Chairman, Patient Care Evaluation Committee — 1985-1989
Department of Psychiatry
University of Southern California School of Medicine
Los Angeles, CA

Chairman, Medical Care Review and Quality Assurance Committee — 1983-1989
University of Southern California School of Medicine
Los Angeles, CA

Director, Division of Professional and Staff Development — 1982-1989
Department of Psychiatry
University of Southern California
Los Angeles, CA

Other Post Graduate Training and Workshop

Certificate, Annual Workshop of the Society for Clinical And Experimental Hypnosis — 10/70 & 10/86
Philadelphia, PA

Course in Marital Therapy and Sexual Incompatibility — 02-05/71
Dr. Harold Lief & Staff
Department of Psychiatry
University of Pennsylvania

Certificate of Completion VI Behavior Therapy Institute Temple University	06/1971

Society Memberships

General Member American Psychiatric Association	05/73-Present
General Member Southern California Psychiatric Society	1973-Present
Member, The John Hopkins University Alumni Association	1967-Present
Society for Biological Psychiatry	1976-Present
Member, American Association for Geriatric Psychiatry	1989-Present
Member, American Academy of Addiction Psychiatry	1989-Present
Member, National Geographic Society	1984-Present
Coordinator (President) The Academy of Persian Physicians	1991
Coordinator Elect (President Elect) The Academy of Persian Physicians	1991
Member, Association for Advancement of Behavior Therapy	1980-1989
Member, American Association for the Advancement of Science	1981-1984
Member, Expert Advisory Committee on Drug Dependence and Alcohol Problems World Health Organization Geneva, Switzerland	1977-1981
Iranian Psychiatric Association	1975-1980
Pennsylvania Psychiatric Association	1971-1973
Philadelphia Psychiatric Society	1971-1973
Member Training American Psychiatric Association	1971-1972
Nu Sigma Nu (NEN) Medical Fraternity	1961-1966
Sigma Chi (EX) Fraternity	1959-1961

Other Activities

Faculty Lecturer 02/1988
"Appropriate Use of Neuroleptics on Medical-Surgical Units"
Medical Staff Meeting, Memorial Hospital of Glendale
Glendale, CA

Board Member 1987
University of Southern California Psychiatry and Behavioral
Associates Faculty Practice Plan
Los Angeles, CA

Lecturer 07/30/86
"Depression: The Hidden Illness"
Elder Med Community Education Program
Verdugo Hills Hospital

Chairman, Education Committee, Department of Psychiatry 1982-1985
Brotman Medical Center
Culver City, CA

Member, Executive Committee, Department of Psychiatry 1982-1985
Brotman Medical Center
Culver City

CURRICULUM VITAE
Ari Kiev, M.D.
SOCIAL PSYCHIATRY RESEARCH INSTITUTE

Education:

1950-1954	Harvard College, Cambridge, Massachusetts- A.B., Magna Cum Laude
1954-1958	Cornell Medical College, New York, NY- M.D.
1984-1988	New York Law School, New York, NY- J.D.

Professional Experience:

2001- Present	Social Psychiatry Research Institute, 3044 Coney Island Avenue, Suite 201 Brooklyn, NY 11235- President
1970- Present	Social Psychiatry Research Institute, 150 East 69th Street, Suite 2H New York, NY 10021- President
1994-Present	LifeSpan DevelopMental Systems, 7 Fox Street, Suite 103 Poughkeepsie, NY 12601- Director of Research
1995	Admitted to Practice Before United States Supreme Court
1990	Admitted to New York Bar
1988	Admitted to New Jersey Bar
1978-1980	United States Olympic Council on Sports Medicine New York, NY Chairman, Psychiatry Division
1977	Wilford Hall Hospital, Lackland Air Force Base, Texas Distinguished Visiting Professor
1975-1976	New York University, New York, NY, Adjunct Professor of Psychology
1967-1968	Brandeis University,Waltham, MA- Visiting Professor of Anthropology
1962-1964	Wilford Hall USAF Hospital, Lackland Air force Base, Texas Staff Psychiatrist, Captain USAF, M.D.
1961-1962	The Institute of Psychiatry, Maudsley Hospital, London, England Clinical Assistant, Postdoctoral Research Fellow (NIMH)
1959-1961	Henry Phipps Psychiatric Clinic, The Johns Hopkins Hospital Baltimore, MD- Psychiatric Resident
1958-1959	New York State Medical College (Downstate),Kings County Hospital Center Brooklyn, NY, University Medical Internship

A Kiev

Professional Memberships/Organizations:

American Psychiatric Association (Life Fellow)
American College of Legal Medicine (Fellow)

Academic Affiliations:

1967-1998	Cornell University Medical College, New York, NY Clinical Associate Professor of Psychiatry
1967-1998	New York Hospital, New York, NY- Associate Attending Psychiatrist
1966-1967	College of Physicians and Surgeons, Department of Psychiatry Columbia University, New York, NY Field Station Director • Psychiatric Epidemiology Research Unit
1964-1967	New York State Psychiatric Institute,New York, NY Assistant Attending Psychiatrist
1964-1967	Department of Psychiatry, College of Physicians and Surgeons Columbia University,New York, NY- Research Associate

Licenses/Certification:

Medical Licenses:
New York # 083337
New Jersey # MA20261
New York DEA # AK 1795559
New Jersey DEA # BK 2206630

Certifications:
1965 American Board of Psychiatry and Neurology

Publications: Available upon request.

Recent Research Experience: 2003

A Multi-center, Double-Blind, Randomized, Placebo-Controlled Comparison of the Effects on Sexual Functioning of Extended-Release Bupropion Hydrochloride (300-450mg) and Escitalopram (10-20mg) in Outpatients with Moderate to Severe Major Depression over an Eight-Week Treatment Period AK130926

A four-week double-blind, placebo and active controlled, dose-ranging study of SL 65.1498-00, 3 doses (5, 15, 50mg per day) and lorazepam (3mg/day) in out-patients with Generalized Anxiety Disorder (GAD) DR14390

A Multi-center, Double-blind, Randomized, Placebo-controlled, Double-dummy Trial of the Use of Quetiapine Fumarate (SEROQUEL™) in the Treatment of Patients with Bipolar Depression 5077US/0049

A Double-blind, Multi-center, Extension Trial in Subjects with Major Depressive Disorder who participated in the Placebo-controlled, Efficacy and Safety Trial of Org 22062 ER and Fluoxetine in Subjects with Major Depressive Disorder 134506

CURRICULUM VITAE

Ramanath Gopalan, MD

Comprehensive NeuroScience of Northern Virginia
6066 Leesburg Pike
Falls Church, VA 22041
703-998-5850

Education:

1983-1985	Arizona Health Sciences Center, Tucson, Arizona Fellowship in Administrative Psychiatry Southern Arizona Mental Health Center and Kino Community Hospital Practical experience
1980-1983	Arizona Health Sciences Center, Tucson, Arizona Psychiatry Residency -- PGY-11-IV
1979-1980	Chicago Medical School, Chicago, Illinois Psychiatry Internship--PGY-I
1975-1976	General Rotating Medical Internship, Bombay, India
1969 – 1975	Topiwala National Medical College, University of Bombay, India – M.B.B.S. (equivalent to MD)
1967-1969	University of Bombay, Bombay, India – Bachelor of Science

Professional Experience:

2001-present	Investigator Comprehensive NeuroScience of Northern Virginia, LLC
1998 – 2002	Principal Investigator ICSL - Clinical Studies Falls Church, VA
1997-1998	Sub-Investigator ICSL - Clinical Studies Falls Church, Virginia

Professional Experience:
(cont'd)

1996-Current	Private Practice in General Psychiatry, 6066 Leesburg Pike Falls Church, Virginia 22041
1996-Current	Psychiatric Consultant at: Burke Health Care Center, Burke, Virginia
1996-Current	Sleepy Hollow Manor Nursing & Convalescent Home Annandale, Virginia
1996-Current	Cherrydale Healthcare Center Arlington, Virginia

Licenses/Certifications:

1994- Current	MD-State of Virginia #0101049249
1985- Current	MD-State of Arizona #15598
1992- Current	American Association of Physicians from India
1982- Current	American Psychiatric Association
1982- Current	Arizona Psychiatric Society
1989- Current	Tucson Psychiatric Society
1979	E.C.F.M.G. Certificate #255-305-5

Admitting Priviledges:

- Dominion Hospital - 2960 Sleepy Hollow Road, Falls Church, VA 22044
- Virginia Hospital Center Arlington - 1701 North George Mason Drive, Arlington, VA 22205
- Northern Virginia Community Hospital - 611 S. Carlin Springs Rd, Arlington, VA 22204

Medical Procedures:

Trained in physical exams, venipuncture, vital signs and administering electrocardiograms.

Proficient In The Following Adult Psychiatric Rating Scales:

Brief Psychiatric Rating Scale (BPRS)
Calgary Depression Scale
Hamilton Anxiety Scale (HAMA)
Hamilton Depression Rating Scale (HAMD)
Leibowitz Social Anxiety Scale (LSAS)
Montgomery and Asberg Depression Rating Scale (MADRS)
Positive and Negative Syndrome Scale for Schizophrenia (PANSS)
Structured Clinical Interview for DSM-IV (SCID)
Structured Clinical Interview for DSM-IV Axis II Disorders (SCID II)
Yale Brown Obsessive Compulsive Scale (YBOCS)
Young Mania Rating Scale (YMRS)

Research Experience:

A Multicenter, Randomized, Double-Blind, Placebo Controlled Study of study medication in the Maintenance Treatment of Patients with Bipolar Disorder

A Multicenter, Randomized, Double-Blind Study of Flexible Doses of study medication Versus Perhenazine In The Treatment of Patients With Acute Schizophrenia

A Multicenter, Double-blind, Randomized Comparison of the Efficacy and Safety of Quetiapine Fumarate (SEROQUEL™) and Risperidone (RISPERDAL™) in the Treatment of Patients with Schizophrenia

Olanzapine versus Risperidone in the Treatment of Bipolar I Disorder, Manic or Mixed

A Multicenter, Randomized, Double-Blind, Study of Aripiprazole Versus Placebo in the Treatment of Acutely Manic Patients with Bipolar Disorder

A randomized, open-label, multicenter, 6-arm, parallel group, safety study evaluating the effect of oral iloperidone at doses of 8 mg b.i.d., 12 mg b.i.d., and 24 mg q.d. on QTc interval duration in the presence and absence of metabolic inhibition, relative to other antipsychotics (Risperidone 4 mg b.i.d., ziprasidone 80 mg b.i.d., and quetiapine 375 mg b.i.d. in the presence and absence of metabolic inhibition), in otherwise healthy patients diagnosed with schizophrenia or schizoaffective disorder

Research Experience:
(cont'd)

A 6½ Month, Multicenter, Randomized, Double-blind, Placebo Controlled Comparison of 150-300mg/day of Extended-release Bupropion hydrochloride and Placebo for the Prevention of Seasonal Affective Disorder in Subjects with a History of Seasonal Affective Disorder

A Double-Blind, Multicenter, Placebo-Controlled Study of MK-0869 in the Treatment of Patients with Major Depressive Disorder

A 12 Week, Multicenter, Randomized, Double-Blind, Placebo-Controlled Evaluation of Donepezil Hydrochloride as Adjunctive Therapy in the Treatment of Cognitive Impairment in Patients with Schizophrenia or Schizoaffective Disorder

An Open-Label, Dose-Blinded, Multicenter, 6-Month Study of Safety and Tolerability of 3 Dose Levels of SM-13496 in Patients with Schizophrenia

A 6-Week, Double-Blind, Randomized, Fixed-Dose, Parallel-
Group Study of the Efficacy and Safety of Three Dose Levels of SM-13496 Compared to Placebo and Haloperidol in Patients with Schizophrenia Who are Experiencing an Acute Exacerbation of Symptoms

A randomized assigned trial of oral XXX versus intramuscular XXX in the emergency treatment of acute psychosis.

XXX cardiovascular treatment assessment versus XXX (XXX).

Safety and efficacy of XXX as combination therapy in the treatment of psychosis associated with schizophrenia.

A multicenter, randomized, double blind study of flexible doses of XXX versus XXX in the treatment of patients with treatment-resistant schizophrenia.

Sustained efficacy study of XXX in patients with panic disorder with or without agoraphobia.

A placebo-controlled 12-week study of the safety and efficacy of two doses of XXX versus XXX for the treatment of acute manic or mixed episodes in subjects with Bipolar I Disorder with an optional open-label extension.

Research Experience:
(cont'd)

A double blind, placebo-controlled dose finding study evaluating the safety and efficacy of XXX/day in the treatment of major depressive disorder.

Safety and efficacy of long-term administration of XXX in the treatment of major depressive disorder. A 4-month double blind extension to study XXX.

Safety of open-label standard antidepressant therapy in the treatment of major depressive disorder. A 1-month follow-up after termination of study XXX.

A 6-week, double blind, placebo-controlled, multicenter study to evaluate the safety and efficacy of 3 doses of XXX and XXX in subjects with major depressive disorder.

A double blind 6-month continuation protocol for patients who successfully completed protocol XXX followed by an optional extension phase of up to a year.

A 364-week (7 year), open extension study evaluating the safety and outcome of XXX daily of oral XXX or XXX BID of oral XXX daily in the treatment of subjects who have participated in previous XXX clinical trials.

A double blind multi-centered study comparing the safety and efficacy of XXX to XXX in patients with schizophrenia or schizoaffective disorder needing in-patient care.

A multicenter, randomized, double blind, placebo-controlled study of flexible doses of XXX in the treatment of hospitalized patients with acute mania.

A multicenter, randomized, double blind, placebo controlled study of XXX in the maintenance treatment of patients with bipolar disorder.

A multicenter, randomized, double blind, placebo controlled study of three fixed doses of XXX in the treatment of patients with acute schizophrenia.

XXX depot (microspheres) vs placebo in the treatment of subjects with schizophrenia.

XXX depot (microspheres) in the treatment of subjects with schizophrenia or schizoaffective disorder.

Research Experience:
(cont'd)

A double blind, placebo and XXX controlled, multicenter study evaluating the safety and efficacy of SR XXX in schizophrenic patients.

A double blind, placebo and XXX controlled, multicenter study evaluating the safety and efficacy of SRXXXXXX in schizophrenic patients.

A randomized, double-blind, placebo and XXX controlled, multicenter study to evaluate the efficacy and safety of two overlapping dose ranges of XXX given b.i.d. for 42 days to schizophrenic patients followed by a long term treatment phase with XXX given q.d.

A double blind, place controlled, parallel group comparison of XXX extended release capsules and XXX in outpatients with generalized social anxiety disorder.

A three-month open label study of the tolerability and safety of XXX in schizophrenic patients.

An open-label follow on study of the long-term safety of XXX in patients with psychosis.

XXX long term extension of Protocol XXX-XXX.

A multi-center, open-label, humanitarian study with sublingual XXX.

A double blind, placebo-controlled study of XXX in the treatment of signs and symptoms of mania in elderly patients with dementia.

XXX in the management of behavioral disturbances and/or psychosis in demented nursing home patients.

Clinical evaluation of efficacy and safety of XXX in the treatment of Alzheimer's disease.

A Phase III randomized study comparing 2 doses of intramuscular XXX in subjects with psychosis and acute agitation.

An open-label study to evaluate the safety and efficacy of XXX through XXX of XXX in patients with mild to severe probable Alzheimer's disease.

A randomized, double blind, placebo-controlled, four-arm dose-finding study.

Research Experience:
(cont'd)

Investigating the efficacy and safety of three doses of XXX in patients with Alzheimer's disease.

A double blind, randomized, comparison of the safety and efficacy of XXX and XXX in treatment resistant schizophrenic patient.
Double blind, haloperidol-controlled, safety and dose finding study in the treatment of schizophrenia.

A double blind, placebo-controlled, haloperidol-referenced study of the safety and efficacy of three doses of XXX administered to schizophrenic patients for 42 days.

An open-label assessment of the long-term safety of XXX.

Long-term safety and efficacy of XXX in the treatment of Alzheimer's disease.

An open-label, long-term, safety study of transdermal XXX in the treatment of anxious outpatients.

An eight-week, multicenter parallel group, double-'blind, placebo-controlled study of XXX in elderly outpatients with DSM-IV major depression.

A multi-center pilot study to examine the clinical effects of cross titration of antipsychotics with XXX in subjects with schizophrenia or schizoaffective disorder followed by an optional open extension phase with continued XXX treatment.

A multi-center pilot study to examine the clinical effects of cross titration of XXX with XXX in subjects with schizophrenia or schizoaffective disorder followed by an optional open extension phase with continued XXX treatment.

The safety and efficacy of XXX vs placebo vs XXX as add-on therapy to mood stabilizers in the treatment of the manic phase of bipolar disorder.

Weekly enteric-coated XXX XXX versus daily XXX or placebo in the continuation treatment of major depressive disorder.

An open-label follow on study of the long-term safety of XXX in patients with psychosis.

XXX added to mood stabilizers in the treatment of bipolar disorder.

Research Experience:
(cont'd)

A phase III double-blind placebo-controlled study of XXX in the treatment of psychosis, with XXX as active control.

A Phase III double-blind placebo-controlled study of XXX in the treatment of psychosis.

A multicenter, double - blind, placebo-controlled evaluation of the safety and efficacy of XXX compared to placebo and XXX in the treatment of an acute manic or mixed episode in patients who have bipolar disorder: Incorporating participation in genotype research which is optional for both study centers and patients.

A double-blind, randomized, active controlled, parallel study comparing ethical XXX XXX 7-day patch 40, 60, 80 ug/day to oral XXX 0.625 mg/day in the treatment of vasomotor symptoms in postmenopausal women.

XXX vs. XXX in the treatment of subjects with schizophrenia.

A multicenter, placebo and active control, double blind, randomized study of the efficacy, safety and pharmacokinetics of XXX (10 and 20mg/day) in schizophrenic and schizoaffective patients.

Multicenter, open-label, long-term follow-up, safety study of XXX tablets in schizophrenic and schizoaffective subjects who participated in protocol XXX or XXX.

A double blind, placebo and haloperidol-controlled, multicenter study evaluating the safety and efficacy of XXX in schizophrenic patients.

A six-week, double-blind, placebo- and fluoxetine-controlled multicenter study to evaluate the safety and efficacy of oral XXX in outpatients with major depressive disorder.

A prospective, randomized, international, parallel-group comparison of XXX/XXX vs XXX in the reduction of suicidality in patients with schizophrenia or schizoaffective disorder who are at risk for suicide.

Safety and efficacy of fixed combination XXX/XXX products as first line therapy in patients with type 2 diabetes mellitus who have inadequate glycemic control with diet and exercise.

Research Experience:
(cont'd)

A multicenter, double-blind, randomized study of continuous transdermal XXX-XXX combinations, compared to continuous XXX XXX, to examine the safety and effect on the endometrium, symptoms and bleeding patterns in postmenopausal women.

Placebo-controlled study of the safety and efficacy of XXX in the treatment of acute manic or mixed episodes in subjects with bipolar I disorder.

A prospective, randomized, double-blind, placebo- and active-controlled, multicenter study to evaluate the efficacy and safety of three fixed doses of XXX (4, 8, and 12 mg/day) given b.i.d. for 42 days to schizophrenic patients with acute or subacute exacerbation, followed by a double-blind, active-controlled, flexible-dose, long-term, 20-week phase with XXX (4, 8, 12 or 16 mg/day) given q.d.

A multicenter, open-label, long-term, safety and efficacy study of XXX tablets once daily in subjects with schizophrenia or other psychotic disorders.

A double blind, multi-center controlled study comparing the safety and efficacy of XXX and XXX to placebo in patients with schizophrenia or schizoaffective disorder needing inpatient care.

XXX versus XXX and placebo in the treatment of psychosis and associated behavioral disturbances in patients with dementia.

A double blind, placebo-controlled parallel-group assessment of the safety and efficacy of two doses of the XXX in patients with major depression.

A randomized, multi-center, double blind, placebo-controlled, fixed-dose seven-week evaluation of the efficacy and safety of XXX in treatment of a major depressive episode in unipolar depressed patients.

A double-blind, randomized, multicenter, parallel group design study to evaluate the efficacy and safety of two dose ranges of XXX in comparison with placebo and haloperidol in the treatment of schizophrenia.

Phase II, six-week, double blind, placebo- and XXX controlled study evaluating the safety and efficacy of oral XXX in schizophrenia and schizoaffective disorder.

Research Experience:
(cont'd)

A double blind, five-armed, fixed-dose active- and placebo-controlled dose-finding study with sublingual XXX in subjects with acute phase schizophrenia.

A multicenter, double blind, placebo-controlled evaluation of the safety and efficacy of XXX compared to placebo in the treatment of an acute manic or mixed episode in patients who have bipolar disorder.

A prospective, randomized, double-blind, placebo- and active controlled, multicenter study to evaluate the efficacy and safety of three fixed doses of XXX given b.i.d. for 42 days to schizophrenic patients with acute or subacute exacerbation, followed by a double-blind, active-controlled, flexible-dose, long-term, 6-month phase with XXX given q.d.

Efficacy of XXX in the treatment of acutely ill non-compliant schizophrenic subjects.

Comparison of the safety and efficacy of XXX and XXX in the treatment of bipolar disorder.

A double blind, multicenter study of two doses of XXX vs. XXX and placebo in the treatment of outpatients with major depressive disorder.

Senior Vice President, National Director of Clinical Research, Comprehensive Neurosciences, Inc.

Medical Director, CNS-IPR of Southern California, Inc., a multi site clinical trials program limited to central nervous system diseases.

Board Status:

Diplomate, Psychiatry, American Board of Psychiatry and Neurology, January 1984

Diplomate, Added Qualification in Geriatric Psychiatry, American Board of Psychiatry and Neurology, 1991

Diplomate, Added Qualification in Addiction Psychiatry, American Board of Psychiatry and Neurology, 1994

Diplomate, American Society of Addiction Medicine, 2000

Licensure: California License #G40374

State of California, Department of Industrial Relations, Industrial Medical Council; Qualified Medical Evaluator
- 1993 to present

Education:

B.A. Psychology, Suma Cum Laude, 1974, SUNY at Buffalo, Buffalo, NY
M.D., 1978, Rush Medical College, Chicago, Illinois

Internship:

Psychiatry, UCLA Neuropsychiatric Institute, 1978-1979

Residency:

Psychiatry, UCLA Neuropsychiatric Institute, 1979-1981

Fellowship:

Psychopharmacology, National Institute of Mental Health, Bethesda, Maryland, 1981-1983

Clinical and Administrative Experience

Senior Vice President, Clinical Services,
Aspen Youth Services, Cerritos California, 1998-2001

President and Medical Director,
College Health IPA, a managed behavioral health group practice, Cerritos California, 1993-2001

Senior Medical Director,
College Hospital, Cerritos, California, 1993-1999

Medical Director,
Los Altos Hospital and Mental Health Center, Long Beach, California
August 1987 to August 1993

Chief, Inpatient Unit,
Clinical Psychobiology Branch, National Institute of Mental Health, Bethesda, Maryland
January 1993 to August 1987

Private Practice Experience,
1982 to Present, predominantly in the treatment of patients with affective and anxiety disorders

Emergency Psychiatric Experience,
L.A. County, Olive View Medical Center, Van Nuys, California
December 1979 to June 1981
Prince George's County General Hospital
December 1981 to June 1983

Honors:

1978 – Phi Beta Kappa

ADDENDUM

RECENT CLINICAL RESEARCH EXPERIENCE

1. "Olanzapine Versus Haloperidol in the Treatment of Schizophrenia and Other Psychotic Disorders", Protocol F1D-MC-HGAJ. Sponsored by Lilly Research Laboratories.

2. "A Comparative Cost Effectiveness Study of Depakote and Usual Care versus Lithium and Usual care in the Treatment of Bipolar Disorder", Protocol M93-111. Sponsored by Abbott Laboratories.

3. "Fluoxetine Plus Pindolol Versus Fluoxetine Plus Placebo in the Treatment of Major Depression", Protocol B1Y-MC-HZAA. Sponsored by Lilly Research Laboratories.

4. "Double-Blind, Randomized, Placebo-Controlled Evaluation of the Safety, Tolerability and Parmacokinetics of Dehydoepiandrosterone (DHEA) in Patients with Alzheimer's Disease", Protocol 01. Sponsored by Neurocrine Biosciences.

5. "An Open-Label, Multicenter Clinical Trial Evaluating the Safety and Efficacy of Donepepezil Hydrochloride (E2020) in Patients with Alzheimer's Disease", Protocol E2020-A001-303.

6. "Strategies for Switching from Conventional Antipsychotic Drugs to Olanzapine", Protocol F1D-MC-HGFW. Sponsored by Lilly Research Laboratories.

7. "U-101387G: Double-Blind, Haloperidol-Controlled, Safety and Dose-Finding Study in the treatment of Schizophrenia". ProtocolM/2745/0004. Sponsored by Pharmacia & Upjohn, Inc.

8. "A Phase III Double-Blind Placebo-Controlled Study of Aripiprazole in the Treatment of Psychosis", Protocol 31-97-201. Sponsored by Otsuka Pharmaceuticals.

9. "An Open-label Follow-On Study of the Long-Term Safety of Aripiprazole in Patients with Psychosis", Protocol 31-97-203. Sponsored by Otuska Pharmaceuticals.

10. "Olanzapine Added to Mood Stabilizers in the Treatment of Bipolar Disorder", Protocol F1D-MC-HGFU. Sponsored by Lilly Research Laboratories.

11. "Olanzapine Alone and in Combination with Fluoxetine versus Placebo in Major Depressive Disorder with Psychotic Features", Protocol F1D-MC-HGGA. Sponsored by Lilly Research Laboratories.

12. "A Multicenter, Placebo and Active Control, Double-Blind Randomized Study of the Efficacy and Safety of M100907 (10 & 20 mg/day) in Schizophrenic and Schizoaffective Patients (3002)", Protocol lM100907/3002. Sponsored by Hoechst Marion Roussel.

13. "A Multicenter, Open-Label, Long-Term, Follow-up Safety Study of M100907 Tablets in Schizophrenic and Schizoaffective Subjects Who Participated in Protocol M100907/3001 or Protocol M100907/3002", Protocol M100907/3005. Sponsored by Hoechst Marion Roussel.

14. "A Prospective, Randomized, International, Parallel-Group Comparison of Clozaril/Leponex Vs. Zyprexa in the Reduction of Suicidality in Patients with Schizophrenia and Schizoaffective Disorder Who Are at Risk for Suicide", Protocol ABA 451. Sponsored by Novartis Pharma AG.

15. "A Multicenter Randomized, Double-Blind, Placebo, Controlled Study of Three Fixed Doses of A

16. "A Double-blind, Placebo-Controlled, Parallel- Group Assessment of the Selegiline Transdermal System in the Reappearance of Symptoms Associated with Major Depression." protocol #S9303-P9806, sponsored by Somerset

17. "A Double-blind, Randomized, Multicenter, Parallel Group design Study to Evaluate the Efficacy and Safety of Two Dose Ranges of EMD 128 130 in comparison with Placebo and Haloperidol in the Treatment of Schizophrenia." Sponsored by Mereck

18. "Protocol M/2020/047 , Reboxetine, Placebo, and Paroxetine Comparison in Patients with Major Depressive Disorder." sponsored by Pharmacia Upjohn

19. "A Multi-center Placebo–Controlled Double Blind Study Comparing the Safety and Efficacy of Ziprasidone and Olanzapine in Subjects with Schizophrenia or Schizoaffective Disorder Needing Inpatient Care" Protocol R-548 Sponsored by Pfizer

20. "A 52 Week (1 year), Open Extension Study Evaluating The Safety and Efficacy Of Continued Administration of 40-160 mg Daily Of Oral Ziprasidone In the Treatment Of Subjects Who Have Participated In Previous Ziprasidone Trials" Protocol R-0585, Sponsored by Pfizer

21. "Olanzapine in the Management of Behavioral Disturbance and/or Psychosis in Demented Nursing Home Patients." Protocol F1D-HGGV, Sponsored by Lilly

22. " A Double-Blind Randomized Comparison of the Efficacy and Safety of Short Acting Intramuscular Olanzapine, Short Acting Intramuscular Haloperidol, and Intramuscular Placebo in Patients with Schizophrenia" Protocol HGHB, sponsored by Lilly

23. "The Efficacy of Olanzapine and Adjunctive Lorazepam, as needed, to Treat Acute Behavioral Agitation in Schizophrenia". Sponsored By Lilly.

24. "A Randomized Double-Blind Study to Evaluate the Anticholinergic Burden in Subjects with Psychosis of Dementia Treated with Risperidone of Olanzapine". Sponsored by Janssen.

25. "A Multicenter, Randomized, Double-Blind, Placebo Controlled Study of Three Fixed Doses of Aripiprazole in the Treatment of Institutionalized Patients with Psychosis Associated with Dementia of the Alzheimer's Type". Sponsored by Bristol-Myers Squibb.

26. "Risperidone Depot (microspheres) vs. Placebo in the Treatment of Subjects with Schizophrenia or Schizoaffective Disorder". Sponsored by Janssen

27. "A Three-Week, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Parallel-Group Safety and Efficacy Study of Extended-Release Carbamazepine in Patients With Bipolar Disorder". Sponsored by Shire.

28. "The Efficacy and Safety of Flexible Dose Ranges of Risperidone vs. Placebo or Divalproex Sodium in the Treatment of Manic or Mixed Episodes Associated with Bipolar I Disorder". Sponsored by Janssen

29. "A 9-Week, Open-Label, Multicenter, Safety Trial of Flexible Dose Ranges of Risperidone in the Treatment of manic or Mixed Episodes Associated with Bipolar I Disorder". Sponsored by Janssen

30. "A Controlled Trial of Olanzipine versus Quetiapine in the Treatment of Schizophrenic and Schizoaffective Subjects with Prominent Negative Symptoms." Protocol #F1D-US-HJGB Sponsored by Lilly

31. "A Multicenter, Randomized, Double-Blind Study of Flexible Doses of Aripiprazole vs. Perphenzaine in the Treatment of Patients with Treatment-Resistant Schizophrenia". Sponsored by Bristol-Myers Squibb

32. A Multicenter, Randomized, Double-Blind, Placebo Controlled, 26 Week Study of a Fixed Dose of Aripprazole in the Treatment of Stabilized Patients with Chronic Schizophrenia". Sponsored by Bristol-Myers Squibb.

33. "A Multicenter, Randomized, Double-Blind Safety and Tolerability Study of Flexible Doses of Aripiprazole and Olanzapine in the Treatment of Patients with Acute Schizophrenia". Sponsored by Bristol-Myers Squibb.

34. "A Double-Blind, Placebo and Haloperidol-Controlled, Multicenter Study Evaluating the Safety and Efficacy of SR46349B in Schizophrenic patients". Sponsored by Sanofi-Synthelabo.

35. "A Double-Blind, Placebo and Haloperidol-Controlled, Multicenter Study Evaluating the Safety and Efficacy of SR141716 in Schizophrenic Patients". Sponsored by Sanofi-Synthelabo.

Guy E. Brannon, M.D.

Curriculum Vitae

Education:

Louisiana State University Medical Center, Shreveport, Louisiana
Department of Psychiatry
Chief Resident 1998-1999
Residency Completed: 1995-1999

Louisiana State University Medical Center, Shreveport, Louisiana
Dr. John M. Bick Award (Louisiana Psychiatric Medical Association)
Borroughs Welcome U.S. Psychiatric Congress Fellow
Chairman's Certificate of Award - Psychiatry Department
M.D. Awarded: June 1995

Louisiana State University, Shreveport, Louisiana
Bachelor of Science Degree in Biology (Cum Laude)
Graduation: May 1991

Airline High School, Bossier City, Louisiana
High School Diploma with Honors
Graduation: May 1986

Current Positions:

Principal Investigator
Brentwood Research Institute

Director of Clinical Research
Director of Adult Psychiatric Unit
Director of Chemical Dependency Unit
Brentwood, A Behavioral Health Company

Assistant Clinical Professor of Psychiatry
Teacher of the Year 2001-2002
Department of Psychiatry
Louisiana State University Health Science Center

Adjunct Professor of Psychology
Louisiana State University in Shreveport

1002 Highland Avenue
Suite 400
Shreveport, LA 71101

Drug Studies: (continued)

Bristol-Myers Squibb
A Multi-Center, Randomized, Double-Blind, Placebo-Controlled Study of an Investigational Medication in the Maintenance Treatment of Patients with Bipolar Disorder. February 2000 – Present
anofi~Synthelabo
A Double-Blind, Placebo and Comparator Controlled, Multicenter Study Evaluating the Safety and Efficacy of an Investigational Medication in Schizophrenic Patients. May 1999 – April 2001
Sanofi~Synthelabo
An Investigational Medication as Sole Therapy for Bipolar Disorder. December 1999 – Present
Sanofi~Synthelabo
A Double-Blind, Placebo and Comparator Controlled, Multi-Center Study Evaluating the Safety and Efficacy of an Investigational Medication in Schizophrenic Patients. December 1999 – August 2000
Otsuka America Pharmaceuticals, Inc.
An Open-Label Follow-on Study of the Long Term Safety and Efficacy of Aripiprazole Administered Orally in Patients with Psychotic Disorders or Psychotic Behaviors of Dementia. September 1999 – Present
Glaxo Wellcome
A Multi-Center, Double-Blind, Placebo-Controlled, Evaluation of the Safety and Efficacy of an Investigational Medication Compared to Placebo in the Treatment of an Acute Manic of Mixed Episode in Patients who have Bipolar Disorder. January 1999 – November 1999
Otsuka America Pharmaceuticals, Inc.
A Phase III, Open-Label, Treatment-Switching Study from Orally Administered Antipsychotic Monotherapy to Orally Administered Aripiprazole Monotherapy on the Treatment of Chronic Paranoid Schizophrenia and Schizoaffective Patients. September 1998 – August 2000
Eli Lilly & Co.
Olanzapine versus Divalproex in the Treatment of Acute Mania. September 1998 – August 2000
Pfizer
A MultiCenter, Placebo-Controlled, Double-Blind Study Comparing the Safety and Efficacy of Ziprasidone and Olanzapine in Subjects with Schizophrenia and Schizoaffective Disorder needing Inpatient Care. June 1998 – Present
Pfizer
A Double-Blind Six Month Continuation Protocol for Subjects who Successfully Completed Protocol #R-0548. June 1998 – August 1999
Pfizer
A 52 Week, Open Extension Study Evaluating the Safety and Efficacy of Continued Administration of 40-160mg Daily of Oral Ziprasidone in the Treatment of Subjects who have participated in Previous Clinical Trials. June 1998 – Present

1002 Highland Avenue
Suite 400
Shreveport, LA 71101

Telephone – (318) 227-4565
Fax - (318) 227-4564

Drug Studies: (continued)

Eli Lilly & Co.
The Comparative Efficacy of Olanzapine, Risperidone, and Haloperidol for Cognition in Schizophrenia. June 1998 – November 2000
Abbott Laboratories
Is There a Difference Between Depakote and Valproic Acid in the Treatment of Bipolar Disorder? May 1998 - April 1999
Hoechst Marion Roussel
A Multi-Center Placebo and Active Control Double-Blind Randomized Study of the Efficacy and Safety of M100907 (10mg and 20mg/day) in Schizophrenia and Schizoaffective Patients. May 1998 – March 1999
Hoechst Marion Roussel
A Multi-Center, Long Term Followup Safety Study of M100907 tablets in Schizophrenic and Schizoaffective Subjects who Participated in Protocol M100907/3001 Protocol M100907/3002. March 1998 – March 1999
Sanofi Research Division
A Double-Blind, Placebo-Controlled, MultiCenter Study Evaluation of the Efficacy and Safety of SR 46349B in Outpatients with Major Depression.
October 1997 – October 1998
Zeneca Pharmaceuticals
Quetiapine (SEROQUEL) Experience with Safety and Tolerability (QUEST).
October 1997 – June 1998
Eli Lilly & Co.
Weekly Enteric-Coated Fluoxetine Hydrochloride versus daily Fluoxetine or Placebo in the Continuation Treatment of Major Depressive Disorder.
October 1997 – July 1999
Otsuka America Pharmaceuticals, Inc.
A Phase III Double-Blind Placebo Controlled Study of Aripiprazole in the Treatment of Psychosis. September 1997 – May 1998
Otsuka America Pharmaceuticals, Inc.
An Open-Label, Follow-on Study of the Long-Term Safety of Aripiprazole in Patients with Psychosis. September 1997 – May 1998
Novartis
An Open-Label Study to Evaluate the Safety and Efficacy of 1.5mg b.i.d.(3mg/day) Through 6mg b.i.d. (12mg/day) of Exelon in Patients with Mild to Severe Probable Alzheimer's Disease in the Community Setting. September 1997 – Present
Pfizer
Comparison of Sertraline and Imipramine in Childhood Depression
July 1997 – Present

1002 Highland Avenue
Suite 400
Shreveport, LA 71101

CURRICULUM VITAE

NAME: David P. Walling, Ph.D. **DATE:** July 2002

PRESENT POSITION:
Chief Executive and Clinical Officer
Collaborative NeuroScience Network
12772 Valley View St. Ste. 3
Garden Grove, CA 92845

HOSPITAL PRIVILEDGES:

Pacific Hospital of Long Beach 2776 Pacific Ave Long Beach, CA 90804	Western Medical Center – Anaheim 1025 S. Anaheim Blvd. Anaheim, CA 92805	Del Amo Hospital 23700 Camino Del Sol Torrance, CA 90505

BIOGRAPHICAL:

Place of Birth: Long Beach, California
Address: REDACTED

Telephone: (714) 799-7799 – office
REDACTED

EDUCATION:

University of Southern California 1989-1993
Ph.D. in Counseling Psychology
APA Accredited

California State University at Fullerton 1987-1989
M.S. in Counseling

California State University at Long Beach 1985-1986
B.A. in Psychology

Golden West College 1983-1985
A.A. in Social Science

Internship:

University of Texas Medical Branch 1992-1993
APA Accredited
Galveston, TX

RESEARCH EXPERIENCE:

Principal Investigator "A Multicenter, Double-blind, Randomized Comparison of the Efficacy and Safety of Two Atypical Antipsychotics in the Treatment of Patients with Schizophrenia (2001 – ongoing).

Principal Investigator " A Phase III, Randomized, Placebo-Controlled Study Evaluating the Safety and Outcome of Treatment with Oral Ziprasidone in Subjects with Mania (A1281083)." Pfizer (2002 – ongoing).

Principal Investigator "A Placebo-Controlled 21-Day Study of the Safety and Efficacy of Topiramate for the Treatment of Treatment-Resistant Bipolar I Disorder with an Optional Open-Label Extension (TOPMAT-PDMD-006)." R.W. Johnson Pharmaceutical Research (2001 – 2002).

Sub-Investigator "A Novel Anxiolytic Versus Placebo in Generalized Anxiety Disorder. A Randomized Double-Blind Placebo and Buspirone Controlled Fixed Dose Parallel Group Multicenter Study of 10 Weeks" (2002 – ongoing).

Sub-Investigator "A Trial of One Atypical Antipsychotic versus Another Atypical Antipsychotic in the Treatment of Schizophrenic and Schizoaffective Subjects with Comorbid Depression." (2001 – ongoing).

Principal Investigator " A Randomized, Double-Blind, Parallel-Group, Placebo-Controlled, Study Evaluating Efficacy and Safety of SB-29060 Controlled Release (12.5 and 25mg/day) versus Placebo in Patients with Major Depressive Disorder." (29060/810) GlaxoSmithKline (2001-2002).

Principal Investigator "A Three-Week, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Parallel-Group Safety and Efficacy Study of Extended-Release Carbamazepine in Patients with Bipolar Disorder." (Protocol 105.301) Shire Laboratories, Inc. (2000- 2001)

Principal Investigator "A Three-Week, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Parallel-Group Safety and Efficacy Study of Extended-Release Carbamazepine in Lithium-Failure Patients with Bipolar Disorder." (Protocol 105.302) Shire Laboratories, Inc. (2000 - 2001).

Principal Investigator "A Six-Month, Open-Label, Multicenter Study of Extended Release Carbamazepine in Patients with Bipolar Disorder – an Extension of Protocols 105.301 and 105.302." (Protocol 105.303) Shire Laboratories, Inc. (2001)

Co-Investigator "A Multicenter, Double-Blind, Randomized, Placebo-Controlled Trial of the Safety and Efficacy of Seroquel as Add-on therapy with Lithium or Divalproex in the Treatment of Acute Mania." (Protocol 5077IL/0099) AstraZeneca (2000 – 2001).

RESEARCH EXPERIENCE (Cont.)

Sub-investigator "Risperidone QD vs. BID Dosing in Schizophrenia: A Double-Blind, Parallel Group, Phase III Multicenter Study." (Protocol RIS-USA-60) Janssen Research Foundation (1995).

Sub-investigator: "A Multicenter, Double-Blind, Randomized Comparison of SEROQUEL (ICI 204,636) and chlorpromazine in the Treatment of Hospitalized Subjects with Treatment Resistant Schizophrenia." (Protocol 0031) ZENECA Pharmaceuticals Group (1994-1996).

Sub-investigator/Therapist: "A Prospective, Multicenter Study Comparing the Safety and Efficacy of Nefazodone HCl to Cognitive Behavioral Therapy - Chronic Depression (CBT-CD) and Combined Nefazodone and CBT-CD for the Acute, Continuation and Maintenance Treatment of Chronic Forms of Depression." (Protocol CN104-132) Bristol-Meyers Squibb Company (1996-1999).

Sub-investigator/Therapist: "Serzone and Cognitive Behavior Therapy for the Chronic Depressives: Pilot Study." Bristol-Myers Squibb Company (1995-1996).

Sub-investigator: "A Double-Blind Placebo-Controlled, Dose-Response Comparison of the Safety and Efficacy of Three Doses of SERTINDOLE and Three Doses of Haldol in Schizophrenic Patients." (Protocol M93-113) ABBOTT Laboratories (1994-1995) completed.

Sub-investigator: "An Open-Label Assessment of the Long-Term Safety of SERTINDOLE in the Treatment of Schizophrenic Patients." (Protocol M92-795) ABBOTT Laboratories (1994-1995) completed.

Sub-investigator: "An Open-Label Assessment of the Long-Term Safety of SERTINDOLE." (Protocol M92-222) ABBOTT Laboratories (1994-1995).

Sub-investigator: "A Multicenter, Double-Blind, Placebo-Controlled, Randomized, Multiple Fixed-Dose Comparison of SEROQUEL (ICI 204,636) and Haloperidol in the Treatment of Hospitalized Subjects with Acute Exacerbation of Chronic or Subchronic Schizophrenia." (Protocol 0013) ZENECA Pharmaceuticals (1993-1994) completed.

Sub-investigator: "Fixed-Dose OLANZOPINE Versus Placebo in the Treatment of Schizophrenia." (Protocol FID-MC-HGAP) ELI LILLY and Company (1993-1994) completed.

Sub-investigator: "A Multicenter, Double-Blind, Randomized, Controlled, Multiple Fixed Dose and Dose Regimen Comparison of SEROQUEL (ICI 204,636) and Haloperidol in the Prevention of Psychotic Relapse in Outpatients with Chronic or Subchronic Schizophrenia." (Protocol 0015) ZENECA Pharmaceuticals (1993-1994) completed.

TEACHING EXPERIENCE:

"Introduction to Clinical Hypnosis." One day seminar presented to psychiatry and psychology residents at the University of Texas Medical Branch at Galveston – Department of Psychiatry – 2000.

"Schizophrenia: Theory, Symptoms and Treatment." Seminar presented as a component of Psychiatric Pharmaceutical Care Certificate Program sponsored by the University of Pittsburgh School of Pharmacy – 1999.

"Introduction to Clinical Hypnosis." One day seminar presented to psychiatry and psychology residents at the University of Texas Medical Branch at Galveston – Department of Psychiatry – 1999.

Medical Hypnosis - five week course presented to all third year medical students during psychiatry rotation. University of Texas Medical Branch at Galveston, 1995-1996.

Therapeutic Hypnosis - Thirty week hypnosis training seminar presented to psychology interns at University of Texas Medical Branch at Galveston, 1994.

Faculty and Small Group Facilitator - Introduction to Patient Evaluation. University of Texas Medical Branch at Galveston: Term III, 1995; Term III, 1996.

Faculty and Small Group Facilitator - Community Continuity Experience/Introduction to Patient Evaluation. University of Texas Medical Branch at Galveston: Term II, 1997.

Faculty - Counseling Practicum, School of Education. University of Houston at Clear Lake: Summer Session, 1994.

Faculty - Senior Medical Student Elective: Forensic Psychiatry - Violence Recovery Program.

WORK EXPERIENCE:

Vice President of Clinical Services 1997-2000
Psychiatric Management Resources &
Stadt Solutions Pharmacy Corporation
San Diego, CA

Assistant Professor of Psychiatry and Behavioral Sciences 1995-1997
Dept. of Psychiatry and Behavioral Sciences
University of Texas Medical Branch - Galveston, TX

WORK EXPERIENCE (cont.):

Clinical Director 1993-1997
The Gulf Coast Center
Intensive Treatment Program
Galveston, TX

Research Scientist 1993-1995
Dept. of Psychiatry and Behavioral Sciences
University of Texas Medical Branch - Galveston, TX

College Hospital - Costa Mesa, CA 1992
Crisis Response Clinician

Harbor View Adolescent Center - Long Beach, CA 1990-1992
Primary Therapist

Huntington Psychotherapy - Huntington Beach, CA 1991-1992
Marriage, Family, & Child Counselor

Bellflower Doctors Hospital - Bellflower, CA 1989-1990
Clinical Coordinator

Western Medical Center - Anaheim, CA 1988-1989
Clinical Social Worker/Unit Therapist

CURRICULUM VITAE

Name: Paul E. Keck, Jr., M.D.

Address: University of Cincinnati Medical Center
231 Albert Sabin Way
Cincinnati, OH 45267-0559

Date of Birth: July 22, 1957

Place of Birth: Pittsburgh, Pennsylvania

Education:

1979 A.B. Dartmouth College, Hanover, New Hampshire

1983 M.D. Mount Sinai School of Medicine, New York, New York

Postdoctoral Training:

Internship and Residencies:

1983-1984 Internship in Internal Medicine, Beth Israel Medical Center, New York, New York

1984-1987 Resident in Psychiatry, McLean Hospital
Belmont, Massachusetts

Research Fellowships:

Research Award, National Institute of Arthritis,
Metabolism and Digestive Diseases

1983 Fellowship, Tucker Foundation, Hanover, New Hampshire

1987-1989 Fellowship, Scottish Rite Schizophrenia Program,
Northern Masonic Jurisdiction, USA

Licensure:

1985-1991 Massachusetts License Registration
1991 Ohio License Registration No. 61382
1991 American Board of Psychiatry and Neurology No. 34691
1995 American Board of Forensic Examiners No. 745

3/5/03

1997 American Board of Psychological Specialties No. 2331

Academic Appointments:

1984-1987	Clinical Fellow in Psychiatry, Harvard Medical School, Boston, Massachusetts
1987-1989	Instructor in Psychiatry Harvard Medical School, Boston, Massachusetts
1989-1991	Assistant Professor of Psychiatry Harvard Medical School, Boston, Massachusetts
1991-1998	Associate Professor of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio
1992-	Associate Professor of Pharmacology and Cell Biophysics (Dual Track), University of Cincinnati College of Medicine, Cincinnati, Ohio
1995-	Adjunct Assistant Professor of Psychology, University of Cincinnati, Cincinnati, Ohio
1997-	Vice Chairman for Research, Department of Psychiatry, University of Cincinnati College of Medicine, Cincinnati Ohio
1998-	Professor of Psychiatry (with tenure), University of Cincinnati College of Medicine, Cincinnati, Ohio

Hospital Appointments:

1986-1987	Chief Resident in Psychiatry, McLean Hospital, Belmont, Massachusetts
1985-1987	Research Fellow in Psychiatry, Laboratories for Psychiatric Research, Mailman Research Center, Belmont, Massachusetts
1987-1990	Assistant Psychiatrist, McLean Hospital, Belmont, Massachusetts
1991-	Attending Psychiatrist, University of Cincinnati Hospital
1992-1993	Consultant, Good Samaritan Hospital, Cincinnati, Ohio
1991-	Attending Psychiatrist, Veterans Administration Medical Center, Cincinnati, Ohio
1992-	Consultant, Children's Hospital Medical Center, Cincinnati, Ohio
1994-	Senior Consulting Psychiatrist Pauline Warfield Lewis Center, Ohio Department of Mental Health, Cincinnati, Ohio
1997-	Attending Psychiatrist, Christ Hospital, Cincinnati, Ohio

Awards and Honors:

1977-1979	New Hampshire Alpha Award for Academic Excellence, Dartmouth College
1979	Phi Beta Kappa Society, Dartmouth College
1979	Magna Cum Laude, Dartmouth College
1983	Alpha Omega Alpha Society, Mount Sinai School of Medicine
1983	M. Ralph Kaufman Award for Excellence in Psychiatry, Mount Sinai School of Medicine
1987	Laughlin Award for Merit, National Psychiatric Endowment Fund
1991	Phillip L. Isenberg Award, Excellence in Teaching McLean Hospital, Harvard Medical School
1993	Exemplary Psychiatrist Award, National Alliance for the Mentally Ill (NAMI)
1994-	Stanley Scholars Program, The Theodore & Vada Stanley Foundation and National Alliance for the Mentally Ill
1994	The Best Mental Health Experts, Good Housekeeping Magazine
1994	Golden Apple Award for Excellence in Teaching Department of Psychiatry, University of Cincinnati College of Medicine
1996	Outstanding Young Men of America
1997	Gerald L Klerman Young Investigator Award, National Depressive and Manic – Depressive Association
1998	Nancy C A Roeske, MD Award for Excellence in Medical Student Education, American Psychiatric Association
1998	Outstanding Young Men of America
1999	Best Doctors in America
1999	Wyeth-Ayerst AADPRT IMG Mentorship Program
1999	Outstanding Physician Partner Award, Postgraduate Institute for Medicine
2000	Crystal Award (2), The Communicator Awards for Continuing Medical Education
2001	Leadership Recognition Award, Neuroleptic Malignant Syndrome Information Service (NMSIS)

Major Committee Assignments:

National and Regional:

Neuroleptic Malignant Syndrome Information Service:

1995- Professional Advisory Council and Director of Scientific Development

U.S. Food and Drug Administration:

2000- Psychopharmacology Drug Advisory Committee (PDAC)

American Psychiatric Association:

1992-1994 APA Practice Guidelines for Bipolar Disorders
Work Group (Formulation of official American Psychiatric Association treatment guidelines for patients with bipolar disorder)

1993-1994 DSM-IV Medication – Induced Movement Disorder
(Formulation of diagnostic criteria for neuroleptic malignant syndrome, akathisia)

2000- APA Institute for Research and Education (Enhance research infrastructure and psychiatric education by fostering collaboration among academic institutions)

2000- APA Practice Guidelines for Bipolar Disorders Work Group (Revise and update treatment guidelines for patients with bipolar disorder)

Local:

McLean Hospital:

1985 Committee on Inpatient Psychotherapy in Residency Training
(Review teaching and supervision of psychotherapy of inpatients by residents)

1986-1987 Committee on Hospital Admissions
(Review problems associated with admission of patients to hospital)

1987 Committee on Residency Training Curriculum and Requirements (Review core residency training curriculum, update and modify in accordance with national standards)

1987-1991 Pharmacy and Therapeutics Committee
(Quality assurance, drug utilization, adverse events)

1990-1991 Hospital Formulary committee
(Review of new drugs for addition to hospital formulary)

University of Cincinnati Hospital:

1991-1997 Hospital Pharmacy and Therapeutics Committee; Chair, Biotechnology Subcommittee, 1993 – (Review of new biotechnology products for submission to hospital formulary committee; involves consultation with experts, cost-benefit analysis)

1998- 2000 Executive Board, Office of Clinical Trials

College of Medicine:

1991-1997	Year II Medical Student Education Committee (Ongoing curriculum review)
1992-1995	Preceptor, Clinical Opportunities Program (Supervision and teaching of medical students wishing to observe clinical care by specialty)
1993-	Medical Student Advisor: David Kriendler, Danielle Kizer
1997-	Dispute Mediation Committee (Assist in mediation of disputes involving faculty)

Department of Psychiatry:

1991-	Medical Student Education Committee (Review department contribution to curriculum of medical school)
1991-1995	Residency Selection Committee (Interview and evaluate resident applicants)
1991-1995	Continuing Education Committee; Chair, 1992-1994 (Coordinate and design Grand Rounds schedule and other CME activities)
1991-	Research Committee; Chair 1997- (Enhance research in department)
1994-1996	Residency Training Committee (Review and improve curriculum, ongoing advisory board to Residency Training Director)
1994-	Steering Committee (Long range resource and personnel planning)
1997-1998	Space Committee (Space allocation for personnel and laboratories)
1999-	Intellectual Property Committee (Assess intellectual property opportunities)
1999-	Community Advisory Committee on Research; Chair (Bioethical considerations of human subjects protocols)
2000-	Appointments and Promotions Committee (Faculty appointments and promotions)

Review and Editorial Boards:

Reviewer:

1987-	Journal of Clinical Psychopharmacology
1988-	Journal of Clinical Psychiatry
1989-	Journal of Neuropsychiatry and Clinical Neurosciences
1989-	American Journal of Psychiatry
1991-	Biological Psychiatry
1991-	Comprehensive Psychiatry
1992-	Journal of Child and Adolescent Psychopharmacology

1992-	Journal of Nervous and Mental Diseases
1993-	Depression
1994-	Drugs
1994-	The Medical Letter
1994-	Harvard Review of Psychiatry
1995-	Anxiety
1995-	Psychiatric Research
1995-	Psychopharmacology
1996-	International Clinical Psychopharmacology
1996-	CNS Drugs
1997-	Journal of Affective Disorders
1998-	Journal of Psychiatric Research
1998-	Critical Reviews in Neurobiology
1999-	Neuro-psychopharmacology & Biological Psychiatry
1999-	Archives of General Psychiatry
1999-	Acta Psychiatrica Scandinavica
1999-	European Neuropsychopharmacology
2000-	Psychosomatic Medicine
2000-	General Hospital Psychiatry
2001-	International Journal of Neuropsychopharmacology
2001-	European Psychiatry

Editorial Boards:

1992-	Psychiatric Annals
1993-	Journal of Clinical Psychiatry
1994-	Psychiatric Times' Bipolar Disorders Letter
1996-1998	Journal of Depressive Disorders: Index and Reviews
1996-	Medscape Mental Health
1996-1998	Journal of Psychotic Disorders
1997-1998	Journal of Bipolar Disorder
1997-	Behavioral Health Advisor, Clinical Reference Systems
1998-	Bipolar Disorder, An International Journal of Psychiatry and Neurosciences
2000-	Journal of Affective Disorders
2000-	Clinical Psychiatry News
2001-	Deputy Editior, Current Psychiatry

Other Professional Activities:

1985-1987	Site interviewer, McLean Hospital, The Structured Clinical Interview for DSM-III-R (SCID), Multisite Test-Retest Reliability Study; Biomedical Research Department, New York State Psychiatric Institute, Arch Gen Psychiatry 1992; 49:630-636
1994	Site participant, University of Cincinnati College of Medicine, DSM-IV General Reliability Field Trial, Expert Phase, American Psychiatric Association

1995	NIMH/NCDEU Workgroup, Assessment of Efficacy in Schizophrenia Clinical Trails
1995	Consensus Panel Expert, The Tri-University (Departments of Psychiatry at Columbia, Cornell and Duke Universities) Consortium, Bipolar Disorder Consensus Evaluation Project
1996	Consensus Panel Expert, The Tri-University (Departments of Psychiatry at Columbia, Cornell and Duke Universities) Consortium, Obsessive Compulsive Disorder Treatment Guidelines
1996	Ad Hoc Consultant, Contracts Review, National Institute of Mental Health, Division of Clinical and Treatment Research, Rockville, MD
1997	Faculty, University Institute for Psychiatry & Law, University of Cincinnati Medical Center
1997	Consultant Veterans Affairs Medical Center Bipolar Disorder Treatment Guidelines
1998	Data Monitoring Board of VA Cooperative Study #430, "Reducing the Efficacy – Effective Gap in Bipolar Disorder"
1998	Consensus Panel Expert, The Tri –University Consortium, Schizophrenia Consensus Evaluation Project
1998	Consensus Panel Expert, The Tri-University Consortium, Posttraumatic Stress Disorder Consensus Evaluation Project
1998-1999	NIMH Intramural Protocols Review Panel
	Consensus Panel Expert Consortium, Health Knowledge Improvement Foundation, Guidelines for Antidepressant Medication in Primary Care
2000	Consultant, American Psychiatric Association Committee on Psychiatric Diagnosis and Assessment, DSM-IV Text Revision Work Group on Mood Disorders
2000	Consultant, NIMH Special Emphasis Panel
2000	Consultant, The Expert Consensus Guideline Series. Medication Treatment of Bipolar Disorder 2000. Postgraduate Medicine Institute
2000	Consultant, Texas Medication Algorithm Project (TMAP), Texas Department of Mental Health and Mental Retardation, Austin, TX

Professional Societies:

1983-1989	American Medical Association
1983-1990	American Psychiatric Association
1989-1991	American Sleep Disorders Association
1991	Society of Biological Psychiatry
1991	American Academy of Clinical Psychiatrist
1991	American Association for the Advancement of Science
1991	Cincinnati Psychiatric Society, Treasurer 1992-1993
1992	Anxiety Disorders Association of America
1993	American Society of Clinical Psychopharmacology
1995	American College of Forensic Examiners, Fellow (1997)
1997	Collegium Internationale Neuro-Psychopharmacologicum
1997	New York Academy of Sciences

1999	International Society for Bipolar Disorders (Councilor)
2001	International Society for Affective Disorders (Fellow)

Major Research Interests:

1. Novel psychopharmacologic agents in the treatment of mood, anxiety, and psychotic disorders
2. Phenomenology, epidemiology, biological abnormalities and treatment of bipolar disorders
3. Neuroleptic malignant syndrome and related side effects of antipsychotic agents

Patent Application: Shapira NA, Goldsmith TD, Keck PE, Jr. Methods of treating obsessive-compulsive spectrum disorders. Filed March 25, 1999.

Principal Clinical and Hospital Service Responsibilities:

McLean Hospital

1987-1988	Clinical and Research Associate, Psychopharmacology Program, McLean Hospital, Belmont, Massachusetts
1988-1991	Psychiatrist-in-Charge, South Belknap I, II (Depression Research, Units McLean Hospital, Belmont Massachusetts)
1989-1990	Assistant Director, Sleep Disorder Center, Neurophysiology Laboratory and Sleep Research Program, McLean Hospital, Belmont, Massachusetts

University Hospital

1991-1996	Co-Director, Biological Psychiatry Program, University of Cincinnati College of Medicine Cincinnati, Ohio
1991-1998	Director, Inpatient Psychobiology Research Unit University Hospital, Cincinnati Ohio

Teaching Experience:

1986-1987	Supervision of medical students and psychiatric residents in emergency psychiatry and psychopharmacology, McLean Hospital
1987-1991	Supervision of residents in psychopharmacology through psychopharmacology program, McLean Hospital
1988-1990	Modern management of acute neuroleptic- induced extrapyramidal syndromes. American Psychiatric Association Annual meeting, Montreal, Canada, May 1-5, 1989; course 90; New York, May 13, 1990; course 26

1988-1999	Supervision of medical students and residents in inpatient psychiatry, McLean Hospital; University Hospital
1989-1995	Neuroleptic malignant syndrome: diagnosis, treatment and aftercare. American Psychiatric Association Annual Meeting, San Francisco, May 9, 1989, W4; New York, May 16, 1990,W47; New Orleans, May 1991; Washington DC, May 1992; San Francisco, 1993; Philadelphia, 1994; Miami, 1995
1990	Side effects of neuroleptics. American Psychiatric Association Annual Meeting, New York, May 17, 1990, PS54
1990	Senior Consultant Psychopharmacology Inpatients Services, McLean Hospital, Belmont, Massachusetts
1991	Visiting Professor, Northeastern Ohio Universities College of Medicine, Akron, Ohio, April, 1991
1991-1993	Integrating research into clinical programs. American Psychiatric Association Annual Meeting, New Orleans, May 1991; Washington DC, 1992; San Francisco, 1993
1993	Visiting Professor, University of Texas Medical Branch at Galveston, Galveston, Texas, February, 1993
1994-1995	Anticonvulsants in Psychiatry. American Psychiatric Association Annual Meeting Philadelphia, May 1994; Miami, 1995
1994	Advances in Treatment of Refractory Depression. American Psychiatric Association Annual Meeting Philadelphia, May 1994
1995	Predictors of Response in Mood Disorder. American Psychiatric Association Annual Meeting Miami, May, 1995
1996	Visiting Professor, McLean Hospital Mini Fellowship in Bipolar Disorder, Belmont, Massachusetts, April 1996
1996	Visiting Professor, Rush-Presbyterian Hospital Mini Fellowship in Bipolar Disorder, Chicago, Illinois, October, 1996
1996	Visiting Professor, Rush-Presbyterian Hospital Mini Fellowship in Bipolar Disorder, Chicago, Illinois, July, 1997
1997	Visiting Professor, New York University Mini Fellowship in Bipolar Disorder, New York, NY, October 1997

Fellowships:

1992 Director, Biological Psychiatry Program Fellowship,

Department of Psychiatry, University of Cincinnati College of Medicine

Fellowship graduates:
- Scott A West, M.D., 1995
- Tammy J. Huber, M.D., 1996
- John M. Hawkins, M.D., 1996
- Cesar A. Soutullo, M.D., 1997
- Vikram Shah, M.D., 1998
- N. Andrew Shapira, M.D., 1999
- Marlene P. Freeman, M.D., 1999
- Shashuka Malhotra, M.D., 2001

Course Developer and Course Director:

1991-1997	Course Director, Psychiatry/Neuroscience Core Curriculum, Second Year Course, University of Cincinnati College of Medicine This integrated course received very high UCCM student evaluations annually since 1991
1992	Designed and organized "Management of Depression in Primary Core Practice," Regional Symposium, April 11, 1992
1992	Designed and organized "Medical Illness and Anxiety Disorders: The Clinical Interface," Regional Symposium, September 24,1992
1993	Designed and organized "Update on the Treatment of Bipolar Disorder," Regional Symposium, October 1, 1993
1993-1999	Course Director, Advanced Psychobiology Clerkship, Fourth Year Course, University of Cincinnati College of Medicine
1999-	Co-Director, Brain and Behavior II, Second Year Course, University of Cincinnati College of Medicine

Course Participant:

1986-1987	Emergency Psychiatry Resident Lecture Series, McLean Hospital
1987-1991	Lecturer in Advanced Psychopharmacology Resident Seminar, McLean Hospital
1987-1991	Lecturer in Affective Disorders Resident Course, McLean Hospital
1990	Course Participant, Comprehensive Update in Clinical Psychiatry, CME Course, McLean Hospital and Harvard Medical School
1991-1993	Lecturer in Psychopharmacology Module, Third Year Clerkship, University of Cincinnati College of Medicine
1991-	Lecturer in Advanced Psychopharmacology Resident Seminar, University of Cincinnati College of Medicine
1991-1999	Lecturer in Psychiatry/Neuroscience Core Curriculum, Second Year, University of Cincinnati College of Medicine
1991-1999	Lecturer in Pharmacology Core Curriculum, Second Year, University of Cincinnati College of Medicine
1992-1998	Lecturer in Introduction to Clinical Practice II Course, Second Year, University of Cincinnati College of Medicine
1999-2001	Lecturer in Forensic Psychiatry Fellowship Didactic Series
1999-	Lecturer in Brain and Behavior II Course, Second Year, University of Cincinnati College of Medicine
2000-	Lecturer in Brain and Behavior I Course, First Year, University of Cincinnati College of Medicine

Invited Lecturer / Grand Rounds:

1987 "Antidepressants in the Treatment of Bulimia"
St. Francis Hospital, Tulsa, OK

1988 "Pharmacologic Treatment of Eating Disorders"
St. Luke's Hospital, St. Louis, MO

1989 "Pharmacologic Approaches to the Treatment of Eating Disorders"
Philadelphia Psychiatric Institute, Philadelphia, PA
"Valproate as a Potential Antimanic Treatment"
University of Massachusetts Medical Center, Worcester, MA
"Diagnosis and Treatment of Neuroleptic Malignant Syndrome"
Massachusetts General Hospital, Boston, MA
"Pharmacologic Treatment of Schizophrenia"
McLean Hospital, Belmont, MA

1990 "Recognition of Sleep Disorders in Psychiatric Practice"
Massachusetts Institute of Technology (MIT), Cambridge, MA
"Why Do We Sleep? Why Do We Study It?"
McLean Hospital, Belmont, MA
"Management of Bipolar Disorder and Comorbid Substance Abuse"

Kevin T. Finnegan Annual Memorial Lecture, University of Utah, Salt Lake City, UT
"Pharmacologic Treatment of Bipolar Disorder – The Future"
University of Cincinnati College of Medicine, Cincinnati, OH
"Alternatives to Lithium in the Treatment of Bipolar Disorder" Lithium – 50th Anniversary in Clinical Medicine Symposium. Lexington, KY
"Atypical Antipsychotics in the Treatment of Acute Mania"
University of Massachusetts, Worcester, MA
"Pharmacotherapy of Schizoaffective Disorder"
McLean Hospital, Belmont, MA
"Principles of Antidepressant Prescribing" Dept. of Internal Medicine, University of Cincinnati Medical Center, Cincinnati, Ohio
"Clinical Update: Antipsychotic and Mood Stabilizer Drug Therapy" Ohio University College of Osteopathic Medicine, Dayton, Ohio

2000 "Why Do We Send Roses? The Neurobiology of Emotion"
University of Cincinnati College of Medicine,
Mini Medical College, Cincinnati, Ohio
"Schizoaffective Disorder" Hillside Hospital – Long Island Jewish Medical Center, Glen Oaks, NY
"Advances in Pharmacotherapy for Bipolar Disorder" University of South Florida, Tampa, FL
"Advances in the Pharmacological Treatment of Bipolar Disorder"
Emory University School of Medicine, Atlanta, GA
"Neurobiology of Bipolar Disorder and Treatment Advances"
University of Southern California School of Medicine, Los Angeles, CA

2001 "Update on Advances in Pharmacotherapy of Bipolar Disorder"
Wright State University School of Medicine, Dayton, OH
"Pharmacologic and Efficacy Comparison of New Atypical Antipsychotic Drugs," Good Samaritan Hospital, Cincinnati, OH
"Latest Treatment Advances for Bipolar Disorder"
St. Elizabeth's Hospital, Washington, DC
"The Many Faces of Bipolar Disorder"
University of Cincinnati College of Medicine
Mini Medical College, Cincinnati, Ohio

2002 "Atypical Antipsychotics: Promise and Controversy"
Jonathan O. Cole Mental Health Consumer Resource Center
McLean Hospital, Belmont, MA
" Recent Advances in the Pharmacological Treatment of Bipolar Disorder"
Massachusetts General Hospital, Boston, MA
"Antiepileptics and Atypical Antipsychotics in the Treatment of Bipolar Disorder" University of Mississippi School of Medicine,
Jackson, MS

Other Teaching Experience and Invited Lectures:

1989 Drug Treatment of Schizophrenia; The Pharmacist and Mental Health Regional Symposium, Northeastern University College of Pharmacy, Waltham, MA
New Advances in the Pharmacologic Treatment of Manic-Depressive Illness, Regional Meeting, National Depressive and Manic Depressive Association, Chattanooga, TN

1990 Recent Research on the Use of Anticonvulsants in Bipolar Disorder; Portraits of Mania Symposium, Third Annual U.S. Psychiatric Congress, San Diego, CA
Clinical Applications of Anticonvulsants in Psychiatric Disorders; Current Trends in the Expanded Use of Anticonvulsants, Ohio Department of Mental Health Conference, Columbus, OH
Recent Research on the Use of Anticonvulsants in Bipolar Disorder; Portraits of Mania, Regional Symposium, Atlanta, GA
The Use of Medications in Treating Psychiatric Illness; Orientation to Mental Health Issues, Pastoral Care and Counseling Symposium, McLean Hospital Belmont, MA
Sleep Disorders and Psychiatric Illness: Diagnosis and Treatment Issues; McLean Hospital Intensive Update in Biological Psychiatry CME Course, Belmont, MA
Differentiating Sleep Disorders from Psychiatric Syndromes; Western Massachusetts Psychiatric Society, Smith College, Northampton, MA
Sleep Disorders; Manic Depressive and Depressive Association of Boston, Boston, MA

1991 Innovative Uses of Anticonvulsants, Henry Ford Hospital Symposium, Dearborn, MI
Pharmacotherapy for Anxiety Disorders; Anxiety Disorders; Recognition, Treatment and Management, Regional Symposium, University of Cincinnati College of Pharmacy, Cincinnati, OH
Alternative Uses of Anticonvulsants; Innovative Uses of Anticonvulsants, Regional Symposium, Case Western Reserve University School of Medicine, Cleveland, OH

Other Possible Uses of Anticonvulsants in Psychiatry; Summit Conference on the Treatment of Bipolar Disorder, National Symposium, School of Medicine, University of Texas Health Science Center at San Antonio, Snowmass, CO

The Clinical Approach to the Differential Diagnosis of Bipolar Disorder; Practical Clinical Guidelines for the Management of Bipolar Disorder, Regional Symposium, Worcester, MA

Rational Use of Traditional Pharmacologic Therapy; Practical Guidelines for the Management of bipolar Disorder, Regional Symposium, Philadelphia, PA

Depression: Recognition and Treatment; Third Annual Mental Health Institute Regional Symposium, Louisville, KY

Reclaiming Lives; Psychiatric Rehabilitation and Clozaril; Third Annual Mental Health Institute Regional Symposium, Louisville, KY

Recent Advances in the Use of Valproate in the Treatment of Bipolar Disorder; Southern California Psychiatric Society, San Bernardino, CA

1992

The Diagnosis of Bipolar II Patients; Bipolar Disorder; Current Progress and Future Directions in Diagnosis and Management; National Symposium, Snowbird, UT

Treatment Refractory Depression, Valley Medical Center, Louisville, KY

Serotonin Reuptake Inhibitor Antidepressants; Charleston Psychiatric Association, Charleston, WV

Traditional Pharmacologic Management for the Treatment of Bipolar Disorder; Bipolar Disorder: Current Progress and Future Directions, Regional Symposium, Chicago, IL

Pharmacologic Treatment of Depression and Panic Disorder; Academy of Medicine, Lima and Allen Counties, OH

Myths of Psychopharmacology; Residency Training Graduation Dinner, Harding Hospital, Columbus, OH

Traditional Pharmacologic Management of Bipolar Disorder; Bipolar Disorder: Current Progress and Future Directions in Diagnosis and Management; Regional Symposium, Detroit, MI

Depression; Association of Indian Psychiatrists, Cincinnati, OH

Depression in Medical Practice: Recognition and Treatment Advances; Current Therapy XXIII, Scioto County 23rd Annual Postgraduate Medical Seminar, Portsmouth, OH

Antiepileptic Drugs in Primary Psychiatric Disorders; Crafts-Farrow State Hospital Eleventh Annual CME Program

New Developments in Sleep Therapy; Central Ohio Academy of Family Practitioners, Columbus, OH

Bipolar Disorder: The Treatment Resistant Patient; Acute Mania: Strategies for Success; Regional Symposium, Ohio State University College of Medicine, Columbus, OH

1993
- Common Pitfalls of Diagnosis; Bipolar Disorder: Meeting the Challenge, National Symposium; Keystone, CO
- Bipolar Disorder; OMEN-TV, Ohio State University, Columbus, OH
- Depression... When the Blues Become More Than Music; Mental Health Association of Franklin County, Columbus, OH

1994
- Management Options in Bipolar disorder; Bipolar Disorder: Diagnostic Challenges, Treatment Optimization; Regional Symposium, Indianapolis, IN
- Lithium, Valproate and Carbamazepine: What Do We Know?; Lithium: The Present and the Future, American Psychiatric Association Symposium, Philadelphia, PA
- Atypical Antipsychotics in Schizophrenia, Schizoaffective Disorder and Psychotic Mood Disorders; Ohio Department of Mental Health Annual Symposium, Columbus, OH
- Management of Bulimia, Body Dysmorphic Disorder and Related Disorders; Diagnosis and Treatment of Depression and Related Disorders: Symposium for Psychiatric Residents; National Symposium, Emory University School of Medicine, Atlanta, GA
- Bipolar Disorder: Case Management; CME Video Symposium, The IMN Group, Psych LINK, Dallas, TX
- Pharmacotherapeutic New Agents in the Treatment of Depression; What's New in Depression? An Update for Clinicians; Regional Symposium, The Ohio State University Medical Center for Continuing Education, Columbus, OH
- Refractory Bipolar Depression and Mania; Complicated and Treatment – Resistant Mood disorders; Regional Symposium, University of Pittsburgh Medical Center, Western Psychiatric Institute and Clinic, Center for Continuing Education in the Health Sciences, Pittsburgh, PA

1995
- The Biology and Treatment of Rapid Cycling Bipolar Disorders; Caribbean Psychopharmacology Congress; National Symposium, CME, Inc., St. Martin, Antilles Francaises
- Treatment of Bipolar Disorder; Bipolar Disorders. Current Breakthroughs in Diagnosis and Treatment; Regional Symposium, University of Miami School of Medicine, Miami, FL
- Treatment of Schizoaffective Disorder. Antipsychotic Drug Therapy: Current Status, Roundtable Symposium. Physicians Postgraduate Press, Inc. New Orleans, LA
- The Promise of New Antipsychotic Medications. Spring Mental Health Conference: Innovations in Mental Health Care in Public Psychiatry. Western Reserve Psychiatric Hospital, Northfield, OH
- Secondary Bipolar Disorder. Comorbidity in Bipolar Disorder, American Psychiatric Association Symposium, Miami, FL
- Practical Perspectives on Bipolar Disorders. CME Library Audio Video. CME, Inc., Santa Ana, CA

Bipolar Disorders, Depressive Disorders, and Psychotic Disorders, Intensive Review of Psychiatry and Neurology CME Inc., Tysons Corner, MD

Human Behavioral and Biochemical Sensitization: Implications for Mood Disorders. American College of Neuropsychopharmacology (ACNP)

Annual Meeting Satellite Symposium – in Honor of Jonathan O. Cole, M.D., San Juan, Puerto Rico

Rapid Stabilization and Treatment of Bipolar Disorder in the Psychiatric Emergency Service. American Psychiatric Association Meeting, Institute on Psychiatric Services, Boston, MA

New Uses of Antidepressants: Social Phobia. Physicians Postgraduate Press, Inc. Roundtable Symposium. Tyson Corner, VA

1996

Clinical Strategies for the Care of Patients with Bipolar Disorder; National Symposium, Co-Chair person. Discovery International, Aspen, CO

New Perspectives on the Treatment of Bipolar Disorder; National Roundtable Symposium, Chairperson. Physicians Postgraduate Press, Inc. Dallas, TX

Strategies for Acute Treatment of Mania; Management of Bipolar Disorder in the Current Environment. American Psychiatric Association Annual Meeting Symposium. New York, NY

Epidemiology and Differential Diagnosis of Bipolar Disorder; Pharmacologic Treatment of Manic-Depressive Illness. Bipolar Disorder Minifellowship, McLean Hospital, Belmont, MA

The Adult Bipolar Patient: Cormorbidity and Treatment; Treating Bipolar Disorder – Comorbidity Issues Throughout the Lifecycle. Massachusetts Psychiatric Society and Cambridge Hospital Symposium. Boston, MA

Health Economic Impact of Bipolar Disorder; Comorbidity and Mixed Mania in Bipolar Disorder - - Cost Effective Strategies, National Symposium Chairperson. Institute on Psychiatric Services, American Psychiatric Association Annual Meeting. Chicago, IL

1997

Role of Antipsychotics in Treating Psychotic Mood Disorders; 4th Annual Psychopharmacology Symposium. Ohio State University School of Medicine. Columbus, OH

Role of Antipsychotics in Treating Mood Disorders; Antipsychotics in Unique Patient Populations. American Psychiatric Association Annual Meeting Symposium, San Diego, CA

Costs and Benefits of Bipolar Pharmacotherapy; Diagnostic and Treatment Advances in Manic Depression. American Psychiatric Association Annual Meeting Symposium. San Diego, CA

Psychopharmacological Treatment of Psychotic Disorders Across the Life Span. American Psychiatric Association Annual Meeting Symposium. San Diego, CA

Treating the Affective Component in Schizophrenia; Depression in Schizophrenia-Expanding Therapeutic Opportunities. World Congress of Biological Psychiatry. Nice, France

The New Antipsychotics and Their Therapeutic Potential; Comprehensive Schizophrenia Update. Alabama Psychiatric Society and the Mississippi Psychiatric Association Annual Meeting, Destin, FL

Pharmacoeconomics of Mood Stabilizers, Acute Manic Phase. International Bipolar Conference. Paris, France

Management of Mixed Mood States and Bipolar Disorder. Mental Health Association of Franklin County Annual Symposium. Columbus, OH

Bipolar Disorder in the Elderly. Institute for Psychiatric Services, American Psychiatric Association Annual Meeting, Washington, DC

Pharmacoeconomics of Bipolar Disorder. Mississippi Psychiatric Society, Jackson, MI

1998

Rapid Pharmacologic Treatment of Acute Mania. Ontario Psychiatric Association, Toronto, Canada

Rapid Loading Strategies in the Treatment of Acute Mania; Pharmacotherapy of Bipolar Disorder: Newest Advances Symposium Chairperson, American Psychiatric Association Annual Meeting, Toronto, Canada

A Biological Basis for Overlap of Mood in Psychotic Disorders; Expanding the Spectrum of Psychoses: The Interface of Affect Symposium. Co-Chairperson, American Psychiatric Association Annual Meeting, Toronto, Canada

Antipsychotics in Schizoaffective Disorder and Mania; Redefining Mood Stabilization: Advances in the Management of Bipolar Disorders. CINP XXIst Congress, Glasgow, Scotland

Making a Difference in Clinical Outcomes – the Profile of IM and Oral Ziprasidone; Making a Difference in Schizophrenia Management. CINP XXIst Congress, Glasgow, Scotland

A Biological Basis for Mood Overlap in Psychotic Disorders; New Advances in the Management of Bipolar Disorder (Chair). 9th Congress of the Association of European Psychiatrists (AEP), Copenhagen, Denmark

Long-term Management of Schizophrenia: The Role of New Antipsychotic; Schizophrenia: Charting a Course Through Mental Illness. Institute on Psychiatric Services Annual Meeting, American Psychiatric Association, Los Angeles, CA

Antipsychotics in Acute Mania: New Findings; Use of Antipsychotics in the management of Bipolar Disorder (Chair). Institute on Psychiatric Services Annual Meeting, American Psychiatric Association Annual Meeting, Los Angeles, CA

Newest Treatment Advances in Bipolar Disorder. U.S. Psychiatric & Mental Health Congress, San Francisco, CA

Atypical Antipsychotics: Efficacy in Treating Affective Symptoms, Hostility and Suicidality in Schizophrenia; Antipsychotic Standard of Care: Redefining the Definition of Atypical Antipsychotics. U.S. Psychiatric & Mental Health Congress, San Francisco, CA

Psychosis and Mood Disorders: Defining Reasonable Expectations for Treatment Outcomes (Chair). Center Net Symposium in conjunction with the Association of Academic Health Centers, Washington, DC

1999

Clinical Assessment of Atypical Antipsychotics: Interpreting the Data. PsychLINK Symposium, Dallas, TX

Update on Clinical Psychopharmacology Research. American Society of Clinical Psychopharmacology Regional Meeting, Cincinnati, OH

Pharmacologic Mechanisms of Mood Stabilization Among Atypical Antipsychotics. Are Atypical Antipsychotics also Mood Stabilizers? (Symposium Chairperson). American Psychiatric Association Annual Meeting, Washington, DC.

Mood Stabilizing Medication. Medication Controversies in Bipolar Disorder Symposium. American Psychiatric Association Annual Meeting, Washington, DC.

Antipsychotics in Schizoaffective Disorder. Global Medical Conference: Focus on Bipolar Disorder. Indianapolis, IN.

Relier L'interface entre les Troubles Psychotiques et les Troubles de l'humeur. Association des Médecins Psychiatres du Quebec. Alymer, Quebec, Canada

The Costs of Treatment of Bipolar Disorder. Bipolar Disorders – 100 years after Kraeplin. Martin Luther Universitat Halle – Wittenburg. Berlin Germany.

Optimizing Outcomes in Bipolar Disorder. Redefining Mood Stabilization: Advances in the Management of Bipolar Disorder. XI World Congress of the World Psychiatric Association. Hamburg, Germany.

Treatment of Psychotic Disorders for the New Century: From Social Containment to Reintegration (Chair). CENTERNET National Videoconference. New York, NY.

Treatment of Bipolar Disorder: Lithium, Anticonvulsants and Atypical Antipsychotics. Advances in Mood Disorders and Schizophrenia: Diagnosis – Biology – Treatment. Palm Beach, Fl.

The Use of Placebo in Studies of Bipolar Disorder: Current Status. Clinical Trials in Mood Disorders. The Use of Placebo, Past, Present and Future. A consensus conference of the National Depressive and Manic-Depressive Association. Washington, DC.

Ask the Doctors. National DMDA Annual Convention. Houston, TX.

New Horizons in Research. National DMDA Annual Convention. Houston, TX.

Clinical Vignettes: Strategies for Psychosis. PsychLink Symposium, Dallas, TX.

Antipsychotics in Acute and Maintenance Treatment of Bipolar Disorder. Role for Antipsychotics in Long-term Mood Stabilization (Program Chair). APA Institute on Psychiatric Services, New Orleans, LA.

Atypical Antipsychotics in the treatment of Mania. Progress in Bipolar Disorders (Program Chair). US Psychiatric & Mental Health congress, CME, Inc. Atlanta, GA.

Filling the Unmet Needs of the Bipolar Patient. Psychlink Symposium, Dallas, TX.

2000

Bipolar Disorder: From Pre-Clinical to Clinical, Facing the New Millenium (Program Chair). Society of Biological Psychiatry, Phoenix, AZ.

Keck PE, Jr. Update on tardive dyskinesia. Tardive dyskinesia in patients with depression including bipolar disorder. J Clin Psychiatry Audiograph Series 2000; 3:1.

Management of Bipolar Disorder for the New Millennium (Program Chair). Provision Medical Education Telecast. Miami, FL.

Thymoleptic mechanisms and activity of atypical antipsychotics. Fifth Annual Psychopharmacology Update. Nevada Association of Psychiatric Physicians. Las Vegas, NV

Rapid stabilization of mood and psychotic symptoms in mania. Defining Bipolar Disorder (Co-Chairman), American Psychiatric Association Annual Meeting. Chicago, IL.

NMS 1960-2000: Forty years of Progress. American Psychiatric Association Annual Meeting. Chicago, IL.

Newest Advances in the Pharmacological Treatment of Psychiatric Illnesses. Wyoming Medical Society Annual Meeting, Jackson Hole, WY

Restoring Balance: Long Term Mood Stabilization in the Bipolar Patient. PsychLink Symposium, Dallas, TX.

Treatment of Bipolar Disorder: Lithium, Anticonvulsants, and Atypical Antipsychotics. Advances in the Diagnosis, Biology and treatment of the Major Psychiatric Disorder. Palm Beach, FL.

Realities of Reintegration: Multidimensional Approaches to Optimize Outcomes in Psychosis and Mood Disorder. Provision Medical Education Telecast. New York, NY.

Redefining Mood Stabilization. The Coming of Age of the Bipolar Spectrum: An International Conference. University of California, San Diego. San Diego, CA.

Interface of Thought, Mood and Behavior. 13th Annual U.S. Psychiatric & Mental Health Congress, San Diego, CA.

Redefining Efficacy in Psychosis and Mood Disorders. 13th Annual U.S. Psychiatric & Mental Health Congress, San Diego, CA.

2001 Update on Treatment Advances in Bipolar Disorder. Sunshine From Darkness, NARSAD Annual Meeting, Sarasota, FL.

Atypical Antipsychotics in the Treatment of Aggressive Behvaviors. Off-Label on the Table: Using New Pharmacological Agents. American Psychiatric Association Annual Meeting, New Orleans, LA.

Manic and Mixed Episodes: The Challenge of Improving Functional Outcome. Providing Complete Treatment for Patients with Bipolar Disorder (Chairperson). American Psychiatric Association Annual Meeting, New Orleans, LA.

New Antiepileptics in the Treatment of Bipolar Disorder. Clinical Issues in Bipolar Disorder: The Stanley Foundation Bipolar Network. American Psychiatric Association Annual Meeting, New Orleans, LA.

Update on Pharmacotherapy and Neuroscience. Fourth International Conference on Bipolar Disorder, Pittsburgh, PA.

What Makes a Drug a Mood-Stabilizer? PsychLink telecast, Interactive Medical Networks, Dallas, TX.

Update on New Treatment Research for Bipolar Disorder. National DMDA 14th Annual Conference, Cleveland, OH.

Bipolar Disorder: An Overview of Diagnosis and Treatment. 150th Annual Meeting of the Kentucky Medical Association, Louisville, KY.

Update on Latest Treatment Advances for Bipolar Disorder. Annual Meeting of the Kentuck Psychiatric Association, Louisville, KY.

Latest Treatment Advances for Bipolar Disorder. Interface of Mood, Thought, and Behavior. U.S. Psychiatric & Mental Health Congress, Boston, MA.

Treating the Acute Phases of Bipolar Disorder: Mania. Progress in Bipolar Disorder. U.S. Psychiatric & Mental Health Congress, Boston , MA.

Acute Efficacy Considerations in Managing Schizophrenia. Redefining Optimal Patients Management in Schizophrenia. U.S. Psychiatric & Mental Health Congress, Boston, MA.

2002

Comprehensive Treatment of Manic-Depressive Illness (Program Chair). Depression Awareness Day: The Latest on Chasing the Blues Away. Albert Sabin Center, Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio.

Doctoral Candidate Committee:

1993-1995 Megan G. Murray, "The Measurement of Life Stress in Biplar Disorder," Committee Member for Major Qualifying Exam (MQE) and Dissertation. University of Cincinnati, Department of Psychology

Scientific Advisory Boards:

1990-	Abbott Laboratories, National Advisory Board, Depakote[R]
1992-1993	SmithKline Beecham, Regional Advisory Board, Paxil[R]
1993-1994	Janssen, Inc., Regional Advisory Board, Risperdal[R]
1994-	National Depressive and Manic Depressive Association, Vice Chairman (1998-2001)
1994-	Alza Pharmaceutical, CNS Drug Delivery Systems
1994-	Stanley Foundation Bipolar Network Study
1995-	Chairman and Faculty Advisor, Psychiatric Residents National Advisory Board, Abbott Laboratories, Depakote[R]
1995-	Park-Davis, National Advisory Board, Neurontin[R]
1995-	Wyeth-Ayerst, National Advisory Board, CNS Pharmaceutical Development
1996-	Eli Lilly and Company, Regional Advisory Board, Zyprexa[R]
1996-	Zeneca Pharmaceuticals, National Advisory Board, Seroquel[R]
1997-	The R.W. Johnson Pharmaceutical Research Institute, Scientific Consultant
1997-	Solvay Pharmaceuticals, National Advisory Board, Lithobid[R]
1997-	Pfizer, Inc., National Advisory Board, CNS Pharmaceuticals
1999-	Pfizer, Inc., Visiting Professorship Program Advisory Board

1998-	Quintiles Pacifica, Inc., La Jolla, CA
2001-	GlaxoSmithKline, National Advisory Board, Lamitcal ®

Scientific Consultant:

2001-	Malignant Hyperthermia Association of the United States (MHAUS)

Community Services:

1991-	Speaker, NAMI of Hamilton County
1992-1997	S.A.Y. Soccer Coach, Summit County Day School
1992-1995	Knothole Baseball Coach, Mt. Lookout Knights
1994-1997	Knothole Baseball Coach, Green Monsters Baseball Team
1995-1996	C.Y.O. Baseball Coach, Summit County Day School
1996-	Board of Trustees, Living Arrangements for the Developmentally Disabled, Cincinnati, Ohio
1997	Speaker, Bipolar Support Group, Hamilton County
1999	Speaker, Annual Meeting of PLAN, Hamilton County
1999-2000	C.Y.O. Basketball Coach, Summit Country Day School
2000	M.V.L.A. LACROSSE Coach, Summit Country Day School

CURRICULUM VITAE

OFFICE ADDRESS:
Comprehensive Clinical Research, CNS, P.C.
130 White Horse Pike
Clementon, NJ 08021
856-566-9000
Fax: 856-566-4101

DATE OF BIRTH: August 11, 1956

PLACE OF BIRTH: Philadelphia, PA

LICENSURE:
Board Certified by the American Osteopathic Board of Family Practice
Osteopathic Physician and Surgeon, State of California
Osteopathic Physician and Surgeon, State of New Jersey
Osteopathic Physician and Surgeon, State of Pennsylvania

CURRENT STATUS:

1998 – Present	Chief Medical Officer Comprehensive Clinical Research, CNS, P.C.
1994 – 1998	Executive Vice-President, Corporate Development FPA Medical Management, Inc.
1984 – 1993	General Practitioner Family Practice Associates of San Diego, Inc.

EDUCATION:

1979 – 1983	Philadelphia College of Osteopathic Medicine, Philadelphia, Pennsylvania Osteopathic Physician and Surgeon, D.O.
1978 – 1979	Drexel University, Philadelphia, Pennsylvania
1974 – 1978	Fairleigh Dickinson University, Madison, New Jersey B.S.
1983 – 1984	Rotating Internship

Phone: (856)566-9000 • Fax (856)566-9701 • 24 Hour E[illegible] (800)913-1843

HOWARD A. HASSMAN, D.O.

University of Medicine & Dentistry
John F. Kennedy Memorial Hospital
Stratford, Cherry Hill, and Washington Township Divisions, New Jersey

POST GRADUATE TRAINING:

1982 – 1994	University of Pennsylvania, Ongoing Clinical Research Training. Instructor for five years in the Department of Psychiatry at University of Pennsylvania. Worked collaboratively with Karl Rickels, M.D., Chairman of the Department of Psychiatry and President of the Private Practice Research Group
1981 – 1984	W. George Case, M.D., Director, University of Pennsylvania 1240 Hours of Training in the Conduct of Clinical Research

HOSPITAL AND ADMINISTRATIVE APPOINTMENTS:

2001 – 2002	Hampton Behavioral Center, Westhampton NJ
2001 – 2002	Scientific Advisory Group of Organon, Inc. for The New Treatment Option for the Mature Depressed Patient, presenter of Patient Trial Program The Plaza Hotel, New York, NY March 24, 2001
2001 – 2002	Scientific Advisory Group of Organon, Inc. for The New Treatment Option for the Mature Depressed Patient, presenter of Patient Trial Program New York Hilton, New York, NY March 25, 2001
2000 – 2001	Eli Lilly and Company Advisory Board on Tomoxetine for ADD and ADHD Pediatrics, Adolescents, and Adults
1999 – Present	Eli Lilly and Company Advisory Board for Pediatric, Adolescent, and Adult ADHD
1999 – Present	Forest Laboratories Advisory Board for Geriatric Study
1999 – 2000	Eli Lilly and Company Advisory Board on Tomoxetine for ADD and ADHD Pediatrics, Adolescents, and Adults
1998 – 2001	JFK Memorial Hospital, University of Medicine and Dentistry, Stratford NJ
1991 – 1995	Staff Member, Hillside Hospital (Closed)
1990 – 1996	Staff Member, Mercy Hospital
1984 – 1998	Staff Member, Grossmont Hospital
1984 – 1987	Staff Member, Executive Committee, Alvarado Hospital

AWARDS AND HONORS:

1996	Entrepreneur of the Year Award, Ernst & Young
1996	Outstanding Efforts in the Healthcare Community The City of San Diego, Susan Golding, Mayor

1995	San Diego Press Club, Headliner
1982	American College of General Practitioners - Osteopathic Medicine and Surgery Preceptor Program
1980 – 1983	Philadelphia College of Osteopathic Medicine Lambda Omicron Gamma, National Medical Fraternity Award for Outstanding Leadership (three-time recipient)

CNS STUDIES

1982 – 1983	Rater and Physician, Alprazelam Anxiety Study #2 PPRG
1982 – 1983	Rater and Physician, Abbott Anxiety Study with PPRG
1984 – 1985	University of Pennsylvania Adinazolam Depression Study
1984	Principal Investigator Cheviak Bigasdh Syndrome Study Independently conducted
1985 – 1987	Downing Anxiety Study with PPRG University of Pennsylvania
1989 – 1991	Miles Laboratories Ipsapirone Study, Anxiety Investigational Research University of Pennsylvania
1990 – 1991	Bristol Myers Laboratories Buspirone Study, Depression in the Elderly Research University of Pennsylvania
1990 – 1991	Bristol Myers Laboratories Gepirone Study, Depression Research University of Pennsylvania
1990 – 1991	Bristol Myers Laboratories Gepirone Study, Anxiety Research University of Pennsylvania
1991 – 1992	Sandoz Pharmaceutical Corporation Abecarnil and Diazepam in Outpatients with Generalized Anxiety Disorder Principal Investigator

1991 – 1992	Wyeth Ayerst Laboratories Hydrochloride Study, Depression Research University of Pennsylvania
1991 – 1993	Wyeth Ayerst Laboratories Hydrochloride Study, Anxiety Research University of Pennsylvania
1991 – 1993	Bristol Myers Laboratories, Gepirone Extended Release, Depression Study University of Pennsylvania
1992 – 1994	Bristol Myers-Squibb Lab Open Multi-Center Trial of Nefazodone in the Treatment of Elderly Patients with Mood Disorders Principal Investigator
1992 – 1993	Bristol Myers-Squibb Lab Buspar ER Extended Release in the Treatment of Anxiety Principal Investigator
1993 –1994	TAP Pharmaceuticals, Inc. Double-Blind, Fixed-Dose, Multi-Center Study Comparing DN-2327 (4&8 Mg. Daily) to Buspar (25mg/day) and Placebo in Patients with Generalized Anxiety Disorder Principal Investigator
1999	B4Z-MC-LYAO Eli Lilly and Company ADHD – Adult A Phase III, Randomized, Double-Blind Comparison of Placebo and Tomoxetine Hydrochloride in Adult Outpatients with DSM-IV Attention Deficit Hyperactivity Disorder
1999	B4Z-MC-LYAB Eli Lilly and Company ADHD – Pediatric A Phase III, Open-Label Safety and Efficacy Study of Tomoxetine in Outpatients with ADHD Ages 6 to 18 Years
1999	SCT-MD-05 Forest Laboratories Anxiety Flexible-Dose Comparison of the Safety and Efficacy of LU26-054 and Placebo in the Treatment of Generalized Anxiety Disorder
1999	CN101-124 Bristol-Myers Squibb Anxiety – Adolescent A Double-Blind, Multi-Center, Randomized, Parallel-Group, Placebo-Controlled Study Evaluating the Efficacy and Safety of Two Flexible-Dose Ranges of an Anxiolitic Agent in Children and Adolescents (Ages 6 to 17) with Generalized Anxiety Disorder (GAD). The product is currently marketed for use in adults
1999	0600B2-397 Wyeth-Ayerst Research Anxiety – Pediatric A Double-Blind, Placebo-Controlled Study of Venlafaxine ER in Children and Adolescents with Generalized Anxiety Disorder

1999 003-901 Organon, Inc.
Depression – Elderly
A Double-Blind, Multi-Center, Randomized, Paroxetine-Controlled Study of the Efficacy and Safety of Remeron (mirtazapine) in Subjects with Major Depressive Disorder who are at least 65 Years of Age

1999 134-004 Organon, Inc.
Depression – Gepirone
A Double-Blind, Multi-Center Randomized, Placebo-Controlled Efficacy and Safety Study of ORG 33062 ER and Fluoxetine in Subjects who Suffer from Major Depressive Disorder with Atypical Features

1999 CN104-181 Bristol-Myers Squibb
Depression – Nefazadone
A Multi-Center, Double-Blind, Flexible-Dose Safety Trial Comparing Nefazodone IR to Nefazodone ER in the Treatment of Depressed Patients

1999 CIT-MD3-97-03 Forest Laboratories
Depression – Old
A Randomized, Double-Blind, Placebo-Controlled Trial of Citalopram In Depressed Patients at Least 75 Years of Age

1999 CIT-MD-22 Forest Laboratories
Depression – Old – Extension
Celexa Open-Label Treatment of Depression

1999 31-98-220 Otsuka America Pharmaceuticals, Inc.
Schizophrenia – Extension
Open-Label Follow-Up of the Long Term Safety of Aripiprazole Administered Orally in Patients with Stable Psychosis

1999 CN 138-004-047 Bristol-Myers Squibb
Alzheimer's
A Multi-Center, Randomized, Double-Blind, Placebo-Controlled Study of Three Fixed Doses of Aripiprazole in the Treatment of Institutionalized Patients with Psychosis Associated with Dementia of the Alzheimer's Type

2000 0600B1-395 Wyeth-Ayerst Research
Depression – Pediatric
An Open-Label, Long Term Safety Study of Venlafaxine ER in Children and Adolescents with Major Depressive Disorder

2000 CIT-MD-20 Forest Laboratories
Depression – Pediatric – Extension
Open-Label Extension Study of the Safety and Efficacy of Citalopram in Children and Adolescents with Depression

2000 003-045 Organon, Inc.
Depression – Pediatric
A Multi-Center, Randomized, Double-Blind, Placebo-Controlled, Efficacy and Safety Study of Remeron in Outpatient Children and Adolescents with Major Depressive Disorder

2000	M2020/0046	Pharmacia & Upjohn Corporation
	Depression – Reboxetine	
	Reboxetine, Placebo and Paroxetine Comparison in Patients with Major Depressive Disorder	
2000	SCT-MD-01	Forest Laboratories
	Depression – Son of Celexa	
	Fixed-Dose Comparison of the Safety and Efficacy of LU26-054, Citalopram and Placebo in the Treatment of Major Depressive Disorder	
2000	SCT-MD-03	Forest Laboratories
	Depression – Son of Celexa	
	Placebo-Controlled Evaluation of the Safety and Efficacy of LU26-054 in the Prevention of Depression Relapse	
2000	003-900	Organon, Inc.
	Depression – SSRI Failure	
	Multi-Center, Randomized, Double-Blind, Sertaline-Controlled Study of the Efficacy and Safety of Remeron (mirtazapine) in Subjects with Major Depressive Disorder who Failed on SSRI Treatment Due to Lack of Efficacy	
2000	F1D-MC-HGIE	Eli Lilly and Company
	Depression – Treatment	
	Olanzapine Plus Fluoxetine Combination Therapy in Treatment Resistant Depression: A Dose-Ranging Study	
2000	SCT-MD-04	Forest Laboratories
	Panic Disorder	
	Flexible-Dose Comparison of the Safety and Efficacy of LU26-054, Citalopram and Placebo in the Treatment of Panic Disorder	
2000	31-98-213	Otsuka America Pharmaceuticals, Inc.
	Schizophrenia	
	An Open-Label Comparison of the Neurocognitive effects of Aripiprazole to Olanzapine Administered Orally in Patients with Stable Psychosis	
2000	B1Y-MC-HCKN	Eli Lilly and Company
	Depression – Switching	
	Switching Subjects from Citalopram, Paroxetine, or Sertraline to Once-Weekly Modified-Release Fluoxetine Hydrochloride in Maintenance of Response for Depression	
2000	28105	Organon, Inc.
	Major Depressive Disorder	
	A Double-Blind, Randomized, Placebo- and Paroxetine- Controlled, Multi-Center Dose Finding Trial in Outpatients with Moderate to Severe Major Depressive Disorder	
2000	B4Z-MC-LYBB	Eli Lilly and Company
	ADHD – Pediatric – Extension	
	A Phase III, Open-Label Safety and Efficacy Study of Tomoxetine Hydrochloride in Pediatric Outpatients (6 to 18 Years) with ADHD	
2000	29060/701	SmithKline Beecham

Depression – Pediatric
A Randomized, Multi-Center, 8-Week, Double-Blind, Placebo-Controlled, Flexible-Dose Study to Evaluate the Efficacy and Safety of Paroxetine in Children and Adolescents with Major Depressive Disorder

2000 SCT-MD-11 Forest Laboratories
Depression – Prophylaxis
An Evaluation of the Safety and Efficacy of LU26-054 in the Prevention of Depression Recurrence

2000 CIT-MD-18 Forest Laboratories
Depression – Pediatric
A Randomized, Double-Blind, Placebo-Controlled Evaluation of the Safety and Efficacy of Citalopram in Children and Adolescents with Depression

2000 SCT-MD-17 Forest Laboratories
Anxiety – Extension
An Open-Label Extension Study of the Safety and Efficacy of LU26-054 in Patients with Generalized Anxiety Disorder

2000 134-502 Organon, Inc.
Depression – Gepirone – Extension
A Double-Blind, Multi-Center Extension Trial in Subjects who Suffer from Major Depressive Disorder with Atypical Features who Participated in the Placebo and Fluoxetine Study of ORG33062ER – Protocol 134-004

2000 H5Z-MC-LUAH Eli Lilly and Company
Anxiety
R-Fluoxetine vs. Placebo in the Treatment of Generalized Anxiety Disorder

2000 0600B1-402 Wyeth-Ayerst Research
Major Depressive Disorder
A Double-Blind, Placebo-Controlled Comparative Efficacy Study of Venlafaxine ER and Sertraline in Producing Remission in Outpatients with Major Depressive Disorder

2000 B4Z-MC-LYAI Eli Lilly and Company
ADHD – Pediatric – Extension
Long-Term, Open-Label, Safety Study of Tomoxetine HCL in Patients 6 Years and Older

2000 F1D-MC-HGGY Eli Lilly and Company
Bipolar I Depression
Placebo-Controlled Olanzapine Monotherapy in the Treatment of Bipolar I Depression

2000 F1J-MD-HMBH Eli Lilly and Company
Depression – Adult
Duloxetine Once-Daily Dosing Versus Placebo in the Acute Treatment of Major Depression.

2000 GAL-INT-10 Janssen Research Foundation
Alzheimer's Disease
Placebo-Controlled Evaluation of Galantamine in the Treatment of Alzheimer's Disease: Safety and Efficacy of a Controlled Release Formulation

2000 GAL-INT-11/18 Janssen Research Foundation

MCI
Galantamine in Patients at Risk for the Development of Alzheimer's Disease

2000 0600B4-389 Wyeth-Ayerst Research
Social Anxiety
A Double-Blind, Placebo-Controlled, Parallel-Group, Flexible-Dose Study for Venlafaxine ER in Adolescent Outpatients with Social Anxiety Disorder

2000 F1D-MC-HGJJ Eli Lilly and Company
Schizophrenia
The Assessment of Sibutramine for the Treatment of Olanzapine-Associated Weight Gain in Patients with Schizophrenia and Related Disorders and Bipolar Disorder

2000 RIS-USA-240 Janssen Research Foundation
Bipolar I
The Efficacy and Safety of Flexible-Dose Ranges of Risperidone vs. Placebo or Divalproex Sodium in the Treatment of Manic or Mixed Episodes Associated with Bipolar I Disorder

2001 MEM-MD-01, 02, 03 Forest Laboratories
Alzheimer's Disease
A Long-Term Study Evaluating the Safety and Tolerability of Four Memantine Dosing Regimens in Patients with Moderate to Severe Dementia of the Alzheimer's Type

2001 0600B5-353 Wyeth-Ayerst Research
Panic
A Double-Blind, Placebo-Controlled, Parallel-Group, Flexible-Dose Study of Venlafaxine Extended-Release Capsules in Adult Outpatients With Panic Disorder

2001 003-048 Organon , Inc.
MDD
A Multi-Center, Randomized, Double-Blind, Fluoxetine- and Placebo-Controlled Study of the Efficacy and Safety of REMERON Sol Tab (mirtazapine) Orally Disintegrating Tablets in Subject with Major Depressive Disorder

2001 B1Y-MC-HCLD Eli Lilly and Company
MDD
Continuation Treatment with Once-Weekly Modified-Release Fluoxetine HCl

2001 B4Z-MC-LYAR Eli Lilly and Company
ADHD – Adult – Extension
Long-Term, Open-Label Safety Study of Tomoxetine HCl in Adult Outpatients with DSM-IV ADHD

2001 SCT-MD-06 Forest Laboratories
Panic Disorder
Flexible-Dose Comparison of the Safety and Efficacy of Escitalopram and Placebo in the Treatment of Generalized Anxiety Disorder

2001 5077US/0043 Astra-Zeneca
Schizophrenia

A Multi-Center, Double-Blind, Randomized Comparison of the Efficacy and Safety of Quetiapine Fumarate and Risperidone in the Treatment of Patients with Schizophrenia

2001 GAL-INT-26 Janssen Research Foundation
Vascular Dementia
A Randomized 26-Week, Double-Blind, Placebo-Controlled Trial to Evaluate the Safety and Efficacy of Galantamine in the Treatment of Dementia Secondary to Cerebrovascular Disease

2001 C-1073-02 Scirex Corporation
MDD
A Phase III, Randomized, Double-Blind, Placebo-Controlled Study of Safety and Efficacy of C-1073 in Patients with Major Depressive Disorder With Psychotic Features

IM STUDIES

1992 – 1994 Whitehall Laboratories
Dimetane Extend Tabs vs. Terfenadine, Allergic Rhinitis
Principal Investigator

1992 – 1995 Glaxo, Inc.
Oral GR122311X Compared with Ranitidine, Duodenal, and Benign Gastric Ulcer
Principal Investigator

1992 – 1995 Forest Laboratories
Fosfomycin Tromethamine vs. Ciprofloxin, Uncomplicated Urinary Tract Infection
Principal Investigator

1992 – 1993 Upjohn Company
Insomnia Treatment Study Comparing Triazolam and Temazepam
Principal Investigator

1992 - 1994 Pfizer, Inc.
Randomized Parallel Comparative Study of the Clinical Effectiveness of Two Nit Combs after Treatment with a Pyrethrin-Based Pediculicide
Principal Investigator

1992 –1993 Harris Laboratories/SmithKline Beecham
Safety and Efficacy of Miconazole Nitrate 2% Vaginal Cream (SB) Compared with Miconazole Nitrate 2% Vaginal Cream (Monistat 7) and Placebo in the Treatment of Vulvovaginal Candidiasis
Principal Investigator

1992 –1994 Otsuka Pharmaceutical, Inc.
Protocol 106-92-206, Double-Blind Active-Controlled Efficacy Study of OPC-17116 - Inpatients with Acute Bacterial Exacerbations of Chronic Bronchitis
Principal Investigator

1992 –1993 Otsuka Pharmaceutical, Inc.
Protocol 106-92-201, Double-Blind Active-Controlled Efficacy

Study of OPC 17116 - Inpatients with Community Acquired Pneumonia
Principal Investigator

1993 –1994 Forest Lab, Inc.
Fosfomycin Tromethamine vs. Nitrofuantoin Monohydrate/Macrocrystals in Uncomplicated Urinary Tract Infections, MON-US-03
Principal Investigator

1998 –1999 Tap Holdings, Inc.
A Phase III, Randomized, Double-Blind Comparative Safety and Efficacy of Cefditoren Pivoxil and Cefadroxil Monohydrate in the Treatment of Patients with Uncomplicated Skin or Skin Structure infection
Principal Investigator

1998 –1999 TAP Holdings, Inc.
A Randomized Investigator-Blinded Active-Controlled, Parallel-Group Phase III Study Comparative Safety and Efficacy of Cefditoren Pivoxil and Augmentin (Amoxicillin/Clavulanate Potassium) in the treatment of Patients with Acute Bacterial Sinusitis
Principal Investigator

1998 –1999 ViroPharma
A Double-Blind, Randomized, Placebo-Controlled Trial of Pleconaril in the Treatment of Picornavirus Respiratory Tract Disease
Principal Investigator

1998 –1999 Scirex Corporation
A Multi-Center, Double-Blind, Placebo-Controlled Trial for Safety and Efficacy Evaluation of Study Drug in the Treatment of Viral Syndrome
Principal Investigator

1999 99-0-054 Fujisawa Healthcare Research Institute
Atopic Dermatitis
An Open-Label Study To Evaluate The Safety Of Topically Applied Tacrolimus Ointment For The Treatment Of Atopic Dermatitis

1999 GFXA4004 Glaxo SmithKline Pharmaceutical
Bronchitis – Chronic
A Randomized, Double-Blind, Multi-Center Comparison of the Efficacy and Safety of Grepafloxacin (Raxar) 400mg or 600mg once daily and Clarithromycin (Biaxin) 500mg twice daily in the Treatment of Patients with
Acute Bacterial Exacerbations of Treatment of Patients with Acute Bronchitis

1999 ALLHAT National Heart, Lung and Blood Institute
Heart Attack Prevention
Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial Consisting of a Double-Blinded First-Line Anti-Hypertensive Drug with Chlorthalidone, Amlodipine, Linsinopril or Doxazosin and an
Open-Labeled Second- and Third-Line Anti-Hypertensive Drug with Reserpine, Clonidine, Atenolol or Hydralazine along with a Lipid Lowering Component of Pravastatin vs. Usual Care

1999	265805/049	SmithKline Beecham
	Pneumonia 2	
	A Randomized, Double-Blind, Double-Dummy, Multi-Center, Parallel-Group Study to Asses the Efficacy and Safety of SB-265805, 320mg Oral Dose Once a Day for 7 or 14 Days Compared with Trovafloxacin, 200mg Oral Dose Once a Day for 7 or 14 Days in the Treatment of Bacterial Community Acquired Pneumonia	
2000	CV138-056	Bristol Myers Squibb
	Diabetes – Medication	
	A Multi-Center, Randomized, Double-Blind, Parallel-Group Trial Comparing the Safety and Efficacy of Metformin/Glyburide to Pioglitazone as First Line Therapy in Patients with Type 2 Diabetes Mellitus Who Have Inadequate Glycemic Control with Diet and Exercise	
2000	AGEE-2064	Nova Nordisk
	Diabetes – Open-Label	
	Repaglinide vs. Pioglitazone vs. Combination in Type 2 Diabetes Patients: A 24-Week, Randomized, Controlled Multi-Center Trial	
2000	FLTA4038	Glaxo Wellcome
	Asthma	
	A Randomized, Double-Blind, Parallel-Group Comparison Study of Inhaled fluticasone propionate (88mcg BID) versus Montelukst sodium (10 mg QD) Subjects Currently Receiving Beta agonists Alone	
2000	SC-397-5098	Astra-Zeneca
	COPD 1	
	A 3 Month, Multi-Center, Multinational, Double-Blind, Group Comparative Study to Investigate the Effects of AR-C68397AA via pMDI Compared with Placebo in Adult Patients with Chronic Obstructive Pulmonary Disease COPD	
2000	SC-397-5163	Astra-Zeneca
	COPD 2	
	A Multi-Center, Multi-National Double-Blind, Double-Dummy, Placebo-Controlled, Group Comparative Study to Investigate the Long Term Safety of ARC68397AA via pMDI Compared with Salmeterol in Adult Patients with Chronic Obstructive Pulmonary Disease	
2000	WV15799	Hoffman LaRoche
	Flu – Contacts	
	A Double-Blind, Randomized, Placebo-Controlled study of RO64-0796 (also known as GS4104) Used for the Prevention of Clinical Influenza Post Exposure in Families	
2000	NAI130012	Glaxo Wellcome
	Flu – Elderly Relenza	
	A Double-Blind, Randomized, Placebo-Controlled, Parallel-Group, Multicentre Study to Investigate the Efficacy and Safety of Inhaled Zanamivir 10 mg Administered Twice Daily for Five Days in the Treatment of Symptomatic Influenza A and B Viral Infections in Subjects Ages 65 years +	
2000	WV15978	Hoffman LaRoche
	Flu – Elderly Tamiflu	
	A Double-Blind, Stratified, Randomized Placebo-Controlled Study of	

Ro64-0796 in the Treatment of Influenza Infection in Elderly Adults

2000 NAI40012 Glaxo Wellcome
Flu – Relenza Device
An Open-Label, Multi-Center Study of the Patient Instructional Leaflet for Relenza Diskhaler

2000 S1673001 Solvay Pharmaceuticals
Hormone Replacement
A Double-Blind Investigation of the Efficacy and Safety of Continuous Transdermal 1% 17 b-Estradiol in Combination with Levonorgestrel Compared with Continuous Transdermal 1% 17 b-Estradiol Alone for the Prevention of Endometrial Hyperplasia in Postmenopausal Women

2000 S3B30011 Glaxo Wellcome
IBS 1
A Twelve Week Randomized, Double-Blind, Placebo-Controlled Study of the Efficacy and Tolerability of Hydrochloride 1mg Twice Daily for Control of Bowel Urgency in Females with Diarrhea-predominant Irritable Bowel Syndrome

2000 S3B30020 Glaxo Wellcome
IBS 2
A 24 Week, Randomized, Open-Label Study of Health Care Resource Used Quality of Life and Productivity with Alosetron 1 mg Twice Daily Versus Traditional Therapy in Females with Non-constipated Irritable Bowel Syndrome

2000 P00691 Schering-Plough
Lipids
A Phase III Double-Blind Efficacy and Safety Study of SCH 58235 (10mg) in Addition to Pravastatin Compared to Placebo in Subjects with Primary Hypercholesterolemia

2000 ZD4522IL/0028 Zeneca Pharmaceuticals
Lipids 1
A Randomized Double-Blind Multi-Center Trial to Compare the Short-Term and Long-Term Efficacy and Safety of ZD4522, Simvastatin and Pravastatin in the Treatment of Subjects with Hypercholesterolemia

2000 ZD4522IL/0033 Zeneca Pharmaceuticals
Lipids 2
A 6-week Randomized Double-blind Multi-Center Trial to Evaluate the Safety and Efficacy of ZD4522 (5,10,20,40, and 80 mg) and Atorvastatin (10,20,40 and 80Mg) Across Their Respective Dose Ranges in the Treatment of Subjects With Hypercholesterolemia

2000 ZD4522IL/0034 Zeneca Pharmaceuticals
Lipids 2A
An Open-Label, Multinational, Multi-Center, Extension Trial to Assess the Long-term Safety and Efficacy of ZD4522 in Subjects in the ZD4522 Clinical Trial Program

2000 ZD4522IL/0035 Zeneca Pharmaceuticals
Lipids 3
A 12 Week Multi-Center Randomized Double-blind Placebo-controlled Trial to Evaluate the Efficacy and Safety of ZD4522 (5,10,20,40 and 80 mg) in the Treatment of Subjects with Hypertriglyceridemia

2000 MT100-304 Pozen
Migraine
A Single Dose, Double-Blind, Safety and Efficacy Study of MT 100, Metoclopramide Hydrochloride and Naproxen Sodium in Subjects with Acute Migraine Attacks

2000 N91-99-02-053 Searle
OA – Knee Valdecoxib
Clinical Protocol for a Multi-Center, Double-Blind, Placebo-Controlled, Randomized Comparison Study of the Efficacy and Upper Gastrointestinal Safety of Valdecoxib 5 mg, 10 mg and 20 mg qd and Naproxen 500 mg Bid in Treating the Signs and Symptoms of Osteoarthritis of the Knee

2000 22-163, 302R1 Roberts Laboratories
OA – Ultram
Double-Blind, Placebo-Controlled, Parallel-Group Comparison Of The Efficacy and Safety of Propiram, Tramadol (Ultram), and Placebo With an Open-Label Extension of Pain Associated With Osteoarthritis of the Knee and/or Hip

2000 MK-0663-018 Merck Research Laboratories
OA 1
A 1 year Randomized, Placebo and Active-Comparator-Controlled, Parallel-Group, Double-Blind Two Part Study to Assess the Safety and Efficacy of MK-0663 versus Naproxen in Patients with Osteoarthritis

2000 MK-0663-019 Merck Research Laboratories
OA 2
A 1-Year Randomized, Placebo and Active-Comparator-Controlled, Parallel-Group , Double-Blind, Two Part Study to Access the Safety and Efficacy of MK-0663 Versus Naproxen in Patients with Osteoarthritis

2000 ALX1-11-93001 NPS-Allelix
Osteoporosis
An 18-Month Double-Blind, Placebo-Controlled, Phase III, Trial with a 12-Month Interim Analysis of the Effect of Recombinant Human Parathyroid Hormone (ALX1-11) on Fracture Incidence in Women with Post-Menopausal Osteoporosis

2000 843-023 Viropharma Inc.
Otitis Media
A Double-Blind, Randomized, Placebo-Controlled Evaluation of Pleconaril in the Prevention of Otitis Media in Children with a History of Otitis Media Following Picornavirus Respiratory Tract Infection

2000 HMR3647 Hoechst Marion Roussel
Pneumonia
A Double-Blind, Multi-Center, Randomized, Active-Controlled, Two-Arm Parallel -Group Comparative Study of the Efficacy and Safety of Oral HMR3647 (800mg once daily) Versus Oral Clarithromycin (500mg twice daily) in the Treatment of Community Acquired Pneumonia in Adults

2000 C99-712 Biogen
Psoriasis
A Randomized, Double-Blind, Placebo-Controlled, Dose Comparison Study to Evaluate the Efficacy and Safety of Intramuscular Administration of LFA3TIP (LFA-3/IgG1 Human Fusion Protein) in Subjects with Chronic Plaque Psoriasis

2000 MK-0663-024 Merck Research Laboratories
RA
An Active-Comparator and Placebo-Controlled, Parallel-Group, Double-Blind, 52 - Week Study to Assess the Safety and Efficacy of Mk-0663 in Rheumatoid Arthritis Patients

2000 MK-0966-088 Merck Research Laboratories
RA – GI Outcome
A Double-Blind, Randomized, Stratified, Parallel-Group to Assess the Incidence of PUB's During Chronic Treatment with MK-0966 or Naproxen in Patients with Rheumatoid Arthritis: U.S. Cohort

2000 LAM IV-307 Shire Laboratories
Renal Failure – Chronic
Dose Titration, Open-Label Study to Evaluate Long-Term Safety and Efficacy of Study Drug in Chronic Renal Failure Patients Receiving Hemodialysis

2000 CEF-97-007 Tap Holdings
Sinusitis
Comparative Safety and Efficacy of Cefditoren Pivoxil and Augmentin (Amoxicillin/Clavulanate Potassium) in the Treatment of Patients with Acute Bacterial Sinusitis

2000 M1260/0065 Pharmacia & Upjohn Corporation
Skin Infection – Pediatric
Linezolid vs. Cefadroxil in the Treatment of Skin and Skin Structure Infections in Children

2000 CEF-97-011 Tap Holdings
Skin Infection
Comparative Safety and Efficacy of Cefitoren Pivoxil and Cefadroxil Monohydrate in the Treatment of Patients with Uncomplicated Skin or Skin Structure Infection

2000 843-032 Viropharma Inc.
Viral/Cold Study
A Double-Blind, Randomized, Placebo-Controlled Trial Of A Tablet Formulation of Pleconaril in the Treatment of Viral Respiratory Infection

2000 HMP-3005 Purdue
OA – Pain
A Double-Blind, Randomized, Parallel-Arm, Placebo-Controlled Trial to Evaluate the Efficacy and Safety of Hydromorphone Hydrochloride Extended Release 12mg Capsules Compared to Placebo in Patients with Osteoarthritis who have Moderate to Severe Pain

2000 CV138-056 Bristol-Myers Squibb
Diabetes – Medication
A Multi-Center, Randomized, Double-Blind, Parallel-Group Trial Comparing the Safety and Efficacy of Metformin/Glyburide to Pioglitazone as First Line Therapy in Patients with Type 2 Diabetes Mellitus who have Inadequate Glycemic Control with Diet and Exercise

2000	WV16193	Roche Global Development
	Flu – Post Exposure Prevention A Randomized, Controlled Study of Tamiflu Used for the Prevention of Clinical Influenza Post Exposure in Families	
2000	KD98-0601	Purdue
	Diabetes – Type II A Randomized, Double-Blind, Exploratory, Comparison of Titrated Doses of V20001 and Glyburide in Type 2 Diabetic Patients	

PROFESSIONAL AFFILIATIONS AND SOCIETIES:

2001 – 2002	Scientific Advisory Group for Organon, Inc. for The New Treatment Option for the Mature Depressed Patient
2000 – 2001	Advisory Board for Eli Lilly on Tomoxetine for ADD and ADHD Pediatrics, Adolescence, and Adults
1999 – Present	Forest Laboratories Advisory Board for Geriatric Study
1999 – Present	Member, Lilly Advisory Board on ADHD
1997 – 1998	California Board for Devereux California
1994 – 1997	Fellow, American Academy of Disability Evaluative Physicians
1993 – 1998	Qualified Medical Evaluator by Department of Industrial Relations Industrial Medical Council
1991 – 1997	Appointed Instructor of Department of Psychiatry, University of Pennsylvania
1991	Appointed Member of San Diego Advisory Committee for State Insurance Commissioner, John Garamendi
1989 – 1997	Alvarado Hospital Medical Center, San Diego, California Supervisor of Surgery Committee
1987 – 1996	College of Osteopathic Medicine Faculty Council Member
1986 – 1987	Alvarado Hospital Medical Center, San Diego, California Family Practice Supervisory Committee Supervisor of Orthopedic Committee
1986 – 1987	Alvarado Hospital Medical Center, San Diego, California Family Practice Supervisory Committee Supervisor of Orthopedic Committee
1986 – 1987	The Prudential Insurance Company, La Jolla, California Assistant Medical Director
1986 – 1987	Alvarado Medical Center Utilization Review Committee
1986 – 1987	Alvarado Medical Center, Family Practice Sub-Supervisory Committee (1987-1988)

1986 – 1987	Alvarado Medical Center Orthopedics Committee (also appointed 1987-88)
1985 – 1987	Associate Medical Director Pru-Care Plus, San Diego
1984 – 1995	Philadelphia College of Osteopathic Medicine Faculty Council Member
1984 – 1995	Pacific College of Osteopathic Medicine Faculty Council Member
1984	American Osteopathic Association of Osteopathic Physicians and Surgeons of California
1983	American Heart Association
1983	New Jersey Association of Osteopathic Physicians and Surgeons
1982	Osteopathic Physicians and Surgeons of New Jersey
1979	American College of General Practitioners in Osteopathic Medicine and Surgery
1979	Philadelphia College of Osteopathic Medicine, Alumni Association
1979	Lambda Omicron Gamma National Osteopathic Medical Fraternity
1979	Pennsylvania Osteopathic Association

CURRICULUM VITAE

MICHAEL T. LEVY, M.D.

7/12/03

EDUCATION

Queens College, B.A., Magna Cum Laude, 1965

Washington University, St. Louis, M.D., 1969

Fellow: The Hampstead Clinic, London, with Anna Freud, 1969

Albert Einstein College of Medicine, Medical Internship, 1969-1970

Albert Einstein College of Medicine, Resident in Psychiatry, 1970-1972

Albert Einstein College of Medicine, Chief Resident, 1972-1973

New York Psychoanalytic Institute, 1973-1983. Graduate Psychoanalyst, 1983.

HONORS

Phi Beta Kappa, 1965

Alpha Omega Alpha, 1969

SPECIALTY CERTIFICATE

American Board of Psychiatry & Neurology, Diplomate in Psychiatry, 1976

American Board of Psychiatry & Neurology, Added Qualifications in Geriatric Psychiatry, 1992-2002

New York State License #: 106805-1

PROFESSIONAL POSITIONS

Albert Einstein College of Medicine
Assistant Director Outpatient Clinic - Clinical Instructor, 1973-74

Mt. Sinai
Clinical Instructor, 1974-1976

Gracie Square Hospital
Director, Inpatient Unit, 1975-1978

Coordinated care on inpatient psychiatric unit, developing an extensive network of community outreach consultation services. Linked hospital services to Protective Services for Adults, Jewish Association for Services tot he Aged, New York City Department for the Aging, et. al.

Geriatric Consultation Center, 1973 to date

Created the first private comprehensive psychiatric group practice in New York dedicated to the assessment and treatment of geriatric patients with psychiatric illness. Developed an extensive network of consultation services to community-based agencies throughout the five boroughs providing home visits, education, outpatient assessment and treatment, inpatient care. Trained social workers and mental health aides in the essentials of psychiatric assessment and care through regular lecture series and individual supervision.

PROFESSIONAL POSITIONS (continued)

Private Practice, 1973 to date
General Psychiatry, Psychoanalysis, Psychopharmacology and Geriatric Psychiatry

Long Island College Hospital
Director, Inpatient Psychiatry & Coordinator of Geriatric Psychiatry, 1985-1989
Developed the Geriatric Psychiatry service consisting of an inpatient unit, consultation and liaison, community and nursing home consultation, teaching, and research. Created a unique system of psychiatric consultation in the patient's home working with teams of social workers from the community throughout New York City.

Eger Health Care Center, Staten Island, New York
Director of Psychiatry , 1989 to date

Staten Island University Hospital 450 Seaview Avenue Staten Island, NY 10305
Director of Gerontology & Associate Director, Department of Psychiatry, 1989-1996
Developed and coordinated a fully comprehensive geriatric psychiatry service including a 35 bed inpatient unit, outpatient services, memory disorder clinic, nursing home consultation, community consultation, teaching and research.

Staten Island University Hospital
Chairman, Department of Behavioral Sciences, 1997 to date
450 Seaview Avenue Staten Island, New York 10305

Director, Behavioral Medical Research of Staten Island, PC
1361 Hylan Blvd Staten Island, New York 10305

CONSULTANT IN GERIATRIC PSYCHIATRY TO:

Jewish Association for Services to the Aged, 1980 to date

New York City Department for the aging, 1984 to date

Thomas Jefferson Home for Adults, 1984 to date	650 East 104th St	Brooklyn, NY 11236
Verrazano Nursing Home, 1990 to date	100 Castleton Ave	Staten Island, NY 10310
New Broadview Manor Home for Adults, 1990 to date	70 Father Capadanno Blvd	SI, NY 10305
Lakeside Manor Home for Adults, 1995 to date	797 Brighton Ave	Staten Island, NY 10301
Hylan Manor Home for Adults , 2000 to date	3565 Hylan Blvd	Staten Island, NY 10308
Mermaid Manor Home for Adults	3602 Mermaid Ave	Brooklyn, NY 11224
Golden Gate Health Care Center	191 Bradley Ave.	Staten Island, NY 10314
Staten Island Care	200 Lafayette Ave.	Staten Island, NY 10301

HOSPITAL APPOINTMENTS

Staten Island University Hospital, 1989 to date

777 Seaview Avenue
Staten Island, NY 10305

375 Seguine Avenue
Staten Island, NY 10309

450 Seaview Avenue
Staten Island, NY 10305

392 Seguine Avenue
Staten Island, NY 10309

LECTURE SERIES

- How to be Home bound Without Being Shut In: Improving the Quality of Life for Frail Elders: Lecturer, March 1981.
- Growth in the 80's Enhancing Mental Health in Old Age: Panelist, October 1981.
- The Physiology of the Aging Process. New York State Office of Mental Health, March 1982.

LECTURE SERIES (continued)

- Organic Brain Syndrome, Brooklyn Community Senior Service Network, June 1984.
- Medical/Legal Issues in Aging, Mayor's Conference on Alzheimer's Disease, November 1984.
- Geriatric Medicine. Lutheran Medical Center, November 1985.
- Coping with An Aging Relative. Mental Illness in Later Years: Myths, Realities and Warning Signs, February, 1988.
- The Family Physician and Medication. Alzheimer's Association of Staten Island, March 1990.
- Mothering Mom & Dad. A special Seminar for the "Sandwich Generation". April 1990.
- Update on New Regulations Impacting on Physician Services in Long Term Care Facilities. The Southern New York Residential Health Care Facilities Association. June 1990.
- Come of Age: Coping with Change. Staten Island University Hospital. April 1991.
- Elder Abuse: Working with the Victim and the Abuser. Catholic Charities. April 1991.
- Mayor's Conference on Alzheimer's Disease, Panel Moderator. Sexuality and Aging, 1993.
- Medicine in China: East Meets West in Clinical Practice. Staten Island University Hospital, South, 1993.
- Review of SSRIs: Psychopharmacology, Efficacy, and Side Effect Profile. Staten Island University Hospital, South. Grand Rounds, 1994.
- Olanzapine (Zyprexa): Atypical Antipsychotics; New Directions in Psychopharmacology. Staten Island University Hospital, South. Grand Rounds, 1995.
- Sleep Problems in the Elderly. Staten Island University Hospital, South. Grand Rounds, 1996.
- New Treatments in Schizophrenia: A Review of Atypical Antipsychotics. Staten Island University Hospital, South, 1997.

RESEARCH

- Clinical Investigator: Olanzapine vs. Placebo in the Treatment of Patients with Psychosis Associated with Depression, Eli Lilly, 1994.

- Clinical Investigator: Olanzapine vs. Risperdal in the Treatment of Schizophrenia and Other Psychiatric Disorders, Eli Lilly, 1995.

- Clinical Investigator: Fluoxtine vs. Sertraline vs. Paroxetine in Major Depression, Eli Lilly, 1996 - 1997.

- Clinical Investigator: Seroquel (Quetiapine Fumarate): Comparison with Haldol and Placebo in Nursing Home Patients, Eli Lilly, 1997 - 1998.

- Clinical Investigator: Olanzapine vs. Risperidone and Placebo in the Treatment of Psychosis and Associated Behavioral Disturbances in Patients with Dementia, Eli Lilly, 1999.

- Clinical Investigator: A Double Blind Comparison of the Efficacy and Safety of Short Acting Intramuscular Olanzapine, Lorazepam, and Placebo in Treating Agitation in Patients with Dementia of the Alzheimer's Type, Vascular Dementia and Mixed Dementia, Eli Lilly, 1999.

- Clinical Investigator: Safety and Efficacy of Olanzapine on Cognitive Symptoms in Subjects with Mild to Moderate Alzheimer's Disease without Psychosis, Eli Lilly, 1999.

- Clinical Investigator: A Double Blind Multi - Center Study Comparing the Safety and Efficacy of Ziprasidone to Olanzapine in Patients with Schizophrenia or Schizoaffective Disorder Needing In - Patient Care, Pfizer. Inc., 1999.

- Clinical Investigator: Olanzapine Plus Fluoxetine Combination Therapy in Treatment-Resistant Depression: A Dose Ranging Study, Eli Lilly, 2000.

- Clinical Investigator: Reboxetine, Placebo and Paroxetine Comparison in Patients with Major Depressive Disorder, Pharmacia & Upjohn, 2000.

- Clinical Investigator: A Randomized, Double-Blind, Placebo-Controlled Trial to Evaluate the Safety and Efficacy of Divalproex Sodium Therapy for Agitation in Nursing Home Residents with Dementia, Alzheimer's Disease Cooperative Study, 2000.

- Clinical Investigator: A Multicenter Randomized Double-Blind Study of Flexible Doses of Aripiprazole Versus Perphenazine in the Treatment of Patients with Treatment-Resistant Schizophrenia, Bristol-Myers Squibb Co., 2000.

- Clinical Investigator: Aripiprazole Study of Psychosis Associated with Dementia of the Alzheimer's Type of Nursing Home Residents, Bristol-Myers Squibb Co., 2000.

- Clinical Investigator: A Controlled Trial of the Efficacy of Rapid Initial Dose Escalation of Olanzapine to Treat Acute Behavioral Agitation in Schizophrenia and Bipolar 1 Disorder, Eli Lilly, 2000.

- Clinical Investigator: A Comparative Effectiveness of Antipsychotic Medications in Patients with Schizophrenia,CATIE,2001

- Clinical Investigator: A Comparative Effectiveness of Antipsychotic Medications in Patients with Alzheimer's Disease, CATIE, 2001

- Clinical Investigator: A Randomized, Double-Blind, Placebo-controlled and Open-Label twelve-month study of the safety of (S)-Zopliclone in Adult Subjects with Insomnia, Sepracor, 2001

- Clinical Investigator: A Randomized, Double-Blind, Placebo-controlled and Open-Label twelve-month study of (S)-Zopliclone in Geriatric Subjects with Insomnia, Sepracor, 2001.

RESEARCH (continued)

- A Multicenter, Double-Blind, Randomized, Placebo Controlled, Crossover Study to Evaluate the Efficacy of a Monophasic Oral Contraceptive Preparation, Containing Drospirenone 3 mg/Ethinyl Estradiol 20 g (as Beta-Cyclodextrin Clathrate), in the treatment of Premenstrual Dysphoric Disorder (PMDD), Berlex Laboratories, 2002.

- A Multicenter, Randomized, Double-Blind, Study of Aripiprazole Versus Placebo in the Treatment Acutely Manic Patients with Bipolar Disorder. Bristol Myers Squibb, 2002.

- Randomized, Double-Blind, Dose-Ranging Study of Intramuscular Aripiprazole in the Treatment of Acute Agitation in Patients with a Diagnosis of Schizophrenia, Schizoaffective, or Schizophreniform Disorder. Bristol Myers Squibb, 2002.

- Switching from Oral Neuroleptics to Risperidone Depot Microspheres, Janssen Pharmaceuticals, 2002.

- A Double-Blind, Placebo-Controlled Multicenter Study of the Long-Term Efficacy of MK-0869 in the Maintenance of Antidepressant Effect in Geriatric Outpatients with Major Depressive Disorder. Merck Laboratories, 2002.

- Clinical Investigator: A Phase III, Randomized, Double-Blind, Placebo-Controlled, Outpatient Study to Assess the Long-Term Safety and Efficacy of Two Dose Levels of NBI-34060 in Adult Patients with Primary Insomnia, Neurocrine Biosciences, Inc., 2002.

- Clinical Investigator: A Double-Blind, Placebo-Controlled, Multicenter Study of the Long-Term Efficacy of MK-0869 in the Maintenance of Antidepressant Effect in Patients with Major Depressive Disorder, Merck Laboratories, 2002.

- Clinical Investigator: Forced Dose Titration, Double-Blind Treatment with Duloxetine Hydrochloride Once Daily Dosing for Evaluation of Safety in Major Depression, Lilly, 2002.

- Clinical Investigator: The Effect of Ortho Tri-Cyclen on Bone Mineral Density in Pediatric Subjects with Anorexia Nervosa: A Double-Blind, Placebo-Controlled Study, Ortho-McNeil Pharmaceutical, Inc., 2002.

BIRMINGHAM PSYCHIATRY PHARMACEUTICAL STUDIES, INC.

Curriculum Vitae
January 10, 2003

Name: H. Edward Logue, M.D.

Position Title: Principal Investigator
Medical Director

Address: Birmingham Psychiatry Pharmaceutical Studies, Inc.
One Independence Plaza, Suite 900
Birmingham, Alabama 35209

Telephone Number: 205-868-4286
Fax Number: 205-868-4293

Education: Medicine AL ML#: 5861

Education:

Institution and Location	Degree	Year Conferred	Field of Study
Medical College of Georgia, Augusta Ga.	*M.D.*	*1963*	*Medicine*
Emory University, Atlanta, Ga.	*B.S.*	*1958*	*Pre-Med*
Emory University, Oxford Georgia	*A.D.*	*1955*	*Science*

Research and Professional Experience:

Position	Institution/Employer and Location	Dates of Employment
Psychiatrist/President/Founder	*Private Practice, Birmingham Psychiatry P.A., Birmingham, Alabama*	*1972 - Present*
Medical Director, Adult Psychiatric Services	*Brookwood Medical Center* *Birmingham, Alabama*	*October 1987-Present*
Founder, Medical Director *Chairman of Board*	*American Behavioral Benefits Managers, Inc.*	*1989 - Present*
Medical Director	*Birmingham Psychiatry Pharmaceutical Studies*, Inc.	*1991 - Present*

President Alabama Psychiatric Society	*State of Alabama*	*1990 - 1991*
Exemplary Psychiatrist Award	*National Alliance for the Mentally Ill* *Birmingham Alliance for the Mentally Ill*	*1998*

Professional Memberships:

(1) American Psychiatric Association

(2) American Medical Association

(3) Alabama Psychiatric Society-District Branch of American Psychiatry Association

(4) Jefferson County Medical Society

(5) Medical Association of State of Alabama

(6) Central Alabama Psychiatric Society

Publications:

Papers presented to Medical Association of Alabama:

1. "Ethics Meets Thanatos" January 1998
2. "Atypical Antipsychotics: What is Here and What is Coming" January 1998

Alabama Medical License Number: 5861

Revised 1-10-2003

Research Experience:

1. Principal Investigator
   "Insomnia treatment study"
   Outpatient study
   The Upjohn Company
   1992

2. Principal Investigator
   "Fluvoxamine vs Placebo in the treatment of Panic Disorder."
   Enrolled: 20 patients (6 months)
   Outpatient study
   The Upjohn Company
   1992-1993

3. Principal Investigator
   "Fluvoxamine vs Placebo in the treatment of Panic Disorder: A long term maintenance, Double Blind study comparing efficacy and safety."
   Enrolled: 20 patients (6 months)
   Outpatient study
   The Upjohn Company
   1993-1994

4. Principal Investigator
   "A Randomized, comparative open-labeled study of Paroxetine in the Treatment of Depression as used in a Clinical Practice Setting."
   Smith-Kline Beecham
   Outpatient study
   Enrolled: 20 patients (3 months)
   1993-1994

5. Principal Investigator
   "Olanzapine versus Haloperidol in the Treatment of Schizophrenia and Other Psychotic Disorders."
   FID-MC-HGAJ
   Enrolled: 44 patients (12 months)
   Inpatient/Outpatient study
   Eli Lilly
   1994-1995

6. Principal Investigator
   "Imitrex Injections in the Treatment of Migraine Headaches."
   Enrolled: 40 patients (2 months)
   Outpatient study
   Glaxo\Pact
   1994

7. Principal Investigator
   "Epidemiologic Survey of Prostep."
   Smoking cessation study
   Enrolled: 20 patients 1993-1994

8. Principal Investigator
" A Double-Blind, Placebo-controlled, dose response comparison of the safety and efficacy of three doses of Sertindole and three doses of Haldol in Schizophrenic Patients."
M93-113
Inpatient Study
Abbott Laboratories
Enrolled: 34 Patients (6 months)
1994-1995

9. Principal Investigator
"An Open-label Assessment of the long-term safety of Sertindole in the treatment of Schizophrenic Patients"
M92-795
Outpatient study
Enrolled: 17 (Continuation Study from M93-113)
Abbott Laboratories
1995

10. Principal Investigator
"An Open-label Assessment of the Safety of Sertindole".
(M94-222)
Enrolled: 15 patients (Continuation Study from M93-113)
Outpatient study
Abbott Laboratories
1995

11. Principal Investigator
"A Phase II comparative study using a single dose of Acetaminophen, Acetaminophen/Cyproheptadine, Cyproheptadine Alone and Placebo in the Treatment of Migraine Headache"
Enrolled: 39 Patients (6 months)
McNeil Laboratories
1994 - 1995

12. Principal Investigator
"A prospective, Multi-center, Open-label study of Serzone (nefazodone) in the Managementof Patients with Symptoms of Depression in Depression in General Psychiatric Practices"
(CN 104-127)
Depression study
Enrolled: 14 patients (3 months)
Bristol-Myers Squibb\ICRC

13. Principal Investigator
"Olanzapine versus Risperidone in the Treatment of Schizophrenia and other Psychotic Disorders"
F1D-MC-HGBG
Enrolled: 49 patients (4 months)
Outpatient study
Eli Lilly 1995

14. Sub Investigator
"A Multi Center, Placebo-Controlled Study of Relapse Prevention By Long-Term Treatment with High or Low Doses of ORG-4428 in Outpatients with Recurrent Major Depressive Episode"
Outpatient study
Organon\Pharmaco Enrolled: 35 patients
1995

15. Principal Investigator
"Open-Label Experience with Olanzapine in Patients Who Have Completed a Previous Olanzapine Clinical Trial" protocol.
Compassionate Use Study
FID-MC-HGDI
Outpatient study
Eli Lilly 1996
Enrolled: 13 patients from previous Olanzapine studies

16. Sub Investigator
"A Randomized Double-Blind, Placebo-Controlled parallel group multicenter, single dose, dose range-finding study to assess the efficacy and tolerability of VML 251 in the acute treatment of migraine."
Outpatient study
April 1996 to June 1996
Vanguard Medica Limited

17. Principal Investigator
"Mazapertine dose finding trial, comparing three fixed dosages of Mazapertine to Risperidone and placebo: multicenter, double-blind parallel group study".
MAZ-INT-01
Janssen Pharmaceutical Research Foundation
March 1996 to July 2, 1996
Inpatient Study Phase II Clinical Trial
Screened: 23 patients Randomized: 20 patients
Janssen Pharmaceutical Research

18. Principal Investigator
"A Comparison of Risperidone and Haloperidol for Prevention of Relapse in subjects with schizophrenia and schizoaffective disorders."
RIS-USA-79 Outpatient Study
Enrolled: 27 patients Janssen Pharmaceutical Research

19. Sub Investigator
"An Open Label, Multicenter Trial Evaluating the Safety and Efficacy of Donepezil Hydrochloride in Patients with Alzheimer's Disease." (E2020)
Outpatient
Pfizer Pharmaceutica

20. Principal Investigator
"A Multicenter Double-Blind, Randomized Comparison of Zolmitriptan and Sumatriptan in The Acute Treatment and of Multiple Migraine Headaches."
Outpatient Zeneca Pharmaceuticals

21. Principal Investigator
"A Multicenter, Double-Blind, Randomized, Placebo Controlled, Parallel Group Study of the Efficacy and Safety of Escalating the Dose of Oral Eletriptan in Subjects with Acute Migraine."
Outpatient
Pfizer

22. Principal Investigator
"A 12-Month Study of VML 251 In the Acute Treatment of Migraine"
Outpatient
Vanguard Medica Ltd.

23. Principal Investigator
"The Safety and Efficacy of Risperdal (Risperidone) vs Placebo vs Haloperidol as Add – On Therapy to Mood Stabilizers in the Treatment of the Manic Phase of Bipolar Disorder"
Inpatient/Outpatient study
Add –On site Enrolled 7 patients

24. Principal Investigator
"A Multi-Center, Randomized, Double-Blind, placebo and active controlled study of MDL 100,907 in Schizophrenic and Schizoaffective Patients."
MDL 100.907 PR0015
Inpatient Study Enrolled 27 Patients Hoechst Marion Roussel, Inc.

25. Principal Investigator
"A Multi-Center, Open-Label, Long-Term Follow-Up, Safety Study of MDL 100,907 In Schizophrenic and Schizoaffective Patients Who Participated in Protocol 100907 PR0015."
MDL 100,907 PR 0018 Inpatient/Outpatient
Hoechst Marion Roussel, Inc.

26. Principal Investigator
"A Phase III, Randomized, Multicenter, Open Label Study Evaluating the Toleration and Safety of 3 Days of Treatment with Intramuscular Ziprasidone (20 to 80 mg. Daily) or Haloperidol (up to 40 mg Daily) Followed by 4 Days of Treatment with Oral Ziprasidone (40 to 200 mg Daily) or Haloperidol in Subjects with a Diagnosis of Psychotic Disorder." (128-121) Inpatient Study
Enrolled 27 Patients Pfizer

27. Principal Investigator
"Risperidone vs Olanzapine in the Treatment of Schizophrenia".
RIS-USA-112 Outpatient Study Janssen Research Foundation

28. Principal Investigator
"Risperidone vs Olanzapine in the Treatment of Schizophrenia".
RIS-USA-113 Outpatient Study Janssen Research Foundation

29. Principal Investigator
"Risperidone vs Olanzapine in the Treatment of Schizophrenia in Elderly Subjects".
RIS-INT-50 Outpatient Study Janssen Research Foundation

30. Principal Investigator
"Fluoxetine Augmentation in Schizophrenic or Schizoaffective Patients with Depressive or Nonresponders to Olanzapine".
FID-MC-HGFT Outpatient Study Eli Lilly

31. Principal Investigator
"Strategies for Switching from Conventional Antipsychotic Drugs to Olanzapine".
FID-MC-HGFW Outpatient Study Eli Lilly

32. Principal Investigator
"Olanzapine Added to Mood Stabilizers in the Treatment of Bipolar Disorder".
FID-MC-HGFU Outpatient Study Eli Lilly

33. Sub-Investigator
"Metrifonate Investigational Nationwide Trial".
(M.I.N.T.) D97-019
Alzheimer' Disease Outpatient Study Bayer Corporation

34. Principal Investigator
"A Phase III, Randomized, Placebo-Controlled Study Evaluating the Safety and Outcome of Treatment with Oral Ziprasidone in subjects with Mania".
128-601 Mania study Inpatient Study Pfizer

35. Principal Investigator
"An Open Extension Study Evaluating the Safety and Outcome of 40-160 mg daily of Ziprasidone in Previous Ziprasidone Clinical Trials".
128-601 Inpatient/Outpatient Study Pfizer

36. Principal investigator
"A Double – Blind, Randomised, Multicenter, Parallel Design Study to Evaluate the Efficacy and Safety of Individual Maximum Tolerated Doses of EMD 68 843 in Comparison with Placebo and Fluoxetine in Outpatients with Major Depressive Disorder"
Merck EMD Outpatient study Merck KGaA

37. Principal investigator
"Phase II, Six-Week, Double-Blind, Placebo and Olanzapine-Controlled Study Evaluating the Safety and Efficacy of Oral CP-361,428 in Schizophrenia and Schizoaffective Disorder"
Schizophrenia study
Pfizer 245-102 Inpatient study Pfizer

38. Principal Investigator
"A double-blind, randomized, multicenter, parallel group design study to evaluate the efficacy and safety of two dosse ranges of EMD 128 130 in comparison with placebo and haloperidol in the treatment of schizophrenia"
EMD 128-130-08
Schizophrenia study Inpatient/Outpatient Study
Merck KgaA Pharmaceutical Co.

39. Principal Investigator
"A prospective, randomized, double-blind, placebo- and active-controlled, multicenter study to evaluate the efficacy and safety of three fixed doses of iloperidone (4, 8, and 12 mg/d) given b.i.d. for 42 days to schizophrenic patients with acute or subacute exacerbation, followed by a double-blind, active-controlled, flexible-dose, long-term, 6-month phase with iloperidone (4, 8, 12, or 16 mg/d) given q.d." ILP 3000
Schizophrenia Inpatient and Outpatient Study Novartis

40. Principal Investigator
Novartis Protocol No.: ABA 451
"A Prospective, Randomized, International Parallel-Group Comparison of Clozaril/Leponex vs. Zyprexa in the Reduction of Suicidality in Patients with Schizophrenia or Schizoaffective Disorder Who are at Risk for Suicide"
Novartis ABA 451
Schizophrenia Outpatient Study Novartis

41. Principal Investigator
"The Assessment of Nizatidine for the Prevention of Olanzapine-Associated Weight Gain in Patients with Schizophrenia"
HGIJ Outpatient Study Eli Lilly

42. Principal Investigator
Protocol: F1D-MC-HGHL
"Olanzapine Versus Placebo in the Prevention of Relapse in Bipolar Disorder
HGHL Outpatient Study Eli Lilly

43. Principal Investigator
"Prevalence of Hyperprolactemia in Schizophrenic Patients Treatees with Antipsychotic Drugs"
Prolactin study HGHC Outpatient study Eli Lilly

44. Principal Investigator
"Allelic Variation in Schizophrenia"
HGGL Outpatient study Eli Lilly

45. Principal Investigator
Protocol: F1D-MC-HGHZ
"The Combination of Olanzapine and Fluoxetine in Treatment Resistant Depression without Psychotic Features"
HGHZ Outpatient study Eli Lilly

46. Principal Investigator
Randomized, double-blind, placebo-controlled multicenter trial to demonstrate the clinical efficacy and safety of two different doses of Ginkgo biloba special extract Egb 761 in patients suffering from Dementia of the Alzheimer's Type according to DSM-IV and NINCDS/ADRA criteria.
Protocol 523001-01-030
Alzheimer's Study Outpatient study Schwabe

47. Principal Investigator
"A Double-Blind, Placebo-Controlled Dose-Finding Study Evaluating the Safety and Efficacy of MKC-242 1.5, 6, and 24 mg/day (0.5. 2, and 8 mg tid) in the Treatment of Major Depressive Disorder."
MKC/A01 Depression study
Outpatient study Mitsubishi

48. Principal Investigator
"Safety and Efficacy of MKC-242 in the treatment of major depressive disorder: A 4 month double-blind extension to study MKC242-A01."
MKC/A02 Depression study
Outpatient study Mitsubishi

49. Principal Investigator
"Safety of open-label standard therapy in the treatment of major depressive disorder: A 1 month follow-up after termination of study MKC-242/A01."
MKC/A03 Depression study
Outpatient study Mitsubishi

50. Principal Investigator
"A Double-Blind, Placebo and Haloperidol-Controlled, Multicenter Study Evaluating the Safety and Efficacy of SR48692 in Schizophrenic Patients"
Schizophrenia study Inpatient study Sanofi

51. Principal Investigator
"A Double-Blind, Placebo and Haloperidol-Controlled, Multicenter Study Evaluating
the Safety and Efficacy of SR141716 in Schizophrenic Patients"
Sanofi 3077 Schizophrenia study Inpatient study

52. Principal Investigator
Abbott M99-010
"Safety and Efficacy of Depakote as Combination Therapy in the Treatment of Psychosis Associated with Schizophrenia"
Inpatient study Abbott Laboratories

53. Principal Investigator
Protocol No. CN138-070 and CN 138-010
"A Multicenter, Randomized, Double-Blind, Placebo Controlled Study of Aripiprazole in the Maintenance Treatment of Patients with Bipolar Disorder."
Bristol-Myers Squibb Pharmaceutical Research Institute
Inpatient/Outpatient study

54. Principal Investigator
Protocol No. F1D-MC-HGIJ
"The Assessment of Nizatidine for the Prevention of Olanzapine-Associated Weight Gain in Patients with Schizophrenia"
Outpatient study Sponsor: Eli Lilly

55. Principal Investigator
Protocol No. F1J-MC-HMAT
"Duloxetine Versus Placebo and Paroxetine in the Acute Treatment of Major Depression" Sponsor: Eli Lilly

56. Principal Investigator
Protocol No. F1D-US-HGJB
"A Controlled Trial of Olanzapine Versus Quetiapine in the Treatment of Schizophrenic and Schizoaffective Subjects with Prominent Negative Symptoms"
Outpatient study Sponsor: Eli Lilly

57. Principal Investigator
Protocol No. F1J-MC-HMBH
"Duloxetine Once-Daily Dosing Versus Placebo in the Acute Treatment of Major Depression"
Outpatient Study Sponsor: Eli Lilly

58. Principal Investigator
Protocol No. TAK 637-00-302
"A Phase II Randomized, Multicenter, Placebo- and Active Controlled Study of Oral TAK-637 in Subjects with Major Depressive Disorder"
Outpatient study Sponsor: TAP Pharmaceutical Products, Inc.

59. Principal Investigator
Protocol No. F1D-MC-HGGY
"Placebo – Controlled Olanzapine Monotherapy in the Treatment of Bipolar I Depression"
Outpatient study Sponsor: Eli Lilly

60. Principal Investigator
Protocol No. F1D-MC-HGJN
"The Assessment of Amantadine for the Treatment of Olanzapine – Associated weight Gain in Patients with schizophrenia, Schizophreniform, Schizoaffective and Bipolar I Disorder"
Outpatient Study Sponsor: Eli Lilly

61. Principal Investigator
Protocol No. ILP 3005
"A randomized, Double-Blind, placebo-and risperidone controlled multicenter study to evaluate the efficacy and safety of two nonoverlapping dose ranges of iloperidone given B.I.D. for 42 days to schizophrenic patients followed by a long-term treatment phase with iloperidone given Qd."
Inpatient and outpatient study
Sponsor: Novartis (Inpatient/Outpatient study)

62. Principal Investigator
Protocol No. D105006
"A Double-Blind, Randomized, Fixed Dose, Placebo-Controlled, Placebo-Controlled, Parallel-Group, 6-Week, Efficacy, Safety, and Tolerability Study of Two Dose Levels of SM-13496 in Patients with Schizophrenia by DSM-IV Criteria Who are Experiencing an Acute Exacerbation of Symptoms"
Sponsor: Sumitomo Inpatient/Outpatient study

63. Principal Investigator
Protocol No. 5077US/0043
"A Multicenter, Double-blind, Randomized Comparison of the Efficacy and Safety of Quetiapine Fumarate (SEROQUEL) and Risperidone (RISPERDAL) in the Treatment of Patients with Schizophrenia"
Sponsor: AstraZeneca Inpatient/Outpatient study

64. Principal Investigator
B99.CT3.005.BUS P02
"A Double-Blind, Randomized, Placebo-Controlled, Parallel-Group, Fixed-Dose Study of the Efficacy, Safety, and Tolerability of 60 mg Buspirone Hydrochloride Extended Release Compared to Placebo in Patients with Generalized Anxiety Disorder"
Sponsor: Biovail Outpatient study

65. Principal Investigator
"An Open-Label Study of the Safety, and Tolerability, and Efficacy of Up to 90mg Buspirone Hydrochloride Extended Release in Patients with Generalized Anxiety Disorder"
B99.CT#3.008.BUS P02
Sponsor: Biovail Outpatient study

66. Principal Investigator
Protocol # Biovail B01. 016. BUS PO2
"A Randomized, Double-blind, Placebo-Controlled, Parallel-Group, Fixed-Dose Study of the Efficacy, Safety, and Tolerability of 60 mg Buspirone Hydrochloride Extended Release Compared to Placebo in Patients with Generalized Anxiety Disorder Who Have Stable Disease Characteristics"
Sponsor: Biovail Outpatient study

67. Principal Investigator
Protocol:
"An Acute and Continuation Phase Study of the Comparative Efficacy of Venlafaxine ER (Effexor XR) and Fluoxetine (Prozac) in Achieving and Sustaining Remission (Wellness) in Patients With Recurrent Unipolar Major Depression; Followed by a Long-term Randomized, Placebo-Controlled Maintenance Treatment Study in Patients Treated Initially with Venlafaxine ER"
Sponsor: Wyeth-Ayerst Pharmaceuticals Outpatient Study

68. Principal Investigator
Protocol: "An International, Multicenter, Large Simple Trial (LST) To Compare the Cardiovascular Safety of Ziprasidone and Olanzapine"
Sponsor Pfizer, Inc. Outpatient study

69. Principal Investigator
Protocol: "A 6-Week, Double-Blind, Randomized, Fixed-Dose, Parallel-Group Study of the Efficacy and Safety of Three Dose Levels of SM-13496 Compared to Placebo and Haloperidol in Patients with Schizophrenia Who are Experiencing an Acute Exacerbation of Symptoms "
Sponsor Sumitomo Pharmaceuticals America, Ltd.
Inpatient/Outpatient study

70. Principal Investigator
Protocol:
"A Phase III, Randomised, Placebo-Controlled, Double-Dummy Study Evaluating the Safety and Efficacy of Oral Ziprasidone vs. Haloperidol and Placebo in In-Patients with an Acute Manic Episode"
Sponsor Pfizer Inc. Inpatient/Outpatient study

71. Principal Investigator
Protocol:
"A Phase III, Three-Week, Multicenter, Randomized, Double-Blind, Placebo-Controlled, Parallel-Group Safety and Efficacy Study of Extended-Release Carbamazepine in the Treatment of Bipolar Disorder"
Sponsor Shire Pharmaceutical Development Inc.
Inpatient/Outpatient study

72. Principal Investigator
Protocol: "A Pilot Study of the Effect of Hormone Replacement Therapy In Recently Postmenopausal Women with Subjective Complaints"
Sponsor Wyeth Pharmaceuticals Inc. Outpatient study

5077US/0048 : 0042

ALABAMA MEDICAL LICENSURE COMMISSION
P.O. BOX 887
MONTGOMERY, ALABAMA 36101-0887

CERTIFICATE OF REGISTRATION
2003

This is to certify that annual registration has been made and license to practice medicine in the State of Alabama has been granted for the year ending December 31, 2003

License # 00005861 **Amount Paid: $200**
Date Issued: 01/21/1972 **Receipt # 265021**

HARRY EDWARD LOGUE , M.D.
ONE INDEPENDENCE PLAZA
SUITE 900
BIRMINGHAM, AL 35209-5604

Jerry N. Guilley M.D.
CHAIRMAN

Drug Substance	Quetiapine fumarate
Study Code	D1441L00001

Appendix 12.1.6

Listing of subjects receiving the various batches of investigational product(s)

This was a Phase IIIb study in which all active treatments were from production batches of an approved, marketed medication. Therefore, there are no listings of patients receiving different batches of research medication contained in this report. The formulation and lot numbers of the over-encapsulated tablets are given in the following table.

Investigational product or other treatment	**Dosage form and strength**	**Manufacturer**	**Formulation number**	**Lot number**
Quetiapine	tablet, 25 mg	AstraZeneca	F12804	7527F
Quetiapine	tablet, 100 mg	AstraZeneca	F12689	7513H
Quetiapine	tablet, 200 mg	AstraZeneca	F12690	7541F
Placebo	tablet, 25 mg	AstraZeneca	F12636	7553F
Placebo	tablet, 100 mg	AstraZeneca	F12637	7550F
Placebo	tablet, 200 mg	AstraZeneca	F12638	1509C

YMRS	Young Mania Rating Scale

1. STUDY DETAILS

1.1 Study Objectives

The primary objectives of the study are to evaluate the efficacy of quetiapine compared to placebo in the treatment of a major depressive episode in patients with bipolar disorder after receiving treatment for up to 8 weeks by comparing

1. The change from baseline to final assessment in the Montgomery-Asberg Depression Rating Scale (MADRS) total score

2. The percentage of patients with a ≥ 50% reduction from baseline in the MADRS total score at final assessment

3. The change from baseline to each assessment in MADRS total score

4. The change from baseline to each assessment in the total Hamilton Rating Scale for Depression (HAM-D), HAM-D Item 1, and the Clinical Global Impression – Severity (-S), and the Clinical Global Impression – Improvement (-I)

The secondary objectives of the study are:

1. To evaluate the incidence of treatment-emergent mania compared to placebo by comparing the percentage of patients who meet the criteria for treatment emergent mania on the Young Mania Rating scale (YMRS) or report an adverse event of mania

2. To evaluate the effect of quetiapine on anxiety compared to placebo by

    - The change from baseline to final assessment in the Hamilton Rating scale for Anxiety (HAM-A) total score

    - The change from baseline to each assessment in the HAM-A total score

3. To evaluate the safety and tolerability of quetiapine in the treatment of patients with bipolar depression by

    - The incidence and nature of overall adverse events

    - The incidence and nature of drug related adverse events

    - Patient withdrawal due to adverse events during double-blind treatment

    - The number of patients having clinically significant changes in vital signs from baseline to end of treatment

    - The change in Simpson-Angus Scale (SAS) total score

- The change in Barnes Akathisa Rating Scale (BARS) global assessment
- The incidence of adverse events related to extra pyramidal symptoms during double-blind treatment

Exploratory objectives:

1. To evaluate the efficacy of quetiapine on sleep quality by comparing the change in sleep quality using the Pittsburgh Sleep Quality Index (PSQI) from baseline to end of treatment
2. To evaluate the efficacy of quetiapine on the overall quality of life using the Quality of Life Enjoyment and Satisfaction Questionnaire (Q-Les-Q) from baseline to end of treatment

1.2 Study Design

This is a double-blind, placebo-controlled, randomized multicenter, 8-week trial evaluating Seroquel at 2 fixed doses as monotherapy in bipolar depression. The randomization is stratified by type of bipolar depression (Bipolar I and Bipolar II).

1.3 Number of Patients

Approximately 530 patients will be enrolled in the trial to obtain 504 evaluable patients.

2. ANALYSIS SETS

2.1 Definition of analysis sets

Data analysis will be based on the following 3 patient populations, defined below.

- The safety population will include all enrolled patients classified according to treatment actually received. Randomized patients who did not receive treatment will be excluded.
- The intention-to-treat (ITT) population will include all evaluable patients in the safety population, classified according to the assigned randomized treatment. It will include all enrolled patients who took study medication and who have a baseline MADRS and at least 1 valid post baseline MADRS assessment. This population will be used to assess the primary efficacy.
- The per-protocol (PP) population will exclude the following; patients with 8 days or less of study treatment, patients who do not meet efficacy related entrance criteria, and patients who do not have a baseline MADRS and at least 1 valid post baseline MADRS assessment. Data will also be excluded based on significant deviations from the protocol (Appendix A details patient/data exclusions).

- Analysis data sets will be developed using the appropriate population designations. Key demographic information will be merged into each analysis data set. This will include, trial, center, patient, age, sex, race, diagnosis, kit number, randomization number, flags for populations (safety, ITT, PP), study treatment start and stop dates, reason for treatment stop, and treatment. Screen failure patients, those without a randomization number, will be flagged and included only in selected demography and safety listings.

Each assessment scale will have an analysis data set created which includes baseline total score, total score, change from baseline total score, % change from baseline total score for MADRS only, an indicator variable for 50% reduction for MADRS only, and similar variables for specified items as appropriate.

Laboratory assessments, including clinical laboratory assessments, vital signs and ECGs will have an analysis data set which includes baseline value, value at visit, change from baseline, and an indicator variables for out of normal range and for potentially clinically significant value based on defined extended normal range criteria for the parameter of interest.

2.2 Violations and deviations

Patients who do not violate the inclusion/exclusion criteria, who are entered into the trial and then do not comply with the protocol are called deviators.

Patients who deviate from the protocol during the course of the trial will be included in the analysis in such a way as to minimize any potential bias; or if this is not possible because of the seriousness of the deviation, they may be excluded from the analysis.

Protocol violations and deviations, which lead to exclusion from analysis data sets, are detailed in Appendix A. In general, protocol violations and deviations, which affect the efficacy of the trial medication, lead to exclusion from the PP population, with continued inclusion in the ITT population. The PP efficacy population will contain all patients randomized to the study who satisfied efficacy inclusion criteria and did not violate efficacy exclusion criteria, detailed in Appendix A, and who did not deviate from the protocol in any way thought to affect the efficacy outcomes. The ITT population will include all patients with data that satisfy the definition of the ITT population in Section 2.1.

After all patients have completed the study, but before the patient data blind is broken, the study team will review all protocol violations and deviations which occurred during the trial and make a determination for each patient regarding inclusion in the PP population.

Certain types of deviation will be handled as defined in sections 2.2.1 through 2.2.6.

2.2.1 Misrandomization

If a patient is randomized to the wrong stratum, the patient will be recoded to the correct stratum based on the actual reported diagnosis for analysis.

If the wrong treatment is administered to a patient then the reason for the incorrect treatment will be fully documented and noted in the report. In the ITT and PP populations, patients will be analyzed as assigned in the original randomization scheme. In the safety population, if a patient went through the entire trial with the incorrect treatment, the patient will be analyzed as treated. Otherwise (e.g., incorrect treatment was administered during part of the trial), the patient will be analyzed as assigned, and the incorrect treatment will be noted.

2.2.2 Patients randomized who fail to receive treatment

If a patient is randomized but fails to receive treatment, the reason for not receiving treatment must be established, and noted in the report. Patients randomized but not receiving treatment will be excluded from Safety, ITT and PP populations, but will be included in patient listings, and enrolment summaries.

2.2.3 Visit compliance

Data will be listed and summarized by visit, providing the visits fall within the following time windows:

Visit	Scheduled Day in relation to first day of randomised treatment	Visit window (days) in relation to first day of randomised treatment
1	Screen	< -1
2	1 (baseline)	-1 to 1
3	8	2 – 12
4	15	13 – 19
5	22	20 – 26
6	29	27 – 33
7	36	34 – 40
8	43	41 – 47
9	50	48 – 54
10	57	55 – *

* last assessment day for completers

If an efficacy measure (MADRS) assessment occurs >4 days after the last dose of study medication the observation will be excluded from the PP analysis.

For observed cases (OC), post baseline data, the following rules will be used: If more than one visit occurs during a visit window, the one closest to the scheduled day will be assigned to the visit for all visits except visit 10, for visit 10 the last visit in the window will be assigned to visit 10. If 2 visits are equidistant from the scheduled day, the later will be assigned to the visit.

For last observation carried forward (LOCF), post baseline data, the following rule will be used: For all missing values, the last available non-missing value, with the exception of baseline, will be used regardless of whether that value was kept for the OC visit under the previous rules.

Baseline data will not be carried forward into the randomized treatment period. If the baseline visit data is missing, the screening assessment will be used as baseline, with the exception of the MADRS which will be set to missing.

All data will be presented in the patient listings. Those assessments, which are dropped from the analysis dataset because of falling outside of the formally defined visit windows, will be indicated as such on the listing.

Visit compliance for the QLESQ and PSQI, which are done monthly will use the following visit windows:

Visit	Scheduled Day in relation to first day of randomised treatment	Visit window (days) in relation to first day of randomised treatment
2	Baseline	≤ 1
6	29	8 – 43
10	57	44 – *

* last assessment day for completers

Visit assignments will follow the same rules for multiple assessments within a window, as those for the weekly assessments but the windows will be larger to capture any post baseline assessment of quality of life.

For assessments of safety and tolerability assessed only at baseline and end of study including, BARS, SAS, ECG and Clinical laboratory data. Post baseline data will be assigned as final visit regardless of visit day. If multiple assessments are made, then the value closest to the date of last dose will be set as the final visit for tabulation, all assessments will be listed regardless of assignment to an analysis visit. If equidistant, the later observation is selected.

Note that record review is also required in selecting the valid visit within a window for vital signs and ECGs, the most complete record within the window should be assigned as the valid and/or carried forward as LOCF.

2.2.4 Compliance with study medication

Individual patient compliance will be assessed based on tablets taken and expected number based on the duration of study participation. The patient will then be classified as fully compliant (≥ 80%), partially compliant (≥ 70% and <80%), or non-compliant < 70%. Non-compliant patients will be excluded from the PP analysis. Patients for whom compliance

cannot be calculated will be indicated as compliant in the listings, and will not be excluded from either the PP or ITT population. Section 4.3.9 describes the computation of compliance; Sections 2.2.6 and 4.5 describes the handling of missing data, and Section 6 details how and why this differs from the protocol.

It should be noted that the calculated compliance is based solely on the prescribed daily number of tablets and count of returned tablets. The duration of treatment will be calculated as the difference between date of last dose and the date of first dose plus one. Compliance will be the number of tablets consumed divided by the total number of expected tablets based on the duration of treatment, converted to a percent. Consequently, a patient who is classified as non-compliant clearly has taken less medication than prescribed (based on number of pills physically returned), while a patient who is classified as compliant may have not actually taken the prescribed medication (e.g., removed but not swallowed, discarded, etc.).

2.2.5 Prior and Concomitant therapy

Prior medication exposure will be tabulated. Selected medications (antidepressants, mood stabilizers, psychotropic medications and hypnotics) will be summarized as the number and percent of patients with 0, 1, 2, 3 or more exposures to the class of medications and also the number and percent of patients receiving 0, 1, 2, 3, or 4 classes of medication.

The use of psychoactive drugs other than those specifically allowed during the trial (i.e., lorazepam and zolpidem tartrate) is restricted. During the first 3 weeks, zolpidem tartrate 5-10 mg at bedtime for insomnia, lorazepam 1-3 mg per day for severe anxiety may be prescribed as long as they do not interfere with any assessments.

Use of these medications after week 3 will be considered a protocol deviation.

Use of any psychoactive drugs including antidepressants, hypnotics, mood stabilizing drugs, and antipsychotics are prohibited for 7 to 28 days prior to randomization through the end of study. The wash out periods was specified for each medication based on the drug half-life, these are pecified in the Protocol, Section 4.3 Table 13.

Medications for medical, non-psychiatric illnesses are permitted, as are oral contraceptives and contraceptive devices.

Potent cytochrome P450 3A4 inducers and inhibitors are prohibited during the study.

Concomitant medication will be categorized and reviewed to determine any protocol deviations. These deviations will be reviewed to determine potential impact on efficacy data.

2.2.6 Missing values

Instances of variables with a large proportion of missing values will be documented in the clinical study report. Such variables will be identified before the data is unblinded, and the impact will be assessed and documented by the study statistician.

Imputation of missing data for purposes of analysis is documented in section 4.

3. PRIMARY AND SECONDARY VARIABLES

The primary variable is the change from baseline assessment to final assessment (Day 57 or LOCF) in the MADRS total score

Secondary variables:

- Change from baseline to each assessment (observed cases) MADRS total score
- MADRS total score at each assessment and final assessment
- Response, defined as a decrease from baseline MADRS total score of ≥50% to each assessment and final assessment
- Individual item scores for the MADRS at each assessment and final assessment
- HAM-D total score and change from baseline at each assessment and final assessment
- HAM-D individual item scores and change from baseline at each assessment and final assessment (analysis will key on HAM-D Item 1)
- CGI-S at each assessment and final assessment
- Change from baseline CGI-S to each assessment and final assessment
- CGI-I at each post-baseline assessment and final assessment
- YMRS at each assessment and final assessment
- Change from baseline YMRS to each assessment and final assessment
- YMRS individual item score at each assessment and final assessment
- Presence or absence of treatment emergent mania (YMRS criteria or AE of Mania)
- HAM-A total score at each assessment and final assessment
- Change from baseline HAM-A to each assessment and final assessment
- HAM-A individual item scores at each assessment and final assessment

Quality of Life variables:

- Q-Les-Q at each assessment and final assessment

- Change from baseline Q-Les-Q to each assessment and final assessment
- PSQI at each assessment and final assessment
- Change from baseline PSQI to each assessment and final assessment

Safety variables:

- Adverse events (from randomization to last dose + 30 days)
- Adverse events (considered drug-related)
- Adverse events leading to withdrawal
- Adverse events meeting criteria for a serious event
- SAS at each assessment
- Value at and change from baseline in SAS to each assessment
- BARS at each assessment
- Value at and change from baseline in BARS to each assessment
- Value at and change from baseline in ECG interval data to each assessment
- Classification of clinical significant changes for QT and QTC intervals
- Value at and change from baseline in clinical laboratory assessments to final assessment
- Classification of clinically important changes for AST, ALT, glucose, TSH, free thyroxin
- Value at and change from baseline in vital signs and weight to each assessment
- Classification of clinically important changes for blood pressure, heart rate, orthostatic changes and weight to each assessment

Demographic and baseline characteristic variables:

- Age at study entry
- Sex
- Origin

- Psychiatric diagnosis – stratification variable: Bipolar I and Bipolar II
- Baseline HAM-D assessment (screening and randomization day)

3.1 Definition of efficacy measures

3.1.1 Response rates

Response at a visit is defined as a decrease from baseline MADRS total score of ≥ 50% at the given visit.

3.1.2 Total scores

For MADRS, HAM-D, YMRS, and HAM-A total score will be calculated as the sum of the component items of the scale for each assessment.

3.1.3 Emergent Mania

Emergent mania symptoms will be defined as present for a patient if one of the follow criteria is met: (1) Adverse event of mania requiring hospitalisation, (2) Adverse event of mania leading to withdrawal from study, (3) YMRS total score ≥16 on 2 consecutive assessments at any time during the trial or final assessment ≥ 16 (4) Adverse event of Mania [not included in criteria (1) and (2)].

In addition those whose final YMRS total score is ≥ 16 will be flagged for a separate summary.

3.1.4 Lorazepam use

Daily use of lorazepam during the first 3 weeks of treatment is restricted to 1-3 mg. The MED form will be evaluated for lorazepam use and the presence or absence denoted per study day. Patients taking lorazepam after day 21 will be considered protocol deviators.

3.1.5 PSQI score

The PSQI score will be calculates as follows:

Component 1 (patient sleep quality) = score for question 6

Component 2 (sleep latency)

> If question 2 is: ≤15 then score=0; if 16-30 then score=1; if 31-60 then score=2; if >60 then score=3
>
> Total = Sum of Score for question 2 to Score for 5(a)
>
> Component 2=: 0 if total=0; 1 if total 1-2; 2 if total 3-4; 3 if total 5-6

Component 3 (sleep duration) will be calculated as follows:

If question 4 >7 then score=0; if 6-7 then score=1; if 5-<6 then score=2; if <5 then score=3

Component 4 (habitual sleep efficiency)

Calculate number of hours in bed question 3 – question 1 = number of hours in bed

Calculate habitual sleep efficiency: (question 4 response/hours spent in bed)* 100= habitual sleep efficiency %

Assign component 4 score as follows: sleep efficiency ≥85% then score=0; 75-84% then score=1; 65-74% then score=2; <65% then score=3

Component 5 (sleep disturbances)

Total disturb=sum of questions 5(b) through 5 (J) – 9 items

Assign component 5 score as follows:

If total disturb=0 then score=0; if 1-9 then score=1; if 10-18 then score=2; if 19-27 then score=3

Component 6 (sleep medication)= score for question 7

Component 7 (daytime dysfunction)

Total daydys= sum of question 8 and question 9

Assign component 7 as follows:

If total daydys=0 then score=0; if 1-2 then score=1; if 3-4 then score=2l if 5-6 then score=3

PSQI total score= sum of component 1 through component 7.

3.1.6 The QLESQ total score

The QLESQ total score is the sum of the first 14 items, and this total score is converted to a % maximum score using the following scoring conversion:

Larger values indicate a higher perceived quality of life enjoyment and satisfaction.

The %Maximum score is calculated as follows (Raw total score –14)*(100/56) and rounded to an integer.

3.2 Definition of Safety measures

3.2.1 Total safety scores

SAS total will be calculated as the sum of the component items of the scale for each assessment. Note that for the BARS, the global clinical assessment score will be used for analysis.

3.2.2 Body Mass Index (BMI)

In order to put any changes in weight into perspective, the patient weight data will also be explored as change in body mass index. Patients will be stratified by BMI category to determine changes within and across categories.

Body mass index will be calculated using the following formula:

BMI = weight in kilograms/(height in meters)^2

For cross tabulation the following categorization will be used:

Category	**BMI (kg/m^2)**
Underweight	Under 18.5
Normal weight	18.5 – 24.9
Overweight	25 – 29.9
Obese	30 – 39.9
Severely Obese	40 and over

Changes in body weight and BMI will be computed as Day 57 (OC) and Day 57 (LOCF) measurement minus the baseline measurement. The key endpoint for weight change is whether a patient gained ≥7% over baseline. Weight loss of ≥7% will be presented as well.

3.2.3 Sleep medication

The only sleep medication allowed during the trial is zolpidem tartrate 5-10 mg during the first 3 weeks of the study. Data from the MED form will be classified as presence or absence of sleep medication by study day. A patient will be considered to have deviated from the protocol if this medication was used beyond Day 21.

3.2.4 Study medication

To summarize patient dose in concordance with the intent-to-treat principle, the prescribed daily dose (number of tablets) will be used to measure the daily dose. The prescription record form captures the daily dose of medication based on number of tablets. Investigator could

reduce the dose by 1 tablet per day after day 8 if needed. A patient is considered compliant if they took 75% of the prescribed tablets during treatment. Non-compliant patients will be listed as having deviated from the protocol.

4. ANALYSIS METHODS

The primary analysis of this trial will test whether the mean difference between each quetiapine dose arm and the placebo arm for the change from baseline MADRS total score to final assessment (Day 57 or LOCF) in the ITT population is statistically significant.

4.1 General principles

All statistical tests will be 2-sided. Where appropriate 95% confidence intervals will be presented.

The primary analyses will use last observation carried forward (LOCF) for the time period of interest.

This trial employed a central randomization with a stratification based on diagnosis (bipolar I and bipolar II); therefore diagnosis, not center, will be included as a stratification variable in the analysis models. Center will be included in the ANCOVA model as a random effect.

For the primary analysis a Simes-Hommel step up procedure will be used to adjust for 2 comparisons with placebo. The p-values obtained from the analysis will be ordered as: $P(1) \leq P(2)$. The following rule will be used to assess statistical significance for the primary analysis:

1) If $P(2) \leq 0.05$, then reject both null hypotheses associated with P(2) and P(1): else proceed

2) If $P(1) \leq 0.025$, the reject null hypothesis associated with P(1)

All secondary analyses will be conducted at the nominal significance level of 0.05, with no adjustment for multiple comparisons.

An ITT analysis will be the primary analysis conducted for the primary efficacy variable. The supportive analysis of efficacy will be restricted to those patients who have completed dose titration and have provided one MADRS assessment beyond the titration period (PP).

Although the data were stratified by entry criteria for diagnosis, bipolar I or bipolar II, if a patient's diagnosis on the case report form differed from the stratification group, the patient will be reclassified into the appropriate diagnostic group for analysis.

Patients who were randomized but subsequently were never dosed will be excluded from both efficacy and safety analyses.

4.1.1 Testing of covariates

In general, baseline values in analyses of changes from baseline will be included as a covariate. In the case of tertiary analyses where the baseline for the measure is expected to be low, the MADRS baseline as a surrogate for disease severity will be included as the baseline covariate. Because randomization was stratified by diagnosis, diagnosis stratum will also be included as a covariate where appropriate.

Potential center effects will be evaluated using a mixed model approach to assess the impact of including center as a random effect in the model. It is not expected that all centers will contribute patients to all strata. Thus imbalances are expected both in terms of number randomized and in the distribution across the strata. The expectation is that approximately 1/3 will be bipolar II and 2/3 bipolar I. There is a limit of 70 patients in a center (13 % of the randomized population) but the median is expected to be >12 patients/center.

As appropriate, assumptions of the intended analysis will be explored using blinded data (e.g., using probability plots when testing the assumption of normality). Subsequent to unblinding of the data, model assumptions for consistency of variance will be assessed. If any of the assumptions are found to be violated, an appropriate transformation or a non-parametric technique will be considered to validate the main results.

4.2 Analysis Methods

4.2.1 Primary analysis for MADRS

The primary analysis of change from baseline to final assessment (LOCF) in MADRS total scores will test the superiority of each dose level of quetiapine using an Analysis of Covariance (ANCOVA) with the baseline MADRS as the covariate and including treatment and diagnosis strata as fixed effects and center as a random effect in the model.

As noted in section 4.1, the primary analysis will have the significance of the pairwise comparisons with placebo ordered and compared to the cut off values for the Simes- Himmel step up procedure to preserve the overall experiment wise error rate and conserve power.

The primary analysis will use the ITT population with a second analysis performed on the PP population to assess sensitivity of results to population.

4.2.2 Secondary efficacy analysis

All secondary analyses are made in order to yield supportive evidence that quetiapine is more effective than placebo. These analyses will use the ITT population and will mainly be presented as point estimates with associated 95% confidence intervals for the treatment effects and the difference between groups. The confidence levels and p-values displayed will be nominal with no adjustment for multiplicity issues.

4.2.2.1 Response

Analysis of the MADRS total score will test the differences between treatment and placebo in response rates at each visit assessment and final assessment (LOCF) using a Cochran-Mantel-Haenszel Chi square test across diagnosis strata. Summary statistics (number and % in each treatment group responding) will be presented along with the p-values and estimated odds ratio with 95% confidence interval. The model will be fit using the PROC FREQ procedure in SAS®. The Breslow Day statistic will be used to evaluate homogeneity of response across the bipolar diagnosis strata.

4.2.2.2 HAM-D

Descriptive statistics will be presented for HAM-D total score, HAM-D Item 1 score, change from baseline for HAM-D total score and change from baseline HAM-D Item 1 by visit and final assessment (LOCF). The ANCOVA model will be used with baseline as a covariate and treatment and diagnosis strata as fixed effects.

4.2.2.3 CGI

Descriptive statistics will be presented for the CGI-S, CGI-Improvement and change from baseline in CGI-S by visit and final assessment.

Two approaches to analysis will be evaluated; one approach will handle the data as if it were continuous and analyze the Change from baseline CGI-S and CGI-I using an ANCOVA model with baseline CGI-S as a covariate and treatment and diagnosis strata as fixed effects.

In addition the CGI-I will be dichotomised into a binomial response 1=improved, 0=unchanged or worse. This will be assessed in the same manner as MADRS response.

4.2.2.4 YMRS total score

Descriptive statistics will be presented for the YMRS total score and the change from baseline in YMRS total score by visit and at final assessment. The ANCOVA model will be used with the YMRS baseline as a covariate and treatment and diagnosis strata as fixed effects.

4.2.2.5 HAM-A

Descriptive statistics will be presented for the HAM-A total score and the change from baseline in HAM-A total score by visit and at final assessment. The ANCOVA model will be used with the HAM-A baseline as a covariate and treatment and diagnosis strata as fixed effects.

4.2.2.6 PSQI

The PSQI will have a total score calculated as described in section 3.1.5. Descriptive statistics will be presented for the PSQI total score, change from baseline in PSQI total score and itemized response to each question by assessment visit and final assessment. The ANCOVA model will be used for PSQI change from baseline to each assessment and final visit with the baseline PSQI total score as a covariate and treatment and diagnosis strata as fixed effects.

4.2.2.7 Patient reported outcomes –QLESQ

Descriptive statistics of overall level of satisfaction with general activities will be presented for the QLESQ raw total score (sum of items 1 to 14), QLESQ % maximum total score, change from baseline in QLESQ raw total score, and change from baseline in % maximum total score by assessment visit and final assessment. The ANCOVA model will be used for QLESQ change from baseline for both raw total score and % maximum score to each assessment and final visit with the appropriate baseline QLESQ total score as a covariate and treatment and diagnosis strata as fixed effects.

4.3 Analysis supporting safety and tolerability

When statistical tests are performed, the tests will be 2-tailed with a significance level of 0.05 unless otherwise stated. Where appropriate 95% confidence intervals will be presented. The main analysis will be the final assessment (LOCF) for the time period of interest.

All safety analysis will be based on the safety population, but where change from baseline is the primary focus of the analysis, only patients with both baseline and post baseline data will be included.

4.3.1 Movement disorders

Modified SAS total score and BARS global assessment score, including changes from baseline for each, will be summarized by visit using descriptive statistics. Statistics will include the number and percentage of patients with non-normal scores. The difference between treatment groups in the proportion of patients whose scores are greater than baseline at the final assessment will be tested using a logistic regression model. The odds ratio will be calculated for each treatment arm compared to placebo, together with a 95% confidence interval, using results from PROC GENMOD, and will be used to compare treatments.

4.3.2 Rescue medication use

Number of days and percent of the first 21 days with lorazapam use or sleep medication use will be calculated for each patient. If a patient withdraws early, the percent will be calculated based on the number of days in the trial if less than 21. These data will be summarized by treatment group and diagnosis strata using descriptive statistics.

If the number withdrawing before day 21 is greater than 20% or has an imbalance among treatment groups, descriptive statistics will also be provided broken down by completion status.

4.3.3 Study withdrawals

Differences between treatment groups in overall rate of withdrawal and category of withdrawal will be tested using a CMH test stratified by diagnosis. Withdrawals on or before day 8 will be examined as part of the consideration of balance between treatment groups due to early withdrawal.

For each visit (week of study) withdrawals will be summarized in total and by reason for withdrawal using descriptive statistics.

4.3.4 Adverse events

Adverse events will be classified using MedDRA system of nomenclature. Number of events and crude event rates will be tabulated by system organ class and preferred term. An event that occurs one or more times in a patient after randomised treatment counts as 1 event in the numerator of the crude event rate, the denominator is the number at risk in the group.

Events will also be classified as prior to treatment, during treatment, during follow up period. Tabulation of events will include all events during treatment and events reported within 30 days of the last dose of trial medication. All other events will appear only in patient listings.

Adverse events will have the primary assessment by treatment arm and a secondary reporting by treatment and diagnosis strata.

Incidence rates will be tabulated and presented for the following categories: all adverse events, serious adverse events, drug related adverse events, adverse events leading to death, and adverse events leading to withdrawal of patients from the study.

An additional analysis will include an assessment of events during titration, that is an event that started on Day 1-8 of study treatment. This will descriptively assess the impact of the once daily dosing with relatively rapid titration.

Other adverse events of interest including: suicide attempt, suicide ideation, EPS symptoms, mania, agranulocytosis, cerebrovascular events, diabetes, hyperglycemia, and orthostatic hypertension will be summarized by treatment group to explore potential dose response effects in these events.

No formal statistical testing is planned.

4.3.5 Weight analysis

Descriptive statistics will be used to assess changes in weight. No formal analysis is planned, but the change from baseline in weight and BMI will be reported as will shift table summary statistics for n and percentage of patients shifting into a new category, see section 3.2.2.

4.3.6 Laboratory data

The clinical laboratory data will include only those patients with both a baseline and post baseline assessment for summary tables, all data will appear in the listings. The clinical laboratory summary data to be presented in this section include the value at the baseline, final visit and change from baseline to final assessment for the following variables: total bilirubin, alkaline phosphatase, AST, ALT, sodium, potassium, chloride, glucose, insulin, bicarbonate, total cholesterol, HDL and LDL cholesterol, triglycerides, thyroide functioning (TSH, T3RU, T4), creatinine, hemaglobin, hematocrit, RBC, WBC, differential %, platelets. These test results will be tabulated using descriptive statistics by treatment group. Shift tables will be

provided using the criteria defined in Quetiapine project agreed extended normal ranges to identify potentially clinically significant changes (Appendix B).

4.3.7 Vital signs

Vital signs are measured at each visit in both supine and standing position. The data will be summarized using descriptive statistics by visit and as change from baseline at each visit and final assessment for the following variables: supine pulse, diastolic and systolic blood pressure, standing pulse, diastolic and systolic blood pressure, and change in pulse, diastolic and systolic blood pressure related to change in position.

Shift tables of the data as related to the extended normal range defined in Appendix B, quetiapine project specific agreed extended ranges) will be provided for the blood pressure values at baseline and final assessment by treatment group

For each visit the number and percentage of patients with changes, which meet the criteria for an orthostatic change will be calculated for each treatment group also defined in Appendix B.

4.3.8 ECG data

The ECG variables will be summarized for those patients with both a baseline and final assessment. All ECG assessments will be listed. The ECG summary tables will include atrial and ventricular heart rates, PR interval, QRS interval, QT interval and Fridericia QTc interval at baseline, final assessment and change from baseline to final assessment.

Descriptive statistics will be presented for each treatment group.

Shift tables of the interval data based on the criteria found in Appendix B, quetiapine project specific agreed extended ranges, will be provided for baseline and final assessment by treatment group.

4.3.9 Study medication

Patients will be classified by the nominal dose for the treatment group to which they are assigned.

The number and percentage of patients for whom dose reduction was initiated will be tabulated by treatment group. Compliance will be checked versus the adjusted number of tablets expected for the period.

Compliance will be calculated for the study based on tablet counts. For each patient the overall compliance will be assessed as the total number of tablets taken divided by the total number expected to be taken (adjusted for those with the dose reduction). The patient will then be classified as fully compliant (≥ 80%), partially compliant (≥ 70% and <80%), or non-compliant < 70%.

Descriptive statistics will be provided on the category of compliance by treatment group and diagnosis.

4.4 Descriptive statistics definitions

4.4.1 Standard descriptive statistics

Standard descriptive statistics will be used to summarize all continuous or semi-continuous variables (categorical data analyzed using ANCOVA).

N: Number of patients

Mean: Mean value of the assessment, across the N patients

SD: Standard deviation

Min, Median, Max: percentile information

Descriptive statistics used to summarize discrete data will include the following statistics:

N: Number of patients

#: number of counts in the category (e.g. number of events)

%: #/N*100 or percent of N in the category

Further statistics will be included as appropriate for the scale at hand, including but not limited to:

SE: standard error of mean (inclusion will facilitate informal between group comparisons)

Baseline mean: mean baseline for the N patients (useful when n changing due to drop outs)

% of baseline: mean score divided by the baseline mean, for N patients

%Zero, %Positive, %negative: Percent of N patients for whom the score is zero, etc.

%Minimal: Percent of patients showing the minimum value for the assessment (if other than zero for a scale)

Effect size: mean difference between treatments/pooled standard deviation

Confidence Interval: the lower and upper limits of the region which has 95% probability of containing the parameter of interest given the data

4.4.2 Definition of Normal values for scales

The following is a table of the minimum values for the scales used in this study.

Scale/subscale	Normal/Minimum value

MADRS	= 0
HAM-D	= 0
HAM-D Item 1	= 0
YMRS	= 0
HAM-A	= 0
CGI-S	= 1
BARS	≤ 1
SAS	Item 10 ≤ 2 and Items 1-9 = 0
PSQI	= 0
QLESQ	=70 (maximum)

4.5 Missing Data

4.5.1 MADRS

The MADRS total score will be set to missing for any patient for whom more than 1 item is missing at an assessment. If one item is missing, the MADRS total based on the non-missing items will be multiplied by 10 (total number of items) and then divided by 9 (number non-missing). Imputed values will not be rounded to whole numbers.

If more than one MADRS item is missing at a particular visit the data will be handled as follows:

- If the baseline MADRS is considered missing due to more than one item missing, the patient will be considered non-evaluable as they do not have a satisfactory baseline assessment and no change from baseline can be calculated.

- If it is a post baseline visit, then the visit will be excluded for that patient, but data for all other visits with satisfactory assessments will not be excluded. When using the LOCF approach, any missing MADRS total scores will be replaced with the previous satisfactory assessment.

4.5.2 HAM-D

Eligibility –Screening and randomization

In order to qualify for the trial the unadjusted total score must be ≥ 20 and Item 1 (depressed mood) score ≥ 2.

The HAM-D total score will be set to missing for any patient with more than 1 item missing at an assessment, excluding item 16. If one item, other than item 16, is missing, the HAM-D total will be calculated as follows:

- If the missing item is on a 0-2 scale (items 4, 5, 6, 12, 13, 14, 17); multiply the total of the non-missing values by 17 and divide by 16.
- If the missing item is on a 0-4 scale (items 1, 2, 3, 7, 8, 9, 10, 11,15); multiply the total of the non-missing values by 17 and divide by 14.

4.5.3 YMRS

If more than 1 item is missing the total score is considered missing. If there is one item missing the following rules will be used:

- If the missing item is on a 0-4 scale (items 1-4, 7, 10, 11); multiply the total of the non-missing values by 15 and divide by 14
- If the missing item is on the 0-8 scale (items 5, 6, 8, 9); multiply the total of the non-missing values by 15 and divide by 13

Imputed values will not be rounded to whole numbers

Eligibility – Screening and randomization

In order to qualify the adjusted total score needs to be ≤ 12.

4.5.4 HAM-A

If more than 1 item is missing the total score is considered missing. If there is one item missing then the total score is imputed as follows: multiply the total of the non-missing values by 14 and divide by 13.

4.5.5 SAS

The SAS total score will be taken to be missing for any patient for whom more than one item is missing. If one item is missing, the SAS total score based on the non-missing items will be multiplied by 10 (total number of items) and then divided by 9 (number non-missing). Imputed values will not be rounded to whole numbers.

4.5.6 PSQI

If the data is not available to calculate a component score the component score will be set to missing and the total score will be set to missing.

4.5.7 Q-Les-Q

If more than 1 of the first 14 items is missing the total score is considered missing. If there is one item missing then the total score is imputed as follows: multiply the total of the non-missing values by 14 and divide by 13.

5. INTERIM ANALYSES

No interim analysis is planned for this study.

6. CHANGES OF ANALYSIS FROM PROTOCOL

The definition of the PP population was changed to be a patient with at least one post titration assessment, that is a patient who completed at least 8 days of dosing with study medication. Patients dropping out prior to day 8 of dosing will be handled in the ITT efficacy and the safety and tolerability section.

MADRS assessment obtained > 4 days after the last dose of study medication will not be included in PP population efficacy analysis.

APPENDIX A. PROTOCOL VIOLATIONS AND DEVIATIONS

Code	Criteria	Computer	Manual	Both	Exclude PP	Exclu
	Inclusion Criteria					
I01	documented ability to provide IC before beginning any study-specific procedures	Yes			Yes	Yes
I02	Male or female patient between 18 & 65 years of age, inclusive	Yes			No	No
I03	Females of childbearing potential, be using reliable method of contraception	Yes			No	No
I04	Women must have negative pregnancy test	Yes			No	No
I05	Meets DSM-IV criteria for bipolar disorder I or bipolar II, most recent episode depressed (296.5x and 296.89x), confirmed by SCID	Yes			Yes	No
I06	outpatient status	Yes			No	No
I07	HAM-D (17-item) total score of 20 or greater	Yes			Yes	No
I08	HAM-D item 1 (depressed mood) score >=2	Yes			Yes	No
I09	YMRS total <= 12	Yes			Yes	No
	Exclusion Criteria					
E01	Patients with current Axis I disorder other than bipolar disorder within 6 months of screening	Yes			No	No
E02	Patients whose depression episode exceeds 12 months or is less than 4 weeks			Yes	Yes	Decisi review
E03	History of non-response to an adequate trial (6 weeks) of more than 2 classes of antidepressants during their current episode			Yes	Yes	No
E04	Patients who meet DSM-IV criteria for substance dependence, for any substance except nicotine, within 12 months of screening	Yes			Yes	No
E05	Patients with positive UDS for illicit substances of abuse	Yes			No	No
E06	Patients who are unable to discontinue all psychoactive medications (excluding benzodiazepines) ar least 7 days prior to randomization [fluoxetine 14 days prior; haloperiodol decanoate or fluphenazine decanoate 28 days prior]			Yes	Decision on review	No
E07	Patients who have not discontinued use of potent P450 inhibitors and inducers			Yes	Decision on review	No
E08	Patients who in the investigator's opinion will require initiation of psychotherapy during the study period	Yes			No	No
E09	Patients who in the investigator's judgment pose a serious suicidal or homicidal risk at Visit 1	Yes			No	No
E10	Patients with a history of clinically significant disease	Yes			No	No
E11	Patients who have had an MI within 1 year before Visit 1	Yes			No	No
E12	Patients with clinically significant abnormal laboratory findings	Yes			No	No
E13	Patients with renal impairment (serum creatinine >=1.5 mg/dl) or hepatic impairment (AST or ALT 3 times the ULN)	Yes			No	No

Code	Criteria	Compu ter	Manual	Both	Exclude PP	Exclu
E14	Patients whose TSH is > 10% over the ULN, Patients on thyroid medication must be euthyroid for at least 3 months			Yes	No	No
E15	Patients with clinically significant abnormalities on ECG	Yes			No	No
E16	Women who have positive HCG pregnancy test at Visit 1, lactating or planning to become pregnant during the course of the study	Yes			No	No
E17	Patients who have participated in a clinical trial of an investigational drug within the past 3 months			Yes	Yes	Decisi review
E18	Patients who, in the opinion of the investigator, would be non compliant with visit schedule or study procedures	Yes			No	No
E19	History of orthostatis hypotension or conditions which would predispose them to hypotension (eg dehydration, hypovolemia)			Yes	No	No
E20	Known history of intolerance, hypersensitivity, or lack of response to quetiapine or any of its components	Yes			No	No
	Deviations Leading to Exclusion from the PP Analysis					No
D01	Patients who take more than 10 mg of zolpidem tartrate for insomnia in first 3 weeks	Yes			Decision on review	No
D02	Patients who take more than 3mg/day of lorazepam for severe anxiety in first 3 weeks	Yes			Decision on review	No
D03	Patients who take zolpidem tartrate or lorazepam after Week 3			Yes	Decision on review	No
D04	Patients who take potent cytochrome P450 3A4 inducers	Yes			Decision on review	No
D05	Patients who take potent cytochrome P450 3A4 inhibitors	Yes			Decision on review	No
D06	Patients who take any antipsychotics during treatment			Yes	Decision on review	No
D07	Patients who take any antidepressants, hypnotics, mood stabilizing drugs during treatment			Yes	Decision on review	No
D08	Patients who reduce trial medication by more than 100 mg			Yes	Decision on review	No
D09	Patients who receive any dose reduction before day 8	Yes			Yes	No
D10	Patients who receive less than 70% of prescribed doses	Yes			Yes	No
D11	Patient does not have both baseline & post baseline assessment (MADRS)	Yes			Yes	Yes
D12	Patients who receive <= 8 days of trial therapy	Yes			Yes	No
D13	Patients who fail to receive prescribed trial medication-randomized but not dosed	Yes			Yes	Yes

Code	Criteria	Computer	Manual	Both	Exclude PP	Exclu
D14	Patients who receive incorrect randomized trial medication		Yes		Decision on review	No
D15	Patients who fail to complete visit required assessments	Yes			No	No
D16	Patients who miss 10 cumulative doses or 3 consecutive days of trial medication				No	No
D17	Psychiatric scale data (MADRS) collected >4 days after last dose of study medication	Yes			Yes	No
D18	Documented drug abuse during study	Yes			Yes	No

APPENDIX B. DEFINITIONS OF POTENTIALLY CLINICALLY SIGNIFICANT LABORATORY VALUES, VITAL SIGNS, AND ELECTROCARDIOGRAPHIC DATA

Definition of potentially clinically significant clinical laboratory values

Hematology laboratory parameter		Potentially significant values
Hematocrit		males ≤ 0.37; ≥0.50 vol fraction females ≤ 0.32; ≥0.55 vol fraction
Hemoglobin		males ≤ 11.5 g/dL; ≥ 18.5 g/dL females ≤ 9.5 g/dL; ≥ 16.5 g/dL
RBC		≤ 3 x 10^{12} cells/L; ≥ 6 x 10^{12} cells/L
Platelet count		≤ 75 x 10^{9} cells/L; ≥ 700 x 10^{9} cells/L
WBC		≤ 2.8 x 10^{9} cells/L; ≥ 16.0 x 10^{9} cells/L
Neutrophils	-- percent	≤ 15%
	-- absolute (calculated)	≤ 1.5 x 10^{9} cells/L
Eosinophils	-- percent	≥ 10%
	-- absolute (calculated)	> 450 x 10^{6} cells/L
Basophils		> 3%
Lymphocytes		≤ 10%
Monocytes		> 20%

Chemistry laboratory parameter	Potentially significant values
ALT	≥ 3 x ULN
AST	≥ 3 x ULN
Alkaline phosphatase	≥ 3 x ULN
Total Bilirubin	≥ 2.0mg/dL
Uric acid	females ≥ 8.5mg/dL; males ≥ 10.5mg/dL
Sodium	≤ 129 mmol/L; ≥ 160 mmol/L
Glucose	≤ 50.0mg/dL; ≥ 230.0mg/dL
BUN	≥ 30mg/dL
Creatinine	≥ 2.1mg/dL
Potassium	<3.0mEq/L; >5.5mEq/L
Chloride	<90mEq/L; >120mEq/L
CO_2	<18mEq/L; >30mEq/L
Total cholesterol	> 200 mg/dL
HDL	< 35 mg/dL; > 65 mg/dL
LDL	< 130 mg/dL; > 160 mg/dL
Triglicerides	> 250 mg/dL
Total T4 and Free T4	< 0.8 x LLN; >1.2 x ULN
TSH	> 5 mU/L

Definitions of potentially clinically significant vital signs and weight

Vital sign	Criterion value	Change from baseline
Systolic blood pressure	≥ 180 mm Hg	increase ≥ 20 mm Hg
	≤ 90 mm Hg	decrease ≥ 20 mm Hg
Diastolic blood pressure	≥ 105 mm Hg	increase ≥ 30 mm Hg
	≤ 50 mm Hg	decrease ≥ 20 mm Hg
Pulse	> 120 bpm	increase ≥ 15 bpm
	< 50 bpm	decrease ≥ 15 bpm
Temperature	> 38.3°C	Change≥1.11°C
Weight	--	change ≥ 7% body weight

Orthostatic changes	
Systolic blood pressure or	decrease ≥ 20 mm Hg from supine to standing after 1 min
Diastolic blood pressure	decrease ≥ 15 mm Hg from supine to standing after 1 min
Pulse	increase ≥ 20 bpm from supine to standing after 1 min
Combined	decrease ≥ 20 mm Hg in systolic BP and increase ≥ 20 BPM in pulse rate

Definition of potentially clinically significant electrocardiogram parameters

ECG parameter	Criterion value	Change from baseline
Heart rate	> 120 bpm	increase ≥ 15 bpm
	< 50 bpm	decrease ≥ 15 bpm
PR	≥ 210 msec	
QRS	≤ 50 msec	
	≥ 150 msec	
QT	≥ 500 msec	
	≤ 200 msec	
QT_C (Fridericia Correction)	≥ 450 msec	
PQ	≥ 200 msec	
	≤ 120 msec

The BOLDER Study Group

Objective: There is a major unmet need for effective options in the treatment of bipolar depression.

Method: Five hundred forty-two outpatients with bipolar I (N=360) or II (N=182) disorder experiencing a major depressive episode (DSM-IV) were randomly assigned to 8 weeks of quetiapine (600 or 300 mg/day) or placebo. The primary efficacy measure was mean change from baseline to week 8 in the Montgomery-Åsberg Depression Rating Scale total score. Additional efficacy assessments included the Hamilton Depression Rating Scale, Clinical Global Impression of severity and improvement, Hamilton Anxiety Rating Scale, Pittsburgh Sleep Quality Index, and Quality of Life Enjoyment and Satisfaction Questionnaire.

Results: Quetiapine at either dose demonstrated statistically significant improvement in Montgomery-Åsberg Depression Rating Scale total scores compared with placebo from week 1 onward. The proportions of patients meeting response criteria (≥50% Montgomery-Åsberg Depression Rating Scale score improvement) at the final assessment in the groups taking 600 and 300 mg/day of quetiapine were 58.2% and 57.6%, respectively, versus 36.1% for placebo. The proportions of patients meeting remission criteria (Montgomery-Åsberg Depression Rating Scale ≤12) were 52.9% in the groups taking 600 and 300 mg/day of quetiapine versus 28.4% for placebo. Quetiapine at 600 and 300 mg/day significantly improved 9 of 10 and 8 of 10 Montgomery-Åsberg Depression Rating Scale items, respectively, compared to placebo, including the core symptoms of depression. Treatment-emergent mania rates were low and similar for the quetiapine and placebo groups (3.2% and 3.9%, respectively).

Conclusions: Quetiapine monotherapy is efficacious and well tolerated for the treatment of bipolar depression.

(Am J Psychiatry 2005; 162:1351–1360)

Depressive episodes in bipolar I and II disorder are an important source of morbidity and mortality. While symptomatic, patients with bipolar I disorder experience depressive symptoms for about threefold longer than manic symptoms, and the recovery time is considerably longer for depressive than manic episodes (1–4). Symptomatic patients with bipolar II disorder spend almost 40 times longer depressed than hypomanic patients (5). Bipolar depression is associated with high rates of disability (6) and an increased risk of suicide, which occurs in 10% to 20% of patients with bipolar disorder (7).

Although multiple agents, including several atypical antipsychotics, have demonstrated efficacy in the treatment of the manic phase of bipolar I disorder (8), the acute treatment of bipolar depression has not been as well studied (9). Lithium and lamotrigine are recommended as initial treatments for acute bipolar I depression (10, 11). However, the response of bipolar depression to lithium is often incomplete in a substantial proportion of patients (12), and the efficacy of lamotrigine in the treatment of acute bipolar I depression has only been demonstrated in one adequately powered placebo-controlled trial (13).

More recently, the atypical antipsychotic olanzapine was found to be superior to placebo in the treatment of acute bipolar I depression as monotherapy when data were pooled from two 8-week trials (14). Fixed doses of olanzapine in combination with the antidepressant fluoxetine were administered to small groups of patients in these studies and were found to be both superior to placebo and superior to olanzapine monotherapy.

Quetiapine is efficacious in the treatment of acute bipolar mania, both as monotherapy and in combination with other mood stabilizers (15, 16). Preliminary evidence for the efficacy of quetiapine in the treatment of depressive symptoms in a variety of psychotic and mood disorders (including bipolar disorder, rapid-cycling bipolar disorder, and adolescent mania) has been reported in several randomized or open-label studies (17–24).

Based on the need for new treatment options for bipolar depression, the effectiveness of atypical antipsychotics in acute mania, and the emerging evidence for their use in bipolar depression, we evaluated the efficacy and safety of quetiapine compared with placebo in the treatment of depressive episodes in patients with bipolar I or bipolar II disorder.

Method

This double-blind, randomized, fixed-dose, placebo-controlled, parallel-group monotherapy study of quetiapine versus placebo was conducted at 39 centers in the United States between September 2002 and October 2003. After a washout period of at least five half-lives of any prior psychotropic medications, subjects were treated for 8 weeks to evaluate the efficacy, safety, and tolerability of 600 and 300 mg/day of quetiapine and placebo in the treatment of depressive episodes in adult patients with bipolar I or II disorder.

The study was approved by institutional review boards for each site and performed in accordance with the current amendment of the Declaration of Helsinki and the International Conference on Harmonization/Good Clinical Practice guidelines. Written informed consent was obtained from all subjects before participation.

Patient Population

Outpatients ages 18 to 65 years who met DSM-IV criteria for bipolar I or II disorder and were experiencing a major depressive episode were eligible for inclusion in the study. The diagnosis was confirmed with the Structured Clinical Interview for DSM-IV. The patients were required to have a Hamilton Depression Rating Scale 17-item score ≥20 (25), a Hamilton depression scale item 1 score ≥2, and a Young Mania Rating Scale (26) score ≤12 at both the screening and randomization visits. Inclusion criteria were based on the Hamilton depression scale rather than the primary efficacy measure (the Montgomery-Åsberg Depression Rating Scale [27]).

Patients were excluded from the study if they were diagnosed with an axis I disorder other than bipolar disorder that was the primary focus of treatment within 6 months before the screening, if the current episode of depression exceeded 12 months or was less than 4 weeks in duration, or if they had a history of nonresponse to an adequate (6-week) trial of more than two classes of antidepressants during the current episode. Additional exclusion criteria included a diagnosis of substance dependence (DSM-IV) or substance use (except for nicotine) within 12 months before the screening or a clinically significant medical illness. Patients who posed a current serious suicidal or homicidal risk were also excluded. Patients were not permitted to take benzodiazepines during the washout period, and only limited use was permitted during the first 3 weeks after random assignment.

Random assignment was achieved in a non-center-specific manner with an interactive voice-response central randomization service. Random assignment was stratified according to bipolar type (I or II) to ensure a relative balance in the total number of patients among groups (1:1:1). The patients were randomly assigned to one of three groups: quetiapine, 600 mg/day; quetiapine, 300 mg/day; or placebo.

Study Medication

Quetiapine (600 mg/day or 300 mg/day) or placebo was administered orally, in a single dose, once a day at bedtime. Quetiapine was initiated at 50 mg/day and administered to achieve a target dose of 300 mg/day by day 4 or 600 mg/day by week 1. All packaging of treatments was identical, with placebo and active tablets identical in appearance and number.

Prior and Concomitant Medication

Nonpsychotropic medication, including over-the-counter medications taken before entry into the study could be continued. Zolpidem tartrate (5–10 mg/day at bedtime for insomnia) and lorazepam (1–3 mg/day for severe anxiety) were permitted at the discretion of the investigator and only during the first 3 weeks of treatment but were withheld for 8 hours before psychiatric assessments were conducted. The use of all other psychotropic drugs was prohibited during the study.

Efficacy Evaluations

Clinical assessments were conducted at baseline and weekly from weeks 1 to 8. The primary efficacy variable was the mean change in the Montgomery-Åsberg Depression Rating Scale total score from baseline to week 8 (27).

Additional efficacy evaluations included a change from baseline to each assessment on the Montgomery-Åsberg Depression Rating Scale, the proportion of patients who achieved a protocol-defined response (≥50% reduction from baseline score on the Montgomery-Åsberg Depression Rating Scale), the time to response, the proportion of patients who achieved remission (Montgomery-Åsberg Depression Rating Scale score ≤12), the time to remission, as well as a Montgomery-Åsberg Depression Rating Scale item analysis. The change from baseline to each assessment on the Hamilton depression scale, the Clinical Global Impression (CGI) (28) severity of illness score, and the CGI improvement score were also assessed.

The effect of quetiapine on anxiety symptoms was assessed with the Hamilton Anxiety Rating Scale (29). Mean change from baseline to each assessment and at week 8 in the Hamilton anxiety scale total score was determined.

Quality of sleep was assessed with the Pittsburgh Sleep Quality Index, which measures several dimensions of sleep, including quality, latency, duration, efficiency, use of medication, and daytime dysfunction (30).

The 16-item short form of the Quality of Life Enjoyment and Satisfaction Questionnaire was used to measure satisfaction with various areas of daily functioning, such as social relationships, living/housing, physical health, medication, and global satisfaction (31). The Pittsburgh Sleep Quality Index and the Quality of Life Enjoyment and Satisfaction Questionnaire were administered at baseline and at weeks 4 and 8.

Safety and Tolerability Evaluations

Safety and tolerability were evaluated by assessing the incidence and severity of adverse events, as well as withdrawals because of adverse events. Extrapyramidal symptoms were assessed with the Simpson-Angus Rating Scale (32), and akathisia was assessed with the Barnes Rating Scale for Drug-Induced Akathisia (33) at random assignment and at week 8. Measurements of vital signs, including weight and fasting serum glucose levels, were obtained at each study visit. Twelve-lead ECGs, clinical chemistry, and hematology assessments were performed at the screening and at week 8.

The incidence of treatment-emergent mania was evaluated by comparing the percentage of patients in each group who had a total Young Mania Rating Scale score of ≥16 on any two consecutive visits or at the final assessment, or an adverse event of mania or hypomania.

Statistical Analyses

Primary and secondary efficacy analyses were performed on the intent-to-treat population, which included all randomly assigned patients who took at least one dose of study medication and had at least one postbaseline efficacy assessment. A last-observation-carried-forward analysis was used to impute missing data for patients who withdrew during the study. All statistical tests were two-tailed. The primary analysis of change from baseline to final assessment in the Montgomery-Åsberg Depression Rating Scale total scores tested the superiority of each dose of quetiapine in the intent-to-treat group (patients with bipolar I or bipolar II disorder) with an analysis of covariance (ANCOVA) with the baseline Montgomery-Åsberg Depression Rating Scale as the covariate and included treatment and diagnosis strata as fixed ef-

TABLE 1. Baseline Demographic Characteristics of Screened Outpatients With Bipolar I or II Disorder Who Experienced a Major Depressive Episode

	Patients Who Did Not Pass Screening (N=296)		Patients Who Were Randomly Assigned to Treatment (N=539)[a]

≥60	10	3.4	5	0.9

[a] Safety population that excluded three patients who did not receive any dose of study medication.

fects in the model, with adjustment for multiple comparisons. Effect size (improvement of quetiapine over placebo divided by pooled standard deviation) was determined with a mixed-model repeated-measures analysis.

Differences in response rates between treatment and placebo groups and in patients with and without rapid cycling were assessed with a Cochran-Mantel-Haenszel chi-square test across diagnostic strata. Hamilton depression scale, CGI severity and improvement, Young Mania Rating Scale, Hamilton anxiety scale, Pittsburgh Sleep Quality Index, and Quality of Life Enjoyment and Satisfaction Questionnaire scores were tested with ANCOVAs. All secondary analyses were conducted at the nominal significance level of 0.05, with no adjustment for multiple comparisons.

Sample sizes were determined to provide 85% power to detect a difference of 3.6 points on the Montgomery-Åsberg Depression Rating Scale with two-tailed pairwise comparisons between treatment groups and placebo at an alpha level of 0.025 in the intent-to-treat population (patients with bipolar I or bipolar II disorder).

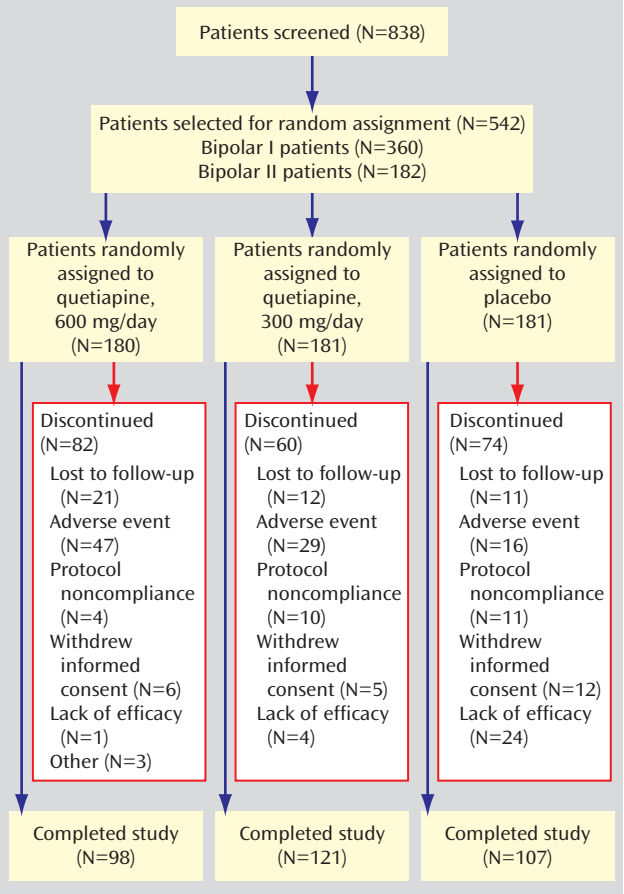
Exploratory analyses were carried out on the bipolar I and II subgroups whose group size was not predetermined to provide power for significance testing. Exploratory analyses were limited to descriptions of the mean changes in primary outcome measure across the three treatment groups, and effect size determinations for the groups taking 600 and 300 mg/day of quetiapine. The repeated measures mixed-effects model included terms for treatment, bipolar diagnosis, treatment-by-bipolar diagnosis, baseline Montgomery-Åsberg Depression Rating Scale total score, visit (week), and treatment-by-visit effects. Several covariance structures were examined, including autoregressive, banded Toeplitz, compound symmetry, and unstructured. The best-fitting covariance structure, the banded Toeplitz, was determined with the Bayesian information criterion.

Results

Patients and Disposition

A total of 838 patients were screened, and 542 patients with bipolar I (N=360) or bipolar II (N=182) disorder were randomly assigned to receive quetiapine, 600 mg/day (N=180); quetiapine, 300 mg/day (N=181); or placebo (N=181). There were no significant differences between the baseline characteristics of patients who did not pass the screening compared with those who were randomly assigned (Table 1). The most common reason for the screening failure was failure to meet eligibility criteria. Figure 1 illustrates the disposition of patients during the study. Of the 542 randomly assigned patients, 539 received at least

FIGURE 1. Disposition of Outpatients with Bipolar I or II Disorder Who Experienced a Major Depressive Episode



one dose of study medication and were included in the safety population. Of these, 511 had at least one postbaseline assessment and were analyzed for efficacy in the intent-to-treat population.

There were no statistically significant differences between treatment groups with respect to any demographic and baseline disease characteristic (Table 2). The mean age was approximately 37 years, and 58.2% of the patients were women. Mean Montgomery-Åsberg Depression Rating Scale scores at baseline were consistent with moderate to severe depression (34).

There were no statistically significant differences between the quetiapine groups and placebo in the proportion of the patients who completed the study: 54% in the 600 mg/day quetiapine group, 67% in the 300 mg/day quetiapine group, and 59% in the placebo group. The most common reasons for withdrawal were related to adverse events in the quetiapine groups (26.1% and 16.0%) and lack of efficacy in the placebo group (13.3%).

The use of lorazepam and zolpidem (permitted during the first 3 weeks of the study) was generally low across groups. Lorazepam use during the study was 5.6% and 9.5% in the 600 and 300 mg/day quetiapine groups, respectively, compared with 8.3% in the placebo group.

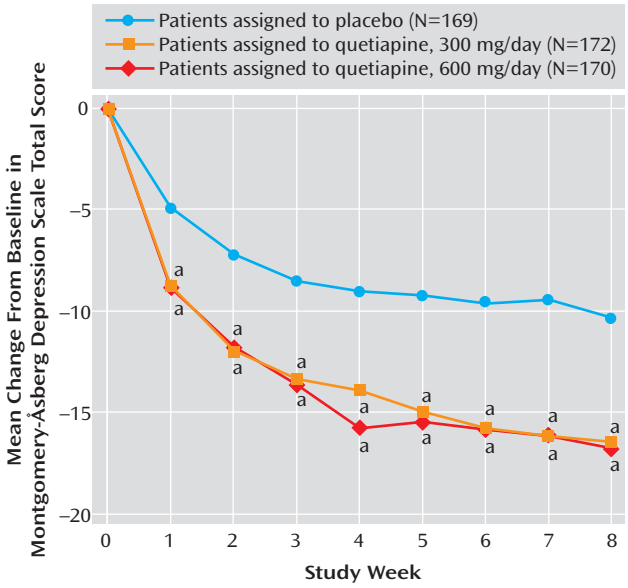
[a] Intent-to-treat analysis.

FIGURE 2. Least-Squares Mean Change From Baseline in Montgomery-Åsberg Depression Rating Scale Total Score at Each Assessment of Outpatients With Bipolar I or II Disorder Who Experienced a Major Depressive Episode[a]



[a] Intent-to-treat, last-observation-carried-forward analyses. Improvement in Montgomery-Åsberg Depression Rating Scale total score with both doses of quetiapine (600 mg/day and 300 mg/day) was significantly greater than placebo at every assessment (p<0.001).

Zolpidem use during the study was 6.7% and 4.5% in the 600 and 300 mg/day quetiapine groups, respectively, compared with 8.3% in the placebo group.

Efficacy

Montgomery-Åsberg Depression Rating Scale. Mean baseline Montgomery-Åsberg Depression Rating Scale scores were 30.3 (SD=5.3), 30.4 (SD=5.0), and 30.6 (SD=5.3) in the 600 mg/day, 300 mg/day, and placebo groups, respectively. Quetiapine at a dose of either 600 or 300 mg/day demonstrated significantly greater mean improvement in Montgomery-Åsberg Depression Rating Scale total scores compared with placebo as early as week 1 and at all time points that followed in the intent-to-treat group of patients with bipolar I or II depression (p<0.001 for both quetiapine doses versus placebo) (Figure 2). The mean change in Montgomery-Åsberg Depression Rating Scale total score from baseline to last assessment was –16.73 in the 600 mg/day group and –16.39 in the 300 mg/day group, compared with –10.26 in the placebo group (p<0.001 for both quetiapine doses versus placebo) (Table 3, Figure 2). The effect sizes were 0.81 for 600 mg/day and 0.67 for 300 mg/day of quetiapine.

Approximately 58% of the patients treated with either dose of quetiapine were responders at the final assessment, and both doses resulted in significantly higher response rates than placebo (36.1%) (p<0.001). Notably, the percentage of patients meeting response criteria with 600 mg/day of quetiapine was significantly higher as early as week 1 (24.3%) versus placebo (10.7%) (p<0.001). In the group taking 300 mg/day of quetiapine, a significantly higher response rate (37.2%) versus placebo (19.5%) was apparent by week 2 (p<0.001). The median time to response was significantly shorter for both 600 mg/day (22 days) and 300 mg/day (22 days) of quetiapine compared with placebo (36 days) (log-rank χ^2=33.1, df=2, p<0.001).

The percentage of patients meeting remission criteria at the final assessment was 52.9% in both the groups taking 600 and 300 mg/day of quetiapine, significantly higher than the placebo rate of 28.4% in each group (p<0.001). The median time to remission was significantly shorter for

TABLE 3. Baseline and Mean Change in Efficacy Measures at the Last Assessment of Outpatients With Bipolar I or II Disorder Who Experienced a Major Depressive Episode[a]

Measure and Treatment	Baseline Score		Change in Score at Last Assessment	Analysis (comparison with placebo)	
	Mean	SD		ANCOVA (df=1)[b]	p

[a] Intent-to-treat, last-observation-carried-forward analyses.
[b] Test, treatment contrast within the framework of the ANCOVA, estimated difference (standard error).

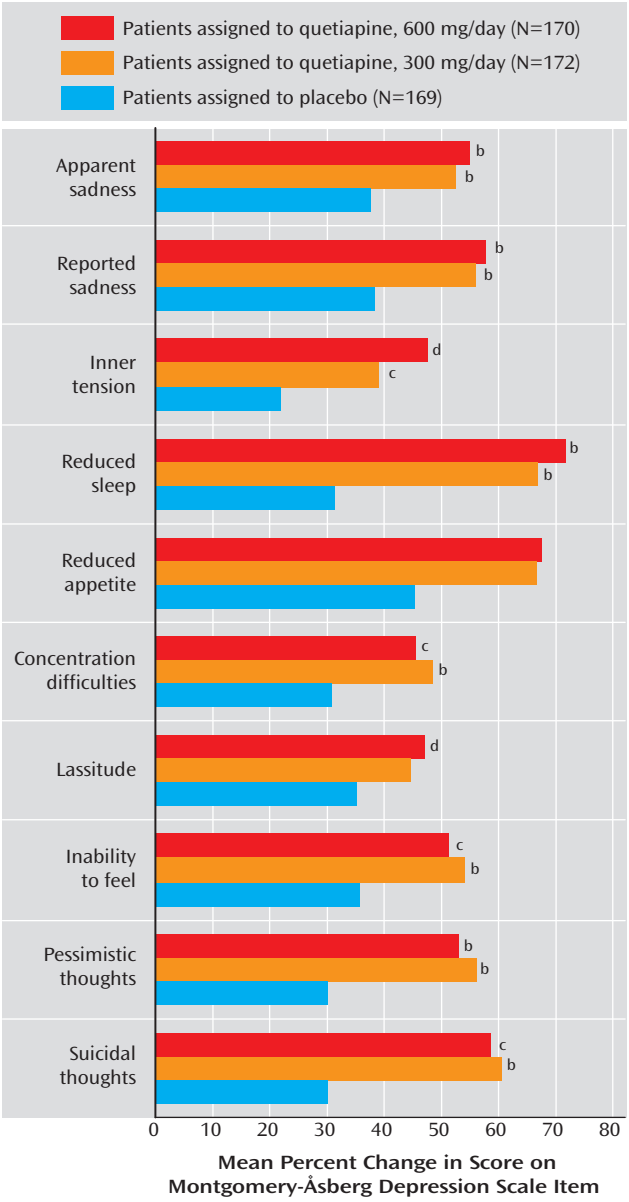
both 600 mg/day (27 days) and 300 mg/day (29 days) of quetiapine compared with placebo (65 days) (log-rank χ^2= 32.8, df=2, p<0.001).

Nine out of 10 Montgomery-Åsberg Depression Rating Scale items were significantly improved from baseline compared with placebo in the 600 mg/day quetiapine group, as were eight items in the 300 mg/day quetiapine group (p<0.05) (Figure 3). With both doses of quetiapine, these items included the core mood symptoms of apparent sadness, reported sadness, inability to feel, pessimistic thoughts, and suicidal thoughts. The core mood symptoms of apparent sadness, reported sadness, and pessimistic thoughts were significantly improved in both quetiapine groups as early as week 1 compared with placebo (p<0.05). An inability to feel and suicidal thoughts were also significantly improved by week 1 in the group taking 600 mg/day of quetiapine compared with placebo (p<0.05). Both doses of quetiapine were more effective than placebo in reducing suicidal thoughts at the final assessment (p≤0.001); the reductions with quetiapine were approximately twice that of placebo.

In the bipolar I subgroup of patients, the mean change in Montgomery-Åsberg Depression Rating Scale total score from baseline to last assessment was –18.05 in the group taking 600 mg/day group of quetiapine and –16.91 in the 300 mg/day group, compared with –9.24 in the placebo group (p<0.001 for both quetiapine doses versus placebo). The effect size in the bipolar I subgroup was 1.09 for those assigned to 600 mg/day and 0.91 for those taking 300 mg/day of quetiapine. In the subgroup of patients with bipolar II disorder, the mean change in Montgomery-Åsberg Depression Rating Scale total score from baseline to last assessment was smaller than in bipolar I patients. Although the change in Montgomery-Åsberg Depression Rating Scale total score from baseline in the patients with bipolar II disorder was statistically superior to placebo at most assessments, it did not reach statistical significance at the final assessment: –14.06 in the group taking 600 mg/day of quetiapine and –14.78 in the group taking 300 mg/day compared with –12.35 in the placebo group. The effect size in the bipolar II subgroup was 0.39 in the 600 mg/day group and 0.28 in the 300 mg/day group.

Significant improvement in Montgomery-Åsberg Depression Rating Scale total scores compared with placebo at the final assessment occurred with quetiapine treatment regardless of the presence of rapid cycling in the intent-to-treat group (patients with bipolar I or II disorder). The mean change in Montgomery-Åsberg Depression Rat-

FIGURE 3. Mean Percent Change From Baseline in Individual Montgomery-Åsberg Depression Rating Scale Items for Outpatients with Bipolar I or II Disorder Experiencing a Major Depressive Episode[a]



[a] Intent-to-treat, last-observation-carried-forward analyses. Nine of 10 and 8 of 10 Montgomery-Åsberg Depression Rating Scale items (including the core mood symptoms of depression [item 1: apparent sadness; item 2: reported sadness; item 8: inability to feel; item 9: pessimistic thoughts; item 10: suicidal thoughts]) were significantly improved from baseline compared to placebo in the groups taking 600 mg/day and 300 mg/day of quetiapine, respectively ($p<0.05$). Apparent sadness, reported sadness, and pessimistic thoughts were significantly improved in both quetiapine groups as early as week 1 compared with placebo ($p<0.05$). Both doses of quetiapine were approximately twice as effective as placebo in reducing suicidal thoughts at the final assessment ($p\leq0.01$).
[b] $p<0.001$ versus placebo.
[c] $p<0.01$.
[d] $p<0.05$.

ing Scale total score at week 8 in the patients with rapid cycling was –17.7 in the 600 mg/day quetiapine group and –18.6 in the 300 mg/day quetiapine group versus –9.9 in the placebo group ($p<0.01$ for both quetiapine doses versus placebo). The mean change in Montgomery-Åsberg Depression Rating Scale total score at week 8 in the patients without rapid cycling was –16.6 in the 600 mg/day group and –15.7 in the 300 mg/day group versus –10.3 in the placebo group ($p<0.001$ for both quetiapine doses versus placebo). A more detailed analysis of patients with and without rapid cycling in this study will be described in a separate report.

In order to explore the role of somnolence or sedation on efficacy, the mean change from baseline in Montgomery-Åsberg Depression Rating Scale total scores in the patients with and without these adverse events were compared. The number of patients in the intent-to-treat group with reported somnolence/sedation was 195 (57%) for the quetiapine groups combined and 24 (14%) for the placebo group. The mean change in the Montgomery-Åsberg Depression Rating Scale total score at week 8 in the patients with somnolence/sedation (either bipolar I or II disorder) was –18.8 in the pooled quetiapine groups (600 or 300 mg/day) versus –18.9 in the placebo group. In the patients without somnolence/sedation, the mean change in the Montgomery-Åsberg Depression Rating Scale total score was –19.3 and –11.7 for in the pooled quetiapine and placebo groups, respectively. The placebo group response was higher in the patients reporting somnolence/sedation, but the results with quetiapine were similar in the patients with or without somnolence/sedation.

Hamilton depression scale. Mean baseline Hamilton depression scale scores were 24.7 (SD=3.5), 24.5 (SD=3.0), and 24.6 (SD=3.3) in the 600 mg/day, 300 mg/day, and placebo groups, respectively (Table 2). Quetiapine at a dose of either 600 or 300 mg/day demonstrated significantly greater mean improvements in Hamilton depression scale total scores compared to placebo as early as week 1 and at all time points that followed in the patients with bipolar I or II depression ($p<0.001$). The mean change from baseline in Hamilton depression scale scores at week 8 was –13.84, –13.38, and –8.54 in the 600 mg/day, 300 mg/day, and placebo groups, respectively ($p<0.001$ for both quetiapine doses versus placebo). At the end of the study, the effect sizes for the group of patients with bipolar I or II disorder with the Hamilton depression scale was 0.93 for 600 mg/day and 0.74 for 300 mg/day of quetiapine.

Significant improvement in the Hamilton depression scale item 1 (depressed mood) was as early as week 1 ($p=0.003$) for both quetiapine doses and continued to be statistically superior to placebo at all time points.

Clinical Global Impression. Quetiapine-treated patients experienced a statistically significant improvement ($p<0.001$) on the CGI severity scale as early as week 1 that was sustained to the end of the study for both quetiapine doses versus placebo. At the final assessment, a larger percentage of patients were rated as "normal, not at all ill," or

TABLE 4. Incidence and Withdrawals Because of Adverse Events Occurring in at Least 10% of the Patients in Any Group of Outpatients with Bipolar I or II Disorder Who Experienced a Major Depressive Episode

	Patients Taking 600 mg/day of Quetiapine (N=180)				Patients Taking 300 mg/day of Quetiapine (N=179)				Patients Taking Placebo (N=180)

[a] Significantly higher than placebo ($p<0.05$).

"borderline ill" in the 600 mg/day (42.4%) and 300 mg/day quetiapine groups (38.1%) compared with the placebo group (23.7%).

A larger percentage of patients was also rated as "much" or "very much" improved on the CGI improvement scale in the 600 mg/day (55.9%) and 300 mg/day quetiapine groups (64.0%) compared with the placebo group (34.3%) at the final assessment.

Anxiety symptoms. Mean baseline Hamilton anxiety scale scores were 18.7 (SD=7.3), 18.7 (SD=7.3), and 18.9 (SD=7.3) in the 600 mg/day, 300 mg/day, and placebo groups, respectively (Table 2). By the study end, the mean Hamilton anxiety scale total score had decreased by –8.75 in the 600 mg/day group, –8.64 in the 300 mg/day group, and –5.54 in the placebo group ($p<0.001$ for both quetiapine doses versus placebo). A significant improvement in the Hamilton anxiety scale total scores as early as week 1 ($p<0.05$) was maintained to the last assessment ($p<0.001$ for both quetiapine doses versus placebo). Individual items of the Hamilton anxiety scale that most differentiated quetiapine-treated patients from those who received placebo included anxious mood, depressed mood, insomnia, genitourinary symptoms, and tension. A more detailed analysis of the results of the effect of quetiapine on anxiety measures in this study has been presented in a separate report (35).

Quality of sleep. The quality of sleep improved significantly among those treated with either dose of quetiapine compared with placebo. The mean improvement in Pittsburgh Sleep Quality Index scores from baseline in patients treated with 600 mg/day (–5.46) and 300 mg/day (–5.16) of quetiapine was significantly greater with both doses ($p<0.001$) than with placebo (–2.94).

Quality of life. Quetiapine-treated patients also experienced statistically significant improvements in quality of life during the study, as determined by the change from baseline in the Quality of Life Enjoyment and Satisfaction Questionnaire total scores. Mean Quality of Life Enjoyment and Satisfaction Questionnaire total scores improved by 11.71 by the last assessment among patients treated with 600 mg/day of quetiapine and by 10.77 among those treated with 300 mg/day of quetiapine, compared with 6.44 in the placebo group ($p<0.001$ for both quetiapine doses versus placebo).

Safety and Tolerability

Adverse events. Common adverse events (whether or not considered treatment related) occurred in ≥10% of patients, and withdrawals due to common adverse events are shown in Table 4. The overall rate of study discontinuation due to adverse events was 26.1% (N=47) in the 600 mg/day group, 16.0% (N=29) in the 300 mg/day group, and 8.8% (N=16) in the placebo group (Figure 1). There were no significant differences in the rates of serious adverse events across treatment groups, and none was treatment related: 5.0% (N=9) in the 600 mg/day group and 3.4% (N=6) in the 300 mg/day group compared with 8.9% (N=16) in the placebo group. Two patients attempted suicide (one in each of the active treatment groups), but no suicides or deaths occurred during the study.

The rate of discontinuation due to adverse events in the subgroup of patients with bipolar I disorder was 23.3% (N=28) in the 600 mg/day group, 13.1% (N=16) in the 300 mg/day group, and 11.9% (N=14) in the placebo group. The incidence of serious adverse events in the subgroup of patients with bipolar I disorder was 5.0% (N=6) in the 600 mg/day group, 4.2% (N=5) in the 300 mg/day group, and 11.9% (N=14) in the placebo group.

In the subgroup of patients with bipolar II disorder, the rate of discontinuation due to adverse events was 31.7% (N=19) in the 600 mg/day group, 22.0% (N=13) in the 300 mg/day group, and 3.2% (N=2) in the placebo group. The incidence of serious adverse events in the subgroup of patients with bipolar II disorder was 5.0% (N=3) in the 600 mg/day group, 1.7% (N=1) in the 300 mg/day group, and 3.2% (N=2) in the placebo group.

The incidence of treatment-emergent mania was low and not significantly different from placebo at either quetiapine dose: 2.2% with 600 mg/day of quetiapine (Cochran-Mantel-Haenszel, odds ratio=0.57, 95% confidence interval (CI)=0.17–1.91, p=0.35), 3.9% with 300 mg/day of quetiapine (Cochran-Mantel-Haenszel, odds ratio=0.97, 95% CI=0.35–2.68, p=0.95), and 3.9% with placebo.

The mean Simpson-Angus Rating Scale total score decreased in all three groups from baseline to the final assessment by –0.1, –0.2, and –0.3 in the 600 mg/day and 300 mg/day quetiapine groups and the placebo groups, respectively. There was no statistically significant difference in the number of patients with an increase from baseline in Simpson-Angus Rating Scale scores between either of the quetiapine groups and placebo: 15% (logistic regression=0.66, df=3, p<0.08), 9% (logistic regression=0.06, df=3, p=0.89), and 9% in the 600 mg/day and 300 mg/day quetiapine and placebo groups, respectively.

At the last assessment, mean Barnes Rating Scale for Drug-Induced Akathisia scores were low and similar in all groups: 0.3 in the 600 mg/day group, 0.2 in the 300 mg/day group, and 0.1 in the placebo group. There was no statistically significant difference in the number of patients with an increase from baseline in Barnes Rating Scale for Drug-Induced Akathisia score between either of the quetiapine groups and placebo: 12% (logistic regression=0.39, df=3, p=0.31), 9% (logistic regression=0.06, df=3, p=0.89), and 9% in the 600 mg/day and 300 mg/day quetiapine and placebo groups, respectively.

Adverse events considered extrapyramidal symptoms were present in 8.9% of the 600 mg/day group, 6.7% of the 300 mg/day group, and 2.2% of the placebo group; discontinuation rates for extrapyramidal symptoms were 2.8%, 1.1%, and 0.6%, respectively.

Laboratory Results and Vital Signs

No clinically relevant differences between groups were seen in the mean change from baseline for any vital signs, ECGs, hematology, or clinical chemistry parameters.

Patients treated with 600 mg/day of quetiapine experienced a mean weight gain of 1.6 kg by the final assessment compared with 1.0 kg in the 300 mg/kg group and 0.2 kg in the placebo group. At the final assessment, 16 patients (9.0%) treated with 600 mg/day of quetiapine, 15 patients (8.5%) treated with 300 mg/day of quetiapine, and three patients (1.7%) who received placebo had a weight gain of ≥7% of their baseline measurement. No patients withdrew from the study because of weight gain.

Mean fasting serum glucose levels at baseline were 86 (SD=12), 87 (SD=13), and 87 (SD=15) mg/dl in the 600 mg/day and 300 mg/day of quetiapine and placebo groups, respectively. By the final assessment, the mean change in fasting serum glucose was 6 mg/dl (SD=17), 3 mg/dl (SD=13), and 4 mg/dl (SD=26) in the 600 mg/day and 300 mg/day of quetiapine and placebo groups, respectively.

Discussion

To our knowledge, this is the first randomized, parallel-group, placebo-controlled trial to evaluate the efficacy of quetiapine in bipolar depression. It may also be the first published large-scale, controlled study to assess the efficacy of any pharmacological treatment in a group of patients with bipolar I or II depression, and one of few studies to examine an antidepressant effect in patients with rapid cycling.

Quetiapine monotherapy has significant antidepressant efficacy in a group of patients with bipolar I or II depression based on the primary efficacy analysis (mean change in Montgomery-Åsberg Depression Rating Scale total score from baseline to last assessment). The magnitude of the clinical improvement was substantial and evident from the first assessment (week 1) and at each visit thereafter. The rates of response and remission and the time to response and remission were significantly improved in the quetiapine groups compared with placebo. Compared with placebo, evidence of early and sustained efficacy was observed consistently with both doses of quetiapine and in all secondary efficacy analyses from week 1 onward.

In the Montgomery-Åsberg Depression Rating Scale item analysis, both doses of quetiapine produced a significant and early improvement in all of the core mood symptoms of depression, including objective and reported sadness, anhedonia, and pessimistic thoughts. Notably, both doses of quetiapine were approximately twice as effective as placebo in reducing suicidal ideation. These findings provide support for the conclusion that quetiapine has specific antidepressant properties.

In this study, significant antidepressant efficacy was demonstrated for quetiapine dosed once a day in the evening. This has important clinical relevance because once-daily dosing has been associated with enhanced medication adherence (36). Dosing at bedtime may also offer a means of improving tolerability, particularly regarding somnolence or sedation that are sometimes seen with quetiapine and may help treat the sleep disturbance that often accompanies bipolar depression.

Both doses of quetiapine were associated with improvements in quality of sleep and quality of life and were effective in patients with a recent history of rapid-cycling bipolar disorder. Exploratory analyses suggest that the clinical effect of both doses of quetiapine was greater in patients with bipolar I disorder than those with bipolar II disorder.

The most common side effects of quetiapine included dry mouth, sedation, somnolence, dizziness, and constipation. The most common side effects leading to withdrawal from the study were sedation and somnolence, with most discontinuations occurring within the first week. Of importance, changes in weight observed in all three groups were relatively small and did not result in withdrawal from the study. Quetiapine treatment was not associated with treatment-emergent mania. The long-term safety of quetiapine

is being explored in ongoing bipolar disorder maintenance studies. However, data from patients with schizophrenia does not suggest that unexpected adverse effects during long-term treatment should be expected (37).

Several aspects of the design of this study were innovative. First, the inclusion of patients with bipolar II disorder into a large-scale study of acute bipolar depression was novel and enhanced the generalizability of the findings, particularly since there is a higher incidence of bipolar II disorder than bipolar I disorder. The inclusion of patients with rapid cycling was also innovative and enhanced the generalizability of the findings to this difficult-to-treat subgroup. Second, rather than focusing solely on depressive symptoms, this study included sleep quality and health-related quality-of-life measures. Sleep-quality assessments (both patient- and bed-partner-rated) indicated improvements in functioning in addition to symptom severity, including several dimensions of sleep quality and daytime dysfunction. The quality-of-life scale provided novel information regarding the effect of quetiapine on social relationships, living/housing arrangements, physical health, satisfaction with medication, and global satisfaction. Improvements in these measures provide evidence for improved function and overall quality of life in addition to reduction in the symptoms of the illness.

Moreover, the inclusion of analyses that quantify the magnitude of the clinical effect through effect size determinations gives clinicians useful information. Knowing if a significant difference is caused by a small clinical effect (<0.4), a moderately sized clinical effect (0.40–0.79), or a large clinical effect (>0.79) has the potential of helping the clinician make decisions on how to use a new medication (38). The effect sizes reported in the bipolar I depression study by Tohen et al. (14) were 0.32 with olanzapine monotherapy and 0.68 with olanzapine-fluoxetine combination therapy compared with 1.09 in the bipolar I subgroup with 600 mg/day of quetiapine in this study.

This study had several limitations. First, the number of enrolled patients with bipolar II disorder was not sufficient to draw firm conclusions regarding efficacy in this subgroup. For this reason, post hoc analyses conducted in the bipolar II subgroup included effect size determinations, which are less affected by sample size than significance testing. Second, moderate rates of sedation or somnolence were observed in both quetiapine groups, which might have compromised the integrity of the double-blind design. If this were a significant factor in the assessment of efficacy, the reduction in Montgomery-Åsberg Depression Rating Scale total score in patients experiencing sedation or somnolence would have been greater than those in patients not experiencing these adverse events. However, this was not the case, and the improvements observed on the Montgomery-Åsberg Depression Rating Scale were comparable in patients with or without sedation or somnolence. Third, although the study indicated that the two doses used—chosen because of their efficacy in bipolar mania and other disorders—were effective, guidance on the best dosing for most patients or subgroups of patients should be assessed in future studies.

In conclusion, this large, randomized, double-blind, placebo-controlled study provides the first pivotal data demonstrating that quetiapine monotherapy is efficacious and well tolerated for the acute treatment of bipolar depression in a group of patients with bipolar I or II disorder.

REVIEW

Is Lithium Still Worth Using? An Update of Selected Recent Research

Ross J. Baldessarini, MD, Leonardo Tondo, MD, John Hennen, PhD, and Adele C. Viguera, MD

The treatment of bipolar disorder has seen greater innovation in the past decade than at any other time since the introduction of lithium and the neuroleptics a half-century ago. The place of lithium in contemporary psychiatric therapeutics has become controversial, calling for the present overview of research findings pertaining to its use in treating patients with bipolar disorder. Lithium, by itself, typically is inadequate for rapid control of acute mania; antipsychotics, divalproex, or potent sedatives are commonly used, with or without lithium, for this purpose. The special usefulness of lithium lies in long-term prevention of recurrences of mania and bipolar depression and in reducing risk of suicidal behavior. Lithium also may be beneficial in recurrent unipolar depression and is an effective adjunct for treatment-resistant depression. Expectations that prolonged untreated bipolar illness, multiple episodes, rapid cycling, or retreatment following discontinuation might routinely lead to lithium nonresponsiveness, and the belief that lithium is too toxic for use during pregnancy, have not been borne out by research. Lithium retains a substantial share of prescriptions for bipolar disorder and is inexpensive. No other treatment has performed as well as lithium in as many aspects of long-term care of bipolar disorder patients, and despite some risks and limitations, lithium remains the standard against which all proposed alternatives are compared. (HARVARD REV PSYCHIATRY 2002;10:59–75.)

Preparations of lithium salts (carbonate immediate and slow-release tablets, citrate liquid) have been the mainstay in long-term maintenance treatment for bipolar disorder patients since the 1960s,[1–5] following discovery of the antimanic actions of lithium carbonate by John Cade in Melbourne in 1949.[6] Bipolar disorder affects more than 1% of the general population, and its lifetime prevalence may exceed 5% if both current standard diagnostic subtypes (types I [with mania, usually also with depression] and II [depression with hypomania]), as well as cyclothymia, are considered, and particularly if pediatric, geriatric, and milder forms are included.[2,7–13] Moreover, bipolar and other major affective disorders with psychotic features are the most common idiopathic psychotic illnesses.[7,14]

There is growing recognition of the major therapeutic challenges and pharmaceutical opportunity represented by

From the Department of Psychiatry, Harvard Medical School, Boston, Mass., the Bipolar and Psychotic Disorders Program of McLean Hospital, Belmont, Mass., and the International Consortium for Bipolar Disorder Research, Belmont, Mass.

Supported, in part, by NIMH grant MH-467370, a grant from the Bruce J. Anderson Foundation, and the McLean Private Donors Neuropharmacology Research Fund (Dr. Baldessarini), as well as by an Investigator Award from NARSAD and an International Center Grant from the Stanley Foundation (Dr. Tondo).

Dr. Baldessarini consults to corporations that market lithium preparations (Solvay and Glaxo-SmithKline) and other antimanic agents (Eli Lilly, Janssen, Protarga).

Some of this material is also presented at a McLean Hospital CME Internet site.

bipolar disorder. There is also a wish to improve on results obtained with lithium while minimizing the risks attending its use and reducing the need for close medical monitoring to maintain effective serum concentrations of lithium and avoid adverse effects, discussed below.[3,6] Such considerations have stimulated unprecedented innovation in the therapeutics of the disorder over the past decade. This development includes clinically valuable new applications of anticonvulsant, antipsychotic, sedative, and antidepressant drugs.[5,15] Marketing of newer antimanic medicines and proposed mood-stabilizing agents greatly disfavors lithium—an inexpensive, unpatentable inorganic salt. Indeed, many American psychiatrists appear increasingly disinclined to consider lithium as the expert-recommended, first-line option for bipolar disorder patients that it is.[2,5,15,16]

The view that lithium should no longer be considered a primary treatment has been encouraged by evidence that many cases of bipolar disorder involve severe, chronic, disabling illness with clinically unsatisfactory response to any available treatment or combination of treatments.[2,3,5,14,16,17–20] But high risks of treatment failure with lithium and alternative therapies can arise from several sources, including inconsistent adherence to recommended long-term treatment, particularly when symptoms are in apparent remission or the patient has comorbid common substance abuse problems; disinclination to accept adverse effects such as weight gain and minor cognitive dulling; inadequate clinical supervision of treatment with an agent that has an unusually narrow margin of safety, requiring regular medical monitoring and blood testing; and inadequate interpersonal support and encouragement of adherence to long-term treatment.[21–24] Moreover, the proportion of bipolar disorder patients followed at specialized referral centers who have relatively treatment-resistant (or otherwise complex and challenging) illness is probably growing, adding further to the impression that neither lithium nor other treatments for bipolar disorder yield consistently satisfactory results in some individuals.[17,22]

A realistic assessment of current clinical knowledge of the utility of lithium in the treatment of bipolar disorder is needed. This overview aims to provide such an assessment, while emphasizing pertinent results of recent investigations of lithium treatment by the International Consortium for Bipolar Disorder Research.

EFFICACY OF LITHIUM IN ACUTE MANIA

The introduction of lithium carbonate by Cade in 1949 can be considered to have heralded the modern era of psychopharmacology.[6,25] The recent fiftieth anniversary of Cade's discovery stimulated new interest in lithium and provided the occasion for several reviews of research on this agent.[5,26–33] Lithium was introduced for the treatment of acute mania and has continued since the 1970s to be recognized by the U.S. Food and Drug Administration (FDA) only for mania (1970) and unspecified recurrences (presumably, of mania) in bipolar disorder (1974).[34] The short-term efficacy of lithium in acute mania is supported by at least five placebo-controlled trials.[30] However, all but one[35] followed a cross-over design and involved short treatment-exposure times, and recovery rates were only twice the surprisingly high 25–35% associated with placebo and nonspecific clinical management.[29,36]

Comparisons of lithium and antipsychotic drugs in acute mania indicate that clinically useful control of manic behavior is more rapid with antipsychotics, but otherwise lithium and antipsychotics are similar in efficacy.[5,26,27,29,30,36] Rapid response has also been observed with apparently safe loading doses of divalproex,[37] although possibly not with more-conservative dosing.[35,38] Similarly rapid quieting effects can be obtained with high doses of potent benzodiazepines such as lorazepam and clonazepam.[39–41] Whether these early effects with agents other than lithium represent "true antimanic" actions or merely sedation continues to be debated. Nevertheless, the requirement for caution in safe dosing with lithium in acute mania, together with contemporary economic pressures to minimize hospitalization, has strongly encouraged initial use of antipsychotic, anticonvulsant, and sedative agents, with or without lithium, for practical clinical management of acute mania, commonly followed by lithium in a prominent role for aftercare.[5,30]

REVIEW OF LONG-TERM EFFECTIVENESS OF LITHIUM IN BIPOLAR DISORDER

Clinically, the most important application of lithium treatment is to reduce long-term risk of recurrences of illness in bipolar disorder.[5,31] Lithium treatment is usually continued following early recovery from an acute episode of mania or bipolar depression to minimize the high risk of early relapse.[2,5,15–17,22,29,31,42] In addition, it is standard practice to recommend prolonged maintenance or prophylactic treatment and continued psychiatric supervision in most cases after two or more recurrences, particularly when dangerous behavioral dyscontrol, suicide attempts, or hospitalization is involved.[2,3,5,31–33,43] This practice is similar to what is done following several recurrences of major depression[4,44] and is supported by unusually abundant research evidence.[3,5,24,27–29,31–33] To place the available findings in a broad perspective, we carried out a meta-analysis of available research trials of lithium treatment.

Methods

Relevant publications were identified through a computerized *Medline* literature search (search terms: "bipolar disorder," "lithium," "manic-depressive disorder") and by examining the reference lists in the studies thus located and the

reviews cited above. In these studies, we compared the recurrence risks with versus without lithium maintenance treatment in bipolar disorder. Recurrence risk ratios and their standard error estimates were calculated for each study, based on Poisson regression methods with adjustment for exposure time. For studies involving the same subjects on and then off lithium, standard errors for the risk ratios were adjusted for estimated covariance within subjects. Risk ratios were summarized using the meta-analytic methods recommended by DerSimonian and Laird.[45] Interstudy heterogeneity of risk ratios was estimated with Q-statistics.[45] To estimate pooled rates and their 95% confidence intervals (CIs), we used a random-effects estimator employing weights based on the inverse of study variances plus a between-studies variance factor.[45] Rate data are reported as mean ± standard deviation or with CI. Statistical significance required two-tailed $p < 0.05$.

Results

We found a total of 28 pertinent studies with interpretable data[46–73] (see Table 1; when multiple reports have appeared from the same study, only the most recent or largest case series is included here). Many investigations included persons with types I and II bipolar disorder and recurrent, typically melancholic or endogenomorphic, major depression—within the broad syndrome of manic-depressive illness as originally defined by Emil Kraepelin a century ago.[13] The proportion of subjects with bipolar disorder for each study is indicated in the table.

The 28 studies involved a total of 2985 different subjects (some observed both with and without lithium treatment), 59.6% of whom were female. Subjects were exposed for an average of 9.94 ± 4.27 years (5.88 ± 5.26 years in 2351 patients with lithium, and 4.10 ± 3.42 years in 2308 patients without lithium), for a total experience of 23,263 person-years. The great majority of subjects (78.4%) were diagnosed with bipolar disorder. There was no significant tendency for bipolar cases to be more prevalent in more recent studies (Spearman $r_s = 0.28, p = 0.14$). A higher proportion of the 23 studies reporting such information up to 1980 (15/15 = 100%) versus later (2/8 = 25%) selected cases for relatively high or recent morbidity (χ^2 [1 df] = 14.4, $p < 0.0001$). This body of investigation into long-term treatment with or without lithium in bipolar disorder far exceeds—in studies, subjects, and exposure times—that available for any other treatment of the condition.[5]

Numerical results varied substantially among the studies, but in all 28 trials, recurrence risk was lower during lithium treatment; the overall crude risk ratio for recurrence was 3.2-fold lower with lithium than without. Among studies involving at least 1 year of lithium treatment and samples of more than 50 patients mainly with bipolar disorder, the sparing of risk ranged from 96% in an early study[48] to only 20% in a recent trial designed primarily to test for the effectiveness of divalproex.[72] By meta-analysis (see Figure 1) based on recommended random-effects-modeling methods,[45] the computed overall risk ratio, and its CI, without versus with lithium was 3.2 (2.7–3.8), with a great heterogeneity of results across studies (Q [25 df] = 9700, $p < 0.0001$).

Effectiveness of lithium maintenance was quite stable over the entire era represented by the studies analyzed. Even though recent maintenance studies have evidently included fewer severely ill persons, recurrence rates during lithium treatment have not changed significantly since the 1960s ($r_s = 0.20, p = 0.30$). This lack of evidence of a secular change involving loss of treatment effectiveness over the years accords with previous analyses of some of this literature[17,22,73,74] and with studies of outcomes at two European centers for treatment started across several decades.[17,75]

The 28 studies reviewed varied greatly in size (5–375 subjects), duration (0.5–146 months), and design (open studies comparing recurrences before vs. during treatment; randomized, blinded, placebo-controlled, parallel-group trials; and others). However, more than half (57%) involved blinded observations, and 50% included a placebo condition (39% also involved prospective randomization to lithium vs. a placebo in parallel groups). Studies with and without blind assessment showed very similar reductions in recurrence risk (61.4 ± 27.2% [n = 16 trials] vs. 67.6 ± 19.2% [n = 12], respectively; F [1; 26 df] = 0.44, $p = 0.51$), as did trials with or without randomized, parallel-group designs (58.3 ± 25.3% [n = 11] vs. 67.8 ± 22.8% [n = 17], respectively; F [1; 26 df] = 1.07, $p = 0.31$). The weighted-average reduction of recurrence risk by 3.6-fold among the 11 parallel-group trials was similar to both the crude and computed risk ratios found across reports (both 3.2). Another selective, quantitative meta-analysis involving nine randomized, placebo-controlled trials of long-term lithium treatment[32] also found a computed inverse risk ratio of 0.29 (95% CI = 0.09–0.93), or approximately 3.4-fold lower risk with lithium.

At least half of the studies analyzed involved discontinuation of ongoing lithium treatment in some subjects, typically to provide a placebo-control condition. Treatment discontinuation might itself inflate drug-placebo differences in studies of lithium[76–82] and many other treatments,[44,81–85] particularly within the first few months following discontinuation. The clinical impact of treatment discontinuation can be limited substantially by slowly lowering the dose over at least several weeks.[76–83] Such gradual discontinuation of ongoing treatment is rarely included in trial designs.[81–83] However, a recent, well-designed multicenter trial comparing divalproex to lithium and placebo for 52 weeks of maintenance treatment in patients with bipolar I disorder featured an initial dose-tapering period over 2 weeks following treatment of acute mania.

TABLE 1. Summary of Major Studies of Long-term Effectiveness of Lithium Maintenance Treatment in Bipolar Disorder

Study	n	Number		% F	High risk[a]	Bipolar (%)[b]	Study design	Lithium discontinued	Months		Episodes/100 person-years		Risk ratio	% Spared

d/c, discontinued; *F,* female; *Pbo,* placebo; *pre/on,* before and during treatment with lithium.
[a]Based on recent history of episodes or hospitalizations.
[b]Bipolar disorder, recurrent mania, or schizoaffective disorder.
[c]Rates based on *persons* with at least one recurrence/100 person-years at risk; otherwise rates are *episodes*/100 person-years at risk.
[d]All subjects were mentally retarded and institutionalized.
[e]May include some subjects from Prien et al.[56]
[f]Bipolar II disorder only.
[g]Placebo controls only for patients with unipolar depression.
[h]Also involved placebo-controlled, 1-month discontinuation with recurrence rate of 720/100 person-years.
[i]Included 187 other subjects maintained on divalproex, at a failure rate of 24.1 episodes/100 person-years.
[j]Weighted by n/study-arm.
[k]Omits two studies[51,66] with less than 1 month observation off-lithium.

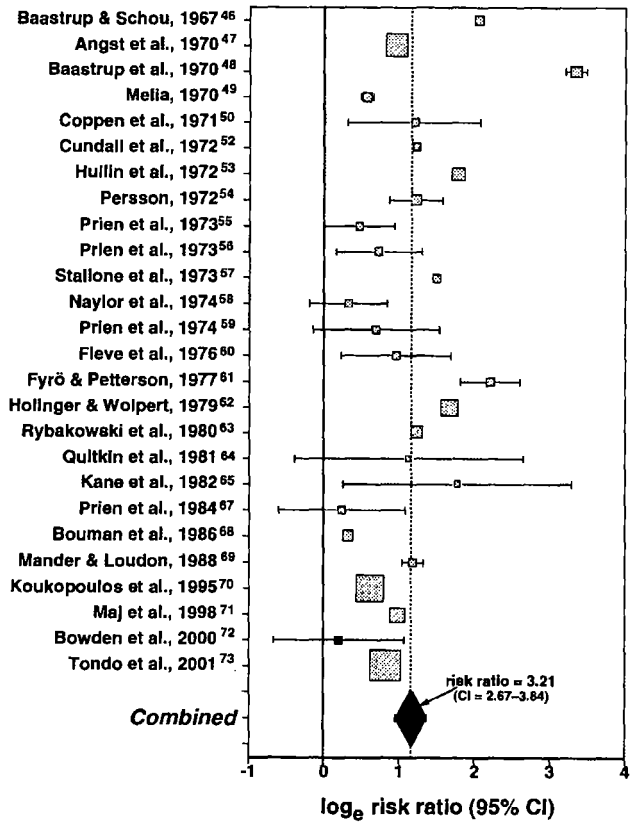

FIGURE 1. Meta-analysis of studies of the ratio of recurrence risk off/on lithium maintenance treatment. Data are the natural logarithm ($\log_e$) of risk ratio and its 95% confidence interval (CI) computed by random-effects modeling, with symbol size (shaded boxes) proportional to weighting by subject count (proportion of n in each study to combined n) and between- vs. within-study variance. The 26 studies included are those summarized in Table 1, minus two small studies having very short observation times off-lithium.[51,66] The computed overall risk ratio (black diamond) of 3.21 (CI = 2.67–3.84) is highly significant (z [25 df] = 12.6, $p < 0.0001$) and similar to the crude average ratio of 3.20 (see Table 1). Findings across studies are highly significantly heterogeneous (Q [25 df] = 9700, $p < 0.0001$).

The phenomenon of excessive early recurrence risk soon after discontinuing or even sharply reducing the dose of lithium, especially if this is done rapidly or abruptly,[81–83] could have had at least a quantitative impact on about half of the trials reviewed, although it seems very unlikely to account for the entire difference in recurrence risk with versus without lithium treatment.[86,87] Among the 25 studies indicating whether discontinuation was involved (n = 14) or not (n = 11), the mean reductions of recurrence risk with versus without lithium treatment are indistinguishable (66.1 ± 28.5% vs. 64.4 ± 16.8%; F [1; 23 df] = 0.03, $p = 0.86$). Of critical importance, even the recurrence rates *off* lithium were not significantly higher in studies involving lithium discontinuation (F [1; 21 df] = 1.62, $p = 0.22$), although they were more variable (418 ± 686 episodes/100 person-years [coefficient of variation, 164%]) than those found in trials apparently not involving lithium discontinuation (123 ± 99.8 episodes/100 person-years [coefficient of variation, 81%]).

Several studies[3,31,53,54,56,63] compared treatment responses in subjects with bipolar and unipolar depression and reported minor or inconsistent outcome differences between these syndromes. Nevertheless, whether lithium is equally effective against recurrences of mania and depression in bipolar disorder and recurrence of nonbipolar depression remains unclear.[2,3,5,24,27,28,31–33] When we divided the 28 studies according to the proportion of subjects in them who had bipolar disorder (15 studies in which at least 75% of subjects had bipolar disorder vs. 13 in which this percentage was lower), we found very similar outcomes. These include sparing of recurrence risk by 63.4 ± 25.5% versus 64.8 ± 22.9%, respectively (F [1; 26 df] = 0.02, $p = 0.88$). Even the five trials involving only a minority of bipolar patients (<50%)[54,56,64,65,67] yielded a similar sparing of recurrences (by 58.8 ± 34.0%).

Although the recurrence-sparing effect associated with long-term lithium treatment was both large and consistent, it was far from complete. The estimated overall reduction of recurrence risk was 54.9%, over 5.9 years of treatment-exposure. This incomplete protection may reflect variable long-term compliance by patients, variable intensity of follow-up and monitoring by treating clinicians, or limitations in effectiveness of the treatment for a severe disorder with a strong tendency toward recurrence.[2,5,15–17,22,24,27–29,31–33,42] It is also important to emphasize that no alternative treatment or combination of treatments has been proved to provide equivalent long-term protection against the risk for recurrences of bipolar disorder.[2,5,15–17,29,31,72]

This large body of diverse investigations is strikingly consistent in showing a substantial, albeit incomplete, lowering of recurrence risk for mania and depression in patients with bipolar disorder or nonbipolar depression. Nevertheless, several important issues remain unresolved in the studies analyzed. These include whether lithium protects against mania more than recurrent depression (in bipolar subtypes or in nonbipolar depressive disorders) and to what extent illness duration and overall morbidity are altered in addition to recurrence frequency.

SARDINIAN STUDIES ON THE EFFECTS OF LITHIUM TREATMENT ON MANIA AND BIPOLAR DEPRESSION

Overall Treatment Effects

Additional information about the relative effectiveness of lithium maintenance treatment in manic and depressive phases in both types I and II bipolar disorder is provided by

TABLE 2. Effects of Lithium Maintenance Treatment in 360 Patients with Bipolar Disorder[a]

Measure	Before treatment	During treatment	% Decrease
All patients			
Duration (y)	8.83 ± 8.38	4.49 ± 4.10	—
Hospitalizations/y	0.33 ± 0.86	0.06 ± 0.22	82

% Time depressed	32.6 ± 21.4	13.0 ± 18.1	60
No recurrences (%)		45.1	—

[a]Results are based on new data and updated earlier findings presented elsewhere.[72,87] Data are shown as mean ± SD. All differences are significant (all paired t-tests ≥ 4.0, two-tailed $p < 0.001$, with correction for multiple comparisons).

results obtained with 360 patients with these conditions treated at a collaborating Sardinian clinic directed by a coauthor (LT). These subjects, unselected other than for meeting DSM-IV diagnostic criteria for bipolar I or bipolar II disorder, were evaluated for periods before (mean, 8.8 years) and during (mean, 4.5 years) lithium maintenance treatment (see results in Table 2). Lithium was used essentially as a monotherapy. Longitudinal data were acquired in regular clinical follow-up, using detailed, life-chart–based assessments, according to methods detailed previously.[73,88]

Substantial reductions were found in recurrences of bipolar illness with lithium maintenance treatment; these results were very similar to the average for all studies (56% vs. 55% sparing of risk, respectively). Total recurrence rates averaged 1.83 episodes per year before versus 0.81 episodes per year during treatment. This overall reduction in recurrence risk was associated with an even larger (82%; from 0.33 to 0.06/year) sparing of hospitalizations. The recurrence rates for mania or hypomania fell by 64% (from 0.99 to 0.36/year), and those for depression by 46% (from 0.84 to 0.45 episodes/year), suggesting only a moderately smaller benefit against bipolar depression than against mania. These differences are all highly statistically significant (all $p < 0.001$ by paired t-tests corrected for multiple comparisons).[73] Notably, however, full protection (zero recurrences) was attained in only 33% of subjects.[73] This experience accords with rates of full protection reported in other long-term studies of lithium treatment.[24,70,71]

Of the available morbidity measures, data on the proportion of days ill per year during versus before maintenance treatment are particularly important clinically. By this measure, there was an overall 56% reduction of bipolar morbid-

ity, from 45.7 to 19.9% of days ill.[73] For mania and hypomania, the morbidity scores fell by 61%, from 20.9 to 8.11%. For depression, they fell by 53%, from 24.8 to 11.7%, only slightly less than for mania/hypomania.

In addition to reduced recurrence rates and time ill, there was also a 25% reduction in the average duration of episodes among patients who suffered recurrences—from 4.03 months before treatment to 3.04 months during treatment. Episodes of mania/hypomania were shortened by 22%, from 3.17 to 2.48 months, and episodes of bipolar depression by 33%, from 4.80 to 3.23 months. These findings are particularly noteworthy, given the greater average duration of depressive than of manic episodes (4.8 vs. 3.2 months) before treatment, the somewhat higher proportion of time ill with depression than with mania (24.9% vs. 20.9%) before lithium, and the strong association of the depressive phase of bipolar disorder with both subjective distress and suicidal behavior. These results are consistent with data from other studies of the treatment of bipolar depression.[73,88–91]

Effects of Lithium in Bipolar Disorder Subtypes

Previously unpublished Sardinian findings distinguished between patients with type I (n = 218) and type II (n = 142) bipolar disorder. Long-term lithium treatment reduced morbidity in both syndromes. Overall, episode frequency in patients with bipolar I disorder fell by 47%, from 1.54 to 0.82 episodes per year. In patients with type II bipolar disorder, this rate fell even more (by 65%), from 2.28 to 0.79 episodes per year. Moreover, overall percentage of days ill fell by 50% (from 43.4 to 21.9%) in patients with bipolar I disorder, compared to a decrease of 67% (from 49.3 to 16.5%) in those with type II.

The effects of lithium treatment were even greater on recurrences of hypomania in patients with bipolar II disorder than on recurrences of mania/hypomania in those with type I. Recurrence rates fell by 52% (from 1.00 to 0.48 manic or hypomanic episodes/year) in subjects with bipolar I disorder, but by 81% (from 0.98 to 0.19 hypomanic episodes/year) for those with bipolar II disorder. In addition, the proportion of days manic or hypomanic fell by 53% (from 23.6% to 11.2%) in type I patients, whereas proportion of days hypomanic decreased by 80% (from 16.7% to 3.4%) in type II patients.

For bipolar depression, patients with type II bipolar disorder again showed greater improvements than did those with type I illness. The recurrence rate for depression fell by 35% (from 0.54 to 0.35 episodes/year) in type I patients and by 54% (from 1.30 to 0.60 episodes/year) in type II patients. Moreover, the proportion of days depressed decreased by 45% (from 19.8% to 10.8%) in bipolar I patients, compared to 60% (from 32.6% to 13.0%) in type II patients. The proportion of patients remaining completely free of recurrences during lithium maintenance treatment was also much greater in type II patients (45.1%, over an average of 4.4 years) than in type I patients (25.2%, over an average of 4.6 years).

Finally, subtyping by the presence of psychotic features, or of mixed manic-depressive states, in a majority of episodes prior to starting lithium maintenance treatment yielded little difference in morbidity during treatment between these patients and those with "more typical" bipolar disorder. For example, in these subgroups, the proportion of days ill during treatment was 20% (among patients with mainly psychotic features) and 23% (among those with mainly mixed states) versus 24% in patients with less complex illnesses.[73]

LONG-TERM EFFECTIVENESS OF LITHIUM IN RECURRENT MAJOR DEPRESSION

Research on lithium treatment also includes at least ten controlled long-term (average, 1.5 years) trials involving a total of over 400 subjects with recurrent major depressive episodes not considered to represent bipolar disorder.[2,3,19,22,50,54,55,60,64,65,67,92–95] In these trials, recurrence risk for apparently nonbipolar depression was reduced by 78%, on average. This effect is highly significant and is at least as great as that shown against mania and bipolar depression, as just reviewed.

In addition, several randomized, blinded, placebo-controlled trials indicate that lithium serves as an effective adjunct among patients in episodes of nonbipolar depression that have responded poorly to apparently adequate antidepressant trials. Based on meta-analysis, recovery rates were increased more than threefold compared to placebo when lithium was added to an ongoing antidepressant regimen, although fewer than half of the patients with treatment-resistant depression were "rescued" with adjunctive lithium.[96]

It is not clear whether the effects of lithium in nonbipolar depression reflect relatively broad mood-stabilizing effects of this agent or selective benefits in a subgroup of patients with depression. Such a subgroup might include individuals with apparently unipolar depression who have some clinical characteristics of bipolar disorder (such as early age of onset, relatively frequent recurrences, and anergic depressions) and might thus be considered to have "pseudounipolar" depressive illness.[12,13] In any event, a major challenge to any long-term treatment for major affective illnesses is to prevent the recurrence of depression and the substantially increased morbidity, disability, and mortality associated with it. Lithium seems to meet at least some of these requirements by reducing long-term morbidity due to recurrent depression, probably in both bipolar and apparently nonbipolar cases, in addition to its better-accepted benefits against mania and hypomania.

EFFECTIVENESS OF LONG-TERM LITHIUM TREATMENT IN REDUCING SUICIDE RISK

Substantial and quite consistent evidence has accumulated to show that rates of suicide and suicide attempts are markedly lower with long-term lithium maintenance treatment. Indeed, with the possible exception of long-term clozapine in schizophrenia,[97,98] the only medical intervention (including options ranging from psychotherapy to electroconvulsive therapy) for which there is credible evidence of reduction of suicide risk in major psychiatric disorders is lithium in the broad range of manic-depressive disorders, and particularly in bipolar disorder.[99,100] Our recent meta-analysis of relevant studies of lithium indicated consistently lower rates of suicidal acts during long-term treatment with lithium. Based on pooled data from all 22 available studies, which included a total of over 5600 patients with manic-depressive disorder, the computed weighted-average suicide rate was 0.88 (95% CI = 0.63–0.12) suicidal acts per 100 patient-years-at-risk (%/year) without lithium treatment versus only 0.16 (0.11–0.20) during lithium maintenance treatment, for a crude estimate of a 5.5-fold (82%) overall decrease in suicidal acts.[101–106] In a separate meta-analysis limited to the 12 studies involving direct comparisons of suicide rates on and off lithium, we[74] reported a nearly ninefold lower risk of completed suicides during lithium maintenance treatment. A recent case-control study involving 56 matched suicidal/nonsuicidal pairs[107] provides an unusual example of findings not supporting an association of probable ongoing lithium treatment with lack of suicide.

Additional analyses of available data on lithium and suicidal behavior in patients with bipolar disorder suggest other interesting trends.[105] Although the risk of suicidal deaths during lithium treatment was lowered by approximately 82% (to ca. 0.16%, or 160/100,000 per year), even this reduced rate was nearly ten times the average seen in the general population (ca. 0.0165%, or 16.5/100,000 per year).[105,106] This conclusion accords with other recent analyses in which suicide rates among patients with bipolar depression and perhaps also those with unipolar depression assigned (but not necessarily adherent) to long-term lithium treatment were compared to rates in the age- and sex-matched general population to estimate a standardized mortality ratio.[108,109] Although suicide risk was substantially lowered with treatment, the standardized mortality ratio remained elevated among persons assigned to lithium maintenance treatment, indicating that risk was not reduced to the level found in the general population.

There is preliminary evidence that mortality due to causes other than suicide may also be reduced with long-term lithium treatment.[99,109] However, the possibility that mortality associated with presumably stress-sensitive general medical illnesses is increased in bipolar disorder patients remains unsettled.[100]

The impact of lithium treatment on clinically significant suicide *attempts* may be even greater than its impact on suicides, since available data[105] suggest a reduction of attempts among bipolar disorder patients from about 2.83% per year to only 0.12% per year during lithium treatment (a 24-fold, or 96%, reduction). Comparisons to suicide attempt rates in the general population, however, are unreliable, and the ratio of suicide attempts to fatalities is uncertain. The ratio of attempts:suicides in the general population averages 18:1 in published reports[104] but is lower with more-severe attempts. It may be as low as 2:1 or 3:1 among persons with a major affective disorder,[104–106] implying that their suicidal acts are more likely to be lethal[105]—or less likely to be reported—than are those in the general population. If a ratio of 18:1 for attempts:suicides is assumed, then risk of suicide attempts in the general population would be approximately 0.30% per year. If we use this estimate, the attempt rate of about 0.12% per year found during lithium maintenance treatment of patients with bipolar disorder may be even lower than the risk for suicide attempts in the general population, which includes individuals with untreated major affective disorder.

The experience with suicidal behavior among over 350 bipolar I and II disorder patients in the collaborating Sardinian clinic has been consistent with the other published results.[103–105] That is, the risk of suicidal acts (life-threatening severe attempts before treatment, and both fatalities and attempts during treatment, so as to compare risks in the same subjects) was reduced 6.5-fold from an untreated rate of just over 2% per year. Lithium maintenance treatment was electively discontinued in some of these patients because of adverse effects or prolonged stability and refusal to continue; during the first 12 months following discontinuation, rates of suicidal acts increased over treated rates by 20-fold, and several of the patients made multiple attempts.[103–105] This early risk was half as great among those who discontinued lithium gradually (over a minimum of 2 weeks) as among those who did so abruptly, which accords with our previous findings with regard to recurrence risks for bipolar depression as well as mania after discontinuing lithium maintenance treatment.[77–83] Of note, after the patients had not received lithium for at least 12 months, rates of suicidal acts returned to the base rates found before lithium treatment was started.

The reason for the markedly lower suicide risk associated with long-term lithium treatment remains incompletely understood. It may reflect special pharmacodynamic properties of this extraordinarily complex agent.[5,110] Protection against recurrence of bipolar depression, which is particularly strongly associated with suicidal behavior,[103–105] is surely an important contribution. The requirement for close medical

monitoring and clinical follow-up for the safe use of lithium may also contribute to reducing suicide risk.[98,105]

RISKS AND BENEFITS OF LITHIUM TREATMENT AND ITS DISCONTINUATION DURING PREGNANCY

Our earlier research on the phenomenon of high early recurrence risk after discontinuation of lithium was recently extended to a collaborative study of women with bipolar disorder undertaken with colleagues at Massachusetts General Hospital's Perinatal Psychiatry Unit and at the Sardinian clinic. As in our previous studies of patients with bipolar disorder,[76–83] discontinuation proved very risky: women untreated for an equivalent time showed similar recurrence rates (about 55% had new episodes of mania or depression, overall, within 9 months without lithium, whether or not they were pregnant).[111] The risk was much lower among women who were discontinued gradually than among those who were discontinued rapidly, as we had found in broader samples of men and women with bipolar disorder.[77–83]

The lack of a difference in recurrence risk between age-matched pregnant and nonpregnant women after lithium has been stopped for an equivalent time may suggest that pregnancy has little effect on recurrence risk, being neither appreciably protective nor destabilizing.[111,112] An alternative possibility is that the impact of lithium discontinuation, itself, may be a more dominant risk factor. In contrast to the similar, substantial early risk of affective illness after discontinuing lithium maintenance treatment with or without pregnancy, there was an extraordinarily high risk of recurrences during the postpartum period among women who had remained clinically stable during pregnancy that was not found in comparable continued observation of nonpregnant women remaining without lithium for an additional 6 months.[111]

Regarding risks of lithium during pregnancy, cardiac teratogenic effects of early fetal exposure to lithium have proved to be less ominous than originally thought. The most characteristic adverse outcome is Ebstein's anomaly (downward displacement and malformation of the tricuspid valve), often together with an atrial septal defect. The base rate for this anomaly is approximately 1 per 20,000 live births in the general population; with exposure to lithium during the first trimester of pregnancy, the risk is increased to perhaps 1 per 1500 births.[113] This cardiac defect can usually be diagnosed in utero by ultrasonography and can often later be repaired with surgery. In striking contrast, the risk of spina bifida, an incurable and potentially crippling anomaly, may exceed 1 per 100 births among women with epilepsy who are exposed early in pregnancy to mood-stabilizing anticonvulsants, particularly divalproex and perhaps also carbamazepine.[5,114–116] With lithium, however, the risk of spina bifida in women with bipolar disorder does not exceed the spontaneous risk in the general population.[113] These considerations are leading to reassessment of the risks and potential benefits of using lithium late in pregnancy and during the neonatal period.[111,112]

RESPONSE TO RETREATMENT FOLLOWING LITHIUM DISCONTINUATION

Another important question about lithium discontinuation concerns the possibility of regaining previous levels of long-term benefits after stopping and then restarting treatment. The answer remains uncertain since some,[70,117–120] but not other,[121,122] investigators have found evidence that responses to secondary treatment are sometimes less satisfactory than are those in an initial trial of lithium. Our experience at the collaborating Sardinian clinic is more favorable, in that secondary long-term treatment responses were only slightly less robust than those seen in initial trials of lithium.[121] This optimistic outcome was unexpected, particularly in view of a substantial body of epidemiological evidence indicating that the natural history of (untreated) bipolar disorder tends toward a worsening course over time and with repeated episodes.[2,42] To some extent, the observed outcome may reflect selection bias based on over-representation of patients who tolerated and benefited from several years of additional lithium treatment. Yet, despite possible selection bias, the effect is surely not entirely artifactual because it is based on comparing the same subjects during their first and later trials of treatment.[121]

EFFECTS OF TREATMENT LATENCY AND NUMBER OF PRIOR EPISODES

The basis of the reported tendency in bipolar illness toward increasing frequency or severity of episodes remains unexplained, although without sustained long-term treatment a worsening course is to be expected clinically. One hypothesis is that episode count or illness duration may have a neurobiological as well as a clinical impact on individuals with bipolar disorder (the "kindling" hypothesis),[123] and a tendency toward worsening over time is best demonstrated in persons with untreated bipolar disorder.[2,42] However, the hypothesis that a loss of treatment response also occurs after delay of treatment, or after greater number of prior episodes, requires empirical testing.

Recent findings based on a literature review[124] and data from the Sardinian clinic sample[125,126] do not support the prediction that treatment response to long-term lithium maintenance may degrade with longer treatment latency or more episodes of mania or depression. This interpretation appears to hold whether treatment response is assessed as episode

frequency, as proportion of time ill during lithium maintenance treatment, or by survival analysis of time to recurrence during lithium treatment. Indeed, we have found evidence that treatment latency is inversely related to illness severity (measured either as recurrence rate or as proportion of days ill), possibly reflecting clinical indications for earlier therapeutic intervention.[125,126] Paradoxically, this relationship can lead to the misleading impression that a relatively greater *decrease* in morbidity with earlier treatment may suggest that treatment delay is followed by a loss of treatment responsiveness.[125,126]

At the Sardinian clinic, we found that delay in starting regular maintenance treatment was very common among patients with bipolar disorder, averaging nearly 9 years. Treatment delay was longest for women with bipolar II disorder and shortest among men with bipolar I disorder, probably reflecting the important behavioral differences between these subgroups and likely clinical responses to aggressive manic behavior in men compared to withdrawn depressive illness in women.[124,127] Another alarming finding was that the mean latency to a first suicide attempt was at least a year shorter than the mean latency to maintenance therapy.[102,103,105]

These findings encourage earlier diagnosis and earlier clinical intervention with sustained treatment than is often encountered currently in an effort to limit long-term morbidity and premature mortality. However, they fail to support the idea that either delay of treatment or number of pretreatment episodes routinely leads to greater morbidity during long-term maintenance treatment with lithium.

RESPONSES TO LITHIUM AND ALTERNATIVES IN RAPID-CYCLING BIPOLAR DISORDER

An additional factor widely considered to predict poor treatment response in bipolar disorder is rapid cycling. Frequently recurring illness can be severely disruptive and even incapacitating when untreated. Some researchers[123,128,129] have suggested that rapid cycling may be particularly unfavorable for response to lithium and, further, that certain anticonvulsants may yield superior results. However, contrary to expectations, our observations[130] do not support the assumption that rapid cycling precludes beneficial response to treatment. Instead, we found that time to a recurrence during lithium maintenance treatment was indistinguishable between bipolar disorder patients in Sardinia who did (n = 53) or did not (n = 307) experience rapid cycling—defined as involving at least four episodes of mania or depression—either within the 12 months before starting lithium (as required by DSM-IV criteria[131]) or during *any* year before lithium treatment began. Moreover, the average cycling rate (episodes/year) before maintenance treatment began did not correlate with response to lithium treatment.[130] We also found that rapid cycling usually was not a consistent pattern among subjects with untreated bipolar disorder who were evaluated over several years before starting regular maintenance treatment.[130]

In a comparative meta-analysis of studies of treatment responses in rapid- and non-rapid-cycling bipolar disorder patients treated with lithium or antimanic anticonvulsants (J. Hennen et al., unpublished manuscript), lithium was by far the most extensively studied option, in terms of numbers of studies (11/16) and subjects, as well as duration of treatment. In the 16 studies (and 25 treatment arms) included in this meta-analysis of 905 rapid- and 951 non-rapid-cycling subjects, treatment response was most commonly evaluated as the all-or-none risk of any recurrence during treatment. When specific agents were compared, lithium was superior to the alternatives among non-rapid-cycling patients. As expected, responses were, on average, at least moderately inferior with all treatments in rapid-cycling subjects. In comparisons with antimanic or antidepressant anticonvulsants proposed as mood stabilizers, lithium was not inferior to divalproex among rapid-cycling patients, and both agents tended to be superior to carbamazepine. The analysis also included the three available studies of lamotrigine and one of topiramate, with inconclusive results owing to the limited data available for these newer agents.

This analysis of the available, albeit limited, research findings clearly suggests that lithium does not differ significantly from alternative treatments in treatment response among patients with rapid-cycling bipolar disorder. The same result was sustained when broader, clinical ratings of improvement, rather than the reoccurrence of a single episode of illness during treatment, were considered as measures of treatment efficacy.

ADVERSE EFFECTS OF LITHIUM

Lithium presents an unusually narrow margin of safety (therapeutic index), in that serum concentrations only two to three times therapeutic levels can be intoxicating.[3,5] Acute intoxication is characterized by vomiting, diarrhea, coarse tremor, ataxia, nystagmus, coma, and convulsions, typically heralded by nausea, abdominal discomfort, sedation or confusion, and fine tremor. In severe overdoses, effects on the nervous system can include potentially irreversible neurological damage, and coma or death. Lithium also commonly causes electroencephalographic slowing and disorganization.[132]

Less-severe adverse effects, including nausea, daytime drowsiness, mild cognitive dulling, polydipsia, weight gain, fluid retention, and dermatological reactions (e.g., acne) can occur even at therapeutic serum concentrations. Occasional

patients treated with lithium develop benign diffuse, nontender thyroid enlargement, suggestive of compromised thyroid function. Serum thyroxin concentration may decrease, and thyroid-stimulating hormone secretion may be moderately elevated, but clinical hypothyroidism is uncommon.[133]

Transient, mild polyuria often appears early in treatment, and reversible nephrogenic diabetes insipidus is seen in a minority of patients later in maintenance treatment.[134] Chronic inflammatory changes in renal tissue have been found occasionally in patients given lithium for prolonged periods, but progressive impairment of renal function is rare. Nevertheless, these various adverse metabolic effects necessitate regular monitoring of serum concentrations of creatinine, electrolytes, thyroid hormones, and thyroid-stimulating hormone, as well as of the lithium ion itself.[5]

DEFINITION AND TESTING OF INNOVATIVE "MOOD STABILIZERS" AS ALTERNATIVES TO LITHIUM

It is also timely to consider appropriate criteria for a true mood-stabilizing agent, with lithium as the standard for comparison. Minimum criteria should include long-term protective action against at least some aspect of bipolar disorder, without worsening other components of the syndrome. Mood-stabilizing treatments should not only have short-term antimanic effects but also protect against recurrences of bipolar depression and mixed dysphoric-agitated states, as well as mania, over prolonged periods, preferably tested for longer than the common 1-year spontaneous cycling interval.[5,135] Ideally, for an agent to be designated as a "mood stabilizer," it should reduce recurrences of both depression and mania in frequency, duration, and severity. However, credible evidence for this degree of benefit, plus substantial evidence of a suicide risk–reducing effect of long-term treatment, exists only for lithium.

Carbamazepine, divalproex, and other anticonvulsants, as well as various antipsychotics, have been shown to have short-term (weeks) benefits in mania,[5,29,30,35,136] as does lamotrigine in acute bipolar depression.[137] In contrast, however, compelling evidence of long-term prophylactic effects in bipolar disorder (and for both bipolar depression and mania) is very limited for all agents other than lithium. Currently, FDA approval has been granted only to lithium, divalproex, and olanzapine for acute mania.[34] In addition, lithium is FDA approved for "recurrences," presumably of mania, in bipolar disorder.[34] Yet there is widespread use of lithium to protect against all phases of the disorder. And despite very limited evidence for long-term mood-stabilizing effects of agents other than lithium, all of the FDA-approved antimanic agents and several other, similar drugs lacking such approval are widely employed "off-label," either alone or in various inadequately tested combinations, in the long-term treatment of bipolar disorder patients.[5,29]

After lithium, perhaps the second most extensively evaluated mood stabilizer is carbamazepine.[3,5,29,31] Based on several direct comparisons,[138–142] carbamazepine appears to be less effective than lithium in preventing mania, bipolar depression, or suicide. However, the combination of lithium with carbamazepine may be therapeutically superior to either agent given alone.[139]

Randomized, long-term therapeutic comparisons of lithium to other mood stabilizers, and systematic evaluations of other combinations of putative mood-stabilizing agents, are rare. In the single long-term randomized trial of potential mood-stabilizing agent candidates,[5] divalproex was compared to placebo and to lithium for 12 months, following short-term treatment of acute mania.[72] In this unusually well-designed study, there was a nonsignificant prolongation of the latency to a first recurrence on divalproex over the alternatives, based on survival analysis. However, the crude relapse rate was 37.1% lower with divalproex than with placebo (24.1 vs. 38.3 failed cases/100 patient-years; χ^2 [1 df] = 6.18, p = 0.013).

Due to current trends in the experimental therapeutics of bipolar disorder, research evidence for long-term benefits comparable to that reviewed above for lithium is becoming increasingly difficult and expensive to acquire.[135] The design and conduct of long-term trials of any new treatment option in this disorder are becoming more challenging, in part reflecting the partial success of available treatments and a tendency for "off-label" maintenance applications following FDA approval for antimanic efficacy, even without adequate long-term testing. There is also a growing tendency to enroll patients with relatively mild illnesses when a placebo condition is involved, possibly due to emerging appreciation of the potential impact of treatment-discontinuation stress as a contributor to risks associated with placebo treatment. All of these factors combine to make clinical generalizations about treatment effectiveness of proposed mood-stabilizing treatments increasingly risky.[5,29,72,78–81,135,143]

CONCLUSIONS

This overview of contemporary knowledge underlying the use of lithium in the treatment of bipolar disorder suggests several provocative conclusions concerning its clinical utility (see Table 3). Lithium, by itself, is generally inadequate for rapid and safe control of acute mania but can be very useful in aftercare, following short-term interventions with other treatments including divalproex, antipsychotics, and high-potency benzodiazepines.[5] Lithium's major contemporary use is in long-term prevention of recurrences of bipolar illness, not only of mania but also of hypomania. Moreover, its effectiveness against recurrences of bipolar depression and closely associated suicidal behavior is well documented. Lithium may also be useful in many cases of recurrent uni-

TABLE 3. Situations in Which Lithium May Be Effective

Effective
Treatment of acute mania (effective, but slow)*
Prevention of recurrence of mania* and depression in bipolar I disorder
Reduction of suicidal risk in recurrent major affective disorders
Probably effective
Treatment of mania or bipolar disorder variants in children and the elderly
Long-term treatment (alone or with valproate) of rapid-cycling bipolar disorder
Long-term treatment after delay or following multiple bipolar episodes
Long-term retreatment after discontinuation
Prevention of recurrences of depression (and hypomania) in bipolar II disorder
Prevention of recurrences in unipolar or pseudounipolar major depression
Supplementation of antidepressants in major depression
Possibly effective or insufficiently investigated
Treatment of acute major depression (particularly bipolar I or II or pseudounipolar)
Long-term treatment of schizoaffective psychosis
Treatment of personality disorders involving cyclothymia or emotional instability
Treatment of episodic impulsive-aggressive behavior in adults or children (including those with developmental delay or brain damage)
Treatment of stimulant-induced euphoria

*Conditions for which lithium is approved by the Food and Drug Administration and recommended by manufacturers. Empirical clinical use for the other conditions is not unusual, especially when alternatives prove unsuccessful.

polar depression, and it has proved to be an effective adjunctive treatment for treatment-resistant acute major depression. The benefits of lithium do not seem to have degraded, on average, over the past several decades among relatively broadly representative samples of patients with bipolar disorder. The findings reviewed also question widely shared beliefs that several clinical factors are usually associated with nonresponsiveness to lithium. These include mixed manic-depressive states, a history of prolonged untreated bipolar illness, multiple episodes of mania or bipolar depression, and even rapid cycling. Moreover, re-use of lithium after its discontinuation was not routinely met with nonresponsiveness. Recent findings of high clinical risk in women who abruptly discontinue lithium to avoid fetal exposure early in pregnancy encourage reassessment of the broad risk/benefit relationships in continued use of lithium in late pregnancy and after delivery.

It seems fair to conclude that lithium continues to offer many clinical advantages, including highly competitive cost-effectiveness, even allowing for the expense of appropriate medical monitoring. It also has significant risks and liabilities, not least of which is its unusually narrow margin of safety, and the potential risk of irreversible neurotoxic or even fatal effects on overdose; it necessitates repeated blood tests to assure ideal and relatively well-tolerated serum concentrations in the range of 0.6–0.8 mEq/L for long-term use.[5,144] On balance, however, lithium continues to set a standard that has yet to be met by any proposed alternative mood-stabilizing treatments.

A Rating Scale for Drug-Induced Akathisia

THOMAS R. E. BARNES

A rating scale for drug-induced akathisia has been derived that incorporates diagnostic criteria for pseudoakathisia, and mild, moderate, and severe akathisia. It comprises items for rating the observable, restless movements which characterise the condition, the subjective awareness of restlessness, and any distress associated with the akathisia. In addition, there is an item for rating global severity. A standard examination procedure is recommended. The inter-rater reliability for the scale items (Cohen's κ) ranged from 0.738 to 0.955. Akathisia was found in eight of 42 schizophrenic in-patients, and nine had pseudoakathisia, where the typical sense of inner restlessness was not reported.

Akathisia is probably the commonest and one of the more distressing of the movement disorders associated with antipsychotic drugs (Lancet, 1986; Barnes, 1987). Following the original descriptions of drug-induced akathisia (Sigwald *et al*, 1947; Steck, 1954), there was little further work on the phenomenology of akathisia, and no consistent or clear operational definition emerged. The diagnosis of akathisia tended to rest upon systematic questioning regarding a patient's inner restlessness. However, reliance on a patient's subjective report alone does not allow for reliable diagnosis (Van Putten & Marder, 1986, 1987).

The lack of delineation of the associated motor behaviour created difficulty in separating akathisia from other movement disorders seen in drug-treated schizophrenic patients. These include Parkinsonian tremor, dystonia, tardive dyskinesia, tics, stereotypies and mannerisms. The distinction between tardive dyskinesia and akathisia is complicated by the common coexistence of the two conditions (Barnes *et al*, 1983). Descriptions of tardive dyskinesia have consistently mentioned motor restlessness, and subjective distress has been found to correlate rather better with trunk and limb movements than with orofacial movement (Rosen *et al*, 1982).

The lack of diagnostic criteria may partly account for the wide range of prevalence figures reported in the literature (Marsden *et al*, 1985): although a figure of around 20% is commonly accepted (Ayd, 1961; Braude *et al*, 1983), Freyhan (1958), for example, found a prevalence of only 12.5%, while Van Putten (1975) recorded a figure of 45%. Furthermore, in a sample of drug-free schizophrenic patients who received haloperidol (10 mg) at bedtime for seven days, Van Putten *et al* (1984) found that 75% experienced akathisia.

In addition, the absence of a precise clinical definition might be partly responsible for the failure of clinicians to recognise the condition consistently (Weiden *et al*, 1987). It may also contribute to the common misinterpretation of motor phenomena of akathisia as the signs and symptoms of psychiatric illness (Van Putten, 1975; Braude *et al*, 1983). If akathisia is misdiagnosed as an exacerbation of agitation or psychotic excitement, this error may prompt an increase in antipsychotic drug dose, which would almost certainly aggravate the problem.

Validity of the scale

The validity of the rating scale (see Appendix) derives from its basis in signs and symptoms found to be characteristic of the condition in our previous studies of both acute psychiatric admissions receiving antipsychotic medication (Braude *et al*, 1983) and schizophrenic out-patients on maintenance medication (Barnes & Braude, 1985).

Subjective item

These studies found that against the background of a relatively non-specific sense of inner restlessness or mental unease, sufferers were often particularly aware of tension and discomfort in their limbs, sometimes with paraesthesia and unpleasant pulling or drawing sensations in their legs. These complaints are akin to symptoms found in the 'restless legs', or Ekbom's, syndrome (Blom & Ekbom, 1961; Lancet, 1986).

In addition, the patients with akathisia would typically experience a desire to move, an awareness that they were unable to keep their legs still, or a compulsion to move which was often particularly referable to the legs. Many patients complained that the condition was least tolerable when they were required to stand still, for example when queueing for meals or medication on the ward, waiting at the supermarket checkout, or standing in the kitchen

while cooking. These symptoms constitute the subjective diagnostic criteria for akathisia included in the item 'awareness of restlessness' of the scale.

The inner restlessness and emotional unease experienced by patients with akathisia is often distressing for patients, and may lead them to refuse further medication. The importance of akathisia as a cause of poor compliance with antipyschotic drugs has been emphasised by Van Putten (1974). The overwhelming and intense nature of the subjective experience in severe cases is illustrated by reports where akathisia has been thought to have contributed to violent, aggressive behaviour (Kekich, 1978; Kumar, 1979; Schulte, 1985) or impulsive suicidal behaviour (Shear *et al*, 1983; Schulte, 1985; Drake & Erlich, 1985; Shaw *et al*, 1986). An item for distress related to restlessness was included in the scale. Any distress associated with akathisia can usually be elicited without difficulty, and is commonly complained of spontaneously.

Objective criterion

The study by Braude *et al* (1983) and a similar investigation by Gibb & Lees (1986) also found that particular patterns of restless leg movements were observed in association with the subjective experience of akathisia. The most characteristic signs that emerged were rocking from foot to foot or walking on the spot when standing. Van Putten & Marder (1987) agree that these foot movements are easily recognisable, and are present in all patients with moderate or severe akathisia. Braude *et al* (1983) observed other patterns of restless movement in seated patients, which accompanied the typical subjective experience of akathisia. They described these as shuffling or tramping of the legs. With severe akathisia, patients appeared to be unable to stand without walking or pacing. Gibb & Lees (1986) generally confirmed these findings, and suggested further that fast walking and swinging of one leg when sitting should also be considered as part of the akathisia syndrome.

These motor phenomena were considered to be observable diagnostic criteria for akathisia, and are included in the 'objective' item of the rating scale.

Global item

The rating of 'absent' refers to the failure of the rater to elicit any subjective awareness or complaint of restlessness. However, in the absence of any report of a sense of inner restlessness or a compulsion to move, some patients may manifest obvious, complex, repetitive movements resembling those seen in akathisia (Barnes & Braude, 1985). A common feature is rocking from foot to foot while standing. These movements seem to be of a volitional rather than choreic nature, and appear to represent motor restlessness. This syndrome has been called pseudo-akathisia (Munetz & Cornes, 1982; Barnes & Braude, 1985), and its relationship with akathisia and tardive dyskinesia is a matter for speculation (Barnes & Braude, 1985; Stahl, 1985; Munetz, 1986).

The signs of motor restlessness are not invariably present in mild cases of acute akathisia (Braude *et al*, 1983). The typical subjective experience of akathisia in the absence of restless movements has been referred to as 'subjective akathisia' (Van Putten & Marder, 1986). In practice, it may be difficult to differentiate between this condition and subtle manifestations of anxiety or emotional distress unrelated to akathisia. This difficulty is acknowledged by the 'questionable' rating in the global item of the scale, and the existence of subjective akathisia is reflected in the 'mild akathisia' rating, as it does not demand the presence of the characteristic restless phenomena.

The ratings for moderate, marked, and severe akathisia reflect increasing degrees of subjective distress and the desire or compulsion to move, an increasing inability to remain sitting comfortably, and an increasing amount of time spent exhibiting restless movements, such as rocking from foot to foot when standing, and pacing up and down.

Reliability

Patients and method

Forty-two chronic in-patients, all of whom fulfilled DSM–III criteria (American Psychiatric Association, 1980) for schizophrenia, and were receiving antipsychotic medication, were each assessed by two raters during the same examination period using the rating scale (Barnes & Halstead, 1988). The age range of the sample was 32–65 (median 52) years, and 13 were women.

Examination procedure

Each patient was observed seated for at least five minutes while consent to take part in the study was obtained and the patient completed a self-rating scale for anxiety, modified from the Leeds Anxiety Scale (Snaith *et al*, 1976). The patient was then asked to stand up, and was examined for evidence of Parkinsonism using the Extrapyramidal Rating Scale (Simpson & Angus, 1970). Still standing, patients were then engaged in conversation on neutral topics for several minutes while being observed, and finally were asked specific questions about inner restlessness, and awareness of the features of akathisia. For example, inquiry was made as to whether they experienced a sense of inner restlessness, and whether restless, fidgety feelings could

TABLE I
Inter-rater reliability

Rating scale item	*Linearly weighted Cohen's κ*
Objective	0.738
Subjective	
Awareness of restlessness	0.827
Distress related to restlessness	0.901
Global clinical assessment	0.955

be localised to any part of their body. Further, they were asked if they had any awareness of difficulty sitting comfortably for long periods, an increasing restlessness and tension when required to stand still, or a compulsive desire to move.

If akathisia was present, additional information was collected regarding any diurnal variation of symptoms, and whether the patient was aware of any particular situations which seemed to provoke or exacerbate the restlessness and any associated distress.

Inter-rater reliability

The agreement between the two raters on the akathisia scale was calculated. There was high inter-rater reliability on the scores for the four items, expressed in terms of Cohen's κ (Table I).

There was complete agreement between the two raters on the presence of akathisia, that is a rating of two or more on the global clinical assessment item. There was disagreement between the raters on the scores for the severity of akathisia in only two patients. The scores differed by one in both cases.

According to the global rating, akathisia was found in eight (19%) of 42 patients. The condition was rated as being of mild or moderate severity in six patients, and marked or severe in only two. Five (12%) of the 42 patients received a rating of 'questionable' akathisia. They manifested non-specific restless movements and described a vague sense of inner tension, but these features were unconvincing for a diagnosis of akathisia.

Nine (21%) patients were rated as having pseudo-akathisia. These patients exhibited akathisic movements, that is, they scored one or more on the 'objective' item, but did not apparently experience any associated inner restlessness or desire to move their legs, that is, they scored 0 on the 'subjective' item.

Discussion

In this small reliability study, the rating scale was found to be viable and practical, and a high level of inter-rater reliability was achieved. The results confirm both the relatively high prevalence of akathisia in chronic schizophrenic patients receiving maintenance antipsychotic drugs, and the existence in a proportion of such patients of pseudoakathisia, where the characteristic movements of akathisia are observed in the absence of the subjective symptoms.

It is envisaged that the rating on the global item alone should be sufficient for diagnostic purposes, and for measuring change in the overall severity of akathisia in response to treatment. Nevertheless, to rate the global item accurately the elements of the three other items need to be taken into account, and these items should be completed first.

The individual ratings on the two subjective items, 'awareness of restlessness' and 'distress related to restlessness', and the 'objective' item may be of value if an investigator wishes to detect whether the objective and subjective components of akathisia are differentially affected by particular drug treatments, or change independently over time. Also, when assessing a patient with pseudoakathisia, either over time or in the context of a treatment trial, the main measure of the condition is the rating on the 'objective' item. However, the emergence of a score for the 'awareness of restlessness' item might warrant a change in diagnosis to akathisia.

It is recommended that the scale is completed after observation of the patient in more than one setting. Preferably, the patient should be unobtrusively watched in a natural setting, for example while involved in activity on the ward, as well as during a formal interview. Experience with the assessment of patients with akathisia suggests that the situation in which the characteristic restless movements of rocking from foot to foot or treading on the spot are most likely to be observed is when the patient is standing with the rater, engaged in casual conversation on some neutral topic.

We are currently using this scale in a placebo-controlled study of β-adrenoceptor-blocking drugs in akathisia, and in a prevalence study in a population of chronic schizophrenic in-patients. The scale is also being employed in studies by other research groups in the UK and internationally. We plan to examine the reliability of the scale further in these studies, and also hope to test the validity of the scale by using an electronic movement meter to quantify the restless activity of patients, to provide an objective measure of the condition.

Appendix: Rating scale for drug-induced akathisia

Patient name:
Patient research no.:
Hospital no.:
Ward:
Rater:

Patients should be observed while they are seated, and then standing while engaged in neutral conversation (for a

minimum of two minutes in each position). Symptoms observed in other situations, for example, while engaged in activity on the ward, may also be rated. Subsequently, the subjective phenomena should be elicited by direct questioning.

Objective

0 Normal, occasional fidgety movements of the limbs
1 Presence of characteristic restless movements: shuffling or tramping movements of the legs/feet, or swinging of one leg, while sitting, *and/or* rocking from foot to foot or 'walking on the spot' when standing, *but* movements present for less than half the time observed
2 Observed phenomena, as described in (1) above, which are present for at least half the observation period
3 The patient is constantly engaged in characteristic restless movements, *and/or* has the inability to remain seated or standing without walking or pacing, during the time observed.

Subjective

Awareness of restlessness

0 Absence of innser restlessness
1 Non-specific sense of inner restlessness
2 The patient is aware of an inability to keep the legs still, or a desire to move the legs, *and/or* complains of inner restlessness aggravated specifically by being required to stand still
3 Awareness of an intense compulsion to move most of the time *and/or* reports a strong desire to walk or pace most of the time

Distress related to restlessness

0 No distress
1 Mild
2 Moderate
3 Severe

Global clinical assessment of akathisia

0 Absent
No evidence of awareness of restlessness. Observation of characteristic movements of akathisia in the absence of a subjective report of inner restlessness or compulsive desire to move the legs should be classified as pseudoakathisia
1 Questionable
Non-specific inner tension and fidgety movements
2 Mild akathisia
Awareness of restlessness in the legs *and/or* inner restlessness worse when required to stand still. Fidgety movements present, but characteristic restless movements of akathisia not necessarily observed. Condition causes little or no distress
3 Moderate akathisia
Awareness of restlessness as described for mild akathisia above, combined with characteristic restless movements such as rocking from foot to foot when standing. Patient finds the condition distressing
4 Marked akathisia
Subjective experience of restlessness includes a compulsive desire to walk or pace. However, the patient is able to remain seated for at least five minutes. The condition is obviously distressing
5 Severe akathisia
The patient reports a strong compulsion to pace up and down most of the time. Unable to sit or lie down for more than a few minutes. Constant restlessness which is associated with intense distress and insomnia

The Pittsburgh Sleep Quality Index: A New Instrument for Psychiatric Practice and Research

Daniel J. Buysse, Charles F. Reynolds III, Timothy H. Monk, Susan R. Berman, and David J. Kupfer

Received May 9, 1988; revised version received August 17, 1988; accepted November 12, 1988.

Abstract. Despite the prevalence of sleep complaints among psychiatric patients, few questionnaires have been specifically designed to measure sleep quality in clinical populations. The Pittsburgh Sleep Quality Index (PSQI) is a self-rated questionnaire which assesses sleep quality and disturbances over a 1-month time interval. Nineteen individual items generate seven "component" scores: subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction. The sum of scores for these seven components yields one global score. Clinical and clinimetric properties of the PSQI were assessed over an 18-month period with "good" sleepers (healthy subjects, $n = 52$) and "poor" sleepers (depressed patients, $n = 54$; sleep-disorder patients, $n = 62$). Acceptable measures of internal homogeneity, consistency (test-retest reliability), and validity were obtained. A global PSQI score > 5 yielded a diagnostic sensitivity of 89.6% and specificity of 86.5% (kappa $= 0.75$, $p < 0.001$) in distinguishing good and poor sleepers. The clinimetric and clinical properties of the PSQI suggest its utility both in psychiatric clinical practice and research activities.

Key Words. Sleep, sleep quality, depression, sleep disorders.

"Sleep quality" is an important clinical construct for two major reasons. First, complaints about sleep quality are common; epidemiological surveys indicate that 15-35% of the adult population complain of frequent sleep quality disturbance, such as difficulty falling asleep or difficulty maintaining sleep (Karacan et al., 1976, 1983; Bixler et al., 1979; Lugaresi et al., 1983; Welstein et al., 1983; Mellinger et al., 1985). Second, poor sleep quality can be an important symptom of many sleep and medical disorders. One frequently measured component of sleep quality, sleep duration, may even have a direct association with mortality (Kripke et al., 1979).

Sleep quality complaints are particularly relevant to psychiatry. Factors relating to anxiety and stress are one of the most important concomitants of sleep complaints in the general population (Karacan et al., 1983), and insomnia associated with psychiatric disorders is the most prevalent type of insomnia seen in sleep disorders centers, accounting for 35% of diagnoses (Coleman, 1983). Furthermore, sleep

Daniel J. Buysse, M.D., is Assistant Professor; Charles F. Reynolds III, M.D., is Professor; Timothy H. Monk, Ph.D., is Associate Professor; Susan R. Berman is Research Associate; and David J. Kupfer, M.D., is Professor and Chairman, Department of Psychiatry, University of Pittsburgh School of Medicine. (Reprint requests to Dr. C.F. Reynolds III, Western Psychiatric Institute and Clinic, University of Pittsburgh, 3811 O'Hara St., Pittsburgh, PA 15213, USA.)

quality disturbances are frequently reported in essentially all psychiatric disorders, including depression, schizophrenia, anxiety disorders, and psychoactive substance use disorders.

Although sleep quality is a readily accepted clinical construct, it represents a complex phenomenon that is difficult to define and measure objectively. "Sleep quality" includes quantitative aspects of sleep, such as sleep duration, sleep latency, or number of arousals, as well as more purely subjective aspects, such as "depth" or "restfulness" of sleep. However, the exact elements that compose sleep quality, and their relative importance, may vary between individuals. Furthermore, because sleep quality is largely subjective, sleep laboratory measures may correlate with perceived sleep quality, but they cannot define it. Finally, the measurement of sleep quality is affected by the type of study in which it is being examined. Large-scale population surveys generally focus on a few general questions about habitual sleep quality and types of sleep disturbances (e.g., Bixler et al., 1979; Karacan et al., 1983). Studies that examine the previous night's sleep (drug efficacy studies, for example) may focus on more subjective, comparative aspects of sleep quality, such as depth of sleep, restfulness, and feelings upon awakening (e.g., Frankel et al., 1976; Webb et al., 1976; Parrott and Hindmarch, 1978).

Given the importance of the construct and the inherent difficulties in its definition and quantification, it is important to have a clinical instrument that measures sleep quality. It is also necessary, however, to assess the "clinimetric" properties (i.e., properties such as sensibility, accuracy, comprehensibility, and reproducibility) of the instrument, all of which are essential to the description and valid measurement of complex clinical phenomena (Feinstein, 1987). Although many sleep questionnaires have been described in previous studies, they share several general difficulties. First, very few of them have used specified time intervals for assessment. Second, previous questionnaires have not been designed to yield a simple, global score to facilitate comparisons between groups or individuals. Third, few of these studies have directly assessed clinimetric properties of the questionnaires. Finally, previous questionnaires have been used primarily with unselected population samples or nonclinical control subjects.

The Pittsburgh Sleep Quality Index was developed with several goals: (1) to provide a reliable, valid, and standardized measure of sleep quality; (2) to discriminate between "good" and "poor" sleepers; (3) to provide an index that is easy for subjects to use and for clinicians and researchers to interpret; and (4) to provide a brief, clinically useful assessment of a variety of sleep disturbances that might affect sleep quality. This article describes the instrument and its clinimetric properties, including internal homogeneity, performance consistency, and validity.

Methods

Instrument Development and Description (Appendix). Items in the Pittsburgh Sleep Quality Index (PSQI) were derived from three sources: clinical intuition and experience with sleep disorder patients; a review of previous sleep quality questionnaires reported in the literature; and clinical experience with the instrument during 18 months of field testing.

The PSQI assesses sleep quality during the previous month. This is a time frame intermediate between postsleep inventories (which assess only the previous night's sleep) and

survey-type questionnaires (which assess difficulties over the previous year or more). A postsleep questionnaire may reflect more accurately the night-to-night variations that occur in sleep quality, but it does not provide information about the frequency or duration of specific problems that may lead a patient to seek help. On the other hand, survey-type questionnaires may not indicate the severity of a particular problem at the present time. In addition, a duration of 2-3 weeks is often used clinically to differentiate transient from persistent sleep-wake disorders (Consensus Conference on Insomnia, 1984). Therefore, administering the PSQI on two occasions separated by approximately 1 month allows for the discrimination of most transient and persistent disturbances.

The PSQI consists of 19 self-rated questions and five questions rated by the bedpartner or roommate. The latter five questions are used for clinical information only, are not tabulated in the scoring of the PSQI, and are not reported on in this article. The 19 self-rated questions assess a wide variety of factors relating to sleep quality, including estimates of sleep duration and latency and of the frequency and severity of specific sleep-related problems. These 19 items are grouped into seven component scores, each weighted equally on a 0-3 scale. The seven component scores are then summed to yield a global PSQI score, which has a range of 0-21; higher scores indicate worse sleep quality.

The seven components of the PSQI are standardized versions of areas routinely assessed in clinical interviews of patients with sleep/wake complaints. These components are subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medications, and daytime dysfunction. Scoring of each component is illustrated in the Appendix. Subject instructions for the PSQI are contained in the text. The entire index requires 5-10 min for the subject to complete, and 5 min to score.

Subjects. The PSQI was administered to three groups of subjects during an 18-month study period. Group 1 consisted of "good" sleepers: 52 healthy control subjects without sleep complaints, recruited for participation in research studies of sleep and aging (MH-37869), nocturnal penile tumescence (MH-40023), and sleep in depression (MH-40023, MH-30915). Group 2 consisted of "poor" sleepers: 34 patients with major depressive disorder, who were again recruited for participation in research protocols relating to sleep, aging, depression, and nocturnal penile tumescence. This group included 24 outpatients and 10 inpatients at the Western Psychiatric Institute and Clinic. Group 3, also consisting of "poor" sleepers, was a clinical sample of 62 physician-referred outpatients at the Sleep Evaluation Center (SEC) of the Western Psychiatric Institute and Clinic. Patients are referred to the SEC for assessment of a variety of sleep/wake complaints, but only patients with Disorder of Initiating and Maintaining Sleep (DIMS, $n = 45$) or Disorders of Excessive Somnolence (DOES, $n = 17$) (Association of Sleep Disorders Centers-ASDC, 1979) were included in this study, since the number of patients with other disorders was too small to permit statistical analysis.

Subjects were not matched for age or sex ratio because of the different requirements for each research protocol, and the absence of any age criteria for the clinical sleep disorders sample. The mean ages for subject groups were as follows: controls 59.9 years (range: 24-83); depressives 50.9 years (range: 21-80); DIMS 44.8 years (range: 20-80); and DOES 42.2 years (range: 19-57). Analysis of variance (ANOVA) indicated a significant difference in age between groups ($F = 5.20, p < 0.001$), with post hoc differences between control subjects and DIMS and DOES patients. Male/female ratios were as follows: controls 40/12; depressives 25/9; DIMS 16/29; and DOES 8/9 ($\chi^2 = 21.2, p < 0.001$). Male subjects had a lower mean age (46.5 years; SD = 16.7) than female subjects (55.4 years; SD = 18.9) ($t = -3.01, p < 0.005$). Many of the male subjects were involved in studies of nocturnal penile tumescence in depression, while female subjects were participating mainly in studies of sleep, aging, and depression.

Evaluation for all subjects included a complete medical history and physical examination. Depressives and controls were excluded from research involvement (and therefore, from the current study) for any medical conditions that would prevent a 2-week medication-free interval, as well as for the presence of known central nervous system disease such as

seizure disorder, cerebrovascular disease, or dementia. No specific exclusion criteria were used for the clinic sample of sleep-disorder patients. All depressed patients and healthy controls were assessed with the Schedule for Affective Disorders and Schizophrenia-Lifetime version (SADS-L) (Endicott and Spitzer, 1978), and diagnosed according to Research Diagnostic Criteria (Spitzer et al., 1978); all depressed patients met criteria for definite or probable current major depressive disorder. Severity of depressive symptoms was assessed with the Hamilton Rating Scale for Depression (Hamilton, 1960); the mean Hamilton score for depressed patients was 21.3 (SD = 4.65). Sleep-disorder patients were evaluated as described elsewhere (Jacobs et al., 1988), and given preliminary diagnoses according to ASDC nosology (ASDC, 1979). Sleep-disorder patients meeting criteria for *DSM-III* (American Psychiatric Association, 1980) major depression were excluded from the current study. All subjects completed a 2-week sleep/wake diary and a sleep habits questionnaire.

All subjects were further evaluated with routine polysomnography following a medication-free interval of at least 2 weeks. For depressed and sleep-disorder patients, this interval followed withdrawal from psychotropic and sedative-hypnotic medications. All subjects were studied with a routine sleep montage, including electroencephalographic (C4, referenced to tied mastoids), electro-oculographic (EOG), and electromyographic (submental) leads. Most subjects had additional monitoring for sleep apnea, myoclonus, or nocturnal penile tumescence, dictated by clinical indications or research protocol involvement. All sleep records were scored in 1-min epochs according to standard criteria (Rechtschaffen and Kales, 1968), using Stage 2 sleep onset, and standard convention for definition of sleep efficiency (time spent asleep/total recording period).

Final diagnoses for depressed and sleep-disorder patients were based on results of clinical and structured interviews, sleep questionnaires, and diaries. In addition, polysomnographic findings were considered in the final diagnoses of the sleep-disorder patients (Jacobs et al., 1988).

All 148 subjects completed the PSQI on at least one occasion (T_1) during the course of their clinical and research evaluation. For the majority of subjects (n = 107), the PSQI was completed before sleep studies. For some subjects with stable sleep/wake complaints (n = 41), the PSQI was completed after sleep studies. A subgroup of 91 subjects (43 controls, 22 depressives, and 26 sleep-disorder patients) completed the index a second time (T_2), an average of 28.2 days later (range: 1-265 days). The second PSQI was completed before any pharmacological treatment began.

Statistical Analyses. Descriptive statistics and ANOVA were used to contrast clinical and demographic features of the patient groups.

Internal homogeneity of separate items was assessed using Cronbach's α statistic and corrected component-total correlation coefficients (Cronbach, 1951). Pearson product-moment correlations were also used to correlate component and item scores with the PSQI global score.

Test-retest reliability (consistency) was assessed with paired t tests and Pearson product-moment correlations for PSQI global score, component scores, and individual items, at Time 1 (T_1) versus Time 2 (T_2). This was done for the entire subject pool, as well as for separate subject groups (except DOES patients, since only five patients had complete questionnaires on two occasions).

As the primary analysis of *validity*, we assessed the degree to which the index detected differences between groups recognized clinically as distinct. This assumes that the index measures differences between groups at the same time point as a clinical "gold standard." In this case, the relevant "gold standard" diagnoses were based on a combination of clinical interviews, structured interviews, and polysomnographic data. For this analysis, an analysis of covariance (ANCOVA) was used to compare patient groups for PSQI global and component scores, and the Student-Neuman-Keul's procedure was used for pairwise comparisons. Age and sex were used as covariates because of group differences in age and sex ratio. A multiple ANCOVA (MANCOVA) was performed for the PSQI global score, again using age and sex as covariates.

As a secondary analysis of validity, we compared PSQI scores with polysomnographic results, being cognizant of the fact that PSQI scores reflect the experience of sleep during the previous month, while polysomnographic data were limited to 2 or 3 nights. PSQI estimates of sleep latency, sleep duration, and sleep efficiency were compared to their homologous polysomnographic measures, using both *t* tests and Pearson product-moment correlations. Global PSQI scores were also compared to polysomnographic variables selected a priori as being likely to correlate with overall sleep quality, again using Pearson correlations. The specific variables selected were REM %, delta %, sleep latency, sleep efficiency, and sleep duration. Finally, group differences for these polysomnographic variables were assessed using one-way ANOVAs.

Results

General Results. Subjects found the PSQI easy to use and understand. Ten subjects out of an original pool of 158 failed to give complete responses to all items, and were therefore omitted from any further analyses; nine of these 10 were DOES patients.

The PSQI global score has a possible range of 0-21 points. Actual scores ranged from 0 to 20 points, with an overall group mean of 7.4, median of 6.0, and SD of 5.1. For individual components, each with a possible range of 0-3, the observed ranges were 0-3.

Age was negatively correlated with the subjective sleep quality ($r = -0.22, p < 0.05$) and daytime dysfunction ($r = -0.29, p < 0.02$) component scores in the healthy controls. The PSQI global score and other component scores (sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, and use of sleeping medications) were not significantly correlated with age.

Internal Homogeneity. The seven *component* scores of the PSQI had an overall reliability coefficient (Cronbach's α) of 0.83, indicating a high degree of internal consistency. In other words, each of the seven components appears to measure a particular aspect of the same overall construct, viz., sleep quality. The largest component-total correlation coefficients were found for habitual sleep efficiency and subjective sleep quality (0.76 for each), and the smallest correlation coefficient was found for sleep disturbances (0.35). The mean component-total correlation coefficient was 0.58. Pearson product-moment correlations between component scores and the PSQI global score were also calculated for the entire group, as well as each group separately (Table 1). Once again, the strongest correlations were seen for habitual sleep efficiency and subjective sleep quality.

Individual *items* were also strongly correlated with each other, indicated by a reliability coefficient (Cronbach's α) of 0.83. Item-total correlation coefficients ranged from 0.66 for question #9 (enthusiasm to get things done) to 0.20 for item #8 (difficulty staying awake). Pearson product-moment correlations between individual items and the global score ranged from 0.83 (subjective sleep quality) to 0.07 (cough or snore during sleep) (Table 2).

Performance Consistency (Test-Retest Reliability). Ninety-one patients completed the PSQI on two separate occasions. Paired *t* tests for the global PSQI score, as well as the seven individual component scores, showed no significant

differences between T_1 and T_2. Two differences were noted for depressed patients, who showed a reduction in sleep disturbances ($t = 2.32$, $p = 0.03$) and daytime dysfunction ($t = 3.46$, $p = 0.002$) at T_2.

1. Pearson product-moment correlations.
2. DIMS = Disorders of Initiating and Maintaining Sleep.
3. DOES = Disorders of Excessive Somnolence.

Pearson product-moment correlations again demonstrated stability in global and component scores. For the entire subgroup in which T_1 and T_2 measures were obtained, the T_1-T_2 correlation coefficient for global PSQI scores was 0.85 ($p < 0.001$). Component scores had coefficients ranging from 0.84 (sleep latency) to 0.65 (medication use) ($p < 0.001$ for each component score). Global PSQI scores for each diagnostic group were also significantly correlated between the two testing times, with r's > 0.40 ($p < 0.005$) for each group. Component scores within each subject group showed more variability across time, but all of these scores were significantly correlated (r's > 0.35, $p < 0.05$). The single exception was medication use in control subjects, which showed no correlation between the two testing times.

Validity. (Table 3, Figs. 1, 2). Global PSQI scores differed significantly between subject groups, using an ANCOVA with age and sex as covariates (Table 3). Control subjects differed from all patient groups (Student-Neuman-Keul's procedure). Furthermore, DIMS and depressed patients had significantly higher scores than DOES patients. Control subjects differed from DIMS and depressed patients on all individual component scores; controls also differed from DOES patients on three components (sleep disturbances, daytime dysfunction, and sleep quality). DOES and DIMS patients had significantly different scores on all components except sleep disturbances, and DOES and depressives patients differed on all components except sleep disturbance and daytime dysfunction.

Group differences resulted in distinctive component and global score profiles, shown in Fig. 1. Depressed and DIMS patients showed similar profiles, which differed from those of DOES patients and control subjects. These differences were further substantiated with a significant MANCOVA for component scores across groups (Hotelling's $T^2 = 2.62$, $p < 0.001$).

Age was a significant covariate only for the daytime dysfunction component; but contrary to expectations, these factors were *inversely* correlated, i.e., reported severity of daytime dysfunction tended to be greater in younger than in older subjects. Sex was a significant covariate for use of sleeping medications and habitual sleep efficiency, with males showing higher scores for each of these components. Age and sex were *both* significant covariates for the PSQI global score, but group differences were highly statistically significant even after covarying for these factors.

The distribution of global PSQI scores also differed between groups (Fig. 2). A post hoc cutoff score of 5 correctly identified 88.5% (131/148) of all patients and controls (kappa = 0.75, $p < 0.001$). This represents a sensitivity of 89.6% and a specificity of 86.5%. The same cutoff score correctly identified 84.4% (38/45) of DIMS patients, 88% (15/17) of DOES patients, and 97% (33/34) of depressives.

Group differences in PSQI global scores were also substantiated by polysomnographic results, which showed significant group differences for sleep latency ($F = 4.53$, $p < 0.001$), sleep efficiency ($F = 5.78$, $p < 0.001$), sleep duration ($F = 4.82$, $p < 0.003$), and number of arousals ($F = 2.87$, $p < 0.04$). Significant group differences were not found for rapid eye movement (REM) % or delta sleep %.

Validity of the PSQI was further examined by comparing PSQI estimates of sleep variables with those obtained by polysomnography. *T* tests showed no differences between PSQI estimates and laboratory findings for sleep latency, but PSQI estimates of the past month's usual sleep duration and efficiency were greater than

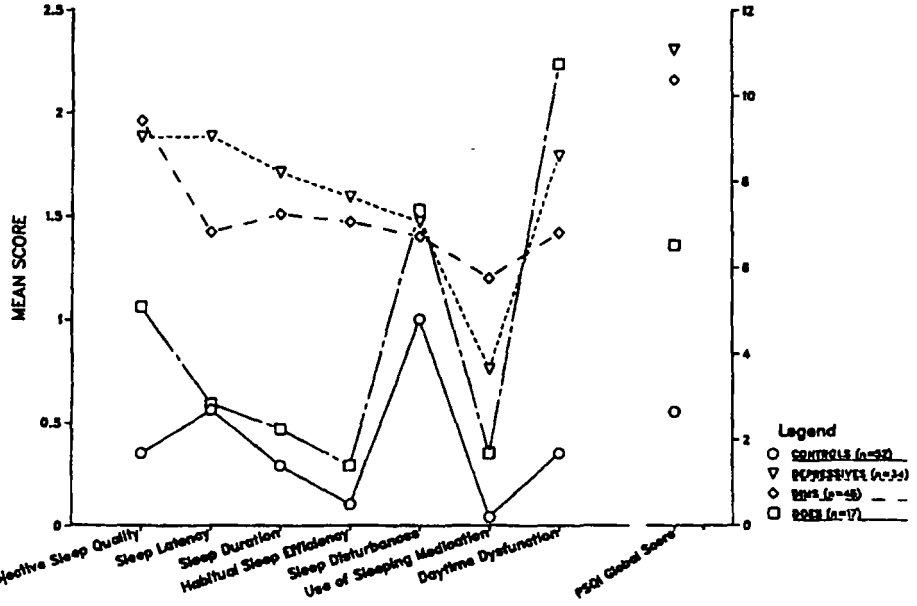
Table 3. Pittsburgh Sleep Quality Index (PSQI) comparisons between diagnostic groups[1]

Component	Mean score ± SD (adjusted mean) Controls ($n = 52$)	Depressives ($n = 34$)	DIMS ($n = 45$)	DOES ($n = 17$)	ANCOVA F	ANCOVA p	Significant Student-Neuman-Keuls' comparisons
Subjective sleep quality	0.35 ± 0.48 (0.40)	1.88 ± 0.88 (1.92)	1.96 ± 0.93 (1.91)	1.06 ± 0.75 (1.02)	35.9	0.0001	Controls vs. depressives, DIMS, DOES; DOES vs. depressives, DIMS
Sleep latency	0.56 ± 0.73 (0.70)	1.88 ± 1.15 (1.96)	1.42 ± 1.01 (1.31)	0.59 ± 0.87 (0.49)	15.3	0.0001	Controls vs. depressives, DIMS; DOES vs. depressives, DIMS
Sleep duration	0.29 ± 0.50 (0.31)	1.71 ± 1.14 (1.74)	1.51 ± 1.20 (1.46)	0.47 ± 0.80 (0.46)	20.4	0.0001	Controls vs. depressives, DIMS; DOES vs. depressives, DIMS
Habitual sleep efficiency	0.10 ± 0.30 (0.11)	1.59 ± 1.18 (1.63)	1.47 ± 1.24 (1.41)	0.29 ± 0.77 (0.30)	25.2[2]	0.0001	Controls vs. depressives, DIMS; DOES vs. depressives, DIMS
Sleep disturbances	1.00 ± 0.40 (0.95)	1.47 ± 0.51 (1.45)	1.40 ± 0.62 (1.43)	1.53 ± 0.72 (1.56)	8.4	0.0001	Controls vs. depressives, DIMS, DOES
Use of sleeping medication	0.04 ± 0.28 (0.12)	0.76 ± 1.21 (0.84)	1.20 ± 1.31 (1.09)	0.35 ± 1.00 (0.31)	7.9[2]	0.0001	Controls vs. depressives, DIMS; DOES vs. depressives, DIMS
Daytime dysfunction	0.35 ± 0.48 (0.44)	1.79 ± 0.69 (1.83)	1.42 ± 0.94 (1.37)	2.24 ± 0.90 (2.16)	33.2[3]	0.0001	Controls vs. depressives, DIMS, DOES; DOES vs. DIMS
PSQI global score	2.67 ± 1.70	11.09 ± 4.31	10.38 ± 4.57	6.53 ± 2.98	45.1[4]	0.001	Controls vs. depressives, DIMS, DOES; DOES vs. depressives, DIMS

1. DIMS = Disorders of Initiating and Maintaining Sleep. DOES = Disorders of Excessive Somnolence.
2. Significant effect of sex as covariate.
3. Significant effect of age as covariate.
4. Significant effect of age and sex as covariates.

Fig. 1. Pittsburgh Sleep Quality Index (PSQI): Mean component score profiles



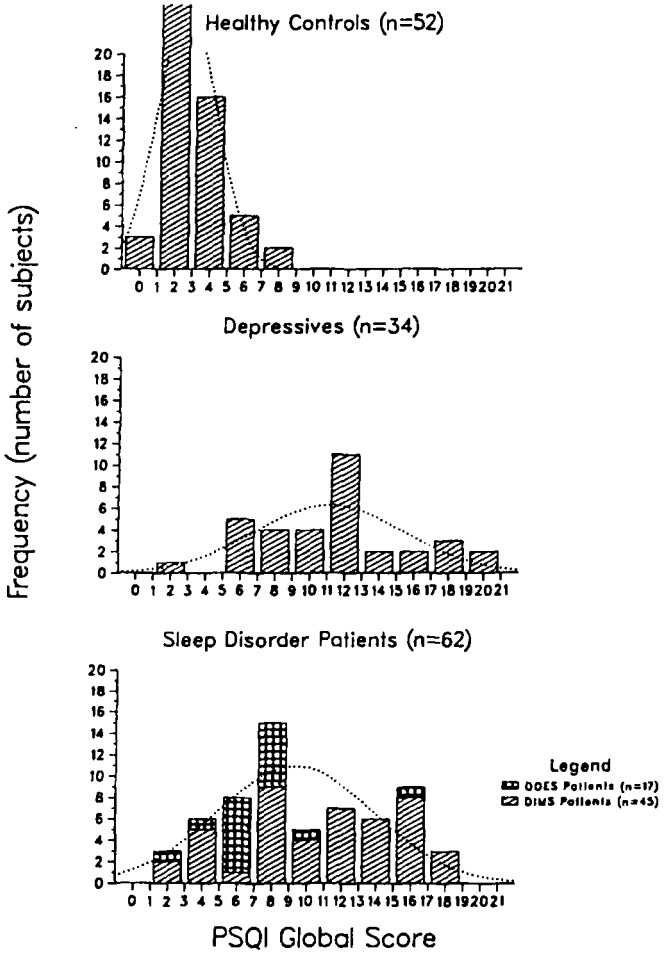
Depressed patients and patients with Disorders of Initiating and Maintaining Sleep (DIMS) have different components score profiles than do control subjects. Patients with Disorders of Excessive Somnolence (DOES) have a profile more similar to controls, but with expected elevations in subjective sleep quality, sleep disturbances, and daytme dysfunction. Significant group differences for individual components and overall profiles were substantiated with analyses of variance and multiple analyses of covariance (Table 3).

those obtained during polysomnography ($t = 9.98$ and 4.50, respectively; both p's < 0.001). This pattern was true for the total subject pool as well as individual subject groups. Pearson correlations demonstrated no significant positive correlations between PSQI estimates and polysomnographic results, except in sleep latency for the total subject pool ($r = 0.33$, $p < 0.001$) and for the depressive subgroup ($r = 0.37$, $p < 0.02$). Similarly, the global PSQI score was compared with several polysomnographic measures which we selected a priori as being likely to correlate with perceived sleep quality. For all subjects, the global score was weakly correlated only with objective sleep latency ($r = 0.20$, $p < 0.01$). For individual subject groups, the global PSQI score correlated only with REM % in controls ($r = 0.34$, $p < 0.006$) and number of arousals in depressives ($r = 0.47$, $p < 0.002$).

Discussion

Eighteen months of field testing with the PSQI have demonstrated that (1) subjects and patients find the index easy to use; (2) the seven major components of the index, as well as the 19 individual questions, are internally consistent; (3) the global scores, component scores, and individual question responses are stable across time; (4) the validity of the index is supported by its ability to discriminate patients from controls, and, to a more limited degree, by concurrent polysomnographic findings. We will

Fig. 2. Pittsburgh Sleep Quality Index (PSQI) global scores



PSQI global scores showed different distributions for control subjects, depressed patients, and sleep-disorder patients. A global score cutoff of > 5 correctly identified 88.5% of all controls and patients, yielding a sensitivity of 89.6% and a specificity of 86.5% (Kappa = 0.75, $p < 0.001$).

further discuss the format and clinimetric properties of the PSQI in relation to previous sleep questionnaires in the literature. We will also discuss possible applications for the PSQI in psychiatric clinical practice and research studies.

Questionnaire Format. A number of previous studies have reported on the use of self-rated or interviewer-administered sleep-quality questionnaires. In general, these instruments are of three types: habitual (i.e., "usual") sleep questionnaires for population surveys; habitual ("usual") sleep questionnaires for clinical investigations; and postsleep inventories.

The first type of questionnaire is used in epidemiological surveys of habitual or usual sleep habits, sleep difficulties, and sleep quality (e.g., McGhie and Russell,

1962; Karacan et al., 1976, 1983; Bixler et al., 1979; Johnson and Spinweber, 1983; Lugaresi et al., 1983; Welstein et al., 1983; Mellinger et al., 1985). The questions are usually few in number and general in scope, typically focusing on sleep duration, the presence of insomnia, and the use of medications for sleep. Habitual sleep questionnaires have also been used in clinical studies, most often to compare subjective reports with polysomnographic correlates (e.g., Monroe, 1969; Baekeland and Roy, 1971; Mendelson et al., 1984, 1986) or to examine differences between groups of subjects (McGhie, 1966; Beutler et al., 1978; Domino et al., 1984). These questionnaires are often more detailed than those used in large-scale surveys, and they include subjective estimates of sleep quality; however, their main focus is again on quantitative measures. The final type of questionnaire found in the literature is postsleep inventories (e.g., Samuel, 1964; Lewis, 1969; Frankel et al., 1973, 1976; Carskadon et al., 1976; Webb et al., 1976; Parrott and Hindmarch, 1978, 1980; Ellis et al., 1981; Mendelson et al., 1984). These instruments ask a variety of quantitative and qualitative questions about the previous night's sleep. They vary considerably in format, and in the number and type of questions. Postsleep inventories have been used to examine differences between subjective reports and objective polysomnographic findings, to study "good" and "bad" sleep, and to assess medication effects on sleep.

The PSQI has some similarities to these other questionnaires, but also has some important differences. The first comparison is in time interval of assessment. Most habitual sleep questionnaires do not specify a particular time frame, although there are some exceptions to this generalization (e.g., McGhie, 1966; Mendelson et al., 1986). The PSQI assesses a 1-month interval, which, as mentioned above, is clinically and scientifically useful. While postsleep inventories are unambiguous in their assessment of a single night's sleep, they are not as useful for detecting patterns of dysfunction, as noted previously.

A second comparison regards the type of questions included in the questionnaire. The PSQI is similar to many of the habitual sleep questionnaires in the type of questions included, e.g., estimates of sleep latency and duration, and frequency and severity estimates of problems. The PSQI's combination of quantitative and qualitative information is not found, however, in some of the more carefully studied questionnaires, such as those of Domino et al. (1984) and Webb et al. (1976).

The use of "component" scores in the PSQI is also similar to several other questionnaires, which have generated between 4 and 11 "factors" relating to sleep quality (Webb et al., 1976; Beutler et al., 1978; Parrott and Hindmarch, 1978; Domino et al., 1984). One major difference is that other questionnaires have more often included factors concerning mental activity before and during sleep. Another difference is that these other questionnaires have used factor analysis to generate specific factors, while the PSQI components are empirical and clinical in origin, rather than statistical.

A third comparison between the PSQI and other questionnaires regards scoring methods. The PSQI assigns ordinal scores to quantitative and qualitative information, allowing for the generation of component scores and a single global score. Except for McGhie (1966) and Beutler et al. (1978), previous questionnaires

do not use numerical scores for components or global scores. In the latter questionnaire, standard scores were determined by transforming the actual values of eight differently weighted "factors," and assigning an arbitrary value of "50" to the control mean. The PSQI global score has the advantages of giving a single overall assessment of sleep quality, being simple to calculate, and allowing for direct comparisons of individual patients or groups.

Finally, the PSQI was designed to assess clinical samples, while most previous questionnaires have been designed to assess normal sleep habits or entire populations. Although some questionnaires have been applied to patients with insomnia diagnosed by ASDC criteria (Mendelson et al., 1984, 1986), most have used patient samples that were not diagnosed according to current sleep disorders or psychiatric nomenclature.

Clinical Properties: Homogeneity and Consistency. The Cronbach's α of 0.83 obtained for PSQI components indicates a high degree of internal homogeneity (Feinstein, 1987). In other words, each of the components measures part of a coherent overall construct. Subjective sleep quality (item #6) showed one of the highest component-total correlation coefficients, which further supports this notion. The low component-total correlation coefficient seen for sleep disturbances may be the result of the large number of items that make up this component, as well as the fact that these items may be particularly susceptible to variation between individuals and over time. The sleep disturbance component also showed the least difference between diagnostic groups.

Data about internal homogeneity have been reported for three other sleep questionnaires, each of which used factor-analytic techniques. Domino et al. (1984) reported a factor analysis which yielded seven factors accounting for 71.7% of the total variance in the questionnaire. Cronbach's α was computed for these factors, with a median α of 0.82. Beutler et al. (1978) analyzed their 186-item questionnaire and found eight factors accounting for 59% of the total variance. The number of questions contributing to each factor ranged between 4 and 17. Finally, the postsleep inventory of Webb et al. (1976) had seven factors accounting for 54.5% of the total variance; specific questions with inter-item correlations higher than 0.65 were deliberately excluded. It is difficult to compare the PSQI with these questionnaires, due to differences in time frame of assessment, number of total questions, and subject populations tested. Most important, components of the PSQI were selected on purely clinical grounds, and not on the basis of factor analysis.

Overall consistency (test-retest reliability) of the PSQI was better for the entire subject pool than for any specific group. Of particular interest is the finding that DIMS patients had the highest correlations across time, while the control subjects had the lowest correlations. One possible explanation for the lower stability in the control subjects' scores is their low scores on all components, and particularly medication use. For both control subjects and DIMS patients, component correlations were highest for sleep latency and sleep duration, two "quantitative" variables. Correlation coefficients were lower for daytime dysfunction and sleep quality, two of the more "qualitative" components, as well as for the sleep disturbances component, which may include items that are variable between individuals and across time.

Consistency for the PSQI is lower than that reported by Domino et al. (1984), who administered their questionnaire on two occasions separated by 10 weeks, and found Pearson correlations for the seven factors of their questionnaire ranging from 0.68 to 0.79. However, this sample did not include patients with sleep or psychiatric disorders.

Clinimetric Properties: Validity. The identification of "good" and "poor" sleepers for research studies relies on subjective assessments of sleep quality, clinical interviews, and polysomnographic studies. The PSQI provides a standardized, quantitative measure of sleep quality that quickly identifies good and poor sleepers, and compares favorably with the "gold standard" of clinical and laboratory diagnosis. In the current study, good and poor sleepers consisted of healthy control subjects and depressed or sleep-disordered patients. A global PSQI score > 5 provided a sensitive and specific measure of poor sleep quality, relative to clinical and laboratory measures. Age and sex did not strongly correlate with PSQI component scores, but they were significant covariates for the global score. Given the differences in mean age and sex ratio between groups (with good sleepers being older than poor sleepers), the current results are likely to underestimate the PSQI's ability to identify good and poor sleepers.

Distinct component score profiles emerged for controls, DOES patients, and DIMS/depressed patients. The PSQI did *not* differentiate DIMS and depressed patients. This is not surprising, since the sleep disturbance of depressives is most often a sleep onset and maintenance insomnia. In fact, the current study lends validity to the classification of depressive sleep disturbance as a DIMS in the ASDC classification.

The PSQI is primarily intended to measure sleep quality and to identify good and bad sleepers, not to provide accurate clinical diagnoses. Nevertheless, responses to specific questions can point the clinician toward areas for further investigation. This is particularly true for the "sleep disturbances" component, which may guide clinical evaluations for specific patients, even though mean scores do not discriminate between groups. Furthermore, a PSQI global score > 5 indicates that a subject is having severe difficulties in at least two areas, or moderate difficulties in more than three areas. The global score is therefore "transparent," i.e., it conveys information about the severity of the subject's problem, and the number of problems present, through a single simple measure (Feinstein, 1987).

A number of other studies have also validated their sleep questionnaires by comparing different subject populations. For example, Domino et al. (1984) validated their scale by administering it to patients with and without complaints of sleep disturbance at a family physician's office, and to patients with and without depressive symptoms at a community mental health center. In each case, the patient groups differed significantly on a number of the questionnaire's scales. Beutler et al. (1978) used a stepwise discriminant function analysis to identify self-proclaimed insomniacs and controls. Their discriminant model, including subject age and three of the eight factors in their questionnaire, correctly identified 93% (86/92) of subjects. A separate discriminant analysis correctly identified 86% (37/43) of insomniacs who used or did not use medications. Mendelson et al. (1984, 1986)

found statistically significant differences on self-report sleep questionnaires for insomniacs versus controls. McGhie (1966) compared depressed and nondepressed psychiatric patients, and found no differences on the total sleep disturbance scale of his questionnaire. Finally, Webb et al. (1976) found differences between "good" and "bad" sleep episodes, and between high school and elderly subjects, with their postsleep inventory. Like these previous questionnaires, the PSQI separates patients with different diagnoses, but differs in that control subjects and patients in this study were diagnosed according to current research and clinical criteria. In addition, except for Beutler et al. (1978), previous reports have not indicated the sensitivity and specificity of their scales.

A number of other studies have reported on the use of polysomnography to validate subjective sleep reports (e.g., Lewis, 1969; Monroe, 1969; Baekeland and Hoy, 1971; Bixler et al., 1973; Frankel et al., 1973, 1976; Carskadon et al., 1976; Mendelson et al., 1984, 1986; Hoch et al., 1987). Several consistent findings emerge from these reports. First, subjects with and without insomnia are not "accurate" in their subjective report of variables such as sleep latency, sleep duration, and number of arousals. However, while control subjects tend to overestimate their ability to sleep, insomniacs tend to underestimate it, perhaps because they misperceive the experience of being asleep (W. Mendelson, personal communication, April 15, 1988). Second, while subjective estimates and objective measures of sleep differ in actual amount, they are often strongly and positively correlated. Finally, postsleep questionnaires yield more accurate subjective estimates that are more strongly correlated with polysomnographic findings. The current findings using the PSQI did not replicate these general findings, as PSQI responses were not found to correlate with polysomnographic measures. It is not surprising that subjects differed in subjective and polysomnographic variables, since the PSQI asks for a global estimate spanning 1 month, and is not sensitive to daily variability.

Applications. The PSQI's simplicity and its ability to identify different groups of patients suggest several clinical and research applications in psychiatry and general medical settings. Most fundamentally, it may be used as a simple screening measure to identify cases and controls, or "good" and "poor" sleepers. In a general clinical setting, the PSQI could be used to screen patients for the presence of significant sleep disturbance. In psychiatric settings, the PSQI may identify patients who are likely to have a sleep disturbance concomitant with their psychiatric symptoms. In addition, it may direct the clinican to specific areas of dysfunction that require further investigation. The PSQI could also be used in clinical research and epidemiological studies to identify groups that differ in the quality of their sleep.

The PSQI may also have several longitudinal applications in clinical practice and research. For example, it could be used to examine the course and natural history of sleep/wake disorders. It could also be used to monitor the progression of sleep disturbances and their interaction with other symptoms during the course of psychiatric illnesses such as depression. Rodin et al. (1988) recently published one of the few studies to examine the interaction between depressive symptoms and sleep disturbance longitudinally. The PSQI may be helpful in future studies of this type, providing more detailed information about types and severity of sleep disturbances

over time. Further, the PSQI could be useful in studying the relation between sleep quality and other variables, such as age, gender, health status, medical and psychiatric conditions, and performance on other psychological variables. Finally, the PSQI could be used to examine the longitudinal effects of specific therapeutic interventions for psychiatric disorders or sleep disorders. For example, sleep quality could be monitored during maintenance treatment of depression with medications or psychotherapy. Used in this way, the PSQI might also detect relapses heralded by the onset or reemergence of sleep disturbance.

Appendix. Pittsburgh Sleep Quality Index (PSQI)

Name _____ ID # _____ Date _____ Age _____

Instructions:

The following questions relate to your usual sleep habits during the past month *only*. Your answers should indicate the most accurate reply for the *majority* of days and nights in the past month. Please answer all questions.

1. During the past month, when have you usually gone to bed at night?

   USUAL BED TIME _____

2. During the past month, how long (in minutes) has it usually take you to fall asleep each night?

   NUMBER OF MINUTES _____

3. During the past month, when have you usually gotten up in the morning?

   USUAL GETTING UP TIME _____

4. During the past month, how many hours of *actual sleep* did you get at night? (This may be different than the number of hours you spend in bed.)

   HOURS OF SLEEP PER NIGHT _____

For each of the remaining questions, check the one best response. Please answer *all* questions.

5. During the past month, how often have you had trouble sleeping because you...

   (a) Cannot get to sleep within 30 minutes

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (b) Wake up in the middle of the night or early morning

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (c) Have to get up to use the bathroom

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (d) Cannot breathe comfortably

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (e) Cough or snore loudly

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (f) Feel too cold

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (g) Feel too hot

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (h) Had bad dreams

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

   (i) Have pain

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

(j) Other reason(s), please describe _____

_____

How often during the past month have you had trouble sleeping because of this?

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

6. During the past month, how would you rate your sleep quality overall?
   - Very good ____
   - Fairly good ____
   - Fairly bad ____
   - Very bad ____
7. During the past month, how often have you taken medicine (prescribed or "over the counter") to help you sleep?

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

8. During the past month, how often have you had trouble staying awake while driving, eating meals, or engaging in social activity?

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

9. During the past month, how much of a problem has it been for you to keep up enough enthusiasm to get things done?
   - No problem at all ____
   - Only a very slight problem ____
   - Somewhat of a problem ____
   - A very big problem ____
10. Do you have a bed partner or roommate?
    - No bed partner or roommate ____
    - Partner/roommate in other room ____
    - Partner in same room, but not same bed ____
    - Partner in same bed ____

If you have a roommate or bed partner, ask him/her how often in the past month you have had...

(a) Loud snoring

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

(b) Long pauses between breaths while asleep

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

(c) Legs twitching or jerking while you sleep

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

(d) Episodes of disorientation or confusion during sleep

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

(e) Other restlessness while you sleep; please describe _____

_____

Not during the past month ____	Less than once a week ____	Once or twice a week ____	Three or more times a week ____

Scoring Instructions for the Pittsburgh Sleep Quality Index

The Pittsburgh Sleep Quality Index (PSQI) contains 19 self-rated questions and 5 questions rated by the bed partner or roommate (if one is available). Only self-rated questions are included in the scoring. The 19 self-rated items are combined to form seven "component" scores, each of which has a range of 0-3 points. In all cases, a score of "0" indicates no difficulty, while a score of "3" indicates severe difficulty. The seven component scores are then added to yield one "global" score, with a range of 0-21 points, "0" indicating no difficulty and "21" indicating severe difficulties in all areas.

Scoring proceeds as follows:

Component 1: Subjective sleep quality

Examine question #6, and assign scores as follows:

Response	Component 1 score
"Very good"	0
"Fairly good"	1
"Fairly bad"	2
"Very bad"	3

Component 1 score: _____

Component 2: Sleep latency

1. Examine question #2, and assign scores as follows:

Response	Score
≤ 15 minutes	0
16-30 minutes	1
31-60 minutes	2
> 60 minutes	3

Question #2 score: _____

2. Examine question #5a, and assign scores as follows:

Response	Score
Not during the past month	0
Less than once a week	1
Once or twice a week	2
Three or more times a week	3

Question #5a score: _____

3. Add #2 score and #5a score

Sum of #2 and #5a: _____

4. Assign component 2 score as follows:

Sum of #2 and #5a	Component 2 score
0	0
1-2	1
3-4	2
5-6	3

Component 2 score: _____

Component 3: Sleep duration

Examine question #4, and assign scores as follows:

Response	Component 3 score
> 7 hours	0
6-7 hours	1
5-6 hours	2
< 5 hours	3

Component 3 score: _____

Component 4: Habitual sleep efficiency

(1) Write the number of hours slept (question # 4) here: _____

(2) Calculate the number of hours spent in bed:

Getting up time (question # 3): _____

− Bedtime (question # 1): _____

Number of hours spent in bed: _____

(3) Calculate habitual sleep efficiency as follows:

(Number of hours slept/Number of hours spent in bed) × 100 = Habitual sleep efficiency (%)

(_____/_____) × 100 = _____%

(4) Assign component 4 score as follows:

Habitual sleep efficiency %	Component 4 score
> 85%	0
75-84%	1
65-74%	2
< 65%	3

Component 4 score: _____

Component 5: Sleep disturbances

(1) Examine questions # 5b-5j, and assign scores for *each* question as follows:

Response	Score
Not during the past month	0
Less than once a week	1
Once or twice a week	2
Three or more times a week	3

#5b score _____
c score _____
d score _____
e score _____
f score _____
g score _____
h score _____
i score _____
j score _____

(2) Add the scores for questions # 5b-5j:

Sum of # 5b-5j: _____

(3) Assign component 5 score as follows:

Sum of # 5b-5j	Component 5 score
0	0
1-9	1
10-18	2
19-27	3

Component 5 score: _____

Component 6: Use of sleeping medication

Examine question # 7 and assign scores as follows:

Response	Component 6 score
Not during the past month	0
Less than once a week	1
Once or twice a week	2
Three or more times a week	3

Component 6 score: _____

Component 7: Daytime dysfunction

(1) Examine question # 8, and assign scores as follows:

Response	Score
Never	0
Once or twice	1
Once or twice each week	2
Three or more times each week	3

Question # 8 score: _____

(2) Examine question # 9, and assign scores as follows:

Response	Score
No problem at all	0
Only a very slight problem	1
Somewhat of a problem	2
A very big problem	3

Question # 9 score: _____

(3) Add the scores for question # 8 and # 9:

Sum of #8 and #9: _____

(4) Assign component 7 score as follows:

Sum of # 8 and #9	Component 7 score
0	0
1-2	1
3-4	2
5-6	3

Component 7 score: _____

Global PSQI Score

Add the seven component scores together:

Global PSQI Score: _____

A Double-Blind Placebo-Controlled Study of Lamotrigine Monotherapy in Outpatients With Bipolar I Depression

Joseph R. Calabrese, M.D.; Charles L. Bowden, M.D.; Gary S. Sachs, M.D.; John A. Ascher, M.D.; Eileen Monaghan; and G. David Rudd, M.S., Pharm.D., for the Lamictal 602 Study Group

Background: More treatment options for bipolar depression are needed. Currently available antidepressants may increase the risk of mania and rapid cycling, and mood stabilizers appear to be less effective in treating depression than mania. Preliminary data suggest that lamotrigine, an established antiepileptic drug, may be effective for both the depression and mania associated with bipolar disorder. This is the first controlled multicenter study evaluating lamotrigine monotherapy in the treatment of bipolar I depression.

Method: Outpatients with bipolar I disorder experiencing a major depressive episode (DSM-IV, N = 195) received lamotrigine (50 or 200 mg/day) or placebo as monotherapy for 7 weeks. Psychiatric evaluations, including the Hamilton Rating Scale for Depression (HAM-D), the Montgomery-Asberg Depression Rating Scale (MADRS), Mania Rating Scale, and the Clinical Global Impressions scale for Severity (CGI-S) and Improvement (CGI-I) were completed at each weekly visit.

Results: Lamotrigine 200 mg/day demonstrated significant antidepressant efficacy on the 17-item HAM-D, HAM-D Item 1, MADRS, CGI-S, and CGI-I compared with placebo. Improvements were seen as early as week 3. Lamotrigine 50 mg/day also demonstrated efficacy compared with placebo on several measures. The proportions of patients exhibiting a response on CGI-I were 51%, 41%, and 26% for lamotrigine 200 mg/day, lamotrigine 50 mg/day, and placebo groups, respectively. Adverse events and other safety results were similar across treatment groups, except for a higher rate of headache in the lamotrigine groups.

Conclusion: Lamotrigine monotherapy is an effective and well-tolerated treatment for bipolar depression.

(J Clin Psychiatry 1999;60:79–88)

More effective treatments for the depressive episodes of bipolar disorder are needed. Currently available mood stabilizers, including lithium, are effective in the treatment of mania but appear to be less effective in the treatment of bipolar depression.[1] The adjunctive use of antidepressant medications is common, but this practice can put patients with bipolar disorder at increased risk for the development of hypomania, mania, or cycle acceleration.[2] During the development of the antiepileptic compound lamotrigine, the drug was observed to improve mood, alertness, and social interactions in some patients.[3] These early observations in patients with epilepsy stimulated interest in the evaluation of lamotrigine as an antidepressant and mood stabilizer. Open-label clinical reports involving over 200 patients suggest that lamotrigine may possess a broad spectrum of mood stabilizing efficacy in bipolar I and II disorder when given as adjunct treatment or as monotherapy.[4–18]

A series of controlled studies has been initiated to evaluate the efficacy and safety of lamotrigine in the various phases of bipolar I and II disorder. This report presents data from the first study in this series, which compared 2 doses of lamotrigine with placebo in the treatment

of a major depressive episode in patients with bipolar I disorder.

METHOD

Patients

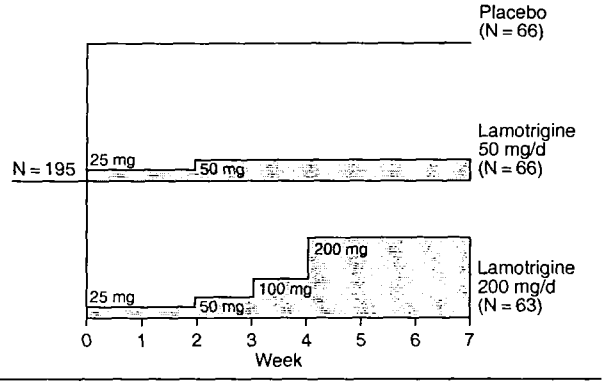
Men and women at least 18 years of age were eligible for the study if they were diagnosed with bipolar I disorder, as defined by DSM-IV criteria, and had at least 2 previous mood episodes during the past 10 years, at least 1 of which was a manic or mixed episode. The diagnosis was confirmed by the Structural Clinical Interview for DSM-IV. Eligible patients were currently experiencing a major depressive episode with a duration ≥ 2 weeks but ≤ 12 months. A minimum score of 18 on the 17-item Hamilton Rating Scale for Depression (HAM-D)[19,20] was required at study entry. Patients with rapid-cycling bipolar disorder; abnormal thyroid function tests; a diagnosis of or treatment for panic disorder, obsessive-compulsive disorder, social phobia, or bulimia nervosa in the previous 12 months; a history of substance dependence (previous year) or abuse (previous month) or with a positive toxicological screen; a chronic cardiac, renal, or hepatic condition or an unstable medical condition; or epilepsy were excluded. Pregnant or lactating women and patients who were actively suicidal were also excluded. Patients with worsening of psychiatric status such that symptoms constituted a danger to them or to others were to be discontinued. Patients must have discontinued any psychoactive drug within a time equal to 5 elimination half-lives prior to randomization.

Study Design and Procedures

This randomized, double-blind, parallel-group, multicenter study (Glaxo Wellcome Protocol 105-602) was conducted to compare the efficacy and safety of lamotrigine monotherapy and placebo in the treatment of bipolar I depression. Careful consideration was given to the use of placebo in this trial. Institutional review board (United States) and ethics committee (outside the United States) approvals were obtained, and patients provided written, informed consent. After screening and baseline assessments confirmed that entry criteria were met, equivalent numbers of patients were randomly assigned to treatment with a target dose of either lamotrigine 50 mg/day (25 mg b.i.d., N = 66), lamotrigine 200 mg/day (100 mg b.i.d., N = 63), or placebo tablets (b.i.d., N = 66) (Figure 1). To balance the effects of recent use of lithium, randomization was stratified according to intensity of treatment with lithium (presence or absence of plasma levels of ≥ 0.4 mmol/L or dosing of ≥ 600 mg/day for ≥ 1 month) during the 5 months preceding study entry.

Patients randomly assigned to lamotrigine 50 or lamotrigine 200 mg/day received active lamotrigine as 25-mg chewable, dispersible tablets. The lamotrigine dose was

Figure 1. Flow Diagram of Study Design and Dose Escalation Schedule



escalated according to the following schedule to reach a target of 50 mg/day (weeks 1–2, 25 mg q.d.; weeks 3–7, 25 mg b.i.d.) or 200 mg/day (weeks 1–2, 25 mg q.d.; week 3, 25 mg b.i.d.; week 4, 50 mg b.i.d.; weeks 5–7, 100 mg b.i.d.) as shown in Figure 1. Placebo tablets were identical in appearance to the active drug. The number of placebo tablets was adjusted at each week and for each lamotrigine dose so that the total number of tablets administered per day (lamotrigine plus placebo) was always 8. Patients were provided with blister cards containing each week's medication. Compliance with the prescribed dosing regimen was determined by returned tablet counts at each treatment visit. The only other psychoactive drugs permitted were chloral hydrate, lorazepam, temazepam, or oxazepam as needed for control of agitation, insomnia, and hostile behaviors during the first 3 weeks of the treatment phase.

Clinic visits were conducted at screening (within 14 days prior to treatment), baseline (the day prior to the start of treatment), on the fourth day of treatment, and the end of every week for the 7-week duration of treatment. At the screening visit, patients underwent the following assessments: demographic characteristics, a modified version of the Structured Clinical Interview for DSM-IV (SCID),[21] psychiatric history (including age at onset of affective symptoms), physical examination, skin rash history, clinical laboratory tests (including thyroid function tests), urinalysis, urine screen for illicit drugs, electrocardiogram, and psychiatric rating scales including the HAM-D, the Montgomery-Asberg Depression Rating Scale (MADRS),[22] the Mania Rating Scale (first 11 items from the Schedule for Affective Disorders and Schizophrenia, Change Version; MRS),[23] and the Clinical Global Impressions scale for Severity (CGI-S).[24] At the baseline visit and each treatment visit, the following assessments were completed: HAM-D, MADRS, MRS, CGI-S, and Clinical Global Impressions scale for Improvement (CGI-I, day 4 onward)[24]; adverse event assessment by standardized verbal probe; and record of study and other

Table 1. Patient Disposition

Event	Placebo N	Placebo %	Lamotrigine 50 mg/day N	Lamotrigine 50 mg/day %	Lamotrigine 200 mg/day N	Lamotrigine 200 mg/day %
Randomized	66		66		63	
Withdrawn prematurely	19	29	23	35	18	29
Adverse event	10	15	12	18	10	16
Death	1	2	0	0	0	0
Inadequate response	2	3	0	0	1	2
Protocol violation	1	2	1	2	2	3
Other	5	8	10	15	5	8
Completed	47	71	43	65	45	71
Received ≥ 1 dose of study drug (safety population)	65		66		63	
Had baseline and ≥ 1 post-randomization assessment (efficacy population)	65		64		63	

medications. The investigators' reports of clinically significant manifestations of manic, hypomanic, or mixed episodes were recorded as adverse events whether or not they met full DSM-IV criteria. Patients who developed a rash were withdrawn unless the rash was clearly unrelated to use of the study drug. At the last treatment visit (day 50 or discontinuation), patients were given physical examinations and clinical laboratory tests.

Blood samples for determination of trough lamotrigine plasma concentrations were drawn at screening, 2 and 4 weeks after the start of treatment, and at the last treatment visit (day 50 or discontinuation). The potential correlation between plasma concentrations and response will be the subject of a future report.

Patients who completed this 7-week study could elect to enter a 1-year open-label continuation study. Patients who withdrew prematurely or chose not to enter the continuation study discontinued lamotrigine dosing without taper. They returned 2 weeks after study treatment for a follow-up visit with psychiatric assessments and reporting of adverse events and concomitant medications. Patients who elected to participate in the continuation trial were initiated (placebo patients) or continued (lamotrigine patients) on lamotrigine treatment during a blinded transition period.

Data Analysis

Efficacy. The study was powered to detect a 5.0-point difference between lamotrigine and placebo on 17-item HAM-D change from baseline scores, estimating mean ± SD placebo change from baseline scores of 6.0 ± 7.0, a 2-sided alpha level of .05, and a power of 0.90. Based on these assumptions, approximately 60 patients were enrolled to provide 40 completed patients per treatment group. All patients who completed baseline assessments and at least 1 postrandomization efficacy assessment were included in the efficacy analyses. In addition to analysis of observed data at each time point, efficacy variables were assessed using last-observation-carried-forward (LOCF) scores. CGI-I scores and change from baseline scores for the other overall efficacy scales (17-item HAM-D, 31-item HAM-D, HAM-D item 1, MADRS, MRS, and CGI-S) were tested for treatment group differences at each week using analysis of variance (ANOVA). Significant differences in change scores were determined for each visit using a 2-tailed comparison alpha level of .05. In addition, a responder analysis was performed on the last observed 17-item HAM-D, MADRS, and CGI-I scores comparing the rate of response among treatment groups by a stratum-adjusted Cochran-Mantel-Haenszel chi-square analysis. A response was categorically defined as 50% or more reduction on the 17-item HAM-D or MADRS scales or a rating of very much improved or much improved on the CGI-I scale.

Medication compliance. All patients who received at least 1 dose of study medication and had dosing records were included in the compliance analyses. Medication compliance during the 50-day treatment phase was assessed from compliance records (tablets taken/tablets prescribed), and the percentage of patients with greater than 70% compliance was calculated.

Safety. All patients who received at least 1 dose of study drug were included in the safety analysis. The incidence of patients reporting a treatment-emergent adverse event (one emerging or worsening after beginning study drug treatment) was summarized. To compare the incidence of adverse events between treatment groups, 95% confidence intervals were determined. For clinical laboratory tests and vital signs, all patients with clinically significant changes, i.e., values or changes from baseline outside predetermined ranges, were listed.

RESULTS

Sample Composition

One hundred ninety-five patients (66 placebo, 66 lamotrigine 50 mg/day, and 63 lamotrigine 200 mg/day) were randomized to treatment at 15 centers in the United States and 6 centers in the United Kingdom, France, and Australia. Approximately 30% of the patients withdrew prematurely from the trial, most frequently for adverse events or other reasons (e.g., lost to follow-up or withdrawn consent, Table 1). Four patients were withdrawn for protocol violations (noncompliance with scheduled visits in 3 cases and continued use of disallowed psychotropic medications in the other). The rate of withdrawals and completions and the specific reasons for withdrawal were similar across the 3 treatment groups. All patients but one on placebo (who was immediately lost to follow-up and had no record of study drug administration) were included in the safety analyses. The 192 patients who received at least 1 dose of study medication and completed the baseline and at least 1 postrandomization assessment were included in the efficacy analyses.

Table 2. Patient Characteristics[a]

Characteristic	Placebo (N = 66)	Lamotrigine 50 mg/day (N = 66)	Lamotrigine 200 mg/day (N = 63)

[a]Abbreviation: CGI-S = Clinical Global Impressions scale for Severity.
[b]Excluding patients with episodes too numerous to count.
[c]Based on Structured Clinical Interview for DSM-IV.
[d]Plasma levels ≥ 0.4 mmol/L or dosing of ≥ 600 mg/day for ≥ 1 month.

Patient Characteristics

The gender, age, psychiatric history, and baseline illness of the patients were similar across treatment groups (Table 2). Approximately 60% of patients in each treatment group were women, and the mean age was approximately 40 years. Over 50% of the patients had been previously hospitalized, and over 30% had attempted suicide. For the majority of patients, the current depressive episode had lasted for at least 8 weeks prior to enrollment. Other indications of their baseline severity (CGI-S, SCID, melancholia) suggest that these patients were moderately to markedly ill when enrolled in the study. Randomization was stratified to balance the groups for the use of lithium at minimally active levels in the 5 months prior to study entry.

Table 3. Previous Treatment for Bipolar Disorder (N = 178)

Treatment	Patients With Prior Treatment[a]	Responders[b] (%)	Intolerant[b] (%)
Antidepressants	85	52	73
Lithium	65	59	34
Valproate	37	45	29
Neuroleptics	28	55	33
Carbamazepine	22	36	44
Electroconvulsive therapy	7	67	25

[a]Percentage based on total number of patients with any prior treatment.
[b]Percentage based on total number of patients with prior treatment in each drug category.

One hundred seventy-eight (91%) of 195 patients had been previously treated for bipolar disorder. Table 3 describes the prior medication history of this patient population, including the percentage responding to and the percentage unable to tolerate individual medications. The incidence of prior treatment described in Table 3 was similar across treatment groups.

Efficacy Results

Observed and LOCF results for all efficacy scales at the last treatment visit are provided in Table 4.

HAM-D scores. 17-Item HAM-D. The mean ± SD baseline 17-item HAM-D score was 24 ± 4 in each treatment group. Both lamotrigine groups demonstrated a mean 13-point improvement in 17-item HAM-D scores over the course of treatment, which was significantly greater than the 9-point improvement in placebo group scores (Table 4; observed scores). Significant improvement for lamotrigine 200 mg/day, but not lamotrigine 50 mg/day, compared with placebo was first noted at week 5 (Figure 2). LOCF results were qualitatively similar, reaching a trend ($p = .084$) at endpoint for the lamotrigine 200-mg/day group only.

HAM-D Item 1. Mean scores for HAM-D item 1 (depressed mood) were reduced over the treatment period by at least 1.1 points in each of the lamotrigine groups versus at least 0.6 points in the placebo group (observed and LOCF scores; see Table 4 and Figure 2). Significant differences compared with placebo were observed by the third week of treatment and continued throughout treatment.

31-Item HAM-D. Mean reductions in 31-item HAM-D of 19.1 in the lamotrigine 50-mg/day and lamotrigine 200-mg/day groups approached significance compared with placebo ($p = .072$ and $p = .086$, respectively, for observed scores; see Table 4). At week 4 only, the mean observed score for the lamotrigine 200-mg/day group was

Table 4. Baseline and Change From Baseline Scores (mean ± SD) on Efficacy Scales at Week 7[a]

[a]Dose > 50 mg/day in lamotrigine 200-mg/d group only after week 3.
[b]$p < .05$ vs. placebo.
[c]$p < .1$ vs. placebo.

significantly reduced compared with placebo. LOCF scores were not significantly different from placebo for either active treatment dose.

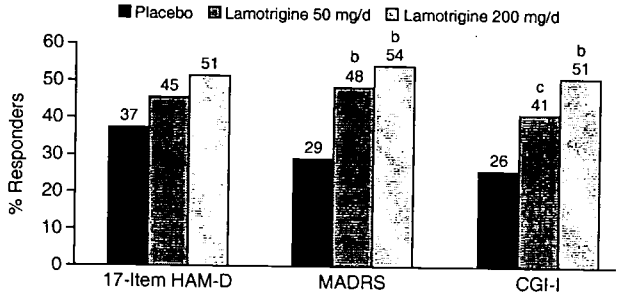
MADRS scores. Mean baseline MADRS scores were 28–29 ± 6–7 across treatment groups. Both lamotrigine 50-mg/day and lamotrigine 200-mg/day treatment resulted in mean 16- to 17-point reductions compared with the placebo reduction of 10 points (observed scores; see Table 4 and Figure 2). Improvement was significant by the third week of treatment and throughout the remainder of the study. LOCF analysis demonstrated statistically significant differences between lamotrigine 200 mg/day and placebo scores beginning at week 5; differences between lamotrigine 50 mg/day and placebo scores at the end of treatment approached significance ($p = .058$).

CGI-S scores. The mean ± SD baseline CGI-S score was 4.4 ± 0.7–0.8 (moderately to markedly ill) in each treatment group. CGI-S scores were significantly reduced compared with placebo by the end of treatment in the lamotrigine 200-mg/day group (observed and LOCF scores) and in the lamotrigine 50-mg/day group (observed scores) (see Table 4).

CGI-I scores. Mean CGI-I scores improved steadily with lamotrigine treatment; statistically significant differences in observed scores between both lamotrigine groups and placebo were observed by the third week and continued to the end of treatment (see Table 4). LOCF scores during weeks 4, 5, and 7 of treatment were significantly lower in the lamotrigine 200-mg/day group, but not the lamotrigine 50-mg/day group, compared with placebo.

Combined week 3 analysis. Since both lamotrigine groups received the same dosing for the first 3 weeks of treatment (≤ 50 mg/day), the first 3 weeks of data were analyzed comparing the entire population receiving lamotrigine (N = 127) with placebo. The lamotrigine-treated patients demonstrated significant improvements by week

Figure 3. Percentage of Patients Showing a Response to Treatment at Endpoint[a]



[a]Response defined as ≥ 50% reduction on the 17-Item HAM-D or MADRS scales or a rating of very much improved or much improved on the CGI-I scale.
[b]$p < .05$ vs. placebo.
[c]$p < .1$ vs. placebo.

3 ($p < .05$) on the following scales: HAM-D Item 1 (observed and LOCF scores), MADRS (observed and LOCF scores), CGI-I (observed scores), and CGI-S (observed scores).

Subgroup analysis. Results of each efficacy measure (17-item HAM-D, HAM-D Item 1, 31-item HAM-D, MADRS, CGI-S, and CGI-I) were compared between the 2 subgroups: patients with recent lithium use at minimally active levels (≥ 0.4 mmol/L or dosing of ≥ 600 mg/day for 1 month) during the 5 months preceding study entry and patients without such lithium use. There were no significant differences between the 2 subgroups on any of the efficacy measures. Furthermore, there was no significant effect of recent lithium use on the treatment group differences for any of the efficacy measures.

Responder analysis. Over 50% of the patients in the lamotrigine 200-mg/day group met the criteria for response to treatment by each of the following scales: 17-item HAM-D, MADRS, and CGI-I (Figure 3). The rate of response to lamotrigine 200 mg/day was statistically significant compared with placebo for both MADRS and CGI-I, whereas the rate of response to lamotrigine 50 mg/day was significantly higher than placebo only on the MADRS.

MRS scores. Mean ± SD baseline MRS scores were 2.0 ± 2.9 for the placebo group, 2.0 ± 3.3 for the lamotrigine 50-mg/day group, and 2.7 ± 3.2 for the lamotrigine 200-mg/day group. During treatment, mean changes in score were small and moved in both positive and negative directions. During treatment, groups did not differ significantly, with the exception that the placebo and lamotrigine 50-mg/day group observed scores demonstrated a reduction of 0.6 and a gain of 1.3, respectively, in MRS score on day 50 (see Table 4).

There were no significant differences between lamotrigine dose groups in efficacy scale change scores or responder rates at any treatment time.

Table 5. Most Common (≥ 5%) Adverse Events[a]

Compliance

In the placebo, lamotrigine 50-mg/day, and lamotrigine 200-mg/day dose groups, the majority (97%, 91%, and 97%, respectively) of the patients were over 70% compliant with medication dosing.

Adverse Events and Other Safety Data

Adverse events that emerged during the treatment phase and were experienced by 5% or more of patients in any treatment group are listed in Table 5. Ninety-two percent of placebo-treated patients reported any adverse event compared with 79% of patients in each lamotrigine group. The most common adverse event was headache, which was the only event observed significantly more frequently in the lamotrigine groups than the placebo group. Other common events were nausea, pain, rash, and dizziness. A smaller percentage of patients had any adverse events that were considered by investigators to be reasonably associated with study drug treatment (placebo, 60%; lamotrigine 50 mg/day, 54%; lamotrigine 200 mg/day, 51%).

There was one death in the placebo group on day 21 owing to probable suicide. Thirty-two other patients withdrew for adverse events (10 placebo, 12 lamotrigine 50 mg/day, and 10 lamotrigine 200 mg/day; see Table 1), including all of the serious adverse events described below. The adverse events accounting for more than one withdrawal included rash (2 placebo, 3 lamotrigine 50 mg/day, 4 lamotrigine 200 mg/day), a worsening of psychiatric de-

pression (1 placebo, 3 lamotrigine 50 mg/day), pruritus (1 placebo, 1 lamotrigine 200 mg/day), suicidal ideation (1 lamotrigine 50 mg/day, 1 lamotrigine 200 mg/day), suicide attempt (1 placebo, 1 lamotrigine 50 mg/day), and mania (2 lamotrigine 200 mg/day).

Nine patients experienced serious adverse events. Most of these events were related to bipolar disorder, including suicide (1 placebo), attempted suicide (1 placebo, 1 lamotrigine 50 mg/day), suicidal ideation (1 lamotrigine 50 mg/day, 1 lamotrigine 200 mg/day), worsening depression (1 lamotrigine 50 mg/day), and a psychotic episode (1 lamotrigine 50 mg/day). The illness-related events of 3 of the 4 patients in the lamotrigine 50-mg/day group (all but the attempted suicide) were the only serious adverse events considered to be possibly drug related. The other 2 events included a ruptured disk (placebo) and a myocardial infarction (lamotrigine 200 mg/day).

Rash was reported by 11% to 14% of patients in each treatment group (see Table 5). Rash led to withdrawal in 9 cases as noted above; the timing of these withdrawals ranged from 4 to 31 days after the start of treatment. None of the cases of rash were considered serious or resulted in hospitalization.

Manic, hypomanic, or mixed episodes were reported as adverse events in 10 patients (3 placebo [2 hypomania, 1 mixed], 2 lamotrigine 50 mg/day [1 hypomania, 1 mixed], 5 lamotrigine 200 mg/day [4 mania, 1 hypomania]; see Table 5), 2 of which led to withdrawal and none to hospitalization. In all but 1 of the 7 lamotrigine patients, these episodes occurred during the first 3 weeks of treatment when both lamotrigine groups were receiving 50 mg/day or less. The seventh patient's episode occurred on day 24, 3 days after the dose was increased to 100 mg/day. Overall, 7 (5.4%) of 129 patients on lamotrigine versus 3 (4.6%) of 65 patients on placebo developed these episodes ($p = .81$).

There were no apparent treatment group differences in clinical laboratory results postrandomization nor were there any patients with clinically significant changes in systolic blood pressure, diastolic blood pressure, pulse, or weight in any treatment group. Mean ± SD body weight at screening in the placebo, lamotrigine 50 mg/day, and lamotrigine 200 mg/day groups was 78.6 ± 16.0, 76.5 ± 17.6, and 82.2 ± 18.9 kg, respectively, and the mean change from screening to day 50 (LOCF scores) was 0.2, –0.4, and 0.0 kg, respectively.

DISCUSSION

This is the first randomized, parallel-group, placebo-controlled trial to evaluate any monotherapy treatment in bipolar I depression. The study results demonstrate that lamotrigine has significant antidepressant efficacy in bipolar I depression and that clinical improvement becomes evident as early as the third week of treatment.

Lamotrigine was significantly more effective than placebo on most, but not all, outcome measures. Patients receiving 200 mg daily exhibited significant improvement on all efficacy endpoints using both LOCF and observed case analyses, except the LOCF analysis of the 17-item HAM-D and both analyses of the 31-item HAM-D total score. Over 50% of patients given 200 mg daily met response criteria on the 17-item HAM-D, MADRS, and CGI-I. For MADRS and CGI-I, this rate of improvement was significantly higher and nearly twice that observed for those given placebo. Compared with the lamotrigine 200-mg/day group, the lamotrigine 50-mg/day group showed significant efficacy on fewer measures and the proportion of responders was somewhat lower.

These placebo-controlled data are consistent with the findings of earlier uncontrolled clinical reports of lamotrigine's efficacy in bipolar depression.[4–18] The largest of these previous studies[18] evaluated 40 depressed patients with either bipolar I or II disorder treated with lamotrigine as add-on therapy or monotherapy over 48 weeks. In it, Corn et al. reported a significant decrease in 17-item HAM-D scores over time compared with baseline and a 48% rate of marked response to lamotrigine.

The design of the current study provides significant advantages over previous studies of lamotrigine and other treatments for bipolar I depression. Published reports of other treatments for bipolar I depression include 9 studies (177 patients) of lithium,[25–33] one study (24 patients) of carbamazepine,[34] and 9 studies (466 patients) of marketed antidepressants.[25,35–42] Although most of these early innovative lithium studies suggest at least modest efficacy in bipolar depression, methodological problems limit interpretation of these data. Most of the studies did not limit enrollment to patients with bipolar depression, nor did the studies employ random assignment to parallel groups. The only efficacy analyses were of observed data (i.e., none employed LOCF analysis). Also, the use of lithium/placebo crossover designs may have confounded early estimates of lithium's antidepressant efficacy.[28,43] In the only double-blind study evaluating the antidepressant efficacy of carbamazepine, Post and colleagues[34] demonstrated significant improvement compared with placebo using a crossover design in a mixed cohort of bipolar and unipolar patients. Although the studies of marketed antidepressants used random assignment to parallel groups, they too had some methodological limitations. Only 6 limited enrollment to patients with bipolar disorder.[25,37,39–42] In contrast to the current study, 3 of these 6 studies permitted concurrent use of mood stabilizers[37,40,42] (2 standardized their use[40,42]), and most efficacy analyses were limited to observed data. These studies provided evidence for the efficacy of several classes of antidepressants, including nonselective monoamine reuptake inhibitors (imipramine, desipramine, bupropion),[25,39–41] selective serotonin reuptake inhibitors (fluoxetine, parox-

etine),[37,42] and MAO inhibitors (tranylcypromine, moclobemide)[38,39,41] when given alone or in combination with mood stabilizers.

Both lamotrigine treatment groups received the same doses of lamotrigine during the first 3 weeks of the study and first showed significant improvement over placebo during the third week when receiving 50 mg/day. Similar time to onset of antidepressant response has been reported for fluoxetine, tranylcypromine, and imipramine.[37,39] Comparisons with the rate of antidepressant response to lithium in bipolar I depression are not possible since the early lithium studies employed crossover designs rather than random assignment to a parallel placebo group.[25–33] Moreover, direct comparison studies would be needed to draw meaningful conclusions about onset of activity for lamotrigine relative to antidepressants or lithium.

Since this trial represents the first randomized, parallel-group, placebo-controlled trial to evaluate monotherapy treatment in bipolar I depression, there was no information available on placebo response rates in this population; the use of placebo was considered essential. The percentage of placebo patients with a response on the 17-item HAM-D in the current study (37%) is similar to that observed in the only other study of bipolar I depression employing random assignment to a parallel placebo group (38%).[37] The placebo-response rates for the MADRS and the CGI-I in our study were 29% and 26%, respectively; there are no previous reports using these 2 rating scales in a placebo-controlled bipolar depression trial. These rates of placebo response are roughly comparable to recently published unipolar depression studies[44,45] and will provide valuable benchmark data for future controlled studies in bipolar depression.

Lamotrigine was well tolerated in this study, and serious drug-related adverse events were uncommon. There was no difference between placebo and either dose of lamotrigine in the number of patients withdrawing from the study due to adverse events. The incidence of headache was higher in the lamotrigine groups compared with placebo; however, only 1 lamotrigine-treated patient was discontinued due to headache, one of several reasons given for discontinuation of this patient. The rates of other adverse events were similar to placebo for both doses of lamotrigine. The types of reported adverse events in this study are consistent with those previously reported for bipolar disorder patients by Corn and colleagues[18] as well as patients who received adjunctive or monotherapy lamotrigine for treatment of epilepsy.[46,47] Across the dose range tested there was no evidence of a dose-response relationship for adverse experiences. It is of interest to note that total adverse events and many of the reported CNS-related adverse events occurred numerically less frequently in the lamotrigine groups than in the placebo group.

The incidence of rash (11%–14%) was similar across placebo and lamotrigine groups and similar to that observed on lamotrigine treatment in open-label and placebo-controlled epilepsy clinical trials.[47,48] In 7 cases (5.4%), rash led to the discontinuation of lamotrigine. This frequency of rash-related withdrawal was similar to the rate for lamotrigine (6.1%) and lower than the rate for carbamazepine (8.9%) in previously reported lamotrigine active-control studies in epilepsy.[47] None of the rashes in the current study was considered serious or required hospitalization. In patients with epilepsy, the incidence of serious rash requiring hospitalization and discontinuation of treatment with lamotrigine has been reported to be approximately 3 in 1000 adults (1 in 100 in children ≤ 16 years old). These rashes usually occur within 8 weeks of the initiation of treatment.[48] There are suggestions, yet to be proven, that the risk of rash may be increased by coadministrating it with valproate, exceeding the recommended initial dose of lamotrigine, or exceeding the recommended dose escalation for lamotrigine.[48] Strict adherence to the recommended dose escalation schedule may diminish the likelihood of rash.

The current monotherapy study reported the rate of development of combined manic, hypomanic, or mixed episodes according to adverse event reports. The frequency of these combined mood episodes was not significantly different between lamotrigine and placebo groups. The event rate of 4.6%–5.4% in the current study that allowed no concurrent psychoactive medications compared favorably to the placebo switch rate of 3.3% in a study allowing concurrent lithium use.[37] In contrast, tricyclic antidepressants and MAO inhibitors evaluated in controlled monotherapy studies of the depressive phase of bipolar disorder suggest a higher rate of switching, as much as 25% for imipramine and 21% for tranylcypromine.[39] Direct comparison studies would be needed to draw meaningful conclusions about switch rates for lamotrigine relative to other antidepressants.

The design of this study had some limitations that could confound interpretation of the data. The fixed-dose titration schedule in this study resulted in both active treatment groups receiving the same dose for the first 3 weeks of the study. Hence, the 200-mg/day group reached target dose 2 weeks after the 50-mg/day group, and the groups had different durations of treatment at target dose (lamotrigine 50 mg/day: 5 weeks; lamotrigine 200 mg/day: 3 weeks). A longer duration for the blinded phase of the study would have lessened the impact of this difference and provided further information on the continued course of antidepressant response to lamotrigine. The ongoing open-label continuation phase of this study should help to address this limitation.

The MADRS appeared to separate efficacy differences between placebo and lamotrigine more robustly than the 17-item HAM-D. The 17-item HAM-D scale is weighted toward somatic symptomatology relative to the MADRS. These results suggest that effects on bipolar depression

(versus unipolar depression) may be more sensitively and reliably measured by scales that focus on nonsomatic depressive symptoms rather than those containing somatic items. Alternatively, effects of lamotrigine (versus other antidepressants) may be more sensitively and reliably measured by such scales.

The data from this first double-blind, placebo-controlled trial of lamotrigine monotherapy in bipolar disorder demonstrate that lamotrigine possesses significant antidepressant efficacy in bipolar I depression. In addition, the use of lamotrigine in patients with bipolar I depression was well tolerated, with a side effect profile similar to that of placebo.

Drug names: bupropion (Wellbutrin, Zyban), carbamazepine (Tegretol and others), chloral hydrate (Noctec), desipramine (Norpramin and others), fluoxetine (Prozac), imipramine (Tofranil and others), lamotrigine (Lamictal), lorazepam (Ativan and others), oxazepam (Serax and others), paroxetine (Paxil), temazepam (Restoril and others), tranylcypromine (Parnate).

Original Research

A Random-Assignment, Double-Blind, Clinical Trial of Once- vs Twice-Daily Administration of Quetiapine Fumarate in Patients with Schizophrenia or Schizoaffective Disorder: A Pilot Study

KN Roy Chengappa, MD[1], Haranath Parepally, MD[1], Jaspreet S Brar, MD MPH[2], Jamie Mullen, MD[3], Ann Shilling, BA[4], Jeffrey M Goldstein, PhD[5]

Objective: To evaluate the efficacy and safety of administering quetiapine once vs twice daily.

Method: Utilizing a double-blind design, 21 hospitalized adult men or women with DSM-IV schizophrenia or schizoaffective disorder, who had received unchanged doses (for 2 weeks) of either 400 or 600 mg daily of quetiapine administered in 2 doses, were randomly assigned to once- or twice-daily administration for 4 weeks and then crossed over to the opposite dosing regimen for an additional 4 weeks. Standard psychopathology and safety measures were used in the study.

Results: Nearly 70% (15/21) of the subjects met the a priori efficacy responder criteria with no statistical differences in response between those assigned to once- or twice-daily quetiapine administration. Statistical analyses confirmed that most subjects maintained efficacy during the switch to once- or twice-daily administration with quetiapine. A minority (15%) did experience worsening of symptoms or orthostatic hypotension during the crossover. Quetiapine was generally well tolerated at either twice- or once-daily administration.

Conclusions: These pilot data suggest that it is clinically feasible to switch most quetiapine-treated subjects receiving a therapeutic twice-daily dosing schedule to a once-daily regimen. A minority may experience worsening of symptoms or orthostatic hypotension during the switch. This strategy of administering quetiapine entirely at bedtime may promote improved adherence to treatment.

(Can J Psychiatry 2003;48:187–194)

Information on author affiliations appears at the end of the article.

Clinical Implications

- In many patients who are receiving a therapeutic dosage of quetiapine fumarate, it is possible to switch a twice-daily dosage schedule to a once-daily regimen.
- Clinical monitoring for orthostatic effects, worsening of symptoms due to cholinergic rebound or possible supersensitivity psychoses, or unmasking of tardive dyskinesia may be prudent in the first few weeks following the switch to once-daily administration; a minority of patients experience worsening symptoms.
- Once-daily administration of quetiapine at bedtime may be convenient for some patients and may promote increased adherence to long-term treatment.

Limitations

- This is a pilot study with a small sample size.
- Switch to a once-daily regimen was tested after a therapeutic dosage was reached rather than at initiation.
- A longer-acting formulation of quetiapine may provide additional data of clinical utility, especially if that formulation can be administered once-daily right at the initiation of treatment.

***Key Words**: quetiapine, once-daily dosing, twice-daily dosing, schizophrenia, schizoaffective disorder, adherence*

Quetiapine, a second-generation antipsychotic agent, has shown efficacy and safety in the treatment of patients with schizophrenia experiencing an acute exacerbation of their illness (1,2). Further, pharmacokinetic data suggest quetiapine has a plasma half-life of nearly 6 hours, which is slightly increased with multiple dosing. Thus, in spite of an elimination half-life that averages 6 hours (range 5.8 to 6.8 hours [3]), quetiapine has been shown to be therapeutically equivalent when dosed at either 2 or 3 times daily (4).

Among the key pharmacokinetic variables that guide dosing of a drug are its plasma elimination half-life, the presence or absence of active metabolites, whether the drug exhibits linear pharmacokinetics, and the time taken to achieve steady-state levels of the drug. Therefore, quetiapine, which exhibits a linear pharmacokinetic profile over its therapeutic dosage range (150 to 750 mg daily), reaches steady-state plasma levels in 2 days. To maintain these steady-state plasma levels, it would follow that quetiapine needs to be administered 2 or 3 times daily. However, there is no known one-to-one correspondence between plasma levels of a drug and its levels in the central nervous system (CNS) or, for that matter, between plasma levels and drug-receptor occupancy. Further, recent positron emission tomography (PET) data suggest that neither high rates of dopamine (D_2) receptor occupancy nor sustained blockade of these receptors is necessary for antipsychotic efficacy (5). These new PET data have led to the concepts of tight (for example, haloperidol) vs loose (for example, clozapine and quetiapine) D_2 receptor binding and sustained (for example, haloperidol) vs transient and surmountable (for example, clozapine and quetiapine) blockade of D_2 receptors to explain the rationale for the efficacy of the second-generation antipsychotic agents, such as clozapine and quetiapine. One corollary to this hypothesis would be to test the dosing frequency of drugs such as clozapine and quetiapine at less frequent intervals than predicted by their pharmacologic half-lives. If quetiapine, with a relatively short elimination half-life, could be dosed as a single daily dose, it might result in a greater adherence to treatment by patients in the long term. The objective of this study was to evaluate whether quetiapine fumarate dosed once a day was therapeutically equivalent to twice-daily dosing in subjects who had reached a stable therapeutic dose.

Methods

Study Design

The trial comprised 3 phases, each of 4 weeks' duration. The first phase (from baseline, time 0, to visit 4 , week 4) involved withdrawal of the previous antipsychotic agent (over 7 to 14 days) as quetiapine was initiated (50 to 100 mg daily) and increased to either 400 or 600 mg daily during the next 7 to 10 days. Once the target dose was achieved (either 400 or 600 mg), quetiapine was administered as 200 mg twice daily (400 mg daily) or 200 mg in the morning and 400 mg in the evening (600 mg daily) for an additional 2 weeks. The second phase of the study (from visit 4, week 4, to visit 8, week 8) was double blind and involved the random assignment (1:1 ratio) to either once- or twice-daily treatment with quetiapine. The once-daily group received either 400 mg or 600 mg at bedtime and one placebo tablet in the morning. The twice-daily group received 200 mg twice daily (along with a placebo tablet at bedtime) for the 400 mg daily group or 200 mg and 400 mg (and a placebo) at bedtime for the 600 mg daily group. This phase lasted 4 weeks. The next phase was also double-blind (from visit 8, week 8, to visit 10, week 12) and involved a crossover for 4 additional weeks. The once-daily group was crossed over to twice daily and vice versa. At the end of this double-blind phase, subjects were dosed openly with quetiapine at either 400 or 600 mg given as a single bedtime dose (or twice daily if they so chose) until they were discharged.

Baseline screening assessments, medical history, and psychiatric history were recorded after written informed consent was obtained from participants. Patients with a diagnosis of schizoaffective disorder were permitted to continue mood stabilizers, either lithium, valproate, or antidepressant medications, unchanged in dosage throughout the double-blind phase. Lorazepam (up to 4 mg daily) was permitted for episodic agitation on an as-needed basis, as were hypnotic agents for insomnia. After the withdrawal of routine antiparkinsonian agents (1 week following the last dosage of the previous antipsychotic agent), their use was permitted only for newly emergent extrapyramidal symptoms (EPS) based on clinical judgement and after ratings for EPS were completed.

Patient Population

Eligible subjects were men and women of any ethnicity aged 18 to 65 years with DSM-IV (6) diagnoses of either schizophrenia (except the catatonic subtype) or schizoaffective disorder who had provided informed consent. They were required to have a Positive and Negative Symptom Scale (PANSS) (7) total score of ≥ 60 but ≤ 120 and a Clinical Global Impression (CGI) severity score ≥ 4 (8); to pass laboratory screening, ECG, slit-lamp ophthalmological, and physical examinations; and to be clinically appropriate candidates for quetiapine treatment. These subjects were referred by their attending psychiatrists, as the current antipsychotic treatments were ineffective (6 to 8 weeks of prior treatment) for these subjects.

Pregnant or lactating women or women of reproductive age without adequate contraception were excluded, as were subjects considered to be actively suicidal or homicidal. Those

receiving injectable long-acting neuroleptic agents (or within one injection cycle of study entry) were excluded.

Assessments

Psychopathology and its severity was assessed at scheduled intervals starting at the baseline through week 12, using the PANSS, CGI Scale, and the 21 item Hamilton Depression Rating Scale (HDRS; 9). EPS, akathisia, and tardive dyskinesia (TD) were assessed at the same time points as the psychopathology measures, using the Simpson Angus Neurological Rating Scale, Barnes Akathisia Scale (BA), and Abnormal Involuntary Movement Scale (AIMS), respectively (10–12). General Assessment of Functioning (GAF; DSM-IV, Axis V) scores were assessed at baseline and exit from the double-blind phase. Adverse events, whether spontaneously reported or in response to an open-ended question, were recorded, and orthostatic blood pressure and pulse were recorded at each visit. Body weight was recorded at quetiapine initiation (that is, baseline) and at the end of the double-blind study.

Statistical Analysis

The primary outcome of the study was to examine the differences, if any, in the therapeutic efficacy between once- vs twice-daily quetiapine administration regimens. A priori, the primary efficacy measure was defined as a $\geq 30\%$ reduction in the total PANSS score from baseline to the last visit in the double-blind phase. The differences between the proportion of subjects meeting the a priori response criteria were compared in the two quetiapine dosing administration groups, using contingency statistics.

A 1-way repeated-measures analysis of variance (ANOVA) was used to examine the relation between successive PANSS total scores and subscale scores at weeks 0, 4, 8, and 12 in the study sample as a whole, as well as in the groups assigned to once- or twice-daily administration separately. If the main effect was significant, post hoc pairwise differences between visit mean changes were examined using Bonferroni's adjustment for multiple comparisons. Subsequently, a mixed-model, repeated-measures ANOVA with the clinical measures (PANSS total or subscale scores) as the within-subject factor and the randomly assigned (once or twice daily) as the between-subject factor was performed to examine the interaction between the 2 factors.

PANSS subscale change scores, as well as change scores for the HDRS, CGI severity, and GAF, were analyzed for the entire group using the last observation carried forward (LOCF) method rather than a "completers" analysis. However, it is pertinent to note that only 2 of 21 randomized subjects dropped out at the penultimate visit of the double-blind phase of the study and that their data were carried forward to the last visit.

Results

Baseline Characteristics

The demography and illness characteristics for the 21 subjects are summarized in Table 1. In terms of switching from the previous antipsychotic agents, 13 were switched from first-generation agents, 4 were switched from risperidone, and 4 were switched from olanzapine. Among the 14 subjects with schizoaffective disorder, 2 were receiving lithium, 8 were receiving valproic acid, and 5 were receiving antidepressants.

Patient Disposition

Four subjects were titrated and stabilized at a daily dosage of 400 mg of quetiapine; the 17 remaining subjects achieved the daily dosage of 600 mg. Nineteen of these 21 subjects completed the 2-month double-blind phase, whereas 1 subject in each of those assigned to either the once- or twice-daily treatment arms reached the penultimate visit and was dropped from the study owing to worsening of their illness during the crossover phase (Figures 1 and 2). Another subject assigned initially to the twice-daily dosing had not shown clinical improvement and also worsened at the crossover point to once-daily dosing but completed the double-blind phase (Figure 2).

Efficacy Analyses

There were no statistically significant differences between the number of patients who met the PANSS response criteria in the once-daily quetiapine administration group (8/10 subjects) when compared with the group treated with twice-daily quetiapine (7/11 subjects). Three of the 4 subjects stabilized at 400 mg daily met the response criteria, and 12 of 17 subjects stabilized at 600 mg daily met the response criteria. In the group as a whole, 15 of 21 subjects (70%) met the response criteria.

Figure 1 Patients (n = 10) who were assigned to once-daily quetiapine administration at week 4

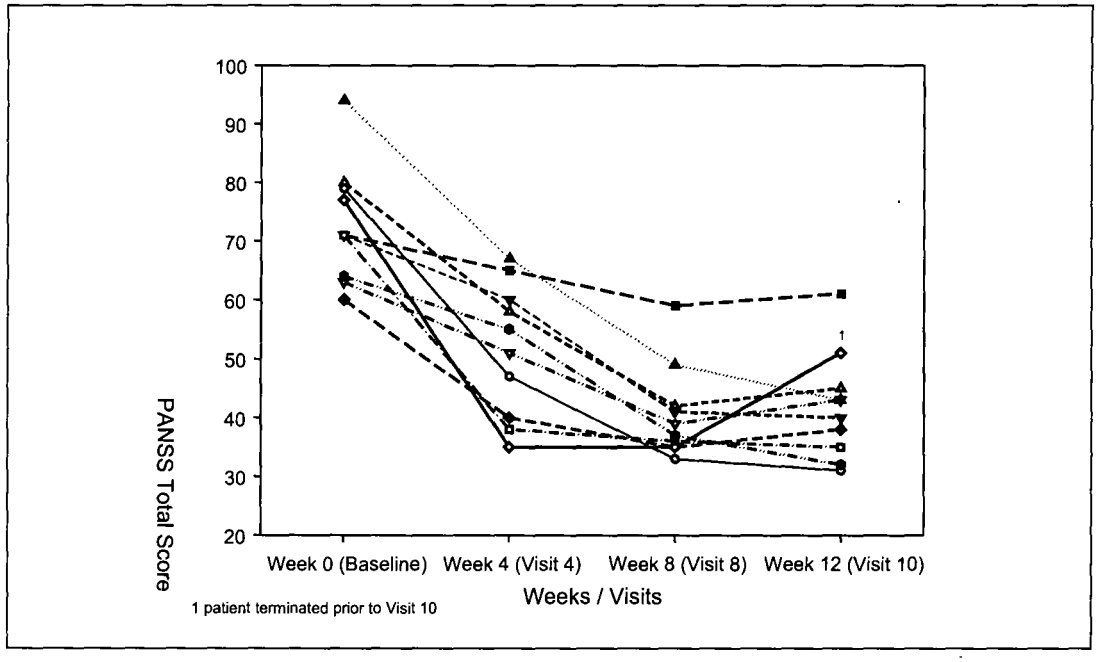

Figure 2 Patients (n = 11) who were assigned to twice-daily quetiapine administration at week 4

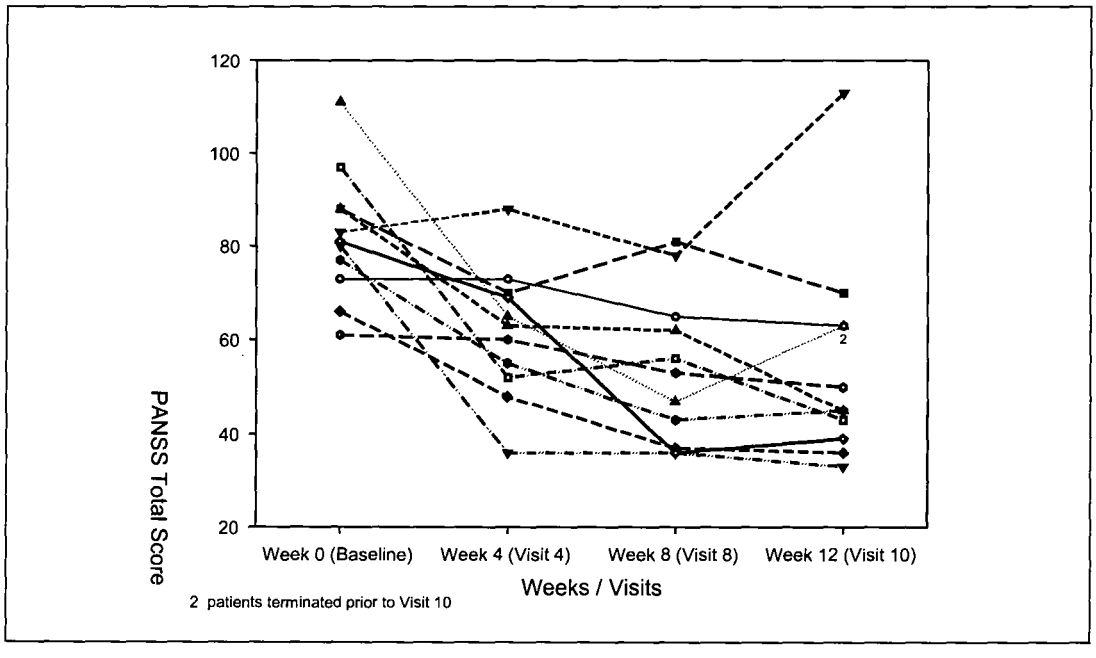

Secondary Analyses

PANSS total scores in the group as a whole showed significant improvement on quetiapine treatment (F = 40.6, df 2.2, 46.9, $P < 0.0005$) with Huynh–Feldt correction. Post hoc pairwise comparisons were all significant ($P < 0.05$ to $P < 0.0005$), except for the difference between week 8 and week 12; that is, most of the improvement had occurred by week 8. Similar results were obtained when the data for PANSS total scores were analyzed separately for those assigned to once- vs twice-daily dosing with quetiapine (Table 2).

The total and subscale change scores of PANSS and other efficacy assessments are presented in Tables 2 and 3 for the entire

Table 2 Baseline to endpoint change scores for PANSS and other scales, based on whether patients were first randomized to once-daily (OD) (group 1) or to twice-daily (BID) (group 2) administration with quetiapine

group as well as for those assigned to either once- or twice-daily dosing with quetiapine. The LOCF analyses for the entire group showed a significant improvement in the PANSS total and subscale scores, as well as the CGI severity scores, HDRS scores, and GAF scores.

Safety Analyses

Clinical Course at the Study Switchover Points, Including Study Withdrawals. The initial dosing switch occurred from the twice-daily (open) phase to the randomization (double-blind) phase. At this switch point, 10 of the 21 subjects were switched to once daily, and 11 subjects continued on the twice-daily regimen. None of the 10 subjects randomized to the once-daily dosing worsened at this switch point as can be noted in Figure 1. The next switch point occurred 4 weeks later and involved a crossover of the dosing regimen. At this point, 3 subjects showed worsening of clinical symptoms. Two subjects who switched from twice daily to once daily (2/11, 18%) evidenced worsening of symptoms, and one subject switched from once- to the twice-daily dosing regimen (1/10, 10%) deteriorated clinically.

The final switchover point occurred at the end of the double-blind phase. Among 15 responding subjects, 14 voluntarily chose the once-daily open treatment, and 1 subject chose the twice-daily regimen. None of the 15 subjects worsened at this switch point.

Additional Safety Evaluation. Adverse effects elicited or reported during the titration and stable administration periods and the double-blind period, at a rate of at least 1 subject (that is, 5%) or more were somnolence (5/21, 24%), headache (4/21, 19%), dizziness (3/21, 14%), constipation (1/21, 5%), urinary incontinence (1/21, 5%), and insomnia (1/21, 5%). These adverse effects were noted mostly in the first 4 to 8 weeks of treatment and were of mild-to-moderate severity. These events did not lead to withdrawal from the study, either resolved in time or with symptomatic treatment, and did not reoccur during the crossover phase, except for somnolence in 1 subject, intermittent headache in 1 subject, and constipation in 1 subject. Symptomatic postural hypotension was noted in 4 subjects (19%) during the titration phase of the study. For 2 of these 4 subjects, symptomatic postural hypotension recurred in the crossover phase of the blinded study. These events occurred during the crossover from once- to twice-daily dosing or vice versa.

Five subjects experienced akathisia at baseline, and 5 subjects evidenced EPS at baseline. Four subjects had TD (using research diagnostic criteria for TD [13]) at baseline. Akathisia resolved in all subjects by 4 weeks of quetiapine treatment, and EPS resolved in 6 to 8 weeks of treatment. No new cases of akathisia or other EPS were noted in the double-blind phases of the study. Two of the 4 subjects with TD showed evidence of worsening (withdrawal dyskinesia) for up to 6 weeks but, by the end of the double-blind study, had AIMS scores lower than at baseline. The other 2 subjects with TD at baseline showed a gradual and steady improvement of the scores during the study. All 4 subjects had lower AIMS scores by the end of the study (data not shown).

The mean body weight for the entire group was 87.7 kg (SD 17.3) at baseline and increased by a mean of 3.1 kg (SD 4.8) toward the end of the double-blind phase of the study

Table 3 Baseline to endpoint change scores of the PANSS[a] and other efficacy scales among all patients in the quetiapine administration trial

Scale or variable	Baseline Mean (SD)	Change in LOCF[b] Mean (SD)	Statistics[c]
PANSS scores			
Total	78.0 (13.0)	−29.3 (19.3)	$t = 7.0$, df 20, $P < 0.001$
Positive	25.4 (5.1)	−10.7 (9.0)	$t = 5.5$, df 20, $P < 0.001$
Negative	20.1 (4.0)	−8.1 (4.6)	$t = 8.1$, df 20, $P < 0.001$
General psychophathology	32.4 (6.8)	−10.6 (7.7)	$t = 6.3$, df 20, $P < 0.001$
CGI - severity[d]	4.5 (0.6)	−1.5 (1.0)	$t = 7.10$, df 20, $P < 0.001$
HDRS[e]	8.0 (4.4)	−4.4 (4.6)	$t = 4.5$, df 20, $P < 0.001$
GAF[f]	43.0 (8.7)	21.4 (13.2)	$t = 7.5$, df 20, $P < 0.001$

[a]Positive and Negative Syndrome Scale (7); [b]Last observation carried forward; [c]All tests remained significant even after applying the Bonferroni correction for multiple comparisons ; [d]Clinical Global Impression of Severity (8); [e]Hamilton Depression Rating Scale (9); [f]Global Assessment of Functioning Scale (Axis V of DSM-IV [6]).

($t = 2.9$, df 20, $P = 0.008$). The weight gain was noted over a duration of 11 to 12 weeks of quetiapine treatment, and it is important to note all subjects with schizoaffective disorders were also receiving either mood stabilizers or antidepressant medicines as concomitant therapy.

During the double-blind phase, there were 27 doses of lorazepam dispensed for episodic agitation or anxiety. These differences were not statistically significant between the once- and twice-daily administration groups and occurred mainly in the first 4 weeks of treatment. There were only 3 instances of anticholinergic use for EPS: once in a person receiving once-daily treatment and twice in subjects assigned to twice-daily dosing. These instances occurred shortly after the switch from the previous antipsychotic agents during the open-titration and stabilization phase.

Adherence to Medications

As all subjects were inpatients, study tablets and other medications were dispensed by nursing staff, and pill counts revealed > 98% adherence to treatment.

Discussion

These preliminary data suggest that most subjects who had reached a therapeutic dose of quetiapine fumarate (400 or 600 mg daily) on a twice-daily administration schedule were switched to the once-daily regimen without significant difficulty. A minority (3/21, 15%) of subjects worsened clinically during the switch, and so it would be clinically prudent to closely monitor subjects for the first 2 to 4 weeks after the switch to once-daily administration.

Just prior to the initiation of the double-blind randomization phase, all subjects were receiving the twice-daily regimen, and 10 subjects were randomized to the once-daily regimen, whereas 11 continued on the twice-daily regimen. None of the 10 subjects randomized to once-daily administration at this point experienced any worsening of symptoms. Four weeks later, at the crossover point, 2 subjects showed evidence of worsening after initial improvement. Based on the initial improvement and worsening shortly following the switch, it is likely that the temporal deterioration in these 2 subjects was associated with the change in the administration schedule. One occurred in a subject crossing from the once- to twice-daily regimen (1/10, 10%) and another in a subject moving from twice- to once-daily regimen (1/11, 9%). Is it possible that supersensitivity has a role to play in these patients (14)? Subjects who had received the previous oral antipsychotic agents for 6 to 8 weeks were tapered off their medicines in 1 to 2 weeks, and the phenomena were noted within 6 weeks (15). Thus, in sensitive individuals who have shown the need for escalating dosages of first-generation neuroleptic agents in the recent past, have increased psychotic symptoms just before a depot neuroleptic injection, or have symptoms of schizophrenia that are different from earlier exacerbations on medication withdrawal may show deterioration in the switching over to quetiapine. In such individuals a slower switch may be appropriate. Interestingly, and similar to the experience of Chouinard and others (16) in treating supersensitivity psychoses, we too noted significant improvement with clozapine in 2 patients who worsened at the switchover point in the current study.

A third subject assigned to the twice-daily regimen, who had not improved through the first 4 weeks of double-blind treatment, worsened at the crossover but stayed the course through the next 4 weeks. While it is possible that the worsening of symptoms in this last subject was caused by the switch in administration schedule, it is also likely that this clinical worsening was associated with the natural course of the illness.

In some subjects, attention to sedation and postural hypotension is clinically advisable both during the titration phase and following the switch to once-daily administration, especially among those subjects who are treated with antihypertensive medicines or have diabetes mellitus. However, in most subjects, administration of the entire dose of quetiapine at bedtime may help minimize the risk of orthostatic hypotension and sedation, as patients are more likely to be recumbent during the peak plasma concentrations of the drug.

It is possible that some subjects switching from agents with an anticholinergic profile to quetiapine could experience a cholinergic rebound, and perhaps a longer taper of the anticholinergic agent may be useful (17). In some subjects, worsening of the preexisting TD may have been caused by unmasking of TD occurring during a switch from a potent and tight D_2 receptor antagonist (first-generation agents) to

quetiapine. However, with the passage of time, the symptoms of TD diminished considerably on continued quetiapine treatment to less than the prequetiapine baseline.

Emerging data sets from PET studies in patients with schizophrenia have begun to suggest that D_2 receptor occupancy by antipsychotic agents need not be very high; further, the question has arisen whether such receptor blockade needs to be sustained continuously (18). The PET data from patients treated with depot haloperidol injections or oral clozapine and quetiapine-treated subjects would argue otherwise (19,20).

A second set of questions raised by recent PET data regarding quetiapine specifically suggest that transiently high D_2 occupancy rates (58% to 64%) may be adequate for treatment response (18). More recently, the same group also noted that first-episode patients who responded to quetiapine did not differ from those who did not, simply based on peak and trough D_2 receptor occupancy rates (20).

A third line of support for once-daily administration of relatively short half-life drugs comes from clinical experience in clozapine clinics. Subsets of subjects who have achieved steady-state drug levels and reached stable target dosages of clozapine (that is, those who are not also encumbered by dosage-related adverse effects: seizures, sedation, and postural hypotension) can be switched to a once-daily dosing regimen (mainly for patient convenience and to increase adherence to treatment) without loss of antipsychotic efficacy. These converging lines of evidence provide the rationale for the dosing of quetiapine fumarate as a single daily dose in subjects who have already reached a stable target dosage.

Nonetheless, these preliminary, random-assignment, double-blind clinical data suggest that bedtime administration of quetiapine among patients stabilized at their therapeutic dosage is clinically feasible. A switch to once-daily quetiapine administration can be considered both for the convenience of the subject and to improve adherence to long-term treatment. However, it must be emphasized that these data do not suggest "drug holidays" are good clinical practice but really that administration frequency based on plasma half-lives may not necessarily be valid for all antipsychotic agents.

Résumé : Essai clinique à répartition aléatoire et à double insu sur l'administration une ou deux fois par jour de fumarate de quétiapine chez les patients souffrant de schizophrénie ou de trouble schizo-affectif : une étude pilote

Objectif : Évaluer l'efficacité et l'innocuité de l'administration de quétiapine une ou deux fois par jour.

Méthode : Au moyen d'une méthode à double insu, 21 hommes ou femmes hospitalisés souffrant de schizophrénie ou de trouble schizo-affectif conforme aux critères du *DSM-IV* qui avaient reçu des doses inchangées (pendant 2 semaines) de soit 400 mg, soit 600 mg par jour de quétiapine administrée deux fois par jour, ont été affectés au hasard à l'administration une ou deux fois par jour pendant 4 semaines puis, ont croisé pour la dose opposée pendant 4 autres semaines. La psychopathologie d'usage et des mesures de sécurité ont été utilisées durant l'étude.

Résultats : Presque 70 % (15/21) des sujets ont satisfait aux critères de réponse efficace a priori, sans différences statistiques dans la réponse entre ceux qui étaient affectés à l'administration de quétiapine une fois par jour et ceux qui la recevaient deux fois par jour. Les analyses statistiques ont confirmé que la majorité des sujets maintenaient l'efficacité durant la transition à l'administration une ou deux fois par jour de quétiapine. Une minorité (15 %) a connu une aggravation des symptômes ou une hypotension orthostatique durant le croisement. La quétiapine était généralement bien tolérée, qu'elle soit administrée une ou deux fois par jour.

Conclusions : Ces données pilotes indiquent qu'il est cliniquement faisable de changer la dose biquotidienne de la majorité des sujets traités à la quétiapine pour un régime quotidien. Une minorité peut connaître une aggravation des symptômes ou une hypotension orthostatique durant la substitution. Cette stratégie consistant à administrer la quétiapine entièrement au coucher peut favoriser l'adhésion au traitement.

Quality of Life Enjoyment and Satisfaction Questionnaire: A New Measure[1]

Jean Endicott, Ph.D., John Nee, Ph.D., Wilma Harrison, M.D., and Richard Blumenthal, Ph.D.[2]

Abstract

The Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) is a self-report measure designed to enable investigators to easily obtain sensitive measures of the degree of enjoyment and satisfaction experienced by subjects in various areas of daily functioning. The summary scores were found to be reliable and valid measures of these dimensions in a group of depressed outpatients. The Q-LES-Q measures were related to, but not redundant with, measures of overall severity of illness or severity of depression within this sample. These findings suggest that the Q-LES-Q measures may be sensitive to important differences among depressed patients that are not detected by the measures usually employed.

***Psychopharmacol. Bull.* 29:321–326, 1993.**

Introduction

Patients with mental disorders frequently experience little enjoyment or satisfaction in many aspects of their life. This is particularly true for patients with mood disorders. Investigators and clinicians who are considering different forms of treatment for various mental disorders have traditionally focused on the need to document partial or complete relief of the major symptoms of the disorder and improvement in functioning in social roles. There is growing recognition that treatments may differ in their effects on other important aspects of a patient's functioning as well. The capacity to obtain pleasure and to feel satisfied with one's ability to function in multiple life activities has been recognized to be as important to many patients as is the absence of signs and symptoms used to define the disorders.

There has been an increased recognition of the need to assess "quality of life" in patients, although there are wide variations in what is covered by this term. Although some measures focus on symptoms, resources, and opportunities, clinicians generally are interested in patients' own assessments of how they feel about what they have, how they are functioning, and their ability to derive pleasure from their life activities. Many measures have been developed for evaluation of the effects of specific physical disabilities or illnesses on quality of life; these were recently reviewed in *Medical Care* (Nelson et al. 1981). Over the past two decades a number of procedures have been developed to help assess these variables in patients with mental disorders as well (e.g., Baker & Intagliata 1982; Bigelow et al. 1991; Heinrichs et al. 1984; Lehman 1988; Malm et al. 1981). However, none of the measures have been widely used or accepted as a standard, most require the use of a trained interviewer, many are quite lengthy, the content of many is closely tied to the specific symptoms of a disorder, and the psychometric properties of some are troublesome or unknown. Furthermore, at times the content is not distinct from the symptoms of the clinical syndromes under study.

The Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) was developed by the authors to enable investigators and clinicians to easily obtain sensitive self-report measures of the degree of enjoyment and satisfaction experienced by subjects in various areas of daily functioning. The intent was to use a format and content applicable for assessment of subjects with a wide variety of mental and medical disorders. An effort was made to avoid items that primarily measured

symptoms of one or more particular disorders. Although an effort was made to keep the language simple, it may be necessary to read the items to some patients who are severely ill or who have limited reading ability.

The Q-LES-Q consists of 93 items, 91 of which can be grouped into eight summary scales that were rationally derived and reflect the organization of the questionnaire. Five of these summary scales are scored for all subjects: Physical Health (13 items), Subjective Feelings (14 items), Leisure Time Activities (6 items), Social Relationships (11 items), and General Activities (14 items). Three are also scored for those subjects for whom the activities are applicable: Work (13 items), Household Duties (10 items), and School/Course Work (10 items). If a subject is expected to be involved in one or more of these three activities but is completely unable to perform them because of being "too upset emotionally," the most severe score possible is used as the summary score. Each of the 93 questions is scored on a 5-point scale that indicates the degree of enjoyment or satisfaction achieved during the past week relative to the particular activity or feeling described in the item. Higher scores are indicative of greater enjoyment or satisfaction. The raw summary scores are converted to and expressed as a percentage of the maximum score possible to facilitate comparisons across areas of functioning within the same subject or groups of subjects. In addition to the eight summary scale scores, there are two individual items that are scored separately: One measures satisfaction with medication (if any is being taken) and the other is a single measure of "overall life satisfaction and contentment." (Examples of items on the questionnaire are shown in Table 1.)

If a procedure is to be useful for the discrimination of differences among groups of subjects or within the same subject over time, it must have demonstrated reliability and validity for these tasks. The reliability of a procedure is an index of the likelihood that the derived scores would consistently discriminate the placement of an individual subject among a group of subjects when the subjects have not changed in their degree of severity relative to each other on the dimension of interest. The validity of a procedure is dependent on the degree to which it provides "meaningful" data that distinguish a subject or group of subjects from others.

TABLE 1. Examples of Quality of Life Enjoyment and Satisfaction Questionnaire Items.

During the past week, how often have you . . .
. . . been pleased with your work accomplishments?
. . . kept your room/apartment/house cleaned to your satisfaction?
. . . shopped for food or other household items to your satisfaction?
. . . had a feeling of accomplishment with regard to household activities?
. . . enjoyed talking with or being with friends or relatives?
. . . looked forward to getting together with friends or relatives?
. . . enjoyed talking with co-workers or neighbors?
. . . joked or laughed with other people?

If the Q-LES-Q is to be used as an outcome measure for the study of patients in treatment for various disorders, it must be shown to discriminate among subjects with the disorder, to be related to the severity of the disorder, and to be sensitive to changes in the severity of the disorder. At the same time, it should not correlate so highly with other measures generally used in such studies as to be essentially redundant and wasteful.

Many measures that can discriminate reliably and validly among subjects with a very wide range of severity of illness, from well to extremely or severely ill, do not perform well with more homogeneous samples. In this report we assess the performance characteristics of the Q-LES-Q among patients who were seeking treatment for depression in an outpatient setting. This sample was selected to provide a very stringent test of the procedure. The range of severity would be restricted and the type of symptoms of primary focus would be those most likely to be correlated with lowered enjoyment and satisfaction in daily activities. Thus we could test the procedure's ability to demonstrate reliability with a sample with restricted variance, as well as its degree of redundancy with the major measures of outcome.

Methods

The Depression Evaluation Service of the New York State Psychiatric Institute is an outpatient

facility that has a number of studies of the treatment of depressive disorders going on at any given time. The Q-LES-Q was added to the intake and outcome portions of several ongoing studies to obtain a large number of evaluations completed during different phases of treatment. Each of these study protocols included one or more visits during the screening phase, a placebo washout phase prior to the prerandomization visit, and outcome evaluations made at various points after randomization. The Clinical Global Impressions (CGI) Severity of Illness and Global Improvement scales (National Institute of Mental Health 1985) and the Hamilton Rating Scale for Depression (HAM-D; Hamilton 1960) were completed by the clinicians at various visits during the studies. The patients also completed the Beck Depression Inventory (BDI; Beck & Beamesderfer 1974) and the Symptom Check List-90 (SCL-90; Derogatis et al. 1973) during some of the visits.

Subjects

The data from patients were used for the Q-LES-Q reliability and validity analyses if the patient met the *DSM-III-R* (American Psychiatric Association 1987) criteria for major depressive disorder at the time of intake. All patients were in good physical health and, for the most part, were free of current comorbid mental disorders, with the exception of a group of subjects in a specific protocol who had a diagnosis of alcoholism. Ninety-five subjects completed at least one Q-LES-Q evaluation. The mean age was 39.1 years (SD = 10.7, range = 18–63); 59 percent were female.

Data Analysis and Results

Subsets of the data were analyzed for the reliability and validity of the procedure. Two types of reliability analyses were performed: the first for test–retest reliability and the second for an assessment of the internal consistency of the summary scale scores.

Test–Retest Reliability

Fifty-four of the subjects who completed two Q-LES-Q evaluations during the prerandomization phase of the studies met criteria for test–retest reliability evaluations. We wished to test the reliability of the Q-LES-Q in a setting where the patients had not changed greatly in severity of illness between occasions. Therefore, the CGI evaluations of severity made at the second visit had to indicate no clinically significant change in the patients' condition and the patients still had to meet the criteria for major depressive disorder.

This selection procedure resulted in a sample of subjects (n = 54) in relatively stable clinical condition, that is, they continued to be moderately to severely ill with a major depressive disorder during the period under study for both Q-LES-Q evaluations. The homogeneity of the sample thus poses a very stringent test of the test–retest reliability of the Q-LES-Q summary scale scores, because none of the subjects were well (or even only slightly ill) and none were so severely ill as to warrant inpatient care.

The second column of Table 2 lists the intraclass coefficients of test–retest reliability for the eight summary scale scores. Even within a very homogeneous sample of depressed patients, these coefficients are quite high and are indicative of a consistent pattern of discrimination among the subjects.

Internal Consistency Reliability

We used a larger sample (n = 83) to test the degree to which the individual items used in the summary scales were measuring the same underlying dimension. We used the alpha internal consistency coefficient of reliability for this task (Kuder & Richardson 1937). To more adequately assess this index, we needed to ensure some variability in severity of illness of the subjects; therefore, we used the Q-LES-Q for the last visit for which we had data for each subject. Approximately 60 percent of these visits occurred before randomization and the other 40 percent were visits after treatment had begun and, in many instances, after improvement would have occurred.

The fourth column of Table 2 indicates that the items assigned to the various summary scales were highly internally consistent. These item sets are "reliably" assessing the same dimension and the underlying dimensions are quite coherent.

TABLE 2. Coefficients of Reliability of Summary Scale Scores of Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) Among Patients With Major Depressive Disorder.[a]

Q-LES-Q Scores	Test-Retest[b]		Internal Consistency[c]	
	n	*r*	*n*	α
Physical Health	54	.82	83	.92
Subjective Feelings	54	.66	83	.91
Work[d]	39	.73	61	.96
Household Duties[d]	52	.73	82	.92
School/Course Work[d]	6	.89	10	.93
Leisure Time Activities	54	.63	83	.92
Social Relationships	54	.82	83	.93
General Activities	54	.74	83	.90

[a]Subjects were patients who sought treatment for depressive symptoms; all met *DSM-III-R* criteria for major depressive disorder.
[b]Intraclass coefficients of reliability. Q-LES-Q was completed twice (during screening and visit 1 or visit 2) before start of active treatment ($n = 54$).
[c]Alpha coefficient of internal consistency ($n = 83$).
[d]Scored only if applicable, i.e., if activities would ordinarily be expected of the subject. If subject was unable to perform these activities at all because of psychopathology, the most severe score possible was assigned.

TABLE 3. Correlations of Summary Scale Scores of Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) with the Clinical Global Impressions Severity of Illness Ratings ($n = 85$).

Q-LES-Q Scores	*r*
Overall Life Enjoyment and Satisfaction	−.62
Physical Health	−.60
Subjective Feelings	−.68
Work ($n = 69$)[a]	−.45
Household Duties ($n = 84$)[a]	−.34
School/Course Work ($n = 15$)[a]	−.34
Leisure Time Activities	−.54
Social Relationships	−.51
General Activities	−.66

NOTE: Subjects were patients who sought treatment for depressive symptoms. All met *DSM-III-R* criteria for major depressive disorder. Mean age = 39.1 yrs (SD = 10.7); 41% male. Sixty-two percent of the questionnaires were completed during visits 1 or 2 (pretreatment visits); 14% during visits 3–10, 24% during visits 11 or 12. Visits 3 and later occurred during treatment with either drug or placebo.
[a]Scored only if applicable, i.e., if activities would ordinarily be expected of the subject. If subject was unable to perform these activities at all because of psychopathology, the most severe score was assigned.

Validity

Several kinds of evidence of the validity of the Q-LES-Q summary scale scores were examined. The concurrent validity of the Q-LES-Q as a measure of the severity of illness was assessed by examining the correlation of the scale scores with the primary measures of severity of illness used in these studies. The ability of the scale scores to assess change in clinical status was also assessed. Both analyses also allowed an evaluation of the degree to which the Q-LES-Q scores were redundant with the other measures or were measuring some aspects of patient functioning that were relatively independent of the other measures.

Correlations of the Q-LES-Q summary scale scores and the CGI Severity of Illness ratings. Table 3 lists the correlations of the Q-LES-Q summary scale scores with the CGI Severity of Illness ratings made at the time of the visit. The same data set used to test internal consistency reliability was used to ensure some variability in severity of illness. The correlations are high enough that we can conclude that the Q-LES-Q scores have validity as measures of severity of illness (range −.34 to −.68). However, the index of shared variance between the two measures (r^2) suggests that the Q-LES-Q and the CGI Severity of Illness as used in this study are also assessing different dimensions of severity. This is further demonstrated by the fact that even at the highest correlation, for Subjective Feelings, only 46 percent of the variance is shared.

Correlations of the Q-LES-Q summary scale scores with measures of depression. Some investigators and clinicians have contended that the ability to enjoy activities or to be satisfied with aspects of daily living represent simply an absence of depression. To assess this assumption, we correlated the Q-LES-Q summary scale scores with the HAM-D total scores and the self-report questionnaire measures of depression. In each set of correlations we used the last evaluations for which both sets of data were available to ensure greater variability of scores than would be manifested at intake. Table 4 lists the correlations of the two types of measures, clinical ratings (HAM-D) and self-report (SCL-90 and BDI). The correlations ranged from −.29 to −.72, indicating that the Q-LES-Q does reflect differences in severity of depression. However, many of the correlations indicate that the Q-LES-Q scores are not simply

TABLE 4. Correlations of Summary Scale Scores of Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) with Measures of Depression.

Q-LES-Q Scores	HAM-D[a] (*n* = 82) *r*	SCL-90[b] (*n* = 73) *r*	BDI[c] (*n* = 33) *r*

Physical Health	−.56	−.74	−.62
Subjective Feelings	−.69	−.72	−.68
Work[d]	−.44	−.55	−.49
Household Duties[d]	−.36	−.29	−.56
School/Course Work[d]	−.33	−.70	−.73
Leisure Time Activities	−.48	−.53	−.34
Social Relationships	−.49	−.63	−.67
General Activities	−.64	−.64	−.67

NOTES: Subjects were patients who sought treatment for depressive symptoms. All met *DSM-III-R* criteria for major depressive disorder.
[a]Hamilton Rating Scale for Depression.
[b]Symptom Check List–90.
[c]Beck Depression Inventory.
[d]Scored only if applicable, i.e., if activities would ordinarily be expected of the subject. If subject was unable to perform these activities at all because of psychopathology, the lowest score was assigned.

TABLE 5. Correlations of Changes in Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) Summary Scale Scores With Clinical Global Impressions (CGI) of Global Improvement Ratings After Intake and With Changes in Hamilton Rating Scale for Depression (HAM-D) Scores.

Q-LES-Q Scores	CGI Global Improvement (*n* = 41)	HAM-D (*n* = 31)
Physical Health	−.48	−.54
Subjective Feelings	−.54	−.40
Work[a]	−.30	−.34
Household Duties[a]	−.38	−.39
School/Course Work[a,b]	—	—
Leisure Time Activities	−.54	−.42
Social Relationships	−.44	−.46
General Activities	−.50	−.41

NOTES: Subjects were patients with major depressive disorder who received treatment with drug or placebo. CGI Global Improvement scores and changes in HAM-D and Q-LES-Q scores were based on contrasts between intake evaluations and those made at various points after randomization.
[a]Scored only if applicable, i.e., if activities would ordinarily be expected of the subject. If subject was unable to perform these activities at all because of psychopathology, the lowest score was assigned.
[b]Number of subjects who completed this summary scale was insufficient to be included in the analysis.

reflecting the absence of depression and are therefore not totally redundant with measures of depression. This is particularly the case for those scores focused more on activities (e.g., Leisure Time Activities, Social Relationships).

Assessment of the Q-LES-Q summary scale scores as measures of change or improvement. We were able to obtain two measures of change in clinical condition for subsets of subjects in this setting: the CGI Global Improvement and pre–post HAM-D change scores. CGI Global Improvement scores were available for 41 subjects and pre–post HAM-D change scores could be calculated for 31 subjects. Q-LES-Q change scores were calculated for these two patient subsets. Table 5 shows the high degree of correlation between the CGI Global Improvement rating and the change scores (between the intake Q-LES-Q and the Q-LES-Q evaluations done at the same visit as the CGI Global Improvement rating). These results demonstrate that the Q-LES-Q scores are sensitive to changes in clinical state but, again, are not simply redundant with the primary measure of change used in many studies. Table 5 also shows the correlation between the change scores on the Q-LES-Q and change scores on the HAM-D. Again, the results demonstrate that the Q-LES-Q summary scale scores are sensitive to changes in level of depressive symptoms but that they are not totally redundant with them.

Conclusions

The analyses summarized in this report indicate that the Q-LES-Q summary scale scores are reliable and valid measures of aspects of quality of life in a group of depressed outpatients. The scores discriminated among the patients and were shown to be sensitive to change. The sample selected for these analyses posed a tough test of the procedure by virtue of its homogeneity and limited variance. The analyses also indicated that the Q-LES-Q scores were measures of important dimensions of illness that are not reflected in the measures of severity and symptoms generally used in studies of treatment for depression. The findings presented here indicate that there is a possibility that these Q-LES-Q measures are capable of detecting differences in

the efficacy of contrasted treatments for depressed patients that would not be reflected in the CGI or measures of depression such as the HAM-D, the SCL-90, or the BDI.

The Q-LES-Q has also been used with a sample of nonpatients in the community and found to have good test-retest reliability and to discriminate between those who were found to meet criteria for a current mental disorder and those who did not (paper in preparation). The procedure is currently being used in a number of studies involving patients with alcoholic, schizophrenic, and anxiety disorders as well as with women who have severe premenstrual depression. Its performance characteristics in these samples is yet to be determined.

The correlation of the Q-LES-Q scores with those of other measures of quality of life have not yet been determined, nor has its prognostic value for predicting response to treatment or relapse. As with all new procedures, its value for a number of specific purposes will be more clearly established as it is used in a variety of studies.

BRIEF PSYCHIATRIC RATING SCALE (Overall and Gorham)

BPRS

INSTRUCTIONS: *Insert General Scoring Sheet and Code 01 Under Sheet Number.*

This form consists of 18 symptom constructs, each to be rated on a 7—point scale of severity ranging from "not present" to "extremely severe". If a specific symptom is not rated, mark "0" = Not Assessed.

Mark the column headed by the term which best describes the patient's present condition.

USE A NO. 2 LEAD PENCIL. BE SURE TO MAKE MARKS HEAVY AND DARK. ERASE COMPLETELY ANY MARKS YOU WISH TO CHANGE.

NOT ASSESSED	NOT PRESENT	VERY MILD	MILD	MODERATE	MODERATELY SEVERE	SEVERE	EXTREMELY SEVERE
0	1	2	3	4	5	6	7

Mark on right half of scoring sheet on row specified			ROW NO.
1.	SOMATIC CONCERN	Degree of concern over present bodily health. Rate the degree to which physical health is perceived as a problem by the patient, whether complaints have a realistic basis or not.	1
2.	ANXIETY	Worry, fear, or over-concern for present or future. Rate solely on the basis of verbal report of patient's own subjective experiences. Do not infer anxiety from physical signs or from neurotic defense mechanisms.	2
3.	EMOTIONAL WITHDRAWAL	Deficiency in relating to the interviewer and to the interview situation. Rate only the degree to which the patient gives the impression of failing to be in emotional contact with other people in the interview situation.	3
4.	CONCEPTUAL DISORGANIZATION	Degree to which the thought processes are confused, disconnected or disorganized. Rate on the basis of integration of the verbal products of the patient; do not rate on the basis of patient's subjective impression of his own level of functioning.	4
5.	GUILT FEELINGS	Over-concern or remorse for past behavior. Rate on the basis of the patient's subjective experiences of guilt as evidenced by verbal report with appropriate affect; do not infer guilt feelings from depression, anxiety or neurotic defenses.	5
6.	TENSION	Physical and motor manifestations of tension, "nervousness," and heightened activation level. Tension should be rated solely on the basis of physical signs and motor behavior and not on the basis of subjective experiences of tension reported by the patient.	6
7.	MANNERISMS AND POSTURING	Unusual and unnatural motor behavior, the type of motor behavior which causes certain mental patients to stand out in a crowd of normal people. Rate only abnormality of movements; do not rate simple heightened motor activity here.	7
8.	GRANDIOSITY	Exaggerated self-opinion, conviction of unusual ability or powers. Rate only on the basis of patient's statements about himself or self-in-relation-to-others, not on the basis of his demeanor in the interview situation.	8
9.	DEPRESSIVE MOOD	Despondency in mood, sadness. Rate only degree of despondency; do not rate on the basis of inferences concerning depression based upon general retardation and somatic complaints.	9
10.	HOSTILITY	Animosity, contempt, belligerence, disdain for other people outside the interview situation. Rate solely on the basis of the verbal report of feelings and actions of the patient toward others; do not infer hostility from neurotic defenses, anxiety nor somatic complaints. *(Rate attitude toward interviewer under "uncooperativeness".)*	10
11.	SUSPICIOUSNESS	Belief *(delusional or otherwise)* that others have now, or have had in the past, malicious or discriminatory intent toward the patient. On the basis of verbal report, rate only those suspicions which are currently held whether they concern past or present circumstances.	11

Continue marking on right half of scoring sheet on row specified			ROW NO.
12.	HALLUCINATORY BEHAVIOR	Perceptions without normal external stimulus correspondence. Rate only those experiences which are reported to have occurred within the last week and which are described as distinctly different from the thought and imagery processes of normal people.	12
13.	MOTOR RETARDATION	Reduction in energy level evidenced in slowed movements. Rate on the basis of observed behavior of the patient only; do not rate on basis of patient's subjective impression of own energy level	13
14.	UNCOOPERATIVENESS	Evidence of resistance, unfriendliness, resentment, and lack of readiness to cooperate with the interviewer. Rate only on the basis of the patient's attitude and responses to the interviewer and the interview situation; do not rate on basis of reported resentment or uncooperativeness outside the interview situation.	14
15.	UNUSUAL THOUGHT CONTENT	Unusual, odd, strange, or bizarre thought content. Rate here the degree of unusualness, not the degree of disorganization of thought processes.	15
16.	BLUNTED AFFECT	Reduced emotional tone, apparent lack of normal feeling or involvement.	16
17.	EXCITEMENT	Heightened emotional tone, agitation, increased reactivity.	17
18.	DISORIENTATION	Confusion or lack of proper association for person, place or time.	18

158

Developed by Overall and Gorham, the Brief Psychiatric Rating Scale (BPRS) is formatted for use with the General Scoring Sheet and consists of the 18-item version of the scale. Developed from the longer Lorr Multidimensional Scale for Rating Psychiatric Patients (MSRPP) and Lorr Inpatient Multidimensional Psychiatric Scale (IMPS), the BPRS provides a rapid and efficient evaluation of treatment response in both clinical drug trials and routine clinical settings. Its focus is primarily inpatient psychopathology. It has been employed in outpatient settings to assess levels of anxiety and depression and to distinguish neurotic from more severely disturbed patients; but the authors caution that the BPRS was not designed to represent the fine distinctions between types of neurotic patients.

APPLICABILITY — Primarily for adult inpatient populations.

UTILIZATION — Once at pretreatment; at least one post-treatment assessment. The number and spacing of post-treatment assessments are at the discretion of the investigator.

TIME SPAN RATED — At a maximum, the interval since the last assessment. At pretreatment, a span of one week is suggested.

SPECIAL INSTRUCTIONS

Brief instructions for rating each item are printed on the scale itself. To increase the degree of communality in interpretation, the items are defined below in greater detail by Overall and Gorham, and the rater is urged to confine his responses within these contexts.

A. Ratings Based Upon Observation of Patient

3. Emotional Withdrawal - This construct is defined solely in terms of the ability of the patient to relate in the interpersonal interview situation. Thus, an attempt is made to distinguish between motor aspects of general retardation, which are rated as "motor retardation" and the more mental-emotional aspects of withdrawal, even though ratings in the two areas may be expected to covary to some extent. In the factor analyses of change in psychiatric ratings, a "general retardation" factor has emerged in several different analyses, and this general retardation factor has included both emotional and motor retardation items. It is difficult to identify the basis for rating of "ability to relate"; however, initial work has indicated that raters achieve reasonably high agreement in rating this quality. Emotional withdrawal is represented by the feeling on the part of the rater that an invisible barrier exists between the patient and other persons in the interview situation. It is suspected that eyes, facial expression, voice quality and variability, and expressive movements all enter into the evaluation of this important, but nebulous, quality of the patients.

6. Tension - It should be noted that the construct "tension" is restricted in the Brief Scale to physical and motor signs commonly associated with anxiety. Tension does not involve the subjective experience or mental state of the patient. Although research psychologists in an effort to attain a high degree of objectivity frequently define anxiety in terms of physical signs, in the Brief Scale observable physical signs of tension and subjective experiences of anxiety are rated separately. Although anxiety and tension tend to vary together, developmental research with an earlier form of the Brief Scale indicated that the degree of pathology in the two areas may be quite different in specific patients. A patient, especially when under the influence of a drug, may report extreme apprehension but give no external evidence of tension whatsoever, or vice versa. In rating the degree of tension, the rater should attend to the number and nature of signs of abnormally heightened activation level such as nervousness, fidgeting, tremors, twitches, sweating, frequent changing of posture, hypertonicity of movements, and heightened muscle tone.

7. Mannerisms and posturing - This symptom area includes the unusual and bizarre motor behavior by which a mentally ill person can often be identified in a crowd of normal persons. The severity of manneristic behavior depends both upon the nature and number of unusual motor responses. However, it is the "unusualness", and not simply the amount of movement, which is to be rated. Odd, indirect, repetitive movements, or movements lacking normal coordination and integration, are rated on this scale. Strained, distorted, abnormal postures which are maintained for extended periods are rated. Grimaces and unusual movements of lips, tongue, or eyes are considered here also. Tics and twitches which are rated as signs of tension are not rated as manneristic behavior.

13. Motor retardation - Motor retardation involves the general slowing down and weakening of voluntary motor responses. Symptomatology in this area is represented by behavior which might be attributed to the loss of energy and vigor necessary to perform voluntary acts in a normal manner. Voluntary acts which are especially affected by reduced energy level include those related to speech as well as gross muscular behavior. With increased "motor retardation" speech is slowed, weakened in volume, and reduced in amount. Voluntary movements are slowed, weakened, and less frequent.

14. Uncooperativeness - This is the term adopted to represent signs of hostility and resistance to the interviewer and interview situation. It should be noted that "uncooperativeness" is judged on the basis of response of the patient to the interview situation while "hostility" is rated on the basis of verbal reports of hostile feelings or behavior toward others outside the interview situation. It was found necessary to separate the two areas because of an occasional patient who refrained from any reference to hostile feelings and who even denies them, while evidencing strong hostility toward the interviewer.

B. Ratings Based Primarily Upon Verbal Report

1. Somatic concern - The severity of physical complaints should be rated solely on the number and nature of complaints of bodily illness or malfunction, or suspiciousness of same, alleged during the interview period. The evaluation is of the degree to which the patient perceives or suspects physical ailments to play an important part in his total lack of well-being. No consideration of the probability of true organic basis for the complaints is required. Only the frequency and severity of complaints are rated.

2. Anxiety - Anxiety is a term restricted to the subjective experience of worry, overconcern, apprehension or fear. Rating of degree of anxiety should be based upon verbal responses reporting such subjective experiences on the part of the patient. Care should be taken to exclude from consideration in rating anxiety the physical signs which are included in the concept of tension, as defined in the scale. The sincerity of the report and the strength of the experience as indicated by the involvement of the patient may be important in evaluating degree of anxiety.

4. Conceptual disorganization - Conceptual disorganization involves the disruption of normal thought processes and is evidenced in confusion, irrelevance, inconsistency, disconnectedness, disjointedness, blocking, confabulation, autism, and unusual chain of associating. Ratings should be based upon the patient's spontaneous verbal products, especially those longer, spontaneous response sequences which are likely to be elicited during the initial, non-directive portion of the interview. Attention to the facial expression of the patient during the verbal response may be helpful in evaluating the degree of confusion or blocking.

5. Guilt feelings - The strength of guilt feelings should be judged from the frequency and intensity of reported experiences of remorse for past behavior. The strength of the guilt feelings must be judged in part from the involvement evidenced by the patient in reporting such experiences. Care should be exercised not to infer guilt feelings from signs of depression or generalized anxiety. Guilt feelings relate to specific past behavior which the patient now believes to have been wrong and the memory of which is a source of conscious concern.

8. Grandiosity - Grandiosity involves the reported feeling of unusual ability, power, wealth, importance, or superiority. The degree of pathology should be rated relative to the discrepancy between self-appraisal and reality. The verbal report of the patient and not his demeanor in the interview situation should provide the basis for evaluation of grandiosity. Care should be taken not to infer grandiosity from suspicions of persecution or other unfounded beliefs where no explicit reference to personal superiority as the basis for persecution has been elicited. Ratings should be based upon opinions currently held by the patient, even though the unfounded superiority may be claimed to have existed in the past.

9. Depressive mood - Depressive mood includes only the affective component of depression. It should be rated on the basis of expressions of discouragement, pessimism, sadness, hopelessness, helplessness, and gloomy thema. Facial expression, weeping, moaning and other modes of communicating mood should be considered, but motor retardation, guilt, and somatic complaints, which are commonly associated with the psychiatric syndrome of depression, should not be considered in rating depressive mood.

10. Hostility - Hostility is a term reserved for reported feelings of animosity, belligerence, contempt, or hatred toward other people outside the interview situation. The rater may attend to the sincerity and affect present in reporting of such experiences when he attempts to evaluate the severity of pathology in the symptom area. It should be noted that evidences of hostility toward the interviewer in the interview situation should be rated on the "Uncooperativeness" item and should not be considered in rating hostility as defined here.

11. Suspiciousness - Suspiciousness is a term which is used to designate a wide range of mental experience in which the patient believes himself to have been wronged by another person or believes that another person has, or has had, intent to wrong. Since no information is usually available as a basis for evaluating the objectivity of the more plausible suspicions, the term "accusations" might be a more appropriate characterization of this area. The rating should reflect the degree to which the patient tends to project blame and to accuse other people or forces of malicious or discriminatory intent. The pathology in this symptom area may range from mild suspiciousness through delusions of persecution or ideas of reference.

12. Hallucinatory behavior - The evaluation of hallucinatory experiences frequently requires judgment on the part of the rater as to whether the reported experience represents hallucination or merely vivid mental imagery. In general, unless the rater is quite convinced that the experiences reported represent true deviations from normal thought and imagery processes, hallucinatory behavior should be rated as "not present".

15. Unusual thought content - This symptom area is concerned solely with the CONTENT of the patient's verbalization; the extent to which it is unusual, odd, strange, or bizarre. Notice that a delusional or paranoid patient may present bizarre or unbelievable ideas in a perfectly straightforward, clear, and organized fashion. Rate only unusualness of content for this item, not degree of organization or disorganization.

16. Blunted affect - This symptom area is recognized by reduced emotional tone and apparent lack of normal feeling or involvement. Emotional expressions are apt to

be absent or of marked indifference and apathy. Attempted expressions of feeling may appear to be mimetic and without sincerity.

COMMENTS OF THE AUTHOR

THE BRIEF PSYCHIATRIC RATING SCALE IN PSYCHOPHARMACOLOGIC RESEARCH

John E. Overall, Ph.D.

The Brief Psychiatric Rating Scale (BPRS) was originally developed to provide an efficient and clinically valid means of assessing efficacy in psychopharmacologic research.[1] Later research demonstrated its utility for descriptive classification of psychiatric patients according to profile pattern.[2,3] The BPRS consists of 18 (originally 16) symptom constructs, each to be rated on a 7-point scale of severity. The ratings are coded 0-6* for the 7 categories of severity ranging from "not present" to "extremely severe".

In most clinical research applications, the BPRS is completed immediately prior to the start of drug treatment and again after a fixed period of time, usually 4 to 6 weeks. Ratings are based on information obtained in a clinical interview of about 20 minutes duration. It is recommended that each patient be interviewed and rated independently by two professional observers to enhance the reliability of ratings, although the advantage gained from duplicate independent ratings is not now considered to be as great as it once was. A minimum of 35 to 40 patients in each treatment group should be included in any study in which the BPRS is used with two independent raters, or approximately 45 to 50 patients per group if a single rater is used.[4] These estimates of sample size do not appear restricted to the BPRS and can be readily calculated for any particular research setting.[5]

The BPRS pre-treatment ratings can be used to describe the patient sample and to classify patients into phenomenological homogeneous sub-types. Profile classification has been found useful in reducing within-treatment variability and in the study of specific indications of psychotherapeutic drugs. Although earlier efforts at profile classification using the BPRS were attempts to provide more objective methods for assigning patients among standard diagnostic categories,[6,7,8] more recent efforts have centered about the use of cluster analysis and related empirical methods to identify the most frequently occurring and thus most representative profile patterns.[9,10] The results of these studies have produced a classification system consisting of six types described as anxious depression, hostile depression, withdrawn-retarded depression, paranoid hostile-suspiciousness syndrome, withdrawn-disorganized thinking disturbance and florid thinking disorder.[11] Most psychiatric patients can be recognized as having symptom patterns fitting closely one of these six types. The six BPRS prototype patterns, which depend upon only the original 16 items, are as follows.

ANXIOUS DEPRESSION

2.6	2.8	1.1	0.5	0.8	0.2	0.2	2.5	0.8	0.4	0.1	1.0	0.3	0.4	1.0

HOSTILE DEPRESSION

0.6	2.7	1.1	1.1	2.0	1.8	0.3	0.3	2.5	2.9	2.2	0.2	0.5	1.0	0.7	0.7

* The ECDEU version of the BPRS is coded 1 - 7 rather than 0 - 6.

WITHDRAWN-RETARDED DEPRESSION

1.4	1.7	3.0	1.2	0.7	1.1	0.6	0.1	3.4	0.5	0.5	0.3	2.2	0.8	0.4	2.7

PARANOID HOSTILE-SUSPICIOUSNESS SYNDROME

1.4	1.5	1.0	1.4	0.4	1.4	0.4	1.0	0.5	3.4	2.6	0.1	0.4	1.6	1.2	0.7

WITHDRAWN-DISORGANIZED THINKING DISTURBANCE

0.7	0.8	3.1	3.4	0.1	1.1	1.3	0.2	0.5	0.4	1.0	1.5	1.8	1.2	2.2	3.6

FLORID THINKING DISORDER

0.7	1.3	2.4	3.9	0.2	2.0	1.5	1.4	0.8	1.4	3.0	3.5	0.7	1.6	4.2	2.6

Patients can be classified among the six phenomenological sub-groups by simply calculating the sum of squared differences between individual profile elements (scored 0-6 for single rater or average of two raters) and the corresponding prototype values, with the patient then being assigned to the group for which the simple d^2 is smallest.[12] For studies involving only pre-screened clinically depressed patients, only the first three profile patterns need be considered. Several more complex profile analysis methods have been programmed for computer to classify patients among the six types and can be obtained from J. E. Overall (University of Texas Medical Branch, Galveston). Dr. Overall also has the facilities to process profiles sent to him in punched cards and has agreed to do so for any ECDEU investigator.

Several composite scores derived from the BPRS are frequently used in evaluating treatment effects. Numerous factor analyses of BPRS ratings have consistently revealed the presence of four major higher order factors which have been described as thinking disturbance, withdrawal-retardation, hostile-suspiciousness and anxious depression.[13] Factor scores are obtained by summing ratings on the three BPRS items most highly related to each factor.

THINKING DISTURBANCE - Conceptual Disorganization, Hallucinatory Behavior and Unusual Thought Content.

WITHDRAWAL-RETARDATION - Emotional Withdrawal, Motor Retardation and Blunted Affect.

HOSTILE-SUSPICIOUSNESS - Hostility, Suspiciousness and Uncooperativeness.

ANXIOUS DEPRESSION - Anxiety, Guilt Feelings, and Depressive Mood.

In addition to the four higher order factor scores, a "total pathology" score is used to represent the total deviation from normality and to evaluate total change during treatment. The total pathology score is the sum of ratings on all 18 rating constructs, each scored on a 0-6 scale. Where patients have been grouped into distinctively different profile types, the total pathology score is recommended for evaluation of treatment outcome because specific symptom factors tend to be too highly related to profile group.

[illegible] has gone into the identification of extrinsic factors which influence BPRS ratings. It is considered that these non-drug factors produce variability in symptom patterns and treatment responses which should be controlled experimentally or statistically in order to improve the precision of clinical psychopharmacologic research. Differences in initial symptom patterns are significantly related to age, race, sex, age of onset, previous course of illness, marital status, education, work achievement and a variety of other less important factors.[14, 15, 16] Differences in treatment outcome have been found to depend significantly on pretreatment level and type of symptomatology, age of onset, previous hospitalizations and/or course of illness, marital status, presence of identifiable precipitating stress and race.[17, 18] Where several different raters are involved in a project, systematic rater differences are often very important.

While work is continuing along these lines, it appears obvious that a variety of factors do influence BPRS evaluations of symptom pattern and treatment outcome, and the above appear to be among the potentially most important. It is recommended that these extrinsic factors be carefully recorded and that their effects then should be removed by using somewhat more complex statistical analyses than have been used in the past.[17] Experimental control can be achieved by holding certain of the extrinsic factors constant, such as age or sex, but this tends to restrict the generality of conclusions that can be drawn.

A completely adequate experimental design involving BPRS evaluations should take into account (a) pre-treatment profile type, (b) pre-treatment level of severity, (c) demographic and sociocultural background characteristics of the patient which may influence outcome independently of drugs, (d) experimentally introduced systematic effects such as hospital differences, rater differences and the like, and (e) drug treatments. Where patients are classified into distinct profile groups, the broad measure of change in total pathology is recommended for evaluation of outcome with differences in pre-treatment level of severity partialled out. In this brief summary, an attempt has been made to provide the investigator with essential information concerning sample size, scoring, patient classification and control variables that will enable him to use the BPRS in as effective a manner as current methodology permits.

A RATING SCALE FOR DEPRESSION

BY

MAX HAMILTON

From the Department of Psychiatry, University of Leeds

The appearance of yet another rating scale for measuring symptoms of mental disorder may seem unnecessary, since there are so many already in existence and many of them have been extensively used. Unfortunately, it cannot be said that perfection has been achieved, and indeed, there is considerable room for improvement.

Types of Rating Scale

The value of this one, and its limitations, can best be considered against its background, so it is useful to consider the limitations of the various rating scales extant. They can be classified into four groups, the first of which has been devised for use on normal subjects. Patients suffering from mental disorders score very highly on some of the variables and these high scores serve as a measure of their illness. Such scales can be very useful, but have two defects: many symptoms are not found in normal persons; and less obviously, but more important, there is a qualitative difference between symptoms of mental illness and normal variations of behaviour. The difference between the two is not a philosophical problem but a biological one. There is always a loss of function in illness, with impaired efficiency.

Self-rating scales are popular because they are easy to administer. Aside from the notorious unreliability of self-assessment, such scales are of little use for semiliterate patients and are no use for seriously ill patients who are unable to deal with them.

Many rating scales for behaviour have been devised for assessing the social adjustment of patients and their behaviour in the hospital ward. They are very useful for their purpose but give little or no information about symptoms.

Finally, a number of scales have been devised specifically for rating symptoms of mental illness. They cover the whole range of symptoms, but such all-inclusiveness has its disadvantages. In the first place, it is extremely difficult to differentiate some symptoms, *e.g.*, apathy, retardation, stupor. These three look alike, but they are quite different and appear in different settings. Other symptoms are difficult to define, except in terms of their settings, *e.g.*, mild agitation and derealization. A more serious difficulty lies in the fallacy of naming. For example, the term "delusions" covers schizophrenic, depressive, hypochrondriacal, and paranoid delusions. They are all quite different and should be clearly distinguished. Another difficulty may be summarized by saying that the weights given to symptoms should not be linear. Thus, in schizophrenia, the amount of anxiety is of no importance, whereas in anxiety states it is fundamental. Again, a schizophrenic patient who has delusions is not necessarily worse than one who has not, but a depressive patient who has, is much worse. Finally, although rating scales are not used for making a diagnosis, they should have some relation to it. Thus the schizophrenic patients should have a high score on schizophrenia and comparatively small scores on other syndromes. In practice, this does not occur.

The present scale has been devised for use only on patients already diagnosed as suffering from affective disorder of depressive type. It is used for quantifying the results of an interview, and its value depends entirely on the skill of the interviewer in eliciting the necessary information. The interviewer may, and should, use all information available to help him with his interview and in making the final assessment. The scale has undergone a number of changes since it was first tried out, and although there is room for further improvement, it will be found efficient and simple in use. It has been found to be of great practical value in assessing results of treatment.

Description of the Rating Scale

The scale contains 17 variables (see Appendix I). Some are defined in terms of a series of categories of increasing intensity, while others are defined by a number of equal-valued terms (see Appendix II). The form on which ratings are recorded also includes four additional variables: Diurnal variation, derealization, paranoid symptoms, obsessional symp-

toms. These are excluded from the scale because the first is not a measure of depression or of its intensity, but defines the type of depression. The other three occur so infrequently that there is no point in including them.

The variables are measured either on five-point or three-point scales, the latter being used where quantification of the variable is either difficult or impossible. No distinction is made between intensity and frequency of symptom, the rater having to give due weight to both of them in making his judgment.

Various problems are to be found with specific symptoms. Thus considerable difficulty is found with the depressive triad: depressive mood, guilt, and suicidal tendencies. These are so closely linked in description and judgment as to be very difficult to separate. It is very important to avoid the halo effect by automatically giving all of them high or low scores, as the case may be.

Depressed Mood.—This tends to have a narrow range of scores, for no diagnosed patients will score zero and few will score 1 or 4. The most useful indicator for depressed mood is the tendency to weep, but it must always be considered against the cultural background, and patients may also "go beyond weeping".

Suicide.—An attempt at suicide scores 4, but such an attempt may sometimes occur suddenly against a background of very little suicidal tendency; in such cases it should be scored as 3. There will be great difficulty sometimes in differentiating between a real attempt at suicide and a demonstrative attempt; the rater must use his judgment.

Work and Loss of Interest.—Difficulties at work and loss of interest in hobbies and social activities are both included. The patient who has given up work solely because of his illness is rated 4.

Retardation.—A grade 4 patient is completely mute, and is therefore unsuitable for rating on the scale. Grade 3 patients need much care and patience to rate, but it can be done.

Agitation.—This is defined as restlessness associated with anxiety. Unfortunately, a five-point scale was found impracticable, and therefore this variable is rated on a three-point scale. The mildest degrees of agitation cause considerable difficulty.

Gastro-intestinal Symptoms.—These occur in connexion with both anxiety and depression. Considerable clinical experience is required to evaluate them satisfactorily. The definitions given have been found very useful in practice.

General Somatic Symptoms.—In depressions these are characteristically vague and ill defined, and it is extremely difficult to get a satisfactory description of them from the patient.

Hypochondriasis.—This is easy to rate when it is obviously present, but difficulties arise with mild hypochondriacal preoccupations. Phobias of specific disease can cause difficulties. A phobia of venereal disease or of cancer will sometimes be rated under "guilt" by the nature of the symptom, but other cases may give rise to much doubt and judgment requires care. Fortunately, phobias are not common, but the whole subject of hypochondriasis could well repay clinical investigation.

Insight.—This must always be considered in relation to the patient's thinking and background of knowledge. It is important to distinguish between a patient who has no insight and one who is reluctant to admit that he is "mental".

Loss of Weight.—Ideally this would be measured in pounds or kilograms, but few patients know their normal weight and keep a check on it. It was therefore necessary to use a three-point scale.

After recovery from depression, some patients sometimes show a brief hypomanic reaction, during which the exuberantly cheerful patient will deny that he has any symptoms whatever, though he is obviously not to be regarded as normal. In such cases, the rating scale is inapplicable and should be delayed until the patient has fully recovered.

Scoring

It is particularly useful to have two raters independently scoring a patient at the same interview, since this gives data for calculating the inter-physician reliability. The score for the patient is obtained by summing the scores of the two physicians. This is, of course, the best way of learning how to use the scale, Where only one rater uses the scale, the scores should be doubled so as to make them comparable. With sufficient experience, a skilled rater can learn to give half-points.

Results

For two raters, the correlation between summed scores for the first 10 patients was 0·84. Adding successively 10 patients at a time, the correlation changed to 0·84, 0·88, 0·89, 0·89, 0·90, 0·90. The last correlation is therefore total for 70 patients.

Product-moment correlations were calculated for the 17 variables on the first 49 male patients (Table I). The correlation matrix was then factor-analysed by extracting the latent roots and vectors (Table II). As the intercorrelations are in general low because of the intense selection of patients, the latent roots (variances extracted by factors) diminish

Latent root	3·4358	2·3439	1·7496	1·3658

slowly. Out of the total variance of 17, the first six roots take up 3·44, 2·34, 1·75, 1·37, 1·28, 1·07, 0·99. The first four factors were used for calculating factor measurements for the patients, in the form of T-scores.

For the interest of those factorists who have a taste for factors rotated to give simple structure, the first three factors were rotated by an orthogonal rotation matrix (Table III) to give the results shown in Table IV. The fourth factor was left as it is, as it already has a fair number of near-zero saturations. The final saturations give a good approximation to simple structure and still retain the advantage of orthogonality.

Factor Saturations.—It is customary to examine the factor saturations in order to give an appropriate name to the factors. When all the variables are positively correlated, the general factor may be regarded as an overall average of the items; but when, as in this case, a group of the variables is negatively correlated with the rest, this notion of an average becomes a little tenuous. Be that as it may, there would be little objection to the proposal to call the first factor "retarded depression" on the basis of its factor saturations. The important ones are, in descending order, depressed mood 0·76, guilt 0·73, retardation 0·68, loss of insight 0·60, suicide 0·53, genital symptoms (loss of libido) 0·47, work and interest 0·46, anxiety (somatic) 0·40, anxiety (psychic) 0·37, loss of weight 0·35, and insomnia (delayed) 0·34. The correspondence with the classical descriptions is remarkably close. The saturations in the second factor are: Somatic symptoms (gastro-intestinal) 0·67, insomnia (initial) 0·61,

agitation 0·54, loss of weight 0·44, retardation 0·37, insomnia (delayed) 0·37, insomnia (middle) 0·36, hypochondriasis 0·37, anxiety (psychic) 0·33, and suicide 0·31. It might be said to be vaguely like agitated depression, which clinically shows anxiety and agitation, together with disturbed sleep (particularly initial insomnia), but the factor is deficient in depression, the first factor having taken out most of the depressive variance. The third factor might be called some sort of anxiety reaction, with saturations of anxiety (psychic) 0·56, agitation 0·50, anxiety (somatic) 0·50, genital (loss of libido) symptoms 0·40, gastrointestinal symptoms — 0·39, general somatic symptoms — 0·36, guilt 0·34, and insomnia (delayed) — 0·30. The fourth factor has saturations of insomnia (middle) 0·64, general somatic symptoms 0·63, anxiety (somatic) 0·42, and insomnia (delayed) — 0·34. It is difficult to attach any label to the third and fourth factors, as they do not bring any clinical pattern to mind.

The situation is no better with the rotated factors. Factor I is still very much like retarded depression, but the negative saturation for gastrointestinal symptoms strikes a most incongruous note. Factor II shows many somatic symptoms and disturbed sleep, but the presence in the factor of agitation without anxiety is disturbing. It cannot be regarded as a factor of objective symptoms, as opposed to subjective, since it includes loss of interest and insight. Factor III could be named "anxiety reaction", but the negative saturations of depression and loss of insight must disqualify any attempt to relate it to clinical syndromes. The fourth factor has been left unrotated.

It is not surprising that the classical clinical syndromes have not appeared from the factor analysis, since this technique is incapable of demonstrating them. It would appear from the literature that psychologists have hoped that factor analysis would elicit the classical syndromes, and perhaps even additional ones, but in practice this does not occur. The clinical syndromes are mutually exclusive, *i.e.*, a patient can be ill with endogenous depression, or reactive depression, or schizophrenia, etc., but not from two or more. Of course, there are always patients who diagnostically are doubtful in-betweens. On the other hand, factors are orthogonal, and any individual patient can have high scores in two or more factors, or conversely, low scores. The discrepancy between clinical syndromes and factors is even greater when correlated factors are obtained by non-orthogonal rotations, for with such factors, patients will tend to score high or low in all factors simultaneously.

The appropriate statistical technique for describing the clinical syndromes in terms of quantified variables is that of discriminant functions. These divide the multidimensional space into regions, the centres of which characterize the typical case, and the meeting of the regions, the "interfaces", are the sites where are located the atypical, anomalous, or half-way cases. Since this procedure requires the initial establishment of criterion groups, already diagnosed, it cannot therefore be used to find syndromes. It can be used to test the (null) hypothesis that the syndromes are not distinct, and to identify new cases.

Factor Measurements

Another way of investigating the nature of the factors is to consider the individuals who have high scores on the factors:—

Factor 1.—A man aged 39 years (Case 39) had factor scores of F_1 76, F_2 37, F_3 49, and F_4 52.

This patient was admitted to hospital after two attempts at suicide, first by electrocution, and, when this failed, by an overdose of phenobarbitone. No psychological precipitating factors were found. On admission he was severely depressed and still actively suicidal. He had strong feelings of guilt, and feared that he had acquired venereal disease and was infecting others with it. He was markedly retarded and showed loss of insight. His sleep was disturbed in all three phases, he had no interest in anything and had complete loss of libido since the onset of his illness four months previously. His symptoms cleared with six courses of electroshock treatment (E.C.T.). Two weeks later he suddenly relapsed and attempted to cut his wrists with a broken tumbler. He again recovered with a further course of E.C.T. and has remained well ever since.

This case was one of classical endogenous depression.

Case 24.—A man aged 54 had factor scores of F_1 64, F_2 51, F_3 44, and F_4 50.

This patient developed symptoms of anxiety two years ago, accompanied by impotence. As a result of physical illness, he had to change his job to one much less satisfactory and with less pay. He worried excessively over this and over his health, and became very depressed. He was given E.C.T. as an out-patient, improved and returned to work for three months. He was twice admitted to hospital, refused E.C.T., and discharged himself. Eventually he agreed to accept E.C.T. but committed suicide just before he was due to attend for treatment. When in hospital he was deeply depressed, had some guilt feelings, suicidal thoughts, and moderate retardation. He had difficulty in falling asleep and woke in the early hours. He showed loss of interest and of libido. He lacked insight, had lost weight, and complained of vague bodily symptoms. He showed little anxiety but was preoccupied with his health and his future prospects.

Psychological precipitating factors cannot be excluded, but the overall picture is that of endogenous depression.

Factor 2.—A man aged 62 years (Case 61) had factor scores of F_1 32, F_2 54, F_3 37, and F_4 38.

This patient had been off work for 11 years for "bad nerves" following an accident at work. He had many hypochondriacal complaints and had undergone many fruitless investigations. Four years ago, he was admitted to hospital for severe depression with delusions and hallucinations. This cleared after E.C.T. He was readmitted a year ago, diagnosed as a case of reactive depression, and improved slowly under general treatment. He was discharged after three months. His condition fluctuated and eventually he was readmitted, given six courses of E.C.T. and showed marked improvement. He was discharged and remained well. His symptoms were of moderate depression, without feelings of guilt or suicidal ideas. He had difficulty in falling asleep and awoke early. He showed moderate loss of interest, anxiety, both psychic and somatic, and suffered from poor appetite and constipation. He was diagnosed as a case of reactive depression, but the relation of the illness to psychological precipitating factors is not certain.

Case 17.—A man aged 72 years had factor scores of F_1 48, F_2 65, F_3 43, and F_4 45.

There was a long history of abdominal complaints, but investigations found nothing to account for them. A year ago the patient became obviously depressed and was admitted to hospital. He showed moderate depression, guilt, and some suicidal preoccupations. His sleep was disturbed in all three phases. He showed loss of interest, some agitation, severe hypochondriasis, and considerable anxiety. His appetite was poor, his bowels were constipated, and he had lost weight. Because of the poor state of his heart, he was not given E.C.T. He improved slowly, finally discharging himself against advice. Eventually he was admitted to a general hospital and died from cancer of the lung.

The clinical picture is that of reactive depression, but the psychological precipitating factors are doubtful.

Factor 3.—A man aged 61 years (Case 2) had factor scores of F_1 41, F_2 38, F_3 63, and F_4 44.

The patient had a history of several attacks of depression, the last one precipitated by the deaths of his wife and daughter. The course of the illness was fluctuating, and the patient showed a poor response to E.C.T. He showed marked depression, guilt, suicidal thinking, retardation, loss of interest, and grossly disturbed sleep. Eventually he recovered and has remained well.

Case 45.—A man aged 53 years had factor scores of F_1 60, F_2 55, F_3 78, and F_4 52.

The patient had had one previous attack of depression four years before. Two years ago, the patient again fell ill, and his symptoms have fluctuated considerably. In hospital he showed much depression, guilt, and loss of interest, much anxiety and agitation, loss of libido and loss of insight. He is a rather inadequate personality and his present illness began when he was offered a post which involved greater responsibility.

Both of these patients have had previous attacks of depression, characteristic of an endogenous type of disorder, but in both cases, there were obvious psychological stresses to account for the onset of the present attack. In the first, the symptoms were of the endogenous (retarded) type, and in the second of the reactive (agitated) type. Clinically, these patients are very unlike, but the factor scores pick them out on account of their resemblance; what this is, is not clear.

Since the factors are derived from a limited number of cases, the fourth factor is of very doubtful stability. (The question of statistical significance is ignored for the moment.) Nevertheless, it is of considerable interest. Both of the following patients showed depression with much anxiety, disturbance of sleep and many somatic symptoms, but it is the background to the illness that is noteworthy.

Factor 4.—A man aged 51 years (Case 62) had factor scores of F_1 39, F_2 41, F_3 56, and F_4 71.

This patient was a hard worker, but could not restrain his heavy drinking and gambled heavily. These caused considerable marital discord. When temporarily out of work after an accident, he stole money from his daughter to continue his "hobbies". He went off to London, stayed in a hotel and decamped without paying. When he eventually returned home, he heard that the theft had been reported to the police. He became desperate, and after a few days attempted to gas himself and was admitted to hospital. His condition cleared after E.C.T.

Case 7.—A man aged 44 years had factor scores of F_1 34, F_2 44, F_3 58, and F_4 71.

This patient came from a disturbed parental home where he had been rejected and deprived. He has always been an odd personality with marked neurotic traits and paranoid attitudes. He served in the Royal Air Force for nine years, during which he was repeatedly delinquent and resistant to authority. Eventually he was discharged for "psychoneurosis". His subsequent occupational history is irregular, with frequent loss of jobs because of quarrelling. He always feels that others are against him. He has not worked for years, has shown much anxiety and in the last six months became depressed, being finally admitted to hospital. He improved a little after E.C.T. but relapsed, subsequently recovering spontaneously.

Both of these patients have obviously abnormal personalities, although it would be an exaggeration to describe them as psychopathic personalities. It has long been recognized that abnormal personalities, particularly of the hysterical type, are liable to attacks of depression, and it is of great interest that such patients should be picked out by reason of the pattern of symptoms of their depression. Nevertheless, the present findings should not be regarded as more than suggestive and worthy of further investigation.

Another way of tackling the relation between factors and clinical syndromes is to take groups of clinically identified patients and compare their mean

factor measurements. Since this is purely a clinical problem and involves other matters, it is reported elsewhere (Hamilton and White, 1959).

Tests of significance have not been applied to these factors. It seems likely that even the smallest factor would become statistically significant if a sufficient number of patients were tested, and the ratings were repeated often enough to make the individual variables highly reliable. The value of factors lies in their use. In this connexion, although the data for the factor analysis were derived from 49 patients, the regression equations were used on the ratings obtained from 64 patients investigated for other purposes. Of these 64 patients, 49 were followed up after treatment (not the same 49). The correlation between factor measurements and total crude score after treatment is for F_1 0·23, for F_2 0·17, for F_3 0·27, and for F_4 — 0·09. Although F_3 has no obvious clinical or psychological meaning, it is the only one of the factors to be correlated with outcome after treatment at a significance level of just over 5%. This is not much, but a large correlation with outcome is not to be expected in such a highly selected group of patients (Hamilton and White, 1959). Furthermore, 16 out of the 49 cases followed up are new cases, so that some of the shrinkage to be expected in a cross-validation group has already occurred. (The situation is not quite the same as when a multiple correlation is calculated, but F_3 has been picked out because it has the highest correlation with outcome. Herein lies the interest of this factor.)

Summary

A rating scale is described for use in assessing the symptoms of patients diagnosed as suffering from depressive states. The first four latent vectors of the intercorrelation matrix obtained from 49 male patients are of interest, as shown by (*a*) the factor saturations, (*b*) the case histories of patients scoring highly in the factors, and (*c*) the correlation between factor scores and outcome after treatment. The general problem of the relationship between clinical syndromes and factors extracted from the intercorrelations of symptoms is discussed.

Thanks are due to Dr. P. F. Fletcher, Physician-Superintendent of Stanley Royd Hospital, Wakefield, for giving me full facilities to work in his hospital, and to him and Professor G. R. Hargreaves, of the Department of Psychiatry, Leeds University, for permission to publish. I have to thank Dr. J. White, not only for providing the patients, but also for collaborating in the assessments to give data on reliability. I am indebted to Miss W. Ashton, B.A., B.Sc., of the Computing Laboratory of Leeds University, for the programming of the correlation matrix, latent roots and vectors, and factor measurements. The research fellowship is in part supported by the Mental Health Research Fund.

APPENDIX II

CHECK LIST OF SYMPTOMS OF DEPRESSIVE STATES

Item No.	Range of Scores	Symptom
1.	0-4	*Depressed Mood* Gloomy attitude, pessimism about the future Feeling of sadness Tendency to weep Sadness, etc ..... 1 Occasional weeping .. 2 Frequent weeping ..... 3 Extreme symptoms 4
2	0-4	*Guilt* Self-reproach, feels he has let people down Ideas of guilt Present illness is a punishment Delusions of guilt Hallucinations of guilt
3	0-4	*Suicide* Feels life is not worth living Wishes he were dead Suicidal ideas Attempts at suicide
4	0-2	*Insomnia, initial* Difficulty in falling asleep
5	0-2	*Insomnia, middle* Patient restless and disturbed during the night Waking during the night
6	0-2	*Insomnia, delayed* Waking in early hours of the morning and unable to fall asleep again
7	0-4	*Work and Interests* Feelings of incapacity Listlessness, indecision and vacillation Loss of interest in hobbies Decreased social activities Productivity decreased Unable to work Stopped working because of present illness only ..... 4 (Absence from work after treatment or recovery may rate a lower score.)
8	0-4	*Retardation* Slowness of thought, speech, and activity Apathy Stupor Slight retardation at interview .. 1 Obvious retardation at interview 2 Interview difficult ..... 3 Complete stupor 4
9	0-2	*Agitation* Restlessness associated with anxiety
10	0-4	*Anxiety, psychic* Tension and irritability Worrying about minor matters Apprehensive attitude Fears
11	0	*Anxiety, somatic* Gastrointestinal, wind, indigestion Cardiovascular, palpitations, headaches Respiratory, genito-urinary, etc.
12	0-2	*Somatic Symptoms, Gastrointestinal* Loss of appetite Heavy feelings in abdomen Constipation

THE ASSESSMENT OF ANXIETY STATES BY RATING

By MAX HAMILTON*

In the last decade many scales have been devised for the assessment of psychiatric symptoms. Most have been designed for use with patients in mental hospitals and have therefore concentrated chiefly on behaviour in the ward and in hospital activities. Not many of the items are concerned with symptoms, and these are chiefly those of schizophrenia and the depressive psychoses. Even less attention is paid to neurotic symptoms, especially anxiety states, despite the fact that the scales are intended generally to cover the full range of psychiatric syndromes. These scales have been designed to enable the research worker to obtain a quantified measure of the patient's clinical status, e.g. for use in clinical trials of treatment. In them, the separate items are summed in groups and a set of scores or 'profile' is obtained for each patient. This 'profile' is often used as a diagnostic aid, although this is not the primary purpose of the scale. Users are generally warned not to use the scale for making a diagnosis.

In practice, these scales have two other functions of great importance. The first is that the investigator can describe precisely certain characteristics of his group of patients using the mean score and standard deviation. The description and definition of the population from which a sample is drawn is of fundamental importance and is one of the difficult problems that faces research in psychiatry. For this purpose diagnostic categories are notoriously unreliable and rating scales are invaluable. The second function is that they help to define syndromes and subsyndromes, and in a manner which permits of reproduction in another enquiry.

The present scale was designed along different lines. It is intended for use with patients already diagnosed as suffering from neurotic anxiety states, not for assessing anxiety in patients suffering from other disorders. Anxiety in greater or lesser degree is found in agitated depression and obsessional states particularly, and also in such states as organic dementia, hysteria and schizophrenia, but it must be clearly emphasized that the scale is not intended to cope with these conditions.

The usual methods for scale design were used. A series of symptoms were assembled which were considered to cover the condition adequately. These were then grouped together according to their nature, or where clinical experiences indicated that they were associated. It was decided that for practical purposes twelve groupings were sufficient. Together with the patient's behaviour at interview, these formed the thirteen variables of the scale. They are: anxious mood (a continued state of apprehension), tension (including irritability), fears (of specific or phobic type), insomnia, cognitive changes (difficulty in concentration and forgetfulness), depression, somatic symptoms of a general type, cardiovascular, respiratory, gastro-intestinal, genito-urinary, and general autonomic symptoms, the latter consisting chiefly of headaches and sweating. Each of the variables was defined in a series of brief statements, headed by the name of the variable, printed on a sheet which faced the interviewer during the interview with the patient (see Appendix 1).

Assessments were made on a five-point scale (see Appendix 2). In practice, the last grade is very rarely used for out-patients, and serves more as a marker, a method of delimiting

* Senior Research Fellow, Department of Psychiatry, University of Leeds. Based on a paper read at the Annual General Meeting of the British Psychological Society, April 1957. Manuscript received 2 August 1958.

the range, rather than as a grade of practical use. In order to determine the reliability of the scale the patients were seen by two interviewers simultaneously. The principal interviewer conducted the interview and endeavoured to obtain information regarding the patient's symptoms. The second interviewer made his ratings independently of the first and could add his own questions if he thought he had not had sufficient information.

Table 1. *Correlations and t tests between raters*

		Raters I	Raters II	Raters III

		Second interview			

The initial testing of the scale involved three psychiatrists. Preliminary discussions eliminated many of the difficulties in the first version of the definitions of the variables. The rating scale was then tried on a number of patients and the discrepancies and agreements between psychiatrists carefully considered in detail, in an endeavour to eliminate difficulties. The scale was then tried on a group of patients and this paper is concerned with the results. An identical procedure was followed throughout. Each patient was assessed by two raters and the results recorded. Afterwards the results were compared and any discrepancies noted and discussed. Nevertheless, once a rating had been made it was not altered. The measure of reliability was based on the sum of crude scores for each patient. Product-moment correlations were calculated between each pair of physicians, and since the patients were interviewed on two occasions for purposes of a drug trial, two such correlations between each pair of physicians is available. The results are to be seen in Table 1. The weighted mean of these correlations, using the z transformation, is 0·89. This is remarkably high and illustrates the reliability of psychiatric assessments under suitable conditions. Since the reliability coefficient does not give information on the bias of raters towards high or low scores, t tests were calculated between pairs of raters in the same way (see Table 1). The weighted mean of these t tests is 0·61 and shows that very little bias is to be found.

The relations between the variables were then examined. Product-moment correlations were calculated between the variables and the resultant matrix factor-analysed by the method of Simple Summation (the matrix of correlations is available on request). Communalities were estimated by five iterations of the process. This is very easily done using the shortened method of Burt (1949). A general and one bipolar factor were extracted. The general factor is clearly a general factor of anxiety and the bipolar divides the symptoms into two groups: The first contains psychic symptoms consisting of tension, fears, insomnia, anxiety, intellectual (cognitive) changes, depression, and behaviour at interview. This was contrasted with a group of somatic symptoms consisting of gastro-intestinal, genito-urinary, respiratory, cardiovascular, somatic general and autonomic symptoms (Table 2).

When the factor saturations are plotted it may be seen that the vectors lie almost completely within a right angle. In other words it is possible to rotate the saturations to give two orthogonal group factors. The variance of the general factor constitutes 27 %, of the bipolar 18 %, giving a total of 45 % of the total variance. This total was probably reduced by selection.

Table 2. *Saturations for centroid and rotated factors*

	G	BP	I	II
Tension	0·60	0·26	0·36	0·54

Communality	2·93	2·09	—	—
Communality as percentage	23	16	—	—

DISCUSSION

This particular matrix of correlations can be resolved either into a general factor of anxiety and a bipolar factor of psychic versus somatic symptoms, or alternatively, into two orthogonal group factors of 'psychic anxiety' and 'somatic anxiety'. Since both factorizations give orthogonal factors, there is no advantage in one over the other. On general grounds, we know that had there been less selection of subjects, so that they extended through the full range from those with trivial symptoms to those severely ill, then in the centroid analysis, the general factor would have had a greater variance, the bipolar factor still being orthogonal to it. In the group factor analysis, the two group factors would have been positively correlated, this implying a general second order factor. The British school of factorists, following Burt, emphasize the value of orthogonality. The American school, following Thurstone, emphasize the value of being able to identify the same factors regardless of the problems introduced by selection. In this particular case, the group factor analysis has the advantage of orthogonality as well.

Despite the apparent advantage of the group factor approach over the general factor approach, it must not be forgotten that mathematically, the two have an equivalence, since the one can be converted into the other by a simple transformation, in this case, the simplest of all, an orthogonal rotation. No new information can appear from such a transformation. (In fact, factor analysis, except for the method of principal components with full variance, actually loses information. Its great advantage is that it makes information clearer and more comprehensible.) The choice between general and group factor analysis must depend on other considerations.

In this case, the selection of patients is based on the fact that they all suffer from anxiety neurosis, and this condition shows itself as a general factor, i.e. a dimension to which all the variables are positively correlated, or on which they all have positive non-zero projections. It may be that, in other circumstances, the division into group factors may be preferred. For example, the response to treatment, or the effects of some drug, may show as a change in one or other of the group factors. Even if this should be so, it would only mean that whereas for such a situation, the group factor is appropriate, for the present situation, i.e. for diagnosis, the general factor is the appropriate one.

It is interesting to compare this rating scale with the factor analysis of the Taylor scale by O'Connor, Lorr & Stafford (1956). Although the present scale is concerned with general symptoms, whereas the Taylor scale deals with specific statements, the two factors A and B correspond roughly with the present general and bipolar factors. Factors A and B correlate 0·068, so they too are orthogonal.

Both the Taylor scale and the scales of Dixon, de Monchaux & Sandler (1957*a*, *b*) differ from the present one in that they are concerned with the content of the patient's

symptoms, rather than the form. This is also true of the Taylor scale. Although in the course of treatment the specific nature of a patient's fears and anxieties may change, it does so much less readily than the intensity. The assessment of both these kinds of changes is of practical and theoretical importance, and therefore the two kinds of scale are complementary.

The present scale obviously invites comparison with that designed by Buss, Wiener, Durkee & Baer (1955). It is important to recognize the difference between the two. The present scale is designed for the rating of anxiety neurosis as a syndrome, not for the rating of anxiety. Until the contrary is proved, it must be regarded as invalid for the rating of anxiety in any other setting. This limits the range of usefulness of the scale but, within these limits, patients can be compared meaningfully. It places great emphasis on the patient's subjective state. (This follows from the medical bias of the author, for in treatment the patient's subjective state takes first place both as a criterion of illness, which brings the patient for treatment, and as a criterion of improvement.) The various symptoms are rated separately, the somatic ones being given equal place with the psychic. This is because in outpatient practice patients place great emphasis on somatic symptoms, and a large number go first to the general medical departments for investigation of these. The scale of Buss *et al.* was used for rating anxiety on all types of patient except those suffering from cerebral damage. It therefore has a wider range of application. This is counter-balanced by the fact that the comparison of scores for anxiety, e.g. schizophrenia, depression and anxiety neuroses, has no clear meaning. It assembles symptoms into fewer groups. It gives less weight to somatic symptoms, or alternatively, gives more weight to psychic symptoms. Both scales group many single items under a limited number of headings, and it would be clearly desirable to investigate the appropriateness and usefulness of this procedure. Both show high reliability in use. I do not intend to suggest that either scale is better than the other. Only practical use will determine which is the more useful, and it is to be hoped that both will be superseded by something better.

The scale can by no means be considered to be in its final state. Ideally, each of the items listed under the heading of a variable should be handled separately for purposes of full item analysis. The sheer labour of doing this in a rating scale (as opposed to a questionnaire) will delay this for a long time. Some of the variables are obviously a rag-bag of oddments and need further investigation. Further work is being done in which the general somatic symptoms are separated into two variables: muscular and sensory.

Experience has shown that grade 2 can be split up into two grades without increasing the difficulty of rating. In practice, grade 4 is almost never used because the rater is reluctant to give the maximum score to subjects who could obviously be much worse. An additional grade would probably be rarely or never used, but would encourage the rater to subdivide grade 3, shifting some of his ratings to the higher grade.

Summary

A rating scale for the symptoms of anxiety neurosis has been prepared as an aid to the quantification of symptoms. It was used on thirty-five patients by three physicians working in pairs. The reliability of the scale, as shown by correlations and *t* tests between raters, is high. The correlations between variables can be factorized into a general factor of anxiety and a bipolar factor contrasting psychic with somatic symptoms; or into two orthogonal group factors of 'psychic' and 'somatic' anxiety.

Acknowledgements

I would like to thank Prof. Hargreaves for permission to publish this paper, and particularly for his advice and guidance in the design of the rating scale. I have to thank him and Dr Roberts for taking part in the ratings of patients. The Research Fellowship is supported in part by a grant from the Mental Health Research Fund to whom thanks are due.

Appendix 1

Symptoms of anxiety states

Anxious mood
- Worries
- Anticipation of the worst
- Apprehension (fearful anticipation)
- Irritability

Tension
- Feelings of tension
- Fatiguability
- Inability to relax
- Startle response
- Moved to tears easily
- Trembling
- Feelings of restlessness

Fears
- Of Dark
- Strangers
- Being left alone
- Large animals, etc.
- Traffic
- Crowds

Insomnia
- Difficulty in falling asleep
- Broken sleep
- Unsatisfying sleep and fatigue on waking
- Dreams
- Nightmares
- Night terrors

Intellectual (cognitive)
- Difficulty in concentration
- Poor memory

Depressed mood
- Loss of interest
- Lack of pleasure in hobbies
- Depression
- Early waking
- Diurnal swing

General somatic (muscular)
- Muscular pains and aches
- Muscular stiffness
- Muscular twitchings
- Clonic jerks
- Grinding of teeth
- Unsteady voice

General somatic (sensory)
- Tinnitus
- Blurring of vision
- Hot and cold flushes
- Feelings of weakness
- Pricking sensations

Cardiovascular symptoms
- Tachycardia
- Palpitations
- Pain in chest
- Throbbing of vessels
- Fainting feelings
- Missing beat

Respiratory symptoms
- Pressure or constriction in chest
- Choking feelings
- Sighings
- Dyspnoea

Gastro-intestinal symptoms
- Difficulty in swallowing
- Wind
- Dyspepsia:
  - pain before and after meals
  - burning sensations
  - fullness
  - waterbrash
  - nausea
  - vomiting
  - sinking feelings
- 'Working' in abdomen
- Borborygmi
- Looseness of bowels
- Loss of weight
- Constipation

Genito-urinary symptoms
- Frequency of micturition
- Urgency of micturition
- Amenorrhea / Menorrhagia / Development of frigidity
- Ejaculatio praecox / Loss of erection / Impotence

Autonomic symptoms
- Dry mouth
- Flushing
- Pallor
- Tendency to sweat
- Giddiness
- Tension headache
- Raising of hair

Behaviour at interview (general)
- Tense, not relaxed
- Fidgetting: hands, picking fingers, clenching, tics, handkerchief
- Restlessness: pacing
- Tremor of hands
- Furrowed brow
- Strained face
- Increased muscular tone
- Sighing respirations
- Facial pallor

Behaviour (physiological)
- Swallowing
- Belching
- High resting pulse rate
- Respiration rate over 20/min.
- Brisk tendon jerks
- Tremor
- Dilated pupils
- Exophthalmos
- Sweating
- Eye-lid twitching

APPENDIX 2

A New Depression Scale Designed to be Sensitive to Change

By STUART A. MONTGOMERY and MARIE ÅSBERG

SUMMARY The construction of a depression rating scale designed to be particularly sensitive to treatment effects is described. Ratings of 54 English and 52 Swedish patients on a 65 item comprehensive psychopathology scale were used to identify the 17 most commonly occurring symptoms in primary depressive illness in the combined sample.

Ratings on these 17 items for 64 patients participating in studies of four different antidepressant drugs were used to create a depression scale consisting of the 10 items which showed the largest changes with treatment and the highest correlation to overall change.

The inter-rater reliability of the new depression scale was high. Scores on the scale correlated significantly with scores on a standard rating scale for depression, the Hamilton Rating Scale (HRS), indicating its validity as a general severity estimate. Its capacity to differentiate between responders and non-responders to antidepressant treatment was better than the HRS, indicating greater sensitivity to change. The practical and ethical implications in terms of smaller sample sizes in clinical trials are discussed.

Introduction

The most common use of psychiatric rating scales is probably for comparison of effects of new drugs to standard treatment. In most trials of antidepressant drugs a difference can be demonstrated between pharmacologically active compounds and placebo (Morris and Beck, 1974) but only rarely are consistent differences found between active drugs even when they are known to have different mechanisms of action.

One possible explanation is that the standard rating scales are not sensitive enough to pick up such differences (Angst, 1972) which is not surprising if the scales were not designed specifically for that purpose. The result has often been that the scales reflect diagnostic features rather than being sensitive to change. We therefore decided to construct a rating scale for depressive illness where sensitivity and accuracy of change estimates were to be major criteria for the inclusion of items. This work was made possible by the recent introduction of a new, comprehensive psychopathological rating scale or CPRS (Åsberg *et al*, 1978). The CPRS is composed of 65 scaled items covering a wide range of psychiatric symptoms.

Patients and Ratings

The selection of items for the depression scale was based on ratings on the CPRS of 106 depressed patients, 33 men and 73 women, participating in clinical trials of antidepressant drugs. Thirty-three were out-patients and 73 in-patients. In the majority of cases, two raters participated in the interview. Only patients with a primary depressive illness (Feighner *et al*,

1972) were included. Inventories (Gurney *et al*, 1972) were applied to ensure diagnostic and descriptive uniformity. Within this group, a wide variation in patient characteristics was sought and the sample includes endogenous and reactive, psychotic and non-psychotic, bipolar and unipolar out-patients and in-patients from a wide age range (18–69 years). Patients from two countries (England n = 54, and Sweden n = 52) were included in order to reduce cultural bias in the selection of items.

CPRS scores after four weeks therapy with four antidepressant drugs with different pharmacological profiles were used to study change with treatment. The drugs were mianserin, amitriptyline, maprotiline and clomipramine. Amitriptyline (Tuck and Punell, 1973), maprotiline (Maitre *et al*, 1971) and clomipramine (Hamberger and Tuck, 1973) block neuronal reuptake of noradrenaline, directly or by means of endogenously formed metabolites. Clomipramine is also a potent serotonin uptake blocker (Åsberg *et al*, 1977). Amitriptyline may also affect serotoninergic neurones (Tuck and Punell, 1973) and has pronounced anticholinergic effects (Mass, 1975); it is also thought to have a stronger sedative effect than the other drugs (Silverstone and Turner, 1974). Mianserin appears to lack uptake inhibiting effects (Ferl *et al*, 1973) as well as anticholinergic effects (Coppen *et al*, 1976) and its mechanism of action is not clear.

Of the 64 patients for whom scores were available from before and after four weeks of treatment 35 were simultaneously rated on the Hamilton Rating Scale (HRS) (Hamilton, 1967) and on a 7-point scale for global severity of illness.

Construction of the Scale

Parametric statistical methods were used except when dealing with ranked data as recommended by Anderson (1961) and Boneau (1961). The difference between pre-treatment scores has been used as an estimate of change, both for individual and sums of items.

Preliminary item selection

The frequency of scores above zero on all of the 65 items as well as the ranking by inci-

TABLE I

Frequency of scores above zero and correlation between English and Swedish raters on the 17 most commonly scored items of the CPRS

Item	Frequency of scores above zero in per cent (both samples combined, n = 106)	Interrater reliability between English and Swedish rater (n = 11)
Reported sadness	100	0.96
Apparent sadness	99	0.90
Lassitude	96	0.78
Inner tension	95	0.90
Pessimistic thoughts	94	0.53
Inability to feel	93	0.41
Worrying over trifles	91	0.78
Concentration difficulties	88	0.80
Observed muscular tension	88	0.74
Suicidal thoughts	87	0.71
Fatiguability	86	0.89
Reduced sleep	83	0.76
Indecision	81	0.27
Reported autonomic disturbances	79	0.72
Reported muscular tension	74	0.59
Reduced appetite	73	0.95
Agitation	73	0.62

dence were remarkably similar in the Swedish and the English samples (r = +.88, rho = +.88, P for both <0.001 (Montgomery *et al*, 1978a). Since the agreement between ratings of English patients by English and Swedish raters was generally high (Table I) it was decided to merge the two samples in the further calculations.

An arbitrary cut-off point of 70 per cent occurrence was used to identify the 17 most common items (Table I) in the total sample of patients. The sum of scores on these 17 items was used as a preliminary estimate of severity of the illness. This estimate was significantly correlated with the HRS scores (r = +.94, P <0.001) and also with the global scores (r = +.89, P <0.001) during the fourth treatment week. Before treatment these correlations were slightly lower as would be expected from the more restricted range of scores (HRS, r = +.73, Global, r = +.61, P for both <0.001).

TABLE II

Mean change (regardless of direction), and correlation between change on each item and sum of change on the preliminary 17 item scale (n = 64). The items are ranked in order of descending sensitivity on both estimates combined

Item	Mean change	Correlation to total change
Apparent sadness	2.12	0.84
Reported sadness	2.19	0.73
Inability to feel	1.98	0.75
Inner tension	1.79	0.73
Suicidal thoughts	2.03	0.64
Lassitude	1.61	0.79
Concentration difficulties	1.79	0.69
Reduced sleep	2.45	0.49
Reduced appetite	1.78	0.63
Pessimistic thoughts	1.69	0.64
Worrying over trifles	1.88	0.46
Fatiguability	1.73	0.58
Muscular tension (reported)	1.41	0.56
Muscular tension (observed)	1.22	0.49
Indecision	1.57	0.44
Autonomic disturbances	1.60	0.40
Agitation	0.99	0.34

Selecting items for sensitivity

Two different estimates of sensitivity were used (Table II). Firstly the mean changes of scores (absolute values) on each of the 17 items after four weeks of treatment were calculated and ranked. The second estimate was the correlation between change on each item and the overall change on the preliminary 17 item scale over the four weeks. These estimates reflect different aspects of sensitivity to change. Ideally, an item should both yield large changes (that can be reliably rated) and be strongly correlated to general amelioration of depression. This is not always the case.

For example, reduced sexual interest yielded large changes but was less well correlated to general outcome. Inclusion of an item like this in a scale might spuriously inflate the change scores.

The summed ranks on both estimates were used to select the 10 most sensitive items for the final depression rating scale, which is shown in the Appendix.

Reliability and Validity of the New Depression Scale

Interrater reliability

Data from the conjoint interviews were used to compute interrater correlations. Comparisons between two English raters, two Swedish raters and one English and one Swedish rater, rating English patients, are given in Table III. The interrater reliability in the simultaneously performed HRS ratings is shown for comparison. The interrater correlations are satisfactory for both scales, for raw scores as well as for difference scores.

To test the robustness of the instrument in the hands of untrained raters, ratings were also performed by a trained psychiatrist and a general practitioner or a psychiatric nurse (a detailed account of the procedure is given elsewhere; Montgomery *et al*, 1978). Also in this setting the interrater correlations were high (Table III).

Validity studies

To test the validity of a scale which estimates the severity of depression a comparison must

TABLE III

Interrater reliability of the new depression scale with different rater pairs. Interrater correlation between simultaneously performed Hamilton scale ratings are shown within brackets for comparison. All correlations are highly significant ($P < 0.001$)

Rater pair	r	n
Two English raters		
before treatment	0.89 (HRS: 0.89)	30 (HRS: 25)
during treatment	0.95 (HRS: 0.98)	20 (HRS: 14)
difference	0.90 (HRS: 0.91)	13 (HRS: 12)
Two Swedish raters		
before treatment	0.95	22

various stages of treatment	0.97	17
Psychiatrist and nurse		
various stages of treatment	0.93	12

be made with an independent measure. An experienced clinician's global judgement as to whether the patient has responded or not is the criterion against which depression scales should be judged. As a preliminary validation of this scale's capacity to identify responders and non-responders to treatment we compared the scale scores with a clinician's global judgement in a sample where there was a clear cut differentiation between responders (18 patients) and non-responders (17 patients).

Point biserial correlations between response category and change scores were calculated for the preliminary 17-item scale, the final 10-item depression scale and the Hamilton Rating Scale. All correlations were highly significant. The correlations were used to determine which of the three scales differentiated better between responders and non-responders to treatment. The best correlation was achieved with the 10-item depression scale ($r = +.70$), the next best was with the 17-item preliminary scale ($r = +.67$). Of the three the HRS was the least able to discriminate ($r = +.59$). Converted into approximate patient numbers needed to achieve equivalent significance at different levels, for a point biserial correlation of this order 28 patients would have been needed to reach a significance at the 0.001 probability level with the HRS, compared with 19 patients on the 10 item scale.

Discussion

The major requirements of a rating scale for antidepressant treatment effects is that it should be short and easy to apply in a clinical setting, relevant for depressive illness, and provide a sensitive and accurate estimate of change (Hamilton, 1976; Carroll *et al*, 1973; Åsberg *et al*, 1973).

It would of course be possible to use a very extensive rating scale covering all aspects of depressive illness. A scale of this type might be more likely to pick up unexpected differences in the spectrum of action of drugs. However, the presence of a large number of items that were scored in only a few patients would tend to introduce and increase the random error. More important, the ratings would be cumbersome and time-consuming to undertake. Unskilled raters might have difficulties in covering a large number of items in a single interview. Repeated asking of questions which appear irrelevant to the patient might also be detrimental to clinical rapport and reduce the validity of the information provided.

When reducing the number of items, it is important that those included are relevant to

the illness and indeed occur in the majority of cases. An item may be both of diagnostic importance and likely to change with treatment but because it occurs so infrequently it might diminish the overall sensitivity of the scale. Examples of this type which failed to meet our frequency criterion for consideration are Ideas of Persecution and Compulsive Thoughts. Similar items were included in the initial version of the Hamilton Rating Scale (Hamilton, 1960) but excluded later (Hamilton, 1967).

Sensitivity of the scale in this context refers to its capacity to measure change. Change will be most sensitively recorded on items which are not restricted in range, but when the full width of the scales are used for the ratings. Restriction of the range might occur if a positive score on an item reflects a personality trait which is unlikely to change with short term treatment, rather than a symptom of an illness. It might also occur as a result of central tendency error, in which raters tend to avoid using the extreme ends of the scales (Guilford, 1954).

Change estimates should also be accurate and reflect a change in general severity of depressive illness. Some items may show a high degree of change without this being related to the illness as such. Hospitalization would be expected to have effects, for instance, on sexual interest and general levels of activity. Increased severity of some symptoms (for instance autonomic disturbances) may be side-effects of an antidepressant drug treatment.

The 10 items included in the new depression scale are all core symptoms of depressive illness. A few characteristic symptoms are, however, not included. Motor retardation (called Slowness of Movement in the full CPRS) is perhaps the most conspicuous omission. It was excluded from the primary selection, since it occurred in relatively few patients (63 per cent of the English patients and 69 per cent of the Swedish patients). Clinical experience shows that motor retardation only occurs in a proportion of patients and this is indeed the background of one of the classifications of depressive illness into retarded and non-retarded forms. In any case the mean change in Slowness of Movement was smaller than for any item included in the scale and the correlation of change to overall amelioration was comparatively low ($r = +.57$).

The large number of rating scales available to clinical investigators is a problem in psychiatric research (Pichot, 1972) and the comparability between scales is rarely known. It is therefore important that a new rating scale should be shown to have clear advantages over existing instruments before it is accepted for research purposes. Our scale appears to have certain advantages, even when compared to the most widely used depression rating scale, the Hamilton Rating Scale.

Our depression scale has fewer items to score than the HRS (10 vs 17) and a reduction in reliability might be expected. However, we have demonstrated equally high reliabilities with the HRS and the 10 item scale. The scale can be used by trained nurses and psychologists as well as by psychiatrists (Montgomery *et al*, 1978b). It appears to be a more precise measure of change than the HRS. This means that significant differences between treatments may be revealed with smaller numbers of patients. In clinical trials this is important for ethical reasons, since fewer patients need to be exposed to possibly inferior treatments.

There is a definite need for simple, clinically oriented rating scales to measure treatment effects in other psychiatric syndromes such as mania, schizophrenia and anxiety states. To our knowledge, the strategy we employed for arriving at an empirically founded scale has not previously been used and should prove valuable in constructing further scales.

APPENDIX

Montgomery and Åsberg (MADRS) Depression Rating Scale.

The rating should be based on a clinical interview moving from broadly phrased questions about symptoms to more detailed ones which allow a precise rating of severity. The rater must decide whether the rating lies on the defined scale steps (0, 2, 4, 6) or between them (1, 3, 5).

It is important to remember that it is only on rare occasions that a depressed patient is encountered who cannot be rated on the items in the scale. If definite answers cannot be elicited from the patient all relevant clues as well as information from other sources should be used as a basis for the rating in line with customary clinical practice.

The scale may be used for any time interval between ratings, be it weekly or otherwise but this must be recorded.

Item List

1. Apparent sadness
2. Reported sadness
3. Inner tension
4. Reduced sleep
5. Reduced appetite
6. Concentration difficulties
7. Lassitude
8. Inability to feel
9. Pessimistic thoughts
10. Suicidal thoughts

1. *Apparent Sadness*

Representing despondency, gloom and despair, (more than just ordinary transient low spirits)

reflected in speech, facial expression, and posture. Rate by depth and inability to brighten up.

0 No sadness.
1
2 Looks dispirited but does brighten up without difficulty.
3
4 Appears sad and unhappy most of the time.
5
6 Looks miserable all the time. Extremely despondent.

---

2. *Reported sadness*

Representing reports of depressed mood, regardless of whether it is reflected in appearance or not. Includes low spirits, despondency or the feeling of being beyond help and without hope.

Rate according to intensity, duration and the extent to which the mood is reported to be influenced by events.

0 Occasional sadness in keeping with the circumstances.
1
2 Sad or low but brightens up without difficulty.
3
4 Pervasive feelings of sadness or gloominess. The mood is still influenced by external circumstances.
5
6 Continuous or unvarying sadness, misery or despondency.

---

3. *Inner tension*

Representing feelings of ill-defined discomfort, edginess, inner turmoil, mental tension mounting to either panic, dread or anguish.

Rate according to intensity, frequency, duration and the extent of reassurance called for.

0 Placid. Only fleeting inner tension.
1
2 Occasional feelings of edginess and ill-defined discomfort.
3
4 Continuous feelings of inner tension or intermittent panic which the patient can only master with some difficulty.
5
6 Unrelenting dread or anguish. Overwhelming panic.

---

4. *Reduced sleep*

Representing the experience of reduced duration or depth of sleep compared to the subject's own normal pattern when well.

0 Sleeps as usual.
1
2 Slight difficulty dropping off to sleep or slightly reduced, light or fitful sleep.
3
4 Sleep reduced or broken by at least two hours.
5
6 Less than two or three hours sleep.

---

5. *Reduced appetite*

Representing the feeling of a loss of appetite compared with when well. Rate by loss of desire for food or the need to force oneself to eat.

0 Normal or increased appetite.
1
2 Slightly reduced appetite.
3
4 No appetite. Food is tasteless.
5
6 Needs persuasion to eat at all.

---

6. *Concentration difficulties*

Representing difficulties in collecting one's thoughts mounting to incapacitating lack of concentration.

Rate according to intensity, frequency, and degree of incapacity produced.

0 No difficulties in concentrating.
1
2 Occasional difficulties in collecting one's thoughts.
3
4 Difficulties in concentrating and sustaining thought which reduces ability to read or hold a conversation.
5
6 Unable to read or converse without great difficulty.

---

7. *Lassitude*

Representing a difficulty getting started or slowness initiating and performing everyday activities.

0 Hardly any difficulty in getting started. No sluggishness.
1
2 Difficulties in starting activities.

3

4 Difficulties in starting simple routine activities which are carried out with effort.

5

6 Complete lassitude. Unable to do anything without help.

8. *Inability to feel*

Representing the subjective experience of reduced interest in the surroundings, or activities that normally give pleasure. The ability to react with adequate emotion to circumstances or people is reduced.

0 Normal interest in the surroundings and in other people.

1

2 Reduced ability to enjoy usual interests.

3

4 Loss of interest in the surroundings. Loss of feelings for friends and acquaintances.

5

6 The experience of being emotionally paralysed, inability to feel anger, grief or pleasure and a complete or even painful failure to feel for close relatives and friends.

9. *Pessimistic thoughts*

Representing thoughts of guilt, inferiority, self-reproach, sinfulness, remorse and ruin.

0 No pessimistic thoughts.

1

2 Fluctuating ideas of failure, self-reproach or self depreciation.

3

4 Persistent self-accusations, or definite but still rational ideas of guilt or sin. Increasingly pessimistic about the future.

5

6 Delusions of ruin, remorse or unredeemable sin. Self-accusations which are absurd and unshakable.

10. *Suicidal thoughts*

Representing the feeling that life is not worth living, that a natural death would be welcome, suicidal thoughts, and preparations for suicide.

Suicidal attempts should not in themselves influence the rating.

0 Enjoys life or takes it as it comes.

1

2 Weary of life. Only fleeting suicidal thoughts.

3

4 Probably better off dead. Suicidal thoughts are common, and suicide is considered as a possible solution, but without specific plans or intention.

5

6 Explicit plans for suicide when there is an opportunity. Active preparations for suicide.

Evaluation of 10 QT Prediction Formulas in 881 Middle-aged Men From the Seven Countries Study: Emphasis on the Cubic Root Fridericia's Equation

BY PAOLO E. PUDDU, M.D.,* RÉMY JOUVE, M.D., PH.D.,* SERGIO MARIOTTI, M.SC.,* SIMONA GIAMPAOLI, M.D., MARIAPAOLA LANTI, M.D.,*† ATTILIO REALE, M.D.,† AND ALESSANDRO MENOTTI, M.D.*

SUMMARY

In 881 middle-aged men from one Italian cohort of the Seven Countries Study, QT and RR intervals were measured in lead 2 from resting ECGs (25 mm/sec) and fitted separately with 10 mathematically different QT prediction formulas. The relative accuracy of fit to data was assessed from the minimum mean-squared residual and the minimum Akaike Information Criterion values. Using the Minnesota code, 588 men had normal (group 1) and 293 had abnormal (group 2) ECGs. A better fit to QT–RR data by all formulas was observed in group 1, compared with group 2. Among one-parameter equations in both groups, the cubic root Fridericia's formula is better suited to fit the data than the Bazett's square root or other formulas. The former compares favorably with multiparameter equations or with the inverse relation and gives the best fit in group 2. Thus the cubic root equation might be more accurate than the square root or several complex formulas for correcting measured QT intervals for cardiac cycle length in middle-aged men.

None[1] of several QT prediction formulas[2–17] used during the past 65 years has been derived from or validated in a residential cohort. Indeed, in most studies data were collected in few normal resting subjects,[1] which leaves a major range of heart rate insufficiently addressed. This may explain, at least in part, why interest in QT has waxed and waned historically among cardiologists.[13,18–21] Even so, corrected QT (QTc), derived from Bazett's formula[4] by dividing the measured QT by the square root of the measured RR, has been reported to predict the onset of life-threatening arrhythmias for values exceeding 440 units in disparate clinical situations.[1,20–23]

The methods required to measure QT interval have been fully detailed,[18,21,24–27] but the best method for correcting the meticulously measured QT for cardiac cycle length, with either curvilinear or linear formulas, remains a crucial and not completely solved problem.[1,16,17,22,26] Yet the best fit to data in the field of human QT–RR relation has been examined only occasionally, and then incompletely.[13,16,19,28]

We compared four previously proposed formulas (square root, cubic root, logarithmic, and linear)[3,4,8,11] relative to four closely related formulas,[16,29] to a more recently described exponential equation,[16] and to a formula derived from equations for the conservation of energy for the heart as a pump and the first law of thermodynamics,[17] to characterize human QT–RR relation under resting conditions in middle-aged men. We believed that the results might provide an accurate

method for obtaining heart rate-corrected QT. Such a method would be applicable in the field of QT-driven pacemakers[1,16] and might improve our ability to predict sudden death, using QT interval calculations, in clinical practice.[1,20–23]

MATERIALS AND METHODS

The Seven Countries Study is an ongoing longitudinal investigation on natural history, epidemiology, and etiology of adult cardiovascular diseases in seven countries, including Italy.[30,31]

The cohort used in this study involves men from Crevalcore, an agricultural district near Bologna. In 1960, there were about 12,000 inhabitants in that area; the entry data include 98.12% (993 of 1,012) of all men then 40–59 years old.[30] The data collected included a resting 12-lead ECG, recorded using the standard methods adopted and described by the Research Group on Epidemiology of Heart Disease.[32] In 1962, an interim study was carried out, with the aim of determining the willingness of the initial study population to participate in follow-up visits, eight-hundred eighty-one men (88.72% of those seen in 1960) were examined and form the study group for this report.

ECG Analysis

Resting supine 12-lead ECGs were recorded on a three-channel inkjet electrocardiograph (Siemens-Elema B31) at 25 mm/sec paper speed. Calibration (10 mm = 1 mV) was performed before the ECG was recorded in any subject. Paper speed was controlled every 25th ECG. One observer coded all ECGs according to the Minnesota code,[33] a reference method developed mainly for epidemiologic purposes and aimed at a standardized and analytic description of ECGs based principally on measurements.

The QT and RR intervals were measured (in msec) in lead 2 by a second observer. The measurements were made manually, with the aid of a caliper and a magnifying device with a grid,[33] from the beginning of the QRS complex to the end of the T wave, where its terminal limb joined the baseline. Intervals preceded by premature beats were not measured, nor were U waves in the QT intervals included.[18] To avoid respiratory influences, we used three to five nonconsecutive QRST complexes to derive average data for both QT and RR intervals, although minimal complex-to-complex variability of both QT and RR intervals might be appreciated. In the presence of atrial fibrillation, 10 nonconsecutive QRST complexes were considered. The measurements were taken to the nearest 0.50 mm (20 msec).

Data Analysis

The QT–RR data from each subject were fitted separately using the following 10 formulas (F1–F10) by means of an IBM 4341 computer using BMDP statistical programs[26]:

$$QT = A1 \cdot \sqrt{RR} \quad (F1)$$

$$QT = A2 \cdot \sqrt{RR} + B2 \quad (F2)$$

$$QT = A3 \cdot \sqrt[3]{RR} \quad (F3)$$

$$QT = A4 \cdot \sqrt[3]{RR} + B4 \quad (F4)$$

$$QT = A5 \cdot \log(RR) \quad (F5)$$

$$QT = A6 \cdot \log(RR) + B6 \quad (F6)$$

$$QT = A7 \cdot RR \quad (F7)$$

$$QT = A8 \cdot RR + B8 \quad (F8)$$

$$QT = A9 + B9 \cdot \mathrm{Exp}(-k9 \cdot RR) \quad (F9)$$

$$QT = A10 + B10 \cdot (RR)^{-1} \quad (F10)$$

where A, B, and k are regression parameters. F1 is the square root Bazett's formula[4]; F3 is the cubic root Fridericia's formula[3]; F6 is the logarithmic Ashman's formula[11]; F8 is the linear formula originally proposed by Adams[9]; F9 is the exponential formula of Sarma et al.[16]; and F10 is the inverse Kovacs' formula.[17] F2, F4, F5, and F7 are related to F1, F3, F6, and F8, respectively, but differ by one parameter each. F1–F6 and F9 and F10 were fitted by nonlinear regression analysis, whereas linear regression analysis was used for F7 and F8.

The relative accuracy of fit to data by the 10 formulas was assessed[10] in two ways. (1) It was assessed from the mean-squared residual (MSR) values, which provide an appropriate and objective means of comparing formulas with differing numbers of observations, using the following equation:

$$MSR = RSS/(N - P) \quad (E1)$$

where RSS is the residual sum of squares, N is the number of observations, and P is the number of parameters in the formula used. The equation with minimum MSR is considered the best representation of a given plot of data, therefore no further statistical analysis is required. (2) It was assessed using the Akaike Information Criterion (AIC) to account for the differences in the number of parameters among the 10 formulas. Akaike[34] and Tanabe[35] defined AIC by the following equation, assuming that the random errors obey Gaussian distribution:

$$AIC = N \cdot \ln(RSS) + 2P \quad (E2)$$

where N is the number of observations, ln is the natural logarithm, RSS is the residual sum of squares, and P is the number of parameters in the formula used. AIC was derived in relation to the maximum likelihood estimation, which is essentially equivalent to estimating the parameters so as to minimize "Kullbach–Leiblers mean information."[34,35] Because the equation with minimum AIC is regarded as the best representation of a given plot of data, this statistical method is called

"minimum AIC estimation" (MAICE). When the RSSs are almost equal for different models, MAICE chooses the model with the smaller number of parameters, according to the principle of parsimony. Therefore, the level of significance and the F table are not required when using MAICE. AIC is also directly related to the number of observations, N; therefore, AICs from groups with different numbers of observations may not be compared. Thus in this study, we used AIC to assess only the relative intragroup accuracy of fit in the QT–RR relation by different formulas.

Accuracy and Repeatability of QT and RR Measurements

Because inspection of the data (Figs. 1, 2) indicates that most of the measurements are multiples of 20 msec, suggesting that there might have been a systematic error in the measurements, we attempted to check the accuracy of these measurements. To this end, we assessed the relative accuracy of fit to data by the 10 formulas on all grouped 881 subjects, based on the methods delineated above. After selecting the "best" fit between QT and RR, we performed a separate MSR analysis on quartiles of the entire population.

To check intraobserver variability,[27] we made duplicate measurements of QT and RR intervals in 25 selected (nonrandom) ECGs. We used the same series to appreciate interobserver variability in selected ECGs. In addition, a third observer measured both QT and RR intervals on all 881 ECGs as a routine part of another study, during which she was unaware of the results from the present investigation; this interobserver variability was also measured. Variability was computed by calculating the technical error (coefficient of variability) for duplicate QT or RR interval measurements with the formula[33]:

$$\sigma = \sqrt{\frac{\sum (X_1 - X_2)^2}{2n - 1}}$$

and expressed as a fraction of the mean from all duplicate observations.

RESULTS

Of the entire population of 881 men aged 42–61 years in 1962, 588 had a normal ECG (Minnesota code 1.0) (group 1) and 293 had an ECG with codable items (Minnesota codes different from 1.0) (group 2). Codable Q waves (code 1.1) were present in one subject. Complete left (code 7.1) or right (code 7.2) bundle branch blocks were observed in 3 and 21 subjects, respectively. Frequent ventricular premature beats (10% or more of record complexes) (code 8.1) were seen in eight subjects. Atrial fibrillation (code 8.3) was present in five subjects. The range of RR intervals was 540–1,180 msec (mean, 846 ± 127 msec; ie, 111–51 beats/min) in group 1 (Fig. 1) and 420–1,280 msec (mean, 812 ± 163 msec) (ie, 143–47 beats/min) in group 2 ($p < 0.002$, one-way analysis of variance) (Fig. 2). However, only nine subjects from group 2 (3.07%) had a resting heart rate greater than 110 beats/min, and two of these nine presented with atrial fibrillation. The range of QT intervals was 300–460 msec (mean, 383 ± 30 msec) in group 1 (Fig. 1) and 300–480 msec (mean, 388 ± 35 msec) in group 2 ($p < 0.05$, one-way analysis of variance) (Fig. 2).

The values of MSR, RSS, and AIC are shown in Table I and of the estimated regression parameters in Table II.

Regression fits by F6–F10 to QT–RR data are depicted in Figures 1 and 2 for groups 1 and 2, respectively. The corresponding plots of residuals against RR interval are also shown in the figures. The data points in these figures are circles representative of a certain number of observations considered during the calculation process but not actually shown. The scatter of QT–RR data and the scatter of residuals against the independent variable RR are greater in group 2 than in group 1. Accordingly, the mean-squared residuals from group 2 are greater than those calculated in group 1, by all formulas.

It is noteworthy that in both groups approximately equivalent QT predictions are reached by either complex multiparameter formulas (Figs. 1, 2),[8,11,15,17,29] including the logarithmic formula of Ashman,[11] the exponential formula of Sarma et al.,[16] and the inverse formula of Kovacs,[17] or the simpler one-parameter cubic root equation of Fridericia.[3] Indeed, with the above-mentioned QT prediction formulas, the residuals against the independent variable RR are randomly distributed about the zero line. In contrast, the other one-parameter equations do not provide accurate predictions. In particular, Bazett's formula,[4] especially in group 2, overcorrects QT interval at high heart rates (positive residuals at short RR intervals) and undercorrects it at low heart rates (negative residuals at long RR intervals).

The MSR and AIC analyses performed on all grouped 881 individuals confirmed these results. All two-parameter equations performed well (MSR: 613, 612, 634, and 617 for F2, F4, F6, and F8, respectively), similar to more complex formulas (MSR: 614 and 617 for F9 and F10, respectively). On the other hand, one-parameter equations provided a less accurate fit to the data (MSR: 764, 779, and 2557 for F1, F5, and F7, respectively), with the notable exception of Fridericia's equation (F3), which provided the best fit

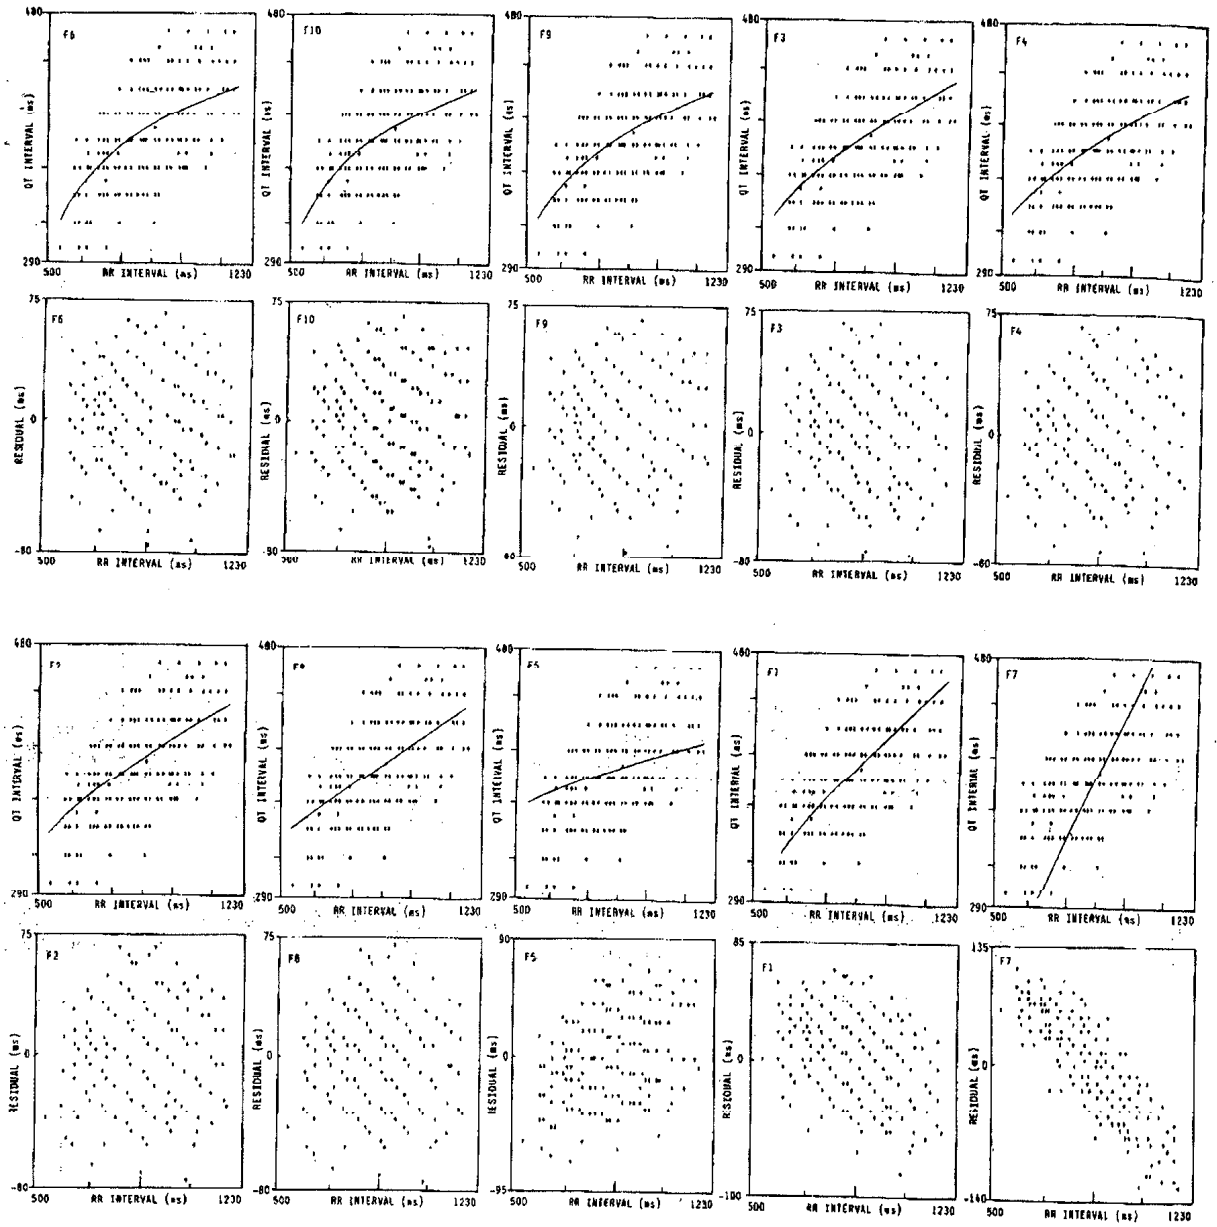

Fig. 1. Pooled QT–RR plots for all group 1 subjects (rows 1 and 3). The least-squared fit of data points are shown for formulas 1–10 (F1–F10), ranked left to right from best to worst, using the results shown in Table I. The residuals corresponding to the same least-squared curves are plotted in rows 2 and 4. Note the differences in the Y axis scales and the apparent dependence of residuals on RR intervals of the plots of residuals corresponding to the last three formulas.

(MSR: 614) also relative to F9 (AIC: 3516 and 3520 for F3 and F9, respectively).

The accuracy of QT relative to RR measurements was therefore assessed assuming Fridericia's equation[3] provided the best fit. Four quartiles of the population were formed based on RR data: 420–720 msec (n = 218), 740–820 msec (n = 221), 840–920 msec (n = 228), and 940–1,280 msec (n = 214). The MSRs were, respectively: 553, 609, 584, and 692. Since the numerical composition of quartiles was similar, this might be interpreted as providing some evidence of independency of QT interval measurement accuracy from RR interval with the Fridericia's equation.

The technical error (coefficient of variability) for duplicate QT and RR measurements was, respectively: 4.77% (±18 msec) and 1.64% (±14 msec), intraindividually (2n = 50); and 6.86%

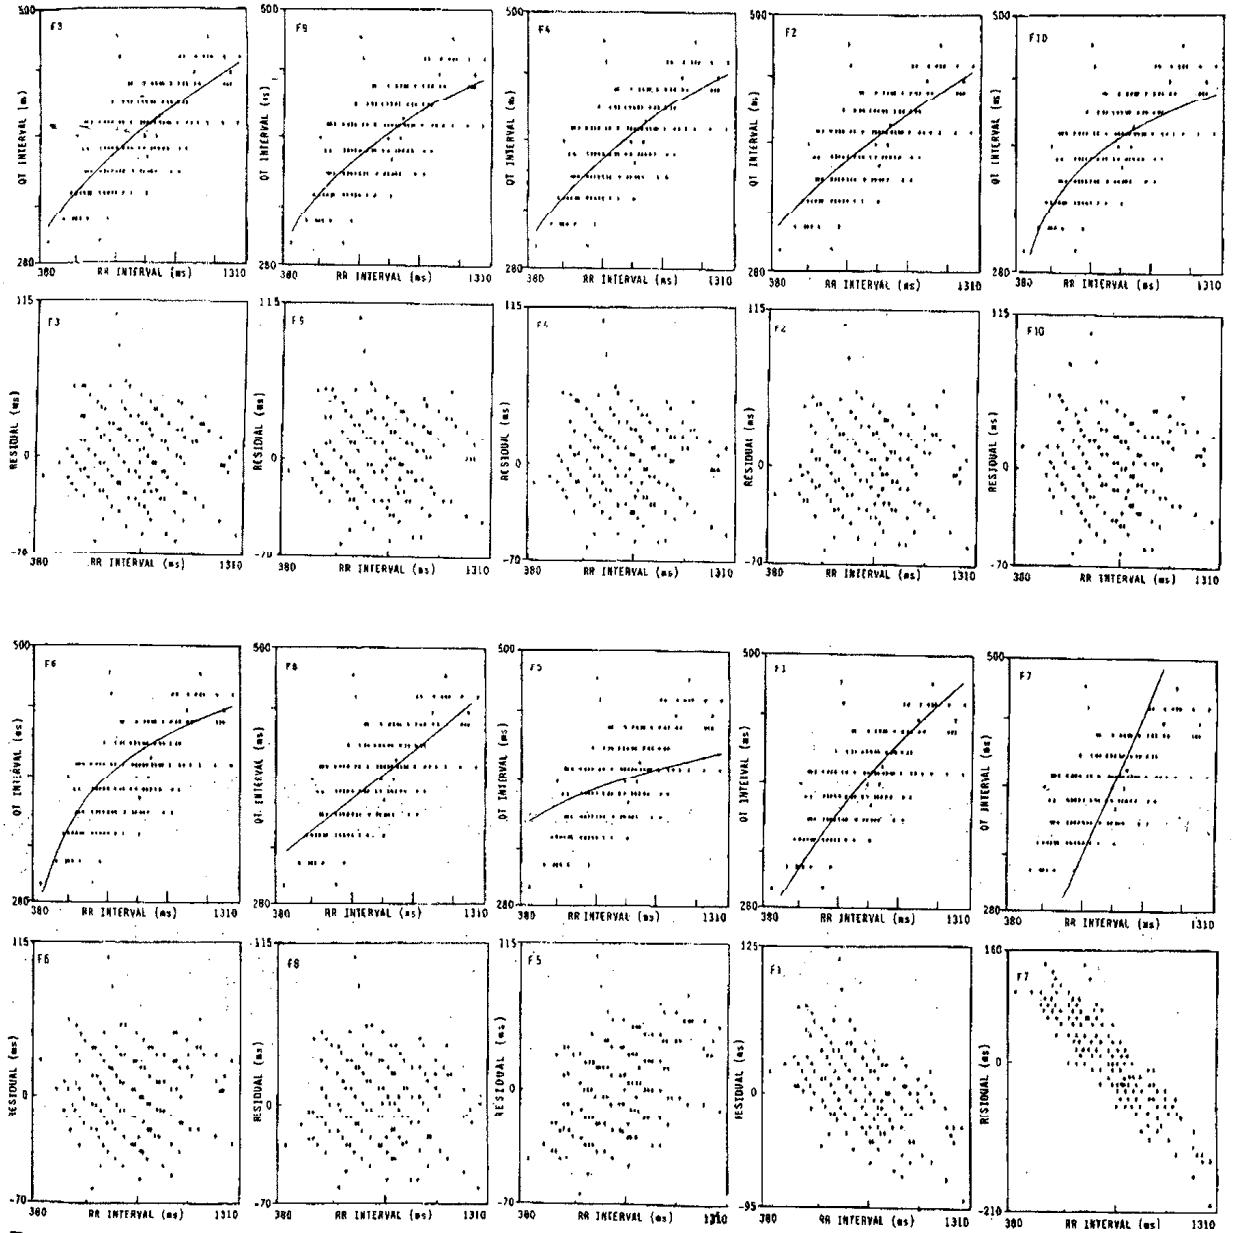

Fig. 2. Pooled QT–RR plots for all group 2 subjects (rows 1 and 3). The least-squared fit of data points are shown for formulas 1–10 (F1–F10), ranked left to right from best to worst, using the results shown in Table I. The plots of residuals corresponding to the same least-squared curves are shown in rows 2 and 4. Note the differences in Y axis scales of the last two plots and the apparent dependence of residuals on RR intervals of the plots of residuals corresponding to the last three formulas.

(±25 msec) and 2.34% (±20 msec) (2n = 50) and 8.90% (±34 msec) and 2.66% (±22 msec) inter-individually (2n = 1,762).

DISCUSSION

This investigation is the first to examine the relative accuracy of fit to QT–RR data by several QT prediction formulas in a residential cohort of middle-aged men. In contrast to previous reports,[2–16] we observed a wider range (47–143 beats/min) of resting heart rate. Since a potentially important application of this investigation relates to the use of QT prediction formulas in subjects at risk for life-threatening arrhythmias,[1,19–23,26] we used the Minnesota code[33] to subdivide the total cohort into subjects with normal (group 1) or abnormal (group 2) ECG. dition, we justified the latter subdivision to derive information applicable in the field of QT-driven pacemakers,[1,16] a device used in subjects who often present with an ECG abnormality.

A better fit to QT–RR data by all formulas was seen in group 1. This may be accounted for by the composition of the groups and by the larger range of RR intervals in group 2. Yet there is evidence that QT prediction equations may be used also in presence of ECG abnormalities. Moreover, it appears that among one-parameter equations, in both groups 1 and 2, the cubic root Fridericia's formula[3] provides the best fit to the QT–RR relation, whereas the logarithmic and the square root Bazett's[4] formulas provided the poorest fit and the straight-line formula is unsuitable. In addition, the fit provided by Fridericia's formula compares favorably with multiparameter equations[8,11,16,17] and in both groups is not improved by a second regression parameter as occurs for the square root, logarithmic, and straight-line one-parameter formulas. Finally, in group 2 the best fit is provided by Fridericia's equation.

It has been pointed out[17] that the commonly cited formulas[3,4,8,11,14–16] for predicting human QT duration have not been derived from basic principles, that rather they result from the approximate fit of an arbitrarily selected algebraic function to a set of data with wide scatter. However, the results from this study suggest that the relation between QT and RR interval is better expressed, in middle-aged men, by the simpler one-parameter cubic root formula derived empirically from 50 normal subjects by Fridericia as early as 1920[3] and almost ignored thereafter.[9,18] This conclusion is not coincidental: the robustness of the statistical method used[16,29] permitted an objective, comparative, and exhaustive analysis, which emphasizes that more sophisticated QT prediction equations are no more accurate.[11,16,17] Nevertheless, no more than one couple of points from a single individual was obtained to derive the QT–RR relation in this study. Therefore caution must be used in interpreting these conclusions or adapting them to different populations.

For example it may be that if QT–RR interval relationships were determined for individual subjects, using multiparameter formulas, many different slopes would be obtained intraindividually.[16] Although these slopes might reside within the scatter of the data described here, it is important to stress that the overall (interindividual) slope may not apply to any single subject. Clearly, further study is needed to clarify these issues.

QT Interval

In most studies, QT and RR intervals have been measured in lead II,[1,4,26] and Lepeschkin[18] has stated that the QT duration is longest in lead II. However, using multiple measurements in four different leads (LI, LII, V_1, and V_6), Ahnve observed that the longest QT interval is not always in lead II.[36] On the other hand, Wanderman et al.,[37] using multiple simultaneous recordings, showed that analysis of time intervals based on mean values in large groups of subjects is little affected by electrocardiographic lead choice. Therefore, the data presented here are from a single lead. We chose lead II to facilitate comparison with most of the previous studies that either assess the accuracy of fit to QT–RR data by various formulas[8,13,19] or provide evidence for QT interval as a risk index for life-threatening arrhythmias.[1,20–23,26]

Although it may be preferable to measure QT and RR intervals at 50[24,27] or 100[16] mm/sec paper speed, most available data on QT–RR relation were obtained from 25 mm/sec tracings.[1] The ECGs from this investigation were recorded in 1962 for epidemiologic purposes, and we had no choice but to use the available records. We tried to improve the readability of 25-mm/sec ECG tracings by using a magnifying device with a grid, to permit measurement to the nearest 0.25 mm (10 msec), but it was more practical to round up to the nearest 0.50 mm (20 msec). Although this may have introduced a systematic error in the data collection, we stress that only one observer was responsible for QT and RR measurements. Indeed, the intrareader variability in QT interval measurements is similar to that in previous reports using 25-mm/sec ECG recordings,[27] and the measurement accuracy seems not to be influenced by heart rate over a large range. Nevertheless, it may be worth repeating this study on new high-quality, high-speed ECG records from other residential cohorts. It might also be of interest to retrieve the existing data of digitized ECGs from the Seven Countries Study and record them on paper at high speed, to determine whether the measurement accuracy of QT interval could be improved and the present results confirmed.

The QT–RR Relation

During the past 65 years, both curvilinear and linear relations have been proposed to fit QT–RR data.[3–18] Most of these relations were derived from selected and generally scanty groups of normal subjects.[1,26] In 1920, Bazett derived, from

only 20 men,[4] an empirical equation where QT = K $\sqrt{RR}$, later used[1,17,18,21,22] to correct measured QT for cycle length in individual cases, based on the assumption that corrected QT = measured QT/$\sqrt{\text{measured RR}}$. Thus Bazett's correction has remained the most frequently used method to derive heart rate corrected QT (QTc).[1,18,22] Even so, Adams, in 1936, found that the QT duration (in seconds) from 50 presumably normal men might be accurately predicted by the formula QT = 0.1536(RR) + 0.2462.[8] However, no statistical analysis supported Adams' conclusion that this straight-line formula better fits the data than curvilinear equations.[8] Later, use of the Bazett's formula was recommended by Hegglin and Holtzmann, based on 700 normal subjects of both sexes,[9] and by Lepeschkin, based on his compiled data from about 5,000 cases from the literature and his own 1,100 cases.[18] In contrast, Fridericia's cubic root formula, also proposed in 1920 from a scanty series of 50 subjects, was considered less suitable for correcting measured QT interval by the same authorities who recommended use of Bazett's formula.[9,18]

Beginning in 1962, Bazett's formula has been criticized.[13,26,28,38–43] In particular, it has been stressed that the square root formula overcorrects the measured QT interval at high heart rates and undercorrects it at low heart rates.[26,28,39,43] Indeed, as shown in the plots of residuals from groups 1 and 2 (Figs. 1, 2), Bazett's formula inaccurately predicts QT duration for a wide range of low and high heart rates. However, dealing with 160 acute myocardial infarction patients, Ahnve recently observed that Bazett's formula fits the relationship between QT interval and heart rate rather well[22]; although the reported range of heart rate appears to be relatively large, no statistical analysis is provided to support his contention.

The "Best" Fit for QT–RR

Finding the "best" empirical formula to fit a set of observations is generally difficult.[16,17] In the field of human QT–RR relation, there is a lack of studies dealing with either a residential cohort or multiple testing of mathematically different equations.[13,16,17,19,28,42,44]

From an analysis of ECGs recorded in 649 men aged 20–59 years, Simonson et al.[13] proposed, in 1962, a straight-line formula (QT duration in sec), where QT = 0.140 (RR) + 0.2423 + 0.0003 (age). In the range of heart rate of 56–115 beats/min, there was an agreement between upper (97.5%) and lower (2.5%) normal limits determined from the percentile distribution and predicted from linear regression equation. However, no extensive statistical analysis demonstrates the best fit for the proposed formula compared with the square root, logarithmic, or two other related formulas.[13]

The mathematical relationship between QT and RR intervals was studied in 1969 by Susmano et al.[19] in eight patients with complete AV block during cardiac pacing at multiple ventricular rates. The results suggest, within the range of heart rate of 35–130 beats/min, that expressing the QT interval as a linear, square root, cubic root, or logarithmic function of the RR interval will provide equivalently valid predictions. However, due to the large variations observed between individuals, no method is suggested to correct the QT duration for a given heart rate.[10]

Preliminary data to reevaluate the QT–heart rate relation were presented in 1983 by Hodges et al.[28] based on 607 normal men and women equally distributed across age decades from 20s to 80s. Compared with Bazett's equation, both linear and logarithmic regressions were shown to fit the QT–heart rate data better. However, for convenience the use of the linear model, where QT = 496 − 1.75 (heart rate), was proposed. The results obtained in this study are in keeping with the findings from the latter study.[28]

In 1983, Staniforth[42] investigated 547 sets of QT–RR data from 27 healthy young men. It was found from pooled data that with the subject in resting supine position, the square root formula gave an unsatisfactory correction for the QT interval following atropine and hyoscine, over a wide heart rate range. Givens that log QT = log K + n log RR,[42] the best n value was 0.35, which is very close to the cube root correction of Fridericia.[4] That there was an optimum value of n in a one-parameter correction formula was also seen[44] when plots of the mean-squared residuals were made for a range of values of n (0.1–0.7) for each subject. In this way, a set of parabolas was produced, with minima centering around 0.3. Although these studies[42,44] indicated that Fridericia's equation is more adequate than Bazett's correction, they failed to test comparatively more complex formulas and therefore need be considered important only for having called attention to the almost neglected cubic root correction.[9,13,18]

In 1984, Sarma et al.[16] analyzed data obtained from 16 disparate subjects who were either exercised on a stationary bicycle to a heart rate of 160 or 180 beats/min or paced until the ventricular rate was progressively increased to 130 beats/

min. They demonstrated that the QT–RR relation is better expressed by a newly proposed exponential formula than by Bazett's formula or two other closely related formulas. They also used an estimate of mean-squared residual values and the AIC,[34,35] as was done in this investigation, to assess the accuracy of fit to QT–RR data. With Bazett's and the exponential formulas in pooled data from sinus-driven subjects, they found values much like those reported here.[16] Although meticulous statistical analysis provided proof that an exponential equation is more suitable for representing the human QT–RR relation than is Bazett's formula,[16] which is in accordance with our results, these conclusions may not be generalized to logarithmic, cubic root, straight-line, or related formulas, which were not comparatively tested in that study.

More recently, Kovacs[17] presented a graphic comparison of the major algebraic classes of formulas (exclusive of exponential equations[16]) for the QT as a function of RR interval and showed the approximate overlap of all curves. In addition, to derive an expression for QT as a function of RR and thereby attempt to resolve the ambiguity among the disparate expressions for QT, Kovacs presented a thermodynamic and conservation of energy argument applied to the normal heart, where $QT \propto K'1 + K'2/RR$. However, the inverse RR dependence (denoted as $(RR)^{-1}$) is incorrectly claimed to be derived from the first principle. In fact, Kovacs' "derivation" is heavily dependent on the empirical relation between the systolic time interval QS_2 and QT,[15] as well as several other empirical assumptions,[17] and should therefore also be considered essentially empirical.[45] More important, no objective measurement is provided to support the author's contention that the inverse relation delineates the nature of the algebraic dependence of QT as a function of RR for the normal heart operating in the physiologic range, as opposed to several other formulas, including Fridericia's and Bazett's equations, therefore Kovacs' conclusion[17] must be regarded as a hypothesis, which is not confirmed by our results.

Implications

The results of this investigation in 881 men aged 42–61 years demonstrate that over a wide range of resting heart rate a better fit to QT–RR relation is achieved using Fridericia's one-parameter cubic root formula[8] than by the Bazett's square root formula.[4] The performance of the former formula is not improved by adding a second regression parameter and compares favorably with more complex formulas,[8,11,29] particularly with those recently proposed by Sarma et al.[16] and by Kovacs.[17] In addition, Fridericia's formula provides the best fit in subjects with any kind of ECG abnormality according to the Minnesota code.[33] These observations may have potentially useful implications, since the cubic root equation is simple and therefore potentially directly applicable for correcting single measurements.[42,44]

Application of the cubic root relation might be useful in the field of rate-adaptive pacemakers, because it may favor the development of a more compliant device.[1,16] Another potentially useful application of this investigation relates to the proposal to use heart rate-corrected QT (QTc) to predict life-threatening arrhythmias and sudden death.[1,20–23,26] For those purposes, it would be appropriate to use a formula whose performance has been successfully tested in a large residential cohort with age ranges related to high incidence rates of the index events. We suggest that Fridericia's simple cubic root equation might be compared with more complex multiparameter formulas or the popular and abundantly adopted Bazett's square root formula to determine whether prediction might be improved.

We have provided evidence that QT is overcorrected by Bazett's formula for a wide range of high heart rate. As a result, more cases may lie above the accepted limit of normalcy than with Fridericia's cubic root correction. This warrants further studies to compare the sensitivity, specificity, and predictive accuracy of these formulas in the prediction of life-threatening arrhythmias and sudden death, reevaluating accordingly the limit of normalcy for heart rate-corrected QT (QTc) duration in humans.

50. REBOXETINE VS VENLAFAXINE IN THE TREATMENT OF SEVERE MAJOR DEPRESSION

Gerri E. Schwartz*, Pedro Such, Alan F. Schatzberg

College of Physicians and Surgeons, Columbia University, New York, NY

Sponsor: Alan F. Schatzberg

Approximately one-third of outpatients with major depressive disorder (MDD) meet the requirements for severe illness (symptom intensity, diagnostic subtype and/or degree of functional impairment) while patients receiving inpatient care are, by definition, more severely ill. The present study was conducted to assess the efficacy and tolerability of the selective norepinephrine reuptake inhibitor (selective NRI) reboxetine in the treatment of adults with severe MDD compared with venlafaxine.

Adult patients (18-65 years) with a confirmed diagnosis of MDD were randomized to receive either reboxetine (8-10 mg/day) or venlafaxine (225-375 mg/day) for up to 8 weeks in this double-blind, parallel group trial. Only patients with severe symptomatology as defined by a HAM-D 17-item total score ≥25 points were included in the study. Clinical efficacy was assessed at weekly intervals using the HAM-D 17-item rating scale. Secondary measures included the Clinical Global Impression Severity (CGI-S) and Improvement (CGI-I) scales and the Social Adaptation Self-evaluation Scale (SASS). Response to treatment was defined as a ≥50% decrease in the HAM-D 17-item total score and remission was defined as a HAM-D 17-item total score of ≤8 points. Adverse events were recorded by direct observation and spontaneous reporting.

The mean HAM-D 17-item total score decreased markedly from baseline to Week 8 in both treatment groups (reboxetine 28.6 ±3.1 to 13.4 ±8.1; venlafaxine 28.8 ±2.8 to 12.2 ±7.7). After 8 weeks of treatment 56% of patients treated with reboxetine were classed as responders compared with 54% of patients in the venlafaxine group. Twenty-four per cent of patients in each treatment group were classed as being in remission after 8 weeks of treatment. A week-by-week analysis of remission rates revealed that by Week 4, a markedly greater proportion of patients treated with reboxetine achieved symptomatic remission compared with those in the venlafaxine group, although by Week 8 remission rates were comparable. Marked improvements were also seen on the secondary efficacy measures.

The results of the present study demonstrate that reboxetine 8-10 mg/day is as effective as venlafaxine 225-375 mg/day in the treatment of severe MDD in adults and is well tolerated.

51. DIVALPROEX VERSUS PLACEBO FOR THE TREATMENT OF BIPOLAR DEPRESSION

Gary Sachs*, Lori Altshuler, Terence Ketter, Tricia Suppes, Natalie Rasgon, Mark Frye, Michelle Collins

Harvard Bipolar Research Program, Massachusetts General Hospital, Boston, MA

Sponsor: Lori Altshuler

Objective: This pilot study sought to evaluate the use of divalproex as treatment for acute bipolar depression.

Methods: A double-blind, multi-center, parallel-group, placebo-controlled trial was carried out as a pilot study of the effect of divalproex on the treatment of acute bipolar depression. Eligible subjects met DSM-IV criteria for bipolar disorder, Types I or II, and criteria for current major depression. A single-blind, placebo lead-in phase lasting up to 14 days was followed by an 8-week double-blind treatment phase and then an open-treatment phase of up to 8 weeks. During the double-blind treatment phase, study drug was initiated at 250 mg QHS and was titrated over a two week period based on safety and efficacy. The primary efficacy measure was recovery, which was defined as the absence of hypomania (YMRS<10) with ≥50% improvement on the HAM-D (26 item). Secondary efficacy measures included mean change from baseline in the HAM-D and YMRS.

Results: A total of 45 subjects were randomized in the double-blind phase of the trial. The mean maximum daily dose of divalproex was 1391 mg. In the intent-to-treat analysis of 43 subjects, 9 of 21 subjects (43%) treated with divalproex met criteria for recovery at the final assessment compared to 6 of 22 subjects (27%) treated with placebo ($p<0.4$). The divalproex-treated subjects had an improvement in the HAM-D depressed mood item that was numerically superior to placebo at every follow-up assessment and this difference reached statistical significance on weeks two, four and five (all p-values <0.05). Among those subjects with bipolar II disorder, 4 of 9 subjects (44%) treated with divalproex and 2 of 9 subjects (22%) treated with placebo met criteria for recovery ($p<0.7$). No statistically significant difference between groups was observed in the incidence or severity of adverse events.

Discussion: The findings of this pilot study are encouraging, although the results from planned analyses did not reach statistical significance. In this study, divalproex-treated subjects were almost twice as likely to meet the recovery criteria than placebo-treated subjects. Improvement found in the depressed mood item score is consistent with specific antidepressant activity, which is of interest given the increased risk of manic episode onset or cycle acceleration that may be associated with standard antidepressants. Results from this small pilot study should be interpreted with caution. A larger, multi-center, placebo-controlled study is required to confirm these data. A power analysis indicates that a sample size of 151 subjects in each group (alpha=0.05, power 0.80) would be required to confirm this difference of improved rate of recovery in the divalproex-treated subjects (43%) versus placebo-treated subjects (27%).

Quetiapine Alone and Added to a Mood Stabilizer for Serious Mood Disorders

Martha Sajatovic, M.D.; Debra W. Brescan, M.D.; Dalia E. Perez, M.D.; Sue K. DiGiovanni, M.D.; Helen Hattab, M.D.; Joan Belton Ray, L.S.W.; and C. Raymond Bingham, Ph.D.

Background: Use of antipsychotic medication intermittently or over the long term may be necessary in treating patients with bipolar disorder whose symptoms have responded suboptimally to standard mood-stabilizing agents. Quetiapine fumarate is an effective novel antipsychotic with mixed serotonergic (5-HT_2) and dopaminergic (D_2) activity. This is an open-label, 12-week prospective study to assess the efficacy and tolerability of quetiapine in the treatment of patients with bipolar and schizoaffective disorder who were suboptimally responsive to mood stabilizers alone.

Method: Participants in the study were inpatients or outpatients with a DSM-IV diagnosis of bipolar or schizoaffective disorder. Baseline psychopathology was evaluated with the Brief Psychiatric Rating Scale (BPRS), the Young Mania Rating Scale (YMRS), and the Hamilton Rating Scale for Depression (HAM-D). Involuntary movements were rated with the Simpson-Angus Neurologic Rating Scale. Quetiapine was added on an open-label basis and increased to optimum clinical dosage. Psychopathology and Abnormal Involuntary Movement Scale ratings were repeated weekly for the first 4 weeks and then again at weeks 8 and 12.

Results: Ten individuals with bipolar disorder and 10 with schizoaffective disorder received quetiapine therapy. Overall, patients improved, with significant improvement in BPRS ($p < .001$), YMRS ($p = .043$), and HAM-D scores ($p = .002$). Simpson-Angus score also significantly decreased ($p = .02$). Overall, quetiapine was well tolerated by patients in this group with serious mood disorders. The mean ± SD quetiapine dose was 202.9 ± 124.3 mg/day (range, 50–400 mg/day). Mean weight gain was 10.9 lb (4.9 kg).

Conclusion: Although limited by its small size, open-label design, and relative gender homogeneity, this study suggests that quetiapine therapy may be useful in the treatment of individuals with serious mood disorders who are suboptimally responsive to mood stabilizers alone. These preliminary findings should be explored in larger, controlled trials.

(J Clin Psychiatry 2001;62:728–732)

Bipolar disorder is a major public health problem with significant morbidity and mortality.[1] In 1990, the economic burden of bipolar disorder in the United States was estimated to be $15.5 billion in diminished or lost productivity in work performance alone,[2] while approximately 11% of individuals with bipolar disorder die by suicide.[3] While 1 or more episodes of acute mood disorder are not generally associated with the personality deterioration that occurs in psychotic illnesses such as schizophrenia, many individuals with bipolar disorder experience persistent symptoms and poor outcome.[4] These patients often have severe impairment in functioning and frequent or long hospitalizations and many times require a complex medication regimen with multiple mood stabilizers. Use of antipsychotic medication intermittently or over the long term may also be necessary in treating patients whose symptoms have responded suboptimally to standard mood-stabilizing agents.[5,6] These patients are frequently maintained on chronic neuroleptic treatment,[7] and combining lithium with other medications, including anti-

psychotics, may provide greater prophylaxis in bipolar disorder.[8]

Individuals with schizoaffective disorder have a prominent affective component in addition to chronic psychosis and usually require maintenance antipsychotic medication along with psychotropic medication for affective symptoms. The use of chronic neuroleptic therapy in seriously ill mood disorder patients often creates additional new problems. These patients may be at greater risk of developing tardive dyskinesia (TD) compared with patients with schizophrenia,[9] and often experience other extrapyramidal adverse effects or central nervous system (CNS) side effects associated with conventional neuroleptics such as sedation. Mukherjee et al.[10] reported that up to 73% of patients meeting criteria for bipolar disorder remained on long-term neuroleptic treatment (average = 8.7 years), whereas the prevalence of TD in individuals with bipolar disorder has been reported to range from 19% to 44%.[11–13]

Quetiapine fumarate is an effective novel antipsychotic with mixed serotonergic (5-HT_2) and dopaminergic (D_2) activity.[14] Clinically, it appears to be generally well tolerated with a low extrapyramidal adverse effect profile.[15] Given the greater risk of neurologic adverse effects of patients with mood disorder compared with patients with schizophrenia, the novel antipsychotics may prove to be a particularly important therapy for individuals who have significant mood disorder and who require antipsychotic medication. This is an open-label, 12-week prospective study to assess efficacy and tolerability of quetiapine in the treatment of patients with serious mood disorders suboptimally responsive to mood stabilizers alone.

METHOD

Eligible participants in the study were inpatients or outpatients with a DSM-IV[16] diagnosis of bipolar or schizoaffective disorder at a large, urban Veterans Affairs (VA) Medical Center. All participants had been taking an antipsychotic medication for at least 6 months with documented inability to wean off of neuroleptic treatment. Inability to successfully stop neuroleptic treatment was manifested by clinical worsening with neuroleptic reduction or discontinuation. Participants who were taking mood stabilizers must have been maintained on a stable and therapeutic dosage of the mood stabilizer (lithium or valproic acid). Individuals with significant or acutely worsening medical illness were excluded, as were individuals with significant alcohol or drug use within the previous 3 months. Baseline psychopathology was evaluated with the Brief Psychiatric Rating Scale (BPRS),[17] the Young Mania Rating Scale (YMRS),[18] and the Hamilton Rating Scale for Depression (HAM-D).[19] Involuntary movements were rated at baseline using the Abnormal Involuntary Movement Scale (AIMS)[20] and the Simpson-Angus Neurologic Rating Scale.[21] Subjective response to antipsychotic medication was rated with the Drug Attitude Inventory (DAI) developed by Awad.[22] Patients who agreed to study participation and met entry criteria were begun on quetiapine, 25 mg b.i.d., on an add-on, open-label basis. Quetiapine was increased as clinically tolerated to therapeutic dosage (possible range, 25–800 mg/day). Conventional antipsychotic medication was incrementally tapered and eventually discontinued as tolerated during the first 4 weeks of the study. This discontinuation was done at the discretion of the treating psychiatrist on the basis of patient clinical status. Patients were permitted to receive lorazepam, 1 mg orally p.r.n., for sleep or agitation and/or anticholinergic medications if required for acute extrapyramidal symptoms. No other new psychotropic drugs were permitted. Quetiapine therapy was continued for a total of 12 weeks. Psychopathology and abnormal involuntary movement ratings were repeated weekly for the first 4 weeks, then again at weeks 8 and 12 (end of study). Data were analyzed using paired t tests comparing baseline psychopathology and abnormal movement scores with endpoint scores. All endpoint scores utilized last observation carried forward (LOCF). This prospective protocol was approved by the local VA Institutional Review Board (Cleveland, Ohio), and appropriate written informed consent was obtained from all study participants.

RESULTS

Twenty individuals (10 with bipolar disorder and 10 with schizoaffective disorder) received quetiapine therapy. Mean ± SD age of the group was 47.8 ± 10.2 years (range, 34–74 years). Not surprisingly, this veteran sample was predominantly male, with 19 men and 1 woman. Racial composition of the group was 14 white individuals (70%) and 6 African American individuals (30%). There were no statistically significant differences between individuals with bipolar disorder and those with schizoaffective disorder in terms of demographic characteristics or baseline psychopathology rating scale scores or movement rating scale scores. Study participants generally had persistent mild-to-moderate psychotic and depressive symptoms at study entry that, by history, had not responded optimally to mood stabilizers alone. Five individuals were maintained on lithium treatment (mean ± SD dosage = 1125 ± 248.8 mg/day), and 8 individuals were maintained on valproate treatment (mean ± SD dosage = 1468.8 ± 471.3 mg/day). Mean ± SD serum levels were 82.0 ± 17.0 μg/mL for valproate and 0.74 ± 0.15 mEq/L for lithium. Seven individuals were not taking a mood stabilizer, and no individual was taking more than 1 mood stabilizer.

Overall, patients improved on quetiapine therapy, with significant improvement in BPRS score ($p < .001$), YMRS score ($p = .043$), and HAM-D score ($p = .002$). Figures 1 through 3 illustrate changes from baseline to

*t = 1.7, df = 35, p = .002 vs. baseline.

endpoint (using LOCF) on these psychopathology scales. There were no statistically significant differences between the bipolar and schizoaffective groups in response on any scale. There were also no significant differences in treatment response between individuals treated with quetiapine alone and individuals treated with quetiapine in combination with a mood stabilizer. Item analysis of the BPRS suggests that the items evaluating conceptual disorganization and suspiciousness changed the most, whereas the items evaluating guilt feelings, tension, hallucinatory behavior, uncooperativeness, excitement, and disorientation changed the least. However, comparing these items, the amount of change between items was not significant at a = .05. Mean ± SD Simpson-Angus scale score also significantly decreased from a baseline of 5.5 ± 4.9 to an endpoint score of 1.9 ± 3.8 (t = 1.7, df = 34, p = .02). There was no statistically significant change in AIMS score or in DAI score.

Overall, quetiapine was well tolerated by patients in this group with serious mood disorders. Three individuals dropped out within 1 week of beginning the study. These included 1 individual who began abusing alcohol within a few days after study initiation, 1 individual who was noncompliant with study medication, and 1 individual who reported the development of agitation, which resolved on quetiapine discontinuation. Mean ± SD quetiapine dose was 202.9 ± 124.3 mg/day (range, 50–400 mg/day) for the 17 individuals who completed the study and 178.8 ± 28.6 mg/day (range, 50–400 mg/day) for the entire sample. Mean ± SD weight gain over the course of the study was 10.9 ± 12.9 lb (4.9 ± 5.8 kg). Of note were 2 individuals who had nutrition/dietician consultation and follow-up at study entry. These 2 individuals had a small amount of weight loss (3 and 4 lb [1.4 and 1.8 kg], respectively) during the study course.

DISCUSSION

Long-term or intermittent use of antipsychotic medication may be deemed necessary for some individuals with serious mood disorders when mood or behavioral symptoms have not adequately responded to mood-stabilizer therapy.[5,7] In individuals with persistent mood symptoms and chronic psychosis, the combination of lithium and antipsychotics appears to be more efficacious than an antipsychotic alone.[23] However, the utilization of antipsychotic medication in individuals with chronic, serious mood disorders presents a number of clinical challenges. Some investigators have suggested that neuroleptics may exacerbate postmanic major depressive episodes and induce rapid cycling in some bipolar persons.[24] Additionally, individuals with primary mood disorders may be particularly vulnerable to the development of TD associated with neuroleptic therapy.[25] Other adverse effects, such as sedation, associated with some antipsychotic medications may reduce quality of life. Finally, suboptimal antipsychotic medication response may be associated with persistent behavioral symptoms and long-term functional impairment. The atypical antipsychotic clozapine has been reported to be beneficial, and may have mood-stabilizing

properties, in the treatment of patients with serious mood disorders.[26,27] A recently reported meta-analysis involving primarily retrospective and open-label studies of clozapine suggested that patients with manic or psychotic phases of schizoaffective or bipolar disorder were significantly more likely to respond to clozapine than patients with schizophrenia.[28] The atypical antipsychotic medication olanzapine has been demonstrated to be effective in acute mania,[29] and it has been reported that the atypical antipsychotic risperidone is as effective as lithium or haloperidol in the treatment of acute mania,[30] as well as being effective in adjunctive treatment with mood stabilizers for patients with bipolar and schizoaffective disorder.[31] Published data on the use of quetiapine therapy in serious mood disorders are extremely limited.

Although limited by its small size, open-label design, lack of a control group, and relative gender homogeneity, this study suggests that quetiapine may be a useful agent in the treatment of individuals with serious mood disorders who are suboptimally responsive to mood stabilizers alone. Overall, patients in the study sample did well on quetiapine therapy, with significant improvements in BPRS, YMRS, and HAM-D scores. Improvements were similarly noted by McConville et al.[32] in both positive and negative symptoms in 10 adolescents with psychotic mood disorders (3 individuals with bipolar disorders and 7 individuals with schizoaffective disorder). Most individuals in the study reported here had persistent depressive symptoms. HAM-D improvements were seen here without the addition of antidepressant medication. In a recent report on affective symptoms in individuals with schizophrenia,[33] quetiapine was superior to placebo and haloperidol in improvements in mood symptom items (depressive mood, guilt feelings, somatic concern, and anxiety) on the BPRS.

It must be noted that the results here at 4 weeks reflected a combined effect of quetiapine and neuroleptic, due to the fact that conventional neuroleptic was tapered over the first 4 weeks of the study. It is not clear how the presence of the neuroleptic might have affected dosage of and/or symptom response to the atypical antipsychotic. It is possible that combined therapy may have contributed to the relatively rapid symptom response and may possibly explain the relatively low mean quetiapine dosage in this study (approximately 200 mg/day). The modest quetiapine dosage might also have been due to the use of a concomitant mood stabilizer for most of the patients in this study or to the older age of some of the study participants. However, it is also possible that effective dose of quetiapine required in individuals with mood disorders may be lower than effective doses that have been reported for individuals with schizophrenia.[34] In clinical practice, combination therapy of an antipsychotic plus a mood stabilizer is frequently utilized in the management of serious mood disorders and may enhance clinical outcomes.[35]

Quetiapine was generally well tolerated in this study population, with only 1 dropout due to adverse effect of medication. This finding is consistent with safety and tolerability reports of quetiapine therapy suggesting that most patients, even the elderly, tolerate quetiapine quite well and that incidence of extrapyramidal effects is minimal.[36,37] Kalali et al.[38] reported on 129 patients who received quetiapine therapy and were assessed for patient satisfaction. The majority of individuals (98%) reported being satisfied with their medication treatment, most commonly identifying improved tolerability and improved general well-being compared with previous conventional antipsychotic agents. Quality of life was generally reported to be improved.

There was a mean weight gain of 10.9 lb (4.9 kg) in this trial. This greater-than-expected weight gain may be at least partially due to combined use of quetiapine plus mood-stabilizing medication, both of which may be associated with weight gain. Guille et al.[39] recently reported that individuals with bipolar disorder receiving mood-stabilizing medication plus atypical antipsychotic medication experience weight gain ranging from a mean of 16.1 lb (7.2 kg) with olanzapine to a mean of 7.8 lb (3.5 kg) with risperidone. Guille et al.[39] also reported a trend for less weight gain among patients receiving a novel antipsychotic with lithium than those receiving other mood-stabilizing agents ($p = .06$). Patients receiving prophylactic dietary consultation in the trial presented here did not gain weight.

In conclusion, quetiapine may be beneficial for some individuals with serious mood disorders. These preliminary findings should be explored in larger, controlled trials.

Drug names: clozapine (Clozaril and others), haloperidol (Haldol and others), lorazepam (Ativan and others), olanzapine (Zyprexa), quetiapine (Seroquel), risperidone (Risperdal), valproic acid (Depakene and others).

Efficacy of Quetiapine and Risperidone Against Depressive Symptoms in Outpatients With Psychosis

Martha Sajatovic, M.D.; Jamie A. Mullen, M.D.; and Dennis E. Sweitzer, Ph.D.

Background: The treatment of psychotic symptoms in patients with mood disorders is a complex challenge. Antipsychotic medications in these individuals may be associated with extrapyramidal symptoms (EPS), worsening of depression, and functional impairment. Atypical antipsychotics such as quetiapine and risperidone are associated with a decreased incidence of adverse events such as EPS. The objective of this study was to compare the efficacy and tolerability of quetiapine and risperidone for the treatment of depressive symptoms in outpatients with psychosis.

Method: In this 4-month, multicenter, open-label trial, patients were randomly assigned in a 3:1 ratio of quetiapine to risperidone, and both drugs were flexibly dosed. Eligible patients had psychoses and demonstrated 1 of several DSM-IV diagnoses, including schizoaffective disorder, bipolar I disorder, major depressive disorder, delusional disorder, Alzheimer's dementia, schizophreniform disorder, vascular dementia, and substance abuse dementia. Patients were classified as mood disordered if they had bipolar disorder, major depressive disorder, or schizoaffective disorder. Efficacy was assessed using the Positive and Negative Syndrome Scale and the Clinical Global Impressions scale. The Hamilton Rating Scale for Depression (HAM-D) was used to assess the level of depressive symptoms. The primary tolerability assessment was presence or absence of substantial EPS, defined as EPS severe enough to require an alteration in treatment.

Results: A total of 554 patients were randomly assigned to quetiapine and 175 to risperidone. Mean doses at 16 weeks were 318 mg for quetiapine and 4.4 mg for risperidone. Although both agents produced improvements in mean HAM-D scores, quetiapine produced a greater improvement than risperidone in all patients ($p = .0015$). Within the mood-diagnosed population, incidences of both substantial EPS ($p = .001$) and at least moderate EPS ($p = .0373$) occurred significantly less frequently among patients taking quetiapine. For patients with non-mood diagnoses, incidences of substantial EPS were fewer for patients taking quetiapine than for those taking risperidone ($p = .062$); however, this was not statistically significant.

Conclusion: These results suggest that quetiapine may be a useful agent in the management of depressive symptoms in patients with psychosis.

Depressive symptoms are common in patients with schizophrenia and may contribute to the 20-fold higher incidence of suicide in this population compared with the general population.[1] Affective disorders in patients with schizophrenia are generally associated with poor outcome, with an increased risk of relapse and a high rate of suicide.[1] In serious mood disorders, such as bipolar depression, the suicide rate is 30 times higher than that of the general population.[2] Thus, treatment of coexisting affective and psychotic symptoms is a complex clinical challenge.

Antipsychotics are commonly added to the treatment regimen for patients with psychotic mood disorders.[3,4] However, antipsychotic medications in these individuals may be associated with extrapyramidal symptoms (EPS), possible worsening of depression, and functional impairment.[5–7]

Recent evidence suggests that atypical antipsychotics may produce an antidepressant effect that could be beneficial in the treatment of depressive symptoms in patients with schizophrenia.[1,8] Compared with conventional antipsychotics, atypical antipsychotics may have superior efficacy for the treatment of schizophrenia with mood symptoms.[9] Additionally, preliminary evidence supports the usefulness of atypical antipsychotics in treating depressive symptoms associated with psychotic and depressive disorders.[10] Because atypical antipsychotics are associated with a decreased incidence of EPS,[11] these medications may have more overall advantages compared with typical antipsychotics.[9,12,13] Quetiapine, in particular,

appears to have low potential for EPS at all dosing ranges[14] and in all populations, including the elderly[15–17] and adolescents.[18]

Quetiapine and risperidone are 2 atypical antipsychotics currently used in the United States for the treatment of patients with schizophrenia and other psychotic disorders. The objective of the present study was to compare the efficacy and tolerability of quetiapine and risperidone for the treatment of depressive symptoms in outpatients with psychotic disorders. This is a subanalysis of data on mood symptoms from the quetiapine experience with safety and tolerability (QUEST) study. The results of the analysis of primary endpoints on psychosis, tolerability, and EPS from the QUEST study are described in another article.[19]

METHOD

Study Design

In this 4-month, multicenter, open-label trial, patients were randomly assigned in a 3:1 ratio of quetiapine to risperidone. Patients completed 7 office visits at weeks 0, 1, 2, 4, 8, 12, and 16.

Both quetiapine and risperidone were flexibly dosed. Patients randomly assigned to quetiapine began with a total daily dose of 50 mg, with upward titration in 50-mg to 100-mg increments every 1 to 2 days. The maximum dose of quetiapine was 800 mg/day.

Patients randomly assigned to risperidone began with 1 mg b.i.d. with increases in increments of 1 mg b.i.d. on days 2 and 3 as tolerated, to a target dose of 3 mg b.i.d. Further dose adjustments, if indicated, occurred at intervals of not less than 1 week.

For both drugs, investigators were instructed to adjust dosage to meet the clinical needs and response of individual patients. Investigators were also instructed to discontinue previous antipsychotic agents within 1 month of trial entry. Patients who failed to stabilize on either quetiapine or risperidone monotherapy were permitted to return to their original antipsychotics.

Patients

Patients were included if they had psychoses and 1 of the following DSM-IV[20] diagnoses: schizoaffective disorder, bipolar I disorder, major depressive disorder, delusional disorder, Alzheimer's dementia, schizophreniform disorder, vascular dementia, or substance abuse dementia. Diagnoses were made based on clinical interviews administered by site investigators. Other eligibility criteria included no evidence of medically significant disorders, no current treatment with clozapine or history of nonresponsiveness to clozapine, and no history of drug-induced agranulocytosis. Patients were classified as having a mood disorder if they had 1 of the following diagnoses: (1) bipolar disorder, (2) major depressive disorder, or (3) schizoaffective disorder. Patients with schizoaffective disorder were grouped with patients with mood disorders because their pharmacologic treatment was more like that of patients with bipolar disorder or psychotic major depressive disorder (i.e., mood medication plus antipsychotic medication) than that of patients with schizophrenia (i.e., usually antipsychotic monotherapy).

Concurrent Medications

Patients could receive concomitant medications that were deemed clinically indicated by the investigator. Another antipsychotic agent was to be prescribed only after attempts to stabilize the patient on quetiapine or risperidone monotherapy failed over a 1-month period. Long-acting injectable antipsychotics (haloperidol or fluphenazine) and clozapine or olanzapine were prohibited during the study period.

Patients who were taking prescribed mood stabilizers and antidepressants were allowed to continue with those medications if they had been on a stable dose for at least 2 weeks before randomization. Rescue medication (e.g., intramuscular haloperidol, benzodiazepines, or anti-EPS agents) for situations such as extreme agitation, acute psychosis, and EPS was permitted at the discretion of the investigator. EPS assessments were not completed within 24 hours after administration of rescue medication.

Efficacy Assessments

The Positive and Negative Syndrome Scale (PANSS)[21] and the Clinical Global Impressions (CGI) scale[22] were used to evaluate efficacy against psychotic symptoms. The Hamilton Rating Scale for Depression (HAM-D)[23] was used to assess the level of depressive symptoms at weeks 0, 8, and 16. The following HAM-D factors were assessed: factor 1—anxiety/somatization (anxiety psychic, anxiety somatic, somatic symptoms gastrointestinal, somatic symptoms general, hypochondriasis, and insight); factor 2—weight (loss of weight); factor 3—cognitive disturbance (feelings of guilt, suicide, agitation, depersonalization and derealization, paranoid symptoms, obsessive and compulsive symptoms); factor 4—diurnal variation (morning or afternoon severity); factor 5—retardation (depressed mood, work and activities retardation, genital symptoms); and factor 6—sleep disturbance (insomnia early, insomnia middle, and insomnia late).

Two domains on the HAM-D were also assessed: (1) vegetative symptoms (insomnia early, insomnia middle, insomnia late; retardation, agitation, anxiety somatic, somatic symptoms gastrointestinal, somatic symptoms general, genital symptoms, weight loss, diurnal variation present, diurnal variation severity) and (2) nonvegetative symptoms (depressed mood, guilt, suicide, work and activities, anxiety psychic, hypochondriasis, insight, depersonalization and derealization, paranoid symptoms, and obsessional and compulsive symptoms).

EPS Assessments

The primary assessment for tolerability was the presence or absence of EPS to a substantial degree. *Substantial EPS* is defined as requiring 1 or more of the following alterations in treatment: (1) prescription of an anti-EPS medication, (2) reduction in dose of randomized treatment, or (3) discontinuation of the randomized treatment. EPS event information was determined from a symptom checklist created by AstraZeneca (available from AstraZeneca upon request).

Statistical Analysis

The overall differences between treatment with quetiapine and treatment with risperidone in postbaseline last-observation-carried-forward (LOCF) HAM-D score were evaluated using an analysis of covariance (ANCOVA). Treatment differences over time according to diagnosis (mood versus non-mood disorders) were assessed using a repeated-measures ANCOVA. Treatment differences over time stratified by baseline HAM-D score (i.e., < 10, 10 to 19, and ≥ 20) were assessed using a repeated-measures ANCOVA within mood and non-mood diagnostic groups.

HAM-D factor scores were summarized with descriptive statistics. Differences in dose of quetiapine or risperidone at 4 months were analyzed using Dunnett's t test. Incidence of EPS was analyzed using generalized estimating equations and included maximum baseline EPS severity and time as covariate factors.

RESULTS

Patient Demographics

The characteristics of the patients randomly assigned to quetiapine (N = 554) or risperidone (N = 175) are shown in Table 1. Both groups of patients showed similar demographics with mean ages of 45 and 46 years for quetiapine and risperidone, respectively. No statistically significant differences between treatments were found for age, sex, or race. The male/female ratio was 50:50 for quetiapine and 54:46 for risperidone. Mood disorders were diagnosed in 316 (57%) of quetiapine patients and 103 (59%) of risperidone patients.

On study entry, 33.7% of patients were using mood stabilizers, 33.7% were taking antidepressants, 26.5% were taking anxiolytics (including benzodiazepines), 13.6% were taking atypical antipsychotics, and 36%, typical antipsychotics. No significant differences in the continuing use of prior medications were found between treatment groups (p = .17).

Dosing

The dosing of quetiapine over time for the different diagnostic groups is shown in Figure 1. The mean dose received by all the patients at week 16 was 318 mg; however, patients with schizophrenia used significantly more quetiapine at all time periods after 2 weeks than patients with mood disorders (p = .036). At 16 weeks, patients with bipolar disorder used less quetiapine (mean difference = −74 mg, p = .062) than patients with schizophrenia. At 16 weeks, patients with major depressive disorder or schizoaffective disorder used 54 mg and 28 mg, respectively, less than patients with schizophrenia; however, this was not statistically significant (p > .25).

Table 1. Demographic Details

Characteristic	Quetiapine Group (N = 554)	Risperidone Group (N = 175)
Age, mean, y	45.1	46.2
Race, N (%)		
White	402 (73)	131 (75)
African American	94 (17)	28 (16)
Other	58 (10)	16 (9)
Sex, N (%)		
Women	277 (50)	80 (46)
Men	277 (50)	95 (54)
Diagnosis, N (%)		
Bipolar disorder	83 (15)	20 (11)
Major depressive disorder	75 (14)	26 (15)
Schizoaffective disorder	158 (29)	57 (32)
Schizophrenia	218 (39)	67 (38)
All mood diagnoses	316 (57)	103 (59)
All non-mood diagnoses	238 (43)	72 (41)

The dosing of risperidone over time for the different diagnostic groups is shown in Figure 2. The mean dose received by all of the patients was 4.4 mg at week 16, and, as with quetiapine, patients with mood disorders required lower doses of risperidone than did patients with schizophrenia (p < .011).

Efficacy Against Psychotic Symptoms

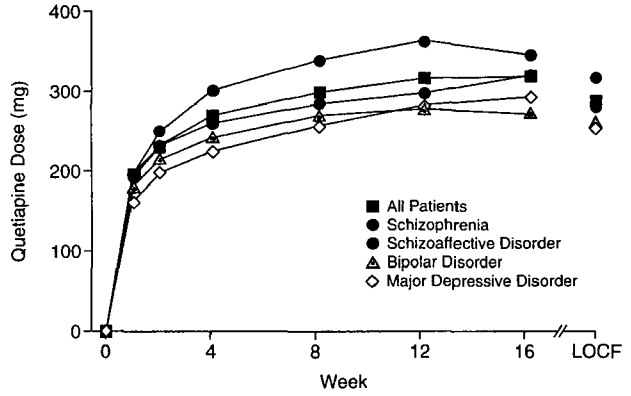
Efficacy against psychotic symptoms was assessed using the PANSS and the CGI. Both quetiapine and risperidone groups showed increasing improvement in clinical condition throughout the trial, according to CGI scores. At trial completion, no significant difference was seen between treatment groups on CGI scores or on PANSS positive scale, negative scale, or total score. These results are reported in full elsewhere.[19]

HAM-D Scores

There was no significant difference in baseline HAM-D scores between quetiapine- and risperidone-treated patients. The mean change from baseline to postbaseline observation in HAM-D score at week 16 (LOCF) was slightly greater (p = .028) in the quetiapine group than in the risperidone group (Figure 3).

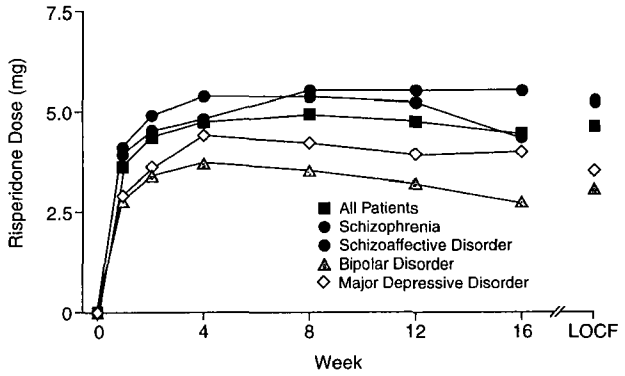
The percentages of changes from baseline for the different diagnostic groups are shown in Table 2. Quetiapine produced a greater improvement in HAM-D scores than did risperidone, both in patients with primary mood disorders and in patients with non-mood disorders.

Figure 1. Mean Quetiapine Dose by Diagnosis[a]



[a]Abbreviation: LOCF = last observation carried forward.

Figure 2. Mean Risperidone Dose by Diagnosis[a]



[a]Abbreviation: LOCF = last observation carried forward.

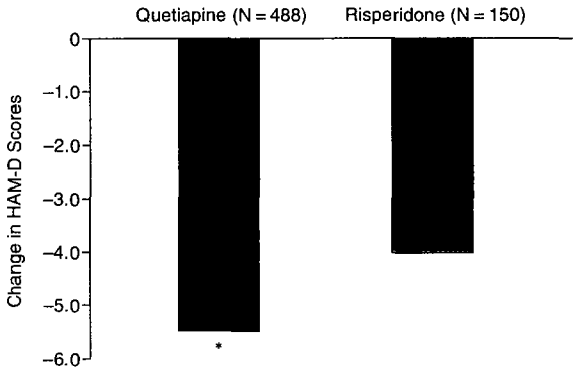
The changes in mean HAM-D scores for patients with and without mood disorders were examined with respect to baseline HAM-D score. In patients with mood disorders and a high baseline HAM-D score (≥ 20), quetiapine produced a significantly greater reduction in HAM-D score than risperidone (–47% vs. –34%, p = .0051, Figure 4A). For patients with mood disorders who had moderate HAM-D scores at baseline (scores of 10 to 19), both drugs were equally effective (–38% vs. –43%, p = .54). For patients with mood disorders who had low baseline HAM-D scores (< 10), neither drug produced a significant improvement or deterioration (–0.1% ± 16.1% vs. –15.2% ± 25.4%, p = .59, for quetiapine and risperidone, respectively).

The changes in HAM-D scores for non-mood disordered patients were similar to the changes seen in mood disordered patients (Figure 4B). For patients with non-mood disorders who had low or moderate baseline HAM-D scores (< 20), there were no significant differences in the improvements produced by quetiapine or risperidone. However, for patients with non-mood disorders and high baseline HAM-D scores (≥ 20), quetiapine produced a significantly greater reduction in mean HAM-D scores than risperidone (p = .008).

The mean changes from baseline for individual HAM-D factor scores are shown in Figure 5. The largest treatment differences (at least 5% of baseline) were in favor of quetiapine over risperidone—these were for HAM-D factors 4 (diurnal variation), 5 (retardation), and 6 (sleep disturbance) and in the vegetative symptom domain. Little difference between quetiapine and risperidone was observed for the HAM-D factors of anxiety/somatization, weight, and cognitive disturbance and in the nonvegetative domain items.

For the group as a whole, patients in the quetiapine group scored significantly better on the retardation, sleep disturbance, and vegetative domain items. Mood disordered patients on quetiapine scored significantly better on

Figure 3. Mean Change in HAM-D Scores for All Patients (baseline to postbaseline, last observation carried forward)[a]



[a]Abbreviation: HAM-D = Hamilton Rating Scale for Depression.
*p = .028.

retardation and vegetative domains. In patients diagnosed with non-mood disorders, and in patients with factor scores of 0 at baseline, differences were not statistically significant.

EPS Assessments

The safety and tolerability of quetiapine and risperidone were compared by examining the incidence of EPS to a substantial degree in the patients diagnosed with either mood disorders (Figure 6) or non-mood disorders. Over the trial period, substantial EPS occurred less frequently among quetiapine-treated patients in both the mood (p < .001) and non-mood (p = .063) diagnosed patients. More of the patients diagnosed with mood disorders and treated with risperidone reported substantial EPS at week 1 (8.3%) compared with the patients with mood disorders treated with quetiapine (1.4%). The incidence of substantial EPS at LOCF was also lower for patients treated with quetiapine (2.9%) compared with patients treated with risperidone (10.1%).

Table 2. Percentages of Change From Baseline HAM-D Scores[a]

Diagnosis	Quetiapine N	Quetiapine Mean Baseline Score	Quetiapine Change (%)	Risperidone N	Risperidone Mean Baseline Score	Risperidone Change (%)	p Value of Difference
All patients	554	15.50	–44.6	175	15.07	–34.4	.0015
All mood diagnoses	316	16.86	–44.1	103	16.58	–35.7	.0364
All non-mood diagnoses	238	13.71	–45.6	72	12.93	–31.1	.0083
Bipolar disorder	83	16.28	–50.4	20	14.60	–33.2	.0956
Major depressive disorder	75	19.11	–42.2	26	20.08	–39.7	.7100
Schizoaffective disorder	158	16.10	–41.6	57	15.74	–34.6	.2149
Schizophrenia	218	13.46	–41.6	67	13.16	–31.4	.0694
Other non-mood[b]	20	16.45	–65.4	5	9.80	–31.1	.0447

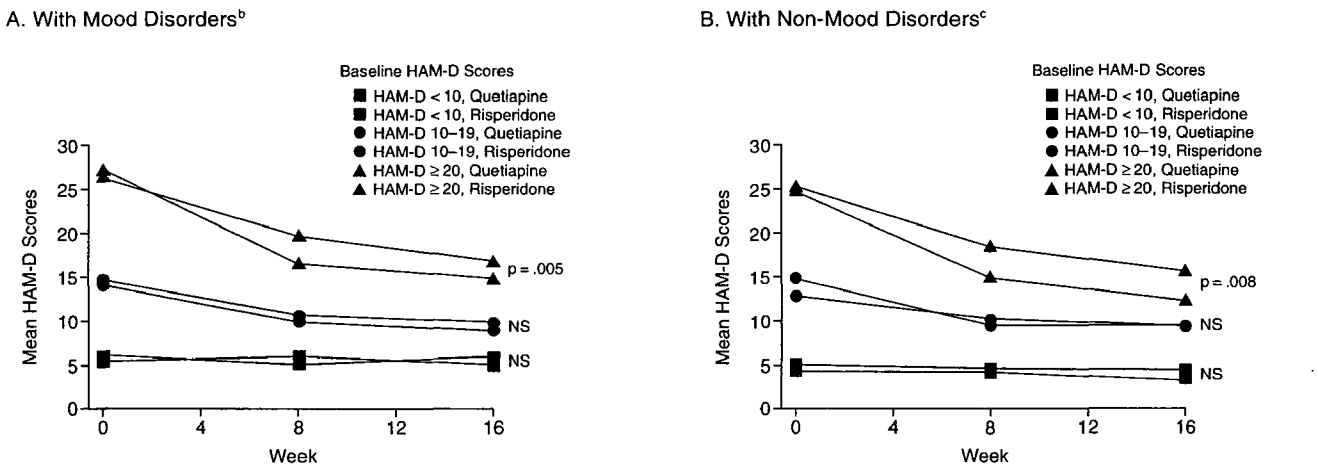
[b]A p value is not reliable for this small number of patients with varying diagnoses, including Alzheimer's dementia, delusional disorder, and substance abuse dementia.

Figure 4. Mean HAM-D Scores for Patients With Psychosis From Baseline to Week 16 for Quetiapine and Risperidone[a]



[a]Abbreviations: HAM-D = Hamilton Rating Scale for Depression, NS = nonsignificant.
[b]Mood diagnoses include bipolar disorder, major depressive disorder, and schizoaffective disorder.
[c]Non-mood diagnoses include delusional disorder, Alzheimer's dementia, schizophreniform disorder, vascular dementia, and substance abuse dementia.

In patients diagnosed with mood disorders, the incidence of substantial EPS and at least moderate EPS was significantly less frequent in patients taking quetiapine than in patients taking risperidone ($p < .001$ for substantial EPS, $p = .037$ for moderate EPS).

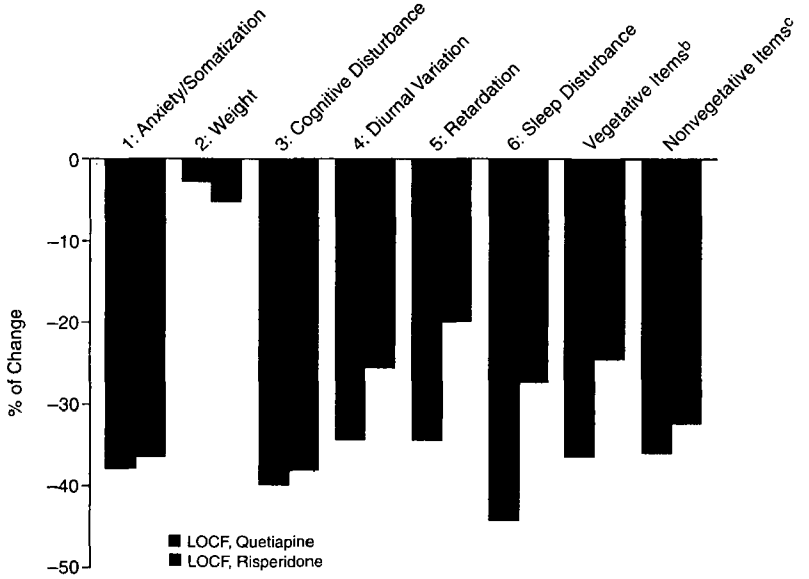
In the subgroup of patients diagnosed with non-mood disorders, substantial EPS was present at week 1 in 2.9% of the patients treated with risperidone, the incidence increased to a peak of 7.8% at month 2, and the overall incidence at LOCF was 4.2%. For quetiapine-treated patients, substantial EPS was present at week 1 in 1.3% of the patients, the incidence subsequently increased to a peak value of 3.5% at month 1, and the overall incidence at LOCF was 3.4% ($p = .063$).

The occurrence of at least moderate hypokinesia or akinesia was rare for both diagnostic groups (3.3% for quetiapine, 9.9% for risperidone). Changes in hypokinesia/akinesia severity and changes in HAM-D scores were found to be correlated and reflected the fact that, on average, both kinesia and mood symptoms improved throughout the study. To rule out a causal link between EPS condition and HAM-D scores, a subset ANCOVA examined patients who had at worst mild akinesia, hypokinesia, or akathisia at baseline and experienced no change in the severity of those 3 symptoms; quetiapine patients still scored significantly better on HAM-D ($p = .017$). No significant difference was found between mood and non-mood diagnoses groups ($p > .40$).

DISCUSSION

This study compared the safety and efficacy of quetiapine and risperidone for the treatment of depressive symptoms in psychotic patients. While both agents produced improvements in mean HAM-D scores, quetiapine produced a greater improvement than did risperidone in

Figure 5. Mean Change From Baseline in HAM-D Composite Factor Scores for Quetiapine and Risperidone[a]



[a]Abbreviations: HAM-D = Hamilton Rating Scale for Depression, LOCF = last observation carried forward.
[b]Includes insomnia early, middle, late; retardation; agitation; anxiety somatic; somatic symptoms gastrointestinal; somatic symptoms general; genital symptoms; weight loss; diurnal variation present; and diurnal variation severity.
[c]Includes depressed mood, guilt, suicide, work and activities, anxiety (psychic), hypochondriasis, insight, depersonalization and derealization, paranoid symptoms, and obsessional and compulsive symptoms.

all patients ($p = .0015$), in patients with primary mood disorders ($p = .036$), and in patients with non-mood disorders ($p = .008$). Quetiapine produced a statistically greater effect than risperidone in treating depressive symptoms in those patients with higher initial HAM-D scores. The clinical significance of the changes produced by treatment with quetiapine is not known. The incidence of substantial EPS was lower in patients treated with quetiapine than in patients treated with risperidone. This was statistically significant for mood diagnoses and showed a trend for non-mood diagnoses ($p = .062$). Both substantial and moderate EPS occurred statistically significantly less frequently among those mood-diagnosed patients who were taking quetiapine.

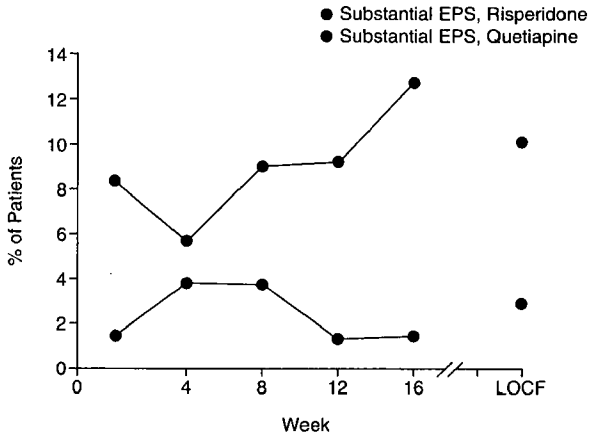
Other groups of investigators have reported that quetiapine and risperidone exhibit efficacy in the treatment of depressive symptoms in patients.[10,24] Sajatovic et al.[25] reported significant improvement on HAM-D scores in 20 individuals with bipolar or schizoaffective disorder who received open-label quetiapine therapy. In a case series of 6 patients with treatment-resistant bipolar disorder treated with quetiapine, 2 patients showed evidence of moderate-to-marked improvement on the Clinical Global Impressions scale modified for bipolar disorder.[26] Sedation was the main side effect noted in the Ghaemi and Katzow report,[26] and the investigators concluded that quetiapine may be a useful treatment for some patients with treatment-resistant bipolar disorder.

A number of open-label studies have investigated the use of risperidone to treat mood disorders with promising results.[27-32] Ostroff and Nelson[29] examined the use of risperidone to augment selective serotonin reuptake inhibitor (SSRI) antidepressants in 8 patients who had not responded to SSRI therapy. The 8 patients showed improvement within 1 week of the addition of risperidone. Vieta et al.[24] reported significant reductions in HAM-D scores for 8 of 10 patients with refractory rapid-cycling bipolar disorder who received open-label risperidone therapy. One double-blind study found risperidone to be as effective as lithium or haloperidol in the treatment of acute mania.[33] Finally, Guille et al.[32] reported that risperidone was as effective as clozapine and olanzapine in the treatment of bipolar disorder.

Induction of mania has been associated with a number of atypical antipsychotics such as risperidone, olanzapine, sertindole, quetiapine, and amisulpride.[34-39] Mania induction was not reported in this study; however, all the patients who were receiving mood stabilizers were permitted to continue this treatment as per protocol. In this analysis and in the larger QUEST study,[19] no mania scale was used; thus, instances of mood induction might not have been detected. Our conclusion of no identified mania induction in this study and in the larger QUEST study, then, is qualified by the small sample size in this study and the limited methodology in the QUEST study.

This study had a flexible-dose design, which allowed clinicians to titrate medications for maximum efficacy and minimum side effects depending upon the needs of each patient. At the time of the trial, risperidone was a U.S. Food and Drug Administration–approved medication and thus had a package insert that specified dosage. Quetiapine was still an investigational drug with optimal dose yet to be determined. Instructions to investigators were identical for both drugs: to titrate dosage according to patients' clinical needs. This dosing plan mirrors what generally occurs in clinical practice and thus provides insight into how study compounds will be used under such conditions. The limitations of this study include the following: (1) this was an open-label clinical trial, with the possibility of investigator and/or patient bias; (2) the trial involved a relatively small number of patients, with correspondingly small numbers of patients with mood and

Figure 6. Incidence of Extrapyramidal Symptoms (EPS) to a Substantial Degree in Patients Diagnosed With Mood Disorders[a]



[a]Substantial EPS is defined as requiring 1 or more of the following alterations in treatment: prescription of an anti-EPS medication, reduction in dose of randomized treatment, a discontinuation of randomized treatment.

non-mood disorders; (3) no standardized diagnostic instrument was used to assign diagnoses to patients; (4) no measurement was made of mania; (5) all patients were psychotic, thus no conclusions can be drawn about patients with bipolar disorder without psychoses; (6) elderly patients were also examined with the HAM-D, although it has been suggested that another scale might be more appropriate (e.g., the Geriatric Depression Screening Scale[40]); and (7) patients were allowed to continue the use of antidepressants and mood medications, thus efficacy and side effects might have been influenced by the concomitant medications.

In conclusion, in this trial, quetiapine produced a greater overall improvement in HAM-D scores compared with risperidone—this was true whether patients had mood or non-mood disorders. Patients with high baseline HAM-D scores improved more than did individuals with lower baseline HAM-D scores. The incidences of substantial EPS were fewer in patients treated with quetiapine compared with patients treated with risperidone. These results suggest that quetiapine may be a useful agent in the management of depressive symptoms in patients with psychotic disorders.

Drug names: clozapine (Clozaril and others), fluphenazine (Prolixin, Permitil, and others), haloperidol (Haldol and others), olanzapine (Zyprexa), quetiapine (Seroquel), risperidone (Risperdal).

A RATING SCALE FOR EXTRAPYRAMIDAL SIDE EFFECTS

G. M. Simpson, M. B., Ch. B. and
J. W. S. Angus, F. R. C. P. (C), D. P. M.

SUMMARY

A modification of an earlier rating scale for extrapyramidal system disturbance is described, and evidence for the validity and reliability of the scale is presented. The usefulness of the scale in studies of neuroleptic drugs is discussed. By its application it is possible to quantify extrapyramidal side effects and to separate them into four principal factors.

INTRODUCTION

The discovery of phenothiazines as useful agents in the treatment of mental disorder was shortly followed by discoveries of their adverse reactions, particularly those affecting the extrapyramidal system (3). This led to claims that side effects were part and parcel of their usefulness (4), and to counter-claims that they were undesirable side effects (6). The extensive studies of Haase (5), who claims that minimal extrapyramidal signs, as demonstrated in handwriting changes, are the "sine qua non" for optimal treatment, represent a somewhat intermediate position in this controversy.

This whole area has been thoroughly reviewed in two recent publications by Bishop, et al. (1) and by Ching-Piao and DiMascio (2). The latter point out that part of the confusion in this area may be related to differences in classification, and that too many investigators use extrapyramidal system disturbance as if it were a unity. We use this term throughout to describe the factors we are actually measuring. We see the difficulty not so much one of classification, but of defining and quantifying what is being observed. Thus, infrequent dystonic reactions and the slightly more frequent akathisia have been omitted from this study. We also feel that the differences between Haase and, for example, the French investigators are not semantic ones or a problem of classification, but merely that a proper comparison or study remains to be done.

We have elsewhere stated our opinion on this point (7, 9), namely that the presence of minimal extrapyramidal side effects seem to be associated with therapeutic improvement, excess extrapyramidal effects with less improvement. Further discussion on this subject would be outside the scope of

the present paper, but it is mentioned merely to highlight the point that all neuroleptic agents, irrespective of their chemical structure, possess two things in common: (1) an effect on psychotic behavior, and (2) an effect on the extrapyramidal system. Within limits, the potency of the drugs seems to be proportional to their propensity for producing extrapyramidal symptoms. If this is so, it is important to have an instrument for assessing accurately the amount of extrapyramidal system disorder produced, a quantitative measure rather than a qualitative description of these side effects.

In a previous investigation a rating scale for measuring extrapyramidal system disorder produced by neuroleptic drugs was described (7), and since that time it has been routinely used in this research unit. This scale was shown to have both clinical validity and high inter-rater reliability, but later attempts at more precise studies of extrapyramidal system disorder led to the need for its revision. Factors such as Salivation and Tremor, which were difficult to quantify, had not been included in the old scale, but in various studies, scores on the scale were diluted by their absence. Thus, zero scores occurred despite obvious tremor or disturbing salivation which frequently required the use of antiparkinson medication. It was, therefore, decided to expand the rating scale to include these factors. It is the purpose of this paper to present this rating instrument with a discussion of its potential usefulness in the field of clinical research.

The original rating scale contained nine items, all of which were common clinical signs, used in the diagnosis of Parkinson's Disease in clinical practice. One of these items, the evaluation of the state of the trunk muscles—a sign which can be of considerable diagnostic importance—was found difficult to quantify and was dropped from the scale. The other eight items were retained and, with the addition of Tremor and Salivation, make up the ten-item scale shown in Table 1. Each item is rated on a 5-point scale, with 0 meaning the complete absence of the condition, and 4 meaning the presence of the condition in extreme form. Each point on the scale was defined and is shown in the appendix. The score on the scale is obtained by adding the items and dividing by 10.

TABLE 1

Neurological Rating Scale for Extrapyramidal Effects

1. Gait	6. Leg Pendulousness
2. Arm Dropping	7. Head Dropping
3. Shoulder Shaking	8. Glabella Tap
4. Elbow Rigidity	9. Tremor
5. Wrist Rigidity	10. Salivation

Two questions of concern in any rating scale involve validity and reliability, and these questions were answered reasonably well in the studies on the

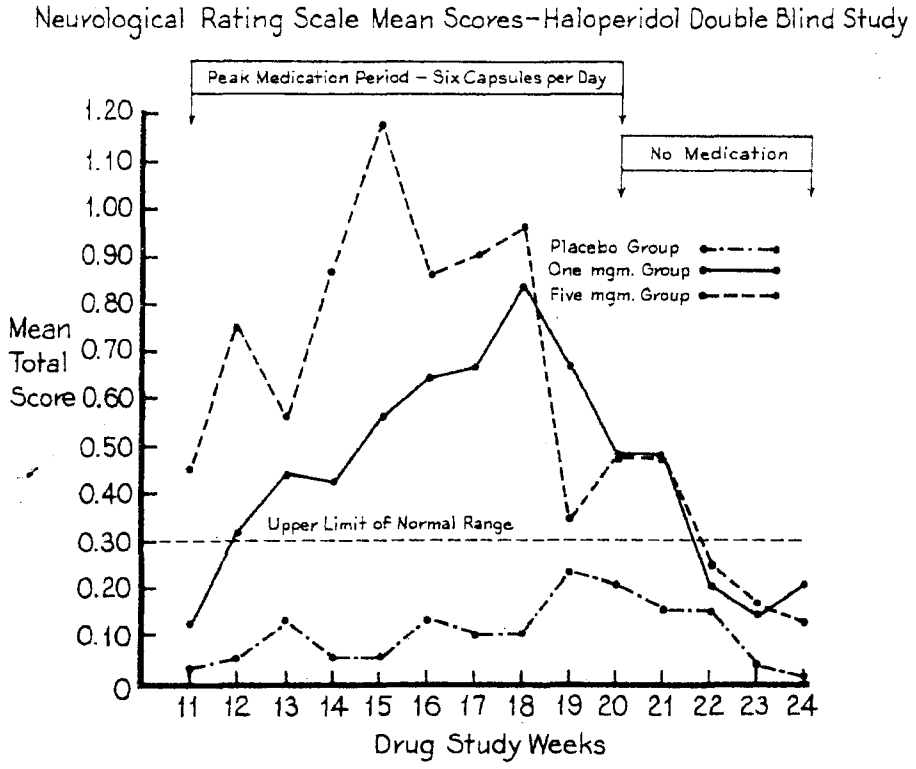

Fig. 1

previous scale (7). The reliability of the present scale was tested during a double-blind study involving two dose levels of the potent neuroleptic haloperidol and a placebo (8). Striking evidence for the validity of the scale was also obtained from the same trial.

METHOD

Fourteen patients who had been off all drugs for four weeks, were treated with identical capsules containing placebo, 1 mg and 5 mg of haloperidol respectively. The regime was fixed so that all patients received one capsule daily during the first week, and an increase of daily dosage by one capsule each week to a maximum of six. The daily dosage was maintained at this level for a further ten weeks, and, following withdrawal of medication, the patients were studied for another four weeks. When the code was broken, four patients had received placebo, five the 1 mg capsule (6 mg/day), and five the 5 mg capsule (30 mg/day).

The graph (Fig. 1) depicts the mean weekly rating on the scale for each group during the period on maximum medication and for the four weeks following withdrawal of medication, all ratings having been made by one physician. It can be seen that the scale satisfactorily separates the three groups. At Week 15 a t-test indicated that the difference between the placebo group and the 1 mg group was statistically significant ($p < 0.01$). The difference between the 5 mg and 1 mg groups just fails to be statistically significant ($p > 0.05$).

Two points should be made. We consider scores of up to 0.3 to be within the "normal range," and we found, on breaking the code, that three patients in the high dose group had been given benztropine mesylate for clinically troublesome side effects, whereas only one in the low dose group received it. This may account for the fall in the scores of the high dose group during the latter part of the drug period, and would certainly have diminished the difference between the 1 mg and 5 mg group mean scores.

In order to test inter-rater reliability, the patients were examined by two doctors during Weeks 11 to 18 of the trial. The patients were examined and rated at the same time of day each week and were seen by the second doctor immediately after examination by the first. Separate examining rooms were used, and the doctors were unaware of each other's ratings and of their own ratings made in previous weeks. There was no discussion or analysis of the data until the study had been completed. Correlation coefficients between raters for each item in each of the seven weeks were obtained and are shown in Table 2.

In our early clinical drug studies and in previous investigations, the total score on the neurological rating scale was the one used most frequently. This is obtained by summing the score for all the rated items and dividing

TABLE 2

Correlation Coefficients Between Raters

Item	Mean	Range
1. Gait	0.52	0.22–0.78
2. Arm Dropping	0.73	0.58–0.89
3. Shoulder Shaking	0.78	0.69–0.94
4. Elbow Rigidity	0.73	0.67–0.92
5. Wrist Rigidity	0.59	0.20–0.89
6. Leg Pendulousness	0.75	0.62–0.78
7. Head Dropping	0.70	0.62–0.78
8. Glabella Tap	0.87	0.60–1.0
9. Tremor	0.56	0.29–0.94
10. Salivation	0.59	0.16–1.0
Total Score	0.87	0.71–0.96

the total by the number of items. Correlations for the total scores between the two investigators ranged from 0.71 to 0.96.

In general, there was a good correlation between the two raters, but in one week, poor correlations were obtained on four items. Otherwise, the ten items rated on seven weeks, that is, seventy correlations, were all of a high order. All the low correlations were recorded in the third week of the study; this included Wrist Rigidity, Salivation, Gait, and Tremor. No explanation can be given for this at this time.

A principal component factor analysis, followed by a normalized Varimax rotation of the four resulting principal components was carried out. The factor loadings for these components are shown in Table 3. The first factor has high loadings on the items Shoulder-shaking, Elbow rigidity, Wrist rigidity, and Leg pendulousness and is obviously a factor involving rigidity. This factor accounted for 34 % of the total variance. The second factor places greatest weight on the items Gait, Salivation, and Head-dropping and accounted for 15 % of the total variance. The item Head-dropping is a difficult one to score, and we expected it to be included in the first factor to which it does contribute. That it should cluster with Gait is not particularly surprising, but no clinical explanation can be given for Salivation being included in this factor. We consider it a statistical artifact. The third factor was Glabella tap, which explained just over 10 % of the variance. Tremor emerged as a fourth factor, accounting for over 9 % of the variance. It would appear, therefore, that in using this scale to study extrapyramidal effects or antiparkinson agents, four factors, which in this study accounted for 68 % of the variance, could be considered: Rigidity, Salivation, Glabella tap, and Tremor.

Because seven of the items in the scale are measurements of rigidity, and because the latter accounted for a major part of the variance, we sepa-

TABLE 3

Factor Loadings for Four Principal Components

	I	II	III	IV
1. Gait	0.216	0.740	0.032	0.106
2. Arm Dropping	0.200	0.260	0.043	0.666
3. Shoulder shaking	0.818	0.262	0.069	0.047
4. Elbow Rigidity	0.799	0.227	0.121	0.140
5. Wrist Rigidity	0.792	0.004	0.249	0.207
6. Leg Pendulousness	0.702	0.231	0.067	0.213
7. Head Dropping	0.441	0.575	0.264	0.053
8. Glabella Tap	0.086	0.037	0.959	0.065
9. Tremor	0.088	0.046	0.119	0.819
10. Salivation	0.185	0.762	0.009	0.170

rated out the rigidity scores for the three groups. As might be expected, they ran parallel to the total score, although the fit was not exact. The discrimination between the placebo group and the drug groups remained, but that between the two drug groups was diminished.

DISCUSSION

There have been many attempts to quantify the phenomena of parkinsonism and its response to treatment. Unfortunately, the scales often contain many items, or the assessment involves time-consuming procedures, such as sorting tests or handwriting. We believe that we have devised a valid, reliable scale that is simple and rapidly applied and requires no equipment other than an examining couch. In addition, the method can be quickly taught to a nurse or research assistant. Its application does not require specialized medical knowledge.

The items on the scale have a certain face validity in that they are commonly used signs in the clinical evaluation of parkinsonism. A further attestation to the validity of the scale was its ability to separate in a double-blind trial not only patients receiving placebo from those receiving potent neuroleptic medications, but also two dose levels of the medication. The relatively high correlations on each item between raters, and the high correlation on the total score, indicate that the scale is reliable. Like every other scale, its use has to be learned, and it is advisable for raters to rate the same patients from time to time, in order to check shifts in definition.

As most of the items are concerned with the measurement of rigidity, it is no surprise that such a factor accounts for a large part of the variance and separates out from Salivation, Tremor, and Glabella tap. Nevertheless, the retention of the latter three items appears to be justified, because the mean total score proved better at separating the two drug groups than the rigidity score alone. The grouping of items in the scale according to these factors might be used to bring greater precision to the assessment of neuroleptic drugs or the use of drugs for treating extrapyramidal symptoms.

We are using the scale routinely both in the work of early clinical drug evaluation and in the investigation of extrapyramidal side effects. It is possible that others, working in psychopharmacology, might find it of value and possible, too, that it may be of interest to neurologists in assessing the treatment of parkinsonism.

APPENDIX

1. *Gait*—The patient is examined as he walks into the examining room, his gait, the swing of his arms, his general posture, all form the basis for an overall score for this item. This is rated as follows:

0 – normal
1 – diminution in swing while the patient is walking
2 – marked diminution in swing with obvious rigidity in the arm
3 – stiff gait with arms held rigidly before the abdomen
4 – stooped shuffling gait with propulsion and retropulsion

2. *Arm Dropping*—The patient and the examiner both raise their arms to shoulder height and let them fall to their sides. In a normal subject a stout slap is heard as the arms hit the sides. In the patient with extreme Parkinson's syndrome the arms falls very slowly:

0 – normal, free fall with loud slap and rebound
1 – fall slowed slightly with less audible contact and little rebound
2 – fall slowed, no rebound
3 – marked slowing, no slap at all
4 – arms fall as though against resistance; as though through glue

3. *Shoulder Shaking*.—The subject's arms are bent at a right angle at the elbow and are taken one at a time by the examiner who grasps one hand and also clasps the other around the patient's elbow. The subject's upper arm is pushed to and fro and the humerus is externally rotated. The degree of resistance from normal to extreme rigidity is scored as follows:

0 – normal
1 – slight stiffness and resistance
2 – moderate stiffness and resistance
3 – marked rigidity with difficulty in passive movement
4 – extreme stiffness and rigidity with almost a frozen shoulder

4. *Elbow Rigidity*—The elbow joints are separately bent at right angles and passively extended and flexed, with the subject's biceps observed and simultaneously palpated. The resistance to this procedure is rated. (The presence of cogwheel rigidity is noted separately.) Scoring is from 0–4 as in Shoulder Shaking test.

5. Fixation of position or *Wrist Rigidity*—The wrist is held in one hand and the fingers held by the examiner's other hand, with the wrist moved to extension flexion and both ulner and radial deviation. The resistance to this procedure is rated as in Items 3 and 4.

6. *Leg Pendulousness*—The patient sits on a table with his legs hanging down and swinging free. The ankle is grasped by the examiner and raised until the knee is partially extended. It is then allowed to fall. The resistance to falling and the lack of swinging form the basis for the score on this item:

0 – the legs swing freely
1 – slight diminution in the swing of the legs
2 – moderate resistance to swing
3 – marked resistance and damping of swing
4 – complete absence of swing

7. *Head Dropping*—The patient lies on a well-padded examining table and his head is raised by the examiner's hand. The hand is then withdrawn and the head allowed to drop. In the normal subject the head will fall upon the table. The movement is delayed in extrapyramidal system disorder, and in extreme parkinsonism it is absent. The neck muscles are rigid and the head does not reach the examining table. Scoring is as follows:

0 – the head falls completely with a good thump as it hits the table
1 – slight slowing in fall, mainly noted by lack of slap as head meets the table
2 – moderate slowing in the fall quite noticeable to the eye
3 – head falls stiffly and slowly
4 – head does not reach examining table

8. *Glabella Tap*—Subject is told to open his eyes wide and not to blink. The glabella region is tapped at a steady, rapid speed. The number of times patient blinks in succession is noted:

0 – 0–5 blinks
1 – 6–10 blinks
2 – 11–15 blinks
3 – 16–20 blinks
4 – 21 and more blinks

9. *Tremor*—Patient is observed walking into examining room and then is re-examined for this item:

0 – normal
1 – mild finger tremor, obvious to sight and touch

2 – tremor of hand or arm occurring spasmodically
3 – persistent tremor or one or more limbs
4 – whole body tremor

10. *Salivation*—Patient is observed while talking and then asked to open his mouth and elevate his tongue. The following ratings are given:

0 – normal
1 – excess salivation to the extent that pooling takes place if the mouth is open and the tongue raised
2 – when excess salivation is present and might occasionally result in difficulty in speaking
3 – speaking with difficulty because of excess salivation
4 – frank drooling

Efficacy of Olanzapine and Olanzapine-Fluoxetine Combination in the Treatment of Bipolar I Depression

Mauricio Tohen, MD, DrPH; Eduard Vieta, MD, PhD; Joseph Calabrese, MD; Terence A. Ketter, MD; Gary Sachs, MD; Charles Bowden, MD; Philip B. Mitchell, MD; Franca Centorrino, MD; Richard Risser, MS; Robert W. Baker, MD; Angela R. Evans, PhD; Karin Beymer, BS, RPh; Sanjay Dubé, MD; Gary D. Tollefson, MD, PhD; Alan Breier, MD

Background: Despite the longer duration of the depressive phase in bipolar disorder and the frequent clinical use of antidepressants combined with antipsychotics or mood stabilizers, relatively few controlled studies have examined treatment strategies for bipolar depression.

Objective: To examine the use of olanzapine and olanzapine-fluoxetine combination in the treatment of bipolar I depression.

Design: Double-blind, 8-week, randomized controlled trial.

Setting: Eighty-four sites (inpatient and outpatient) in 13 countries.

Patients: A total of 833 randomized adults with bipolar I depression with a Montgomery-Åsberg Depression Rating Scale (MADRS) score of at least 20.

Intervention: Patients were randomly assigned to receive placebo (n=377); olanzapine, 5 to 20 mg/d (n=370); or olanzapine-fluoxetine combination, 6 and 25, 6 and 50, or 12 and 50 mg/d (n=86).

Main Outcome Measure: Changes in MADRS total scores using mixed-effects model repeated-measures analyses.

Results: During all 8 study weeks, the olanzapine and olanzapine-fluoxetine groups showed statistically significant improvement in depressive symptoms vs the placebo group ($P<.001$ for all). The olanzapine-fluoxetine group also showed statistically greater improvement than the olanzapine group at weeks 4 through 8. At week 8, MADRS total scores were lower than at baseline by 11.9, 15.0, and 18.5 points in the placebo, olanzapine, and olanzapine-fluoxetine groups, respectively. Remission criteria were met by 24.5% (87/355) of the placebo group, 32.8% (115/351) of the olanzapine group, and 48.8% (40/82) of the olanzapine-fluoxetine group. Treatment-emergent mania (Young Mania Rating Scale score <15 at baseline and ≥15 subsequently) did not differ among groups (placebo, 6.7% [23/345]; olanzapine, 5.7% [19/335]; and olanzapine-fluoxetine, 6.4% [5/78]). Adverse events for olanzapine-fluoxetine therapy were similar to those for olanzapine therapy but also included higher rates of nausea and diarrhea.

Conclusions: Olanzapine is more effective than placebo, and combined olanzapine-fluoxetine is more effective than olanzapine and placebo in the treatment of bipolar I depression without increased risk of developing manic symptoms.

Arch Gen Psychiatry. 2003;60:1079-1088

BIPOLAR DEPRESSION, or the depressive phase of bipolar disorder, represents a difficult-to-treat and disabling form of depression. However, relative to its impact, an insufficient number of studies have explored its treatment. Studies indicate that patients with bipolar disorder spend more time in and take longer to recover from the depressive phase than the manic phase. Judd et al[1] reported that patients with bipolar disorder experience depressive symptoms more than 3 times longer than they experience manic symptoms. Keller et al,[2] using a naturalistic study design, found that the median time to recovery from the depressive phase was 9 weeks but from the manic phase was 5 weeks and that 22% of patients in the depressive phase but only 7% in the manic phase remained ill for at least 1 year. Moreover, Hlastala et al,[3] in a controlled study of maintenance therapies, found that the median time to full remission was 16.8 weeks for a manic episode but 40.0 weeks for a depressive episode. In addition to being longer and more persistent, the depressive phase of bipolar disorder is associated with higher rates of morbidity and mortality. Dilsaver et al[4] reported the relative risk of suicidality among patients with bipolar depression to be 34.9 times greater than that among patients with pure mania. Depres-

Author affiliations are listed at the end of this article.

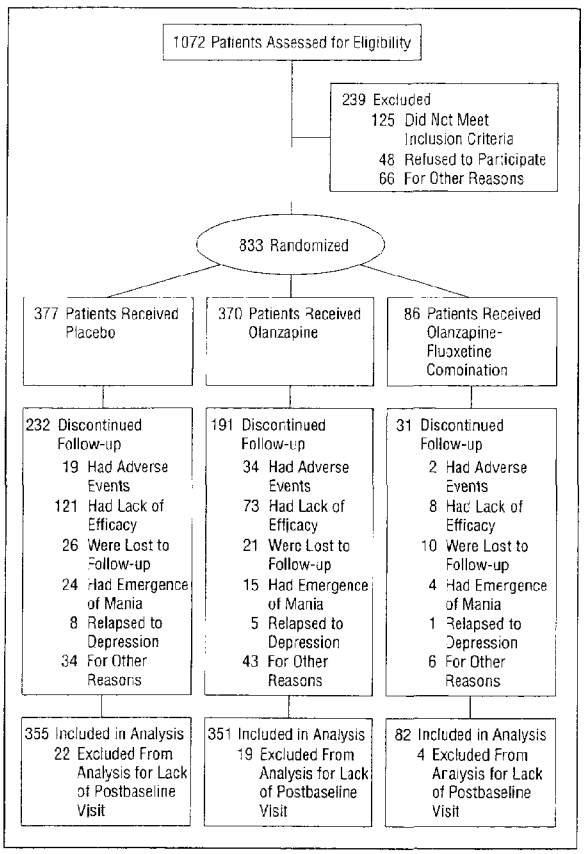

Figure 1. Flow diagram of patient progress through phases of the study.

sive symptoms have also been found to be a strong predictor of disability in patients with bipolar disorder.[5]

Nevertheless, despite the clear clinical and public health implications of these findings, treatment of bipolar depression remains an understudied area, as clinicians and researchers have historically focused more on treatment of mania.[6] Although a wide range of mood-stabilizing medications is available, treatment options for bipolar depression remain more limited, and no medication has been formally approved for this indication. At present, the 2002 treatment guidelines from the American Psychiatric Association recommend either lithium or lamotrigine as first-line treatment.[7] Although reviews[8,9] of clinical trials have concluded that there is evidence of lithium's acute efficacy for bipolar depression, patients in those clinical trials frequently did not achieve a full response.[10] Anticonvulsants such as lamotrigine and valproate sodium have also been used to treat bipolar depression.[11,12] However, although Calabrese and colleagues[11] reported the antidepressant efficacy of lamotrigine therapy in a placebo-controlled trial of patients with bipolar depression, lamotrigine requires a slow upward titration to avoid the risk of rash.[11,13] Other common treatments include the adjunctive use of antidepressants with a mood stabilizer. However, some antidepressants, particularly tricyclics, are problematic for their potential to induce mania or hypomania or to accelerate cycling.[14,15] Thus, alternative effective and safe treatment options are needed.

Olanzapine has demonstrated efficacy in the treatment of acute bipolar mania[16-18] and has been found to improve depressive symptoms in patients with schizophrenia.[19] The present study was thus designed to test the antidepressant efficacy of olanzapine in treating the depressive phase of bipolar I disorder. For exploratory purposes, a small group of patients was treated with olanzapine combined with the selective serotonin reuptake inhibitor fluoxetine. The olanzapine-fluoxetine combination was previously found to be effective in a small sample of patients with treatment-resistant unipolar depression.[20] The present study represents the first controlled trial, to our knowledge, of an atypical antipsychotic agent alone or combined with an antidepressant for the treatment of bipolar depression.

METHODS

STUDY DESIGN

The primary objective of this 8-week, randomized, double-blind, parallel study was to compare the efficacy and safety of olanzapine monotherapy and placebo in the treatment of bipolar I disorder, depressed. An olanzapine-fluoxetine combination treatment arm was also included concurrently for exploratory purposes. Qualified patients who completed a 2- to 14-day screening and washout period were therefore randomized in a 4:4:1 allocation, as specified in the protocol, to receive olanzapine, 5 to 20 mg/d (n=370); placebo (n=377); or olanzapine-fluoxetine combination, 6 and 25, 6 and 50, or 12 and 50 mg/d (n=86) in a flexible dosing schedule. Olanzapine monotherapy was initiated at 5 mg and could be adjusted upward in increments of 5 mg/d. Olanzapine-fluoxetine combination therapy was initiated at 6 and 25 mg/d but could be administered at 6 and 50 or 12 and 50 mg/d after at least 1 day at each dose. No other dose combinations were allowed. Combination dosing was based on the positive findings from a study[20] of patients with treatment-resistant depression. Olanzapine and fluoxetine were administered as separate capsules, taken together once daily in the evening. Patients receiving placebo or olanzapine monotherapy also received 2 pills per day. Randomization was stratified by site and used a blinded voice response system. All clinical and statistical investigators, site personnel, and patients were blinded to treatment.

Patients were permitted adjunctive use of benzodiazepines (up to 2 mg of lorazepam equivalents per day) throughout the screening and acute therapy phases of the study. Anticholinergic therapy (benztropine mesylate or biperiden, ≤6 mg/d, or trihexyphenidyl, ≤12 mg/d) was permitted throughout the study for treatment of extrapyramidal symptoms but not for prophylaxis. Use of other psychotropic drugs was not permitted, and all such medication was tapered during the 2- to 14-day screening period at the discretion of the investigator and was completed at least 1 day before randomization.

PATIENTS

All patients were 18 years or older and met *DSM-IV*[21] criteria for bipolar I disorder, depressed. A total of 1072 patients were recruited from the inpatient and outpatient services of 84 study sites in 13 countries between June 1, 2000, and December 31, 2001 (**Figure 1**). Diagnosis was confirmed by the *Structured Clinical Interview for the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Patient Version*.[22] Patients were required to have a Montgomery-Åsberg Depression Rating Scale (MADRS)[23] total score of at least 20 at the screening visit and at the time of

Table 1. Patient and Illness Characteristics at Baseline

Characteristic	Placebo Group (n = 377)	Olanzapine Group (n = 370)	OFC Group (n = 86)	Total (N = 833)	P Value
Age, mean (SD), y	41.7 (12.4)	42.2 (12.5)	40.3 (13.0)	41.8 (12.5)	.91*

*$F_{2,809} = 0.1$.
†Rapid cycling was defined as more than 4 mood episodes (depressive, manic, or mixed) in the past 12 months.
‡Based on available data (placebo group, n = 302; olanzapine group, n = 310; and OFC group, n = 66).
§$X^2_2 = 10.38$.

randomization. Patients were also required to have a history of at least 1 previous manic or mixed episode of sufficient severity to require treatment with a mood stabilizer or an antipsychotic agent. Exclusion criteria included a history of alcohol or substance dependence within the previous 3 months, suicidal behavior within the previous 3 months, or an unstable or untreated medical disorder. For safety reasons, any patient with worsening of manic symptoms, as verified by a score of 15 or greater on the Young Mania Rating Scale (YMRS)[24] during weeks 1 to 3 of treatment, was discontinued from the study. Before participation, all patients provided written informed consent; the study was approved by the institutional review board at each site.

ASSESSMENTS

Clinical visits were conducted at baseline and at weeks 1, 2, 3, 4, 6, and 8. The protocol-defined primary measure of efficacy was the change in MADRS total score from baseline to week 8. Secondary efficacy measures included the Clinical Global Impressions Bipolar Version–Severity of Depression scale (CGI-BP-S),[25] the YMRS, and the Hamilton Anxiety Rating scale (HAM-A).[26] Rates of and time to response and remission were also assessed. Response was defined as 50% or greater improvement in the MADRS total score from baseline to an end point and completion of at least 4 weeks of study. Remission was defined as a MADRS total score of 12 or less at an end point and completion of at least 4 weeks of study.

Screening included a standard history and physical examination, psychiatric examination, laboratory profile, and electrocardiogram. Adverse events were recorded at each visit and were coded using the *Coding Symbol for Thesaurus of Adverse Reaction Terms*.[27] Extrapyramidal symptoms were assessed using the Simpson-Angus Rating Scale[28] and the Abnormal Involuntary Movement Scale.[29] Adverse events or abnormal values that originally occurred or worsened in severity during double-blind therapy were considered treatment emergent.

STATISTICAL ANALYSIS

All analyses were conducted on an intent-to-treat basis and were performed using statistical software (SAS version 6.09; SAS Institute Inc, Cary, NC). Treatment effects were tested at a 2-tailed α level of .05. Interaction effects were tested at a 2-tailed α level of .10. As specified a priori, analysis of the primary measure of efficacy was performed using a mixed-effects model repeated-measures (MMRM) method, which has been shown to provide highly accurate modeling of treatment outcome while accounting for nonrandom missing data (ie, patient dropout).[30,31] Initially, an unstructured covariance matrix was used to model within-patient error. Independent factors included in this model were treatment, investigator, treatment × investigator interaction, visit, and treatment × visit interaction, with the treatment × investigator interaction excluded if not statistically significant. Next, the best-fit covariance structure for each analysis was determined using a maximum Schwartz's Bayesian criterion and is reported in the tables. Possible structures included autoregressive, banded Toeplitz, compound symmetric with or without heterogeneous variances, spatial power, and unstructured. Treatment differences for each visit were tested using a single *df* contrast, based on least squares means from the final model. Inference from the repeated-measures analyses was based on the restricted maximum likelihood solution and on approximated F tests and *t* tests using *df*'s estimated by Satterthwaite's approximation. The MADRS items and secondary efficacy measures were similarly analyzed, except for the HAM-A, which used an analysis of variance (ANOVA) model due to assessments being taken only at baseline and an end point on that measure. Thus, all reported MADRS, MADRS item, CGI-BP-S, and YMRS mean change scores represent least squares means. The MMRM analyses were performed using the SAS PROC MIXED procedure, version 6.09 (SAS Institute Inc, Cary, NC).

The ANOVA models were also used to evaluate safety data, using mean change from baseline to end point based on a last-observation-carried-forward strategy. These models included terms for treatment and country plus treatment × country interaction if statistically significant. The Kruskal-Wallis test was used to analyze baseline length of the current episode because of the presence of outliers. The Fisher exact test was used to analyze treatment differences for categorical patient and illness characteristics. Odds ratios (and 95% confidence intervals [CI]) characterize group differences in clinical response. Kaplan-Meier analysis and the log-rank test were used to compare treatment groups for time-to-event data.

RESULTS

PATIENTS

A total of 833 patients were enrolled and randomized to treatment groups. The baseline characteristics of each group are given in **Table 1**. All of the groups were mod-

Abbreviations: NA, not applicable; OFC, olanzapine-fluoxetine combination.
*Time to discontinuation uses Kaplan-Meier survival analysis, with curves compared using the log-rank test.

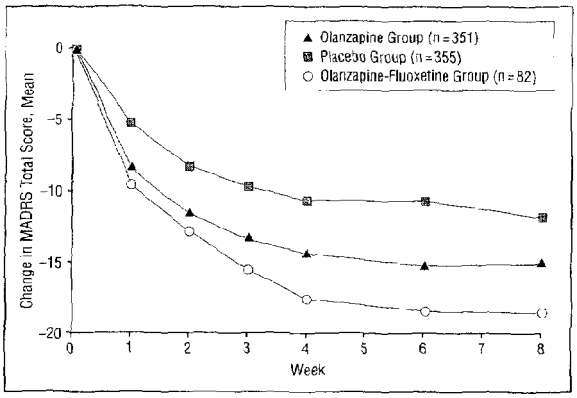

Figure 2. Least squares mean change in Montgomery-Åsberg Depression Rating Scale (MADRS) total scores during the 8-week study. Improvement in MADRS scores with use of olanzapine and the olanzapine-fluoxetine combination was significantly greater than with use of placebo throughout the study ($P<.001$). Improvement in MADRS scores with use of olanzapine-fluoxetine combination was significantly greater than with use of olanzapine at weeks 4 to 8 ($P<.02$).

erately to severely depressed, with baseline mean MADRS scores of 31.3, 32.6, and 30.8 for the placebo, olanzapine, and olanzapine-fluoxetine groups, respectively. Length of current depressive episode was statistically significantly shorter for the olanzapine group.

Mean modal drug dose for the olanzapine monotherapy group was 9.7 mg/d. Mean drug dose for the combination group was 7.4 mg/d for olanzapine and 39.3 mg/d for fluoxetine. The percentage of patients who used benzodiazepines at least once during the study was not statistically significantly different among groups (placebo group, 43.5%; olanzapine group, 43.0%; olanzapine-fluoxetine group, 36.0%; overall $P=.44$).

PATIENT DISPOSITION

Rates of study completion and reasons for discontinuation are reported in **Table 2**. Patients taking olanzapine-fluoxetine had the highest rates of completion (64.0%) and were less likely to discontinue due to lack of efficacy or adverse events. The most frequent adverse event resulting in discontinuation from the olanzapine monotherapy group was somnolence. There were no differences among groups in the rate of discontinuation due to emergence of mania. Three patients (all in the placebo group) died during the study: 1 was a homicide victim and 2 committed suicide.

Times to study discontinuation are also reported in Table 2. Median estimated times to discontinuation for any reason were 41, 56, and 65 days for the placebo, olanzapine, and olanzapine-fluoxetine groups, respectively, with patients in the placebo group discontinuing significantly earlier than those in the olanzapine group (log-rank test $\chi^2_1=5.06$; $P=.02$) or the olanzapine-fluoxetine group (log-rank test $\chi^2_1=17.02$; $P<.001$) and with those in the olanzapine group discontinuing earlier than those in the olanzapine-fluoxetine group (log-rank test $\chi^2_1=7.68$; $P=.006$).

EFFICACY

Mean ± SD baseline MADRS scores ranged from 30.8 ± 6.1 to 32.6 ± 6.2. The MMRM analyses of visitwise mean changes in MADRS scores are depicted in **Figure 2**. There were significant main effects for treatment ($F_{2,806}=25.14$; $P<.001$) and for visit ($F_{5,1036}=55.91$; $P<.001$), with no significant treatment × visit interaction ($F_{10,1044}=1.01$; $P=.43$). Between-group comparisons for visitwise MADRS mean change scores are given in **Table 3**. Starting as early as week 1 and continuing throughout the study, the olanzapine and olanzapine-fluoxetine groups demonstrated significantly greater mean improvements in MADRS total scores than those receiving placebo. Starting at week 4 and continuing to week 8, the olanzapine-fluoxetine group also demonstrated significantly greater mean improvement in MADRS total scores than the olanzapine monotherapy group. The therapeutic effect sizes for olanzapine and olanzapine-fluoxetine were 0.32 and 0.68, respectively. Due to the differences among groups in epi-

OFC	−18.5 ± 1.3 (−21.1 to −16.0)	−4.53	577	<.001	−2.46	571	.01

Abbreviations: CI, confidence interval; MADRS, Montgomery-Åsberg Depression Rating Scale; MMRM, mixed-effects model repeated-measures; NA, not applicable; OFC, olanzapine-fluoxetine combination.

*Baseline MADRS scores, mean ± SE: placebo group, 31.3 ± 0.3; olanzapine group, 32.6 ± 0.3; OFC group, 30.8 ± 0.7. The MMRM analysis used a heterogeneous banded Toeplitz structure for the within-patient error covariance structure.

sode length, this variable was subsequently entered into the MMRM model. After adjustment for episode length, week 8 MADRS mean ± SE change scores were −11.9 ± 0.8, −15.0 ± 0.7, and −18.6 ± 1.3 for the placebo, olanzapine, and olanzapine-fluoxetine groups, respectively. Because episode length was not a significant predictor of MADRS change score in this model ($F_{1,864} = 0.06$; $P = .81$) and resulted in negligible adjustment to the scores, Table 3 reports the MADRS mean change scores without this adjustment.

The response rate for the olanzapine group was 39.0% (137/351), which was significantly higher than the rate for the placebo group of 30.4% (108/355; $P = .02$; odds ratio, 1.46; 95% CI, 1.07-2.00). The response rate for the olanzapine-fluoxetine group was 56.1% (46/82), which was significantly higher than that for the placebo ($P < .001$; odds ratio, 2.92; 95% CI, 1.79-4.80) and olanzapine ($P = .006$; odds ratio, 2.00; 95% CI, 1.23-3.26) groups. Median times to response for the placebo, olanzapine, and olanzapine-fluoxetine groups were 59, 55, and 21 days, respectively (**Figure 3**). Time to response was significantly shorter for the olanzapine group compared with the placebo group (log-rank test $\chi^2_1 = 6.62$; $P = .01$) and shorter still for the olanzapine-fluoxetine group compared with the placebo (log-rank test $\chi^2_1 = 23.78$; $P < .001$) and olanzapine (log-rank test $\chi^2_1 = 7.93$; $P = .005$) groups.

The remission rate for the olanzapine group was 32.8% (115/351), which was significantly higher than the rate for the placebo group of 24.5% (87/355; $P = .02$). The remission rate for the olanzapine-fluoxetine group was 48.8% (40/82), which was significantly higher than that for the placebo ($P < .001$) and olanzapine ($P = .007$) groups. Median estimated times to remission for the placebo, olanzapine, and combination groups were 59, 57, and 42 days, respectively. Time to remission was significantly shorter for the olanzapine group compared with the placebo group

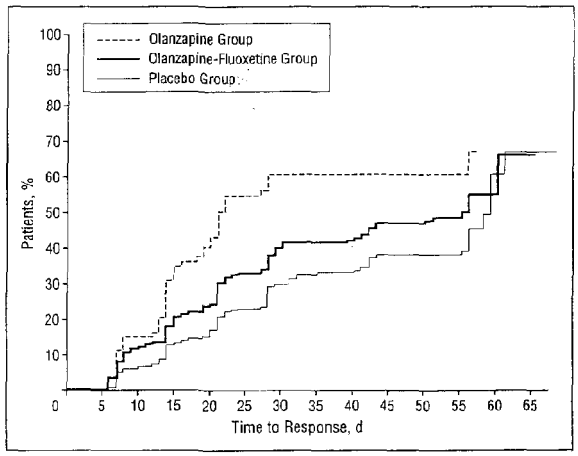

Figure 3. Kaplan-Meier estimates of time to response. Response is defined as a decrease in Montgomery-Åsberg Depression Rating Scale total score of 50% or more after at least 4 weeks of treatment. Median time to response for the olanzapine group (55 days) was significantly earlier compared with the placebo group (59 days). Median time to response for the combined olanzapine-fluoxetine combination group (21 days) was significantly earlier than for the olanzapine and placebo groups.

Abbreviations: CI, confidence interval; MADRS, Montgomery-Åsberg Depression Rating Scale; MMRM, mixed-effects model repeated-measures; NA, not applicable; OFC, olanzapine-fluoxetine combination.

*The MMRM analysis used a banded Toeplitz structure for the within-patient error covariance structure based on maximum Schwartz's Bayesian criterion for items 1, 3, 4, 5, 7, 8, 9, and 10 and a heterogeneous banded Toeplitz structure for the within-patient error covariance structure based on maximum Schwartz's Bayesian criterion for items 2 and 6.

(log-rank test $\chi^2_1=5.05$; $P=.02$) and again significantly shorter for the olanzapine-fluoxetine group compared with the placebo (log-rank test $\chi^2_1=17.95$; $P<.001$) and olanzapine (log-rank test $\chi^2_1=6.01$; $P=.01$) groups.

Analyses of the individual MADRS items are given in **Table 4**. The olanzapine and olanzapine-fluoxetine groups showed statistically significant improvements on inner tension, reduced sleep, and reduced appetite compared with the placebo group. In addition, the olanzapine-fluoxetine group showed statistically significant improvement on core mood items, including apparent sadness, reported sadness, lassitude, inability to feel, and pessimistic thoughts, compared with the olanzapine and placebo groups.

Analyses of the secondary measures of efficacy are given in **Table 5**. The olanzapine group showed greater mean improvement on the CGI-BP-S than the placebo group, and the olanzapine-fluoxetine group showed greater mean improvement than the placebo and olanzapine groups. In addition, the olanzapine and olanzapine-fluoxetine groups showed greater mean improvement on the HAM-A than the placebo group but were not significantly different from each other.

TREATMENT-EMERGENT MANIA

Treatment-emergent mania was defined as a YMRS score less than 15 at baseline and 15 or greater at any time thereafter. In all 3 groups, the incidence of treatment-emergent mania was low, and there were no statistically significant differences among groups ($P=.86$). Rates of treatment-emergent mania were 6.7% (23/345) for the

Nausea	4.3	11.6	8.8	.02	.41	.02

Abbreviation: OFC, olanzapine-fluoxetine combination.

placebo group, 5.7% (19/335) for the olanzapine group, and 6.4% (5/78) for the olanzapine-fluoxetine group. Mean change scores on the YMRS are reported in Table 5. Mean mania scores decreased significantly in the olanzapine and olanzapine-fluoxetine groups compared with the placebo group, with no significant difference between the olanzapine and olanzapine-fluoxetine groups.

SAFETY

Adverse events that emerged during the study or that were present at baseline and then worsened in severity were considered treatment emergent. **Table 6** lists treatment-emergent adverse events reported by 10% or more of patients in any treatment group. The adverse event profile for olanzapine-fluoxetine combination therapy was similar to that for olanzapine monotherapy but also included statistically significantly higher rates of nausea and diarrhea.

Mean change in and emergence of extrapyramidal symptoms were low, with no statistically significant differences across treatment groups. The percentage of patients who used anticholinergic medications at least once during the trial was statistically significantly greater in the olanzapine-fluoxetine group (8.1% [7/86]) compared with the olanzapine group (2.8% [10/360]; $P=.03$) but not the placebo group (3.7% [14/377]; $P=.09$).

Mean±SD weight gain was higher in treated patients than in those who received placebo (olanzapine vs placebo: 2.59±3.24 kg vs −0.47±2.62 kg, $F_{1,774}=194.36$, $P<.001$; olanzapine-fluoxetine vs placebo: 2.79±3.23 kg vs −0.47±2.62 kg, $F_{1,774}=80.87$, $P<.001$). Weight gain was not significantly different between the olanzapine and olanzapine-fluoxetine groups ($F_{1,774}=0.16$; $P=.69$). In addition, the percentage of patients who had a potentially clinically significant change in weight, defined as a 7% or greater increase from baseline, was significantly greater for the olanzapine (18.7% [65/347]) and olanzapine-fluoxetine (19.5% [16/82]) groups compared with the placebo group (0.3% [1/355]) ($P<.001$ for all) but did not differ between the olanzapine and olanzapine-fluoxetine groups ($P=.88$). In the olanzapine-fluoxetine group, 7.3% (6/82) of the patients had potentially clinically relevant orthostatic hypo-

tension, defined as a 30 mm Hg or greater decrease in systolic blood pressure from supine to standing. This percentage was significantly greater than that in the placebo (1.4% [5/352]; $P=.008$) and olanzapine (1.4% [5/346]; $P=.009$) groups. In addition, 4.9% (4/82) of the olanzapine-fluoxetine group had a potentially clinically relevant increase in high supine systolic blood pressure (≥180 mm Hg with an increase ≥20 mm Hg); this percentage was significantly greater than that in the olanzapine group (0.6% [2/349]; $P=.01$) but not that in the placebo group (1.7% [6/354]; $P=.10$). There were no clinically relevant QT prolongations. Only 2 women (1 in the placebo group and 1 in the olanzapine group) had treatment-emergent QTc intervals of 470 milliseconds or greater, and no men had treatment-emergent QTc of 450 milliseconds or greater (Fridericia corrected).

Mean±SD baseline cholesterol levels were high across all groups (207±47 mg/dL [5.35±1.21 mmol/L] for placebo, 206±46 mg/dL [5.34±1.18 mmol/L] for olanzapine, and 207±68 mg/dL [5.36±1.75 mmol/L] for olanzapine-fluoxetine) but increased significantly at the end point for the olanzapine (6±31 mg/dL [0.16±0.80 mmol/L]; $F_{1,667}=16.66$; $P<.001$) and olanzapine-fluoxetine (10±67 mg/dL [0.27±1.74 mmol/L]; $F_{1,667}=11.54$; $P<.001$) groups compared with the placebo group (−6±30 mg/dL (−0.15±0.78 mmol/L]), with no significant difference between the olanzapine and olanzapine-fluoxetine groups ($F_{1,667}=0.82$; $P=.37$). Mean±SD changes in nonfasting glucose levels were significantly higher for the olanzapine (4±30 mg/dL [0.2±1.7 mmol/L]; $F_{1,658}=5.41$; $P=.02$) and olanzapine-fluoxetine (6±40 mg/dL [0.3±2.2 mmol/L]; $F_{1,658}=9.99$; $P=.002$) groups compared with the placebo group (−4±26 mg/dL (−0.2±1.5 mmol/L]), with no significant difference between the olanzapine and olanzapine-fluoxetine groups ($F_{1,658}=0.16$; $P=.69$). The incidence of treatment-emergent glucose elevation of 200 mg/dL or greater (≥11.1 mmol/L) was 0.3% (1/298) for the placebo group, 1.4% (4/289) for the olanzapine group, and 1.5% (1/65) for the olanzapine-fluoxetine group. These percentages were not significantly different (overall $P=.30$).

COMMENT

To our knowledge, this is the first placebo-controlled trial comparing the use of an antipsychotic or mood-stabilizing agent alone and in combination with an antidepressant agent. Results indicate that olanzapine therapy significantly improved depressive symptoms in patients with bipolar depression and that the olanzapine-fluoxetine combination had an even more robust antidepressant effect without a greater risk of switch into mania. The reduction in depressive symptoms by both therapies was evident by week 1 of acute therapy and was maintained throughout the 8-week trial. The olanzapine-fluoxetine combination was statistically significantly superior in all efficacy measures of depression compared with olanzapine monotherapy, including higher completion rates, lower discontinuation rates due to adverse events, higher rates of response and remission, and quicker times to response and remission. Analysis of the individual items on the MADRS indicated that the olanzapine-fluoxetine combination, but not olanzapine, was effective at reducing core mood symptoms of depression.

Despite some methodological and sample differences, the present findings may be compared with those of a recent double-blind, placebo-controlled, 7-week study of lamotrigine therapy for bipolar I depression.[11] In that study, patients receiving lamotrigine had MADRS response rates of 48% to 54%, depending on dose, with a placebo response rate of 29%. The present study had response rates of 39% for olanzapine and 56% for olanzapine-fluoxetine, with a placebo response rate of 30%. Note, however, that the present study required at least 4 weeks of treatment to be eligible for response. Also, comparison of baseline illness characteristics indicates that the lamotrigine sample may have been less symptomatic, as indicated by fewer melancholic patients, no inpatients, and no patients with a rapid cycling course.

Divalproex sodium, another anticonvulsant agent known to be effective in treating bipolar mania,[32,33] has also been studied in bipolar depression. In an 8-week, double-blind pilot study of bipolar I and II patients with major depression, Sachs and collaborators[34] found that patients treated with divalproex had a recovery rate of 43% compared with the placebo rate of 27%, with recovery defined as a 50% improvement on the Hamilton Depression Rating Scale and a YMRS score less than 10. However, this difference was not statistically significant.

Regarding the possibility of treatment-emergent mania, the present findings indicate no additional risk when fluoxetine was added to olanzapine therapy. Mean ratings of manic symptoms, which were low at baseline, showed small (not clinically meaningful) but statistically significant improvement in patients treated with olanzapine and olanzapine-fluoxetine compared with placebo. Moreover, there were no significant differences in the incidences of treatment-emergent mania among the 3 groups. Lastly, the rates of treatment-emergent mania reported in this study approximate those reported previously for placebo[11,35] and are lower than rates reported with tricyclic antidepressant use.[35]

In terms of safety, the olanzapine adverse event profile was consistent with previously reported findings,[36,37] whereas the olanzapine-fluoxetine profile was similar to that of olanzapine, except for higher rates of nausea and diarrhea. Mean weight increases of 2.6 and 2.8 kg were noted in patients treated with olanzapine and olanzapine-fluoxetine, respectively, and small but statistically significant mean increases in glucose and cholesterol levels were also seen.

One question raised by the present findings is whether similar results could be achieved by using other atypical antipsychotic agents, such as risperidone or quetiapine, in combination with a selective serotonin reuptake inhibitor or other antidepressants. Controlled clinical trials are needed to determine the therapeutic efficacy of different combinations. The safety of such combinations must be considered as well.

Limitations of the present study should be noted when interpreting the results. One limitation was the high overall dropout rate. Although the present rates were in line with those of a previous 6-week study[38] of bipolar depression, which reported a placebo group completion

rate of 34% (compared with 38.5% in the present 8-week study), this is in direct contrast to the placebo group completion rate of 71% in the 7-week lamotrigine study,[11] which may have had a less severe and more stable population given that rapid cyclers were excluded. Nevertheless, examination of the current between-group differences in dropout due to lack of efficacy is informative. The higher rate of dropout due to lack of antidepressant efficacy with olanzapine monotherapy suggests that although this treatment may be effective for some patients, the addition of an appropriately tested antidepressant drug may be warranted for others. Another limitation was the lack of a fluoxetine monotherapy comparison arm because of concerns regarding possible induction of mania. Future studies might also more thoroughly address the issue of patients' baseline proneness to mania. For example, the present finding that the addition of fluoxetine did not increase the risk of mania would be further strengthened by similar findings in a bipolar I depressed population specifically selected for recent manic episodes. Studies with longer durations are necessary to evaluate maintenance of response and to determine the safety and efficacy of olanzapine monotherapy after treatment with olanzapine-fluoxetine combination therapy. Also, head-to-head controlled trials would be useful to establish how the efficacy of this combination compares with that of lamotrigine or other putative combination treatments for bipolar depression.

In summary, the results of this study suggest that although olanzapine may be effective in the treatment of bipolar depression, these effects are significantly enhanced with the coadministration of fluoxetine. In addition, patients receiving such combination therapy did not demonstrate any higher likelihood of treatment-emergent mania. The roles of olanzapine and olanzapine-fluoxetine, as well as other combinations of antidepressants with lithium, anticonvulsants, or atypical antipsychotics, in the longer-term treatment of patients with bipolar disorder should be further evaluated in controlled studies.

A Rating Scale for Mania: Reliability, Validity and Sensitivity*

By R. C. YOUNG, J. T. BIGGS, V. E. ZIEGLER and D. A. MEYER

SUMMARY An eleven item clinician-administered Mania Rating Scale (MRS) is introduced, and its reliability, validity and sensitivity are examined. There was a high correlation between the scores of two independent clinicians on both the total score (0.93) and the individual item scores (0.66 to 0.92). The MRS score correlated highly with an independent global rating, and with scores of two other mania rating scales administered concurrently. The score also correlated with the number of days of subsequent stay in hospital. It was able to differentiate statistically patients before and after two weeks of treatment and to distinguish levels of severity based on the global rating.

Introduction

While several rating scales are available to quantitate the severity of depression (Hamilton, 1960, 1976), there is a less satisfactory choice of instruments for the rating of mania. Treatment studies of mania frequently employ a global rating combined with a non-specific scale such as the Brief Psychiatric Rating Scale (Overall and Gorham, 1962). Dissatisfaction with the results of this type of rating procedure has been expressed (Shopsin *et al*, 1975).

Attempts to devise a specific scale for quantitating the severity of mania have been limited. Beigel *et al* (1971) reported a ward behaviour rating scale for mania (Beigel Scale) intended to be completed by nursing personnel. This scale consists of twenty-six items. A frequency score (0 to 5) and an intensity score (1 to 5) are assigned separately, and the individual item score is the product of these ratings. The reliability and validity of the scale have been examined in detail by its developers (Beigel and Murphy, 1971; Murphy *et al*, 1974). Bech *et al* (1975) reported on its use both as a ward rating scale and as a clinician-administered interview scale. It has also been utilized in a treatment study (Murphy and Beigel, 1974). Blackburn *et al* (1977) have recently modified the Beigel Scale for interview use, expanding it to twenty-eight items.

Petterson *et al* (1973) reported a clinician-administered interview scale for mania (Petterson Scale) consisting of seven items, each scored on a one to five scale of severity. The Petterson Scale evaluates a more narrow range of abnormal signs and symptoms than the Beigel Scale but gives explicit definitions for the various grades of severity within each item. The Petterson Scale appears to sacrifice breadth for potentially greater inter-rater agreement, particularly between centres.

Experience with these scales has indicated the need for a clinician-administered interview scale with broader scope and greater sensitivity than the Petterson Scale, but shorter and more explicit in its rating of item severity than the Beigel Scale. The Mania Rating Scale (MRS) reported here (Appendix) consists of eleven items, each with five explicitly defined grades of severity. The choice of items was made on the basis of published descriptions of the core symptoms of the manic phase of bipolar affective disorder (Winokur *et al*, 1969; Carlson and Goodwin, 1973) and includes those abnormalities which were felt to exist over the entire range

* Supported in part by U.S. Public Health Service Grant MH 05804.

of illness from mild to severe. Depressive symptoms, although frequently present in mania, were omitted, since previous reports (Beigel *et al*, 1971; Blackburn *et al*, 1977) have shown them to be poorly correlated with the severity of mania.

The MRS follows the style of the Hamilton Rating Scale for depression (Hamilton, 1960) and is intended to be administered by a trained clinician during a fifteen- to thirty-minute interview. A severity rating is assigned to each of the eleven items, based on the patient's subjective report of his or her condition over the previous forty-eight hours and the clinician's behavioural observations during the interview, with the emphasis on the latter. Four items (5, 6, 8 and 9) are given twice the weight of the remaining seven in order to compensate for poor cooperation from severely ill patients. This report introduces the MRS and examines its reliability, validity and sensitivity.

Method

The MRS was examined by paired evaluations of manic patients on several measures during an eight-hour period. Two psychiatrists (R.Y. and J.B.) trained in the use of the MRS and the Petterson Scale administered both scales independently during a joint fifteen- to thirty-minute semi-structured interview with the patient. Two independent psychiatrists (V.Z. and D.M.) assigned a global rating after a joint unstructured interview of similar duration. An eight-point global rating was used (euthymic 0, 1; hypomanic, 2, 3; manic, 4, 5; severely manic, 6, 7). Members of the hospital nursing staff were trained in the use of the Beigel Scale, and on the day of evaluation two nurses completed this scale independently, based on their observations over an eight-hour period. The training period for the two psychiatrists who administered the MRS and the Petterson Scale consisted of six practice interviews, each followed by a discussion between the interviewers of the ratings assigned.

During a three-month period, all adult patients admitted to Renard Hospital, the teaching hospital of Washington University, were evaluated. Consecutive patients meeting research criteria for the diagnosis of mania (Feighner *et al*, 1972) were asked to participate in the study. No patient refused to participate. Twenty patients were evaluated during their first week in hospital, and fifteen of these were re-evaluated two weeks after the initial interview. In the interval, patients were treated in an uncontrolled manner by their individual psychiatrists, who were unaware of the scores. The usual treatment consisted of a combination of lithium carbonate and neuroleptics. A total of thirty-five sets of ratings was obtained. The number of days from each rating to discharge was noted, and thirty days after discharge the patient was followed up to determine if re-admission had been necessary.

Since rating scales yield ordinal level measures, non-parametric statistics (Spearman rank-order correlation coefficient, Kruskal-Wallis one-way analysis of variance, and the Mann-Whitney U Test) were used throughout the analysis (Siegel, 1956). All probabilities are two-tailed.

Results

Reliability

The inter-rater reliability of the MRS was examined by comparing the scores assigned by the two physicians independently administering the scale during a joint interview. These correlations for the total score and the individual item scores of the MRS are given in Table I along with the inter-rater reliability of the global rating, the Petterson Scale, and the Beigel Scale. The lower correlation between the two nurses completing the Beigel Scale is expected, since 12 members of the nursing staff participated in the study, thus introducing more variation in the completion of the scale. The correlation between the total scores on the MRS was 0.93 and ranged from 0.66 for item 9, disruptive-aggressive behaviour, to 0.95 for item 4, sleep. All correlations were significant at the 0.001 level.

Validity

The concurrent validity was examined by correlating the mean score of the two raters completing each scale with the mean scores of the other scales. These correlations are given in Table II. All were significant at the 0.001 level. The total scores on the MRS correlated

TABLE I

Interrater reliability. Spearman rank-order correlation coefficient (r_s) between the two raters for each scale and for the individual items of the MRS ($N = 35$)

Scale	Correlation (r_s)*
Global rating	0.77

*P < 0.001 for all correlations

highly with the global rating (0.88) and the Petterson Scale (0.89). The correlation with the Beigel scale, although of a lower magnitude (0.71), was acceptable. The correlation between the global rating and the MRS score for the twenty initial interviews was 0.86 (P < 0.001) and for the fifteen repeated interviews was 0.53 (P < 0.05). The lower correlation for the repeated interviews is a reflection of the more narrow range of scores.

TABLE II

Spearman rank-order correlation coefficient between the various rating scales ($N = 35$)

Ratings	Global	Beigel	Petterson
Mania rating scale	0.88	0.71	0.89
Petterson scale	0.80	0.65	—
Beigel scale	0.66	—	—

P < 0.001 for all correlations

The correlations between the change in the global rating and the changes in the various scales were calculated for the fifteen patients rated on two occasions. This correlation was 0.76 (P < 0.05) for the MRS, 0.80 (P < 0.01) for the Petterson Scale, and 0.54 (P < 0.05) for the Beigel Scale.

The correlations between the individual items of the MRS and the total MRS score and the global rating are given in Table III. The correlations between the item scores and the total score ranged from 0.41 for item 10, appearance, to 0.85 for item 7, language-thought disorder. The correlations between the item scores and the global rating ranged from 0.32 for item 10, appearance, to 0.85 for item 7, language-thought disorder.

TABLE III

Spearman rank-order correlation coefficient (r_s) of the individual items of the Mania Rating Scale (MRS) with the total score and the global rating ($N = 35$)

Individual MRS item with:	Total MRS score*	Global score*
1. Mood	0.76	0.75
2. Energy	0.84	0.79
3. Sexual interest	0.69	0.67
4. Sleep	0.59	0.61
5. Irritability	0.56	0.39
6. Speech	0.64	0.60
7. Language-Thought disorder	0.85	0.85
8. Content	0.84	0.77
9. Disruptive-Aggressive behaviour	0.64	0.43
10. Appearance	0.41	0.32
11. Insight	0.57	0.40

*$r_s \geq 0.35$, P < 0.050 $r_s \geq 0.45$, P < 0.01; $r_s \geq 0.56$, P < 0.001

The predictive validity of the various scales was examined by correlating the scores with the number of days of continued stay in hospital following completion of the scale. This correlation was 0.66 (P < 0.001) for the MRS, 0.58 (P < 0.001) for the Beigel Scale and 0.50 (P < 0.01) for the Petterson Scale. Two of the three patients with total MRS scores greater than 15.0 who were discharged within one week of being rated were readmitted within thirty days. None of the patients with lower MRS scores, discharged within one week, were re-admitted during this interval.

Sensitivity

The sensitivity of the various scales was examined by comparing the scores before and after two weeks of treatment, for the 15 patients on whom these ratings were available, by the Mann-Whitney U Test. The MRS differentiated the pre-treatment and post-treatment scores at the 0.005 level, as did the Petterson Scale and the Beigel Scale. The pre-treatment and post-treatment scores on the three scales were not significantly correlated (MRS, 0.05; Petterson, 0.31; Beigel, 0.35).

A more rigorous test of sensitivity of the MRS was undertaken by dividing the 35 sets of ratings into four groups based on the severity of the global rating, with sample sizes as equal as possible. The ability of the MRS to differentiate these four groups overall and from adjacent severity levels was then examined and compared to that of the Petterson and Beigel Scales. The median scores on each of the four severity groups and the results of the Kruskal-Wallis one-way analysis of variance are given in Table IV. The distributions of all three scales were significant at the 0.001 level. The ability of each scale to differentiate each severity level from adjacent levels by the Mann-Whitney U Test was then examined. These results are given in Table V. The Petterson Scale did poorly in the mild range and the Beigel Scale in the mid-severity range. The MRS was the most consistent of the three scales over the entire range of severity.

TABLE V

Sensitivity of the three scales in differentiating a severity level based on the global rating, from adjacent levels

Severity levels to be differentiated (Global)	Probability of the differentiation	
	Scale	p*
I (0 to 1.5) from II (2.0 to 2.5)	Mania rating scale	<0.070
	Petterson scale	<0.960
	Beigel scale	<0.016
II (2.0 to 2.5) from III (3.0 to 4.0)	Mania rating scale	<0.021
	Petterson scale	<0.012
	Beigel scale	<0.562
III (3.0 to 4.0) from IV (>4.0)	Mania rating scale	<0.003
	Petterson scale	<0.004
	Beigel scale	<0.004

*By the Mann-Whitney U test.

To examine the effect of weighting four (5, 6, 8 and 9) of the eleven items of the MRS twice as heavily as the remaining items, the analysis presented was repeated without the weighting. Only minor variations occurred, none of which affected the reliability, validity or sensitivity of the MRS. This was because only a few of the patients rated in this study were severely agitated. If more had fallen into this category the advantage of the weighted items would have become evident. This is based on experience during the development of the scale, when a minority of patients with acute mania

TABLE IV

Median rating scale scores of the patients grouped by the global severity and the probabilities of the distributions

	Severity by global rating				
	I	II	III	IV	
Global Rating	0—1.5	2.0—2.5	3.0—4.0	>4.0	
N	11	7	11	6	p*
Mania rating scale	12.5	19.3	25.5	37.9	<0.001
Petterson scale	12.5	11.8	16.5	22.0	<0.001
Beigel scale	31.0	80.0	59.3	161.8	<0.001

* By the Kruskal-Wallis one-way analysis of variance.

were found to be so severely agitated that the usual semi-structured interview was impossible. The weighting allowed these patients to be rated in an abbreviated manner while still yielding scores representative of the severity of mania present.

Discussion

The MRS was found to be a reliable, valid and sensitive rating scale to measure the severity of mania by the criteria for psychiatric rating scales discussed by Hamilton (1974). The scale appears to function over the entire range of severity and is sensitive to differences in severity in sample sizes similar to those found in treatment or biological studies. The scale is not intended to be used as a diagnostic instrument. It appears to measure the manic 'state', as opposed to traits, since there was virtually no correlation between scores in individuals rated before and after two weeks of treatment.

The MRS should have a high degree of inter-centre reliability, since specific instructions are given for scoring the severity of each item. In a separate procedure this characteristic was examined. Nine psychiatric residents participated in one of two group interviews with the same patient on the same day. Each completed the MRS without exposure to the scale prior to the interview. The scores assigned by the nine residents ranged from 10 to 22 with a mean of 14.5 and a standard deviation of 3.3. These results were felt to support the communicability of the MRS.

There has been a limited selection of rating scales with which to evaluate mania. While the two existing mania scales function reasonably well, the MRS adds a broader and more sensitive instrument than the Petterson Scale and is both shorter and more explicitly defined than the Beigel Scale or its modified versions.

The usual practice in psychopharmacological studies has been to use a number of different scales with a central focus to measure various aspects of behaviour, such as the use of both self-rating and clinician-administered scales in depression studies. In studies where the quantification of the severity of mania is required, the combined use of a ward behaviour scale, such as the Beigel Scale, and a clinician-administered interview scale is recommended.

Acknowledgements

We wish to express our appreciation to the nursing staff of Renard Hospital and to Ms Patricia Stanfield, R.N., in particular, for their assistance in this project.

Appendix: Mania Rating Scale

Guide for Scoring Items—The purpose of each item is to rate the severity of that abnormality in the patient. When several keys are given for a particular grade of severity, the presence of only one is required to qualify for that rating.

The keys provided are guides. One can ignore the keys if that is necessary to indicate severity, although this should be the exception rather than the rule.

Scoring between the points given (whole or half points) is possible and encouraged after experience with the scale is acquired. This is particularly useful when severity of a particular item in a patient does not follow the progression indicated by the keys.

1. *Elevated Mood*
   0. Absent
   1. Mildly or possibly increased on questioning
   2. Definite subjective elevation; optimistic, self-confident; cheerful; appropriate to content
   3. Elevated, inappropriate to content; humorous
   4. Euphoric; inappropriate laughter; singing

2. *Increased Motor Activity-Energy*
   0. Absent
   1. Subjectively increased
   2. Animated; gestures increased
   3. Excessive energy; hyperactive at times; restless (can be calmed)
   4. Motor excitement; continuous hyperactivity (cannot be calmed)

3. *Sexual Interest*
   0. Normal; not increased
   1. Mildly or possibly increased
   2. Definite subjective increase on questioning
   3. Spontaneous sexual content; elaborates on sexual matters; hypersexual by self-report
   4. Overt sexual acts (toward patients, staff, or interviewer)

4. *Sleep*
   0. Reports no decrease in sleep
   1. Sleeping less than normal amount by up to one hour
   2. Sleeping less than normal by more than one hour
   3. Reports decreased need for sleep
   4. Denies need for sleep

5. *Irritability*
   0. Absent
   2. Subjectively increased
   4. Irritable at times during interview; recent episodes of anger or annoyance on ward
   6. Frequently irritable during interview; short, curt throughout
   8. Hostile, unco-operative; interview impossible.

6. *Speech (Rate and Amount)*
   0. No increase
   2. Feels talkative
   4. Increased rate or amount at times, verbose at times
   6. Push; consistently increased rate and amount; difficult to interrupt
   8. Pressured; uninterruptible, continuous speech

7. *Language-Thought Disorder*
   0. Absent
   1. Circumstantial; mild distractibility; quick thoughts
   2. Distractible; loses goal of thought; changes topics frequently; racing thoughts
   3. Flight of ideas; tangentiality; difficult to follow; rhyming, echolalia
   4. Incoherent; communication impossible

8. *Content*
   0. Normal
   2. Questionable plans, new interests
   4. Special project(s); hyperreligious
   6. Grandiose or paranoid ideas; ideas of reference
   8. Delusions; hallucinations

9. *Disruptive-Aggressive Behaviour*
   0. Absent, co-operative
   2. Sarcastic; loud at times, guarded
   4. Demanding; threats on ward
   6. Threatens interviewer; shouting; interview difficult
   8. Assaultive; destructive; interview impossible

10. *Appearance*
    0. Appropriate dress and grooming
    1. Minimally unkempt
    2. Poorly groomed; moderately dishevelled; overdressed
    3. Dishevelled; partly clothed; garish make-up
    4. Completely unkempt; decorated; bizarre garb

11. *Insight*
    0. Present; admits illness; agrees with need for treatment
    1. Possibly ill
    2. Admits behaviour change, but denies illness
    3. Admits possible change in behaviour, but denies illness
    4. Denies any behaviour change
