of the pan-pacific invasive alien plant *Miconia calvescens* (miconia) from South America has effectively broken the complete canopy cover of *Miconia calvescens* allowing native species to return, but manual removal is still important in ongoing ecosystem restoration (Meyer, 2008).

A review of 76 relevant case studies suggested that the majority of the management conducted by Indigenous Peoples and local communities is species-based (**Supplementary material 5.1**). Therefore, some Indigenous Peoples and local communities have developed knowledge and culture that are critical for motivating species-based actions and prioritizing targets, in many cases utilizing available resources as part of local management. In Canada, *Fraxinus nigra* (black ash) is threatened by the invasive alien beetle *Agrilus planipennis* (emerald ash borer). The Indigenous Kahnawake People use *Fraxinus nigra* trees for basket making, which has increased the public demand for conserving *Fraxinus nigra* (IPBES, 2020). In Hawaii, traditional gatherers of native ferns for cultural practices incorporate manual control of invasive alien plants to manage the fern resource (Ticktin *et al.*, 2006). In a different approach, management can be done through utilization of targeted invasive alien species. For example, the Indigenous Maya Kaqchikel community in Guatemala has recognized the negative impacts of *Pseudopanax laetevirens* (sauco tree or saúco cimarrón in Spanish) and community control efforts have included developing alternative uses for *Pseudopanax laetevirens*, including in food and medicine, which has improved awareness of the benefits and impacts of the tree, helping to limit its spread (IPBES, 2020). Similarly, the loss of native vegetation for livestock feed in various local communities in East Africa (Kenya and Tanzania) from the invasion of the *Prosopis juliflora* (mesquite) tree since the 1970s led to the development of alternative uses of it for firewood and livestock food supporting livelihoods (**Chapter 4**, **Box 4.9**). Nonetheless, spread has continued unabated (Mbaabu *et al.*, 2019) and *Prosopis juliflora* has been declared as a major invasive alien species in Ethiopia, Kenya, India, South Africa and the Sudan (Chandrasekaran & Swamy, 2016; R. T. Shackleton *et al.*, 2014).

Box 5 3 **Case study: Species-based management of invasive alien corals through resource use in Brazil.**

Tubastraea spp. (sun corals; **Figure 5.10**) are highly invasive and widely spread along the Brazilian coast, where, at some locations, they occupy 80 per cent of the shallow subtidal seabed (Mantelatto *et al.*, 2020). *Tubastraea tagusensis* forms dense clusters with up to 872 colonies per m^2 (Paula & Creed, 2005; de Oliveira Soares *et al.*, 2018), and has been recorded from depths of up to 40m (Figueroa *et al.*, 2019). *Tubastraea micranthus* (black sun coral) and *Tubastraea coccinea* (orange-cup coral) has been recorded at 138m and 90–96m below sea level, respectively (Sammarco *et al.*, 2013). *Tubastraea* spp. are considered to have spread with shipping and offshore oil infrastructure. Mantelatto *et al.* (2020) recorded the occurrence of *Tubastraea coccinea* and *Tubastraea tagusensis* attached to floating wood debris and marine litter indicating rafting over long distances may be another mechanism of range expansion. Genetic analysis of these species revealed multiple invasions, secondary introductions, and clonality (Capel *et al.*, 2019). The species-based management goal has been to slow the spread and reduce the negative impacts (Creed *et al.*, 2017). More than 231,000 sun coral colonies (about 8.3 tonnes along the coast of Rio de Janeiro) have been manually collected by trained divers using standard protocols. While preventing dispersal across extensive areas or coastlines was not feasible, focused removal and harvesting efforts provided value by generating income for coral harvesters (Creed *et al.*, 2017). Creed *et al.* (2021) documented manual removal as a recommended option to control and slow the spread and/or eradicate *Tubastraea* spp., however, *Tubastraea* spp. are widely spread in western Atlantic (Gulf of Mexico, Caribbean, Brazil), occur in dense clusters, and extend to depths beyond accessibility through recreational diving and are also nearly year-round prolific reproducers. Dispersal vectors are ubiquitous, which may assist colonization from surrounding areas. Although used as a resource, containment or controlling these species is unfeasible, even at local scale. This really questions the tractability of manual removal-based eradication of these species (Sammarco *et al.*, 2013).

Figure 5 10 **Invasive alien coral *Tubastraea* spp. (sun coral or coral-sol in Portuguese) off the Brazilian coast.**

The colony on the right has been manually removed as part of a species-based management programme. Photo credit: Joel C. Creed, Projeto Coral-Sol/UERJ – under license CC BY 4.0.

Alternative uses of invasive alien species resources have also been adopted in freshwater ecosystems (e.g., invasive paiche *Arapaima gigas* (arapaima) in the Bolivian Amazon; Macnaughton *et al.*, 2015) and marine ecosystems (e.g., *Paralithodes camtschaticus* (red king crab) in Finnmark; Broderstad & Eythórsson, 2014). Some local communities derive local names for some invasive alien species based on their impacts, which can assist recognition and understanding of the different invasive alien species in their areas (IPBES, 2020). Similarly, Indigenous herders in central Uganda use local names for plants in the area, including invasive alien species, which helps monitoring biodiversity (Oba *et al.*, 2008). In southern Tanzania, an invasive alien plant education and awareness campaign improved local appreciation of undesirable impacts, and voluntary manual removal together with basic equipment and the provision of seedlings of alternative desirable plant species provided community benefits (Foxcroft, Witt, *et al.*, 2013). Indigenous

Peoples and local communities can also assist in mitigation measures such as native seed collection, storage and restoration. In southern India, craftsmen harvest *Lantana camara* (lantana) for furniture and basket making which reduces local *Lantana camara* density and size classes (Kannan *et al.*, 2016), but beyond the villages, large regional scale abundance cannot be managed by harvesting.

5.3.1.3 Implementing site-based and ecosystem-based management programmes

Site-based management is likely to include removal of invasive alien species present in a site to achieve ecosystem restoration objectives in terrestrial and inland aquatic ecosystems. Site-based management is sometimes termed "asset protection" since it generally includes site revegetation and restoration (either towards the original or some new desired state) to increase site value and resilience to future invasion (Downey & Sheppard, 2006). Site-based management has been categorized into "susceptible" and "sensitive" sites (McGeoch, Genovesi, *et al.*, 2016). "Susceptible sites are those "with the greatest exposure to invasive alien species propagules and a high probability that these propagules will establish in the area", whereas sensitive sites are those "exposed to the greatest invasive alien species impacts" (McGeoch, Genovesi, *et al.*, 2016). To evaluate progress towards site-based management objectives of reducing community and ecosystem level impacts, ongoing monitoring is critical.

Site-based management is primarily focussed on a particular geographic location, while ecosystem-based management is focussed on a higher level of particular impacted ecosystems. For example, ecosystem-based management could include managing river flow regimes at the catchment scale to keep a myriad water bodies and riparian wetlands healthy and dominated by native species. Such hydrological management can be local (e.g., watering directly) or regional (managing environmental flow allocation) thus affecting multiple sites or ecosystems (Catford *et al.*, 2011, 2014; Ruhi *et al.*, 2019). Both site- and ecosystem-based approaches are on the same continuum defined by the objective(s) of the management, and the location and type of management actions needed to achieve those objectives. Similarly, management of whole socioecological systems at larger scales is also undertaken **(Box 5.2)**. In some contexts (e.g., United Nations Educational, Scientific and Cultural Organization (UNESCO) Man and Biosphere reserves; **section 5.3.2**), site-based management is approached from a socioecological systems perspective (**Chapters 1** and **6**). One example is the management of invasive alien plant (Jellinek *et al.*, 2014) and fishery resources in the Galápagos Islands marine reserve (Castrejón *et al.*, 2014; **Box 5.5** in **section 5.3.1.4**). For areas with limited biodiversity information, site-based management objectives may be expressed in terms of habitat, which facilitates the understanding, conservation or restoration status and economic value of the ecosystem (Dymond *et al.*, 2008).

Sites prioritized for management by Indigenous Peoples and local communities are likely to be sites where there already is an integrated management of culturally important sites and values with conservation outcomes or active community involvement in the control of invasive alien species (Bach *et al.*, 2019; **Chapter 2**, **Box 2.6**). Indigenous lands cover more than a quarter of the world's terrestrial area (Garnett *et al.*, 2018) and the relationship between invasive alien species, site cultural value and negative socioecological effects are often highly complex, contextual and often contradictory (Howard, 2019; Pfeiffer & Voeks, 2008). Sites of high cultural value may be valued for provision of food and medicine because they are also biodiversity refuges for native species. For example, Aboriginal-owned freshwater billabongs in northern Australia have cultural assets as hunting and fishing grounds, and therefore site-based management to exclude feral animals is being experimented collaboratively by researchers and Aboriginal people (E. Ens *et al.*, 2016). Invasive alien species have been incorporated into local cultural systems of Indigenous Peoples and local communities, leading to cultural enrichment (Pfeiffer & Voeks, 2008). The Lower Mekong Basin is a large-scale socioecological system where sites and invasive alien species are managed in an integrated manner (Miththapala, 2007). Indigenous Peoples and local communities utilize invasive alien species as a natural resource in the process of management **(Box 5.4)**.

5.3.1.4 Integrating pathway, species-based and site-based management

Pathway, species- and site-based management can be implemented at various spatial scales along the invasion continuum (**Figures 5.1** and **5.4**; **Box 5.4**). Integrating the use of pathway, species-based and site-based management can promote more informed resource allocation and decision-making (McGeoch, Genovesi, *et al.*, 2016). Integrated use of pathway, species-based and site-based management strategies can be implemented in larger, socioecological complex systems such as the Galápagos Islands **(Box 5.5)**. Differences in societal perceptions and values, impacts and management responses to invasive alien species can decrease the likelihood of success, a principle referred to as socioecological incompatibility (Beever *et al.*, 2019; **Chapter 1**, **section 1.5.2**; **Chapter 4**, **section 4.6**). Management therefore needs to include inter-agency, multi-stakeholder community cooperation from local to national levels for successful outcomes (van Wilgen *et al.*, 2020) if such integrated programmes are to be fruitful.

Box 5 4 Case study: Management of biological invasions in a socioecological system in Asia: the case of the Lower Mekong Basin.

The Mekong River flows through six countries (China, Myanmar, Thailand, Lao People's Democratic Republic, Cambodia and Vietnam), draining an area of 795, 000 km^2. The Lower Mekong Basin is a biodiversity hotspot with numerous endemic and endangered species, and home to about 60 million people, some of whom are Indigenous Peoples and local communities (Miththapala, 2007). Invasive alien species (e.g., *Pontederia crassipes* (water hyacinth), **Figure 5.11**) are impacting biodiversity (e.g., the invasive alien *Mimosa pigra* (giant sensitive plant) displacing native wetland species), human health (e.g., the invasive alien *Pomacea canaliculata* (golden apple snail) vectors and the nematode *Angiostrongylus cantonensis* (rat lungworm) causing eosinophilic meningoencephalitis in humans) and causing severe impacts on important food resources (e.g., rice). As part of the Mekong Wetlands Biodiversity Conservation and Sustainable Use programme (Friend, 2007), a multi-national biological invasion strategy was developed for the whole Lower Mekong Basin and has been implemented at national and local levels, focusing on 14 invasive alien plants and 15 animals (including 10 invasive alien fish and three invasive alien snails). The strategy includes a) pathway management by preventing further entry of invasive alien species and controlling the spread of priority invasive alien species, especially in protected areas; b) increasing public awareness and support (in local languages for communities dependent on the Mekong River); c) building capacity and strengthening national and regional policies and legislation; d) identifying alternative uses for invasive alien species to support control and providing additional benefits; e) evaluating economic impacts of invasive alien species; and f) developing early detection and rapid response and monitoring systems. However, the impacts from the construction of hydropower dams and increasing saline water intrusion have continued to cause degradation of the Mekong delta (Chua *et al.*, 2022; E. Park *et al.*, 2022; Sor *et al.*, 2020; Soukhaphon *et al.*, 2021).

Box 5 5 Case study: Integrated pathway, species-based and site-based management in the Galápagos Islands, Ecuador.

The Galápagos Islands is a World Heritage site due to its exceptional levels of endemism (Toral-Granda *et al.*, 2017). Although geographically isolated, at least 1,579 alien terrestrial and marine species have been introduced in the Islands, of which 1,476 have become established. From the arrival of the first people in 1535 until 1975, alien species arrival accelerated from an average of less than one species to about 30 new species per year, with half of them being intentionally introduced. These unintentionally and intentionally introduced species include 687 terrestrial plants, 17 animals for agriculture and 11 pet species. Unintentional plant contaminants (including seeds and plant-associated material) included 196 insects, 11 other terrestrial invertebrates, 53 marine invertebrates and 127 terrestrial plants. An integrated pathway (I. Keith *et al.*, 2016), species-based and site-based management plan could facilitate a comprehensive approach to the management of biological invasions to, and within, the Galápagos Islands. For example, pathway management could address external arrivals and movements between the islands (Veitch & Clout, 2002). Cargo quarantine and inspection is currently undertaken at a

Box 5.5

single facility supported by a centralized database of plane, boat, residents, tourists and cargo arrivals analysed to evaluate strengths and weaknesses in the control system. Efficient pathway management would include a marine biosecurity programme and developing regulations (Carlton *et al.*, 2019; Toral-Granda *et al.*, 2017). Educational programmes for residents and tourists, and risk assessments of human mobility and associated transports provide further information on how to manage pathways. Site-based management for plants is applied to terrestrial protected areas and urban centres to maintain remnant habitats and native biodiversity. A number of species-based programmes focus on species prioritization and priority plant (Gardener *et al.*, 2010) and mammal eradication (Cayot *et al.*, 2021) and biological control (Zachrisson & Barba, 2020; **Figure 5.12**).

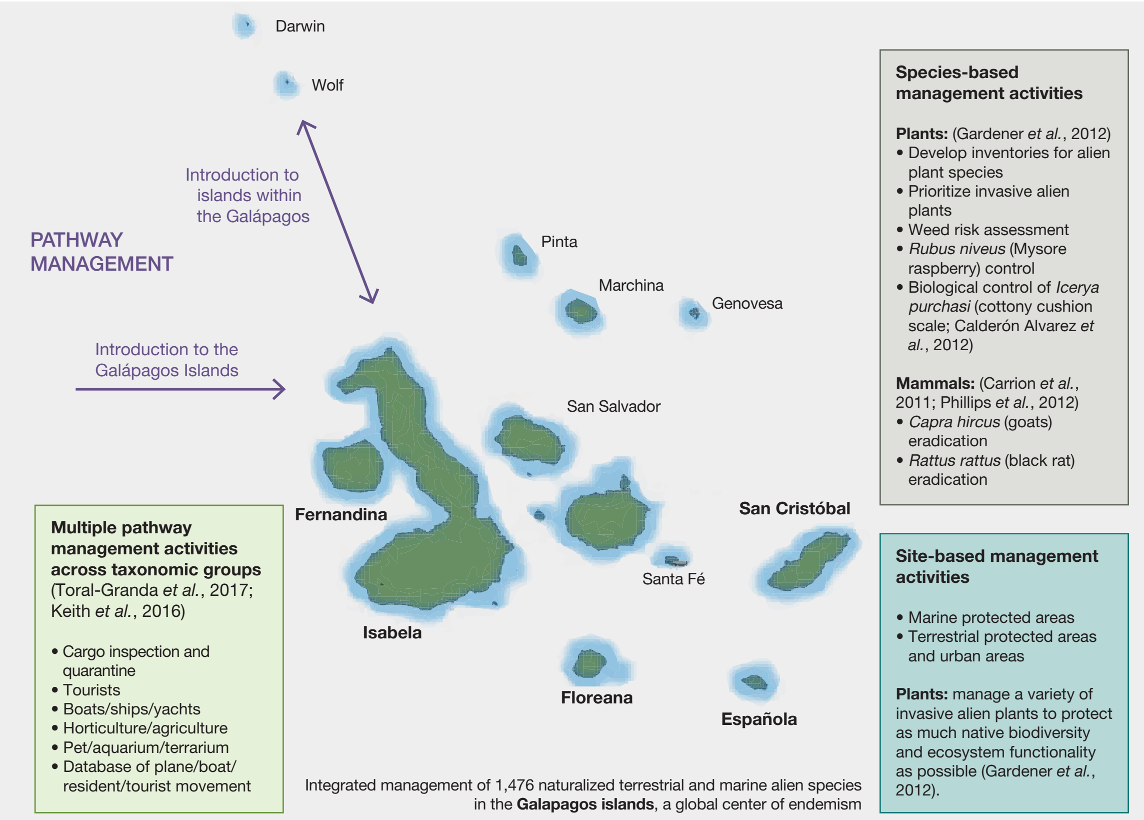

Figure 5.12 **Map of the Galápagos Islands showing examples of pathway, species-based and site-based management activities.**

These islands are a global centre of endemism where 1,476 naturalized terrestrial and marine alien species have been recorded (Calderón Alvarez *et al.*, 2012; V. Carrion *et al.*, 2011; Gardener *et al.*, 2012; I. Keith *et al.*, 2016; Phillips *et al.*, 2012; Toral-Granda *et al.*, 2017). Source of underlying map from: Andrew Z. Colvin, WM Commons – under license CC BY-SA 4.0.

5.3.2 Managing invasive alien species impacts in protected areas, islands, national parks, Ramsar Sites, Man and Biosphere reserves and World heritage sites

A Global Invasive Species Programme (GISP) report (De Poorter, 2007) covering largely terrestrial sites identified 487 protected areas with an invasive alien species threat, while a different study listed 135 protected areas which had a range of science-based management and monitoring programmes in place (Foxcroft, Pyšek, *et al.*, 2013). There are examples of successful species-based and site-based invasive alien species management programmes in protected areas. For example, a study that reviewed the status and outcomes of control over a 30-year period in 24 nature reserves across savanna, arid environments, islands and Mediterranean type ecosystems (Usher, 1988) showed that invasive alien mammals were decreased by 43 per cent after 30 years, but invasive alien plants continued to pose the greatest threat, increasing in 31 per cent of the nature reserves studied (R. T. Shackleton, Foxcroft, *et al.*, 2020). **Chapter 4**, **sections 4.3.1.2** and **4.4.1.2** discuss impacts in protected areas and **Chapter 6**, **section 6.3.1.4(5)**, discusses the need to incorporate management of biological invasions into protected area management plans.

National Parks are also often reservoirs of invasive alien vertebrates because of lack of resources to control them, which often raises concern for surrounding landowners. Mountain reserves have typically been considered resistant to invasions, however studies forecast an increase of invasions due to climate warming and anthropogenic related activities, including the expansion of tourism (Kueffer *et al.*, 2013). Pathway, species- and site-based management approaches can be applied by minimizing general access to wilderness areas, thereby reducing dispersal pathways **(Box 5.6)**. Globally, most protected areas are reliant on income from tourism (Meyerson & Reaser, 2002), a driver that promotes biological invasions (**Chapter 3**, **section 3.2.3.4**), to achieve their mandate and resource the management of biological invasions and reintroduction of native species (**section 5.5.3**). Pathway management may therefore have to account for vehicles and yachts (L. G. Anderson *et al.*, 2015), horses (Pickering & Mount, 2010), trail running (K. Smith & Kraaij, 2020) and tourist associated infrastructure such as in Masai-Mara National Reserve, Kenya (Witt *et al.*, 2017) and Kruger National Park, South Africa (Foxcroft *et al.*, 2019). Surveillance can be directed to areas of heightened concern, such as along roadsides (Pauchard & Alaback, 2004), in developed areas (including staff and tourist facilities) and disturbed areas. In the European Union, the Emerald Network of Areas of Special Conservation Interest formed under Natura 2000 aims to integrate these approaches for management of biological invasions across European designated protected areas (Bartula *et al.*, 2011; Kati *et al.*, 2015; **Chapter 6**, **Box 6.8**).

The Global Wetland Outlook (Ramsar Convention on Wetlands, 2018) indicated that in 2018, 40 per cent of the parties reported a comprehensive national inventory of invasive alien species impacting wetlands. However, few (26 per cent) had developed policies or guidelines to manage invasive alien species in wetlands (Ramsar Convention on Wetlands, 2018). The aim of management of biological invasions in Ramsar sites is to prevent water quality deterioration and facilitate use of the wetland substrate as resources for people in addition to biodiversity protection (Ramsar Convention Secretariat, 2010). Ramsar guidelines recommend prevention, eradication and control, by focusing on pathway, species-based and site-based management (Ramsar Convention Secretariat, 2010). Invasion by *Pontederia crassipes* (water hyacinth) in Malagarasi-Muyovozi (Tanzania) affects the livelihoods of local fisherman communities as fishing camps were closed (Kalumanga, 2015). Nyul Nyul rangers in the Kimberly region of Western Australia manage feral animals and invasive alien plants on their wetlands (The Commonwealth of Australia, 2016). In Beung Kiat Ngong Ramsar Site (Lao People's Democratic Republic) locals had to deal with the socio-economic impacts of *Pomacea canaliculata* (golden apple snail) by harvesting and selling them (Cranmer *et al.*, 2018).

A review of 241 World Heritage Sites identified 290 invasive alien species as a threat (R. T. Shackleton, Bertzky, *et al.*, 2020). For example, a management programme was recommended in 2006 for *Mimosa pigra* (giant sensitive plant), which is considered the largest threat to the biodiversity of Tonle Sap Biosphere Reserve (north-west Cambodia), a highly important floodplain habitat for fish and endangered waterbirds in South-East Asia (Goes, 2005). Widespread management at landscape scales was considered unfeasible (Ferguson & Chun, 2011), but as the species is river-dispersed, the programme recommended increased surveillance targeting *Mimosa pigra* and a basin-wide plan to reduce the risk of further introduction and establishment of other invasive alien species (van Zalinger, 2006). *Mimosa pigra* management in Kakadu National Park (World Heritage and Ramsar site) in Australia using classical biological and integrated control has provided long-term control. Effort is now turning to management of *Urochloa mutica* (para grass), *Hymenachne amplexicaulis* (hymenachne) and *Andropogon gayanus* (tambuki grass) (Setterfield *et al.*, 2013). Classical biological control of *Pontederia crassipes* (water hyacinth) is also underway in the Delta du Senegal (World Heritage and Biosphere reserve), Senegal (Amer *et al.*, 2015).

Islands are areas of special concern for management. On islands that are susceptible to invasive alien species introduced by trade and human movement (**Chapter 2**, **Box 2.5**; **Chapter 3**, **section 3.2.3**), a key strategy is to prevent the establishment of introduced invasive alien species. As human activities expand into more remote regions, including the Arctic, Antarctica and the South Atlantic and Pacific, biogeographic dispersal barriers are weakening (e.g., the Tristan da Cunha islands; D. Moser *et al.*, 2018) and rigorous biosecurity programmes are extremely important. The sub-Antarctic islands fall almost entirely in protected areas but have had numerous introductions of invasive alien species (Convey & Lebouvier, 2009; Frenot *et al.*, 2005). As a result, biosecurity measures have been generally implemented by the five sovereign nations to reduce future introductions of invasive alien species and undertake eradications and other management (Chown *et al.*, 2012; **Chapter 6**, **section 6.3.3.1**), which has led to increased awareness of biosecurity across all stakeholders. Elsewhere, various Small Island Developing States (SIDS) are also initiating successful biosecurity campaigns with good results (**Boxes 5.7** and **5.8**).

Invasive alien species are a major driver of species extinctions on islands (Sax *et al.*, 2002; Simberloff *et al.*,

Box 5 6 Case study: Management and use of *Sus scrofa* (feral pig) and *Axis axis* (Indian spotted deer) in El Palmar National Park, north-eastern Argentina, by local communities.

Both *Sus scrofa* **(Figure 5.13)** and *Axis axis* are considered to be a major threat within invaded ranges around the world. They impact on plant community structure and dynamics, compete with native grazers and livestock and may transmit zoonotic pathogens. In the El Palmar National Park in north-eastern Argentina created in 1965 to preserve one of the last high-density stands of the *Butia yatay* (yatai palm tree), *Sus scrofa* reduced recruitment by consuming fruits or seeds and killing saplings (Ballari *et al.*, 2015). The park rangers' initial efforts to cull *Sus scrofa* in 1983 were unstructured. A revised management programme based on hunting with trained dogs and spotlight hunting from the back of slow-moving vehicles initiated in 1995 was successful for *Axis axis*, but again proved unsustainable for the *Sus scrofa* population which continued to increase. Valuable lessons were learnt forming the foundation of a new multi-stakeholder management programme incorporating sustainability, broad social participation, safe procedures, close supervision and a regulated framework targeting both species in 2006. Controlled shooting teams worked uniformly across the park, without catch quotas. Each hunter was allowed to take home most of each carcass to minimize selective hunting and the rest were donated to local public schools, community shelters and retirement homes (Gürtler *et al.*, 2017).

This programme reduced *Sus scrofa* abundance within two years to levels causing minimal soil damage (Gürtler *et al.*, 2017). Recruitment rate of yatay palm trees significantly increased a decade later. *Axis axis* numbers however continued to increase, the reasons for which remain unclear (Gürtler *et al.*, 2018).

Figure 5 13 ***Sus scrofa*** **(feral pig, jabalí in Spanish) in El Palmar National Park where a management programme was implemented to control the invasive alien species.**

Box 5 7 Case study: Biosecurity in the Republic of Seychelles.

Trade and travel increased the threats of biological invasions to the Seychelles archipelago although there were important weaknesses in the biosecurity policies for trade (Rocamora, 2015). Under an Environment Management Plan project, a new Biosecurity Service was created with strengthened technical and institutional capacities which helped the development of an emergency plan and operational manuals (Senterre & Dine, 2022). The entry and internal movement of animals and plant pests and diseases was regulated leading to improvements in the conservation status of native species. An unexpected result was that Seychelles was able to join the World Trade Organization (WTO) due to the strengthening of its biosecurity institutions, policy and legislation. Project challenges included finding qualified staff and consultants, creating a cost-recovery mechanism to support the Biosecurity Service and the creation of a group to coordinate knowledge management and information sharing at the national level (GEF, 2007).

2013; **Chapter 4**, **section 4.3.1**), however, eradication and control of invasive alien species on some islands, especially vertebrates, has been highly effective with rapid biodiversity benefits (Howald *et al.*, 2007; H. P. Jones *et al.*, 2016; Genovesi, 2011; **section 5.5**). On the Motuopao Island (New Zealand), a species-based control programme of invasive alien plant species assisted native grasslands to recover following the control of *Malva arborea* (tree mallow; Beauchamp & Ward, 2011). Holmes *et al.* (2019) identified 169 globally important islands where invasive alien mammal eradications would assist threatened vertebrate species. This was based on a conceptual framework considering biogeographic (i.e., extinction risk, irreplaceability, severity of impact from invasive alien species) and technical feasibility of eradication (i.e., operational cost of the programme, size of the island, no permanent human settlements) as well as socio-political feasibility to initiate an invasive mammal eradication project by 2020 or 2030. The list included some SIDS such as Bermuda, Cape Verde, Cuba, Fiji, Kiribati, Palau and the Seychelles.

Island eradication programmes employing species-based approaches focus on the eradication of multiple invasive alien species which, although challenging in planning, proved to be both successful and cost-effective. For example, a plan to eradicate five invasive alien mammal species on six islands in the archipelago of French Polynesia led to recovery of critically endangered species **(Box 5.9)**. Such management programmes on islands have also been part of large programmes focussing on social, economic and environmental objectives (**section 5.5**). On Mexican islands, a comprehensive national programme to eradicate invasive alien species and restore ecosystems, including habitat for coastal and terrestrial birds, has changed local stakeholder understanding and engagement in biosecurity policies and regulations **(Box 5.9)**. Recognizing the effectiveness of management on islands, the Global Environment Facility (GEF) has prioritized its invasive alien species funding programme towards island conservation projects (GEF, 2020).

Box 5 8 Case study: Eradication of five species of invasive alien vertebrates in the archipelago of French Polynesia.

On six islands of the archipelago of French Polynesia, a project was undertaken in 2015 to eradicate five species of invasive alien vertebrates: *Rattus exulans* (Pacific rat), *Rattus rattus* (black rat), *Felis catus* (cat), *Oryctolagus cuniculus* (rabbits) and *Capra hircus* (goats). The project was successful on five of the six islands (Pacific rats survived at one site). A management plan was developed and implemented that aimed to restore populations of the endangered *Pampusana erythroptera* (Polynesian ground dove), *Nesofregetta fuliginosa* (Polynesian storm-petrel) and *Aechmorhynchus parvirostris* (Tuamotu sandpiper), as well as other native plant and animal species. International and local conservation non-governmental organizations as well as local communities were involved from the planning phase to the execution of the management actions. Although implementation was challenging, this collective approach proved more cost-effective than if each island had been targeted individually. Effective engagement of stakeholders was key for the success of the project. The livelihood of local communities was also improved through the project (Griffiths *et al.*, 2019).

Box 5 9 Case study: National Program for Island Restoration in Mexico.

The eradication of invasive alien species was the first step of the National Program for Island Restoration in Mexico together with active ecosystem restoration for the recovery of seabirds (Bedolla-Guzmán *et al.*, 2019), biosecurity protocols (Latofski-Robles *et al.*, 2019), vegetation and soil restoration (Luna-Mendoza *et al.*, 2019), and environmental learning with local communities (Aguirre-Muñoz *et al.*, 2016). Mexican islands are extraordinarily diverse, including semi-arid islands in the Eastern Pacific Ocean; desert islands in the Gulf of California; and subtropical and tropical islands in the Pacific Ocean, the Gulf of Mexico and the Caribbean (Aguirre-Muñoz *et al.*, 2016). On these islands, 21 endemic species and subspecies of vertebrates have gone extinct in the last 100 years, and all but four of these extinctions were caused by invasive mammals see **Chapter 4**, **Box 4.4** and **section 4.3.1**). Islands were selected for ecosystem restoration and action (i.e., control or eradication of invasive alien species) based on conservation value, management efficiency, social acceptance and technical and financial feasibility (Latofski-Robles *et al.*, 2014). Initiated in 1995 at some islands, the number of target islands and species increased, and by April 2018, 60 populations of invasive alien mammals were successfully removed from 39 islands, 30 of which are now completely free of invasive alien mammals. The extent of the success of the eradication programmes can be illustrated by the numbers of populations and invasive alien species controlled across the islands: 32 populations of 12 species from 15 islands of the Pacific Ocean, 21 populations of 5 species from 18 islands of Gulf of California and 7 populations of 3 species from 6 islands of Gulf of Mexico and Caribbean. These actions are estimated to be protecting at least 147 endemic taxa of mammals, reptiles, birds and plants, as well as 227 seabird breeding colonies (Aguirre-Muñoz *et al.*, 2018).

5.3.3 Decision tree for selection of management approach

Choosing the most appropriate management objective is the first step to deciding between a pathway, species-based, site-based or ecosystem-based management approach for biological invasions, but it is not always straightforward (**section 5.2**). Objectives of a management programme for biological invasions may be aimed at economic, social or environmental outcomes or at multiple benefits. For example,

Box 5 10 **Case study: Decision tree for separating site-based versus species-based management of invasive alien plants (after Owen & Sheldon, 1996).**

The New Zealand Department of Conservation outlined a collective approach encompassing both species-based and site-based programmes for decision-making for the management of invasive alien plants. In their approach, species-based initiatives are aimed at new incursions and providing the best conservation outcome, and site-based initiatives are aimed at protecting biodiversity in terms of the collective threat and urgency for management from all alien species present, or the value of protecting a site from all invasive alien species (Timmins & Popay, 2002). Some species-based programmes are specifically aimed at protecting biodiversity (Downey, 2010). The main decision criterion for selecting sites may be the presence of one or more major invasive alien species threatening biodiversity allowing targeted control and threat abatement (Downey, 2013). To assist in making such decisions, the following decision tree may be of use **(Figure 5.14)**.

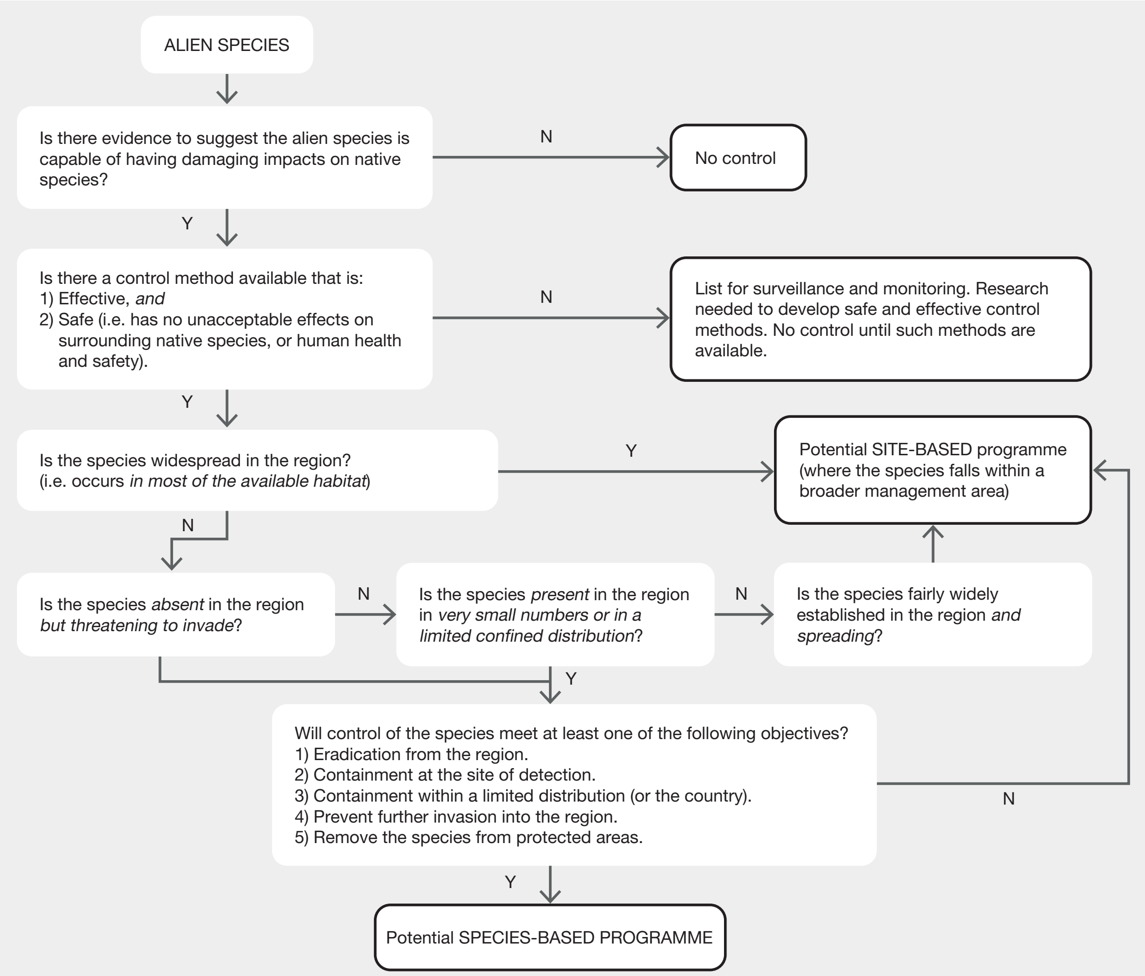

Figure 5 14 **Decision tree for choosing between site-based and species-based management of invasive alien plants.**

Double bordered rectangles are terminal nodes. Adapted from Owen & Sheldon (1996), https://caws.org.nz/old-site/awc/1996/awc199615161.pdf, under license CC BY 4.0.

programmes aimed at managing invasive alien pigs could produce benefits for biodiversity and ecosystems (nature), Indigenous Peoples and local communities' livelihoods (good quality of life and nature's contributions to people), livestock disease and property damage management (agriculture), reduced carbon emissions (mitigating climate change), or all of these (Nordberg *et al.*, 2019; Zivin *et al.*, 2000). The most cost-effective way to ensure the survival of threatened and endangered species in a region may be a collective regional planning approach to management of biological invasions (Carwardine *et al.*, 2012). It is worth considering one or all the available approaches. Confusion and considerable debate around whether and when management of biological invasions should follow a pathway, species-based or site-based management approach appears to result from poorly defined management objectives, which too often simply focus on species prevention or suppression (Downey & Sheppard, 2006). For example, the Australian Weeds of National Significance programme (Thorp & Lynch, 2000) and associated invasive alien plant classical biological control programmes (Downey & Sheppard, 2006) target the highest priority invasive alien plant species. Thus, it is important that the aim of any species-based or site-based invasive alien species initiative be clearly articulated. **Box 5.10** describes a decision-support system developed to help decide when to undertake pathway, species-based or site-based management for invasive alien plants.

5.4 REVIEW OF KEY DATABASES, MANAGEMENT TOOLS AND TECHNOLOGIES FOR BIOLOGICAL INVASIONS

From countries to communities, cost-effective solutions for managing pathways, invasive alien species and invaded sites and ecosystems are needed to prevent increasing economic, environmental and social impacts (Ricciardi *et al.*, 2017). A wide range and increasing number of data sources, tools and technologies support actions towards a) prevention, preparedness, surveillance, detection and monitoring of pathways, b) species-based eradication, containment and management and c) site-based and ecosystem-based management to protect key biodiversity assets to build resilience to further invasion. This section provides explanatory information on databases, tools, technologies, platforms and approaches to support their adoption and use, and the context in which they can be used in the management of biological invasions. Limitations, challenges, advantages, and disadvantages of these are also covered in either the body of the section or in the **Supplementary materials 5.3** to **5.8**. These key databases, management tools and technologies for biological invasions are categorized under a) databases, b) surveillance, detection and diagnostics and c) intervention technologies. For the last two categories, the tools and technologies are grouped in the context of managing pathways, species and sites. In each of these categories, stakeholder engagement frameworks and decision-support tools have been covered in **section 5.2**. Some of the latest technologies with significant potential, but not yet applied in the context of biological invasions, are also briefly discussed. The rapid development of novel technologies and approaches has produced tools capable of massively improving management of biological invasions. However, understanding how to facilitate context specific adoption, application and operationalization of such technologies in a policy and community acceptability context is lagging behind (Burke *et al.*, 2005; Stilgoe *et al.*, 2020; van Rees *et al.*, 2022; **Chapter 6**, **section 6.3.3.4**).

Summary tables are provided to frame each tool, technology, approach or platform in terms of the aspects of management they address, their relevance to different types of invasive alien species and the temporal and spatial scale of their application.

5.4.1 Relevant databases for management of biological invasions

Accurate and real-time publicly accessible geospatial databases of invasive alien species provide considerable value for underpinning management (e.g., Seebens *et al.*, 2017; **Chapter 2**, **section 2.1.4**; **Chapter 6**, **sections 6.6.1** and **6.6.2**). There remain considerable sensitivity issues for invasive alien species important for trade and market access, but most species data is on publicly available platforms (e.g., GBIF). Big-data analytics are proving increasingly valuable for understanding and managing priority invasive alien species issues (Hay *et al.*, 2013; Bennett, 2015), but are undertaken by dedicated data analysis groups in academia, governments and industry which does not help social engagement (Lawrence, 2006). Such databases are relevant for analysing species distribution and abundance, outbreak management and also capture of management activities and their effectiveness. Globally, documentation and data on management and control costs are very limited in terms of final outcomes on nature and nature's contributions to people. One recent significant database on impacts is the InvaCost database (**Chapter 4**, **Box 4.13**). Global, regional and taxon specific databases relevant for invasive alien species management are listed in **Table 5.4** for a range of information types. Important databases for management of biological invasions include the Database of Island Invasive Species Eradications (DIISE), Biological Control of Weeds – a world catalogue of agents and their target weeds, and BIOCAT for invertebrate pest biocontrol. The IUCN Red List of Threatened Species, which currently has assessed the risk of extinction for 142,577 species, uses a hierarchical classification scheme to record drivers of species decline, including threats from invasive alien species (Salafsky *et al.*, 2008).

All these databases are subject to some degree of geographical and taxonomic or sampling bias (Yesson *et al.*, 2007). Data sharing and data integration work as long as international data standards are defined and followed. Achieving this in developing countries remains a challenge and it is important to have sustained support to ensure databases are not just a snapshot in time. In this context the CBD invasive alien species *ad hoc* technical expert group made the following observations:

- Ensure open access to databases, knowledge sources and analytical data tools *via* national and international data portals.
- Improve databases for marine, invertebrates, microorganisms and fungi and collect and integrate deoxyribonucleic acid (DNA) sequence data into existing databases, where possible.
- Develop internationally agreed data standards to facilitate data sharing.
- Develop invasive alien species filters for existing species databases (e.g., ECOLEX & FAOLEX; **Table 5.4**)
- Collectively collate data and knowledge on best practice invasive alien species policy and regulatory, voluntary codes of conduct across sectors across and international agencies and conventions.

Table 5 4 **Information components including description and importance of the information for documenting and managing biological invasions (reason) of existing invasive alien species databases (data and knowledge products) relevant for planning and implementation of management.**

Websites are provided at the first mention of each database (see **Chapter 2** for databases relevant for status and trends and **Chapter 6**, **section 6.6.3** for databases supporting policy options). Identified gaps identified within the data and knowledge products are also given. Adapted from CBD (2019).

5.4.2 Surveillance, detection and diagnostics supporting prevention and preparedness

There are a range of tools and technologies for surveillance, early detection and monitoring of invasive alien species including measuring the effectiveness of management actions. These include remote sensing (satellite and aerial imagery, drones, under water remote vehicles, camera traps etc.), sensor networks and crowd sourcing and the traditional use of trained detector dogs (e.g., Browne *et al.*, 2006). These tools are becoming increasingly cost-effective for early detection (**section 5.1**). Early detection also needs effective species-based diagnostics tools, not all of which are based on taxonomy or morphological characteristics as described here. Technology adoption is heavily driven by cheaper price differentiation under novel business models. This is what is frequently termed "disruptive technologies".

5.4.2.1 Pathway surveillance tools and technologies

a) Digital data mining – crowdsourcing general surveillance

Citizen surveillance, through crowdsourcing and data-mining or web scraping, social media and other data streams filtering on invasive alien species content, can be used as a cost-effective complementary form of general surveillance supporting species-based risk assessment (Grossel *et al.*, 2017; Lyon, 2010; Welvaert & Caley, 2016). Data mining is extracting information from large databases. Resources scanned can include internet search engines, Really Simple Syndication (RSS) feeds and Twitter, which often contain invasive alien species photographic, taxonomic or detection-based content. Searches can be targeted at specific species or can be more general (e.g., symptoms/impacts) and can include other terms such as climate and land use change. Software exists (e.g., International Biosecurity Intelligence System (IBIS)) which can automatically search the internet daily looking for invasive alien species reports, grey literature, articles from relevant journals and any other articles or comments, thereby generating invasive alien species intelligence. Crowdsourcing surveillance can include early warning, mapping, eradication, containment, understanding real-time impacts, proof of area wide pest/disease freedom (for trade purposes) and knowledge sharing. Once an article is found, third-party web services such as AlchemyAPI and GeoNames can be used to extract information from the article such as the title, text, author, language and locations. This approach accesses citizens as surveillance agents, as "eyes and ears" over large areas. The key difficulty lies in delineating real incursion events from background "noise". Costs are limited to crowdsourcing system development, hardware and software maintenance. Systems exist for biosecurity (e.g., IBIS; Grossel *et al.*, 2017), animal and public health diseases (e.g., Program for Monitoring Emerging Diseases (ProMED; M. Carrion & Madoff, 2017), linked to EpiSPIDER (Tolentino *et al.*, 2007); BioCaster (Collier *et al.*, 2008). The multiple global and jurisdictional coronavirus disease 2019 (COVID-19) dynamic online case number dashboards are other examples of real-time automated invasion surveillance data feeds.

b) Sensor networks and smart traps

An emerging cost-effective approach to passive surveillance is through the use of sensor networks (Farouk & Zhen, 2019; Rundel *et al.*, 2009) and mobile smart traps (Potamitis & Rigakis, 2015). Wireless sensor networks generally consist of a number of different sensors connected wirelessly, that typically collect audio, image and body temperature observations produced by monitored targets, and use machine learning and pattern recognition algorithms to identify targets of interest automatically from these observations. Such networks can provide effective methods for small-scale continuous monitoring applications. They provide multiple observations operating independently over long time periods. The infrastructure deployment and maintenance costs, however means spatial coverage is limited (Preti *et al.*, 2021). Key advantages include low power allowing for the deployment of many and varied sensors across a landscape, continuous data streams provide real-time data transferred *via* the mobile network even if accessible by only a few sensor nodes. Such systems can be applied in terrestrial, aquatic (Kong *et al.*, 2005) or aerial (Kgori *et al.*, 2006) settings. Attaching sensors to mobile objects, such as domestic and wild animals, has the potential to greatly extend the spatial coverage of fixed sensors (Duda *et al.*, 2018). Sensor networks can be deployed in tracking invasive alien species movement and activities, invasive alien species in lakes, rivers, or reefs, as well as on birds, flying foxes or similar (Jurdak *et al.*, 2013; K. Li *et al.*, 2014). Networked mobile suction traps or smart lure traps can also be cost-effective and be used at high- risk sites such as ports of entry or at jurisdictional borders to monitor pest movement pathways (Harrington *et al.*, 2012). Trap contents can potentially be analysed *via* metabarcoding environmental DNA (Lagos-Kutz *et al.*, 2020; **section 5.4.2.2h**; **Glossary**).

Over the past decades, wireless sensor networks (including lightweight telemetric tags) have been deployed successfully in a number of invasive alien species contexts reviewed by Jurdak *et al.* (2015), including to detect insect pests (López *et al.*, 2012), invasive alien vertebrates (Fleming *et al.*, 2014), invasive frogs (Hu *et al.*, 2009), fish (Jurdak *et al.*, 2015; Kottege *et al.*, 2012) and flying foxes (Sommer *et al.*, 2016). Infrared cameras have also been used for livestock biosecurity to collect body temperatures of cattle as a sign of disease infection (Rainwater-Lovett *et al.*, 2009). Low-power image-sensor networks have been used to detect and classify insect pests (Jurdak *et al.*, 2015) and invasive alien vertebrates. See **Supplementary material 5.2** for further details.

c) Screening technologies

X-ray screening devices are now in operation at most airports and have been a standard technology of biosecurity operations at borders for a number of years (Whyte, 2006). Their quality as a screen technology is variable due to the cost of both software and proper training of personnel. Human behaviour can also compromise effectiveness, for example proper fluid detection systems are often circumvented by staff because they cause frequent machine errors. Next generation 3D x-ray machines are however much more sophisticated and are being installed at airports and postal mail sorting centres in some countries (e.g., Australia and New Zealand; Australian Government, 2021a). Digital triage of these types of images will increasingly be run autonomously with machine learning algorithms trained to risk profiling key indicators of suspect material (Marturana *et al.*, 2015). This could potentially lead to autonomous screening of luggage or postal mail triaging suspect items for human inspections. Similar systems are also under development for scanning shipping containers (C. H. Lim *et al.*, 2021).

d) Environmental DNA

All organisms leave a genetic trace of themselves within their environment and there are multiple ways of sampling and analysing this environmental DNA for species detection (C. I. M. Adams *et al.*, 2019; Herder *et al.*, 2014; Truelove *et al.*, 2022) including for invasive alien species (Rees *et al.*, 2014; Bylemans *et al.*, 2019). When applied within pathway or ecosystem surveillance, control or eradication programmes (Carim *et al.*, 2020), environmental DNA analysis provides a sensitive and efficient means to detect the presence of a particular or multiple species and is applicable to all organisms including microbes that exceed the sensitivities of conventional observational monitoring (Furlan *et al.*, 2019), particularly for situations where other novel detection technologies are not applicable (Bylemans *et al.*, 2019; **Chapter 6**, **section 6.6.1.2**; **Box 6.19**). Environmental DNA analysis has the potential to be applied across most fields of invasive alien species, environmental research and land management, particularly for aquatic and marine invasive alien species (C. Abbott *et al.*, 2021) as many conventional and novel methods for detection do not work well (if at all) in these environments. Environmental DNA can be applied, for example, to identify species within aquatic or marine environments using polymerase chain reaction (PCR, see **Glossary**) tools or for whole community assessments using metabarcoding (Rees *et al.*, 2014; Bylemans *et al.*, 2019). Portable environmental DNA PCR units are also increasingly available. More recently studies are demonstrating the capacity to also capture and analyse aerial environmental DNA (Banchi *et al.*, 2018). Cross-phyla studies combining environmental DNA metabarcoding with taxonomy and population genetics is also being used to detect new introductions of species and genotypes (Holman *et al.*, 2019). Care is needed in the interpretation of results, as the presence of a species' DNA does not necessarily mean that live individuals are also present and cannot determine where in the sampled environment the species are/were. Environmental DNA density may not be correlated to species abundance as DNA can accumulate or persist in certain situations or be degraded or lost in others. Some target species have a strong seasonal release/availability of environmental DNA (e.g., crabs and other marine fauna), which complicates detection. Sampling design may substantially influence sensitivity (Furlan *et al.*, 2016; Hinlo *et al.*, 2017) and abundance biases (Furlan *et al.*, 2018). Broad-scale environmental DNA sampling is relatively of low cost, and data acquisition and extraction can be streamlined. Environmental DNA sampling is non-invasive and non-destructive to sensitive environments.

Environmental DNA is consistently used to demonstrate absence of selected invasive alien species, and could be combined with other approaches where possible. To help manage the issue of live and dead species in samples, a refined system is being developed where only DNA from whole cells in the sample are collected. These sorts of approaches are rapidly being adopted in relevant biosecurity monitoring programmes in for example Australia and New Zealand and can also be usefully combined with citizen science (E. R. Larson *et al.*, 2020).

Sampling for environmental DNA analysis can be coupled to unmanned vehicles, including aerial, ground-based and aquatic or marine vehicles with sample analysis undertaken autonomously. In some scenarios, this combined approach might effectively automate the process of surveillance and enable far greater penetration of inaccessible landscapes or environments. See **Supplementary material 5.2** for further details.

e) Sentinel surveillance and monitoring

Sentinel surveillance has been developed for early detection, surveillance and monitoring of invasive alien disease incursions. It involves sampling from a sentinel species and may be configured to identify a single or a range of invasive alien species. Targets commonly include infectious animal diseases (Batista *et al.*, 2012; McCluskey & Salman, 2003) and plant pests and pathogens (Kenis *et al.*, 2018). Animal disease examples include West Nile virus using chickens and mosquitos (Reisen *et al.*, 2004), cattle for bluetongue disease in sheep (Elbers *et al.*, 2008) and bovine ephemeral fever virus in cattle (St George, 1985) or bovine tuberculosis using pigs, badgers and cattle (McInerney *et al.*, 1995;

Murphy *et al.*, 2011). Relatively less is known about the sensitivity, practicality and other characteristics of sentinel disease surveillance using wild species providing for sentinel surveillance. In one example in Estonia and Latvia, regular testing (and aerial vaccine bait dropping) is undertaken for wild animal rabies (e.g., raccoon dog) (Holmala & Kauhala, 2006). The monitoring of wildlife to understand the incidence and risk of particularly zoonotic diseases is likely to increase post COVID-19 (Latinne *et al.*, 2020).

The principles and value of sentinel surveillance are also acknowledged by WOAH, and can be utlized in the One Health approach (**Glossary**; **Chapters 1** and **6**). There are no existing regulatory precedents for the use of wildlife species in sentinel surveillance. The increasing development and use of novel point-of-detection rapid diagnostics creates an opportunity for sentinel surveillance to be augmented (**section 5.4.3.2**). In addition to sentinel plant surveillance nurseries for plant pests and diseases[5] (Eschen *et al.*, 2019; Kenis *et al.*, 2018), sentinel sites (**Glossary**) have also been proposed for monitoring for new invasive alien plant invasions in key disturbed locations close to points of entry (T. J. Mason *et al.*, 2005), such as sites where there are generally high records of alien plant naturalizations such as waste dumps (Clements & Foster, 1994). See **Supplementary material 5.2** for further details.

5.4.2.2 Species-based surveillance, detection and diagnostics tools and technologies

a) Citizen science – surveillance data input portals and diagnostics platform

Citizen science reporting of invasive alien species presence and or impacts through data portals or hotlines (explicitly dedicated telephone numbers) is now widely recognized as a very effective form of active general surveillance (Crall *et al.*, 2011; Welvaert & Caley, 2016; E. R. Larson *et al.*, 2020; Johnson *et al.*, 2020; Aceves-Bueno *et al.*, 2017; **Chapter 1**, **section 1.6.8**, **Box 1.15**; **Chapter 6**, **section 6.6.2.1**). Large scale citizen-science is being used to monitor disease-carrying mosquitos in southern Europe (Mosquito Alert, 2021). New Zealand has effectively directly targeted its population in biosecurity campaigns as the "eyes and ears" of their national biosecurity system. Reporting of species sightings is through smart phone apps and other online biological recording or reporting platforms such as *iNaturalist* and national reporting hotlines often supported by online taxonomic tools and resources. Many local and open-source adaptable biodiversity, pest and disease reporting apps exist now in many countries (e.g., BioCollect hubs on the Atlas of Living Australia). Portals can be regionally specific, habitat or biome specific (e.g., RedMap in Australia or European Alien Species Information Network in Europe) or organism type specific. In Canada, citizen science is being used for marine invasive alien species surveillance (Delaney *et al.*, 2008). A purpose-built regionalized system is the "Invaders of Texas program" (Gallo & Waitt, 2011).

Limitations around relevance only to relatively easily observable and identifiable species are being addressed by automated off the shelf digital platforms (Schmidt-Lebuhn & Norton, 2017; Wäldchen *et al.*, 2018; **section 5.4.3.2c**). Citizen science portals are less effective for species generally requiring laboratory-based diagnostics (e.g., for micro-organisms and diseases) but not always (see AshTag App. in the United Kingdom for ash dieback). There are also privacy concerns if publicly searchable data repositories can identify landowners legally responsible for invasive alien species on their properties or include unvalidated records of potentially trade-sensitive species of biosecurity relevance. Citizen science reporting is also relevant beyond species distribution and abundance to outbreak management. Data input portals can also be used to capture management activities and their effectiveness.

b) Earth observation – remote sensing detection

Remote sensing is an important tool supporting invasive alien species surveillance and monitoring (C. Joshi *et al.*, 2004), eradication, containment and widespread management (Walsh, 2018). The growing availability and adaptability of remote sensing could make large-scale eradication programmes cost-effective.

Earth observation data from satellites and manned and unmanned aerial systems allows rapid, large-scale and repeatable assessment of areas inaccessible to ground surveys (Pettorelli *et al.*, 2014; Royimani *et al.*, 2019). Artificial Intelligence algorithms allow unmanned aerial systems to return to suspected detections and take repeat images from a number of angles for confirmation (Gonzalez *et al.*, 2016). The capacity for real-time analysis and information delivery is evolving as computing power improves. Ongoing technological and analytical advancements continue to improve both sensitivity and cost-effectiveness. The availability of specific algorithms is a key limitation, as these would need to be developed for each application. Data generally come from two types of sensors; the passive sensors (such as multispectral, hyperspectral, or thermal) and active sensors, such as radar or light detection and ranging (Lidar) using laser pulses to measure reflection times in space, and providing detailed information on vegetation structure and understory (Dash *et al.*, 2019).

While advancements are in progress, satellite imagery is still limited by the resolution, time, frequency of overhead passage and spatial detail which for passive sensors is

5. https://www.plantsentinel.org

limited to cloud-free periods. Satellite imagery currently complements aerial systems, however, the deployment of small low orbital satellite constellations could, in addition to providing capacity for the internet-of-things to remote areas, help specific invasive alien species recognition and monitoring (Schnase *et al.*, 2002). With the growing availability of free or low-cost higher spatial resolution operational satellites such as Sentinel and CubeSats, larger infestations can be monitored; however, small patches and individual plants are still impossible to detect on coarser resolution data, being especially true for the highly heterogeneous landscapes where the occurrence of invasive alien species plant populations is rather patchy (Perroy *et al.*, 2017). While conventional manned aircraft (including helicopters) are still widely used, advances in miniaturization of imagery platforms on unmanned aerial systems is leading to replacement. Very high spatial resolution and flexibility of unmanned aerial systems holds great potential to support targeted monitoring, identify priorities for management and assist eradication and suppression of invasions (Müllerová *et al.*, 2017). Remote sensing from drones (**Supplementary material 5.3** for their limitations) can target specific tasks in time and across limited space, but at finer detection resolutions, working below clouds and avoiding excessive wind speeds. Multiple sensors and high resolution massively increases the data storage and complexity, analytics and processing time (Müllerová, 2019). Sensors can target invasive alien species directly using a specific optical signature or can detect their presence indirectly through methods such as rapid change in a landscape parameter over time caused by their spread. See **Supplementary material 5.3** for further details.

Examples of the use of remote sensing employing unmanned aerial systems imagery in invasive alien plant detection and active management include multiple life forms from the wet and dry tropics to Mediterranean and temperate regions (Elkind *et al.*, 2019; Hill *et al.*, 2017; Lehmann *et al.*, 2017; Lopatin *et al.*, 2019). In the European Union radar is being applied to track Asian hornets (LIFE STOPVESPA, 2021). Remote sensing can also be used well beyond mapping pest and disease distribution, density

Box 5 11 Case study: *Solenopsis invicta* (red imported fire ant) eradication.

In Brisbane (Australia), the eradication of fire ant is dependent on airborne imagery. A camera is mounted beneath a helicopter, which flies over the target area at a height of 150m. Images are captured in three separate frequency ranges: visible, near infrared and thermal. These are then processed in parallel to identify objects that may be fire ant nests which are then destroyed by direct injection **(Figure 5.15)**. As the size and weight of the camera decreases, there is potential to replicate the approach using unmanned aerial systems. This would be significantly cheaper than the use of helicopters, and would allow for significantly more surveillance. Red imported fire ant has been eradicated five of the six times they have established in Australia and these and other tramp ants have been intercepted a total of more than 225 times in recent years. Airborne imaging is a critical technology in this context and may also be applicable to other tramp ant eradication programmes (Hoffmann *et al.*, 2016).

Figure 5 15 **The manual application of a chemical treatment of *Solenopsis invicta* (red imported fire ant) in Brisbane Australia as part of an eradication campaign.**

and damage. GIS and remote sensing technologies are highly advanced in mapping invasive alien species. Indirect remote sensing has been used to detect and map cryptic understory invasive alien species in forests (C. Joshi *et al.*, 2006). Remote sensing is also being used to detect diseases before symptoms occur (e.g., *Xylella fastidiosa* (Pierce's disease of grapevines)) and for assessing habitat suitability for invasive alien species (e.g., Zarco-Tejada *et al.*, 2018). Thermal imagery has been used to replace surveys of invasive alien vertebrates at low density in open habitats and inaccessible locations (Amstrup *et al.*, 2004; Storm *et al.*, 2011) and for monitoring tramp ants **(Box 5.11)**.

c) Automated image-based diagnostics

Machine learning or artificial intelligence is being developed to contribute to the automatic identification and diagnosis of plant pests and diseases (Dawei *et al.*, 2019; Jia & Gao, 2020). Automated image library based digital diagnostics platforms for invasive alien plants, invertebrates and pathogens that can be used on mobile devices are supporting biosecurity inspections and citizen science (Chen *et al.*, 2021; Schmidt-Lebuhn & Norton, 2017; Wäldchen *et al.*, 2018). Artificial intelligence or machine learning algorithms combined with image-processing-based species-recognition software provide automated triage of identification likelihood quickly and easily either back to the user or for uploaded images being signalled to an expert in the context of possible high priority targets. This reduces the effort in searching for false positive notifications which weaken analyses of species distributions (Mo *et al.*, 2017). Similar systems are already being used in public health as a technological tool enabling rapid screening with high accuracy (Chowdhury *et al.*, 2020; van de Kant *et al.*, 2012). The learning architectures and algorithms are becoming highly sophisticated with the development of the convolutional neural network, a deep learning network important in image recognition (Luaibi *et al.*, 2021). For example, the architecture was useful in classifying citrus diseases and insect damage from leaf images to best accuracy with data augmentation to a level of 97.9 per cent (Luaibi *et al.*, 2021) and chicken sound convolutional neural networks were used to differentiate Avian influenza in poultry (Cuan *et al.*, 2020).

d) Volatile detection technologies

Volatile detection technologies can be configured to identify any or multiple targets with a unique volatile profile, or footprint (Cui *et al.*, 2018). These technologies have relevance for a) detection of terrestrial invasive alien species offshore, at port of entry or onshore, b) detection of plants and animals infested with pests or diseases supporting conventional disease diagnostics (Knobloch *et al.*, 2009; Laothawornkitkul *et al.*, 2008), c) screening of international goods, postal mail, travellers, luggage, cargo, containers, ships and aircraft (e.g., Staples & Viswanathan, 2008) and d) improving invasive alien species traps and lures (e.g., Sweeney *et al.*, 2004).

Trained detector dogs are the conventional approach in most situations for a wide range of invasive alien species threats (A. Y. Moser *et al.*, 2020), but require direct human support and high training and maintenance costs. Many hand-held point-of-use detections systems have been developed for volatile detection, including miniaturized portable gas chromatography mass spectrometry and Fourier-transform infrared spectroscopy (FTIR), array-based sensors such as electronic noses and biosensors (Berna *et al.*, 2009; A. D. Wilson, 2017). Key advantages of the volatile detection technologies include reliable detection from small samples, use for single or multiple targets, and low search effort and faster potentially automated screening. International approval may be required where proposed for use to replace other tests agreed under trade conventions (e.g., WTO) to demonstrate equivalent sensitivity and specificity. See **Supplementary material 5.3** for further details including on advantages and disadvantages of the different volatile detector technologies.

e) Pheromone and semiochemical lures

In addition to the traditional use of pheromone lure traps for the management of established invasive alien species (mostly invertebrates as pests largely in horticulture (El-Sayed *et al.*, 2006), such lures can and are being very effectively used in surveillance and detection (Augustin *et al.*, 2012) and delimitation and spread in eradication and containment programs (Brockerhoff *et al.*, 2010; Suckling *et al.*, 2014) of newly established alien species. The general approach is the application of chemical ecology to identify and then manufacture specific pheromones (volatile chemicals used by species e.g., in sexual attraction) or other semiochemicals that attract the target invasive alien species. These chemicals are then distributed in a lure or bait (usually made of material that can store and also slowly release the chemical) inside a trap, such that the target species is attracted too and trapped for detection and identification. The distribution of a network of lures in the area where detection is considered most likely provides a detection system (generally attracting males of the species to a female sex pheromone) that is very useful for demonstrating whether species (in numbers capable or reproduction) are present/absent and to some degree determining species abundance (R. A. Hayes *et al.*, 2016; Suckling, 2015).

f) Acoustic/ultra-sound sensors

Ultra-sound and acoustic surveillance devices can be used to detect target invasive alien animals (Demertzis *et al.*, 2017; Jurdak *et al.*, 2015). Performance is affected by many factors including the sensor type and frequency used, the size and behaviour of the target, the distance between the target and the sensor, the sampling time and the structure of the substrate where the target is found. Some invasive alien animals produce diagnostic sounds and there are a range of acoustic, sound and vibration sensors commercially available. Beyond this, investment may be needed to determine the suitability acoustics for different invasive alien animals in different contexts and to build the digital platforms for data collection and analytics. For marine species identification, an advanced machine hearing framework can be applied to target invasive alien species based on the sound they produce. The hearing framework uses two effective machine learning algorithms, the online sequential multilayer and the graph regularized extreme learning machine autoencoder that provides a higher level of generalization (Demertzis *et al.*, 2018). Checking whether the recognized species is native to its locality or not is carried out by using global positioning systems (Demertzis *et al.*, 2018). There may also be some utility for niche applications such as detection of invasive alien insects in containers, which would be supported by a large body of research on stored grain pest detection and pests in timber (Zahid *et al.*, 2012). Bioacoustic sensor networks have been developed and deployed to detect invasive alien frogs (*Rhinella marina* (cane toad); Hu *et al.*, 2009) and invasive fish (Kottege *et al.*, 2012) from their calls.

g) Point of Care / Lab on a chip, rapid test diagnostics

Handheld rapid diagnostic test platform Point-of-Care (PoC) diagnostics and Lab on a chip (LoC) are becoming increasingly common to diagnose human (Riccò *et al.*, 2020), animal (Gattani *et al.*, 2019) and plant diseases (Lau & Botella, 2017). The global spread of African swine fever and associated rapid diagnostic platform development illustrates their value for tracking invasive alien diseases (Ye *et al.*, 2019). Most handheld systems are designed to detect specific gene sequences or proteins. PoC options for many pathogens rely on immunoassays in dipstick, lateral flow devices or increasingly microfluidic platforms (Weng *et al.*, 2019). These PoC and LoC are new diagnostic kits that generally need to be rigorously tested for sensitivity, selectivity, or performance. While microfluidic options lend themselves to multiplexing to diagnose multiple pathogens, a true combinatorial approach to diagnostics would be required to deliver a generic diagnostic platform. Currently, to detect a pathogen a specific sensor is required and to detect two different pathogens two different sensors are required and so forth. A combinatorial approach with sensors with broad but overlapping detection of pathogens would allow a multiplexed diagnostic that could sense more pathogens than the number of sensors it contains. Pooling samples will depend entirely on the sensitivity of the PoC diagnostic as pooling may dilute the target analyte. There are many lateral flow devices available for diagnosis of particular pathogens, however, there are little data comparing the performance, sensitivity, and specificity of the tests compared to standard laboratory diagnostic assays. International approval may be required where proposed for use to replace other tests agreed under trade conventions (e.g., WTO) to demonstrate equivalent sensitivity and specificity. Next generation sequencing (NGS) may be able to detect the presence of many pathogens and DNA tests are more sensitive than immunoassays. Currently, NGS technology is not available at the PoC as it still requires multiple steps for sample preparation, amplification, sequencing and in-depth analysis. NGS technology improvements are emerging at a faster rate as it is a hot topic of research to enable human health diagnostic improvements. A large research effort would be needed to target next generation sequencing (NGS) to plant pathogens or other targets. The next level of automation is to deploy LoC technology that is capable of high-throughput screening for the pathogens of interest, utilizing a small quantity of fluid samples (Zhu *et al.*, 2020).

h) Track and trace next generation sequencing and meta-barcoding to identify invasive alien species

The COVID-19 pandemic (**Chapter 1**, **Box 1.14**) has demonstrated the effectiveness of real-time genome sequencing on tracking and tracing the virus through movement trajectories of new mutations and strains and therefore spread of an invading organism. This technology approach is being applied now to the management of biological invasions by building global or regional genomics database of a key invasive alien species, both present or considered a potential threat. This allows a) quick identification of any new detections or introductions in terms of origin and likely pathway of spread (Otim *et al.*, 2018; Suarez-Menendez *et al.*, 2020), b) information on global invasion patterns that can help evaluate invasion and impact risks and pick up local rapid evolution or adaptation to new situations (Tay *et al.*, 2022), c) allow real-time monitoring of strategies for and effectiveness of management actions (eradication, containment or widespread management; Yainna *et al.*, 2021).

5.4.2.3 Future technologies

A number of new technologies are being developed and improved for surveillance, detection, monitoring and automated response. These include biosensors and nanotechnology sensors, Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) diagnostics, multiplexed diagnostic real-time handheld Point-of-Care (PoC) diagnostic platforms and disease mRNA biomarkers. These are covered in more detail in the **Supplementary material 5.4**.

5.4.3 Intervention technologies

When an action needs to be taken a) to manage a pathway risk or consequence, b) once a new invasive alien species has been detected or in order to eradicate, contain or control it, or c) in order to manage a site or ecosystem to eliminate or reduce the impacts of invasive alien species or restore ecosystem function, then this is an intervention. This section covers tools, technologies and approaches available to support interventions.

5.4.3.1 Pathway management – prevention options

Managing biological invasion pathways across borders supports prevention of arrival of new alien species and establishment and the movement of invasive alien species through trade supply chains. The traveller, effects and trade pathways for invasive alien species movement are through air and sea travel, conveyance and transport, postal mail delivery and transport *via* parcels, luggage and container transported traded goods.

Prevention treatments for planes and ships are now widely recognized and regularly applied. Planes are decontaminated before take-off or treated with insecticides prior to arrival to prevent the entry of pathogens and insects including disease vectors such as mosquitos. Shipping is subject to the International Convention for the Control and Management of Ships' Ballast Water and Sediments (BWM Convention, **section 5.5.1**). The two main management options include ballast water exchange in accordance with regulation D-1, which is an interim option, and compliance with the discharge standard in regulation D-2, which is ultimately what all ships eventually have to comply with. The three main methods for ballast water exchange are the "sequential" method (complete ballast replacement with seawater), "flow-through" method and the “dilution” method performed at sea at an agreed distance from the arrival country (Molina & Drake, 2016). Organisms are physically removed by the flow, while the higher salinity level of open seawater can kill any coastal organisms present in ballast tanks (Santagata *et al.*, 2008). The flow-through method pumps flow through seawater into a ballast water tank at a volume sufficient for least 300 percent water replacement (Molina & Drake, 2016), but can lead to lower exchange efficiencies than the sequential method because of mixing between the influent and effluent water (Noble *et al.*, 2016). Most ballast water management systems actually employ a combination of two or more additional treatments (Werschkun *et al.*, 2014). The first of these is mechanical filtration of larger particles (organisms) with self-cleaning filter systems followed by electrochlorination or UV irradiation. Other treatments include ultrasound, cavitation and heating which can also lead to physical destruction of undesirable organisms. The other important prevention approach for shipping is the management of hull biofouling and specific niche areas of the hull. There is, however, currently no international convention regulating biofouling and only national or local regulations exist in a few jurisdictions such as Australia, New Zealand and California in the United States. The International Maritime Organization does have biofouling guidelines (**section 5.5.1**). Context and effectiveness of biofouling management have been reviewed by Arndt *et al.* (2021).

Prevention treatments for biosecurity risks associated with cargo (traded commodities, packaging and containers) are already in widespread use. These include chemical fumigation particularly of wooden pallets and cardboard packaging (still largely using methyl bromide even though regulations under the Montreal protocol have been agreed for some time to phase it out to avoid ozone damage). The IPPC have approved sulfuryl fluoride as a treatment for compliance for ISPM-15 (FAO, 2018a) and additional options include dielectric heating and non-wooden pallets. It is recognized that sulphuryl fluoride is a highly effective greenhouse gas (Papadimitriou *et al.*, 2008). Replacements for methyl bromide are rapidly being sought to support irradiation and cold treatment along supply chains for horticultural commodities. Phosphine is currently in use as an alternative to methyl bromide and is widely used to treat most durable commodities and for disinfestation of stored seed and food grains (Fields & White, 2002). However, there is phosphine resistance in many stored grain beetle pests and this has been documented in Australia, India, Morocco, Brazil, the United States and China (Benhalima *et al.*, 2004; Chaudhry, 1997; Collins *et al.*, 2003; H. Navarro & Navarro, 2016; Nayak *et al.*, 2003; M. A. G. Pimentel *et al.*, 2009). Phosphine resistance in stored grain pests has been increasing in severity and is a threat to the continued use of phosphine as an effective control method (Schlipalius *et al.*, 2015).

Low atmosphere pressure systems (Paul *et al.*, 2020) and microwaves are also used for horticultural commodities but are not generally accepted under multilateral trade agreements (Gamage *et al.*, 2015). When managing the threats of biosecurity contamination *via* trade for agricultural commodity supply chains, bilateral agreements are increasingly considering system-based approaches where more than one approach or treatment are applied in sequence to minimize the risk of pest and pathogen contamination (IPPC, 2017b; van Klinken *et al.*, 2020). See **Supplementary material 5.6** for further details.

5.4.3.2 Species-based management technologies

a) Mechanical and manual control of invasive alien invertebrates and plants

Mechanical and manual management takes many forms and operates at different scales, but in general primarily applies to the management of invasive alien plants (Liebman *et al.*, 2001; Csiszár & Korda, 2015; Hussain *et al.*, 2018). Physical management, like chemical management, if not targeted or sustained is more often ineffective than effective particularly if the seedbanks of invasive plants are not considered or addressed. Mechanical control is occasionally applied to other types of invasive alien species, such as rabbits in Australia where it has proved to be a more cost-effective option than poisoning (Mutze, 1991).

For invasive alien plants, physical management comes in a number of forms including manual pulling, uprooting, mowing, cut and removal, bulldozing, mulching, debarking of trees from the collar region, ploughing and grazing (DiTomaso, 2000; Hussain *et al.*, 2018). Mechanical control, in some form can be an effective strategy as part of integrated management of invasive alien plants or/and ecosystem restoration and some "best practice" can be developed for some targets (e.g., S. King *et al.*, 1996). A key understanding is a preference to limit levels of ecosystem disturbance during the treatment, because more disturbance will assist invasive alien plant reinvasion without additional ecosystem restoration activities (DiTomaso, 2000). Generally human applied physical management approaches for invasive alien plants can be effective locally but are not generally practical or effective at larger scales, particularly when only cutting is used, because targeted species, particularly with large rhizomes, resprout and regenerate (e.g., Mwangi & Swallow, 2005). Moreover, the short-term efficacy and the necessity for periodic implementation for sustained control makes physical methods such as cutting uneconomical. An exception to this is the large scale Working for Water Programme in South Africa (**Box 5.19** in **section 5.5.5**) where the programme, has also offered many additional ecosystem service and social benefits for the local communities supported by government investment (Richardson & van Wilgen, 2004; van Wilgen & Wannenburgh, 2016).

Using grazing animals for invasive alien plant control has a huge literature in the pastoral sector (R. G. Smith *et al.*, 2006; Popay & Field, 1996) and also in rangelands (DiTomaso, 2000; Frost & Launchbaugh, 2003; Sheley *et al.*, 1996), but it has also been used in forests (S. N. Adams, 1975) and other ecosystems (Randall, 1996). Most grazing management occurs through the use of livestock species but, in natural ecosystems, goats are often used with obvious risks of grazing native plants as well or escaping containment, which demands care (Frost & Launchbaugh, 2003; R. G. Smith *et al.*, 2006). The use of grazing animals can also spread invasive alien plants species adapted to attach to animal hides or when invasive alien plant seeds are consumed but may pass into animal faeces (e.g., *Vachellia nilotica* (gum arabic tree); Kriticos *et al.*, 1999). Like other forms of physical management of invasive alien plants, the effectiveness of grazing management generally depends on long-term controlled application as the benefits can be quickly lost when the treatment is halted. This limits control cost-effectiveness, unless part of an integrated management or/and ecosystem restoration programme, where there are multiple other benefits for the local communities (Reyes-García *et al.*, 2019).

b) Pesticide management of invasive alien animals and plants

Chemical pesticides remain a key local tool for invasive alien species management. Herbicides can be sprayed on grasses, herbs and shrubs, applied on cut stumps to prevent sprouting, or injected in tree trunks. For invasive alien plants this is the most widely used control method and a wide array of herbicides are available on the market. Different products are used to control invasive alien animals, especially baits under controlled situations. Social acceptability, risks of non-target impacts and wider environmental risks are increasing societal issues and concerns associated with pesticide use. When addressing these societal issues, it is important to take into account the context of values and policies of individual countries. In order to increase the level of safety and acceptability, it is important that control projects include training and protocols to ensure the use of proper personal protective equipment, good quality materials to prevent leaking, proper disposal of pesticide containers, necessary permits, trained personnel and follow-up routines to increase effectiveness. The use of pesticides is also context-dependent, so local conditions need to be assessed to define limitations. For example, as proximity to water is a strong concern, herbicide spraying regulations require minimum distance from water bodies be maintained. This is equally true for vertebrate pest control programmes. The aerial application of the brodifacoum bait to eradicate *Rattus norvegicus* (brown rat) was conducted on the 267-hectare Ulva Island in New Zealand. This resulted in a residual concentration in several coastal species of fish and shellfish (Masuda *et al.*, 2015). Although the concentrations found were low as was the risk for human exposure to the chemical, this example highlights the importance of being aware of the potential side effects. Similar programmes in Italy appear to have not raised such concerns (Capizzi *et al.*, 2016).

There is a large literature dedicated to applications of chemical use in invasive alien species management beyond the scope of the IPBES assessment of invasive alien species. Most best practice manuals seek to optimize and minimize use as well as choose active ingredients and surfactants that degrade fairly quickly and do not contaminate the soil or water. The use of pesticides in invaded natural ecosystems often generates concern so needs to be highly regulated, particularly close to water bodies to avoid off target impacts (Kolpin *et al.*, 1998). In most countries, use depends on local jurisdictional legislation, registration and approval processes. Approval is needed from regulators to use a particular type of chemical or active ingredient, they also approve how the chemical is to be stored and applied and the targets against which it can be used. This is particularly challenging in the context of the use in natural ecosystems, where across jurisdictions generally few registrations exist and this is a problem for management (Pergl *et al.*, 2020). Whereas pesticides developed for controlling alien fish in rivers are very unselective (e.g., Rotenone used in some countries but banned in others), in China an organophosphate pesticide has been evaluated for its selective efficacy against *Oreochromis niloticus* (Nile tilapia) compared to many non-target native species and based on good results it is being proposed to control this target in the wild where impacts on aquatic ecosystems have been very high (Gu *et al.*, 2018, 2019). In an environmental context, the incorrect (e.g., not complying with regulatory and label restrictions) or non-strategic use of pesticides (how and where they are applied) is probably one of the largest causes of failure to achieve effective local management of invasive alien species in space and time (D. Pimentel *et al.*, 1992; D. Pimentel

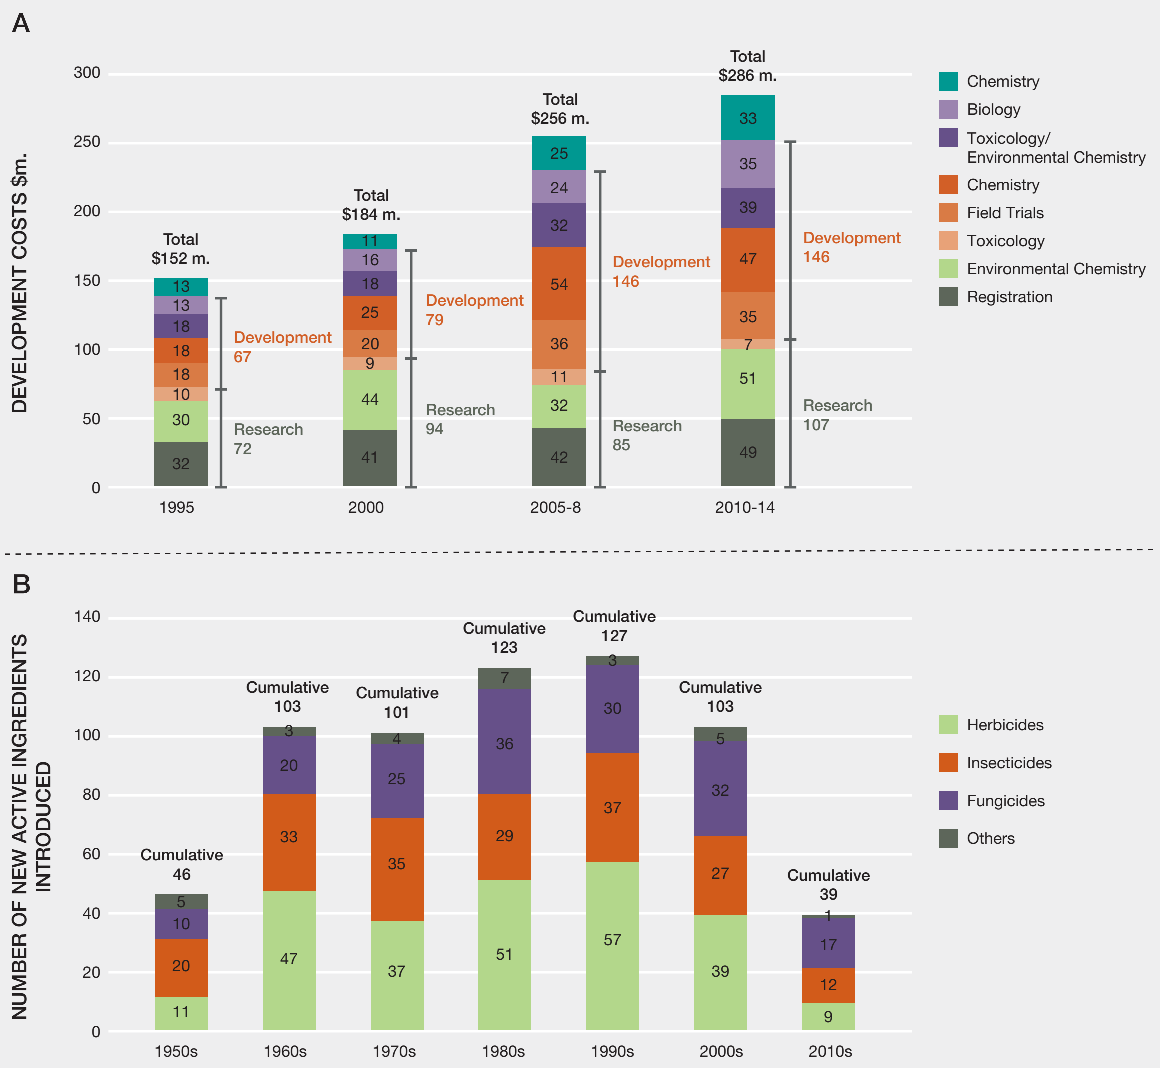

Figure 5 16 **Evolution of new crop protection product.**

Top: discovery and development cost of a new crop protection product (y axis) in 1995, 2000, 2005-8 and 2010-14 (x axis). The overall costs of discovery and development of a new crop protection product increased by 21.1 per cent from $152 million in 1995, to reach $184 million in 2000. From 2000 to 2005-8 period, costs increased by 39.1 per cent to $256 million. From 2005-8 to 2010-14 period, costs increased by 11.7 per cent to $286 million. Source: McDougall (2016), https://croplife.org/wp-content/uploads/2016/04/Cost-of-CP-report-FINAL.pdf, under license CC BY 4.0. Bottom: number of new active ingredients introduced (y axis) per decade (x axis): 1950s to present day. Source: McDougall (2018), https://croplife.org/wp-content/uploads/2018/11/Phillips-McDougall-Evolution-of-the-Crop-Protection-Industry-since-1960-FINAL.pdf, under license CC BY 4.0.

& Andow, 1984) and certainly, results in most human and environmental harm and associated loss of public acceptability associated with their ongoing use. Ongoing use of chemical control needs to be highly regulated and part of effective adaptive management strategies (**section 5.4.3.3**).

Registering new active ingredients has become so lengthy and costly demanding a very large market to be viable and so very few novel pesticides are currently seeking registration (E. D. Booth *et al.*, 2017; Nishimoto, 2019; Phillips McDougall, 2016; **Figure 5.16**). Most new registrations are around new formulations for existing pesticide groups. The main challenges are a) application approaches need to minimize the build-up of pesticide resistance and the global spread of pesticide resistant invasive alien species genotypes (Beckie *et al.*, 2019; Sparks & Nauen, 2015); b) increasing deregistration of key chemical active ingredients (e.g., organophosphates, nicotinoids and glyphosate; WHO, 2010; Sharma *et al.*, 2020) leading to increased illegal off label use (Galt, 2010); c) designing treatment regimes to minimize off target effects (e.g., bitou bush in Australian Coastal heaths –Flower, 2004; Vranjic *et al.*, 2012), d) use in aquatic environments (very few chemicals or adjuvants approved for this; Mesnage & Antoniou, 2018; Grung *et al.*, 2015) and e) an absence of registered herbicides in developing countries can be a major impediment in the control of invasive alien species (Handford *et al.*, 2015). It is critically important that all chemical interventions are undertaken under the regulations for that application and with a strong safety culture for the application staff and the environment (FAO & WHO, 2014).

Nanotech has the potential to reduce pesticide application rates through efficient delivery paving the way for novel applications, devices and systems for delivery of pesticides for invasive alien species management *via* development for agriculture (Manjunatha *et al.*, 2016; Anandhi *et al.*, 2020). Current interest is on three formulation types: polymer-based nano-formulations, inorganic nanoparticles such as silica and titanium dioxide and nano-emulsions. These novel formulations allow the release of active ingredients in a slow and targeted manner, protecting them against degradation and increasing "solubility" of even poorly water-soluble formulations (Manjunatha *et al.*, 2016). Potential risks of nano particles to human and environmental health (the so-called "nanomaterials paradox") has led to delays in application as national nanotech policy and regulatory risk analysis protocols are agreed so the risks are appropriately evaluated (OECD, 2012; Kah, 2015; Agathokleous *et al.*, 2020).

With regard to biopesticides, which come under the same regulatory registration process as chemical pesticides, a review (Glare *et al.*, 2012) stated "Biopesticides based on living microbes and their bioactive compounds have been researched and promoted as replacements for synthetic pesticides for many years. However, lack of efficacy, inconsistent field performance and high cost have generally relegated them to niche products. Recently, technological advances and major changes in the external environment have positively altered the outlook for biopesticides. Significant increases in market penetration have been made, but biopesticides still only make up a small percentage of pest control product". Biopesticides are being applied, for example, against some moths of economic importance (Shao *et al.*, 2018), however they have not been commercially viable against invasive alien plants (Arora, 2003).

c) Robotic technology for targeted management

Robotic technology is increasingly applied to invasive alien species management although this will be challenging in many developing countries without support from international aid programmes. The benefits for management and control activities may be most marked in remote, inaccessible, or broad-scale applications where human actions are costly or dangerous. Robotics can be used to map and characterize invasive alien species (**section 5.4.2.2**) and to deliver a management action (e.g., the application of foliar or granular herbicides; (Carwardine *et al.*, 2016). An autonomous robot can be deployed to operate continuously and may result in significantly less use of chemicals and a reduction of the costs and generally harmful environmental impacts of manned vehicles. Unmanned robotic vehicles are suited to a wide range of aerial, terrestrial and marine applications and can have particular potential for deployment in the management of established pests, weeds and diseases (Jurdak *et al.*, 2015) including marine invasive alien species, but the current technology will be limited for most sessile slow-moving species (D. Smith & Dunbabin, 2007). Robotic platforms can be customized relatively easily to specific tasks and machine learning and artificial intelligence algorithms continue to advance (Devitt *et al.*, 2017). In the field of agriculture, autonomous unmanned ground-based vehicles exist that, in addition to programmed target detection and rapid learning to identify new targets with high accuracy, also include the capability for management decisions and actions. Unmanned ground-based vehicles-based systems are in prototype or in commercial use for many agricultural tasks including pest, weed and disease management, using a range of methods which may be applicable to some invasive alien species management situations. Unmanned Aerial Systems are also being used to deliver pesticides with high levels of precision (Bawden *et al.*, 2017; Lee *et al.*, 2014). There are also robotic technologies currently available for in-water hull cleaning to remove biofouling (**section 5.4.3.1**). Similarly, a robotic automated underwater vehicle developed for environmental monitoring adapted and tested against an undesirable sea urchin on the Great Barrier Reef (Clement *et al.*, 2005; Dayoub *et al.*, 2015) and similar technology is being applied to address vessel in-water biofouling (Scianni & Georgiades, 2019; Tamburri *et al.*, 2020)

The robotic control of unmanned vehicles can be customized to each new application, meaning that each functional system has a high level of invasive alien species target specificity. Systems exist that either recognize the crop and treat all other green material or have learnt to identify specific invasive alien species (Bawden *et al.*, 2017). For example, robotic technologies are starting to be used for weed treatments in crops, pastures and national parks (Olsen *et al.*, 2019; Westwood *et al.*, 2018). Robotic systems for weed management have also been applied against *Vachellia nilotica* (gum arabic tree) in savannas **(Box 5.12)** and alligator weed in rivers (Göktoğan *et al.*, 2010).

Considering system complexity, development costs and sophistication, such technology can only become cost-beneficial and applicable above a certain land value threshold. In the field of marine pest control, the high cost of alternative approaches (including the deployment of divers) may increase the cost-effectiveness. The full costs for the development of an automated underwater vehicle with a robotic injection system for controlling the native crown-of-thorns starfish have not yet been accrued (Dayoub *et al.*, 2015).

Robotics technology can now be bought off-the-shelf. While no full setup for particular invasive alien species applications is readily available, many could be adapted, as demonstrated by several proof-of-concept complexity-testing bespoke systems for invasive alien species management (Ball *et al.*, 2015; Jurdak *et al.*, 2015; Bawden *et al.*, 2017). Technical challenges remain in the field of autonomous on-ground navigation – in particular, using real-time perception and decision-making in harsh environments (Carwardine *et al.*, 2016). Also, requirement of permissions over private land, full control and the "Visual line of sight" in many countries limits the use of unmanned particularly aerial systems. As computing power increases, sophisticated real-time data processing and decision-making using machine learning algorithms will enable a platform to be targeted at particular tasks (Devitt *et al.*, 2017). Current bespoke

Box 5 12 **Case study: Management of *Vachellia nilotica* (gum arabic tree) with robotic technology in Australia.**

In management trials in Australia's Desert Channels region of western Queensland, unmanned ground-based vehicles were deployed for low density infestations of *Vachellia nilotica* **(Figure 5.17)** whereas for poor access infestations, autonomous unmanned aerial systems were deployed for both foliar and granular herbicide applications. Autonomous unmanned ground-based vehicles were used for spraying of low-density *Vachellia nilotica* infestations or configured specifically for spraying over dense stands in open habitats and desert channels. This can increase precision, especially for areas requiring flight beyond visual line-of-sight, reducing both the costs and amount of herbicide, and so the non-target impacts. Still the development costs are extremely high (Carwardine *et al.*, 2016).

systems are complex, whereas use cases are often quite simple tasks. Any current limitation for adaptable data processing systems is likely to be quickly resolved as the technology continues to mature.

d) Lethal control of invasive alien vertebrate pests

Despite lethal control being the basis of nearly all successful invasive alien vertebrate population suppression (Robertson *et al.*, 2017) and eradication programmes (Holmes *et al.*, 2019) and remaining an important tool for managing their impacts on native vertebrates (see below), ethically, it is increasingly controversial (e.g., van Eeden *et al.*, 2020; **Chapter 1**, **section 1.5.3**). Many countries have animal rights laws and have banned or are banning lethal control options and deregistering key toxicants such as sodium fluoroacetate (1080) and Rotenone. Engaging stakeholders is important for decision-making, particularly assessing the acceptability of lethal control particularly for invasive alien species that cause the loss of threatened and endangered native species and harmful impacts on economic livelihoods of local communities (Deak *et al.*, 2019; Sinclair *et al.*, 2020, **Box 5.13**; **Chapter 4**, **section 4.5**). Often politics controls the decision-making, as in the case for management of alien *Hippopotamus amphibious* (hippopotamus) populations in Colombia. Despite high densities there has been limited political will to cull this charismatic species (Castelblanco-Martínez *et al.*, 2021).

Nonetheless, lethal control is still a conventional approach in countries where large populations of invasive alien vertebrates have massive ecological impacts and cause high native species extinction rates. Lethal control has been the main basis of highly successful vertebrate eradication programs on islands around the world (Holmes *et al.*, 2019; B. A. Jones *et al.*, 2016). On large land masses, lethal control can also be effective at reducing the impact of

Box 5 13 The conflicts of lethal control of invasive alien vertebrates' case study: managing wild horses in the Australian Alps National Park.

Equus caballus (horse) is alien to alpine Australia, but wild horse (local name "Brumbies") populations exist there since grazing properties were first allowed on these Indigenous lands in the mid 1800 **(Figure 5.18)**. Since then, wild horses have been enshrined in classic Australian literature and, even after alpine cattle grazing was banned in the 1990s, horses were left unmanaged. Following this, the Indigenous Peoples and local communities and other communities have been in conflict over whether the horses should be cherished or removed. Culling programmes stopped in 2002 and in 2018 these horses were protected under heritage state legislation. Today numbers have increased seven-fold since 2002 clearly decimating the unique habitats of threatened native alpine species (broad-toothed rat, corroboree frog and she-oak skink) with horse rehoming (the only allowed management strategy) proving insufficient (Driscoll *et al.*, 2019). Choice between native and charismatic alien species is always hard, but the Australian Royal Society for the Prevention of Cruelty to Animals (RSPCA, 2021) has decided to support an aerial culling programme, much to the dismay of the horse lovers.

invasive alien vertebrates across short time frames (up to a few years) applied by hunting, poisoning or trapping. It has a long history to support its cost-effectiveness where expertly strategically planned and implemented (Burrows, 2018), but this is rarely the case (Hone, 2007). Where effective, the environmental benefits are well-recognized, even though benefit-cost analyses are rare and are subject to much uncertainty (Newsome *et al.*, 2017). Effective widespread control can be achieved with a good understanding of the local distribution, abundance and population connectedness and planning management at an appropriate spatial scale, together with continual investment (Lurgi *et al.*, 2016). The niche created by removing one invasive alien vertebrate may be quickly filled by immigrants of the same species or by a different species.

Shooting carried out by trained professionals can be a highly-target-specific technique and can minimize the number of animals that need to be culled. In the case of large herbivores or omnivores (including pigs, goats, donkeys, camels, cattle and horses), helicopter-based aerial shooting can achieve rapid population control over large areas. This is less effective where vegetation is dense and not so effective against forest dwelling species such as deer, where ground-based shooting by specialist hunters is more commonly used. Shooting campaigns often involve attaching a tracking device to individual often sterilized animals for social species. Making use of their gregarious nature the tagged animal locates other conspecifics to improve cull efficiency especially at low density. This technique (controversially often termed as the "Judas" approach) has been demonstrated to be highly successful against invasive alien populations of, for instance, *Capra hircus* (goats; K. Campbell & Donlan, 2005), buffalo and feral cattle (More *et al.*, 2015), donkeys (Woolnough *et al.*, 2012), *Camelus* spp. (camels; Edwards *et al.*, 2016) and less effective against pigs (Ramsey *et al.*, 2009). It has also been used against invasive fish (Bajer *et al.*, 2011).

Culling can enhance fertility through earlier reproduction or select for phenotypes that make control more difficult (Newsome *et al.*, 2017). Having the public hunt invasive alien species through the sale of licenses or tags, while potentially cheap, generally leads to perverse trade-offs. Hunters generally reduce their effort as target numbers decline to perpetuate their benefits or there are conflicts of interest when targets are also a food source for the hunter community. Reintroductions into cleared areas are a common occurrence in such situations (Rondeau, 2001). For these reasons, without good collective understanding and planning the benefits of recreational ground-based hunting for invasive alien vertebrates will be largely unquantified and elusive (Bengsen & Sparkes, 2016).

Lethal baiting is a key tool in New Zealand's Predator Free 2050 campaign to remove rodents, possums and stoats (Russell *et al.*, 2015). The combination of toxic bait and delivery system can provide very targeted and species-specific delivery. Available poisons include acute toxicants (e.g., sodium fluoroacetate – or 1080, sodium nitrite or zinc phosphide and para amino-propiophenone (PAPP)), anticoagulants (e.g., pindone and brodifacoum) or fumigants (e.g., carbon monoxide and phosphine; L. McLeod & Saunders, 2013). Zinc phosphide baits are commercially supplied for broad-scale control of mouse plagues and remain an effective way of treating large areas in a relatively short period of time. Electrofishing and piscicide (an odourless, colourless, crystalline isoflavone) are the dominant means used to control invasive alien fish. Rotenone is being de-registered in some jurisdictions because of non-target impacts (McLeod & Saunders, 2013). Widespread and high-density use of these toxicants remains controversial for a number of reasons but is generally highly regulated by jurisdictions to address concerns. Lethal control in a conservation context has been very effective for rodent and rabbit eradication programmes on islands (S. Gregory *et al.*, 2014; Howald *et al.*, 2007; Russell *et al.*, 2015). Island use has continued to be refined, with an increase in the size of island from which rodents can feasibly be eradicated (Howald *et al.*, 2007; B. A. Jones *et al.*, 2016). In most other settings the likelihood of total eradication of an invasive alien species is low. There are reviews of eradication success (Mill *et al.*, 2020; H. P. Jones *et al.*, 2016) and the European Union has guidelines for the eradication of invasive alien vertebrates (Genovesi, 2001). Prolonged use of a single toxicant leads to development of resistance (Twigg *et al.*, 2002). Registration of all toxicants is required for each jurisdiction covering environmental safety, efficacy and relative humaneness with required label registration for use against each specific target. Nonetheless, development of new toxicants for vertebrate pest control continues in the United States, Australia, New Zealand and Europe along with baits and delivery methods specific to particular target species (Begley *et al.*, 2021; T. A. Campbell *et al.*, 2013; Eason *et al.*, 2017; Robertson *et al.*, 2017). In the future, the use of existing self-resetting traps (Carter *et al.*, 2016; Stanley, 2004), toxicant delivery systems, advanced lures and new toxicants with lower residues could be improved. Ongoing use of the same bait-based toxicants causes bait shyness (neophobia) in surviving populations (Garvey *et al.*, 2020). Effectiveness of baiting and trapping varies greatly with the target alien invasive vertebrate species. Cats, rats and to a lesser extent wild dogs are notoriously bait and trap shy and need to be tricked into bait taking (Garvey *et al.*, 2020).

Camera trapping can be used to improve trapping outcomes (Fleming *et al.*, 2014; Meek *et al.*, 2015) and is advancing rapidly with increasingly complex algorithms allowing individual animal recognition either from patterns or facial features. Grooming traps (or sentinel automated spray devices) use shape recognition technology designed to recognize species (e.g., cats) and spray a lethal amount of a toxicant only on the target animal which is then ingested by grooming. Ejector technologies include direct delivery of a lethal toxicant into the mouth of a predator by combining a spring-loaded mechanism with a carnivore lure, which is more likely to be activated by foxes and wild dogs, thereby increasing target specificity (Fleming *et al.*, 2006). Lethal control methods are also best used as part of an adaptive and integrated management approach that aims to reduce the overall quantity of toxicants entering the environment.

e) Fertility control for invasive alien vertebrates

Fertility control tools aim to decrease or stabilize a pest animal population by reducing or halting reproduction. Modelling suggests that targeting females has the greatest chance of effective control at the population level (Caughley *et al.*, 1992). Successful fertility control reduces target population sizes unless flow-on effects (e.g., increased survival of adults and juveniles) exceed the effects of reduced fertility. Fertility is controlled through a) the disruption of key reproductive hormones, b) the use of chemicals to deplete follicles at various stages of development, or c) immune contraception approaches where an immune response is elicited to key reproductive antigens that subsequently interferes with fertilization and/or successful embryo implantation. Effective hormonal or immune contraception methods are available; however, they require the capture or restraint/sedation of the animal to apply the treatment either *via* injection or implant followed by release, or remote delivery *via* darts, which is generally at high cost. With growing public concern about lethal control methods, public acceptability for fertility control approaches is usually high, for high-profile, iconic species.

Fertility control has been applied in the United Kingdom, United States, New Zealand and Australia in rodents, goats, horses, deer, kangaroos and canines (Asa & Moresco, 2019; Cowan *et al.*, 2020) but generally still at very localized scales. There remain very few cases where fertility control has been successfully used to control free-living populations or to achieve eradications. Nonetheless, this approach potentially has broad range of application in vertebrates, limited primarily by the lack of effective bait delivery systems useful in the wild (T. A. Campbell *et al.*, 2011). Other challenges include optimum dose levels, stakeholder opposition (e.g., hunters) and sex specific welfare implications. Applications requiring oral bait delivery or self-disseminating fertility control agents still await development. Applications to-date are principally in containment and control, although fertility control can also aid in eradication of small populations (Hobbs *et al.*, 2000). Surgical sterilization has been used in the management of grey squirrels (Scapin *et al.*, 2019) and bullfrogs (Descamps & De Vocht, 2017) in Europe. For registration, commercially available fertility control vaccines must undertake delivery and effectiveness trials, which generally require a minimum three to five years. See **Supplementary material 5.6** for further details.

f) Classical biological control of invasive alien plants and invertebrates

Classical biological control has an over 100- year history and has been accepted as a long term and effective management tool for invasive alien species by both the IPPC (IPPC, 2017a) and the CBD (ISSG, 2018), particularly for invasive alien plants and invertebrates (ISSG, 2018; Julien & White, 1997; Waterhouse & Sands, 2001; Heimpel & Mills, 2017) in both agricultural and environmental settings (Van Driesche *et al.*, 2010). Classical biological control programmes aim to release host-specific natural enemies of an invasive alien species target, generally from the native range and suited to the recipient environment of the target (Briese, 2000). Classical biological control has not been developed for marine environments, because of safety concerns partly because they are globally contiguous and in general less understood than terrestrial or freshwater ecosystems (Lafferty & Kuris, 1996; Thresher *et al.*, 2000; Secord, 2003). While some consider it remains an option worth considering (Bax *et al.*, 2003), others consider the use of alien biocontrol agents too risky in marine systems (Atalah *et al.*, 2015).

The application of biological control dates back to the uncontrolled use of generalist vertebrate predators as biocontrol agents from the 1700s to early 1900s prior to import restrictions on alien species or regulations built on robust risk assessment (Huffaker & Messenger, 1976; Moran *et al.*, 2013; Waterhouse & Sands, 2001). This includes the release of cats to control rodents, mongoose to control snakes on islands and toads to control sugar cane pests. This gave biological control a bad name because many of these agents became pests in their own right (**Chapter 3, section 3.3.5.2**). These are not examples of classical biological control as these "biocontrol agents" were not selected based on specificity (some being generalist fish; e.g., Fenichel *et al.*, 2010; Ip *et al.*, 2014) or *via* a risk-assessment-based regulatory process and often released against native pests. Classical biological control now has mature regulatory processes for the identification of agents, and for the importation, assessment and release of agents in recipient countries (A. W. Sheppard *et al.*, 2003; Day & Witt, 2019; Barratt *et al.*, 2021) built on internationally agreed best practice principles and guidelines (IPPC ISPM-3; Sheppard *et al.*, 2003; M. Day & Witt, 2019; Barratt *et al.*, 2021). The risk of non-target impacts has been given considerable attention with some considering them too high (e.g., Simberloff & Stiling, 1996), a lead critic has since recognized that the benefits merit careful ongoing use (Van Driesche *et al.*, 2010). The specific and broad international benefits and undesirable non-target impacts of historical biological control programmes are well documented and the benefits far outweigh the risks in the vast majority of programmes (CBD, 2018). Under the CBD, biological control activities now need to take into account access and benefit sharing regulated under the Nagoya protocol, however as a discipline biological control has embraced this process and continues to operate (P. G. Mason *et al.*, 2021).

Successful classical biocontrol agents have included the following:

- Biotrophic fungi for plant targets (particularly rusts, e.g., *Puccinia* spp.) and arthropods (*Beauveria* or *Metarhizium* strains) (Hershenhorn *et al.*, 2016; Morin, 2020; Morin *et al.*, 2006)
- Invertebrate predators or parasites of invertebrate alien species such as parasitoid wasps and flies, entomopathogenic nematodes (Hajek *et al.*, 2007; P. G. Mason, 2021; Waterhouse & Sands, 2001)
- Viruses to control certain invertebrates, such as *Oryctes rhinoceros* (coconut rhinoceros beetle) across the Pacific (Paudel *et al.*, 2021).
- Herbivorous invertebrates from a broad range of groups for invasive alien plants (Julien *et al.*, 2012; McFadyen, 1998; Winston *et al.*, 2014).

Classical biological control programmes can only be initiated against a specific invasive alien plant or invertebrate if there is broad agreement across different stakeholder communities (scientists, conservation organizations, other land managers, policy makers and the general public) and Indigenous Peoples and local communities of the harmful nature of the target. This process needs to consider social, economic and environmental impacts and any conflicts of interest (**section 5.2**). Where the target has spread across multiple jurisdictions with contiguous borders, affected jurisdictions also need to agree about the target and the regulatory processes under which the biological control programme will operate. A precautionary approach may be adopted because classical biological control is invariably of high risk, biocontrol agent releases generally being without controls and self-perpetuating. As classical biological control programmes are not always successful, the public need to understand this. The regulatory process prior to any release decision being made needs to include effective risk communication between all stakeholder communities. The use of structured decision-making processes, supported by rigorous cost-benefit and risk analyses, not only provide a sound broadly accepted rationale for investment in what is generally a long-term activity but also to contribute to the credibility and success of this approach (S. Liu *et al.*, 2011).

Classical biological control is generally not used for eradication, which is a very rare outcome even as part of integrated control (e.g., Morin *et al.*, 2009). Only recently has classical biological control been developed pre-emptively for invasive alien species before establishing in a country and only when eradication is very unlikely following establishment (Charles *et al.*, 2019).

Classical biological control programmes generally have four phases: i) agent selection, ii) agent risk assessment, iii) agent release and iv) post release evaluation (CBD, 2018; Heimpel & Mills, 2017). Each phase may require two to five years.

Agent selection is sourcing a potentially suitable biocontrol agent in the native range of the invasive alien species target. Genetics, such as barcoding, has assisted this reducing the time required to identify and classify candidate classical biological control agents.

Risk assessments for biological control agents evaluate host-specificity of the agent using internationally accepted protocols (Bigler *et al.*, 2006; ISSG, 2018), either in the native range or a post entry quarantine facility in the country of introduction that considers:

- direct impact of the biocontrol agent on non-target species;
- potential for indirect impacts of the biocontrol agent, including effects on organisms that depend on the target pest and non-target species and competition with resident biocontrol agents and other natural enemies (not all practicing jurisdictions require this);
- possible direct or indirect impact on threatened and endangered species, ecosystems, agriculture and forestry, in the country of introduction;
- impact of the biocontrol agent on humans (health, social and cultural), and impact of the biocontrol agent on the physical environment (e.g., water, soil and air).

Risk assessment is generally less onerous for secondary jurisdictions if a biological control agent has been widely tested and established safely in numerous countries.

Agent release can only happen following application for and approval of a release permit by an independent regulatory body based on the risk assessment. Release submissions generally require public comment, scientific peer review and consultation with neighbouring countries before making a decision. The decision assumes that the agent will have unlimited uncontained spread across the target population. Releases may require modification of the recipient environment (e.g., initial cages or nutrient levels) to improve the control agent's establishment and spread.

Post release evaluation is critically important to measure both positive and negative impacts of the biological control agent. Such impacts may appear within two years, but full effectiveness may also take a further 10 or more than 20 years. The best measure of success likelihood is if agents have already been successful in other jurisdictions against the same target. Generally, more than 50 per cent of classical biological control programmes deliver some level of success and benefit cost ratios of total jurisdictional investments in this approach are generally above 20:1 (ISSG, 2018).

Advantages of classical biological control include its relative cost-effectiveness and broad-scale, long-term, non-chemical and target-specific application. The initial implementation costs are generally high compared to, for example, manual adaptive management approaches, but not compared to new pesticide registration and control when it occurs is generally widespread and enduring.

International collaboration is critically important in classical biological control programmes for the following reasons:

- To respect the Nagoya Protocol, as biocontrol agents are generally sourced from the native ranges (in other countries) of invasive alien plants and invertebrates;
- To avoid released biocontrol agents spreading across international borders;
- To share experience and approaches in classical biological control between experienced and inexperienced countries;
- To save considerable time and costs in controlling savings based on sharing of research, control agents, risk assessments and funding for control programmes against shared invasive alien species.

Classical biological control for invasive alien species management is not a profit-making activity and so, outside of agriculture, is usually funded by public or not-for-profit agencies with responsibilities in environmental management. Countries in North America have also worked together under the North American Plant Protection Organization (NAPPO) to take a regional (continental) approach to collectively manage biological control release activities that affect multiple jurisdictions.

The public acceptance of classical biological control globally still remains mixed, despite a high success rate in countries such as Australia, New Zealand, South Africa, Canada and the United States and an extensive history across many countries (Winston *et al.*, 2014; Cock *et al.*, 2016; P. G. Mason, 2021). Some countries have high public and regulatory perceptions of risk around the use of pathogens as biological control agents (for example, United States) even though forty years of evidence elsewhere suggests otherwise (ISSG, 2018). Some classical biological control agents have been released even in the recent past without the application of a rigorous risk based precautionary approach and have led to significant non-target impacts that were avoidable (for example, *Harmonia axyridis* (harlequin ladybird) in Europe; H. E. Roy *et al.*, 2016). Persistent concerns about non-target impacts continue to be addressed through learnings from past practices (Follett & Duan, 2000; Louda *et al.*, 2003) and through rigorous risk assessment (ISSG, 2018; P. G. Mason, 2021).

g) Sterile insect technique and other relevant invasive alien invertebrate augmentative approaches

Sterile Insect Technique is based on mass releases of irradiated infertile males and is a mature technology based on conventional approaches that have proven to be effective for 65 years (Dunn & Follett, 2017). The infertile males compete with wild males to breed with wild females, and this leads to a reduction in offspring and a decline in population numbers. Eventual local pest population extinction is possible. Sterile insect technique is primarily used for agricultural pest management but also has a history of success for managing invasive alien disease vectors (FAO & AEG, 2016). The approach was first used in the 1940s to control *Cochliomyia hominivorax* (New World screwworm) and subsequently *Glossina* spp. (tsetse fly), *Pectinophora gossypiella* (pink bollworm), *Cydia pomonella* (codling moth) and *Delia antiqua* (onion fly), with recent applications against mosquitos (e.g., *Aedes aegypti* (yellow fever mosquito), *Aedes albopictus* (Asian tiger mosquito)) as vectors of arbovirus diseases (e.g., Dengue fever) (Dyck *et al.*, 2005; Poncio *et al.*, 2019). The technique has also been applied to crayfish (Aquiloni *et al.*, 2009). The technique requires the production and release of enough sterile males to achieve at least 50 per cent of all matings by wild females and to compensate for loss of fitness caused by the irradiation treatment (Helinski & Knols, 2008; Holbrook & Fujimoto, 1970; Mayer *et al.*, 1998) and is also considered more effective if females are not released (Dyck *et al.*, 2005; A. S. Robinson, 2002). With the advent of modern genetics of fertility novel approaches could broaden out Sterile Insect Technique to a range of other invasive alien invertebrate targets (Choo *et al.*, 2018). Sterile insect technique is frequently used as part of integrated pest management strategy, in combination with insecticides and baiting strategies. See **Supplementary material 5.7** for further details.

h) Viral biological control of invasive alien vertebrates

Viral biological control is a special case of classical biological control where the classical biological control agent is a taxon-specific virus (critical), and the target invasive alien species is (in general) an invasive alien vertebrate. Viral biological control is predicated on the discovery of a suitable viral agent and is generally most effective when the invasive vertebrate target is an animal population naïve to the pathogen. Such pathogens also require high virulence, transmissibility and relative humaneness in the method and speed of kill (when compared to other approved control methods). Over time resistance builds up to an equilibrium of lower viral pathogenicity or virulence as individual and "herd" (population-level) immunity develops. Therefore, viral biological control programmes need a long-term strategy to find new more virulent viral strains for re-release to resuppress target population (Cox *et al.*, 2013; McColl *et al.*, 2016). As with classical biological control, viral-based approaches rarely eradicate a widely established target population. The best results will be obtained when viral biological control is one component of an integrated pest-management strategy that includes other (conventional or novel) approaches. Viral biological control depends on strong public support and a bespoke national regulatory system to vet the non-target and any other environmental risks or international concerns (Cooke & Fenner, 2002).

This approach has only ever been applied for alien vertebrates in Australia and then carried to New Zealand through the release and natural dissemination of the Myxoma virus (MYXv) in the 1950s and Rabbit haemorrhagic disease virus (RHDv) in the 1990s for the viral biological control of *Oryctolagus cuniculus* (rabbits; Cooke *et al.*, 2013; Saunders *et al.*, 2010). That Australia and New Zealand are islands reduces the risk of the pathogen spreading back to the native range of European rabbits, although the viruses released in Australia were already present in the native range from where they were largely sourced. This approach is not appropriate where contiguous land masses or water bodies can allow epidemic spread between targeted invasive and native populations. A contemporary example is the ongoing evaluation of cyprinid herpesvirus 3 (Cy-HV3, carp virus) as a viral biological control agent for European carp in Australian waterways. Despite extensive searches, a species specific lethal natural pathogen of *Rhinella marina* (cane toad) has not yet been identified (Shanmuganathan *et al.*, 2010), demonstrating a key limitation in this approach. Similarly viral biological control of feral cats has been used to aid the eradication of cats from sub-Antarctic Marion Island (Bester *et al.*, 2002), but has little practical use elsewhere as this virus is endemic in most cat populations globally so resistance will be widespread and no others are currently considered suitable (Tracey *et al.*, 2015).

Public acceptance of releasing viruses to control invasive alien species may differ depending on differing socio-political perspectives. Lethal biological control methods for sentient lifeforms such as vertebrate pests continue to raise animal welfare concerns particularly in targets also kept as pets or farm animals. Values are changing. From a humanness perspective Myxoma virus (MYXv) would unlikely be approved for release in Australia today, and RHDv was considered more humane than other approved rabbit control methods due to its extremely fast disease progression (Sharp & Saunders, 2011). Continued use of RHDv nonetheless still encounters resistance, but mainly from outside Australasia. In Australia the approach is supported by the local Royal Society for the Prevention of Cruelty to Animals (RSPCA, 2019). Many animal diseases (e.g., Cy-HV3, carp virus) are notifiable under the WOAH presenting another challenge, although the WOAH also assesses levels of specificity for all notifiable pathogens. Risks can be managed if animal and animal product movement can be controlled and developing a vaccine to protect non-target individuals (i.e., pets) may be prudent (Schirrmeier *et al.*, 1999). See **Supplementary materials 5.6** for further details.

i) RNA Interference

RNA interference (RNAi) describes the process whereby a mirror image double-stranded RNA (dsRNA) molecule of the target gene is created, applied, and once it has entered a cell, will silence or modify target gene expression without genetic modification. RNAi is a widely used molecular technique for selectively inactivating genes without the need to create a special strain or modify the genome of the target organism **(Table 5.5)**. Delivering dsRNA molecules to virtually all eukaryotes induces the RNAi silencing process, whereby the dsRNA molecules mediate a highly-specific destruction of any messenger RNA with a complementary sequence, resulting in suppression of a targeted gene's expression (D. H. Kim & Rossi, 2008). Due to RNAi's sequence-specificity, dsRNA molecules can be designed to be highly species-specific (Baum *et al.*, 2007; Pan *et al.*, 2016; Whyard *et al.*, 2015).

The RNAi approach has been proposed as a novel means by which to control plant pathogens, including viruses (Tenllado & Díaz-Ruíz, 2001; Mitter *et al.*, 2017) and the fungus *Fusarium* (Koch *et al.*, 2017; Machado *et al.*, 2018; Weiberg *et al.*, 2013), invasive alien plants such as Phragmites (reed; Hazelton *et al.*, 2014) and invasive alien ants (Gruber *et al.*, 2017), moths (e.g., *Helicoverpa armigera* (cotton bollworm); Z. X. Lim *et al.*, 2016) and *Aedes aegypti* (yellow fever mosquito; Whyard *et al.*, 2015). RNAi is also applicable to animal, zoonotic and human diseases. Linke *et al.* (2016) used bacterial vectors that targeted avian mucosal epithelial cells to deliver RNAi against two avian influenza genes. In this application, RNAi is injected into the tail of wild-caught female prawns. The offspring of these females can then be introduced into farm ponds with a reduced risk of introducing the diseases circulating within wild prawns – including the devastating disease, white spot. Advantages and disadvantages of RNAi are given in **Table 5.5**.

Mutations in the RNAi machinery of the target organism might compromise RNAi effectiveness (Khajuria *et al.*, 2018).

Table 5 5 **The advantages (left column) and disadvantages (right column) of RNA interference in the context of controlling invasive alien species.**

Summarized from information in Vogel *et al.* (2019)

Advantages	Disadvantages
Exogenous RNA interference does not use a genetically modified technology (free of genetically modified regulatory requirements in most jurisdictions)	Endogenous RNA interference use required genetically modified targets (Subject to genetically modified regulations); exogenous RNA interference may require regulatory review in some jurisdictions
Highly- specific and yet adaptable to many species	Limited to one target invasive alien species for each application
Wide range of potential target genes could be targeted	Requires an annotated genome of target for gene selection
Non-chemical (biological) and hence negligible impact on the environment	Poorly stable in the environment so requires an effective encapsulation and delivery mechanism
Likely social and has market acceptability	Likely to be expensive until biotech develops low-cost production systems
Target resistance development can be quickly countered through realigning RNA interference sequence to the resistance gene	Sequence homology in other species
Can improve, facilitate or supplement existing strategies when used in the context of an integrated pest management strategy	Lack of uptake by some species

Should a target evolve resistance, the dsRNA molecules can be quickly redesigned to circumvent the resistance gene mutations. In plant pathogens such as viruses, where any treatment is difficult, or for fungal pathogens where increasingly virulent strains emerge, or fungicide resistance is developing, RNAi provides strong new potential opportunities. The key challenge in the development of an RNAi application lies in formulating the product to deliver the dsRNA effectively to the target animals and the relevant target cells.

The exogenous use of this approach is generally considered safe and does not require regulation in some countries. The only material concerns seem to be persistence of the formulated delivery systems, but new stable formulations are being developed. If nanotechnology is used, then separate concerns may arise from this. It is anticipated that the technology will gain reasonable community acceptance. As this approach is still relatively new with technical challenges still to be addressed there remain very few cases where RNAi as a topical application has provided effective invasive alien species management (Das & Sherif, 2020). The method could become the next generation of pesticides or may improve the cost-effectiveness by replacing irradiation for the sterile insect technique (**section 5.4.4.2.g**). See **Supplementary material 5.6** for further information.

j) Genetic-control approaches (including gene-drive)

The objective of genetic-control approaches is to reduce the fitness or success of an invasive alien species in its invaded environment. The aim is generally to force the population towards one sex (generally male biased) which, if complete, will lead to extinction (Teem *et al.*, 2020). Research into these methods, particularly for invasive alien animals, has made significant advances towards application (Bax & Thresher, 2009; Gierus *et al.*, 2022; Thresher, van de Kamp, *et al.*, 2014). There are two general approaches to genetic control: (a) exploiting natural genetic variants that lead to sex bias in progeny, such as the Trojan Y-Chromosome strategy (Gutierrez & Teem, 2006); or (b) genetic modifications that lead to sex biases or induce population fitness reductions in other ways. A few are being explored (e.g., *Limnoperna fortunei* (golden mussel); Rebelo *et al.*, 2018), but no off-the-shelf genetic-control tools are currently available. Genetic control could be applicable to most sexually reproducing invasive alien species and, for environmental applications, could address currently uncontrollable widespread established invasive alien species in contained settings (e.g., invasive alien fish in closed river systems or invasive rodents on islands).

Genetic-control approaches have a number of significant advantages:

- Locked in and spread only within sexual reproducing populations i.e., strict species specificity (except possibly in some fungi which exhibit asexual gene transfer).
- Dissemination of control is mediated by the invasive alien species itself.
- No environmental residues where successful eradication is the outcome. Genetic modification is of only a few genes which are naturally broken down on death.

- Potentially effective over large geographic areas (depending on gene flow in pest population).

- Humaneness – these technologies are not lethal if reducing reproduction is targeted (Teem *et al.*, 2020), though strongly sex-biased populations may result in behavioural stress.

The Trojan Y-chromosome strategy in fish (currently under development for carp and tilapia) naturally alters the sex determination chromosomes XX♀ and XY♂ to create sex-reversed super-males (YY♀) which, if continuously released into invasive alien species populations in the field, generate only male or super-male progeny through standard Mendelian inheritance (traits in 50 per cent of progeny) (Teem *et al.*, 2020). The resulting male-biased population could ultimately collapse leading to extinction. Broader application of this approach to other target species will depend on whether they have appropriate sex determination systems.

Synthetic genetic modification allows increased opportunities for sex manipulation. An approach for "daughterless" carp for example has made it to the proof-of-concept stage (Thresher, van de Kamp, *et al.*, 2014). Here sex-biasing gene constructs are implanted in the genome of candidate fish. Their fertile offspring, if released and make up a high enough proportion of the population should, through natural inheritance (a reproductive event where a wild-type passes the gene construct on to 50 percent of offspring), drive populations male-biased. This requires large single or multiple releases of these genetically modified invasive alien species genotypes. Large initial invasive alien species population size increases the cost of application (numbers of modified individuals that need to be bred up and released) and time to control. An expert assessment of genetic options for the management of sea lampreys in the United States prioritized such a Mendelian "sex-ratio drive" approach (Thresher *et al.*, 2019). In theory, this approach is applicable to other invasive alien species (Thresher, van de Kamp, *et al.*, 2014). If this type of control fails (or succeeds) the associated genetically modified organisms will be bred out of the population.

A meiotic "gene-drive" mechanism is one in which inheritance of such genetically modified deleterious gene constructs would be much higher than 50 per cent. This could deliver a step-change in population suppression or eradication rates. Natural gene-drive mechanisms exist. The t-allele is a natural, lethal when homozygous, mutant in mice that is inherited by greater than 50 per cent of progeny of heterozygous male carriers. Genetically linking the t-allele to the male Y sex chromosome (called T-Sry) could also mean a far greater proportion of progeny are male (Kanavy & Serr, 2017). A synthetic T-Sry approach for mice is now at the proof of concept stage (Gierus *et al.*, 2022). There are several other naturally occurring selfish genetic elements in wild populations of most organism types (so called natural gene-drives) that could potentially be modified into self-sustaining meiotic gene-drive systems without the need for synthetic genetic modification (Ågren & Clark, 2018; Wang *et al.*, 2014).

Synthetic genetically modified gene-drive mechanisms have now been demonstrated in mosquitoes (Adolfi *et al.*, 2020) and rodents (Gierus *et al.*, 2022). New CRISPR-based gene-editing tools have provided a step-change for this technology development. Synthetic gene-drive systems could drive any potentially deleterious gene into the population. The highest precision genetic engineering tool so far is a new class of "base editors" (programmable protein machines) that can individually replace all four nucleotides of DNA selectively and efficiently, without the need for double-stranded DNA breaks (Gaudelli *et al.*, 2017). These have the potential to make single nucleotide alterations; the smallest and most precise way to make deleterious modifications to genes for invasive alien species control. This may bring broader applications beyond sex-biasing, for example, altered disease resilience or susceptibility to otherwise innocuous chemical agent etc (Legros *et al.*, 2021). Once constructed, the modified organism needs to be assessed for efficacy and the heritability of the deleterious gene into the invasive population prior to regulatory approval. Effectiveness will be slower for target species that have lower reproductive rates, although releasing more modified individuals may speed up time to effectiveness.

Addressing public acceptability for genetic control tools in their various forms has become an independent research focus (Kirk *et al.*, 2019; MacDonald *et al.*, 2020; Mankad *et al.*, 2022; Simon *et al.*, 2018). To progress this there are several open online networks and forums, open and transparent research principles and codes of ethics that the key research agencies have signed up for both the research and field trials. Risk analysis and addressing public concerns of such approaches is therefore critical for seeking and obtaining approvals and supporting prior and informed consent with Indigenous Peoples and local communities in areas where this technology is being considered for deployment (Taitingfong, 2019). As with all invasive alien species control programmes, ecological and genetic modelling studies are also critically important for pre-evaluating effectiveness and likely impacts for any given invasive alien species (e.g., Birand *et al.*, 2022; Thresher, Hayes, *et al.*, 2014; **section 5.6.3.2**). Regulatory acceptance and approval are also mandatory so as to ensure researchers work closely with regulators from the start to ensure common understanding of the risks and the concerns.

Gene-drives that could spread "uncontrolled" within a species are highly unlikely to be acceptable. There is always a risk of gene transfer into desirable native populations of the same species. Risk management could be through developing and including a genetic mechanism to stop the unlimited spread of synthetic gene-drive carrying individuals. This is a focus of current research and a process of risk analysis has been developed to assess this in detail (K. R. Hayes, Hosack, Ickowicz, *et al.*, 2018). As no successful gene-drive system has been developed and applied, it is too early to consider that uncontrolled gene-drive systems are the only option (Esvelt & Gemmell, 2017). If gene-drives fail to eradicate the target or only suppress target populations. synthetic gene-drive carrying individuals could also theoretically persist in the environment (Champer *et al.*, 2021). Persistence in any form may not be acceptable (Legros *et al.*, 2021).

The United States National Academy of Science Engineering and Medicine has released its landmark discussion paper, Gene-Drives on the Horizon (National Academies of Sciences, Engineering, and Medicine, 2016). A shorter discussion paper was also released by the Australian Academy of Science and Technology, titled Synthetic Gene-Drives in Australia (Australian Academy of Science, 2017). Both reports discuss the practicalities and risks of the science and its application and make recommendations in relation to physical containment. The IUCN has also recently released a report entitled "Genetic frontiers for conservation: an assessment of synthetic biology and biodiversity conservation" reviewing the risks and potential of these technologies (Redford *et al.*, 2019), as has the National Invasive Species Council in the United States (ISAC, 2017). This report includes a number of case studies and chapters on governance. Some more recent relevant reports include: a) Synthetic gene drive: between continuity and novelty (Simon *et al.*, 2018), b) Gene Drive Organisms: Implications for the Environment and Nature Conservation (Dolezel, Simon, *et al.*, 2020) and c) Beyond limits – the pitfalls of global gene drives for environmental risk assessment in the European Union (Dolezel, Lüthi, *et al.*, 2020). See **Supplementary material 5.6** for further information.

5.4.3.3 Site-based management approaches

Site-based management and ecosystem-based management strategies as discussed in **sections 5.1**, **5.2** and **5.3**, aim to suppress the long-term impacts of invasive alien species on biodiversity and ecological assets at that location or in that ecosystem. These approaches tend to integrate invasive alien species suppression and site/ecosystem restoration. This section briefly covers integrated invasive alien species management and the incorporation of restoration science mainly in terrestrial ecosystems. Restoration in marine environments is currently considered to be largely ineffective once invasive alien species are established and spread.

a) Adaptive integrated management strategies

Integrated management of invasive alien species is the equivalent of integrated pest and weed (Hatcher & Melander, 2003) management strategies in an agricultural context. Integrated strategies are where more than one approach is used in combination either in sequence or parallel. This could be a combination of approaches (e.g., chemical and biological) to manage one or more invasive alien species at a given location, or it could mean the integration of invasive alien species management with site/ecosystem restoration or both. What is very important in integrated strategies as for sites or ecosystems is that they are very context dependent. As such they need to be treated as an experiment from the start and developed and extended using an adaptive management approach. Fire is also often used as part of integrated invasive alien plant management in grasslands, savannas and rangelands, but needs to be used with caution (L. Provencher *et al.*, 2007; Weidlich *et al.*, 2020). The African invasive alien plant *Vachellia nilotica* (gum arabic tree) has become a major savanna invasive alien species in Asia and Australia. In Indonesia a management programme has been supported by the United Nations Global Environment Fund in the Baluran National Park in east Java since 2016 (Zahra *et al.*, 2020). Multiple management options of physical action (4 options), fire, biochar, biological (competitors and antagonists) and social (education and adaptation) are being integrated through an adaptive management approach in this ecosystem **(Figure 5.19)**.

While the number of invasive alien species exceeds the capacity for management, not all species pose the same risk to the nature, nature's contributions to people and good quality of life (**Chapter 4**, **sections 4.3**, **4.4**, **4.5**, **4.6**). Thus, it becomes critical to evaluate the feasibility of applying different management strategies, taking into consideration the cost and benefits of each. Unsuccessful programmes do not encourage public and stakeholder support for future actions (Zimmerman *et al.*, 2011), so management decision-making processes (**section 5.2**) bear the responsibility of first assessing the likelihood of success of any management action **(Figure 5.1)**. Management programmes are dynamic in time and space and operate at different temporal scales (Kueffer *et al.*, 2013) as they must change with the invasion status of the target species (e.g., a species' distribution, position on the invasion curve, abundance or impact), and as scientific knowledge and societal perceptions change (e.g., Davies *et al.*, 2020). Management is implemented within unpredictable, complex socioecological systems (Pyšek *et al.*, 2020; R. T. Shackleton, Larson, *et al.*, 2019). This adaptive management approach is fundamental to all effective natural resource management and has two components: (1) to learn and adapt and (2) to do so purposefully with relevant partners (Latombe *et al.*, 2019; Roux *et al.*, 2011). The core principle of adaptive

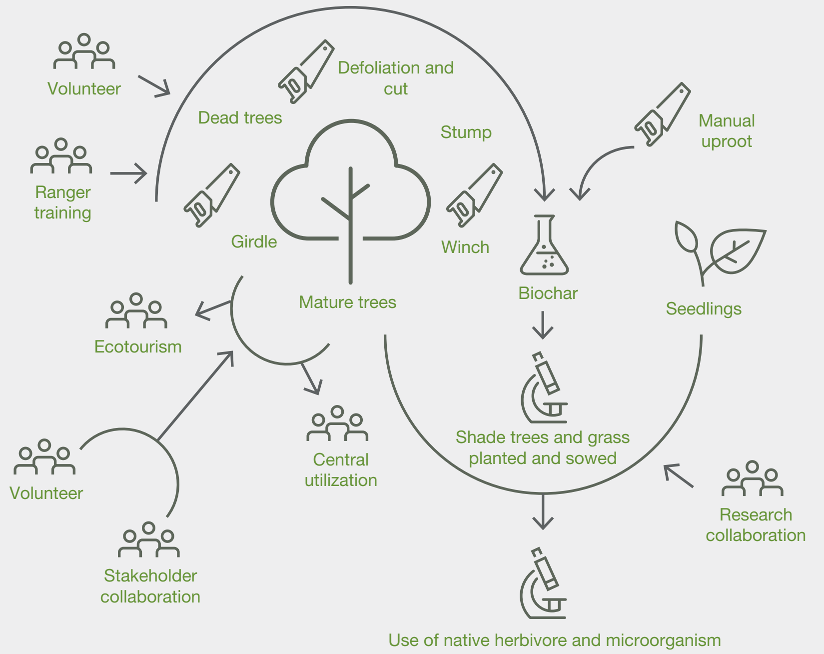

Figure 5 19 **Plan for integration of stakeholder engagement and management strategies for *Vachellia nilotica* (gum arabic tree) management in Baluran National Park, Indonesia.**

This figure shows the suggested optimum method integration of control strategies of *Vachellia nilotica*. Source: Zahra *et al.* (2020), https://doi.org/10.13057/biodiv/d210115, under license CC-BY-NC-SA 4.0.

management includes setting clearly articulated objectives around a future desired state (K. Park, 2004). Adaptive management is learning by doing approach so is contingent on the implementation of a monitoring programme that is able to quantify which action(s) led to changes in the distribution and abundance of invasions, and the ecosystem response and why. The agreed best course of management from a possible suite of actions is then selected and modified in a continuous adaptive cycle of implementing actions, monitoring, learning, and adjustment of new actions to improve the efficiency of management practices (Roux *et al.*, 2011; Zalba & Ziller, 2007; **section 5.3**). Adaptive management can be supported by sequentially considering prioritization based on actual and/or potential impacts, assessing the feasibility and likelihood of success of different control approaches, and clearly defining the goal of the management response (**section 5.2**). This assists in adjusting and selecting the most appropriate management strategy (Lyons *et al.*, 2008). Uncertainties and gaps in information are inherent in the knowledge base upon which adaptive management is applied, and when new information becomes available and scientifically tested, management strategies can be adjusted and improved (K. Park, 2004; **section 5.6.2**). Stakeholders are an integral part of the system, and their full support is a precondition of success. The likelihood of long-term sustainable co-management can be enhanced with a common understanding of the problem, including the responsible management agency, general public and other stakeholders and Indigenous Peoples and local communities (R. T. Shackleton, Adriaens, *et al.*, 2019; R. T. Shackleton, Larson, *et al.*, 2019; **section 5.4.1**).

b) Ecosystem restoration

Invasive alien species not only alter *in situ* ecological community assembly, but also the intended endpoint communities following ecosystem restoration (D'Antonio & Meyerson, 2002; **Chapter 1**, **Box 1.7**; **Chapter 6**, **Table 6.7**, **section 6.7.1**). As such, controlling invasive alien plants has become a significant ecosystem restoration management problem (D'Antonio *et al.*, 2016; Prior *et al.*, 2018; Weidlich *et al.*, 2020). Ecosystem restoration is also an important follow-up to invasive alien species management. Because invasive alien species may hinder the establishment and growth of native species, passive ecosystem restoration (the removal of the invasive alien species) may not be enough, and active ecosystem restoration may be implemented (Brancalion *et al.*, 2019). This may include the use of alternative native species to functionally replace the removed invasive alien plants (Gigon, 2007) or more controversially use of invasive alien species for restoration, when this might be acceptable (e.g., Vimercati *et al.*, 2020). Ecosystem restoration through increased biotic resistance (**Glossary**), can also help prevent colonization of these sites and ecosystems by other invasive alien species that might replace those removed. Legacy effects, where the degradation history of the invaded site or ecosystem including changes in soil nutrients (Nsikani *et al.*, 2018), determines the capacity of the site to self-restore or lead to unexpected consequences following removal of the invasive alien species, need to be understood and managed (Stephens *et al.*, 2009; **Chapter 3**, **section 3.3.5.1**; **Chapter 6**, **section 6.3.3.3**). In some contexts it may be important to ensure restored sites are connected to unrestored sites such as in aquatic restoration situations (Besacier-Monbertrand *et al.*, 2014). The success of ecosystem restoration on sites where invasive alien species are managed also depends on long-term monitoring to understand and manage any further incursions or re-invasions (Trowbridge *et al.*, 2017). A recent global review has shown that non-chemical (mainly mowing and prescribed fire) and chemical (mainly glyphosate) control of invasive alien species was used in 58 per cent and 42 per cent of studies respectively (Weidlich *et al.*, 2020). Decisions on which control method to use are dependent on the growth form of the invasive alien species and resources available for control. The review also found most studies were in temperate deciduous forest and grasslands in developed countries, where chemical control was widely used, whereas in developing countries (low access to technology solutions) where ecosystem restoration has been undertaken used only non-chemical methods. Greater knowledge is needed on how best to manage invasive alien species as part of ecosystem restoration in developing countries (where most high diversity ecosystems occur). A number of guidance documents exist on how to manage the risks of invasive alien species during ecosystem restoration management (UPGE, 2020). As the Indigenous Peoples Local Biodiversity Outlook noted, traditional knowledge can provide contributions to ecosystem restoration in relation to invasive alien species. Incorporating traditional knowledge into ecosystem restoration provides opportunities to strengthen partnerships leading to improved project implementation while increasing ecological viability, social acceptance and economic feasibility (Forest Peoples Programme *et al.*, 2016). See **Supplementary material 5.7** for more details and Indigenous Peoples and local community examples.

5.4.4 Summary tables

Based on the evidence collated in this section we provide three comparative summary tables for these technologies, tools and approaches for a) broad effectiveness of each approach, tool or technology for four different management contexts across the invasion continuum **(Table 5.6)**, b) broad relevance of each technology for application to a given weed, pest or disease type by sector **(Table 5.7)** and c) comparative summary for each technology across management contexts for cost-effectiveness, the time between the application of the technology and some desired outcome/impact and relevance of application at different spatial scales of response or management **(Table 5.8)**. The application of these technologies is limited for marine systems, but where applications have been made these have been discussed.

Table 5 6 **Comparative guide to applicability of decision-support tools and each approach, tool or technology discussed in sections 5.2 and 5.4.**

Assessment categories relate to use contexts discussed in the individual technology specific subsections. The table distinguishes four broad areas of management action associated with the four stages of invasion curve in **Figure 5.1**. The assessment categories are generally relevant (✓), not generally relevant (✗) and some relevance (✗✓), with footnotes providing additional information.

TECHNOLOGY	BROAD AREAS OF MANAGEMENT ACTIONS			
	Surveillance/ Detection	Eradication	Containment	Widespread Control
Decision-support tools				
Qualitative and quantitative decision-support tools	✓	✓	✓	✓
Relevant databases and analytics for management of biological invasions	✓	✓	✓	✓
Surveillance, detection and diagnostics				
Digital data mining – crowdsourcing general surveillance	✓	✓	✓	✓
Sensor-networks and smart traps	✓	✓	✓	✗✓
Screening technologies	✓	✗	✗	✗

Table 5 6

Ecosystem restoration	✗	✗	✗✓	✓

6. Remote sensing supporting landscape management and only likely to increase as global broadband internet access become ubiquitous e.g., *via* low orbital satellite constellations
7. Pheromones and semiochemical lures are considered under surveillance, detection and diagnostics but it is reconized that they may be used as an intervention technology (**section 5.5.4**).
8. Generally, these approaches do not provide widespread long-term control except when populations are contained i.e., within an offshore or mainland island context.

Table 5 7 **Comparative guide to the applicability of decision-support tools and technologies discussed in sections 5.2 and 5.4.**

The table distinguishes application of decision-support tools and technologies to invasive alien plants, invertebrates, vertebrates or disease pathogen by sector. Decision-support tools and technologies were assessed with consideration to the contexts in which they are used, as discussed in the individual technology specific subsections. The assessment categories are generally relevant (✓), not generally relevant (✗) and some relevance (✗✓), with footnotes providing additional information. In the context of zoonotic diseases this table refers to diseases transmissible between animals to humans rather than diseases of animal origin largely transmitted between people (e.g., COVID-19).

TECHNOLOGY	Terrestrial invasive alien plants	Aquatic invasive alien plants	Agricultural invertebrate invasive alien species	Environ. invertebrate invasive alien species	Terrestrial vertebrate invasive alien species	Aquatic vertebrate invasive alien species	Plant pathogens	Terrestrial animal pathogens	Aquatic animal pathogens	Zoonotic/ Vector borne pathogens	Marine invasive alien species [9]

17. Only shows effectiveness for fungal pathogens in agriculture using fungicides no demonstrated effectiveness in native ecosystems invaded by invasive alien pathogens.
18. Rarely effective (Scott, 1995).
19. Genetic-control approaches for disease resistant commercial plants and animals is widely used in agriculture but this is not discussed in **section 5.4.4.2**

Table 5 8 Comparative guide to decision-support tools and technologies discussed in sections 5.2 and 5.4.

This table provides an assessment of decision-support tools and technologies for cost-effectiveness, the time between the application of the technology and some desired outcome/impact and relevance of application at different spatial scales of response or management. Decision-support tools and technologies were assessed with consideration to the contexts in which they are used, as discussed in the individual technology specific subsections. Timeframe of benefit can be: short (quick but effective only in the short-term effective); medium (effective only in the medium term); long (within years of application and providing long-term effectiveness). The assessment categories are generally relevant (✓), not generally relevant (✗) and some relevance (✗✓), with footnotes providing additional information.

TECHNOLOGY	Cost-effectiveness	Timeframe of benefit	Site	Catchment	Region (within country)	Country

20. Pheromones and semiochemical lures are considered under surveillance, detection and diagnostics but it is reconized that they may be used as an intervention technology (**section 5.5.4**).
21. Likely to vary on context e.g., land values and/or area of application.
22. Only in contained populations so far without an oral delivery system (not currently available).
23. Where feasibility and success likelihood are high on species by species basis.
24. Where feasibility and success likelihood are high for some invertebrates (sterile insect technique or RNAi) and pathogens (RNAi) only.
25. As not yet field tested so only cost-effective if it works.

5.5 MANAGEMENT STRATEGIES

This section reviews the effectiveness, successes and failures of pathway management (prevention) and species-based (eradication, containment, control) and site- and ecosystem-based (integrated management and restoration) management illustrated with case studies.

5.5.1 Prevention – managing pathways

It is widely accepted that preventing invasive alien species introductions, where possible, is the most cost-effective initial response to managing aquatic and terrestrial biological invasions (Wittenberg & Cock, 2003), but for marine biological invasions it is currently the only efficient option (Hewitt & Campbell, 2007; Galil *et al.*, 2019). The imperatives (**section 5.1.1**), decision-support tools (**section 5.2.2.1**), approaches (**section 5.3.1**) and tools and technologies (**sections 5.4.2**, **5.4.3**) have been addressed in previous sections. This section reviews the effectiveness of implementing prevention and preparedness strategies.

In a terrestrial context, the IPPC and its ISPMs support effective management of most invasive alien species pathways associated with plant trade (**section 5.3.1.1**; Schrader & Unger, 2003; Hedley, 2005). While no formal review has been undertaken on the effectiveness of the IPPC in preventing international movement of invasive alien species, it is widely accepted that these have contributed to significantly reducing unintentional introductions (**section 5.3.1.1**; **Chapter 6**, **Table 6.8**). Nonetheless, many invasive alien species move unaided across contiguous land masses, and are therefore poorly contained by trade controls in this context. The global spread of *Spodoptera frugiperda* (fall armyworm) is a recent example (Tay *et al.*, 2022). Countries within contiguous land masses have been largely ineffective at halting the natural spread of invasive alien species. This is so between jurisdictions in general and political unions (e.g., the United States (Corn & Johnson, 2013) and the European Union (Hulme *et al.*, 2009), trade blocs such as the Association of Southeast Asian Nations (ASEAN; Castriciones & Vijayan, 2020) and Mercado Común del Sur in South America (Southern Common Market, Mercosur; Black & Bartlett, 2020) or international aid and trade initiatives, which may have led to more rapid natural spread of invasive alien species despite any form of curtailment (**Chapter 3**, **sections 3.2.2.3** and **3.2.3**; Liu *et al.*, 2019). Evidence that prevention works for island nations stems largely from reviews of Australian (CSIRO, 2020; Schneider *et al.*, 2020) and New Zealand's (Delane, 2019) national biosecurity systems which also are well established and enacted scrupulously. In any case, a biosecurity system is worth the investment especially for all island nations. The most obvious metric of the effectiveness of these systems is that establishment rates of new invasive alien species are near zero for invasive alien vertebrates and animal diseases and largely constant in invasive alien plants, invertebrates and plant pathogens (Bailey *et al.*, 2020; CSIRO, 2020; Hulme, 2020b; A. W. Sheppard & Glanzing, 2021) and predicted to remain so for some groups rather than continuing to grow at fast rates in most other countries (Seebens *et al.*, 2017). One clear example is the processes put in place across Australasia (Australian Government, 2021b) and New Zealand (Ministry for Primary Industries, New Zealand, 2021) for the pathway management of *Halyomorpha halys* (brown marmorated stink bug) as a very high priority threat to the agricultural sectors of both countries intercepted in significant numbers every year. Both countries have put in place a systems-based pathway management approach that is causing a decline in the numbers of interceptions (Australian Department of Agriculture, 2019). This suggests that systems-based approaches (a series of risk mitigation interventions along the supply chains) are an effective way of managing pathways for terrestrial invasive alien species (**section 5.4.3.1**; van Klinken *et al.*, 2020). Effective prevention is also supported by effective intelligence gathering on changing and future trade and pathway risks and effective national preparedness (**sections 5.2.2.4** and **5.3.1.1**). Compared to this, most developing countries are not so successful in implementing effective pathway management because of outdated biosecurity systems or a lack of diligence and capacity in enacting the regulations contained therein (Gupta & Sankaran, 2021).

WOAH Standards aim to prevent movement of animal diseases (**Chapter 6**, **Table 6.8**), however, many of these have been poorly implemented internationally as seen by the current pandemic spread of African Swine Fever particularly through Asia (Dixon *et al.*, 2020) and now into the Americas. Pandemic spread of African swine fever is largely due to it being a highly contagious haemorrhagic viral disease spread through wild, domesticated, dead and live pigs, contaminated feed and fomites and trough pork products (Ward *et al.*, 2021).

Pathway management is currently the only effective option for preventing marine biological invasions (Hewitt & Campbell, 2007; Galil, McKenzie, *et al.*, 2019; **section 5.5.3** and **Figure 5.1B**) as recorded number and spread of marine invasive alien species are increasing with few exceptions (Bailey *et al.*, 2020). Ballast water has been an important dispersal pathway of invasive alien species since the late 1800´s. The first major comprehensive review of the biology of ballast water was in 1985 (Carlton, 1996), based on quantitative data only available from mid 1980s (**Chapter 3**, **section 3.2.3.1**). Since then, ballast water research grew exponentially with 400 publications from

1955 to 2013 (Bailey, 2015). Several countries started to regulate ballast water management from 1989 at regional or national levels (Bailey, 2015; Hewitt *et al.*, 2004). Today, the BWM Convention has been adopted by the International Maritime Organization (IMO) and entered into force in 2017 to help prevent the spread of potentially harmful aquatic organisms and pathogens in ships' ballast water. Adoption the BWM Convention requires ships to manage their ballast water so that aquatic organisms and pathogens are removed or rendered harmless before the ballast water is released into a new location (IMO, 2004). The efficacy of the ballast water management (for details see **section 5.4.3.1**) has only been tested in a few countries, and more long-term studies are needed to understand its efficacy on preventing new species introductions. Bailey *et al.* (2011) evaluated the efficacy of ballast water tank flushing to reduce the introduction of invasive alien species and found a declining rate of detections of them in the Great Lakes. It is estimated that nearly 70 per cent of the marine invasive alien species established worldwide were introduced *via* biofouling (Hewitt & Campbell, 2010). In countries and regions where biofouling regulations exist, the efficacy of these in managing invasions is not well understood given that regulations are recent and were implemented only in a few countries and regions (K. R. Hayes *et al.*, 2019).

Regulations covering several biofouling management strategies were reviewed for New Zealand by Morrisey and Wood (Morrisey & Woods, 2015) and include:

- In-water cleaning and capture systems, which, according to a recent study, can reduce biofouling by 82-94 per cent (Tamburri *et al.*, 2020). However, evaluation of different factors affecting system performance (vessel parameters – type, design, coating; environmental parameters – water visibility, currents, winds, water quality; and in-water cleaning system design and operations – operator experience, debris capture, frequency and rate of operation, etc.) is needed (Tamburri *et al.*, 2020).

- Manual cleaning after beaching the vessel, which can be effective in certain conditions and when vessels are small or stable (e.g., recreational vessels; Castro *et al.*, 2020; and also Government of Canada, 2021).

- Encapsulation treatment (with seawater alone or added with acetic acid or chlorine in small recreational vessels). Tests showed that treatment with seawater for 5 days was enough for eliminating 100 per cent of the organisms (Keanly & Robinson, 2020), but the additives highly reduced kill time (Atalah *et al.*, 2016; Forrest *et al.*, 2007; Morrisey *et al.*, 2016; Roche *et al.*, 2015).

An adaptive or systems-based management approach is needed when applying these different management methods as efficacy is subject to local regulatory, logistical and environmental conditions which differ from one region to another, even within the same country.

Some Indigenous Peoples and local communities apply local quarantine measures prohibiting the transport of certain species that are not used in their cultural practices and customs. Elders provide awareness raising, education and capacity-building passing on oral knowledge from one generation to the next. Teso and Bukusu/Bagisu Kenya-Uganda transboundary customs and cultural practices transfer knowledge during festivals and ceremonies (Angujo, 2015; Barasa, 2012).

5.5.2 Surveillance, detection and monitoring

The main purpose of surveillance is to detect or ensure the absence of new invasive alien species or disease incursions at the border and onshore on time to attempt eradication (**section 5.3.1.2**). Failure to detect incursions rapidly is the major factor limiting the effectiveness of eradication programmes **(Figure 5.1)**. **Box 5.14** shows how surveillance can play an important role in global biosecurity systems, by helping early detection of invasive alien species which have led to successes in eradication of newly established populations (Gerda, 2021). Monitoring of established populations and risk analysis are also important to understand invasiveness to support management actions (Jarrad *et al.*, 2015). Surveillance systems are rarely perfect and this is one of the reasons why eradications can be hard (Rout *et al.*, 2009). In South Africa, surveillance was used to detect and manage populations of *Asphodelus fistulosus* (onionweed) as part of an eradication programme (Jubase *et al.*, 2019). Active specific surveillance in conjunction with general public surveillance (using awareness raising and solicited reporting) were undertaken. Detected populations were treated and monitored over a four-year period to assess the feasibility of eradication leading to effective management. A number of studies also demonstrate that effective surveillance designed for detection at low prevalence or incidence maximizes the effectiveness and lowers the costs of eradication programmes (Kalwij *et al.*, 2014; Pluess, Jarošík, *et al.*, 2012; Reaser, Burgiel, *et al.*, 2020; Simberloff, 2003). Some surveillance programmes seek to optimize post eradication detection to ensure management success is maintained (Epanchin-Niell *et al.*, 2014). See **Supplementary material 5.9** for further details. A case study which also demonstrates the effectiveness of structured surveillance is the Australian red imported fire ant eradication programme **(Box 5.14)**.

A risk-based approach to surveillance can identify priority invasive alien animal and plant and diseases and provide a basis for resource allocation (A. R. Cameron, 2012;

Box 5 14 **The New Zealand National Invasive Ant Surveillance Programme as an example of early detection for successful eradication of invasive ants.**

Established in 2003, following a successful eradication of *Solenopsis invicta* (red imported fire ant) incursion at Auckland International airport in 2001, New Zealand's National Invasive Ant Surveillance programme ensured surveillance of shipping ports, airports and international cargo facilities. Since 2002, approximately 418 baited traps with food attractant deployed over 18 sampling seasons in the programme have recorded invasive ant species. Most of these detections were of ants from newly established nests (Peacock *et al.*, 2019), eradicated under "urgent measures" soon after detection. In 2019, there were 19 ant detections, of which 11 were associated with established ant nests (Peacock *et al.*, 2019) and were eradicated for 29,000 New Zealand dollars (NZ$). The ant surveillance programme costs approximately NZ$ 500,000 per annum. The cost-benefit ratio of continued surveillance is high compared to NZ$ 8.6 million spent over 3 years to eradicate the red imported fire ant in Whirinaki, Napier, New Zealand from 2006 to 2009 (Gerda, 2021, 2021). The cost of living with red imported fire ant in New Zealand without the programme has been estimated at NZ$ 318 million per annum (Anon, 2001; **Figure 5.20**).

Figure 5 20 **Invasive alien ant trap used in New Zealand as part of a surveillance programme.**

Hoinville *et al.*, 2013; Oidtmann *et al.*, 2013). For example, Grace *et al.* (2020) demonstrated an effective risk-based surveillance system for bluetongue virus built on multiple components to know where and when to target surveillance to ensure disease freedom. The risk-based surveillance components consisted of international disease monitoring and post import testing of livestock from high risk areas, and arrival and establishment of the vector, *Culicoides* spp. (biting midges; Grace *et al.*, 2020). Syndromic surveillance of disease status based on clinical signs or other data has been effective for picking up changes in the incidence of disease (Hoinville *et al.*, 2013). This was useful for detecting the first sign of Bluetongue disease serotype 8 in North Western Europe in 2006 (Elbers *et al.*, 2008). Passive surveillance in animal health is when farmers report potential diseases to their veterinarians and the information is collated and reported (del Rocio Amezcua *et al.*, 2010). In Tanzania's animal health system, disease reporting is mostly passive. Clinical observation data from 13 primary sources (mainly livestock farmers, abattoirs, livestock markets, etc.) provide an overall picture of animal health (George *et al.*, 2021).

The international plant sentinel network (**Supplementary material 5.3**) is an effective early warning system for new and emerging pest and pathogen risks through a global network of National Plant Protection Organizations, scientists, botanic gardens and arboreta around the world (Barham *et al.*, 2016). This network aims to report plant health issues safeguarding susceptible plant species worldwide. CABI's PlantwisePlus programmes[26] is another effective plant health support system for smallholder farmers in developing countries across Africa, Asia and Latin America (Cameron *et al.*, 2016). Farmers bring pests or damaged crops for identification and receive pest and disease management advice, contributing to the early detection of new plant pests (Migiro & Otieno, 2020).

26. https://www.plantwise.org

ProMED-mail, the programme for monitoring emerging diseases, also reports on outbreaks of human infectious diseases and monitors diseases of agricultural importance in plants and animals using the internet to mine information sending online reports to subscribers (Yu & Madoff, 2004). Reports are validated by expert moderators. Other effective early warning systems include PestLens (US Department of Agriculture), European and Mediterranean Plant Protection Organization (EPPO) alert list and reporting service for member countries. The NAPPO Phytosanitary Alert System provides a similar service for Canada, United States and Mexico. The IPPC provides a similar service for all national plant protection organizations (Noar *et al.*, 2021).

Most successful examples of priority quarantine pest and invasive alien species surveillance are from developed countries (Mphande, 2016). Elsewhere, such surveillance is under-reported or not practiced on a regular basis. Most one-off surveillance and monitoring surveys of invasive alien species in the Pacific region are not formally published. In contrast, the Pacific Invasive Ant Toolkit provides advice on biosecurity and surveillance for invasive ants (Gruber *et al.*, 2016) rapidly spreading across the Pacific (McGlynn, 1999). General surveillance requires diagnostic and investigative support services (Froud & Bullians, 2010). New Zealand's general surveillance system covers animal, plant and environment health (Bleach, 2019; Tana, 2014) with a National Call Centre emergency phone service supported by experts, laboratory diagnostics and investigators. The results are published online quarterly (Ministry for Primary Industries, New Zealand, 2020).

A mobile phone-based identification tool designed jointly by the New Zealand Government and the Māori community called Find-A-Pest has improved public passive surveillance reporting levels (Pawson *et al.*, 2020) such that 95.5 per cent public identifications were correct with a 56.1 per cent successful hit record for high priority species profiled on the factsheets embedded in the Find-A-Pest application. General surveillance has also been successful in New Zealand for a range of marine species by different communities: the ascidian *Eudistoma elongatum* reported by marine aquaculture (Smith *et al.*, 2007), the *Charybdis japonica* (lady crab) by commercial fishers (Smith *et al.*, 2003) and Ostreid herpesvirus Type 1 (OsHV-1) from noticed mortalities in juvenile oysters by the industry (Bingham *et al.*, 2013). Other examples include a surveillance programme developed to detect invasive alien mosquitoes (Mosquito Alert, 2021) and FAMEWS, a mobile app used for monitoring and early detection of fall armyworm (FAO, 2021)

Environmental DNA metabarcoding (**section 5.4.2.1d**) is being used in marine systems in some countries but it is an expensive tool, and sequence databases/libraries are being developed for many species at a slow rate. Zaiko et al (2015) found it was five times more effective than classical morphological analyses in detecting invasive alien species in plankton samples in the Baltic Sea, although accuracy can be a concern (Ricciardi *et al.*, 2021; **Chapter 6**, **Box 6.19**).

Activities and knowledge systems of some Indigenous Peoples and local communities' effectively support surveillance (Ingold, 2000). The Mayan lobster diver-fishers were the first to detect *Pterois* spp. (lionfishes) in the Parque Nacional Arrecife Alacranes (southern Gulf of Mexico; López-Gómez *et al.*, 2014). Some Indigenous Peoples and local communities have robust invasive alien species detection systems **(Box 5.15)** which have many similarities with internationally recognized systems (ICIPE, 2018; Shine, 2005). In some communities, the council of elders for a given region monitors and evaluates the entire ecosystem situation and gives reports during the meeting of Indigenous Peoples and local communities. The council of elders works in harmony with the People's culture and customs (Aiken *et al.*, 2015).

Effective surveillance by Indigenous Peoples and local communities of native ecosystems in Kimberley, Northwest Australia is part of hunting, fishing and gathering, and the

Box 5 15 **Surveillance and management of invasive alien species by Indigenous Peoples and local communities – A case study of The Bukusu community in Kenya.**

The Bukusu community notifies an elder when a new plant species is first found in their environment. A council of elders confirms the detection and quarantine is imposed. A date is then set for a ritual ceremony to determine whether management of the plant should proceed. At the ceremony, a sheep is slaughtered at the detection site and its stomach contents together with samples of plant shoot (called *Lufufu*) are mixed in water which the elder places on and around the plant while some ceremonial statements are made. On the 3rd day the *Lufufu* leaves are checked to see if they are dry, following which the plant is uprooted and burnt. If the leaves are still healthy the plant is considered good for the native ecosystem, given a local name and its uses and applications are defined based on similar local plant species. If a new animal species is detected (whether *Esang'i*- the eaten animal species or *Esolo*- a non- eaten animal species) the council of elders identify its foot prints and a child is given a mixture of *Kulandula* plant to put in the foot prints as the elders curse the animal never to return since its effects to the native ecosystem, economy and livelihoods are not known (Wanzala *et al.*, 2012).

reporting of new species is encouraged. Barter trade is strictly conducted only with known fauna, flora and/or minerals. This knowledge of fauna, flora and/or minerals is held by elders by memory and trust and is passed on from generation to generation by word of mouth (Wanzala *et al.*, 2012; Weir & Duff, 2015). Combining both Indigenous and scientific knowledge has improved the understanding on the spread of invasive alien species among local communities. The observations of forest-dwelling Soliga community of South India on *Lantana camara* (lantana) invasion have helped to better understand the process of invasion and plan future management of the species (Sundaram *et al.*, 2012). The Māori Tuawhenua community of Ruatahuna in New Zealand has developed extensive knowledge systems around endemic biodiversity and forest health perceiving changes in the forest and introduced invasive alien species over 65 years (Lyver *et al.*, 2016). See **Supplementary material 5.9** for more examples of effective surveillance. Although surveillance for invasive alien species is a regular process in the developed countries, it is seldom conducted in some of the developing countries for want of updated technical know-how and resources (Gupta & Sankaran, 2021).

5.5.3 Eradication

Successful eradication of an invasive alien species is underpinned by effective surveillance, detection and extirpation of all individuals of the species, which is supported by efficient methods to remove all pre-reproductive individuals (**section 5.4**), good decision-support systems (**section 5.2**) and sustained public and financial support. Sustained monitoring can ensure that there are no new recruitments (Genovesi, 2001; Rejmanek& Pitcairn, 2002; Lehtiniemi *et al.*, 2015; Simberloff, 2020), and the success of any eradication programmes depends on adequate resourcing until all the individuals are removed (Simberloff, 2009). In general, successful eradication programmes that interacted with human activities were achieved with strong stakeholder support through effective engagement, education and communication (Myers *et al.*, 1998; Simberloff, 2003). It is also important to evaluate in advance the conditions which may thwart an eradication programme – for example, an eradication attempt of *Prosopis juliflora* (mesquite) in Ethiopia failed due to lack of resources (Rettberg, 2010; **section 5.6**).

A review of eradication programmes of invasive alien plants conducted by Rejmanek & Pitcairn (2002) concluded that management of populations spread across habitats greater than 1000 hectares is very unlikely to be successful, especially if the target has high spread rates (e.g., *Lantana camara* (lantana); Ranjan, 2019) or seedbanks are hard to detect. It is difficult to eradicate invasive alien plants compared to invasive alien vertebrates (Robertson *et al.*, 2019). Moreover, successful eradications of invasive alien plants were of those which infested smaller areas than those of invasive alien vertebrates (Rejmanek & Pitcairn, 2002; Robertson *et al.*, 2019). At a global scale, several programmes have been implemented since the 1970s to eradicate invasve alien forest insects, with most documented examples proving successful (Brockerhoff *et al.*, 2010; Liebhold *et al.*, 2016; Liebhold & Kean, 2019; Tobin *et al.*, 2014). The cost of forest pest eradication programmes increases with the size of the area affected (Brockerhoff *et al.*, 2010; **Box 5.16**; **Supplementary material 5.10** for more examples).

An eradication programme of *Oryctolagus cuniculus* (rabbits) in Tierra del Fuego (Argentina), which disturbed soil and threatened native species, was legally challenged by animal rights supporters (CADIC-CONICET, 2020; **section 5.6.2**). A mosquito surveillance programme was set up in New Zealand in 1998 in response to the infestation of *Aedes camptorhynchus* (southern saltmarsh mosquito), and its eradication programme which lasted over 10 years costed NZ$ 70 million (Kay & Russell, 2013; **Supplementary material 5.10**). In 2018, the programme detected a few mosquito *(Culex sitiens)* larvae in marshland (McGinn & Disbury, 2019), and a bacterium (*Bacillus thuringiensis israelensis* (Bti)) that kills the mosquito larvae was used as treatment. Three rounds of aerial spraying of Bti were carried out across 5 km from the initial detection sites to eradicate the mosquito. Subsequent surveillance revealed no further infestation of the mosquito.

Reinvasion risk also needs to be addressed in eradication programmes (Pyšek *et al.*, 2020; Spatz *et al.*, 2022) through both natural (e.g., long-distance flights) and anthropogenic (i.e., human-assisted) pathways (Harris *et al.*, 2012). Eradication of *Didemnum vexillum* (carpet sea squirt), a widespread colonial coastal species in western Europe, North America and New Zealand affecting shellfish farms and submerged structures (McKenzie *et al.*, 2017), was attempted in Shakespeare Bay (about 1 km^2), New Zealand (costing NZ$ 650,000) and Holyhead Harbour, Wales, United Kingdom (costing GBP 350,000) (Galil *et al.*, 2019). Approaches included exposing the colonies to desiccation, chemicals, freshwater and physical removal (Rolheiser *et al.*, 2012), but recolonization occurred soon after the eradication efforts stopped. This is a common feature of eradication attempts targeting marine invasive alien species (Galil *et al.*, 2019; McKenzie *et al.*, 2017). Long-term monitoring of all small infestations after eradication is critical in marine systems (Pluess, Cannon, *et al.*, 2012). The eradication of *Carcinus maenas* (European shore crab) was attempted in South Africa using different management techniques including traps, crab condos, diver collections and sediment dredging. However, after one year, crabs were still present and numbers increased as soon as the eradication efforts ceased (Mabin *et al.*, 2020).

Box 5 16 Case study: Successful eradiation of an invasive scale insect in Kerala, India.

Figure 5 21 ***Ceroplastes cirripediformis* (barnacle scale) on a host plant.**

Photo credit: Dr. T. V. Sajeev – under license CC BY 4.0.

Ceroplastes cirripediformis (barnacle scale; **Figure 5.21**) is a highly polyphagous scale insect that causes negative impacts to host plants belonging to 119 genera in 63 families in over 32 countries (García Morales *et al.*, 2016). It sucks the sap of host plants and excretes honey dew resulting in the formation of coal smudge on the affected plant parts. The barnacle scale was identified as an invasive alien species by the Centre for Agriculture and Biosciences International (CABI) in 2017 since it causes significant damage to host plants in its invaded range. It was first recorded in India in 2021 (Joshi *et al.*, 2021). The Nodal Centre for Biological Invasions, Kerala Forest Research Institute, India issued public notices to detect its distribution in Kerala state and it was spotted at one site each in Dhoni and Parali villages in Palakkad District. The host of the insect was a *Passiflora* sp. (passionflower). The identity of the insect was confirmed using molecular methods. Since its spread was very isolated, rapid control was attempted by removing and burning the infested stems and killing the insects at the spot. No new outbreaks were recorded during a 8-month post-eradication period (Swathy, 2021). Surveillance for the insect is being continued.

A global analysis of 173 eradication campaigns in anthropogenic habitats involving 94 species of invertebrates, plants and plant pathogens showed that only 50.9 per cent of the programmes were successful (**section 5.6.1.1**). Both location- and context-specific factors were important for success of eradication, while species-specific characteristics were of minor importance. Invaded areas smaller than 5000 ha had more than 80 per cent of successful eradication probability in man-made habitats (Pluess *et al.*, 2012). It is important to prioritize sites (such as protected areas) for targeting eradication (**section 5.3.2**). Lower success rates were recorded from natural or semi-natural habitats than man-made habitats where success was comparatively more likely due to high economic impacts (**Chapter 4**, **Box 4.13**) and the resultant greater commitments. Eradication success can be ensured with cross-border collaboration and greater cooperation amongst nations (Pluess *et al.*, 2012).

Vertebrate eradication programmes on islands have been particularly successful, especially with rodents (Howald *et al.*, 2007; Spatz *et al.*, 2022), with success numbers increasing exponentially since 1980 (Towns *et al.*, 2019; Carrion *et al.*, 2011; Robertson *et al.*, 2019). Details on successful eradication of invasive alien species on islands can be found in the DIISE **(Table 5.4)**. Recent data show that the success rate was 88 per cent from 1,550 attempts on 998 islands during the last 100 years (Spatz *et al.*, 2022). These successes have been attributed to isolation and small surface area of the islands (Simberloff, 2001). With improved baiting technology (**section 5.4**), eradications were also possible on larger islands which was considered impossible a decade ago (Veitch *et al.*, 2011). This led to targeting human-inhabited islands and continental settings (Malmierca *et al.*, 2011; Zabala *et al.*, 2010; Glen *et al.*, 2013). Roberston *et al.* (2017) found that twelve of fifteen (80%) large-scale mammal removals from Northern Europe since 1900 were successful within defined management boundaries (mean area 2,627 km^2). As such, most programmes were mostly not aimed at eradication from large land masses.

Detailed information on successful eradication programmes (i.e., rate of removal of individuals and techniques applied to achieve results) is generally limited and even less information is available on unsuccessful attempts (Roy *et al.*, 2009; Simberloff, 2020; **section 5.6.2**). In this situation, adaptive management is the most effective approach to eradication, especially when there are data gaps and uncertainty on how best to continue the programme based on early results. A successful example is the removal of *Capra hircus* (goats) from Santiago Island **(Box 5.17)**.

Information on the costs of eradication programmes are necessary to evaluate the economically optimal strategies, however, cost-benefit analyses usually used to evaluate the feasibly of management plans are not frequently published (Pluess, Cannon, *et al.*, 2012). While eradication programmes can only be achieved with access to high immediate costs, they are generally cheaper than long term and permanent control costs and impacts (Bomford & O'Brien, 1995). The eradication of well-established population of *Myocastor coypus* (coypu) through trapping in Great Britain is another success story of eradication. An 11-year campaign (1981-1992) at a total cost of EUR 5 million included dynamic estimate of remaining populations which helped to understand trapping effects on coypu and the trap numbers (Gosling & Baker, 1989; Panzacchi *et al.*, 2007). This programme is comparable to the long-term coypu control programme in Italy which costed EUR 14 million over six years (Panzacchi *et al.*, 2007). In most eradication programmes, the costs of removing individuals escalates greatly based on the fact that the fewer the individuals that are left, the final (remaining) individuals are harder to find. In the eradication of *Cyprinus carpio* (common carp) from Tasmania, Australia, it took just a few years to reduce carp numbers down to a few breeding females, but it took another ten years to track and remove the final individuals, which has only been successful in one of two lakes 25 years after the decision to eradicate was made. Complete success, therefore, has not yet been achieved (Yick *et al.*, 2021).

The costs of eradication can be very high when eradication is only considered as an option at the point when the negative impacts due to the species become visible (Genovesi, 2001). Several invasive alien species projects funded by the Global Environment Facility have focussed on eradication efforts. But, in many cases these were not cost-effective (GEF, 2007; **section 5.3.2**). The costs of multi-species eradication programmes can be lower than eradicating individual species if eradication approaches can simultaneously remove multiple species or the removal of some species facilitates removal of others. Such projects targeting eradication of

Box 5 17 Eradication of goats on Santiago Island, Ecuador.

The large-scale eradication of *Capra hircus* (goats) from Santiago Island, Galápagos Islands, Ecuador **(Figure 5.22)** is an excellent example of successful island eradication. Over 79,000 individual goats were removed from over 58,000 ha in 4.5 years (2001-2005) at a cost of United States Dollar (US$) 6.1 million. This adaptive management programme included ground hunting using specialized techniques, aerial hunting by helicopter, and the use of sterilized Judas (tagged goats used to find other goats through social behaviour; **section 5.4.3.2**) and Mata Hari (females with hormone implants) goats to find and remove the remaining individuals. Methods were constantly revised and adjusted. Different hunting methods were integrated, and hunting efficiencies and escape rates constantly evaluated, contributing to the success of the programme at reduced costs. Removal of the last goats costed $2 million, while the monitoring costs to confirm eradication was $467,064 (Cruz *et al.*, 2009).

multiples species in multi-sites have been proven to be cost-effective. For example, in the Archipelago of French Polynesia, the project cost for eradication of various mammal species from six islands was only EUR 1.4 million while the total cost of actions on each island separately was estimated to be EUR 4.6 million. Savings were made on fixed costs such as the costs of helicopters, transport and staff travel (Griffiths *et al.*, 2019; **Box 5.8**).

A clear idea on the size of the area invaded is a pre-requisite to ensure the success of all eradication plans. This is exemplified by the success of species eradication from islands since the area is often smaller compared to large land masses. On large land masses, defining the extent of an invasive alien population may be compounded by the presence of multiple populations, especially when the populations are inter-connected. It is, therefore, essential to understand the meta-population context of a species targeted for eradication, which will help planning the programme and ensuring its efficacy (Robertson *et al.*, 2019). A lack of this understanding given limited resources, is why most culling programmes are ineffective and unsuccessful in the long-term (**section 5.4.3.2**). The ongoing eradication programme of *Oxyura jamaicensis* (ruddy duck) from Europe covers 1,535,509 km^2 requiring participation and investment from several countries (Robertson *et al.*, 2015). The cost of eradication decreases slightly in proportion to the area targeted but there is an island size limit above which eradication may not be successful (Brockerhoff *et al.*, 2010; Robertson *et al.*, 2017, 2019; **Figure 5.23**). In general, the eradication cost per area seems to be similar for both islands and mainland programmes. This example indicates that large scale eradications can be successful.

Aquatic eradication programmes are more frequent in freshwater than marine ecosystems (Simberloff, 2021). In freshwater systems, such programmes are generally restricted to small rivers and lakes and within enclosed bays. Examples include eradication of freshwater bass (*Micropterus* spp.) in a small river in South Africa (O. L. F. Weyl *et al.*, 2013) and programmes targeting species of invasive alien aquatic plants that applied different strategies (Simberloff, 2021). Eradication programmes with invertebrates and small taxa in aquatic ecosystems are less known and have poor success rates given the complex nature of these environments for implementing management procedures and the lack of visibility.

Evidence suggests that there have been no fully successful eradication programmes for well-established invasive alien species in marine ecosystems (Galil *et al.*, 2019). Where

they have been attempted, targets have been restricted to very small initial populations, to sessile biota and small areas. An eradication programme against *Mytilopsis sallei* (Caribbean false mussel), which was discovered in 1999 by local divers, occurring in large densities in three marinas in the port of Darwin in Australia used liquid chlorine and copper sulphate. This killed the mussels and other marine life (Willan *et al.*, 2000; F. E. Wells, 2019). In 2000, *Caulerpa taxifolia* (killer algae) was discovered in a lagoon and then in a harbour in California, United States. A rapid response was activated since this species was included in the Federal Noxious Weed List in 1999. Algal beds were treated with liquid chlorine and a monitoring programme continued and by 2005 the species was considered fully eradicated (Anderson, 2005). In both cases, eradication was possible because the managed area was small, and eradication was carried out soon after locating the species. It is critical to improve eradication programmes in marine ecosystems during the early detection stage, as most attempts at eradicating or containing invasive alien species have been ineffective so far (Galil *et al.*, 2019). Thorough knowledge of each system is needed to avoid failures and non-target impacts which will potentially degrade the ecosystems further and the high costs involved for eradication (Grosholz *et al.*, 2021).

Social aspects of eradication

Successful eradication can lead to ecological and social benefits. In the Seychelles islands, where natural resources have supported the tourism industry (see **section 5.3.2** on management in protected areas), eradication of invasive alien plants and vertebrates, and subsequent reintroduction of native species, has improved tourism, benefiting local people (Samways *et al.*, 2010). In North America, clearance of the invasive shrub *Lonicera maackii* (Amur honeysuckle) altered the behaviour of *Odocoileus virginianus* (white-tailed deer) and its disease vector parasite *Amblyomma americanum* (lone star tick), reducing the risk of vector-borne diseases in humans (Allan *et al.*, 2010). In the arid and semiarid climates of western United States, eradication of the invasive alien plant *Tamarix* sp. (tamarisk) from riparian areas, where it depleted water availability and increased river sedimentation, led to large social and economic benefits to municipalities, farmers, the hydropower industry and fishermen and reduced flood damage in invaded areas (Zavaleta, 2000). On a local scale, therefore, eradication success can lead to increased good quality of life when targeting invasive alien species causing significant negative impacts on economic wellbeing, human health and access to natural resources. Where invasive alien species have commercial, cultural or spiritual value, however, eradication is unlikely to be acceptable (Kelsch *et al.*, 2020; Oppel *et al.*, 2011; **Box 5.18**). The eventual abandonment of *Bubalus bubalis* (Asian water buffalo) eradication in Northern Australia, where the animals were valued by the Indigenous Peoples and local communities, is an example (Ridpath & Waithman, 1988). Where Indigenous Peoples and local communities use invasive alien species for practical, cultural and spiritual purposes eradication could lead to negative consequences on these communities (Atyosi *et al.*, 2019; Haregeweyn *et al.*, 2013; Maldonado Andrade, 2019; **section 5.3.1.3**; **Chapter 1**, **section 1.6.7.1**; **Chapter 4**, **section 4.6.4**).

5.5.4 Containment

Containment is a strategic option to prevent establishment, multiplication and spread of an invasive alien species outside a specific area, often when attempts at eradication become unsuccessful or abandoned (Grice *et al.*, 2012, 2020). Containment aims at delimiting the spread of a species through various management measures though, at times, certain environmental factors may also restrict its spread. This method is often used to manage the spread of invasive alien plants. However, "slowing the spread" is also an option for managing invasive alien pests (Sharov *et al.*, 2002; Sharov & Liebhold, 1998). When opting for containment, resources may be allocated to reduce propagule pressure in

Box 5 18 **Local eradication of cacti *Opuntia* sp. (pricklypear) improves good quality of life in Madagascar.**

Opuntia sp. cacti from South America was first introduced into Madagascar as a defence barrier in the 1700 (Binggeli, 2003). Some species in this highly invasive alien genus are also beneficial providing fodder and some have medicinal properties (Shackleton *et al.*, 2017). Those species with fodder value quickly became a crucial resource for local pastoralists in Madagascar (Kaufmann, 2004), allowing them to have larger herds than the "natural" environmental capacity would allow (Middleton, 1999). The cacti also provided food and water for local communities during dry season. However, range expansion of dense thickets of the cacti reduced land available for crops and native bushy plants (Binggeli, 2003). When *Opuntia* was successfully controlled in southern Madagascar through biological control using *Dactylopius* spp. (cochineal insects), positive outcomes were also achieved that benefitted people in the central highlands. However, loss of *Opuntia* severely affected livelihoods of the pastoralists, who depended on it for food and fodder during droughts which led to migration from the area (Binggeli, 2003; Shackleton *et al.*, 2011).

the zone dominated by the species and in the buffer zone to delimit long-distance dispersal (Grice *et al.*, 2013).

Grice *et al.* (2013) suggested that, for invasive alien plants, containment can be considered as a choice in two main contexts: 1) where an invasive alien species is also a commercially valuable species which can be exploited for that purpose and managed and 2) for a species with no commercial value especially when it has not fully occupied an invaded area. For commercially valuable species, containment also depends on the traits of the species, the reason for its cultivation and the characteristics of the area where it is cultivated (Grice, 2006). Several methods are available to contain commercial and non-commercial species (Grice *et al.*, 2013). However, the methods need to be adapted to the dispersal capacity of the species and containment of each infestation or population may have to be attempted separately. Most importantly, containment may be treated only as a short-term measure, while other management methods are being developed for implementation.

The economic viability of "slowing the spread" was demonstrated for the invasive alien pest *Lymantria dispar* (gypsy moth) in North America (Sharov & Liebhold, 1998). In the forestry sector, the successful containment of gypsy moth was reported from the United States (from Wisconsin to North Carolina) where pheromone traps were used to disrupt mating of the moth or alternatively treating the population with *Bacillus thuringiensis* (Sharov *et al.*, 2002).

Similarly, in agriculture, sterile insect techniques may be used to contain invasive alien pests (**section 5.4.3.2**). Containment is a viable strategy when used within zoological or botanical gardens or when predator free fences are used to exclude invasive alien vertebrates from invading native wildlife reserves (Ringma *et al.*, 2018). Use of this method in marine ecosystems may be ineffective in the long-term but has been used as a rapid response plan to manage diseases in aquaculture in disconnected water systems. In 1997, *Styela clava* (Asian tunicate) was first noted invading an aqua-cultured *Mytilus edulis* (common blue mussel) in Prince Edward Island, Canada (Locke *et al.*, 2009). After confirming the identity of the species, a group of stakeholders implemented a containment strategy in 2001 to manage the species (Locke *et al.*, 2009). Transfer and harvest of blue mussels were restricted in tunicate-infested areas and responsible practices were encouraged. Although no cost-benefit-risk analysis was done, the results proved that benefits outweighed the costs. The manual handling and disposal costs totalled 0.24 Canadian dollar per kilogram of harvested mussel (Locke *et al.*, 2009). This forms a good example of a successful containment programme but was effective only in the short term. The use of a combination of methods (including chemical control) and long-term monitoring may be necessary to mitigate tunicate impacts and develop a sustainable mussel aquaculture industry (ACRDP, 2010).

5.5.5 Control

Successful invasive alien species control is generally assessed as the levels of invasive alien species suppression. Objective-driven invasive alien species management may also measure improvements to biodiversity and ecosystem services in the context of sustained ecosystem restoration **(Box 5.19)**. Invasive alien species control requires long-term monitoring for continued management actions so as to ensure sustained control. Long-term monitoring is also essential to assess efficacy and outcomes of management actions, and assess return on investments and benefits to local communities.

Lissachatina fulica (giant African land snail), native to East Africa, is listed as one among 100 of the world's worst invasive alien species (Lowe *et al.*, 2000). Recorded from over 50 countries in all continents except Antarctica, it causes

Box 5 19 **The Working for Water programme: Social benefits from controlling invasive alien plants.**

Control of widespread invasive alien species requires large-scale and continuous efforts to reduce their density. South Africa's Working for Water programme, introduced in 1995, took advantage of the need to clear invasive alien vegetation as part of a water conservation campaign and poverty relief programme by creating job opportunities for thousands of local people (e.g., 20,000 jobs per year over the first 15 years of the programme; Lukey & Hall, 2020; van Wilgen *et al.*, 2012). The programme also provided training in entrepreneurial and management skills and a sense of community among workers, especially women (Binns *et al.*, 2001). The programme addressed a national imperative to improve good quality of life of predominantly poor rural communities, while managing the spread of many invasive alien plants, and for some species, reducing the area of invasion (Wilson *et al.*, 2013). Although sustainability of the programme has been a concern (Binns *et al.*, 2001), the Working for Water programme has been ongoing for more than 25 years and is seen as a successful example of invasive alien species control which has brought ecological and social benefits in partnership with various stakeholders (Lukey & Hall, 2020). The programme contributed primarily to employment generation, rural development and water security.

significant impacts on crops (Sankaran, 2008). Physical and chemical methods were unsuccessful in managing the snail. Common molluscicides are useful for short term control but resulted in soil and water pollution and affected non-target snails. The Kerala Forest Research Institute, India has since developed a non-polluting method, which is effective for *Lissachatina fulica* management in the longer term. The control method involves two stages 1) baiting and 2) point chemical treatment, resulting in 100 per cent mortality without non-target impacts. Dead snails are buried in soil. Local communities have accepted this method and are now practicing it (Maneetha *et al.*, 2017).

Box 5 20 African smallholder farmer management of the recent *Spodoptera frugiperda* (fall armyworm) invasion.

Fall armyworm management adopted by African farmers uses combinations of chemical, physical, cultural or traditional methods (**Figure 5.24**; FAO, 2018b; Kansiime *et al.*, 2019; Tambo *et al.*, 2019; Murray *et al.*, 2019; Rwomushana *et al.*, 2018; Asare-Nuamah, 2020; Koffi *et al.*, 2020; Gebreziher *et al.*, 2021; Houngbo *et al.*, 2020; Tambo, Day, *et al.*, 2020; Tambo, Kansiime, *et al.*, 2020; Bariw *et al.*, 2020).

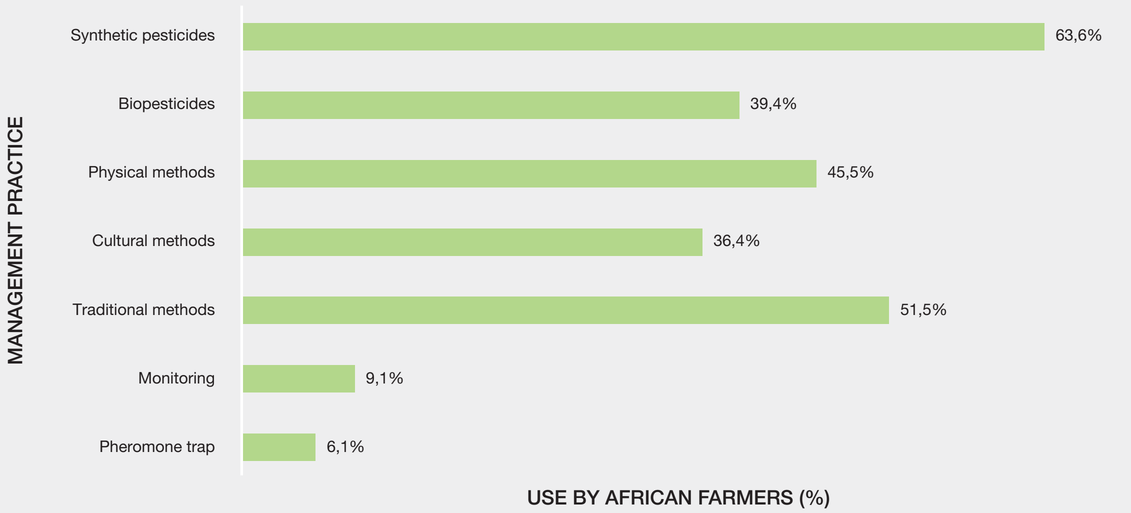

Figure 5 24 **Fall armyworm management adopted by African farmers uses combinations of chemical, physical, cultural or traditional methods.**

(FAO, 2018b; Kansiime *et al.*, 2019; Tambo *et al.*, 2019; Murray *et al.*, 2019; Rwomushana *et al.*, 2018; Asare-Nuamah, 2020; Koffi *et al.*, 2020; Gebreziher *et al.*, 2021; Houngbo *et al.*, 2020; Tambo, Day, *et al.*, 2020; Tambo, Kansiime, *et al.*, 2020; Bariw *et al.*, 2020).

Synthetic pesticides were the most commonly used control method (64 per cent of studies). Cultural methods (36 per cent of studies) involved agronomic practices such as early planting, intercropping with non-host plants, weeding of the field constantly to remove alternative host plants, push-pull technology and fertilization to produce healthy plants that are resilient to attack. Traditional methods (52 per cent of studies) included the application of household detergents, soaps, ash, sand or urea on larvae. Integrated pest management consisted of regular monitoring of maize fields for fall armyworm with the use of pheromone traps to monitor or capture the adults.

As fall armyworm was a new pest, farmers needed information on identification, biology, monitoring and effective control, including information on pesticide use and safety, but this was largely unavailable or inadequate (Nyangau *et al.*, 2020; Girsang *et al.*, 2020; Murray *et al.*, 2021; Tambo *et al.*, 2021). Pesticide cost was high and supplies and resources were low (Bariw *et al.*, 2020). Handpicking of larvae was labour-intensive (Chimweta *et al.*, 2020).

In terms of effectiveness, pesticides were most effective (Rwomushana *et al.*, 2018), while early planting, handpicking, planting resistant varieties, crop rotation and replanting were all perceived as highly to moderately effective in Namibia. Early planting and handpicking were considered relatively ineffective by farmers in Benin (Houngbo *et al.*, 2020). Ash application was considered ineffective in Namibia (FAO, 2018b) and Benin (Houngbo *et al.*, 2020). Further information can be found in **Supplementary material 5.11**.

China has lost millions of native pine trees (*Pinus tabuliformis* (Chinese pine) and *Pinus bungeana* (lace bark pine)) to *Dendroctonus valens* (red turpentine beetle) introduced from North America in logs in the 1980s, which has led to loss of tree cover leading to ecosystem change, lost carbon sequestration and biodiversity. To manage this invasive alien species, China has adopted an adaptive integrated management approach built on strong regulatory controls on timber movement and silvicultural, insecticidal and semiochemical trapping. The programme has limited the rapid pest spread and further impact on the native pine trees (Yan *et al.*, 2005; J. Sun *et al.*, 2013; Wan *et al.*, 2017).

Most Indigenous Peoples and local communities control invasive alien species through physical removal, especially invasive alien plants. Managing crop weeds on smallholder cropping lands in Africa is largely done by women and children, and is often their most time-consuming activity (Chikoye *et al.*, 2006; Orr *et al.*, 2002; Terefe *et al.*, 2020; Vissoh *et al.*, 2004); for example, *Opuntia* spp. (pricklypear) in East Africa (R. T. Shackleton *et al.*, 2017) as repeat weeding is required. For *Pontederia crassipes* (water hyacinth), physical removal has proved futile as the plant quicky grows back and seeds, which remain viable for 15 years, can spread through animal faeces (Heuzé *et al.*, 2015; Gopal *et al.*, 2019). Indigenous Peoples and local communities from western Kenya uproot the parasitic *Striga hermonthica* (witchweed) from maize plantations but control is ineffective (Oswald, 2005). Ineffective management strategies can also have social impacts. Pastoralists of Baadu (Ethiopia) failed in the efforts to remove *Prosopis juliflora* (mesquite), and this has led to changes in the good quality of life including social conflicts (Rettberg, 2010; Rettberg & Müller-Mahn, 2012).

Indigenous Peoples and local communities have attempted multiple methods to control *Spodoptera frugiperda* (fall armyworm) as it spread across Africa and Asia from the Americas to save their livelihoods, but often to little effect. In Ghana, some Indigenous Akan People applied So Klin (a washing detergent solution) to reduce the negative impacts of fall armyworm (Asare-Nuamah, 2020; **Box 5.20**; **Supplementary material 5.11**). More traditional approaches included cultural and spiritual practices and management by fire. The Yellomundee Aboriginal Bushcare in Australia (Barber & Glass, 2015) believe that it is "a cool fire that burns the invasive alien plants but allows native species to regenerate". Early season patch fire management removes biomass and stimulates native seedlings while not burning surrounding trees. This traditional approach to fire management is now widely recognized, supported and practiced across Northern Australia. In the Kimberley, Western Australia, the place-based (a type of site-based) invasive alien plant management approach, developed by rangers on behalf of the Bunuba People, protects sacred sites (Aiken *et al.*, 2015). The Rajbanshi People from North Bengal in India practices sacred bathing in winter and autumn, such as Maghali sinan and Bauni sinan and also worships rivers at the onset of monsoon season to get timely rains, which will help the fight against invasive alien invertebrates (A. D. Gupta, 2015). Local farmers in Lao People's Democratic Republic use wood ashes for coating stems of crops to protect them from invasive alien invertebrates (Upadhyay *et al.*, 2020). A community-led approach often results in success. The Holok system of customary law and other cultural practices of the Ifugao people of Hingyon utilizes parts of more than 25 plants to produce a biopesticide against several invasive alien invertebrates. The holok, as traditionally practiced, was part of the hongan di pageh, the system of Ifugao rituals on rice culture (IPBES, 2020).

5.5.5.1 Mechanical, manual and chemical methods

See **section 5.4.3.2** for more information.

5.5.5.2 Lethal control programmes

There is a very high success rate of invasive alien vertebrate eradication programmes on islands (**section 5.5.3**), and there are some successful programmes removing mammals from within defined larger land mass boundaries (Robertson *et al.*, 2017). The vast majority mainland landscape management programmes to suppress uncontained invasive alien vertebrate based on culling (lethal population suppression) have however been ineffective (reviewed by Hone, 2007; **section 5.4.3.2d**). This is because lethal control programmes are generally poorly planned and implemented based on:

- inadequate understanding of population sizes, distributions and metapopulation dynamics of the target in time and space,
- ineffective tracking of populations in hunting programmes leading to culling mainly being concentrated where and in seasons when the target is most abundant (minimizing the chance of suppressing a population below an ecological impact threshold), limiting effectiveness of removal with respect to environmental impacts;
- lack of sustained investment and activity leading to only temporary population suppression; and
- failure to use as part of integrated management including fencing to protect cleared areas and sustain the short-term management benefits.

Developing effective selective baits and trapping is also a strong criterion for success, particularly for shy and hard to track feral animals such as cats. Public opinion is also likely to affect management programme success. In the United States, advocates for feral *Felis catus* (cat), listed as one of the 100 worst invasive alien species, blocked federal legislation that would have funded removal of various invasive alien species, potentially including cats, from national wildlife refuges (Longcore *et al.*, 2009). In Italy, management of invasive *Sciurus carolinensis* (grey squirrel) was hindered by a lack of public acceptance (Hulme, 2006). Although most non-government organizations supported management using humane euthanasia of the squirrel, strong opposition from animal rights organizations interrupted the activities allowing subsequent squirrel range expansion (Genovesi & Bertolino, 2001). Effective invasive alien predator management has led to increased abundance of native animals in Australia (Bengsen *et al.*, 2012; Doherty *et al.*, 2017) and New Zealand (O'Donnell *et al.*, 1996; PREDATOR Free NZ, 2021).

5.5.5.3 Classical biological control programmes: successes and failures

The practice of classical biological control to suppress populations of invasive alien species has a successful history of well over 100 years (**section 5.4.3.2f**). Biological control is a widely used invasive alien species management approach in many countries and continues to be applied to manage a range of invasive alien plants, invertebrates and to a lesser extent plant microbes and a few invasive alien vertebrates (Cock *et al.*, 2016).

For invertebrate targets, the BIOCAT database shows that there have been 6158 biocontrol agents released to control invasive alien invertebrates before 2010, and the probability of successful establishment and impact of introductions continues to improve (Cock *et al.*, 2016). This led to the successful management of 172 different target organisms. Van Driesche *et al.* (2010) reviewed releases against environmental targets and found a 62 per cent success rate for complete control with a further 19 per cent partially controlled. *Oryctes rhinoceros* (coconut rhinoceros beetle) is a major pest across the Pacific islands that has been widely managed using a well-established classical biocontrol agent, *Oryctes rhinoceros* nudivirus (OrNV), for many years, however recently beetle numbers have been rapidly increasing, severely disrupting nature's contributions to Indigenous Peoples and local communities through free access to coconuts across many islands in the Pacific. This resulted in Vanuatu declaring a national emergency. Recent research suggests the effectiveness of the virus has declined and this may be a rare example where the invasive alien species target has generated resistance to the biocontrol agent (Etebari *et al.*, 2021).

The global catalogue of biocontrol agents and their use against target alien invasive plants shows that up to 2018, 468 biocontrol agents have been released against 175 species of invasive alien plants across 48 families and 90 countries. Some form of successful control was achieved against 65.7 per cent of the plant species targeted, for which sufficient time has elapsed to assess effectiveness. One third of targets no longer required any other form of control (Schwarzländer *et al.*, 2018; e.g., **Box 5.21**). The biological control programme against *Ambrosia artemisiifolia* (common ragweed) in China, the pollen of which has a very high allergy rate in humans leading to high medical costs, has released two biological control agents (*Ophraella communa* (ragweed leaf beetle) and *Epiblema strenuana* (ragweed borer)). These biocontrol agents successfully suppressed the target in southern China, however in colder northern China biological control needs to be supplemented by chemical control and restoration with native plants (Wan *et al.*, 2017). Biological control effectiveness is related to the level of abundance of the target plant in the native range, the mode of reproduction (sexual *versus* asexual) and the habitat type (aquatic *versus* terrestrial; Paynter *et al.*, 2012). Although many biological control programmes targeting invasive alien species take many years with no guarantee of success, this approach remains very cost-effective because the control benefits, when they occur, are generally high and self-sustaining (Briese, 2000). For invasive alien plants,

Box 5 21 **Case study of biological control of *Mikania micrantha* (bitter vine) in the Asia-Pacific region.**

Mikania micrantha is a fast-growing invasive alien plant native to Central and South America. It invades plantations and agricultural systems, thereby reducing productivity threatening the livelihood of rural communities in the Asia-Pacific region (Anitha *et al.*, 2017; Day *et al.*, 2016; Ellison & Sankaran, 2017). A microcyclic rust fungus *(Puccinia spegazzinii)*, which causes necrosis of leaves and cankers on the stem and petioles in the native range of the species, was introduced into India in 2006 and then in China, Papua New Guinea, Fiji, Guam, Palau, Vanuatu and the Cook Islands (2006 – 2012) (Day, Kawi, Fidelis, *et al.*, 2011; Day *et al.*, 2016; Orapa, 2017). The rust established in five countries (Taiwan, Province of China, Papua New Guinea, Fiji, Vanuatu and the Cook Islands) and has kept the spread of the bitter vine well under control, especially in Papua New Guinea and Vanuatu (Ellison & Cock, 2017). However, in India, the rust fungus failed to survive in the field apparently due to a low inoculum load and inappropriate time of release (Sankaran & Suresh, 2013). Paucity of resources prevented further releases in India.

a third of programmes only release one biocontrol agent and often one agent provides the necessary control, but as selecting agents based on likely future effectiveness is hard, the release of multiple agents is often required (Schwarzländer *et al.*, 2018). When such programmes are unsuccessful, termination is generally more to do with perceived levels of risk to non-target native species, failed agent establishment or lack of funding and political will than that all biocontrol agent options have been exhausted (Fowler, 2000; Sankaran & Suresh, 2013).

Approximately 50 per cent of classical biological control programmes for invasive alien plant or invertebrate species do not deliver much effective return on investment (Cooke *et al.*, 2013; Julien *et al.*, 2012; Waterhouse & Sands, 2001). The benefits of successful programmes, however, can more than pay for projects that were not successful. In Australia, where a total benefit-cost assessment has been undertaken for classical biological control against invasive plants in agricultural systems, the national effort over 100 years gave a return on investment of 23:1 including the costs of both successful and unsuccessful programmes. This was an annual benefit of 95.3 million Australian dollar (AU$) a year in 2006 (Page & Lacey, 2006). As the monetary benefits cannot easily be measured for the impacts of invasive alien plant targets in natural ecosystems, based on the number and benefit magnitudes of successful programmes, the returns on investment were considered at least equivalent against invasive plants. Benefit-cost ratios of six programmes in South Africa ranged from 34:1 to 4333:1 (van Wilgen *et al.*, 2004). Some invasive alien plant species are best managed by integrating biological control with other management practices (Moran *et al.*, 2005). Evidence indicates that biological control alone may not be efficient to manage some of the invasive alien plants where integrated management is the most viable option.

A viral-based classical biological control programme against *Oryctolagus cuniculus* (rabbits) in Australia has also been highly successful and also had the support of the local peak body on the prevention of cruelty to animals (RSPCA Australia; **section 5.4.3.2f**). Since the release of the first biological control agent in the late 1940s the programme had delivered AU$ 70 billions of benefit by 2011 (Cooke *et al.*, 2013; **Supplementary material 5.12**). Classical biological control has been considered but not adopted against other invasive mammals, invasive alien fish, amphibians, reptiles and birds (CBD, 2019; A. W. Sheppard *et al.*, 2019). Marine invasive alien species have not been targeted for biological control although the approach has been considered (Simberloff, 2021). Secord (2003) and Lafferty and Kuris (1996) have undertaken reviews of the opportunities and the risks and doubt its relevance.

The application of rigorous and internationally agreed risk analyses starting in the 1950s has reduced incidents of unpredicted non-target impacts to a very low and largely predictable level, a trend that may continue with the systematic inclusion of molecular tools, behavioural studies, chemical ecology and future scientific and analytical advancements (**Chapter 3**, **section 3.3.5.2**). There are exceptions, such as *Harmonia axyridis* (harlequin ladybird) in Europe (Brown *et al.*, 2008; **section 5.4.3.2** for other non-target impacts). Direct non-target impacts from biological control programmes have been repeatedly reviewed and found to be predictable and minor compared to the native ecosystems' benefits from control, except for some early unregulated releases of generalist predators (e.g., the release of cats and mongoose on islands). Indirect impacts have received much less attention being less obvious and more difficult to measure. Where studied they are minor and ephemeral if control is achieved and generally confined to areas in close proximity to the target invasive alien plant for biocontrol agents that have undergone rigorous risk assessment. The completely unregulated introduction of *Tyto alba* (barn owl) in Hawaii in the late 1950s to control rats is a rare but unsurprising counter example, although this release did not follow the precautionary approach now applied in the context of modern classical biological control programmes. By 1966, the owls were established and breeding and a recent review found these owls were an important avian predator of at least eight seabird species (Raine *et al.*, 2019). A management programme to control owl populations has been undertaken in 2015. Biological control in any form, like most other management tools, is not risk-free (CBD, 2018).

5.5.6 Management in an ecosystem restoration context

Restoration of an ecosystem after invasive alien species control is both expensive and hard to achieve, unless the ecosystem retains a strong regeneration potential. This is especially true in marine ecosystems where invasive alien species management has proven to be largely ineffective (Lopez *et al.*, 2006). Integrating management and restoration into an adaptive management approach requires long-term monitoring to assess efficacy, outcomes and timely detection of lost resilience and reinvasion. Benefits of management, particularly to local communities, also need to be evaluated. In successful cases of restoration in terrestrial ecosystems, efforts are limited in space and time and goals are clearly defined and achievable with available resources (IPBES, 2018). See **section 5.4.3.3** for a description of site-based integrated invasive alien species management with ecosystem restoration strategies. China has been attempting an ecosystem restoration project for controlling *Sporobolus alterniflorus* (smooth cordgrass) introduced in 1979, which now covers hundreds of thousands of hectares in the Yangtze River estuary. The Shanghai government is spending 1.3 billion Yuan to control *Sporobolus alterniflorus* invasion and restore habitats for migratory birds (Wan *et al.*, 2017). The integrated management includes cofferdam construction for containment, mechanical harvesting, flooding, revegetating with native plants and managing water levels (Xiao *et al.*, 2011).

In a review on site restoration as a part of controlling invasive alien species, Kettenring and Adams (2011) observed that, a) the use of herbicides effectively but temporarily controlled invasive alien plants but did not lead to significant native revegetation; b) prescribed fire reduced the biomass of native species and increased the biomass of the invasive alien species; and c) cutting/removal of the invasive alien species slightly decreased invasive alien species biomass but not that of native species. However, most studies failed to quantify the effectiveness of ecosystem restoration since they had failed to measure the initial status of native vegetation. This has led to inconsistent conclusions regarding the best invasive alien plant control option that may lead to the most effective ecosystem restoration.

One of the common methods to restore terrestrial ecosystems invaded by invasive alien plants is to plant fast-growing native (annual/perennial) species or disperse seeds of such species following effective management of the invasive alien species. Though such ecosystem restoration attempts may not be sufficiently efficient to enhance resistance to invasive alien species, growth and spread of planted native species may help to suppress regeneration of the invasive alien species community by filling recruitment niches (Byun *et al.*, 2013; Byun, Oh, *et al.*, 2020). However, large seedbanks of the invasive alien species may often interfere with these attempts. Therefore, success of ecosystem restoration depends on ensuring a well-established seed bank of native plants at the site and on long-term monitoring of the restored habitats to ensure establishment of the planted seedlings and to manage re-invasions (Byun, de Blois, *et al.*, 2020; Byun *et al.*, 2018). Assisted natural regeneration of native plants by protecting the area from grazing, fire and other interventions may also help successful ecosystem restoration. Local community cooperation is essential for the success of assisted regeneration.

Field experiments have shown that a good knowledge of the functional-trait-based biotic resistance and diversity-resistance in the community will help to achieve successful restoration of native communities on sites where invasive alien plants were successfully managed. Resistance to invasive alien species may be associated with community functional diversity (Byun, Blois, *et al.*, 2020; Byun *et al.*, 2013, 2018; **Chapter 1**, **section 1.4.3**), and functional diversity could be (based on trait complementarity) a good indicator of invasibility. A recent study of communities invaded by *Phragmites australis* (common reed) in Canada (Byun, de Blois, *et al.*, 2020; Byun *et al.*, 2013) proved that functional diversity-based resistance to invasive alien species differs between invasive alien species, and restoring functional diversity could provide resistance against multiple invasive alien species. It is certainly prudent to restore functional diversity as part of ecosystem restoration since the process of restoration will be easier if functional diversity is not lost.

5.5.7 Management costs

The global economic cost of invasive alien species is over \$1 trillion and the cost is rising (**Chapter 4**, **Box 4.13**; (Diagne *et al.*, 2021). This cost represents documented expenditures with management of biological invasions (e.g., prevention, control and monitoring) and economic losses associated with the impact of invasive alien species. The global reported costs of management of biological invasions (excluding impacts of invasive alien species) totalled \$120.5 billion (2017 US\$ values) over the last 50 years (**Figure 5.25**; (Diagne *et al.*, 2020). The geographic distribution of management costs **(Figure 5.26)** shows that the documented costs were highest in the Americas (\$103.5 billion), followed by Asia-Pacific (\$6 billion) and Africa (\$5 billion). Management costs for invasive invertebrates were the highest (\$29 billion), followed by plants (\$5.7 billion) and the management costs were highest for terrestrial ecosystems (\$107.8 billion). Data on whether higher management costs were spent on prevention *versus* management were equivocal, but funds being spent globally on research for the management of biological invasions were low (\$2.78 billion). On a global scale, a study showed that eradication of invasive alien species can make substantial savings on costs devoted to the protection of threatened native species (Jones *et al.*, 2016), suggesting that eradication of invasive alien species is a very cost-effective investment for protecting threatened and endangered species in comparison.

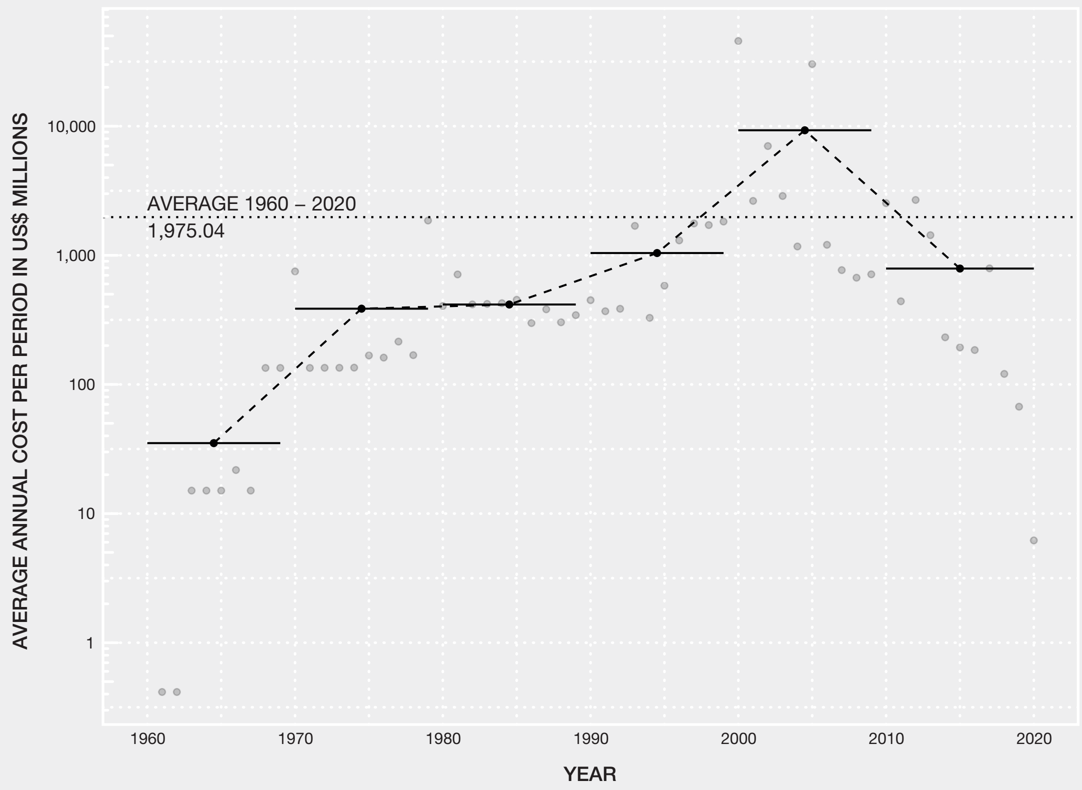

Figure 5 25 **Annual cost reported globally with the management of biological invasions between 1960 and 2020 (2017 monetary values).**

Light dots represent annual average cost reports and dark dots (with lines on each side) connected by dashed lines represent the decade averages. Data source: Diagne *et al.* (2020).

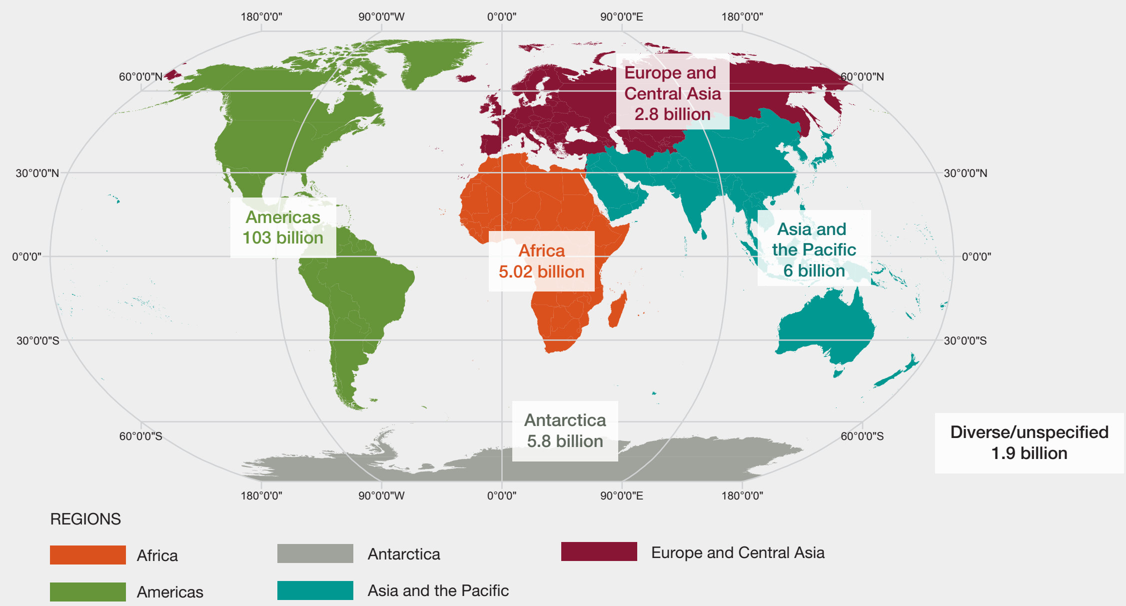

Figure 5 26 **Total reported economic cost of management of biological invasions actions across all IPBES regions (in USD) between 1960 and 2020 (2017 monetary values).**

Data source: Diagne *et al.* (2020).

5.6 CONTEXT SPECIFIC CHALLENGES AND KNOWLEDGE GAPS IN MANAGEMENT

5.6.1 Context specific challenges

5.6.1.1 Challenges to management success across taxa and ecosystems

The conceptualized invasion management-invasion continuum **(Figure 5.1)** provides a simplified schematic of the typical process and potential management options for biological invasions. However, the context (where in the invasion continuum), invasive alien species type (Booy *et al.*, 2020), unique environmental conditions (A. W. Sheppard *et al.*, 2002) and the economic costs for each management scenario will differ between situations (Pluess, Jarošík, *et al.*, 2012). For example, an analysis of 173 eradication attempts across 94 invasive alien species showed that eradication was more likely in anthropogenic than in semi-(natural) sites (Pluess, Jarošík, *et al.*, 2012; **section 5.5.3**). The study also showed that eradication attempts are only likely to be successful if initiated within four years after introduction (Pluess, Jarošík, *et al.*, 2012). Globally it has been shown that alien vertebrates are easier to eradicate than alien generalist invertebrates, pathogens and plants (Booy *et al.*, 2020). Plants and fungi, for example, produce seeds/spores or other propagules which are hard to find and may remain dormant for many years (Mack & Lonsdale, 2001). One classical example of eradication is that of *Myocastor coypus* (coypu) from a large region of south-eastern England (Gosling & Baker, 1989). Although highly context- and scale-dependent, there are examples of aquatic plants and freshwater fish being eradicated (Simberloff, 2021). In Norway, the invasive alien fish that have been successfully eradicated include *Phoxinus phoxinus* (European minnow), *Rutilus rutilus* (roach), *Esox lucius* (pike) and *Coregonus lavaretus* (common whitefish) (Bardal, 2019). The feasibility of eradication of invasive alien species in marine ecosystems at any scale is, however, generally small (Booy *et al.*, 2020).

For individual invasive alien species, different populations within one habitat will vary in their density and impacts (**section 5.3**; Dassonville *et al.*, 2008). This variability alters options for optimal management. For example, *Undaria pinnatifida* (Asian kelp) has invaded most temperate regions worldwide, but conditions for successful biological invasion could not be generalized across regions (Epstein & Smale, 2017). Also, in the marine context, invasive alien species are notoriously difficult to control, because the whole system is open and there are complexities in detection and implementing and evaluating responses to management actions (Simberloff, 2021).

An analysis of 76 case studies documenting the management of invasive alien species by Indigenous Peoples and local communities showed that plants are the most frequently reported target of management (**Supplementary material 5.1**), although plants are relatively difficult to eradicate. Vertebrate animals are also often targeted by Indigenous Peoples and local communities for management. However, the attempts of managing invasive alien animals, especially mammals, on Indigenous lands may not be successful, because of cultural or spiritual conflicts rather than the biological characteristics of the taxa (Koichi *et al.*, 2012; Peltzer *et al.*, 2019). There are few case studies reporting the management of invertebrates, fungi and pathogens implemented by Indigenous Peoples and local communities. The majority of the case studies reviewed have focused on terrestrial ecosystems, whereas there are much fewer studies documenting the attempts in freshwater and marine ecosystems (**Supplementary material 5.1**). This might imply that Indigenous Peoples and local communities have not actively attempted management of invasive alien species in aquatic ecosystems since it is notoriously less feasible than terrestrial ecosystems (but see **section 5.3.1.2** for examples of uses of aquatic invasive alien species by Indigenous Peoples and local communities leading to the control of species).

Management of cryptic, marine and infectious and zoonotic diseases remain a challenge. However, recent advances in environmental DNA are improving detection capability, and the improvements in automated underwater vehicles are making detection and management of marine invasive alien species easier, but authentic identification of marine species is one of the greatest obstacles (**sections 5.4.4**, **5.5**). For zoonotic (e.g., Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2), Covid-19 (C. R. Wells *et al.*, 2020)) and other infectious diseases (e.g., Foot and mouth disease; (Tildesley *et al.*, 2006), management is also benefiting from genetic surveillance tools as prevention and preparedness are critical to avoid impacts.

5.6.1.2 Management challenges for conflict species

The concept of an invasive alien species is a human construct and therefore perceived risks, benefits, costs and impacts from them vary depending on a diversity of human perspectives (Kelsch *et al.*, 2020; **Chapter 1**, **section 1.5.2**; **Chapter 4**, **section 4.1.2**; **Box 4.9**). There are many cases where species provoke strong disagreement on the requirement of management between stakeholders. The most common conflict comes from species that offer both benefits in some sectors (e.g., agriculture and nature's contributions to people) and negative costs or impacts in other sectors (e.g., biodiversity, nature's contributions to people and good quality of life) (Pejchar & Mooney, 2009). This value-based context dependency of particular species is often significant enough to prevent effective decision-making and management (R. Gregory *et al.*, 2006; Kelsch *et al.*, 2020; **Table 5.9**). Public value put on common pets such as *Felis catus* (cat), *Oryctolagus cuniculus* (rabbits) or gold fish often biases understanding of their invasive impacts (Nogales *et al.*, 2013). Attraction to charismatic species, such as *Myiopsitta monachus* (monk parakeet; (Crowley *et al.*, 2019) and hedgehogs (C. Jones *et al.*, 2005) can also bias recognition of environmental impacts. In such cases effective community-based communication programmes generally help (Jarić *et al.*, 2020).

Conflicts based on value systems include utilitarian, moralistic, spiritual, humanistic, naturalistic/dominionistic/aesthetic and risk perceptions (Estévez *et al.*, 2015). They are based on people's different beliefs, knowledge and experience with the invasive alien species and the social, cultural, landscape and policy contexts (Shackleton, Adriaens, *et al.*, 2019). Perceptions and values differ between countries and regions, policymakers, communities, managers, conservationists and Indigenous Peoples and local communities (Kelsch *et al.*, 2020), even if globally, values regarding environmental conservation are aligning. Some species may have been deliberately introduced for a particular service but, while providing that service, have negative impacts on other sectors. For example, introduced *Sus scrofa* (feral pig) are culturally important in Hawaii and are hunted for subsistence, ceremony and recreation (Pejchar & Mooney, 2009), but are considered keystone species in driving and maintaining alien plant invasions and causing forest ecosystem disruption, and therefore are primary modifiers of the remaining Hawaiian rainforest (Loope *et al.*, 2013). Elsewhere in the United States, introduced *Sus scrofa* are valued by hunters but cause annual losses to six crops of nearly $200 million, and potentially carry zoonoses or diseases that may affect wildlife and livestock (Lewis *et al.*, 2019). Indigenous Peoples and local communities often value invasive alien species culturally if they have become a food or livelihood source, and therefore may have adopted or adapted to use and value a particular invasive alien species that has established in their communities, even if the same species is causing significant environmental impacts (e.g., cats in Australia (I. Abbott, 2002) or mesquite in Africa and India (Chandrasekaran & Swamy, 2016; Mbaabu *et al.*, 2019) for which compromises can be found). For example, for feral ungulates, one solution adopted by Indigenous Peoples and local communities in Australia is the selection and fencing of a priority area (e.g., Heritage sites and high biodiversity wetlands) with the animals removed from these sites but still harvested sustainably outside the protected zone (E. Ens *et al.*, 2016). A similar solution was found in a hunting programme in Argentina **(Box 5.6)**. Many other invasive alien species are also used for sport. Stocks of *Micropterus salmoides* (largemouth bass) are supplemented for recreational fishing in South Africa despite severe ecological impacts on macroinvertebrate fauna and communities (O. L. F. Weyl *et al.*, 2015; P. S. R. Weyl *et al.*, 2010). Trouts are a globally prized recreational fish, restocked into rivers every year in many countries outside their native range, however, this conflict has been analysed only in South Africa (Marire, 2015).

Participation of different stakeholder communities in invasive alien species management can also lead to conflicts and perverse outcomes. Harvesting and recreational hunting are often considered as incentives for invasive alien vertebrate management, but whether their inclusion as part of management programmes improves or simply perpetuates the problem as the target becomes a resource, is strongly debated (C. Booth, 2010; Nuñez *et al.*, 2012; Gentle & Pople, 2013; Zivin *et al.*, 2000). Australia is the world's largest exporter of goat meat (Meat & Livestock Australia, 2021) based on harvesting feral goats as an economic safety net for rural communities in times of drought. This is a significant impediment to widespread management of the environmental impacts of feral goats (D. M. Forsyth *et al.*, 2009).

In the horticultural sector, about 75 per cent of the global established alien flora are grown in domestic gardens (van Kleunen *et al.*, 2018), which presents a particular challenge when seeking to gain public support for their management. Generally, when supported by information campaigns and when the impacts after escaping the garden fence are realized, the public understands the need to avoid some plant species in their gardens and nurseries voluntarily agree not to stock them (Burt *et al.*, 2007). Another approach is to encourage the benefits of gardens with native plants (Shaw *et al.*, 2017). Codes of conduct and agreed prohibited lists have been developed between government agencies responsible for managing invasive alien plants and the nursery trade to address these conflicts (Atkinson & Sheppard, 2000). These include the horticultural industry, conservation and environmental agencies and the plant protection sectors (including regulatory bodies) and can improve management of invasive alien plants without impacting on an important economic industry (Heywood & Brunel, 2011).

Some alien plant species with high economic value become invasive in other contexts, for example for forage production or plantation forestry (van Wilgen & Richardson, 2014). Scasta *et al.* (2015) documented that the cultivation of *Lespedeza cuneata* (sericea lespedeza), a declared invasive alien species by the state invasive council, for forage production was publicly recommended in the state of Alabama. Similarly, Nuñez *et al.* (2017) documented a case where forestry plantation of a pine species, *Pinus contorta* (lodgepole pine), had been heavily subsidized by national government until recently, even though high invasiveness of the species has been recognized. Agreeing on management of some of the agriculturally valuable but environmentally harmful invasive alien grasses (e.g., African grasses in Australia; Cook & Dias, 2006) remains a challenge, but biological control of *Acacia mearnsii* (black wattle) timber trees in South Africa found a compromise by selecting biological control agents that only reduce propagule production (i.e., flower and seed feeding agents) (Impson *et al.*, 2011; Impson *et al.*, 2021). This illustrates how different stakeholder communities can be brought together to understand the different perspectives and seek a joint solution. Information campaigns for the general public around charismatic invasive alien species also play a key role in raising awareness in the community. Explicit consideration of the factors creating the different views through education and inclusion is critical if management measures are to be mutually agreed (Jarić *et al.*, 2020).

Table 5 9 **Examples of invasive alien species that were intentionally introduced for beneficial purposes, conflict resolution and potential management response (Chapter 4, section 4.6.4).**

Groups include terrestrial plant; freshwater/marine plant; microorganism; bird/fish/mammal/reptile; insect.

Invasive alien species	Taxonomic group	Time and location of introduction	Native range of introduced species	Primary purpose of the introduction	Co-operative efforts to develop management options
Lates niloticus (Nile perch)	Vertebrate (freshwater fish)	Lake Victoria; 1960s	Afrotropical; Congo, Nile, Senegal, Niger, Lake Chad, Volta, Lake Turkana	To promote the fisheries industry as the dominant endemic haplochromine species were perceived to have low economic value (Njiru *et al.*, 2005)	The Kenyan, Ugandan and Tanzanian governments established a regional mechanism in 1994 – Lake Victoria Fisheries Organization – to coordinate the management and conservation. The three countries agreed to enforce legislation and regulations to protect the lake and its basin (Njiru *et al.*, 2005).
Procambarus clarkii (red swamp crayfish)	Invertebrate (freshwater crustacean)	Present in 40 countries across all continents except Australia and Antarctica (Nunes *et al.*, 2017; Oficialdegui, Sánchez, *et al.*, 2020)	Southern United States and north-eastern Mexico	Aquaculture	In one example in Europe, where the red swamp crayfish has a high economic value, legislation regulating the red swamp crayfish on the basis of biodiversity protection was overridden to allow continued use due to public opposition and socioeconomic interests. Therefore, the legislation did not achieve the desired environmental outcomes, leading to the recommendations that context specific legislation is more likely to receive wider support (Oficialdegui, Delibes-Mateos, *et al.*, 2020).
Robinia pseudoacacia (black locust)	Terrestrial tree	Europe	North America	Wood and honey production, amelioration and soil stabilization (Vítková *et al.*, 2017)	Societal concern resulted in the species not being included in the list of regulated species at the European level. In some countries, management is based on site-specific approaches leading to tolerance in selected areas and strict eradication at sites of high conservation value.
Prosopis juliflora (mesquite)	Terrestrial tree	35 countries in Africa; over 20 countries in Asia and the Pacific	The Americas	Soil stabilization and to provide fuel and livestock fodder It was introduced into South India for fuelwood purposes and to benefit the dryland economy	In one region a national plan to manage the invasion is under development, driven by bottom-up concerns, as a community requested compensation from the government after losing their cattle due to the effects of *Prosopis juliflora*. As it was introduced in a government programme (Shackleton *et al.*, 2014), the community was awarded compensation (Castillo, 2019). The use of *Prosopis juliflora* is a socio-economic concern in southern India where management is a complex issue as charcoal from the tree is a source of income for local people (Walter & Armstrong, 2014). Increased use of the wood through proper silvicultural management was proposed to control spread.

Table 5 9

Invasive alien species	Taxonomic group	Time and location of introduction	Native range of introduced species	Primary purpose of the introduction	Co-operative efforts to develop management options
Grasses and legumes (8200 species; V. M. Adams & Setterfield, 2015; G. D. Cook & Dias, 2006)	Terrestrial plant	Australasia	All continents	For pastoral improvement	Of all the species introduced, twice as many became invasive alien species than became useful (Lonsdale, 1994). Management options are being developed for two species, *Andropogon gayanus* (tambuki grass; V. M. Adams & Setterfield, 2015) and *Cenchrus ciliaris* (buffel grass; Grice *et al.*, 2012).
33 *Acacia* spp. including *Acacia mearnsii* (black wattle; Magona *et al.*, 2018)	Terrestrial trees	South Africa	Australia	For timber and as ornamentals	Agreeing and selecting biological control agents that only reduce propagule production (i.e., flower and seed feeding agents; Impson *et al.*, 2011, 2021).
Bombus terrestris (bumble bee)	Invertebrate (Insect)	Japan	Africa, Asia and Europe	For pollination of commercially important crops (Inoue *et al.*, 2008)	In principle, introduction, breeding and release are prohibited by the Invasive Alien Species Act, but farmers may use bumble bees on the condition that measures to prevent escape be taken and official permission be obtained (Goka, 2010; Lohrmann *et al.*, 2022).
Capra hircus (goats)	Terrestrial mammal	Mexico, Guadalupe Island	Asia	Meat production	Goats were introduced in the early 19th century by fur traders to have fresh meat. Later, there were permits from Mexico's government to use the goats as dry meat. Overgrazing by goats decreased forest coverage from 3,850 hectares to 85 hectares, while some vegetation communities disappeared. Because of the latter, with the support of federal government agencies (including the Mexican Navy), the local fishing community and the specialized private organization Grupo de Ecología y Conservación de Islas, the goats were eradicated (Aguirre-Muñoz *et al.*, 2011). The eradication of goats took place between 2003 and 2006. Seedlings of endemic trees that were absent in 2003, and species of plants believed extinct, reappeared, including species not seen in 100 years. To date, the vegetation has recovered rapidly, both naturally and through active ecosystem restoration (Luna-Mendoza *et al.*, 2019).

5.6.1.3 Management strategies for biological invasions under climate change and changing land-use as multiple drivers of change

Climate change is a driver that facilitates biological invasions (**Chapter 3**, **section 3.3.4**), and associated extreme climate events increase ecosystem susceptibility to biological invasions (Diez *et al.*, 2012; **Chapter 3**, **section 3.4**). Climate change and habitat loss or conversion are linked. Climate change influences land-, freshwater- and sea-use, which adds to the susceptibility of ecosystems to invasive alien species (**Chapter 2**, **section 2.1**, **Chapter 3**, **section 3.5.1**). Invasive alien species reduce the resilience of ecological communities and habitats to extreme events (Godfree *et al.*, 2019), therefore, prevention and management can increase the long-term climate change functional resilience of threatened ecosystems and habitats. In short, climate change poses increasing challenges for the management of biological invasions (Walther *et al.*, 2009). The interactions between climate change, habitat change and invasive alien species will alter drivers that facilitate biological invasions, resulting in new pathways of introduction, vector efficacy and species previously environmentally constrained overcoming establishment, reproduction and spread barriers (**Figure 5.27**; Walther *et* *al.*, 2009; **Chapter 3**). While models and scenarios give insights into the trends of likely impacts of climate change on invasive alien species (**Chapter 1**, **section 1.6.7.3**; **Chapter 2**, **sections 2.6.2**, **2.6.3**, **2.6.4**), mainstreaming these concepts into action to minimize future impacts will be challenging (Hellmann *et al.*, 2008). Similarly, building concerns related to management of biological invasions into climate change response planning is also essential, since ecosystem resilience to climate change is eroded by invasive alien species. This imperative cuts across the many sectors involved in climate planning, including human health, agriculture and aquaculture, forestry, fisheries management and wildlife conservation; it is acutely essential when co-planning adaptive management with Indigenous Peoples and local communities (**Chapter 4**, **section 4.7.2**; **Chapter 6**, **sections 6.1.1**, **6.3.1**).

The individual or synergistic effects of increased carbon dioxide levels, changes in air and seawater temperature, floods and droughts, increased frequency and intensity of fire regimes, higher saltwater incursions, changes in ocean currents, extreme events and precipitation patterns, and their interactions with invasive alien species is likely to be highly uncertain (Walther *et al.*, 2009). Future management of biological invasions will need to adapt, based on knowledge of how potential risks and impacts will vary with changing climate drivers (e.g., spatio-temporal rainfall shifts; Beaury *et al.*, 2020). Current "sleeper" (i.e., invasive alien species of low apparent risk; Hulme, 2020b) may become more invasive as climates change. Environmental monitoring (e.g., *via* sentinel sites) could help identifying these (**section 5.4.3**). Future sources of invasive alien species are also likely to differ from current sources under climate change, as geospatial matched climate changes across the globe (**Chapter 3**, **section 3.3.4**). New source regions and species threats will require prioritization with associated adjustments to pathway management actions.

Adaptive management will be needed to adapt monitoring, decision-making and management under climate (**section 5.4**) and habitat change. There is the possibility that climate change may alter the efficacy of existing successful species-based management programmes (e.g., biological control; Y. Sun *et al.*, 2020). This may require the development of new management practices to ensure that new control programmes, or gains made during current control programmes, are not impeded. Site-based management priorities may have to be reconsidered based on changing climate (**Chapter 3**, **section 3.3.4**) and reduced resilience of habitats to invasive alien species. The most vulnerable sites being offshore and mainland islands, mountain tops and coastal environments will be critical for supporting threatened and endangered species. The IUCN recognizes the likely increased use of species translocations to save endangered species from declining climate niches and has produced guidelines to support this, but there are risks and consequences (Webber & Scott, 2012; Lozier *et al.*, 2015). Integrating biological invasions management strategies into assisted translocation actions under climate change could help avoid unintended consequences (Webber & Scott, 2012; IUCN/SSC, 2013).

Relevant stakeholder community actions as recommended by the CBD (2022b) include:

- engaging all sectors including agriculture and public health agencies and industries in invasive alien species planning where climate change risks are cross-sectoral;
- raising public awareness, including with local and Indigenous Peoples and local communities, of changing invasive alien species threats arising from climate change and include the participation of the public and all relevant sectors in response planning;
- minimizing the potential of biological invasions or develop spatial response planning for areas in which communities are threatened with a high risk of extreme weather events (e.g., relocate zoos, botanical gardens, aquaculture facilities using alien species, from extreme-event-prone areas).

Currently, invasive alien species are considered under the 2030 Agenda for Sustainable Development only in the context of the terrestrial environment (Sustainable Development Goal (SDG) Indicator 15.8.1), but under climate change it will need to be considered equally in marine environments. Climate change and habitat transformation interactions with invasive alien species at various stages of the biological invasion process are illustrated in **Figure 5.27**.

5.6.1.4 Management challenges in urban areas and coastal developments

Urban and peri-urban environments are the fastest growing ecosystems on earth and provide easy opportunities for invasive alien species introductions (Gaertner *et al.*, 2017); (**Chapter 2**, **section 2.5.5.1**; **Chapter 3**, **section 3.2.2.4**). There are four recognized zones of urbanization in most cities, and urban areas often have different microclimates from the surrounding countryside (Erz, 1966). They are heterogeneous and highly complex human-made ecosystems influenced by strong social and political drivers (Cadenasso & Pickett, 2008). Natural spaces within urban areas are critically important for some constituents of good quality of life such as physical and psychological health. These nature refuges, parks and gardens are still largely human-designed or disturbed so acceptance of some alien species (**Glossary**) is to be expected, which needs to be recognized by management frameworks (Gaertner *et al.*, 2016). Urban environments are often close to country ports of entry, so they experience high propagule pressure from

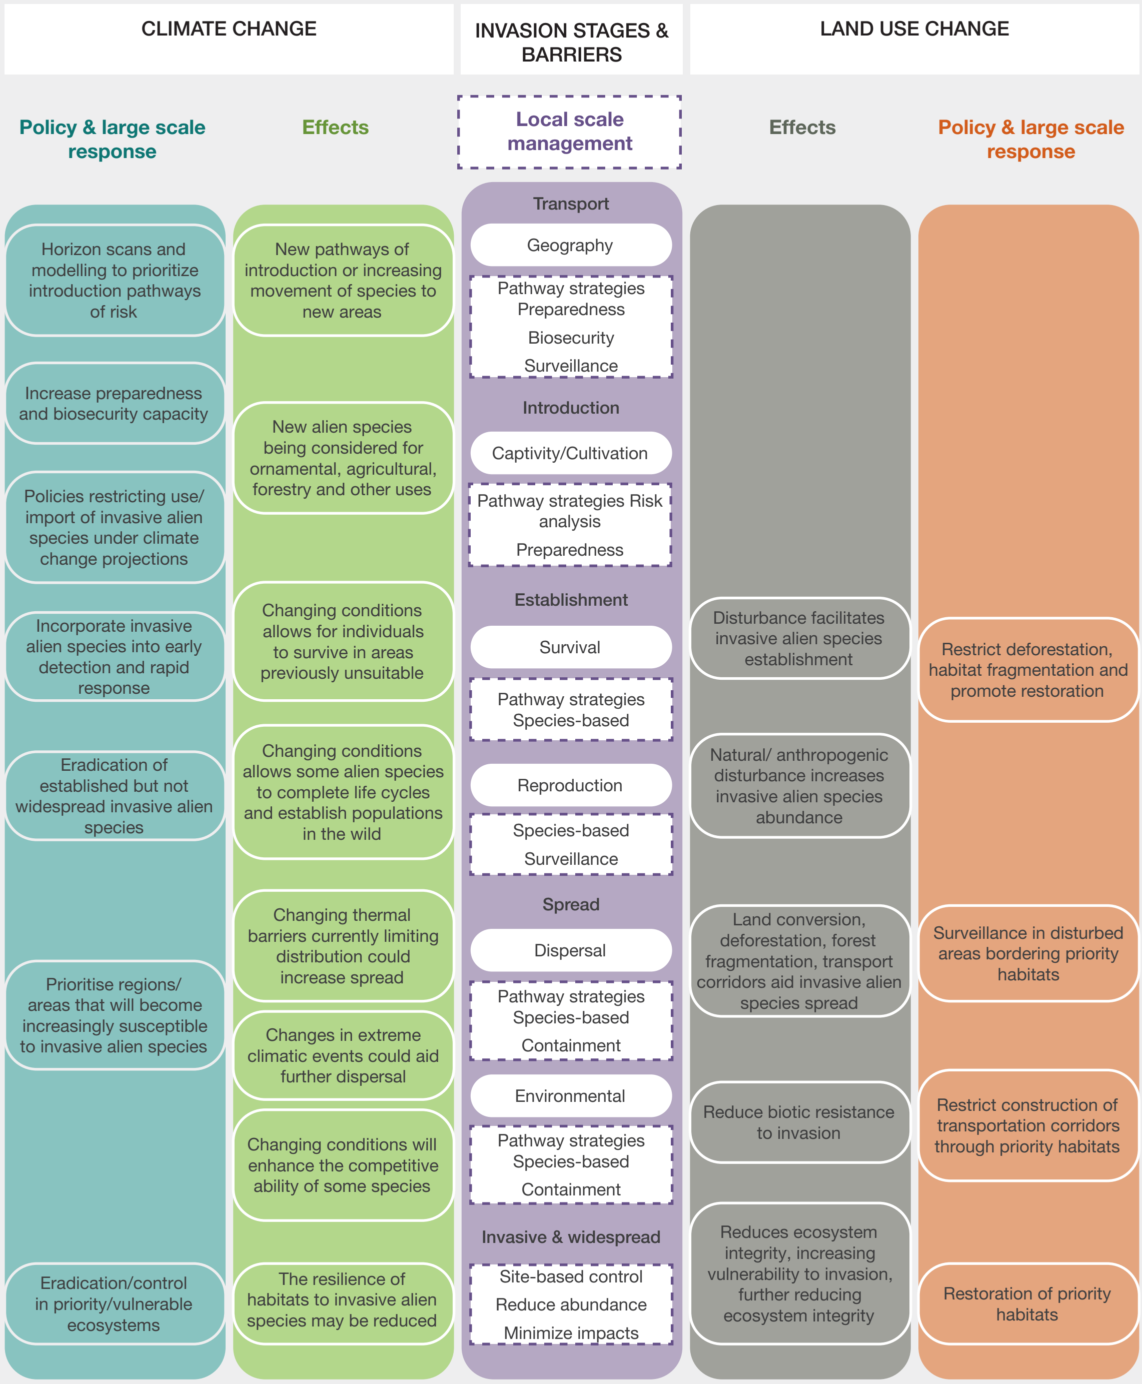

Figure 5 27 **Climate change and habitat transformation interactions at various stages of the biological invasion process, and potential management responses.**

Adapted from Walther *et al.*, (2009), https://doi.org/10.1016/j.tree.2009.06.008, under copyright 2009 Elsevier Ltd. See also **Chapter 3**, **section 3.4.2**.

alien species and provide direct pathways between urban centres globally (Elmqvist *et al.*, 2013; Weiss *et al.*, 2018). Urban areas form a nexus (**Glossary**) of railway and road networks, which are pathways for a wide range of invasive alien species (Ascensão & Capinha, 2017). Being generally highly disturbed, urban areas are therefore susceptible to alien species establishment and the high levels of human activity facilitate spread. One study showed that on average 28 per cent of the flora of the urban areas globally comprise of non-native species (Aronson *et al.*, 2014).

Most intentionally introduced species are alien garden plants, which along with released pets, predominate in the urban and peri-urban settings to which they may be pre-adapted. A global review found that most alien species are intentionally introduced in cities and were either released or had escaped from confinement (Padayachee *et al.*, 2017). Many widespread invasive alien species are well adapted to human landscapes, but some are so well adapted that they may not spread any further (e.g., domestic pigeons; Erz, 1966).

The peri-urban fringe of cities is increasingly interweaved into surrounding agricultural and natural ecosystems, allowing much more intimate interactions between people and wildlife (Seto *et al.*, 2013). This, for example, has recently been recognized as increasing the risk of emerging zoonotic diseases (Di Marco *et al.*, 2020) and the need to invest in pandemic prevention (Dobson *et al.*, 2020). Even though many introduced alien species may not have any perceived impacts in urban areas (McLean *et al.*, 2017), they can spread beyond city limits and invade natural and semi-natural habitats as a growing number of protected landscapes and marine reserves fall within a matrix of broader land-use types or zonation (Seto & Shepherd, 2009). Natural areas surrounded by urban areas also suffer from higher-than-normal propagule pressure from the urban areas. For instance, numerous new city reserves suffer from arthropods, dogs, cats, livestock (e.g., goats) and alien plants that live in close association with humans, the incursions of which reduces the resilience of these ecosystems (Lacerda *et al.*, 2009; Lessa *et al.*, 2016; Paschoal *et al.*, 2016; Spear *et al.*, 2013). Management of biological invasions in urban contexts is especially challenging because on the one hand urban environments to a degree actively encourage alien species for physical, cultural and political reasons, but natural areas connected to them are most threatened by invasive alien species from higher levels of human activity spilling over from nearby urban areas (Gaertner *et al.*, 2017).

Continuous monitoring of urban biota improves early detection of potential invasive alien species (Paap *et al.*, 2017). This is best done by assessing alien species impacts to distinguish non-invasive and invasive alien species as this is critically important for management so resources are used cost-effectively. Urban forests have been used as sentinel sites for the detection of *Agrilus planipennis* (emerald ash borer) helping managers to manage outbreaks early (Poland & McCullough, 2006). *Euwallacea fornicatus* (polyphagous shot-hole borer) and an associated pathogen (*Neocosmospora euwallaceae*) were first detected in urban environments in United States (California), Israel and South Africa, threatening to spread into nearby plantations and native forests (Paap *et al.*, 2020). An advantage of urban areas is the high availability of human support for invasive alien species management through citizen science-based surveillance, detection and rapid response activities (**section 5.4.3.2**). Citizen science initiatives have supported the early detection of *Halyomorpha halys* (brown marmorated stink bug) in Europe (Maistrello *et al.*, 2016) and New Zealand (Payne *et al.*, 2021). The widespread access to smartphones carrying biodiversity or pest recording platforms (e.g., iNaturalist and SIS-Geo) supports these activities giving the entire population the potential as detectors of invasive alien species (New Zealand MPI Biosecurity 2025; Bejakovich *et al.*, 2018; **sections 5.4**, **5.5**).

Coastal and associated off-shore infrastructures offer novel habitats for both biodiversity and the establishment and spread of marine invasive alien species (**Chapter 3, section 3.3.1.4**; Airoldi & Bulleri, 2011; Bulleri & Airoldi, 2005; Giachetti *et al.*, 2020). The total marine surface created by marine construction (as gas and oil platforms, aquaculture and wind farms, recreational and commercial ports, wave and tidal farms, breakwaters, shipwrecks, artificial reefs) was 32,000 km^2 in 2018 and projected to increase 23 per cent by 2028, which is probably an underestimation (Bugnot *et al.*, 2021). Ocean infrastructure is developing faster than marine spatial management and planning, which is struggling to include management of biological invasions, even though eco-engineering may provide solutions (Dafforn, 2017).

5.6.2 Gaps and impediments to implementing management

5.6.2.1 Societal and social impediments to effective management

The likely number of attempts to manage invasive alien species compared to the relatively few that are reported as successful could imply that most attempts did not provide long-term success with objectives achieved. But this need not always be true and invasive alien species management success rates generally increase as decision-making and stakeholder engagement improves and best practice is understood and adopted (**sections 5.2.1**, **5.2.2.1**). For example, there have been high rates of success in invasive alien species eradication on islands (**section 5.5.3**) and in classical insect and weed biological control programmes (**section 5.5.5**). Failures of management can result from numerous procedural, societal and capacity-related constraints (**Table 5.10**; Day & Witt, 2019), as for example the absence of long-term funding necessary to achieve the goals and avoid reinvasions (Dana *et al.*, 2019). These constraints, and the fact that in many cases there is a lack of understanding or the drivers of change that favour the introduction of invasive alien species are not identified (**Chapter 3**), make it difficult to implement pathway, species-based and site- or ecosystem- based management (**section 5.3**), thereby obstructing effective prevention,

Table 5 10 **Identified constraints of effective management that impede successful management at each management approach (pathway, species-based and site/ecosystem based) explained in this section.**

Dark grey cells indicate when there are constraints to effective management approaches.

Constraints		Most affected management approaches		
		Pathway	Species-based	Site/ ecosystem based
Procedural	Jurisdictional boundaries			
	Policy inadequacies			
	Stakeholder engagement			
Capacity-related	Lack of expertise			
	Inadequate communication			
	Resourcing			
Societal	Resistance to management approaches and technologies			
	Lack of awareness			

eradication, containment and control of invasive alien species. Since invasive alien species are a human-caused issue, the constraints described in this section are generally related to the context of the values and perceptions on invasive alien species.

Jurisdictional boundaries: As invasive alien species are impervious to human-created political and legal borders, addressing cross-border invasion (be it property, local, national or international borders) in a cooperative manner is difficult from both a legal responsibility and financial liability perspective. Examples are: a) eradication of the invasive alien species *Hemitragus jemlahicus* (Himalayan tahr) in New Zealand was considered no longer possible because of private legal property rights preventing enforcement of an official eradication programme (Forsyth & Tustin, 2001) and b) in Ireland, a number of protected sites under the European Habitats Directive (Special Areas of Conservation) span the border between the Northern Ireland (non-European Union) and the Republic of Ireland (European Union) (Stokes *et al.*, 2006). There is no formal mechanism for coordinated cross-border control for managing biological invasions, effective management of invasive alien species is challenging even within individual protected areas.

Policy inadequacies: Contradictory or inadequate legislations, policies and regulations are a very common impediment to management of biological invasions. From a prevention perspective, regulating which species can and cannot be introduced live into a jurisdiction is the first line of control (Garcia-de-Lomas & Vilà, 2015). Regulated species lists are lists of species that are either allowed or not into a country. Unregulated species can generally be imported live across jurisdictional boundaries without control. Countries generally ban certain regulated species and allow all others to be imported (most countries), or regulate which species can be imported and ban all species that are unregulated (Australia and New Zealand). In the latter context, for a species to be regulated for import it will need to have been approved under an independent import risk assessment process (**section 5.2.2.1**). Regulating banned species only is a reactive approach while regulating species for import is a proactive biosecurity approach (Burgiel *et al.*, 2006). Allowing any unregulated species (implies no import risk assessment has been undertaken) to be imported creates a major invasive alien species biosecurity risk (Hulme *et al.*, 2018; Simberloff, 2006). At the post-border stage, regulatory power of policies can be an issue of concern. For example, in the United States, most authorized invasive plant lists do not carry any regulatory weight against the use of listed species (Niemiera & Holle, 2009), thereby allowing release and escape of many invasive alien species except for those banned by federal or state governments.

Also, several developing countries lack comprehensive relevant legislation for biological invasions, and even fewer have recognized lists of invasive alien species and an associated regulatory system (Banerjee *et al.*, 2021).

For example, Indonesia has an existing invasive alien species National Strategy and Action Plan built on risk analyses and management priorities, however, it is not supported by effective cross-sector policy regulating importation and movement of invasive alien species, and public understanding of the issue is also inadequate (Setyawati *et al.*, 2021). Such socio-political realities often lead to governmental lethargy even for invasive alien species with actual or potential impacts to the economy (Nuñez & Pauchard, 2010; Zenni *et al.*, 2017; K. Gupta & Sankaran, 2021) and in some cases such species are seen only as potential economic opportunities (Hänfling *et al.*, 2011). This clearly has direct and indirect implications for implementation of effective management. When governments propose tighter regulations on invasive alien species, industries that sell invasive alien species as products lobby against this on the basis that business generates tax benefits for governments (Hulme *et al.*, 2018; Mack *et al.*, 2000), for example, horticulture (Niemiera & Holle, 2009). Most countries are, however, now parties to the CBD which supports national invasive alien species legislation under the Kunming-Montreal Global Biodiversity Framework (CBD, 2020a).

Stakeholder engagement: In most countries important stakeholders related to management of biological invasions are disconnected from the problem. But, identifying stakeholder responsibilities and engaging them in the management of biological invasions are key to successful outcomes (Kamigawara *et al.*, 2020; **Chapter 1**, **section 1.5.1**; **Chapter 6**, **section 6.4**). A comprehensive study investigating the development and sales of alien pasture plants in eight countries located across six continents showed that the vast majority of agribusinesses in these countries, as well as government agencies and other private companies, do not manage the risk of their products; agribusiness could integrate risk analysis with development of new products and avoid trading species which have a high risk of invading natural areas (Driscoll *et al.*, 2014). A similar situation was also reported in ornamental horticulture industry (Niemiera & Holle, 2009). This lack of recognition of social responsibility is at least partly due to a lack of incentives (as they do not see this as their problem) and legal responsibilities (Driscoll *et al.*, 2014; Simberloff *et al.*, 2005). Coordinated participation of private landowners is also crucial, but is often lacking in the actual management (Drescher *et al.*, 2019; Meier *et al.*, 2017) frequently due to lack of legal responsibility or incentives (Epanchin-Niell & Wilen, 2015), hindering effective management of biological invasions across entire landscapes (Glen *et al.*, 2017). There are however many examples where effective regulatory, social responsibility and incentive-based systems support effective industry (Harrington *et al.*, 2003; Burt *et al.*, 2007; Conser *et al.*, 2015) and landowner (G. R. Marshall *et al.*, 2016; Niemiec *et al.*, 2017) engagement in prevention and management of biological invasions.

Lack of expertise: Declining numbers of specialist taxonomists and a shortage of invasive alien species management specialists creates capability impediments to management of biological invasions (e.g., Pyšek *et al.*, 2013) and regulations at policy level (Hieda *et al.*, 2020), leading to errors in decisions in many cases (Bortolus, 2008). This is also a weakness for understanding the status and trends (**Chapter 2**) and impacts (**Chapter 4**) of invasive alien species. *Sporobolus densiflorus* (denseflower cordgrass) introduced in California from south-eastern America was confused with *Sporobolus foliosus* (California cordgrass) and ecosystem restoration activities along the west coast of North America led to its spread (e.g., present in 94 per cent of the Humboldt Bay) until 1985 (Bortolus, 2008; Kittelson & Boyd, 1997) preventing effective eradication (Pickart, 2012). In Australia, *Asterias amurensis* (northern Pacific seastar) was also confused with the native species *(Uniophora granifera)* and by the time this was realized, eradication and control were no longer possible (M. L. Campbell *et al.*, 2007). In Kerala, India, the invasive tree *Senna spectabilis* (whitebark senna) was misidentified as the native *Cassia fistula* (Indian laburnum) and widely planted, and is now widespread in the Wayanad wildlife sanctuary and in the Nilgiris causing impacts to natural and planted forests and coffee plantations (Vishnu Chandran & Gopakumar, 2018). In developing countries, lack of capability in the use of effective prevention and management approaches for biological invasions, tools and technologies are severe impediments to implement better management approaches and could be a focus of international support and aid programmes

Resourcing: Seeking adequate resources to undertake effective and sustainable management of biological invasions is a global problem, while many resources aree being used ineffectively (Courchamp *et al.*, 2017). Making the case for investment requires a) evidence-based economic, social and environmental impact analyses (**Chapter 4, section 4.1.1**) and b) demonstration that any particular invasive alien species management approach provides cost-effective and sustainable mitigation of these impacts, in competition with other government investment priorities. The lack of success of many invasive alien species management programmes does not help this case (Latombe *et al.*, 2019). Some management approaches such as biological control have a long history of cost-effectiveness (**section 5.5.5.3**) and create a strong case for investment. This will need to be demonstrated for the new technologies under development. Developing national capability and capacity for management of biological invasions is also linked to sustained funding (Nuñez & Pauchard, 2010).

Resistance to management approaches and technologies: Public opposition to uncertainty, often resulting from a poor understanding of management approaches for biological invasions and technologies, is a significant impediment to effective management (**Chapter 3**,

sections 3.3.2.4, **3.3.5.2**). Classical biological control, despite a long history of development and benefits and support by both the IPPC and the CBD still attracts negative views (Downey & Paterson, 2016). This is based on historic evidence of non-target impacts (Carvalheiro *et al.*, 2008; Pearson & Callaway, 2005; Willis & Memmott, 2005), some from a time before regulations under internationally agreed risk analysis (Howarth, 1991; **sections 5.5.5.3**, **5.5.5**). Acceptability is impeded by a general lack of government investment to monitor non-target impacts (Barratt *et al.*, 2021; Simberloff *et al.*, 2005). Pesticide-based chemical control is also becoming less acceptable related to short term efficacy and non-target effects (**section 5.4.3.2**; Simberloff *et al.*, 2005). Similarly, opinions on the use of lethal control of invasive alien vertebrates vary widely based on country and stakeholder groups, with the ethical consideration thereof now of high importance (**Chapter 1**, **section 1.5.3**; **section 5.4.3.2**). This is not helped by the many baiting and culling programmes that are poorly planned/implemented or unsustainably resourced. Some Indigenous Peoples and local communities have a moral dilemma about using chemical and biological control methods to manage invasive alien species, because the methods can be incompatible with their spiritual connections with the land (IPBES, 2022a). Animal welfare constraints can also arise from opposing public perspectives on invasive alien species (Estévez *et al.*, 2015), which is detailed in **section 5.6**.

Inadequate communication and lack of awareness: Lack of understanding of invasive alien species impacts (Kleitou *et al.*, 2019) and linguistic problems in communication can be a constraint in management planning across culturally different stakeholder groups, but can be addressed through co-developed communication planning. Stakeholder groups are also likely to be more engaged and committed to implement management strategies in ecosystems they use, which may lead to a bias in management towards terrestrial ecosystems (Mungi *et al.*, 2019). Sosa *et al.* (2021) suggested that support to manage biological invasions can be enhanced by promoting communication between educators and teachers, which will encourage public participation in the process. They also proposed increasing awareness among students by including invasive alien species identification and their potential threats in educational curricula from Kindergarten to University levels (Sosa *et al.*, 2021; **Chapter 6**, **section 6.7.2.4**).

5.6.2.2 Knowledge and implementation gaps in the management of biological invasions

This chapter has identified gaps in the implementation of knowledge, or knowledge gaps that constrain successful long-term control, in pathway, species-based and site/ecosystem-based management of biological invasions. Addressing the gaps identified below can directly support improved management actions, in cases providing the minimum information for decision-making. Alternatively, while certain tools and methods have been developed, how to use them in a particular scenario or at a large enough scale, is not currently known. A summary of these is presented in **Table 5.11**.

Table 5 11 **A summary of gaps in knowledge and implementation impeding management of biological invasions.**

The gaps were developed through an expert elicitation process with authors of **Chapter 5**.

Gap type and category		Gap description	Why is it important?	Cross-reference
Pathway Management	**Knowledge and implementation;** potential instruments, including policy and enabling approaches	Eradication strategies and guidelines for generalist invasive alien invertebrates, diseases and hard to detect freshwater and marine invasive alien species (not restricted to defined hosts).	These groups have been understudied. Even where information is available, developing and implementing guidelines remains difficult and is seldom done.	5.2.2.1, 5.2.2.2, 5.5.3
	Knowledge; gaps on biomes, units of analysis or taxonomic gaps	Risk management, cost-effective species-based surveillance and detection strategies for multiple invasive alien species groups, e.g., fungi and other microbes.	Species-based approaches are limited by taxonomic un- certainty, e.g., microbes. Strategies are needed at a higher taxonomic level than species in such cases.	5.2.2.1, 5.3.1.2, 5.4.3.2
	Implementation; potential instruments, including policy and enabling approaches	Risk analysis for movement of marine invasive alien species.	Risk analysis tools are available but not consistently applied. Pathway management is the highest priority for marine species.	5.2.2.1, **Figure 5.4**
	Implementation; potential instruments, including policy and enabling approaches and management	Managing alien species movements and biosecurity risks along trade supply chains, e.g., *via* shipping containers.	Trade based pathways such as shipping containers and illegal mail order remain poorly managed, particularly for contaminating pests and diseases.	5.3.1.1, 5.4.3.1, **Box 5.2**

Table 5 11

	Gap type and category	Gap description	Why is it important?	Cross-reference
Pathway Management	**Implementation;** potential instruments, including policy and enabling approaches and management	Effective management and compliance of biofouling policy.	International (and national) policy instruments are available but not consistently applied. New biofouling treatments are needed.	5.5.1, Chapter 6, section 6.2.1(5)
	Implementation; management	Management of deliberate movements of species across jurisdictional land-borders. Domestic quarantine is poorly implemented in several developing countries.	Needs better policy to support management. Natural pathways cannot be prevented, but may benefit from improved surveillance.	5.6.2.1, **Table 5.10**
	Knowledge; integrated scenarios and models; technical development	Understanding of direct and indirect non-target impacts of chemical, manual, mechanical and biological control of an invasive alien species on other species and ecosystems.	Non-target impacts can be substantial and are important therefore data need to be collected and included in risk analysis.	5.5.5
Species-based Management	**Knowledge;** gaps on biomes, units of analysis or taxonomic gaps	Incorrect taxonomic species identification (or varieties) impeding management.	Access to strong taxonomic capability for invasive alien species in all key groups is critical.	5.4.3.2, 5.6.2.1, **Table 5.4**, **Table 5.12**
	Knowledge and implementation; integrated scenarios and models; technical development	Prioritizing invasive alien species management and developing the necessary strategies under climate change and habitat or land-use change.	Considering climate change effects on invasive alien species and their management is rare but will be critical in the future.	5.6.1.3, **Figure 5.27**; Chapter 6, section 6.7.2.2
	Knowledge and implementation; integrated scenarios and models; technical development	Prioritizing management of biological invasions over other actions (e.g., threatened and endangered species protection and management).	Protecting threatened species and communities may be improved by understanding cost-effectiveness of different actions including management of biological invasions to prioritize investments.	5.2.2.2, 5.3.1.4
	Implementation; management	Containment of slow spreading pervasive invasive alien invertebrates and plants.	Slow spreading invasive alien species are often a lower priority for management but they may be harder to control later and have greater long-term impacts.	5.5.4
	Implementation; technical development	Humane management approaches for invasive alien species subject to animal ethics.	Humane management approaches for invasive alien species often increases social acceptability.	5.4.3.2, 5.5.5.2
	Implementation; integrated scenarios and models; technical development	Management of invasive alien invertebrates and plants under increasingly restrictive chemical control options.	With the preference to alternative management options, it is important to proactively consider and develop better integrated management approaches including biological options.	5.4.3.2, 5.4.3.3
	Implementation; management	Management of marine invasive alien species for population suppression.	All current marine invasive alien species management programmes have been unsuccessful in the long-term as a means of control.	5.6.1.1, **Box 5.3**
	Implementation; management	Management approaches for widespread established invasive alien species using available and novel tools and methods.	Once prevention has been optimized there is a need to consider and develop better technologies for control of widespread species.	5.5.5
	Implementation; integrated scenarios and models	Management decision-making approaches for invasive alien species with benefits in some contexts (i.e., conflict species).	Policy and collective decision-making approaches need to better address conflict species to prevent management being stalled.	5.6.1.2, **Table 5.9**; Chapter 6, section 6.4.1
	Knowledge; integrated scenarios and models	Prioritizing site-based management under multiple management contexts (i.e., nature, nature's contributions to people and good quality of life).	Site-based, ecosystem-based and restoration generally focuses on biodiversity protection but needs to include impacts on Indigenous Peoples and local communities.	5.3.1

Table 5 11

	Gap type and category	Gap description	Why is it important?	Cross-reference
Site/ecosystem-based Management	**Knowledge;** integrated scenarios and models; technical development	Cost-effective scenarios and modelling for invasive alien species management and evaluation use.	Scenarios and modelling are generally underutilized for invasive alien species management planning.	5.2.2.4, 5.6.3.2, **Table 5.14**, **Table 5.15**
	Knowledge; potential instruments, including policy and enabling approaches and management	Managing urban and peri-urban areas, including urban-marine linked areas, in the context of impacts on surrounding ecosystems and ecosystem services on which local communities depend.	As urban and peri-urban areas put increasing pressure on native communities through local biodiversity loss, managing this driver of invasive alien species impacts needs to be prioritized and addressed.	5.6.1.4
	Implementation; management	Effective inclusion of Indigenous and local knowledge in management design and decision-making.	Indigenous and local knowledge is critical for long-term, integrated, management of biological invasions.	5.1.3, 5.5.2, 5.7, **Box 5.15**
	Implementation; management	Adaptive integrated invasive alien species management with ecosystem restoration to improve ecosystem resilience and broader ecosystem-based management.	Improving adaptive management from governance to implementation is a priority, as it is a proven approach to managing dynamic ecosystems.	5.4.3.3, 5.5.6, 5.6.2.5; Chapter 6., Box 6.14 and Box 6.16
Other implementation gaps	**Essential supporting processes as impediments to invasive alien species management;** potential instruments, including policy and enabling approaches and management	Procedural (policy, cross-jurisdictional, stakeholder engagement). Capacity-related (capability, lack of knowledge on modern tools and techniques, resourcing and communication). Societal (lack of awareness, resistance) challenges will need to be addressed.	Biosecurity and invasive alien species have a human cause, are a function of human values and endeavour, and therefore need greater cooperation and social and societal analysis and solutions.	5.6.3.3, **Table 5.10**; Chapter 6, sections 6.4 and 6.7
	Uncertainty; integrated scenarios and models; technical development	Decision-making in the context of uncertainty.	The precautionary approach argues that actions should not be hampered by incomplete knowledge where doing nothing is not an option.	5.2.2.3, 5.6.2.5

5.6.2.3 Challenges to management in relation to knowledge gaps in invasion biology

While technological advances (**section 5.4**) are assisting management of biological invasions, it is critically important that ecological understanding at the species and community levels (Zavaleta *et al.*, 2001) and Indigenous and local knowledge underwrite their application to avoid perverse outcomes (e.g., Caut *et al.*, 2009; **section 5.5.4**). Since biological invasions are non-linear and dynamic (**Chapter 6**, **section 6.6.1.1**) the resulting complexity needs to be recognized when preventing and managing biological invasions around the world. There are multiple examples of invasive alien plant replacements following mis-informed management that can make the system worse (Pearson *et al.*, 2016). Invasive alien vertebrate management programmes can also lead to unexpected consequences. Invasive pig control in Hawaiian rainforest removed a disturbance agent supporting native species recovery in some areas (Loope *et al.*, 2013), but led to a five-fold increase in the invasive alien plant *Psidium cattleianum* (strawberry guava) in others (Kellner *et al.*, 2011). Similarly invasive cat suppression can allow invasive alien rodent densities to increase (Karl & Best, 1982; Zavaleta *et al.*, 2001). In Kakadu National Park (Australia), expansion of *Urochloa mutica* (para grass) expansion followed invasive *Bubalus bubalis* (Asian water buffalo) removal (Morris, 1996; **Chapter 3**, **section 3.3.5.2**). Monitoring biodiversity and freshwater ecosystems using macroinvertebrate-based indices is a widely-used method globally, however knowledge is lacking on how invasive alien species may affect the metric scores and therefore classification of a river's status (Guareschi & Wood, 2019).

5.6.2.4 Insufficient technological expertise in implementing management techniques

Based on the available information, the numbers of invasive alien species in developed countries are significantly higher compared to developing countries (IPBES, 2019). However, this could be an incorrect assertion since several developing countries are underexplored for invasive alien species and/

or data are unavailable, especially for some ecosystems (e.g., for marine ecosystems), resulting in significant data gaps. As a result, invasive alien species are poorly managed or unmanaged in these regions (McGeoch *et al.*, 2010). This may also be due to the gaps in capacity and capability (i.e., expertise and experience) between developed and developing countries in management of biological invasions. Technologically advanced countries may provide strategies and solutions through aid programmes to developing countries, but aid programmes rarely have the long-term support to ensure systemic adoption (Boy & Witt, 2013) and generally fail when development of local expertise is not supported, not adequately co-designed, institutionalized and resourced. This creates a huge impediment for the adoption of the many effective tools and technologies currently available (**section 5.4**) as many regions are unable to utilize them. Local communities' distrust of unfamiliar techniques is also one of the impediments for adoption (**sections 5.4**, **5.5**). For monitoring, lack of resources or skills precludes adopting many advances in technology such as environmental DNA, remote sensing, or the use of unmanned aerial vehicles for invasive alien species detection (**section 5.4.3.1**). Technological solutions need to be set in the local context encouraging local communities to adopt them in a manner applicable to their conditions, experience and resourcing. Adoption of autonomous technological solutions in developing countries has been effective in other sectors (e.g., vaccine delivery in Ghana). In many regions, the use of pesticides is disallowed due to lack of regulations and for fear of non-target effects. For weeding in agricultural areas, which frequently includes invasive alien plants, this leaves manual removal as the only option. In Africa and the Asia-Pacific region manual removal is the most time consuming and costly activity for local farming communities (Day, Kawi, Tunabuna, *et al.*, 2011; FAO, 2006; Muraleedharan & Anitha, 2000; Sims *et al.*, 2012). In such cases, the use of classical biological control may provide long-term solutions, however aversion to such techniques needs to be overcome (Boy & Witt, 2013). Sharing of technological expertise to manage biological invasions can be achieved with international cooperation and by building long-term relationships (Hulme, 2020b; **section 5.6**; **Chapter 6**, **sections 6.3.1**, **6.6.2.2**).

5.6.2.5 Applying adaptive management under uncertainty

Adaptive management is a key approach in management of biological invasions (Foxcroft & McGeoch, 2011; Zalba & Ziller, 2007), assisting decision-making in management where there are data and knowledge gaps (**Chapter 6**, **section 6.6**, **Figure 6.20**). This is usually the case when resources are limited, and the management system is socially and ecologically complex (**sections 5.4**, **5.5**). Uncertainty often leads to the tendency of inaction and delaying management actions for want of complete information (Salafsky *et al.*, 2001), however, this needs to be compared to the consequences of inaction. In management of biological invasions, some decisions and actions need to be taken rapidly, for example, to manage a pathway during an unexpected incursion, or to initiate species-based eradication while it is still feasible (S. Liu *et al.*, 2011). Therefore, management decisions need to be made and actions implemented based on the best available knowledge (Stohlgren & Jarnevich, 2009). Accurate information is a precondition for undertaking effective and timely management measures, including species identification, gained from field and literature surveys (e.g., Island Conservation, 2018). Errors often lie across the scales and types of invasive alien species data with potentially serious consequences for prevention and management (McGeoch *et al.*, 2012). Examples are given in **Table 5.12**. Field validation of knowledge is important and can be obtained during the management implementation using an adaptive management approach.

Table 5 12 **Impacts of errors in data on invasive alien species presence, distribution, socio-economic and political perceptions and potential responses to improve the efficacy of management interventions on biological invasions.**

Adapted from McGeoch *et al.* (2012). See **sections 5.4** and **5.5** for details on management methods.

Type of error	Explanation	Effect on management or policy development	Management responses (instruments tools and approaches)
Data collection	There can be a lack of survey information on the presence, extent, and population dynamics outside the native range of a species. Resolution of data and scaling in the introduced range of the invasive alien species: he low-resolution of alien species distribution maps or geographic regions can lead to overestimation of species distribution.	a) Data on the establishment and spread is required to designate alien species as invasive. Insufficient survey information results in failure to recognize invasive alien species. b) Invasive alien species assemblages are dynamic, and the lack of regular surveys can lead to inaccurate species lists and data on distribution and population sizes.	Increased attention to detail and taking care to record data correctly, and increasing efforts to search for information to ensure correct species identification (including synonyms, name changes, incorrect names). Increased frequency of data surveys for a better recognition and definition of invasive alien species distribution

Table 5 12

Type of error	Explanation	Effect on management or policy development	Management responses (instruments tools and approaches)
Data collection		c) Populations may be incorrectly delimited (prevalence known) leading to incorrect decision-making and management errors. d) Prematurely declaring eradication campaigns successful when not enough monitoring has been done to ensure confidence in eradication as cryptic populations remain un-detected.	(**Chapter 6**, **sections 6.6.2.4** to **6.6.2.7**).
Data and knowledge not documented or not readily or widely accessible	Data are not available in books and peer-reviewed literature, electronic, or online databases. Information may exist (and specialists may recognize invasive alien species), but is not yet documented, or is outdated. Grey literature is not easily accessible and may be in different languages. Some of the new taxa data are published in obscure journals. A wide range of data sources exist, but are not always sufficiently well collated, published or easily accessible.	This may result, for example, in a time delay between discovery and publication. This may influence the likelihood of eradication opportunities. Eradicated or extirpated species may also remain on species lists. Inadequate native range information (e.g., cryptogenic species – see **Glossary**), may result in subjective or incorrect listing of species as being alien or not. Identifying an alien species incorrectly, a lack of information on how to implement management, and a lack of specific/appropriate management tools.	Enhance connectedness of global repositories (**section 5.4**), especially for data and grey literature (**section 5.4**). Use of taxonomic expertise (Pyšek *et al.*, 2013) and identification tools to assist in correct species identification (**section 5.4**; **Chapter 6**, **section 6.6.2.2**).
Incomplete information/ literature searches and species misidentification	Erroneous information in lists and databases may be perpetuated.	Misidentification of species, without recognizing synonyms, changing names and other errors in data entry. Lack of comprehensive information searches can result in incomplete lists. Alien species can be misidentified as a result of lack of taxonomic data, such as undescribed species or taxa where the systematics have not been fully resolved.	Conscientious and thorough reviews and assessments before decision-making (**section 5.2**; **Chapter 6**, **section 6.6.1**).
Socio-economic and perception data	Differing perspectives leading to different perceptions in the community concerning management. E.g., hunters have a vested interest not to reduce density of an invasive alien species of their interest or completely eliminate the target species.	Difficulty to gain consistent perspectives on invasive alien species management directions and planning.	Collaborative and adaptive co-management (**section 5.4**; **Chapter 1**, **section 1.5.2**; **Chapter 6**, **section 6.7.2.4**).
Political perspectives	Political will may vary with different political perspectives and situations.	Management of biological invasions is not a priority item for some countries and may receive only limited/ intermittent funding. Jurisdictional boundaries complicate management responses (**section 5.5**).	Globally, implementing treaties and conventions (**section 5.5**; **Chapter 6**, **section 6.1.3**). Locally, initiatives such as Trans-frontier protected areas or biospheres reserves provide vehicles for collaboration (**section 5.3**; **Chapter 6**, **section 6.3**).

5.6.3 Supporting approaches to improve the uptake of effective management of biological invasions

5.6.3.1 Role of national and international networks and regional partnerships in management

The capacity of governments and resource managers to prevent and manage biological invasions depends on open and quick access to the best available scientific information, data and evidence of impacts (including socio-economic impacts) and access to suitable management tools and approaches (**Chapter 6**, **section 6.6.1**). National and international networks and partnerships are key to achieve these goals (**Supplementary material 5.13**; Fonseca *et al.*, 2013; Simpson, 2004; Simpson *et al.*, 2009; Soubeyran *et al.*, 2015; Wallace *et al.*, 2020) through trust and a feeling of shared responsibility (S. Graham *et al.*, 2019; Nourani *et al.*, 2018). **Table 5.13** presents an overview of common challenges in national and international network development as opposed to local collaborative governance networks focused on active management implementation (**Chapter 6**, **section 6.4.4**). Networks and partnerships also encourage collective efforts which may lead to socially acceptable and feasible strategies for management (S. Graham *et al.*, 2019; Nourani *et al.*, 2018). International conventions and organizations such as IPPC for plant-based trade, the WOAH for animal health, the IMO for shipping pathways (ballast water and biofouling), the CBD for e-Commerce and Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) for movement of protected species help global coordination and cooperation in the management of pathways which is crucial to significantly reduce unintentional introductions *via* international pathways. **Chapter 6**, **sections 6.3.2**, **6.4.4** and **Box 6.9** cover the role of networks and partnerships in managing biological invasions in more detail.

5.6.3.2 Scenarios and models to support the design and implementation of management

Many useful scenarios and modelling approaches have been developed and used to support decision-making and implementation in the context of biological invasions (e.g., Buchadas *et al.*, 2017; Dinis *et al.*, 2020; Gallien *et al.*, 2010; Hall *et al.*, 2021; **sections 5.2** and **5.4**). Indeed, ecological population modelling as a discipline started through the exploration of the predator-prey relationships linked to classical biological control management systems against invertebrate pests (e.g., Hassell, 1978; Mills & Getz, 1996; Murdoch *et al.*, 2013). Since then, species ecological-based and epidemiological-based models have been used in a multitude of forms including deterministic and stochastic models, matrix-based, agent-based and simulation models. These have all actively been used to assist the understanding and management effectiveness of many terrestrial and a few aquatic invasive alien species including plants (e.g., Buckley *et al.*, 2003a, 2003b, 2007), vertebrates (e.g., Calvete, 2006; Garrott *et al.*, 1992; K. Graham *et al.*, 2021; C. M. King & Powell, 2011; McCarthy *et al.*, 2013), plant disease-causing organisms (e.g., Filipe *et al.*, 2012; Harwood *et al.*, 2011) and invertebrates (e.g., Herms & McCullough, 2014). Process-based models, where the physiological or environmental characteristics of the invasive alien species are inputs and underly the model outputs have been used for decision-making and implementation of multiple management actions (Strand, 2000; Sutherst *et al.*, 2011) including biological control (Shea *et al.*, 2002). They are used most frequently in scenario and modelling studies as identified in the literature review to this assessment (107 of 183 studies; **Table 5.14**; Lenzner *et al.*, 2021).[27] These models have supported strategies at national and sub-national level, on

Table 5 13 **Overview of challenges in international and national network development and potential solutions to address them.**

Review and synthesis of S. Graham *et al.* (2019); Groom, Desmet, *et al.* (2019); Katsanevakis *et al.* (2013); Lucy *et al.* (2016); Piria *et al.* (2017); Reaser, Simpson, *et al.* (2020); Simpson *et al.* (2006); and Simpson *et al.* (2009).

Challenge	Solutions
Technical	Co-develop tools for early detection, eradication and control
	Provide high quality, up-to date and accessible data
	Assure interoperability and data standardization
Societal	Raise awareness
	Drive political choices
	Ensure access to funds wherever necessary
Coordination	Overcome national boundaries
	Avoid overlaps and fill gaps in knowledge
	Link thematic group and local networks
	Designate governance and responsibility

terrestrial invasive alien plants and invertebrates. Economic and bioeconomic models have also been developed to support management such as for feral pigs (Zivin *et al.*, 2000), diseases (Petucco *et al.*, 2020) and invertebrates (Marten & Moore, 2011; Vannatta *et al.*, 2012). Modelling has also been applied to the understanding of invasive alien plant management as part of integrated management and ecosystem restoration (Caplat *et al.*, 2012; Firn *et al.*, 2010). However, the consistent use and application of these approaches to support management of biological invasions including decision-making and response actions to prevent or reduce negative impacts is lacking, particularly in marine systems where there are significant gaps.

Correlative models, mostly found in the literature review conducted for this assessment (**Chapter 1**, **section 1.6.7.3**, have only been developed and applied to individual management activities (49 of 183 studies considering management; such as control. These correlative models have principally been implemented on invasive alien invertebrates and mammals from Asia and the Pacific, estimating and quantifying potential impacts and changes in species occurrence or abundance. Correlative models are also often used to build species risk maps both under current and future conditions to estimate invasion potential (e.g., under different climate change scenarios; **section 5.2.2.4**; **Chapter 1**, **section 1.6.7.3**). Hybrid and expert-based models, far less found in the literature (22 and 6 of 183 studies considering management respectively), have been applied especially in Africa, Antarctica, Europe, Oceania and Central Asia, to help assess the prevention and preparedness for the management of biological invasions across many different invasive alien taxa (e.g., amphibians, birds, fungi, fishes, reptiles) in freshwater and marine realm considering an international extent and context.[27] Examples are given in **Table 5.15**. The use of scenarios and models for the management of marine and cryptic species remains challenging due most likely to a lack of environmental data and data on species occurrence that can be used to develop scenarios.

As the process of invasion is dynamic, scenarios and models help make projections to assist, independently or in combination, with preparedness and management goals and decision-making (**Figure 5.1**; **section 5.2.2.4**). Both long (until 2050-2100) and mid-term (until 2030-2050) projections have been obtained under varying management scenarios, but they were little used in retrospective policy evaluations (IPBES, 2016; C. M. Jones *et al.*, 2021). Similarly, projections have been made on single or multiple management approaches addressing one or more drivers in the context of invasive alien species scenarios **(Table 5.14)**. Scenarios supporting management goals have been both qualitative and quantitative, mainly exploratory (109 of 183 studies considering management),[27] and they have principally considered scenarios of management, invasive alien species characteristics (i.e., demographic, dispersal, interaction; 29 publications), climate change (35 publications) and land- and sea-use change (12 publications) as drivers, alone or along with other drivers (**Table 5.14**; **section 5.6.1.3**).

Models and scenarios can be important tools to understand opportunities and contexts of desirable outcomes of management in terms of biodiversity, nature's contributions to people and good quality of life (IPBES, 2016). For example, different scenarios of effective management of rats and an introduced *Philornis downsi* (avian vampire fly), on nesting success of the critically endangered *Camarhynchus heliobates* (mangrove finch) were developed as part of a management programme on Isabela Island in the Galápagos archipelago. These scenarios were used to understand potential management interventions on finch population recovery to identify positive biodiversity outcomes (Fessl *et al.*, 2010). Similarly, an agent-based model was developed for understanding hypothetical agricultural subsidy scenarios aimed at controlling invasive guava and assess the resulting population and land cover dynamics effecting community livelihoods on the same island (Miller *et al.*, 2010). Management options have also been explored to provide positive outcomes to nature's contributions to people (e.g., reduction of economic losses and carbon emissions; Alaniz *et al.*, 2020). Scenarios and models have been poorly used, however, to evaluate the outcomes of management programmes for nature's contributions to people (around 12 per cent of 183 studies) and good quality of life (only 10 per cent of the studies; **Table 5.14**). Scenarios and models with emphasis on Indigenous and local knowledge or Indigenous Peoples and local communities (e.g., with participatory target-seeking scenarios) have been rare (4 per cent of studies focused on management), though involvement of Indigenous Peoples and local communities may lead to better invasive alien species management (**section 5.5**). See **section 5.6.2.1** and **Chapter 6**, **section 6.6.1.6**, for gaps and future directions of scenarios and models which may support management of biological invasions. Scenarios and models have also been used to translate the potential impact of management actions into consequences to good quality of life. For example, for *Aphis glycines* (soybean aphid), an invasive pest of *Glycine max* (soyabean), a dynamic bioeconomic model was developed to estimate the optimal chemical control strategy while considering explicitly the economic value of natural pest control (i.e., the control of the aphid by their natural enemies). Thus, this approach would reduce the economic inefficiency of pesticide use, leading to income security (W. Zhang & Swinton, 2009).

Table 5 14 **Overview of model and scenario types as well as drivers.**

Overall, 183 publications were identified to include management of biological invasions. Numbers for the different groups can be higher than 183 if multiple model or scenario types or multiple drivers were considered in the same study. Evidence from the systematic literature review on scenarios and models undertaken for the IPBES invasive alien species assessment. Table 5 15 **Examples of scenarios and models used for invasive alien species management.**

Biomes	Type of action	IPBES zones	Examples
Terrestrial	Prevention, containment	The Americas	Spatial model screening the economic cost of programmes preventing the spread of satellite populations of an invasive beetle, under different scenarios of success and simulations of spread, versus the estimated delayed cost of control, under different scenarios of actions as removal, and/or no action. Preventing the establishment of new populations is cost-effective (Kovacs *et al.*, 2011).
	Early detection, containment, eradication	Not stated	Economic simulation model evaluating the cost and success of eradication or containment potential actions under different scenarios of detection rates and search efforts (i.e., early detection; Cacho *et al.*, 2010).
	Eradication, containment	Europe and Central Asia	Simulation population model evaluating percentage of reduction in invasive plant species range under different scenarios of removal of individuals, human density and invasive populations characteristics (Wadsworth *et al.*, 2000).
	Eradication	Asia and the Pacific	Stochastic spatio-temporal model evaluating the rate of spread of invertebrates under different eradication scenarios (Kadoya & Washitani, 2010).

Table 5 15

Biomes	Type of action	IPBES zones	Examples
Terrestrial	Containment	Oceania	Process-based model of the impact of climate change on the distribution change of an invasive shrub based on its physiological tolerances for growth and reproduction (Kriticos *et al.*, 2003).
	Control	The Americas	Epidemiological model to understand the capacity for spread of the pathogen *Phytophthora ramorum* (sudden oak death) and the degree to which this is likely to influence management options (Filipe *et al.*, 2012).
		Oceania islands	Matrix-based population model for estimating the population growth rate of stoats to define dulling strategies that will lead to effective population and impact suppression of this introduced predator of ground nesting birds (C. M. King & Powell, 2011).
	Control, biological control	Oceania	Multi-level mixed effects and individual based ecological models allowed management strategy ranking based on potential to suppress population size of the invasive plant *Hypericum perforatum* (St John's wort; Buckley *et al.*, 2003b).
		The Americas	Bio-economic model to develop a general stochastic optimal control framework for the management of an invasive invertebrate using integrated pest management (Marten & Moore, 2011).
	Biological control	The Americas	Deterministic and stochastic ecological population model evaluating the 20-year effective biocontrol of citrus red scale (Murdoch *et al.*, 2006).
	Restoration, management	The Americas	Process-based state-transition model evaluating positive and negative impacts of different restoration scenarios of fire, livestock and grazing and invasion rates of non-native plant species (Forbis *et al.*, 2006).
Freshwater	Prevention	The Americas	Correlative models are used in cost–benefit analyses for prevention efforts, considering various scenarios of lakes at risk of being invaded by crayfish and different actions, from full protection (i.e., all lakes) to few lakes protected. Even with high expenditure on lake protection, net economic benefits were higher (Keller *et al.*, 2008).
	Eradication	Africa	Spatial ecological model evaluating potential management scenarios of pond-breeding frog species considering pond networks, ecotypes (i.e., arboreal, aquatic, terrestrial), access for managers to ponds due land use change (i.e., number of pods targeted) and percentage of individual removal (Vimercati *et al.*, 2017).
	Eradication, Containment	The Americas	Process based model evaluating potential management scenarios that included selective and non-selective removal of fish individuals based on age-group (Chizinski *et al.*, 2010).
	Containment	Asia and the Pacific	Ecological population model evaluating potential management scenarios on abundance of invasive alien species considering river flow conditions for various corridors and containment through commercial fishing or trap removal of individuals (Koehn *et al.*, 2018).
	Control, biological control	Oceania	Correlative hydrological, ecological and epidemiological based spatio-temporal habitat suitability modelling to prioritize future areas for common carp biocontrol in Australia using the virus CyHV-3 (K. Graham *et al.*, 2021).
Marine	Prevention	Europe and Central Asia	Correlative age-base modelling and hydrodynamic models of surface flow are used to evaluate the risks of spreading of fish and invertebrates, associated with intentional or unintentional discharges of ballast water, and considering scenarios of dispersal (i.e., types spreading of groups of organisms) and connectivity (Hansen *et al.*, 2015).
		The Americas	A Bayesian network relative risk modelling is used to detect the areas of a coastal region at greatest risk of invasion. Risk reduction is evaluated under ballast water treatment scenarios considering a decrease in non-native species introductions or their removal after introduction (Herring *et al.*, 2015).
	Eradication; Containment	Not stated	Matrix models are used to explore the efficacy of possible control strategies by removal of crab individuals at critical stage ages and seasons (Z. Zhang *et al.*, 2019).
		The Americas	Correlative models are used to evaluate the success of various fishermen harvest scenarios as control strategies, different levels of interaction complexity among the biotic and abiotic components of the ecosystem and restoration programmes of native species (Ortiz *et al.*, 2015).
		Asia and the Pacific	Process-based spread models are used to forecast areas of potential arrival of invasive crabs through different pathways. These models are complemented with quarantine scenarios preventing transport of crabs by vessels and estimated delayed times of arrival are estimated for areas with greater risk (Koike & Iwasaki, 2011).

5.6.3.3 Biosecurity policy built on prevention and preparedness

The cost-effectiveness of investing in prevention (e.g., pathway management) to thwart introduction and establishment of invasive alien species has been emphasized in this chapter. However, absolute prevention is not always possible and cannot be expected to be successful in all circumstances. It is also difficult to prove that preventative measures are effective, especially when the pathways are diverse and complex. Prevention is therefore best complemented by preparedness, by ensuring that the government, industry and the community are ready when new threats are intercepted, become established and start to spread (e.g., Bacon *et al.*, 2012). Therefore, while preventive measures and biosecurity are essential components of a management strategy, best practice includes investment in preparedness (**section 5.4.2**). Well-developed biosecurity systems in island lead to the interception of large numbers of potentially invasive alien species, which significantly reduces the rates of new introductions (in the case of Australasia exponential introduction rates have been reduced to linear introduction rates; CSIRO, 2020). New introductions are inevitable in any system, but preparedness and associated rapid response strategies help suppress impacts **(Box 5.2)**. In this context, the Australian biosecurity system has recently been forward valued at AU$ 314 billion over the next 50 years, suggesting significant benefits (Dodd *et al.*, 2020).

5.7 CONCLUSIONS

Chapter 5 reviews and assesses the efficacy of various approaches, programmes and tools, to prevent biological invasions and manage invasive alien species and their negative impacts on biodiversity, threatened and endangered species and communities, sociological and economic systems and nature's contributions to people. The chapter focuses on identifying solutions to manage these impacts across ecosystems, species and regions. To do so, the generalized invasion management continuum or invasion curve **(Figure 5.1)** was used to illustrate the progression of invasion from pre-introduction to widespread invasion. This figure also provides insights into potential management actions at different phases of invasion.

The chapter provides evidence that a large body of knowledge and experience already exists for the development and successful implementation of suitable biological invasion management plans at the local, regional and national levels (**sections 5.2**, **5.6.3**). These management plans rely on active engagement and knowledge-sharing of broad stakeholder groups and Indigenous Peoples and local communities in goal-setting, decision-making and intervention through management actions. Since invasive alien species is a human concept, management of these species may cause conflicting values, interests and perceptions for different stakeholders and Indigenous Peoples and local communities (**section 5.1.3**).

Explicit decision-making for the management of biological invasions is transparent, adaptable, repeatable and ensures stakeholder participation, education and endorsement of management choices (**sections 5.2**, **5.6.2**; **Chapter 6**, **section 6.2**). This chapter has presented a range of decision-support tools available for the identification of hazards, the prioritization of pathways, species and sites, the choice of the best management option and the evaluation of progress to achieve the desired outcomes (**section 5.2.2**, **Table 5.6**). Indigenous Peoples and local communities have unique systems for decision-making, from recognition of the need to manage invasive alien species to the choice of management options. The chapter also underlines the need of utilizing both scientific and Indigenous and local knowledge to make the optimal management decisions (**section 5.2.1**).

Limited evidence and/or uncertainty on invasive alien species and their potential or actual impacts are not an obstacle to the implementation of management strategies. Instead, the adoption of a precautionary approach, as appropriate, risk assessments and adaptive management approaches has been shown to provide long-term opportunities (**sections 5.2.2**, **5.3.1**, **5.3.3**, **5.4.3.3**). Management of biological invasions can be achieved by managing pathways, species and site/ecosystem, which can be effectively done individually or in combination, depending on the management goals, the status of invasion, the type of ecosystem and the socio-economic context (**section 5.3.1**). Their combined use fosters more informed decision-making and resource allocation and can be applied at multiple scales (**section 5.3.3**). Of these, pathway management is critical since permeability of pathways may promote introduction and spread of new invasive alien species (**section 5.3.1**).

Many efficient management methods, tools and technologies such as precision application of pesticides, baits, biological control and gene drive technology are increasingly becoming available, and new technology is being rapidly developed (**section 5.4.4**). These methods relate to pathway management (**sections 5.4.2.1**, **5.4.3.1**, **5.5.1**), surveillance and detection, rapid response and eradication (**sections 5.4.2.2**, **5.5.2**, **5.5.3**), containment, local to landscape level management (**sections 5.4.3.2**, **5.5.4**, **5.5.5**) and ecosystem restoration (**sections 5.4.3.3**, **5.5.6**). Scenarios and modelling approaches are important in management of biological invasions to assess management responses, to predict the risk of future incursions and to plan effective eradication-containment–control approaches (**section 5.6.3.2**).

Involvement of all stakeholders is central for planning, decision-making and implementing management programmes for biological invasions, through the promotion of co-implementation, social learning and broad partnerships (**sections 5.2.1**, **5.6.2**; **Chapter 6**, **section 6.2**). Also, stakeholder-led adaptive management involving Indigenous Peoples and local communities promotes wide acceptance and capacity-building and optimization of management success and economic, environmental and social outcomes (**sections 5.2.1**, **5.6.1.2**). Averting this partnership may impact good quality of life of people who are dependent on or have adapted to utilizing invasive alien species as a resource.

Prevention and rapid intervention are the most efficient and cost-effective management approach sustainable in the long-term, which is crucial for marine ecosystems (**section 5.5.1**). However, prevention may not always be successful. National biosecurity systems and invasive alien species legislation can underwrite prevention by ensuring that jurisdictions have suitable regulations and incentives in place and that there is preparedness (surveillance and monitoring) and rapid response capability in the community to address future incursions (**section 5.6.3**; **Chapter 6**, **section 6.3.2**). Surveillance for newly introduced species through citizen science and social media provides broader security by upskilling and engaging the public (**section 5.5.2**). Prevention through pathway management may be successful only if international biosecurity standards are implemented scrupulously (**section 5.5.1**).

Effective eradication approaches have been developed and may be cost-effective only on smaller islands, mountain tops, wetlands and other refuges of high socioecological and biodiversity values (**section 5.5.3**). Eradication elsewhere is unlikely to succeed, unless the incursion is very localized, easy to detect (no hidden propagules), delimited and spreads slowly. There is demonstrable technical know-how to eradicate invasive alien animals on islands, but success depends on a supporting community to implement actions.

Challenges to management of biological invasions include knowledge gaps (**section 5.6.2.1**), inadequate legislation, lapses in implementing the legislation, poor awareness, lack of capacity and capability, know-how and resources (**sections 5.6.2.2**, **5.6.2.4**; **Chapter 6**, **sections 6.6**, **6.5**) and conflict of interests around invasive alien species that are harmful in one context or sector but beneficial in another (**section 5.6.1.2**). These impediments significantly challenge management attempts, especially in the developing economies (**section 5.6.2**).

A comprehensive review of the effectiveness of management of biological invasions leading to measurable improvements in reducing the impacts of invasive alien species on biodiversity and ecosystem services was beyond the scope of this assessment. However, there is strong evidence that management success can be achieved if pathway, species-based and site-based management strategies, identified through evidence-based decision-making, are implemented using appropriate tools and techniques (**sections 5.2**, **5.3**, **5.4**, **5.5**). These approaches may be applied during all stages of the biological invasion process in the proper context and depending on the types of invasive alien species and ecosystems (**sections 5.1**, **5.5**). Adaptive management strategies assist the process supported by stakeholder engagement and Indigenous and local knowledge (**sections 5.4.3.3**, **5.6.2**). The outcomes of these integrated approaches will provide maximum benefits for nature, nature's contributions to people, including the economy, good quality of life (**section 5.4.3.3**).

Chapter 5 has taken a positive and solutions-focussed approach. Although the vast majority of actions taken to manage biological invasions around the world over the last 70 years have not provided long-term success, this chapter did not undertake a complete and objective review of successes *versus* failures. Chapter 5 recognizes that, around the world, failures have led to continued learning and this has resulted in an increasing number of successful programmes and outcomes. Successful results come from failures, from learning about the techniques and tools available and under development, and from understanding when, where and how they work best. Future management approaches will need to be taken in the context of climate change impacts on biodiversity, which will be a greater challenge.

Globally, it may not be possible to address all impacts from undesirable invasive alien species, but the successes described in this chapter show how management of biological invasions can deliver positive outcomes. This may save many threatened and endangered species and communities and improve ecosystems, nature's contributions to people and good quality of life, using the tools and approaches that have been and continue to be developed. Management of biological invasions is critical to improve ecosystem resilience and protect biodiversity in the context of future environmental changes, especially climate change.

GOVERNANCE AND POLICY OPTIONS FOR THE MANAGEMENT OF BIOLOGICAL INVASIONS[1]

COORDINATING LEAD AUTHORS:
Melodie A. McGeoch (Australia, South Africa/Australia), Alejandro Ordonez (Colombia, Netherlands [Kingdom of the]/Denmark)

LEAD AUTHORS:
Ernesto Brugnoli (Uruguay, Italy/Uruguay), Bridget Bwalya (Zambia), Chaeho Byun (Republic of Korea), Miguel Fernandez (Bolivia/United States of America, Germany), Quentin J. Groom (United Kingdom of Great Britain and Northern Ireland/Belgium), Patricia L. Howard (Netherlands [Kingdom of the], United States of America/Netherlands [Kingdom of the], United Kingdom of Great Britain and Northern Ireland), Stanislav Ksenofontov (Russian Federation/United States of America), Henn Ojaveer (Estonia/Denmark, Estonia), Bharat B. Shrestha (Nepal), Daniel Simberloff (United States of America)

FELLOWS:
Ninad A. Mungi (India/Denmark, India), Betty Rono (Kenya/Germany, Kenya)

1. Authors are listed in alphabetical order with, in parentheses, their country or countries of citizenship, separated by a comma when they have more than one; and, following a slash, their country of affiliation, if different from that or those of their citizenship, or their organization if they belong to an international organization. The countries and organizations having nominated the experts are listed on the IPBES website (except for contributing authors who were not nominated).

CONTRIBUTING AUTHORS:
Steven M. Alexander (United States of America/Canada, United States of America), Örjan Bodin (Sweden), Olaf Booy (United Kingdom of Great Britain and Northern Ireland), Giuseppe Brundu (Italy), Stanley W. Burgiel (United States of America), Steven L. Chown (Australia), Norman Dandy (United Kingdom of Great Britain and Northern Ireland), Edgardo Díaz-Férguson (Panama, United States of America/Panama), Llewellyn C. Foxcroft (South Africa), Sonia Graham (Australia, Spain/Australia), Sankaran Kavileveettil (India), Rachel I. Leihy (Australia), Bernd Lenzner (Germany/Austria), Shana M. McDermott (United States of America), Shyama N. Pagad (New Zealand), Mark S. Reed (United Kingdom of Great Britain and Northern Ireland), John Rusbarsky (United States of America), Evangelina Schwindt (Argentina), Andy W. Sheppard (Australia, United Kingdom of Great Britain and Northern Ireland, Canada, France/Australia), Laura Verbrugge (Netherlands [Kingdom of the]/Finland), Joana R. Vicente (Portugal)

REVIEW EDITORS:
Julie L. Lockwood (United States of America), Sophie Riley (Australia)

Chapter **6**

GOVERNANCE AND POLICY OPTIONS FOR THE MANAGEMENT OF BIOLOGICAL INVASIONS

EXECUTIVE SUMMARY

1 Despite some successes over the past decade, there has been limited progress towards meeting international goals and targets for biological invasions, such as Aichi Target 9 of the Strategic Plan for Biodiversity 2011-2020 and Target 15.8 of the 2030 Agenda for Sustainable Development *(well established)* {6.1.2} (Table 6.4). Many countries have little or no funding for activities to prevent or control biological invasions *(well established)* {6.1.3}, and most national invasive alien species targets lack sufficient ambition to substantively contribute to the achievement of Aichi Biodiversity Target 9 *(well established)* {6.1.2, 6.3.3}. Legislative and other policy instruments addressing biological invasions and their implementation vary greatly across countries *(well established)* {6.1.2} and sectors within countries *(well established)* {6.3.1.1, 6.3.3.1}. Data for assessing the effectiveness of pathway- and species-management are mostly unavailable *(well established)* {6.6.1.2}, highlighting the need for the generation of new and up-to-date information on the appropriate level of implementation and on the successes and failures of management interventions {6.6.1, 6.7.2.6}. Furthermore, there is limited dedicated interdisciplinary research on the governance for biological invasions in a broader environmental governance context *(well established)* {6.2.2, 6.3.3.3, 6.6.1.4}.

2 Effective governance for biological invasions can address policy gaps and limits, and improve policy coherence and its implementation *(well established)* {6.2.3, 6.7.2.3}. This could be achieved with a context-specific integrated governance approach for biological invasions, that focuses on coordinated and sequential implementation of strategic actions *(established but incomplete)* {6.2.4, 6.7.2}. Integrated governance can be achieved through robust institutions that are responsive to changing contexts, and strategies to ensure effective implementation of strategic actions *(well established)* {6.7.3} **(Figure 6.21)**. A conducive environment for integrated governance is equitable and respects different value systems and perspectives *(well established)* {6.7.3} **(Figure 6.21)**. This in turn promotes inclusive decision-making, shared efforts and commitments, the understanding of specific roles of all actors, catalyses the sharing of knowledge, data and resources, and promotes the development and implementation of multidisciplinary solutions *(well established)* {6.7.2} **(Figure 6.21)**. Integrated governance includes explicitly considering negotiation and trade-offs as an integral part of the process *(established but incomplete)* {6.2.2} **(Figure 6.21)**. By focusing on the relationships between the scales, levels of governance, sectors and stakeholders involved, the integrated governance approach identifies and addresses feedbacks, efficiencies and trade-offs in the management of biological invasions *(well established)* {6.2.4, 6.2.3.3, 6.7.2, 6.7.3} **(Table 6.7)**.

3 Multilateral coordination and cooperation are key for bringing about progress towards achieving invasive alien species goals and targets, and coherent, mutually supportive actions *(well established)* {6.2.3.3, 6.3.2.3, 6.4.4, 6.7.2.2}. Widespread and purposeful cooperation could improve the effectiveness of policy instruments to prevent and control invasive alien species *(well established)* {6.3.2.3, 6.7.2.2}. The need for cooperation emerges from the diversity of stakeholders and perspectives involved {6.4.1}; problems created by uncoordinated responses and little-considered trade-offs across sectors {6.3.1.1, 6.7.2.2}; the multiple geopolitical scales at which policy and management are needed {6.3.2}; widespread economic constraints in some regions {6.1.3}; and the interdependence between invasive alien species and other drivers of change in nature {6.3.1.3, 6.7.2.2} *(established but incomplete)*. Strategies for achieving such cooperation and for managing the collective action costs of widespread collaboration can include: enhancing coordination and collaboration across international and regional mechanisms {6.2.3.4, 6.7.4}; long-term resourcing, including developing the capacity needed, and commitment from governments and institutions at the highest levels {6.2.3.2, 6.5.1, 6.7.2.3} **(Table 6.1)**. Other options to accelerate progress include research on the relationships between actors and institutions {6.6.1}; engagement of the general public including awareness campaigns {6.2.3.3, 6.4.2.2, 6.6.2.1}; inclusion of Indigenous Peoples and local communities and recognition of their rights {6.4.3.1, 6.4.3.2, 6.6.1.5}, and information platforms to support decision-making that are developed and sustained for the long-term *(established but incomplete)* {6.2.3.1(3), 6.6.2}.

4 One of the most effective ways to manage biological invasions is to develop policy instruments that seek synergies between human health, agriculture, forestry, fisheries and environment sectors at national and international levels *(established but incomplete)* {6.1.2, 6.3.1.1}. Many national laws and regulations, as well as multilateral agreements, aimed at preventing the introduction of invasive alien species have been adopted *(well established)* {6.1.2}. They have jointly contributed to reducing the risk of invasive alien species' impacts on nature's contributions to people and good quality of life *(well established)* {6.1.2}. However, there are still gaps, limitations, and inconsistencies in the scope, taxonomic coverage, procedures and standards of current policy instruments both within countries and across regions *(well established)* {6.2.2}. Close collaboration between the different national agencies overseeing trade policy, agriculture and forestry, the environment and health can deliver a coordinated approach to biological invasions *(well established)* {6.3.1.1}. Existing approaches for achieving the necessary coordination (such as EcoHealth, One Health and One Biosecurity approaches) provide frameworks for cross-disciplinary thinking in support of the development and implementation of policies and policy instruments *(established but incomplete)* {6.3.1.1, 6.7.2.2}. While economic incentives can potentially enhance compliance with biosecurity protocols *(established but incomplete)* {6.5.2.1}; financial deterrents in the form of tariffs and penalty systems can also be used to prevent mismanagement of species introductions and the revenues they generate as means to fund incentives and/or government control programmes *(established but incomplete)* {6.5.2.2, 6.5.2.3, 6.5.3, 6.5.4, 6.5.6}. Governance for biological invasions would also benefit from the expansion of dedicated inter- and transdisciplinary research *(well established)* {6.2.4, 6.6.1.4}. Research on the impacts of invasive alien species across the health, agriculture, forestry, fisheries and environment sectors could support the development of coherent policy instruments *(established but incomplete)* {6.2.4} **(Table 6.2)**.

5 Implementation-focused national strategies and action planning for biological invasions, aligned with international regulatory frameworks, could stimulate action and help improve the effectiveness and efficiency of management efforts *(well established)* {6.2.3.2, 6.3.3.1, 6.7.2.3}. Implementation-focused strategies and action plans can provide enabling conditions for the successful governance of biological invasions, including coordination and collaboration across international and regional mechanisms *(established but incomplete)* {6.2.4, 6.7.3}, legal, regulatory and institutional frameworks {6.3.3.1}, market-based instruments that provide economic incentives and deterrents {6.5.2} and multisector inclusion {6.2.3.3, 6.3.1.1}. These national strategies could prioritize the measurement and monitoring of the resource inputs, processes, outputs and outcomes needed to improve implementation and accelerate progress towards meeting invasive alien species goals and targets at multiple levels of governance *(established but incomplete)* {6.2.3, 6.3.3.3, 6.6.2, 6.6.3, 6.7.2.6}. National strategies can define the governance models, policy instruments and support tools needed to ensure shared efforts and commitments, and understanding of the specific roles of all actors *(well established)* {6.2.3.2, 6.7.2.5} and include plans for the effective engagement across private and government stakeholders and Indigenous Peoples and local communities *(established but incomplete)* {6.4.3, 6.6.1.5, 6.7.2.4, 6.7.2.5}. They can also include market-based instruments to fund and promote activities to prevent and manage biological invasions in national budgets *(established but incomplete)* {6.5.2, 6.5.3, 6.5.4, 6.5.6} and ensure the efficient use of resources for biological invasions *(well established)* {6.2.3.2, 6.2.3.4, 6.3.3.2, 6.7.2.2}. National strategies provide a mechanism to operationalize the Convention on Biological Diversity's fifteen guiding principles for the prevention, control and mitigation of impacts of invasive alien species, which remain highly relevant but are not yet adequately implemented *(well established)* {6.1.2, 6.2.3.2, 6.3.3.3, 6.7.2.3}. National strategies are central to guiding actions to implement context-specific integrated governance for addressing biological invasions *(established but incomplete)* {6.2.4, 6.7.1}.

6 An open, interoperable information platform can effectively support changing information needs on biological invasions and enable the rapid flow of information for decisions across international, national and local levels *(well established)* {6.6.2.3, 6.6.2.4, 6.6.3, 6.7.2.6}. Such a platform could ensure that knowledge is readily available to all stakeholders involved in addressing biological invasions, particularly for those whose actions are currently limited by a lack of resources *(well established)* {6.6.2.3, 6.6.3, 6.7.2.6}. Integrated data workflows and rapid data publication could considerably reduce the time lag between the establishment of evidence and making the evidence available for a wider community and for policy, including regarding Target 6 of the Kunming-Montreal Global Biodiversity Framework *(well established)* {6.6.2.3}. Conforming to the data principles of findability, accessibility, interoperability and reusability (FAIR) makes data easier to access and use for monitoring, modelling and forecasting *(established but incomplete)* {6.6.2.4}. Continuously collecting and sharing up-to-date information on biological invasions can help evaluate the effectiveness of policy instruments and management actions *(established but incomplete)* {6.6.2.3, 6.3.3} and improve management outcomes *(well established)* {6.6.2, 6.6.3, 6.7.2.3}. Such an information platform could maintain and deliver indicators of the different dimensions of biological invasions to track progress at national and global scales, and in the medium to long term as part of a responsive and adaptive policy environment {6.1.2, 6.1.3, 6.2.3, 6.6.3, 6.7.2.6} *(well established)*. Targeted investment in specific research and monitoring programmes can rapidly and effectively deliver relevant data and information for policies and management of biological invasions *(well established)* {6.6.2, 6.7.2.6}.

7 Committed engagement with stakeholders and Indigenous Peoples and local communities can benefit the management of biological invasions by improving understanding and awareness, social learning, collaboration, surveillance and data generation *(well established)* {6.2.3.3, 6.4.2.1, 6.7.2.6}. Inclusive engagement can help build policy and management plans to address biological invasions that are coherent, legitimate and reflect local environmental and cultural realities. Adaptive-collaborative governance can foster collaboration and coordination grounded in disciplinary integration, experimentation, monitoring, the use of the best available technology and social learning *(established but incomplete)* {6.2.3.3, 6.4.3}. Engagement activities can be explicitly linked with the measurement and monitoring of management actions through national strategies aimed at enhancing respect for Indigenous Peoples and local communities' knowledge, rights and priorities *(established but incomplete)* {6.4.1, 6.4.3.2}. Biocultural community protocols developed by Indigenous Peoples and local communities can frame how they wish to be engaged in the activities that impact them *(established but incomplete)* {6.4.3.2}. These protocols can facilitate a deeper engagement with the knowledge and customary governance systems of Indigenous Peoples and local communities within, rights-based frameworks and in accordance with national legislation, benefitting both good quality of life and effective management of biological invasions *(established but incomplete)* {6.4.3.2}. Social research can help to better inform management and policy and build trust between sectors of society *(established but incomplete)* {6.4.4, 6.6.1.4}. Social research can also provide valuable information on how best to share knowledge and on invasive alien species status and trends on land managed by stakeholders and Indigenous Peoples and local communities *(well established)* {6.4.1, 6.6.1.5, 6.2, 6.4}.

8 The current understanding of the biological invasion process, which includes extensive information on many of the currently most impactful species and well-established principles for prevention and control, is adequate for guiding effective action on invasive alien species *(well established)* {6.1.2, 6.1.3, 6.2.3, 6.2.4}. The complexity and uncertainty of social, economic and environmental costs and benefits of invasive alien species is broadly acknowledged *(well established)* {6.2.2} and is a central obstacle to predicting biological invasions, including the outcomes of invasion, necessitating a precautionary approach *(well established)* {6.1.2, 6.2.2, 6.3.1.2}. Nonetheless, the key aspects of this complexity are understood, including the multiple sectors and stakeholders that contribute to and are affected by invasive alien species *(well established)* {6.2.3}. Which sectors and stakeholders are involved is context dependant and their specific roles depend on the invasive alien species involved and the ecosystems affected *(well established)* {6.2.3.3, 6.3.1.1, 6.4.1, 6.7.2.5}. A further dimension of complexity that can be considered in the governance and management of biological invasions is the interaction between invasive alien species and other key drivers of change in nature, including climate change, pollution and land-use change *(well established)* {6.3.1.3}. Given the strong interactions between these drivers, considering all forms of global environmental change can yield benefits for effective environmental governance *(well established)* {6.2.3.3, 6.3.1.3, 6.7.2.2}. Despite these complexities and the uncertainty that can affect decision-making, scientific and technical solutions exist for designing efficient and effective options to deal with biological invasions {6.2.3}, and for supplying the information needed to support policy and management decisions *(well established)* {6.6.2}. Strategic investment in research to keep data and information up to date and to fill key gaps will improve the efficiency and effectiveness of management of biological invasions *(well established)* {6.6.1} **(Table 6.10)**.

9 An integrated governance approach that connects and combines key strategic interventions and creates robust governance system properties can bring about context-relevant transformative change for the effective prevention and control of invasive alien species *(established but incomplete)* {6.2.4, 6.7.1} (Figure 6.21). Positive transformation can be achieved by (a) strengthening the connectivity within the invasion governance system, using information technology and international partnerships {6.6.2.7, 6.7.2.6}; (b) developing stronger and broader global regulatory instruments to address invasions threats {6.3.1, 6.7.2.3} as well as higher visibility of biological invasions in national legislations and environmental actions plans {6.2.4.2, 6.3.2, 6.7.2.1}; (c) engaging all relevant sectors including health, environment, agriculture, fisheries and forestry, and all relevant stakeholders including the private sector, the general public and Indigenous Peoples and local communities{6.2.3.3, 6.3.1.1, 6.4.2.2, 6.7.2.4, 6.7.2.5}; and (d) supporting innovative science and environmentally sound technologies for solutions-focused approaches {6.3.3.4, 6.7.2.6}. Governance that is responsive to changes in biological invasion risk and management contexts, focuses on effective implementation, sustains investment and commitment to goals, and is equitable and inclusive across both those affected and responsible, can bring about a step change in the prevention and control of invasive alien species *(well established)* {6.2.4, 6.7.3}.

6.1 INTRODUCTION AND OUTLINE

This chapter evaluates past and possible future governance models and challenges, policy instruments and support tools, collectively called response options (**Glossary**). These response options are aimed at managing biological invasions (**Chapter 1**, **Figure 1.1**; **Glossary**) to reduce their impacts on nature, nature's contributions to people and good quality of life (**Box 6.1**; **Glossary**). Governance models (**section 6.2**) target specific components of the socioecological system, are complimentary and tend to draw on specific sets of policy instruments, tools and methods. Policy instruments (**sections 6.3** and **6.5**) are the set of options (means or mechanisms) used at any scale by individuals or organizations for building or strengthening international, national and local efforts to manage biological invasions. Policy support tools and methods (**section 6.6**) are approaches that can inform, assist and enhance relevant decisions, policy-making and implementation at the local, national, regional and international levels, to better prevent and control these species and their impacts (**Glossary**).

Multiple international organizations and programmes have highlighted the roles of governance models **(Table 6.1)**, policy instruments and policy support tools and methods **(Table 6.1)** as means to achieve international policy targets for preventing and controlling invasive alien species and managing biological invasions (**Chapter 1**, **Box 1.1**). They include the Convention on Biological Diversity (CBD), the International Union for Conservation of Nature (IUCN)

Box 6 1 **Rationale of the chapter.**

This chapter builds on previous chapters of the IPBES invasive alien species assessment to present response options for improving and strengthening the governance for biological invasions. The chapter explores governance models and policy instruments (legal, regulatory and incentive-based) and support tools available for multilateral efforts and national strategies to prevent and control invasive alien species. Together, the integration of these strategic actions could lead to positive transformative change (**Glossary**).

Guiding questions:

- What are the challenges facing biological invasions governance?
- What are the current gaps, overlaps and inconsistencies in existing legal and regulatory instruments focused on biological invasions management (**Glossary**)?
- Which decision and engagement tools can be used to manage biological invasions?
- What economic instruments can be implemented to fund or promote the various prevention, eradication, containment, mitigation, restoration and ecosystem-based management options (**Glossary**)?
- How to develop information systems (**Glossary**) to help design, implement and monitor response options to the biological invasions problem?

Keywords:
Governance, policy instruments, community engagement, integrated governance, goals and targets, multilateral coordination, implementation strategies, coherent policy regimes, open data, information systems.

Table 6 1 **Array of possible governance and policy response options for managing biological invasions.**

Possible response options that can be used to (i) prevent or mitigate the main drivers responsible for biological invasions and (ii) prevent the impacts of invasive alien species on nature and society. The response options include models of governance, categories of policy instruments and families of support tools and methods (IPBES, 2019a).

Governance Models	Categories of Policy instrument	Families of support tools and methods (main governance model/s in brackets)
A. Hierarchical	Legal and regulatory	Assembling data and knowledge (B)
B. Scientific-technical	Economic and financial	Assessment and evaluation (B)
C. Governing strategic behaviour	Rights-based and customary norms	Public discussion, involvement and participatory process (D)
D. Adaptive-collaborative	Social and cultural instruments	Selection and design of policy instruments (A, B)
		Implementation, outreach and enforcement (A, C)
		Training and capacity-building (B, D)
		Social learning and innovation (D)

Invasive Species Specialist Group (ISSG), the Food and Agriculture Organization of the United Nations (FAO), the World Health Organization (WHO), the International Plant Protection Convention (IPPC), the World Organisation for Animal Health (WOAH, founded as OIE), the World Trade Organization (WTO), the International Maritime Organization (IMO), the World Bank and the Centre for Agriculture and Biosciences International (CABI). Many of these organizations participate in the Inter-agency Liaison Group on Invasive Species established by the Executive Secretary of the CBD.

Guided by the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) conceptual framework (**Chapter 1**, **section 1.6.1**; **Figure 6.1**), possible options to prevent and manage biological invasions outlined in this chapter respond to direct and indirect drivers of change responsible for biological invasions, and to the possible impacts of invasive alien species on nature, nature's contributions to people and good quality of life. **Section 6.2** presents options to strengthen the governance systems within which policy instruments and support tools for biological invasions are implemented. These include options for enhancing the coverage and strategic nature of biological invasions governance, dealing with multiple levels and sectors of society, as well as enhancing governance capabilities. **Section 6.3** evaluates the limitations of and opportunities for the current array of legal and regulatory frameworks, highlighting the need for strategies that bridge and coordinate across sectors, geopolitical units and stages of the biological invasion process. **Section 6.4** lays out the role of widespread engagement and the context and reasons for the broad and specific inclusion of stakeholders and Indigenous Peoples and local communities. This section examines the range of approaches for coordination and collaboration and shows how stakeholder and Indigenous Peoples and local communities' engagement can improve biological invasions governance. **Section 6.5** outlines financial and economic policy options that provide incentives for international organizations, governments, financial institutions and individuals to invest in invasive alien species prevention, containment, mitigation, or eradication (**Glossary**). This section assesses the role of tariffs, cost-sharing and penalty systems as deterrents to invasive alien species (**Glossary**) introduction and spread and as a financing alternative. This section also presents support tools for analysing the costs and benefits of invasive alien species. **Section 6.6** specifies options for generating and maintaining the information and knowledge needed to govern and manage biological invasions. This section identifies knowledge gaps and options for access to the information needed for the creation of early warning systems, for forecasting the spread and impact of invasive alien species and for assessing management effectiveness. Information needs for the purpose of developing and reporting on the effectiveness of policy instruments are also described. Finally, **section 6.7** summarizes the key governance and policy challenges and opportunities for sustainable biological

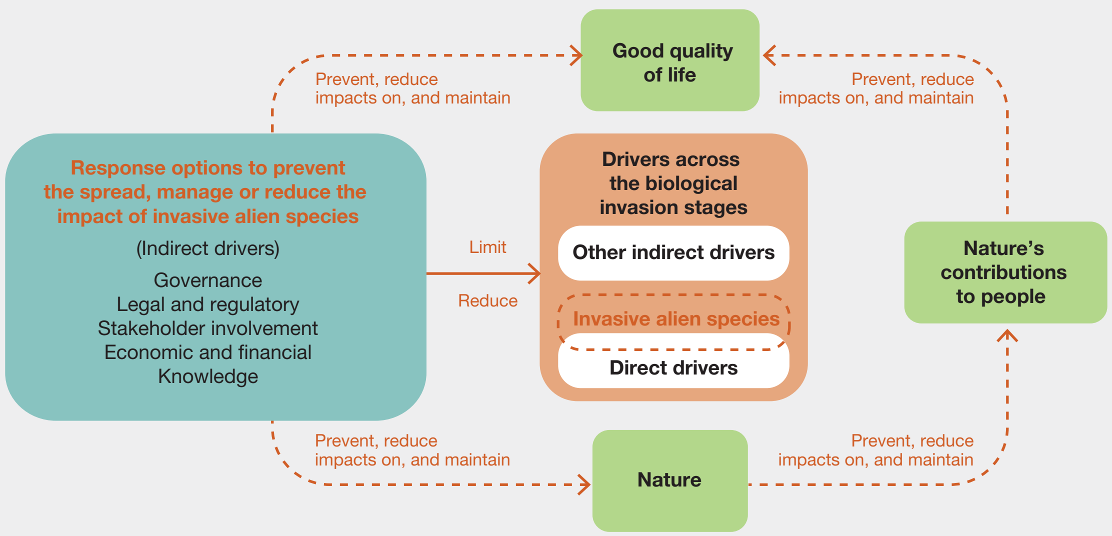

Figure 6 1 **Framework for governance and policy response options and how they relate to nature, nature's contributions to people and good quality of life.**

Simplification of the IPBES conceptual framework that describes the array of response options (left box) to limit the drivers facilitating biological invasion and the spread of invasive alien species (middle box) and mitigate their negative impacts on good quality of life (surrounding boxes connected by dashed arrows). Modified from S. Díaz *et al.* (2015), https://doi.org/10.1016/j.cosust.2014.11.002, under license CC BY-NC-SA 3.0.

invasion management that emerge from the assessment. This section outlines the set of strategic actions and governance system properties that can jointly construct an integrated approach to the governance for biological invasions that can bring about a step change in progress to achieving related policy and management goals.

6.1.1 Risks and opportunities

The IPBES invasive alien species assessment and previous IPBES assessments (as outlined in **Table 6.2**) identify risks and opportunities that provide the basis for determining future options and strategies to prevent and mitigate the impacts of invasive alien species on nature, nature's contributions to people and good quality of life **(Figure 6.1)**. These risks and opportunities can be categorized into ten groups **(Table 6.2)** and lay the foundation for the strategic identification of governance policy instruments and options. These risks and opportunities also reveal where adaptation is the most feasible option, when eradication or adequate management is no longer feasible, and when such an adaptive response could lead to a positive system transformation.

Table 6 2 **Risks (hazard or impact taking place) and opportunities (circumstances that make it possible to act) for managing biological invasions as defined in the IPBES invasive alien species assessment and other IPBES assessments.**

The risks and opportunities showcased provide an overview of the main governance challenges, policy instruments and knowledge needs that are highlighted in this chapter to effectively manage biological invasions. The relevant sections within the IPBES invasive alien species assessment and other IPBES assessments are highlighted for each of the points raised.

Risks and/or opportunity	Description (relevant chapter sections of this/previous IPBES assessments)
Information disparity	• Geographic, taxonomic, data access and publication biases (**Chapter 6**, **section 6.6.1**; **Chapter 4**, **section 4.7.2**; IPBES, 2018a) • Comparatively limited knowledge of invasive alien species impacts on fisheries, coral reefs and marine ecosystem functioning (**Glossary**; **Chapter 4**, **section 4.7.2**)
Information uncertainty	• Uncertainty about management cost, efficacy, limitations, success, collaborations and adaptation (**Chapter 5**; IPBES, 2018b) • Uncertainty about dispersal pathways, transboundary and regional collaboration (**Glossary**; **Chapter 3**, **section 3.6.1**; IPBES, 2018b) • Uncertainty about the impacts of novel assemblages/ecosystems emerging due to invasive alien species (**Chapter 4**)
Framing biological invasions in terms of their interactions with other environmental problems	• Inadequate integration of biological invasion problems in policies and management interventions aimed at addressing other environmental problems such as land degradation or climate change (**sections 6.3.1** and **6.7**; IPBES, 2016, 2018d)
Policies as drivers facilitating biological invasions	• Lack of coordination of policies on environment, infrastructure, health, agriculture, forests, environment, nutrition and biological invasion management can catalyse invasive alien species spread (**section 6.3.1**; IPBES, 2018d) • Inefficient policies on climate change, pollution, human population, land-use change, pet and wildlife trade, afforestation, horticulture and health had severe consequences on spread and impacts of invasive alien species (**section 6.3**) • Lack of coordination between policies of different sectors (**section 6.3.1**) and between national and regional regulations (**sections 6.3.2** and **6.3.3**)
Impact disparity	• Management of biological invasions is particularly difficult when they simultaneously have both serious negative environmental impacts and benefits for good quality of life or are characterized by value conflicts (**Chapters 4** and **5**) • Use of potentially invasive alien species in programmes aimed to ensure food security or promote economic development (**section 6.3**)
Technological advancement	• Absence of early detection systems and rapid response actions for prevention and eradication of invasive alien species (**section 6.6**) • Lack of monitoring (**Glossary**) programmes to track the effectiveness of responses and progress in managing biological invasions (**section 6.2**) • Lack of inter-operable and standardized databases (**section 6.6**; IPBES, 2018c, 2019a)
Economic synergies	• Conflict of interest in international regulatory frameworks with a direct or indirect focus on preventing invasive alien species introductions (**sections 6.3** and **6.5**) • Difficulties with assessing the collective investment in prevention and control of invasive alien species, how adequate they are, and costs avoided as a result (**section 6.1**)

Table 6 2

Risks and/or opportunity	Description (relevant chapter sections of this/previous IPBES assessments)
Societal response	• Lack of public support, financial resources and awareness of risks associated with invasive alien species among all stakeholders (**sections 6.4** and **6.5**, IPBES, 2018a, 2019a) • Absence of institutions that coordinate and provide oversight on invasive alien species prevention, control and mitigation strategies, and promote the flow of information (**sections 6.3** and **6.7**)
Engagement with Indigenous Peoples and local communities	• Engaging with stakeholders and Indigenous Peoples and local communities (**section 6.4**) • Lack of integration of stakeholder and Indigenous and local knowledge (**Glossary**) and limited engagement of stakeholders and Indigenous Peoples and local communities in decision-making for biological invasions (**section 6.4**)
Gaps in knowledge of governance	• Lack of information about the success of governance in management interventions (**section 6.2**) • Limited dedicated interdisciplinary research on the governance for biological invasions in an environmental governance context (**section 6.2**)

6.1.2 Progress towards international and national goals and targets for invasive alien species

The CBD is currently the most encompassing and directly relevant global environmental governance mechanism for biological invasions. It has the following three objectives: the conservation of biological diversity; the sustainable use of the components of biological diversity; and the fair and equitable sharing of the benefits arising out of the utilization of genetic resources (**Figure 6.1**, **section 6.1.2**). The Conference of the Parties (COP) to the CBD has also specifically recognized that invasive alien species represent one of the primary threats to biodiversity, especially in geographically and evolutionary isolated ecosystems, such as small island developing States (SIDS). As early as 2002, the CBD COP adopted a series of Guiding Principles for improving the governance for biological invasions **(Table 6.3)**. These Guiding Principles remain highly relevant and provide a list of options to accelerate and sustain progress on invasive alien species and their control. The responsibilities of Parties to the CBD are therefore longstanding, and gaps and shortcomings in the governance for biological invasions over the last several decades (**section 6.1.3**) have meant that actions have not been sufficient to stop their spread (**Chapter 2**).

Under the recent Kunming-Montreal Global Biodiversity Framework (CBD, 2022a), the invasive alien species target (Target 6) encompasses eliminating, reducing and mitigating impacts through pathway management (**Glossary**), prevention and with a focus on priority species and priority sites (**Chapter 1**, **Box 1.1**). With the addition of some new elements Target 6 reinforces the key elements of the previous Aichi Biodiversity Target 9, based on which current progress has been evaluated. Assessment of the progress towards meeting Aichi Biodiversity Target 9 (invasive alien species prevented and controlled) concluded that, while increases in the adoption of related policy was encouraging, there was still a considerable gap between the development and adoption of invasive alien species policy, and implementation at national levels (Secretariat of the CBD, 2020; **Table 6.4**).

The fifth edition of the Global Biodiversity Outlook also indicated that there has been no reduction in the pressure from invasive alien species on biodiversity, ecosystems and society (Secretariat of the CBD, 2020). Factors identified as underlying the imperfect achievement of Aichi Biodiversity Target 9 included: inadequate policy implementation due to limited capacity and resourcing of relevant governmental agencies; lack of coherence across multiple, relevant policies; and the fact that policy adoption does not equate directly to management effectiveness. This Global Biodiversity Outlook report further pointed out the lack of research and data on biological invasion policy effectiveness at a global scale (Secretariat of the CBD, 2020). Subsequent studies have also identified poor governance as a factor limiting national-level progress to achieving other Aichi Biodiversity Targets (Buchanan *et al.,* 2020).

The Sustainable Development Goals (SDGs) also include a target for invasive alien species (Target 15.8; **Chapter 1**, **Box 1.1**) closely related to Aichi Target 9 of the Strategic Plan for Biodiversity 2011-2020. This target aims to track progress in the commitment by countries to relevant multilateral agreements, and the proportion of countries with national strategies, legislation and policy for invasive alien species. However, the indicators that were selected to track progress of Target 15.8 of the 2030 Agenda for Sustainable Development also included for the first time an “input response” element (i.e., the extent to which the measures identified are resourced; **section 6.2.1**).

Table 6 3 **The 15 Guiding Principles for the prevention, introduction and mitigation of impacts of alien species that threaten ecosystems, habitats or species.**

The text associated with these principles is not provided in full here – abbreviated notes are shown where particularly relevant to invasive alien species governance as discussed in **section 6.2** (**Chapter 1**, **section 1.3.1**). Source: CBD (2002).

No.	Guiding Principle
A. GENERAL	
1	**Precautionary approach:** efforts to identify and prevent unintentional introductions as well as decisions concerning intentional introductions should be based on the precautionary approach as described in Principle 15 of the 1992 Rio Declaration.
2	**Three-stage hierarchical approach:** prevention is the top priority; followed by early detection, rapid response and eradication; and then containment, long-term control measures and examination of the benefits and costs.
3	**Ecosystem approach:** as described in decision V/6 of the Conference of the Parties.
4	**The role of States:** States should recognize the risk that activities within their jurisdiction or control may pose to other states and should take appropriate individual and cooperative actions to minimize that risk, including making information on the identity of invasive alien species available to other states.
5	**Research and monitoring:** Research on an invasive alien species should focus on the history and ecology of invasions, the biological characteristics of the invasive alien species, and the associated impacts. Monitoring should involve multiple sectors and include both targeted and general surveys.
6	**Education and public awareness:** Promote education and public awareness of the causes of invasion and the risks associated with the introduction of alien species.
B. PREVENTION	
7	**Border control and quarantine measures:** Putting in place appropriate measures to control introductions of invasive alien species based on risk analysis of threats and potential pathways of entry.
8	**Exchange of information:** CBD Parties should assist in developing an inventory and synthesis of relevant databases, and developing information systems and an interoperable distributed network of databases for compilation and dissemination of information on alien species. The Parties should provide all relevant information on their specific import requirements for alien species and make this information available to other States.
9	**Cooperation, including capacity-building:** Cooperation should be based on programmes developed to share information as well as cooperative research and funding efforts. Capacity-building may involve technology transfer and the development of training programmes, especially for countries that lack expertise and resources.
C. INTRODUCTION OF SPECIES	
10	**Intentional introduction:** No first-time intentional introduction or subsequent introductions of an alien species already invasive or potentially invasive within a country should take place without prior authorization from a competent authority of the recipient state(s).
11	**Unintentional introductions:** Provisions to address unintentional introductions need to be set in place.
D. MITIGATION OF IMPACTS	
12-15	(full text not provided here) Including mitigation of impacts (no.12), eradication (no.13), containment (no.14) and control (no.15) (**Chapter 5**).

By comparison, multilateral instruments or organizations such as the IPPC and WOAH have been widely successful in developing and implementing instruments to mitigate the risks of invasive alien species considered to be pests or to affect animal health. There are over 40 adopted international standards for phytosanitary measures (ISPMs, developed by IPPC),[2] 31 Diagnostic Protocols, and 39 Phytosanitary Treatments aimed to protect the environment, forests and biodiversity while also facilitating economic and trade development. The standards and codes developed by the IPPC and WOAH have provided a foundation for multilateral collaboration in managing the risks posed by invasive alien species.

Table 6 4 **Progress against invasive alien species policy goals and targets.**

Indicator category	Indicator[3]	Elements of Aichi Biodiversity Target (AT) 9 and SDG Target 15.8	Global progress against Target or Goal
Driver	Trends (**Glossary**) in pathways of introduction and spread	Measures are in place to manage pathways to prevent introduction and establishment (AT); Introduce measures to prevent the introduction of invasive alien species (SDG)	Progress has been made, but at an insufficient rate. This target has not been achieved (high confidence; (Secretariat of the CBD, 2014, 2020). Major pathways are not efficiently controlled at a global scale (Secretariat of the CBD, 2014), but major advancements have been made in the context of shipping (in particular, an agreement to prevent biological invasions *via* ballast water).
		Pathways identified and prioritized (AT 9.2)	Major pathways have been identified (Faulkner *et al.,* 2020; IUCN, 2017; Saul *et al.,* 2017; Secretariat of the CBD, 2014). However, the pathways of introduction of more than a third of introduction events are unknown (McGrannachan *et al.,* 2021).
Pressure	Trends in numbers of invasive alien species and their impacts	None	The number of documented, new introductions of alien species continues to increase (Seebens *et al.* 2017). Progress towards target has been made, but at an insufficient rate (Secretariat of the CBD, 2014).
		Invasive alien species are identified and prioritized (AT 9.1)	Measures have been taken in many countries to develop checklists of invasive alien species (Secretariat of the CBD, 2014, 2020). Target partially achieved.
State	Trends, mechanisms and severity of invasive alien species impacts	Introduce measures to significantly reduce the impact of invasive alien species (SDG)	A negative trend in the conservation status of species threatened by invasive alien species in the Red List Index (McGeoch *et al.,* 2010) suggests that this target has not been achieved. Overall, there has not been an improvement in conservation status of species threatened by invasive alien species, although some progress has been made for some species and for species on islands (CBD, 2020b; Secretariat of the CBD, 2014).
Response Input	Trends in the allocation of resources towards the prevention or control of invasive alien species	Proportion of countries adopting relevant national legislation and adequately resourcing the prevention or control of invasive alien species (SDG)	Of the 195 countries party to the CBD, almost half have no national budget and no funding *via* global mechanisms for invasive alien species prevention and control activities (Pagad *et al.,* 2020).
Process	Trends in establishment and national adoption of international agreements relevant to the prevention and control of invasive alien species	Trends in policy responses, legislation and management plans to control and prevent spread of invasive alien species (Pagad *et al.* 2020)	Between 30 and 90 per cent of all countries are signatory to the nine multilateral agreements relevant to the prevention or control of invasive alien species, including the CBD, with most countries' signatory to the World Heritage Convention, IPPC and the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES; 2% increase since 2010; Pagad *et al.,* 2020). Likewise, most of the world shipping tonnage (over 91%) is under regulation under the International Convention for the Control and Management of Ship's Ballast Water and Sediments (BWM Convention; IMO, 2022). Trends in adoption overall are positive since 1970 (Pagad *et al.,* 2020).
	Trends in numbers of countries with national legislation and other policy measures relevant to the prevention and/or control of invasive alien species	Proportion of countries adopting relevant national legislation and adequately resourcing the prevention or control of invasive alien species (SDG)	Only 10% of reporting parties have national targets of similar scope and ambition to Aichi Biodiversity Target 9 and are on track to meet them (CBD, 2020b). Party self-assessment is variable as assessed against their own national targets (Secretariat of the CBD, 2020). Most countries (190) party to the CBD have some form of national legislation relevant to invasive alien species; 17% of these are specifically focussed on invasive alien species (Pagad *et al.,* 2020). 39% of countries have developed a national invasive species strategy and action plan (NISSAP; Pagad *et al.,* 2020). 10% of countries rely entirely on international funding for invasive alien species prevention and control activities (Pagad *et al.,* 2020). Of the countries party to the CBD (195), 80% have invasive alien species targets in their national biodiversity strategies and action plans (NBSAPs), 74% are aligned with Aichi Biodiversity Target 9 (Pagad *et al.,* 2020).
Output	Trends in the prevention of invasive alien species	Measures are in place to manage pathways to prevent introduction and establishment; Priority species are controlled or eradicated (AT 9.4); Introduce measures to control or eradicate priority invasive alien species (SDG)	There has been no significant overall progress towards this target (Secretariat of the CBD, 2014). Some measures have been put in place but are not sufficient to prevent the continuing increase in invasive alien species.

Table 6 4

Indicator category	Indicator[3]	Elements of Aichi Biodiversity Target (AT) 9 and SDG Target 15.8	Global progress against Target or Goal
Output	Growth in information relevant to informing policy on invasive alien species prevention and control	none	In progress
Outcome	Trends in successful control and eradications of invasive alien species	Priority species are eradicated (AT 9.3)	Progress towards target, but at an insufficient rate (Secretariat of the CBD, 2020). Some control and eradication, but data limited. Progress has been made, but Target has not been achieved.25% of invasive alien species mammal eradications on islands have occurred since 2010 (Secretariat of the CBD, 2014, 2020).
		Priority species are controlled (AT 9.3)	Data limited (Secretariat of the CBD, 2020). Target unlikely to have been achieved.

3. The indicator here is expressed in an inclusive general form, encompassing relevant alternative formulations of closely related indicators.

6.1.3 Specific progress towards governance-related invasive alien species goals

Response plans and monitoring for invasive alien species

In general, goals specific to societal "responses" to biological invasions are very poorly developed, as is the availability of data on response plans and response monitoring (**section 6.6.3**; Vicente *et al.,* 2021). Nonetheless, some components of existing invasion targets and associated indicators fall into this "response" category, and these are highly relevant to the governance for biological invasions at global and national scales. These include the existence and uptake of multilateral agreements and national legislation relevant to the prevention and control of invasive alien species, and resourcing of invasive alien species prevention and control activities (McGeoch *et al.,* 2010; Pagad *et al.,* 2020; **section 6.6.3**).

Multilateral agreements

Monitoring of the response targets that do exist (**section 6.6.3**) shows that there has been a small increase in the number of countries that are signatories of seven relevant multilateral agreements in the last decade, and country adoption ranges from about 60 per cent to 98 per cent across these agreements (**Figure 6.2**; Pagad *et al.,* 2020). Of these, IPPC and WOAH have been critical instruments for preventing the introduction of invasive alien species and defining the roles of authorities working on biosecurity (**Glossary**) to prevent introductions of invasive alien species. Likewise, the eighth, and most recent, agreement – the BWM Convention – has reached a country signatory level of 33 per cent since it was established in 2004 (**Figure 6.2**; **Chapter 5**, **section 5.5.1**), although it was ratified only in 2017. The over 60 country signatories to this convention are responsible for 91 per cent of the world's shipping tonnage (IMO, 2022), making it a potentially powerful instrument for preventing invasive alien species; interestingly, this is the only multilateral treaty adopted specifically to prevent the spread of invasive alien species.

National legislation

The development and adoption of relevant national legislation is split across agricultural and environmental sectors, and in some cases also split across industries involving plants and those involving animals **(Figure 6.3)**. Only 17 per cent of countries have invasive alien species-dedicated national legislation (Pagad *et al.,* 2020), whereas an estimated 69 per cent have invasive alien species-specific legislation as part of legislation in other sectors (in addition to plant and animal health legislation that is broadly relevant to invasive alien species; Pagad *et al.,* 2020).

Overview of progress

The development of action plans for invasive alien species by CBD parties can help them achieve biological invasion-relevant goals and targets, such as occurred under the previous Aichi Target 9 of the 2011-2010 Strategic Plan (CBD, 2020). However, across the elements of Aichi Biodiversity Target 9 and related Target 15.8 of the 2030 Agenda for Sustainable Development, limited progress was made over the decade to successfully prevent, control

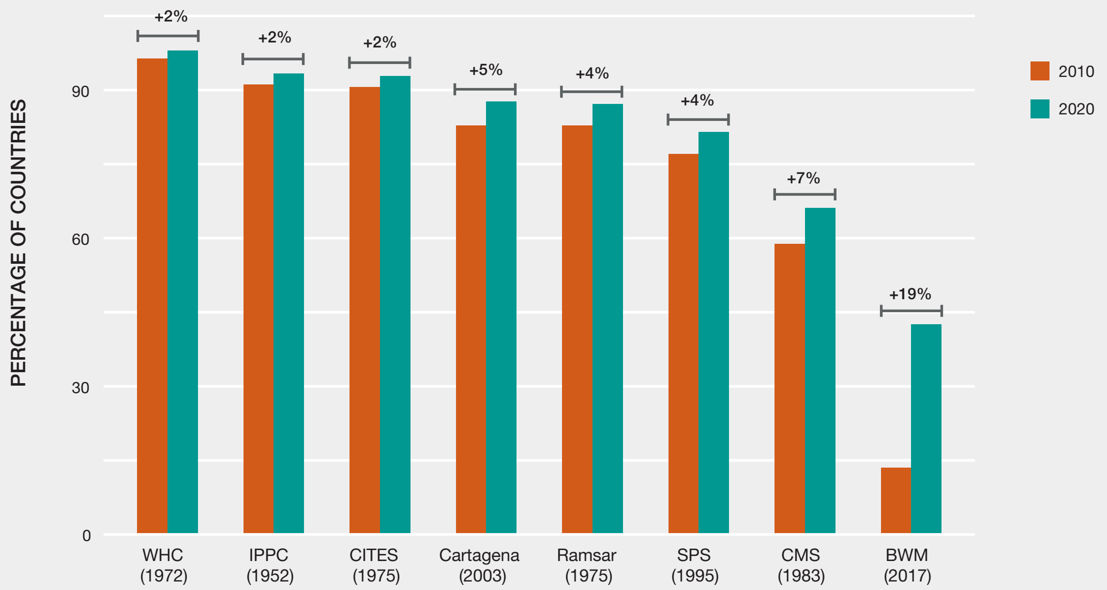

Figure 6 2 **Percentage of countries (y axis) signatory to eight multilateral agreements relevant to the prevention and control of invasive alien species (x axis).**

Data is shown for 2010 (left bars; n = 192) and 2020 (right bars; n = 195), with % increase since 2010 (shown above), signatory countries to eight multilateral agreements relevant to the prevention and control of invasive alien species. Only countries party to the CBD at the time of reporting were considered in the analysis. The eight multilateral agreements (year of establishment below acronym in figure) analysed were the Cartagena Protocol on Biosafety to the CBD (CBD, 2000), the IPPC (IPPC, 1952), the Agreement on the Application of Sanitary and Phytosanitary Measures of the WTO (WTO SPS; WTO, 1995), CITES (CITES, 1975), the Convention on Wetlands of International Importance (Ramsar) (Secretariat of Convention on Wetlands, 1971), the Convention on the Conservation of Migratory Species of Wild Animals (CMS) (CMS, 1979), the World Heritage Convention (WHC) (UNESCO, 2017) and the BWM Convention) (IMO, 2004). The WOAH (WOAH, 2011) has a high level of uptake (93%) and showed no change between 2010 and 2020 and is therefore not included in the figure. and reduce the impacts of invasive alien species (**section 6.1.2**; **Table 6.4**). Most countries (about 196 countries; Pagad *et al.,* 2022) now have checklists of introduced and invasive alien species, but the documented numbers of new introductions continue to increase (**Chapter 2**; Seebens *et al.,* 2017). The overall conservation status of species threatened by invasive alien species (Blackburn *et al.,* 2019) continues to worsen, many countries have little to no funding for invasive alien species activities (Blackburn *et al.,* 2019; **section 6.1.2**), and most national invasive alien species targets lacked ambition relative to Aichi Target 9 **(Table 6.4)**. Legislative and other policy instruments for invasive alien species are highly variable across countries and across sectors within countries (Pagad *et al.,* 2020; **section 6.1.2**). Data available for assessing the management of pathways of introduction of invasive alien species and of alien species (**Chapter 5**, **section 5.3.1**), and the effectiveness of this management, are inadequate and largely unavailable **(Table 6.4)**.

Resourcing

Estimates of the financial cost of biological invasions to countries vary widely, depending on the data source, location and evaluation method used (Diagne *et al.,* 2020). Based on country-sourced data (Pagad *et al.,* 2020), estimates of country investment in the prevention and control of invasive alien species (**section 6.5**) show that close to half of countries allocate no funds, with most such countries concentrated in Africa (**Figure 6.4** and **Figure 6.5**). Indeed, Africa depends most heavily on globally-sourced funding for the prevention and control of invasive alien species **(Figure 6.5)** and needs additional resources to support policy development and reporting (Egoh *et al.,* 2020). In the other IPBES regions, funds are allocated through a mix of national and international sources **(Figure 6.5)**. Europe and Central Asia have the highest rates of nationally derived funding. However, even where relevant legislation has been adopted, countries face significant resource shortages (Outhwaite, 2018). It is important to note that in these indicators, investment in resourcing of biological invasions policy and management implementation is different from the realized "cost" of invasive alien species measured as damage or loss from invasive alien species and expenditure on management (Diagne *et al.,* 2020).

In summary, globally representative, country-relevant data on the governance for biological invasions and related policy instruments show generally high levels of compliance with multilateral agreements. Such agreements do contribute to prevention and control of invasive alien species and stimulate the existence of many different national instruments, though in most countries these

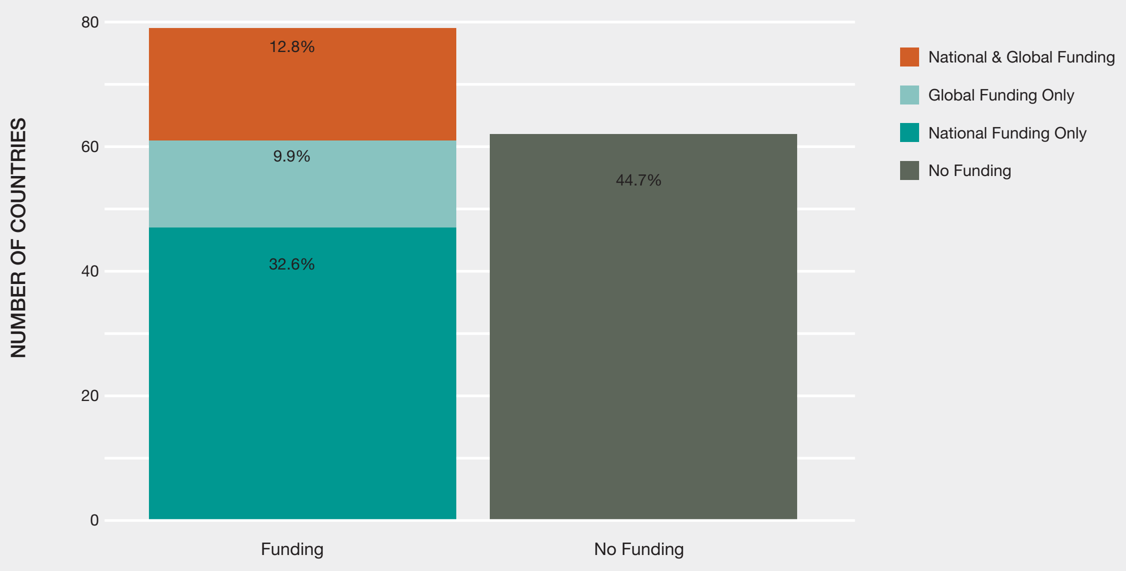

Figure 6 4 **Allocation of financial resources to the prevention and control of invasive alien species, including both national and global financial mechanisms.**

Africa: n = 38, Americas: n = 25, Asia and the Pacific: n = 32, Europe and Central Asia: n = 46. Source: Pagad *et al.* (2020), https://opal.latrobe.edu.au/articles/report/International_Adoption_of_Invasive_Alien_Species_Policy/13065158, under license CC BY 4.0.

instruments are siloed within industry sectors **(Figure 6.3)**, most of which are not dedicated to invasive alien species prevention and control. A thorough analysis of national legislative instruments for biological invasions is still lacking (perpetuating the situation identified mid-term in the Strategic Plan for Biodiversity 2011-2020), as are assessments of the effectiveness of invasive alien species legislation (Leadley *et al.,* 2014).

Although evidence for progress in establishing and advancing effective governance for biological invasions is patchy and incomplete, the weight of evidence points to a failure to adequately resource, prevent and control invasive alien species (throughout this assessment and **section 6.6.3**). While it is not possible to establish how much worse the situation would be in the absence of the substantial collective investment made to date to prevent and control invasive alien species (**Chapter 5**, **section 5.5.7**), it can be inferred that governance approaches and governance systems for biological invasions have been inadequate. Strengthening related governance provides an overarching option for improving the prevention and control of invasive alien species and making faster progress toward achieving multilateral goals and targets (Buchanan *et al.,* 2020).

6.2 GOVERNANCE RESPONSE OPTIONS

This section provides context for assessing governance options for biological invasions. It aims to clarify the understanding of the governance system within which a policy instrument or policy support tool for biological invasions is being implemented **(Box 6.2)**. "Good governance is an enabling condition for policy implementation, distributing the resulting positive impacts evenly across society" (IPBES, 2019b). This section identifies governance considerations from invasive alien species-specific literature and contextualizes these within environmental governance more broadly. A key finding is that there is little dedicated interdisciplinary research on the governance for biological invasions in an environmental governance context.

The concept of governance is defined and used in several ways. This assessment uses the formulation and rationale of Gilek *et al.* (2016):

> "Governance includes both structures – such as policy contexts, existing power relations among key actors,

Box 6 2 **Governance for biological invasions.**

Governance encompasses the norms, rules, laws, values, expectations, relationships and structures that affect or guide the behaviour of individuals and institutions, public and private. In the context of biological invasions, governance is aimed at the specific public purpose of preventing and reducing the spread and preventing the harm, caused by invasive alien species (Andonova & Mitchell, 2010; M. S. Reed & Curzon, 2015). The governance for biological invasions therefore encompasses formalized arrangements such as national strategy and legislation, as well as informal decision-making processes involving the range of effecting and affected stakeholders (**section 1.5.1** in **Chapter 1** for more information on stakeholder groups, Reed & Curzon, 2015). A key feature of governance for biological invasions is that it is a continuous, cooperative process that accommodates diverse and conflicting interests to enable action (Riley, 2012).

> regulatory frameworks and organizational forms of decision-making, reflexivity and participation – and processes. Processes comprise aspects such as the evolution of institutions and interactions between, for example, science and policy, as well as communication and interaction among policymakers, scientists, and other stakeholders. Processes also include the development of strategies, framings, communication, and learning."

Strong governance can help to address the problem of invasive alien species, as it enables the legislation, regulations, cooperation, participation and monitoring of actions to mitigate key drivers (T. Evans *et al.,* 2018).

6.2.1 The theory of change and indicator frameworks for improving implementation

The Driver-Pressure-State-Response (DPSR) model, sometimes including impacts (DPSIR; OECD, 2003), is a strategic framework used for reporting on global and national progress toward meeting goals and targets. It is designed to directly link monitoring of the problem with the actions taken to deal with it. The Kunming-Montreal Global Biodiversity Framework (CBD, 2022a) now extends this, using a theory of change for accelerating action to achieve biodiversity goals for the planet and people (CBD, 2021a); it distinguishes four types of response, i.e., input, process, output and outcome (OECD, 2019; **Table 6.5**). This more detailed and specific identification of the types of responses

Table 6 5 **Four types of societal responses that can be measured and monitored for the purpose of limiting the spread and reducing the impacts of invasive alien species.**

The four types of responses are in the context of a DPSR framework. Adapted from OECD (2019), with the addition of invasive alien species-specific examples.

Response type	Definition	Invasive alien species examples
Input	Measures the material and immaterial pre-conditions and resources – both human and financial – provided for an activity, project, programme, or intervention	• Budget allocated for invasive alien species research, education, monitoring, prevention and control • Number of staff allocated to invasive alien species monitoring, prevention and control
Process	Measures the progress of processes or actions that use inputs and the ways in which programme services and goods are provided	• A national inter-Ministerial Committee for biosecurity established • Targeted education programmes for local communities affected by invasive alien species
Output	Measures the quantity, quality and efficiency of production of goods or services because of an activity, project, programme or intervention	• New legal or policy instruments • Studies such as national invasive alien species assessments completed • The costs of invasive alien species integrated into national accounts
Outcome	Measures the intermediate broader results achieved through the provision of outputs	• Increased eradications of invasive alien species • Reduced ranges of priority invasive alien species • Reduced impacts of invasive alien species

Box 6 3 The Driver-Pressure-State-Response framework for invasive alien species.

This framework **(Figure 6.6)** is intended to guide investment in monitoring and to enable evidence-based causality to be assigned to the relationships among drivers affecting biological invasions (**Chapter 3**, **section 3.5**), invasive alien species and their impacts (**Chapter 4**) and societal responses to dealing with the problem (**Chapter 5**). The indicators listed under each part of the framework below are examples from the application of this framework to the Antarctic (for a global example see McGeoch *et al.,* 2010). For example, trends in invasive alien species eradication at different scales (response) lead to reduced numbers of alien and invasive alien species (pressure) and reduced extinction risk of species threatened by invasive alien species (state). Trends in the number of tourists in the region (driver – note that the term driver in this context differs from its general use in this assessment) provide the information needed to inform policy (response).

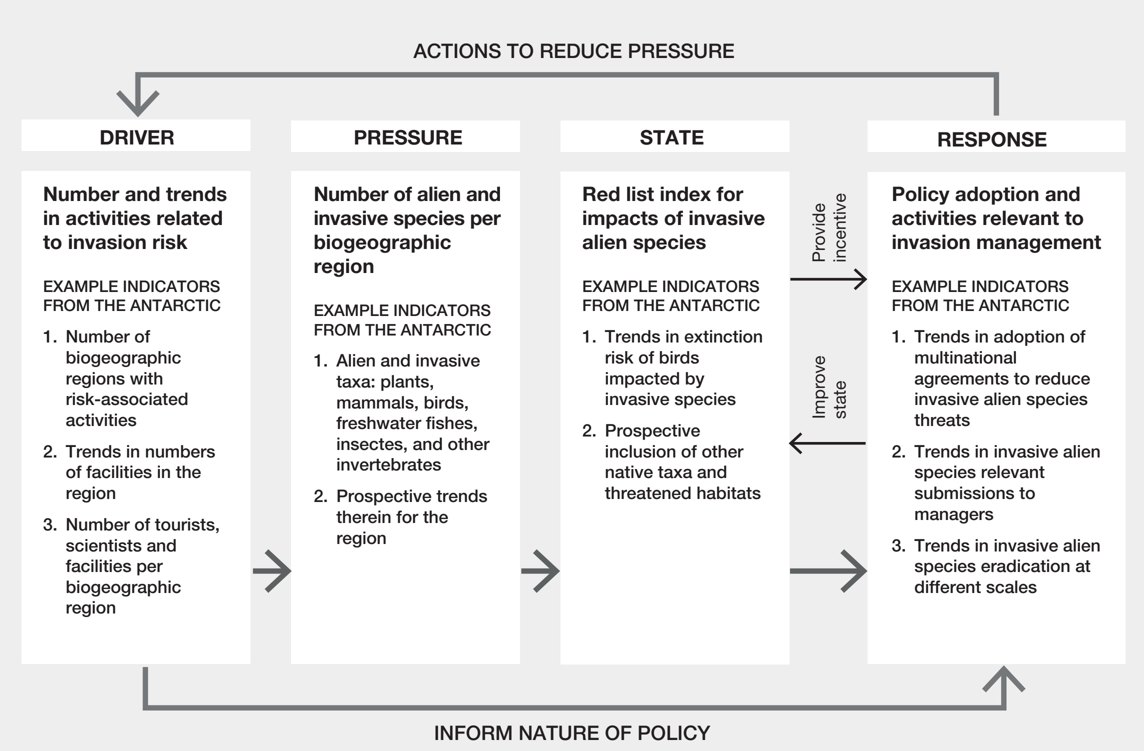

Figure 6 6 Driver-Pressure-State-Response (DPSR) framework for invasive alien species in the Antarctic context.

The DPSR applied to the Antarctic context as an example (non-bold text). Adapted from McGeoch *et al.* (2010, 2015), https://doi.org/10.1111/j.1472-4642.2009.00633.x, https://doi.org/10.1016/j.gloenvcha.2014.12.012, under license CC BY 4.0 and Elsevier license 5406200304811 respectively.

needed to bring about urgent positive change is intended to strengthen the power of monitoring, analysis and reporting (**section 6.6.2**; CBD, 2021b). In other words, if these four responses are effective, they would result in a reduction in invasive alien species pressure and an improvement in the state of socioecological systems negatively impacted by invasive alien species (**section 6.6.2**; Essl *et al.,* 2020).

The DPSR and theory of change frameworks are valuable strategic governance tools for biological invasions because, by design (OECD, 2019), they explicitly connect the causes (drivers) facilitating biological invasions, the size of the problem (pressure), its impact (state) and societal responses to dealing with it (McGeoch *et al.,* 2010; **Box 6.3**), although there are currently gaps in its application and implementation (Vicente *et al.,* 2022). By tracking change in each of these components (for example, using indicators), it becomes possible to design evidence-based, well-motivated and targeted policies for invasive alien species. The framework further makes it clear that the type, size and effectiveness of societal responses will determine the extent to which drivers decline (for example McGeoch *et al.,* 2015; **Box 6.3**). Importantly, the focus of the Kunming-Montreal Global Biodiversity Framework is on the "R, response" in

DPSR, *via* a theory of change, so that the slow progress of implementation can be accelerated.

6.2.2 Identifying the challenges of governing biological invasions

Environmental governance involves increasingly complex and interconnected arrangements, and the governance for biological invasions is no exception (Andonova & Mitchell, 2010; Gilek & Karlsson, 2016). Despite notable successes (**Chapter 5**, **section 5.5**), there are shortcomings in the prevention and control of invasive alien species, leading to a sustained global presence of invasive alien species introductions (**Chapter 2**, **section 2.2**). Understanding the underlying reasons for governance and management failures, across multiple environments, regions and taxonomic groups of invasive alien species helps to design better response options. Ten features emerged from a review of the governance challenges posed by invasive alien species.[4] These challenges are often interdependent (one may drive another for example) and jointly undermine effective prevention and control efforts (Jacobs, 2017; Linke *et al.,* 2016; J. Reed *et al.,* 2016). These key challenges are outlined below as the foundation for the options discussed in **section 6.2.4** and in the rest of this chapter.

(1) Complexity

The governance for biological invasions is considered to be complex because the process of biological invasions is naturally dynamic in space and time (**Chapter 1**, **section 1.4**). It has multiple stages and drivers, involves a large and diverse set of stakeholders, and crosses jurisdictional boundaries (Brenton-Rule *et al.,* 2016; Liu *et al.,* 2018; **Figure 6.7**; **Chapter 1**, **section 1.5.1**). The dynamic and difficult-to-predict behaviour of new technological options (such as the potential use of gene drives; **Chapter 5**, **section 5.4.4.2.j)** adds another level of complexity (Mitchell *et al.,* 2018). Context-specific application of integrated governance for biological invasions (**Glossary**) thus involves multiple trade-offs and the consideration of social, technological and ecological contexts and risks (Lubell *et al.,* 2017) across all levels of governance (Lansink *et al.,* 2018; Riley, 2012; **Figure 6.7**).

(2) Uncertainty

A high degree of uncertainty is associated with the biological invasion process because many species are involved and the likelihood of any species invading is determined by a combination of multiple biological, driver and pathway characteristics (Cooney & Lang, 2007; Udovyk & Gilek, 2013; **Chapter 1**; **Chapter 3**; **Chapter 5**, **section 5.2.2.3**; **Figure 6.7**). Biological invasion processes are non-linear and the uncertainty is “inherent, fundamental and persistent” (D. C. Cook *et al.,* 2010; Cooney & Lang, 2007). The outcomes of this complexity are difficult to predict within specific, narrow contexts, and therefore understanding the likely success of interventions is also difficult (Moon *et al.,* 2017; Smolarz *et al.,* 2016). Time lags (**Glossary**) between different parts of the invasion process, and in policy and management responses to invasive alien species, add to this uncertainty (**Chapter 1**, **section 1.4.4**; **Chapter 2**, **section 2.2**; Jacobs, 2017; J. Reed *et al.,* 2016).

(3) Information availability, flow and access

Information silos across stakeholder groups hinder effective governance (Collins, 2018; Nourani *et al.,* 2018; Peltzer *et al.,* 2019). Effective, sustained communication and collaboration across large, multi-layered networks is however difficult to achieve and has a high transaction cost (Lubell *et al.,* 2017; Nourani *et al.,* 2019). The flow of information relevant to biosecurity within and across countries and trading partners is also limited (D. C. Cook *et al.,* 2010). Actors involved at different scales and levels of governance tend to have access to different types of knowledge (Omondiagbe *et al.,* 2017). This includes the gap between science and practice (Aslan *et al.,* 2009; Esler *et al.,* 2010). There is also an imbalance of information between those who bear the costs of invasive alien species (affected actors; those who tend to have good knowledge of invasive alien species), and the actors responsible for exacerbating biological invasion risk (causal actors; **Glossary**; **section 6.6**; Cook *et al.,* 2010).

(4) Over-reliance on hierarchical governance

The currently dominant, hierarchical forms of governance for biological invasions tend to be centralized, top-down, process-heavy and reactive and, while necessary, are on their own not adequate for preventing and controlling invasive alien species (Cook *et al.,* 2010; Evans *et al.,* 2018; Reed & Curzon, 2015; **Figure 6.7**). Policy models can rely too heavily on rigid, non-adaptive, top-down approaches (Cooney & Lang, 2007). Hierarchical governance can be slow, culturally inappropriate, and not in step with the latest technological developments or scientific understanding (Barnhill-Dilling *et al.,* 2019; Boström *et al.,* 2016; Head & Atchison, 2015; Hughes & Convey, 2014; Trump *et al.,* 2018). Invasive alien species differ in key ways from other drivers of change in nature; for example, a strong precautionary approach (**Glossary**) that is often not enabled by traditional governance approaches is crucial (T. Evans *et al.,* 2018; Smolarz *et al.,* 2016). In addition, the power imbalances that can develop under highly centralized governance can lead to, for example, incoherent policy,

4. Data management report available at: https://zenodo.org/doi/10.5281/zenodo.5762739

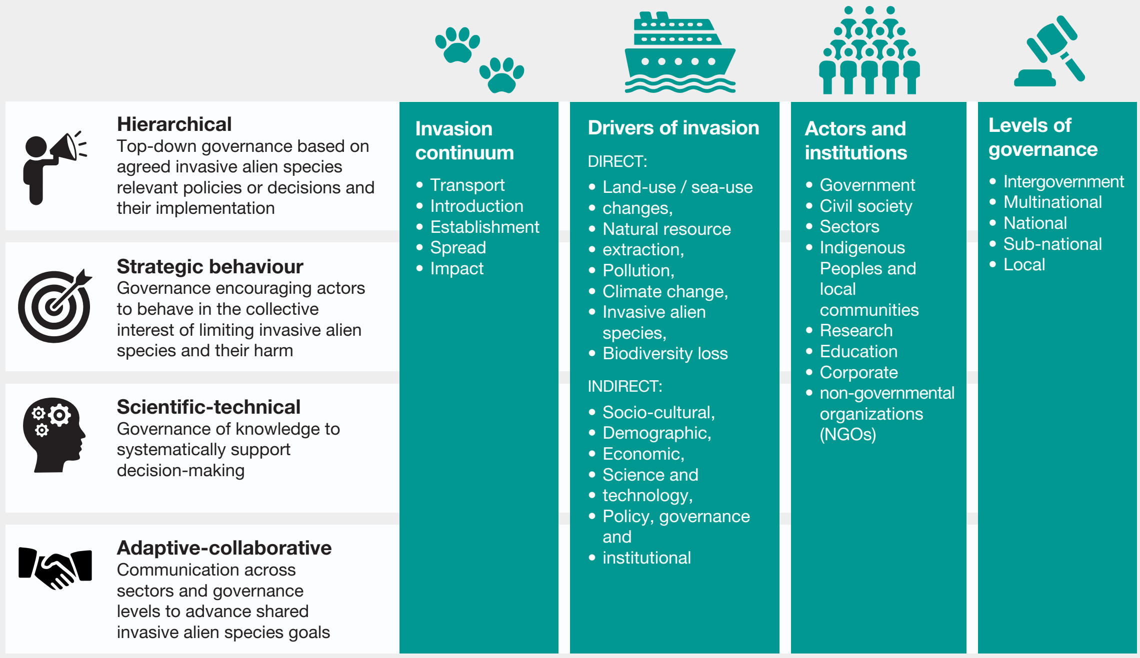

Figure 6 7 **The complex socioecological system characterizing biological invasions.**

The complex socioecological system (vertical boxes) that characterizes biological invasions and their management, and the four, complementary governance models (horizontal boxes) needed to enable successful policy implementation through integration within and across these components of the system (**section 6.2.4**). Data from: IPBES-PEG (2019b).

disengagement, or conflict amongst the broad range of stakeholders affected by invasive alien species (Neale & Macdonald, 2019; A. L. Smith *et al.,* 2013). It is now widely recognized that governments as decision-making authorities are necessary but insufficient for effective invasive alien species prevention and control (Miyanaga & Nakai, 2021; **section 6.2.3.1**).

(5) Fragmentation of policy instruments and their application

Current policy on invasive alien species and its implementation is often fragmented, with multiple, often isolated decision-making centres. As a result current policy is less effective than it could be (Gilna *et al.,* 2014; Nourani *et al.,* 2019; Praseeda Sanu & Newport, 2010; Rudd *et al.,* 2018). At the highest level, as assessed by Outhwaite (2018), there is no "full and coherent applicable body of international law". This fragmentation also includes policy differences between levels of governance and between actors and institutions, e.g., across industry sectors such as agriculture, forestry and the environment **(Figure 6.7)**, between countries and regions, and national and subnational levels of governance (Lubell *et al.,* 2017; P. Martin *et al.,* 2016). Fragmentation can result in, for example, overlapping jurisdictions, incompatible objectives, and unbalanced power relations (Visseren-Hamakers, 2015). Fragmentation of risk communication mechanisms can also undermine prevention and control efforts and public confidence (Jonsson *et al.,* 2016).

(6) Externalities

The negative impacts of invasive alien species often occur outside of the social or economic contexts responsible for their introduction and spread (**section 6.3.1.2**, also called telecoupling). For example, the cost of invasive alien species impacts are not included in the price of traded goods (Stoett, 2010). Invasion risk is sometimes not considered in the development of new agricultural and forestry technologies (Driscoll *et al.,* 2014), when deploying disaster relief aid or when developing international assistance programmes (Murphy & Cheesman, 2006); insect pests can be unintentionally imported with products used to rebuild infrastructure after natural disasters (**Chapter 3**, **section 3.2.2.2**). Negative environmental consequences of invasive alien species are often spatially and temporally diffuse, and this can undermine the legitimacy of environmental concerns (Neale & Macdonald, 2019). Biological invasion as an unintended consequence of trade is an example of a spill-over system, and spill-over effects can tend to be neglected in governance systems (J. Liu, Dou, *et al.,* 2018). The costs, liability and responsibilities for biological invasions need to be balanced between those directly responsible for species introductions and the general public, because health and biodiversity are a public good (i.e., nature's contributions to people and good quality of life; Outhwaite, 2010). One consequence of treating invasive alien species as an externality (**Glossary**) is that the welfare of the supply-side of trade is considered in isolation (D. C. Cook *et al.,* 2010). The trade-offs that occur as a result of unaccounted-for externalities result in conflicting interests (Hewitt & Campbell, 2007; Marire, 2015; Rouillard *et al.,* 2018; A. L. Smith *et al.,* 2013). Trade-offs also become increasingly political and difficult to resolve as they shift from within particular governance systems or sectors to between and outside of them (Visseren-Hamakers, 2015).

(7) Hurdles to implementation of policy

Although the arguments for invasive alien species policy implementation are empirically well supported, the extent and success of existing policy at international, national and sub-national scales is highly variable (**Figures 6.2**, **6.3**, **6.4** and **6.5**) and considered inadequate (Leadley *et al.,* 2014). Differences exist in the extent to which regulatory measures are implemented across countries (Brenton-Rule *et al.,* 2016) and laws are not always supported by regulation or implementation plans (Riley, 2012). There is no international authority, global coordination, or oversight mechanism for all invasive alien species, and the implementation of biosecurity practices under trade agreements is inconsistent (Stoett, 2010). There are several reasons why both policy and management implementation are challenging, including for example austerity measures and resource shortages (VanNijnatten, 2016), lack of capacity and expertise (Angulo & Gilna, 2008), as well as a number of the other challenges outlined in this section. Often there is a lack of monitoring to gather scientific evidence to support effective implementation, including information to evaluate the success of management approaches, such as knowledge generated from adaptive management (**Glossary**; Reed *et al.,* 2016; Smolarz *et al.,* 2016).

(8) The need for collective action

Effective prevention and control of invasive alien species can be achieved by cooperating and building of trust and social norms across actors, institutions, levels and sectors (**Figures 6.7** and **6.8**; McKiernan, 2018). However, conflicting interests and diverse values and perspectives mean that prevention and control programmes often fail (Graham *et al.,* 2019; Guerrero *et al.,* 2015; Smolarz *et al.,* 2016; **Chapter 1**, **section 1.5.2**; **Chapter 5**, **section 5.6.1.2**). For example, ineffective prevention and control can occur when individual land managers have an incentive to avoid invasive alien species control costs, thereby resulting in risks to others (Graham *et al.,* 2019). Similarly, actors that benefit from activities that increase risk of invasive alien species often have little incentive to acknowledge the risks and impacts of invasive alien species on other actors (Angulo & Gilna,

Primary driving forces **MANAGEMENT**	• Transport companies; Transport network designers; Organized individual businesses; Individual businesses • Trade industry; Tour operators; Agro-chemical sector; Consumer association; Local and regional authorities • Farmers and fishermen; protected area managers; forestry and horticulture managers; trade unions
Secondary driving forces **POLICY**	• EU institutions for Trade, Development, Environment, Climate, Water; Regional and National Authority • New countries; Sectoral associations for agriculture, horticulture, forestry, chemical industry, landscape planning • Social lobbies for consumers and business; Non-governmental organizations (NGOs); Media; Researchers
Tertiary driving forces **LIFESTYLE**	• Education systems; Research funders; Social lobbies and NGOs; Media and marketing industry • Politicians; Policy-makers; Consumers/Citizens • International/Multilateral institutions; Third countries
Base Short term **EXOGENOUS**	• General public and Migrant communities • National governments (demographic policy); European and national institutions and policymakers for climate • International/Multinational institutions; Third countries

Figure 6 8 **An example of the many relevant stakeholders for managing biological invasions from the Ebro River, Spain.**

There are four categories of stakeholders (on the left) and examples of stakeholders (on the right) involved in decision-making that affects the outcome of biological invasion, based on freshwater invasive alien species in the Ebro River, Spain. Adapted from Rodríguez-Labajos *et al.* (2009), https://doi.org/10.1016/j.ecolecon.2009.08.022, under copyright 2009 Elsevier B.V.

2008; Lubell *et al.,* 2017). Tensions between free trade and the governance of biosecurity risk further undermine the collective action (**Glossary**) that is needed on invasive alien species (Lansink *et al.,* 2018). The context-dependence of social settings and, therefore, of appropriate design of collaborative solutions, exacerbates this challenge (Lubeck *et al.,* 2019; P. Martin *et al.,* 2016). The transaction costs of administration, supervision and capacity development for implementing management of biological invasions can also undermine collective action (P. Martin *et al.,* 2016).

(9) Awareness, perception and values

There is often a lack of awareness and understanding, or neglect, of invasive alien species and their negative environmental, social and economic impacts. This is the case amongst a number of sectors, actors and stakeholders including amongst policymakers (**Chapter 1**, **section 1.5.2**; Moon *et al.,* 2015; Stoett, 2007). Perceptions of invasive alien species can also vary widely for several reasons (Shackleton, Richardson, *et al.,* 2019; Zengeya & Wilson, 2020), such as a focus on economic (instrumental) *versus* intrinsic and cultural (relational) values (**Chapter 1**, **section 1.5.2**; Leventon *et al.,* 2021). Understanding and the concept of biological invasion risk differs across and within groups and communities (Maclean *et al.,* 2022). Local communities, for example, may be very familiar with individual invasive alien species and their negative impacts on good quality of life, but remain unaware of the concept of biological invasions and the context of management and policy (Shrestha *et al.,* 2019; **section 1.6.7.1 (ii)**). Lack of awareness and different values can result in a lack of public support (Vane & Runhaar, 2016), exacerbate differing perceptions, and ultimately undermine collective efforts to manage biological invasions (Kohl *et al.,* 2019; **Chapter 3**, **section 3.2.1**). Public and private sector consultation and engagement can successfully underpin invasive alien species prevention and control efforts when they include effective risk communication and rely on the contributions of stakeholders and Indigenous Peoples and local communities (Ekanayake *et al.,* 2020; Falkenmark, 2007; Jonsson *et al.,* 2016).

(10) Conflicting interests and trade-offs

Conflicting interests and trade-offs happen when externalities are not considered and when a priori risk assessment is not done (e.g., Driscoll *et al.,* 2014), or is not inclusive of sectors and stakeholders (Woodford *et al.,* 2016; Zengeya *et al.,* 2017). Since some invasive alien species can have both positive and negative impacts, control and eradication programmes can spark conflict (**Chapter 1**, **Figure 1.1**, **section 1.5.2**; **Chapter 4**, **section 4.1.2**). There is also the often challenging need to strike a balance between short term needs and the long-term maintenance of good quality of life, alongside the uncertainty and challenges in making predictions outlined above.

6.2.3 Options for strengthening the governance for biological invasions

"Current environmental challenges call for new interdisciplinary approaches at the interface of natural and social sciences, framed in a context of governance and decision-making by actors from the state, market and civil society" (Padt *et al.,* 2014).

The challenges outlined in the previous section provide a platform for identifying a range of options for strengthening the governance for biological invasions. Governance-related options that emerged from the literature review[5] are summarized in **Table 6.6** under six general topics: strategy; multilevel and multisector governance; coordination and cooperation; policy environments that are enabling; research and information and their communication; and governance capability, capacity and resourcing. Governance provides an overarching instrument for dealing with complex systems and is considered one of the most important factors to achieve desired environmental outcomes (Bennett & Satterfield, 2018). The many considerations and elements of

5. Data management report available at: https://zenodo.org/doi/10.5281/zenodo.5762739

Box 6 4 **Restoring the Kafue flats: a case study of integrated management and effective governance of the invasive shrub, *Mimosa pigra* in Zambia.**

Impact on good quality of life and protected areas: In the early 1980s, *Mimosa pigra* (giant sensitive plant) invaded the Kafue Flats – a 6,500 km^2 floodplain located in the southern region of Zambia and a designated Wetland of International Importance under the Ramsar Convention. The flood plain is world-renowned for its abundant floodplain wildlife, including the endemic antelope, *Kobus leche kafuensis* (Kafue Lechwe), and rich diversity of birdlife including the *Bugeranus carunculatus* (wattled crane) and *Balearica regulorum* (gray crowned-crane). The flood plain hosts two national parks, surrounded by buffer zones inhabited by smallholder farmers and fishers, whose livelihoods depend on the land and water resources of the floodplain. It has been suggested that the *Mimosa pigra* invasion was triggered by hydrological alterations resulting from hydropower dams (Blaser, 2013; Mumba & Thompson, 2005). What started as a small infestation of about

Box 6 4

2 ha spread rapidly and covered over 3000 ha of the floodplain (Blaser, 2013; Shanungu, 2009; Solomon Genet, 2007; Thomas, 2007). Consequently, the native floodplain vegetation was replaced by *Mimosa pigra*, and many wildlife species of conservation concern including the *Kobus leche kafuensis* and *Bugeranus carunculatus* were displaced as their habitat shrank (**Glossary**; Blaser, 2013).

Multiparty governance: In 2017, The International Crane Foundation/Endangered Wildlife Trust Partnership (ICF/EWT Partnership), World Wide Fund for Nature (WWF) – Zambia, and Zambian Department of National Parks and Wildlife (DNPW) embarked on a three-year cooperative project to address the continued spread of *Mimosa pigra*, restore the floodplain grasslands and enhance their ability to support important biodiversity of the flats, and control up to 95 per cent of the baseline cover of *Mimosa pigra* in an effort with substantial community involvement.

Stakeholder and Indigenous Peoples and local communities involvement and benefits: The project also focused on developing the Zambian Department of National Parks and Wildlife local staff capacity in invasive plant management and habitat restoration. This included ecological research to enhance global understanding of large-scale *Mimosa pigra* control methods and their measurable impact on biodiversity, livelihoods options, and the broader economy through agriculture, fisheries and tourism **(Figure 6.9)**. The project took an ecosystem approach with a focus on the wider Kafue Flats ecosystem – including the two National Parks and the buffer zones – with a strong emphasis on a multi-sector approach in the management of the invasive alien species.

The project intended to engage non-traditional stakeholders including the private sector. The integrated management approach adopted combined physical, chemical and biological control options (**Glossary**).

Sustainable successes: By 2020, all management options described above had been implemented. About 450 workers from local communities were employed to undertake community-based restoration work through large-scale physical removal and chemical spraying of *Mimosa pigra*. Biological control trials through the importation and direct release of the control agent *Carmenta mimosa* commenced in May 2019. Six months after direct release, a monitoring exercise was undertaken to determine if there were signs of the control agent's survival. The presence of adults and actively feeding larvae six months after the introduction indicated that the biocontrol agent survived successfully and was reproducing. By June 2020, the area invaded by *Mimosa pigra* had been reduced by approximately 68.8 per cent of the total invaded area at baseline. Ecological surveys indicate that there is regeneration of native vegetation in areas previously covered by *Mimosa pigra* and use of the restored sites by herbivores including the *Kobus leche kafuensis*, as well as various species of resident and migratory waterbirds including breeding pairs of *Bugeranus carunculatus* and *Balearica regulorum*. Some members of the community employed by the project had been able to use their income to invest in livestock and improved housing while others had used it to educate their children.

Long-term efforts were undertaken to restore water conditions through environmental flow releases from the dam upstream that might limit future *Mimosa pigra* establishment.

successful governance for biological invasions are well illustrated by the case of the invasive alien shrub, *Mimosa pigra* (giant sensitive plant), in Zambia **(Box 6.4)**.

As context for the sections to follow, three key points can be made about the literature and evidence in support of governance approaches for biological invasions:

- While there is literature on the topic of biological invasions governance (assessed and drawn upon in the formulation in this section), only a small proportion of this literature critically evaluates, with empirical data in an invasive alien species context, the strengths and weaknesses of particular or alternative governance models and overarching governance systems.
- The most useful and evidence-based literature comes from comparatively extensive and relevant work on environmental governance more broadly.
- As a result, many of the options, tools and approaches are not particular to biological invasions and evidence for them is steeped in different domains and areas of expertise (Weitz *et al.,* 2017). Since an assessment of environmental governance is beyond the scope of this assessment – the field is interdisciplinary and itself developing rapidly – this section draws on some of the general frameworks and thinking on environmental governance that align with insights from biological invasion-specific literature, and refers to key findings in depth only where there is evidence specific to biological invasions.

Table 6 6 **Overview of governance response considerations.**

This table presents six types of response options (left column), and examples of relevant support tools, methods and frameworks (middle column) alongside examples of publications (right column).

Response option	Examples of relevant support tools, methods and frameworks	Example publications
Strategy, including approaches to deal with inherent complexity **(sections 6.2 to 6.7)**	• Empirical analysis of invasive alien species policy and governance • Objective review and evaluation • National invasive alien species Strategy and Action Plans • Sustainability: Environmental – social – economic • Pressure-State-Response type models • Ecosystem-based approach to management (EBM) • Adaptive governance (**Glossary**) model	Barnhill-Dilling *et al.,* 2019; Boström *et al.,* 2016; Chaffin *et al.,* 2016; Cooney & Lang, 2007; P. Martin *et al.,* 2016; McGeoch, Shaw, *et al.,* 2015; Rudd *et al.,* 2018; Smolarz *et al.,* 2016; Termeer *et al.,* 2010
Multi-level and sectoral integration **(sections 6.3, 6.7)**	• Integrated governance for biological invasions • Transnational environmental alliances • Conflict resolution • Negotiation of values • Inter-agency coordination to co-ordinate across policies and agencies and to monitor (stakeholder and Indigenous Peoples and local communities-wide or) government-wide activity. • Multidisciplinary, comparative research on invasive alien species policy regimes (**Glossary**)	Bennett & Satterfield, 2018; Daviter, 2017; Herrick, 2019; Justo-Hanani & Dayan, 2020; Visseren-Hamakers, 2015; Weitz *et al.,* 2017
Coordination and collaboration across international and regional mechanisms **(section 6.2.3.4)**	• Stakeholder and Indigenous Peoples and local communities mapping • Actor network analysis • Measures to build public support • Bridging organizations (**Glossary**) • Extension personnel • Institutions that build cooperation amongst relevant actors • International cooperation on information sharing, monitoring, implementation and best practice	Angulo & Gilna, 2008; D. C. Cook *et al.,* 2010; Gilna *et al.,* 2014; Lubell *et al.,* 2017a; Nourani *et al.,* 2019; Stoett, 2010
Policy that is enabling, including the consideration of inclusion, the distribution of power and adaptation **(sections 6.4, 6.5)**	• Policy risk analysis • Assess the distribution of costs and benefits of governance actions • Stakeholder and Indigenous Peoples and local communities mapping • Ecosystem Based approach to Management (EBM) • Mechanisms to identify the need for and enable the establishment of temporary task forces • Networked, polycentric governance (**Glossary**) • Legitimize decision-making at local scales • “Landcare” model	Catacutan *et al.,* 2009; Chaffin *et al.,* 2016; Linke *et al.,* 2016; Marshall *et al.,* 2016; P. Martin *et al.,* 2016; P. Martin & Taylor, 2018; McKiernan, 2018; Moon *et al.,* 2015; Peltzer *et al.,* 2019; Smolarz *et al.,* 2016

Table 6 6

Response option	Examples of relevant support tools, methods and frameworks	Example publications
Effective communication of research, information and learning **(section 6.6)**	• Biosecurity collectives for information sharing • Structured process by which knowledge can influence relevant actors • Knowledge sharing platforms and infrastructures at multiple scales • Clear assignment of responsibilities for risk communication • Public information campaigns • Context-specific messaging to encourage strategic behaviour • Information brokers	D. C. Cook *et al.,* 2014; Cooney & Lang, 2007; Jonsson *et al.,* 2016; Lubeck *et al.,* 2019, 2019; Moon *et al.,* 2015; Nourani *et al.,* 2019
Governance capability, resourcing and capacity **(sections 6.2 to 6.6)**	• Build capacity in key governance capabilities • Campaigns to make necessary technical concepts part of the public agenda • Consider gains and losses from activities (e.g., trade) in negotiations • Cost sharing arrangements • Assess potential inequity and incapacity	D. C. Cook *et al.,* 2014; Ford-Thompson *et al.,* 2012; Jonsson *et al.,* 2016; P. Martin *et al.,* 2016; P. Martin & Taylor, 2018; Outhwaite, 2017; Termeer *et al.,* 2016; Termeer & Dewulf, 2014

6.2.3.1 Employing multiple models of governance

Together, four complementary models of governance (1-4 below) provide a high-level framing for comprehensive governance and for guiding the development of national invasive alien species strategies (**Figure 6.6**; IPBES, 2019b). These models provide alternative but, importantly, not mutually exclusive mechanisms for bringing about policy implementation, and together they encompass a focus on all relevant actors (Primmer *et al.,* 2015; **Figure 6.7**). Each of these models thus plays a role in the comprehensive and strategic governance for biological invasions; each encompasses options for strengthening governance that are outlined in further detail in **sections 6.3** to **6.6**.

(1) Hierarchical governance: Top-down governance based on agreed invasive alien species -relevant policies or decisions and their implementation

Governments enact legislation, develop aligned regulatory policy, and provide the funding needed to implement risk assessment and surveillance (**Glossary**; Lodge *et al.,* 2006), i.e., provide a comprehensive, centralized and science-based control regime, administered through one or more national agencies (Herrick, 2019). Hierarchical governance provides an existing and necessary backbone as well as, *via* legislation and regulation, the strongest category of instruments for invasive alien species implementation and control. While shortcomings in the hierarchical governance for biological invasions are identified and discussed above and in multiple sections of this assessment (**section 6.2.2.(4)**), hierarchical multilateral and national policy and legislative instruments will remain central to governance for biological invasions (**section 6.3**).

(2) Strategic-behavioural governance: Governance encouraging actors to behave in the collective interest of limiting invasive alien species and their harm

Beyond legislated policy, broad stakeholder and Indigenous Peoples and local communities support is essential to the effectiveness of invasive alien species prevention and control, including the full breadth of relevant actors (**Figures 6.7** and **6.8**; Vane & Runhaar, 2016). Strategic institutional arrangements can create enabling environments for collaboration, achieving agreement, and enhancing effective action. Perceived costs and risks of invasive alien species as well as opposition based on moral or ethical considerations can undermine management outcomes, whereas community groups, lobbies and public support can be particularly powerful in altering actions that affect invasive alien species outcomes (Crowley *et al.,* 2019; P. Martin *et al.,* 2016). Public support and voluntary, collective action are needed, for example, to manage weeds that cross boundaries. The willingness of land owners to participate in interventions is determined by many individual, collective and context-specific factors (Finkel & Muller, 1998; Lubeck *et al.,* 2019; Vane & Runhaar, 2016). The research and design of tailored behaviour-change strategies, effective communication and outreach and the analysis of policy risk to anticipate undesirable outcomes are all key components of successful strategic-behavioural governance (Lubeck *et al.,* 2019). The net balance of incentives and disincentives determines the likelihood of participation in invasive alien species prevention and control efforts. The focus of strategic-behavioural governance is therefore on social and economic mechanisms for bringing about public support and behavioural change (Martin *et al.,* 2016; **sections 6.4** and **6.5**).

(3) Scientific-technical governance: Governance of knowledge to systematically support decision-making

Effective governance for the prevention and control of invasive alien species demands a wealth of information, efficient delivery of this information, and context-appropriate means by which to communicate it. Scientific-technical governance deals with the governance of knowledge within and across the components of the socioecological system that characterizes biological invasion (**Figure 6.7**; McGeoch & Jetz, 2019). This includes the role of international collaboration in delivering and sharing knowledge (Latombe *et al.,* 2017) and regional early warning and information systems for invasive alien species. Scientific-technical governance includes the structure of information systems and platforms, assignment of responsibilities for data and information generation, sharing and communication (including risk communication; **Chapter 5**, **section 5.2.2.1.h**). It also includes strategies for delivering and communicating different types of information to different stakeholders. For example, the European Commission has developed an invasive alien species information system (European Alien Species Information Network, EASIN) that ensures transparent and authoritative data on invasive alien species (European Environment Agency, 2010a). Scientific-technical governance could also involve introducing, or strengthening existing, mechanisms that support a more ecosystem-based approach to governance, i.e., that includes systematic collection of essential data, use of best available evidence, and impact assessments as a pre-condition for new activities, policy change and involvement of stakeholders (Smolarz *et al.,* 2016).

(4) Adaptive-collaborative governance: Communication across sectors and governance levels to enhance shared invasive alien species goals

This model of governance involves a systematic approach to improve the planning and management of invasive alien species by "learning from doing". It involves joint formulation of management objectives, specification of multiple management options, forecasting and estimating uncertainty, implementing management options, monitoring (social learning) to improve forecasting and reduce uncertainty, and changing management responses throughout a policy cycle (**Glossary**; Niemiec *et al.,* 2019; Richardson *et al.,* 2020). To date, many approaches to governance for biological invasions that refer to adaptive management have included only scientists, other experts or formal invasive alien species managers, and top-down modes of governance. In contrast, the concept and practice of adaptive collaborative governance and management are based on the involvement of stakeholders in decision-making at all levels, and on the establishment of vertical and horizontal institutional linkages spanning governance scales. These linkages support integrating and sharing knowledge. Adaptive-collaborative governance and management is ultimately "concerned with enhancing and including the capacity of all actors with a stake for sustainably managing the resource at hand" (Plummer *et al.,* 2012). Options involving this model of governance are covered in further detail in **section 6.4**.

6.2.3.2 Developing effective strategy for biological invasions

Recognizing the significance of strategic planning for invasive alien species, one indicator under the SDGs (Indicator 15.8.1) aims to track the percentage of countries with national strategies for preventing and controlling invasive alien species (UN, 2021). The need for strategy to deal with biological invasions is driven by:

1. The sheer size of the problem and the need to prioritize resources and actions;

2. The multidimensional and interconnected nature of the problem across invasion stages (**Glossary**), sectors and actors; and

3. The interdependence between invasion and other forms of environmental change.

Strategic planning

The way strategies are designed, their content and the incorporation of good and environmental governance principles are key to guarantee their effectiveness (**Chapter 5**, **section 5.2** for more information on evidence-based decisions). In complex contexts, such as those faced by countries dealing with invasive alien species and their impacts, strategic planning can be improved by clear and cyclical assessment, option formulation, action, and re-assessment to achieve the goals of prevention, control and minimization of negative impacts (Andonova & Mitchell, 2010), including regular, objective review and evaluation (Martin *et al.,* 2016; **Table 6.6**). Given limited resources, strategic planning can drive prioritization, including determining which species need prevention, control, or adaptation responses (McGeoch *et al.,* 2016). The strategic planning phase would consider all four governance models discussed above as part of a comprehensive strategy. Widely accepted steps in the development of strategy include: (1) evidence-based situation analysis; (2) development of a strategy and action plan; (3) identification and prioritization of tools and methods to enable strategic action, including legislation, financing, institutional arrangements, stakeholder and Indigenous Peoples and local communities participation; and (4) mechanisms to ensure implementation (Falkenmark, 2007).

National strategies

National strategies are critical for achieving invasive alien species goals and targets, as this is the level at which legislative and resourcing commitment by countries is strongest (CBD, 2020c). National strategies for invasive alien species have been called for, *inter alia*, to design implementation regimes, for example in the form of national invasive alien species strategy and action plans or national-level biosecurity strategies (Sustainable Development Solution Network, 2021). Such strategy could aim to include or address:

- The means to achieve coherent legislative frameworks;
- Coordination mechanisms to manage and communicate with the range of government and non-government sectors and actors involved;
- A coordinating body able to harmonize law such that no conflicts exist between sectors (Riley, 2012; Shine *et al.,* 2005);
- Collaborative and inclusive definition of goals and objectives for invasive alien species across sectors and levels that can be integrated into national strategies (Barnhill-Dilling *et al.,* 2019; Praseeda Sanu & Newport, 2010; Smolarz *et al.,* 2016);
- The identification, prioritization and management of pathways and drivers;
- Prioritizing established and future invasive alien species threats and committing related resources accordingly;
- Optimizing surveillance, early detection and rapid response, eradication, containment and control programmes at local and sub-national scales;
- The prioritization of national strategies to improve the efficiency of deployment of limited resources for invasive alien species prevention and control;
- National strategies can also define instruments and processes to encourage shared efforts and commitments, and understanding of the specific roles of all sectors and actors (Indigenous Peoples, community and industries) and multi-scale coordination of response programmes (e.g., Maclean *et al.,* 2021);
- Mechanisms for specifying the distribution of responsibility (financial, planning, infrastructure, etc.) amongst stakeholders (Smolarz *et al.,* 2016);
- Coordination and justification for efficient and effective investment (whether national and sub-national) and appropriate support and reporting on invasive alien species guiding principles **(Table 6.3)**, guidelines, goals and targets under multilateral agreements, in the context of societal and economic goals of sustainable development and international trade;
- Mechanisms to drive institutional and organizational structures that allow for flexible strategic thinking and reflection (Boström *et al.,* 2016) and adaptive cooperation between stakeholders (Smolarz *et al.,* 2016);
- National strategies that address the need for and design of, local and subnational strategies for the eradication of priority species.

6.2.3.3 Including actors across scales, levels and sectors

There is increasing evidence and a growing realization that the involvement of multiple sectors, stakeholders and Indigenous Peoples and local communities, together with the consideration of diverse perspectives and interests, can achieve effective governance and management of biological invasions (Guerrero *et al.,* 2015); thus, a sustainability framework for an invasive alien species strategy could be appropriate (e.g., Barnhill-Dilling *et al.,* 2019; Vaas *et al.,* 2017). Governing invasive alien species within a sustainability framework provides a widely-accepted departure point for national environmental strategies (Nourani *et al.,* 2018), including strategies for invasive alien species. Including stakeholders and Indigenous Peoples and local communities with different knowledge, perceptions and socio-cultural contexts can help achieve shared efforts and commitments, the understanding of the specific roles of all actors, improve the efficiency of proposed mechanisms and build trust (Maclean *et al.,* 2022; Shackleton, Richardson, *et al.,* 2019). In other words, everyone has a role to play in the governance for biological invasions.

Such joint or integrated approaches (**section 6.2.4**) across the components and processes that characterize the socioecological system relevant to biological invasion (i.e., multilevel and multisector governance) can improve the effectiveness and efficiency with which the complexity of the invasive alien species problem can be managed (Lubeck *et al.,* 2019; Stoett, 2007; **Figure 6.7**). While the terms "level" and "scale" are often used interchangeably, they have distinct, complementary meanings in governance for biological invasions. Because of their importance to the design of effective governance systems, these dimensions and the roles that they play are outlined below and discussed in terms of their importance for sectors and networks.

Scales and governance – spatially and temporally continuous structures and processes

One way of viewing governance is through a scaling lens (Padt & Arts, 2014). While the impacts of invasive alien species occur locally, the drivers that facilitate biological invasions operate across scales from global to local, and the impacts also accumulate upwards to affect national and global economies and ecosystem processes (Andonova & Mitchell, 2010; Boström *et al.,* 2016; Termeer & Dewulf, 2014). As a global change phenomenon, biological invasion is both complex and dynamic because it involves interacting social, biological and abiotic environmental dimensions, often with context-specific outcomes (**Chapter 1**, **section 1.5**). Biological invasions are also transboundary in nature. This is a consequence of the fact that species movements are not naturally constrained by geopolitical boundaries: borders can be fluid for stakeholders and Indigenous Peoples and local communities and trade and human movement across natural and geopolitical borders are the primary drivers promoting biological invasion (S. Muller *et al.,* 2009). As a result, solutions for managing biological invasions demand strategy, communication, cooperation, data and information that are similarly geopolitically unbounded **(Figure 6.7)**. Agencies responsible for management are often local and the transfer of knowledge and management technology to this level is crucial (**section 6.6**). Biological invasions and management events at one place or time, and the reporting of such events, have a fundamental bearing on relevant response options at scales beyond which they occur. The process of biological invasion operates continuously across spatial scales from local – sites at which populations of invasive alien species establish or have impact – to the large regions over which invasive alien species are transported, cross borders and spread. Similarly, invasive alien species management spans short-term actions – such as rapid responses to eradicate newly established invasive alien species – to long-term efforts to contain or control well-established invasive alien species in order to mitigate their impacts. Investing in invasive alien species management systems is a long-term endeavour to protect and maintain good quality of life and nature's contributions to people. Therefore, it is appropriate, for example, that invasive alien species information systems, management of invasive alien species, and governance for biological invasions structures account for such scales. All of these information, structures and processes are planned and implemented across multiple spatial and temporal scales of biological organization (i.e., considering genetic diversity and adaptation, species population dynamics, community processes and ecosystem function; Padt & Arts, 2014).

Levels of governance – vertical interactions

Invasive alien species are governed and managed at multiple levels of societal organization, from regional to national and sub-national (**Chapter 1**, **Figure 1.9**). Levels of governance encompass civil society groups, for example, that contribute to weed clearing in local neighbourhoods, to sectoral land-management at a sub-national scale (such as protected and production areas), to states and provinces, countries, regions and broader intergovernmental arrangements (**Figures 6.7** and **6.8**). When a mismatch exists between the level of governance and the scales at which biological invasion occurs, policy and resulting interventions are less likely to succeed (Primmer *et al.,* 2015). Biological invasions policy is relevant and necessary at all levels of governance, and specification of those levels is useful, if not essential, in strategic planning and decision-making (Lescrauwaet *et al.,* 2015). Stakeholders and institutions affected by and responsible for governance for biological invasions operate across either more or less hierarchical or inclusive levels of responsibility and cooperation. At a sub-national level, there are several possible invasive alien species management institutions, such as state/province-wide management programmes (bounded by sub-national government borders), cooperative management areas (delineated by land use or ownership) and volunteer groups (**Figures 6.7** and **6.8**). For example, the Landcare movement across multiple IPBES regions provides a tested option for government-supported, community-led information sharing and action, including partnerships among business, researchers, natural resource management agencies, governments, stakeholders and Indigenous Peoples and local communities, resulting in several successful cases of local implementation (Catacutan *et al.,* 2009; McKiernan, 2018).

Sector governance – horizontal interactions

Invasive alien species prevention and control activities, including legal and regulatory instruments for biological invasions, involve multiple institutions with global (CBD, WTO, IMO) or regional (Council of Europe) mandates and tend to be developed for and organized within key industry sectors (Hulme, 2020). As discussed further in **section 6.3.1**, these sectors include environment and biodiversity, transport, trade, production systems, extraction systems and public health. One main limitation of the current policy regime for managing biological invasions is the narrow sectorial focus, where legal and regulatory instruments focus only on addressing either biosafety or biodiversity issues. The need for information flows and communication across governance systems from different sectors has been identified as a major challenge that undermines the effectiveness of invasive alien species management (Roura-Pascual *et al.,* 2021; **Chapter 5**, **section 5.6.2.2**) and a limitation for effective horizontal integration of invasive alien species management approaches. Moreover, many of these sectors influence public policy and resources (notably production, extraction, development aid and health sectors), so the explicit consideration and inclusion of all sectors is critical for effective governance for biological invasions.

Network governance – horizontal and vertical interactions

From an analytical perspective, and with the purpose of better understanding the roles and interactions among actors, scales, levels and sectors **(Figure 6.7)**, governance systems can be considered as networks (Lubell *et al.,* 2017; Provan & Kenis, 2008; **Chapter 5**, **section 5.6.3.1**). Networks are a useful way to jointly consider the scales, levels and sectors outlined above. For example, the multiple relationship links between stakeholders needed to manage aquatic invasions in rivers in **Figure 6.8** can be viewed and as a network to better understand the strengths, weaknesses and gaps in governance for biological invasions in this freshwater context. A network approach is useful for understanding the roles and contributions of stakeholders and institutions for cooperation and for strengthening the effectiveness of working relationships (Moon *et al.,* 2015; VanNijnatten, 2016). A network view of governance for biological invasions encompasses the concept of polycentric governance (one with multiple centres of power in decision-making) that has been identified as a successful and complementary model for inclusive governance for biological invasions (Marshall *et al.,* 2016; Vaas *et al.,* 2017). Some of the advantages of polycentric governance include better information generation and flow within and across actors (nodes) in the network compared to monocentric governance, as well as short social and physical distances between interacting nodes (Cook *et al.,* 2010, 2014; Vaas *et al.,* 2017; **section 6.4.4**).

6.2.3.4 Coordination and cooperation to support the governance for biological invasions

Regardless of the view taken (scaled, multilevel or multisector, networked, or integrated), governance for biological invasions is achieved through cooperation, coordination and effective communication (Jacobs, 2017; Lubell *et al.,* 2017; McKiernan, 2018; Vaas *et al.,* 2017). Options for enabling integrated governance for biological invasions thus include identifying and supporting stakeholders who are able to play a bridging role across otherwise disconnected nodes of the network, the establishment of formal coordination bodies, and the use of extension personnel (Ekanayake *et al.,* 2020; Nourani *et al.,* 2019; Vaas *et al.,* 2017; **sections 6.2.4** and **6.4**). International networks and partnerships play a decisive role in sharing information, capacity-building, promoting collaboration, and sharing novel tools and techniques to manage biological invasions (**Chapter 5**, **section 5.6.3.1**). For example, sharing of knowledge between native and invaded ranges (**Glossary**) helps to predict entry and establishment risks and the potential impacts of alien species (Nourani *et al.,* 2018). International collaboration is critical in managing biological invasions since the alien species are mobile and do not respect political or legal boundaries (Graham *et al.,* 2019).

Governance for biological invasions is therefore in part a collective action problem that provides collaborative solutions (Hershdorfer *et al.,* 2007; Epanchin-Niell *et al.,* 2010; McLeod & Saunders, 2011; Bagavathiannan *et al.,* 2019) including, for example, public-private partnerships (Mato-Amboage *et al.,* 2019). As outlined earlier, the mobility of invasive alien species means that preventing spread and managing established populations can be achieved through cooperation and coordination across property and jurisdictional boundaries (Graham, 2014; Yung *et al.,* 2015; Howard *et al.,* 2018; **section 6.4**). Achieving such cooperation is challenging because diverse actors have different perceptions and values (**Chapter 1**, **section 1.5.2** and varying levels of interest, skills, resources, capacity, and time to commit to invasive alien species prevention and control (Donaldson & Mudd, 2010; Graham, 2013; Ma *et al.,* 2018; Kropf *et al.,* 2020). Successful collective action would include developing stakeholder and Indigenous Peoples and local communities networks, and building the trust to forge a common understanding of the problem, agree on a common goal, identify measures of success, and encourage participation in individual and group activities (Stallman & James, 2015; Niemiec *et al.,* 2016; Graham & Rogers, 2017; T. M. Howard *et al.,* 2018; Bagavathiannan *et al.,* 2019). Micro-interventions implemented during community engagement activities can increase participation and change social perceptions, such as facilitating increased communication amongst community members, setting collective goals, achieving public commitment, and enhanced visibility of contributions (Niemiec *et al.,* 2019). There are many examples of how local communities have successfully mobilized to collectively manage invasive alien species (**section 6.4.3**).

6.2.3.5 Considering human adaptation to invasive alien species in governance systems

Adaptation to invasive alien species is emerging as a critical consideration for policy and management. Two concepts of adaptation are relevant: the first is "planned" adaptation, derived from a concept used by the Intergovernmental Panel on Climate Change (IPCC), which is "the result of a deliberate policy decision, based on an awareness that conditions have changed or are about to change and that action is required to return to, maintain, or achieve a desired state" (IPCC, 2007); the second is "autochthonous" adaptation, defined as "deliberate adaptation actions undertaken by individuals or small social groups that are specific to and occur within a local system, where human populations are ultimately affected" (P. L. Howard, 2019). This type of adaptation has four characteristics: (1) it is deliberate; (2) it refers to individuals and small groups of individuals; (3) it is specific to the locality – specific environmental, social and cultural conditions that prevail in specific places where people live and act and (4) it occurs within a local system, which is affected by multi-scalar drivers and feedbacks, thus it is affected by many external influences, including planned adaptation (P. L. Howard & Pecl, 2019).

When human adaptation becomes a response

Adaptation is relevant in cases where invasive alien species are established and, for environmental, management, or socio-economic reasons, there may currently be no other option (Kleinschroth *et al.,* 2021). It is also relevant when invasive species impact human well-being and people attempt to manage them or adapt to their impacts (König *et al.,* 2020). Adaptation may be the only option in cases where, due to the type of invasive and invasion scale, resources are unavailable to effectively mitigate or control invasive alien species, such as in forests, rangelands, savannahs, and large water bodies, including oceans (Godfree *et al.,* 2017). It may also be necessary in cases where there are currently no known effective control methods, or effective methods cannot currently be deployed due to non-target effects or strong political, ethical, or social objections to available controls methods. For example, recreational fishing lobbies can stand in the way of formulating invasive alien species regulations (Zengeya *et al.,* 2017; **Box 6.16**). Adaptation may be the only option when invasive alien species generate substantial social, economic or ecological benefit and have been incorporated into socioecological systems to such a degree that control or eradication would generate serious negative socioecological impacts (Bhattacharyya & Larson, 2014; P. L. Howard, 2019; Roder, 2001). When invasive alien species have negative impacts on good quality of life (**Chapter 4**, **section 4.5**), people attempt to change these impacts and, if possible, turn harm to benefit. A review of 70 case studies on adaptation to invasive alien species across the globe found that this is done in many ways – such as managing invasive alien species, using invasive alien species, changing their cropping and livelihood systems to accommodate harmful changes, or using the resources that invasive alien species can in some cases provide (P. L. Howard, 2019). When the impacts are too severe, people may be forced to abandon their homelands altogether or to migrate to find resources such as forage grass in new regions (**Chapter 4**, **sections 4.5.1** and **4.6.3.2**). Adapting to invasive species, then, often means mobilizing and reorganizing relationships and assets within communities, which has knock-on effects not only for individual members but as well for entire communities and socioecological systems (P. L. Howard, 2019).

Governance implications of human adaptation to invasive alien species

The practical and policy implications of such local-level adaptation to invasive alien species are significant. No matter how wide the reach of planned interventions, such adaptation may still be necessary. Governments often have limited resources and rely on local actors and their cooperation to implement invasive management actions (P. L. Howard & Pecl, 2019; Pecl *et al.,* 2019). Adaptations to invasive alien species occur in different spheres of individual, household, or collective activity related to production systems and the enactment of daily life (P. L. Howard, 2019). Local-scale adaptation is an important means to mitigate the impacts of invasive alien species, restore socioecological resilience (**Glossary**) and, where necessary and possible, transform socioecological systems to more desirable and sustainable states. In cases where adaptation includes use of the invasive alien species as a resource, a balance needs to be achieved between local benefits arising from such use and the potential of such use exacerbating negative outcomes from further invasive alien species spread (P. L. Howard & Pecl, 2019).

Understanding and considering human adaptation to invasive alien species can lead to the formulation of policies and practices (related to sectors such as land management and pesticide use) that seek to influence local adaptation in ways that increase adaptive capacity, resilience and sustainability. It is therefore an important, although to date little considered, phenomenon and can be considered as a viable response option in inclusive, integrated governance for biological invasions (**section 6.2.3.5**).

6.2.4 Integrated governance for biological invasions

Drawing on the approaches above and recognizing the relevance of multiple scales, sectors and levels of governance, "Integrated Environmental Governance" provides an option for improving the effectiveness of invasive alien species prevention and control because it focusses attention on the relationships between the necessary components of governance systems for biological invasions **(Box 6.5)**. In this way, context-specific application of integrated governance potentially simultaneously helps to address the challenges of fragmentation, complexity and information flow that are currently pervasive in governance

Box 6 5 Integrated governance for biological invasions.

Integrated governance for biological invasions consists of establishing the relationships between the roles of actors, institutions and instruments, and involving as appropriate all those elements of the socioecological system that characterize biological invasion and its management, for the purpose of identifying the strategic interventions needed to improve invasive alien species prevention and control outcomes.

for biological invasions (**section 6.2.2**). Coherent and better integrated policy regimes (**Glossary**) have been called for that aim to enable more effective and efficient policy outcomes, reduce policy conflicts, implementation delays, confusion and lack of clarity for stakeholders, wastage of resources and unanticipated outcomes in the complex contexts that characterize the governance and management of biological invasions (Riley, 2012; Vaas *et al.,* 2017). The definition of integrated governance for biological invasions below **(Box 6.5)** is in line with and built upon the concept of integrated environmental governance (Visseren-Hamakers, 2015; Visseren-Hamakers *et al.,* 2021)

Integrated governance, including for biological invasions, includes not only integration across sectors (so-called "nexus" in sustainable transitions literature; S. Díaz *et al.,* 2019; **Glossary**; **Chapter 1**, **Box 1.14**), but also a range of strategic actions and governance system properties characterize good governance for biological invasions (Weitz *et al.,* 2017). In other words, policy integration is only one part of the integration needed, and attention may also be given to the properties of the broader system that delivers invasive alien species policy (Leventon *et al.,* 2021).

A key part of the recognition of the need for integrated governance for biological invasions concerns the need for integration across the sectors that in some way intersect with the problem of invasive alien species – as either causal, affected or managing actors **(Figure 6.7)**, as discussed above. These sectors include environmental, human, animal and plant health (Hulme, 2020). This approach is referred to more broadly in governance literature as the "nexus approach" (S. Díaz *et al.,* 2019; Weitz *et al.,* 2017), and it "focuses on the relationships between different policies and sectors (e.g., agriculture, transport, environment) with the aim of coordinating across sectors without preferring one over the other in order to promote coherence" (Visseren-Hamakers, 2015). The intention of such integration is to improve policy coherence by "identifying synergies and trade-offs, optimizing policy options, and adapting governance arrangements" (Weitz *et al.,* 2017). This approach aims therefore to reduce undesirable outcomes for invasive alien species management that result from conflicting policy and interests across sectors. An example is the "One Biosecurity" approach: "an interdisciplinary approach to biosecurity policy and research that builds on the interconnections between human, animal, plant and environmental health to effectively prevent and mitigate the impacts of invasive alien species" (Hulme, 2020; **Glossary**).

While considering what needs to be integrated (e.g., research, sectors, policy) and how (e.g., stakeholder and Indigenous Peoples and local communities' inclusion, analysis, collective action) holds significant promise to achieve better outcomes for invasive alien species prevention and control, there are also limits to this approach that are important to recognize. The status of biological invasions and the most effective management approaches are to a large degree context-dependent, therefore, comprehensive and strongly centralized policy integration may be neither possible nor desirable (Herrick, 2019; Hoff *et al.,* 2019). New approaches or decision-making structures are not developed from a clean slate and can be strategically designed to strengthen or fill gaps in existing governance systems (Visseren-Hamakers, 2015).

Nonetheless, there is substantial evidence to suggest that a greater degree of policy integration would be beneficial in many instances (Lansink *et al.,* 2018; Smolarz *et al.,* 2016), and the benefits to building on existing policy settings have been highlighted (Trump *et al.,* 2018). To this end options for more effective invasive alien species policy, including integration where it is needed, include a number of desirable features, such as policy coherence and political legitimacy (Daviter, 2017; Herrick, 2019). Several tactics that enable this reform can be incorporated into invasive alien species strategies at national and other levels and sectors **(Table 6.7).** Other key considerations include external influence and dealing with the factors that influence integration beyond cross-sector relationships and policy (**section 6.2**). Finally, negotiation and building trust can improve the governance of biological invasions; addressing trade-offs and improving policy integration is a political process built on negotiation across stakeholders with different interests, values, and perspectives, which requires trust, ownership of the process, and learning (**section 6.4**).

Table 6 7 **Tactics to enable policy reform for invasive alien species policy.**

	Tactic	Expected benefit	Key references
1	Multidisciplinary to transdisciplinary research on invasive alien species policy regimes	Building robust and long-term resilience and the adaptive capacity of the governance systems for invasive alien species	(Daviter, 2017; Herrick, 2019)
2	Policy narratives to deal with the full continuous spectrum of service delivery or regulation, from prevention, eradication, control and restoration rather than treating each in isolation	Better integrated and effective policy regimes	(Daviter, 2017; Herrick, 2019)

Table 6 7

	Tactic	Expected benefit	Key references
3	Drawing on the full suite of adaptive and control-focused instruments as relevant **(Figure 6.8)**, including a combination of voluntary measures with regulatory and legislative frameworks	More comprehensive, effective and efficient governance for biological invasions	(Herrick, 2019; Primmer *et al.*, 2015; Shine *et al.*, 2000; Termeer *et al.*, 2010)
4	Inter-agency coordination to co-ordinate across policies and agencies and to monitor (stakeholder and Indigenous Peoples and local communities-wide or) government-wide activity	Increased efficiency and effectiveness of resource allocation and knowledge sharing	(Daviter, 2017; Herrick, 2019)
5	High autonomy for decision makers combined with strong, coherent, overarching policy	More efficient and targeted local solutions	(Vaas *et al.*, 2017)
6	Strategic and programmatic coordination that has adequate resourcing and authority to enable coordination	Improved effectiveness of implementation measures	(Daviter, 2017; Herrick, 2019)
7	Work towards intergenerational sustainability for invasive alien species by linking the consideration of ecosystem functions and process with management actions	Achieving environmental sustainability and political, stakeholder and Indigenous Peoples and local communities support	(Smolarz *et al.*, 2016)
8	Knowledge systems that enable sharing of information, concepts and arrangements across all stakeholders and scales	Improving learning to empower all stakeholders and Indigenous Peoples and local communities to manage invasive alien species	(Smolarz *et al.*, 2016; Staples & Hermes, 2012)
9	Creating space for multiple knowledge systems and experiences to encourage the recognition of different values	Building trust and social capital for effective collaboration and cooperation (collective action)	(Leventon *et al.*, 2021; McKiernan, 2018)
10	Implementing mechanisms for reviewing and monitoring policy effectiveness, including gathering data for "Response" indicators (following the Theory of Change, **section 6.2.1**) so that the success of management interventions can be assessed and fed into adaptive planning	Overcoming slow and inadequate implementation of policy	(McGeoch *et al.*, 2010; McGeoch & Jetz, 2019; OECD, 2019)
11	Integrating invasive alien species considerations into policies related to other environmental threats, including climate change	Policy that recognizes the inherent inter-dependencies of multiple forms of environmental change	(Smolarz *et al.*, 2016)
12	A focus and research on the relationships between policy instruments within and between sectors to determine what invasive alien species -relevant policy gaps exist, where policy conflicts occur, and how new policy can best complement existing policy – as the basis for a transition to integrated governance for biological invasions	Policy coherence, filling policy gaps and avoiding perverse incentives	(Visseren-Hamakers, 2015)

6.3 LEGAL AND REGULATORY OPTIONS

A broad array of international and national legal and regulatory instruments that directly or indirectly reference invasive alien species exist **(Table 6.8)**. These instruments aim to manage invasive alien species by preventing their introduction and spread and mitigating their impacts. They provide the formal rules upon which other policy instruments (e.g., economic, social; **Table 6.1**) can be framed and operated, and are also associated with multiple global, regional and national organizations. These instruments regulate or propose voluntary standards for the activities of different sectors (e.g., environment, production, extraction, health, trade and transport), often at different stages of the invasion process. This division of sectors, organizations, geopolitical scales and management by invasion stages highlights some of the main governance challenges of managing biological invasions discussed in **section 6.2**.

This section presents a suite of possible policy instruments to address the drivers and impacts of invasive alien species from a sectorial (**section 6.3.1**), geopolitical (**section 6.3.2**) and national (**section 6.3.3**) perspective. The options presented are brought together in **section 6.7**, where the need for alignment and coordination between legal and regulatory instruments across sectors, geopolitical scales and invasion stages is described. Meeting these needs would solve the current significant gaps in coverage of regulations and/or standards targeting invasive alien species and help to implement integrated governance based on sharing efforts and commitment and understanding the specific role of all actors (related to the principle of shared but differentiated responsibility). A key finding of the present assessment is that there is a need for coordination between policy initiatives to promote free trade, protect animal, plant and human health, or address other drivers of biodiversity loss, such as climate change and land-use and sea-use change. The section also shows options to improve the efficiency and effectiveness of invasive alien species intervention efforts at the national level and their integration at a regional scale.

6.3.1 Legal and regulatory options at and across sectors

Legal and regulatory instruments from many interacting sectors deal with management of biological invasions, either directly or indirectly. This section presents and discusses the legal and regulatory instruments aimed at solving some of the main challenges in the five key sectors described in **Table 6.8**. Rather than describing specific sector-by-sector solutions, legal and regulatory instruments that apply, in many cases, to more than one sector are presented. The options described here focus on addressing four main governance challenges:

- fragmentation across sectors,
- externalities,
- conflicting interests and trade-offs, and
- hurdles to policy implementation.

Table 6 8 **Some of the international legal, regulatory and organization-based instruments relevant to invasive alien species by sector.**

Adapted from Burgiel (2015).

Sector	Activities	Examples of relevant legal and regulatory instrument	Type of instrument*
Biodiversity and environment	Conservation and natural resource management	CBD	Binding
		Ramsar Convention	Voluntary
		Bern Convention	Binding
		United Nations Framework Convention on Climate Change (UNFCCC)	Voluntary
		Protocol on Environmental Protection to the Antarctic Treaty (the Madrid Protocol)	Binding
Transport and trade	Movement of goods, sanitary and phytosanitary measures and border security	WTO	Binding
		IMO	Binding
		International Civil Aviation Organization (ICAO)	Voluntary
		IPPC	Binding
		WOAH	Binding
		World Customs Organization (WCO)	Voluntary
Production systems	Agriculture (silviculture, horticulture, livestock husbandry), aquaculture, and Living Modified Organisms[6]	IPPC	Binding
		WOAH	Binding
		FAO	Voluntary
		Cartagena Protocol on Biosafety	Binding
Extraction systems	Forestry and fisheries	FAO	Voluntary
Public health	Protection against public health threats	WHO	Voluntary
		One Health Joint Plan of Action	Voluntary

* Binding instrument refers to those where signatories have a legal obligation to implement and/or achieve their commitments

6. Living modified organisms are any living organism that possesses a novel combination of genetic material obtained through the use of modern biotechnology as defined by the Cartagena Protocol (Bail *et al.*, 2014).

6.3.1.1 Addressing fragmentation challenges

Building on the interconnections between different sectors (e.g., transport, human health, trade, agriculture and aquaculture, forestry and biodiversity) to overcome policy fragmentation would provide a pathway for the effective prevention of invasive alien species (**Figure 6.10**). Such a pathway would benefit from a coordinated view of biosecurity across relevant agencies, and a clear definition of the roles and responsibilities of relevant national offices.

(1) Develop a coordinated approach to biosecurity across relevant agencies

A coordinated approach to biosecurity may help facilitate the export of products that otherwise would be subject to import restrictions in other countries. At the same time, it could protect agriculture, forestry, horticulture, fisheries, native biodiversity and human health. A coordinated view of biosecurity would mean blurring the lines between strong sectorial identities associated with specific international standards, individual economic sectors such as health, agriculture and the environment, specific research communities, and unique stakeholder and Indigenous Peoples and local communities involvement. Biosecurity can benefit from close collaboration between the various national agencies that oversee human health, trade policy, agriculture and aquaculture, forestry and biodiversity (CBD, 2012, 2018).

Efforts in the direction of cross-agency coordination have been proposed in reviews of existing biosecurity arrangements; for example, Australia's quarantine and biosecurity arrangements (CSIRO, 2022; Durant & Faunce, 2018) are at the core of the Great Britain Non-Native Species Strategy and its Secretariat (**Box 6.6**). A broader coordinated biosecurity approach can be achieved through close dialogue between health, agriculture and environment sectors; global, national and local authorities; and natural and social sciences. For example, the One Biosecurity approach (Hulme, 2020) provides a framework to tackle multiple social and environmental challenges: climate change, increasing urbanization, agricultural intensification, human global mobility, loss of technical capability as well as public resistance to pesticides and vaccines. This framework can benefit policy development regardless of the type of invasive alien species

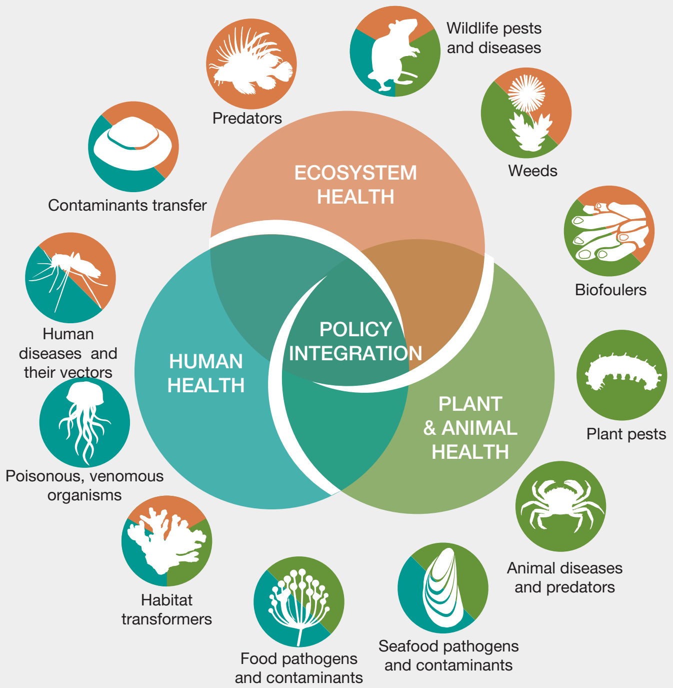

Figure 6 10 **A conceptual diagram of the links between different types of invasive alien species, human, animal, plant and environmental health that arise from the impacts of invasive alien plants, animals and pathogens, as described by the One Biosecurity approach (Hulme, 2020).**

Different types of invasive alien species will have different drivers, pathways and impacts, but their management and policy development aimed at prevention can all benefit from explicit recognition of the inseparability of human, ecosystem and plant and animal health and coordinated engagement by sectorial agents operating within each of those spheres.

presenting threats to nature, nature's contributions to people and good quality of life **(Figure 6.10)**.

A coordinated approach to biosecurity can be improved by additional capacity, including personnel, expertise and equipment. National agencies concerned with biological invasions may be able to build on efforts by agricultural and trade ministries to incrementally improve their sanitary and phytosanitary measures and border control systems. There may also be opportunities to fast-track development of these systems and address any knowledge and policy gaps by making relevant information available when and where it is needed across different offices. In many cases, knowledge sharing and adapting the practices and methods of countries with more advanced biosecurity systems could be an effective strategy in countries lacking biosecurity protocols (Hulme, 2021) and **section 6.6**. Finally, there may be creative opportunities to tailor capacity-building resources and materials currently offered by groups such as the World Bank, the IPPC, the WOAH **(Table 6.8)**, the WCO, regional development banks and national or regional research and development organizations.

(2) Clearly define roles and responsibilities across existing national offices within legal and regulatory instruments

Risk assessments are the most common approach to prevent the introduction of potentially harmful alien species from imports (**Chapter 5**, **section 5.2.2.1.e**), and are an essential component of any legislation enforcing regulations of trade. In fact, as explicitly stated by the WTO SPS Agreement, countries have the legal right to take proportional measures affecting trade based on the application of scientific principles. Deciding which governmental authority is responsible for assessing the risks of specific imports is important for preventing unwanted introductions. A clear definition of the roles and responsibilities of all agencies involved in the prevention of alien species introductions can help to devise effective management strategies (Hewitt *et al.,* 2006). Moreover, these roles and responsibilities can be supported by legal and regulatory frameworks that allow governments to execute the assigned tasks (Hewitt *et al.,* 2006). The questions in **Box 6.6** can help to guide governments to identify the most appropriate authority, and to strengthen the tools and methods for decision-making (as discussed in **Chapter 5**, **section 5.2.2**). These decisions could focus on defining the appropriate level of protection, and trade-offs between good quality of life benefits of the import and potential impacts on biodiversity. It is important to highlight that although one authority might be considered responsible for assessing the potential impact of an import, continuous communication and coordination between government agencies could ensure that all possible risk dimensions are taken into consideration.

Box 6 6 Governance and management questions to guide decisions on import proposals for aquaculture, horticulture, or silviculture species.

Adapted from Hewitt *et al.* (2006).

1. Does the government permit the importation of alien species?
2. Will any new species imports be allowed for production purposes?
3. Has an adequate risk assessment been conducted to support the decision to import the new species and provisions for managing potential harm?
4. Under what national regulation(s) will the import of a new species occur?
5. Which government agencies are responsible for management of these regulations?
6. Will these new species be allowed for uncontrolled release, within controlled or quarantine facilities?
7. Will the responsibility for managed species (e.g., in aquaculture/horticultural) be different from wild (e.g., wild, feral, or released species) populations?
8. Who will be responsible for the importation (e.g., private individual, research agency/university, industry, or government)?
9. Under what legislative arrangements will release into either a managed facility or the natural environment occur?
10. Who will be responsible for managing the release (e.g., private individual, research agency/university, industry, or government)?
11. Are there appropriate monitoring systems in place to detect and manage accidental releases in the environment?
12. Could neighbouring jurisdictions potentially be affected, and if so, are communication pathways in place to manage the risk?
13. Will neighbouring countries be involved in the decision-making process?
14. Do emergency response measures exist, including identification of the responsible authorities, in case of unforeseen negative impacts?

6.3.1.2 Addressing the indirect costs of biological invasions to uninvolved third parties: externalities

The overarching goal of the policy options presented in this section is to incorporate the negative impacts of invasive alien species into the social or economic context responsible for their introduction and spread. Such an approach would align the private, environmental and social costs of invasive alien species, so that trade-focused decisions take into consideration the environmental needs of society. It would ensure that all responsible government agencies are involved in attributing associated costs and that prices carry all the relevant information. This option would benefit from clear delineation of the environmental jurisdiction of non-environmental multilateral agreements and defining liability and redress from the negative impacts of invasive alien species on nature, nature's contributions to people and good quality of life.

(1) Delineate the environmental jurisdiction of trade agreements, so that the mandates of multilateral environmental agreements are enforceable

The tug-of-war between the philosophical underpinnings of biodiversity centred (grounded on the precautionary approach) and trade-related multilateral agreements (grounded on the evidence of adverse effects of an introduction) creates a conflict between trade and the environment (Stilwell & Turk, 1999). One way to avoid such conflict in the context of biological invasions is for governments to proactively define the relationship between trade and environmental centred agreements when negotiating multilateral environmental agreements. As discussed in Stilwell & Turk (1999), defining this relationship should not rely on exemptions ("saving clauses") in multilateral environmental agreements. Rather, agreements would better aim to establish a mutually supportive relationship between trade and the environment. Determining when the provisions in one of these two sets of agreements should supersede the other would help to internalize the externality of alien species impacts. It would also enhance policy coherence between multilateral agreements on trade and the environment, making these mutually supportive in favour of sustainable development (OECD, 2020). Specifically, this could bring about balanced and effective multilateral agreements for this transboundary and global environmental problem without the fear of trade barriers being invoked (Stilwell & Turk, 1999). This clarity would also help preserve the integrity of the multilateral trading system, which is increasingly criticized for its tendency to override social and environmental policies (European Commission, 2021). Likewise, it would address the view of social and environmental agreements as attempting to override multilateral trading rules (European Commission, 2021). Overall, such policy integration would also reduce the tendency and need to resort to unilateral trade measures, which would result in a lack of coordination and collaboration across jurisdictions.

(2) Defining liability and redress from the negative impacts to biodiversity of invasive alien species in multilateral and national legal and regulatory instruments

Invasive alien species can be viewed as a form of "self-regenerating pollution" (De Klemm, 1996). A "legal personality" (**Glossary**) or entity could therefore be regarded as liable for the damages caused from their involvement in the introduction of an invasive alien species. Preamble 33 of European Union Regulation 1143/2014 affirms that Member States should impose effective, proportionate and dissuasive sanctions for infringements, considering the nature and gravity of the infringement, the principle of recovery of the costs and the polluter pays principle. The same legislation, at art. 21 on cost recovery, says that "in accordance with the polluter pays principle … Member States shall aim to recover the costs of the measures needed to prevent, minimize or mitigate the adverse impact of invasive alien species, including environmental and resources costs as well as the restoration cost." However, the idea of liability and reparation for the impacts of an invasive alien species is missing from many multilateral environmental agreements. One notable exception is the Bern Convention which makes a formal recommendation about liability. Another example is the Convention on Civil Liability for Damage Resulting from Activities Dangerous to the Environment in Europe (Council of Europe, 1993) that specifies liability for genetically modified organisms or micro-organisms that present a significant risk for humans, the environment, or property.

Different objectives and guiding principles across legal and regulatory instruments raise complex questions about how liability for biological invasions can be assigned; and how liability can be enforced under the current state of international law. The use of environmental liability directives such as the Principle of Polluter-pays (for example, EU Directive 2004/35/CE) or nuisance laws (Pidot, 2005) provides one pathway to incorporate liability and redress provisions into the current multilateral environmental agreements. In these cases, damages are recognized as any unwanted change in protected species and natural habitats, water resources and/or soils (**Chapter 5, section 5.3.2**): namely, negligence or intentional actions of legal persons or entities involved in activities resulting in "environmental damage". In the context of transnational impacts, the best approach is that national legal and regulatory frameworks reflect obligations under international law and emphasize transboundary cooperation and collaboration concerning management of biological invasions, including liability for harm.

Given the nature of biological invasions, enforcing environmental liability would require shifting the burden of proof from the prosecution to the defendant(s) (Kramer, 2005; Pidot, 2005). Under such a regime, the prosecution would only have to demonstrate objective facts about the presence of an invasive alien species associated with a given activity of a legal person(s) or entity(ies); then the defendant(s) would need to prove the resulting invasion was not the product of negligence (Secretariat of the CBD, 2001). These proofs would be provided by all parties that received some form of financial benefit from the transport, sale and/or introduction of the species liable for some part of the harm (Secretariat of the CBD, 2001). Reframing who should be the target of punitive proceedings has the potential to develop a culture of accountability and responsibility, focused on encouraging voluntary compliance and implementations of best practices, though it is important that punitive actions are maintained as a potential last resort (Kramer, 2005; Pidot, 2005).

6.3.1.3 Addressing conflicting interests and trade-offs

Balancing the interests of multiple sectors and activities can be achieved through the development of legal and regulatory instruments, and reduce inconsistencies and misalignment in the objectives of legal and regulatory instruments. This approach could remove perverse incentives and, for example, encourage the transition to native species (**Glossary**) in production systems, stop the promotion of alien species as a tool to reduce poverty and increase food security, and increase the awareness of invasive alien species problems in disaster relief and assistance programmes.

(1) Removal of perverse incentives in sector-specific legal and regulatory instruments

Legal and regulatory instruments that promote trade, agriculture and aquaculture, infrastructure management and tourism can also facilitate invasive alien species introductions (**Chapter 3**, **section 3.2.5**) and exacerbate their impacts on biodiversity (**Chapter 4**, **section 4.3**). The removal, phase out, or reform of these incentives harmful to biodiversity is one of the Kunming-Montreal Global Biodiversity Framework targets (Target 18). As discussed by Herrick (2019) and Lodge *et al.,* (2006) aligning economic, social and environmental goals is the first step towards resolving perverse incentives (CBD, 2011). Such alignment can be achieved through careful evaluation of the trade-offs between policies with well-intentioned objectives, for example those aiming to improve good quality of life and nature's contributions to people but that promote the use of invasive alien species to do so. **Figure 6.11** showcases some examples of such perverse incentives. There are existing policy guidelines relevant to this topic (such as the European Union Green Paper on the Reform of the Common Fisheries; Commission of the European Communities, 2009), and new ones could be developed that focus on addressing specific perverse incentives. The analytical and policy guidance tools developed by the Organisation for Economic Co-operation and Development (OECD; OECD *et al.,* 2007; Sovacool, 2017) and the United Nations Environment Programme (UNEP; Morgan, 2008; Sovacool, 2017) are also valuable tools to start evaluating and addressing the possible biodiversity impacts of current and future legal and regulatory instruments.

Two factors could be considered to remove perverse incentives associated with activities that contribute to biological invasions. First is the resistance to substantive reform. In many cases, removing or modifying a policy can raise legitimate concerns about the economic consequences and the political capital cost of such changes. This is exemplified by the criticism of several countries of CBD COP decision VI/23 (CBD, 2002). In their view, Guiding Principle 7 (which advises member states to "implement border controls and quarantine measures, for alien species… based on a risk analysis of the threats posed by alien species and their potential pathways of entry") could be used as a tool to implement disguised trade barriers, thereby contravening the WTO SPS Agreement. A second factor to consider is the scale (spatial and temporal) at which proposed changes could potentially have an impact. In many cases, policy changes that can prevent invasive alien species introductions or reduce possible invasion drivers will have a direct, short-term economic and social cost for local communities, although communities would benefit from such changes in the long term. Identifying, understanding and adequately responding to the possible short-term social impacts of activities that promote the use of invasive alien species is one of the most challenging aspects of reforming policy instruments.

In addition to the examples shown in **Figure 6.11**, the development of a carbon sequestration economy could facilitate introductions of alien species (**Chapter 3**, **section 3.2.5**). This could take place *via* tree plantations through initiatives like Reducing Emissions from Deforestation and forest Degradation (REDD; Harvey *et al.,* 2010), national and multilateral initiatives on the use of biomass for energy production (i.e., EU, 2018; Jonsson *et al.,* 2021), and other restoration strategies (Brundu *et al.,* 2020) involving invasive, or potentially invasive, alien species. Tree planting is at the core of many national and regional climate strategies (i.e., carbon neutrality commitment by the European Union, China, United States, South Africa, Japan, South Korea and Canada; Climate Action Tracker, 2020). However, the most frequently used species in forestry plantations are trees from the genera *Pinus, Eucalyptus* and *Acacia* species. Though these species have traits that make them suitable for relatively rapid afforestation, they are also potentially highly invasive (Doughty, 2000; Eldridge *et al.,*

(A) Agriculture

Chemical control of alien agricultural pests has generated great concern by virtue of its non-target impacts on species of conservation concern. Carson (1962) raised this issue in her book that helped launch the environmental movement, and use of other broad-spectrum insecticides has led to similar impacts.

(B) Aquaculture

There are several instances where unintentional introductions may be associated with cultured target species; one of these being introduction of *Sargassum muticum* (wire weed) with oyster imports.

(C) Public health

The use of broad-spectrum insecticides to control introduced mosquitoes that vector human diseases, such as DDT, affected many bird species, including those of conservation concern, through eggshell-thinning. It also exacerbates pesticide resistance.

(D) Forestry

The forest-based industries and/or the energy production sector can be impacted by biological invasions. An example is *Eucalyptus globulus* (Tasmanian blue gum), which has invaded many forestry adjacent sites in North-West Spain.

(E) Infrastructure management

Road construction and roadside maintenance have often fostered invasion by non-native plants. Increasing establishment of mobile and immobile artificial structures (e.g. ships, barges, coastal defences, artificial reefs, offshore platforms) and canals play major roles in transmission, establishment and spread of aquatic non-native species.

(F) Military facilities

Midway Atoll was the site of a U.S. Naval Air Station from 1940 through 1996. The invasive plant *Verbesina encelioides* (golden crownbeard) was first observed in 1955 but was maintained at low abundance by intensive road and landscape maintenance. A shift in the 1990s to greatly reduced mowing and herbicide use triggered massive growth of this plant to the detriment of nesting seabirds, especially albatrosses.

(G) Tourism

National actions to promote local tourism (e.g., artificial reefs) in marine protected areas. Brazil's Tourism Ministry launched a plan to sink 1200 scrapped ships, trains, and airplanes, most of them inside marine protected areas, supposing that they will promote diving tourism business. Artificial reefs, such as those that would be created by sinking those vehicles, are used by invasive alien species (e.g., *Tubastraea* spp. (sun corals)) as stepping-stones to natural reefs, causing ecological, social, and economic deterioration.

(H) Biomass

Prosopis spp. (mesquite) are a group of species native to Central and South America which have been introduced in Australia, Asia, and Dryland Africa for fuel wood, fodder, to improve soils and reduce erosion. After the demand for *Prosopis* crashed, many plantation were abandoned without management or eradication. As a result *Prosopis* has become a major problem, particularly in Africa. It has severely impacted traditional livelihoods of pastoral communities.

Figure 6 11 **Examples of perverse incentives where actions aimed at promoting an activity fail to take into account the existence of environmental externalities.**

Examples present cases where (a) agriculture (Carson, 1962; Herms & McCullough, 2011), (b) aquaculture (Engelen *et al.,* 2015), (c) public health (Carson, 1962; Walker *et al.,* 2003), (d) forestry (Calviño-Cancela & Rubido-Bará, 2013), (e) infrastructure management (Galil *et al.,* 2017; Mineur *et al.,* 2012; Skultety & Matthews, 2017), (f) military facility management (Taylor *et al.,* 2020), (g) tourism (Miranda *et al.,* 2020) and (h) biofuels (Pasiecznik, 1999) can promote biological invasions. Miller, USDA Forest Service, Bugwood.org – under license CC BY 3.0 US / (b) Graça Gaspar, WM Commons – CC BY-SA 3.0 / (c) LSIS Helen Frank, WM Commons – Public domain / (d) Ignacio Amigo – CC BY 4.0 / (e) Rept0n1x – Walk to Lunt (102), WM Commons – CC BY-SA 2.0 / (f) Forest & Kim Starr, WM Commons – CC BY 3.0 US / (g) Paula Raposo – CC BY 4.0 / (h) Thamizhpparithi Maari, WM Commons – CC BY-SA 3.0.

1994; D. M. Richardson & Rejmanek, 2004). While not invasive, *Elaeis guineensis* (African oil palm) plantations have been promoted as a climate mitigation strategy, yet they have limited biodiversity and conservation value (Harvey *et al.,* 2010). Therefore, not considering fundamental environmental values, including safeguarding biodiversity in climate mitigation initiatives, can result in serious negative ecological consequences. Examples of impact include biotic homogenization (**Glossary**, Olden *et al.,* 2004), genetic swamping (R. C. Barbour *et al.,* 2010) and altered ecosystem processes (Simberloff *et al.,* 2009). Moreover, the escape of these plantation species can become costly to manage and lead to significant biodiversity losses (D. M. Richardson & Rejmanek, 2004).

(2) Encourage the transition to native species in production systems

Reducing the dependence of the still growing aquaculture, horticultural and silvicultural sectors on alien species is one of the most pragmatic approaches to reduce translocations of problem species within and across national borders. There are options to replace some cultivated alien species with native species (e.g., Jones Jr & Foote, 1991; Pérez *et al.,* 2003; van Heezik *et al.,* 2012). Mainstreaming this perspective can be done through technical and policy developments that promote potential candidate native species that are preferred by their respective communities and local consumers. Nonetheless, it is important to highlight that alien species constitute as much as 75 per cent of the species used for consumption (Palacios, 1997), and that these constitute the cornerstone for the economic activities of multiple communities. Therefore, such transition needs to consider the possibility of alien species replacement to fulfil food security and economic needs, with fisheries and forestry species more frequently invasive than terrestrial food crops (De Silva *et al.,* 2009; FAO, 2019).

Some alien species used in many production systems are causing significant losses in performance, primarily from inbreeding (E. O. Wilson, 1999). Rather than replenishing the stocks of these alien species with fresh germplasm obtained from their natural range, policy and voluntary codes of practice could promote the development of viable and profitable culture techniques for suitably selected native species. The pangasid fish culture (*Pangasianodon hypophthalmus* (sutchi catfish)) in the Mekong Delta is a successful example of the viability of gradually reducing the dependence on alien species *via* the replacement by native species (De Silva *et al.,* 2009; Nguyen, 2007). The aquaculture production of *Piaractus mesopotamicus* (small-scales pacu) in Argentina is another example of the successful use of native species to address decreases in capture fisheries (Quirós, 1990). *Piaractus mesopotamicus* production is now the second largest aquaculture species-based production in Argentina (FAO, 2016). However, success is mixed across examples of shifts to native species in production systems, with shifts not being feasible in aquaculture in Indonesia, Malaysia and Thailand, but underway in some cases in India and Bangladesh (De Silva *et al.,* 2006, 2009). Similar contrasting trends have been reported in aquaculture in Europe (Turchini & De Silva, 2008).

In the case of silviculture, options for the replacement of invasive alien with native species seem limited in commercial forestry with the most productive forestry species being alien (D. M. Richardson, 1998; D. M. Richardson & Higgins, 1998). In the Galapagos, where other invasive alien species (*Centrolobium paraense, Juglans neotropica* (andean walnut), *Swietenia macrophylla* (big leaved mahogany) and *Tectona grandis* (teak)) are established, conservation authorities are encouraging the replacement of invasive alien timber species with non-invasive alien timber species (*Cedrela odorata* (Spanish cedar) and *Cordia alliodora* (Ecuador laurel)) and horticultural species (*Psidium guajava* (guava), *Cinchona pubescens* (quinine tree); Richardson, 1998).

(3) Stop the promotion of alien species as a tool to reduce poverty and increase food security

Alien species are the cornerstone of many aquacultural practices aimed at improving food security. Examples are alien tilapia (*Coptodon* spp., *Oreochromis* spp. and *Sarotherodon* spp.), salmonids (*Salmo trutta* and *Oncorhynchus mykiss*) and oysters (*Crassostrea* spp., *Ostrea* spp. (flat oyster), *Argopecten* spp.; De Silva, 2012; Paini *et al.,* 2016; McBeath & McBeath, 2010). This also been the case for silvi/agro-cultural initiatives aimed at reducing poverty, where species such as eucalypts and *Leucaena leucocephala* have been introduced in Southeast Asia. Grasses and legumes from Australia, South Africa and North America have been introduced in experimental farms near Santa Cruz (Bolivia) and *Prosopis juliflora* (mesquite) has been introduced in Africa **(Figure 6.11)** for fuel-wood for the rural poor (Murphy & Cheesman, 2006; **Chapter 4**, **Box 4.9**). These species can escape production environments and have adverse impacts on biodiversity and ecosystems (**Chapter 3**, **sections 3.2.5** and **3.3.1.1**). A first step to avoid this problem could be a strategy shift by development assistance organizations to embed the preferred use of native species into their codes of practices. Exploring viable native alternatives as primary species for human consumption or as animal feed is an option for such organizations. This shift will benefit from being coupled with national policy that promotes a culture of native species cultivation valued by Indigenous Peoples and local communities.

However, the implementation of a “native species”-centred approach would require careful consideration in each case. For example, it is critical to consider if native species can provide viable alternatives to assure food security for ever increasing human populations, especially in rural populations of developing countries (De Silva *et al.,* 2009; Murphy & Cheesman, 2006; Shackleton, Richardson, *et al.,* 2019). It would be important to consider socioeconomic conditions, as well as the views and needs of Indigenous Peoples and local communities, so that good quality of life is not adversely affected. This is clearly the case for alien tilapias (*Coptodon* spp., *Oreochromis* spp. and *Sarotherodon* spp.) in China, Indonesia, the Philippines and Sri Lanka, where they play a major role in subsistence aquaculture systems by providing a relatively cheap source of animal protein, as well as considerable export income (De Silva *et al.,* 2004, 2009); simply put, shifting to a less productive native species may not be feasible.

(4) Develop guidance documents and codes of practice to reduce pathway risks for disaster relief and assistance programmes

The lack of awareness of the possible problems caused by invasive alien species in international development programmes has made disaster relief and assistance an major invasion pathway (Murphy & Cheesman, 2006; **Chapter 3**, **section 3.2.2.2**). Specifically, the invasive alien species problems created by international disaster relief and assistance programmes arise unintentionally from activities inspired by humanitarian motives. Many anecdotal reports (summarized by Murphy & Cheesman, 2006) link invasive alien species to these programmes (**Chapter 3**, **section 3.2.2.2**). As the negative effects of alien species (un)intentionally introduced *via* this pathway can be long lasting and outweigh positive impacts, increasing this awareness is important.

The most efficient line of defence to identify possible invasive alien species in aid packages might be developing biosecurity protocols, voluntary codes of practice and risk assessment protocols focused on preventing (un) intentional introduction in these programmes. Addressing the problems that have resulted from invasive alien species (un)intentionally introduced by past international assistance and aid /relief activities could be a priority for all associated stakeholders. However, conflicts of interest may arise where an environmentally damaging species is contributing to local livelihoods (as reviewed in Shackleton, Shackleton, *et al.,* 2019; **Chapter 5**, **section 5.6.1.2**). Therefore, careful consideration is necessary of the trade-offs between reductions in nature and good quality of life benefits due to invasive alien species impacts and the immediate needs of vulnerable populations.

6.3.1.4 Addressing implementation challenges in key areas

Effective management of biological invasions can be promoted in multilateral and national legal and regulatory instruments by including early warning systems (**Chapter 5**, **section 5.5.2**) in all environmental legal and regulatory instruments; considering all alien species as possible environmentally hazardous living organisms; developing strategies to regulate cross-border e-commerce (**Glossary**); increasing awareness of and improved compliance with (voluntary) codes of practices; and incorporating prevention and control of invasive alien species into protected areas and island management plans.

(1) Include early warning systems for invasive alien species into multilateral environmental agreements and national legal and regulatory instruments

Although biodiversity-related policy instruments dealing with invasive alien species have generic surveillance provisions (e.g., the Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization to the CBD, Article 29 and subsequent decisions; Cartagena Protocol, Article 17; International Treaty on Plant Genetic Resources for Food and Agriculture Article 17.2, or the Ramsar Convention on Wetlands, Articles 3(2), 4(1), 4(3), 6(2) (InforMEA, 2021)), no instrument has a direct requirement for monitoring or the development of early warning systems. The need to develop effective global early warning and rapid response systems has been stated as a priority action by the CBD COP (decision IX/4 "In-depth review of ongoing work on alien species that threaten ecosystems, habitats, or species" and by the "Charter of Syracuse" on biodiversity, adopted at the G8 Environment Ministers Meeting (22–24 April 2009, Syracuse, Italy). Early warning and rapid response systems for invasive alien species can detect the occurrence of new invasive alien species, supported by activities to identify new species correctly and acquire all related information (European Environment Agency, 2010b).

The lack of clear provisions on early warning systems is due to the need for cross-national integration of effort and standards for effective surveillance, which has proven difficult for biodiversity policy instruments (Hulme, 2021). A notable exception that incorporates monitoring provisions is the Bern Convention. Monitoring and early warning system provisions is also part of many management recommendation documents, such as guidelines by the IUCN (IUCN, 2000; Tye, 2018) and the Council of Europe (Genovesi & Monaco, 2013). Monitoring and early warning system provisions could be incorporated into multilateral environmental agreements and national policy instruments. For these provisions to be effective, they could encourage participation across government and non-government agencies, the scientific community and the general public. Such engagement could, for example, be *via* a complaint system to a dedicated national authority, which has proven to be a successful monitoring tool for the Bern Convention (C. L. Díaz, 2010). Also, similarly to the reporting mechanism under the UNFCCC, periodic reporting on the numbers and identity of invasive alien species by member states could be part of the provisions of multilateral environmental agreements. An international biosecurity convention organization (similar to the secretariat of the Convention on the Conservation of Migratory Species of Wild Animals (CMS)), if established, could implement a global surveillance and monitoring network to provide early warning of new threats (Hulme, 2021). Creating an international warning system is a large task, but there is already ongoing research in this direction (Latombe *et al.,* 2017; Pagad *et al.,* 2018; Essl, Lenzner, *et al.,* 2020).

(2) Inclusion of all invasive alien species as environmentally hazardous living organisms

Three areas central to biosecurity are: the management of risks associated with the accidental introduction of pests and diseases with food and agriculture, the introduction and release of genetically modified organisms and their products, and the deliberate introduction and management of invasive alien species and genotypes (FAO, 2003; **Chapter 3**, **sections 3.3.1** and **3.3.5.2**). Many biosecurity protocols do not cover "hitchhikers" or contaminants (e.g., spiders in produce, ants in taro plants), making the case for a broader definition of hazardous organisms, one that includes possible alien species that may affect the environment, the economy and/or human health (such as the New Zealand Import Health Standards that include provisions for hitchhikers and contaminants).

In addition to a broad definition of "hazardous organisms" in trade-related biosecurity protocols, clear and accurate labelling for consignments of all living organisms being transported is needed to prevent invasion. Labelling can be supported by regulated species lists with prohibited (strict approach) or permitted (lenient approach) species listed by jurisdiction and supported by import risk analyses. This protocol could be accompanied by handling protocols that promote environmental safety during transport. Adequate labelling needs to be developed and implemented through an efficient exchange of information between vendors and national authorities. The WCO has developed cross-border e-commerce frameworks (WCO, 2018) and technical standards (WCO, 2019) for this purpose, focusing on the need for electronic data to manage the risks of cross border movements of goods, and has been asked at COP15 of the CBD to look specifically at the question of e-commerce and invasive alien species (CBD, 2022c). Through the exchange of advanced electronic data, and considering all traded species as hazardous organisms, national authorities can ensure compliance with regulatory requirements. Furthermore, the use of detailed and accurate labelling of consignments would make exporters active participants in biosecurity and responsible for clean trade (**Glossary**, Hulme, 2021).

The UN Economic and Social Council's Sub-Committee of Experts on the Transport of Dangerous Goods will consider including environmentally hazardous living organisms in chapter 2.9, class 9, of the United Nations *Recommendations on the Transport of Dangerous Goods – Model Regulations*,[7] at its upcoming session in 2023, taking into account the risk of unintentional introduction of invasive alien species, including pathogens. This could be a significant step forward if governments are willing to accept it.

(3) Develop and raise awareness of codes of practices and standards and other mechanisms to regulate cross-border e-commerce

The rise of e-commerce contributes to invasive alien species spread (**Chapter 3**, **section 3.2.3.1**), and is becoming an increasingly critical biosecurity concern (Ricciardi *et al.,* 2017; **Chapter 5**, **section 5.3.1.1**). However, the online trade of living organisms is poorly regulated (Lenda *et al.,* 2014; Mazza *et al.,* 2015). Also, the high level of anonymity in online trade can circumvent accountability and taxes. Individuals and small companies that sell through the internet may not be legally registered and often do not disclose their specific location of operation. As a result, consignments of regulated articles can be imported into a country without any effort to meet the phytosanitary requirements of the receiving country (Derraik & Phillips, 2010; Keller & Lodge, 2007; Morrisey *et al.,* 2011). Buyers and sellers in the plant and animal trade may be ignorant or misinformed on potential dangers and biosecurity regulations, or may incorrectly identify their products (Giltrap *et al.,* 2009; Walters *et al.,* 2006). As such, national lists of regulated species are more important than ever. For example, the European Union, through the European Union Regulation 1143/2014, has adopted a List of species of Union Concern that are banned from import into the Union, and for which there is a general obligation to eradicate or control when recorded in the territory of a member state. The list is regularly updated. In 2004, Japan adopted an Invasive Alien Species Act that includes a list of regulated species.

Based on these lists, voluntary codes of conduct for e-commerce platforms could be developed as cost-effective approaches to address the trade-off between the economic benefits of e-commerce and the risk of environmental harm from the scope of these species (Monaco & IUCN Invasive Species Specialist Group, 2021; Shackleton, Adriaens, *et al.,* 2019). Specifically, the adoption of voluntary codes of conduct could prevent sales and auctions of species into countries where they are regulated and improve correct labelling of traded species. These conduct codes could

7. United Nations publication, Sales No. E.19.VIII.1.

stimulate e-commerce platforms to self-regulate by screening their own listings for species of concern and proactively complying with countries' invasive alien species laws, requiring sellers on online platforms to provide information on the species they sell. At a minimum, this information would include taxonomy, a record of potential invasiveness of these species, and appropriate measures that a buyer could use to prevent a species escape or release. Clear labelling of consignments, combined with lists of prohibited or permitted organisms, is perhaps the best way to prevent environmental harm without imposing major constraints on e-trade.

Such voluntary guidelines are in the process of being implemented for endangered and threatened species trade by the world's leading technology companies, including e-commerce and social media companies (e.g., Alibaba, eBay, Facebook, Google, Instagram, Microsoft, Pinterest, etc.). One example of a related effort is the work by the Coalition to End Wildlife Trafficking Online.[8] It is a partnership between environmental organizations such as Trade Records Analysis of Flora and Fauna in Commerce (TRAFFIC), World Wildlife Fund for Nature (WWF) and the International Fund for Animal Welfare (IFAW) with companies from across the globe to reduce wildlife trafficking online. Expanding these standards to include invasive alien species would help reduce introductions of invasive alien species through e-commerce.

The effectiveness of voluntary guidelines, codes of conduct and standards can be improved through the development of an efficient information exchange system accessible to all parties involved in trade and transport. At COP15, CBD parties considered measures on e-commerce and associated risks of invasive alien species (CBD, 2022c). One of these measures is considering the implementation of a single-entry system that facilitates the sharing of standardized information and documents with a single-entry point (i.e., a "Single Window approach") to fulfil all import, export and transit-related regulatory requirements.

(4) Increase awareness, participation and compliance with (voluntary) codes of practice for the translocation and exploitation of invasive alien species

Increasing governmental support for deregulation combined with industry opposition to restrictive legislation has led to a progressive emphasis on corporate responsibility and voluntary codes of practices worldwide (Sethi, 2011). Several activity-specific voluntary codes of practices have been developed to address the management of invasive plant species by the ornamental nursery industry (Baskin, 2002; Heywood & Brunel, 2009 and **Box 6.7**), aquaculture and forestry. Similar codes of conduct have been developed in Europe for several relevant activities, including boating, botanic gardens, hunting, international travel, pets, recreational fishing, zoological gardens and aquaria (such as the European code of conduct on hunting and invasive alien species, and other available at EASIN (2021)). These codes of practice provide practical and concise guidance in establishing common standards of good practice and responsible attitudes and behaviours for use of alien species in production activities. Their recommendations are intended to be complementary, not replace, the binding obligations embedded into national legislation and action plans that regulate any activity that transports, sells, or uses alien species.

The effectiveness of voluntary codes of conduct has limits but can be a valuable part of integrated systems to reduce the risk of invasive alien species. In fact, several codes of practice on invasive alien plants are in use throughout the world. Codes of practices on invasive alien species have two main goals: (1) to reduce deliberate introductions of invasive plants and (2) to increase the level of awareness-raising (Halford *et al.,* 2014). For example, the European and Mediterranean Plant Protection Organization (EPPO) standard PM 3/74(1) provides guidelines on the development of a Code of practice on horticulture and invasive alien plants (EPPO, 2009).

(5) Policy to support incorporation of management of biological invasions into protected area management plans

The designation of parcels of land- or seascapes as protected areas does not confer immunity from the effects of invasive alien species, and the invasion of protected areas erodes the maintenance of species diversity and natures contributions to people (e.g., terrestrial plants, Foxcroft *et al.,* 2013; Liu *et al.,* 2020; and marine systems, Gallardo *et al.,* 2017; Giakoumi *et al.,* 2019). This has become a concern at an international level, with many global conventions, policies or strategies focused on the threat of invasive alien species in protected areas in development (Foxcroft *et al.,* 2017; Shine *et al.,* 2000). The designation of protected areas will likely increase as a result of the Kunming-Montreal Global Biodiversity Framework adopted at COP15 of the CBD in late 2022, which clearly encouraged governments to increase protected areas on land and in water by restoring (Target 2) or protecting (Target 3) at least 30 per cent of terrestrial, inland water and of coastal and marine areas.

Due to the importance of protected areas, policy instruments could be developed to elevate protected areas to priority invasive alien species management sites, using a site-based management strategy (**Glossary**; **Chapter 5**, **section 5.3.1.3**). The development of such instruments may lead to the formalization of alien species management plans into the protected area management planning process.

8. https://www.endwildlifetraffickingOnline.org/

Box 6 7 **The way forward for ornamental horticulture and invasive alien plants: How to reduce risks and achieve sustainability?**

Ongoing innovation, cultivation and introduction of new plants has been considered critical to the survival and profitability of the horticultural sector, and can result in the ongoing introduction of alien species (Seaton *et al.,* 2014). Ornamental horticulture fosters plant invasions in a number of ways (Culley *et al.,* 2011). First, it often involves multiple introductions which include both the initial introduction as well as the subsequent sale and distribution of cultivated individuals through supply chain, retail centres, mail order catalogues, and over the internet (Culley *et al.,* 2011). Second, selective breeding may unintentionally favour traits, such as rapid growth, rapid seed germination, drought tolerance and disease resistance, that can enhance spread and invasive potential. Third, ornamental horticulture may promote invasiveness through commercialization of cultigens (plants known only in cultivation; Spencer & Cross, 2007). Although some may be self-sterile, different cultigens planted together may cross-pollinate and form viable fruit that is dispersed into natural areas. This has already been documented, for example, in *Pyrus calleryana* (callery pear) and *Lythrum salicaria* (purple loosestrife; **Figure 6.12**; Culley *et al.,* 2011; Culley & Hardiman, 2007, 2009).

To prevent further plant invasions resulting from ornamental horticulture, countries could commit to promote the inclusion of specific guidelines for the ornamental horticulture sector and supply chain, within the framework of national strategies on biological invasions and within related national policy (for example those relevant to biodiversity, SDGs, sustainable agriculture and forestry). As discussed by Hulme *et al.* (2018), closing this plant invasion pathway can be achieved by government-industry agreements to fund effective pre-and post-border weed risk assessments. This can be supported by widely adopted industry codes of practices. One example is the Code of Conduct for Invasive Alien Trees (Brundu & Richardson, 2016), which complements other European existing codes of practice dealing with horticulture and botanic gardens (Heywood & Sharrock, 2013). Codes of practice help producers and consumers make informed choices and help to target public education needed about horticultural invasion risks. For example, Green Lists of non-native ornamental species that have been assessed as having a low risk of escaping cultivation can contribute to the prevention of plant invasions (Dehnen-Schmutz, 2011)

For example, the European Union Natura 2000 network aims to ensure the long-term survival of valuable and threatened species and habitats. Therefore, management plans are needed to prevent the deterioration of habitats and significant disturbance to species (Underwood *et al.,* 2020). The European Union invasive alien species regulations also provide legal support to prevent the introduction and spread of invasive alien species of Union concern, as Member States are obliged to undertake action to prevent and/or limit the impact of invasive alien species of Union concern (Underwood *et al.,* 2020). In Argentina, the national invasive alien species strategy requires management plans for the control of invasive alien species to be incorporated into protected area management and annual operational plans in national, provincial and municipal protected areas and private reserves (Paola & Kravetz, 2004). Protected areas in marine and connected systems are, however, less likely to achieve successful management following establishment of an invasive alien species (**Chapter 5**, **Figure 5.1**; Simberloff, 2021; **Box 6.8**). Therefore, high-level policy instruments are needed to focus on preventative measures, for example, ballast water management systems and biofouling protocols (**Table 6.4**; **Chapter 5**, **section 5.4.4.1**).

The application of high-level indicators downscaled from global to local levels may provide a framework for protected areas to assess progress in managing biological invasions. For example, in protected areas, it is possible to monitor the number of alien taxa, the species negatively impacting biodiversity, and the trends therein (**section 6.6.3**). This indicator can be read in conjunction with indicators such as trends in species at risk of localized extinction in a protected area. Response indicators provide protected areas and conservation agencies with feedback on the extent to which essential policy and management approaches have been adopted (McGeoch *et al.,* 2010; **section 6.6.3**). Collated at a national level these responses can be used to inform global indicators such as those for measuring progress in achieving the targets of the Kunming-Montreal Global Biodiversity Framework.

Box 6 8 **Marine protected areas as hotspots of invasive alien species.**

Marine protected areas are created to conserve the diversity of native species and associated habitat, and protect this biodiversity from threats such as invasive alien species (Francour *et al.,* 2010). Yet, evidence is emerging that suggests marine protected areas do not provide effective, or even adequate, resistance to the introduction, establishment and spread of invasive alien species (Usher *et al.,* 1988). For example, a survey of the venomous *Pterois* spp. (lionfishes) in 71 Caribbean reefs shows that they have established in high densities on reefs with depauperate native predator assemblages, and on reefs with both a high diversity and high biomass of native predators (Hackerott *et al.,* 2013; **Figure 6.13**). A census of lionfish in the Florida Keys National Marine Sanctuary, long considered a safe refuge for biodiversity (Hickerson *et al.,* 2012), revealed a rapid increase in their spread, abundance and biomass (Ruttenberg *et al.,* 2012). On the island of Martinique, despite intensive population control efforts (e.g., public awareness, authorize and equip dive centres for Lion-fish removal; Trégarot *et al.,* 2015) inspired by the Regional Caribbean Lionfish Strategy (Gómez Lozano *et al.,* 2013), lionfish colonized the west coast of Martinique, most of it designated as marine protected areas [9]. The lionfish also colonized the isolated Parque Nacional Arrecife Alacranes and the offshore coral reefs of the Flower Garden Banks National Marine Sanctuary in the Gulf of Mexico (Johnston *et al.,* 2017; López-Gómez *et al.,* 2014).

Figure 6 13 **Lionfish are now invading the western Atlantic Ocean, from North Carolina to Brazil.**

Box 6 8

In a global hotspot (**Glossary**) of marine invasive alien species, the Mediterranean Sea, a survey of rocky reef fish assemblages in 30 marine protected areas did not find evidence for any effect of marine protected areas on invasive alien species (Guidetti *et al.,* 2014). There is evidence of up to two times higher biomass of invasive alien fish in some marine protected areas than in adjacent unprotected areas (Giakoumi *et al.,* 2012), with up to 50 per cent of fish biomass in protected areas being invasive alien species (Giakoumi, Pey, *et al.,* 2019). An assessment of the vulnerability of 142 Mediterranean Sea marine protected areas to invasive fishes and algae found that Levantine marine protected areas are dominated by invasive alien species (D'Amen & Azzurro, 2020). Effective invasive alien species policy for marine protected areas should therefore include a strong focus on prevention, along with context-specific environmental management to minimize the suitability of local habitats to invasion as currently proposed in the Action Plan Concerning Species Introduction and Invasive Species in the Mediterranean Sea (UNEP, 2014).

6.3.2 Legal and regulatory options across geopolitical scales

This section presents and discusses strengthening legal and regulatory instruments at multilateral scales **(Table 6.4)**. The goal is to present the main strategies by which agreements, laws and regulatory instruments and voluntary codes relevant at broad geopolitical scales can be strengthened. The options presented focus on the need for clear national strategies, embedded in a regional context and framed by coordinated multilateral environmental agreements.

6.3.2.1 Link national invasive alien species strategies into regional plans to align efforts and complement national strategies

The drivers facilitating invasive alien species are transboundary in nature (**Chapter 3**, **sections 3.1.1** and **3.1.3**), and their impacts are rarely restricted within political boundaries (**Chapter 4**, **sections 4.3**, **4.4**, **4.5**, **4.6**). Actions by individual countries are therefore not enough to mitigate the drivers and address the impacts of invasive alien species. Therefore, effective responses are based on shared objectives, means and approaches across legal and regulatory instruments, while also being supported by cross national collaborative actions. The need for countries to work together to identify, share information on, and coordinate around common priorities on invasive alien species could be a priority in any future or renegotiation of regional agreements. Efforts in this direction are in place in multiple trading blocs like the Southern Common Market (MERCOSUR) and the European Union **(Box 6.9)**. Ensuring this coordination may be the most effective means of reducing the risk of new invasive alien species and further spread of invasive alien species. Moreover, the gains achieved by placing national policy priorities within the context of regional and international instruments outweigh the investment required for any country deciding to go "solo". This is clearly evidenced by the existing web of policy ties across geographic scales that transcend the invasive alien species issue.

9. http://campam.gcfi.org/CaribbeanMPA/mapview.php

Box 6 9 **From Regional policy to national priorities: MERCOSUR and European Union cases.**

MERCOSUR is a regional trade agreement whose members are Argentina, Brazil, Paraguay, Uruguay and Venezuela. These countries have agreed on several regional commitments promoting action on invasive alien species: MERCOSUR Biodiversity Declaration (2006); Article 7 of the MERCOSUR Environment Framework and the Work Plan of the MERCOSUR Working Group, which acknowledges the need for managing priority invasive alien species. Also, the MERCOSUR working subgroup on the environment (SGT6) acknowledged the need to define a joint work plan on invasive alien species, including prevention, control and eradication priority actions, as part of multilateral environmental agreements and the MERCOSUR Framework Agreement on the Environment (LXIV Ordinary Meeting, 2017). The adoption of risk assessment protocols for introduction of species and MERCOSUR Resolution GMC 38/2019 on Guidelines for the Prevention, Control and Mitigation of Invasive Alien Species to reduce impacts on biodiversity, environment, health, production, economy and culture, is one of the recent regional agreements (MERCOSUR, 2019).

These agreements have not been reflected in Actions plans or in practical measures to deal with invasive alien species in different MERCOSUR countries. Two exceptions are Argentina and Brazil, both of which developed a national strategy on invasive alien species (GEF, 2016; Ministério do Meio Ambiente/ Secretaria de Biodiversidade, 2018). Uruguay recently included the promotion of the control of invasive alien species as a general goal in their National Strategy of Biodiversity (Uruguay:

Box 6 9

MVOTMA-DINAMA, 2016) and, in Paraguay, the national policies of invasive alien species are related to Wild Life Law and Resolutions 1184-85 (SEAM, 2006), which deal with control of introduction of exotic fauna and flora species.

The European Union as a party to the CBD took actions to ensure its policies comply with Article 8h of the Convention, on invasive alien species. In 2014 the European Union agreed to a legislative text related to invasive alien species, adopted by the European Parliament and the European Council: Prevention and Management of Invasive Alien Species, European Union Regulation 1143/2014 (Council of the European Communities, 2014), fulfilling Action 16 of Target 5 of the European Union 2020 Biodiversity Strategy, as well as Aichi Target 9 of the Strategic Plan for Biodiversity 2011–2020 under the CBD (Baquero *et al.,* 2021). This adoption resulted in the immediate existence of an enforceable law for all Member States (January 2015). This Regulation also emphasizes prevention, early warning systems and rapid response, while also recognizing that when prevention fails, eradication is the best management alternative, alongside long-term control measures. In summary, Regulation 1143/2014 allowed overcoming the limited coordination of national strategies on invasive alien species assisted by an information system, the European Alien Species Information Network (EASIN)[10] including an early warning system supporting early detection of invasive alien species of Union concern in Europe. It stimulates strengthening of ecosystem resilience through restoration linking with other policies, e.g., the Marine Strategy Framework Directive and the Water Framework Directive to improve the control of aquatic invasive alien species in European Union countries (Boon *et al.,* 2020; Council of the European Communities, 2008). An interesting component of the European legislation is that it includes an obligation for Member States, at Art. 13, to enforce an action plan addressing relevant pathways of introduction of invasive alien species, thus focusing on prevention rather than on reaction to new invasive alien species.

6.3.2.2 Increase coordination across multilateral environmental agreements

Over the past decade, there has been widespread adoption of multilateral environmental agreements (**section 6.1.3**). However, this pool of multilateral legal and regulatory instruments is piecemeal in the way the pathways and impacts of invasive alien species are addressed. One way to overcome this is to consider a more comprehensive international approach that focuses on sustainable development *via* the protection of biodiversity and maintaining good quality of life. The Inter-agency Liaison Group on Invasive Alien Species established by the Executive Secretary of the CBD was central to this process, but has been inactive for several years. However, at COP15, Parties invited “the Secretariat of the United Nations Economic and Social Council, the World Customs Organization [WCO], the International Plant Protection Convention [IPPC], the World Organisation for Animal Health [WOAH], the World Health Organization [WHO], the Food and Agriculture Organization of the United Nations [FAO] and its Codex Alimentarius, the Secretariat of the Convention on International Trade in Endangered Species of Wild Fauna and Flora [CITES] and the Invasive Species Specialist Group [ISSG] of the International Union for Conservation of Nature [IUCN], within the scope of their respective mandates, to support the national implementation of the Kunming-Montreal Global Biodiversity Framework with regard to targets and actions related to invasive alien species, including their monitoring and reporting”(CBD, 2022c).

While discussions leading to an increase in coordination across multilateral instruments is more likely to take place for global scale instruments due to their global scale implications, coordination of regional multilateral instruments faces many difficulties and obstacles, particularly in developing countries. Linguistic, cultural and political differences within regions also pose major obstacles for coordination. As discussed by Burgiel (2015), the Caribbean region is an example of the difficulties of integrating regional policy instruments due to multitude of languages and historical affiliations, the status of overseas territories and political issues. That said, the efforts of regional intergovernmental or nongovernmental entities provide a primer for building synergies and increasing coordination across legal and regulatory instruments (Burgiel, 2015).

6.3.2.3 Embed in multilateral agreements mechanisms to enhance coordination and information exchange between policy instruments

The inherent complexity in managing biological invasions could be countered by communication and information exchange among a wide range of stakeholders including across national borders and across government agencies, the private sector, the scientific and research community and the general public. A system for communication and information exchange would be supported by a well-functioning infrastructure. Effective decision-making for alien species is only possible with timely access to scientific and technical information. Embedding the need of institutions that facilitate/mandate information generation and exchange into multilateral agreements can provide a mechanism

10. https://easin.jrc.ec.europa.eu/easin/

to achieve the goals of existing agreements and provide information for the application of guidance documents. At a minimum, identification and monitoring of alien species would be part of the mandate of the proposed knowledge-generating institutions. Most of the international legal instruments, agreements and texts relevant to invasive alien species highlight the importance of risk analysis principles, notification procedures and information exchange. Examples of information exchange infrastructures include the CBD Access and Benefit-sharing Clearing-House and the FAO Forest invasive species home. However, information is usually sectorized in instrument focused clearing houses. There is also a problem with limited exchange of information across government agencies, and from the scientific and research community to policymakers and the public (**section 6.6**).

The need for an organizing (multi)national authority is clear due to the fragmented nature of existing policy instruments, which limits the capacity of a coordinated and unified response to the invasive alien species problem (Shine *et al.,* 2000; Stoett, 2007). The benefits of creating such an organizing (multi)national authority are the capacity to:

- Coordinate policy across national agencies and countries within a trading block;
- Unify risk analysis of invasive alien species introduction pathways, and how these risk analyses are implemented by relevant authorities;
- Develop effective early detection and rapid-response activities;
- Promote the exchange of information among all the stakeholders and Indigenous Peoples and local communities involved in the prevention, control and eradication of invasive alien species;
- Enhance the capacity to be cost effective in preventing and mitigating strategies given the interdependence of management;
- Enhance the capacity to synthesize and integrate information from international agreements, regional/national agencies, sectorial initiatives and university research.

An example of such a multilateral coordinating body is the Committee for Environmental Protection (CEP) which has, for example, developed a Non-Native Species Manual for activities of the nations active in the Antarctic **(Box 6.10)**.

Box 6 10 **The Committee for Environmental Protection as a coordinating body for Antarctic alien species problems.**

Policy context: Policies that are relevant to biodiversity and to ecosystem services in the Antarctic region are developed, usually independently, by the Antarctic Treaty Consultative Parties (ATCPs), the Commission for the Conservation of Antarctic Living Resources (CCAMLR) and by the States responsible for the islands in the Southern Ocean (north of 60°S). The ATCPs are advised by the Committee for Environmental Protection (CEP), established by the Protocol on Environmental Protection to the Antarctic Treaty of 1991 and by the Scientific Committee on Antarctic Research (SCAR), a committee of the International Science Council (Protocol Article 10.2; **Supplementary material 6.1**).

Invasive alien species: Based on the advice of the CEP, the ATCPs have placed significant focus on preventing invasive alien species introductions to and impacts on the area south of 60°S. Current guidance for doing so is encapsulated in the Non-Native Species Manual of the CEP (ATCM, 2019), hereafter the Manual). The Manual covers the unintended introduction of species to the Antarctic region and the movement of species within Antarctica, and is an example of the effective translation of recent research to policy through the CEP (e.g., Hughes & Convey, 2010, 2012; Lee & Chown, 2011). Although the pace of such translation and uptake has been criticized and there is a lack of evidence to quantify the implementation of different biosecurity measures across more than a handful of national programmes, the rate of development of responses within the Antarctic Treaty System (ATS) has been relatively rapid, with these responses exceeding those typically expected elsewhere, as measured through a comparison with international responses to the relevant Aichi Targets of the Strategic Plan for Biodiversity 2011-2020 (Chown *et al.,* 2017).

Practical guidelines: The Manual has also been supplemented by other practical guidance for those operating in the region. Perhaps the best example is the COMNAP/SCAR Invasive alien Species Voluntary Checklists for Supply Chain Managers (SCAR & COMNAP, 2019), which provides practical guidance (and the evidence underlying it) to prevent the introduction of non-indigenous species to Antarctica. Other organizations, such as the Antarctic tourism industry body, the International Association of Antarctica Tour Operators (IAATO), have similar guidance for its members (IAATO, 2020). In the 2019/2020 season, more than 74,000 tourists visited the Antarctic and numbers are expected to rise.

Although the Manual makes reference to marine invasions, including the Practical Guidelines on Ballast Water Exchange in the Antarctic Treaty Area (ATCM, 2006), it also identifies the need for further guidelines for preventing and responding to marine invasive alien species (McCarthy *et al.,* 2019). The

Box 6 10

Manual contains a great deal of advice for terrestrial systems, including flow charts on how to respond to introductions. Notwithstanding all of the advice and agreements, Antarctic Treaty policy implementation proceeds through implementation in national law, which is highly variable between the nations that are party to the Antarctic Treaty and Protocol (Hughes & Pertierra, 2016). These include all nations that are active in Antarctica.

Progress and prospects: What should be done to limit the impacts of invasive alien species and the reasons for doing so, are uniformly articulated to the ATCPs *via* the Manual (ATCM), 2019). As a result, considerable progress has therefore been made in addressing the requirements for reducing the introduction and spread of invasive alien species, in monitoring the situation, and in responding to new incursions and developing eradication approaches (Hughes & Convey, 2012; McGeoch *et al.,* 2015).

The broader Antarctic region is changing rapidly as a consequence of global climate change (Le Roux & McGeoch, 2008; Lebouvier *et al.,* 2011; Rintoul *et al.,* 2018; Swart *et al.,* 2018), with most analyses indicating that risks of establishment, spread and impact of alien species will increase (Frenot *et al.,* 2005; Aronson *et al.,* 2015; Duffy *et al.,* 2017; McClelland *et al.,* 2018; McCarthy *et al.,* 2019; Pertierra *et al.,* 2020). Human activity in the region is also growing due to growth in scientific stations and numbers of science and support personnel, and in numbers of tourists (Chown & Brooks, 2019). Thus, invasive alien species policy requirements for the future will have to focus especially on what these changes mean for introductions from elsewhere into the Antarctic region. In the face of these challenges, a focus on better and coordinated biosecurity measures, for prevention, and the development of clear surveillance policy and practices to identify and characterize new establishments as they occur is essential, especially for marine systems (Aronson *et al.,* 2015; Hughes *et al.,* 2015; Hughes & Pertierra, 2016).

6.3.3 Legal and regulatory options at national scales

National investment in invasive alien species prevention and control generally requires governments to take the lead, especially if outcomes are intended to fulfil the public interest (Early *et al.,* 2016). As discussed above, a coordinated approach can indeed be challenging for several reasons, including administrative fragmentation and the need to take into account free trade agreements. To take the lead, each level of government needs the legal mandate to develop its relevant invasive alien species strategy (e.g., Genovesi & Shine, 2004) and collectively agreed implementation plan (e.g., National Invasive Species Council, 2008). In addition to these plans, countries could adopt legal and regulatory options to address invasive alien species, such as regulation of import; regulation of possession, trade, transport and reproduction in captivity; regulation of introduction into the wild; mandatory management of pathways of introduction; or mandatory eradication or control actions.

As with all significant government-led investments, legislative authority is necessary to engage budgetary expenditure (V. M. Adams *et al.,* 2018). Quarantine, biosecurity, environmental protection or marine protection acts of government can form the legislative basis for spending (Genovesi *et al.,* 2015; Pyšek *et al.,* 2020). Once legislative authority is in place then national invasive alien species strategies and management plans can be developed and implemented through collective decision-making and a co-investment process following (as far as possible) best practices (e.g., Victorian Government, 2010). National scale benefits from management of biological invasions cannot happen without this legislative authority empowering a government led response.

6.3.3.1 National invasive alien species strategies that identify the full suite of policy and management needs and priorities

Except for some provisions under the Sanitary and Phytosanitary Agreement, most governments have done relatively little to establish policies and programmes intended to limit the movement of invasive alien species (**section 6.1.3**; Early *et al.,* 2016; Pagad *et al.,* 2020; Turbelin *et al.,* 2017). Specifically, relatively few countries have invested in a comprehensive "biosecurity" approach or coordinated policies and programmes across relevant sectors for the management of biological invasions (**section 6.3.1**). One of the most effective and comprehensive approaches that governments can implement to minimize the spread and impact of invasive alien species is the development of national strategies and associated action plans, such as National Invasive Species Strategies and Action Plans (NISSAPs). Strategies for preventing and controlling invasive alien species can also be incorporated into NBSAPs to ensure policy connections and coherence. NBSAPs could also be used to enhance the coordination between other sectors, as suggested in **section 6.3.1.1**, *via* a national office as has been the case for the Great Britain Invasive Non-Native Species Strategy **(Box 6.11)**.

Following the recommendations and considerations included in multiple CBD decisions, strategy and action plans could:

- Define clear and measurable national targets (CBD decision X/2 paragraphs 3(b) and (c)).
- Mainstream biodiversity, communication, monitoring and reporting (CBD decisions X/2 paragraphs 3(d) and (f); XI/8 paragraph 4) into broader environmental, economic and social national and local plans (CBD decisions X/2 paragraph 3(d), X/33 paragraph 8(k)).
- Define funding needs (CBD decisions X/31 paragraph 11 and XI/ paragraph 17).
- Have a clear mechanism for providing financial resources (CBD decisions X/26 paragraph 3 and XI/ paragraph 17, 25) and ensuring resource mobilization (CBD decision X/3 paragraph 2).
- Promote cooperation with other multilateral environmental agreements (CBD decisions X/5 paragraph 3 and XI/6 paragraphs 10 and 11), particularly those focused on addressing climate change (X/33 paragraph 8(k) and XI/19 paragraph 7(a)).
- Have specific considerations for protected areas (CBD decisions X/31 paragraphs 1(c), 11, 26 and XI/2 paragraph 1(a)).
- Have specific considerations for different ecosystems such as marine/coastal (CBD decision X/29 paragraphs 7, 18, 67), islands (CBD decision X/15 paragraph 4(b)), mountains (CBD decision X/30 paragraphs 4, 8) and dry and sub-humid lands (CBD decision X/35 paragraph 2(g)).
- Broadly consider the value of nature by engaging multiple sectors (CBD decisions X/32 paragraph 2(g) and X/44 paragraph 6).
- Provide positive incentives (direct or indirect) that encourage achievement of biodiversity-friendly outcomes or support activities that promote the conservation and sustainable use of biodiversity (CBD decisions X/44 paragraph 6 and XI/30 paragraphs 3, 6, 7, 9).
- Consider gender dimensions (CBD decisions X/19 paragraph 5 and XI/9 paragraph 7), Children and youth (CBD decision XI/8 B paragraph 1).
- Involve civil society (CBD decisions XI/8 C paragraph 1) and Indigenous and local communities (CBD decisions XI/14 B paragraph 17).

Box 6 11 Coordinating action against invasive alien species in Great Britain: Great Britain Invasive Species Strategy and integration with plant and animal health.

The Great Britain Invasive Non-native Species Strategy (Secretariat, Great Britain Non-native Species, 2015) is an example of a National Invasive Alien Species Action Plan. It sets the strategic vision and national objectives for invasive alien species management in Britain and identifies 59 key actions to achieve their delivery. It is a partnership document developed by a combination of government bodies, environmental non-governmental organizations and organizations representing trade and industry.

The implementation of the Great Britain Strategy is overseen by a Programme Board comprising eleven government departments and delivery bodies. This reflects the wide range of threats posed by invasive alien species. The work of this Board is facilitated by a small secretariat (3.6 staff), which acts as a point of contact for stakeholders, establishes working groups on behalf of the Board to deliver specific actions, coordinates communications activity and runs a risk analysis mechanism.

The strategy has been broadly successful and has led, among other things, to the development of an invasive alien species risk analysis mechanism to support the ban on sale of invasive alien species; action plans to tackle key pathways of introduction; two awareness raising campaigns to reduce spread of aquatic organisms and ornamental plants; contingency plans and rapid responses; and a network of local action groups established to help tackle more widespread species (**Glossary**) in their local area. Examples of success include the eradication of five species from Britain (*Vespa mandarinia* (northern giant hornet), *Xenopus laevis* (African clawed frog), *Pimephales promelas* (fathead minnow), *Ameiurus melas* (black bullhead), *Lithobates catesbeianus* (American bullfrog)) and the ongoing eradication campaigns for three others (*Ludwigia grandiflora* (water primrose), *Myiopsitta monachus* (monk parakeet) and *Pseudorasbora parva* (topmouth gudgeon)). Britain has pioneered one of the largest invasive alien bird eradications in the world. In order to protect the indigenous *Oxyura leucocephala* (white-headed duck), the alien *Oxyura jamaicensis* (ruddy duck) has been reduced from a peak of over 6,000 individuals in 2001 to a handful of individuals in 2015 (Handerson, 2009; Secretariat, Great Britain Non-native Species, 2015).

However, despite these notable successes, overall indicators show the strategy is having little impact on the total numbers of invasive alien species establishing and spreading in Britain. There are about 2,000 alien species established in the United Kingdom, 10-15 per cent of which are invasive. Despite the Great Britain Strategy this number is increasing by

Box 6 11

approximately 10-12 new species per annum. An independent parliamentary enquiry (UK Parliament, 2019) attributed this increase to the dearth of resources available to tackle invasive alien species, including the lack of an inspectorate to prevent and intercept incursions. Only 0.4 per cent of Great Britain's total biosecurity budget is spent on invasive alien species despite their being similar, in terms of numbers of harmful organisms, to animal and plant health regimes. Unsurprisingly, other biosecurity regimes with much greater funds and dedicated inspectorates have been largely successful in their objectives by comparison. Indeed, animal and plant health regimes in Britain have prevented the introduction of 98 per cent of listed species in the past 20 years. By comparison, with no invasive alien species inspectorate, attempts to stem the flow of invasive alien species into Britain have been largely unsuccessful, with approximately 25 new invasive alien species establishing in the last 20 years.

Since 2013 the Department for Environment, Food and Rural Affairs in the United Kingdom has been working to develop a more integrated approach to biosecurity, incorporating animal health, plant health and invasive alien species. This has included establishing monthly meetings to review new and developing biosecurity threats across these regimes. Meetings are chaired by the Minister for Biosecurity, Marine and Rural Affairs, and attended by the Chief Vet, Chief Plant Health Officer and Chief Non-native (Alien) Species Officer. To support these meetings, emerging threats from invasive alien species, pests and diseases are reviewed within the same risk matrix. The matrix uses information from existing risk assessments to place organisms according to likelihood of an outbreak and potential impact. Impact is assessed using standardized criteria for economic, environmental and human health, which are then monetized to produce a single metric. This approach provides a straightforward overview of changing biosecurity threats and allows the minister and officials to compare and prioritize threats for action. It has resulted in greater integration across biosecurity regimes and the opportunity to utilize the greater experience of plant and animal health teams to support response to invasive alien species.

Strong and implementable NBSAPs, aligned with international regulatory frameworks, can help to spur the strategic actions and establish the properties required for the successful prevention and control of biological invasions, in alignment with the Kunming-Montreal Global Biodiversity Framework (CBD, 2022a) invasive alien species target (Target 6). Furthermore, coordinated efforts to strengthen national regulatory instruments can help address for online trading (aligned with Target 5), the creation of appropriate policies for the development and use of responsible environmentally sound technologies (aligned with Target 17), as well as making available data and information accessible (aligned with Target 21).

It is important to highlight that national action plans should implement existing international standards as a minimum standard but could also take full advantage of the rights under international agreements that allow for stricter protection measures. Also, a key instrument of national action plans is the possibility of creating departments or agencies specifically dedicated to the governance and implementation of invasive alien species legislation. By taking these steps, national strategies can define instruments and processes to ensure the need for shared efforts and commitments, and the understanding of the specific roles across sectors and Indigenous Peoples and local communities and multi-scale coordination of response programmes.

6.3.3.2 Careful delineation of legal authorities that would enable the implementation of risk assessment and surveillance protocols

The nature of the risks of invasive alien species depends on the stage of the biological invasion (Epanchin-Niell, 2017; Springborn *et al.,* 2011). In the introduction stage, preventing or minimizing alien species arrivals is achieved through actions that address both intentional and unintentional introductions. Prevention is also best achieved when clearly defining "who" has the authority for the detection of potential invasive alien species and understanding which responsible bodies of the legal and regulatory framework, such as Phytosanitary (defined under the IPPC) and animal health (defined under WOAH) mandates, allow actions. Actions designed to prevent establishment of potential invasive alien species are termed "early detection and rapid response" (EDRR), with the desired response eradication of the incipient invasive alien species (Meyerson & Simberloff, 2020).

Policies aimed at preventing or minimizing the possible effects of intentional introductions need to consider who is the responsible body for providing transport and introduction permits. The actions of these offices should focus on providing permits for proposed planned introductions and should be based on information coming from risk assessment procedures such as the Australian Weed Risk Assessment (Pheloung *et al.,* 1999), the Plant Protection and Quarantine weed risk assessment (PPQ WRA; Koop *et al.,* 2012) and the Non-native Species

Secretariat (NNSS) Risk Assessment Scheme for Great Britain (NAPRA Network, 2010). In the context of transport and introduction, a policy of inspection and/or treatment at the port of departure can duplicate the effect of other policy of inspection and/or treatment at a port of entry. However, if a departure and arrival policy is established, policy integration would require an international agreement. A key part of such agreement is aligning the authorities with the mandate of inspection and/or treatment.

6.3.3.3 Embed both surveillance and monitoring into policy instruments focused on invasion management

Invasive alien species can cross borders and, therefore, preventing their introduction can only be achieved with pre-border, border and post-border surveillance systems (Anderson *et al.,* 2017; Poland & Rassati, 2019). Successfully controlling invasive alien species or preventing biological reinvasions relies on long-term monitoring for early detection and rapid response (Amorim *et al.,* 2014; European Environment Agency, 2010b; Franklin *et al.,* 2011; Oswalt *et al.,* 2021; Roy & Roy, 2008). These activities are essential to minimizing their impacts, developing economically efficient and ecologically relevant management programmes and promoting citizen engagement and educational outreach (McGeoch & Squires, 2015; Oswalt *et al.,* 2021). Furthermore, these activities are at the core of CBD Guiding Principle 5: Research and monitoring (CBD, 2002) and are considered a fundamental tool to address the problem of invasive alien species. Continuous monitoring systems that use essential biodiversity variables (EBVs; **Glossary**; **section 6.6**) can also help evaluate the effectiveness of policy and management strategies and fill a fundamental knowledge gap in environmental policy.

For example, the European Union Regulation 1143/2014 on invasive alien species (Council of the European Communities, 2014) has specific provisions for member states regarding the implementation of surveillance systems to detect the presence of alien species of Union concern as early as possible and take rapid eradication measures to prevent their establishment. However, as noted by Latombe *et al.* (2017), in 2010, only 26 per cent of countries reported the establishment of national surveillance systems and monitoring activity. Additionally, the capacity to detect and react promptly to new invasions or re-invasions is often limited (see, for example, Genovesi, 2005) and is usually not comparable across countries (Latombe *et al.,* 2017). Furthermore, when monitoring takes place, it occurs at multiple unconnected scales – from national programmes to local citizen science (**Glossary**) initiatives (McGeoch & Squires, 2015; Oswalt *et al.,* 2021), which further complicates their interoperability. As a result, which agency oversees surveillance and monitoring activities, and where/when/how such activities occur, varies widely between countries.

Technical scientific bodies must be tasked with continuous monitoring activities, diagnosis, risk assessment, storage and circulation of information, reporting, identification and enforcement of appropriate responses. At a higher level, a global monitoring system is a critical tool to be included in multilateral environmental agreements to manage biological invasions effectively. This goal is within reach, as pointed out by Latombe *et al.* (2017).

6.3.3.4 Develop policy and regulatory instruments to underpin innovative management programmes

New technologies can be developed or translated from other contexts to improve any aspect of innovative management programmes for biological invasions (van Rees *et al.,* 2022). Innovation is the translation of invention through proof-of-concept to readiness to be deployed, leading to desirable outcomes (Baregheh *et al.,* 2009). Frameworks can drive innovation in management of biological invasions, particularly in the context of public good outcomes (van Rees *et al.,* 2022). Indeed, government support is also needed to find better solutions to management challenges from idea and blueprint to a full technology readiness level. Not all the technologies needed are available, nor is it clear what future valuable technologies might be. Only through policy development will governments invest in technology development and deployment (Burke *et al.,* 2005).

Innovation can be achieved with cultural change through community acceptance of the value of the technology interacting with institutional change, aligning to regulate technology deployment (Stilgoe *et al.,* 2020). Achieving cultural acceptance of technology is not guaranteed and often hinges on obtaining social license and acceptability and demonstrating that the benefits of the technology outweigh any risks, including ethical considerations. Cultural acceptance is never a fixed position (Crowley *et al.,* 2017b). Institutional change includes the necessary policy or regulatory environment that will regulate use (Burke *et al.,* 2005). An example was the invention and adoption of chemical pesticides for pests, weeds and diseases from the 1940's. Starting with dichlorodiphenyltrichloroethane (DDT), the consequences of its initial use led to completely national risk-based legislation and regulation on how when and where it could be used. This eventually resulted in DDT being banned as evidence of negative impacts became available (Mansouri *et al.,* 2017). This nonetheless opened the door for development and application of future generations of less toxic chemicals to which the initial regulations needed to be adapted (Handford *et al.,* 2015). Even the most benign chemical pesticides have now increasingly lost public favours based on long-term evidence mediated through changing cultural acceptance (Kudsk & Mathiassen, 2020). The same processes are necessary in the adoption of any new technology however beneficial, so it is the role of government to manage and respond to this culturally driven policy and regulatory process, without which any benefits from new technologies towards management of biological invasions will not be obtained.

6.4 ENGAGEMENT AND COLLABORATION WITH STAKEHOLDERS AND INDIGENOUS PEOPLES AND LOCAL COMMUNITIES

The engagement of stakeholders (**Chapter 1**, **section 1.5.1** for the definitions of stakeholder groups) and Indigenous Peoples and local communities can help construct coherent policy and management plans that are appropriate to local environmental and cultural realities (e.g., Adriaens *et al.,* 2015; Bravo-Vargas *et al.,* 2019; Bryce *et al.,* 2011; Dehnen-Schmutz *et al.,* 2010; Fischer *et al.,* 2014; Gaertner *et al.,* 2017; García-Llorente *et al.,* 2008; S. Liu *et al.,* 2010; Marchante *et al.,* 2017; Novoa *et al.,* 2016; M. S. Reed, 2008; M. S. Reed *et al.,* 2009; M. S. Reed & Curzon, 2015; Shackleton, Adriaens, *et al.,* 2019; Stokes *et al.,* 2006; Touza *et al.,* 2014). As outlined earlier (**Chapter 5**, **section 5.6.2.1**), there are many examples where effective regulatory, social responsibility and incentive-based systems have and continue to support effective industry and landowner engagement in the prevention and control of invasive alien species. This section outlines the context and summarizes the purposes of engaging stakeholders and Indigenous Peoples and local communities (**section 6.4.1**). It assesses the general enabling factors for successful engagement (**section 6.4.2**), as well as factors contributing to successful collaboration with Indigenous Peoples and local communities on biological invasions more specifically (**section 6.4.3**). Finally, the section explores the different governance network options for collaborative action (**section 6.4.4**).

6.4.1 Reasons for inclusive engagement

New approaches to governance for biological invasions reflect broader shifts in environmental governance (Chaffin *et al.,* 2014), emphasizing the interconnectivity of ecological and social systems and the uncertainty associated with complexity and rapid environmental change (**section 6.7**). These approaches recognize the need for more integrated multi-level or "polycentric" governance (Anderies *et al.,* 2013; Bodin, 2017; Lubell, 2013; Ostrom, 2010) and democratic legitimacy (Stoett *et al.,* 2019), as well as the imperative to achieve societal consensus, engagement and fairness (CBD, 2020a). The general shift is toward greater consideration of the adaptive-collaborative governance model (**section 6.2.4.1**), where a collective decision-making process is one "that allows diverse sets of actors who share an interest or stake in a policy or management issue to work together toward mutually beneficial outcomes" (Lynch, 2020).

As an early example, **Box 6.12** describes how New Zealand's biosecurity legislation underpins new collaborative forms of governance of invasion pathways in marine areas.

There has been no comprehensive review of the on-the-ground experiences of stakeholders and Indigenous Peoples and local communities or their engagement in management and governance of biological invasions (but see Shackleton *et al.,* 2019 for a review of stakeholder involvement in invasive alien species research). The following reasons for engagement are taken from a limited selection of the literature based on experiences with governance and management of biological invasions:

Knowledge-related

Engaging with stakeholders and Indigenous Peoples and local communities facilitates knowledge and information sharing, creating information flows across scales (Lansink *et al.,* 2018). This contributes to the development of sufficient shared awareness of biological invasions, including understandings of drivers, processes, impacts and possible responses (Carter *et al.,* 2021). Bridging different knowledge systems associated with different disciplines and perspectives (Barney *et al.,* 2019) provides greater legitimacy of knowledge underpinning actions and leads to higher quality and more context-relevant decisions (J. M. Evans *et al.,* 2008; M. S. Reed & Curzon, 2015). This also permits social learning for adaptive management that can assess and reduce uncertainty, build adaptive capacity (S. Liu & Cook, 2016; Maclean *et al.,* 2018; Novoa *et al.,* 2016; Söderström *et al.,* 2016), make monitoring more cost effective (Novoa *et al.,* 2016) and facilitate collaborative research (Shackleton, Adriaens, *et al.,* 2019).

Risk assessment

Engaging with stakeholders and Indigenous Peoples and local communities facilitates decision-making about risk prioritization by addressing people's concerns so that: (1) associated uncertainty can be discussed (S. Liu *et al.,* 2011), (2) diverse values and perceptions can be brought into the risk assessment/decision process to negotiate consensus, (3) risk can be contextualized in broader contexts, (4) measures targeted to the local context can be formulated, (4) decision-making becomes transparent and

Box 6.12 New Zealand's shift towards adaptive collaborative governance for biological invasions.

In part due to the recognition that reactive species-specific management designed for terrestrial invasions is not suited to the marine environment, New Zealand made a major shift towards adaptive collaborative governance. Legislatively enacted in a 2012 amendment to the Biosecurity Act 1993, governance for biological invasions was moved away from species-specific management to a proactive focus on vectors (**Glossary**) and invasion pathways that could better serve to prevent establishment rather than undertake costly remedial action. The first Marine Regional Pathway Management Plan, developed in Fiordland, a World Heritage Site of the United Nations Educational, Scientific and Cultural Organization (UNESCO; **Figure 6.14**), was "driven by a community-based, multi-stakeholder and Indigenous Peoples and local communities and government agency partnership" initiated by the Fiordland Marine Guardians, a stakeholder and Indigenous Peoples and local communities group composed of "representatives of Ōraka Aparima Rūnaka Inc of Ngāi Tahu iwi, commercial fishers, recreational fishers and charter boat operators". The "Guardians" are responsible for the integrated management of the Fiordland Marine Area and were officially empowered by national legislation to advise and recommend government and management agencies on all aspects of management, facilitate and promote integrated management, prepare and disseminate information and monitor and advise on threats, among others (Cunningham *et al.,* 2019).

Figure 6.14 **Fiordland National Park.**

The Marine Regional Pathway Management Plan developed in Fiordland is an example of adaptive-collaborative governance. Photo credit: Bernard Spragg. NZ from Christchurch, New Zealand – Milford Sound New Zealand., WM Commons – Public domain.

(5) complex trade-offs between different options can be assessed (Carter *et al.,* 2021; S. Liu & Cook, 2016; Moon *et al.,* 2015). For example, the Mohawks of Kahnawá:ke (Quebec, Canada) oppose spraying chemicals on the land as they feel it would contradict their spiritual connection with nature (IPBES, 2022). There can also be concerns over animal welfare and rights when considering possible management and eradication interventions **(Box 6.13)**. A particular trade-off to consider is the need for rapid response to maximize the likelihood of eradication early in the invasion curve (**Glossary**), *versus* the time and cost of broad stakeholder inclusion in decision-making. This trade-off can however be managed by ensuring as far as possible that collaborative and inclusive decision-making structures are in place before new invasive alien species arrive.

Consensus building

By increasing their involvement, developing shared aims, overcoming barriers to coordination and collaboration, and building trust (Carter *et al.,* 2021; Graham, 2019; Lynch, 2020), engagement with stakeholders and Indigenous Peoples and local communities can reduce and help manage conflict (Moon *et al.,* 2015; Shackleton, Adriaens, *et al.,* 2019), including around "conflict species" (Woodford *et al.,* 2016; **Chapter 5**, **section 5.6.1.2**). It increases public support, acceptance, ownership and buy-in (Lansink *et al.,* 2018), which minimizes the risk of unintended consequences and avoids the costs of failed measures (S. Liu & Cook, 2016; M. S. Reed & Curzon, 2015). Engagement can help to better manage the unequal distribution of costs and benefits (Novoa *et al.,* 2016) by appropriately sharing and differentiating responsibilities for management and increasing enforcement capacity (S. Liu & Cook, 2016; **section 6.7**).

Economic effectiveness and efficiency

Engaging with stakeholders and Indigenous Peoples and local communities ensures that interventions are efficient, equitable, and provide the correct incentives (e.g., that are not perverse for some or over-reward other stakeholders). This also increases the participation of economic stakeholders such as land owners, small businesses and corporations, and can help avoid the "tragedy of the commons" (**Glossary**; McAllister *et al.,* 2015).

Decision-making under uncertainty and complexity

Engaging with stakeholders and Indigenous Peoples and local communities enables adequate characterization and management of complex problems. It can also help to find solutions when conflicting perspectives, objectives and management goals make invasion problems difficult to characterize or resolve (J. M. Evans *et al.,* 2008; Woodford *et al.,* 2016). It allows a balancing of social, economic and ecological sustainability objectives and values across multiple interrelated interests (Carter *et al.,* 2021), leading to better decision-making under a diversity of local contexts. Action can then be adapted to local ecological, social and political contexts (McAllister *et al.,* 2015).

Coordination

Engaging with stakeholders and Indigenous Peoples and local communities facilitates coordination in complex situations between many apparently independent groups that have a wide range of interests, motivations and resources and who are directly or indirectly engaged in some aspect of invasions at multiple spatial scales (Barney *et al.,* 2019; Dandy *et al.,* 2017). It may help to create "institutional fit" within scales, bridge scales and develop cross-scale interactions to match the multiple scales of the problem (McAllister *et al.,* 2015). It can also help to meet multiple goals of different stakeholders with different needs for nature's contributions to people arising from the same ecosystem (Failing *et al.,* 2013; D. M. Martin *et al.,* 2018; Nel *et al.,* 2016). Responses to biological invasions may indeed need or benefit from the combination of public and private assets and joint actions by public and private sectors. Better coordination avoids competition and free-riders and contributes to reducing overall costs (Failing *et al.,* 2013; D. M. Martin *et al.,* 2018; Nel *et al.,* 2016), or shifting costs of management or impacts from one community, stakeholder to another.

Respect for rights, fairness

Engaging with stakeholders and Indigenous Peoples and local communities promotes democratic governance, where stakeholders have a direct voice in decisions that affect their environments and lives. It also encourages public engagement in publicly-funded efforts, influences decisions that affect people's good quality of life, and ensures accountability and fairness (Carter *et al.,* 2021; J. M. Evans *et al.,* 2008; S. Liu & Cook, 2016; M. S. Reed & Curzon, 2015). Finally, it ensures compliance with governance directives and stakeholder and Indigenous Peoples and local communities demands and rights for engagement (IPBES, 2022).

Box 6 13 **Invasive alien species control and animal rights.**

When invasive alien species are prioritized for control, ecological and economic aspects often take precedence, whereas species welfare can be underappreciated. In cases where the invasive species is associated with human values, and the control mechanism is lethal, unaddressed ethical issues in management actions can create conflict between stakeholders and Indigenous Peoples and local communities, including animal welfare groups and invasive alien species managers (**Figure 6.15**; **Chapter 5**, **Box 5.13**). Such conflict has been observed during lethal control of invasive *Erinaceus europaeus* (European hedgehog) on the Scottish island of South Uist (Warwick, 2012), of *Equus caballus* (horse) in parts of Northern America (Bhattacharyya & Larson, 2014), of *Trichosurus vulpecula* (brushtail possum) in New Zealand (Beausoleil *et al.,* 2016), and of the introduced *Epiphyas postvittana* (light brown apple moth) in parts of the United States of America (Zalom *et al.,* 2013). Such conflict delays invasive alien species control programmes, thereby potentially escalating the impact on native biodiversity, a point which is often not acknowledged by the parties in conflict (Russell *et al.,* 2016).

Consensus amongst invasive alien species managers, stakeholders and Indigenous Peoples and local communities, including animal welfare groups, has often been achieved through informed conversations. For example, in parts of the United States managers involved animal welfare groups early in the process of management to gain support for lethal control of invasive alien *Sus scrofa* (feral pig; Perry & Perry, 2008). Furthermore, involving local people while planning invasive alien species control measures can not only spread awareness

Box 6 13

about the severe impacts of such species, but also result in socially acceptable mechanisms for controlling invasive alien species. For example, government and indigenous community co-management of Kakadu National Park in Australia resulted in acceptable control of invasive feral pigs (Robinson *et al.,* 2005). These examples suggest that management of biological invasions can be achieved with horizontal integration of different sectors and vertical integration of different governance scales (**section 6.3**). Latent development of public awareness on invasive alien species control and use of popular media to communicate evidence (or curb misinformation) during a conflict-like scenario remains central to inclusive and successful invasive alien species management programmes (Crowley *et al.,* 2017a).

6.4.2 Options for improving engagement with invasive alien species-related activities

6.4.2.1 How Indigenous Peoples and local communities participation can be better integrated with national policies and global efforts

Collaboration between Indigenous Peoples and local communities and other stakeholders is an underlying theme in calls for their participation in invasive alien species management efforts (S. M. Alexander *et al.,* 2017; Peltzer *et al.,* 2019; Reo *et al.,* 2017). This collaboration could take the form of "a strong and sustainable institution that can raise awareness, mobilize communities and design appropriate management plans" (**section 6.7**; Tilahun *et al.,* 2017), including:

- Use of community-led institutions that can bring together community members and make rapid decisions to respond to change, manage or pool communal resources, build leadership, facilitate interaction and demonstrate practices (Guneratne, 2002);
- Collaboration between Indigenous Peoples and local communities, researchers and government officials to prevent, detect and respond to invasive alien species, and
- Efforts to ensure the conservation of habitats on indigenous lands and leadership in biodiversity conservation and facilitate voluntary partnerships (Schuster *et al.,* 2019). For example, an agreement was signed between Sami people and the Norwegian government, grounded in the International Labour Organization Convention on Indigenous and Tribal Peoples in independent countries. This provides Sami

people with the right to be consulted on all matters of importance for the Sami (Broderstad & Eythórsson, 2014), using integrated approaches in which potential methods of control are implemented on a case-by-case basis (Broderstad & Eythórsson, 2014).

6.4.2.2 Factors contributing to failure and success of engagement with stakeholders and Indigenous Peoples and local communities

There are now many documented examples of stakeholders and Indigenous Peoples and local communities engagement processes that have failed to deliver intended outcomes for the environment, or even led to negative unintended consequences (Coglianese, 1997; Cooke & Kothari, 2001; Gerrits & Edelenbos, 2004; Lane & Corbett, 2005; Staddon *et al.,* 2015), for example, by inflaming latent conflicts (Emery *et al.,* 2015; Redpath *et al.,* 2013). As a result, criticisms of engagement practice have ranged from tokenism, where participants are manipulated to legitimize decisions, to broader critiques that key groups may not have the information, skills or equality needed to participate in effective governance, knowledge sharing, or learning processes (**section 6.4.4**).

There is no reliable "one-size-fits-all" blueprint for collaborative governance (**section 6.2.3.1**), but in response to these criticisms, Reed *et al.* (2018) distinguished different levels of engagement, and factors that might in theory explain why engagement does or does not deliver intended outcomes. Levels of engagement can be adapted to the purpose and context of the process, rather than necessarily aiming for the highest levels of engagement, such as co-production (**Figure 6.16)**. A conceptual model of participation that is inclusive and empowering can be used to build stronger participation and engagement (Bell & Reed, 2022):

- Before: Consider the role of factors that precede an effective participatory process (e.g., the creation of safe spaces and overcoming barriers to engagement to ensure the process is inclusive, including women and other marginalized groups).
- During: Take into account the factors that affect empowerment during the engagement process (e.g., equality between participants that respects and values different knowledge systems – including local knowledge and experience of invasive alien species) and agency, including freedom (from fear) and access to the resources and other means necessary to actively participate.
- After: Foresee factors that may continue to build empowerment or disempower participants after the process has concluded (e.g., accountability, ensuring decisions are implemented and reflect outcomes from the process and feedback loops that inform people how

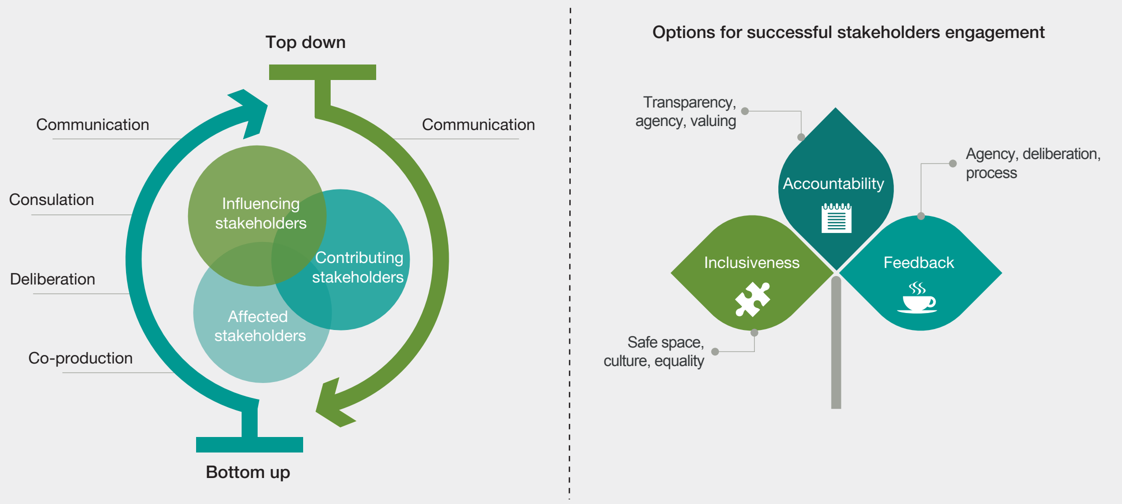

Figure 6 16 **Options for successful engagement of stakeholders and Indigenous Peoples and local communities.**

This figure shows the different options available to engage with stakeholders and Indigenous Peoples and local communities (left), and a focus on empowerment (right). Adapted from Reed *et al.* (2018), https://doi.org/10.1111/rec.12541, under copyright 2017 Society for Ecological Restoration and Bell and Reed (2022), https://doi.org/10.1093/cdj/bsab018, under license CC BY 4.0.

their knowledge has been used to manage invasive alien species in their area or sector; **Figure 6.16**).

An understanding of stakeholders and Indigenous Peoples and local communities' influences and interests, how each are likely to be involved in different invasion stages, and their participation as equal partners, can therefore contribute to the success of any attempt to represent, empower people and co-design biological invasion management and governance. If communicative and consultative approaches can deliver significant benefits (Shackleton, Adriaens, *et al.,* 2019), co-productive approaches may be more appropriate than hierarchical governance approaches, especially in contexts where there is significant conflict of interest or mistrust between stakeholders.

6.4.3 Coordination, collaboration and Indigenous Peoples and local communities[11]

Indigenous Peoples and local communities often have detailed knowledge of invasive alien species (**Chapter 1**, **section 1.6.7.1**), including their dynamics (**Chapter 2**, **Box 2.6**), drivers (**Chapter 3**, **Box 3.14**), impacts (**Chapter 4**, **section 4.6**), and the ability to manage or adapt to their presence (**Chapter 5**). Many Indigenous Peoples and local communities also have their own customary governance systems and institutions that may already be working to support management of biological invasions. There have indeed been many cases where management plans or techniques have negatively impacted the food security, culture and values of Indigenous Peoples and local communities (IPBES, 2022). This section will discuss efforts to avoid this scenario.

6.4.3.1 Rights of Indigenous Peoples and local communities

In some contexts, there are legal obligations to recognize the rights of Indigenous Peoples and local communities to manage their own lands and waters. The adoption of the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) in 2007 has provided a specific framework for engaging with Indigenous Peoples. Free, prior and informed consent (FPIC) is a specific right that pertains to Indigenous Peoples, which allows them to give or withhold consent for a project that may affect them or their territories, which could include efforts to manage or eradicate invasive alien species. Furthermore, free prior and informed consent enables them to negotiate the conditions under which a project will be designed, implemented, monitored and evaluated. The framework is less clear for "local communities", but some countries have specific legal frameworks for working with specific groups.

Many Indigenous Peoples and local communities have requested that their own customary governance systems and institutions be recognized within efforts to manage biological invasions, recognizing that these systems can be strengthened and, in some cases, revitalized by support from outside institutions (IPBES, 2022). Recognition and clarification of land tenure, including access and ownership of land, waters and biological resources can support Indigenous Peoples and local communities to manage biological invasions (IPBES, 2022; Kamelamela *et al.,* 2022).

These specific knowledge and governance systems and normative frameworks often mean that Indigenous Peoples and local communities do not wish to be considered or approached in the same ways as other "stakeholders" discussed above, as such broad multi-stakeholder processes can often serve to diminish their participation and obscure their rights and goals. A deeper engagement with their knowledge and customary governance systems within rights-based frameworks and in accordance with national legislation can therefore benefit both communities' good quality of life and biological invasions management strategies.

6.4.3.2 Co-production of Indigenous Peoples and local communities planning and Biocultural community protocols

Despite the reasons for engaging with Indigenous Peoples and local communities and their knowledge and governance systems discussed above, many discussions of Indigenous Peoples and local communities rely on a "vulnerability narrative" which considers them as passive victims of damage from environmental change. This can lead to policies and management actions that interfere with community wellbeing and do not support capacity-building and cultural continuity (Reo *et al.,* 2017; **Chapter 4**, **Box 4.14**).

Many cases (70 per cent of reviewed cases)[11] suggest that, even where collaborations between outsiders and Indigenous Peoples and local communities are reported to be successful, they do not necessarily consider Indigenous and local knowledge and governance. Some cases report that outsiders tend to focus instead on teaching Indigenous Peoples and local communities about management of invasive alien species using scientific methods. This can cause the loss of knowledge and important cultural practices of Indigenous Peoples (Sillitoe, 1998), as well as undermine long-term management success. There are however positive examples of the inclusion of Indigenous and local knowledge, community governance and institutions in the management of biological invasions.[11]

11. Data management report available at: https://doi.org/10.5281/zenodo.5760266

For example, forest scientists partnered with Indigenous Peoples and local communities in Michigan, United States to co-design invasive alien species control experiments using traditional ecological knowledge (Poland *et al.,* 2017). Indigenous Peoples and local communities were involved in decision-making processes for weed control in Western Australia. Rangers consulted Indigenous Peoples and local communities' elders about their work eradicating weeds and used "place centred" methods (Bach *et al.,* 2019).

Overall, key aspects that Indigenous Peoples and local communities have highlighted in relation to successful co-production and co-management include respect for community knowledge, institutions and protocols, allowing enough time to build trusting relationships, and broad distribution of benefits from biological invasion management, which do not need to be financial and can include capacity-building in research and management.[11]

Some Indigenous and local communities have developed biocultural community protocols (**Glossary**), documents that consider their values, procedures and priorities to frame how they wish to be engaged in projects that impact them. They set out rights and responsibilities under customary, state and international law as the basis for engaging with other stakeholders (Natural Justice, 2022). Biocultural community protocols could be a foundation for discussions with communities on policies related to managing invasive alien species and restoring ecosystems. For instance, in Hawaii, a biocultural community protocol has been developed to support the successful ecosystem restoration of the Puʻuwaʻawaʻa Community-Based Subsistence Forest Area (Kamelamela *et al.,* 2022). Co-production of planning and decision-making, or support of existing Indigenous Peoples and local communities' invasive alien species management systems could indeed benefit communities beyond biological invasions management. It provides recognition of their knowledge systems and incentives to continue or revitalize traditional monitoring, management and knowledge transmission and simultaneously enhances the efficacy of biological invasions management (IPBES, 2021, 2022)

6.4.4 Governance networks for collective action

Engaging with stakeholders and Indigenous Peoples and local communities, and considering diverse actors involved in governance for biological invasions (**section 6.2.3.3**) can be achieved by establishing informal or formal mechanisms for collective action (**Glossary**). Simply recognizing this need does not mean that collective action will happen, nor that collective initiatives and arrangements will be effective at solving the problems at hand (Koontz & Thomas, 2006; Lubell, 2004). Collective action outcomes often emerge through self-organization (where overall organization arises spontaneously from local interactions) – as when numerous individual managers acting independently apply cultural controls that together change the invasibility of landscapes (P. L. Howard, 2019). As demonstrated in an Australian rural landscape through a Landcare program, successful collective action emerged through the key role of a leader, building trust and social norms in the community, along with contracts that strengthened commitment and steered action towards the control of high priority invasive alien species (McKiernan, 2018).

Collective action is also often jointly planned and executed, based on place-based or culturally-based rules and norms where community members jointly assume responsibility for invasive species management (e.g., Graham *et al.,* 2019; Lien *et al.,* 2021; Lubeck *et al.,* 2019; Sullivan *et al.,* 2017; Yung *et al.,* 2015). However, the conditions required to engage in collective action are often absent; for example, an awareness of cross-boundary relationships, beliefs and expectations that other people will carry out appropriate actions, an absence of effective leadership or low confidence that collective efforts will be effective (Bodin *et al.,* 2019; Lubeck *et al.,* 2019; **Figure 6.24** in **section 6.7.3**). Even in cases where collective action mechanisms are in place and function well, there is often a need to support or coordinate such actions at higher levels of governance. Research has shown that a number of micro-interventions during community engagement can change opinions, beliefs and commitment leading to improved management outcomes (Niemiec *et al.,* 2019).

6.4.4.1 Coordination *versus* cooperation: challenges and options

It is important to differentiate biological invasion problems that are more related with coordination from those requiring cooperation (Bodin *et al.,* 2020). Effective coordination depends on finding ways for stakeholders who generally share the same viewpoints and interests to agree on how best to address a problem. This mainly involves mechanisms "to accomplish a generally agreed upon objective through, for example, efficient resource allocation, synchronization of different activities and a suitable division of labour for common tasks" (Bodin *et al.,* 2020). This is the case, for example, with *Fusarium* dieback (an invasive alien pathogen vectored by beetles that causes disease that damages avocado and more than 39 other tree species) in California, United States, which quickly prompted numerous government and non-government stakeholders who cooperate at different scales with very similar objectives to coordinate and confront the issue and develop a cohesive state-wide strategy (Lynch, 2020). **Box 6.14** presents another example of a governance network solution to achieve coordination between stakeholders who held similar interests in invasive

Box 6 14 Coordinating American mink eradication in North East Scotland through community partnerships and adaptive management.

In Northeast Scotland, when small-scale American mink removal projects failed due to mink recolonization from surrounding uncontrolled areas, adaptive-coordination strategies (**Table 6.1**; **section 6.2.3.1(4)**) were devised and implemented to eradicate mink over a large area. Due to uncertainties about the size of the mink population, mink's dispersal capacity, and the volunteer resources that would be needed and available to effectuate mink eradication, an adaptive management approach was developed involving formal coordination between diverse stakeholders. The project was initiated by scientists and supported by a government agency, a national park authority and local fisheries boards, all of whom shared an interest in mink eradication.

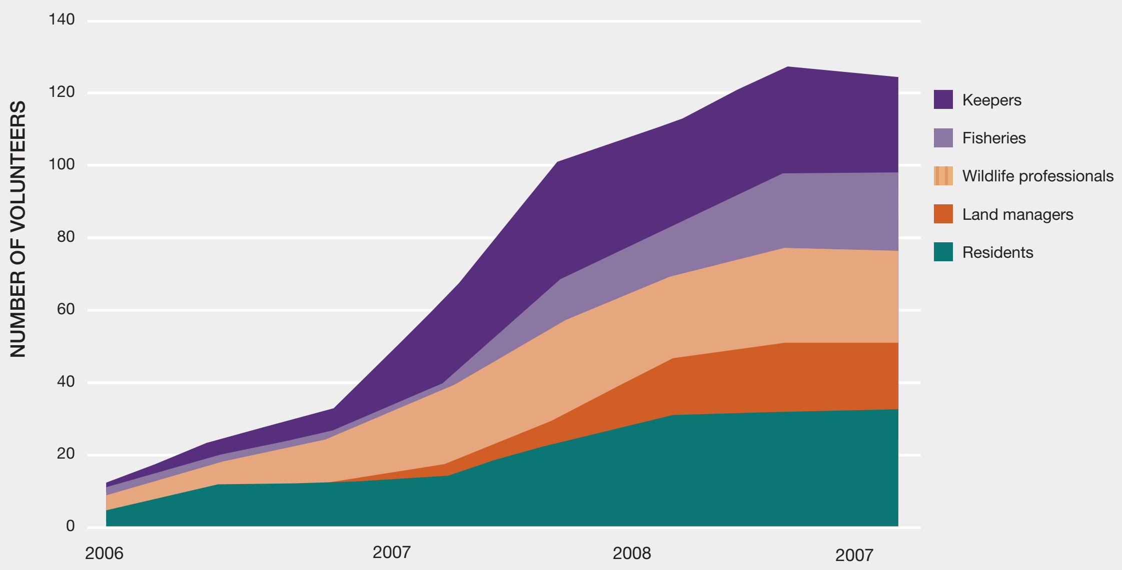

Figure 6 17 **Cumulative mink captures over the entire project area showing an increasing number of captures by volunteers, with the total number of active volunteers.**

Throughout the project shown by category. Source: Bryce *et al.* (2011), https://doi.org/10.1016/j.biocon.2010.10.013, under license CC BY 4.0.

Together, a coordinated coalition of trained volunteers was created to detect and trap mink **(Figure 6.17)**. These groups created a formal partnership that funded the project and provided in-kind contributions. The project achieved "multi-scale mink removal over 10570 km^2 with 10000 appearing to ¬be free of breeding mink 3 years after inception." Over time, the number of the local volunteers detecting and trapping mink grew – especially among local residents, land managers and wildlife professionals (Lambin *et al.,* 2012). "The defining factors underpinning the success of the project are strong volunteer involvement, efficient and systematic methods of monitoring and control, an adaptive approach to suit local conditions, the strategic use of topography to minimize recolonization and an ambitious vision; elements that are applicable to other invasive alien species and areas. It is a strong testament to what can be achieved when empowering local communities to take a stake in their local biodiversity and thus reason for optimism that the tide of invasion can be rolled back on a large scale where the convergent interest of local communities can be harnessed" (Bryce *et al.,* 2011).

alien vertebrate eradication, and where adaptive responses were needed to overcome uncertainties.

However, in many cases, invasive alien species present a cooperation problem rather than a coordination problem, as they involve stakeholders "with opposing interests seeking and finding agreeable ways to solve collective problems and dilemmas where their different interests are at stake, and where a solution often requires actors to make some sacrifices" (Bodin *et al.,* 2020). Thus, cooperation is associated with conflicts of interest, inherent trade-offs and subsequent tensions among actors. This was the case, for example, with the Panama Tropical Race 4 incursion in banana plantations in north Queensland, Australia. Many banana growers argued that their value- and cost-losses were not sufficiently compensated when implementing state-mandated biosecurity measures, leading ultimately to negotiations between the growers' industry body and the government on new standards and guidelines for production post-infection (Maclean *et al.,* 2018). Very often, there are multiple groups of "outcome winners" and "cost, value and collateral" losers whose interests and perceptions of invasive species are in conflict. Compared with coordination, cooperation is thus associated with higher risk for all of the actors involved (Berardo & Scholz, 2010). Thus, there is much greater need for processes of engagement that involve consensus-building, negotiation, knowledge integration and development of trust.

6.4.4.2 Tailoring collaborative governance networks

Collaborative governance networks consist of individuals and organizations that have come together to solve common problems that would be difficult or even impossible for a single organization to address alone (**section 6.2.3.3**). Governance itself can be characterized as a "polycentric network" of relations between government and non-governmental stakeholders whose knowledge, behaviour or interests are involved in different aspects of environmental policy-making (Berardo & Lubell, 2019; Bodin, 2017; Bodin *et al.,* 2017; Kluger *et al.,* 2020; Lubell, 2013). Such networks span a range of types, from "completely decentralized with all participants connected, to completely centralized with all collaboration brokered by a single organization" (Lubell *et al.,* 2017). Multiple types of networks across this span are likely to be needed for progress towards and implementation of integrated governance for biological invasions in each context (**section 6.2.3.1**).

The distinction between coordination and cooperation has strong implications for the type of governance network and collective action arrangements that are, more or less, suited to the tasks at hand. Such networks typically take three different forms, each with its own advantages and limitations (Provan & Kenis, 2008; **section 6.2.3.3**):

1. In participant-governed networks, there is no obvious central leading actor – all actors contribute fairly and equally to the collective effort. These networks tend to be dense (there are many social ties between the participants) and can work very effectively, but typically suffer when the number of members is high, since the lack of a hierarchical structure makes it difficult to coordinate numerous actors.

2. The second form is where one or a few of the participating actors take on a leading role, and the network subsequently takes a centralized "hub-and-spoke" structure where the leaders are directly connected to all or most other actors, thus becoming the hubs in a wheel-shaped network.

3. In the third form of network, a dedicated coordinating actor (a "Networker" stakeholder and a representative of Indigenous Peoples and local communities) is appointed as the central leader – a network administrative organization (NAO), also referred to as a bridging organization (Crona & Parker, 2012) or a collaborative institution (Lubell *et al.,* 2010). The network administrative organization can be created by the network members or provided or imposed externally. An external actor that wants to build a governance network to address invasive alien species could create a network administrative organization either to enhance and strengthen (and/or possibly control) existing governance networks, or to build a governance network from scratch.

An example of a successful network administrative organization (NAO)-led network management is found in the management of a hybrid between introduced *Sporobolus alterniflorus* (smooth cordgrass) and native *Sporobolus foliosus* (California cordgrass) in San Francisco Bay, a multi-tenure area where government agencies, private landowners and others are involved in efforts to eradicate this ecosystem engineer that will reinfest if it is not eliminated in all areas of the Bay. The management of *Sporobolus* is governed by a collaborative partnership between private landowners, government agencies and other stakeholders called the Invasive Spartina Project. The California State Coastal Conservancy, an agency whose mission is to protect the coast, and an environmental consultant founded the project with state funding. Together they serve as "central brokers" that coordinate the activities of stakeholders as a NAO. The project has "successfully removed 95% of invasive *Spartina [Sporobolus]*, and is now engaged in suppressing re-invasion and ecological restoration…the [project] has been very effective in comparison with other local collaborative partnerships" (Lubell *et al.,* 2017). However, such arrangements may not be effective for invasive alien species that have very different ecological dynamics, such as with very fast spreading marine species, where a myriad of organizations and individuals would be involved at short notice.

Hybrid networks may consist, for example, of bottom-up, participant-led initiatives that are provided with support and coordinated by a "networker" stakeholder. This is the case with the award-winning Victoria Rabbit Action Network (VRAN), which was developed in Victoria, Australia, in response to the failure of a largely top-down regulation and enforcement regime (L. B. Adams, 2014; L. B. Adams *et al.,* 2019; **Box 6.15**). In Central Burnett, Queensland, Australia, when the state reduced support for management of *Bactrocera tryoni* (Queensland fruit fly) and encouraged greater grower self-reliance, growers and their industry body formed an Area-Wide Management Committee, which acted as a network administrative

Box 6 15 **Case study illustrating a successful expansion and temporal shift in governance from top-down regulation to community-led action.**

A case that demonstrates the shift from top-down, regulation and enforcement based governance toward a government-supported, community based approach is found in a United Nations Award-winning initiative developed to manage one of Australia's most costly invasive vertebrates, the European rabbit (L. B. Adams, 2014). Prior to the development of the programme, information and power asymmetries limited the effectiveness of rabbit management, as those responsible for on-the-ground control – landowners and community organizations – were "kept at arm's length," at the same time that conflicting perspectives on the need to control rabbits, animal welfare concerns and changes in land use presented barriers to top-down regulation and targeted programmes (Reid *et al.,* 2019). The Victorian Rabbit Action Network (VRAN) was developed by the National Rabbit Facilitator collaborating with groups involved in rabbit management, and adopted "systems-thinking…to understand how rabbit management works from a range of perspectives, test assumptions, and…develop and test strategy ideas" (L. B. Adams, 2014). The initiative focused on building networks and improving information flows and knowledge sharing through knowledge brokers. Communities were seen as sources of "socio-political and technological innovation, as opposed to consumers" and innovation was stimulated through competitive grants (Reid *et al.,* 2019). A democratic, participatory approach not only allowed a diversity of perspectives and experiences to be shared – conflicts inherent in the process "served as a driver of innovation, in that differing perspectives were discussed in respectful and authentic ways, allowing the emergence of innovative ideas and new ways of working together." The evaluation by Allen (2017) of VRAN's activities found that communities were exercising their agency and acting collectively, with decreased reliance on government (Allen, 2017). In four years, over 5,300 people were surveyed and 84 per cent of respondents were using an integrated rabbit management approach. In part due to this success, an additional programme was introduced in 2017 to support coordinated community-led action around the use of a new strain of calcivirus (rabbit haemorrhagic disease virus, RHDV K5) for biocontrol (Reid *et al.,* 2019). Unfortunately, overall outcomes on rabbit numbers and impact were not monitored.

Checklist of principles and requirements for successful community-led action on rabbits (L. B. Adams, 2014):

1. Leadership with empowered community groups
2. A community owned vision, philosophy, purpose and narrative
3. A partnership approach among the institutions and groups involved in rabbit management, with joint decision-making, responsibility, action and resourcing
4. Coordinated planning and action guided by a strategy, with understanding of:
   a. Community concerns and motivations that are generating interest in rabbit management
   b. What the community seeks to achieve and can realistically achieve – short and longer-term
   c. Current management practices: adaptive natural resource management, integrated pest management (**Glossary**), consideration of longer-term options to reduce rabbit impacts which goes beyond a focus on reducing rabbit populations, consideration of regulation and compliance requirements, consideration of options to assess and monitor a rabbit problem and rabbit impacts, consideration of the short and longer-term benefits and costs of different control options
   d. The available resources and tools that can assist community planning, action, learning, awareness, education, leadership development and innovation
   e. How best to navigate institutional arrangements that affect community capacity and action on rabbits
   f. How best to focus resources and effort
5. Demonstration and celebration of results and success linked to the community's vision and purpose
6. Government support for compliance
7. Recognition that community-led action and collaborative strategies involving all groups with rabbit management responsibilities are critical for success

organization (NAO), together with government staff, local growers, the industry body and other local stakeholders. Among other activities, it carried out management trials, fine-tuned management to suit individual grower operations, provided resources for treatments in towns funded by voluntary grower contributions, transferred expert knowledge and engaged in awareness raising. Reported results were "spectacular" – peak trap catches prior to the new governance arrangements were 240 flies per trap each day, reducing to one fly within a few years (Kruger, 2016).

With respect to the relation between governance networks and cooperation or collaboration problems, it is argued that denser, overlapping networks reduce monitoring and sanctioning costs involved in resolving collective action problems, for example, if some members freeride (e.g., allowing other participants to do the bulk of the work) or do not cooperate. Coordination problems, on the other hand, favour more "open" network structures. However, "the advantage of central coordination declines with the complexity and need for consultation involved in crafting solutions" (Berardo & Scholz, 2010).

Participant-governed networks are more effective at addressing cooperation problems (albeit only for smaller networks), while centralized networks (with or without a network administrative organization) are better suited for coordination problems (Bodin, 2017). Recent research has nuanced the proposed relationship between network structures and coordination/cooperation problems by explicitly accounting for trust, costs and risks as intermediate factors (Bodin *et al.,* 2020). More research in varied biogeographic and socio-economic contexts will contribute to improve governance networks.

6.4.4.3 Collective action

Governance for biological invasions is in part a collective action problem with coordination or collaboration solutions (Hershdorfer *et al.,* 2007; Epanchin-Niell *et al.,* 2010; McLeod & Saunders, 2011; Bagavathiannan *et al.,* 2019) including, for example, public-private partnerships (Mato-Amboage *et al.,* 2019). As outlined earlier, the mobility of invasive alien species means that prevention of their movement and management of established populations can benefit from collaboration and coordination across property and jurisdictional boundaries (Graham, 2014; Yung *et al.,* 2015; T. M. Howard *et al.,* 2018). Achieving such cooperation is challenging because diverse actors have varying levels of interest, skills, resources, capacity and time to commit to management of biological invasions (Donaldson & Mudd, 2010; Graham, 2013; Ma *et al.,* 2018; Kropf *et al.,* 2020). Successful collective action can be achieved through stakeholder and Indigenous Peoples and local communities networks. Social norms and trust can be established to develop a common understanding of the problem, agree on a common goal, identify measures of success and encourage participation in individual and group activities (Stallman & James, 2015; Niemiec *et al.,* 2016; Graham & Rogers, 2017; T. M. Howard *et al.,* 2018; Bagavathiannan *et al.,* 2019). There are sets of useful questions that are consistent across these cooperative invasive alien species management initiatives **(Table 6.9)**. While consideration of these factors listed in **Table 6.9** does not guarantee success, the questions do provide practical insights into what collective action offers for improving the governance for biological invasions into the future.

Table 6 9 **Collective action questions towards improved governance for biological invasions.**

Leadership	**Who will lead the collective action initiative?**
Working relationships	Who to include?
	Are there existing relationships among participants?
	How can trust be built among group members?
Shared goal	What is the shared goal?
	What are the ecological, economic and social dimensions of the goal? (What motivates one person may not motivate another)
	Does the goal focus on a single species or a whole ecological community?
	What area does the goal cover?
	What does success look like?
Pooling resources	What are the asymmetries in the programme?
	Who needs support?
	How can such support be provided?
	Where will resources come from over the short and long term?
Coordination	How can disparate efforts be connected?
	Who will make the connections?
	What support can be provided across initiatives?
	How will gaps be filled?

6.4.4.4 Applications of network analysis to support adaptive-collaborative governance

Network analysis of governance structures and stakeholders is useful for understanding and improving cooperation, coordination and information flows across a large number of actors and organizations engaged in biosecurity. As an example, in Australia, there is a "recognition that government players are neither resourced sufficiently to fill all required roles and responsibilities, nor necessarily the most capable of filling all roles…biosecurity now turns to multiple purpose networks that seek to mesh diverse tasks such as surveillance, policy development, response to incursion, awareness building, and research and development" (McAllister *et al.,* 2020). An independent marine pest network was formed to provide continuous communication for surveillance and rapid response (i.e., a "suite of organizational interactions that emerge around the Government's Marine Pest Sectoral Committee"), and includes scientists, industry and members of the public. The network is focused on communication, surveillance and engagement but does not manage incursions. Social network analysis showed that the "network is well-structured for information dissemination and there is evidence that nongovernment actors already play some role in integrating and brokering information", however, improvement is required, as it was found that, while information is provided to the community, there is a "near absence of ties for receiving information from the community" (McAllister *et al.,* 2020).

Adaptive-collaborative governance thus involves multi-level and multi-actor coordination and collaboration based on knowledge and disciplinary integration, experimentation, monitoring, the use of the best available technology and social learning (Kirkfeldt, 2019; **section 6.2.3.1(4)**). Many frameworks have been developed that explicitly consider the interactions between social and ecological systems. Not all frameworks, however, give equal emphasis to humans and ecosystems or their dynamic interactions (Binder *et al.,* 2013). Those that do, insist that involving stakeholders in collaborative environmental governance of such systems is imperative. Some of these approaches focus on networks of human-ecological interdependencies either within bounded geographical areas or, more often, across geographical barriers or boundaries and governance realms. This includes, for example, marine protected networks that usually involve large geographic areas, ecological connectivity, and many different government agencies and stakeholder and Indigenous Peoples and local communities groups (S. M. Alexander *et al.,* 2017).

Network analysis may be used to examine both the "fit" between governance and ecological scales and processes and the need to achieve coordination and collaboration among a large number of government agencies and stakeholders. Multilevel horizontal and vertical governance ties bring actors together to form multilevel (local to national) networks to coordinate, collaborate and share knowledge that is needed, e.g., to address a lionfish invasion in Jamaica's marine protected areas **(Box 6.16)**. Another example of how collaborative governance networks can be established to achieve greater ecological and governance fit is presented by network administrative organization-led coordination of *Phragmites australis* (common reed) management in the Great Lakes, United States **(Box 6.16)**.

Box 6 16 **Two examples of network analysis and adaptive-collaborative governance to strengthen the prevention and control of invasive alien species.**

(1) Horizontal and vertical governance ties to achieve social–ecological fit in response to a lionfish invasion an emerging marine reserve network in Jamaica.

Invasive alien species context: *Pterois volitans* (red lionfish) and *Pterois miles* (lionfish) favour near-shore reef habitat and are now prevalent across the Caribbean, Gulf of Mexico and Western Atlantic. First sited in the Bahamas in 2004, populations and distributions expanded rapidly (Côté *et al.,* 2013). By 2009, their range had expanded to Jamaica, with populations becoming established around the entire island within a year (Schofield, 2009). With no natural predators, lionfish consume a significant amount of especially juvenile native fish, depleting near-shore fisheries and coastal biodiversity in Jamaica. A study in the Bahamas found that, over a 2-year period, an increase in lionfish biomass coincided with a 65 per cent decrease in the biomass of 42 native species (Green *et al.,* 2012).

Governance context: The Jamaican Government has established, to date, 17 "special fishery conservation areas" (i.e., marine no-take areas that range from about 1 km^2 to 18.73 km^2). The majority of these conservation areas are close to small coastal communities with active small-scale and artisanal fisheries that use mixed gear (e.g., fish traps, spear guns) and target multiple species (e.g., conch, lobster, reef fish). It also established co-management arrangements with local non-governmental organizations and/or fisher cooperatives that devolve roles and responsibilities (e.g., monitoring) associated with the day-to-day management of these marine reserves (S. M. Alexander *et al.,* 2015).

Box 6 16

A multi-actor network: Social network analysis revealed that the governance structure of the Special Fishery Conservation Areas is constituted of ties between actors, including government and non-governmental organizations (S. M. Alexander *et al.,* 2016). Many of the ties emerged through one of the following three processes: (i) formal partnerships (e.g., co-management arrangements, capacity-building); (ii) personal connections and relationships; and (iii) joint membership on committees, boards and projects. For example, the Lionfish Project – funded by the Global Environment Facility (GEF) – fostered network ties between government agencies, non-governmental organizations, community-based organizations and private resorts. Collectively, the resulting governance network provided a critical foundation for an island-wide lionfish monitoring and culling programme. Multi-actor network ties connect actors horizontally across local sites of action and management that are geographically distributed, which is essential when effective responses to a biological invasion occurs simultaneously across sites. However, research revealed a lack of strong ties and information sharing between those local level management organizations with a mandate to manage one or more special fishery conservation areas. Multi-actor governance networks that span sectors, departments and agencies can contribute to increased coordination, which is central for effectively responding to and governing biological invasions and the multiple dimensions of socioecological fit associated with marine protected areas. Multi-level network ties can be central to linking action at multiple scales and tightening feedback, which are critical processes for effectively responding to and managing biological invasions. Multilevel linkages played the greatest role in enhancing fit in the marine reserve network. However, the long-term propensity of the multi-actor and multilevel networks to enhance social–ecological fit is uncertain given the prevalence of weak social ties, lack of a culture of information sharing and collaboration and limited financial resources.

(2) An adaptive collaborative governance approach to *Phragmites australis* (common reed) management in the Great Lakes, United States.

An example of adaptive collaborative governance is presented by the Great Lakes Restoration Initiative,[12] which supports a basin-wide initiative called the Great Lakes *Phragmites* Collaborative (Braun *et al.,* 2016). *Phragmites australis* is an invasive alien wetland species that affects ecosystem functions, biodiversity and social and economic values, and threatens restoration, generating large financial burdens for land management. A total of $16 million was invested in the Great Lakes Restoration Initiative from 2010-2015 to support the Great Lakes *Phragmites* Collaborative, which was developed to address numerous barriers to *Phragmites australis* management, including a lack of organized communication among managers and between managers and researchers; a failure to address *Phragmites australis* at a landscape scale (multi-state and bi-regional), and a lack of a common agenda or strategic plan in a context where stakeholders working independently were producing isolated impacts or duplicating efforts, leaving gaps that undermined management.

As a “neutral facilitating” entity, the Great Lakes *Phragmites* Collaborative serves as a regional representative for impacted stakeholders, providing support to develop common agendas, mutually reinforce activities and share measurements for assessing progress. An advisory committee represents a diversity of disciplines and expertise across different state and non-state organizations and geographical areas. The committee articulated a vision statement and common agenda that will be elaborated on, as much as possible, by consensus, which also includes support for individual initiatives. An adaptive collaborative process “involves stakeholders progressing toward a goal through a structure that facilitates mutually reinforcing activities and regular feedback… aligned efforts, support for discovery of new practices, and widespread adaptation of successful practices…an adaptive management technique because it promotes learning and adaptation.” A shared measurement system is considered to be essential for adaptive management – to assess progress, align individual strategies with landscape-level goals, and provide empirical information for adaptation. It showcases best management practices and lessons learned, and responds to needs identified in a stakeholder and Indigenous Peoples and local communities survey by providing access to information resources, information sharing and technology transfer (Braun *et al.,* 2016).

Network analysis can also be applied to both the biophysical and social processes entailed in pathways of introduction or spread of invasive pathogens, plants, or mammals, which includes international and domestic transport and other types of movements involving stakeholders, agents (e.g., ships), events and species or hosts that interact in space and time (D. C. Cook *et al.,* 2010; Hulme *et al.,* 2018; Lansink *et al.,* 2018). Within-sector (e.g., livestock, forestry) network analysis is related to the movement of invasive vectors and hosts through chains that link vector stakeholders and Indigenous Peoples and local communities with contributors in supply or value chains (**Glossary**). The FAO promotes such analysis to provide an evidence-base for animal diseases epidemiology to inform risk analysis and develop strategic plans for disease control and surveillance (FAO, 2011). Contact networks (i.e., networks and linkages in value chains that connect production systems, markets and

12. https://www.greatlakesphragmites.net/

consumers) can favour the transmission of contagious diseases within and between sectors, and need to be taken into account in the development of risk management strategies for the control and prevention of animal diseases (FAO, 2011). The input of a wide range of stakeholders is essential for this network analysis to be effective.

6.4.4.5 Challenges of collaborative governance approaches and success factors

Governance approaches themselves can be a significant source of conflict in invasive species management, particularly when various groups of influencers or interested stakeholders and Indigenous Peoples and local communities are not consulted, their knowledge is not taken into account, or they are not involved in implementation actions that affect them (Crowley *et al.,* 2017a; Estévez *et al.,* 2015; Lynch, 2020). Adaptive-collaborative management benefits from good governance, and vice versa. Plummer *et al.* (2013) examined the literature on adaptive collaborative management for governance content and found multiple relationships: among others, good governance is necessary to facilitate adaptive collaborative management, which helps facilitate a shift to good governance and can operationalize governance, while stressing multi-level, multi-sector and multi-stakeholder and Indigenous Peoples and local communities engagement (**section 6.7**). Common themes that emerge include the need for: accountability and legitimacy, the involvement of diverse stakeholder groups and Indigenous Peoples and local communities and bridging organizations, the need to achieve organizational fit, interplay and scale; for adaptiveness, flexibility and learning, as well as social learning and knowledge sharing[13] (drawn together in **section 6.7**).

In addition to giving citizens and stakeholders a voice in decisions that affect them, it is claimed that collaborative approaches to environmental governance can reduce conflict, build trust and facilitate learning among citizens and stakeholders, increasing the likelihood that decisions are implemented on the ground and over the long-term (e.g., Beierle, 2002; De Vente *et al.,* 2016; Derak *et al.,* 2018; M. S. Reed, 2008; M. S. Reed *et al.,* 2018). However, stakeholders and Indigenous Peoples and local communities involvement can only be successful when tailored to the problem and context (**section 6.4.1**). In some cases, stakeholders and Indigenous Peoples and local communities need to be involved in "deeper, two-way, co-productive engagement (possibly over long time-scales)" (Shackleton, Adriaens, *et al.,* 2019). This may be the case, for example, when coordination of the management of biological invasions occurs across multiple land tenures or land-use settings (Bryce *et al.,* 2011; Shackleton *et al.,* 2015), or where cooperation problems are evident and thus the potential for conflict or lack of cooperation is high. These conditions may call for stakeholder and Indigenous Peoples and local communities' involvement in the co-design or co-development of risk assessments, strategies and management approaches, co-creation of knowledge and co-implementation.

Several factors seem to be key to the success of adaptive-collaborative governance for biological invasions. One of them is the breadth of involvement of stakeholders and Indigenous Peoples and local communities, ensuring that all stakeholders with influence and interests are included lends governance the legitimacy it needs for policy implementation. Another factor is the deliberative and transparent nature of the collaborative process, as well as its ability to account for and manage power imbalances and conflicts (Newig *et al.,* 2018). Finally, high levels of social interaction among the participating actors favour positive outcomes and help to build commitments, knowledge and trust (S. M. Alexander *et al.,* 2018; Bodin, 2017; Newig *et al.,* 2018). These in turn are instrumental for collectively addressing coordination and collaboration problems. In other words, one key factor that is needed to achieve successful collective action is to build appropriate governance networks where relevant actors, individuals and/or organizations are included and engaged with each other (DeFries & Nagendra, 2017). Other critical factors that affect the effectiveness of networks include consensus around goals and the need for "network competencies," or specializations, among the network's participants, such as research competence (Lubell *et al.,* 2017).

Engagement with stakeholders and Indigenous Peoples and local communities is therefore an essential element of integrated governance of biological invasions (**section 6.7**). While it may not be possible, due to time or resource constraints, to develop effective adaptive-collaborate governance networks, deep stakeholder and Indigenous Peoples and local communities engagement can be built into any governance and policy development approach.

13. Data management report available at: https://zenodo.org/doi/10.5281/zenodo.5762739

6.5 ECONOMIC AND FINANCIAL OPTIONS

Although the costs associated with invasive alien species have been estimated to be in the trillions of dollars globally (Diagne *et al.,* 2021; **Chapter 4**, **Box 4.13**), the economic, political and financial systems have not yet sufficiently internalized these estimates. Therefore, biological invasions remains largely unaddressed at the national and international level (Pimentel *et al.,* 2005). Many impacts are unrecorded due to serious data gaps in several regions and there are ongoing methodological challenges about how to estimate social costs. It is clear, however, that the costs of impacts far outweigh the costs of management (**Chapter 5**, **section 5.5.7**; Diagne *et al.,* 2021).

Of particular concern are the indirect impacts of invasive alien species, as they are both inherently difficult to quantify and, in some cases, magnified under the prism of climate change (Mainka & Howard, 2010). Invasive alien species pose an enormous risk to good quality of life through their effects on social, economic and environmental systems (**Chapter 4**, **sections 4.5** and **4.6.3**). In some cases, such as invasive alien species-related agricultural losses, these effects can potentially destabilize socioeconomic and democratic structures by causing famine and social unrest (Goss *et al.,* 2014; Singh & Kaur, 2002).

These indirect impacts are yet to be incorporated into national accounting measurements of economic growth (e.g., gross domestic product (GDP) and gross national product (GNP)). For example, economic growth measures include exports as a benefit but ignore possible damage from potential unintentional species introductions. Several researchers and governments have recognized the importance of accounting for economic activity's environmental impact, called green national accounting (Fenichel & Abbott, 2014; Kubiszewski *et al.,* 2013). Progress in green national accounting has been seen in the Genuine Progress Indicator (Kubiszewski *et al.,* 2013), the Index of Sustainable Economic Welfare (Beça & Santos, 2010; Stockhammer *et al.,* 1997) and the Gross National Happiness measure (Ura *et al.,* 2012). Nonetheless, most of these green national accounting measures (aside from Beça & Santos, 2010) continue to ignore invasive alien species, which is a significant oversight. According to a recent report from the CBD on the resources needed to implement the Kunming-Montreal Global Biodiversity Framework, the cost of the continuous management of alien invasive species is estimated at $36 billion to $84 billion per year, depending on the assumptions used in the calculations (CBD, 2021b). To halt and reverse the trends of biodiversity loss and impacts on good quality of life, it is urgent to make the case for the importance of invasive alien species in the larger context of global biodiversity change (Mooney & Hobbs, 2000); cross-sector policy, coordination and collaboration have been identified as essential to invasive alien species prevention and control (**sections 6.2** and **6.3**).

Identifying financial and economic mechanisms to address invasive alien species is challenging for three principal reasons:

1. they affect public goods, which complicates the important task of defining responsibilities (Perrings *et al.,* 2002; **section 6.3.1.1**);

2. many of the costs and benefits of investment in invasive alien species management are non-market values (Perrings *et al.,* 2010), in some cases affecting values that cannot be monetized thereby limiting their consideration in economic flows and return on investment analyses (Auerbach *et al.,* 2014), and their use as arguments for generating resources and investment;

3. the ambiguous property rights of some goods and services that are affected by invasive alien species make it extremely difficult to implement public policy, legislation and regulatory mechanisms to protect these goods and services (Reichard *et al.,* 2005).

These three characteristics, compounded by the probabilistic nature of a successful invasion event (Fournier *et al.,* 2019) and the lag time that often separates an introduction from a successful invasion (Essl *et al.,* 2011), make it difficult to internalize the effects of invasive alien species, and therefore argue successfully for investing the resources necessary to adequately confront this global issue in a given region.

This IPBES assessment of invasive alien species cannot offer a comprehensive global review of existing financial and economic mechanisms, nor can it define a road map for success in the management of biological invasions (**section 6.2**). Rather, it presents some of the economic instruments available to finance different aspects of the invasion process, including prevention, eradication, containment, mitigation and restoration. The IPBES assessment of invasive alien species also examines some of the challenges, benefits, appropriateness and implications of adopting these instruments in different contexts and at various scales. It provides some insights for generating the economic incentives and deterrents that support a sustainable global effort to address the problem of invasive alien species in a more coordinated and better-financed manner. Some of the options presented are likely to resonate better in some regions than in others, and work best at some scales rather than others; the instruments outlined here are scale and context dependent. This simply reflects the diversity of the planet, its human societies and political systems, as well as the tremendous complexity of biological invasion process and its relationship with global biodiversity change.

Finally, there is no doubt that the power to advance the global invasive alien species agenda lies primarily in the hands of governments that lead legal and regulatory initiatives, supported by economic command-and-control instruments, tariffs and penalty systems. Government agencies are, and will likely continue to be, the organizations with the greatest capacity to respond to invasive alien species (Leadley *et al.,* 2014). However, in many cases, especially in countries with developing economies, multilateral and bilateral development aid will play a significant role. The magnitude and intrinsic characteristics of the problem call for an urgent and coordinated diversification of financing options and mechanisms.

6.5.1 Government financing

Government financing continues to play a leading role in invasive management efforts. However, this varies greatly between regions and countries (**Figures 6.4** and **6.5**), partly because of specific national fiscal and regulatory policies and public sector development strategies. In many countries there is considerable government investment in management of biological invasions through sub-national and national support programmes. However, these rarely translate to a multilateral coordinated effort required to adequately address the problem (Tollington *et al.,* 2017). Surveillance and monitoring are also aspects that receive government funding through the efforts of different agencies, but most of these activities have short time horizons, are limited to a few species and lack coordination, which all work to diminish their impact over time (Liebhold *et al.,* 2021).

To achieve adequate management of public funds to respond to invasive species, it is useful to coordinate robust policies at all levels of government in which diverse areas of administration are involved, including but not limited to financial, economic and environmental regulatory bodies, as well as those in charge of international trade and commerce and foreign policy (Tollington *et al.,* 2017, **sections 6.2** and **6.3**). Likewise, it is important to finance educational and outreach strategies to gain public support for the investment of resources into prevention, control and eradication projects (Bertolino & Genovesi, 2003).

Dividing the main sources of tax revenue into four broad categories allows us to understand how each could provide opportunities to respond to invasive alien species at different stages of the biological invasion process:

Direct taxes

The first group is direct taxes paid by households and businesses, which include income taxes, payroll taxes and corporate income taxes, among other taxes (i.e., capital gains and other investment incomes). A portion of direct taxes, which in theory are a reliable source of tax revenue, could be redirected to invasive alien species projects. Specifically, direct taxes are best used to address pre-invasion stages. In pre-invasion stages, biological invasions can be prevented with constant vigilance, including surveillance and monitoring, and therefore sustained funding. Also, investments made in preventing invasions pay dividends, as they eliminate invasions and all the associated costs.

Indirect taxes

The second category comprises indirect taxes, or taxes paid to the government or other public body through a third party, such as a retailer or suppliers. This category includes value added taxes, sales taxes, special taxes on products such as alcohol or tobacco and import duties. Indirect taxes are slightly less dependable than direct taxes because they vary with both household and commercial consumption patterns, as well as the specific tax policies of a given jurisdiction within a nation. Additionally, some subcategories of indirect taxes such as excise taxes can place an unequal burden on taxpayers at different income levels, as the tax per unit of a given good or service will constitute a higher portion of a lower-income taxpayer's income. However, the mandatory nature of this category of tax revenue means that they still are by-and-large a dependable source of tax revenue. Thus, they are appropriate sources of revenue for regular post-invasion control, mitigation and management programmes.

Non-tax revenues

In the third category are non-tax revenues from state-owned enterprises, including revenues from natural resources such as oil and gas. This category could help in research stages, as revenues from such sources already subsidize research in public universities and other institutions in some regions of the globe. Funding for research could be directed towards creating partnerships between public research institutions and natural resource management programmes to increase communication between academia and those responsible for implementing management programmes for biological invasions. This idea is particularly attractive as surveys of invasive alien species programme managers commonly cite a lack of communication with invasive alien species experts as a major barrier to implementing holistic invasive alien species management programmes (Beaury *et al.,* 2020).

External sources

Finally, there is funding from external sources, such as from bilateral or multilateral funding agencies (i.e., World Bank Group: International Bank for Reconstruction and Development (IBRD), International Development Association

(IDA), International Finance Corporation (IFC), Multilateral Investment Guarantee Agency (MIGA), International Centre for Settlement of Investment Disputes (ICSID), Asian Development Bank (ADB), International Monetary Fund (IMF) and International Fund for Agricultural Development (IFAD)), that are also considered public funding when the funds are disseminated through the recipient governments. Governments that depend heavily on funding from these sources are likely to not have other robust sources of tax revenue meant for controlling invasive alien species, and such funds therefore could be used to address the most pertinent areas of management of biological invasions in that region. In regions where there is significant government capacity for managing biological invasions, these funds could be directed specifically towards increasing international coordination of management efforts such as prevention and monitoring. External funding sources could support any action considered as a priority by the government, that requires special support and/or is very costly, such as eradication, or action that depend on international coordination, such as prevention and monitoring.

In summary, the coordinating role and much of the economic drive to address and reduce the risk of invasive alien species currently involves state actors. However, biological invasions are a complex problem with many facets and actors involved (**section 6.2**), so it cannot be thought of as the sole responsibility of governments. While fiscal policies and regulations at the national level have the potential to establish central guidance and coordination mechanisms, it is also important to manage multilateral and bilateral mechanisms, philanthropic support and, above all, to involve the private sector to reinforce government initiatives and address neglected aspects of the problem (Epanchin-Niell, 2017).

6.5.2 Laws, regulations and incentives for the private sector

Three examples of tools available to governments that incentivize the private sector to address invasive alien species prevention and control efforts include: ambient taxes, Pigouvian taxes and compensation, subsidies and fiscal incentives, and promoting the private sector to engage with prevention and control of invasive alien species.

6.5.2.1 Ambient taxes and subsidies

Beyond the more standard sources of tax revenue mentioned above are ambient taxes. Ambient taxes' purpose is to levy taxes on industries responsible for generating non-point sources of pollution, such as carbon emissions or invasive alien species. This type of taxation in the context of invasions, as introduced by Segerson (1988), would incentivize risk reduction by encouraging a shift towards more eco-friendly choices and ensure socially optimal behaviour in both the short and the long run (K. R. Jones & Corona, 2008). Furthermore, these taxes could serve as a cost recuperation strategy (to help pay for invasion impacts) and provide both the financial resources for prevention (including subsidies, surveillance and monitoring) and control strategies. Research has suggested that ambient taxes can be applied to users of ports to incentivize vessels to use proper, resource-appropriate, biosecurity measures (K. R. Jones & Corona, 2008). Effective ambient taxes are tailored to the nature and impacts of invasive alien species from specific ports of entry, which is achieved through greater levels of communication between regulators, researchers and industry stakeholders to reach appropriate tax rates. Furthermore, more research is needed to ensure that these taxes are levied without placing an undue and unequal burden on actors in international trade and into how to properly value the impacts of invasive alien species (Epanchin-Niell, 2017; K. R. Jones & Corona, 2008).

6.5.2.2 Pigouvian taxes

Pigouvian taxes, also known as an "introducers pay" tax, are another market-based approach to addressing invasive alien species control and are a particularly important policy tool when the private control of invasive alien species introductions is insufficient because of negative externalities or impacts from introductions that extend outside the market. Pigouvian taxes aim to tax individuals or companies to interiorize external costs not included in the market price (Sandmo, 2008). The overall aim is to incentive invasion prevention by inducing a cost to the expected damages from an invasive alien species to a level that equals the marginal cost to producers of reducing the risk of invasions. By doing this, producers would interiorize the societal costs not usually included in the market price (i.e., externalities). These taxes are usually perceived as a socially efficient strategy for reducing invasion risk (Epanchin-Niell, 2017), as these taxes force producers to account for the costs accrued to all of society from the risks of possible invasions. However, it is essential to notice that for Pigouvian taxes to yield qualitatively socially desirable behaviours, revenues from these taxes need to be used to offset the impacts caused by the introduced species (Fenichel *et al.,* 2014; Sandmo, 1975). Pigouvian taxes could be considered for imported goods or for dealing with neighbouring or spatial spillover effects (McDermott *et al.,* 2013). In some instances, Pigouvian taxes may even be more efficient than other market-based approaches like ad valorem taxes or tradable permits (McDermott, 2015; Richards *et al.,* 2010). However, like all biological invasions policies, a one-size fits all approach is not recommended and would require significant evaluation and consideration before implementation (Fenichel *et al.,* 2014; Knowler & Barbier, 2005; McAusland & Costello, 2004).

6.5.2.3 Leveraging compensation, subsidies and fiscal incentives and mechanisms

The widely used mitigation hierarchy framework (BBOP, 2012; IFC, 2012) establishes compensation mechanisms in cases of unavoidable and irreparable damage to biodiversity (Arlidge *et al.,* 2018). In instances involving damage by invasive alien species, these measures could be associated with robust and transparent mechanisms for monitoring, regulation and planning, as well as the creation of legislation that provides information on processes and responsibilities. In the case of subsidies, especially in the agricultural sector, these measures could likewise be well legislated and regulated as they can push producers to focus on improving production through reducing the use of unsustainable practices such as monocultures and excessive use of pesticides that can reduce the resilience of ecosystems to possible invasions (OECD, 2017; Robin *et al.,* 2003). It is therefore important to promote interdisciplinary research to develop evaluation mechanisms and indicators that help to anticipate the unexpected effects that these mechanisms may have at different scales and in different agricultural production modalities. In relation to fiscal and economic incentives (Fernandez, 2011), these could not only be oriented to reduce risk, but also to increase the resilience of ecosystems and social groups at high risk of invasions, i.e., the creation of fiscal and economic incentives that promote activities that help prevent, control, manage and eradicate invasions; but also, fiscal and economic incentives that discourage activities that promote the transport, introduction and establishment of invasions; but also, fiscal and economic incentives that discourage activities that promote the transport, introduction and establishment of invasions such as exotic gardens (Dutta *et al.,* 2021) and exotic pet trade (Gippet & Bertelsmeier, 2021).

6.5.3 Multilateral and bilateral financing organizations

Multilateral and bilateral funding organizations already support development and infrastructure programmes around the globe, but their resources and capacity to foster long-term change vary widely with both their organizational priorities and the regions in which they operate (Ray, 2021; **section 6.2**). However, there are opportunities for these organizations to partially redirect their efforts to support the invasive alien species problem without significantly altering their organizational priorities. One potential mechanism would be to update aspects of environmental impact assessments in development and infrastructure projects to place greater emphasis on invasive alien species. Environmental Impact Assessments already gather information on biodiversity (GBIF Secretariat & IAIA, 2020) that, with some effort and coordination, could be oriented to become mandatory, funded mechanisms that provide data for invasive alien species monitoring and prevention systems. Furthermore, environmental auditing has becoming an integral part of infrastructure and other developmental projects (W. Cook *et al.,* 2016). Inclusion of invasive alien species as an indicator in the environmental auditing of such developmental projects may indirectly fund the invasive alien species prevention and control activities. These same mechanisms could also assist in the selection of native species for restoration programmes.

While technical mechanisms are used by multilateral agency groups to incorporate environmental considerations into their investment portfolios, such as Performance Standard 6 (IFC, 2012), these standards do not directly address biological invasions. Though organizations such as the Equator Principles already work with development agencies to explicitly address biological invasions in their environmental considerations, it is also urgent to work with new multilateral and bilateral funding agencies that include large emerging economies countries such as Russia, China, India, Brazil and South Africa. Furthermore, while national governments could require multilateral funding organizations to carry out long-term monitoring of the impacts of development projects, this is often difficult in practice due to the limited capacity of some governments. Therefore, it is important that multilateral funding organizations include in their priorities and budgets adequate resources for sufficient invasive alien species monitoring and evaluation processes.

In order to help to ensure the necessary precautions are taken in the investment portfolios of multilateral organizations, insurance companies and financial institutions could be required to invest in modelling and managing the risks associated with invasive alien species within their various investment activities. Due to the sheer scale of global capital invested in transportation, infrastructure, energy, extractives and other development activities, modelling and management of invasion risk presents an opportunity to prevent negative impacts before they occur. However, for this to be effective it is necessary to develop instruments that interiorize the externalities of societal and environmental impacts of invasions (**section 6.5.2.2**). It is important that these agencies also create funding mechanisms to support research, monitoring and the creation of indicators by sectors such as non-governmental organizations and academia.

Finally, it is important to mention a recent movement to reduce funding for programmes that focus solely on increasing agricultural production and redirect that funding to develop the circular economy (**Glossary**) and incentivize bio-economic considerations and regenerative agriculture activities (Geng *et al.,* 2019). This could become an opportunity to broaden the investment portfolio of multilateral organizations to support countries in their efforts to establish taxes and fees that benefit invasion prevention and mitigation activities indirectly through strengthening ecosystem resilience to invasive alien species.

6.5.4 Private sector

Investment risk and firm reputation are two important factors driving the private sector (Kocovsky *et al.,* 2018). The private sector could increase its capacity to assess how investment decisions that maximize short-term economic returns also have the potential to trigger biological invasions that can have a devastating effect on its own finances in the medium and long run. As with multi- and bilateral funding organizations, mechanisms could be promoted to help the private sector include the invasion risk component in its economic analysis of different investment options.

To this end, it is important that governments develop and implement policies and legislation at the national and regional level that encourage private firms to include and disclose invasion risk in their reporting frameworks. These analyses can be supported by scientists and contribute to wider research on the development of analytical frameworks and risk indicators. Furthermore, large private sector companies with significant influence and investments in supply chains can help their respective industries to take the necessary considerations to reduce risk through introducing mechanisms that certify products (i.e., green labels), track origin, and generate freely available information to assess, anticipate and monitor the risk of invasion (Kotchen, 2013; Padilla & Williams, 2004). This latter approach could have the extra benefit of raising public awareness of the private sector's role in purposefully or inadvertently creating invasions, thereby making it more attractive for private firms and governments alike to invest in invasive alien species management to protect their public image (Hanley & Roberts, 2019).

Voluntary and self-regulating models, such as corporate social responsibility (CSR) strategies, can also be valuable tools for preventing biological invasions. These strategies imply companies are conscious of the realized and potential impact their activities have on all aspects of society, including economic, social and environmental (Lindgreen & Swaen, 2010). CSR strategies can take multiple forms. These can be voluntary programmes and partnerships to mitigate the environmental impact of industrial plants and production methods (Lindgreen & Swaen, 2010; Rondinelli & Berry, 2000). Alternatively, strategies can include the development of sourcing and marketing initiatives that protect social welfare and commit to environmental benefits (Lindgreen & Swaen, 2010; Roberts, 2003). Wildlife trafficking can be used as an example as to how the private

Box 6 17 Synergies with control mechanisms for illicit wildlife trafficking.

Illegal trafficking of biodiversity has been shown to be one of the main sources of invasive alien species in regions receiving illegally trafficked animals and plants (García-Díaz *et al.,* 2017). Efforts are underway to create new funding mechanisms and strengthen existing ones to combat illegal wildlife trafficking (Wright *et al.,* 2016). One element that can help to deter this illegal activity is the speed of response in relation to species identification (e.g., Kretser *et al.,* 2015). This can be achieved by supporting integration mechanisms of control systems at regional and global levels and increasing the response capabilities of regulatory institutions such as customs and migration agencies at ports of entry and exit (Fajardo del Castillo, 2016).

Previous studies of government response to invasive alien species have identified increased collaboration amongst countries as essential to any future management efforts for biological invasions (Hardisty *et al.,* 2019; Perrings *et al.,* 2010). One option is to develop software intended to foster communication networks (Wallace & Bargeron, 2014; Wise, 2019) and disseminate technical training between and amongst regulatory organizations at the international level (**sections 6.3.1** and **6.6**). However, the process of technification and delivery of capacity-building to regulatory entities and personnel is costly (e.g., Juffe-Bignoli *et al.,* 2016). One way to avoid placing the burden solely on state organizations would be to increase both the criminal and civil liabilities of international freight companies to incentivize those organizations to take the proper precautions to avoid those penalties. This would also help the economic sustainability of expert regulatory entities to maintain the employment of trained technical staff.

Although the private sector has great potential to leverage mechanisms and business practices to help with the issue of invasive alien species, this will not happen without the support of consumers willing to pay the premium for safe products (Akerlof, 1970; Cason & Gangadharan, 2002). Governments could also create mechanisms and conditions for the private sector to feel that it is profitable to invest in invasive alien species prevention, monitoring and the certification of processes and products that directly address the issue of invasive alien species. One way to do this is the promotion of codes of practice for the translocation and exploitation of invasive alien species (**section 6.3.1.3(4)**) and green labelling (**section 6.5.5**). Empowering consumers to exert pressure on large, multilateral corporations to make decisions that help with this problem such as marking products with certifications that consider biological invasion processes can be an acceptable mechanism for the private sector (Kotchen, 2013) that in turn will provide companies with the favourable standing needed to succeed in a competitive global market.

sector is stepping up to help end the illegal commerce of species (e.g., the United States Wildlife Trafficking Alliance) and the tools that can be used to prevent biological invasions **(Box 6.17)**. In this context, codes of practice (**section 6.3.1.3 (4)**) are a viable way by which the pledges made in corporate social responsibility (CSR) strategies can be translated into resources and actions to address the problem of biological invasions.

6.5.5 Role of global supply chains

The impact of global supply chains on the transport and introduction of invasive alien species is undeniable (Hulme *et al.,* 2018; Seebens *et al.,* 2017). The introduction and establishment of invasive alien species are closely related to international trade flows and global trade routes, with international shipping being the main vector for the introduction of invasive alien species (Seebens *et al.,* 2015; Westphal *et al.,* 2008). If the trend of global trade growth continues, it is estimated that the direct annual cost of management of biological invasions in 2050 could reach $36 to $84 billion per year (Deutz *et al.,* 2020).

Incentivizing changes in supply chain management practices offers the opportunity to strengthen the prevention of alien species introductions and therefore decrease the costs associated with controlling and eradicating invasive alien species. One of the key components in driving change in supply chain management practices is elevating the importance of invasive alien species in the minds of end consumers (Hanley & Roberts, 2019). The changes made would encompass corporate commitments to assessing and improving corporate policies, internal standards and funding mechanisms to ensure that supply chains take appropriate precautionary measures, especially in producer countries.

Investments can be made to both improve current practices and elevate the importance of invasive alien species – safe practices in the minds of those responsible for setting corporate strategy (Kocovsky *et al.,* 2018). Importing countries could collaborate with exporting countries to improve sustainable practices that reduce the probability of invasions through their integration into regulations and international trade agreements (**sections 6.3.1.3** and **6.3.2.2**). In this sense, the integration of the component of biological invasions in green labels and certification systems (e.g., Blackman & Rivera, 2010) is especially important because these systems have been shown to be effective in raising public awareness of issues such as deforestation, though labelling by itself does not directly decrease deforestation (van der Ven *et al.,* 2018). Increased public awareness of invasive alien species is a fundamental component in garnering support for new funding mechanisms and policies that have the potential to address invasive alien species more directly. These methods also transfer a large part of the decision to consumers, thereby increasing awareness of the invasive alien species among the public.

6.5.6 Role of philanthropy, non-governmental organizations and academia

While philanthropy represents a significant source of funding for environmental issues such as invasive alien species in some regions, it is almost non-existent in others due to prevailing economic and social systems at the national and subnational level. In some cases, foundations and their philanthropy programmes may be limited by their internally defined priorities, which in many cases are aligned with topics of more widespread public concern (E. R. Larson *et al.,* 2016; Macdonald *et al.,* 2017). This dynamic makes it difficult to develop far-reaching programmes in less visible, but nonetheless important aspects of the invasion process. On the other hand, philanthropic organizations also offer funds to explore innovative invasive alien species programmes (E. R. Larson *et al.,* 2016), but these are quite limited in scope and tend to be used to support specific efforts that align with larger strategic goals of the organizations that receive them. Philanthropic funds are perhaps best used to finance the development of tools and pilot projects that can act as proofs of concept for later implementation by larger, better-funded entities such as governments or financial organizations such as the Global Environment Facility (GEF). In the case of funds that come from corporate social responsibility programmes and multilateral corporations, one option would be to develop metrics and methodological frameworks that the private sector can integrate into their business models to help them report on the impact and investment risk of invasive alien species.

Non-governmental organizations benefit, in large part, from funding sources that have their origins in philanthropy. Although philanthropic organizations have internal mechanisms to define priorities, non-governmental organizations are more transparent in this sense and can channel different philanthropic funds and articulate them to coordinate with programmes pursuing the same objective. Non-governmental organizations, in their constant search for funding to sustain themselves, have the flexibility to change their strategic goals swiftly. This apparent flexibility of the non-governmental organizations can be seen as an asset, as it allows the adaptability of their programmes to be maintained over time; but it also has the potential to drive significant changes in their programmes, and even terminate them altogether.

Finally, there is academia, which also moves with funding from philanthropy, but also receives significant government funding in many parts of the world. The way in which lines of research are often established early in a researcher's career presents the opportunity to begin cultivating a new generation of invasive alien species specialists in diverse fields. Addressing biological invasions can be achieved through greater coordination between academia and those responsible for implementing invasive alien species best practices; therefore, investments in invasive alien species research can essentially be seen as investments in invasive alien species prevention. One example of this is the Global Register of Introduced and Invasive Species (GRIIS) – a collaborative output demonstrating best practice use of biodiversity informatics to make invasive alien species checklists open (Pagad *et al.,* 2018, 2022). While it is important that foundations provide the funding that supports non-governmental organizations and academia to generate the early ideas that catalyse larger efforts, these efforts could be connected to the private sector, multilateral banks, and the governments to move ideas from pilot projects and proofs of concept to established, long-term programmes. National strategies for invasive alien species are a central mechanism by which this connection can be enabled.

6.5.7 International funding

The mechanisms described here are not the complete solution to financing the global invasive species problem. However, these mechanisms can drive significant change if they are supported, enacted and implemented by governments, multilateral and bilateral organizations, multilateral development banks, philanthropic foundations, non-governmental organizations, academia and the private sector, in a coordinated manner with strong support from informed citizens.

All the options reviewed in the IPBES invasive alien species assessment could benefit from considering different socioeconomic and cultural realities, and presenting common and coordinated strategies that take into account the communities most affected by biological invasions. There are large differences between countries in their capacity to tackle the problem of invasive alien species (Early *et al.,* 2016) and a significant geographic bias in data availability regarding the invasive alien species (**Chapter 2**, **section 2.1.4**; **section 6.6.1(3)**). These limitations have hampered global efforts to reduce the introduction of alien species and prevent their impacts. Flow of financial and other resources from developed countries to developing countries, particularly in Asia and Africa, can improve the understanding of the complex phenomena associated with biological invasions and help developing countries in their efforts to prevention and control of invasive alien species.

Multilateral development banks are in a great position to lead change towards suitable development (Handl, 1998; Trillo, 2021) and achieving the targets set by the Kunming-Montreal Global Biodiversity Framework. At UNFCCC COP 26 in Glasgow, United Kingdom, ten multilateral development banks signed a joint statement on Nature, People and Planet (Messetchkova, 2021), which recognizes that "tackling global poverty, climate change, and the drivers of nature and biodiversity loss are inextricably linked and affirms their commitment to further mainstream nature into their policies, analyses, investments, and operations." under this banner, projects sponsored by these institutions could consider projects aimed at reversing the nature loss caused by invasive alien species.

While it is true that the CBD or the Global Environment Facility could serve to mobilize financial resources, the burden of financing a global strategy need not fall solely on governments and their fiscal policies. It is beneficial to involve all sectors and actors in order to expand the financial resources available. This could also increase the scope of public policies and private sector practices towards sustainability. The need to increase the level of financial resources from all sources and increase the availability of these resources for developing countries is embedded in Target 19 of the Kunming-Montreal Global Biodiversity Framework. Key to this effort will be framing these efforts as medium- and long-term investment opportunities, rather than as necessary sacrifices.

The report on the global biodiversity financing gap estimates that between 722 and 967 billion dollars would be needed to sufficiently confront the crisis, with invasive alien species alone representing between 36 and 84 billion dollars (Deutz *et al.,* 2020). However, these estimates have wide ranges of error due to the limited availability of global biodiversity indicators (Mcowen *et al.,* 2016), as well as many of the data gaps described elsewhere in this assessment. Many uncertainties are related to future investments and the different funding mechanisms that could directly or indirectly support efforts against invasive alien species, but two things are clear: it is possible to reduce the need to invest in the control of and increase investment in the prevention of invasive alien species.

In the era of climate change wherein there is a growing understanding of the interconnectedness of all human activities, both sustainable and unsustainable, it is also paramount not to ignore the ways in which invasive alien species and efforts to combat them might influence and be influenced by other conservation efforts. For example, an important source of funding for biodiversity conservation in general is the carbon credit market, wherein governments voluntarily create offset mechanisms for sustainable forestry practices. Although this funding does not explicitly target biological invasions, establishing transnational safeguards in relation to reforestation and other restoration practices will help to quantify the contribution of carbon credit markets financial mechanisms to preventing invasions.

6.6 INFORMATION OPTIONS

Knowledge of invasive alien species is deeply embedded in the knowledge of the natural world, such as how organisms live, reproduce, disperse and interact. This knowledge is in turn disseminated as information, in different languages, cultures, media and disciplines. Much of it is not permanently preserved, either because it is experience in the minds of practitioners or because it is documented on temporary media. Some information, particularly from scientific publications, is available only from specialized libraries and databases or only at great expense or in a limited number of languages (Nuñez & Amano, 2021). Other knowledge, for example, of pastoralists, is passed down orally between generations and is not necessarily documented. Some knowledge has been rigorously tested using the scientific method, whereas other knowledge is based on observations or on a belief system (Shackleton, Richardson, *et al.,* 2019).

Even if invasive alien species knowledge were all documented and adequately archived there are problems associated with delivering this knowledge to the people who need it. For example, alien species are, by definition, remote from their origins. In the initial stages of an invasion, knowledge of the invader is likely to be better in its native range, or in previously invaded areas, than in the newly invaded range. This disparity includes both access to written knowledge and communication with practitioners who have experience of the invader. Thus, much knowledge that exists on invasive alien species is not adequately findable.

Invasive alien species span the full taxonomic range of species, from large mammals and trees to protozoa and algae (**Chapter 1**, **section 1.3.1**). It is therefore hard to generalize about the information required to support policy on invasive alien species. Knowledge is required both in depth and breadth. That is to say, detailed information on some invasive alien species can provide strong evidence for policy decisions. Yet a broad overview of all alien species would be needed to foresee future threats and to understand the impact of invasive alien species on other species and on people. This makes prioritization of knowledge acquisition difficult, particularly in view of the level of uncertainty in the threats.

Much of the information on invasive alien species is provided by general sources of biodiversity knowledge (Ramírez-Albores *et al.,* 2019). Knowledge sources specific to invasive alien species are also available (Ricciardi *et al.,* 2000), but are restricted to those species known to be alien. In both cases, these sources are often nationally or regionally circumscribed and created for local readers in their own language.

This section first broadly summarizes the knowledge needs identified by previous chapters of this assessment (summarized in **Table 6.10**; **Supplementary material 6.2**), and then discusses key options (**section 6.6.2**) for strengthening the generation and flow of policy and management-relevant invasive alien species information. It also introduces the particular problems faced by Indigenous Peoples and local communities, or isolated communities.

Table 6 10 **Cross-chapter synthesis of gaps in data, information, knowledge and understanding.**

Category	Gap
Gaps on biomes, units of analysis and species groups (section 6.6.1.1)	Incomplete or lack of inventories of invasive alien species in marine, tropical and Arctic ecosystems (**Chapter 2**, **sections 2.5.2.1**, **2.5.2.4**, **2.5.2.5**, **2.5.4**)
	Incomplete or lack of inventories of invasive alien microorganisms and invertebrates (**Chapter 2**, **sections 2.3.1.11**, **2.3.3.3**)
	Lack of understanding of the drivers facilitating biological invasion for some animal groups (notably invertebrates), fungi and microbes (**Chapter 3**, **section 3.6.1**)
	Lack of understanding and synthesis of the impact of invasive alien microbes (**Chapter 4**, **section 4.7.2**)
	Poor understanding of drivers facilitating biological invasions in aquatic and marine systems (**Chapter 3**, **section 3.6.1**)
Regional gaps in data and knowledge (section 6.6.1.1)	Comparatively incomplete inventories of invasive alien species in Africa and Central Asia (**Chapter 2**, **sections 2.4.2.5**, **2.4.5.5**)
	Comparative lack of understanding of the drivers facilitating biological invasions in developing economies (**Chapter 3**, **Box 3.12**)
	Lack of data and knowledge of the drivers facilitating biological invasions in sub-Saharan Africa, tropical Asia and South America (**Chapter 3**, **section 3.6.3**)
	Incomplete data on the impact of invasive alien species across Africa and Central Asia (**Chapter 4**, **section 4.7.2**)

Table 6 10

Category	Gap
Interoperable data for monitoring and research on invasive alien species and on the effects of drivers of biodiversity change **(section 6.6.2)**	Lack of standardization of terminology for invasive alien species monitoring (**Chapter 2**, **section 2.4.4.5**; **Chapter 6**, **sections 6.6.2.3**, **6.6.2.7**)
	The drivers facilitating biological invasions for some animal groups (notably invertebrates) and in fungi and microbes are poorly understood (**Chapter 3**, **section 3.6.1**)
	Lack of information on the role of indirect drivers, especially governance and sociocultural drivers, in affecting biological invasions (**Chapter 3**, **section 3.6.1**, **Box 3.12**)
	Lack of understanding of the net effects of multiple interacting drivers in shaping and promoting biological invasions (**Chapter 3**, **section 3.5**, **Box 3.10**, **section 3.6.1**, **Box 3.13**)
	Lack of knowledge on interactions and feedbacks across drivers in promoting invasions (**Chapter 3**, **section 3.6.3**)
	Lack of integration of data and knowledge sources on impacts across languages (**Chapter 4**, **section 4.7.2**)
	Incomplete data to undertake risk management, cost-effective species-led surveillance and detection of fungi, microbes and marine pests (**Chapter 5**, **Table 5.11**)
	Incomplete data to prioritize biological invasion management under climate, sea- and land-use change (**Chapter 5**, **section 5.6.1.3**)
	Lack of inventories at fine scales and for specific taxon and biome contexts to support decision makers in determining when to implement species-led and site-based management (or both) (**Glossary**; **Chapter 5**, **sections 5.6.2.1**, **5.7**)
	Incomplete data to develop pathway risk assessments and management for different taxonomic groups and biomes (**Chapter 5**, **Table 5.11**, **section 5.6.2.5**)
	Incomplete data and understanding of site-based and ecosystem-based management concepts (**Chapter 5**, **section 5.6.2.1**)
	Incomplete data and understanding of the conditions that facilitate successful integration of policy developments into management plans (**section 6.6.1.4**)
	Lack of indicators[14] of the various dimensions of biological invasion that are policy-relevant, sensitive, reliable, relevant at national and global scales, sustained for medium-to-long-term tracking of progress and part of a responsive policy environment (**section 6.6.3**)
Gaps on how invasive alien species affect Nature's contributions to people **(section 6.6.1.4)**	Incomplete data on impact on nature's contributions to people and good quality of life (**Chapter 4**, **section 4.7.2**)
Management and policy approaches **(section 6.6.1.2)**	Lack of control options for marine invasive alien species and invasive microbial fungal pathogens of plants and animals (**Chapter 5**, **section 5.6.1.1**)
	Lack of agreed-upon methods of supporting management decision-making for invasive alien species with both positive and negative impacts (**Chapter 5**, **section 5.6.1.2**)
	Lack of methods of managing pathways for invasive alien species arriving as contaminating invasive alien species, or through shipping containers, e-commerce (legal/illegal), biofouling or ports, and across land borders and along trade supply chains (**Chapter 5**, **Table 5.11**, **section 5.6.2.4**)
	Lack of methods for adaptive management of invasive alien invertebrates and plants using alternative approaches given the declining number of chemical control options (**Chapter 5**, **section 5.6.2.5**)
	Lack of eradication guidelines and strategies for generalist invasive alien invertebrates, diseases and hard-to-detect freshwater and marine invasive alien species (**Chapter 5**, **section 5.6.2.1**, **Table 5.11**)
	Missing information on the implementation of adaptive-collaborative governance for biological invasions and factors important for the success of this governance strategy (**section 6.4.4.4**)
	Incomplete data on the effectiveness of policies, management strategies and actions related to biological invasions (**section 6.6.3**)
	Lack of scenarios and models of invasive alien species that consider interactions with other drivers of change in nature (**Chapter 2**, **section 2.6.5**; **Chapter 6**, **section 6.6.1.6**)
	Lack of biological invasion research that includes social dimensions to generate socially relevant additional data and knowledge, better inform management and policy and build trust between sectors of society (**sections 6.4**, **6.6.1.4**)

Table 6 10

Category	Gap
Management and policy approaches **(section 6.6.1.2)**	Lack of multidisciplinary to interdisciplinary research on policy regimes and governance for biological invasions (**sections 6.2.4**, **6.5.1**)
	Lack of tools and frameworks to predict biological invasions (**sections 6.2.1**, **6.6.1.6**, **6.7.2.7**)
Gaps to fill to support the implementation of policy and management **(sections 6.6.1.2, 6.6.1.3, 6.6.1.6)**	Lack of tools to reduce the barriers to information-sharing within and across countries (**section 6.6.2**)
	Lack of research and data on how best to implement context-specific integrated governance systems to manage biological invasions (**sections 6.6.1.3**, **6.6.1.4**, **6.6.2**)
	Lack of mechanisms that allow effective collaboration among different aspects of the socioecological systems (**Figure 6.7**, **section 6.7**)
	Policy for new and emerging technological innovations for invasive alien species management to support effective development and implementation and prevent or manage risks (**section 6.3.3**)
	Additional, particularly fine scale, data on how invasive alien species are introduced and spread to support prioritization of introduction pathways and pathway management (**Chapter 2**, **section 2.1.2**; **Chapter 5**, **section 5.6.2**; **Chapter 6**, **section 6.6.1.2**)
	Research and design of economic options, including the tailoring of ambient taxes and analyses and indicators to assist private companies (**section 6.5.1.1**)
Knowledge gaps on invasive alien species of particular relevance to Indigenous Peoples and local communities **(section 6.6.1.5)**	Lack of information on invasive alien species status and trends on land and water managed by Indigenous Peoples and local communities (**Chapter 2**, **Box 2.6**)
	Lack of clarity on how knowledge, resources and data on invasive alien species should be treated under the Nagoya Protocol (**section 6.6.1.5**)
	Mechanisms for sharing knowledge on invasive alien species with Indigenous Peoples and local communities (**section 6.6.1.5**)
	Understanding the on-the-ground experiences of stakeholders and Indigenous Peoples and local communities and their engagement in invasive species management and governance (**section 6.4.1**) and related network analysis (**section 6.4.4.4**)

14. A headline indicator has been proposed for planning and tracking of progress towards target 6 of the Kunming-Montreal Global Biodiversity Framework, with opportunities to build on existing indicators for biological invasions (**section 6.6.3**).

6.6.1 Invasive alien species information needs

Knowledge gaps result from extreme heterogeneity in the collection and distribution of information and data. Given limited resources so-called gaps could therefore be defined by the questions and the problems that need solutions.

There are many unknowns about the biology of invasive alien species. These are, in part, known limits to what one knows about these species **(Box 6.18)**. Such limits can be described in terms of expressions of uncertainty or as knowledge gaps. The most problematic cases are those species that are entirely unexpected when they start to invade (so-called "unknown-unknowns", or "ignorance" in **Figure 6.18**; Taleb, 2007). Nevertheless, such cases may be novel only to certain sectors and locations. Therefore, inter- and intra- sectoral communication is essential to ensure that the number of surprises (unexpected cases) are minimized. Without such communication it is unrealistic to expect actors in policy and management of biological invasions to be adequately prepared.

Table 6.10 presents a synthesis of knowledge gaps identified in the IPBES invasive alien species assessment. Some of the knowledge gaps are relevant globally, for example the need to increase understanding of the outcomes of multiple interacting indirect and direct drivers of change in nature. Others apply to specific nations or regions and highlight the potential to improve the information and data flow from some regions. There are also gaps in the understanding of the interplay between social, economic and environmental factors that link policy and governance structures. These gaps are best perceived as opportunities to embrace emerging tools and technologies to underpin decision-making and management of biological invasions; indicators and targets on invasive alien species will benefit from improved scenarios and models which are currently limited by the knowledge gaps outlined in this chapter.

Box 6 18 **A case that illustrates the problems of unknowns in knowledge dissemination is the spread of ash dieback disease in Europe.**

This fatal disease of *Fraxinus excelsior* (ash) was detected in Europe the mid-1990s. It was then described as a new species *Chalara fraxinea* (Kowalski, 2006). It subsequently spread across the whole of the European range of *Fraxinus excelsior* (ash). In 2009 ash dieback was identified as being the anamorph of *Hymenoscyphus albidus* that had been described from Europe in 1850 and was apparently native (Kowalski, 2006). However, it was subsequently realized that *Chalara fraxinea* and *Hymenoscyphus albidus* are two cryptic species largely indistinguishable morphologically (Queloz *et al.,* 2011). One causes the pathogenic disease of ash and the other is a harmless saprophyte. This determination led to the establishment of yet another name, *Hymenoscyphus pseudoalbidus*. However, it was later found that *Hymenoscyphus pseudoalbidus* was conspecific with Japanese specimens named *Lambertella albida* (Zhao *et al.,* 2013). Finally, due to the nomenclatural rules of priority and recent changes in the Code of Nomenclature for algae, fungi and plants, the name was changed to *Hymenoscyphus fraxineus* (ash dieback; Baral *et al.,* 2014).

It took twenty years since ash dieback was first discovered in Europe for a stable name for it to be arrived upon, making it possible to connect the species to what is thought to be the native range in Eastern Asia. It is difficult to know how much this confusion over the origin and name of this species contributed to a slow response to the spread of the disease and how much this has obstructed research. This example illustrates the different types of uncertainty associated with biological invasions, in this case both taxonomic uncertainty as well as the need for more research on the distribution and identity of this species group. Furthermore, in the case of ash dieback, once its origins were revealed it allowed information to be brought together from distant sources in time and space.

6.6.1.1 Biodiversity information needs

All seven of the general types of biodiversity knowledge shortfalls (Hortal *et al.,* 2015) are equally relevant to knowledge on invasive alien species and the information needed to resolve this problem, i.e., taxonomy, distribution, populations, evolution, traits and functions, tolerances and ecological interactions. The section below details these types of information needs for policy support on biological invasions and discusses current sources of information and how these are created and disseminated.

(1) Addressing taxonomic biases in research

Taxonomic bias is pervasive in knowledge of biodiversity (Haque *et al.,* 2020; Zamora-Gutierrez *et al.,* 2019), conservation sciences and practices (Creighton & Bennett, 2019) and ecological research (Rosenthal *et al.,* 2017), and such biases have not changed over time (Creighton & Bennett, 2019; Rosenthal *et al.,* 2017; Troudet *et al.,* 2017; **Chapter 2**, **section 2.3.1.11** for an example of information gap on animals). There are probably a number of causes for this. When compared, invasive alien species were more likely to be studied than non-invasive naturalized species (Pyšek *et al.,* 2008), although for many taxonomic groups invasive alien species are also poorly investigated. Other factors that drive taxonomic biases in research include societal preference, research funding, conservation policy (Jarić *et al.,* 2019; Troudet *et al.,* 2017) and probably also research tractability of the species.

Pauchard *et al.* (2011) found that the principal focus of invasive alien species publications in Latin American and Caribbean countries was introduced animals (65 per cent, 119 articles), and often the more tractable or emblematic species. The most studied aquatic alien taxa in South America were fish (26.8 per cent) and molluscs (25.2 per cent), followed by crustaceans, algae, cnidarians, polychaetes and ascidians (Schwindt & Bortolus, 2017).

Taxonomic biases limit the ability to understand the complex processes and interactions that underlie biological invasions. The information obtained from the study of single taxonomic groups is not necessarily transferable to others, for example, due to differences in impacts and dispersal pathways (Jeschke *et al.,* 2012). Therefore, studies targeting few species render generalizations either inaccurate or incomplete (Jeschke *et al.,* 2012). In invasion biology, few studies have examined failure of invasions (Pyšek *et al.,* 2008). However, studying both biological invasion success and failure is important to test invasion hypotheses and understand the overall process of biological invasions (Zenni & Nuñez, 2013; Diez *et al.,* 2009).

Given that taxonomic bias is recognized, any effort to minimize this shortfall will improve information of biological invasions and produce better informed management and policy decisions (Pyšek *et al.,* 2008). Strategies to reduce taxonomic bias include advertising poorly documented and under-studied species among professional and citizen scientists (Troudet *et al.,* 2017), and promoting cross-taxonomic studies that involve a set of invasive alien species that belong to different taxonomic groups (Jeschke *et al.,* 2012).

Tractability of collecting and processing species occurrence data is likely to be a component of these research biases.

Box 6.19 Genetic tools for detection, characterization and traceability of marine and aquatic invasive alien species.

The management of biological invasions can be improved through accurate identification of species to connect with information on their natural history and ecology. Traditionally, these species were identified using methods that require direct observation, or occasionally tracks and signs. In marine and aquatic ecosystems this is particularly problematic due the inaccessibility of working in much of the habitat. Genetic characterization provides an accurate molecular identification of the species and generates information to parameterize population models, genetic relationships, connectivity among populations and the effective population size (Díaz-Ferguson & Moyer, 2014; Díaz-Ferguson & Hunter, 2019; Estoup & Guillemaud, 2010). Molecular genetics can be used to detect founder effects, bottlenecks and hybridization processes that can occur during invasion (Roman & Darling, 2007; Frankham *et al.,* 2010). Genetic approaches can be used to answer questions such as: Are invasive alien species present in an area or region (application challenged in areas where information on native biota is incomplete, e.g., deep sea)? How many organisms are present in an area? Are these organisms able to reproduce? Where are the source populations of these organisms? (A. Barbour *et al.,* 2010; Estoup & Guillemaud, 2010).

For example, identification, genetic characterization and tracking of invasive alien species is only possible due to the development of genetic markers (Pochon *et al.,* 2013). A genetic marker is a deoxyribonucleic acid (DNA) target sequence used for molecular identification of a species or to determine its variability (Díaz-Ferguson, 2012). Since the advent of polymerase chain reaction (PCR; **Glossary**) and quantitative PCR methods several markers have been developed to identify, track and characterize the spatial variation of marine and aquatic populations including invasive alien species (Hulata, 2001; Féral, 2002). More recently the use of mini barcoding and quantitative PCR detection of environmental DNA allows scientists and managers to detect fragments of DNA left behind by species in non-living components of the environment (i.e., soil, sediments and water) without the need to observe or collect the focal species (Díaz-Ferguson & Moyer, 2014). Environmental DNA, although still developing as a technology to narrow uncertainty, has been demonstrated to be efficient at detecting species with a small population size such as invasive alien species in the course of establishment, or imperilled, threatened and endangered species (Jerde *et al.,* 2011). Marine ecosystems are just one of the areas where environmental DNA surveys are likely to radically change the detection and monitoring of invasive species (Chown *et al.,* 2015; Darling *et al.,* 2017; Holman *et al.,* 2019). These methods and others are covered in more depth in **Chapter 5**, **section 5.4.4.2**.

Next generation sequencing (environmental DNA; **Box 6.19**), machine observations (e.g., camera traps and space-based remote sensing) and machine learning will likely make new taxonomic research more feasible.

(2) Overcoming gaps in impact analysis

The number of alien plant species worldwide has been estimated to be in the thousands, but in 2013, robust impact studies were only available for fewer than 200 species (Pyšek *et al.,* 2013; **Chapter 4**). For example, information on the impacts of alien species on biodiversity and on Indigenous Peoples and local communities is a key gap, with particularly acute gaps on impacts across Africa and Central Asia and at the ecosystem level (**Chapter 4**, **sections 4.6.4** and **4.7.2**; **Table 6.1**). Even more substantial information gaps occur in the marine realm where only a small proportion of organisms have been evaluated for their impact in their non-native range, particularly in the deep sea and pelagic open ocean. In a meta-analysis of the impacts of invasive macroalgae data on only 12 species were found, of which only eight had experimental evidence of impact (Maggi *et al.,* 2015). Another review of marine aliens in Europe found only 13 per cent of the reported impacts were supported by experiments and most were only inferred from abundance of the alien and co-occurrence with potentially impacted native species (Katsanevakis *et al.,* 2014). See **Chapter 4**, **section 4.7.2**, for more details on the data and information needs to understand impacts and **Chapter 5**, **section 5.2**, for other use in decision-making.

(3) Reducing geographic bias in research

Invasive alien species are pervasive, but there is disparity of data availability and research efforts across geographic regions. All the studies that examined geographic patterns of data availability (i.e., species occurrence data) and research effort (i.e., publication efforts, ecological study sites) showed geographic biases with a general pattern of high data availability and research efforts in Europe, Australia and North America and low availability in Asia and Africa (Boakes *et al.,* 2010; Yesson *et al.,* 2007; **Chapter 2**, **Figure 2.6**). Such geographic bias is also prevalent among scenarios and modelling studies related to invasive alien species (**Chapter 1**, **section 1.6.7.3**). Geographic bias has already been highlighted in the other chapters (particularly **Chapter 2**, **Figure 2.6** and **section 2.4**; **Chapter 4**, **section 4.7.2**; **Box 6.18**). The recent publication of national checklists of invasive alien species for most of the world's countries helps to overcome this geographic bias, with the focus of these checklists being on invasive alien species with biodiversity impacts and not on all alien species (Pagad *et al.,* 2022).

A systematic review investigated invasive alien species in natural ecosystems (Lowry *et al.,* 2013) and found that such studies were mostly concentrated in North America, Western Europe, Eastern Australia, New Zealand and Hawaii, while there was a dearth of studies in countries located in the tropics, such as in Asia, Africa and Central and South America. This pattern is close to the geographic distribution of sites of overall ecological studies in terrestrial systems (L. J. Martin *et al.,* 2012). Nearly three-quarters of field studies have been done in terrestrial systems, with freshwater and marine ecosystems significantly underrepresented in studies of natural ecosystems (Lowry *et al.,* 2013; **Chapter 2**, **section 2.5.1**). Similarly, countries with a high percentage of IUCN Red Listed vertebrate species that are threatened by invasive alien species (e.g., Mexico, Colombia, Peru, Argentina, Madagascar, India, Indonesia) have a low percentage of publications on biological invasions (Bellard & Jeschke, 2016). In contrast, the countries with a low percentage of invasive alien species-threatened Red Listed species (e.g., Canada, United States, China) have high publication efforts on biological invasions. Alien birds, for example, have been reported in 247 regions across the world, but environmental impact data is available for only 60 regions (24 per cent; T. Evans & Blackburn, 2019).

Taking the example of Latin American and Caribbean countries, the number of articles on invasive alien species over the last 20 years was 344, with an increase after 2003 and a higher percentage between 2003 and 2008 (Pauchard *et al.,* 2011). The country with most articles on invasive alien species was Argentina (105), followed by Brazil (85), Chile (53) and Mexico (41). These four countries contributed 82.5 per cent of all the articles on invasive alien species from Latin American and Caribbean countries. Differences among countries reflect the asymmetry in invasive alien species research among the Latin American and Caribbean countries, but also the effect of country size. Most countries on the continent began publishing on invasive alien species only in the 1990s (Speziale *et al.,* 2012). However, the differences among countries in research effort on alien species does not seem to be just a matter of research budgets, nor differences between developed or developing countries, nor differences due to their higher biodiversity and the interest in protecting it. Although an explanation might be a lower number of invasive alien species in South America, scientific information to properly assess this remains lacking (Speziale *et al.,* 2012).

Generating timely and adequate information across geographic regions is an opportunity for implementing effective management strategies. This is particularly important for the aquatic realm, where eradication and control efforts are viable only at the very initial stages of the invasion process (Lehtiniemi *et al.,* 2012). Lack of information in regions highly vulnerable to invasive alien species may result in a delayed response to invasive alien species at an early stage (Bellard & Jeschke, 2016; **Chapter 5**, **section 5.6.2**). As a consequence of a lack of monitoring, occurrences of invasive alien species can remain unnoticed, thereby reducing the chances of early detection and eradication.

Low research investment and data availability in certain regions, such as parts of Asia and Africa (Bellard & Jeschke, 2016; T. Evans & Blackburn, 2020; Lowry *et al.,* 2013; Pyšek *et al.,* 2008), can mean that these regions are less understood and thus underrepresented when frameworks and theories are developed for biological invasions and their management. Therefore, collaborations between invasion scientists in developed and developing countries, and developing research capacity in less developed countries improves data availability for better understanding of the processes associated with biological invasions (Bellard & Jeschke, 2016). Since geographic biases are also apparent in authorship (corresponding author) of the research articles published in journals like *Biological Invasions*, with disproportionately high submission by authors from North America, Europe and Australasia, such biases can be minimized by encouraging manuscript submissions from countries of other regions (Nuñez *et al.,* 2021). Owing to a lack of study or expertise, discovery of invasive alien species in invaded areas can lag by decades or longer. The numbers of recorded marine invasive alien species are, for example, particularly likely to be underestimated. The size of this gap is difficult to assess, and it varies among different taxa, habitats and regions. Information is most accurate for large, conspicuous, multicellular organisms (Galil *et al.,* 2014; Ojaveer *et al.,* 2015).

(4) Invasive alien species – native and invaded ranges

There are significant data gaps on the spatial delimitation of the edges of species native and invaded ranges, particularly at scales fine enough to inform management decisions (Hardisty *et al.,* 2019; Latombe *et al.,* 2017). Species distribution, specifically native and invaded range, are derived from a wide variety of sources. Indeed, how the definition of what constitutes a native or alien species varies globally depending on the history of human migrations (**Chapter 1**, **Figure 1.1**, **sections 1.3.1** and **1.5.2**; Carthey & Banks, 2012). These differences in definition influence the scope of invasive alien species policy and although the differences can be subtle, they could be considered when directly comparing national alien species inventories (Jackson *et al.,* 2017). Native status is derived from the definition and an evaluation of the available evidence. Such evidence might be direct, such as, from fossil remains, specimens and first-hand accounts. However, native status is often evaluated indirectly from an assessment of the habitat, distribution, evolutionary history and life history of a species (Essl *et al.,* 2018; Hoagstrom *et al.,* 2009). For certain taxonomic groups evidence is particularly elusive. For example, rare soft-bodied organisms in deep marine habitats are rarely surveyed, and often given the status of "cryptogenic species" (Carlton, 1996; **Glossary**; **Chapter 2** for more examples). Assessments of native status are often made in plant and amimal surveys and are published in taxonomic checklists. In most cases the categorization is uncontroversial. However, in some cases the designation can have political and practical consequences.

6.6.1.2 Uncertainty of information on introduction pathways

Pathways of introduction, particularly in the marine realm, are not always known with high certainty (**Chapter 2**, **section 2.1.2**). Only occasionally are there documented deliberate releases, or clear evidence linking donor and invaded regions, and where species' life history and historical records point to an obvious introduction pathway. In most cases, vectors and pathways are assumed based on the biological and ecological traits of the species, the habitats they occupy in the native and introduced range, and the timing of first record, trade patterns, human use and vector activity (Faulkner *et al.,* 2016; Galil *et al.,* 2014; Hewitt *et al.,* 2004; Wonham & Carlton, 2005). For most species the precise details of their introduction history will not be known with any certainty (Wonham & Carlton, 2005). This might be the reason why only 10 per cent of the studies related to future scenarios and modelling of invasive alien species included pathways (**Chapter 1**, **section 1.6.7.3**). This limits options for governance because without adequate information on introduction pathways, it is difficult to implement policy for biosecurity, prioritize where to invest in interventions to manage biological invasions, or assign responsibility to actors responsible for unwanted introductions (**Chapter 2**, **section 2.1.2** for more information on knowledge and data gaps on introduction pathways and **Chapter 5**, **section 5.3.1** on pathway management strategies).

6.6.1.3 Balancing basic and applied research on biological invasions

There is no clear dividing line between so-called, "pure" research conducted solely for increasing information and applied research that has clear practical applications. Nevertheless, the distinction is made below to help us evaluate the balance of funding and resources devoted to different aspects of science.

In response to the problem, the number of peer-reviewed publications on biological invasions has increased steadily (Vaz *et al.,* 2017). These research publications can be broadly divided into basic research focusing on the process, patterns and impacts of invasive alien species, and applied research, focusing on their management and mitigation. While basic research allows us to understand temporal and spatial patterns of invasive alien species and their underlying mechanisms, applied research builds on the information generated from basic research to develop contextualized management strategies at varying spatial and governance scales.

Basic research dominates peer-reviewed publications on biological invasions (Esler *et al.,* 2010). This disparity may be accounted for by the publication of much applied research in grey literature, such as governmental reports (Lowry *et al.,* 2013). There is also large variation in the use of research methods in basic research. For example, nearly half (46 per cent) of the studies that attempted to understand the fundamental process of biological invasions are field observational studies, while less than one-fifth (18 per cent) were field experimental studies (Lowry *et al.,* 2013).

Similarly, a meta-analysis of biological invasions research from Latin American and Caribbean countries, between 2006 and 2008 found that only 5 per cent of publications focussed on invasive alien species management (Pauchard *et al.,* 2011). Of 185 articles, 57 per cent focused on analysing only one species and 43 per cent on more than one species. Invasion patterns were analysed in 39 per cent of them, invasion mechanisms in 25 per cent, bibliographic invasive alien species reviews comprised 12 per cent, impacts were the focus of 19 per cent, and new invasive alien species were reported in 17 per cent (Pauchard *et al.,* 2011). Basic research focussed on invasive alien species listing, population dynamics, biotic factors that promote invasion and ecological relationships (facilitation, competition and mutualism). The applied research focused on restoration, eradication or control measures (Pauchard *et al.,* 2011 and references therein). Publications on aquatic and marine invasive alien species in South American countries cover six major basic research themes: biology/ecology (58 per cent); invasive alien species new records (20.5 per cent); aquaculture (3 per cent); range expansions; genetics; and general reviews of aquatic species with a remarkably low number (all below 3 per cent), although the proportion of applied research papers is not reported (Schwindt & Bortolus, 2017). Uruguay is an example of a country that has developed both basic and applied research on terrestrial and aquatic non-indigenous and invasive alien species in the last 15 years (Brazeiro *et al.,* 2021; Brugnoli & Laufer, 2018).

Despite the apparent greater investment in basic compared to applied research, knowledge of some basic science questions is still inadequate globally. For example, in an evaluation of country-level checklists of invasive alien species, these were found to suffer from one or more of 10 different error categories, mostly related to poor information or measurement errors (epistemic uncertainties; McGeoch *et al.,* 2012). Important errors include: species misidentified as alien due to taxonomic uncertainty; failure to recognize invasive alien species as a result of insufficient surveying; overestimation due to the coarse spatial resolution of alien species distribution maps or species listing; delays in the publication of data; poor data management that leads to data being unfindable; incorrect decisions to list a species as "alien" (**Glossary**) due to inadequate and ambiguous information on species' native range; incorrect decision of listing species as "invasive" due to limited information on their population dynamics and impacts, and lack of evidence-based standardized and universal criteria for designating a species as invasive (**Chapter 5**, **section 5.6.2.5**, **Table 5.12**).

While acknowledging that the errors could not be eliminated completely, (McGeoch *et al.,* 2012) suggested some measures to minimize errors associated with country-level checklists, including expanding investment in invasive alien species research and monitoring, improving findability and accessibility of invasive alien species data, improving the speed at which a correction can be applied to a list, and improving transparency and repeatability of invasive alien species listing methods, along with standardized uses of terms and concepts.

Information generated from basic research is translated to management and policy responses through applied research. Poor representation of applied research in peer-reviewed publications (Esler *et al.,* 2010), might have contributed to the continuous increase in the number of alien species across taxonomic groups and biogeographic regions (Seebens *et al.,* 2018). Additional investment of resources for applied research would generate information suitable for managers and policymakers to make decisions.

6.6.1.4 Socioecological research to support policy and management

The prevention and sustainable management of biological invasions depends on an effective integration of environmental, social and economic components in management strategies (D. L. Larson *et al.,* 2011). This implies that an understanding of the socio-economic dimensions of biological invasions is as important as the knowledge held in the fields of biology, taxonomy and other scientific specializations. In spite of the obviously strong human and social dimensions of the invasion process, impacts of invasive alien species and their management (Shackleton, Shackleton, *et al.,* 2019), a 2017 study found that more than 90 per cent of research publications on biological invasions since 1958 were related to ecology and environment, while only 3.2 per cent of the publications primarily addressed socioecological dimensions (Vaz *et al.,* 2017). Similarly, only 3 per cent of 364 research articles related to invasive alien species produced by South Africa's iconic Working for Water Programme between 1995 and 2017 addressed human dimensions associated with invasive alien species (Abrahams *et al.,* 2019).

These scenarios suggest an under-representation of socially relevant research in biological invasion science; expanding it to include social dimensions of invasive alien species through interdisciplinary and transdisciplinary approaches will help to generate socially relevant additional data and information (Abrahams *et al.,* 2019; Esler *et al.,* 2010; Shackleton *et al.,* 2017; **Chapter 4**, **Box 4.5** and **section 4.7.1**). These approaches can not only better inform current management and policy decisions but may also better predict future invasions in an era of global change (Kueffer *et al.,* 2014). Furthermore, a transdisciplinary approach linking ecological and social sciences to generate data and knowledge is also helpful in building trust between communities and resource managers while managing invasive alien species that carry social value (Beever *et al.,* 2019). Ultimately, integrating knowledge systems will be the most fruitful approach to addressing biological invasions, and this includes crosscutting work with the fields of epidemiology, health sciences, economics, political science, sociology, psychology, anthropology, history and others.

6.6.1.5 Knowledge of Indigenous Peoples and local communities[15]

It has long been recognized that Indigenous Peoples and local communities hold unique knowledge on biodiversity. They often inhabit remote, biodiverse landscapes from which they derive diverse resources. Their knowledge may not be documented but may be important to understand ecosystem processes and resource management. Indigenous and local knowledge has been recognized and accepted as relevant to the development and good quality of life of Indigenous Peoples (Sillitoe & Marzano, 2009; Williams & Hardison, 2013). Nevertheless, Indigenous Peoples and local communities have often been excluded from decision-making and would wish to take more control over their cultural and intellectual knowledge (Bolhassan *et al.,* 2014). Historically the power imbalance between the holders and potential users of traditional knowledge have meant that the benefits derived from this knowledge have not been shared equally. Mistrust and misunderstanding has often developed in both directions between academic science and Indigenous Peoples and local communities (Bohensky & Maru, 2011; Mulligan & Stoett, 2000).

Internationally, the need to ensure equitable distribution of the benefits of knowledge and genetic resources has been recognized in the Nagoya Protocol (Buck & Hamilton, 2011). Though the Nagoya Protocol does improve the situation, it

15. Data management report available at: https://doi.org/10.5281/zenodo.5760266

is an intergovernmental agreement, and its implementation varies with jurisdiction and does not necessarily include the needs, aspirations and wishes of Indigenous Peoples and local communities. Furthermore, it is far from clear how knowledge, resources and data on invasive alien species themselves should be treated under the Nagoya Protocol because the Protocol is concerned with the benefits of biodiversity and invasive alien species are largely detrimental. The origin of the knowledge and genetic resources can be obscure, and species used by Indigenous Peoples and local communities traditionally are often alien species (e.g., de Almeida *et al.,* 2010). In the case of biological control agents best practices have been drawn up for access and benefit sharing (Mason *et al.,* 2018; D. Smith *et al.,* 2018). However, little consideration of the interests of Indigenous Peoples and local communities is given in these best practices.

Knowledge of invasive alien species by Indigenous Peoples and local communities is vital for not only the community itself, but also for policymakers and practitioners for the purpose of implementing control and management options (Williams & Hardison, 2013). An analysis of the sources of invasive alien species knowledge showed that the majority of Indigenous Peoples and local communities obtain their knowledge from self-learning, observation and experimentation. Another large group mentioned a mix of both contemporary and traditional knowledge sources. A smaller percentage relied on scientific knowledge, showing that Indigenous and local knowledge plays a big role. This also shows how important it is to incorporate both Indigenous and local knowledge and contemporary science while informing policies (Bolhassan *et al.,* 2014).

Communication of information and Indigenous Peoples and local communities[15]

A diverse array of stakeholders and institutions can work together to ensure smooth and effective communication of invasive alien species information. This is not only relevant to Indigenous Peoples and local communities but also to governments, policymakers and to bridge the gap between research and implementation (Barnard & Waage, 2004; Piria *et al.,* 2017). An analysis done on organizations with effective communication on invasive alien species showed that central governments (39 per cent) often have the financial capacity and resources to effectively communicate on invasive alien species. Thanks to their proximity to Indigenous Peoples and local communities, local governments (36 per cent) are also in a position to effectively communicate on invasive alien species. Person-to-person communication (individually; 32 per cent) can be effective as well but often faces geographical limitations and language barriers, which could lead to misinformation (Wald *et al.,* 2019; Zeng *et al.,* 2021). Finally, there are cases of effective communication on invasive alien species through community-led organizations (22 per cent), international and non-governmental organizations (16 per cent).

Knowledge and information needs of Indigenous Peoples and local communities[15]

For an effective and holistic involvement of Indigenous Peoples and local communities and other stakeholders in the control of invasive alien species and management of biological invasions, knowledge dimensions and improvement are vital (IUCN, 2000; Shine, 2003) both in science and practice. Many Indigenous Peoples and local communities (43 per cent of the reviewed case studies) are seeking scientific knowledge, through training, reading and contacting governments and non-governmental organizations, on how to control and manage invasive alien species. Thirty per cent are seeking Indigenous and local knowledge while 17 per cent combined both Indigenous and local knowledge and scientific knowledge. In only 10 per cent of the reviewed case studies, Indigenous Peoples and local communities seek additional knowledge through self-learning. From these findings, it is important for all players to make their data and information available and useful (Groom *et al.,* 2017) to all the stakeholders. The pace towards meaningful participation of Indigenous Peoples and local communities into various sectors of management could be fast-tracked to fill knowledge needs.

Indigenous Peoples and local communities and scientific knowledge[15]

There is significant agreement between Indigenous and local knowledge and science on invasive alien species. There are also some significant divergences, which suggests that continued dialogue will be useful (Byrne *et al.,* 2020; Lopian, 2005) including on species identification, their impacts and pathways of spread. For example, many Indigenous Peoples and local communities recognize invasive plants or animals as foreign in their areas. They were however ready to try different ways to make these useful, for example as food for livestock or food for humans. In other cases, Indigenous Peoples and local communities did not recognize some species as alien, while science would classify them as invasive alien species. This will likely have ramifications for effective communication and control measures, and the involvement of Indigenous Peoples and local communities in decision-making on environmental conservation in different settings. Indigenous Peoples and local communities are using science to supplement and further build on their understandings of invasive alien species. Some report that they supplement the knowledge they acquired from observation and experimentation (self-learning), with science-based training they received.

6.6.1.6 Information needed for invasion scenarios and models[16]

Given the high socioecological relevance of invasive alien species, it is essential to understand how future trends and impacts can be mitigated. There is a strong need to develop scenario narratives, and subsequent quantitative analyses, that assess possible outcomes of various potential trends in alien species distribution, spread and impacts on the environment, economy and society. Here the integration of all information, whether from scientific hypothesis testing or Indigenous and local knowledge, can be vital to developing realistic qualitative baselines to inform subsequent models. Together with robust and relevant targets (e.g., comparable to the 1.5°C target in the climate change discourse), scenarios can underpin decision-making by providing examples of various opportunities and avenues to reach these targets and so inform policy nationally and internationally.

Scenarios and model literature on biological invasions reveals several information needs about policy, future research and action on biological invasions. Most (about 70 per cent) of the studies including both scenarios and models were based on alien species distributions, with only 30 per cent of studies focusing on other biodiversity variables. Species abundance or impacts of invasive alien species and life-history information (e.g., growth, survival) are largely absent from scenarios (19 per cent, 9 per cent and 6 per cent of the publications). The literature is dominated by exploratory scenarios, while target-seeking and policy scenarios are only marginally represented (6 and 7 per cent respectively). Studies using expert-based opinion are practically absent in the available scenarios and models literature (only 1 per cent of papers consider expert opinions). Publications including scenarios and models largely neglect anthropogenic drivers such as demographics, governance, values and technology (each represented in less than 2 per cent of the publications), as well as interactions among different environmental, socio-economic, or cultural drivers. Finally, most studies do not consider policy and management (4 per cent and 21 per cent respectively).

6.6.2 Options for strengthening the generation and flow of information relevant for policy and management

When facing information gaps during the development of governance and policy for biological invasions, or when planning for their management, understanding the type of information gap provides an effective guide for identifying the most appropriate decision-support tools **(Figure 6.18)**. Using a risk assessment framework, it is possible to identify information gaps on the likelihood of invasion outcomes and use this to construct knowledge response options **(Figure 6.18)**. This is also a mechanism for directly connecting specific management scenarios with scientific support tools, including those discussed in the following sections and elsewhere in the assessment (**Chapter 5**, **section 5.6.3.2**).

6.6.2.1 Citizen science as an option for generating information on invasive alien species

Ecological research has long benefited from the voluntary participation of the general public, with participating members often being referred to as citizen scientists (Dickinson *et al.,* 2010; **Chapter 1**, **Box 1.15**; **Chapter 5**, **section 5.4.3.2.a**). In recent decades, citizen science has emerged as an indispensable tool for generating complementary data and information relevant to addressing the problems of invasive alien species and other global environmental changes (Theobald *et al.,* 2015) by tapping the potential of technologies from websites to smartphones for recording biological and environmental data (August *et al.,* 2015). Citizen science approaches can cover larger geographic areas and collect data over a longer period of time than professional scientists alone with the investment of comparable resources (McKinley *et al.,* 2017) and has contributed substantially to monitoring of global biodiversity (Chandler *et al.,* 2017). Some citizen science initiatives have filled geographic gaps for particular taxa (e.g., eBird; Amano *et al.,* 2016; B. L. Sullivan *et al.,* 2014). The options for citizen science to help fill information gaps on invasive alien species are therefore promising (**Chapter 1**, **Box 1.15**).

Commonly recorded parameters in citizen science initiatives are species name, geographic coordinates, photographs, species abundance and habitat description (Johnson *et al.,* 2020). From these primary data, several essential biodiversity variables (EBVs) such as species distribution, population abundance, phenology, demographic traits, migratory behaviours and disturbance regimes have been derived (Chandler *et al.,* 2017). Citizen science has been successfully used in spatio-temporal distribution mapping of invasive alien species (Brown *et al.,* 2018; Johnson *et al.,* 2020; Mannino & Balistreri, 2018; Marchante *et al.,* 2017), prediction of species' suitable climatic niches (Johnson *et al.,* 2020; Tiago *et al.,* 2017), early detection (Giovos *et al.,* 2019; Hiller & Haelewaters, 2019; Palmer *et al.,* 2017; **Box 6.20**), and understanding animal behaviour and plant phenology (Johnson *et al.,* 2020). In addition, citizen science can be helpful in spotting elusive invasive alien species, such as *Python bivittatus* (Burmese python; Falk *et al.,* 2016). It increases public awareness and involvement in the management of invasive alien species while generating scientifically valid data at a very low cost (McKinley *et*

16. Data management report available at: https://doi.org/10.5281/zenodo.5706520

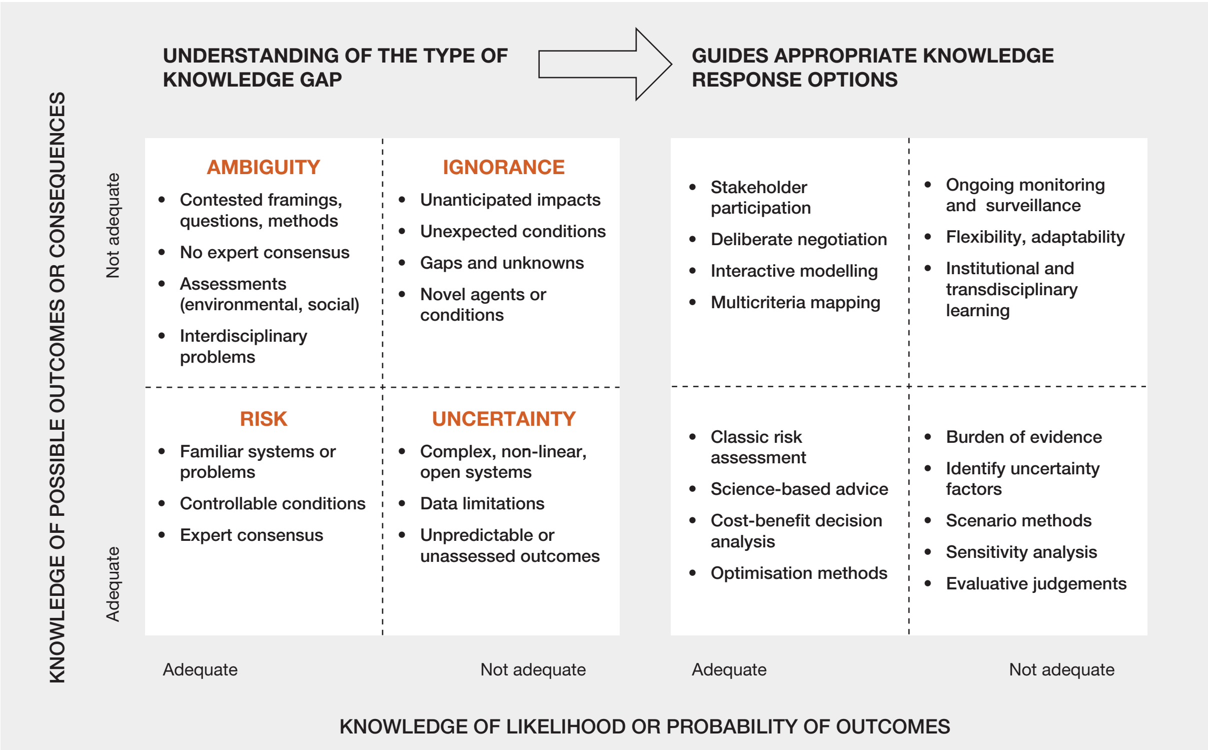

Figure 6 18 **Governing invasive alien species knowledge.**

An understanding of the multiple reasons for invasive alien species knowledge being either incomplete or inadequate (left), leading to the identification of appropriate options for strengthening the evidence base for invasive alien species governance (right; position of quadrants in right panel match those on left). The categories show how traditional, linear invasive alien species risk analysis methods (lower left quadrants in each panel) are on their own inadequate tools for governing the knowledge on invasive alien species needed to inform policy. For example, "Assessments" outline the broad suite of policy questions relevant to biological invasion, make it clear that no single solution is adequate and that options can be context dependent (Stirling, 2010). Adapted from Linke *et al.* (2016) https://doi.org/10.1007/978-3-319-27006-7_8, under license CC BY 4.0 and Stirling (2010) https://doi.org/10.1038/4681029a, under copyright 2010, Springer Nature Limited.

al., 2017; Palmer *et al.,* 2017). For recording species' distribution data, citizen science can be more cost-effective, nearly eight times less in case of Mosquito Alert, than the traditional expert-driven approach for data of comparable quality (Palmer *et al.,* 2017). Citizen science data can contribute substantially to existing species information data (e.g., early detection, species distribution range size, regional species pool) collected by professional scientists (Crall *et al.,* 2015; Palmer *et al.,* 2017; Soroye *et al.,* 2018).

Nevertheless, there are limitations to the use of citizen science, as shown by Pocock *et al.* (2019). There are large taxonomic and geographic gaps in data. For example, eight of the 26 citizen science initiatives with a web/mobile app evaluated focused on single (e.g., Mosquito Alert) or several priority invasive alien species (e.g., That's Invasive!, iMapInvasives) while the remaining initiatives (e.g., iNaturalist, eBird) include both native and alien species (Johnson *et al.,* 2020). Similarly, the number of invasive alien species focused citizen science initiatives leading to scientific publication was higher in Western Europe (11) and North America (10), and there was no such initiative in Asia (Johnson *et al.,* 2020). This is expected because 42 per cent and 32 per cent of all citizen science programme activities (N = 420) linked to biodiversity monitoring have been operating in North America and Europe, respectively (Chandler *et al.,* 2017). Expanding taxonomic and geographic coverage of citizen science initiatives increases the scientific values of the data generated. Adaptive sampling, whereby volunteers are guided to make observations in locations which will optimally improve species maps, has the potential to improve the effectiveness of citizen science for early warning of invasive alien species.

Citizen science programmes for invasive alien species detection and surveillance have recently expanded to marine systems (Delaney *et al.,* 2008; Thiel *et al.,* 2014), with active involvement of fishers, divers and the public at large. The contribution of citizen science is expected to expand over time, helping to address the limited funding and spatial/temporal coverage available with current programmes (Pocock *et al.,* 2018, 2019). However, some constraints could be considered in programme design and expectations, including selecting large-bodied, conspicuous taxa with easy-to-recognize diagnostic characteristics. In the future, genetic tools may be also adopted by citizen science programmes to enhance the potential taxonomic scope and for validation purposes (Ojaveer *et al.,* 2018).

Data from citizen science can contribute significantly towards a better understanding of biological invasions and other global environmental changes, provided that these data are adequately used in peer-reviewed publications (Theobald *et al.,* 2015). Some scientists are reluctant to use citizen science data, though relevant to their objectives, due to uncertainties related to data collection methods and data attributes (Burgess *et al.,* 2017). Accompanying citizen science data with metadata describing data quality, availability, conservation issues being addressed, study taxon and system, spatial and temporal scales of measurement, sampling intervals and data standardization protocols improves transparency and encourages scientists to use citizen science data (Burgess *et al.,* 2017).

In spite of the voluntary contribution of participants, citizen science data are not always openly shared (Groom *et al.,* 2017). In a recent study, nearly half (54 per cent) of the 26 invasive alien species-relevant citizen science initiatives evaluated did not share data with other similar initiatives or other biodiversity data-sharing facilities (Johnson *et al.,* 2020). Sharing data among other citizen science initiatives working in similar geographic regions/scales and taxa, and consolidating results in shared databases, would increase use values of citizen science data in scientific research, and policy and management decisions (Johnson *et al.,* 2020).

6.6.2.2 Professional networks and platforms for coordination and information exchange

It is important to understand patterns and processes of biological invasions at varying spatial scales for effective management. Several information systems and approaches are available at national, regional, continental and global

Box 6 20 **Citizen science for early detection and rapid response.**

After prevention, early detection and rapid response (EDRR) is the most effective and least costly way to manage invasions. The main hitch is the inability to generate enough resources to support a sufficiently large professional staff to survey with adequate frequency the vast amount of land and water that can house recently arrived invaders. Yet a well-informed, educated public can vastly increase the number of “eyes” on the lookout for incipient invasions; and individual citizens in the course of other activities have spotted hugely damaging invasive alien species in time to permit complete eradication before the species had spread widely. Such was the case of an individual sawing off an overhanging tree branch in Chicago and noting signs of *Anoplophora glabripennis* (Asian longhorned beetle; Kridel, 2008; Manier & Martin, 1998) and a recreational diver finding the famed *Caulerpa taxifolia* (killer algae) in a California lagoon (Muñoz, 2016).

Rather than simply relying on publicity about invasions and the hope that an alert citizen will happen to observe a recently arrived invader and know how to report it, several organizations have trained citizen volunteers and organized their search activities to maximize the probability of detecting recently arrived and potentially invasive plants. In the Australian state of Victoria, the Victorian Weed Spotters program, initiated in 2008, trains citizens to find and report state-prohibited weeds, and these reports are viewed as valuable components of the state programme to prevent weed establishment (Munakamwe *et al.,* 2018). In 2012 in the state of Washington, United States, the Pacific Northwest Invasive Plant Council organized an EDDR Citizen Science Invasive Plant Program to train volunteers to support county, state and federal management agencies to locate and eradicate invasive plants, a programme that has now expanded to the state of Oregon (PNW-IPC, 2018). Perhaps the most expansive such programme was organized by the Invasive Plants Atlas of New England (IPANE) in 2001 to integrate independent efforts of the six New England States. The programme, associated with an atlas of invasive plants in this region, trains volunteers both to find and to identify invasive plants, assigning particular monitoring routes. The programme is associated with EDDMapS (EDDMapS, 2019), a system of reporting and mapping alien species in the United States. However, the death in 2010 of the key innovator of the IPANE programme has led to a dearth of funds for training volunteers, and the programme itself has lapsed.

Aceves-Bueno *et al.* (2015) examined 83 citizen science programmes that entailed monitoring, of which five (including IPANE) targeted invasive alien species. In addition to substantial contributions to various resource management activities (including managing invasions), this study pointed to the important benefit of engaging a wide swathe of the public in recognizing and dealing with environmental issues, whether or not they associate themselves with formal programmes such as those described above. An important consideration, however, is the accuracy of monitoring records reported by citizen scientists, as noted by Crall *et al.* (2011) for an organized effort to monitor for invasive plants. This consideration supports the importance of substantial training for citizen volunteers, which bears a non-negligible cost. Another important step is to implement validations of citizen science invasive alien species data by experts (e.g., taxonomists) or through automated machine learning approaches (e.g., computer vision) or even by Artificial Intelligence.

scales to support information flow across jurisdictions (Katsanevakis & Roy, 2015; Mulligan & Stoett, 2000). Global analyses, for example, are essential for informing international policy to address the problems of invasive alien species, including those focussed on particular habitats and ecosystems. Collecting empirical data from diverse geographic areas will be improved by collaboration across strong networks of researchers, managers, practitioners and informaticians (Packer *et al.,* 2017). Previous and current examples of such collaborative networks include the Mountain Invasive Research Network (MIREN); European Information and Research Network on Aquatic Invasive Species (ERNAIS); Global Invader Impact Network (GIIN); Global Invasions Research Coordination Network; *Phragmites* Network (PhragNet); the Southern Hemisphere Network on Conifer Invasions (Packer *et al.,* 2017) and the Pacific Invasives Partnership, that is part of the Secretariat of the Pacific Regional Environment Programme (SPREP; for additional examples see **Supplementary material 6.3**).

International networks

GRIIS is supported by a broad collaboration of agencies and country experts. GRIIS provides open country checklists as well as a collated compendium of invasive alien species across countries (Pagad *et al.,* 2018, 2022). GRIIS data are openly available through an online repository, through the Global Biodiversity Information Facility (GBIF), and *via* country pages of the CBD Access and Benefit-sharing Clearing-House. GRIIS is founded on a transparent set of methods and biodiversity information standards (**section 6.6**) and provides both a baseline information source and mechanism for supporting an international information platform for invasive alien species (Pagad *et al.,* 2018, 2022).

At its 15th meeting, the CBD COP called for multiple international networks to continue supporting the implementation and monitoring of the Kunming-Montreal Global Biodiversity Framework (including Target 6 for invasive alien species), most notably the Statistical Commission, the Group on Earth Observations Biodiversity Observation Network (GEO BON), the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem and Services (IPBES) and the Biodiversity Indicators Partnership (BIP) (CBD, 2022b), as well as the ISSG, GBIF and CABI (CBD, 2022c).

Previous and current international networks on invasive alien species that promote data sharing and collaboration include the ISSG, The Inter-American Biodiversity Information Network (IABIN), the Asia-Pacific Forest Invasive Species Network (APFISN), the European Network on Invasive Alien Species (NOBANIS) and CABI (which produces the Invasive Species Compendium). The European Alien Species Information Network (EASIN) provides opportunities for pan-European cooperation for sharing of information and assists implementation of European policies on biological invasions (Katsanevakis *et al.,* 2013). Also, a European Co-operation in Science and Technology (COST) action was launched to establish an alien species and citizen science network to develop and support citizen science initiatives (Roy *et al.,* 2018).

National and subnational networks

Examples of national or subnational initiatives, in this case from Europe are: a) a French working group on biological invasions in aquatic environments which aims at promoting expert knowledge, providing access to scientific information and guidance to decision-making for capacity-building to manage biological invasions (Sarat *et al.,* 2017) and b) a national code of conduct to prevent the introduction and spread of aquatic invasive plant species in the Netherlands (Verbrugge *et al.,* 2014).

Aquatic networks and information systems

An online information system on aquatic non-indigenous species and cryptogenic species (AquaNIS),[17] or species that might be considered to be invasive alien species, stores and disseminates information on invasive alien species introduction histories, recipient regions, taxonomy, biological traits, impacts and other relevant documented data (Olenin *et al.,* 2014). AquaNIS is being routinely updated by the supporting network (including by the members of the Working Group on Introductions and Transfers of Marine Organisms of the International Council for the Exploration of the Sea, ICES WGITMO) and contains information from various parts of the world.

Standard protocols

The Mountain Invasive Research Network was established in July 2005 during an international workshop on plant invasions into mountain regions in order to generate and share information of biological invasions in mountain regions of the world (Dietz *et al.,* 2006). The network has developed standardized protocols for data collection. Participating researchers use the same protocol while collecting data in mountain regions around the world. Use of empirical data collected from different parts of the mountain regions through this network has provided broad understanding of plant invasion patterns in mountain regions (e.g., J. M. Alexander *et al.,* 2011; Liedtke *et al.,* 2020; Seipel *et al.,* 2012). Similarly, the Global Invader Impact Network (GIIN) has developed a standard protocol for quantifying baseline ecological impacts (Barney *et al.,* 2015) and the methods have been already used to study impacts of species like *Impatiens glandulifera* (Himalayan balsam, Čuda *et al.,* 2017) and *Microstegium vimineum* (Nepalese browntop; Tekiela &

17. http://www.corpi.ku.lt/databases/index.php/aquanis

Barney, 2017). Some networks have become inactive and no longer collect data or update online resources.

Supporting active networks and platforms, re-activating previously established networks and developing new networks focusing on relatively less studied (e.g., wetlands) and difficult to quantify (e.g., marine) ecosystems creates opportunities for collecting and collating data using standardized protocols to improve knowledge of biological invasions.

6.6.2.3 Integration of information

Invasive alien species data in a biodiversity data context

The concept of essential biodiversity variables (EBVs) has been proposed to harmonize and unify efforts towards being able to provide regular, reliable and up-to-date information on key measurements of biodiversity change (Pereira *et al.,* 2013). Key elements of the EBV approach include aggregating and integrating biodiversity information (including on genes, species populations, traits, communities and ecosystems) across multiple sources, advancing the biodiversity information standards needed to achieve this, and state of the art modelling to deal with data gaps and provide estimates of uncertainty around projections. Generating such data products at a global scale has been challenged by the slow mobilization of data, inconsistent use of standards, a lack of standards and unevenness of data availability; problems which are now being overcome (Jetz *et al.,* 2019; Kissling *et al.,* 2015). Indeed, one of the goals of defining essential biodiversity variables (EBVs) is intended to be supporting the collections of up to date and higher quality raw observations of biodiversity **(Box 6.21)**. To create such essential biodiversity variables (EBVs) and tackle the underlying difficulties, automated workflows could make it feasible to repeat the process regularly and in a timely way (Best *et al.,* 2007; Kissling *et al.,* 2018). Workflows would output information that can be easily digested by policymakers and other stakeholders, who do not necessarily understand all the details of the workflow, but who need an appreciation of the data's limitations (Jetz *et al.,* 2019).

Integration of invasive alien species data through essential biodiversity variables

Three essential biodiversity variables (EBVs) have been identified as critical for measuring change in invasive alien species and underpinning invasive alien species indicators: alien species occurrence, the status of an individual or species as native or alien and invasive alien species impact (Latombe *et al.,* 2017; McGeoch & Jetz, 2019). To generate EBVs adaptable automated workflows are envisaged that can harvest raw data, aggregate them and standardize them to output the final EBVs product (Hardisty *et al.,* 2019).

Automated workflows for invasive alien species data integration and analysis have the advantage over bespoke programmes and semi-automated processes in that

Box 6 21 **Institutionalizing invasive alien species monitoring: a case study from India.**

Purpose

An example of how invasive alien species monitoring can be mainstreamed into government mandates is that of India's *National Tiger Estimation Program*. The government of India uses this program to estimate tiger populations at a national scale every fourth year and the program has been running since 2006. This monitoring not only produces an account of tiger numbers at a national scale, but also uses this charismatic species to garner resources and public support for protecting natural systems and their functions (Jhala *et al.,* 2021).

Approach

The National Tiger Estimation Program sampling protocol is developed to collect information on the distribution of important carnivore and herbivore animals, as well as their habitat quality. The protocol for assessing habitat quality is used for collecting information on invasive plants and native weeds. The primary objective of monitoring is tiger conservation, whereas weed monitoring is a conservation objective in its own right. The case demonstrates how, with appropriately well-integrated strategy and planning at national and sub-national scales, multiple biodiversity monitoring objectives can be simultaneously met – including invasion monitoring.

India has a large human resource with a mandate to monitor and protect forest ecosystems **(Figure 6.19)**. The National Tiger Estimation Program uses this trained capacity in collaboration with scientific institutions to sample forested areas at a 10×10 km resolution. Within every cell of 100 km^2, 20-40 plots of 10-30 m diameter are sampled to record the abundance of available plants. Since 2018, the data are recorded through an open-access mobile app (MSTrIPES) that stores this information in native language, along with geotagged photographs of the plot. These data are transferred to a cloud server, where existing algorithms compute trends in invasion of different species at a desired scale (e.g., Mungi *et al.,* 2020). The system can be further used to relate invasive alien species presence to herbivore and carnivore distribution. These analyses are reported back to the data collectors and managers, who can use them to prioritize evidence-based invasive alien species management and research (e.g., Mungi *et al.,* 2021).

Box 6 21

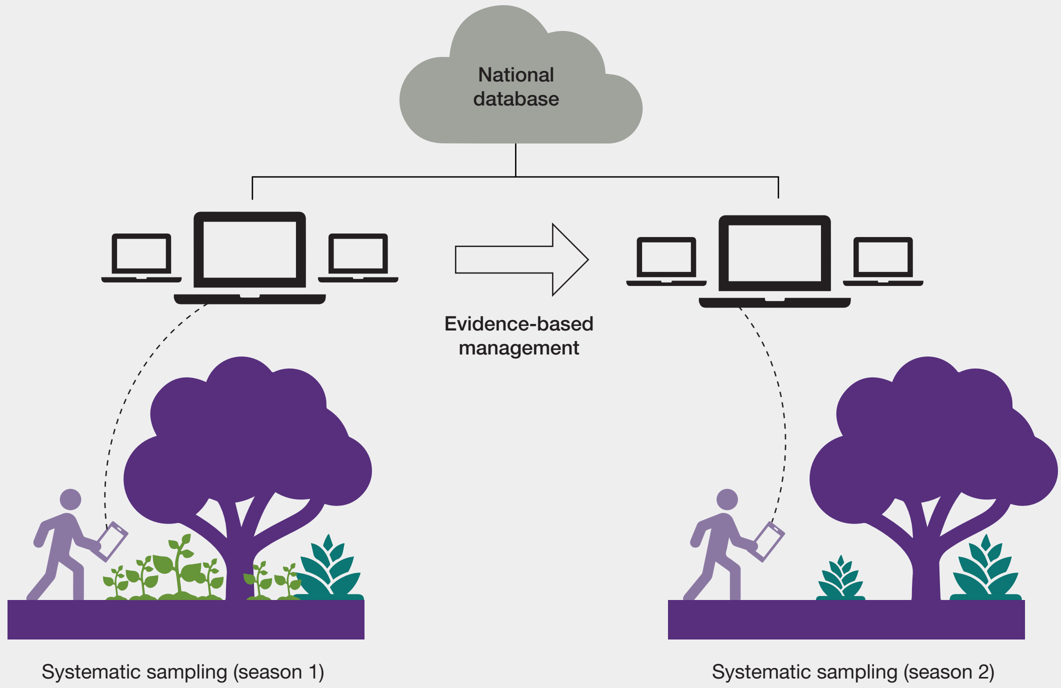

Figure 6 19 **Systematic monitoring scheme for invasive plants in Indian forests.**

The research team records abundance of invasive plants in sampling plots of every 100 km^2 cell across tropical India. The information is recorded on mobile apps that transfer field data to a regional workstation and cloud server, where spatial analyses are done to map and prioritize invasive plant management. The process is repeated at a national scale every four years. Recent monitoring in 2018 was the most extensive with more than 150,000 habitat plots sampled, revealing that 76 per cent of Indian forests invaded by different invasive plants at an alarming rate.

Combining monitoring and management

Importantly, the present monitoring protocol not only generates data, but it is also proactive. The sampling teams are equally involved in habitat management. In addition to evidence-based science, the present sampling protocol convinced the stakeholders to monitor invasive plants for conserving forest habitat that will help increase herbivore densities. This in turn will ensure sustenance of top predators, including the tiger. Serving as a unique platform to host scientific and management priorities, the present monitoring protocol is mandated by government agencies for continual application in India. This case can serve as an exemple for other countries who wish to mainstream and institutionalize invasive alien species monitoring with the limited resources availed for conserving iconic species.

they are flexible, repeatable, easily shared and can be repurposed (e.g., Seebens *et al.,* 2020; Reyserhove *et al.,* 2020). They can also take advantage of code written by many people and use shared resources. Workflows fit well into the ethos of open source and open science practice (Goble *et al.,* 2010). Although they are not yet widely used for invasive alien species data analysis, examples exist (De Giovanni *et al.,* 2016; Seebens *et al.,* 2020; **Box 6.21**).

A trial was conducted on the species distributions for three widespread invasive alien species to generate data ready to be used in essential biodiversity variables (EBVs; Hardisty *et al.,* 2019). This work identified some areas where research investment in data information systems for invasive alien species is needed. The workflow was based on the large open infrastructures GBIF and Atlas of Living Australia. They encountered several difficulties in fully automating their workflow, which served the purpose of identifying where further advances are needed in data integration methods and standards. Even though these infrastructures are based on the same standards, they encountered many inconsistencies between datasets, and required considerable manual expert input to complete the workflow. At a continental scale, a completely automated workflow has been created in the programming language R, specifically for generating indicators and models of invasive alien species distributions

(Oldoni *et al.,* 2020). Ultimately, it is conceivable that automated workflows will be built to generate essential biodiversity variables (EBVs) at a global scale; however, research and development are still needed to resolve data consistency problems and to develop analytic models.

6.6.2.4 Open science – open data for invasive alien species

The Open Knowledge Foundation defines “Open” as “… anyone can freely access, use, modify and share for any purpose (subject, at most, to requirements that preserve provenance and openness)” (Open Knowledge Foundation, 2021). The open data movement has been an important driving force increasing access to data (Molloy, 2011), and can do the same for invasive alien species data. This development has been motivated by the desire to improve transparency and reproducibility of science, but it also aims to improve the efficiency of science by avoiding unnecessary duplication of effort. The push toward open data is energized by the need for interoperability, particularly in complex, data-intensive science, such as invasion biology (Reichman *et al.,* 2011). Several widely supported declarations have been penned to encourage open data sharing in biology and science in general (Budapest Open Access Initiative, 2012; pro-iBiosphere Consortium, 2014). Indeed, there have been specific calls for data on invasive alien species, in particular, to be open (Groom *et al.,* 2015, 2017).

Related, but not synonymous with Open Data are the Findable, Accessible, Interoperable and Reusable (FAIR) data principles (Wilkinson *et al.,* 2016). Openness does facilitate findability, accessibility and reusability, which is why FAIR data often go hand-in-hand with open data. One motivation for promoting FAIR data is that research data are easily lost once the research they support has been published (Vines *et al.,* 2014). Without FAIR open data on invasive alien species, it is difficult to provide informed, integrated policy support nationally or globally.

Many online resources are available for sharing information about invasive alien species (**Chapter 5**, **Table 5.4** for examples). These resources vary considerably in how well they conform to the FAIR data principles, and how readily complementary information can be integrated from multiple sources to answer questions about biological invasions (**section 6.6.2.3**). There is considerable room for improvement and innovation to make resources for biological invasions more findable, accessible, interoperable and reusable.

6.6.2.5 CARE principles for Indigenous data governance

In analogy to the FAIR Data Principles, and complementary to them, are the Collective Benefit, Authority to Control, Responsibility and Ethics (CARE) Principles for Indigenous Data Governance [18] (RDA, 2019). These Principles try to address some of the historical and ongoing imbalances in governance of data concerning Indigenous Peoples. The letters of the acronym refer to Collective Benefit, Authority to Control, Responsibility and Ethics. The collective benefit, authority to control, responsibility and ethics (CARE) principles are not specific to data types and make no mention of particular issues related to data on biodiversity and invasive alien species. However, they are mentioned here because they are important guidelines concerning Indigenous and local knowledge and useful guidelines for the ethical management of any data needed on biological invasions.

6.6.2.6 Open access publication

Closed access to invasive alien species research has been recognized as a hindrance to conservation, wildlife management and policy on invasive alien species (Groom *et al.,* 2015; Jeschke *et al.,* 2019). This has led to the establishment of an international association, International Association for Open Knowledge on Invasive Alien Species (INVASIVESNET), to support the open dissemination of information on invasive alien species (Lucy *et al.,* 2016). Several open access academic journals have been established specifically on the subject of invasive alien species, their biology and management. For example, *Management of Biological Invasions*, *Aquatic Invasions* and *BioInvasions Records* are published by the Regional Euro-Asian Biological Invasions Centre (REABIC) and Neobiota is published by Pensoft. However, these discipline-specific journals publish only a small fraction of the academic research on invasive alien species. For scholarly literature in general, about 28 per cent is open access, but that percentage is increasing (Piwowar *et al.,* 2018). There is also clear evidence for an Open Access “advantage” in terms of citation (Eysenbach, 2006; Niyazov *et al.,* 2016; Piwowar *et al.,* 2018). However, this advantage may come at the expense of lower discoverability and access to other valuable research because closed access publications may be inaccessible to many researchers, particularly in low-income countries.

Information on invasive alien species is published in a wide variety of media and outlets, from journals and pamphlets to books. Much of this body of knowledge is not in publications dedicated to invasive alien species specifically but embedded within literature on biodiversity or ecology in general. Rapid access to scientific publications is essential to inform practitioners about a species and even to identify it in the first place. Nevertheless, those publications that are confined to paper are available for sale only for a short time after publication and then are available only in specialist or local libraries. Access to digital repositories, such as Zenodo, is providing a place where grey literature

18. https://www.gida-global.org/care

can be deposited for long-term preservation and findability. However, there also needs to be a change to the publishing culture so that all publishers consider the long-term archival of their work.

Researchers use indexes, such as Google Scholar, to discover potentially useful publications, though the accessibility of those publications varies. Gold Open Access publications are completely accessible to users and their licensing usually makes them reusable. However, at the other extreme are closed access publications that require large sums to access. Researchers are often adept at avoiding such costs and piracy of closed access publications is rife (Timus & Babutsidze, 2016). Even academics with legitimate access to scientific publications appear to find it easier to access papers illegitimately (Bohannon, 2016). This shows a demand for this scientific knowledge globally and a problem with the marketplace for academic knowledge (Björk, 2017), with particularly serious implications for research areas where environmental, social and economic costs of delays in the dissemination of information are serious, such as invasion biology.

6.6.2.7 Data standards for invasive alien species data

Global standards for invasive alien species information facilitate rapid, unambiguous communication and enable the delivery of indicators of invasions, regional comparisons, which in turn feed into policy support tools. Standards for data exchange of taxon observations have been around for a number of years and Darwin Core is predominant among them. Darwin Core has been adopted by GBIF (Canhos *et al.,* 2004). Until recently Darwin Core lacked some important features to make it useful for communicating about invasive alien species. However, recently proposals have been made to include the degree of establishment and introduction pathway within Darwin Core, together with controlled vocabularies for those terms. These changes have now been implemented by GBIF and it now requires data publishers to embrace these terms and use them (Groom *et al.,* 2019).

Few other official standards exist for specific data related to invasive alien species. However, several quasi standards exist under the umbrella term "framework". For example, Hulme (2009) published a framework for introduction pathways. The intention was to have a globally applicable pathway classification that could be used for all invasive alien species, whatever their natural habitat. This was to address a need to monitor pathways of introduction and to communicate pathway information in a more comparable way. A guide has been written to help users of the framework to interpret different pathway categories and improve consistency (IUCN, 2017). The CBD (2014a, 2014b) has developed a pathways framework, as has the ISSG (Pagad *et al.,* 2015). This is tied to the Aichi Biodiversity Target of identifying, prioritizing and managing pathways of invasive alien species. Armed with such information it becomes easy to provide the evidence to support policy on pathways (**Chapter 5**, **section 5.3.1**).

Nevertheless, the framework is still only a standard suitable for human interpretation and unsuitable for machine interoperability. Only by formalizing the framework as a data standard can the latter be achieved. The Invasive Organism Information Task Group of the Biodiversity Information Standards organization has proposed changes to Darwin Core to incorporate pathway vocabulary, adopted by the CBD (Groom *et al.,* 2019). These recommendations have been ratified by the Biodiversity Information Standards organization who manage Darwin Core but may take a number of years to be adopted by the wide range of stakeholders who gather, manage and use these data. Progress towards machine readable standard data will make the vision of creating rapid and reliable workflows towards policy-relevant indicators feasible (McQuilton *et al.,* 2016; Rocca-Serra *et al.,* 2016).

6.6.3 Tracking and reporting on policy and management effectiveness: indicators, metrics and datasets to support policy

Reporting on the effectiveness of policy in generating progress towards targets and goals for invasive alien species takes place at multiple jurisdictional levels – from global to subnational. Regardless of the level at which evaluation of policy effectiveness is needed, such evaluation relies on relevant and adequate data and analysis. The information needed for reporting on invasive alien species includes (i) the identity and spread of invasive alien species, including the pathways *via* which this occurs, (ii) the type and severity of impacts incurred by particular invasive alien species, (iii) societal values impacted, including for example, biodiversity, agricultural and human and animal health and (iv) data on management interventions (left of **Figure 6.20**; **Box 6.22**).

A key instrument to progressing efforts to deal with invasive alien species is the use of a range of indicators of status and trends in invasive alien species. These indicators are designed to be used for reporting on policy goals and targets at national and global scales, including the Kunming-Montreal Global Biodiversity Framework (Target 6 for invasive alien species) and the Sustainable Development Goals. Importantly, such indicators, supported by relevant metrics and data, have a longevity beyond medium term reporting cycles so that progress can be tracked consistently over the long-term. To date, invasion indicators that are global in scope have been used across five Global Biodiversity Outlook Reports (SCBD 2001-2020), and to

Box 6 22 Sustainable delivery of information on invasive alien species for reporting on policy and management effectiveness.

Figure 6.20 below shows a proposed framework for closely linking invasion targets with the data and tools needed to measure and make progress to achieving them (McGeoch & Jetz, 2019). Combined in digital, modular platforms with custom tools and interfaces the framework enables both evaluation of global progress and decision-support for local actions.

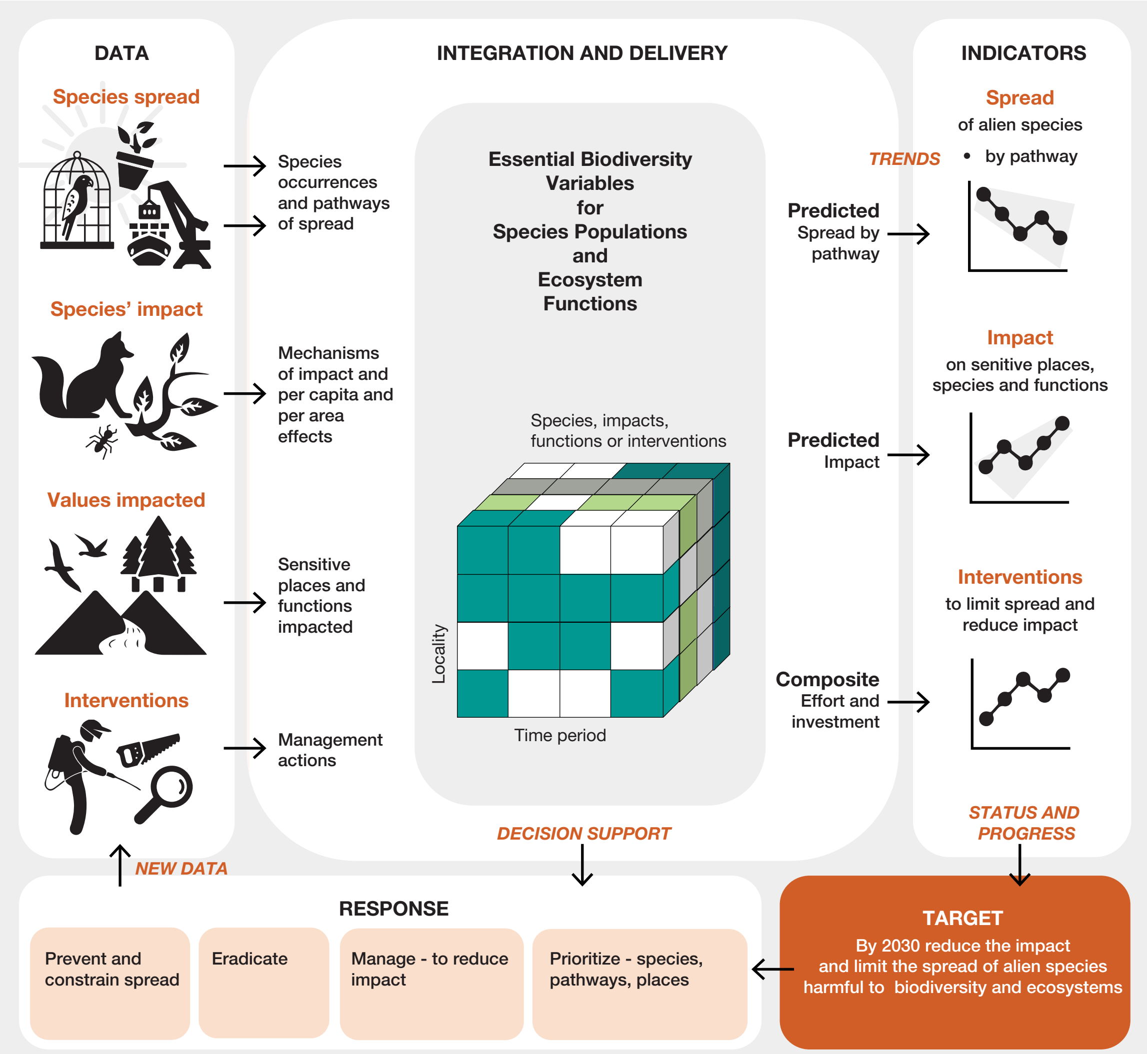

Figure 6 20 **Proposed framework for closely linking invasions targets with the data and tools needed to measure and respond to them.**

The target (lower right) frames and guides data generation, integration and delivery *via* modelled decision support products and indicators, to target responses for more effective intervention and a next generation of improved outcomes on biological invasion. Data (left) on the three key dimensions of the problem, (1) spread, (2) impact (both its type and consequence) and (3) interventions are integrated in a set of workflows that combine primary evidence in informatics infrastructure. Data providers are multiple and include for example GBIF, GRIIS, CABI – Invasive Species Compendium, the IUCN and the World Database on Protected Areas (WDPA). Currently data on interventions for invasion and their effectiveness are poorly collated with no dedicated infrastructure. Integration and delivery (centre) are at the core of the framework. Data, with the support of models, are used to predict occurrences or abundances of invasive alien species across pathways of introduction and spread (including establishment) and over contiguous spatio-temporal units, representing the Species Populations Essential Biodiversity Variables (EBVs) for invasive alien species (GEO BON). This is supplemented with data and essential variables that capture ecosystem functions and sensitive priority areas impacted by invasion, as well as data on management actions to predict impact and quantify intervention effort. Indicators (right) build on the delivered invasion-relevant Essential Biodiversity Variables and are

Box 6 22

Figure 6 20

populated using modelled predictions with associated uncertainty on spread, impact and interventions (Vicente *et al.,* 2022). Response (lower left) consists of the four major interventions – prevention, eradication, management and prioritization. These activities are guided by decision-support tools and products (such as alien species distribution maps for protected areas and location-specific automated alerts for new invasions) provided from integration and delivery directly or *via* indicators. The responses in turn deliver much-needed new data, including data on intervention effort and success. From McGeoch & Jetz, (2019), https://doi.org/10.1016/j.oneear.2019.10.003, under Copyright Elsevier.

support the summary for policymakers of the IPBES Global Assessment (IPBES, 2019c); and have been considered to various degrees in national reporting (Secretariat of the CBD, 2020; J. R. U. Wilson *et al.,* 2018). Proposed headline indicators for monitoring the implementation of the Kunming-Montreal Global Biodiversity Framework have been published by the CBD (2022b), including a specific headline indicator for biological invasions "6.1 Rate of invasive alien species establishment".

Indicators of biological invasion are broadly classified into indicators of (1) the drivers that facilitate biological invasion, (2) the size of the invasion problem (pressure indicators), (3) impacts on biodiversity and society (state indicators) and (4) societal responses to invasion (response indicators; Butchart *et al.,* 2010; McGeoch *et al.,* 2010a; **Table 6.2**). Under a theory of change framework, response indicators are now further subdivided (into input process, output, outcome, impact) to capture the stages of implementation necessary to bring about the desired progress (OECD, 2019; J. R. U. Wilson *et al.,* 2018; **Table 6.11**).

Although central to tracking the success of interventions to prevent and reduce the harm caused by invasive alien species, the development, adoption and fitness for purpose of invasion indicators has to date been inadequate (Vicente *et al.,* 2022). No existing indicators meet all the criteria ideal for robust, policy-relevant indicators (Vicente *et al.,* 2022). Challenges also include invasive alien species indicators that are not supported by robust and repeatable scientific methods, a lack of indicators to report on some important aspects of the problem, and indicators that are reliant on increasingly old data, which as a result are not able to report on recent progress (Vicente *et al.,* 2022). Although a number of intergovernmental and research partnerships have supported this endeavour over the last decade, including GBIF, IUCN Species Survival Commission (SSC) ISSG and GEO BON, two key factors are responsible for the slow progress. First, there has not yet to date been widespread agreement and adoption of a coherent, fit for purpose suite of indicators that can be used for long-term reporting **(Table 6.2)**. Second, there has to date been no institutional home with the resources and capacity to drive the research and reporting needed to sustain a robust suite of invasive alien species indicators (Vicente *et al.,* 2022). One of the evident outcomes of this is that the multiple indicators identified in CBD-related documentation change from reporting period to reporting period, and some are not able to be delivered or updated at the end of reporting cycles.

The options for strengthening the information value of invasive alien species indicators and their relevance for policy are clear. These include:

- Invest in the on-ground monitoring systems needed to deliver up to date information on the identity, spread and impacts of invasive alien species; and on the implementation and effectiveness of responses, including the implementation and effectiveness of management actions (Latombe *et al.,* 2017);
- Complete the research needed to support robust scientific formulations of indicators, the metrics on which they based, how they are modelled and interpretation of the uncertainty associated with them (Jetz *et al.,* 2019; McGeoch & Jetz, 2019);
- Establish a stable partnership to support invasion indicators that has the scientific expertise, data and analytic capacity and resourcing necessary to sustain these indicators over the long-term;
- Support the open infrastructures, data sources and collation processes required to aggregate and inform invasive alien species indicators, such as GBIF and the Global Register for Introduced and Invasive Species that jointly provide the data foundational to informing on invasive alien species (Pagad *et al.,* 2018);
- Assess and progress the extent to which each indicator can be downscaled and expressed at country level and the extent to which they are suitable for use at a national scale (J. R. U. Wilson *et al.,* 2018).

Table 6 11 **Categories of currently used invasive alien species indicators at a global scale, their information content and development needs.**

The indicators listed are phrased broadly to represent multiple closely related indicators that have been expressed in slightly different ways across the literature, policy documentation and historical, current and proposed reporting cycles.

Indicator category	Indicator expressed in an inclusive general form, encompassing relevant alternative formulations of closely related indicators	Data sources	Development needs
Driver	Trends in pathways of introduction and spread	No current FAIR source	Although raw trends can be produced, research is needed to develop these into a robust indicator with estimates of uncertainty (McGrannachan *et al.,* 2021) GRIIS has the potential to inform this indicator in future
Pressure	Trends in numbers and spatial distribution of invasive alien species and their impacts	GRIIS GBIF First Records	Further research to deliver downscaling to countries
State	Trends, mechanisms and severity of invasive alien species impacts	Environmental Impact Classification for Alien Taxa (EICAT) GRIIS GBIF	IUCN Red list Index for invasive alien species is well established EICAT progressing but still under development Downscaling to ensure relevance to countries required
Response and Theory of Change sub-categories (section 6.2.1)			
Input	Trends in the allocation of resources towards the prevention or control of invasive alien species	IUCN SSC ISSG	The methodology could be improved through peer review and further development
Process	Trends in establishment and national adoption of international agreements relevant to the prevention and control of invasive alien species	IUCN SSC ISSG	Reaching saturation as the majority of countries adopt most agreements, but still room for improvement on the most recently adopted (2010) relevant convention (BWM Convention)
	Trends in numbers of countries with national legislation and other policy measures relevant to the prevention and/or control of invasive alien species	IUCN SSC ISSG	Further research and development are needed to assess cross-country comparability of policy instruments and their fit for this purpose
Output	Trends in the prevention, eradication and control of invasive alien species	No current FAIR data source Data largely not been collected and collated by countries	Disaggregation is needed for priority sites
	Growth in information relevant to informing policy on invasive alien species prevention and control	GBIF First Records GRIIS EICAT	There is potential for disaggregation from a global indicator of information status on species populations
Outcome	Trends in successful eradications	Database of Islands and Invasive Species Eradications (DIISE)	Currently limited to birds and mammals on islands Requires taxonomic and geographic expansion
Impact	Improvement in conservation status of species threatened by invasive alien species	IUCN Red List of Threatened Species	Requires expression at sub-global scales

6.7 TRANSFORMATIVE OPTIONS FOR ADDRESSING THE PROBLEM OF BIOLOGICAL INVASIONS

This section addresses the following question: What will it take to tip the current systems – including socio-institutional, socio-technical and socioecological systems – that drive and manage biological invasions in the direction of sustainability (Loorbach *et al.,* 2017; Westley *et al.,* 2011)? The section begins by describing what integrated governance for biological invasions is and why such an approach is relevant for biological invasions. It also suggests how this approach could be implemented using a set of strategic actions and governance system properties that will bring about transformative change, challenges to setting these actions in motion and how these could be overcome.

Sustainability science has emerged as an applied field in response to the need for sustainable development and acknowledging the complexity of the socioecological systems that need to be governed and managed in order to achieve it (Clark & Harley, 2020; Loorbach *et al.,* 2017). The problem of invasive alien species is one instance of a threat posed to both society and the environment because of unsustainable development. Invasive alien species are a direct driver of nature's decline (IPBES, 2019c), and tackling these is therefore key to bending the curve of biodiversity loss. Therefore, invasive alien species as a problem share many of the features of sustainable development challenges, and an awareness of the risks posed by these is essential to the effective delivery of several of the SDGs (in particular, goals addressing the conservation of marine biodiversity (Goal 14) and terrestrial biodiversity (Goal 15, including but not restricted to target 15.8), food security (SDG 2), sustainable economic growth (SDG 8), sustainable cities (SDG 11), as well as climate change (Goal 13) and health and wellbeing (Goal 3)).

Many of the options for achieving goals and targets for invasive alien species will be enabled by systemic changes that parallel and reinforce the solutions needed to achieve sustainability more broadly (Chan *et al.,* 2020; S. Díaz *et al.,* 2019). Transformative change becomes necessary to achieve sustainable management of biological invasions because, like other key environmental threats, biological invasion is driven by demographic, social, economic and technological factors (Visseren-Hamakers *et al.,* 2021; **Chapter 3**, **sections 3.3** and **3.6**).

This assessment therefore builds on the sustainability science framing of the IPBES conceptual framework and enablers of transformative change (S. Díaz *et al.,* 2019; Scoones *et al.,* 2020): To reverse nature's decline while addressing inequality, a "fundamental, system-wide reorganization across technological, economic and social factors making sustainability the norm" (S. Díaz *et al.,* 2019). In this context, governance is the "formal and informal (public and private) rules, rulemaking systems and actor networks at all levels of human society that enable transformative change" (Visseren-Hamakers *et al.,* 2021). For invasive alien species, transformative change depends on a system-wide reorganization, including technological, normative, economic and social factors, needed to achieve the goals enshrined in multilateral agreements and national strategies.

6.7.1 Integrated governance can bring about transformative change that improves the management of biological invasions

To bring about such system-wide reorganization for managing biological invasions, the approach could focus on the "deeper system properties" (Leventon *et al.,* 2021; Meadows, 1999) that characterize biological invasion governance. The full suite of governance models, policy instruments and support tools and methods identified in this chapter **(Table 6.1)** are available as options which, in combination, can be drawn on to achieve this ambition. These include (*sensu* Scoones *et al.,* 2020):

1. structural options that involve fundamental changes to the way policy and management of biological invasions is organized, legislated, regulated (**sections 6.3** and **6.5**);

2. systemic options that involve "changes targeted at the interdependencies of specific institutions, technologies and constellations of actors across scales and geography to steer complex systems" of stakeholders and Indigenous Peoples and local communities contributing to, influencing and affected by invasive alien species (**sections 6.2** and **6.6**); and

3. enabling options that "foster the human agency, values and capacities necessary to manage uncertainty, act collectively, identify and enact pathways" to futures where the risks and negative impacts of invasive alien species are substantially reduced (**sections 6.2** and **6.4**).

As defined in **Box 6.5**, integrated governance for biological invasions means establishing relationships between the roles of actors, institutions and instruments and involving, as appropriate (in other words the specific features will depend on the national and local contexts), all those elements of the socioecological system that characterize biological invasion and its management, for the purpose of identifying the strategic interventions needed to improve prevention and

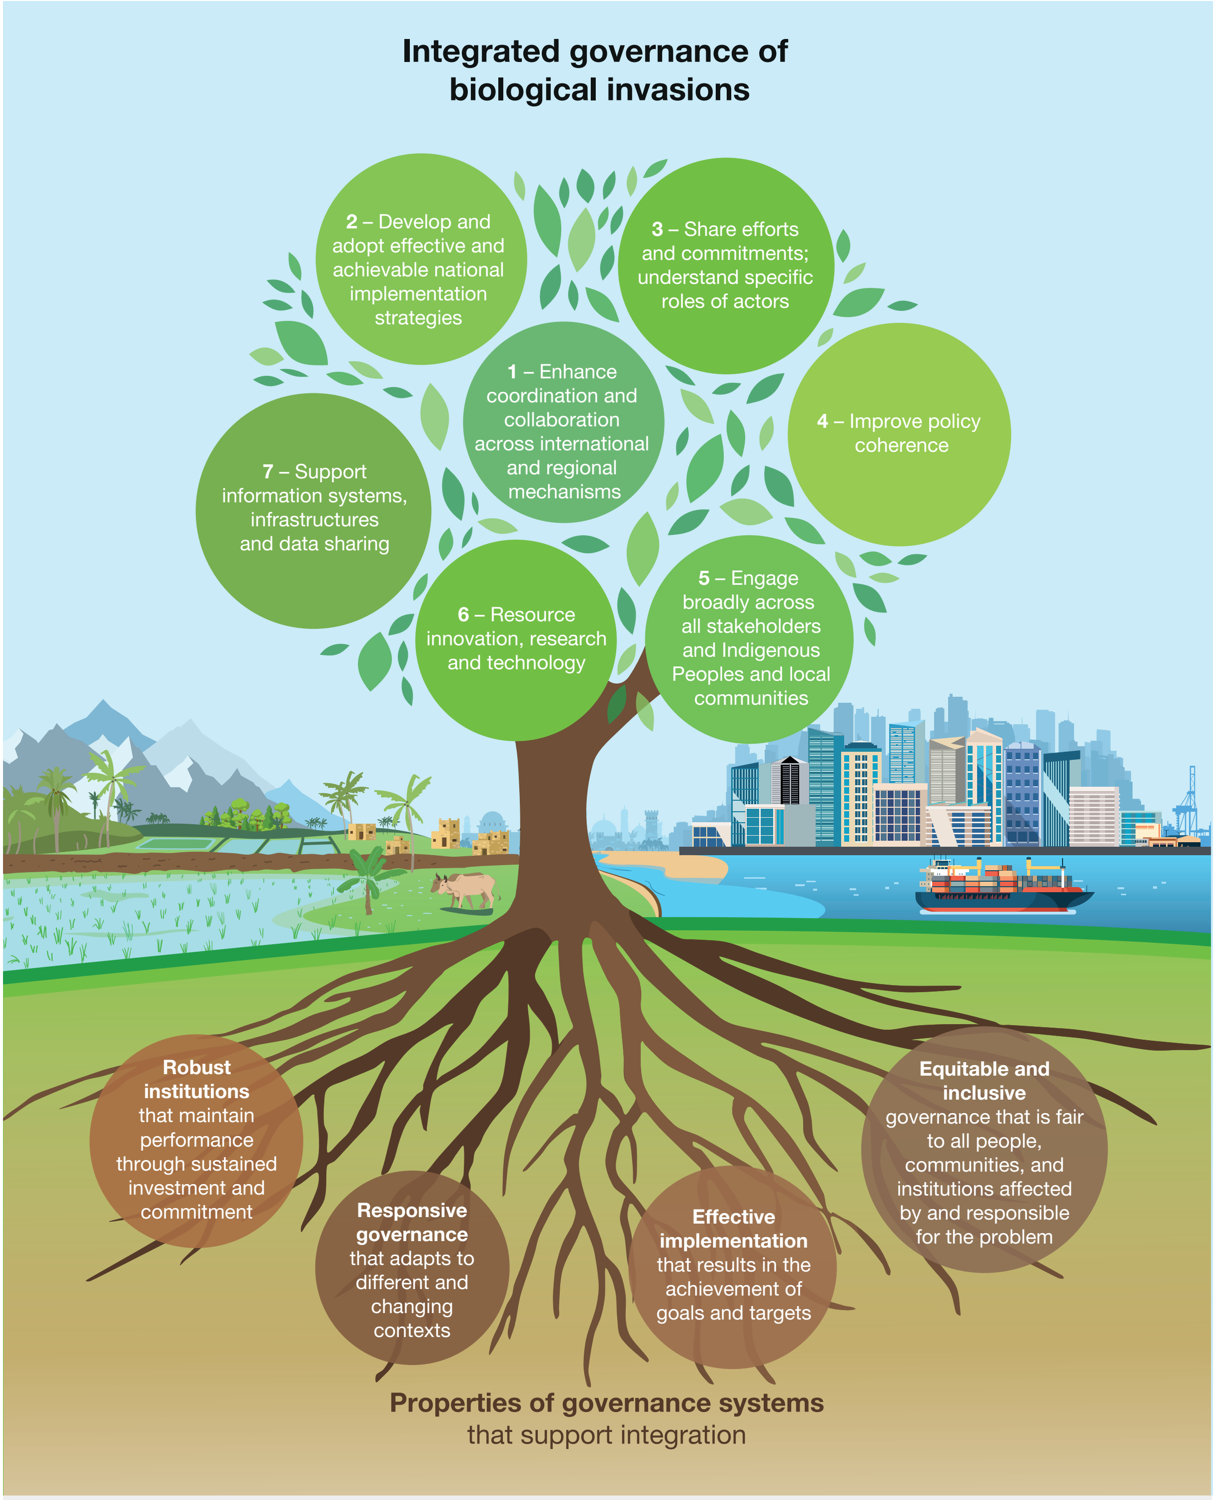

Figure 6 21 **Integrated governance for biological invasions.**

A context-specific integrated governance approach of biological invasions is enabled by a governance system with properties that support integration and a set of strategic actions that together are designed to bring about the progress needed to meet national and international goals and targets for biological invasions. Integrated governance is rooted (below) in four essential properties of governance systems that support the strategic actions (above) to be achieved. Together, the properties and actions will bring about the step change needed for effective and sustainable management of biological invasions. Integrated governance for biological invasions reinforces the enabling conditions identified as necessary to fulfil the 2030 mission of the Kunming-Montreal Global Biodiversity Framework. An integrated governance approach activates specific strategic actions that promote transformative change to meet the goals of preventing and controlling biological invasions.

Figure 6 21

The strategic actions (branches) are:

1. Enhance coordination and collaboration across international and regional mechanisms.
2. Develop and adopt effective and achievable national implementation strategies.
3. Share efforts and commitments, and understanding of the specific roles of all actors.
4. Improve policy coherence.
5. Engage broadly across governmental sectors, industry, the scientific community, Indigenous Peoples and local communities and the wider public.
6. Support, fund and mobilize resources for innovation, research and environmentally sound technology.
7. Support information systems, infrastructures and data sharing.

The proposed strategic actions are enabled when the system-wide properties of governance (roots) are robust, equitable and inclusive, responsive and focused on effective implementation. The numbers on the branches do not imply a ranking.

control outcomes **(Figure 6.21)**. While at face value this appears to be a monumental task, many of the processes and elements for preventing and controlling invasive alien species are already established and in play. Enhancing, strengthening and improving implementation and better integrating the actions and system properties that make up integrated governance for biological invasions could bring about a step change in progress.

Integrated governance for biological invasions is also establishing relationships between the roles of actors, institutions and instruments to ensure a shared, connected, coherent and differentiated effort to manage biological invasions **(Figure 6.23)**. It also involves the engagement of all the appropriate elements of the socioecological system that characterize biological invasion and their management to define the best strategies in those areas when invasive alien species impose socio-economic impacts (Bacher *et al.,* 2018). Last, it acknowledges that good governance, while essential to achieving sustainable outcomes for the prevention and control of invasive alien species, is somewhat of an experiment (Clark & Harley, 2020) and would therefore need to be adaptive as well as coordinated to facilitate learning (Brauman *et al.,* 2020). **Figure 6.21** illustrates "integrated governance for biological invasions" as the framework by which transformative governance (**Glossary**) for invasive alien species could be achieved, encompassing seven strategic actions and four governance system properties.

6.7.2 Strategic actions

6.7.2.1 Enhancing coordination and collaboration across international and regional mechanisms

The most important proactive (e.g., border control) and reactive (e.g., eradication) measures to address biological invasions are administered at the national or subnational level. However, the nature of biological invasions means that multilateral and transnational approaches are also needed. While there is no shortage of organizations focused on addressing the problem of biological invasions, one of their main limitations has been their disconnected nature. Cooperation amongst different regional and national efforts will not arise spontaneously and will need concerted leadership, resourcing and commitment from governments and institutions at the highest level (Leclère *et al.,* 2020; Ruckelshaus *et al.,* 2020; **section 6.2.3.1**). Therefore, establishing or enhancing global coordination mechanisms (similar to the Convention on the Conservation of Migratory Species of Wild Animals (CMS)) for biological invasions, or embedding this role into existing coordinating bodies (e.g., the CBD), are options for achieving one of the key strategic actions for transformative progress **(Figure 6.21)**. Such coordination mechanism could promote the exchange of best practices and other knowledge between regions and nations, help to establish the appropriate roles and responsibilities of actors (Stoett, 2007), enable global species listings and strengthen the effectiveness of the Inter-Agency Liaison Group on Invasive Alien Species. While the CBD currently covers invasive alien species as a cross-cutting issue, this assessment has amassed sufficient evidence to suggest the theme needs a more pronounced coordinating mechanism at the global level.

6.7.2.2 Developing and adopting effective and achievable national implementation strategies

Failure to adopt existing guiding principles (e.g., **Table 6.3**), and to implement legislation and action plans, have been a central impediment to progress on invasive alien species targets (**sections 6.2.2** and **6.3.1.4**). Implementation focused strategies for biological invasion management can assist in overcoming this hurdle **(Figure 6.21)**. This can be achieved by revisiting implementation strategies at all levels of governance, and in particular at those most relevant to the strategic actions identified in **Figure 6.21**. Options for this include, amongst others, consistent enforcement of relevant law (Chan *et al.,* 2020) and investment in monitoring and learning from the successes and failures of interventions **(Box 6.23)**.

Feeding this information into response-focused theory of change indicators, including indicators that track the allocation of resource inputs, the establishment and

Box 6 23 Overcoming the implementation gap for invasive alien species.

Two key hurdles to improving the management of invasive alien species, are:

1. the need for more effective prioritization of where and when to intervene, and
2. the lack of information on which interventions are most successful and in which contexts.

Both these hurdles can be overcome by generating essential data and knowledge on resource inputs, processes, outputs and outcomes (OECD, 2019) of efforts to manage invasive alien species **(Box 6.6; Figure 6.22)**.

Resource inputs: How much are governments and other responsible actors spending on invasive alien species management? What are the gaps in appropriately qualified, existing capacity and expertise that can be filled?

Processes: What coordination and oversight mechanisms are in place, from local communities to governments, to enable investment and ensure effective implementation of invasive alien species management?

Outputs and actions: What new or strengthened instruments are in place to improve policy coherence, to guide strategic investment and to adequately share and differentiate responsibilities for invasive alien species prevention and control?

Outcomes: Has the rate of new introductions and newly established invasive alien species declined? Has their spread and impact been reduced?

A sustained information platform for invasive alien species can then deliver this information when it is needed and to where it is needed (**section 6.6.2.4**). With the data that are collated, instrumental indicators will be able to report on progress and, based on the knowledge they provide, to iteratively refine and improve the efficiency of responses (i.e., adaptive governance, planning and management; **Figure 6.22**). Together, this approach can catalyse the collection of the information most needed to manage invasive alien species, reduce uncertainty and improve efficiency in decision-making. It can also support reporting on sustainable development and progress to meeting national and multilateral goals and targets for invasive alien species. Clearly linked to and embedded in national strategies for invasive alien species, this approach can leverage the responses needed to overcome current implementation gaps and provide a backbone for integrated governance.

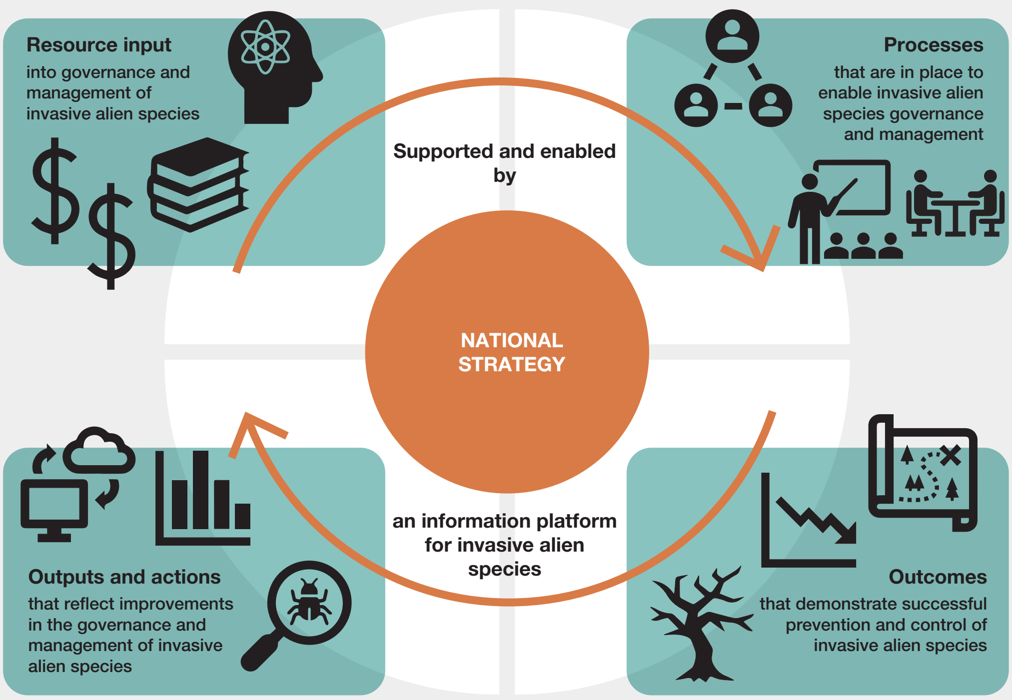

Figure 6 22 Monitoring progress in four types of responses to invasive alien species to leverage activity to overcome the implementation challenge.

If these responses are effective, they should manifest in a reduction in the numbers, spread, impacts and costs of invasive alien species.

uptake of implementation processes, and the outputs and outcomes of these interventions are in line with the Kunming-Montreal Global Biodiversity Framework (CBD, 2022a; OECD, 2019; J. R. U. Wilson *et al.,* 2018; **Table 6.11**; **Box 6.23**). While a strategy is necessary for effective governance at multiple levels and in multiple sectors (**section 6.3**), national scale strategy can be particularly instrumental in achieving the scope and cohesion needed to implement action both above (multilateral) and below (at local and subnational) national government.

6.7.2.3 Sharing efforts and commitment, and understanding the specific role of all actors across governments, Indigenous Peoples and local communities, and industries

The principle of shared, connected and specific roles builds on the fact that individuals, communities, industry and governments share the benefits from nature and therefore also share the responsibility of mitigating the risks imposed by drivers of change such as invasive alien species. This definition is a contextual application of the international environmental law principle of common but differentiated responsibilities (Stone, 2004) as it considers all parties as equally responsible for addressing the problem, but their knowledge and tasks are clearly differentiated based on their relationship to the problem; this is fundamental for a successful application of integrated governance for biological invasions **(Figure 6.23)**.

The management of biological invasions is a collective effort where individuals, communities, industry and governmental agencies play a unique but coordinated role. Such coordination builds from engagement of all actors concerned with the mitigation needed to avoid environmental, economic and health impacts from invasive alien species **(Figure 6.23)**. This can be achieved through a co-production approach that acknowledges that all

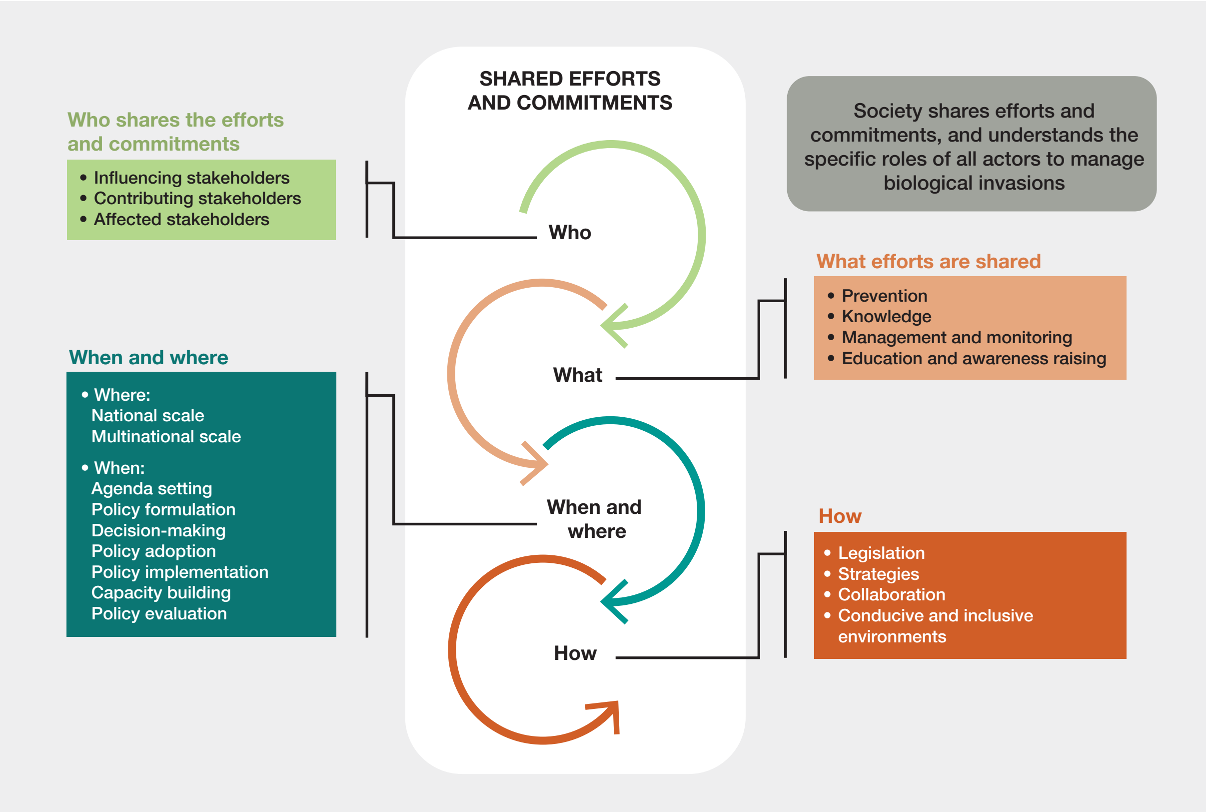

Figure 6 23 **Sharing efforts and commitments, and understanding the specific role of all actors for the prevention and control of invasive alien species.**

This approach emphasizes that people, knowledge, governance and policy instruments have a specific role and need to be connected. The shared efforts and commitments principle means that all actors are part of the solution, so that actions to manage invasive alien species are connected (i.e., there is effective flow of communication between all actors) between people, knowledge, governance approaches and policy instruments. The understanding of the specific roles of all actors, is an idea based on the principle that every institution and stakeholder have a specific part to play in the coordinated and coherent strategy that is the integrated governance for biological invasions.

stakeholders involved hold relevant knowledge and expertise; and that defines strategic connections between people, knowledge, governance approaches and policy instruments (Lemos *et al.,* 2018; Turnhout *et al.,* 2020).

Concrete actions by industries involved in potential pathways for invasive alien species are necessary to increase compliance with current legislation, and voluntary codes of practice can limit the biosecurity risks posed by industrial actors. International organizations can help here: for example, tourism can operate as a pathway and the World Tourism Organization (UNWTO) was asked at CBD COP15 to examine collaborative efforts to reduce invasive alien species introductions. The engagement of the general public *via* citizen science platforms, awareness campaigns, or community-driven eradication campaigns is critical for generating shared efforts and commitments by understanding the specific role of all actors play for addressing the invasive alien species problem. Also critical is the context-contingent involvement of specific stakeholders (e.g., agriculture producers, hobby associations, leisure groups) and Indigenous Peoples and local communities. The engagement and empowering of Indigenous Peoples and local communities is a crucial part of developing inclusive systems that recognize the rights of these communities and their knowledge, practices and values in the management of biological invasions. Such engagement strategies can generate ownership of biological invasion management while supplementing surveillance and management efforts.

6.7.2.4 Improving policy coherence

Global environmental change (with climate change as an example)

Invasive alien species impacts can compound the negative effects of climate change on good quality of life, acknowledging that this outcome is dependent on the species, regions and local conditions involved (e.g., Bradley & Wilcove, 2009; Shabani *et al.,* 2020). It is important that the transformative change needed to prevent and control invasive alien species is not neglected in the current context of a necessarily strong policy focus on climate change. The direct effects of invasive alien species on biodiversity are one of the ways in which the consequences of climate change are translated into direct negative outcomes for nature's contributions to people and good quality of life. Although invasive alien species and climate change are projected to affect fewer species than land-use change, these drivers can interact to become critically important at local scales and can impact people directly (Leclère *et al.,* 2020). The integration of invasive alien species and climate change policy considerations through environmental governance more broadly are options supported by a groundswell in forward-looking thinking and strategy on how to achieve environmental sustainability. The integrated governance approach that focusses attention on the intersections, linkages and trade-offs – and the research, policy and governance instruments needed to achieve complex objectives – is an option for advancing this ambition (J. Liu, Dou, *et al.,* 2018). The exploration of governance arrangements across many different goals and drivers of change is an option for overcoming the multiple needs for building and maintaining reflexive (learning by self-reflection) governance capacity (Clark & Harley, 2020).

Coherence between sectorial policies and institutions

One of the main reasons behind the current failures to address biological invasions has been the strong sectoral silos between sectors that characterize policy regimes. This division has resulted in disjointed decision-making (**section 6.3.1.1**). The development of a coordinated biosecurity approach that blurs the traditional boundaries between sectors would help address environmental, health and agricultural challenges (Hulme, 2021). This cross-sector coordinated approach could provide a better way forward but is not without challenges. Collaborative, multisectoral and transdisciplinary approaches such as One Health (**Glossary**), Eco Health and One Biosecurity provide frameworks to achieve coordination between multiple sectors as well as across economies and cultures. Such coordination would facilitate the prevention and mitigation of the growing threats posed by invasive alien species. Promoting relationships between stakeholders and institutions is one option for achieving one of the key levers for transformative progress **(Figure 6.21)**. Improving policy coherence would help overcome current significant gaps in coverage of regulations targeting invasive alien species. It can also facilitate sharing efforts and commitment and understanding the specific role of all actors (**section 6.7.2.5**).

6.7.2.5 Engaging broadly across governmental sectors, industry, the scientific community, Indigenous Peoples and local communities and the wider public

General tools and approaches and frameworks exist for stakeholder engagement (**Chapter 5**, **section 5.2.1**). However, the purpose of engaging with different groups – the industrial sectors, the general public, Indigenous Peoples and local communities and the scientific community – differ **(Table 6.12)**. The design of effective engagement strategies will have context dependent elements and will take these different purposes into account (**Chapter 5**, **section 5.2.1**). The funding of engagement activities can be built into management plans and budgets to support multiple purposes in the management of biological invasions. To be effective, engagement activities can also be included within monitoring and evaluation of invasive alien species management actions, so that progress can be tracked and strategies refined over time. In this way, the effectiveness of engagement activity can also be refined and improved over time. All these elements are important for public engagement and inclusion activities to effectively contribute to implementing an integrated governance approach for biological invasions **(Figure 6.21)**.

An understanding of stakeholder and Indigenous Peoples and local communities influence and interests and how stakeholders are likely to be involved in different stages of the biological invasion process is crucial to any attempt to engage, represent, empower and co-design biological invasion management plans, and directly engage stakeholders, including citizens, as equal partners. It is clear that communicative and consultative approaches can deliver significant benefits (Shackleton, Adriaens, *et al.,* 2019). In contexts where there are significant conflicts of values or mistrust between actors, or where significant buy-in will be required to implement governance measures, it is likely to be worthwhile investing in co-productive approaches. Policy design for dealing with the anticipated impacts of invasive alien species that is sensitive to the needs and perspectives of vulnerable groups, stakeholders and Indigenous Peoples and local communities can also help achieve social justice (Blythe *et al.,* 2018; Patterson *et al.,* 2018; Temper *et al.,* 2018).

6.7.2.6 Supporting, funding and mobilizing resources for innovation, research and environmentally sound technology

(1) Improved risk assessment

There is wide variability in the capacity to respond to biological invasions amongst countries (Early *et al.,* 2016). Such variability showcases considerable imbalance in the knowledge base and implementation of best practices. Addressing such an imbalance means tracking biological invasions beyond country boundaries (Latombe *et al.,* 2017), building on the idea of connecting knowledge systems *(point 3)*. However, knowledge sharing could be paired with capacity-building and transboundary and cross-sector risk assessment tools **(Figure 6.21)**. For example, intervention strategies could focus on slowing the rates of new introductions taking place at a regional scale (e.g., African Union, European Union, MERCOSUR, USMCA/CUSMA). Thus, it is necessary to define the regions with capability deficits to determine where and how multilateral and bilateral partnerships could be forged to support those countries with limited biosecurity capabilities (Hulme, 2021). Then, within connected regions, sharing insights on invasive alien species of relevance, border control principles and methods is critical for an effective regional approach to prevention (Hulme, 2011, 2020). More generally, a coordinated and nuanced approach to risk-assessments and intervention could be extended to a global context, taking lessons from the current efforts to prevent and contain the spread of the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2).

Table 6 12 **Engagement of stakeholders on biological invasions has a number of purposes and associated approaches and tools (options) that support the process.**

	Purpose of engagement to achieve:	Example options
1	Inclusive decision-making for biological invasions	Decision support tools (**Chapter 5**, **sections 5.2** and **5.4**), Deliberative multi-criteria analysis (**Chapter 5**, **section 5.2.2.1.j**), communication feedback systems (**section 6.3.1.4(5)**)
2	Public education and awareness raising about biological invasions	Training and risk-communication platforms (**Chapter 5**, **section 5.2.2.1** and **Table 5.6**)
3	Social learning and knowledge sharing about biological invasions; attempting to accommodate conflicting values	Co-design, co-creation and co-implementation of research and management actions (**Chapter 5**, **section 5.2.1** and **Figure 5.19**, **section 6.4.2**)
4	Coordination and collaboration for governance and management of biological invasions	Build shared trust, community-based management using adaptive management approaches (**sections 6.4.2**, **6.4.4**) and implementing appropriate, context-relevant network design for the governance structure (**sections 6.4.4.2**, **6.5.6**)
5	Surveillance and monitoring for early detection, data generation and evaluating the effectiveness of interventions for invasive alien species	Citizen science and citizen surveillance activities, including apps and data input portals (**Chapter 1**, **Figure 1.13** and **Box 1.15**; **Chapter 5**, **section 5.4.3.2** and **Table 5.6**, **section 6.6.2.1**; Box 6.20)

Developing new risk assessment tools (**Chapter 5**, **section 5.2.2.1.e**) also means employing coordinated regulatory instruments that support coherent governance for biological invasions **(Figure 6.21)** and address the fractured and disjointed approach to invasive alien species management resulting from policies that solely address issues within sectorial silos (Shine, 2007; Outhwaite, 2013; Hulme, 2021). As described in **section 6.7.2.7**, this integration could be achieved by focusing on the links between risk assessment tools of legal and regulatory instruments currently within human, animal, plant and environmental sectors.

(2) Forecasts, scenarios and models

The development of forecasting tools based on drivers that facilitate biological invasions (Essl, Lenzner, *et al.,* 2020), or mechanistic models (Sarà *et al.,* 2013; Chapman *et al.,* 2017) is vital. These forecasting tools should also focus on predicting the impacts of invasive alien species by considering the synergies in interacting drivers including invasive alien species, invasive alien species interactions and impacts (Gaertner *et al.,* 2014). These tools would then need a description of the possible scenarios of change based on shifts of the drivers in facilitating biological invasions (**Chapter 3**, **section 3.1.1**). The scenarios would describe the alternative trajectories for biological invasions within the context of complex and uncertain future socioecological developments (Alien scenarios, 2021; Roura-Pascual *et al.,* 2021).

Incorporating a wide range of modelling and scenario techniques could enable assessment of multiple pathways across spatial scales and through integration of different domains (i.e., a nexus approach; J. Liu, Hull, *et al.,* 2018). Currently joint scenario and modelling studies have a strong focus on correlative modelling approaches using single driver assessments and exploratory scenarios[19] (**Chapter 1**, **section 1.6.7.3**). Other gaps, such as the vast absence of policy-screening and target-seeking scenarios, quantifiable sustainability and policy targets for biological invasions or the widespread lack of process-based models have to be filled in order to understand the needs for and development of transformative change pathways that account for the adverse effects of invasive alien species on biodiversity, nature's contribution to people and good quality of life (**section 6.6.1.6**). Existing initiatives for transformative change related to biodiversity change (Leclère *et al.,* 2020), climate change (e.g., Burch *et al.,* 2014; Schot & Steinmueller, 2018) or food security (A. Muller *et al.,* 2017) can be taken as blueprints for the steps that can be taken to use scenarios and models to support transformative change.

19. Data management report available at: https://doi.org/10.5281/zenodo.5706520

(3) Innovative science and environmentally sound technologies to support prevention and control

The continued increasing rate in invasive alien species introductions (**Chapter 2**) highlights the need for innovative science and technologies to support the detection of and rapid response to invasive alien species (Chown *et al.,* 2015; NISC, 2016). There is a need for development of new approaches but also improvements in the effectiveness and cost-efficiencies of existing methods. In the context of technological innovations **(Figure 6.21)**, these might come from efforts or programmes focused on detection (using visual, chemical, acoustic, or genetic attributes) and/or identification for military intelligence, or human health purposes, which have not traditionally focused on invasive alien species (Martinez *et al.,* 2020; Conservation X Labs, 2017). The deployment of artificial intelligence driven internet monitoring systems for invasive species is another powerful technological advancement for the early detection of sources of known invasive alien species prior to their potential entry (Suiter & Sferrazza (2007) for an example of the application of such technology). A fundamental dimension of this development is to ensure the applicability of current technologies in diverse contexts (Martinez *et al.,* 2020; Kamenova *et al.,* 2017; **section 6.3.1.4**).

6.7.2.7 Support information systems, infrastructures and data sharing to connect knowledge systems using digital processes and international partnerships

Current understanding of the biological invasion process is adequate for taking preventive effective action. However, there remain key data, information and knowledge gaps in invasion biology and social science for bringing about widespread progress across invasion stages that could be beneficial in maximizing the efficacy of actions **(Table 6.10)**. Information systems and sharing are essential for the integrated governance for biological invasions (**Figures 6.21** and **6.23**) as these would (i) provide direction for filling key data and information gaps, (ii) enable open and equitable access to information across well and poorly resourced regions and stakeholders, (iii) facilitate the research and capacity-building needed to respond to ongoing and changing demands for information on the multiple dimensions of the problem of invasive alien species and (iv) mobilize the knowledge needed to support effective implementation of prevention and control measures (Caniglia *et al.,* 2021). Importantly, to avoid wasted investment in information platforms that collapse as resourcing changes across funding cycles, a mechanism for long-term, sustained support for an information sharing system is desirable (**sections 6.2.3.1(3)** and **6.6**).

6.7.3 Promoting a conducive environment and enabling conditions for integrated governance and transformative change

Creating a conducive environment to achieve the change that is needed is an important part of effective prevention and control of invasive alien species **(Figure 6.24)**. Good governance systems are characterized by being effective, robust, responsive and equitable (Bennett & Satterfield, 2018), and employing the strategic actions and priority interventions that bring about these characteristics **(Figure 6.24)**. These four qualities can be achieved by drawing on a broad suite of policy instruments, methods and support tools, using formal and informal decision-making structures and facilitated by processes such as negotiation, conflict resolution and knowledge sharing, particularly at local scales.

Designing, building and strengthening governance systems for biological invasions with effective, robust, responsive and equitable purposes in mind is, therefore, likely to be one of the most important determinants of progress to achieving goals for invasive alien species management. Indeed, several of the factors identified in this section, based on invasive alien species evidence, reinforce the enabling conditions identified as necessary to the 2030 mission for the Kunming Montreal Global Biodiversity Framework (CBD, 2021a), namely:

- Building participation of all stakeholders, including Indigenous Peoples and local communities;
- Inclusion of multiple sectors in decision-making;
- The need for synergies across relevant multilateral agreements and policy coherence and effectiveness monitoring;

INVASIVE ALIEN SPECIES GOVERNANCE

EFFECTIVE

Limits the spread and reduces the negative impacts of invasive alien species on nature and society by bringing about the prevention and control of invasive alien species

Levers
- Strategy and action planning for invasive alien species
- Coordination to clarify the roles, functions and mandates of actors and institutions responsible for and affected by invasive alien species
- Capacity, skills and resources, for example including strong leadership and mechanisms to resolve conflict
- Informed by evidence and a diversity of knowledge types and systems, including Indigenous and local knowledge
- Accountable, including procedures for transparent decision-making and reporting
- Efficient, for example, by prioritizing where to invest in action

RESPONSIVE

Enables adaptation to the diverse invasion stages and contexts in which invasive alien species are a concern and to the background of a changing climate

Levers
- Learning takes place across the network - from institutions to local communities - to produce, document and share information
- Anticipatory including scenario planning and supported by risk analysis and monitoring
- Adaptive so that processes to revisit, assess and evolve are institutionalized
- Innovative, enabling experimentation and higher risk tolerance, for example with appropriately regulated new technologies
- Flexible and responsive so that policies are in touch with local contexts and their diversity

EQUITABLE

Uses processes that include all relevant stakeholders and that produce fair outcomes

Levers
- Policy and processes consider and respect the diversity of perspectives, values and cultures
- Participation by having structures and spaces for engagement and collective decision making
- Mechanisms are in place to ensure fair distribution of costs and benefits, rights and responsibilities
- Just laws and policies that protect rights and provide access to justice

ROBUST

Ensures that institutions responsible for invasive alien species policy and its implementation are strong, resilient to shocks and able to maintain performance

Levers
- Legitimacy with a common vision and public support
- Connected, with strong vertical and horizontal links and relationships, supported by bridging organisations
- Nested with responsibility conferred to the lowest level possible and self-organisation encouraged
- Multiple decision-making and action centres, with some redundancy and overlap enabling resilience

Figure 6 24 **The conditions that support integrated governance for biological invasions reflecting the desirable, inter-dependent qualities of governance systems (i.e., the properties of governance systems in Figure 6.21).**

Adapted from Bennett & Satterfield (2018), https://doi.org/10.1111/conl.12600, under license CC BY 4.0.

- The establishment of cooperation mechanisms that enable collective action;
- Active involvement of sub-national and local decision-making nodes and clear assignment of roles and responsibilities;
- Preventing indirect and negative telecoupling effects (also called spill over processes), such as invasive alien species themselves;
- Recognition of the challenges at the highest levels of government and political will to act.

6.7.4 Conclusion

This chapter, supported by evidence from policy studies and other fields, and reflecting knowledge gained from previous chapters, has identified numerous options which could substantially improve invasive alien species prevention and control across multiple scales, levels of governance and sectors. It is important not to underestimate the immense threat to nature, nature's contributions to people and good quality of life posed by invasive alien species, which, at their worst are a form of persistent or irreversible pollution that can be considered as a "kind of calculable oppression" of future generations (Dasgupta, 2021; Sen, 1982). Optimal governance and policy-making conditions can be formed by policymakers, experts and citizens who are cognizant of the diverse existing approaches. Implementing integrated governance for biological invasions will only be achieved through deep cross-disciplinary discussions and planning and sustained, vigilant effort. A new focus on integrated governance stands to benefit not only invasive alien species management, but provides exciting paths towards new mechanisms and opportunities for communities to sustain good quality of life while addressing the intertwined threats to biodiversity that also threaten human civilization.

The overarching message of this chapter and of the IPBES invasive alien species assessment is clear: though there has been success in understanding and managing biological invasions, a robust, sustained and socially inclusive global commitment is necessary to avoid the most harmful impacts of invasive alien species on nature and people. The goals on reducing invasive alien species adopted by the parties to the CBD as part of the Kunming-Montreal Global Biodiversity Framework in late 2022 are attainable, but there is no time to waste in their earnest pursuit.

ANNEXES

ANNEX I
Glossary

A

Adaptive governance: refers to flexible and learning-based collaborations and decision-making processes involving both state and nonstate actors, often at multiple levels, with the aim to adaptively negotiate and coordinate management of social–ecological systems and ecosystem services across landscapes and seascapes (Folke *et al.,* 2005).

Adaptive management: a philosophy that accepts that management must proceed even without complete information. It views management not only as a way to achieve objectives, but also as a process for probing to learn more about the resource or system being managed. Learning is an inherent objective of adaptive management. Adaptive management is a process where policies and activities can adapt to future conditions to improve management success (CCBA, 2008).

Alien species: a species whose presence in a region is attributable to human actions, intentional or unintentional, that enable them to overcome biogeographical barriers (Richardson *et al.,* 2010; Figure 1.1). This includes species, subspecies or lower taxon, and any part (gametes, seeds, eggs, or propagules) of such species that might survive and subsequently reproduce (CBD, 2002).

B

Biocultural community protocol: a biocultural community protocol is a document that is developed after a community under-takes a consultative process to outline their core cultural and spiritual values and customary laws relating to their traditional knowledge and resources (LPP and LIFE Network *et al.,* 2010).

Biocultural management (or biocultural approaches to conservation or biocultural approaches to environmental management): actions made in the service of sustaining the biophysical and sociocultural components of dynamic, interacting, and interdependent social–ecological systems (Gavin *et al.,* 2015; Lyver *et al.,* 2019).

Biological control: the use of living organisms to suppress the population density or impact of a specific invasive alien species, making it less abundant or less damaging than it would otherwise be (Eilenberg *et al.,* 2001).

Biological invasion (or invasion process): a process involving the transport of a native species outside of its natural range, intentionally or unintentionally, by human activities to new regions where it may become established, spread and ultimately adversely impact nature, nature's contributions to people, and good quality of life (Blackburn *et al.,* 2011; Figure 1.6).

Biosecurity: for the purpose of this assessment, a strategic and integrated approach that encompasses the policy and regulatory frameworks (including instruments and activities) for identifying, analysing and managing risks, including invasive alien species, to human, animal and plant life and health, and associated risks to the economy and the environment (FAO, 2007).

Biotic facilitation: any interaction where the action of one species has a beneficial effect on another. This includes mutualistic interactions where both the facilitated and facilitator benefit (+/+), those which are commensal (+/0) when the effects of the facilitated on the facilitator are neutral as well as those which are antagonistic (+/–) when the facilitated negatively impact the facilitator. Note that this concept partially overlaps with that of mutualism, ecological engineering and niche construction (Zélé *et al.,* 2018).

Biotic homogenization: also referred to as the 'anthropogenic blender' (Olden, 2006), the loss of biotic uniqueness, where local community assemblages are becoming more similar to each other on average, and this biotic homogenization (Finderup Nielsen *et al.,* 2019; McKinney & Lockwood, 1999; Yang *et al.,* 2021).

Biotic resistance to invasion: the ability of species in a community to limit the recruitment or invasion of other species (Catford *et al.,* 2009; Levine *et al.,* 2004). It is central to our understanding of how communities at risk of invasion assemble after disturbances, but it has yet to translate into guiding principles for the restoration of invasion-resistant communities (Byun *et al.,* 2013).

Bridging organizations offer a means to improve environmental management outcomes by spanning the science-policy interface to allow for the effective sharing of data, information, and knowledge. Bridging organizations are institutions that use specific mechanisms such as working groups to link and facilitate interactions among individual actors in a management setting." (Kowalski & Jenkins, 2015)

C

Casual species: species that do not have self-sustaining populations and which rely on repeated introductions for their persistence i.e., not yet an established species (Blackburn *et al.,* 2011).

Circular economy: model of production and consumption, which involves sharing, leasing, reusing, repairing, refurbishing and recycling existing materials and products as long as possible. In this way, the life cycle of products is extended (European Parliament, 2015).

Citizen science: diverse range of approaches in which scientific research is conducted, in whole or in part, by volunteers with varying levels of expertise (also known as community science, participatory monitoring, community-based environmental monitoring, crowd science, crowd-sourced science, civic science, or volunteer monitoring). Citizen science often contributes to surveillance of invasive alien species (Gardiner & Roy, 2022; Pocock *et al.,* 2018).

Classical biological control: the intentional introduction of an alien species, usually co-evolved, as a biological control agent for permanent establishment and long-term control (Eilenberg *et al.,* 2001).

Closed water systems: in the context of management of biological invasions, bodies of water that do not directly or indirectly drain with continuous and intensive flow into an ocean or river, recognizing that no natural systems may be entirely closed (e.g., some inland surface waters and water bodies/freshwater).

Collective action: action taken together by a group of people whose goal is to achieve a common objective. It is a term that is used in many areas of the social sciences including psychology, sociology, anthropology, political science and economics (Hardin, 2015).

Colonization pressure: the number of species introduced or released to a single location, some of which will go on to establish a self-sustaining population and some of which will not (Blackburn *et al.,* 2020; Lockwood *et al.,* 2009).

Connected water systems: in the context of management of biological invasions, bodies of water that are directly or indirectly connected to an ocean or a main river (e.g., cryosphere, shelf ecosystems and coastal areas).

Containment: the application of measures in and around an infested area to prevent spread of invasive alien species. Containment may also apply in the context of keeping an invasive alien species out of a defined geographic region within a broader infestation (in pest management this is also termed "area-wide management") (FAO, 2019). Any action taken to delimit the distribution of an invasive alien species through whatever means possible.

Control: direct action(s) taken to reduce or suppress the distribution, abundance, spread and impacts of invasive alien species within a defined geographic area (FAO, 1995) (see management).

Cost-benefit analysis: an analytical tool for judging the economic advantages or disadvantages of an investment decision by assessing its costs and benefits in order to assess the welfare change attributable to it. The analytical framework of CBA refers to a list of underlying concepts which is as follows: opportunity cost, long-term perspective, calculation of economic performance indicators expressed in monetary terms, microeconomic approach, incremental approach (European Commission, 2015).

Cost-effectiveness analysis: an analytical tool to identify the best activity, process, or intervention that justifies/minimizes resource use to achieve a desired result (BetterEvaluation, 2014).

Cryptogenic species: a species, which cannot be reliably demonstrated as being either alien or native (Carlton, 1996).

D

DNA barcoding: a commonly used molecular method (e.g., for detection of species, revealing species interactions and assessment of diversity of community assemblages) that involves the amplification of a short section of DNA from a specific gene or genes. Recent advances have extended the application of this approach from the identification of individual specimens to identification of multiple specimens within mixed samples through DNA metabarcoding (Klink *et al.,* 2022).

E

E-commerce: "online ordering, sale, communication and payment, in particular, business to consumer and consumer to consumer transactions but can also be applicable to business-to-business transactions" (WCO, 2018).

Eco-evolutionary dynamics: reciprocal interactions between ecological and evolutionary processes. Ecological and evolutionary time-scales can be so similar that evolutionary change might be rapid enough to influence ecological dynamics (Brunner *et al.,* 2019; Schoener, 2011).

Ecosystem: a dynamic complex of plant, animal and micro-organism communities and their non-living environment interacting as a functional unit (IPBES glossary).

Ecosystem-based management: an environmental management approach that recognizes the full array of interactions within an ecosystem, including humans, rather than considering single issues, species, or ecosystem services in isolation (NOAA, 2020).

Eradication: elimination/extirpation of an invasive alien species from a defined geographic area even in the absence of all preventive measures obviating the necessity for further control measures (Dowdle, 1998). The time period after which an invasive alien species can be considered eradicated depends on the species and location.

Essential Biodiversity Variables: measurement required for study, reporting, and management of biodiversity change (Pereira *et al.,* 2013).

Established alien species: alien species which produce self-sustaining and viable populations for a given period of time, during which climatic extremes typical for the invaded region are experienced, without direct intervention by humans or despite human intervention (Blackburn *et al.,* 2011; Pyšek *et al.,* 2004; Rojas-Sandoval & Acevedo-Rodríguez, 2015).

Externality: an economic concept of uncompensated environmental effects of production and consumption that affect consumer utility and enterprise cost outside the market mechanism (OECD, 2003).

F

Feedback loops: processes that either amplify (positive feedback loop) or diminish (negative feedback loop) the effects of a biological invasion**.** Feedback loops may make the impacts of biological invasions stronger or weaker, starting a chain reaction that repeats again and again. **Negative feedback loop:** A human-natural feedback that continually stabilizes or reduces ongoing or future biological invasions (also known as a 'balancing' feedback loop). **Positive feedback loop:** A human-natural feedback that continually increases ongoing or future biological invasions (also known as 'exacerbating' or 'reinforcing' feedback loops) (Sinclair *et al.,* 2020).

G

Good quality of life: within the context of the IPBES Conceptual Framework – the achievement of a fulfilled human life, a notion which varies strongly across different societies and groups within societies. It is a context-dependent state of individuals and human groups, comprising aspects such as access to food, water, energy and livelihood security, and also health, good social relationships and equity, security, cultural identity, and freedom of choice and action. "Living in harmony with nature", "living-well in balance and harmony with Mother Earth" and "human well-being" are examples of different perspectives on a "Good quality of life" (IPBES glossary).

Governance: the way the rules, norms and actions in a given organization are structured, sustained, and regulated (IPBES glossary).

H

Habitat: "the area, characterized by its abiotic and biotic properties, that is habitable by a particular species" (IUCN Standards and Petitions Committee, 2013).

I

Impacts: changes to nature, nature's contributions to people, and/or the good quality of life (Ricciardi *et al.,* 2013). Impacts can be observed or unobserved. More specifically, impacts to nature (formerly 'ecological impact'), is defined as a measurable change to the properties of an ecosystem (Ricciardi *et al.,* 2013), and implies that all introduced species can have an impact, even when not yet established or widespread, which may vary in magnitude, simply by integration into the ecosystem.

Indigenous and local knowledge systems: social and ecological knowledge practices and beliefs pertaining to the relationship of living beings, including people, with one another and with their environments. Such knowledge can provide information, methods, theory and practice for sustainable ecosystem management (IPBES glossary).

Information and Communication Technology (ICT): a broader term for Information Technology (IT), which refers to all communication technologies, including the internet, wireless networks, cell phones, computers, software, middleware, video-conferencing, social networking, and other media applications and services enabling users to access, retrieve, store, transmit, and manipulate information in a digital form (FAO, 2017b).

Information systems: infrastructures for organising data and information. As examples, the Global Biodiversity Information Facility (GBIF) and Ocean Biogeographic Information System (OBIS) are international on-line infrastructures for organizing data of species presences in space and time. For examples of invasive alien species information systems see Katsanevakis & Roy (2015) and Latombe et al. (2017).

Integrated governance for biological invasions: establishment of relationships between the roles of actors, institutions and instruments, and involving as appropriate all those elements of the socio-ecological system that characterize biological invasion and its management, for the purpose of identifying the strategic interventions needed to improve invasive alien species prevention and control outcomes (definition originated from this assessment, from the thinking on integrated environmental governance).

Integrated pest management: careful consideration of all available pest control techniques and subsequent integration of appropriate measures that discourage the development of pest populations and keep pesticides and other interventions to levels that are economically justified and reduce or minimize risks to human and animal health and the environment. Integrated pest management emphasizes the growth of a healthy crop with the least possible disruption to agro-ecosystems and encourages natural pest control mechanisms (FAO, 2017a). This management method seeks control using the most economical means, and with the least possible hazard to people, property, and the environment (U.S. EPA, 2015b).

Integrated policy for biological invasions: an integrated approach to planning and implementing future options to reduce the spread and limit the impact of biological invasions considers the fact that (1) multiple levels of governance are relevant, (2) diverse actors and decision-makers are involved, (3) the invasion process is multi-staged, and (4) drivers of invasion are multiple and interacting (Herrick, 2019).

Introduction pathway: a suite of processes that result in the introduction of a species from one geographical location to another. It means: 1) geographic routes by which a species is moved outside its natural range (past or present); 2) corridors of introduction (e.g., road, canal, tunnel); and/or 3) human activity that gives rise to an intentional or unintentional introduction. More than one vector (see definition of vector below) within a pathway may be involved in a transfer of species (Pyšek *et al.,* 2011; Genovesi & Shine, 2004).

Invasion cold spot: areas of low alien species richness relative to other regions with similar biogeographic characteristics (O'Donnell *et al.,* 2012). Biodiversity hot spots of diversification and species richness are defined as geographic regions with high diversification rates or high species richness, respectively, while conversely cold spots are geographic regions with low diversification rates or species richness (Melián *et al.,* 2015).

Invasion curve: depiction of the different stages of invasive alien species management from prevention to early detection and eradication, containment and adaptive management (Invasive Species Centre, 2021). The curve shows that eradication of an invasive alien species is less probable and more costly as it spreads over time. Choosing a management action relies on where a species is on the invasion curve.

Invasion debts: the potential increase in biological invasions at a site over a particular time frame in the absence of any interventions (Rouget *et al.,* 2016). It is composed of the number of new species that will be introduced (introduction debt), the number of species that will become invasive (species-based invasion debt), the increase in area affected by invasions (area-based invasion debt), and the increase in the negative impacts caused by introduced species (impact-based invasion debt) (Zengeya & Wilson, 2020).

Invasion hotspot: areas of high alien species richness relative to other regions with similar biogeographic characteristics (O'Donnell *et al.,* 2012). Biodiversity hot spots of diversification and species richness are defined as geographic regions with high diversification rates or high species richness, respectively, while conversely cold spots are geographic regions with low diversification rates or species richness (Melián *et al.,* 2015).

Invasion stages: stages (transport, introduction, establishment, and spread) that a species must pass through on the invasion continuum from native to (invasive) alien species, recognising the need for a species to overcome the barriers (geography, captivity or cultivation, survival, reproduction, dispersal and environmental) that obstruct transition between each stage (Blackburn *et al.,* 2011).

Invasional meltdown: the amplification of impacts of invasive alien species through community-level processes in which there is a cascade of effects, positive feedback loops, arising from the interactions amongst species, in this case alien species, which ultimately affect ecosystem functions (Simberloff, 2006).

Invasive alien species: animals, plants or other organisms introduced directly or indirectly by people into places out of their natural range of distribution, where they have become established and dispersed, and generating an impact on local ecosystems and species (IPBES, 2016); see Chapter 1 for further discussion). Invasive alien species are a subset of established alien species that have negative impacts.

L

Lag phase: the time between when an alien species arrives in a new area and the onset of the phase of rapid, or exponential, increase. Multiple factors are frequently implicated in the persistence or dissolution of the lag phase in biological invasions, including an initial shortage of suitable sites, the absence or shortage of essential mutualists, inadequate genetic diversity, and reduction in competition or predation (due to other alterations in the resident biota) (Zengeya & Wilson, 2020).

Legal personality: any entity that has the ability to conclude and negotiate international agreements in accordance with its external commitments; become a member of international organizations; join international conventions, such as the European Convention on Human Rights, stipulated in Article 6(2) of the Treaty on European Union (EUR-Lex, 2022).

M

Management: for the purpose of the assessment, any action taken to address the threats, risks, distribution, abundance and impacts of an invasive alien species within a defined geographic area (Hulme, 2006; Pyšek *et al.,* 2020). Management includes prevention, preparedness, eradication, containment, and control (Robertson *et al.,* 2020).

Monitoring: for the purpose of this assessment, the continued or regular observation of an ecosystem to detect invasion/reinvasion by invasive alien species and/or their impacts.

N

Native species: taxa that have originated in a given area (their natural range) without human involvement, or that have arrived there without intentional or unintentional intervention of humans, from an area in which they are native (IPBES glossary). This definition excludes products of hybridization involving alien taxa since "human involvement", in this case, includes the introduction of an alien parent (Pyšek *et al.,* 2004).

Nature: in the context of IPBES, refers to the natural world with an emphasis on its living components. Within the context of western science, it includes categories such as biodiversity, ecosystems (both structure and functioning), evolution, the biosphere, humankind's shared evolutionary heritage, and biocultural diversity. Within the context of other knowledge systems, it includes categories such as Mother Earth and systems of life, and it is often viewed as inextricably linked to humans, not as a separate entity (see "Mother Earth") (IPBES glossary).

Nature's contributions to people: all the contributions, both positive and negative, of living nature (i.e., diversity of organisms, ecosystems, and their associated ecological and evolutionary processes) to the quality of life for people. Beneficial contributions from nature include such things as food provision, water purification, flood control, and artistic inspiration, whereas detrimental contributions include disease transmission and predation that damages people or their assets. Many nature's contributions to people may be perceived as benefits or detriments depending on the cultural, temporal or spatial context (IPBES glossary).

Nexus: interlinkages among biodiversity, climate change, adaptation and mitigation including relevant aspects of the energy system, water, food, and health (IPBES, 2021).

O

One Biosecurity: interdisciplinary approach to biosecurity policy and research that builds on the interconnections between human, animal, plant, and environmental health to effectively prevent and mitigate the impacts of invasive alien species. It provides an integrated perspective to address the many biosecurity risks that transcend the traditional boundaries of health, agriculture, and the environment. Individual invasive alien plant and animal species often have multiple impacts across sectors: as hosts of zoonotic parasites, vectors of pathogens, pests of agriculture or forestry, as well as threats to biodiversity and ecosystem function (Hulme, 2020, 2021).

One Health: an integrated, unifying approach that aims to sustainably balance and optimize the health of people, animals, and ecosystems. It recognizes the health of humans, domestic and wild animals, plants, and the wider environment (including ecosystems) are closely linked and interdependent (One Health High-Level Expert Panel (OHHLEP) *et al.,* 2022).

P

Pathway management: any action taken (single or via systems approach) towards a particular anthropogenic invasive alien species arrival pathway (e.g., trade) to prevent or address the threats and risks of an invasive alien species arriving and establishing via that pathway either between or within jurisdictions (Robertson *et al.,* 2020).

Policy: a definite course or method of action selected from among alternatives and in light of given conditions to guide and determine present and future decisions (IPBES, 2019). See also Governance.

Policy cycle: a framework describing the policy process in terms of four linked phases: agenda setting, policy design, policy implementation, and policy review (IPBES glossary).

Policy regime: constructs that depict the mix of institutional mechanisms that make up the governing arrangements addressing a particular problem (Herrick, 2019), noting that for the purpose of this assessment the term "regime" is used for a governance system, affecting more than one country, for a specific issue area, such as invasive alien species (Andonova & Mitchell, 2010).

Polycentric governance: an organizational structure where multiple independent actors mutually order their relationships with one another under a general system of rules (Ostrom, 2010).

Polymerase chain reaction (PCR): sometimes called "molecular photocopying," the polymerase chain reaction (PCR) is a fast and inexpensive technique used to "amplify" - copy - small segments of DNA. Because significant amounts of a sample of DNA are necessary for molecular and genetic analyses, studies of isolated pieces of DNA are nearly impossible without PCR amplification (National Human Genome Research Institute, 2020).

Precautionary approach: where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environment degradation (Principle 15 of the 1992 Rio Declaration, (CBD, 1992).

Preparedness (in the context of invasive alien species management): any policy and/or action undertaken to prepare for the probable arrival of a potential invasive alien species including any preventative or adaptive response activity (Australian Government - Department of Agriculture, Fisheries and Forestry, 2019).

Prevention: for the purpose of this assessment, any policy and/or action/ response undertaken to prevent the arrival and/or introduction of alien and invasive alien species, between and within countries and regions. Prevention is generally far more cost-effective and environmentally beneficial than measures taken following introduction and establishment of an invasive alien species (CBD, 2002).

Propagule pressure (also termed 'introduction effort'): a measure of introduction intensity, including release from captivity or cultivation, comprising both the number of individuals of a species introduced per introduction (propagule size) and the frequency of introductions (Lockwood *et al.,* 2005).

R

Range: "the current limits of distribution of a species, accounting for all known, inferred or projected sites of occurrence" (IUCN, 2016).

Resilience: for the purpose of this assessment, the ability of an ecosystem to adapt, withstand and respond to alien species invasions, recover rapidly from their impacts and continue to develop (U.S. EPA, 2015a).

Restoration: any intentional activity that initiates or accelerates the recovery of an ecosystem from a degraded state (IPBES glossary). More specifically, in the context of invasive alien species management, it refers to the process of assisting the recovery of a degraded, damaged, or destroyed ecosystem, as a consequence of biological invasions, to reflect values regarded as inherent in the ecosystem and to provide goods and services that people value (adapted from Martin, 2017).

Risk: probability of the occurrence of a particular adverse event at a specific time and the magnitude of the consequent damage caused, depending on various factors such as exposure to the hazard, the frequency of exposure and the severity of any consequent damage done (FAO, 2011b). The term risk is regarded as a product of three factors: Exposure x Likelihood x Consequence (Kinney & Wiruth, 1976). Exposure results from the introductions, establishment and spread of an alien species, whereas Likelihood is the probability of an alien species affecting nature, nature's contributions to people, good quality of life and/or the economy, and Consequence is the magnitude of impacts if an introduction event occurs (D'hondt *et al.,* 2015).

S

Safe trade: export of products that are free from invasive alien species (Burgiel *et al.,* 2006).

Sentinel sites or locations: selected locations with heightened levels of detection and effective reporting through concentration of activities on subpopulations to enhance detection and improve cost-effectiveness of invasive alien species surveillance efforts (Keeling *et al.,* 2017).

Site-based management: programmes that aim to manage the impacts of invasive alien species within a site/area through both implementation of control measures and where necessary restoration (sometimes referred to as asset protection) e.g., within high value protected sites/areas.

Species-led management: invasive alien species management (in all contexts) focused on reducing the threats and impacts of specific or multiple invasive alien species.

Surveillance: actions, including extended programme of surveys and general surveillance (capturing unstructured and untargeted surveillance data and information from a wide range of sources), undertaken in order to directly or indirectly detect the presence of one or many invasive alien species over time (CEPM, 1996; Clift, 2008; CPM, 2015).

T

Tragedy of the commons: a situation in which individuals with access to a public resource (also called a common) act in their own interest and, in doing so, ultimately deplete the resource (Spiliakos, 2019).

Transformative change: a fundamental, system-wide reorganization across technological, economic, and social factors making sustainability the norm (Díaz *et al.,* 2019).

Transformative governance: the set of formal and informal (public and private) rules, rulemaking systems and actor networks at all levels of human society that enable transformative change (Visseren-Hamakers *et al.,* 2021).

Trend: temporal trends are directional long-term changes (i.e., decades to centuries) in numbers of species, populations or individuals introduced, or the spatial extent of colonization (Buckland *et al.,* 2017). In this assessment report, trends are presented as indicators of species numbers (species richness) and rates of accumulation of species (e.g., first records of a species in a given location) over time.

V

Value chains (that link production systems, markets and consumers): a contact network, which provides opportunities for the transmission of contagious diseases within and between sectors. It follows that these chains (networks) can be understood and taken into account in planning risk management strategies for disease prevention and control" especially in relation with "risky parts of the value chain" (FAO, 2011a).

Vector: Any living or non-living carrier that transports living organisms intentionally or unintentionally (ICES, 2005).

W

Widespread species: species that are able to maintain viable populations across a range of environments leading to a large range size. Widespread species are likely to experience a large range of ecological and climatic conditions within their range. A large niche width – based on the current distribution of a species – seems to be a general pattern in widespread species (Gaston, 2003; Vincent *et al.,* 2020).

Willingness to pay: the stated price that an individual would accept to pay for avoiding the loss or the diminution of an environmental service (United Nations, 2003).

ANNEX II
Acronyms

ASEAN	Association of Southeast Asian Nations
AU$	Australian dollar
BWM Convention	International Convention for the Control and Management of Ships' Ballast Water and Sediments
CABI	Centre for Agriculture and Biosciences International
CARE	Collective Benefit, Authority to Control, Responsibility and Ethics
CBD	Convention on Biological Diversity
CITES	Convention on International Trade in Endangered Species of Wild Fauna and Flora
CO_2	Carbon dioxide
COP	Conference of the Parties
COVID-19	Coronavirus disease 2019
CRISPR	Clustered Regularly Interspaced Short Palindromic Repeats
DIISE	Database of Island Invasive Species Eradications
DNA	Deoxyribonucleic Acid
DPSR	Driver- Pressure- State- Response
dsRNA	double-stranded Ribonucleic Acid
EICAT	Environmental Impact Classification for Alien Taxa
€	Euro
FAIR	Findable, Accessible, Interoperable and Reusable
FAO	Food and Agriculture Organization (of the United Nations)
GDP	Gross Domestic Product
GEF	Global Environment Facility
GEO BON	Group on Earth Observations Biodiversity Observation Network
GISD	Global Invasive Species Database
GloNAF	Global Naturalized Alien Flora
GRIIS	Global Register of Introduced and Invasive Species
IMO	International Maritime Organization
IPBES	Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services
IPCC	Intergovernmental Panel on Climate Change
IPPC	International Plant Protection Convention
ISPM	International Standards for Phytosanitary Measures
ISSG	Invasive Species Specialist Group
IUCN	International Union for Conservation of Nature
MERCOSUR	Mercado Común del Sur (Southern Common Market)
NBSAPs	National Biodiversity Strategies and Action Plans
NZ$	New Zealand dollars
PCR	Polymerase Chain Reaction
RHDV	Rabbit Haemorrhagic Disease Virus
RNAi	Ribonucleic Acid Interference
SARS-CoV-2	Severe Acute Respiratory Syndrome Coronavirus 2
SCOPE	Scientific Committee on Problems of the Environment
SDGs	Sustainable Development Goals
SEICAT	Socio-Economic Impact Classification for Alien Taxa
SIDS	Small Island Developing States
SPS Agreement	Agreement on the Application of Sanitary and Phytosanitary Measures
SSC	Species Survival Commission
UNESCO	United Nations Educational, Scientific, and Cultural Organization
UNFCCC	United Nations Framework Convention on Climate Change
US$	United States dollars
WCO	World Customs Organization
WHO	World Health Organization
WOAH	World Organisation for Animal Health
WTO	World Trade Organization

ANNEX IV
List of authors and review editors

Co-chairs

Aníbal Pauchard
Co-chair
Universidad de Concepción
Chile

Helen E. Roy
Co-chair
UK Centre for Ecology & Hydrology
United Kingdom of Great Britain and Northern Ireland

Peter Stoett
Co-chair
Ontario Tech University
Canada

Chapter 1

Aníbal Pauchard
Coordinating Lead Author
Universidad de Concepción
Chile

Helen E. Roy
Coordinating Lead Author
UK Centre for Ecology & Hydrology
United Kingdom of Great Britain and Northern Ireland

Peter Stoett
Coordinating Lead Author
Ontario Tech University
Canada

Tatsiana Lipinskaya
Fellow
Scientific and Practical Center for Bioresources of the National Academy of Sciences of Belarus
Belarus

Joana R. Vicente
Fellow
CIBIO, Centro de Investigação em Biodiversidade e Recursos Genéticos, InBIO Laboratório Associado, Campus de Vairão, Universidade do Porto; Departamento de Biologia, Faculdade de Ciências, Universidade do Porto, Portugal & BIOPOLIS Program in Genomics, Biodiversity and Land Planning, CIBIO, Campus de Vairão,
Portugal

Piero Genovesi
Review Editor
1) Institute for Environmental Protection and Research ISPRA,Italy
2) Chair IUCN SSC Invasive Species Specialist Group, Switzerland
Switzerland, Italy

John R. Wilson
Review Editor
South African National Biodiversity Institute, Kirstenbosch Research Centre, Cape Town, South Africa & Centre for Invasion Biology, Department of Botany and Zoology, Stellenbosch University, Stellenbosch, South Africa
South Africa

Chapter 2

Laura A. Meyerson
Coordinating Lead Author
University of Rhode Island
United States of America

Sebataolo J. Rahlao
Coordinating Lead Author
Scientific Services, Ezemvelo KZN Wildlife
South Africa

Hanno Seebens
Coordinating Lead Author
Senckenberg Biodiversity and Climate Research Centre
Germany

Alla Aleksanyan
Lead Author
Institute of Botany after A. Takhtajyan NAS RA
Armenia

Franck Courchamp
Lead Author
CNRS - Université Paris-Saclay
France

Emre Keskin
Lead Author
Ankara University, Agricultural Faculty, Department of Fisheries and Aquaculture, Evolutionary Genetics Laboratory (eGL)
Turkey

Petr Pyšek
Lead Author
Czech Academy of Sciences, Institute of Botany
Czech Republic

Alifereti Tawake
Lead Author
Locally Managed Marine Area (LMMA) Network International
Fiji

Elena Tricarico
Lead Author
Department of Biology, University of Florence
Italy

Bernd Lenzner
Fellow
Bioinvasions, Global Change, Macroecology Group, Department of Botany and Biodiversity Research, University of Vienna
Austria

Hanieh Saeedi
Fellow
Marine Zoology Department, Senckenberg Research Institute and Natural History Museum, Frankfurt am Main
Germany

Cang Hui
Review Editor
Department of Mathematical Sciences, Stellenbosch University; Mathematical Biosciences, African Institute for Mathematical Sciences
South Africa

Victoria Werenkraut
Review Editor
INIBIOMA (CONICET - Universidad Nacional del Comahue)
Argentina

Chapter 3

Philip E. Hulme
Coordinating Lead Author
Lincoln University
New Zealand

Tohru Ikeda
Coordinating Lead Author
Hokkaido University
Japan

Vigdis Vandvik
Coordinating Lead Author
University of Bergen
Norway

Ryan Blanchard
Lead Author
SAEON - South African Environmental Observation Network
South Africa

Morelia Camacho-Cervantes
Lead Author
Instituto de Ciencias del Mar y Limnología, Universidad Nacional Autónoma de México
Mexico

Ileana Herrera
Lead Author
Universidad Espíritu Santo
Ecuador

Asuka Koyama
Lead Author
Forestry and Forest Products Research Institute
Japan

Carolina L. Morales
Lead Author
Consejo Nacional de investigaciones Científicas y Técnicas (CONICET), Instituto de Investigaciones en Biodiversidad y Medio Ambiente (INIBIOMA), Universidad Nacional del Comahue
Argentina

Linus K. Munishi
Lead Author
The Nelson Mandela-African Institution of Science and Technology (NM-AIST)
Tanzania

P. K. T. Nirmalie S. Pallewatta
Lead Author
University of Colombo
Sri Lanka

Jan Pergl
Lead Author
Institute of Botany CAS
Czech Republic

Anthony Ricciardi
Lead Author
McGill University
Canada

Esra Per
Fellow
Gazi University
Turkey

Rafael O. Xavier
Fellow
Instituto de Biologia - Universidade de Campinas
Brazil

Franz Essl
Review Editor
Bioinvasions, Global Change, Macroecology Group, University Vienna
Austria

Aveliina Helm
Review Editor
University of Tartu
Estonia

Chapter 4

Sven Bacher
Coordinating Lead Author
University of Fribourg
Switzerland

Bella S. Galil
Coordinating Lead Author
The Steinhardt Museum of Natural History and Israel National Center for Biodiversity Studies, Tel Aviv University
Israel

Martin A. Nuñez
Coordinating Lead Author
1) INIBIOMA, CONICET-Universidad Nacional del Comahue, Argentina
2) University of Houston, department of Biology and Biochemistry, United States of America
United States of America, Argentina

Michael Ansong
Lead Author
Kwame Nkrumah University of Science and Technology
Ghana

Phillip Cassey
Lead Author
University of Adelaide
Australia

Katharina Dehnen-Schmutz
Lead Author
Coventry University
United Kingdom of Great Britain and Northern Ireland

Georgi Fayvush
Lead Author
Institute of Botany after A. Takhtajyan NAS RA
Armenia

Ankila J. Hiremath
Lead Author
Ashoka Trust for Research in Ecology and the Environment (ATREE)
India

Makihiko Ikegami
Lead Author
National Institute for Environmental Studies
Japan

Angeliki F. Martinou
Lead Author
The Cyprus Institute & Joint Services Health Unit
Cyprus

Shana M. McDermott
Lead Author
Trinity University
United States of America

Cristina Preda
Lead Author

Anne Larigauderie
Executive Secretary

Hien T. Ngo
Consultant

Bonnie Myers
Programme Management Officer

Simone Schiele
Head of Work Programme

Robert Spaull
Head of Communications

Mariana Cantu Fernandez
Consultant

Alyssa Weinstein
Consultant

ANNEX V
List of expert reviewers

Expert reviewers of the IPBES thematic assessment report on invasive alien species and their control

We would like to thank all of the IPBES Multidisciplinary Expert Panel members and the Bureau – both past and current - for submitting comments during the internal and external expert review stages. We would also like to thank the members of the technical support units on knowledge and data and on Indigenous and local knowledge for their inputs when reviewing the drafts of the chapters and summary for policymakers.

All of the following expert reviewers listed below that directly participated in the invasive alien species assessment as authors submitted comments on chapters to which they were not involved.

We would like to acknowledge the following governments (including the national focal point) for submitting comments on the IPBES invasive alien species assessment:

- **Government of Antigua and Barbuda**
- **Government of Argentina**
- **Government of Armenia**
- **Government of Australia**
- **Government of Belgium**
- **Government of Brazil**
- **Government of Bulgaria**
- **Government of Canada**
- **Government of Chile**
- **Government of China**
- **Government of Estonia**
- **Government of Ethiopia**
- **Government of Finland**
- **Government of France**
- **Government of Germany**
- **Government of Ghana**
- **Government of Guinea Bissau**
- **Government of Ireland**
- **Government of Italy**
- **Government of Japan**
- **Government of Mexico**
- **Government of Myanmar**
- **Government of the Kingdom of the Netherlands**
- **Government of New Zealand**
- **Government of Norway**
- **Government of Oman**
- **Government of Portugal**
- **Government of South Africa**
- **Government of Spain**
- **Government of Sudan**
- **Government of Sweden**
- **Government of Switzerland**
- **Government of Trinidad and Tobago**
- **Government of Turkey**
- **Government of the United Kingdom of Great Britain and Northern Ireland**
- **Government of the United States of America**
- **The European Union**

The Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES)

is the intergovernmental body which assesses the state of biodiversity and ecosystem services, in response to requests from Governments, the private sector and civil society.

The mission of IPBES is to strengthen the science-policy interface for biodiversity and ecosystem services for the conservation and sustainable use of biodiversity, long-term human well-being and sustainable development.

IPBES has a collaborative partnership arrangement with UNEP, UNESCO, FAO and UNDP. Its secretariat is hosted by the German government and located on the UN campus, in Bonn, Germany.

Scientists from all parts of the world contribute to the work of IPBES on a voluntary basis. They are nominated by their government or an organisation, and selected by the Multidisciplinary Expert Panel (MEP) of IPBES. Peer review forms a key component of the work of IPBES to ensure that a range of views is reflected in its work, and that the work is complete to the highest scientific standards.
