Study dates		**Phase of development**
First patient enrolled	30 September 2002	Therapeutic use (IV)
Last patient completed	17 September 2003	

Objectives

Primary:

To evaluate the efficacy of quetiapine compared to placebo in the treatment for a major depressive episode in patients with bipolar disorder after receiving treatment for up to 8 weeks as assessed by comparing

1. The change from baseline to final assessment in the Montgomery-Asberg Depression Rating Scale (MADRS) total score
2. the percentage of patients with a ≥50% reduction from baseline in the MADRS total score at final assessment
3. the change from baseline to each assessment in the MADRS total score

4. the change from baseline to each assessment in the Hamilton Rating scale for Depression (HAM-D), HAM-D Item 1, and the Clinical Global Impression – Severity (CGI-S)

5. the Clinical Global Impression – Improvement (CGI-I)

Secondary:

1. to evaluate the incidence of treatment-emergent mania compared to placebo by comparing the percentage of patients who meet the criteria for treatment-emergent mania on the Young Mania Rating Scale (YMRS) or report an adverse event of mania or hypomania

2. to evaluate the effect of quetiapine on anxiety compared to placebo by comparing

   – the change from baseline to final assessment in the Hamilton Rating Scale for Anxiety (HAM-A) total score

   – the change from baseline to each assessment in the Hamilton Rating Scale for Anxiety (HAM-A) total score

3. to evaluate the safety and tolerability of quetiapine in the treatment of patients with bipolar depression by comparing

   – the incidence and nature of all adverse events

   – the incidence and nature of drug-related adverse events

   – patient withdrawal due to adverse events during double-blind treatment

   – the number of patients having clinically significant changes in vital signs from baseline to end of treatment

   – the change in Simpson-Angus Scale (SAS) total score

   – the change in Barnes Akathisia Rating Scale (BARS)

   – the incidence of adverse events related to extrapyramidal symptoms during double-blind treatment

Exploratory

1. to evaluate the efficacy of quetiapine on sleep quality by comparing the change in the Pittsburgh Sleep Quality Index (PSQI) from baseline to end of treatment

2. to evaluate the efficacy of quetiapine on the overall quality of life using the Quality of Life Enjoyment and Satisfaction Questionnaire (Q-Les-Q) from baseline to end of treatment.

Study design

This study was a randomized, multicenter, double-blind, placebo-controlled, double-dummy, parallel group, fixed-dose comparison of quetiapine vs placebo in the treatment of bipolar depression. Randomized treatment assignment was stratified in a 1:1:1 ratio for drug within bipolar diagnosis (bipolar I vs bipolar II).

Target subject population and sample size

Outpatients, aged 18 to 65 years, with a diagnosis of bipolar I or bipolar II disorder with a current major depressive episode of duration less than one year but greater than 4 weeks were enrolled in the trial. The patient's HAM-D (17-item scale) score had to be ≥20; the HAM-D item 1 (depressed mood) score had to be ≥2; the YMRS score had to be ≤12 at both Visit 1 and Visit 2 (randomization) for the patient to be eligible for entry into the trial. Approximately 530 patients were expected to be enrolled in the trial to obtain 504 evaluable patients.

Investigational product and comparator: dosage, mode of administration and batch numbers

Quetiapine fumarate was increased in a blinded manner to a total daily dose of 300 mg/day by Day 4 in the 300-mg/day treatment group and to a total daily dose of 600 mg/day by Day 8 in the 600 mg/day treatment group. Thereafter, oral doses of the study drug were administered in a blinded fashion once daily at bedtime (qhs) in a dose of 300 or 600 mg/day. One-time dose reductions for intolerability of 100 mg/day in both the 300 mg/day and in the 600 mg/day treatment groups were allowed at the discretion of the investigator after Day 8. Placebo was administered once daily with tablets matching in number and appearance to blinded quetiapine dosing. Study treatment was given in tablets of the following doses (lot #): quetiapine 25 mg (7527F), quetiapine 100 mg (7513H), quetiapine 200 mg (7541F), placebo 25 mg match (7553F), placebo 100 mg match (7550F), placebo 200 mg match (1509C).

Duration of treatment

Patients received double-blind, double-dummy treatment for up to 8 weeks (56 days), following an initial washout period of between 7 to 28 days (depending on the medications involved) and came in to the clinic on Day 57 for final assessments.

Criteria for evaluation (main variables)

Efficacy

- Primary variable: Montgomery-Asberg Depression Rating Scale (MADRS) Total score change from baseline at last assessment

- Secondary variables: Percentage of patients with a ≥50% reduction from baseline to final MADRS Total score, MADRS Total score change from baseline at each assessment, Hamilton Rating Scale for Depression (HAM-D), HAM-D Item 1, Clinical Global Impression Severity of Illness (CGI-S) score, Clinical Global Impression Improvement (CGI-I) score, Young Mania Rating Scale (YMRS) Total score, Hamilton Rating Scale for Anxiety (HAM-A), Pittsburgh Sleep Quality Index (PSQI), Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q)

Safety

Safety assessments included: adverse events, patient withdrawal due to adverse events, adverse events of special interest (EPS, diabetes, mania/hypomania, suicidality), hematology and chemistry findings, vital signs, Simpson-Angus Scale (SAS), the Barnes Akathisia Rating Scale (BARS) and specific inquiries of relevant data for metabolic syndrome, cardiac function, neutropenia/agranulocytosis and thyroid function.

Statistical methods

All statistical tests were 2-sided. The primary analyses used last observation carried forward (LOCF) for the time period of interest. Analysis of Covariance (ANCOVA) was used for comparative analysis of continuous variables with the baseline score as the covariate and including treatment and diagnosis strata as fixed effects and center as a random effect in the model. The Simes-Himmel step up procedure was used to control for multiple comparisons with placebo for the MADRS change from baseline in order to preserve the overall experiment-wise error rate and conserve power. Cochran-Mantel-Haenszel Chi square tests (CMH) were used for categorical comparisons. Descriptive statistics were used for safety assessments except for SAS and BARS which were analyzed by CMH.

Subject population

Baseline subject characteristics are shown in Table S1.

N (%) of patients	Completed	121	98	107
	Discontinued	60	82	74
N safety[a]		179	180	180
N efficacy ITT[b]		172	170	169
N efficacy PP		152	147	154

a Number of subjects who received at least one dose of study drug
b Number of subjects who took at least 1 dose of study treatment and had at least 1 data point after dosing, excluding 2 patients who enrolled at 2 separate sites.
ITT=Intention to treat; N=Number; PP=Per-protocol

The three groups were well-matched as to number and demographic and baseline disease characteristics. Adverse events were the main reason for withdrawal in quetiapine-treated patients, while lack of efficacy was the main reason for withdrawal in placebo-treated patients.

Efficacy results

The comparison of change from baseline in total MADRS score supported the hypothesis that quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment of a

depressive episode in patients with bipolar disorder was superior to placebo in reducing the level of depressive symptoms. A treatment advantage for quetiapine over placebo was statistically significant by Day 8 and continued to be so through Day 57. Analysis of secondary outcome variables also supported the superiority of quetiapine over placebo in the treatment of depression in patients with bipolar disorder. For most secondary outcome variables the treatment advantage was apparent by Day 8 and continued through Day 57.

Table S2 Efficacy results at final assessment (LOCF, ITT population)

Outcome variable	Quetiapine 300 mg (N=172)		Quetiapine 600 mg (N=170)		Placebo (N=169)	
	Day 8	Day 57	Day 8	Day 57	Day 8	Day 57
MADRS LS mean change from baseline	-8.67[a]	-16.39[a]	-8.78[a]	-16.73[a]	-4.89	-10.26
Proportion with ≥50% MADRS response	17%	58%[a]	24%[a]	58%[a]	11%	36%

a $p<0.001$ comparison with placebo
b $p<0.01$ comparison with placebo
c $p<0.05$ comparison with placebo

Safety results

Both the 300 mg and 600 mg once-daily doses of quetiapine were generally well-tolerated. Analysis of adverse events indicated that nervous and gastrointestinal events predominated, with dry mouth, sedation, somnolence, dizziness and constipation occurring at higher rates with quetiapine compared to placebo. Most adverse events were mild to moderate. Sedation and somnolence were the adverse events most associated with discontinuation by quetiapine-treated patients, with higher rates of discontinuation in the quetiapine 600 mg group. SAEs were infrequent in all treatment groups. Treatment emergent mania and hypomania were low in incidence and did not differ across the treatment groups. An increase in the incidence of EPS events was noted for both groups of quetiapine-treated patients. The incidence of adverse events associated with suicidality for quetiapine-treated patients was no different than that for placebo-treated patients. No cases of neutropenia or agranulocytosis following quetiapine

treatment were reported. Increases in weight, triglycerides, total cholesterol and LDL, and decreases in HDL were consistent with the known safety profile for quetiapine.

Table S3 Adverse event overview (safety population)

Category of adverse event	Number (%) of subjects who had an adverse event in each category[a]					
	Quetiapine 300 mg (N=179)		Quetiapine 600 mg (N=180)		Placebo (N=180)	
Any adverse events	166	(92.7)	165	(91.7)	148	(82.2)
Serious adverse events	6	(3.4)	9	(5.0)	16	(8.9)
Serious adverse events leading to death	0	(0)	0	(0)	0	(0)
Discontinuations of study treatment due to adverse events	29	(16.2)	47	(26.1)	15	(8.3)

[a] Subjects with multiple events in the same category are counted only once in that category. Subjects with events in more than 1 category are counted once in each of those categories.

Conclusions

- Quetiapine in doses of either 300 mg or 600 mg once-daily was superior to placebo in treating depression in patients with bipolar disorder.
- The antidepressant effect of quetiapine treatment was observed as early as 7 days after treatment initiation and was maintained throughout the 8-week treatment course.
- Quetiapine in doses of either 300 mg or 600 mg once-daily was superior to placebo in treating anxiety symptoms in patients with bipolar disorder who were experiencing a depressive episode.
- Quetiapine in doses of either 300 mg or 600 mg once-daily was superior to placebo in improving the quality of life for patients with bipolar disorder who were experiencing a depressive episode.
- Quetiapine in a dose of either 300 mg or 600 mg once-daily was generally safe and well-tolerated in patients with bipolar disorder who were experiencing a depressive episode. A higher rate of discontinuations due to sedation and dizziness was seen with the 600 mg once-daily dose. The most common adverse events associated with quetiapine treatment were dry mouth, somnolence, sedation, dizziness and constipation.
- Quetiapine in doses of either 300 mg or 600 mg once-daily was associated with low rates of treatment-emergent mania or hypomania similar to placebo.

1. ETHICS

1.1 Ethics review

The study protocol, including Amendments 1 through 5, was approved by the Institutional Review Board (IRB) for each study site.

Names and addresses of each of the IRBs for each of the centers is provided in Appendix 12.1.3.

1.2 Ethical conduct of study

The study was performed in accordance with the ethical principles that have their origin in the Declaration of Helsinki and that are consistent with ICH/Good Clinical Practice and applicable regulatory requirements and the AstraZeneca policy on Bioethics.

1.3 Patient information and consent

Patients gave written, informed consent before screening. The master version of the consent form is included in Appendix 12.1.2.

2. INVESTIGATORS AND STUDY ADMINISTRATIVE STRUCTURE

2.1 Staff at investigational sites

Participating personnel at study sites are listed in Appendix 12.1.4.1.

2.2 AstraZeneca study personnel

2.3 Other participants

2.3.1 Non-sponsor organizations or individuals

Monitoring of study sites, clinical data base administration, and safety reporting services were provided by Lineberry Research Associates, Inc (LRA). A complete list of participating LRA personnel is included in Appendix 12.1.4.4.

ECG scoring and interpretation was performed by eResearch Technology, Inc. A complete list of participating eResearch Technology personnel is included in Appendix 12.1.4.4.

Quintiles Laboratories served as the central laboratory for this trial. A complete list of participating Quintiles Laboratories personnel is included in Appendix 12.1.4.4.

Concordant Raters, Inc. trained investigators in the administration of the Montgomery-Asberg Depression Rating Scale (MADRS), the Hamilton Rating scale for Depression (HAM-D), the Hamilton Rating scale for Anxiety (HAM-A) and the Young Mania Rating Scale (YMRS). Concordant Raters also supplied the ICI-D to selected study sites and monitored results of

testing (see Section 5.6.1). A complete list of participating Concordant Raters personnel is included in Appendix 12.1.4.4.

Randomization of treatment assignments was provided by Interactive Clinical Technologies, Inc. (ICTI). A complete list of participating ICTI personnel is included in Appendix 12.1.4.4.

2.3.2 Study committee(s)

No study committees were utilized for this trial.

3. INTRODUCTION

Quetiapine fumarate (SEROQUEL®, quetiapine) is a dibenzothiazepine derivative approved by the United States Food and Drug Administration (FDA) on 26 September 1997 following clinical development by AstraZeneca Pharmaceuticals LP (also referred to as the sponsor) for the treatment of subjects with schizophrenia. Quetiapine fumarate is designated chemically as bis [2-(2-[4-(dibenzo[b,f][1,4]thiazepin-11-yl) piperazin-1-yl]ethoxy)ethanol] fumarate.

The bipolar disorders are psychiatric disorders in which a disturbance in mood is the predominant feature. Bipolar I disorder is characterized by one or more manic or mixed episodes, usually accompanied by major depressive episodes. Bipolar II disorder is characterized by one or more major depressive episodes accompanied by at least one hypomanic episode. Bipolar depression refers to the major depressive episodes that occur with bipolar I and II disorder.

The prevalence of bipolar disorder is estimated to be 1 to 3.5%, evenly divided between men and women. The length of time between onset and symptoms and proper diagnosis and treatment is approximately 10 years and it is estimated that only 60% of those suffering from a bipolar disorder are receiving appropriate pharmacotherapy.

Although there is extensive and emerging literature guiding the treatment of the manic phase of bipolar I disorder as well as many approved compounds for the treatment of unipolar depression, the treatment of bipolar depression has not been as widely studied. The use of currently available antidepressants for monotherapy for bipolar depression may require careful clinical monitoring as they may “switch” patients into hypomania or mania from depression, or increase cycle acceleration in patients with a rapid cycling course. The adjunctive use of mood stabilizing medications such as lithium carbonate ($LiCO_3$) is common and may decrease the likelihood of these complications.

Evidence indicates that medications with mood stabilizing properties which produced low levels of mania, hypomania, or cycle acceleration may be useful as monotherapy in the treatment of bipolar depression. The antiepileptic lamotrigine produced improvement in HAM-D and MADRS scores in a 7-week, double-blind, placebo controlled trial for the patients who completed this study (Calabrese 1999). The anti-manic agent divalproex demonstrated numerical improvement over placebo in the percentage of patients with bipolar depression having a 50% reduction in the HAM-D scores without mania in an 8 week trial

(Sachs 2001) but this difference was not statistically significant. Lithium carbonate, also approved for the treatment of mania, has been demonstrated to be effective in reducing the recurrence of bipolar depression (Baldessarini et al 2002).However, there are efficacy and tolerability limitations which may prohibit widespread use of divalproex, lamotrigine or lithium.

Currently there is only one product, a combination tablet of the antidepressant fluoxetine and the atypical antipsychotic olanzapine (OFC), that has been approved for marketing only in the US for the treatment of bipolar depression. The approval was based on two placebo controlled trials, in which OFC-treated patients (combined N=83) demonstrated significantly greater improvement in mean MADRS change than did patients treated with olanzapine monotherapy, or placebo. In these trials, patients treated with olanzapine alone (N=833) also demonstrated significant improvement in MADRS mean change, but without the addition of the antidepressant, the magnitude of effect was lower than that seen with the combination (Tohen et al 2003).

There is some evidence that medications with mood stabilizing properties may be useful as monotherapy in the treatment of bipolar depression. The potential efficacy of quetiapine in depressive symptoms is provided in data from the Quetiapine Experience with Safety and Tolerability Trial (QUEST) and from investigator-initiated trials in mood disorder patients. In an open-label trial evaluating the safety and tolerability of quetiapine over 700 subjects with schizophrenia and other psychotic disorders were randomized to treatment with quetiapine or risperidone (Sajatovic et al 2002). Quetiapine-treated patients experienced a greater improvement in depressive symptoms compared with risperidone-treated patients, with a mean difference of 1.3 points on the HAM-D after adjustment for baseline differences (P=0.028).

A trial of quetiapine in 20 neuroleptic-dependent patients with bipolar or schizoaffective disorder also suggested positive effects on the depressive and psychotic symptoms in these disorders (Sajatovic et al 2001). Overall, in 10 patients with bipolar disorder and 10 with schizoaffective disorder who received open-label quetiapine, significant improvement in Brief Psychiatric Rating Scale (BPRS), Young Mania Rating Scale (YMRS), and HAM-D scores was noted.

In summary, the paucity of satisfactory treatments available signify an unmet medical need for the treatment of bipolar depression. There are signals of efficacy from clinical trials for the antidepressant properties of atypical antipsychotics such as quetiapine.

4. STUDY OBJECTIVES

4.1 Primary objectives

The primary objectives of the study were to evaluate the efficacy of quetiapine compared to placebo in the treatment for a major depressive episode in patients with bipolar disorder after receiving treatment for up to 8 weeks by comparing

1. the change from baseline to final assessment in the Montgomery-Asberg Depression Rating Scale (MADRS) total score

2. the percentage of patients with a ≥50% reduction from baseline in the MADRS total score at final assessment

3. the change from baseline to each assessment in the MADRS total score

4. the change from baseline to each assessment in the total Hamilton Rating Scale for Depression (HAM-D), HAM-D Item 1, and the Clinical Global Impression - Severity (CGI-S), and the Clinical Global Impression - Improvement (CGI-I).

4.2 Secondary objectives

The secondary objectives of the study were:

1. to evaluate the incidence of treatment-emergent mania compared to placebo by comparing the percentage of patients who meet the criteria for treatment-emergent mania on the Young Mania Rating Scale (YMRS) or report an adverse event of mania or hypomania

2. to evaluate the effect of quetiapine on anxiety compared to placebo by

   - the change from baseline to final assessment in the Hamilton Rating Scale for Anxiety (HAM-A) total score

   - the change from baseline to each assessment in the Hamilton Rating Scale for Anxiety (HAM-A) total score

3. to evaluate the safety and tolerability of quetiapine in the treatment of patients with bipolar depression by

   - the incidence and nature of overall adverse events

   - the incidence and nature of drug-related adverse events

   - subject withdrawal due to adverse events during double-blind treatment

   - the number of patients having clinically significant changes in vital signs from baseline to end of treatment

   - the change in Simpson-Angus Scale (SAS) total score

   - the change in the Barnes Akathisa Rating Scale (BARS) total score

   - the incidence of adverse events related to extrapyramidal symptoms during double-blind treatment

Exploratory:

1. to evaluate the efficacy of quetiapine on sleep quality by comparing the change in sleep quality using the Pittsburgh Sleep Quality Index (PSQI) from baseline to end of treatment

2. to evaluate the efficacy of quetiapine on the overall quality of life using the Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) from baseline to end of treatment

5. STUDY PLAN AND PROCEDURES

The overall study design and plan are presented and discussed in Section 5.1 and Section 5.2, respectively. The study population and its relationship to the intended target population are defined in Section 5.3. Study treatments and dosing regimens are described in Section 5.4.Study measurements and variables are described and justified in Section 5.5, and measures taken to ensure the quality of study data are described in Section 5.6.Statistical methods and presentation of the data are detailed in Section 5.7. Any changes to the planned conduct of the study, or planned statistical analyses, are presented in Section 5.8.

5.1 Overall study design

This multicenter, double-blind, randomized, placebo-controlled, double-dummy, parallel group trial consisted of a washout period (from 7 to 28 days depending on the medications involved) followed by 8 weeks of treatment to evaluate the efficacy, safety, and tolerability of quetiapine fumarate in the treatment of a major depressive episode in adult subjects with bipolar disorder. A total of approximately 740 subjects were to be screened to obtain 530 enrolled subjects to yield 504 evaluable subjects at approximately 75 centers, with a target enrollment of 8 patients per center (maximum 70). Subjects were required to have a HAM-D (17-item scale) score of ≥20 and a YMRS of ≤12 at screening baseline (Visit 1).

The trial comprised the following 2 periods:

- Washout period
  Subjects underwent HAM-D, SCID, YMRS, and safety evaluations at screen (Visit 1) and if they qualified to participate they commenced a washout of antidepressant, antipsychotic, and mood stabilizer medications. The number of days for washout depended upon the medication they were taking. These medications had to be discontinued for a period of at least 7 days prior to randomization (Day 1, Visit 2), with the exception of fluoxetine which had to be discontinued for a period of 14 days prior to randomization (Day 1, Visit 2) and depot injections of haloperidol decanoate or fluphenazine decanoate which required 28 days washout before randomization.

- 8-week double-blind randomized treatment period (Weeks 1 to 8)
  Eligible subjects were randomized on Day 1 (Visit 2) to 1 of 3 treatment groups: quetiapine 300 mg/day, quetiapine 600 mg/day, or placebo. The randomization was done using a stratification based on diagnosis. Treatment was administered once daily at bedtime for 8 weeks (Days 1 - 56). Subjects did not receive medication on Day 57 which was only for final assessments. Doses were titrated to achieve target doses of 300 mg/day within 4 days or 600 mg/day within 8 days. A dose reduction of 100 mg was allowed to improve patient tolerance in each treatment group. MADRS assessments (used to evaluate the primary efficacy variable) were performed at Days 1, 8, 15, 22, 29, 36, 43, 50, and 57.

Table 2 summarizes the study procedures and assessments conducted at each time point.

a Washout of antidepressants, antipsychotics, mood stabilizer for 7 to 28 days depending on the medications involved and a 14-day washout for fluoxetine
b Repeated laboratory tests and ECG only if results outside of normal range and clinically significant at Screening
c Height and weight on screen and weight on Day 57
d Physical exam included ophthalmoscopic exam on screen
e Blood pressure obtained in supine and standing positions

5.2 Rationale for study design, doses and control groups

This trial was designed as a double-blind placebo-controlled evaluation of quetiapine as monotherapy in bipolar depression. At the time of trial initiation there was no currently approved compound for use in bipolar depression; nor was there a clinically accepted "gold standard" monotherapy agent. Conventional antidepressants are not commonly used as monotherapy because of the need for close clinical monitoring to avoid the induction of manic symptoms. Due to the lack of a reasonable monotherapy alternative, and the high placebo rate in bipolar depression trials (approximately 30%), the use of a placebo treatment arm for comparison was clinically justified.

Trial treatment was administered as quetiapine monotherapy once daily at bedtime. The current label specifies twice daily (BID) but a double-blind crossover study in patients indicated that once daily (qd) was well tolerated and as effective as BID dosing (Chengappa et al 2003).

A period of 7 to 28 days is adequate for washout of most psychoactive medications including antidepressants, antipsychotics (including depot agents), and mood stabilizers to ensure that subjects are not experiencing residual psychotropic effects from any such medications they were taking before randomization. The double-blind treatment period of 8 weeks is consistent with the time period that is generally accepted to be required to see a clinically meaningful response in depressive symptoms.

The trial was designed as a fixed-dose evaluation due to the frequent failure of flexible dose regimens in other psychiatric disorders. The dosages are based on clinical trial data with quetiapine in patients with a mood disorder. In the QUEST trial, the average dose of quetiapine in patients with a primary mood disorder (N=316) was approximately 250 mg/day at 16 weeks (Sajatovic et al 2002). In 20 patients with bipolar or schizoaffective disorder treated with open-label quetiapine, the mean dose was approximately 200 mg/day (Sajatovic et al 2001). Based on these data, 300 mg/day administered as monotherapy is an appropriate low-dose treatment arm, and 600 mg/day is an appropriate high-dose treatment arm that should exhibit efficacy without a high rate of AEs or noncompliance.

The MADRS is a standardized, well-validated measure of depressive symptoms that is sensitive to treatment effects in depressed outpatients.

5.3 Selection of study population

5.3.1 Inclusion criteria

For inclusion in the study, patients had to fulfill all of the following criteria at Screening;

1. Documented ability to provide informed consent before beginning any study-specific procedures

2. Male and female patients between 18 and 65 years of age, inclusive

3. Females of childbearing potential, were to be using a reliable method of contraception. Reliable methods included hormonal contraceptives (eg, oral contraceptive or long-term injectable or implantable hormonal contraceptive), double-barrier methods (eg, condom and diaphragm, condom and foam, condom and sponge), intrauterine devices, and tubal ligation

4. Women must have had a negative pregnancy test

5. Met DSM-IV criteria for bipolar disorder I or bipolar II, most recent episode depressed (296.5x and 296.89x)

6. Outpatient status

7. HAM-D (17-item) total score of 20 or greater

8. HAM-D item 1 (depressed mood) score ≥2

9. YMRS total ≤12

Patients had to fulfill all of the following criteria at Randomization;

1. HAM-D (17-item) total score of 20 or greater

2. HAM-D item 1 (depressed mood) score ≥2

3. YMRS total ≤12

5.3.2 Exclusion criteria

Any of the following was regarded as a criterion for exclusion from the study:

1. Patients with a current Axis I disorder other than bipolar disorder within 6 months of screening

2. Patients whose current episode of depression exceeded 12 months or was less than 4 weeks

3. History of non-response to an adequate trial (6 weeks) of more than 2 classes of antidepressants during their current episode

4. Patients who met DSM-IV criteria for substance dependence, for any substance except nicotine, within 12 months of screening

5. Patients with a positive urine toxicology screen for illicit substances of abuse

6. Patients who were unable to discontinue all psychoactive medications (excluding prn benzodiazepines), including antidepressants, antipsychotics, and mood

stabilizer, at least 7 days prior to randomization and consistent with the pharmacokinetics of the drug

- Patients treated with fluoxetine who had not discontinued this medication for at least 14 days prior to randomization

- Patients treated with haloperidol decanoate or fluphenazine decanoate who had not discontinued these medications 28 days prior to randomization

7. Patients who had not discontinued the use of potent P450 inhibitors and inducers (See Section 5.4.5, Table 10)

8. Patients who in the investigators opinion would have required initiation of psychotherapy during the study period. Note: ongoing psychotherapy for a minimum of 3 months could continue

9. Patients who, in the investigator's judgment, posed a current serious suicidal or homicidal risk at Visit 1 (HAM-D Item 3 score of 3 or greater), or had made a suicide attempt within the past 6 months

10. Patients with a history of clinically significant cardiac, renal, neurologic, cerebrovascular, metabolic or pulmonary disease, or other disease or clinical finding that was unstable or that, in the opinion of the investigator, would have been negatively affected by study medication or that would have affected study medication

11. Patients who had had a myocardial infarction within 1 year before Visit 1

12. Patients with clinically significant abnormal laboratory findings at Visit 1

13. Patients with renal impairment (serum creatinine ≥1.5 mg/dL) or hepatic impairment (ALT or AST 3 times the upper limit of normal)

14. Patients whose TSH was ≥10% over the upper normal limit. Patients maintained on thyroid medication had to be euthyroid for a period of at least 3 months before Visit 1

15. Patients with clinically significant abnormalities on ECG

16. Women who had a positive human chorionic gonadotropin (HCG) pregnancy at Visit 1 or who were lactating or planning to become pregnant during the course of the study

17. Patients who had participated in a clinical trial of an investigational drug within the previous 3 months

18. Patients who, in the opinion of the investigator, would have been non-compliant with the visit schedule or study procedures

19. History of orthostatic hypotension or conditions that would have predisposed them to hypotension (eg dehydration, hypovolemia)

20. Known history of intolerance, hypersensitivity, or lack of response to quetiapine or any of the components of Seroquel tablets, as judged by the investigator

5.3.3 Restrictions

Patients were required to adhere to the following special restrictions:

1. Use of any psychoactive drugs including antidepressants, hypnotics (with the exceptions noted in Section 5.4.5), mood stabilizing drugs, and antipsychotics was not permitted from a period of 5 elimination half-lives (28 days for haloperidol decanoate and fluphenazine decanoate) prior to randomization to end of study. Fluoxetine was to be discontinued at least 14 days prior to randomization.

2. Use of cytochrome P450 3A4 inducers and potent inhibitors were not permitted from 14 days prior to randomization to end of study (see Table 10)

5.3.4 Discontinuation of subjects from treatment or assessment

5.3.4.1 Criteria for discontinuation

Subjects could be discontinued from study treatment and assessments at any time, at the discretion of the investigator. Specific reasons for discontinuing a subject from this study were:

1. Withdrawal of informed consent

2. Worsening psychiatric symptoms such that the symptoms constituted a danger to the patient or to others

3. Use of psychotropic medications at any time during the double-blind treatment period

4. Pregnancy at any time during the double-blind treatment period

5. A clinically significant or serious adverse event that would not be consistent with continuation in the study, as determined by the investigator, AstraZeneca, or the patient.

5.3.4.2 Voluntary discontinuation by a subject

Subjects were free to discontinue their participation in the study at any time, without prejudice to further treatment. Subjects who discontinued were asked about the reasons for their discontinuation and about the presence of any adverse events. If possible, they were seen and

assessed by an investigator. Adverse events were to be followed up, and any investigational products and study materials were to be returned by the subject.

5.3.4.3 Incorrectly enrolled or randomized subjects

Incorrectly enrolled were to be discontinued from further study treatment and assessments. If a patient was given an incorrect randomized treatment, the patient was to continue on that treatment.

5.3.4.4 Procedures for discontinuation

All study procedures required at Day 57 were to be conducted when a patient discontinued from the trial (See Table 2).

5.4 Treatments

5.4.1 Investigational products

The details of the investigational product and any study treatment are given in Table 3.

Table 3 Details of investigational product and any other study treatments

Investigational product or other treatment	Dosage form and strength	Manufacturer	Formulation number	Lot number
Quetiapine	tablet, 25 mg	AstraZeneca	F12804	7527F
Quetiapine	tablet, 100 mg	AstraZeneca	F12689	7513H
Quetiapine	tablet, 200 mg	AstraZeneca	F12690	7541F
Placebo	tablet, 25 mg	AstraZeneca	F12636	7553F
Placebo	tablet, 100 mg	AstraZeneca	F12637	7550F
Placebo	tablet, 200 mg	AstraZeneca	F12638	1509C

All investigational products were to be kept in a secure place under appropriate storage conditions.

5.4.2 Doses and treatment regimens

Quetiapine and placebo for each trial center were packaged in blister cards. The 8-week supply consisted of 8 double-blind blister cards that were packaged in subject-specific cartons.

Trial medication was provided for each subject in an 8-card carton that contained the following:

- 1-week titration double-blind treatment cards for Days 1-7

- Seven 1-week double-blind treatment cards for Days 8-56, with individual cards provided for treatment Days 8-14, 15-21, 22-28, 29-35, 36-42, 43-49, and 50-56. Each one-week blister card included a 2-day treatment overage to accommodate visit schedules.

The Week 1 titration card consisted of 25 mg tablets, 100-mg tablets, and 200-mg tablets or matching placebo for each of the 300 mg/day and 600 mg/day treatment groups and placebo treatment group (Table 4, Table 6, Table 8).

Blister cards for Weeks 2 through 8, for each treatment group, consisted of 9 days of dosing with the same number of pills for each group (300-mg, 600-mg, and placebo) respectively. The cards for each treatment group consisted of 2 yellow tablets (quetiapine 100 mg or matching placebo) and 2 white tablets (quetiapine 200 mg or matching placebo) per day at bedtime (Table 5, Table 7, Table 9).

Quetiapine or placebo was administered once a day at bedtime with dose titration designed to reach a target dose of 300 mg/day by Day 4 in the 300 mg/day treatment group and 600 mg/day by Day 8 in the 600 mg/day group. Patients were instructed to take all the tablets in the row of the blister pack for the corresponding day of treatment.

Extra Day	100-mg placebo	100-mg placebo	200-mg placebo	200-mg placebo

Dose reduction

Dose reduction for intolerability was allowed after Day 8. Dose reductions of 100 mg/day were achieved by reducing the dose by one 100-mg tablet. Each column in the blister packs was numbered 1-4. By Day 6 Columns 1 and 2 of the blister packs each contained a 100-mg tablet or matching placebo (Table 5, Table 7, Table 9). Dose reductions were implemented by instructing the patient to not take the tablet in Column 1 of the blister pack

5.4.3 Method of assigning subjects to treatment groups

This trial utilized a non-center-specific labeling randomization which was stratified in a 1:1:1 ratio for treatment group within bipolar diagnosis (bipolar I vs bipolar II). Randomization to trial treatment was done via an Interactive Voice Response System (IVRS) at ICTI on Day 1 (Visit 2) in balanced blocks within each bipolar stratum in order to ensure relative balance in total number of subjects among treatment groups and strata. The randomization schedule was created under the auspices of AstraZeneca Quantitative Decision Sciences Group and allocated subject numbers to the treatment regimens. Clinical supplies contained a 4-digit kit number. A separate randomization assigned kits of packaged drugs to the sites. The IVRS system at ICTI allocated a kit number at the site for the treatment assigned through the stratified randomization.

5.4.4 Blinding and procedures for unblinding the study

5.4.4.1 Methods for ensuring blinding

All packaging of treatments was identical with placebo and active tablets identical in size and color. The number of tablets dispensed on each card was identical across all treatment arms.

The patient treatment assignment randomization was generated by an AstraZeneca randomization staff member not associated with the trial and was provided directly to the medication packaging group and to ICTI Clinical Supplies Management Group for incorporation into the IVRS system. No member of the study team in AstraZeneca, at investigational sites or the contract research organization handing data had access to the randomization scheme during the conduct of the study.

5.4.4.2 Methods for unblinding the study

Treatment codes, indicating the treatment randomization for each randomized subject, were available to the investigators or pharmacists at the study center. The treatment code was not to be broken except in medical emergencies when the appropriate management of the subject necessitated knowledge of the treatment randomization. The investigator was to document and report to AstraZeneca any breaking of the treatment code. AstraZeneca retained the right to break the code for serious adverse events that were causally related to treatment and potentially required expedited reporting to regulatory authorities and, in exceptional circumstances, for other safety reasons. Treatment codes were not to be broken for the planned analyses of data until all decisions on the availability of the data from each individual subject were made and documented.

5.4.5 Pre-study, concomitant, and post-study treatments

Nonpsychotropic medication, including over-the counter medications, taken by the subject before entry into the trial could be continued during the trial. Medications required to treat illnesses or complaints that occur during the trial could be used at the discretion of the investigator. Use of cytochrome P450 inducers and potent inhibitors was restricted (see Table 10, below).

Women who entered the trial with an intrauterine device in place, using oral contraceptives, or using injectable or implantable hormonal agents designed to prevent pregnancy could continue these treatments throughout the trial.

The use of psychoactive drugs other than those specifically allowed during the trial (ie, lorazepam and zolpidem tartrate) was restricted. Medications specifically prohibited or restricted, and those permitted during the trial are listed in Table 10.

Table 10 Permitted, restricted and prohibited medications

Use category	Type of medication
Permitted	Previous medications for medical, nonpsychiatric illnesses
	Oral contraceptives and contraceptive devices
Restricted	Zolpidem tartrate 5-10 mg at bedtime for insomnia
	Lorazepam 1-3 mg per day for severe anxiety
	These drugs could be prescribed during the first 3 weeks of the study as long as they did not interfere with any assessments
Prohibited	Potent cytochrome P450 3A4 inducers (including but not limited to barbiturates, carbamazepine, rifampin, and St John's Wort)
	Potent cytochrome P450 3A4 inhibitors (including but not limited to ketoconazole, itraconazoole, fluconazole, erythromycin, clarithromycin, troleandomycin, indinavir, nelfinavir, ritonavir, and saquinavir)
	Antipsychotic medications (including but not limited to phenothiazines, risperidone, olanzapine, ziprasidone, clozapine, loxapine, thiothixene, molindone)
	Use of any psychoactive drugs including antidepressants, hypnotics, mood stabilizing drugs, and antipsychotics from a period of 7 to 28 days depending on the medications involved (eg. 28 days for haloperidol decanoate and fluphenazine decanoate) prior to randomization to end of study.
	Fluoxetine had to be discontinued at least 14 days prior to randomization.

Other medication considered necessary for the subject's safety and well being could be given at the discretion of the investigators. The administration of all medication (including investigational products) was recorded in case report forms (CRFs).

5.4.6 Treatment compliance

Compliance was assessed by returned tablet counts. Compliance was calculated as the number of tablets taken (dispensed - returned) divided by the prescribed number of tablets (number of days times number of tablets per day) expressed as a percent. Based on this calculation a subject with at least 75% compliance with study medication during study participation was classified as compliant.

If, in the opinion of the investigator, there were any significant irregularities in compliance the patient was to be withdrawn from the study.

5.5 Measurements of study variables and definitions of outcome variables

5.5.1 Primary variable

The primary outcome variable was the change from baseline to final assessment in the MADRS total score. This outcome variable was the basis for the sample size calculation (Section 5.7.5).

5.5.2 Screening and demographic measurements

The following data were collected at screening:

- date of birth, sex and race. Race was defined by the geographic origin of the patient's family. Caucasian was used for family origins in Europe, India, Pakistan, Afghanistan, Arabia, North Africa, Middle East countries, and Asia Minor. Black was used for Africa but not North Africa. Oriental was used from Asia (except for Asian countries classified as Caucasian) and for Greenland. Other was used for mixed races and for Aboriginal, Maori, Melanesian, Pygmean, and Tamil. Hispanic was not specifically defined in the CRF and was left to the discretion of the investigator.
- vital signs, height, weight
- supine and standing blood pressure and pulse
- significant medical history (including current adverse events)
- physical examination including ophthalmoscopic exam
- 12-lead electrocardiogram
- clinical chemistry and hematology
- pregnancy test (if female of childbearing potential)
- HAM-D assessment
- YMRS
- CGI-S
- DSM-IV diagnosis, based on SCID assessment

5.5.3 Efficacy measurements and variables

5.5.3.1 Summary of efficacy objectives and variables

Table 11 summarizes the efficacy variables of this study, and shows how they relate to the study objectives.

Table 11 Efficacy objectives, and outcome variables relating to each objective

Objective	Summary outcome variables for analysis (including timepoint and population)
Primary	**Primary outcome variable**
Evaluate the efficacy of quetiapine compared to placebo in the treatment of a major depressive episode in patients with bipolar disorder after receiving treatment for up to 8 weeks	Change from baseline to final assessment in the MADRS total score in the Intention-to-treat (ITT) population
	Secondary outcome variables
	Percentage of patients in the ITT population showing a ≥50% reduction from baseline in MADRS total score (responders) at each assessment and at final assessment
	Percentage of patients in the ITT population showing a MADRS total score ≤12 (remitters) at each assessment and at final assessment
	Change from baseline to each assessment for the MADRS total score in the ITT and PP populations
	Change from baseline to each assessment in the total HAM-D total score in the ITT population
	Change from baseline to each assessment in the HAM-D Item 1 score in the ITT population
	Change from baseline to each assessment and at final assessment for the CGI-S in the ITT population
	CGI-I score at each assessment and at final assessment in the ITT population
Secondary	**Secondary outcome variables**
Evaluate the effect of quetiapine compared to placebo on symptoms of anxiety	Change from baseline to each assessment and to final assessment in the HAM-A total score in the ITT population

The timings of the efficacy assessments are presented in the study plan in Section 5.1. The methods for collecting efficacy data are presented below.

5.5.3.2 Primary variable: MADRS total score change from baseline at last assessment

(a) Methods of assessment

The MADRS is a 10-item instrument that was used to rate the patient's depressive symptoms for the preceding week (Montgomery and Asberg 1979). Scoring for each of the items was made on a 0- to 6-point scale, with higher scores indicating more severe depression.

(b) Calculation or derivation of outcome variable

The MADRS total score was calculated by summing the scores from each of its 10 items. Change from baseline in the MADRS total score was calculated by subtracting the baseline total score from the visit score. Alleviation of depressive symptoms was thus indicated by a negative change score.

5.5.3.3 Secondary variable: MADRS response

(a) Methods of assessment

As specified in Section 5.5.3.2.

(b) Calculation or derivation of outcome variable

Response at a visit was defined as a decrease from baseline MADRS total score of ≥50% at the given visit.

5.5.3.4 Secondary variable: MADRS remission

(a) Methods of assessment

As specified in Section 5.5.3.2.

(b) Calculation or derivation of outcome variable

Remission at a visit was defined as a MADRS total score ≤12 at the given visit.

5.5.3.5 Secondary variable: MADRS total score change from baseline at each assessment

As specified in Section 5.5.3.2 for each visit.

5.5.3.6 Secondary variable: change from baseline in HAM-D total score

(a) Methods of assessment

The HAM-D is a 17-item instrument that was used to rate the patient's depressive symptoms for the preceding week (Hamilton 1960). The items are scored on a 0- to 2-, 0- to 3-, or 0- to 4-point scale, with higher scores indicating more severe depression. The maximum score is 53.

(b) Calculation or derivation of outcome variable

The HAM-D total score was calculated by summing the scores from each of its 17 items. Change from baseline in the HAM-D total score was calculated by subtracting the baseline total score from the visit score. Alleviation of depressive symptoms was thus indicated by a negative change score.

5.5.3.7 Secondary variable: change from baseline in HAM-D Item 1 score

(a) Methods of assessment

Item 1 of the HAM-D is a 0- to 4-point rating of depressed mood.

(b) Calculation or derivation of outcome variable

Change from baseline in the HAM-D Item 1 score was calculated by subtracting the baseline score from the visit score. Alleviation of depressed mood was thus indicated by a negative change score.

5.5.3.8 Secondary variables: change from baseline in CGI

The CGI is a three-item scale used to assess treatment response in psychiatric patients (Guy 1976). Only Items 1 and 2 were recorded on the CRF and evaluated in this study. They are: Severity of Illness (CGI-S) and Global Improvement (CGI-I)[1]. Item 1 is rated on a seven-point scale (1=normal to 7=extremely ill) and item 2, on a seven-point scale (1=very much improved to 7=very much worse).

(a) Methods of assessment – CGI-S

The Severity of Illness item requires the clinician to rate the severity of the patient's illness at the time of assessment, relative to the clinician's past experience with patients who have the same diagnosis. Considering total clinical experience, a patient is assessed on severity of mental illness at the time of rating according to: normal (not at all ill); borderline mentally ill; mildly ill; moderately ill; markedly ill; severely ill; or extremely ill.

(b) Calculation or derivation of outcome variable

Change from baseline of the CGI-S was calculated by subtracting the baseline score from the visit score. Alleviation of symptom severity was thus indicated by a negative change score.

(c) Methods of assessment – CGI-I

The Improvement item requires the clinician to rate how much the patient's illness has improved or worsened relative to a baseline state. Compared to condition at baseline, a

[1] The abbreviation for the CGI Global Improvement scale was changed from "CGI-C" as used in the protocol to "CGI-I" to be consistent with the clinical literature.

patient's illness is compared to change over time, and rated according to: very much improved; much improved; moderately improved; minimally improved; no change; minimally worse; moderately worse; much worse; or very much worse.

(d) Calculation or derivation of outcome variable

For the CGI-I, symptomatic improvement from status at entry into the trial was thus indicated by scores of 3 or less while symptomatic deterioration was indicated by scores of 5 or more.

5.5.3.9 Secondary variable: incidence of treatment-emergent mania -- YMRS

(a) Methods of assessment

The YMRS is an 11-item instrument that was used to rate the patient's mania symptoms for the preceding week (Young et al 1978). Scoring for the items was made on a 0- to 4-point scale for 7 of the items and on a 0- to 8-point scale for the remaining 4 items. Reports of investigator-diagnosed cases of treatment-emergent mania or hypomania were compiled from adverse events reports.

(b) Calculation or derivation of outcome variable

Treatment-emergent mania for a patient was scored if the patient's YMRS total score was ≥16 at any two consecutive visits or final visit or if they received an AE report of mania or hypomania from the investigator. Change from baseline in the YMRS score was calculated by subtracting the baseline score from the visit score. The primary variable, the change from baseline in YMRS, was defined as the YMRS total score at Day 57 or final assessment minus the YMRS total score at baseline (Visit 2; Day 1). An increase in mania or hypomania symptoms was thus indicated by a positive change score.

5.5.3.10 Secondary variable: change from baseline in HAM-A

(a) Methods of assessment

The HAM-A is a 14-item instrument that was used to rate the patient's anxiety symptoms for the preceding week (Hamilton 1959). Scoring for each of the items was made on a 0- to 4-point scale of increasing severity.

(b) Calculation or derivation of outcome variable

Change from baseline in the HAM-A score was calculated by subtracting the baseline score from the visit score. Alleviation of anxiety symptoms was thus indicated by a negative change score.

5.5.4 Patient-Reported Outcomes (PROs) measurements and variables

5.5.4.1 Summary of PRO objectives and variables

Table 12 shows how the efficacy outcome variables of this study relate to the study objectives.

Table 12 Quality of life objectives and outcome variables relating to each objective

Objective	Summary outcome variables for analysis (including time point and population)
Exploratory	**Exploratory measure**
evaluate the effect of quetiapine compared to placebo on the overall quality of life	Change from baseline to each assessment and final assessment in short form Q-LES-Q in the ITT population
evaluate the effect of quetiapine compared to placebo on quality of sleep	Change from baseline to each assessment and final assessment in PSQI in the ITT population

The methods of collecting quality of life data are described below.

5.5.4.2 Change from baseline in the Q-LES-Q

(a) Methods of assessment

The Q-LES-Q is a quality of life questionnaire assessing physical health, subjective feelings, leisure activities, social relationships, and medication and life satisfaction (Endicott et al 1993).Higher scores indicate better quality of life. The Q-LES-Q short form consisting of the 16-item "General Activities" scale of the Q-LES_Q long form was used. The items are scored on a 5-point scale.

(b) Calculation or derivation of outcome variable

The short form has 16 self-rated questions, and the first 14 were incorporated into percent of maximum score by converting the raw summary scores and expressing them as a percentage of the maximum possible score (100). The change from baseline was calculated at each assessment (observed cases) and final assessment in the Q-LES-Q by subtracting the baseline score from the visit score. Improvement in quality of life was thus indicated by a positive change score.

5.5.4.3 Change from baseline in the PSQI

(a) Methods of assessment

The PSQI is a 10-item questionnaire which the patient used to rate sleep quality for the previous month (Buysse et al 1989). Higher scores indicate more severe difficulties in sleep quality.

(b) Calculation or derivation of outcome variable

The first 9 questions were incorporated into 7 component scores which were added together to yield one total "global" score (see the Statistical Analysis Plan in Appendix 12.1.9). The

change from baseline was calculated at each assessment (observed cases) and at final assessment (LOCF) by subtracting the baseline score from the visit score. Improvement in sleep quality was thus indicated by a negative change score.

5.5.5 Health Economics measurements and variables

Not applicable.

5.5.6 Pharmacokinetic measurements and variables

Not applicable.

5.5.7 Safety measurements and variables

5.5.7.1 Summary of safety objectives and variables

Table 13 summarizes the safety variables assessed in this study, and shows how they relate to the study objectives.

Table 13 Safety objectives and outcome variables relating to each objective

Objective	Summary outcome variables for analysis (including time point and population)
Evaluate the safety and tolerability of quetiapine in the treatment of patients with bipolar depression	Incidence and severity of adverse events during double-blind treatment Incidence of drug-related adverse events during double-blind treatment Incidence rate of adverse events related to extrapyramidal symptoms during double-blind treatment
	Incidence of subject withdrawal due to adverse events
	Clinical laboratory assessments change from baseline to Day 57 in the safety population
	Incidence of potentially clinically important changes in clinical laboratory assessments
	Change in weight and body mass index (BMI) from baseline to Day 57 in the safety population
	Vital signs from baseline to Day 57 in the safety population
	Incidence of potentially clinically important changes in vital signs
	Electrocardiogram (ECG)
	Incidence of potentially clinically important changes in ECG
	Change in the SAS total score from baseline to final assessment

Table 13 Safety objectives and outcome variables relating to each objective

Objective	Summary outcome variables for analysis (including time point and population)
	Change in BARS Global Assessment score from baseline to final assessment
Evaluate the incidence of treatment-emergent mania in quetiapine-treated patients compared to placebo-treated patients	Proportion of patients exhibiting a YMRS total score ≥16 on two consecutive assessments or at final assessment or having an AE report of treatment-emergent mania or hypomania. Change from baseline to each assessment and to final assessment in the YMRS total score in the ITT population

The timings of the safety assessments are presented in the study plan in Section 5.1. The methods for collecting safety data are described below.

5.5.7.2 Adverse events

(a) Definitions

An adverse event was defined as the development of an undesirable medical condition or the deterioration of a pre-existing medical condition following or during exposure to a pharmaceutical product, whether or not considered causally related to the product. This definition included events in any screening period or during any follow-up period specified in the study protocol. An undesirable medical condition could be symptoms (eg, nausea, chest pain), signs (eg, tachycardia, enlarged liver) or the abnormal results of an investigation (eg, laboratory findings, electrocardiogram).

A serious adverse event was defined as an AE occurring during any study phase (ie, run-in, treatment, washout, follow-up), and at any dose of the investigational product, comparator or placebo, that fulfilled one or more of the following criteria:

- resulted in death
- was immediately life-threatening
- required in-patient hospitalization or prolonged existing hospitalization
- resulted in persistent or significant disability or incapacity
- was a congenital abnormality or birth defect
- was an important medical event that might have jeopardized the subject or might have required medical intervention to prevent one of the outcomes listed above?

Study drug abuse was to be considered an SAE, even when there are no symptoms or additional AEs. Misuse of study drug was considered to be an AE but was not considered an SAE unless accompanied by serious sequelae.

All overdoses, with or without associated symptoms, were to be reported as AEs.

Suicide and attempted suicide, irrespective of the method, but occurring in connection with the use of study drug, was to be reported as AEs (serious or non-serious). The event was to be identified as suicide or attempted suicide, and the method of the suicide or attempt was to be provided. If an attempted suicide meets the criteria for an SAE, the event was to be reported as such.

(b) Recording of adverse events

All AEs that occur before, during treatment, or within 30 days following the cessation of treatment, whether or not related to the study drug, had to be recorded on the CRF provided by the sponsor.

A description of the event, its intensity, duration, action taken and outcome were to be recorded, along with the investigator's causality assessment of the relationship of the event to the study drug. If a diagnosis of the patient's condition was made, then the diagnosis was to be recorded as the AE. However, if a diagnosis of the patient's condition had not been made, or if the individual symptoms were not well-recognized, then the individual symptoms were to be recorded separately.

AEs were entered coded according to the MedDRA dictionary by AstraZeneca personnel.

In general, abnormal laboratory tests or vital signs were not to be reported as AEs unless they fulfilled the criteria for an SAE or lead to discontinuation. If an abnormal laboratory test result or vital sign was associated with clinical signs and symptoms, the sign or symptom was reported to be an AE, and the associated test result or vital sign was to be recorded on the CRF.

Any detrimental change in the patient's condition after the patient entered the study was to be discussed with the investigator. Where the detrimental change was considered by the investigator to constitute a progression or relapse of bipolar depression or a lack of efficacy, the change was not considered to be an AE event where hospitalization was necessitated or prolonged. If it was believed that study medication contributed to deterioration, it was recorded as an AE. If it was not believed that the study medication contributed to deterioration, it was recorded as lack of efficacy.

Signs & symptoms noted in patient reported outcome instruments (PSQI & Q-LES-Q) were not reported as AEs.

Pregnancy in itself was not regarded as an adverse event unless there was a suspicion that the investigational product under study may have interfered with the effectiveness of a

contraceptive medication. However, the outcome of all pregnancies (spontaneous miscarriage, elective termination, normal birth or congenital abnormality) was to be followed up and documented even if the subject was discontinued from the study. All reports of congenital abnormalities, birth defects and spontaneous miscarriages were to be recorded as SAEs. Elective abortions without complications were not to be considered as adverse events. All outcomes of pregnancy were to be reported to AstraZeneca on the pregnancy outcomes report form.

(c) Reporting of serious adverse events

All SAEs were to be reported, whether or not they were considered causally related to the investigational product. When an investigator became aware of an SAE during the course of the study, the SAE was to be reported to the local monitor or other AstraZeneca representative in accordance with the AstraZeneca study protocol. If any SAEs were recorded during the 30-day follow-up period, all concomitant medications taken during the 30-day follow-up were also to be recorded on the CRF.

5.5.7.3 Laboratory safety measurements and variables

Laboratory safety variables assessed in this study are summarized in Table 14.

Table 14 Laboratory safety variables

Type of assessment	Variables
Fasting hematology	Hemoglobin
	Hematocrit
	Red blood cell count (RBC)
	White blood cell count (WBC)
	Differential white blood cell count (% and absolute)
	Platelet count
Clinical chemistry	
Hepatic function	Alanine transaminase (ALT)
	Aspartate transaminase (AST)
	Alkaline phosphatase
	Total bilirubin
Renal function	Creatinine
Lipids	Total cholesterol
	low-density lipoprotein cholesterol
	high-density lipoprotein cholesterol
	triglycerides

Table 14 Laboratory safety variables

Type of assessment	Variables
Electrolytes	Sodium
	Potassium
	chloride
	bicarbonate
Thyroid function	Thyroid stimulating hormone (TSH)
	Triiodothyronine resin uptake (T3RU)
	Free thyroxine (T4)
Other	Insulin
	Glucose

Laboratory results were converted to standard units according to conversion factors listed in Table 11.3.7.1.1.1 and Table 11.3.7.1.2.1. Change from baseline (the final test value minus the screening test value) was derived for all subjects who had a screening laboratory test and a final laboratory test. Abnormal laboratory findings were identified as outside the normal range according to local laboratory criteria or as clinically important according to the criteria presented in Table 15, which presents criteria specified in the statistical analysis plan and the criteria that were adopted as the safety analysis proceeded. The criteria for clinically important changes were revised to reflect changes in medical standards and to insure consistency across the Seroquel programs as defined in 2005 and agreed with regulatory authorities.

Table 15 Definition of clinically important clinical laboratory values

Laboratory assessment	Units	Low	High
Hematology			
Hematocrit (males)	vol fraction	≤0.37	≥0.50
Hematocrit (females)	vol fraction	≤0.32	≥0.55
Hemoglobin (males)	g/dL	≤11.5	≥18.5
Hemoglobin (females)	g/dL	≤10.5	≥16.5
RBC	10^{12} cells/L	≤3	≥6
Platelet count	10^{9} cells/L	≤100	≥600
WBC	10^{9} cells/L	≤3.0	≥16.0
Neutrophils			

Table 15 Definition of clinically important clinical laboratory values

Laboratory assessment	Units	Low	High
proportion	%	None	None

LLN Lower limit of normal
ULN Upper limit of normal
NA Not applicable
a Criterion for neutropenia
b Criterion for agranulocytosis

5.5.7.4 Vital signs measurement

Vital signs included supine and standing pulse, and systolic and diastolic blood pressure. Changes from baseline at each visit for each of these variables were calculated. Differences in supine and standing scores were also computed.

Vital signs assessed are shown in Table 16, along with criteria for potentially clinically important values.

Table 16 Definitions of potentially clinically important vital signs by FDA criteria

Vital sign	Criterion value	Change from baseline
Pulse	>120 bpm	increase ≥15 bpm
	<50 bpm	decrease ≥15 bpm
Systolic blood pressure	≥180 mm Hg	increase ≥20 mm Hg
	≤90 mm Hg	decrease ≥20 mm Hg
Diastolic blood pressure	≥105 mm Hg	increase ≥30 mm Hg
	≤50 mm Hg	decrease ≥20 mm Hg
Orthostatic changes		
Systolic blood pressure or	decrease ≥20 mm Hg from supine to standing after 1 min	
Diastolic blood pressure	decrease ≥20 mm Hg from supine to standing after 1 min	
Pulse	increase ≥20 bpm from supine to standing after 1 min	
Combined	Decrease ≥20 mm Hg in systolic BP and increase ≥20 bpm in pulse rate	

bpm beats per minute

5.5.7.5 ECG safety measurements and variables

Twelve-lead ECGs were performed at screening and on Day 57. ECGs for patients at all trial sites were acquired at the site using an approved unit and were transmitted to eResearch Technology. Quality assurance of the ECG waveform and patient demographics was conducted by a central laboratory operator at eResearch Technology. ECGs were processed through a computer interpretation program and then reviewed first by an ECG analyst and then by a board-certified cardiologist. QTc intervals were calculated using the Fridericia formula (Puddu 1988). ECG parameters are shown in Table 17 , along with criteria for potentially clinically important values.

Table 17 Definition of potentially clinically important electrocardiogram parameters

ECG parameter	Criterion value	Change from baseline
Heart rate	>120 bpm	increase ≥15 bpm
	<50 bpm	decrease ≥15 bpm
PR	≥210 msec	NA
QRS	≤50 msec	NA
	≥120 msec	NA
QT	≥500 msec	Increase ≥60 msec
	≤200 msec	NA
QT_C (Fridericia Correction)	≥450 msec	Increase ≥60 msec

NA Not applicable

5.5.7.6 Weight and Body Mass Index (BMI)

Patient weight data were also explored as change in BMI. Patients were stratified by BMI category to determine changes within and across categories.

Body mass index was calculated using the following formula:

BMI = weight in kilograms ÷ (height in meters)^2

For cross tabulation the following categorization was used:

Category	BMI (kg/m^2)
Underweight	Under 18.5
Normal weight	18.5 – 24.9
Overweight	25 – 29.9
Obese	30 – 39.9
Severely Obese	40 and over

Changes in body weight and BMI were computed as Day 57 (LOCF) measurement minus the baseline measurement. The key endpoint for weight change was whether a patient gained ≥7% over baseline. Weight loss of ≥7% has been presented as well.

5.5.7.7 Physical examination

New positive findings on last-visit physical examination were to be reported as adverse events.

5.5.7.8 Simpson-Angus Scale (SAS)

The SAS (Simpson and Angus 1970) is the sum of a 10-item scale that is used to rate the presence and intensity of extrapyramidal motor symptoms, with the score for each item ranging from 0 to 4. The investigator could also enter each item as "not ratable." Items rated as "not ratable" were scored as a "9" in the database and were treated as missing data and not included in the total score (See Statistical Analysis Plan, Appendix 12.1.9, for further detail). Increases from baseline in total score thus indicated an increase in extrapyramidal motor symptoms.

5.5.7.9 Barnes-Akathisia Rating Scale (BARS)

The BARS (Barnes 1989) has 4 items and is used to assess objective and subjective attributes of akathisia. Only one item of the BARS, the Global Assessment of Akathisia, with a score ranging from 0 to 5 was analyzed. Increases from baseline in the global assessment item score thus indicated an increase in akathisia.

5.6 Data management and quality assurance

The quality of study data was assured through monitoring of investigational sites, provision of appropriate training for study personnel, and use of data management procedures, as detailed below.

AstraZeneca's quality assurance and internal quality control procedures provide reassurance that the clinical study program was carried out in accordance with GCP guidelines. AstraZeneca undertakes a GCP audit program to ensure compliance with its procedures and to assess the adequacy of its quality control measures. Audits, by a Global Quality Assurance group operating independently of the study monitors and in accordance with documented policies and procedures, are directed towards all aspects of the clinical study process and its associated documentation.

5.6.1 Monitoring

An investigator's meeting was held before the start of the study. During the study, the LRA monitors had regular contact with the investigational sites; these contacts included visits to confirm that the facilities remained acceptable, that the investigational teams were adhering to the protocol, that data were being accurately recorded in the CRF and to provide information and support to the investigator. The monitor ensured that drug accountability was being carried out. Source data verification (a comparison of the data in the CRF with the hospital and other records at the investigational site) was also performed. The monitors or other LRA personnel were available between visits to provide any information or advice required by the investigator.

5.6.2 Training

Investigational personnel were trained and tested on the administration of the MADRS, the HAM-D, the HAM-A and the YMRS at an investigators meeting in San Diego in September 2002. Testing standards were set at ±2points for each test item. If trainees failed to meet this

standard for ≥3 items, or if their total test score was deviant by 4 points or more, they were required to repeat the test using a new test videotape. Training but no testing was also provided by Michael B First, MD, Columbia University for the SCID.

In addition, all site personnel were given a refresher course on study procedures by one of 5 WEBEX meetings in May of 2003. The refresher course also covered known points of difficulty based upon experience in the trial to date.

5.6.3 Data management

Case report forms were provided for recording of data. The forms were printed in triplicate on carbonless paper. Data were to be recorded directly and legibly onto the case report forms with black ink, preferably with black ball-point pen. If any data were not available, omissions were to be indicated on the case report forms. Corrections were to be made legibly and be initialed and dated by approved personnel; the reasons for significant changes had to be provided. Correction fluid or covering labels could not be used. The top 2 sheets were collected and returned to AstraZeneca Pharmaceuticals and the 3rd sheet was retained by the investigator.

Data from the completed CRFs were entered into a Microsoft ACCESS database version 97 at LRA and transferred to AstraZeneca as SAS datasets. The process was documented in the Data Management Plan and the Data Management Validation Guidelines and the validation performed under the direction of the responsible Data Manager. Centrally collected ECG data were sent from eResearch Technology in an electronic format to be loaded by batch process.

Clinical laboratory data were transferred to AstraZeneca from Quintiles Laboratories as SAS datasets.

Data management activities (i.e, cleaning of data) were performed using the ACCESS database version 97. Any data queries raised following validation were dealt with using data query sheets. The distribution of copies was as for the CRFs.

5.7 Statistical methods and determination of sample size

5.7.1 Statistical evaluation

The statistical evaluation of study data was performed by Margaret Minkwitz of the AstraZeneca Quantitative Decision Sciences group using SAS® Version 8.

5.7.2 Description of outcome variables in relation to objectives and hypotheses

Definitions of efficacy outcome variables are given in Section 5.5.3. Definitions of patient-reported outcome variables are given in Section 5.5.5. Definitions of safety outcome variables are given in Section 5.5.7.

Statistical comparisons of the primary outcome variable, the change from baseline at Day 57 (LOCF) in the MADRS total score, tested the hypothesis that treatment with quetiapine 300 mg once daily or with quetiapine 600 mg once daily would produce larger reductions than

would treatment with placebo. The same hypotheses were tested for the following secondary efficacy, exploratory efficacy and safety outcome variables:

- Change from baseline at each assessment of MADRS total score
- Change from baseline to each assessment in the total HAM-D total score
- Change from baseline to each assessment in the HAM-D Item 1 score
- Change from baseline to each assessment and at final assessment for the CGI-S score
- CGI-I score at each assessment and at final assessment
- Change from baseline to each assessment and at final assessment for the Q-LES-Q score
- Change from baseline to each assessment and at final assessment for the YMRS score
- Change from baseline at final assessment for the PSQI score
- Change from baseline at final assessment for the BARS score

Analysis of the secondary outcome variables of response to treatment (≥50% reduction in MADRS total score from baseline) and remission (achievement of MADRS total score ≤12) following treatment tested the hypotheses that treatment with quetiapine 300 mg once daily or with 600 mg once daily would produce a larger proportion of patients that met criteria within either of the treatment groups compared to the placebo group.

Analysis of the secondary outcome variables of change from baseline to each assessment and to final assessment in the HAM-A total score tested the hypotheses that treatment with quetiapine 300 mg once daily or with quetiapine 600 mg once daily would produce similar or larger reductions than would treatment with placebo.

5.7.3 Description of analysis sets

Data analysis was based on the following 3 patient populations:

- The safety population included all enrolled patients classified according to treatment actually received. Randomized patients who did not receive treatment were excluded.
- The intention-to-treat (ITT) population included all evaluable patients in the safety population, classified according to the assigned randomized treatment. It included all enrolled patients who took study medication and who had a baseline MADRS and at least 1 valid post baseline MADRS assessment. Two patients who had

enrolled at two separate sites and who were randomly assigned to placebo treatment at both sites were not regarded as evaluable. Their exclusion reduced the original placebo group by 4. The ITT population was used to assess the primary efficacy outcome variable.

- The per-protocol (PP) population excluded patients from the ITT population with protocol violations and deviations that were regarded as interfering with an accurate efficacy assessment (see Statistical Analysis Plan in Appendix 12.1.9 for further detail).

5.7.4 Methods of statistical analysis

5.7.4.1 General principles

All statistical tests were 2-sided. The primary analyses used last observation carried forward (LOCF) for the time period of interest.

This trial employed a central randomization with a stratification based on diagnosis (bipolar 1 and bipolar 2); therefore diagnosis (not center) was included as a stratification variable in the analysis models. Center was included in the ANCOVA model as a random effect.

For the primary analysis a Simes-Hommel step up procedure was used to adjust for the 2 comparisons of each quetiapine dose with placebo. The p-values obtained from the analysis were ordered as: $P(1) \leq P(2)$. The following rule was used to assess statistical significance for the primary analysis:

1. If $P(2) \leq 0.05$, then reject both null hypotheses associated with P(2) and P(1): else proceed

2. If $P(1) \leq 0.025$, the reject null hypothesis associated with P(1)

All secondary analyses were conducted at the nominal significance level of 0.05, with no adjustment for multiple comparisons.

The primary analysis of efficacy was performed on the ITT population. A PP analysis was also conducted for the primary efficacy variable to assess sensitivity of results.

Although the data were stratified by entry criteria for diagnosis, bipolar I or bipolar II, if a patient's diagnosis on the case report form differed from the stratification group, the patient was reclassified into the appropriate diagnostic group for analysis.

Patients who were randomized but subsequently were never dosed were excluded from both efficacy and safety analyses.

5.7.4.2 Testing of covariates

In general, the baseline value for a given score was included as a covariate in an analysis of change from baseline for that score. Because randomization was stratified by diagnosis, diagnosis stratum was also included as a covariate where appropriate.

Potential center effects were evaluated. It was not expected that all centers would contribute patients to all strata. Thus imbalances were expected both in terms of number randomized and in the distribution across the strata. The expectation was that approximately 1/3 would be bipolar II and 2/3 bipolar I. There was a limit of 70 patients in a center (13% of the randomized population) but the median was expected to be >12 patients/center.

Assumptions of the intended analysis were explored using blinded data (e.g., using probability plots when testing the assumption of normality and consistency of variance). If any of the assumptions were found to be violated, an appropriate transformation or a non-parametric technique was considered to validate the main results.

5.7.4.3 Efficacy analysis methods

Efficacy analysis methods are summarized below. Changes from the original statistical analysis plan are described in Section 5.8.2.

Primary analysis for MADRS

The primary analysis of change from baseline to final assessment (LOCF) in MADRS total scores tested the superiority of each dose level of quetiapine using an Analysis of Covariance (ANCOVA) with the baseline MADRS total score as the covariate and including treatment and diagnosis strata as fixed effects and center as a random effect in the model.

The significance of the pairwise comparisons of quetiapine dose groups to placebo were ordered and compared to the cut off values for the Simes-Himmel step up procedure to preserve the overall experiment-wise error rate and conserve power.

The primary analysis used the ITT population with a second analysis performed on the PP population to assess sensitivity of results to population.

A further analysis of the change from baseline in MADRS total score was performed using a repeated measures mixed effects model. The model included terms for treatment, bipolar diagnosis, treatment x bipolar diagnosis, baseline MADRS total score, visit (week), and treatment x visit effects. Several covariance structures were examined, including autoregressive, banded Toeplitz, compounded symmetry and unstructured. The best fitting covariance structure, the banded Toeplitz, was determined using the Bayesian information criterion.

Secondary efficacy analysis

All secondary analyses were made in order to yield supportive evidence that quetiapine was more effective than placebo. These analyses used the ITT population and mainly have been

presented as point estimates with associated 95% confidence intervals for the treatment effects and the difference between groups. The confidence levels and p-values displayed are nominal with no adjustment for multiplicity.

MADRS item analyses

Although item analysis for the MADRS was not initially described in the SAP, the items were analyzed using an ANCOVA model. Analysis was conducted for completeness to identify aspects of the scale where quetiapine treatment separated from placebo.

Response

Analysis of categorized MADRS response (at least a 50% reduction from baseline) tested the treatment and placebo difference at each visit and at final assessment (LOCF) using a Cochran-Mantel-Haenszel Chi square test across diagnosis strata. Summary statistics (number and % in each treatment group responding) have been presented along with the p-values and estimated log-odds ratio with 95% confidence interval. The model was fitted using the PROC FREQ procedure in SAS®.

Remission

Post-hoc analysis of categorized MADRS remission (total score ≤12) tested the treatment and placebo difference at each visit and at final assessment (LOCF) using a Cochran-Mantel-Haenszel Chi square test across diagnosis strata. Summary statistics (number and % in each treatment group responding) have been presented along with the p-values and estimated log-odds ratio with 95% confidence interval. The model was fitted using the PROC FREQ procedure in SAS®.

HAM-D

Descriptive statistics have been presented for HAM-D total score, HAM-D Item 1 score, change from baseline for HAM-D total score and change from baseline HAM-D Item 1 by visit and final assessment (LOCF). The ANCOVA model was used with baseline as a covariate and treatment and diagnosis strata as fixed effects.

CGI

Descriptive statistics have been presented for the CGI-S, CGI-I and change from baseline in CGI-S by visit and final assessment.

Two approaches to analysis were evaluated; one approach handled the data as if they were continuous and analyzed the change from baseline CGI-S and CGI-I using an ANCOVA model with baseline CGI-S as a covariate and treatment and diagnosis strata as fixed effects.

In the second approach, the CGI-I was dichotomized into a binomial response: improved (defined as rating of “much improved” or “very much improved”) or not improved (defined as any lesser rating than “much improved”). This was assessed in the same manner as MADRS response.

YMRS total score

Descriptive statistics have been presented for the YMRS total score and the change from baseline in YMRS total score by visit and at final assessment. The ANCOVA model was used with the MADRS baseline as a covariate and treatment and diagnosis strata as fixed effects.

HAM-A

Descriptive statistics have been presented for the HAM-A total score and the change from baseline in HAM-A total score by visit and at final assessment. The ANCOVA model was used with the MADRS baseline as a covariate and treatment and diagnosis strata as fixed effects.

PSQI

The PSQI score was calculated as described in Section 5.5.4.3. Descriptive statistics have been presented for the PSQI total score, change from baseline in PSQI total score and itemized response to each question by assessment visit and final assessment. The ANCOVA model was used for PSQI change from baseline to each assessment and final visit with the baseline PSQI total score as a covariate and treatment and diagnosis strata as fixed effects.

Q-LES-Q

Descriptive statistics of overall level of satisfaction with general activities have been presented for the Q-LES-Q raw total score, Q-LES-Q % maximum total score, change from baseline in Q-LES-Q raw total score, and change from baseline in % maximum total score by assessment visit and final assessment. The ANCOVA model was used for Q-LES-Q change from baseline for both raw total score and % maximum score to each assessment and final visit with the appropriate baseline Q-LES-Q total score as a covariate and treatment and diagnosis strata as fixed effects.

5.7.4.4 Safety analysis methods

All safety analysis were based on the safety population, but where change from baseline was the primary focus of the analysis, only patients with both baseline and post baseline data were included.

Adverse events incidence rates were tabulated and presented for the following categories: all adverse events, serious adverse events, drug related adverse events, adverse events leading to death, and adverse events leading to withdrawal of patients from the study. No formal statistical testing was performed for adverse events.

Safety areas of special interest defined for the Seroquel program included extrapyramidal syndrome (EPS), QT prolongation, neutropenia/agranulocytosis, weight changes, metabolic syndrome, diabetes and suicidality. For this trial, suicidality was defined on the basis of adverse events only. QT prolongation, neutropenia/agranulocytosis, weight changes, metabolic syndrome and diabetes were evaluated on the bases of both adverse event reports and clinical findings. EPS was examined by using adverse event and anticholinergic medication data along with SAS and BARS scores.

Laboratory, weight, vital signs and ECG data have been analyzed as descriptive statistics for change from baseline, as shifts from normal/abnormal values and as shifts from positive/negative potentially clinically important findings.

Glucose metabolism variables were evaluated for the general safety population and for the 3 subgroups of patients defined as 1) known to be diabetic, 2) regarded as at-risk for diabetes, and for those who were 3) neither diabetic nor at-risk for diabetes. Patients were considered as known to be diabetic if they had a history of diabetes or had a baseline fasting glucose assessment ≥126 mg/dL. Patients were considered to be at-risk for diabetes if they had a history of gestational diabetes, a BMI ≥35, or a baseline fasting glucose assessment ≥100 mg/dL but <126 mg/dL. Patients were considered to be neither diabetic nor at-risk for diabetes if they did not meet criteria for diabetes or diabetes risk. Diabetes and at-risk subgroups were also classified on the basis of criteria for random glucose sampling (≥200 mg/dL for diabetes; random criteria were not applied to classify the at-risk category) to explore the possibility of variable fasting status for blood sampling.

As insulin and glucose were measured in this study, post hoc analysis of their functional relationship considered insulin resistance ($HOMA_R$) and insulin sensitivity (QUICKI) as additional summary variables. $HOMA_R$ was computed using the formula:

$$HOMA_R = Insulin\ (\mu U/mL) \times glucose\ (mmol/L)/22.5$$

QUICKI was computed using the formula:

$$QUICKI = 1/\{\log_{10}[fasting\ insulin\ (\mu U/mL)] + \log_{10}[fasting\ glucose\ (mg/dL)]\}$$

A post-hoc evaluation of the glucose change from baseline and the insulin, $HOMA_R$, and QUICKI final assessment results were performed to determine the impact of treatment on those measures. ANCOVA models were applied, with treatment, diabetes risk group, baseline assessment results and study site (random variable) as explanatory variables.

Metabolic syndrome risk factors were evaluated by determining which patients had relevant medical history at baseline or who exhibited combinations of the following findings:

- BMI ≥30 kg/m^2
- Supine systolic blood pressure ≥130 mmHg or diastolic blood pressure ≥85 mmHg averaged over the last 2 assessments
- Triglycerides ≥150 mg/dL
- HDL <40 mg/dL for men or <50 mg/dL for women
- Glucose ≥110 mg/dL or random glucose ≥140 mg/dL

Patients who met an aggregate of at least 3 metabolic syndrome risk factors were considered to be at risk for metabolic syndrome. Patients were classified as meeting or not meeting each individual criterion at baseline and at final assessment. The number and proportion of patients shifting from meeting 0, 1, or 2 criteria to meeting either fewer than 3 vs 3 or more criteria at final assessment were determined. The contribution of each criterion factor to the meeting of 3 or more criteria was evaluated within the population meeting aggregate risk criteria by determining the proportion of patients who shifted from not meeting to fulfilling each individual criterion. A more detailed presentation of the methods used for analyzing metabolic syndrome risk factors is included in Appendix 12.1.9.

The difference between treatment groups in the proportion of patients whose SAS scores and BARS scores were greater than baseline at the final assessment was tested using a logistic regression model. The odds ratio was calculated for each treatment arm compared to placebo, together with a 95% confidence interval, using results from PROC GENMOD and was used to compare treatments. Statistical tests were performed as 2-tailed, with a significance level of 0.05. The main analysis was the final assessment (LOCF) for the time period of interest.

5.7.4.5 Study medication compliance and exposure

To summarize patient dose in concordance with the intent-to-treat principle, the prescribed daily dose (number of tablets) was used to measure the daily dose. Investigators could reduce the dose by 1 tablet per day after day 8 if needed. The number and percentage of patients for whom dose reduction was initiated was tabulated by treatment group.

Individual patient compliance was assessed based on tablets taken and expected number based on the duration of study participation. The patient was then classified as fully compliant (≥80%), partially compliant (≥70% and ≤80%) or non-compliant (<70%).

Patients were classified by the nominal dose for the treatment group to which they were assigned. Descriptive statistics have been provided on the category of compliance by treatment group and diagnosis.

5.7.4.6 Sleep medication use

Number of days and percent of the first 21 days with lorazepam use or sleep medication use was calculated for each patient. If a patient withdrew early, the percent was calculated based on the number of days in the trial if less than 21. These data were summarized by treatment group and diagnosis strata using descriptive statistics.

5.7.4.7 Withdrawals

Differences between treatment groups in overall rate of withdrawal and category of withdrawal were tested using a CMH test stratified by diagnosis. Withdrawals on or before day 8 were examined as part of the consideration of balance between treatment groups due to early withdrawal.

For each visit (week of study) withdrawals were summarized in total and by reason for withdrawal using descriptive statistics.

5.7.5 Determination of sample size

As there were no data using the MADRS instrument in the assessment of quetiapine in treating bipolar subjects with depression, the sample size estimation was based on published data from bipolar depression trials with lamotrigine (Calabrese et al 1999) and olanzapine monotherapy (Tohen et al 2003). The percentage change in the HAM-D across these lamotrigine studies in bipolar depression is similar to that observed with quetiapine (Sajatovic, Mullen and Sweitzer 2002). MADRS scores correlate significantly with those of the HAM-D (Montgomery and Asberg 1979).

Sample size was estimated using an Bonferroni correction for the 2 comparisons with placebo. A clinically meaningful 3.6-unit difference between quetiapine treatment and placebo was used to estimate the effect size (with 3.1 units considered a minimally effective and detectable difference). The variability used for calculation was 10 units, the variability seen in the olanzapine study. A sample size of 168 subjects/arm (504 subjects total) would provide 85% power for 2-sided pair-wise comparisons with placebo at α=0.025 which provides an overall experiment wise type I error rate of 0.05. Therefore, 740 patients were planned for screening and approximately 530 for randomized assignment to treatment (allowing for a 5% early drop out rate), to insure 504 patients with post baseline data available for analysis (MITT analysis population). This sample size would provide 72% power to detect a 3.1 unit difference from placebo.

5.7.6 Interim analyses

There were no interim analyses for this study.

5.7.7 Data and safety monitoring board

There were no data or safety monitoring boards for this study.

5.8 Clinical study protocol amendments and other changes in the conduct of the study or planned analyses

5.8.1 Changes in the conduct of the study

Amendments to the study protocol are shown in Table 18, which also indicates when amendments came into force with respect to the recruitment of subjects.

Table 18 Protocol amendments

Number (date of internal approval)	Key details of amendment (Section of this report affected)	Reason for amendment	Persons who initiated amendment[a]
Amendments made before the start of subject recruitment			
Amendment 1 30 September 02	Inclusion/exclusion criteria adjusted (Section 5.3)	Criteria clarified and better specified	Study team

Table 18 Protocol amendments

Number (date of internal approval)	Key details of amendment (Section of this report affected)	Reason for amendment	Persons who initiated amendment[a]
	QOL and safety outcome variables removed from Days 8, 15, 22, 35 and 43 assessments (Section 5.1)	Assessments deemed unnecessary	Study team
Amendments made after the start of subject recruitment			
Amendment 2 4 December 02	Established administration of the ICI-D (Section 5.5.3.2)	Quality control for MADRS administration	Study team
Amendment 3 21 April 03	Procedure for reporting AEs and for follow-up of AES for 30 days after cessation of study treatment changed to 7 days. (Section 5.5.7.2)	Follow-up limited to no more than 5 half-lives of quetiapine	Study team
	Specification of washout period for psychoactive medications simplified. (Section 5.3.3)	Allowed for greater consistency throughout protocol	
Amendment 4 12 May 03	Minimum and maximum number of patients enrolled per site changed from 4 and 50 to none and 70, respectively (Section 5.1)	Allowed greater enrollment without loss of balance across sites	Study team
	Day 57 or discontinuation assessments of CGI-I, CGI-S and Q-LES-Q added; all psychiatric assessments dropped when patient has missed 72 hours of study drug before visit. (Section 5.1)	Quetiapine's half-life of 4 hours makes 72-hour post dose assessment of questionable value	
	Text added to specify that patient data would be given privacy protection with patient authorization. (Section 1)	Protocol made compliant with HIPAA.	
Amendment 5 14 July 03	Procedure for reporting AEs and for follow-up of AES for 7 days after cessation of study treatment changed to 30 days. (Section 5.5.7.2)	Restored FDA-requested procedures.	Study team

a All protocol amendments were approved within AstraZeneca before being implemented.

5.8.2 Changes to planned analyses

Changes to the planned analyses are shown in Table 19. This table indicates when any changes were made in relation to the unblinding of study data.

Table 19 Changes to planned analyses

Key details of change (Section of this report affected)	Reason for amendment	Persons who initiated amendment
Changes made before unblinding of study data		
Hypotheses for HAM-A outcome variable changed from protocol statement "quetiapine….will be similar or better than placebo in producing anxiety symptoms" to "similar or better than placebo in reducing anxiety symptoms"	Error correction	Study team
Outcome variable name for BARS assessment corrected from "total score" to "global assessment score"	Error correction	Study team
Criteria for treatment-emergent mania/hypomania redefined as YMRS ≥16 on two consecutive assessments or at final assessment or an adverse event of mania or hypomania	Clearer, more inclusive criteria	Study team
Analysis of change from baseline for Q-LES-Q and PSQI at all assessments specified	Clearer, more inclusive criteria	
Criteria for treatment compliance changed in SAP from that stated in protocol	Clearer, more precise definition	Study team
Changes made after unblinding of study data		
Item analysis for MADRS added	Additional interpretive material on efficacy obtained	Study team
Comparative analysis of the rates of remission for each treatment group, defined as the proportion of patients with MADRS scores ≤ 12 at any visit was added to the analysis plan	Additional interpretive material on efficacy obtained	Study team
Comparative analyses of changes from baseline in MADRS item scores for each treatment group added to the analysis plan	Additional interpretive material on efficacy obtained	Study team
Criteria for binomial categorization of CGI-I redefined from that given in SA.	Definition more in accord with accepted criteria in medical literature	Study team
Computation of $HOMA_R$ and QUICKI at each visit added to safety analysis	Additional interpretive material on safety obtained	Study team

Table 19 Changes to planned analyses

Key details of change (Section of this report affected)	Reason for amendment	Persons who initiated amendment
Thyroid function assessments specified as T3 resin uptake instead of triiodothyronine	Clinical laboratory notified study team that incorrect analysis was reported	Study team
Safety assessments of special interest expanded to include EPS, diabetes, QT prolongation, neutropenia/agranulocytosis, weight changes, and metabolic syndrome risk factors	Identified as areas of regulatory interest and necessary for program consistency	Study team
Clinically important criteria revised as specified in Table 15 through Table 17	Criteria adjusted to current standards and for program consistency	Study team

6. STUDY SUBJECTS

A summary of the subject population is given in Section 6.1. Thereafter, the following aspects of the study population are considered: disposition (Section 6.2), adherence to the study protocol (Section 6.3), populations analyzed (Section 6.4), demography and other baseline characteristics (Section 6.5), and treatment compliance and use of concomitant medication (Section 6.6). Conclusions on the suitability of the subject population with respect to the overall purpose of the study are given in Section 6.7.

6.1 Summary of subjects

In total, 838 patients were screened and 542 patients with either bipolar I disorder and bipolar II disorder exhibiting moderate to severe depression were randomly assigned to receive either quetiapine 300 mg daily, quetiapine 600 mg daily or placebo. Bipolar I patients made up 66.4% of the total and bipolar II patients, 33.6%. Approximately 21% of all patients had rapid cycling courses (≥4 mood episodes in past year). The first patient was enrolled on 30 September 2002 and the last patient completed the study on 17 September 2003. Of the 542 patients recruited, 539 received treatment and were included in the safety population, of whom 511 were analyzed for efficacy in an intention-to-treat analysis set and 453 in a per-protocol analysis set. The three groups were well-matched in number and demographic and baseline disease characteristics. The mean patient age was approximately 37 years, and approximately 58% of the patients were female. Approximately 75% to 85% of patients in each treatment group were Caucasian, and most of the remainder were Black. Within the safety population,

67% of quetiapine 300 mg patients, 54% of quetiapine 600 mg patients and 59% of placebo patients completed the protocol. Adverse events were the main reason for withdrawal in quetiapine-treated patients, while lack of efficacy was the main reason for withdrawal in placebo-treated patients.

Table 20 shows where the data supporting this section are presented.

Table 20 Location of supporting data on study subjects

Concomitant medication use	Table 11.1.7.6 to Table 11.1.7.10	Appendix 12.2.10.7
Treatment compliance	Table 11.3.1.4 to Table 11.3.1.6	Appendix 12.2.5

6.2 Disposition

The disposition of study subjects is summarized in Figure 1.

Figure 1 Subject disposition (completion or discontinuation)

	Quetiapine 300 mg	Quetiapine 600 mg	Placebo
Randomized	181	180	181
Not treated[a]	2	0	1
Received drug	179	180	180
Discontinued study treatment	60	82	74
Lost to follow-up	12	21	11
Adverse event	29	47	16
Protocol noncompliance	10	4	11
Informed consent withdrawn	5	6	12
Lack of efficacy	4	1	24
Other	0	3	0
Completed study	121	98	107

a Patients not treated are also included in the discontinued from study treatment population due to protocol noncompliance

Data derived from Table 11.1.1.1, Table 11.1.2.1 and Table 11.1.4.1

Rates of study completion were 68% for quetiapine 300 mg patients, 54% for quetiapine 600 mg patients and 59% for placebo-treated patients. However, the differences between active treatment groups and the placebo group were not statistically significant (quetiapine 300 mg vs placebo: p = 0.109; quetiapine 600 mg vs placebo: p = 0.343; see Table 11.1.4.5). Similar proportions of patients in the quetiapine 300 mg group (99.4%), the quetiapine 600 mg group (96.1%) and the placebo group (98.9%) participated in the study through the first 8 days of treatment (see Table 11.1.4.3) although some had discontinued study therapy during the first 8 days (see Table 21).

Among all patients assigned to treatment, lack of efficacy was cited as the reason for withdrawal of 2.2% of quetiapine 300 mg patients, 0.6% of quetiapine 600 mg patients and 13.3% of placebo patients (see Table 11.1.4.1). Patients treated with quetiapine 600 mg had higher rates of withdrawal than did quetiapine 300 mg patients and placebo-treated patients due to being lost to follow-up (11.7%, 6.6% and 6.1% respectively; see Table 11.1.4.1). Patients treated with placebo showed higher withdrawal rates due to withdrawal of informed consent than did either quetiapine treated group (placebo: 6.6%; quetiapine 600 mg: 3.3%; quetiapine 300 mg: 2.8%; see Table 11.1.4.1). Withdrawal due to adverse events was seen in 16.0% of quetiapine 300 mg patients, 26.1% of quetiapine 600 mg patients and 8.8% of placebo-treated patients in the randomly-assigned population (see Table 11.1.4.1). Of all patients randomly assigned to treatment, 55.3% of Bipolar I patients and 48.6% of Bipolar II patients completed the protocol (see Table 11.1.4.4).

6.3 Protocol violation and deviations leading to exclusion from the PP population

The number of subjects with protocol violations or deviations in each treatment group that lead to exclusion from the PP population are summarized in Table 21.

Table 21 Protocol violations and deviations leading to exclusion from the PP population

Protocol deviation or violation	Number (%) of ITT subjects		
	Quetiapine 300 mg N=172	Quetiapine 600 mg N=170	Placebo N=169
Protocol violators and deviators[a]	20 (11.6)	23 (13.5)	15 (8.9)
YMRS total score >12 at screen or baseline visit	0 (0)	1 (0.6)	0 (0)
Depression episode >12 months or <4 weeks	0 (0)	1 (0.6)	2 (1.2)
History of substance dependence	1 (0.6)	1 (0.6)	0 (0)
Use of psychoactive medications within 7-28 days prior to randomization[b]	3 (1.7)	4 (2.4)	4 (2.4)
TSH >10% over the ULN at screen/baseline	0 (0)	0 (0)	3 (1.8)

Table 21 Protocol violations and deviations leading to exclusion from the PP population

Protocol deviation or violation	Number (%) of ITT subjects		
	Quetiapine 300 mg N=172	Quetiapine 600 mg N=170	Placebo N=169
Zolpidem use >10 mg in first 3 weeks	1 (0.6)	0 (0)	0 (0)
Zolpidem or lorazepam use after Week 3	1 (0.6)	0 (0)	0 (0)
Potent P450 inhibitor use	0 (0)	1 (0.6)	0 (0)
Antipsychotic use during study	1 (0.6)	1 (0.6)	0 (0)
Antidepressants, hypnotics, mood stabilizers during study	1 (0.6)	3 (1.8)	2 (1.2)
Subjects who reduced study medication by more than 100 mg	0 (0.0)	4 (2.4)	0 (0.0)
Subjects who received any dose reduction before Day 8	3 (1.7)	3 (1.8)	2 (1.2)
Subjects who received less than 70% of prescribed doses	2 (1.2)	2 (1.2)	1 (0.6)
Subjects who received <=8 days of study therapy	15 (8.7)	16 (9.4)	7 (4.1)
MADRS assessment collected >4 days after last dose of study medication	6 (3.5)	6 (3.5)	1 (0.6)
Documented drug abuse during study	1 (0.6)	1 (0.6)	0 (0)
No post-baseline assessment after data exclusions	2 (1.2)	0 (0)	0 (0)

a Patients in this category may have multiple reasons listed below
b See Section 5.1 for drug washout requirements
Data derived from Table 11.1.3.2 and include only items with counts

Patients were excluded from the PP population in similar proportions and for similar causes among the 3 treatment groups overall. Exclusion for receiving less than 9 days of treatment was the most common reason for all treatment groups.

6.4 Subject populations analyzed (analysis sets)

The analysis sets and the number of subjects in each analysis set are summarized in Figure 2. Definitions of the analysis sets are given in Section 5.7.3.

Figure 2 Analysis sets

	Quetiapine 300 mg n = 181	Quetiapine 600 mg n = 180	Placebo n = 181
Excluded from safety population			
Not treated	2	0	1
Safety population	179	180	180
Excluded from ITT population	7	10	11
No valid baseline or post-baseline MADRS score	7	10	7
Multiple center participation	0	0	4
Intent-to-Treat Population	172	170	169
Excluded from PP population see Table 21 for reasons	20	23	15
PP population	152	147	154

Data derived from Table 11.1.2.1, Table 11.1.3.1 and Table 11.1.3.2.

All decisions on the inclusion or exclusion of patients from analyses were made while the data were masked.

Protocol deviations and violations leading to exclusion of quetiapine-treated patients from the ITT population were restricted to missing MADRS data that made computation of change from baseline impossible. Two placebo-treated patients were excluded for participating in the study at more than one site, resulting in a loss of 4 from the ITT population. Altogether, ten of the 180 patients treated with quetiapine 600 mg, 7 of the 179 patients treated with quetiapine 300 mg and 11 of the 180 patients treated with placebo were excluded from the ITT population (see Table 11.1.3.1). Exclusions from the PP population are described in Section 6.3.

6.5 Demographic and other patient characteristics

6.5.1 Sex, age, race and weight

The demographic and key baseline characteristics of study subjects in the ITT population are summarized in Table 22. Data for the safety population are presented in Table 11.1.5.1.1 and Table 11.1.5.2.1.

Table 22 Demographic and baseline characteristics of the ITT population

Demographic or baseline characteristic		Treatment group		
		Quetiapine 300 mg (N=172)	Quetiapine 600 mg (N=170)	Placebo (N=169)
Demographic characteristics				
Sex: n(%)	Male	79(45.9)	71 (41.8)	64 (37.9)
	Female	93(54.1)	99 (58.2)	105 (62.1)
Age (years)	Mean (SD)	36.6 (11.2)	37.3 (11.4)	38.3 (11.1)
	Minimum	18	18	18
	Maximum	65	63	62
Age distribution: n (%)	18-39 years	103 (59.9)	99 (58.2)	96 (56.8)
	40-65 years	69 (40.1)	71 (41.8)	73 (43.2)
Race: n(%)	Caucasian	141 (82.0)	144 (84.7)	129 (76.3)
	Black	23 (13.4)	18 (10.6)	26 (15.4)

	≥40 kg/m^2	17 (10.0)	15 (9.0)	16 (9.5)

Data derived from Table 11.1.5.1.2 and Table 11.1.5.2.2.

The safety and PP populations were similar to the ITT population in distribution of demographic and baseline characteristics. The treatment groups were well-matched in all analysis populations (see Tables 11.1.5.1.1, and 11.1.5.1.2 and Tables 11.1.5.2.1 and 11.1.5.2.2).

6.5.2 Baseline disease characteristics

Baseline disease characteristics for the ITT population are displayed in Table 23. Baseline disease characteristics for the safety population are presented in Table 11.1.6.1 and Table 11.1.6.2).

Table 23 Baseline disease characteristics (ITT population)

Data derived from Table 11.1.6.1, Table 11.1.6.3, Table 11.2.1.1.1, Table 11.2.2.1.1, Table 11.2.3.1.1, Table 11.2.5.1.1, Table 11.2.6.1, Table 11.1.6.5, Table 11.3.8.1..7.1

MADRS total scores at baseline ranged from 13 to 48; the mean MADRS total score was between 30 and 31 in the 3 groups within the ITT population. The PP population was similar to the ITT population with respect to baseline MADRS scale scores (see Table 11.2.1.1.1 and Table 11.2.1.1.3). HAM-D total scores at screening ranged from 20 to 35; the mean HAM-D total score was between 24 and 25 in the 3 groups within the ITT population. CGI-S scores at screening ranged from 3 to 6 with means of 4.3 to 4.5 for the 3 groups.

Descriptive parameters for years since first depressed episode, for the number depressed episodes over lifetime and for the number of manic or hypomanic episodes over lifetime were similar for the 3 treatment groups (see Table 23).

The ITT population comprised two-thirds Bipolar I and one-third Bipolar II patients, with similar proportions for each treatment group (see Table 11.1.6.1). Both Bipolar I and Bipolar II patients exhibited baseline mean MADRS scores of 30 to 31 points and mean screening HAM-D scores of 24 to 25 points (see Table 11.2.1.1.2 and Table 11.2.2.1.1). CGI-S scores for the Bipolar I patients ranged from 4.4 to 4.5 for the 3 groups, while for the Bipolar II patients, from 4.2 to 4.4 (see Table 11.2.3.4.1). Patients with a rapid cycling course (≥4 mood episodes in the past year) made up 21% of patients in all three treatment groups (see Table 11.1.6.5).

6.6 Treatment compliance and use of concomitant medication

6.6.1 Treatment compliance

Compliance was uniform and high within the entire safety population for the 3 treatment groups. One hundred seventy six quetiapine 300 mg patients (98.3%), 177 quetiapine 600 mg patients (98.3%) and 178 placebo patients (98.9%) were classified as being compliant on the basis of tablet counts that were consistent with at least 80% consumption of doses (see Table 11.3.1.4).

6.6.2 Concomitant medication

6.6.2.1 Use of medication at study entry

The use of psychoactive medications at Visit 1 (screening) in the ITT population is summarized in Table 11.1.7.2. Approximately 16% to 17% of patients in the safety population were taking an antidepressant before Visit 1 (screening); 4% to 12% were taking an antipsychotic, and 3% to 8% were taking both an antipsychotic and an antidepressant (see Table 11.1.7.5). The treatment groups were well-matched with respect to recent medication history.

6.6.2.2 Use of concomitant medication after randomization

The use of psychoactive medications after study entry in the ITT population is summarized in Table 11.1.7.7. Lorazepam use was noted for 9.9% of quetiapine 300 mg patients, 5.3% of quetiapine 600 mg patients and 8.3% of placebo patients. Zolpidem use was noted for 4.1% of quetiapine 300 mg patients, 6.5% of quetiapine 600 mg patients and 7.7% of placebo patients. Deviations from the protocol list of excluded medications were recorded for a small number of patients in the safety population and were distributed across all three treatment groups. Most of these cases arose from hospitalizations for psychiatric AEs (see individual patient narratives in Section 11.3.5.3) or from prescriptions initiated at the close of a patient's participation in the study.

Anticholinergic use for any indication was low (<7% at any week) for all treatment groups (see Table 11.1.7.10). One patient (Patient 0014012; see Table 12.2.10.7) treated with 600 mg of quetiapine daily for 18 days was given diphenhydramine 10 mg for 2 days to treat akathisia.

6.7 Conclusions on study subjects

The 542 patients with either bipolar I disorder or bipolar II disorder exhibiting moderate to severe depression who participated in this study provided an adequate number to meet the design requirements to provide adequate statistical power. The patients were representative of the general patient population -- bipolar I patients made up 66.4% of the total, and 21.1% of all patients had rapid cycling courses. The three treatment groups were well-matched in number and demographic and baseline disease characteristics. The mean patient age was approximately 37 years, and approximately 58% of the patients were female. Approximately 75% to 85% of patients in each treatment group were Caucasian, and most of the remainder were Black. Within the safety population, 67% of quetiapine 300 mg patients, 54% of quetiapine 600 mg patients and 59% of placebo patients completed the study. Adverse events were the main reason for withdrawal in quetiapine-treated patients, while lack of efficacy was the main reason for withdrawal in placebo-treated patients.

7. EFFICACY RESULTS

A summary of the efficacy results is given in Section 7.1. Full results are given in following sections, and any issues potentially affecting these results are discussed in Section 7.6. Conclusions on efficacy are given in Section 7.7.

7.1 Summary of efficacy results

The comparison of change from baseline in total MADRS score supported the hypothesis that quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment of a depressive episode in patients with bipolar disorder was superior to placebo in reducing the level of depressive symptoms. Quetiapine treated groups also showed superiority to placebo at Day 57 for changes from baseline in HAM-D total score, HAM-D Item 1, CGI and the HAM-A, and for MADRS-defined response. A treatment advantage for quetiapine over placebo for the primary and most secondary outcome variables was statistically significant by Day 8 and continued to be so through Day 57. The proportion of patients showing ≥50% reduction in MADRS total score (responders) was statistically significantly higher for the quetiapine 600 mg group compared to the placebo group by Day 8 and for the quetiapine 300 mg group by Day 15.

Table 24 shows where the data supporting this section are presented.

7.2 Efficacy results

7.2.1 Primary variable: MADRS total score change from baseline at last assessment

Results of the analysis of Day 57 change from baseline in MADRS total score are shown in Table 25.

Table 25 MADRS total score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	**Baseline Mean (SD)**	**LS mean change or difference**	**Upper 95% Limit**	**p-value**
Quetiapine 300 mg	172	30.3 (5.03)	-16.39	-14.59	
Quetiapine 600 mg	170	30.3 (5.29)	-16.73	-14.92	
Placebo	169	30.6 (5.27)	-10.26	-8.45	
Quetiapine 300 mg vs placebo			-6.13	-3.94	<0.001
Quetiapine 600 mg vs placebo			-6.47	-4.26	<0.001

Data derived from Table 11.2.1.2.1

MADRS total scores decreased for both quetiapine and placebo-treated patients, but the decrease was significantly greater for the quetiapine-treated patients (see Table 25). At the end of the 8-week course of treatment, quetiapine 300 mg patients in the ITT population had a least square mean of 6.13 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 6.47 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo:$p<0.001$; see Table 25). The same general magnitude of mean difference between treatments was also seen in the PP patients in the ITT population in which quetiapine 300 mg patients had a least square mean of 6.39 points lower score than did placebo-treated patients and quetiapine 600 mg patients had a least square mean of 7.14 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 11.2.1.2.3). The OC analysis of the ITT population, revealed that patients treated with quetiapine 300 mg had a least square mean of 5.67 points lower than placebo-treated patients and those treated with quetiapine 600 mg, had a least square mean of 7.74 points less than placebo-treated patients at Day 57 (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 300 mg vs placebo: $p<0.001$; see Table 11.2.1.2.2).

Analysis using the MMRM technique supported the primary analysis findings (see Table 11.2.1.2.7).

Change from baseline in MADRS total score is shown by bipolar diagnosis in Table 26.

Table 26 MADRS change from baseline at Day 57 by bipolar diagnosis (LOCF, ITT population)

	QTP 300		QTP 600		Placebo	
	N	Mean change	N	Mean change	N	Mean change
Bipolar I	116	-17.1	114	-18.2	112	-9.5
Bipolar II	56	-15.2	56	-13.9	57	-12.2

Data derived from Table 11.2.1.4.1

Bipolar I and bipolar II patients treated with either 300 mg or 600 mg of quetiapine showed greater improvements in MADRS total score compared to patients treated with placebo. Bipolar I patients exhibited larger differences from placebo at final assessment than did bipolar II patients. The less pronounced differential effect for Bipolar II patients was due to a smaller reduction in MADRS total score for each quetiapine treatment group and a greater reduction in score for Bipolar II placebo patients compared to Bipolar I placebo patients (see also Figure 11.2.1.5.1).

Descriptive statistics of MADRS data classified by race, age or sex did not reveal any notable differences between the treatment groups (see Table 11.2.1.7, Table 11.2.1.8 and Table 11.2.1.9).

Comparison of quetiapine treatment groups to the placebo treatment group for MADRS individual item changes from baseline at Day 57 is shown in Table 27.

Table 27 MADRS item comparisons at Day 57 (LOCF, ITT population)

	Quetiapine 300 mg		Quetiapine 600 mg	
MADRS item	**LS mean difference from placebo**	**p-value**	**LS mean difference from placebo**	**p-value**
1. Apparent sadness	-0.57	<0.001	-0.66	<0.001
2. Reported sadness	-0.67	<0.001	-0.80	<0.001
3. Inner tension	-0.49	0.002	-0.75	<0.001
4. Reduced sleep	-1.28	<0.001	-1.38	<0.001
5. Reduced appetite	-0.34	0.056	-0.29	0.107
6. Concentration difficulties	-0.61	<0.001	-0.51	0.005
7. Lassitude	-0.32	0.080	-0.40	0.028
8. Inability to feel	-0.59	<0.001	-0.55	0.002
9. Pessimistic thoughts	-0.81	<0.001	-0.71	<0.001
10. Suicidal thoughts	-0.43	<0.001	-0.41	0.001

Data derived from Table 11.2.1.11.1 through Table 11.2.1.11.10

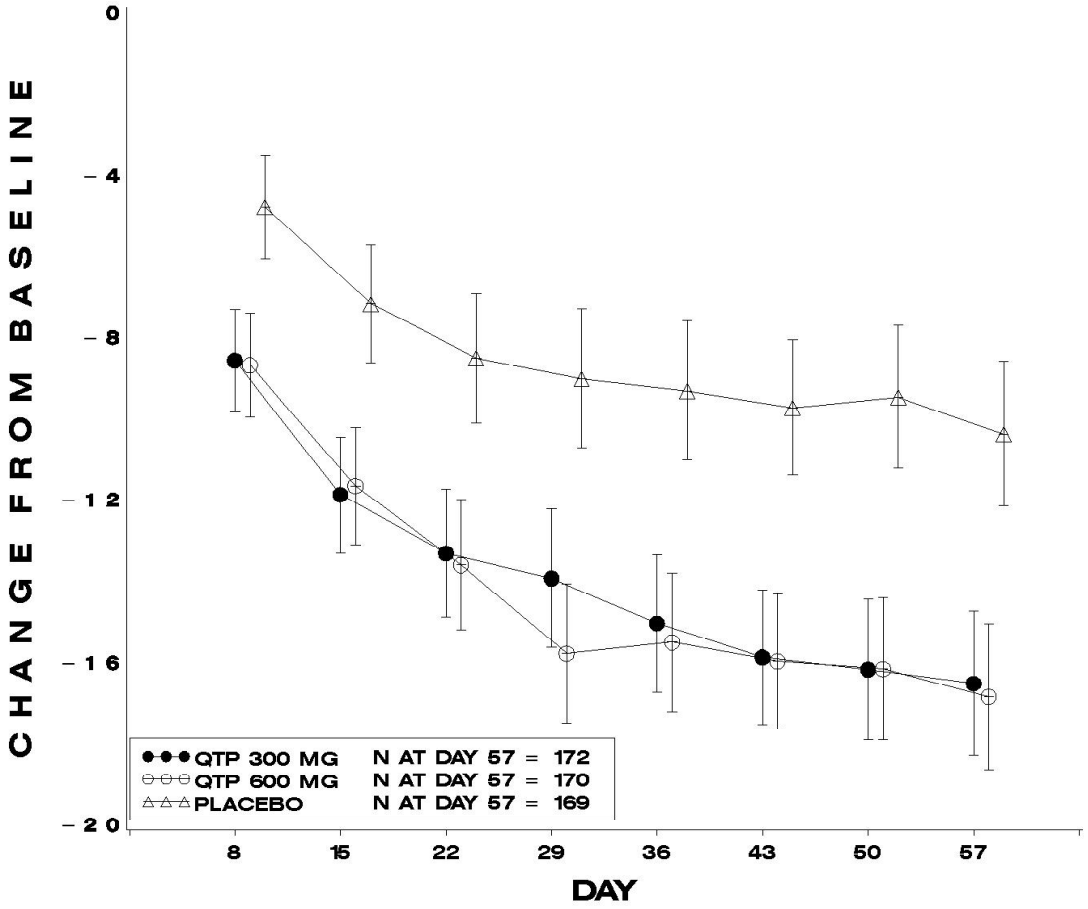
All of the ten individual MADRS item scores were reduced more by quetiapine treatment than by placebo treatment, with the largest treatment differences in Reduced Sleep and Reported Sadness items. The Reduced Appetite and Lassitude items were the only two that did not reach p-values <0.05 for both doses of quetiapine.

7.2.2 Secondary variables

7.2.2.1 Change from baseline to each assessment for the MADRS total score

Changes from baseline in the MADRS total score at each visit for ITT patients are shown in Figure 3.

Figure 3 **MADRS total score change from baseline -- LS mean (95% CI) (LOCF, ITT population)**

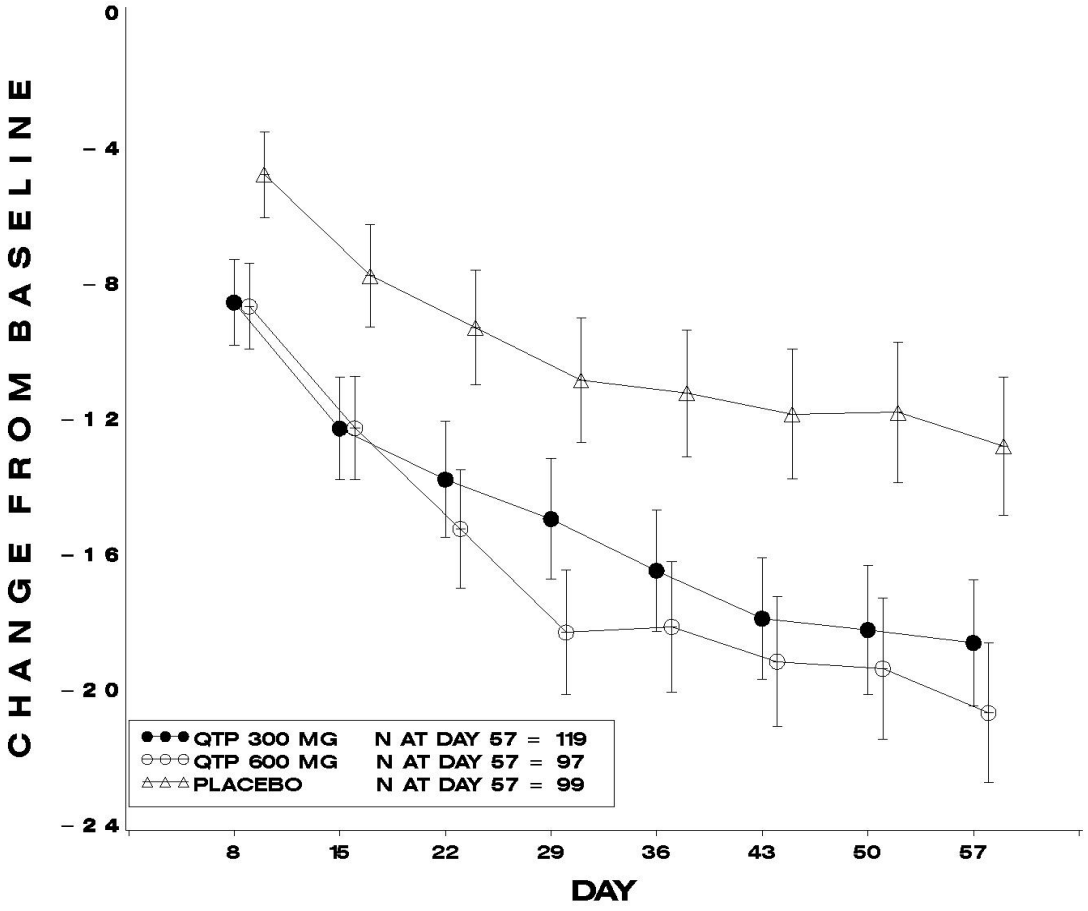


Replication of Figure 11.2.1.3.5

Baseline MADRS values were similar for the 3 groups. The change from baseline for both quetiapine treatment groups was significantly better than placebo at Day 8 (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$) and continued to be superior to placebo at all subsequent assessments (see Table 11.2.1.2.1).

Changes from baseline in the MADRS total score at each visit for observed cases in the ITT population are shown in Figure 4.

Figure 4 **MADRS total score change from baseline -- LS mean (95% CI) (OC, ITT population)**



Replication of Figure 11.2.1.3.6

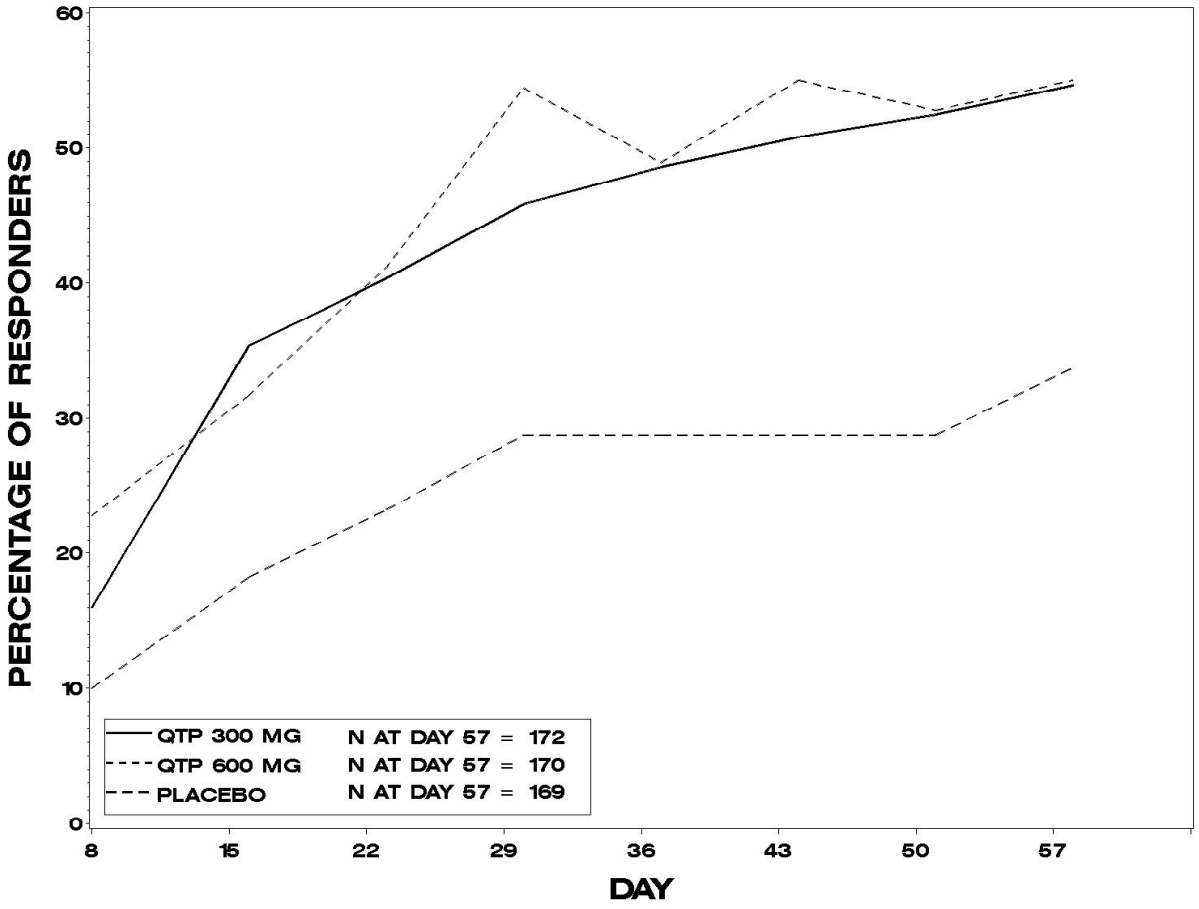
Changes from baseline in MADRS score for observed cases showed greater separation from placebo for the two quetiapine treatment groups at Day 8 and continued to be superior to placebo at all subsequent assessments. The OC analysis indicated that patients taking 600 mg of quetiapine showed greater improvement than did those taking 300 mg of quetiapine.

Throughout the course of treatment, OC data revealed that bipolar I and bipolar II patients treated with either 300 mg or 600 mg of quetiapine showed greater improvements in MADRS total score compared to patients treated with placebo (see Figure 11.2.1.5.1).

7.2.2.2 MADRS response

The percentage of patients showing a MADRS response, at least a 50% improvement from baseline in MADRS total score, is shown for each visit in Figure 5.

Figure 5 **MADRS response (≥50% score reduction) -- percent of patients responding by visit day (LOCF, ITT population)**



Replication of Figure 11.2.1.14

At final assessment, 58% of quetiapine 300 mg patients, 58% of quetiapine 600 mg patients and 36% of placebo patients had achieved a status of MADRS responder (quetiapine 300 mg vs placebo p<0.001; quetiapine 600 mg vs placebo p<0.001; see Table 11.2.1.13.1). The statistically significant differential between quetiapine and placebo groups was established by Day 15 for the quetiapine 300 mg group (p<0.001) and by Day 8 for the quetiapine 600 mg group (p<0.001) and continued to be superior to placebo at all subsequent assessments for both quetiapine groups (see Table 11.2.1.13.1). Similar comparisons of the three treatment groups were noted when criteria for response were varied from 30% to 70% (see Table 11.2.1.12).

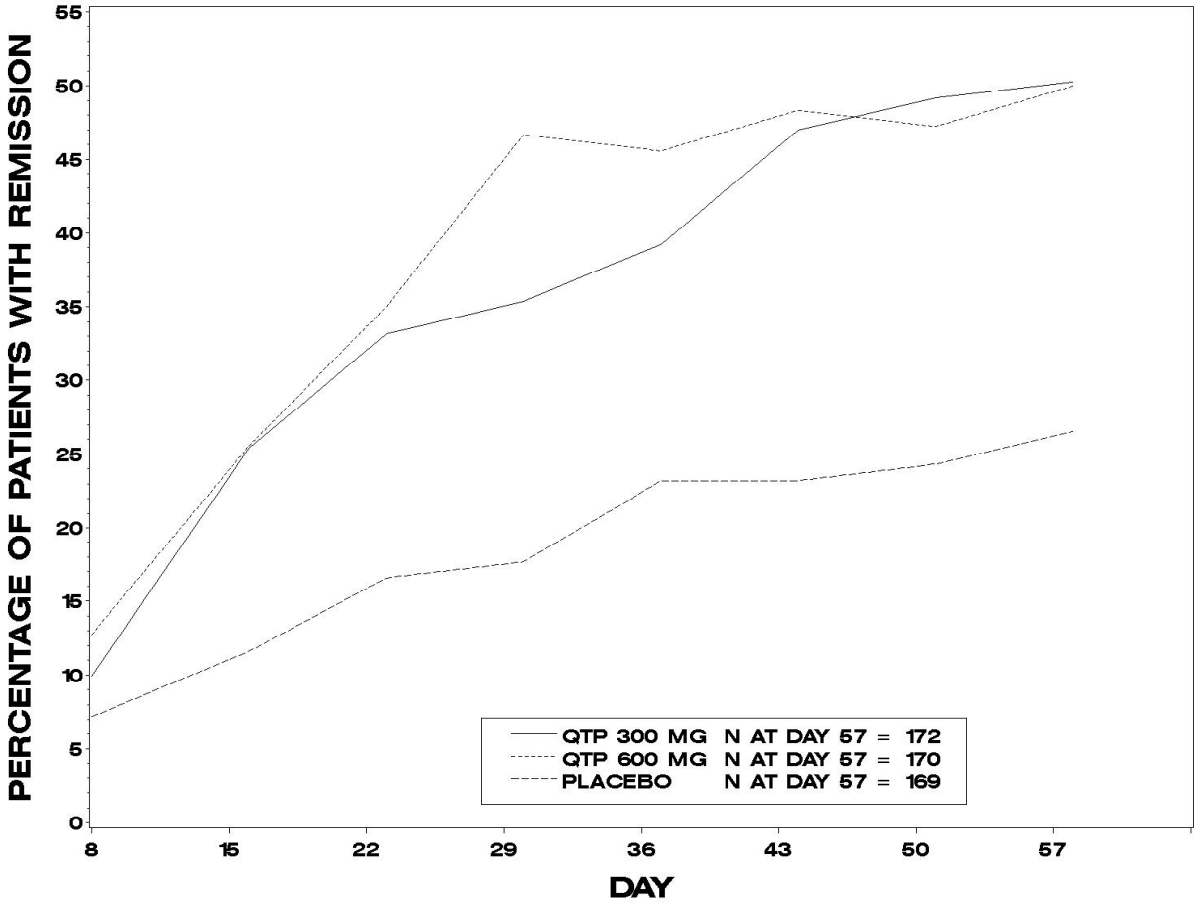
Among those who completed the study, 68% of patients treated with quetiapine 300 mg, 74% of patients treated with quetiapine 600 mg and 46% of patients treated with placebo met criteria for MADRS response (quetiapine 300 mg vs placebo p=0.002; quetiapine 600 mg vs placebo p<0.001; see Table 11.2.1.13.2).

Within the Bipolar I population at Day 57, 62% of quetiapine 300 mg patients, 64% of quetiapine 600 mg patients and 33% of placebo patients had achieved a status of MADRS responder. For Bipolar II patients, the response rates were 48% for quetiapine 300 mg patients, 46% for quetiapine 600 patients and 42% for placebo patients (see Table 11.2.1.13.1).

7.2.2.3 MADRS-defined remission

The percentage of patients showing a reduction in MADRS score to ≤12, is shown for each visit in Figure 6.

Figure 6 MADRS-defined remission (MADRS score ≤12) -- percent of patients by visit day (LOCF, ITT population)



Replication of Figure 11.2.1.17

At last assessment, 53% of quetiapine 300 mg patients, 53% of quetiapine 600 mg patients and 28% of placebo patients had achieved a MADRS score of ≤12 and were regarded as being in remission (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 11.2.1.16.1). The statistically significant difference between quetiapine and placebo

groups was established by Day 15 for both quetiapine-treated groups (p<0.001) and continued to be superior to placebo at all subsequent assessments (see Table 11.2.1.16.1).

7.2.2.4 Change from baseline to each assessment for the HAM-D total score

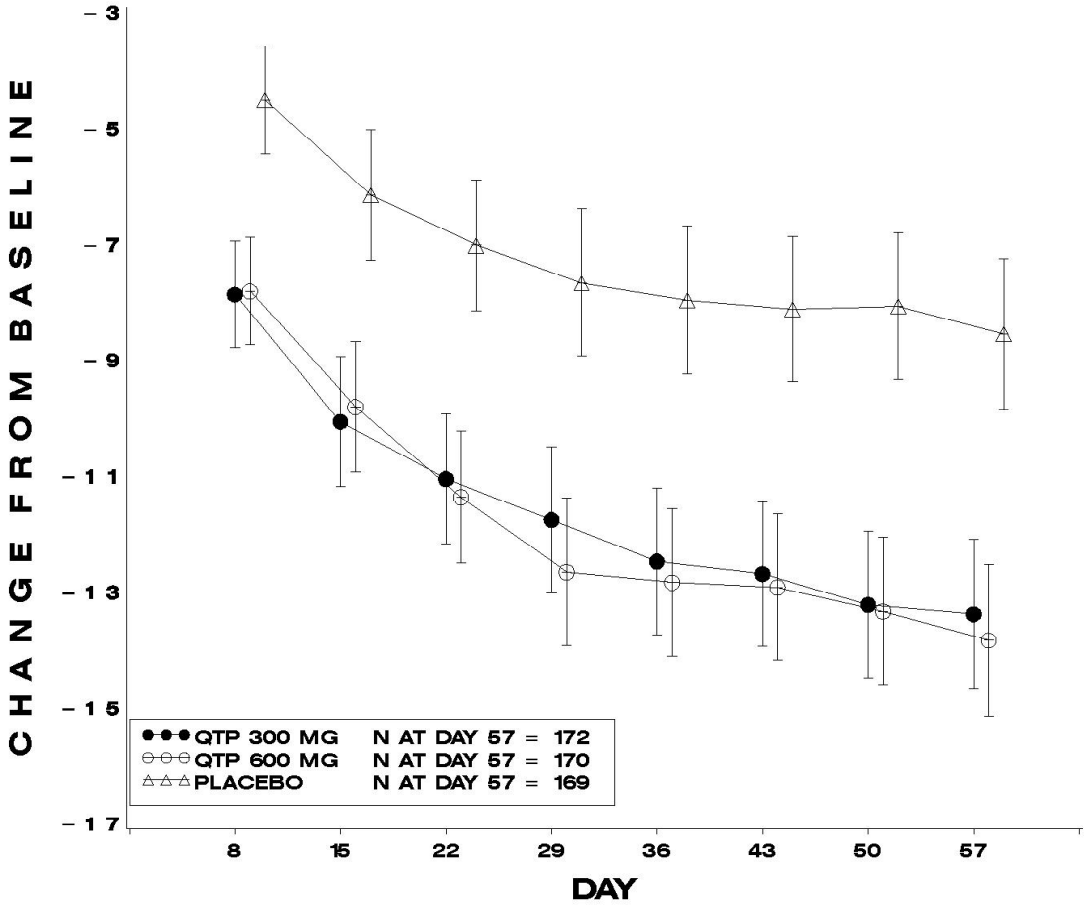
Results of the analysis of Day 57 change from baseline in HAM-D total score are shown in Table 28. Changes from baseline in the HAM-D total score at each visit for ITT patients are shown in Figure 7.

Table 28 HAM-D total score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	**Baseline Mean (SD)**	**LS mean change or difference**	**Upper 95% Limit**	**p-value**
Quetiapine 300 mg	172	24.5 (3.00)	-13.38	-12.07	
Quetiapine 600 mg	170	24.7 (3.51)	-13.84	-12.51	
Placebo	169	24.6 (3.29)	-8.54	-7.22	
Quetiapine 300 mg vs placebo			-4.84	-3.26	<0.001
Quetiapine 600 mg vs placebo			-5.29	-3.71	<0.001

Data derived from Table 11.2.2.2.1

Figure 7 **HAM-D total score change from baseline --LS mean (95% CI) (LOCF, ITT population)**



Replication of Figure 11.2.2.3.5

Baseline HAM-D values were similar for the 3 groups. The improvement for both quetiapine treatment groups was significantly better than placebo at Day 8 (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$) and continued to be superior to placebo at all subsequent assessments (see Table 11.2.2.2.1 and Figure 7). At the end of the 8-week course of treatment, quetiapine 300 mg patients in the ITT population had a least square mean of 4.84 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 5.29 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 28).

Among patients who completed the study, quetiapine 300 mg patients in the ITT population had a least square mean of 4.46 points lower HAM-D total score at Day 57 than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 6.32 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 11.2.2.2.2).

Mean individual HAM-D item scores were lower for quetiapine-treated patients compared to those for placebo-treated patients, with the largest treatment differences in Depressed Mood, Anxiety Psychic, Work and Activities and the 3 insomnia items (see Table 11.2.2.5.1 and Table 11.2.2.5.2).

7.2.2.5 Change from baseline to each assessment for the HAM-D Item 1 (depressed mood) score

Results of the analysis of Day 57 change from baseline in HAM-D Item 1 (depressed mood) score are shown in Table 29.

Table 29 HAM-D Item 1 score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	**Baseline Mean (SD)**	**LS mean change or difference**	**Upper 95% Limit**	**p-value**
Quetiapine 300 mg	172	2.9 (0.46)	-1.65	-1.46	
Quetiapine 600 mg	170	2.9 (0.48)	-1.68	-1.49	
Placebo	169	2.9 (0.44)	-1.11	-0.92	
Quetiapine 300 mg vs placebo			-0.54	-0.30	<0.001
Quetiapine 600 mg vs placebo			-0.57	-0.33	<0.001

Data derived from Table 11.2.2.6.1

Baseline HAM-D Item 1 values were similar for the 3 groups. The improvement for both quetiapine treatment groups was significantly better than placebo at Day 8 (quetiapine 300 mg vs placebo: p=0.003; quetiapine 600 mg vs placebo: p=0.003) and continued to be superior to placebo at all visits (see Table 11.2.2.6.1). At the end of the 8-week course of treatment, quetiapine 300 mg patients in the ITT population had a least square mean of 0.54 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 0.57 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo p<0.001; quetiapine 600 mg vs placebo p<0.001; see Table 29).

Among patients who completed the study, quetiapine 300 mg patients in the ITT population had a least square mean of 0.51 points lower HAM-D Item 1 score at Day 57 than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least

square mean of 0.64 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo p<0.001; quetiapine 600 mg vs placebo p<0.001; see Table 11.2.2.6.2).

7.2.2.6 Change from baseline to each assessment for the CGI-S score

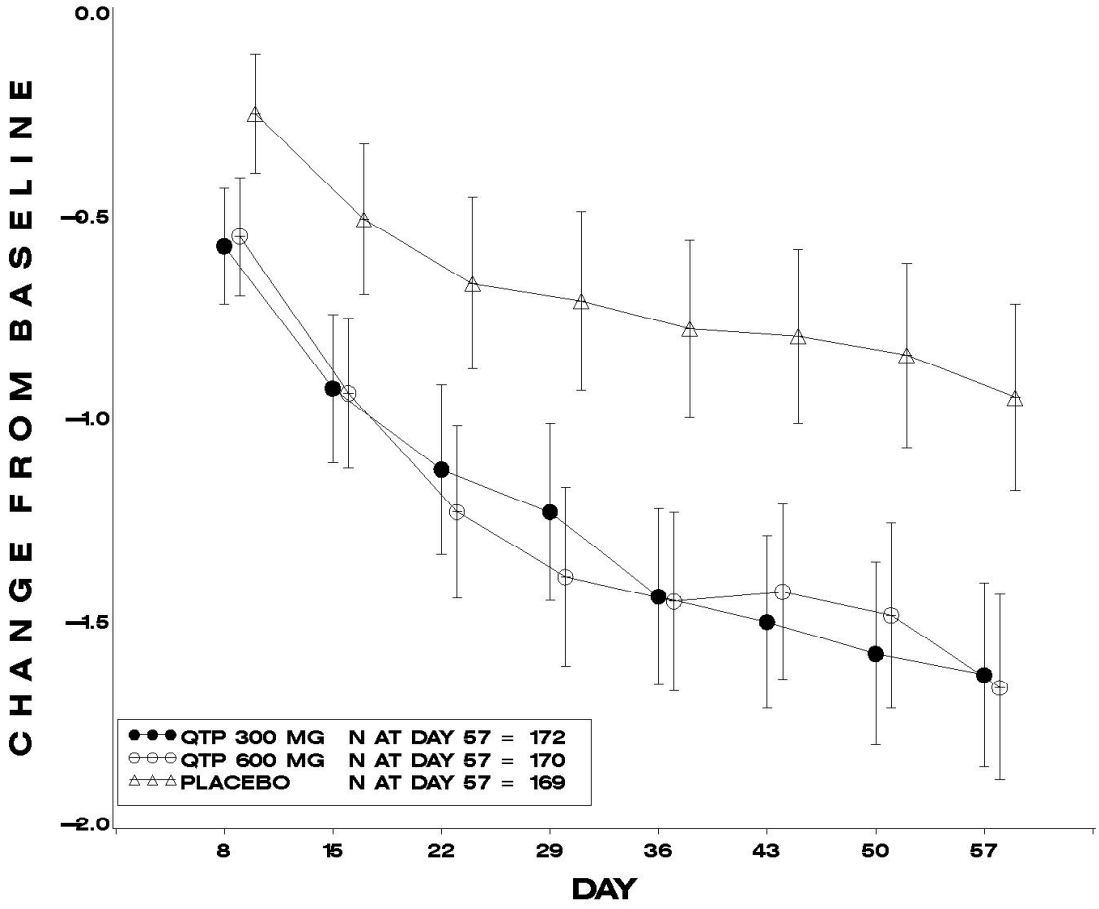
Results of the analysis of Day 57 change from baseline in CGI-S score are shown in Table 30. Changes from baseline in the CGI-S score at each visit for ITT patients are shown in Figure 8.

Table 30 CGI-S score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	**Baseline Mean (SD)**	**LS mean change or difference**	**Upper 95% Limit**	**p-value**
Quetiapine 300 mg	172	4.4 (0.52)	-1.63	-1.40	
Quetiapine 600 mg	170	4.5 (0.62)	-1.66	-1.43	
Placebo	169	4.4 (0.60)	-0.95	-0.71	
Quetiapine 300 mg vs placebo			-0.68	-0.42	<0.001
Quetiapine 600 mg vs placebo			-0.72	-0.45	<0.001

Data derived from Table 11.2.3.2.1

Figure 8 **CGI-S score change from baseline -- LS mean (95% CI) (LOCF, ITT population)**



Replication of Figure 11.2.3.3.3

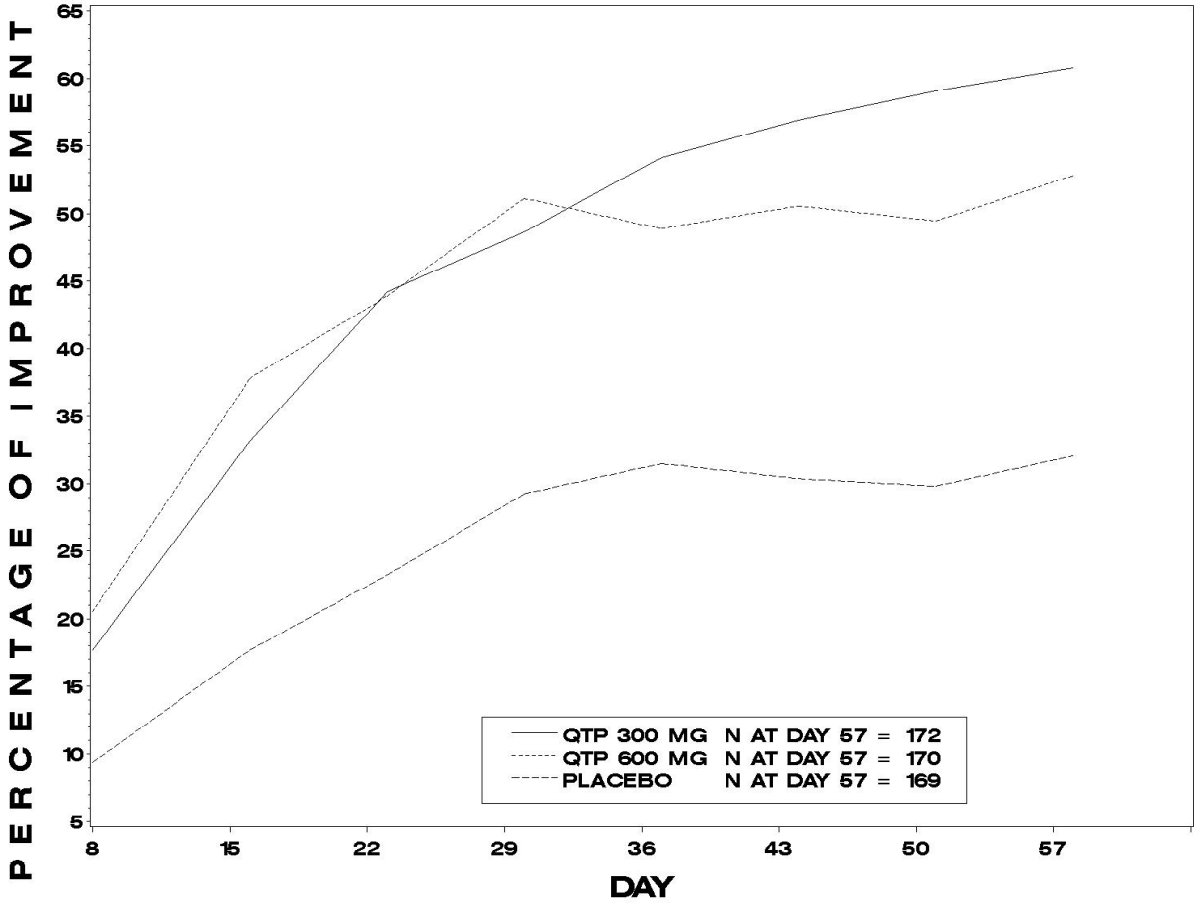
Baseline CGI-S values were similar for the 3 groups within the ITT population. The response for both quetiapine treatment groups was significantly better than placebo at Day 8 (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$) and continued to be superior to placebo at all visits (see Table 11.2.3.2.1 and Figure 8). At the end of the 8-week course of treatment, quetiapine 300 mg patients in the ITT population had a least square mean of 0.68 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 0.72 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 30).

Among ITT patients who completed the study, on Day 57 quetiapine 300 mg patients in the ITT population had a least square mean of 0.62 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 0.98 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$; see Table 11.2.3.2.2).

7.2.2.7 CGI-I

The percent of patients rated as "much improved" or "very much improved" on the CGI-I at each visit is presented in Figure 9.

Figure 9 **CGI-I scale -- patients "much improved" or "very much improved" (LOCF, ITT population)**



Replicated from Figure 11.2.4.3

At last observation, 64% of quetiapine 300 mg patients, 56% of quetiapine 600 mg patients and 34% of placebo patients were rated as "much improved" or "very much improved" in the CGI-I (quetiapine 300 mg vs placebo: $p < 0.001$; quetiapine 600 mg vs placebo: $p < 0.001$; see Table 11.2.4.2.5). The differentiation between quetiapine and placebo treatment was apparent at earlier assessments and persisted to the final assessment. At Day 8, 19% of quetiapine 300 mg patients, 22% of quetiapine 600 mg patients and 10% of placebo patients had shown global improvement in the CGI-I (quetiapine 300 vs placebo: $p = 0.024$; quetiapine 600 mg vs placebo: $p = 0.003$; see Table 11.2.4.2.5).

Among patients who completed the study, at Day 57, 74% of quetiapine 300 mg patients, 77% of quetiapine 600 mg patients and 42% of placebo patients were rated as "much improved" or "very much improved" in the CGI-I (quetiapine 300 mg vs placebo: $p < 0.001$; quetiapine 600 mg vs placebo: $p = 0.001$; see Table 11.2.4.2.6).

Results of the ANCOVA of Day 57 CGI-I scores are shown in Table 31.

Table 31 CGI-I score at Day 57 (LOCF, ITT population)

		ANCOVA results		
	N	**CGI-I LS mean change or difference**	**Upper 95% limit**	**p-value**
Quetiapine 300 mg	172	2.27	2.49	
Quetiapine 600 mg	170	2.37	2.59	
Placebo	169	2.97	3.20	
Quetiapine 300 mg vs placebo		-0.71	-0.44	<0.001
Quetiapine 600 mg vs placebo		-0.60	-0.34	<0.001

Data derived from Table 11.2.4.2.1

The response for the CGI-I score for both quetiapine treatment groups was significantly better than placebo at Day 8 (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$) and continued to be superior to placebo at all visits (see Table 11.2.4.2.1). At the end of the 8-week course of treatment, quetiapine 300 mg patients in the ITT population had a CGI-I least square mean of 0.71 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 0.60 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 31).

Among patients who completed the study, quetiapine 300 mg patients in the ITT population had a CGI-I least square mean of 0.68 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 0.83 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo $p<0.001$; quetiapine 600 mg vs placebo $p<0.001$; see Table 11.2.4.2.2).

7.2.2.8 Change from baseline the HAM-A total score

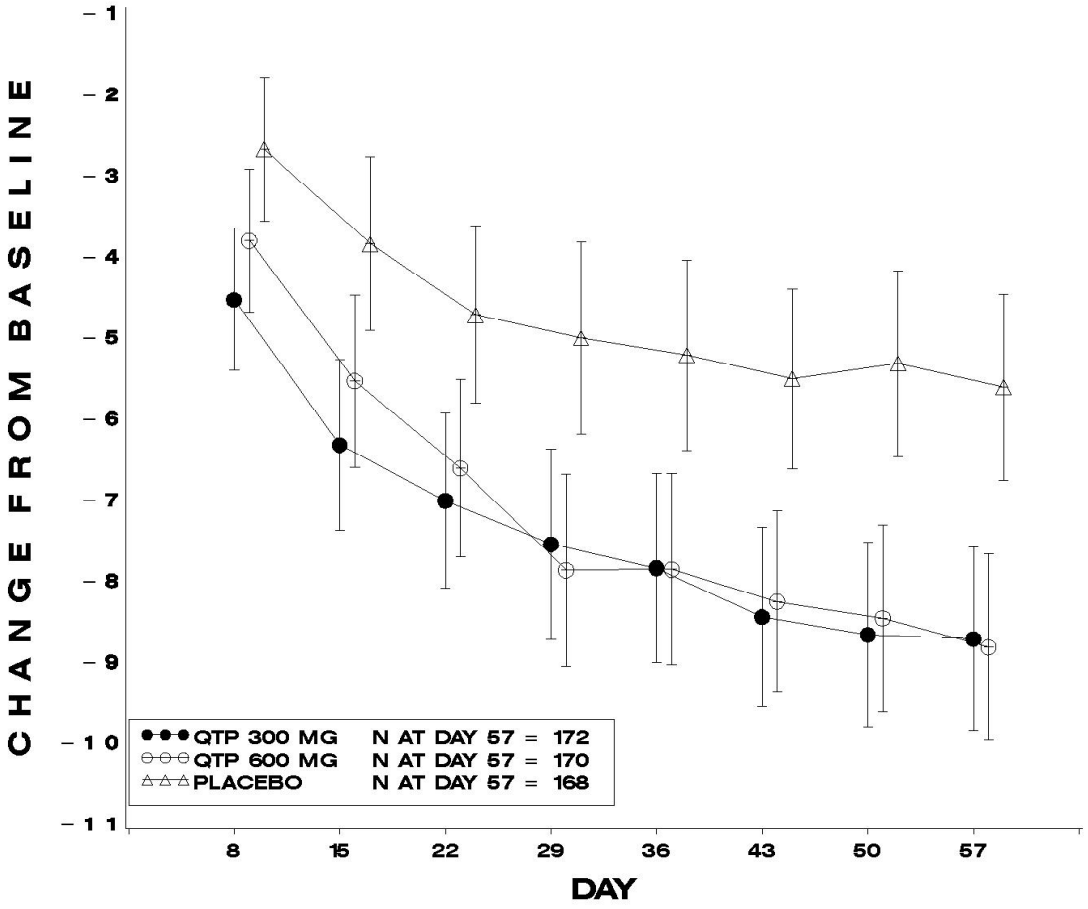
Results of the analysis of Day 57 change from baseline in HAM-A total score are shown in Table 32. Changes from baseline in the HAM-A score at each visit for ITT patients are shown in Figure 10.

Table 32 HAM-A score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	**Baseline mean (SD)**	**LS mean change or difference**	**Upper 95% limit**	**p-value**
Quetiapine 300 mg	172	18.7 (7.28)	-8.64	-7.49	
Quetiapine 600 mg	170	18.7 (7.32)	-8.75	-7.59	
Placebo	168	18.9 (7.25)	-5.54	-4.38	
Quetiapine 300 mg vs placebo			-3.10	-1.61	<0.001
Quetiapine 600 mg vs placebo			-3.20	-1.71	<0.001

Data derived from Table 11.2.5.2.1

Figure 10 **HAM-A score change from baseline -- LS mean (95% CI) (LOCF, ITT population)**



Replication of Figure 11.2.5.3.3

The response for the HAM-A score for both quetiapine treatment groups was significantly better than placebo at Day 8 (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p=0.031$) and continued to be superior to placebo at all visits (see Table 11.2.5.2.1 and Figure 10). At the end of the 8-week course of treatment, quetiapine 300 mg patients in the ITT population had a HAM-A least square mean of 3.10 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 3.20 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine: 600 mg vs placebo $p<0.001$; see Table 32).

Among patients who completed the study, at Day 57 quetiapine 300 mg patients in the ITT population had a HAM-A least square mean of 3.21 points lower score than did placebo-treated patients, and quetiapine 600 mg patients in the ITT population had a least square mean of 4.37 points lower score than did placebo-treated patients (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine: 600 mg vs placebo $p<0.001$; see Table 11.2.5.2.2).

Individual items of the HAM-A that most differentiated quetiapine-treated patients from placebo patients were Anxious Mood, Depressed Mood, Insomnia, Genitourinary and Tension (see Table 11.2.5.4.1 and Table 11.2.5.4.2).

7.3 Patient Reported Outcomes

7.3.1 Summary of patient reported outcomes

Table 33 shows where the data supporting this section are presented.

Table 33 Location of supporting data on patient reported outcomes

Data	Location	
	Summary tables (Section 11.2)	**Individual subject data (Appendix 12.2.6)**
Q-LES-Q	Table 11.2.6.1 to Table 11.2.6.3	Table 12.2.6.7
PSQI	Table 11.2.7.1.1, to Table 11.2.7.3.2	Table 12.2.6.6

7.3.2 Patient reported outcomes results

7.3.2.1 Q-LES-Q

Results of the analysis of Day 57 change from baseline in Q-LES-Q total score are shown in Table 34.

Table 34 Q-LES-Q percent-of-maximum-score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	**Baseline Mean (SD)**	**LS mean change or difference**	**Lower 95% Limit**	**p-value**
Quetiapine 300 mg	156	39.5 (14.05)	19.27	16.33	
Quetiapine 600 mg	157	35.9 (14.65)	20.93	18.02	
Placebo	158	36.0 (13.24)	11.54	8.64	
Quetiapine 300 mg vs placebo			7.72	3.68	<0.001
Quetiapine 600 mg vs placebo			9.39	5.37	<0.001

Data derived from Table 11.2.6.2.3

The Q-LES-Q responses for both quetiapine treatment groups were significantly better than placebo at final assessment (quetiapine 300 mg vs. placebo: <0.001; quetiapine 600 mg vs. placebo: p<0.001; see Table 34). On Day 29, it was observed that the quetiapine 300 mg group had a change from baseline 6.09 points greater than the placebo group (p=0.001) and the quetiapine 600mg group had a change from baseline 8.52 points greater than the placebo group (p< 0.001). At end of treatment, the quetiapine 300 mg group showed a 7.72 point advantage over the placebo group and the quetiapine 600 mg group showed a 9.39 point advantage over placebo. The mean Q-LES-Q score at final assessment for both quetiapine 300 mg and 600 mg patients was 46.2 points, compared to 40.9 points for placebo patients (see Table 11.2.6.1). Among patients who completed the trial, quetiapine 300 mg patients exhibited a mean Q-LES-Q score of 47.7, quetiapine 600 mg patients, a score of 50.2, and placebo patients, a score of 43.4 (see Table 11.2.6.1).

7.3.2.2 PSQI

Results of the analysis of Day 57 change from baseline in PSQI total score are shown in Table 35.

Table 35 PSQI score change from baseline at Day 57 (LOCF, ITT population)

			ANCOVA results		
	N	Baseline Mean (SD)	LS mean change or difference	Upper 95% Limit	p-value
Quetiapine 300 mg	150	11.4 (3.82)	-5.16	-4.53	
Quetiapine 600 mg	152	11.6 (4.16)	-5.46	-4.83	
Placebo	150	11.7 (3.82)	-2.94	-2.31	
Quetiapine 300 mg vs placebo			-2.22	-1.36	<0.001
Quetiapine 600 mg vs placebo			-2.52	-1.66	<0.001

Data derived from Table 11.2.7.3.1

Baseline PSQI values were 11.4 to 11.7 for the 3 groups, indicating moderate to severe sleep difficulty. The improvement for both quetiapine treatment groups was significantly better than placebo at final assessment (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$; see Table 35). An observed cases analysis showed that on Day 29 the quetiapine 300 mg group had a change from baseline 2.48 points greater than the placebo group ($p<0.001$) and the quetiapine 600 mg group had a change from baseline 2.81 points greater than placebo ($p<0.001$). By Day 57 patients who completed the study showed a 1.72 point advantage over placebo for the quetiapine 300 mg group, and a 2.76 point advantage for the quetiapine 600 mg group (quetiapine 300 mg vs placebo: $p<0.001$; quetiapine 600 mg vs placebo: $p<0.001$; see Table 11.2.7.3.1). The mean PSQI score at final assessment for quetiapine 300 mg patients was 6.4, for quetiapine 600 mg patients, 6.2 and for placebo patients, 8.8, all above the normative cut-off of 5.0 for non-disordered sleep (Buysse et al 1989; see Table 11.2.7.1.1).

7.4 Health Economics results

Not applicable.

7.5 Pharmacokinetic results

Not applicable.

7.6 Potential issues affecting efficacy results

No potential issues affecting efficacy results have been identified.

7.7 Conclusions on efficacy results

The linkage between these conclusions, the specific efficacy and pharmacokinetic objectives of the study, and the study variables selected to address each objective, is presented in Table 36.

Table 36 Efficacy objectives, variables, and conclusions

Objective	Variables	Conclusions
Primary	**Primary**	
Evaluate the efficacy of quetiapine compared to placebo in the treatment of a major depressive episode in patients with bipolar disorder after receiving treatment for up to 8 weeks	Change from baseline to final assessment in the MADRS total score in the Intention-to-treat (ITT) population	Quetiapine fumarate at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression was superior to placebo in reducing the level of depressive symptoms as measured by the change from baseline on the MADRS total score.
	Secondary	
	Percentage of patients in the ITT population showing a ≥50% reduction from baseline in MADRS total score (responders) at each assessment and at final assessment	Quetiapine fumarate at a dose of either 300 mg daily or 600 mg daily in patients with bipolar depression was superior to placebo in reducing the level of depressive symptoms as measured by the percentage of patients achieving a 50% reduction in MADRS total score. Superiority was evident for both quetiapine treatment groups on Day 15 of treatment and was maintained at each assessment to Day 57 of treatment.
	Change from baseline to each assessment for the MADRS total score in the ITT population	Superiority of quetiapine at a dose of either 300 mg daily or 600 mg over placebo was evident in MADRS total score change from baseline on Day 8 of treatment in patients with bipolar depression and was maintained at each assessment to Day 57 of treatment.

Table 36 Efficacy objectives, variables, and conclusions

Objective	Variables	Conclusions
	Change from baseline to each assessment in the HAM-D total score in the ITT population	Quetiapine fumarate at a dose of either 300 mg daily or 600 mg daily in patients with bipolar depression was superior to placebo in reducing the level of depressive symptoms as measured by the change from baseline to up to 8 weeks of treatment on the HAM-D. Superiority of quetiapine at a dose of either 300 mg daily or 600 mg daily over placebo was evident in HAM-D total score change from baseline on Day 8 of treatment and was maintained at each assessment to Day 57 of treatment.
	Change from baseline to each assessment in the HAM-D Item 1 score in the ITT population	Quetiapine fumarate at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression was superior to placebo in reducing the level of depressed mood as measured by the change from baseline on the HAM-D Item 1. Superiority of quetiapine at a dose of either 300 mg daily or 600 mg daily over placebo was evident in HAM-D Item 1 score change from baseline on Day 8 of treatment and was maintained at each assessment to Day 57 of treatment.
	Change from baseline to each assessment and at final assessment for the CGI-S in the ITT population	Quetiapine fumarate at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression was superior to placebo in reducing the severity of illness as measured by the change from baseline on the CGI-S. Superiority of quetiapine at a dose of either 300 mg daily or 600 mg daily over placebo was evident in CGI-S score change from baseline on Day 8 of treatment and was maintained at each assessment to Day 57 of treatment.

Table 36 Efficacy objectives, variables, and conclusions

Objective	Variables	Conclusions
	Change from baseline to each assessment and at final assessment for the CGI-I in the ITT population	Quetiapine fumarate at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression was superior to placebo in improving the patient's clinical status as measured by the CGI-I. Superiority of quetiapine at a dose of either 300 mg daily or 600 mg daily over placebo was evident in CGI-I score on Day 8 of treatment and was maintained at each assessment to Day 57 of treatment.
Evaluate the effect of quetiapine compared to placebo on symptoms of anxiety	Change from baseline to each assessment and to final assessment in the HAM-A total score in the ITT population	Quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression was superior to placebo in reducing anxiety symptoms as measured by change from baseline in the HAM-A total score. Superiority of quetiapine at a dose of either 300 mg daily or 600 mg daily over placebo was evident in HAM-A score on Day 8 of treatment and was maintained to Day 57 of treatment.
Exploratory		
Evaluate the effect of quetiapine compared to placebo on the overall quality of life	Change from baseline in the short form Q-LES-Q in the ITT population	Quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks for treatment in patients with bipolar depression was statistically superior to placebo in improving Quality of Life Enjoyment and Satisfaction, measured by the 14-item Q-LES-Q (Quality of Life Enjoyment and Satisfaction Questionnaire) short-form.
Evaluate the effect of quetiapine compared to placebo on quality of sleep	Change from baseline to final assessment in the PSQI total score in the ITT population	Quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression was superior to placebo in improving the quality of sleep, measured by the PSQI.

8. SAFETY RESULTS

Safety data in this report are presented under the following headings:

- Summary of safety (Section 8.1)
- Exposure (Section 8.2)
- Adverse events (Section 8.3)
- Deaths, serious adverse events, discontinuations due to adverse events, and other significant adverse events (Section 8.4)
- Clinical laboratory evaluation (Section 8.5)
- Vital signs, ECG, physical findings and other observations related to safety. (Section 8.6).

8.1 Summary of safety

Both the 300 mg and 600 mg once-daily doses of quetiapine were generally well-tolerated. Analysis of adverse events indicated that nervous and gastrointestinal events predominated, with dry mouth, sedation, somnolence, dizziness and constipation occurring at higher rates with quetiapine compared to placebo. Most adverse events were mild to moderate. Sedation and somnolence were the adverse events most associated with discontinuation by quetiapine-treated patients ,and a larger proportion of patients in the higher quetiapine dose group discontined than did patients in the lower dose group. SAEs were infrequent in all treatment groups. Treatment emergent mania and hypomania were low in incidence and did not differ across the treatment groups. An increase in the incidence of EPS events was noted for both groups of quetiapine-treated patients, but the mean change from baseline in SAS and BARS scores was generally in the direction of improvement for all three groups. The incidence of adverse events associated with suicidality for quetiapine-treated patients was no different than that for placebo-treated patients. No cases of neutropenia or agranulocytosis following quetiapine treatment were reported. Increases in weight, tryglycerides, total cholesterol and LDL were consistent with the known safety profile for quetiapine. The incidence of aggregate shifts of blood pressure, BMI, triglycerides, HDL and glucose to criteria for possible metabolic syndrome was higher for quetiapine-treated patients compared to placebo. Increases in weight, triglycerides, total cholesterol and LDL, and decreases in HDL were consistent with the known safety profile for quetiapine.

Subjects with dose reduction	n (%)	30 (16.8%)	40 (22.2%)	9 (5.0%)

Data derived from Table 11.3.1.1 and Table 11.3.1.3
a Median computed over days in study rather than days of dosing

8.3 Adverse events

This section gives an overview of the adverse events reported in the study.

8.3.1 Categories of adverse events

A summary of adverse events in each category is presented in Table 39.

Table 39 Subjects who had an adverse event in any category (safety population)

Category of adverse event	Number (%) of subjects who had an adverse event in each category[a]					
	Quetiapine 300 mg (n=179)		Quetiapine 600 mg (n=180)		Placebo (n=180)	
Any adverse events[a]	166	(92.7)	165	(91.7)	148	(82.2)
Serious adverse events	6	(3.4)	9	(5.0)	16	(8.9)
Serious adverse events leading to death	0	(0)	0	(0)	0	(0)
Study drug-related adverse events	152	(84.9)	156	(86.7)	85	(47.2)
Discontinuations of study treatment due to adverse events[b]	29	(16.2)	47	(26.1)	15	(8.3)

a Subjects with multiple events in the same category are counted only once in that category. Subjects with events in more than 1 category are counted once in each of those categories.
b Adverse events were regarded as associated with discontinuation if they were present at the discontinuation visit.
Data derived from Table 11.3.2.1.

Quetiapine-treated patients exhibited an overall adverse event rate of approximately 92% to 93%, 10 percentage points higher than the rate for the placebo group. In contrast, SAEs were more common (8.9%) in the placebo group than in either the quetiapine 600 mg (5.0%) or quetiapine 300 mg (3.4%) groups. Approximately 26% of quetiapine 600 mg patients, 16% of quetiapine 300 mg patients and 8% of placebo patients discontinued treatment due to adverse events.

Categories of adverse events are shown for bipolar I and bipolar II patients in Table 11.3.2.2.

8.3.2 Most common adverse events

The most common adverse events in the study, summarized by system organ class, are shown in Table 40.

Table 40 Adverse events by system organ class, sorted by decreasing order of incidence (safety population)

System organ class	Quetiapine 300 mg (N=179)		Quetiapine 600 mg (N=180)		Placebo (N=180)	
	n	(%)	n	(%)	n	(%)
Nervous system	134	(74.9)	132	(73.3)	74	(41.1)

Data derived from Table 11.3.2.3.
Note: Data are ordered by descending incidence in the quetiapine 300 mg group.

Quetiapine treatment was associated with a greater incidence of adverse events in the nervous and gastrointestinal systems. The quetiapine 300 mg and 600 mg groups showed similar rates of adverse events in these two systems, with a difference in incidence of 33.8 percentage points compared to the placebo group for the nervous system events and one of approximately 25.3 percentage points for the gastrointestinal system events. The incidence of adverse events in the general disorders classification was at least 5 percentage points higher for the quetiapine 600 mg group than for the quetiapine 300 mg group. The incidences of adverse events in the infections and in the injury classifications were higher for the placebo group than for either of the quetiapine groups.

The incidence of adverse events by system organ class is presented for bipolar I and bipolar II patients in Table 11.3.2.4.

The most common adverse events, as summarized by preferred term, are shown in Table 41.

Table 41 Subjects with commonly-reported adverse events, sorted by decreasing order of frequency (safety population)

Weight increased	3	(1.7)	11	(6.1)	1	(0.6)
Pain in extremity	2	(1.1)	9	(5.0)	4	(2.2)

Note: This table uses a cut-off of 5% in any group. Data are ordered by descending incidence in the quetiapine 300 mg group.
Data from Table 11.3.2.5

The most commonly reported AE for the quetiapine-treated groups was dry mouth. The onset of dry mouth in quetiapine-treated patients most often occurred in the first 8 days of treatment (see Table 11.3.2.7). Mild to moderate dry mouth was reported for 72 quetiapine 300 mg patients, 65 quetiapine 600 mg patients and 14 placebo patients. Severe dry mouth was reported for 7 quetiapine 300 mg patients, 8 quetiapine 600 mg patients and no placebo

patients (see Table 11.3.2.6). Study treatment-related dry mouth was judged in 78 quetiapine 300 mg patients, 72 quetiapine 600 mg patients and 12 placebo patients (see Table 11.3.2.8).

Sedation and somnolence was more often seen in the quetiapine treatment groups than in the placebo group. The onset of sedation and somnolence in quetiapine-treated patients most often occurred in the first 8 days of treatment (see Table 11.3.2.7), and sedation was the most often cited event in association with discontinuation (see Section 8.4.3). Mild to moderate sedation was reported for 48 quetiapine 300 mg patients, 49 quetiapine 600 mg patients and 9 placebo-treated patients (see Table 11.3.2.6). Five quetiapine 300 mg patients, 9 quetiapine 600 mg patients and 2 placebo-treated patients experienced severe sedation. Study treatment-related sedation was judged in 52 quetiapine 300 mg patients, 58 quetiapine 600 mg patients and 11 placebo patients (see Table 11.3.2.8). Mild to moderate somnolence was reported for 39 quetiapine 300 mg patients, 37 quetiapine 600 mg patients and 15 placebo patients. Ten quetiapine 300 mg patients, 7 quetiapine 600 mg patients and no placebo-treated patients experienced severe somnolence (see Table 11.3.2.6). Study treatment-related somnolence was judged in 49 quetiapine 300 mg patients, 44 quetiapine 600 mg patients and 12 placebo-treated patients (see Table 11.3.2.8).

Dizziness was more often seen in the quetiapine treatment groups than in the placebo group. Mild to moderate dizziness was reported for 28 quetiapine 300 mg patients, 32 quetiapine 600 mg patients and 13 placebo-treated patients. Two patients treated with quetiapine 300 mg, 9 patients treated with quetiapine 600 mg and 2 patients treated with placebo reported severe dizziness (see Table 11.3.2.6). The onset of dizziness in quetiapine-treated patients most often occurred in the first 8 days of treatment (see Table 11.3.2.7). Study treatment-related dizziness was judged in 28 quetiapine 300 mg patients, 37 quetiapine 600 mg patients and 8 placebo patients (see Table 11.3.2.8).

Headache was more often seem in the placebo treatment group than in the quetiapine treatment groups. The onset of headache in all three treatment groups most often occurred in the first 8 days of treatment (see Table 11.3.2.7). Mild to moderate headache was reported for 20 quetiapine 300 mg patients, 15 quetiapine 600 mg patients and 35 placebo patients. Severe headache was reported for 2 quetiapine 300 mg patients, 3 quetiapine 600 mg patients and 1 placebo patient. Study treatment-related headache was judged in 9 quetiapine 300 mg patients, 11 quetiapine 600 mg patients and 28 placebo patients (see Table 11.3.2.8).

Akathisia occurred with higher incidence (5.0%) in the quetiapine-treated groups than in the placebo-treated group (1.1%). Akathisia and EPS findings are discussed in detail in Section 8.4.4.1.

Other gastrointestinal system adverse events occurring frequently were constipation, dyspepsia, nausea and diarrhea. For all groups, most of these events were mild to moderate ones. No group experienced many severe digestive adverse events (see Table 11.3.2.6). Constipation was attributed to study medication for approximately 9% to 11% of quetiapine-treated patients and 3% of placebo-treated patients. Study treatment-related judgments for dyspepsia, nausea and diarrhea were similar for the 3 groups (see Table 11.3.2.8).

Mild to moderate weight increase was noted in 3 quetiapine 300 mg patients, 11 quetiapine 600 mg patients and 1 placebo patient. No patients experienced severe weight gain (see Table 11.3.2.6). Study treatment-related weight increase was judged in 3 of quetiapine 300 mg patients, 8 quetiapine 600 mg patients and no placebo patients (see Table 11.3.2.8).

8.3.3 Discussion of common adverse events

In general, the known adverse event profile for quetiapine was reported in patients with bipolar depression. Adverse events classified within the central nervous system and the gastrointestinal system were most common. The most common adverse events, dry mouth, sedation, somnolence, dizziness and constipation, are consistent with the established safety profile for quetiapine. Dry mouth, somnolence and sedation were most-often reported as mild to moderate.

8.4 Deaths, serious adverse events, discontinuation due to adverse events, and other significant adverse events

8.4.1 Deaths

No patient deaths were reported in this trial.

8.4.2 Serious adverse events other than deaths

Serious adverse events are summarized by system organ class and preferred term in Table 42. All subjects who had a serious adverse event other than death are listed in Table 43.

Table 42 SAE incidence by system organ class (safety population)

a Includes 2 reports for same event in same patient reported by 2 different investigators because patient enrolled in study at two sites and was randomized to placebo treatment at both sites.

Data derived from Table 11.3.4.1.1

A total of 30 patients reported 40 SAEs. Six of the 30 patients with SAEs were treated with quetiapine 300 mg, 9 with quetiapine 600 mg and 15 with placebo. Serious psychiatric disorders were observed in 4 patients treated with quetiapine 300 mg, 4 patients treated with quetiapine 600 mg and 4 patients treated with placebo. One placebo-treated patient who enrolled at two different study sites, and thus received two enrollment numbers (E0026028 and E0028031), is shown in Table 42 and Table 43 as having psychotic symptoms described by each of the two investigators. Four of 7 SAEs for quetiapine 300 mg treatment, 3 of 14 SAEs for quetiapine 600 mg treatment and 10 of 19 SAEs for placebo treatment were associated with withdrawal from the trial.

Serious adverse events for bipolar I and bipolar II patients are described in Table 11.3.4.1.2.

Data derived from Table 11.3.5.1.1

Patients discontinuing from the study due to AEs totalled 29 (16.2%) of the quetiapine 300 mg group, 47 (26.1%) of the quetiapine 600 mg group, and 15 (8.3%) of the placebo group. Nervous system disorders constituted the largest portion of the DAEs, with a total of 20

(11.2%) patients in the quetiapine 300 mg group, 31 (17.2%) patients in the quetiapine 600 mg group and 2 (1.1%) in the placebo group. Sedation was noted as associated with discontinuation in 10 (5.6%) quetiapine 300 mg patients, 17 (9.4%) quetiapine 600 mg patients and no placebo patients. Somnolence was cited for 7 (3.9%) quetiapine 300 mg patients, 5 (2.8%) quetiapine 600 mg patients and no placebo patients. Dizziness was listed for 1 (0.6%) quetiapine 300 mg patients, 6 (3.3%) quetiapine 600 mg patients and no placebo patients (see Table 44.). Most of the nervous system DAEs occurred in the first 8 days of the trial during the titration period (see Table 45).

Adverse events leading to discontinuation are displayed by bipolar I and bipolar II diagnosis in Table 11.3.5.1.2.

Table 45 Patient listing for study treatment discontinuation due to an adverse event (safety population)

Treatment and dose regimen	Subject number	Sex (M/F)	Age (year)	Adverse event (preferred term)	Adverse event (investigator text)	Time from start of treatment to onset of AE (days)	Duration of AE (if resolved)[a]	Reported as a serious adverse event (yes/no)	Causality (as assessed by the investigator)

Data from Table 11.3.5.2

a Events of unknown duration were ongoing at the time of discontinuation.

8.4.4 Adverse events of special interest

8.4.4.1 Adverse events related to EPS

Adverse events related to EPS are summarized by system organ class and preferred term in Table 46.

Table 46 Adverse events coded to EPS (safety population)

	Quetiapine 300 mg (N=179)		Quetiapine 600 mg (N=180)		Placebo (N=180)	
Preferred term	**n**	**(%)**	**n**	**(%)**	**n**	**(%)**
Total[a]	21	(11.7)	23	(12.8)	8	(4.4)
Akathisia	9	(5.0)	9	(5.0)	2	(1.1)
Tremor	5	(2.8)	5	(2.8)	1	(0.6)
Dyskinesia	4	(2.2)	2	(1.1)	0	(0)
Dystonia	2	(1.1)	5	(2.8)	1	(0.6)
Restlessness	2	(1.1)	1	(0.6)	2	(1.1)
Extrapyramidal disorder	0	(0)	2	(1.1)	1	(0.6)

Psychomotor hyperactivity	0	(0)	1	(0.6)	0	(0)
Muscle rigidity	0	(0)	0	(0)	1	(0.6)

a Subjects with multiple events in the same category are counted only once in that category. Subjects with events in more than 1 category are counted once in each of those categories.

Data derived from Table 11.3.6.1.

MedDRA-encoded as EPS-related symptoms were reported for 11.7% of quetiapine 300 mg patients, 12.8% of quetiapine 600 mg patients and 4.4% of placebo patients. Akathisia was noted in quetiapine-treated patients with an incidence of 5.0% compared to one of 1.1% in placebo-treated patients. All EPS events were reported as mild to moderate for all groups.

If an AE was reported that coded to an EPS, the investigator was asked whether or not they judged this AE as being due to EPS. A summary of adverse events coded as extrapyramidal adverse events by MedDRA as shown in Table 46 with the exclusion of those considered by the investigators to not be extrapyramidal symptoms is shown in Table 47.

Table 47 Adverse events coded as EPS and not excluded as EPS by investigators (safety population)

Dyskinesia	3	(1.7)	1	(0.6)	0	(0)
Dystonia	2	(1.1)	4	(2.2)	1	(0.6)
Extrapyramidal disorder	0	(0)	2	(1.1)	1	(0.6)
Psychomotor hyperactivity	0	(0)	1	(0.6)	0	(0)

a Subjects with multiple events in the same category are counted only once in that category. Subjects with events in more than 1 category are counted once in each of those categories.

Data derived from Table 11.3.6.2.

After EPS-coded adverse events specified by investigators as not being due to EPS were removed from those reported in Table 46, the remaining data (reported in Table 47) contained reports of extrapyramidal symptoms for 6.7% of patients in the quetiapine 300 mg group, 8.9% of patients in the quetiapine 600 mg group and 2.2% of patients in the placebo group.

8.4.4.2 Adverse events related to QT prolongation

No adverse events encoded to the MedDRA terms of "long QT syndrome," "electrocardiogram QT corrected interval prolonged," "electrocardiogram QT prolonged," "long QT syndrome congenital," "torsades de pointes," "cardiac arrest," "cardio-respiratory arrest," "cardiac death," "electromechanical dissociation" or "sinus arrest" were reported for patients in any of the three treatment groups.

8.4.4.3 Adverse events related to neutropenia and agranulocytosis

No adverse events encoded to the MedDRA terms of "band neutrophil count decreased," "band neutrophil percentage decreased," "febrile neutropenia," "neutropenia," "neutropenic infection," "neutropenic sepsis," "neutrophil count decreased," "neutrophil percentage decreased," "granulocyte count decreased," "granulocytopenia," "idiopathic neutropenia," "neutrophil count abnormal," "neutrophil percentage abnormal" or "agranulocytosis" were reported for patients in any of the three treatment groups.

8.4.4.4 Adverse events related to treatment-emergent mania and hypomania

Adverse events related to treatment-emergent mania and hypomania are summarized by system organ class and preferred term in Table 48.

Table 48 Treatment-emergent mania and hypomania (LOCF, safety population)

	Quetiapine 300 mg (N=179		Quetiapine 600 mg (N=180)		Placebo (N=180)	
Criteria	**n**	**(%)**	**n**	**(%)**	**n**	**(%)**
All[a]	7	(3.9)	4	(2.2)	7	(3.9)
YMRS alone[b]	4	(2.2)	4	(2.2)	6	(3.3)
Adverse events alone	3	(1.7)	2	(1.1)	2	(1.1)

Data derived from Table 11.3.8.1.7.14.
a Subjects with multiple events in the same category are counted only once in that category. Subjects with events in more than 1 category are counted once in each of those categories.
b YMRS >15 at two consecutive visits or at final visit

The rates of treatment-emergent mania were similar among the three treatment groups.

Both quetiapine-treated groups showed greater improvement in YMRS scores compared to placebo at end of treatment (quetiapine 300: p=0.002; quetiapine 600: p=0.012; see Table 11.3.8.1.7.3).

8.4.4.5 Adverse events related to diabetes

Four cases of adverse events possibly related to diabetes, all of which were "increased thirst," were identified. Two of the cases (patients E0006005 and E0027003) were treated with quetiapine 300 mg daily. The remaining two cases (patients E0014017 and E0028010) were treated with placebo. Review of these cases revealed no evidence of other signs or symptoms of diabetes.

8.4.4.6 Adverse events related to suicidality

Adverse events related to suicidality are summarized by system organ class and preferred term in Table 49.

Table 49 Adverse events related to suicidality incidence (safety population)

	Quetiapine 300 mg (N=179)		Quetiapine 600 mg (N=180)		Placebo (N=180)	
Preferred term	**n**	**%**	**n**	**%**	**n**	**%**
Total[a]	4	(2.2)	3	(1.7)	3	(1.7)
Suicidal ideation	3	(1.7)	3	(1.7)	3	(1.7)
Suicide attempt	1	(0.6)	1	(0.6)	0	(0)

a Subjects with multiple events in the same category are counted only once in that category. Subjects with events in more than 1 category are counted once in each of those categories.

Data derived from Table 11.3.6.1.

The incidence of adverse events related to suicidality in quetiapine-treated patients was similar to that of placebo patients. All three treatment groups exhibited an incidence of 2%.

8.4.5 Discussion of deaths, serious adverse events, discontinuation due to adverse events, and other significant adverse events

There were no deaths reported in this study, and serious adverse events were infrequent in all three treatment groups. More quetiapine-treated patients discontinued the study due to adverse events than did placebo-treated patients. Sedation and somnolence, most often occurring in the first 8 days of treatment, were the adverse events most-frequently associated with discontinuation after administration of quetiapine. The incidence of discontinuation in association with an adverse event may have been increased due to the requirement that the investigator regard any adverse event reported at the discontinuation visit as being associated with discontinuation.

Adverse events of special interest included EPS, diabetes, QT prolongation, neutropenia/agranulocytosis, treatment-emergent mania/hypomania and suicidality. Low rates of EPS-related adverse events were noted with most events being mild to moderate and not-often associated with discontinuation. The incidence of suicidality and treatment-emergent mania/hypomania were both similar to placebo for both quetiapine treatment groups. No cases of QT prolongation or neutropenia/agranulocytosis were reported.

8.5 Clinical laboratory evaluation

Clinical laboratory results are presented separately for hematology and clinical chemistry variables. Within each of these categories, results are examined in 3 ways: changes in mean values over time, changes in individual subjects over time, and individual clinically important abnormalities. The results for all clinical laboratory evaluations are discussed collectively in Section 8.5.3.

8.5.1 Hematology

8.5.1.1 Changes in mean values over time in hematology

Changes in hematology from baseline to Day 57 are shown in Table 50.

Table 50 Hematology changes from baseline (LOCF, safety population)

	Treatment								
	Quetiapine 300 mg N=179			Quetiapine 600 mg N=180			Placebo N=180

Lymphocytes (10^9/L)	155	-0.13	0.59	141	-0.09	0.45	149	-0.11	0.58
Monocytes (10^9/L)	155	-0.00	0.14	141	-0.02	0.15	149	-0.01	0.15

Data derived from Table 11.3.7.1.1.2.

There were no clinically relevant differences between treatment groups in mean change from baseline for any hematology assessments.

8.5.1.2 Changes in individual subjects over time in hematology

The number of patients within each treatment group with positive findings of categorical shifts to out-of-range hematology abnormalities are summarized in Table 51. Complete shift analyses for hematology assessments are presented in Table 11.3.7.1.1.3.1 (see also Figure 11.3.7.1.1.4.1 through Figure 11.3.7.1.1.4.10).

Table 51 Hematology shifts exceeding laboratory norms - incidence (safety population)

	Shift to low			Shift to high		
	Quetiapine 300 mg	Quetiapine 600 mg	Placebo	Quetiapine 300 mg	Quetiapine 600 mg	Placebo

Potassium (mmol/L)	156	-0.01	0.46	146	-0.10	0.45	152	-0.02	0.46
Chloride (mEq/L)	156	1.02	3.13	146	0.42	2.93	152	0.70	3.16
Bicarbonate (mEq/L)	156	-0.50	3.42	147	-0.33	3.15	152	-0.28	3.12
Triglycerides (mg/dL)	156	35.17	98.89	147	21.61	78.45	152	6.47	140.59
Total cholesterol (mg/dL)	156	1.25	27.27	147	1.78	27.95	152	-1.11	32.28
HDL (mg/dL)	156	0.21	8.83	147	-1.50	10.02	152	-0.26	8.19
LDL (mg/dL)	156	-3.65	24.76	147	-1.01	26.35	152	-2.91	24.59
TSH (mU/L)	156	0.11	1.09	140	-0.07	0.91	152	0.08	1.22
Total T4 (nmol/L)	156	-9.63	18.41	147	-18.23	24.24	152	-0.84	17.86

Data derived from Table 11.3.7.1.2.2.

Kidney function and electrolyte test changes from baseline were similar for the three treatment groups. Liver function tests were similar for the three groups for AST and ALT but alkaline phosphatase exhibited a slight increase with quetiapine treatment.

Triglycerides and total cholesterol exhibited higher mean increases from baseline for the quetiapine-treated patients than for the placebo-treated patients. Triglyceride median changes from baseline were consistently lower than the corresponding means for all three treatment groups (quetiapine 300: 13.5 mg/dL; quetiapine 600: 12.0 mg/dL; placebo: 2.0 mg/dL; see Table 11.3.7.1.2.2) and the standard deviations for change from baseline were large compared

to the means. Triglyceride standard deviations for final assessment were larger than those for baseline assessments for all three treatment groups. LDL showed a mean decrease that was more pronounced for the quetiapine 300 mg group and the placebo group than for the quetiapine 600 mg group.

Quetiapine-treated patients exhibited a greater, apparently dose-related, mean decrease in total thyroxine than did the placebo-treated patients. Mean TSH concentrations were little-changed from baseline for all treatment groups.

While glucose was increased slightly for all three treatment groups, mean insulin levels increased in an apparent dose-response relationship with the most pronounced increase in the quetiapine 600 mg group. However, the data were highly variable, with the variability increasing as the mean increased. Median changes from baseline for glucose and insulin were generally lower than mean changes for all but placebo group insulin concentrations (Glucose -- quetiapine 300: 2.5 mg/dL; quetiapine 600: 3.0 mg/dL; placebo: 1.0 mg/dL; Insulin -- quetiapine 300: 6.9 pmol/L; quetiapine 600: 27.8 pmol/L; placebo: 13.9 pmol/L; see Table 11.3.7.1.2.2). Part of the variability of insulin concentration could be explained by the variation in blood sampling time of day; as many samples were collected past morning (>50%), and were probably not taken while patients were in the fasting state (see Figure 11.3.7.1.2.4.11 and Figure 11.3.7.1.2.4.12). For this reason, analyses of glucose findings have been presented using presumption of both fasting and random criteria. Separate examination of patients with pre-existing diabetes or risk for diabetes did not reveal changes in insulin or glucose concentrations that would indicate a deterioration of diabetic status when analyzed by either an LOCF or an OC method (see Table 11.3.7.1.2.3.5, Table 11.3.7.1.2.3.6, Table 11.3.7.1.2.3.7 and Table 11.3.7.1.2.3.8). Analysis using the ANCOVA method allowed examination of insulin final values (log_{10} transformed) to reveal significantly higher concentrations in patients treated with QTP 600 mg compared to either placebo (log_{10} difference = 0.24; p=0.007) or to QTP 300 mg (log_{10} difference = -0.17; p=0.046). No significant differences in final insulin concentration were noted for patients treated with QTP 300 mg compared to those treated with placebo. ANCOVA of change from baseline in glucose concentration did not demonstrate significant differences among the three treatment groups (see Table 11.3.7.1.2.3.9).

Changes from baseline in $HOMA_R$, an estimator of insulin resistance, and QUICKI, an estimator of insulin sensitivity, are shown in Table 54.

Table 54 Insulin resistance and sensitivity change from baseline (LOCF, safety population)

	Quetiapine 300 N=157			Quetiapine 600 N=147			Placebo N=152		
	n	Median change	Mean (SD) change	n	Median change	Mean (SD) change	n	Median change	Mean (SD) change
$HOMA_R$	144	0.4	1.72 (8.52)	138	1.1	4.26 (13.33)	144	0.3	0.06 (11.59)
QUICKI	144	-0.0075	-0.0106 (0.0426)	138	-0.0237	-0.0227 (0.0460)	144	-0.0131	-0.0158 (0.0496)

Data derived from Table 11.3.7.1.2.3.5
N Number of patients in dose group. n Number of patients in analysis subset.

The changes from baseline to final assessment in the $HOMA_R$ estimate of insulin resistance and the QUICKI estimate of insulin sensitivity were highly variable with relatively small deviations from no change. Patients who completed the study and thus received exposure to treatment for the full 8 weeks, showed similar patterns of response (see Table 11.3..7.1.2.3.6 and Table 11.3.7.1.2.3.8). Examination of data for quetiapine-treated and placebo-treated patients with diabetes or diabetes risk did not reveal systematic differences for $HOMA_R$ or QUICKI assessments (see Table 11.3.7.1.2.3.5 and Table 11.3.7.1.2.3.6). Analysis using the ANCOVA method allowed examination of $HOMA_R$ final values to reveal significantly higher concentrations in patients treated with QTP 600 mg compared to placebo (difference = 3.91; $p=0.002$) but not to those treated with QTP 300 mg (difference = -2.25; $p>0.05$). No significant differences for $HOMA_R$ final values were noted for patients treated with QTP 300 mg compared to those treated with placebo. ANCOVA of QUICKI final assessment values did not demonstrate significant differences among the three treatment groups (see Table 11.3.7.1.2.3.9).

8.5.2.2 Changes in individual subjects over time in clinical chemistry

The number of patients within each treatment group with findings of categorical shifts to out-of-range chemistry abnormalities are summarized in Table 55. Complete shift analyses for chemistry parameters are presented in Table 11.3.7.1.2.3.1 (see also Figure 11.3.7.1.2.4.1 through Figure 11.3.7.1.2.4.10).

Table 55 Clinical chemistry shifts exceeding laboratory norms - incidence (safety population)

Parameter	Shift to low			Shift to high		
	Quetiapine 300 mg	Quetiapine 600 mg	Placebo	Quetiapine 300 mg	Quetiapine 600 mg	Placebo

LDL	NA	NA	NA	10.1	17.2	11.2
TSH	0.7	3.6	1.4	1.9	0.7	2.6
Total T4	1.3	4.8	0.7	0.0	1.4	0.7

Incidence (%) of cases with out-of-normal range findings at final visit in the population of patients who did not have out-of-normal range findings at baseline are noted in each cell. Normal ranges are shown in Table 11.3.7.1.2.1.
Data derived from Table 11.3.7.1.2.3.2

More quetiapine-treated patients with low or normal baseline liver function tests showed shifts to out-of-range high results after treatment compared to placebo-treated patients. However, the incidence across AST, ALT and alkaline phosphatase shifts was fewer than ten percentage points over placebo for either quetiapine group. Insulin showed a 24% to 31% incidence of shift to high concentrations for all three treatment groups. Triglycerides, total cholesterol and LDL concentrations shifted to out-of-normal-range concentrations for quetiapine-treated patients with incidences that were 2 to 10 percentage points higher compared to placebo-treated patients. HDL concentrations shifted to out-of-range lower concentrations for quetiapine-treated patients with incidences that were 3 to 6 percentage points lower compared to placebo-treated patients.

8.5.2.3 Individual clinically important abnormalities in clinical chemistry

The number of patients within each treatment group with positive findings of categorical shifts to potentially clinically important clinical chemistry abnormalities are summarized in Table 56. Complete shift analyses for potentially clinically important chemistry results are presented in Table 11.3.7.1.2.3.3 (see also Figure 11.3.7.1.2.4.1 through Figure 11.3.7.1.2.4.10).

Table 56 Clinical chemistry shifts to clinically important values - incidence (safety population)

	Shift to low			Shift to high		
	Quetiapine 300 mg	Quetiapine 600 mg	Placebo	Quetiapine 300 mg	Quetiapine 600 mg	Placebo

TSH	NA	NA	NA	3.3	0.7	2.6
Total T4	0.0	0.0	0.0	0.0	0.7	0.0

Incidence (%) of cases with clinically important findings at final visit in the population of patients who did not exhibit clinically important findings at baseline are noted in each cell Clinically important criteria are shown in Table 15.
Data derived from Table 11.3.7.1.2.3.4

Quetiapine 300 mg-treated patients showed a 8.6-percentage-point-higher incidence of clinically important elevated tryglyceride concentration than did placebo-treated patients. The incidence of clinically important low concentration of HDL was 2 to 3 percentage point higher for quetiapine-treated patients compared to placebo-treated patients.

8.5.2.4 Metabolic syndrome risk factors

Shifts in metabolic syndrome risk factors using criteria for fasting and random glucose elevations are presented in Table 57. An analysis of individual risk factors for shifting to meeting criteria for metabolic syndrome for patients who did not meet risk criteria and baseline is presented in Table 11.3.8.1.4.3. Shifts in metabolic syndrome risk factors using criteria for fasting and random glucose elevations are presented in Table 11.3.8.1.4.1 and Table 11.3.8.1.4.2 with proportions calculated as a percentage of all patients with baseline and post-baseline data.

Table 57 Metabolic syndrome risk factors, shift from baseline (safety population)

		QTP 300 (N=179)		QTP 600 (N=180)		PLA (N=180)	
Factor	**Shift criteria**	**N at risk**	**n (%) shifting**	**N at risk**	**n (%) shifting**	**N at risk**	**N (%) shifting**
Metabolic syndrome risk (fasting glucose criterion)	≥3 risk factors	145	18 (12.4)	146	20 (13.7)	140	4 (2.9)
Metabolic syndrome risk (random glucose criterion)	≥3 risk factors	145	16 (11.0)	147	19 (12.9)	141	4 (2.8)

Data derived from Table 11.3.8.1.4.1 and Table 11.3.8.1.4.2

Note: Patients classified as "at risk" in each treatment group did not meet criteria for the specific risk factor at baseline. The proportion (%) who shifted to meeting 3 or more risk factors is computed from the "at risk" population within each treatment group.

Quetiapine-treated patients showed an 8 to 10 percentage point higher rate of shift than did placebo patients to meeting criteria for an aggregate of 3 metabolic syndrome risk factors. The most pronounced differential shifts to meeting criteria among quetiapine-treated patients compared to placebo-treated patients were observed for increases in triglycerides, while the least pronounced were for increases in blood glucose (see Table 11.3.8.1.4.4).

The incidence of meeting aggregate metabolic syndrome risk factors after the criterion for triglyceride elevation has been removed is shown in Table 58.

Table 58 Metabolic syndrome risk factors without triglyceride criterion, shift from baseline (safety population)

Factor	Shift criteria	QTP 300 (N=179) N at risk	QTP 300 (N=179) n (%) shifting	QTP 600 (N=180) N at risk	QTP 600 (N=180) n (%) shifting	PLA (N=180) N at risk	PLA (N=180) N (%) shifting
Metabolic syndrome risk (fasting glucose criterion)	≥3 risk factors	161	11 (6.8)	163	11 (6.7)	157	4 (2.5)
Metabolic syndrome risk (random glucose criterion)	≥3 risk factors	162	7 (4.3)	163	10 (6.1)	159	3 (1.9)

Data derived from Table 11.3.8.1.4.4

Note: Patients classified as "at risk" in each treatment group did not meet criteria for the specific risk factor at baseline. The proportion (%) who shifted to meeting 3 or more risk factors is computed from the "at risk" population within each treatment group.

When the criteria for triglyceride elevation was ignored, quetiapine-treated patients showed a 2 to 4 percentage point higher rate of shift than did placebo-treated patients to meeting criteria for an aggregate of 3 metabolic syndrome risk factors.

8.5.3 Discussion of clinical laboratory results

In this study, the known clinical laboratory profile for quetiapine was reported in patients with bipolar depression. Decreases in the concentrations of thyroxine without accompanying increases in TSH, and increases in transaminases were seen in this population. These findings have been well-characterized in previous studies in patients treated with quetiapine for other disorders.

The increases in cholesterol and triglycerides seen in this study are also known effects of quetiapine, although the increase in triglycerides in this study may have been somewhat exaggerated by possible non-fasting assessments for some patients. The distribution of data for triglycerides, glucose and insulin were skewed and highly variable, with markedly higher concentrations detected for some patients but not for others. The distribution of blood sampling times-of-day suggests that many samples were likely drawn from non-fasting patients. Therefore, it is not possible to know to what degree increases in triglycerides, glucose and insulin are due to quetiapine versus recent food intake of indeterminate fat or carbohydrate content. Statistically significant differences in insulin concentration between the QTP 600 mg group and the other treatment groups could be interpreted as due to increased hunger or increased carbohydrate craving as easily as to differences in insulin sensitivity. The increase in appetite for patients whose depression was improving with treatment as shown by the MADRS item scores could also account for some differential effect for quetiapine in comparison with placebo.

Increases in levels of cholesterol, triglycerides, glucose and insulin led to exploration of possible decreased insulin sensitivity (increased insulin resistance). While quetiapine-treated patients exhibited numerically-higher-but-highly-variable $HOMA_R$ scores and numerically-lower-but-highly-variable QUICKI scores, those indexes were computed from insulin and glucose concentrations. To the degree that insulin and glucose data are spurious due to non-fasting conditions, so will the $HOMA_R$ and QUICKI estimates of insulin resistance and sensitivity be spurious, as both indexes assume fasting conditions. When shifts in metabolic syndrome risk factors were explored taking into account blood pressure, body mass index, and HDL concentrations as well as triglyceride and glucose concentrations, quetiapine-treated patients showed a higher proportion of patients shifting to meet aggregate criteria for risk for metabolic syndrome. However, the evidence for shifts to criterion levels for risk of metabolic syndrome were heavily influenced by elevated triglyceride concentrations that were of questionable validity.

Examination of clinical laboratory data for patients with pre-existing diabetes showed no clinically relevant findings to suggest that progression of diabetes had occurred. Examination of data for patients considered to be at-risk for diabetes showed no clinically relevant findings to suggest that diabetes was emergent in these patients. These data were in accord with the lack of adverse events that might suggest the development of diabetic symptoms.

Examination of hematology data did not reveal the development of neutropenia or agranulocytosis in any patients, and there were no adverse event reports of those conditions.

8.6 Vital signs, ECG, physical findings and other observations related to safety

Results for vital signs and ECG are grouped together. In the vital signs and ECG section, results are examined in 2 ways: trends or group changes over time and individual potentially clinically important abnormalities. The results for all vital signs, ECG and other physical findings are discussed collectively in Section 8.6.4.

8.6.1 Changes in vital signs and ECG over time

Changes in vital sign and ECG parameters from baseline to Day 57 are shown in Table 59. Tables 11.3.8.1.1.1 through 11.3.8.1.1.3 include presentation of standing blood pressure and orthostatic changes.

Table 59 Vital signs and ECG parameters change from baseline (LOCF, safety population)

	Treatment								
	Quetiapine 300 mg N=179			Quetiapine 600 mg N=180			Placebo N=180		
	n	Mean	SD	n	Mean	SD	n	Mean	SD
Vital signs									
Supine pulse (bpm)	174	3.4	10.9	171	4.7	12.5	175	1.1	9.5
Supine systolic BP (mmHg)	174	1.0	11.4	171	0.2	12.8	175	-0.5	11.8
Supine diastolic BP (mmHg)	174	0.8	9.8	171	1.3	10.1	175	-0.4	8.7
ECG									
Heart rate (bpm)	155	6.4	10.9	146	9.8	10.9	150	1.7	10.2
PR interval (msec)	155	-0.1	16.7	146	-0.5	15.8	150	0.6	15.6
QRS interval (msec)	155	-0.5	6.5	146	-0.4	6.2	150	-0.9	6.3
QT interval (msec)	155	-14.8	26.7	146	-19.2	26.4	150	-4.9	25.2
Fridericia corrected QTC interval (msec)	155	-3.7	21.1	146	-1.7	19.4	150	-2.1	19.3

Data derived from Table 11.3.8.1.1.3 and Table 11.3.8.1.2.1.

Small mean increases in heart rate were observed in quetiapine patients, suggesting a dose-related response. There was no indication of an increase in the QTC interval in any treatment group.

8.6.2 Individual clinically important abnormalities in vital signs and ECG

Patients within each treatment group with positive findings of categorical shifts to clinically important vital sign abnormalities are summarize in Table 60. Complete shift analyses for clinically important vital sign results are presented in Table 11.3.8.1.1.4 and Table 11.3.8.1.1.5 and for ECG results in Table 11.3.8.1.2.4 and Table 11.3.8.1.2.5 (also see Figure 11.3.8.1.2.2 and Table 11.3.8.1.2.3). A summary of clinically important of shifts in orthostatic changes is presented in Table 61.

Table 60 Vital signs and ECG shifts to potentially clinically important values - incidence (safety population)

Parameter	Shift to low			Shift to high		
	Quetiapine 300 mg %	Quetiapine 600 mg %	Placebo %	Quetiapine 300 mg %	Quetiapine 600 mg %	Placebo %
Vital signs						
Supine pulse	0	0	0	0	0	0
Supine systolic BP	1.2	1.2	2.9	0	0	0
Supine diastolic BP	0	0.6	0.6	0	1.2	1.7
ECG						
Heart rate	0.7	1.4	2.1	0	0	0
PR interval	NA	NA	NA	0.7	0	0
QRS interval	0	0	0	0	0	0
QT interval	0	0	0	0	0	0
Fridericia corrected QTC interval	NA	NA	NA	0	0	0

Incidence (%) of cases with clinically important findings at final visit in the population of patients who did not exhibit clinically important findings at baseline are noted in each cell
Data derived from Table 11.3.8.1.1.5 and Table 11.3.8.1.2.5

Table 61 Orthostatic change shifts to clinically important values - incidence (safety population)

Orthostatic change	Shift to positive findings		
	Quetiapine 300 mg %	Quetiapine 600 mg %	Placebo %
Pulse	3.6	6.9	1.2
Systolic BP	0.6	1.2	2.9
Diastolic BP	1.7	0.6	0
Combined pulse & SBP	0	0.6	0.6

Incidence (%) of cases with clinically important findings at final visit in the population of patients who did not exhibit clinically important findings at baseline are noted in each cell
Data derived from Table 11.3.8.1.1.6

While an apparent dose-response for an increased pulse rate change upon standing with quetiapine administration was noted, combined criteria for orthostatic changes did not show any differential effect of quetiapine administration compared to placebo.

Shifts in ECG assessments did not show any differential effect of quetiapine administration compared to placebo.

8.6.3 Physical findings and other observations related to safety

8.6.3.1 Physical examinations

Abnormal findings from physical examination were to be reported as adverse events.

8.6.3.2 Weight and BMI

At end of treatment, placebo patients showed a mean loss of 0.2 kg of body weight, quetiapine 300 mg patients showed a mean gain of 1.0 kg and quetiapine 600 mg patients showed a mean gain of 1.6 kg. (see Table 11.3.8.1.3.1.1). Among patients who completed the protocol, quetiapine 300 mg patients showed a gain of 1.1 kg; quetiapine 600 mg patients showed a gain of 2.0 kg; and placebo patients, a gain of 0.2 kg (see Table 11.3.8.1.3.1.2). Changes in body weight and BMI from baseline to final visit are shown in Table 62 for patients categorized by baseline BMI classification.

Table 62 Body weight (kg) and BMI (kg/m^2) change from baseline by BMI category (LOCF, safety population)

		Treatment								
		Quetiapine 300 mg N=			Quetiapine 600 mg N=			Placebo N=		
BMI category		N	Mean	SD	N	Mean	SD	N	Mean	SD
≤18.49										
	Weight	0	NA	NA	2	0.5	2.12	2	0.0	2.83

		N	Mean	SD	N	Mean	SD	N	Mean	SD
	Weight	14	0.4	3.76	11	1.2	4.21	13	2.1	3.17
	BMI	14	0.1	1.40	11	0.4	1.56	13	0.8	1.17

Data derived from Table 11.3.8.1.3.2.
Note: Due to data errors Subjects E0041009, E0019020, E0026029, and E0035013 have been excluded from this table

No consistent pattern of differential weight gain dependent upon baseline BMI was noted. At end of treatment, 15 (9.7%) quetiapine 300 mg patients, 16 (11.2%) quetiapine 600 mg patients and 3 (2.0%) placebo patients showed a weight gain ≥7% (see Table 11.3.8.1.3.5).

8.6.3.3 SAS

At the end of treatment, quetiapine 300 mg patients showed a mean SAS total score of 0.3 (SD = 0.7), quetiapine 600 mg patients showed a mean total score of 0.6 (SD = 1.3) and placebo patients, a mean score of 0.3 (SD = 0.6). The three treatment groups were similar in mean change in the SAS total score at end of treatment (quetiapine 300 mg: -0.2 (SD = 1.1); quetiapine 600 mg: -0.1 (SD = 1.4); placebo: -0.3 (SD = 1.2); see Table 11.3.8.1.5.1).

The distribution of patients whose SAS score improved, worsened or stayed the same is shown in Table 63.

Table 63 SAS categorical change from baseline (LOCF, safety population)

	Quetiapine 300 N= 179		Quetiapine 600 N= 180		Placebo N= 180	
	n	%	n	%	n	%
Improved	33	21.9	29	20.1	34	22.8
No change	104	68.9	93	64.6	102	68.5
Worsened	14	9.3	22	15.3	13	8.7
Total	151	100.0	144	100.0	149	100.0

Data derived from Table 11.3.8.1.5.3
N Number of patients in dose group. n Number of patients in analysis subset.

There was no statistically significant difference between either quetiapine treatment group and placebo in the number of patients showing increases from baseline in SAS score (quetiapine

300 mg vs placebo: p=0.888; quetiapine 600 mg vs placebo: p=0.075; see Table 11.3.8.1.5.2).

8.6.3.4 BARS

At the end of treatment, quetiapine 300 mg patients showed a mean BARS Global Assessment score of 0.2 (SD = 0.6), quetiapine 600 mg patients showed a mean score of 0.3 (SD = 0.8) and placebo-treated patients, a mean score of 0.1 (SD = 0.4). The three treatment groups were similar in mean change in the BARS Global Assessment score at the end of treatment (quetiapine 300 mg: -0.1 (SD = 0.7); quetiapine 600 mg: -0.0 (SD = 0.8); placebo: -0.1 (SD = 0.6); see Table 11.3.8.1.6.1).

The distribution of patients whose BARS score improved, worsened or stayed the same is shown in Table 64.

Table 64 BARS Global Assessment categorical change from baseline (LOCF, safety population)

	Quetiapine 300 N= 179		Quetiapine 600 N = 180		Placebo N= 180	
	n	%	n	%	n	%
Improved	24	15.7	27	18.6	24	16.1
No change	115	75.2	100	69.0	112	75.2
Worsened	14	9.2	18	12.4	13	8.7
Total	153	100.0	145	100.0	149	100.0

Data derived from Table 11.3.8.1.6.3
BARS. Barnes Akathisia Rating Scale. N Number of patients in dose group. n Number of patients in analysis subset.

There was no statistically significant difference between either quetiapine treatment group and placebo in the number of patients showing increases from baseline in BARS score (quetiapine 300 mg vs placebo: p=0.888; quetiapine 600 mg vs placebo: p=0.306; see Table 11.3.8.1.6.2).

8.6.4 Discussion of vital signs, ECG, physical findings and other observations related to safety

The small increases in heart rate and body weight are consistent with known effects of quetiapine in other populations. SAS and BARS assessments were not statistically significantly different for quetiapine treated patients compared to placebo treated patients and this finding was inconsistent with the slight increase in EPS adverse events for quetiapine-treated patients.

8.7 Conclusions on safety results

Treatment of patients with a depressive episode in bipolar disorder with either quetiapine 300 mg or quetiapine 600 mg daily was generally safe and well tolerated. Most adverse events

and clinical findings seen in these patients have been previously identified in patients treated with quetiapine for other disorders. Sedation and somnolence were the adverse events most often associated with discontinuation in quetiapine-treated patients. The rate of discontinuation due to adverse events may have been over-estimated because investigators were required to attribute a discontinuation to an adverse event if the patient was experiencing an adverse event at the time of discontinuation.

The linkage between these conclusions, the specific safety objectives of the study, and the study variables selected to address these objectives, is presented in Table 65.

Table 65 Safety objectives, variables and conclusions

Objective	Variables	Conclusions
Evaluate the safety and tolerability of quetiapine in the treatment of patients with bipolar depression	Incidence and severity of adverse events during double-blind treatment	The most common AEs associated with quetiapine administration were dry mouth, sedation, somnolence and constipation.
	Incidence of drug-related adverse events during double-blind treatment	AEs most-often attributed to quetiapine administration were dry mouth, sedation, somnolence and constipation.
	Incidence rate of adverse events related to extrapyramidal symptoms during double-blind treatment.	Low rates of EPS were noted with most events being mild to moderate and not-often associated with discontinuation. The incidence of suicidality was similar to placebo for both quetiapine treatment groups.
	Incidence of subject withdrawal due to adverse events	Somnolence and sedation were the most common adverse events associated with discontinuation. Higher rates of withdrawal due to adverse events were associated with the quetiapine 600 mg dose than with the 300 mg dose.
	Clinical laboratory assessments change from baseline to Day 57 in the safety population	There were no clinically relevant hematology findings for quetiapine-treated patients in comparison with placebo-treated patients.
	Incidence of potentially clinically important changes in clinical laboratory assessments	Decreases in the concentrations of thyroxine (without increases in TSH) and increases in transaminases were consistent with those seen in other patient populations. Increases in tryglycerides and glucose, while confounded by probable non-fasting assessments were elevated and contributed to a higher estimate of shift to metabolic syndrome risk factors among quetiapine-treated patients.

Table 65 Safety objectives, variables and conclusions

Objective	Variables	Conclusions
	Change in weight and body mass index (BMI) from baseline to Day 57 in the safety population	Quetiapine-treated patients showed a slight increase in body weight consistent with findings in other patient populations.
	Vital signs from baseline to Day 57 in the safety population	Small mean increases in heart rate were observed in quetiapine patients.
	Incidence of clinically significant changes in vital signs	An apparent dose-response for an increased pulse rate change upon standing with quetiapine administration was noted, but combined criteria for orthostatic changes did not show any differential effect of quetiapine administration compared to placebo.
	Electrocardiogram (ECG)	ECG interval changes were consistent with an increase in heart rate in quetiapine-treated patients, with no indication of an increase in the QTC interval in any treatment group.
	Incidence of potentially clinically important changes in ECG	Shifts in ECG assessments did not show any differential effect of quetiapine administration compared to placebo.
	Change in the SAS total score from baseline to final assessment	Quetiapine-treated patients were similar to placebo-treated patients in final score, change from baseline and the number of patients showing increases in SAS score.
	Change in BARS Global Assessment score from baseline to final assessment	Quetiapine-treated patients were similar to placebo-treated patients in final score, change from baseline and the number of patients showing increases in BARS score.
Evaluate the efficacy of quetiapine compared to placebo in the incidence of treatment-emergent mania	Proportion of patients exhibiting a YMRS total score ≥16 on 2 consecutive assessments or on the final assessment or having an AE report of mania or hypomania.	Quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment in patients with bipolar depression indistinguishable from placebo in producing treatment-emergent manic of hypomanic symptoms as measured by change from baseline in the YMRS total score or an adverse event of mania.

9. DISCUSSION AND OVERALL CONCLUSIONS

9.1 Discussion

In total, 832 patients were screened and 542 patients with either bipolar I disorder or bipolar II disorder, with or without a rapid cycling course, exhibiting moderate to severe depression were randomly assigned to receive either quetiapine 300 mg daily, quetiapine 600 mg daily or placebo. Of the 542 patients recruited, 539 received treatment and were included in the safety population, of whom 511 were analyzed for efficacy in an intention-to-treat analysis set and 453 in a per-protocol analysis set. The three treatment groups were well-matched in number and demographic and baseline disease characteristics and were representative of the general population of patients with bipolar disorder.

The study was well-conducted and high levels of compliance with study drug administration were inferred from tablet counts. Study completion rates were within the expected ranges for depression studies. Within the safety population, 54% of quetiapine 600 mg patients, 68% of quetiapine 300 mg patients and 59% of placebo patients completed the study. Adverse events were the main reason for withdrawal in quetiapine-treated patients, while lack of efficacy was the main reason for withdrawal in placebo-treated patients.

The primary objective for this study was to evaluate the efficacy of quetiapine compared to placebo in the treatment of a major depressive episode in patients with bipolar disorder for up to 8 weeks. The comparison of change from baseline in total MADRS score supported the hypothesis that quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment of a depressive episode in patients with bipolar disorder was superior to placebo in reducing the level of depressive symptoms. A relatively small numerical advantage in treatment effect for MADRS change from baseline was seen for the quetiapine 600 mg group compared to the quetiapine 300 mg group, and that advantage was more pronounced for patients who completed the full 8 weeks of treatment. Treatment advantages for both quetiapine groups over placebo were statistically significant by Day 8 and continued to be so through Day 57. The superiority for both doses of quetiapine over placebo in MADRS total score was due to improvements across all ten of the MADRS items, each evaluating different symptoms of depression.

Analysis of secondary outcome variables also supported the superiority of quetiapine over placebo in the treatment of depression in patients with bipolar disorder. The proportion of patients showing ≥50% reduction in MADRS total score (responders) was statistically significantly higher for the quetiapine 600 mg group compared to the placebo group by Day 8 and for the quetiapine 300 mg group by Day 15, and continued through trial completion for both quetiapine groups. The changes from baseline in HAM-D total score, HAM-D Item 1 and CGI-S were statistically significantly greater for the quetiapine groups compared to the placebo groups by Day 8, with greater differential effect compared to placebo to Day 57. The CGI-I comparisons of quetiapine groups to placebo were also statistically significant by Day 8 and continued to be significant through Day 57. As with the MADRS change from baseline, secondary outcome variables exhibited a more pronounced numerical advantage for

quetiapine 600 mg compared to quetiapine 300 mg for patients who completed the full 8 weeks of treatment in the last-observation-carried-forward analysis.

Bipolar I and bipolar II patients showed greater improvement in MADRS change from baseline with either dose of quetiapine than with placebo. The change from baseline in MADRS score was greater for bipolar I patients than for bipolar II patients, but the study was under-powered for statistical comparison of bipolar I vs bipolar II subgroups or for either diagnostic subgroup vs placebo. Subgroups categorized by sex, race and age also showed a therapeutic advantage for quetiapine treatment. There was no diagnostic or demographic subgroup that did not exhibit an improvement with quetiapine treatment compared to placebo treatment.

The evaluation of the effect of quetiapine on anxiety in bipolar patients with depression was a secondary objective of the study. The comparison of change from baseline in total HAM-A score supported the hypothesis that quetiapine at a dose of either 300 mg daily or 600 mg daily for up to 8 weeks of treatment of a depressive episode in patients with bipolar disorder was superior to placebo in reducing the level of anxiety symptoms. Treatment advantages for both quetiapine groups over placebo were statistically significant by Day 8 and continued to be so through Day 57.

The evaluation of the safety and tolerability of quetiapine in the treatment of bipolar patients with depression was a secondary objective of the study. Analysis of adverse events indicated that nervous system and gastrointestinal events predominated, with dry mouth, sedation, somnolence, dizziness and constipation occurring at higher rates with quetiapine treatment compared to placebo treatment. Most adverse events were mild to moderate. Serious adverse events were reported for a greater proportion of patients given placebo than for those given quetiapine. Adverse events leading to discontinuation were more numerous for the quetiapine-treated groups than for the placebo-treated group and occurred at a higher rate in the quetiapine 600 mg group than in the quetiapine 300 mg group. Sedation and somnolence were the adverse events most associated with discontinuation by quetiapine-treated patients. Sedation and dizziness were associated with discontinuation in patients receiving the 600 mg dose more than in those receiving the 300 mg dose. As attribution of withdrawal as due to an adverse event was forced if any adverse event was present at withdrawal, the rate of withdrawal due to adverse events may be overestimated in this study compared to studies without such a definition.

The evaluation of treatment-emergent mania/hypomania was a secondary objective of the study. Treatment-emergent mania was not associated with quetiapine treatment -- it was noted in 7 patients treated with placebo, 7 patients treated with quetiapine 300 mg daily and 4 patients treated with 600 mg daily. Consistent with these findings, the decrease in YMRS scores at final assessment showed a statistically significant advantage for both groups of quetiapine treated patients compared to placebo.

Safety events of special interest included EPS, QT prolongation, neutropenia/agranulocytosis; weight changes, metabolic syndrome, diabetes and suicidality.

Akathisia was reported at higher rates with quetiapine treatment than with placebo treatment. This finding may be due to increased sensitivity in bipolar depression patients and will be assessed in future studies.

No cases of neutropenia or agranulocytosis following quetiapine treatment were reported. Increases in weight, triglycerides, total cholesterol and LDL were consistent with the known safety profile for quetiapine. Increases in glucose and insulin were observed but were confounded by probable non-fasted sampling. The incidence of aggregate shifts of blood pressure, BMI, triglycerides, HDL and glucose to criteria for risk of metabolic syndrome was higher for quetiapine-treated patients compared to placebo.

The incidence of adverse events associated with suicidality for quetiapine-treated patients was no different than that for placebo-treated patients.

Exploratory objectives included the evaluation of the Q-LES-Q change from baseline and the PSQI change from baseline, both of which are patient-reported outcomes. The improvements in Q-LES-Q score from baseline values were superior for quetiapine-treated patients compared to placebo-treated patients, indicating that quetiapine-treated patients judged that their quality of life had improved over placebo levels. Improvements in subjective sleep quality were also apparent following quetiapine treatment, with the PSQI change from baseline confirming that quetiapine-treated patients felt that they were sleeping better than did placebo-treated patients.

The efficacy results of this study suggest that quetiapine could be an important treatment for depressive episodes in bipolar disorder. The improvement in the entire range of depression symptoms assessed by the MADRS, the HAM-D and the HAM-A demonstrated that the core mood disturbance, the somatic symptoms and anxiety overlays were addressed by the treatment with the net subjective effect being an improvement in quality of life. The alleviation of the full range of depression symptoms was apparent by Day 8 of the study -- 7 days after the beginning of treatment, when both the quetiapine 300 mg and the quetiapine 600 mg groups demonstrated separation from placebo in most efficacy assessments. This is a relatively rapid onset of effect, given that most antidepressants do not show such separation until approximately 3 weeks after the start of treatment.

Evaluation of safety and tolerability in this study revealed a safety profile for quetiapine in patients with bipolar depression that is generally consistent with that seen in previous studies of inpatients with schizophrenia or mania. However, there was some indication that the outpatients in this study were less tolerant of the sedative, somnolent and dizziness effects of quetiapine, especially at the 600 mg daily dose. As these outpatients were functioning in their community, maintaining employment, driving and contributing to their families, somnolence and dizziness may have been more disruptive than to inpatients that were evaluated in previous studies. Nonetheless, these outpatients reported improvements in their quality of life, suggesting that the inconvenience of the adverse events was outweighed by the alleviation of depression, resulting in a positive benefit/risk assessment.

9.2 Overall conclusions

- Quetiapine in doses of either 300 mg or 600 mg once-daily was superior to placebo in treating depression in patients with bipolar disorder.

- The antidepressant effect of quetiapine treatment was observed as early as 7 days after treatment initiation and was maintained throughout the 8-week treatment course in patients with bipolar disorder who were experiencing a depressive episode.

- Quetiapine in doses of either 300 mg or 600 mg once-daily was superior to placebo in treating anxiety symptoms in patients with bipolar disorder who were experiencing a depressive episode.

- Quetiapine in doses of either 300 mg or 600 mg once-daily was superior to placebo in improving the quality of life for patients with bipolar disorder who were experiencing a depressive episode.

- Quetiapine in a dose of either 300 mg or 600 mg once-daily was generally safe and well-tolerated in patients with bipolar disorder who were experiencing a depressive episode. A higher rate of discontinuation due to sedation and dizziness was seen with the 600 mg daily dose. The most common adverse events associated with quetiapine treatment were dry mouth, somnolence, sedation, dizziness and constipation.

- Quetiapine in doses of either 300 mg or 600 mg once-daily was associated with low rates of treatment-emergent mania or hypomania similar to placebo in patients with bipolar disorder who were experiencing a depressive episode.

WEEK 8	123	1	0.8	105	1	1.0	109	4	3.7

* Number of patients in the study at the start of the treatment interval.
** Number of patients receiving at least one dose of medication during the treatment interval.
Percentages are calculated as n**/N* x 100.

11.3.4.3 Narratives of serious adverse events other than death

Study 5077US/0049 Patient 0002/016 placebo

Serious: Hemiparesis

This narrative concerns a 56-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of right-sided weakness (MedDRA: hemiparesis) on Day 22 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. On Day 23, the patient was hospitalized for a sudden onset of weakness on the right side of her body. The table below outlines the assessments performed. No evidence of stroke was found. The patient was treated with clopidogrel bisulfate (PLAVIX®, Bristol-Myers Squibb and Sanofi-Synthelabo) 75 mg/day for prophylaxis. The serious adverse event of right-sided weakness resolved with sequelae right sided weakness (reduced intensity) on Day 28 at discharge. Study treatment was not withdrawn due to this event.

Table 1 Clinical Assessments

Study day	Assessments	Results
Day 23	CT brain without contrast	Intermediate age small lacunar infarct of subcortical white matter of left frontal lobe
Day 24	Anticardiolipin antibody level	Less than 14
	Antiphospholipid level	Less than 11
	Protein S	105%
	Protein C	124%
	Factor V Leiden	0.96
	Antithrombin III	84%
	Magnetic Resonance Imaging (MRI) brain	Findings do not suggest acute ischemia
	Bilateral carotid doppler	1-39% stenosis of the right common and proximal internal carotid artery (ICA). Left proximal carotid artery velocities suggested stenosis in the severe range (60-79%).
	Magnetic Resonance Angiography (MRA) head	No evidence of aneurysm or malformation
	Two dimensional echocardiogram	No stenosis or insufficiency for aortic valve, pulmonic valve, and tricuspid valve. Mitral valve has no stenosis and trace regurgitation. Left ventricle (LV) shows normal E:A ratio
Day 26	MRA of the neck	No hemodynamically significant stenosis

The patient had a relevant medical history of high cholesterol and hypertension. The patient's screening and final visit physical examinations were unremarkable. Before entering the study, the patient was treated with simvastatin (ZOCOR®, Merck) 40 mg/day for high cholesterol, valsartan / hydrochlorothiazide (DIOVAN HCT®, Novartis) 80 mg/day for hypertension, and aspirin 500 mg/day for prophylaxis. The patient continued treatment with these medications throughout the study.

The investigator considered the hemiparesis to be not related to study treatment.

Study 5077US/0049 Patient 0004/006 placebo

Serious: Drug Hypersensitivity

This narrative concerns a 37-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of hypersensitivity reaction to Lamictal®, (MedDRA: drug hypersensitivity) that was considered by the investigator to be severe in intensity. The patient completed the study and started lamotrigine (LAMICTAL®, GlaxoSmithKline) 50 mg/day on the day of the final study visit, one day after the final dose of study medication. Twelve days after the final dose of study medication (placebo), the patient experienced headache, fever of 103 degrees Fahrenheit, and body aches. The patient was not experiencing any symptoms of rash. Fourteen days after the final dose of study medication, the subject was hospitalized with fever and a rash on her face and arms. The patient was given vancomycin and levofloxacin (LEVAQUIN®, Ortho-McNeil) for treatment of this event. The table below outlines the assessments performed during this patient's hospitalization.

Table 2 Clinical Assessments

Study day	Assessments	Results
14 days after last dose of study medication	Elevated AST	78
	Elevated ALT	53
	Direct Bilirubin	0.3
	WBC	2.75
	Ultrasound	Fatty Liver

Eighteen days after the final dose of study medication, the event resolved and the patient was discharged from the hospital. The patient had a relevant medical history of allergic reactions to penicillin, sulfa, and betadine. The screening and final visit physical examinations were unremarkable.

The investigator considered the drug hypersensitivity to be not related to study treatment.

Study 5077US/0049 Patient 0005/019 placebo

Serious: Non-accidental Overdose

This narrative concerns a 22-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of intentional overdose (over the counter sleeping pills) (MedDRA: non-accidental overdose) on Day 2 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. Per the patient's report, she was feeling depressed and hopeless on Day 2, and took an overdose of over the counter sleeping pills. The patient could not remember the amount or type of medication taken, but reported that it was possibly one bottle of diphenhydramine hydrochloride (NYTOL®, GlaxoSmithKline) tablets. The patient reported that she was found by a friend and taken to the emergency room, where her stomach was pumped; however, she was not admitted to the hospital. The event of non-accidental overdose resolved on Day 2. Hospital records for this event were not available; therefore, the information regarding the event and emergency room treatment was reported based on the patient's verbal report and could not be confirmed. The patient reported this event to the study site staff on Day 9, and at that time denied any suicidal ideations and refused hospitalization. The investigator considered the non-accidental overdose to be an important medical event, and withdrew study treatment. The patient's last dose of study treatment was on Day 7.

The patient did not have any relevant medical history. Before entering the study, the patient was treated with acetaminophen / diphenhydramine hydrochloride (TYLENOL® PM, McNeil Consumer) for insomnia secondary to bipolar disorder. No relevant concomitant medications were taken during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the non-accidental overdose to be not related to study treatment.

Study 5077US/0049 Patient 0007/003 placebo

Serious: Duodenal Ulcer Hemorrhage

This narrative concerns a 53-year-old white man with bipolar I disorder.

The patient had a serious adverse event of bleeding ulcer (duodenal) (MedDRA: duodenal ulcer hemorrhage) beginning on Day 23 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. According to hospital records, on Day 23 the patient had shortness of breath, black stool, and fatigue. On Day 27 the patient was brought to the Emergency Room in an ambulance with severe stomach pain and was diagnosed with a duodenal ulcer hemorrhage. The investigator withdrew study treatment for this event. The patient's last dose of study treatment was on Day 26. During the hospitalization, the patient was treated with lansoprazole / amoxicillin / clarithromycin (PREVPAC®, TAP Pharmaceuticals) 1 tab/day, and pantoprazole sodium (PROTONIX®, Wyeth) 80 mg/day for bleeding ulcer. Two days after the last dose of study treatment, the

patient was given midazolam (VERSED®, Roche) 3 mg IV, and meperidine hydrochloride (DEMEROL®, Sanofi-Synthelabo) 50 mg IV for an Esophago-Gastro-Duodenoscopy (EGD) procedure. The table below outlines the assessments performed during the patient's hospitalization. Three days after the last dose of study treatment, the serious adverse event of duodenal ulcer hemorrhage resolved and the patient was discharged from the hospital.

Table 3 Clinical Assessments

Study day	Assessments	Results
One day after last dose	X-ray Thoracic Spine	Thoracic Spondylosis/Kyphosis
	X-Ray Chest PA/LAT	Placement of nasogastric tube – no disease.
Two days after last dose	EGD with coagulation of bleeding site and biopsy	Active duodenal ulcer
Three days after last dose	RBCCT	3.23 (reference range = 4.60-6.20)
	HGB	10.1 (reference range = 13.5-18.0)
	HCT	29.6 (reference range = 42.0-52.0)

The patient had a relevant medical history of anemia, chronic obstructive pulmonary disease, coronary artery disease, hyperlipidemia, hypertension, peptic ulcer disease, and status post cardiac stent. Before entering the study, the patient was treated with lisinopril 20 mg/day and felodipine 5 mg/day for hypertension; these medications were continued concomitantly during study treatment. The patient took acetaminophen (TYLENOL®, McNeil Consumer) 2925 mg/day on Days 25 and 26 for right hip pain. Medical records indicated that the patient also took acetaminophen / hydrocodone bitartrate (LORTAB®, UCB Pharma) 5 mg/day and metaxalone (SKELAXIN®, Monarch) 400 mg/day starting on Day 8 and continuing throughout study treatment for back pain. The patient did not disclose this information to the site personnel during the study. The screening and final visit physical examinations were unremarkable.

The investigator considered the duodenal ulcer hemorrhage to be not related to study treatment.

Study 5077US/0049 Patient 0009/001 600 mg

Serious: Influenza Like Illness

This narrative concerns a 36-year-old black woman with bipolar I disorder.

The patient had a serious adverse event of flu-like symptoms (MedDRA: influenza like illness) on Day 49 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The patient reported taking her last dose of study treatment on Day

56. One day after the last reported dose of study treatment, the patient was hospitalized due to the influenza like illness. The patient was treated and discharged from the hospital two days after she reported taking her last dose of study treatment. The investigator did not consider the event significant enough to warrant withdrawal from study treatment. However, the patient did not return for another study visit and was lost to follow up. The patient did not return the last study treatment blister card dispensed; therefore, for data collection purposes, the final day of dosing prescribed on this blister card (Day 57) was used as the last study treatment dose. The day of resolution of influenza like illness is unknown.

On Day 48, the patient had a non-serious adverse event of somnolence that was considered by the investigator to be mild in intensity and related to study drug. On Day 49 of randomized treatment, the patient had a non-serious adverse event of nasal congestion that was considered by the investigator to be mild in intensity and not related to study medication. The patient had a relevant medical history of insomnia, headaches, and migraine headaches. Before entering the study, the patient had been treated with aspirin / salicylamide / caffeine (BC®POWDER, GlaxoSmithKline) and aspirin / acetaminophen / caffeine (GOODY'S® POWDER, GlaxoSmithKline) for headaches and acetaminophen / aspirin / caffeine (EXCEDRIN® MIGRAINE, Bristol-Myers) for migraine headaches. During the study, the patient was given aspirin for headaches and acetaminophen / pseudoephedrine hydrochloride (ALKA SELTZER PLUS® COLD AND SINUS, Bayer) for nasal congestion. The screening physical examination revealed moderate obesity. The final visit physical examination was not performed.

The investigator considered the influenza like illness to be not related to study treatment.

Study 5077US/0049 Patient 0010/014 600 mg

This narrative concerns a 38-year-old white woman with bipolar I disorder.

Serious: Hernia NOS

The patient had a serious adverse event of recurrent bowel hernia (MedDRA: hernia NOS) on Day 30 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity.

Also on Day 30 of randomized treatment, the patient had a non-serious adverse event of constipation that was considered by the investigator to be mild in intensity and related to study treatment. This adverse event of constipation had not resolved prior to the final study visit and was therefore continuing at study completion.

The investigator considered the hernia NOS to be not related to study treatment.

Serious: Intestinal Obstruction NOS

The patient had a serious adverse event of strangulated bowel (MedDRA: intestinal obstruction NOS) seven days after the final dose of study medication was taken. The event

was considered by the investigator to be severe in intensity. The patient had a serious adverse event of hernia NOS on Day 30 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. After completing the study, the patient underwent a scheduled hernia repair and abdominoplasty seven days after taking the final dose of study medication. During the surgery the intestinal obstruction was found and a bowel resection was performed. After the surgery the patient was given cephalexin (KEFLEX®, Dista) as prophylaxis and hydrocodone for pain management. The event resolved and the patient was discharged from the hospital ten days after the final dose of study medication.

The investigator considered the intestinal obstruction NOS to be not related to study treatment.

The patient had a medical history of an appendectomy, cholecystectomy, elevated blood sugar, incarcerated hernia repair, obesity, hypertension, and unilateral oophorectomy. Before entering the study, the patient had been treated with lisinopril / hydrochlorothiazide (PRINZIDE®, Merck) one tablet daily for hypertension and acetaminophen / pseudoephedrine / diphenhydramine hydrochloride (BENADRYL® ALLERGY, Pfizer Consumer) as needed for mild insomnia. During the study, the patient continued to take lisinopril / hydrochlorothiazide (PRINZIDE®, Merck) for hypertension. The screening and final study visit physical examinations were unremarkable.

Study 5077US/0049 Patient 0014/001 placebo

Serious: Pancreatitis NOS

This narrative concerns a 25-year-old white woman with bipolar II disorder.

The patient had a serious adverse event of pancreatitis (MedDRA: pancreatitis NOS) on Day 25 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The patient was evaluated at the study site on Day 28 and was doing well. On Day 29 the patient was hospitalized due to severe abdominal pain. The patient reported at hospitalization that she had experienced upset stomach, diarrhea, back pain, upper abdominal pain, and dehydration, starting on Day 25. A physical exam revealed abdominal tenderness. An abdominal CT scan was performed and revealed mild pancreatitis. A diagnosis of pancreatitis was made; however, the attending physician indicated that bulimia nervosa appeared to be associated with the pancreatitis and suspected that it was the underlying etiology. On Day 29 the patient was treated with 12.5 mg of dolasetron mesylate (ANZEMET®, Aventis) and 50 mg of promethazine hydrochloride (PHENERGAN®, Wyeth-Ayerst) for nausea and heparin for hypercoagulativity. On Days 29 and 30, famotidine was given for heartburn and hydromorphone hydrochloride (DILAUDID®, Abbott) for pain. On Days 30 and 32, enoxaparin was given for hypercoagulativity. On Days 31 and 32, acetaminophen / hydrocodone bitartrate (LORTAB®, UCB Pharma) was given for pain and ranitidine for heartburn. On Day 32, the event of pancreatitis resolved, and patient was discharged from the hospital. Treatment with study medication was temporarily withdrawn from Day 29 to Day 31.

Table 4 Clinical Assessments

Study day	Assessments	Results
Day 29	Amylase, serum	152 U/L
	Alkaline Phosphatase	793 U/L
	Lipase, serum or plasma	2450 U/L

From Day 3 to Day 28, the patient had a non-serious adverse event of fatigue that was considered by the investigator to be severe in intensity and related to study drug. From Day 10 to Day 35 the patient had a non-serious adverse event of frequent bowel movements that was considered by the investigator to be mild in intensity and related to study medication. The patient had a relevant medical history of back pain, cholecystectomy, hysterectomy, joint pain, kidney/renal failure, and pelvic pain. During the hospitalization, the patient reported a medical history of bulimia, chronic hypokolemia, history of neurologic disorder of unknown etiology, and history of deep vein thrombosis; however, the subject did not report this medical history to the site study staff at the screening visit. Before entering the study, the patient had not been treated with any relevant medications. The screening and final visit physical examinations were unremarkable.

The investigator considered the pancreatitis to be not related to study treatment.

Study 5077US/0049 Patient 0018/007 600 mg

This narrative concerns a 42-year-old white woman with bipolar I disorder.

Serious: Deep Vein Thrombosis

This narrative concerns a 42-year-old white woman with bipolar I disorder.

The patient had a serious adverse event (SAE) of recurrent deep vein thrombosis without pulmonary embolism (MedDRA: deep vein thrombosis) on Day 5, one day after the last dose of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. On Day 4 of randomized treatment, the patient had a non-serious adverse event of worsening of left leg pain that was considered by the investigator to be moderate in intensity and not related to study treatment. One day after the last dose of study treatment, the patient was seen in the Emergency Room for left lower extremity swelling and cramping. An ultrasound showed clotting in her left femoral vein system and a diagnosis of deep vein thrombosis (DVT) was made. The patient was admitted to the hospital and treated with enoxaparin sodium (LOVENOX®, Aventis) and warfarin sodium (COUMADIN®, Bristol-Myers Squibb). The table below provides Prothrombin levels that were measured during this event. The investigator withdrew study treatment and the patient's last dose was on Day 4. The patient was discharged from the hospital two days after admission. The final physical examination, performed eleven days after the last dose of study treatment, revealed increased

left leg circumference secondary to deep vein thrombosis. The serious adverse event of deep vein thrombosis resolved eighty days after the last dose of study treatment.

Table 5 Assessments performed in relation to event

Study day	Prothrombin Levels
One day after last dose	Protime – 10.0
Four days after last dose	Protime – 14.4
Five days after last dose	Protime – 20.7
Six days after last dose	Protime – 19.9
Seven days after last dose	Protime – 26.0
Eight days after last dose	Protime – 29.2
Nine days after last dose	Protime – 30.4

The investigator considered the deep vein thrombosis to be not related to study treatment.

Serious: Migraine NOS

The patient had a serious adverse event (SAE) of migraine headache (MedDRA: migraine NOS) two days after her last dose of randomized study treatment to 600 mg which was considered by the investigator to be severe in intensity. The day after the patient was admitted to the hospital for treatment of deep vein thrombosis, she had a migraine NOS that extended her hospitalization. Per hospital records, there were no medications given to treat this event and the migraine NOS resolved the same day. The patient was discharged from the hospital two days after admission.

The investigator considered the migraine NOS to be not related to study treatment.

Three days after the last dose of study treatment, the patient had non-serious adverse events of chest pain and nausea that were considered by the investigator to be moderate in intensity and not related to study treatment. According to hospital records, seventeen days after the last dose of study treatment, the patient had an adverse event of Factor II deficiency, based on the results of tests ordered during the hospitalization for work-up of hypercoaguable state in this woman with a third episode of DVT. This event was considered by the investigator to be mild in intensity and not related to study treatment. The patient had a relevant past medical history of deep vein thrombosis, ankle fracture with open reduction and internal fixation, and a relevant current medical history of intermittent leg pain and migraines. The screening physical examination was unremarkable. Before entering the study, the patient was treated with conjugated estrogen (PREMARIN®, Wyeth) 1.25 mg/day for hormone replacement therapy, which was discontinued during her hospitalization one day after the last dose of study treatment. During the study, the patient was given a calcium supplement, hydromorphone hydrochloride (DILAUDID®, Abbott), and morphine for left leg pain.

Study 5077US/0049 Patient 0020/013 300 mg

Serious: Suicide Attempt

This narrative concerns a 23-year-old white man with bipolar I disorder.

The patient had a serious adverse event of suicide attempt one day after the last dose of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The patient took his regularly scheduled study treatment dose on Day 12 of randomized treatment. The next day, the patient had an argument with a friend and his girlfriend, and the patient took an unknown amount of acetaminophen / diphenhydramine hydrochloride (TYLENOL® PM, McNeil Consumer), acetaminophen / codeine (TYLENOL® #3, Ortho-McNeil), and oxycodone / acetaminophen (PERCOCET®, Endo). A total of approximately 60 pills were taken. The patient became unconscious, and the patient's girlfriend called an ambulance. The patient was treated in the emergency room with 50 grams of charcoal with sorbitol, and 5 cc of sodium chloride. Naloxone hydrochloride (NARCAN®, Endo) 0.4 mg was given as a narcotic antagonist and 1000 cc of sodium chloride was given for hydration. The patient was released from the emergency room that same day, and the event of suicide attempt was considered resolved. The patient did not take any study treatment doses after Day 12. The patient reported the suicide attempt to the site personnel eight days after the last dose of study treatment. Nine days after the last dose of study treatment, the patient returned to the study site for his final study visit and was evaluated by the investigator. During this visit, no acute distress was noted, no physical complaints were reported, and the patient reported no thoughts, plans, or intentions of harming himself. The event of suicide attempt was determined to be life threatening by the investigator, and the investigator withdrew treatment due to this event.

Table 6 Clinical Assessments

Study day	Assessments	Results
One day after last dose	ETOH Blood Level	143 (units not available)
	Blood Tylenol Level	33 (units not available)

The patient did not have any relevant medical history. The patient was not taking any medications before entering the study. The screening and final visit physical examinations were unremarkable.

The investigator considered the suicide attempt to be not related to study treatment.

Study 5077US/0049 Patient 0022/011 placebo

This narrative concerns a 28-year-old white man with bipolar I disorder.

Serious: Hip Fracture

Serious: Spinal Fracture NOS

The patient had a serious adverse events of hip fracture and multiple spinal fractures T11-L4 (MedRA: spinal fracture NOS) one day after his first and only dose of randomized treatment to placebo, both of which were considered by the investigator to be mild in intensity. The patient took his first and only confirmed dose of study treatment on Day 1. The next day, the patient was involved in a skiing accident resulting in a hip fracture and spinal fracture. Study treatment was withdrawn due to these events and a subsequent deep vein thrombosis (see below). The patient was initially hospitalized out of state and then transferred to a local hospital one day later. The patient was treated with traction and did not require surgery. Hydromorphone hydrochloride (DILAUDID®, Abbott), promethazine hydrochloride (PHENERGAN®, Wyeth-Ayerst), meperidine hydrochloride (DEMEROL®, Sanofi-Synthelabo), morphine sulfate, diazepam (VALIUM®, Roche), and midazolam (VERSED®, Roche) were given for pain management. The patient was also treated with metoclopramide (REGLAN®, Schwarz) and Lactated Ringer's Solution. The patient was discharged from the hospital seven days after he took his first and only dose of study medication. The hip fracture was considered resolved once the patient was considered independently ambulatory and pain free, ninety-seven days after the patient took his first and only dose of study medication.

The investigator considered the hip fracture and the spinal fracture NOS to be not related to study treatment.

Serious: Deep Vein Thrombosis

The patient had a serious adverse event of deep vein thrombosis left leg (MedDRA: deep vein thrombosis) while hospitalized for hip spinal fractures sustained in a skiing accident. The thrombosis started five days after his first and only dose of randomized treatment to placebo that was considered by the investigator to be mild in intensity. Treatment with warfarin sodium (COUMADIN®, Bristol-Myers Squibb) and enoxaparin sodium (LOVENOX®, Aventis) continued until the event resolved. The patient was discharged from the hospital seven days after he took his first and only dose of study medication. The deep vein thrombosis resolved 172 days after he took his first and only dose of study medication.

The investigator considered the deep vein thrombosis to be not related to study treatment.

The patient did not have any relevant medical history. The screening physical examination was unremarkable. The final physical examination was not done.

Study 5077US/0049 Patient 0022/022 300 mg

Serious: Conversion Disorder

This narrative concerns a 23-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of conversion disorder beginning on Day 42 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. On Day 46 the patient was admitted to the hospital for evaluation of numbness and weakness in her lower extremities. At admission, a MRI of the spine and CBC were performed. The results of both tests were normal. Based on her previous episodes of rapid onset of symptoms in the midst of psychosocial stressors, and the lack of physical cause for the patient's symptoms, the investigator determined conversion disorder to be the most likely cause of the event. The investigator did not consider the event significant enough to warrant withdrawal of study treatment. However, the patient decided to withdraw from study treatment as a result of this event. The last dose of study treatment was taken on Day 45. The patient was discharged from the hospital five days after the last dose of study treatment. Thirty-four days after the last dose of study treatment, the serious adverse event of conversion disorder resolved.

The patient had a relevant medical history of orthostatic dizziness. The patient's screening physical examination was unremarkable. The end of study physical examination revealed loss of soft touch sensation, motor activity, and vibration sense attributed to the conversion disorder. During the study, the patient had non-serious adverse events of akathisia and myoclonus that were considered to be moderate in intensity and related to study treatment. The akathisia was treated with lorazepam 3 mg/day. Both of these non-serious adverse events began on Day 2 and continued through Day 20 of randomized treatment. The patient also had a non-serious adverse event of sedation that was considered by the investigator to be moderate in intensity and related to study treatment. This event began on Day 2 and was ongoing as of the patient's last study visit, fifteen days after the last dose of study treatment.

The investigator considered the conversion disorder to be not related to study treatment.

Study 5077US/0049 Patient 0022/036 300 mg

Serious: Suicidal Ideation

This narrative concerns a 22-year-old white man with bipolar I disorder.

The patient had a serious adverse event of suicidal ideation twenty-one days after completing randomized treatment to 300 mg. This event was considered by the investigator to be moderate in intensity. The patient sent a letter to a friend detailing his suicide plan of jumping from a bridge. The friend contacted police and the patient was involuntarily hospitalized twenty-one days after the final dose of study medication. No actual suicide attempt was made. The patient was depressed and suicidal at hospital admission. The patient's lithium dose was increased from 900 mg (the dose prescribed four days after study

completion) to 1200 mg and he was started on fluoxetine. The patient was no longer suicidal twenty-three days after the final dose of study medication and the event was considered resolved. Temazepam (RESTORIL®, Mallinckrodt) was given for bipolar disorder thirty-three, thirty-five, thirty-eight, and forty-one days after the final dose of study medication. The patient was discharged from the hospital forty-four days after the final dose of study medication. At discharge, the patient was free of suicidal ideation, his depression had improved, and a treatment plan was in place.

The patient had no relevant medical history. No relevant medications were taken prior to study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the suicidal ideation to be not related to study treatment.

Study 5077US/0049 Patient 0023/034 300 mg

Serious: Adnexa Uteri Pain

This narrative concerns an 18-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of ovarian cyst pain (MedDRA: adnexa uteri pain) four days after the last dose of randomized study treatment to 300 mg that was considered by the investigator to be severe in intensity. The investigator did not consider the event significant enough to warrant withdrawal from the study. However, the investigator withdrew the patient because of poor protocol compliance. The last dose of study treatment was taken on Day 49. The onset of ovarian cyst pain occurred four days after the last dose of study treatment. Study treatment was not withdrawn for this event. Per patient report, hospital discharge occurred five days after the last dose of study treatment. The patient refused to release medical records from the hospitalization; therefore, no further information is available with regard to the event.

The patient's medical history and screening physical examination were unremarkable. The final visit physical examination performed nine days after the last dose was significant for ovarian cyst. Before entering the study, the patient was not taking any medications. During the study, the patient took ibuprofen 400 mg/day for a non-serious adverse event of dysmenorrhea from Day 17 to Day 19. This event was considered to be moderate in intensity and not related to study treatment. On Days 24 through 28 and Day 32 through four days after the last dose of study treatment the subject had two non-serious adverse events of nausea that were both considered by the investigator to be moderate in intensity and not related to study treatment.

The investigator considered the adnexa uteri pain to be not related to study treatment.

Study 5077US/0049 Patient 0026/003 600 mg

Serious: Prostatitis

This narrative concerns a 46-year-old white man with bipolar II disorder.

The patient had a serious adverse event of acute prostatitis (MedDRA: prostatitis) on Day 57 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. On Day 50 of randomized treatment the patient had fever, chills, night sweats, diarrhea, vomiting, dysuria, headache, nuchal rigidity, and increased urinary frequency. On Day 57 the patient was hospitalized for these symptoms. The table below outlines the assessments performed during this hospitalization. According to hospital records, prior to cerebrospinal fluid (CSF) results, the patient was given ceftriaxone sodium 2 mg IV every 12 hours for suspected meningitis. With growth of Klebsiella in the urine, and only two white blood cells (WBC) detected in spinal fluid, a prostatic exam was performed which showed a mildly enlarged, firm prostate. The patient was switched to levofloxacin 500 mg/day for acute prostatitis. The patient also received morphine hydrochloride and hydrocodone with acetaminophen for the acute prostatitis. Study treatment was not discontinued for this event and the patient took his final dose of study treatment on Day 57 while in the hospital. The patient was discharged in stable condition three days after the completion of study treatment. Five days after the completion of study treatment the prostatitis resolved.

Table 7 Clinical Assessments

Study day	Assessments	Results with details from hospital records
Day 57	Chest x-ray	Normal
Day 57	Head CT	Normal
Day 57	Acute abdominal series	Reported as normal with the exception of some air filled non-dilated small bowel loops in the right mid-abdomen
Day 57	Lumbar Puncture	CSF with 2 WBCs, protein = 87 gm/dL, and negative Gram stain
Day 57	Blood cultures	No growth
Day 57	Liver function tests	Essentially normal
Day 57	EKG	Normal
Day 57	Urine culture	Grew greater than 100,000 colony-forming units of Klebsiella that was sensitive to fluoroquinolones as well as third generation cephalosporins

Hospital records showed that the patient also had a relevant medical history of hepatitis B, human immunodeficiency virus (HIV), non-Hodgkin's lymphoma, and seizure disorder. This information was not disclosed to the site personnel at the screening visit. The patient's screening physical examination was unremarkable. The end of study physical examination revealed a diffusely tender abdomen, which was attributed to the diagnosis of prostatitis.

Before entering the study, the patient was taking topiramate (TOPAMAX®, Ortho-McNeil), gabapentin (NEURONTIN®, Parke-Davis), lopinavir / ritonavir (KALETRA®, Abbott) for HIV, and lamivudine / zidovudine (COMBIVIR®, GlaxoSmithKline) for HIV. These medications were not disclosed at screen and according to hospital records, were continued by the patient during the study.

The investigator considered the prostatitis to be not related to study treatment.

Study 5077US/0049 Patient 0026/023 600 mg

Serious: Mental Status Changes

This narrative concerns a 20-year-old white man with bipolar II disorder.

The patient had a serious adverse event of altered mental status (MedDRA: mental status changes) three days after the completion of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The patient arrived at the study clinic for his final scheduled visit somnolent, unsteady, incoherent, and complaining of nausea and dizziness. Several sets of vital signs were recorded during the patient's visit; on one occasion, the patient was hypotensive (60/48) and tachycardic (150 bpm). The hypotension was reported as a non-serious adverse event. The patient reported that he had not eaten in three days and the attending physician suspected dehydration. The patient was given juice and food. Following oral food and fluid, the patient's vital signs were normal, but the patient's level of somnolence increased to the point of being difficult to arouse. The patient was taken via ambulance to the emergency room and admitted for evaluation. Per medical records, the subject did not receive any treatment for this event. Assessments performed during the patient's hospitalization are listed in the table below. Based on the results of these assessments, it was concluded that the patient's mental status changes were likely of psychiatric etiology. Four days after the completion of randomized treatment the serious adverse event of mental status changes was considered to be resolved and the patient was discharged from the hospital.

Table 8 Clinical Assessments

Study day	Assessments	Results
Three days after completion	CT Scan	Normal
	Chest x-ray	Normal
	Liver Function Tests	ALT = 13 units/L (5-35 units/L) AST = 16 units/L (10-40 units/L)
	Electrolytes	Normal
	Creatinine	1.0 mg/dL (0.3-1.0 mg/dL)
	Glucose	78 mg/dL (less than 140 mg/dL)

Study day	Assessments	Results
	CPK	111 IU/L (15-190 IU/L)
	Ammonia	33 uMol/L (11-35 umol/L)
	ETOH level	Less than 4 mg/dL
	Tylenol level	Less than 10 mcg/mL (toxic levels greater than 150 mcg/mL)
	CBC	Within normal limits, except for mild anemia
	Salicylate level	Less than 10 mg/dL (toxic levels greater than 30 mg/dL)
	Urine drug screen	Negative
	Hemoglobin	13.2 g/dL (14-18 g/dL)

The patient had a relevant medical history of past alcohol abuse. The screening physical examination was unremarkable. An end of study physical examination was not performed.

The investigator considered the mental status changes to be not related to study treatment.

Study 5077US/0049 Patient 0026/027 placebo

Serious: Convulsions NOS

This narrative concerns a 40-year-old white woman with bipolar II disorder.

The patient had a serious adverse event of seizure (MedDRA: convulsions NOS) on Day 1 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. On Day 7 of randomized treatment, the patient contacted the study site to report that she had experienced a possible seizure on the day of her baseline visit, prior to taking her first dose of study medication. The patient stated that after leaving the study site, she went to the grocery store and woke up in an ambulance. While in the emergency room, she was told that she had a possible seizure. The patient was started on phenytoin (DILANTIN®, Parke-Davis) 300 mg/day for seizures. The patient stated that she left the hospital against medical advice and that she was not admitted to the hospital. After being informed of the event, the investigator discontinued study treatment. The patient's last dose of study treatment was on Day 5. The patient refused to sign a medical release for hospital records, but did admit to having a history of seizures. This information was not provided at screen.

The patient's screening physical examination was unremarkable. The subject refused to return to the clinic for a follow-up examination. The patient's medical history was unremarkable except for a past history of seizures. No relevant medications were given prior to study treatment.

The investigator considered the convulsions NOS to be not related to study treatment.

Study 5077US/0049 Patient 0026/028 placebo

Serious: Major Depressive Disorder NOS

This narrative concerns a 35-year-old white man with bipolar I disorder.

The patient had a serious adverse event (SAE) of psychotic depression (MedDRA: major depressive disorder NOS) on Day 22 of randomized treatment to placebo that was considered by the investigator to be severe in intensity.

Nine days after the patient's last dose of study treatment, the patient returned to the study site for an early termination visit. During the early termination visit, the patient informed the study staff that he had been previously admitted to the hospital for major depressive disorder NOS on Day 22 of randomized treatment. Hospital records for this hospitalization (Days 22-24) were reviewed. According to the patient, he continued to take study medication during the hospitalization for major depressive disorder, although this is not reflected in the hospital records. The patient took his last dose of study treatment on Day 25. During the hospitalization for this event, the patient was treated with gabapentin (NEURONTIN®, Parke-Davis), oxcarbazepine (TRILEPTAL®, Novartis), risperidone (RISPERDAL®, Janssen), quetiapine fumarate (SEROQUEL®, AstraZeneca), and escitalopram oxalate (LEXAPRO®, Forest) for bipolar condition, acetaminophen (TYLENOL®, McNeil Consumer) for headache, zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) for insomnia, clonazepam (KLONOPIN®, Roche) for agitation, ramipril (ALTACE®, Monarch) and atenolol for hypertension, and pantoprazole sodium (PROTONIX®, Wyeth) for gastro-reflux. The patient was discharged against medical advice on Day 24 of randomized treatment. At the time of the early termination visit, the event of major depressive disorder was ongoing. The patient was lost to follow-up after the early termination visit and it is unknown when the event resolved.

The investigator considered the major depressive disorder NOS to be not related to study treatment.

Serious: Acute Psychosis

The patient had a serious adverse event of acute psychosis on Day 26 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. According to Emergency Room admission records, the patient was brought to the hospital by police, and admitted for paranoid schizophrenia, auditory hallucinations, suicidal ideation, left anterior chest pain, and palpitations. The patient stated that he used amphetamines the evening prior to his admission, however urine drug screen results were negative for amphetamines. A urine test for alcohol was also negative. The patient took his last dose of study treatment on Day 25, one day before admission to the hospital for acute psychosis. At his early termination visit nine days after the last dose of study treatment, the patient reported that he was hospitalized for four days. The patient did not provide a release form for hospital records and was lost to

follow-up after the early termination visit; therefore, confirmation and details of this hospitalization are not available. During the early termination visit, the patient informed the coordinator that he had been hospitalized for a major depressive disorder from Day 22 to Day 24, prior to the hospitalization for acute psychosis (see separate narrative). The investigator withdrew the patient from the study because of these two serious adverse events.

The investigator considered the serious adverse event of acute psychosis to be not related to study treatment.

The patient's medical history and screening and final visit physical examinations were unremarkable. No relevant medications were taken prior to study treatment.

Note: This patient was enrolled at two separate study sites. His other enrollment number was (E0028031). Both sites reported this patient as having a serious adverse event. The separate narratives reflect the information provided by the separate sites.

Study 5077US/0049 Patient 0028/003 placebo

Serious: Cholecystitis NOS

This narrative concerns a 53-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of cholecystitis exacerbation (MedDRA: cholecystitis NOS) on Day 4 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The patient had a history of cholecystitis that was asymptomatic at screen. Exacerbation of the cholecystitis began on Day 4. The patient took oxycodone / acetaminophen (PERCOCET®, Endo) for the event on Day 15 and Day 16. Due to worsening symptoms, a cholecystectomy was scheduled. On Day 36, the cholecystectomy was performed and the cholecystitis resolved. The patient remained in the hospital overnight for post-operative care and she was discharged on Day 37. Treatment was not withdrawn due to this event and the patient's final dose of study medication was taken on Day 57.

The patient had a non-serious adverse event of post procedural pain starting on Day 36 and ending on Day 42 that was considered by the investigator to be moderate in intensity and not related to study treatment. The patient had a relevant medical history of past cholecystitis, current obesity, and was post menopausal. The patient had not been treated with any relevant medications before entering the study. The patient took an herbal preparation as prophylaxis from Day 18 to Day 22. General anaesthesia was used on Day 36 for gall bladder surgery. Surgery pain was treated with meperidine hydrochloride (DEMEROL®, Sanofi-Synthelabo) on Day 36 and hydrocodone bitartrate / acetaminophen (VICODIN®, Abbott) from Day 37 to Day 38. The screening physical examination was unremarkable. The final visit physical examination revealed a cholecystectomy scar on the abdomen.

The investigator considered the cholecystitis NOS to be not related to study treatment.

Study 5077US/0049 Patient 0028/007 600 mg

Serious: Non-accidental Overdose

This narrative concerns a 22-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of overdose of study medication (intentional) (MedDRA: non-accidental overdose) on Day 39 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The patient used crystal methamphetamine on Day 38. The morning of Day 39 the patient began experiencing a panic attack and took 8 tabs of study medication in an attempt to alleviate the panic attack symptoms. The patient had nausea and vomiting after taking the 8 tabs of study medication. The patient's husband took her to the emergency room where she was given 50 grams of activated charcoal, a NG tube, and 20 MEQ of potassium chloride (KCL). The patient recovered and was discharged on that same day. This event was considered by the investigator to be an important medical event. The study medication overdose was intentional, but was not considered a suicide attempt. The patient returned to the clinic on Day 42 and was withdrawn from the study due to the illicit drug use with methamphetamine. The final dose of study medication was taken on Day 41.

Table 9 Clinical Assessments

Study day	Assessments	Results
Day 39	Potassium	3.1 mmol/L
	Glucose	155 mg/dL
	Creatinine	0.6 mg/dL
	Toxicology	Positive for Amphetamines
	RDW	10.9 %
	Neutrophils	71.1 %
	Lymphs	15.7 %

The patient had a non-serious adverse event of drug abuse (methamphetamine) on Day 38 which was considered by the investigator to be severe in intensity and not related to study drug. The patient had a non-serious adverse event of panic attack on Day 39, which was considered by the investigator to be severe in intensity and not related to study drug. Also on Day 39, the patient had non-serious adverse events of nausea and vomiting, which were considered by the investigator to be severe in intensity and related to study drug. The patient had a relevant past medical history of polysubstance abuse. No relevant concomitant medications were taken prior to study treatment. During the study, the patient was treated with activated charcoal and KCL on Day 39 for treatment of non-accidental overdose. No other relevant concomitant medications were given during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the non-accidental overdose to be not related to study treatment.

Study 5077US/0049 Patient 0028/023 600 mg

Serious: Suicide Attempt

This narrative concerns a 55-year-old black man with bipolar I disorder.

The patient had a serious adverse event of suicide attempt on Day 48 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The patient reported his last dose of study medication was taken on Day 48. At some point prior to the suicide attempt, the patient began experiencing suicidal ideation (exact start date unknown). On the day of the suicide attempt, the patient was found unconscious and transported by ambulance to the acute care hospital where he was admitted to the intensive care unit for management of a drug or alcohol overdose. An initial blood alcohol level was 0.186%. The patient was treated with naloxone hydrochloride (NARCAN®, Endo) because, at the time the ambulance technicians first found him, he was wearing several medication skin patches thought to be fentanyl transdermal system (DURAGESIC®, Janssen) patches. He was also managed with charcoal by gastric lavage. His initial urine drug screen was negative, however, and the final diagnoses from the acute care hospital were suicide attempt and alcohol overdose. The patient was treated with sertraline hydrochloride (ZOLOFT®, Pfizer) for depression, beginning on the day of hospital admission (Day 48). The event of suicide attempt resolved on Day 48; however, the patient continued to experience suicidal ideation. Three days after the patient's last dose of study medication, he was stabilized and transferred to a mental hospital for further treatment because he continued to pose a risk to himself. Suicidal ideation resolved and the patient was discharged twenty-four days after the last dose of study medication. Study treatment was withdrawn due to the suicide attempt.

Table 10 Clinical Assessments Performed During Hospitalization

Study day	Assessments	Results
Day 48	CT Scan	Head; showed no acute disease and showed evidence of old, small left cerebellar stroke
	Urine Drug Screen	Negative
	ETOH Blood Level	0.186
Two days after last dose	EEG	No evidence of seizure focus

The patient had a non-serious adverse event of seizure two days after the last dose of study medication, and was treated with 1 mg of lorazepam (ATIVAN®, Wyeth Ayerst) and phenytoin (DILANTIN®, Parke-Davis) 900 mg/day. These events were considered by the investigator to be severe in intensity and not related to study medication. The patient reported

a medical history of chronic back pain at the screening visit. Hospital records indicated that the patient also had a medical history of hypothyroidism, past alcohol abuse, past polysubstance abuse, hepatitis C, seizure disorder (secondary to head trauma), myocardial infarction, and stroke. The patient did not disclose this medical history to the site personnel at the screening visit. The patient did not report taking any relevant medications prior to entering the study. However, according to the medical records, the managing physicians at the two hospitals learned that the patient had been prescribed phenytoin (DILANTIN®, Parke-Davis) intermittently for many years for management of his seizure disorder. The patient had not taken the prescribed phenytoin (DILANTIN®, Parke-Davis) for several weeks or months prior to hospital admission because he had run out of his prescription. In addition, the patient told his hospital physicians that he commonly acquired medication in Mexico, including hydrocodone bitartrate and acetaminophen (VICODIN®, Abbott) and oxycodone hydrochloride controlled-release (OXYCONTIN®, Purdue Pharma), which he takes for his chronic back pain. The screening and final visit physical examinations were unremarkable.

The investigator considered the suicide attempt to be not related to study treatment.

Study 5077US/0049 Patient 0028/031 placebo

Serious: Hallucination, Auditory

This narrative concerns a 35-year-old white man with bipolar I disorder.

The patient had a serious adverse event of self mutilating auditory hallucinations (MedDRA: hallucination, auditory) one day after the last dose of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The patient took his last dose of study treatment on Day 16. Three days after the last dose of study treatment, the patient went to the hospital emergency room with auditory hallucinations that were telling him to self mutilate. The patient was considered a danger to himself and was admitted to the behavioral health unit of the hospital for treatment. Four days after the last dose of study treatment the patient began treatment with gabapentin (NEURONTIN®, Parke-Davis) 1800 mg/day, lithium 1200 mg/day, risperidone (RISPERDAL®, Janssen) 2 mg/day, benztropine mesylate (COGENTIN®, Merck) 0.5 mg/day, and clonazepam (KLONOPIN®, Roche) 1 mg/day for bipolar disorder. The self mutilating auditory hallucinations resolved five days after the last dose of study treatment and the patient was discharged from the hospital. The investigator did not consider the event significant enough to warrant withdrawal of study treatment. However, the patient withdrew from the study due to this event. The patient's final study visit was twenty-two days after the he took his final dose of study medication.

The patient had non-serious adverse events of headache and somnolence starting on Day 3 and ending two days after the last dose of study treatment. These events were considered by the investigator to be mild and moderate in intensity, respectively, and related to study treatment. The patient did not have any relevant medical history. No relevant medications were taken prior to the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the hallucination, auditory to be not related to study treatment.

Note: This patient was enrolled at two separate study sites. His other enrollment number was (E0026028). Both sites reported this patient as having a serious adverse event. The separate narratives reflect the information provided by the separate sites.

Study 5077US/0049 Patient 0028/032 600 mg

Serious: Bipolar I Disorder

Serious: Suicidal Ideation

This narrative concerns a 36-year-old white man with bipolar II disorder.

The patient had a serious adverse event of mixed episode with psychosis (MedDRA: bipolar I disorder) on Day 55 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. Eighteen days after the last dose of study treatment the patient returned to the clinic for his last study visit and reported that he was not able to return sooner because he had been hospitalized. On Day 56 of randomized treatment the patient took his last dose of study treatment. One day later, he went to his normally scheduled psychiatric visit and was hospitalized for bipolar I disorder and suicidal ideation. The patient had auditory hallucinations telling him to self-mutilate and kill himself, and was treated for superficial self-inflicted cuts from a razor on both his right and left forearms. He also had urinary incontinence, which was attributed to his instability. Significant assessments performed during this hospitalization are listed in the table below. During his hospitalization, the patient was treated with bupropion (WELLBUTRIN®, GlaxoSmithKline), olanzapine (ZYPREXA®, Lilly), topiramate (TOPAMAX®, Ortho-McNeil), risperidone (RISPERDAL®, Janssen), and doxepin hydrochloride (SINEQUAN®, Pfizer). Nine days after the patient's last dose of study treatment, the serious adverse event of bipolar I disorder resolved and the patient was discharged without psychosis.

Table 11 Clinical Assessments

Study day	Assessments	Results
Day 57	Urine drug screen	Positive for Propoxyphene
Day 57	Urinalysis	Ketones 1+
Day 57	Urinalysis	Specific gravity – 1.030 (reference range > 1.005)

Hospital records indicated that the patient had a medical history of suicidal ideation, auditory hallucinations, self-mutilation, and urinary incontinence, although the patient did not admit to this history at screen. The screening and final visit physical examinations were unremarkable.

The investigator considered the bipolar I disorder and suicidal ideation to be not related to study treatment.

Study 5077US/0049 Patient 0028/045 300 mg

Serious: Suicidal Ideation

This narrative concerns a 46-year-old white man with bipolar I disorder.

The patient had a serious adverse event of suicidal ideation with acute psychosis (MedDRA: suicidal ideation) on Day 39 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The patient visited the study site on Day 13 and did not contact the site personnel again until Day 72. On Day 72 the patient reported that since his last visit to the study site, he had been hospitalized for suicidal ideation. On Day 39 the patient presented at the emergency room complaining of being delusional, having a persecution complex, and feeling suicidal. The patient did not have a suicide plan. The patient was hypomanic with pressured speech, had disorganized thoughts, and lability. The patient was also having auditory hallucinations and appeared paranoid with psychotic features. The patient voluntarily admitted himself to the hospital on Day 39. During the hospitalization, the patient was treated with aripiprazole (ABILIFY®, Bristol-Myers Squibb and Otsuka America Pharmaceuticals), lithium, topiramate (TOPAMAX®, Ortho-McNeil), haloperidol (HALDOL®, Ortho-McNeil), lorazepam (ATIVAN®, Wyeth Ayerst), methocarbamol (ROBAXIN®, Schwarz Pharma), and quetiapine fumarate (SEROQUEL®, AstraZeneca). The suicidal ideation resolved on Day 42, and the patient was discharged from the hospital on Day 44. The patient withdrew from the study due to this event. The patient's last study treatment blister card was dispensed on Day 13, containing nine days of study treatment doses. The patient's final study treatment day and dose is unknown. However, for the purpose of case report form completion, Day 21 has been used as the estimated last dose of study treatment. The patient's final study visit was on Day 86.

Table 12 Clinical Assessments Performed During Hospitalization (Days 39 – 44)

Study day	Assessments	Results
UNK	WBC	7.6 x 10^3/mm^3
	Hematocrit	39.7 %
	MCV	92 FL
	Platelets	153 x 10^3/μL
	BUN	7 mg/dL
	Creatinine	0.9 mg/dL
	Potassium	3.5 mmol/L
	Librium	< 0.2
	Sodium	144 mmol/L
	Bicarbonate	28 mmol/L
	Chloride	113 mmol/L

Study day	Assessments	Results
	Glucose	81 mg/dL
	Calcium	8.9 mg/dL
	Ethanol	No Measurable Amount
	Toxicology Screen	Positive for Amphetamine

The patient had non-serious adverse events of dyskinesia, headache, and insomnia starting on Day 28 and ongoing at the patient's final study visit (Day 86). These events were considered by the investigator to be moderate in intensity and not related to study treatment. The patient had a non-serious adverse event of mania starting on Day 28 and ending on Day 42 that was considered by the investigator to be severe in intensity and not related to study treatment. The patient had a non-serious adverse event of methamphetamine abuse starting on Day 45 and ending on Day 56. The patient also had a non-serious adverse event of injury resulting from a falling episode secondary to methamphetamine abuse starting and ending on Day 55. Both of these events were considered by the investigator to be moderate in intensity and not related to study treatment.

The investigator considered the suicidal ideation to be not related to study treatment.

Serious: Bipolar I Disorder

The patient had a serious adverse event of bipolar affective disorder mixed state with mood congruent psychosis (MedDRA: bipolar I disorder) on Day 55 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The patient visited the study site on Day 13 and did not contact the site personnel again until Day 72. On Day 72 the patient reported that since his last visit to the study site, he had been hospitalized for bipolar I disorder. The patient was initially taken to the hospital on Day 55 for acute insomnia. The patient had fallen asleep while at a local market and paramedics were called. The patient was arousable at the scene by the paramedics. The patient reported that he had not slept in four days due to methamphetamine use. Once at the emergency room, the patient had a physical exam, laboratory exam, and a CT scan of the head performed, all of which were unremarkable. During the emergency room stay, the patient demonstrated manic features, delusions, paranoia, irritability, and grave disability. At that time the subject was admitted to the psychiatric unit. The patient was complaining of being depressed, anxious, having trouble sleeping, and a poor appetite. The patient was treated for bipolar I disorder. On Day 71 the patient was considered medically stable and was discharged from the hospital. The patient withdrew from the study due to this event.

Table 13 Clinical Assessments Performed During Hospitalization (Days 55 – 71)

Study day	Assessments	Results
UNK	Urine Drug Screen	Positive for Amphetamine
	Chemistry	Unremarkable

Study day	Assessments	Results
	CBC	Unremarkable
	Urine Profile	Unremarkable
	Blood Alcohol Level	Negative

The investigator considered the bipolar I disorder to be not related to study treatment.

The patient had a relevant past medical history of post traumatic stress disorder, concussion, and substance dependence and a relevant current medical history of hypothyroidism. Before entering the study, the patient had been treated with lithium for bipolar disorder for approximately 16 years, bupropion (WELLBUTRIN®, GlaxoSmithKline) for depression for approximately 3 years, and topiramate (TOPAMAX®, Ortho-McNeil) for bipolar disorder for approximately 3 years. Medical records indicated that the patient was also prescribed aripiprazole (ABILIFY®, Bristol-Myers Squibb and Otsuka America Pharmaceuticals) for bipolar disorder approximately one month prior to study entry. However, the patient did not disclose this information at screen, and it is unknown if this medication was taken concomitantly during study treatment. The patient was also being treated with levothyroxine (SYNTHROID®, Abbott) for hypothyroidism, which continued through study treatment. Seven days prior to randomization, the patient was given lorazepam (ATIVAN®, Wyeth Ayerst) for anxiety, which continued through study treatment. The following relevant medications were given on Day 28 of the study and were ongoing at the patient's final study visit: lithium, bupropion (WELLBUTRIN®, GlaxoSmithKline), topiramate (TOPAMAX®, Ortho-McNeil), paroxetine hydrochloride (PAXIL®, GlaxoSmithKline), aripiprazole (ABILIFY®, Bristol-Myers Squibb and Otsuka America Pharmaceuticals), quetiapine fumarate (SEROQUEL®, AstraZeneca), and divalproex sodium (DEPAKOTE®, Abbott). Bupropion (WELLBUTRIN® SR, GlaxoSmithKline) was given for bipolar disorder on Day 59 and was ongoing at the patient's final study visit. Also given during the study were haloperidol (HALDOL®, Ortho-McNeil) for extreme restlessness and methocarbamol (ROBAXIN®, Schwarz Pharma) for muscle spasms, both starting on Day 28 of the study and ongoing at the patient's final study visit. The screening and final visit physical examinations were unremarkable.

Study 5077US/0049 Patient 0031/021 300 mg

Serious: Injury

This narrative concerns a 27-year-old black man with bipolar II disorder.

The patient had a serious adverse event of stab wounds (MedDRA: injury) on Day 36 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The patient was attacked by someone he knew and stabbed with scissors in the neck, shoulder, and knee. The patient was hospitalized as a result of this event. During the hospitalization, the patient had suture repair of lacerations in the neck, knee, and shoulder

(with local anaesthetic) and was managed with intravenous fluids and oral analgesics. The patient was discharged from the hospital on Day 37. The event ended on Day 56, as the wounds were considered by the investigator to be healed. The investigator did not withdraw treatment due to this event. The final dose of study medication was taken on Day 54 of randomized treatment.

The patient had a non-serious adverse event of worsening of depression due to stab wounds starting on Day 36 of randomized treatment and ending on Day 47 that was considered by the investigator to be mild in intensity and not related to the study treatment. The patient did not have any relevant medical history. The screening physical examination was unremarkable. The final visit physical exam revealed the sutures for treatment of the injury. No medications were taken prior to study treatment.

The investigator considered the injury to be not related to study treatment.

Study 5077US/0049 Patient 0033/010 placebo

Serious: Ectopic Pregnancy

This narrative concerns a 26-year-old black woman with bipolar I disorder.

The patient had a serious adverse event of ectopic pregnancy diagnosed on Day 44 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. On Day 43 (day of last dose of study treatment), the patient was seen by her doctor. A pregnancy test was performed with positive results. The patient was discontinued from study treatment due to this event. According to hospital records, the patient reported having abdominal pain and vaginal bleeding at least one week prior to her doctor visit. An ultrasound was performed one day after the last dose of study treatment, which showed fluid in the abdomen and a right ovarian cyst. The patient was sent to the emergency room and exploratory surgery was performed that evening in order to rule out an ectopic pregnancy. During the surgery, the patient was diagnosed with an ectopic pregnancy, the left fallopian tube with pregnancy was removed as well as the cyst on the right ovary, and the fluid was removed from the abdomen. The event was considered resolved immediately following the surgery. The patient remained in the hospital for four days after the surgery for observation. According to hospital records, the patient was given general anaesthesia on the day of the surgery, was treated with antibiotics, and was given acetaminophen (TYLENOL®, McNeil Consumer) for pain.

Table 14 Clinical Assessments

Study day	Assessments	Results
One day after last dose	CBC	Not clinically significant
	Urinalysis	Not clinically significant
	UHCG	Positive
	Beta HCG	7133 mIU/L

The patient did not have any relevant medical history. No medications were taken by the patient before entering the study. No additional relevant concomitant medications were taken during study treatment. The screening physical examination was unremarkable. The final visit physical examination revealed a post-surgical suprapubic incision, well-healed.

The investigator considered the ectopic pregnancy to be not related to study treatment.

Study 5077US/0049 Patient 0033/014 placebo

Serious: Intervertebral Disc Herniation

This narrative concerns a 53-year-old white man with bipolar I disorder.

The patient had a serious adverse event of herniated spinal disc pain (MedDRA: intervertebral disc herniation) on Day 31 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. The patient visited the study site on Day 34 for his regularly scheduled study visit and was prescribed ibuprofen (ADVIL®, Wyeth Consumer) 200 mg/day for this pain and for an unrelated non-serious adverse event (headache). One day after the last dose of study treatment, the patient contacted the site personnel and indicated that he had been hospitalized since his Day 34 visit due to "a problem with a herniated spinal disc." The patient reported that during his hospitalization, he received parenteral analgesics. The patient also reported that he did not take study medication on some or all days of the hospitalization. The patient withdrew himself from the study and did not return to the study site for another study visit. The hospitalization and discharge days for this event were not confirmed. The event was ongoing as of the last contact with the patient, one day after the last dose of study treatment. The last confirmed dose of study medication was taken on Day 40. The investigator did not withdraw treatment due to this event.

The patient had a relevant medical history of current herniated spinal disc. Before entering the study, the patient was not treated with any medication relevant to the intervertebral disc herniation. The screening physical examination was unremarkable. A final visit physical examination was not done.

The investigator considered the intervertebral disc herniation to be not related to study treatment.

Study 5077US/0049 Patient 0035/002 placebo

Serious: Suicidal Ideation

This narrative concerns a 46-year-old white man with bipolar I disorder.

The patient had a serious adverse event of suicidal ideation on Day 24 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. The patient was hospitalized on Day 24 due to suicidal ideation. The patient had no suicide plan and no attempt was made. The patient was contacted by the site personnel during the hospitalization on Day 27. He reported during this contact that he became suicidal after arguing with his girlfriend. The last confirmed dose of study medication was taken on Day 27. The event was ongoing as of the study site personnel's last contact with the patient on Day 27. The investigator did not consider the event significant enough to warrant withdrawal of study treatment. However, the patient withdrew from the study and did not return for any additional study visits.

The patient had a relevant past medical history of alcohol (ETOH) and cocaine abuse three months prior to study treatment. Before entering the study, the patient had been treated with divalproex sodium (DEPAKOTE®, Abbott) 1000 mg/day as a mood stabilizer for 3 years. Treatment with this medication was discontinued nine days before the patient began study treatment. The patient also took 1 mg of lorazepam (ATIVAN®, Wyeth Ayerst) for insomnia eight days before study treatment began. The patient was not treated with any concomitant medications during the study. The screening physical examination was unremarkable. A final visit physical examination was not performed.

The investigator considered the suicidal ideation to be not related to study treatment.

Study 5077US/0049 Patient 0039/028 600 mg

Serious: Chest Pain

This narrative concerns a 39-year-old black man with bipolar I disorder.

The patient had a serious adverse event of chest pain (not cardiac related) (MedDRA: chest pain) on Day 46 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. Treatment was not withdrawn due to this event. On Day 46 this patient was hospitalized due to chest pain. An electrocardiogram (ECG) was done revealing non-specific s-t changes, but was otherwise normal. A chest x-ray was also done and indicated early Chronic Obstructive Pulmonary Disease (COPD) with no active lung disease and normal heart. Myocardial infarction was ruled out during this hospitalization. The patient

was given a urine drug test and results were positive for cocaine. On Day 46 the event of chest pain resolved and the patient was discharged from the hospital on Day 47. The table below outlines selected assessments performed during this patient's hospitalization.

Table 15 Clinical Assessments

Study day	Assessments	Results
Day 46	Urine Drug Test	Positive Cocaine
	Lithium	Less than 0.10 mmol/L
	ECG	WNL
	CXR	Early COPD with no active lung disease and normal heart
	CK	297 u/L , CKMB 0.9
	CK	281 u/L , CKMB 0.4
	CK	243 u/L , CKMB 0.3
	CK	239 u/L , CKMB 0.3
	CK	193 u/L , CKMB < 0.3
		normal ranges: CK (24-195 u/L) , CKMB (<2.4mg/mL)
		CKMB levels obtained from medical records

The investigator considered the chest pain to be not related to study treatment.

The patient had two adverse events of worsening hypertension that were considered by the investigator to be mild in intensity and not related to study medication. The first event started on Day 22 of randomized treatment and ended on Day 29 of randomized treatment. The second worsening of hypertension adverse event started on Day 43 of randomized treatment and ended fifteen days after the final dose of study medication was taken. During the study, the patient was given metoprolol 100 mg/day starting on Day 23 and hydrochlorothiazide 25 mg/day starting on Day 44 of randomized treatment for hypertension. Both medications were ongoing on the day of discontinuation.

Serious: Suicidal Ideation

During discharge from a hospitalization for chest pain on Day 47, the patient had a serious adverse event of suicidal ideation. The patient was transferred to a psychiatric hospital on that same day (Day 47) due to the suicidal ideation and remained hospitalized until Day 54. During the hospitalization for suicidal ideation the patient had increased auditory hallucinations and admitted to recent cocaine use. The investigator withdrew study treatment due to suicidal ideation. The patient had been taking risperidone (RISPERDAL®, Janssen) 3 mg/day and lithium 900 mg/day for bipolar disorder starting nineteen days prior to the baseline visit through two days after the final dose of study medication was taken on Day 51. The patient did not disclose to the site personnel that he was taking these medications concomitantly with study treatment. The patient had a non-serious adverse event of increased auditory hallucinations starting two days after the patient's final dose of study medication that

was considered by the investigator to be severe in intensity and not related to the study treatment. This adverse event had not resolved as of the last contact with the patient. Three days after the final dose of study medication was taken, the patient started risperidone (RISPERDAL®, Janssen) 1mg/day and lithium 600 mg/day. The suicidal ideation resolved three days after the patient's last dose of study medication, and the patient was discharged from the hospital. The patient's final study visit was also completed three days after the last dose of study medication.

The investigator considered the suicidal ideation to be not related to study treatment.

Serious: Depression

The patient had a serious adverse event of worsening of depression (MedDRA: depression) on Day 58, seven days after taking his last dose of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The patient reported that he was hospitalized for worsening of depression from fifteen days to twenty-four days after his last dose of study medication. According to the patient, the event of worsening of depression resolved twenty-one days after the patient's last dose of study medication. When the site personnel requested hospital records, the hospital indicated that there was no record of the patient being hospitalized during the dates reported by the patient.

The investigator considered the depression to be not related to study treatment.

The patient had a medical history of hypertension, acid reflux, angina, obesity, and pain in neck and shoulders. The screening and final physical examinations revealed obesity.

Study 5077US/0049 Patient 0039/030 placebo

Serious: Suicidal Ideation

This narrative concerns a 52-year-old white woman with bipolar I disorder.

The patient had a serious adverse event of suicidal ideation nineteen days after the final dose of study medication. The event was considered by the investigator to be severe in intensity. At the final study visit, one day after the final dose of study medication, the patient was prescribed open-label quetiapine fumarate (SEROQUEL®, AstraZeneca) 200 mg/day. The actual start date of this medication is unknown. Twelve days after the final dose of study medication, the patient returned to the site and requested a decreased dose of quetiapine fumarate (SEROQUEL®, AstraZeneca). She was prescribed 25 mg, but did not have the prescription filled. The last confirmed dose of open-label quetiapine fumarate (SEROQUEL®, AstraZeneca) 200 mg/day was eleven days after the final dose of study medication. The patient was hospitalized nineteen days after the final dose of study medication due to suicidal ideation. Per hospital records the patient was described as hopeless, helpless, tearful, and suicidal at admission. Upon admission, the patient admitted to a history of multiple personality disorder, alcohol and drug dependence, and pathological gambling. During the hospitalization the patient was given fluoxetine hydrochloride (PROZAC®, Dista), initially 20 mg/day, then increased to 40 mg/day for depression. Other medications given during the

patient's hospitalization include trazodone 50 mg/day for insomnia, ibuprofen 400 mg for pain, and Mylanta (MYLANTA®, Johnson & Johnson - Merck Consumer Pharmaceutical Company) 30 cc for nausea. The patient was also given one dose of haloperidol (HALDOL®, Ortho-McNeil) for agitation. The serious adverse event of suicidal ideation resolved and the patient was discharged in stable condition twenty-five days after the final dose of study medication. The table below outlines the assessments performed during the patient's hospitalization. The exact date of the assessments is unknown.

Table 16 Clinical Assessments

Study day	Assessments	Results
UNK	AST	86 IU/L
	ALT	80 IU/L
	Potassium	3.4 mEq/L
	Calcium	8.7 mg/dL

The patient had a medical history of insomnia, arthritis, hepatitis C, obesity, and is post menopausal. According to the medical records, the patient also had a current medical history of hepatitis A and hepatitis B; however, these conditions were not disclosed to the site personnel during the screening visit. The screening and final visit physical examinations were unremarkable. Before entering the study, the patient had been treated with fluoxetine hydrochloride (PROZAC®, Dista) 20 mg/day for bipolar depression for approximately seven years. At the time of the baseline visit, the patient had not taken a dose in thirty days. Also before entering the study, the patient had been treated with temazepam 15 mg/day for insomnia for approximately eight months. At the time of the baseline visit the patient had not taken a dose in twenty-six days. No relevant concomitant medications were given during the study.

The investigator considered the suicidal ideation to be not related to study treatment.

Study 5077US/0049 Patient 0039/038 placebo

Serious: Asthma NOS

This narrative concerns a 40-year-old black woman with bipolar I disorder.

The patient had a serious adverse event of asthma attack (MedDRA: asthma NOS) on Day 13 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The patient was hospitalized due to this event on Day 13. At the time of admission, the patient had been smoking crack cocaine and drinking alcohol for approximately three days; the admitting diagnoses included alcoholic ketoacidosis and alcohol withdrawal. Per hospital medical records, a psychiatric consultation was also performed on Day 14. The attending psychiatrist noted suicidal ideations and referred to the patient's use of crack

cocaine and alcohol as a suicide attempt. During the hospital stay the study treatment was temporarily stopped and the patient did not take study treatment doses on Days 14 – 16. Management of the patient's asthma included albuterol (Day 13 and ongoing), prednisone (Days 13-29), cortisone (Day 17), dexamethasone (DECADRON®, Merck) (Days 13 to 17), guaifenesin (ROBITUSSIN®, Wyeth Consumer Health Care) (Days 13 to 17), fluticasone propionate (FLOVENT®, GlaxoSmithKline), and azithromycin (Day 18 and ongoing). From Day 13 to Day 15, the patient received diazepam 5 mg/day for anxiety and on Day 13 the patient also received 2 mg of lorazepam (ATIVAN®, Wyeth Ayerst) for anxiety. The asthma resolved on Day 17 and the patient was discharged from the hospital on Day 18. The study treatment was restarted on Day 17.

Table 17 Clinical Assessments

Study day	Assessments	Results
Day 12	Urine protein	100 mg/dL
	Urine glucose	100 mg/dL
	Urine ketone	40 mg/dL
	Arterial oxygen saturation	95 %
Day 14	WBC	17.1 $x10^3/\mu L$
Day 15	Serum glucose	447 mg/dL
	WBC	14.0 $x10^3/\mu L$
Day 16	Serum glucose	216 mg/dL
	Glycohemoglobin ACZ	11.5%
	Hepatitis C	Positive
	WBC	16.2 $x10^3/\mu L$
Day 17	Serum glucose	361 mg/dl
	WBC	11.8 $x10^3/\mu L$
Day 18	Serum glucose	292 mg/dL
	WBC	15.8 $x10^3/\mu L$

The patient had a non-serious adverse event of accidental overdose of study medication on Day 13 (two doses were taken). This event was considered by the investigator to be moderate in intensity and not related to study treatment. The patient had a relevant medical history of asthma and obesity. The patient also tested positive for hepatitis C during hospitalization. However, a history of hepatitis C was not disclosed to the site personnel at the screening visit. The patient had not taken any relevant medications prior to study treatment. No additional relevant medications were taken during the study. The screening and final visit physical examinations were unremarkable.

The investigator considered the asthma NOS to be not related to study treatment.

Study 5077US/0049 Patient 0041/010 placebo

Serious: Mania

This narrative concerns a 32-year-old white man with bipolar I disorder.

The patient had a serious adverse event of manic episode (MedDRA: mania) on Day 39 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The patient had decreased need for sleep, increase in irritability, reports of inappropriate social responses, feelings of restlessness, racing thoughts, difficulty concentrating, increased libido, and euphoric mood. The symptoms began on Day 39 and the patient was hospitalized due to mania on Day 43. The investigator withdrew study treatment for this event. The final dose of study treatment was taken on Day 42. During the 3-day hospitalization, the patient was treated with open-label quetiapine fumarate (SEROQUEL®, AstraZeneca) for mania (100 mg one day after last dose and 200 mg two days after last dose and at discharge), lorazepam (ATIVAN®, Wyeth Ayerst) for insomnia (1 mg/day one and two days after last dose), and divalproex sodium (DEPAKOTE®, Abbott) for mania (750 mg/day one, two, and three days after last dose). The manic episode resolved three days after the last dose of study treatment and the patient was discharged.

The patient had a relevant medical history of intermittent anxiety, intermittent agitation, and intermittent insomnia. Before entering the study, the patient had been treated for approximately seven weeks with divalproex sodium (DEPAKOTE® ER, Abbott) 1500 mg/day for bipolar disorder. Treatment with divalproex sodium (DEPAKOTE® ER, Abbott) was discontinued eight days before the patient took the first dose of study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the mania to be not related to study treatment.

11.3.5.3 Narratives of discontinuations due to adverse events

Study 5077US/0049 Patient 0001/006 600 mg

Withdrawal: Fatigue, Muscle Cramps, Muscle Twitching, Muscle Twitching

This narrative concerns a 29-year-old white man with bipolar II disorder.

The patient had non-serious adverse events of fatigue, muscle cramps not due to Extrapyramidal Syndrome (EPS) (MedDRA: muscle cramps), muscle twitching not due to EPS (MedDRA: muscle twitching), and lips twitching not due to EPS (MedDRA: muscle twitching). The patient had fatigue on Day 1 through Day 7 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. Muscle cramps and muscle twitching not due to EPS occurred on Day 2 through Day 7 with intensities of severe. Lips twitching not due to EPS occurred on Day 2 and had an intensity of moderate according to the investigator. The investigator withdrew treatment due to these events. The patient took his final dose of study medication on Day 5. The fatigue, muscle cramps, and muscle twitching not due to EPS resolved two days after the final dose of study medication. The lips twitching not due to EPS had not resolved as of the last contact with the patient, ten days after the last dose of study medication.

The patient's medical history revealed asthma, seasonal allergies, and sleep apnea. Before entering the study, the patient had been treated with cetirizine hydrochloride (ZYRTEC®, Pfizer) and fluticasone propionate (FLONASE®, GlaxoSmithKline) for allergies and Metabolife (METABOLIFE®, Metabolife International, Inc.) for weight loss. No additional concomitant medications were given during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the fatigue, muscle cramps, muscle twitching not due to EPS, and lips twitching not due to EPS to be related to study treatment.

Study 5077US/0049 Patient 0002/004 placebo

Withdrawal: Depression

This narrative concerns a 33-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of anxiety related to depression (MedDRA: depression) eight days prior to randomized treatment to placebo that was considered by the investigator to be moderate in intensity. The patient was treated with lorazepam (ATIVAN®, Wyeth Ayerst) 3 mg/day for anxiety, and zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 10 mg/day for insomnia. At baseline, the patient's anxiety was ongoing for eight days. The patient was assigned to a treatment cohort and issued blinded medication for the first week of the study. The anxiety did not resolve. The investigator withdrew the patient from study treatment due to this ongoing adverse event. The patient did not return for any follow-up visit

and the resolution of the depression is unknown. It is also not known how much, if any, of the study medication was taken.

The patient's medical history was unremarkable. The screening physical examination revealed pluritic chest pain. Before entering the study, the patient was treated with olanzapine (ZYPREXA®, Lilly) 5 mg/day for bipolar disorder and clonazepam (KLONOPIN®, Roche) 1 mg/day for anxiety; these drugs were discontinued eight and five days prior to baseline.

The investigator considered the depression to be not related to study treatment.

Study 5077US/0049 Patient 0002/018 300 mg

Withdrawal: Somnolence

This narrative concerns a 48-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of drowsiness (MedDRA: somnolence) on Day 1 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. Although the investigator did not determine the somnolence to be severe enough to warrant withdrawing the patient, the patient withdrew from the study due to somnolence. The last dose of study medication was taken on Day 3 and the somnolence resolved one day after the last dose of study treatment.

The patient had a medical history of arthritis. No medications were taken prior to or during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0003/016 600 mg

Withdrawal: Irritability

This narrative concerns a 33-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of irritability on Day 19 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment and the patient's final dose of study medication was on Day 21. The irritability ended one day after the last dose of study treatment.

The patient had a non-serious adverse event of feeling jittery starting on Day 3 and ending twenty-two days after the final dose of study treatment. This adverse event was considered by the investigator to be severe in intensity and related to study medication. The patient had a non-serious adverse event of insomnia starting on Day 13 and ending one day after the last dose of study treatment that was considered by the investigator to be severe in intensity and

related to the study treatment. The patient had a relevant medical history of past anxiety. The screening and final visit physical examinations were unremarkable. The patient was not taking any relevant medications prior to or during the study.

The investigator considered the irritability to be related to study treatment.

Study 5077US/0049 Patient 0004/001 600 mg

Withdrawal: Sedation and Dysarthria

This narrative concerns a 33-year-old hispanic woman with bipolar I disorder.

The patient had non-serious adverse events of sedation and slurred speech in P.M. (MedDRA: dysarthria). Sedation occurred during randomized treatment to 600 mg on Days 1 through 13, Days 13 through 22, and Day 22 through two days after the last dose of study treatment with intensities of moderate, mild, and severe, respectively. Dysarthria occurred on Days 7 through 13 and Day 22 through two days after the last dose of study treatment with intensities of mild and moderate, respectively. The dose of study medication was reduced due to these events. The dose was reduced by two tablets on Days 6, 11, 12, 14-16, and 18-21. The patient missed her doses on Days 13 and 17, and the dose was reduced by one tablet on Days 22 through 31. The patient did not take any doses of study medication after Day 31. Both dysarthria and sedation continued after dose reduction. The patient requested that study treatment be stopped due to the dysarthria and sedation. The investigator determined that only the sedation was severe enough to warrant withdrawal. Both adverse events resolved two days after the patient's last dose of study treatment.

The patient had a non-serious adverse event of dizziness on Days 1 through 13, Days 13 through 22, and Day 22 through two days after the last dose of study treatment with intensities of moderate, mild, and severe, respectively. Dizziness also contributed to the decision to reduce the dose of study medication. The dizziness was considered by the investigator to be related to the study treatment. The patient's relevant medical history revealed dysmenorrhea, irritable bowel syndrome, headaches, and nausea. The patient was not taking any relevant medications prior to or during study treatment. The screening and final visit physical examinations revealed right tympanic membrane blocked by serum. The final visit physical examination also revealed pain on percussion of bilateral flanks.

The investigator considered the sedation and dysarthria to be related to study treatment.

Study 5077US/0049 Patient 0004/013 300 mg

Withdrawal: Sedation

This narrative concerns a 24-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of AM sedation (MedDRA: Sedation) on Day 2 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment and the patient's final dose of study medication was on Day 22. The sedation ended three days after the last dose of study medication.

The patient had a medical history of asthma and obesity. The screening and final visit physical examinations revealed that the patient was slightly obese. Before entering the study, the patient had been treated with albuterol for asthma starting approximately 12 years prior to treatment and continuing during study treatment. During the study, the patient took propoxyphene napsylate / acetaminophen (DARVOCET-N®, AAI Pharma), hydrocodone bitartrate / ibuprofen (VICOPROFEN®, Abbott), and morphine sulfate (KADIAN-SR®, Alpharma Branded) 20 mg/day to treat a non-serious adverse event of left breast cyst. The propoxyphene napsylate / acetaminophen (DARVOCET-N®, AAI Pharma) was started on Day 2 and stopped on Day 3. It was then started again on Day 20 and was continuing at the final visit. Hydrocodone bitartrate / ibuprofen (VICOPROFEN®, Abbott) was taken from Day 17 to Day 19 and the morphine sulfate (KADIAN- SR®, Alpharma Branded) was taken on Day 19 only.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/004 300 mg

Withdrawal: Lethargy and Sedation

This narrative concerns a 36-year-old white woman with bipolar I disorder.

The patient had non-serious adverse events of lethargy and sedation on Day 2 of randomized treatment to 300 mg that were considered by the investigator to be moderate in intensity. The investigator reduced the dose of medication due to these adverse events on Day 15. These events continued after the dose reduction. The investigator determined that these events were not significant enough to warrant withdrawal from study treatment; however, the patient decided to withdraw from study treatment due to these events. The patient took her final reduced dose of study medication on Day 21. The patient did not return to the clinic for a final visit and the day of resolution for the lethargy and sedation is unknown.

The patient had a relevant past medical history of anemia (iron deficiency) and a relevant current medical history of heart murmur and shortness of breath. No additional medications were given prior to or during the study treatment. The screening physical examination revealed a heart murmur. The final visit physical exam was not done.

The investigator considered the lethargy and sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/009 600 mg

Withdrawal: Sedation

This narrative concerns a 24-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of sedation on Day 1 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient took his final dose of study medication on Day 4 and the event resolved two days later.

The patient had a relevant medical history of current sinusitis and migraine headaches. No relevant medications were given prior to or during the study treatment. The screening physical examination was unremarkable. The final visit physical exam was not done.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/013 300 mg

Withdrawal: Sedation, Dizziness, and Dyskinesia

This narrative concerns a 43-year-old white woman with bipolar I disorder.

The patient had non-serious adverse events of sedation, dizziness not related to orthostatic hypotension (MedDRA: dizziness), and motor incoordination (dyskinesia) (MedDRA: dyskinesia) on Day 1 of randomized treatment to 300 mg that were considered by the investigator to be moderate in intensities. The investigator withdrew study treatment due to these events. The patient took her last dose of study medication on Day 4 and the event of dizziness resolved one day later. The events of sedation and dyskinesia resolved three days after the patient took her last dose of study medication.

The patient had a medical history of current rhinitus/sinusitis, sinus headaches, recurrent neck pain, nausea, insomnia, indigestion, constipation, gallstones in the past, and is allergic to sulfa drugs. Before entering the study, the patient was treated with alprazolam (XANAX®, Pharmacia and Upjohn) 0.5 mg/day and acetaminophen / pseudoephedrine / diphenhydramine hydrochloride (BENADRYL® ALLERGY, Pfizer Consumer) 50 mg/day for insomnia. These medications were discontinued prior to study treatment. The patient was given zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 20 mg/day for insomnia and phosphorated carbohydrate solution (EMETROL®, Pfizer) 2 tbsp/day for nausea starting prior to study treatment and continuing after the patient's final study visit. The screening physical examination was unremarkable. The final visit physical examination was not done.

The investigator considered the sedation, dizziness, and dyskinesia to be related to study treatment.

Study 5077US/0049 Patient 0005/019 placebo

Withdrawal: Non-accidental Overdose

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0005/022 600 mg

Withdrawal: Sedation

This narrative concerns a 25-year-old white man with bipolar I disorder.

The patient had two non-serious adverse events of sedation during randomized treatment to 600 mg that were both considered by the investigator to be moderate in intensity. The first episode of sedation began on Day 3 and resolved on Day 4. The second episode began on Day 7. The investigator reduced the dose of study medication due to the sedation. The patient took a reduced dose of study medication from Day 24 through Day 31 and on Day 33. The patient did not take any study medication on Day 32. The sedation continued during the dose reduction. The investigator withdrew the study treatment due to the sedation. The patient took his final dose of study medication on Day 33. The sedation resolved two days after the patient took the final dose of study medication.

The patient's medical history was unremarkable. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered both events of sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/025 600 mg

Withdrawal: Sedation

This narrative concerns a 40-year-old white woman with bipolar I disorder.

The patient had two non-serious adverse events of sedation during randomized treatment to 600 mg. The first episode of sedation began on Day 2, resolved on Day 16, and was considered by the investigator to be moderate in intensity. The second episode began on Day 17 and was considered by the investigator to be mild in intensity. On Day 15, the patient began taking a reduced dose of study medication due to sedation. The sedation continued during the dose reduction. The investigator did not consider the event significant enough to warrant withdrawal of study treatment. However, the patient decided to withdraw study treatment as a result of this event. The patient took her final dose of study treatment on Day 35, and the second episode of sedation resolved three days later.

The patient had a relevant medical history of hypothyroidism. Before entering the study, the patient was treated with levothyroxine (SYNTHROID®, Abbott) 75 µg/day for

hypothyroidism, and continued treatment with this medication during study treatment. No additional medications were taken during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/027 300 mg

Withdrawal: Sedation

This narrative concerns a 41-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of sedation on Day 2 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator reduced the dose of study medication on Days 16 through 19 due to this event; however, the sedation continued through the dose reduction. The investigator withdrew study treatment due to the sedation. The patient took his final dose of study medication on Day 19 and the event resolved two days later.

The patient had a relevant medical history of current exercise induced asthma, hyperlipidemia, seasonal allergies, sinus headaches, and vertigo. Before entering the study, the patient was treated with escitalopram oxalate (LEXAPRO®, Forest) 10 mg/day for depression, which was stopped ten days prior to study treatment, and loratadine (CLARITIN®, Schering) 10 mg/day for seasonal allergies, which continued through study treatment. No additional relevant concomitant medications were given prior to or during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/033 600 mg

Withdrawal: Nasal Congestion

This narrative concerns a 33-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of nasal congestion on Day 6 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. During the study, the patient was treated with 4-Way Nasal Spray and cetirizine hydrochloride (ZYRTEC®, Pfizer) on Day 12, fluticasone propionate (FLONASE®, GlaxoSmithKline) and fexofenadine hydrochloride (ALLEGRA®, Aventis) on Day 13, loratadine (CLARITIN®, Schering) 10 mg/day and Dristan Nasal Spray (DRISTAN® NASAL SPRAY, Whitehall-Robins, Inc.) on Day 14, and pseudoephedrine hydrochloride (SUDAFED®, Pfizer) 120 mg/day and fexofenadine hydrochloride (ALLEGRA®, Aventis) from Day 16 though Day 21. The patient's dose of study medication was reduced from 4 to 3 tablets per day on Day 11 and from Day 15 to Day 19, to 2 tablets per day on Day 12 and Day 13, and took no tablets on

Day 14. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 19 and the event resolved ten days later.

The patient had no relevant medical history. Before entering the study, the patient was not taking any relevant medications except for Nyquil (NYQUIL®, Vicks) 2 tbsps/day, taken to manage insomnia. During the study, the patient was given Nyquil (NYQUIL®, Vicks) 2 tbsps/day and zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 10 mg/day for insomnia. The screening and final visit physical examinations were unremarkable.

The investigator considered the nasal congestion to be related to study treatment.

Study 5077US/0049 Patient 0005/036 300 mg

Withdrawal: Sedation

This narrative concerns a 40-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of sedation on Day 1 of randomized treatment to 300 mg considered by the investigator to be moderate in intensity. The patient's Day 5 dose of study medication was not taken due to sedation. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 7 and the event resolved one day later.

The patient had no relevant medical history. No relevant medications were given prior to the study treatment. The patient had non-serious adverse events of dyskinesia, dry mouth, akathisia, and sinus congestion all starting on Day 1 and ending one day after the patient took her last dose of study medication. All events were considered by the investigator to be related to study drug and to be moderate in intensity except for dyskinesia, which was mild in intensity. During the study, the patient was given celecoxib (CELEBREX®, Pharmacia and Upjohn) 200 mg/day for headaches and benztropine mesylate (COGENTIN®, Merck) 1 mg/day for restless legs. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0005/038 600 mg

Withdrawal: Sedation

This narrative concerns a 31-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of sedation on Day 1 of randomized treatment to 600 mg considered by the investigator to be moderate in intensity. The dose of study medication was reduced from 4 to 3 tablets per day from Day 16 through Day 22, but the

sedation continued. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 22. This event had not resolved at the time of the site personnel's last contact with the patient, which occurred one day after the final dose of study medication.

Other non-serious adverse events during the study included akathisia (Day 1 and ongoing at last patient contact, judged related to study medication by the investigator), dysphagia (Day 1 to Day 19, judged related to study medication by the investigator), and dyspnoea (Day 10 and ongoing at last patient contact, judged related to study medication by the investigator). The patient had a relevant medical history of asthma, constipation, and headaches. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations revealed obesity.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0006/018 300 mg

Withdrawal: Somnolence and Coordination Abnormal NOS

This narrative concerns a 57-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of extreme sleepiness (MedDRA: somnolence) on Day 1 of randomized treatment to 300 mg considered by the investigator to be severe in intensity. The patient also had a non-serious adverse event of loss of coordination (not due to Extrapyramidal Syndrome) (MedDRA: coordination abnormal NOS) on Day 3 of randomized treatment that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to these events. The patient took his last dose of study treatment on Day 4. The somnolence and coordination abnormal NOS resolved one day after the patient's last dose of study treatment.

The patient's medical history was unremarkable. The screening and final visit physical examinations revealed bilateral ear occlusion. The patient did not take any relevant medications prior to or during study treatment. On Day 2 of randomized treatment, the patient had a non-serious adverse event of dysarthria that was considered by the investigator to be moderate in intensity and related to study treatment. One day after the patient's last dose of study treatment, this event resolved.

The investigator considered the somnolence and coordination abnormal NOS to be related to study treatment.

Study 5077US/0049 Patient 0007/003 placebo

Withdrawal: Duodenal Ulcer Hemorrhage

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0007/006 placebo

Withdrawal: Rash NOS

This narrative concerns a 39-year-old black man with bipolar I disorder.

The patient had a non-serious adverse event of rash (MedDRA: rash NOS) on Day 18 of randomized treatment to placebo considered by the investigator to be mild in intensity. The investigator withdrew study treatment on Day 22. The final dispensed blister card was not returned to the site personnel by the patient. The date of final dose was based on the maximum number of available doses dispensed on the blister card. The patient's final dose of study medication was estimated to have been taken on Day 23. The rash resolved four days after the patient took his estimated final dose of study medication.

The patient had no relevant medical history. No concomitant medications were taken prior to or during the study treatment. The screening visit physical examination was unremarkable. The final visit physical examination performed on Day 22, revealed rash on the extremities, thorax, and scalp.

The investigator considered the rash NOS to be related to study treatment.

Study 5077US/0049 Patient 0007/008 300 mg

Withdrawal: Sedation

This narrative concerns a 42-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of sedation on Day 1 of randomized treatment to 300 mg considered by the investigator to be moderate in intensity. On Day 4 the patient took 1 of the 2 prescribed tablets, on Days 5 and 6 the patient did not take any study medication, and on Day 7 the patient only took 1 of the 3 prescribed tablets. The investigator withdrew study treatment and the patient took her final dose of study medication on Day 7. The sedation resolved one day after her final dose of study medication.

The patient had no relevant medical history. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations revealed obesity.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0007/009 600 mg

Withdrawal: Sedation

This narrative concerns a 29-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of sedation on Day 3 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator determined that this event was severe enough to warrant withdrawal. The patient took her final dose of study medication on Day 5. The sedation resolved three days after the final dose of study medication.

The patient had no relevant medical history. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0009/009 300 mg

Withdrawal: Somnolence

This narrative concerns a 23-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of drowsiness (MedDRA: somnolence) on Day 1 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The investigator withdrew the study treatment due to the somnolence. The patient took her final dose of study medication on Day 10. The somnolence resolved one day after the patient took her final dose of study medication.

The patient had a relevant medical history of current insomnia and current toothache. Before entering the study, the patient had been treated with hydrocodone bitartrate / acetaminophen (VICODIN®, Abbott) and acetaminophen (TYLENOL®, McNeil Consumer) for the toothache. The hydrocodone bitartrate / acetaminophen (VICODIN®, Abbott) was last used 15 days prior to the patient's first dose of study medication. The patient continued to take acetaminophen (TYLENOL®, McNeil Consumer) during the study treatment. No additional medications were given during the study treatment. The screening visit physical examination revealed mild inspiratory wheezing. The final visit physical examination was unremarkable.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0009/012 placebo

Withdrawal: Extrapyramidal Disorder

This narrative concerns a 28-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of Extrapyramidal Syndrome (EPS) (involuntary movement of mouth) – dystonia (MedDRA: extrapyramidal disorder) on Day 1 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. The patient only took the first dose of study medication. The extrapyramidal disorder resolved one day after the patient took his final dose of study medication. The investigator withdrew study treatment as a result of the extrapyramidal disorder.

The patient had a relevant current medical history of headaches. Before entering the study, the patient had been treated with ibuprofen / pseudoephedrine (ADVIL® COLD AND SINUS, Wyeth Consumer) for headaches. The last dose of this medication was taken sixteen days prior to the patient's first dose of study medication. The patient began treatment with escitalopram oxalate (LEXAPRO®, Forest) 10 mg/day for bipolar depression nine days after the last dose of study medication was taken. The screening and final visit physical examinations were unremarkable.

The investigator considered the extrapyramidal disorder to be related to study treatment.

Study 5077US/0049 Patient 0010/002 600 mg

Withdrawal: Orthostatic Hypotension, Dizziness, Feeling Cold

This narrative concerns a 46-year-old white man with bipolar I disorder.

The patient had non-serious adverse events of light-headed (due to orthostatic hypotension) (MedDRA: orthostatic hypotension), fainting feeling (not due to postural hypotension) (MedDRA: dizziness), and cold flash (MedDRA: feeling cold) on Day 1 of randomized treatment to 600 mg that were all considered by the investigator to be mild in intensity. The patient took his first and only dose of study treatment on Day 1. The investigator withdrew study treatment due to these events. On Day 1 the non-serious adverse events of orthostatic hypotension, dizziness, and feeling cold resolved.

The patient's medical history and final visit physical examination were unremarkable. The patient's screening physical examination revealed mild hyperemia of the left ear canal and tympanic membrane. The patient was given lorazepam 1 mg/day for anxiety starting eleven days prior to study treatment and continuing through study treatment. The patient did not take any additional relevant concomitant medications prior to or during the study.

The investigator considered the orthostatic hypotension, dizziness, and feeling cold to be related to study treatment.

Study 5077US/0049 Patient 0010/023 600 mg

Withdrawal: Paranoia

This narrative concerns a 28-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of paranoid thinking (MedDRA: paranoia) on Day 4 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took her last dose of study treatment on Day 11. The adverse event of paranoia resolved one day after the patient's last dose of study treatment.

The patient's medical history and screening and final visit physical examinations were unremarkable. For two months prior to entering the study, the patient had been treated with amphetamine / dextroamphetamine (ADDERALL®, Shire) 15 mg/day (as needed) and venlafaxine hydrochloride (EFFEXOR®, Wyeth) 150 mg/day for depression. The patient discontinued treatment with these medications twenty days prior to entering the study. The patient was not treated with any concomitant medications during the study.

The investigator considered the paranoia to be related to study treatment.

Study 5077US/0049 Patient 0010/027 600 mg

Withdrawal: Anxiety

This narrative concerns a 32-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of increased anxiety (MedDRA: anxiety) on Day 13 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. Four days prior to the first dose of study treatment, the patient began treatment with lorazepam 3 mg/day for severe anxiety [secondary to bipolar depression]. The patient continued to take lorazepam concomitantly throughout the study. Beginning on Day 13, the patient had increased anxiety. The investigator withdrew study treatment due to the increased anxiety, and the patient took his last dose of study treatment on Day 13. The adverse event of increased anxiety resolved five days after the patient took his last dose of study treatment.

The patient's medical history and screening and final visit physical examinations were unremarkable. Before entering the study, the patient was not taking any medications. Eleven days prior to the first dose of study treatment, the patient began treatment with zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 5 mg/day for sleep. The patient continued to take this medication concomitantly during the study.

The investigator considered the anxiety to be related to study treatment.

Study 5077US/0049 Patient 0010/028 placebo

Withdrawal: Insomnia

This narrative concerns a 32-year-old hispanic woman with bipolar I disorder.

The patient had a non-serious adverse event of worsening of insomnia (MedDRA: insomnia) on Day 17 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The patient was given zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 10 mg/day for insomnia seven days prior to baseline through Day 23 of randomized treatment. The patient took her last dose of study treatment on Day 28, and the investigator withdrew the patient from the study on Day 30. Eleven days after the last dose of study treatment, the insomnia resolved.

The patient had a relevant current medical history of insomnia. The patient's screening and final visit physical examinations were unremarkable. On Day 13 of randomized treatment, the patient had anxiety that was considered by the investigator to be moderate in intensity and related to study treatment. This event resolved four days after the discontinuation of study treatment. On Day 4 the patient had a headache, which was considered by the investigator to be mild in intensity and related to study treatment. This event resolved four days after the discontinuation of study treatment. During the study the patient was given lorazepam (ATIVAN®, Wyeth Ayerst) 3 mg/day for agitation.

The investigator considered the insomnia to be related to study treatment.

Study 5077US/0049 Patient 0010/032 300 mg

Withdrawal: Sedation, Nausea, and Orthostatic Hypotension

This narrative concerns a 38-year-old white woman with bipolar I disorder.

The patient had non-serious adverse events of sedativism (MedDRA: sedation), nausea, and fainting feeling (due to postural hypotension) (MedDRA: orthostatic hypotension). Sedation occurred on Day 2 of randomized treatment to 300 mg and was considered by the investigator to be moderate in intensity. Nausea and orthostatic hypotension occurred on Day 5 of randomized treatment and were considered by the investigator to be moderate and mild in intensity, respectively. The investigator withdrew study treatment for these events. The patient took her last dose of study treatment on Day 6. At the time of final study assessments, two days after the last dose of study treatment, the non-serious adverse events of sedation, nausea, and orthostatic hypotension were ongoing.

The patient had a relevant medical history of mild pharyngeal hyperemia. The screening physical examination revealed mild pharyngeal hyperemia. The final visit physical examination was unremarkable. The patient was not treated with any non-study medications prior to or during the study.

The investigator considered the sedation, nausea, and orthostatic hypotension to be related to study treatment.

Study 5077US/0049 Patient 0011/008 placebo

Withdrawal: Mania

This narrative concerns a 23-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of onset of manic symptoms (MedDRA: mania) four days after the last dose of randomized treatment to placebo that was considered by the investigator to be mild in intensity. The patient took his last dose of study treatment on Day 11. Four days later, the patient returned to the clinic for a premature discontinuation visit. During this visit, the investigator determined that the patient was experiencing mania and that the withdrawal of study treatment was warranted. Mania was ongoing at the time of the site personnel's last contact with the patient (at the premature discontinuation visit).

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient was not treated with any medications prior to or during the study.

The investigator considered the mania to be related to study treatment.

Study 5077US/0049 Patient 0011/020 600 mg

Withdrawal: Orthostatic Hypotension

This narrative concerns a 33-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of dizziness secondary to postural hypotension (MedDRA: orthostatic hypotension) on Day 2 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew the patient from study treatment. The patient took his last dose on Day 2 and the orthostatic hypotension resolved one day later.

The patient had a non-serious adverse event of sedation that started on Day 2 and resolved two days after the last dose of study treatment. This event was considered by the investigator to be moderate in intensity and related to study treatment. No relevant concomitant medications were given prior to or during study treatment. The patient's medical history and screening and final visit physical examinations were unremarkable.

The investigator considered the orthostatic hypotension to be related to study treatment.

Study 5077US/0049 Patient 0013/006 600 mg

Withdrawal: Dystonia

This narrative concerns a 28-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of dystonia on Day 8 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The patient took study medication on Day 1, as instructed. However, she did not take study medication on Day 2 through Day 5. The patient then took study medication on Day 6 through Day 8, using the doses labeled for Day 2 through Day 4, respectively. The investigator withdrew study treatment due to the dystonia. The patient's last dose of study medication was on Day 8. The dystonia also resolved on Day 8.

The patient had non-serious adverse events of irritability and somnolence from Day 3 to Day 10 that were considered by the investigator to be moderate in intensity and related to study treatment. The patient had a non-serious adverse event of dizziness from Day 5 to Day 9 that was considered by the investigator to be moderate in intensity and related to study treatment. The patient had a non-serious adverse event of sensation of throbbing vessels (sensation of blood rushing in the veins) on Day 8 that was considered by the investigator to be severe in intensity and related to study treatment. The patient had a relevant medical history of headaches. Before entering the study, the patient had been treated with acetaminophen (TYLENOL®, McNeil Consumer) 1000 mg/day for headaches and this medication continued through study treatment. No additional medications were given during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the dystonia to be related to study treatment.

Study 5077US/0049 Patient 0013/007 300 mg

Withdrawal: Somnolence

This narrative concerns a 49-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of drowsiness (MedDRA: somnolence) on Day 1 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient took his last dose of study medication on Day 9. The somnolence resolved two days later.

The patient's medical history revealed type II diabetes and high cholesterol. Before entering the study, the patient had been treated with metformin hydrochloride (GLUCOPHAGE® XR, Bristol-Myers Squibb) 1000 mg/day for diabetes and atorvastatin (LIPITOR®, Pfizer) 10 mg/day for high cholesterol. These medications continued through study treatment. No additional medications were given during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0013/014 600 mg

Withdrawal: Akathisia and Pruritus

This narrative concerns a 48-year-old white man with bipolar I disorder.

The patient had non-serious adverse events of (restlessness) akathisia (MedDRA: akathisia) and itchiness (MedDRA: pruritus) on Day 4 of randomized treatment to 600 mg that were determined to be moderate in intensity. The investigator withdrew study treatment due to these events. Akathisia and pruritis occurred during randomized treatment on Day 4 through Day 20 and again for one day, two days after the patient's last dose, with intensities of moderate for both events. The patient's last dose of study treatment was taken on Day 20.

The patient had a non-serious adverse event of nightmare starting on Day 2 that was ongoing as of the site personnel's last contact with the patient, eight days after the last dose of study treatment. This event was considered by the investigator to be moderate in intensity and related to study treatment. The patient's medical history was unremarkable. Before entering the study, the patient had been treated with clonazepam 0.5 mg/day for approximately two years and gabapentin (NEURONTIN®, Parke-Davis) 300 mg/day for approximately two years, both for anxiety. Zaleplon (SONATA®, King) 25 mg/day was given for insomnia for approximately two years and paroxetine hydrochloride (PAXIL®, GlaxoSmithKline) 50 mg/day was given for depression for approximately five months. All of these medications were discontinued prior to study treatment. No medications were started during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the akathisia and pruritus to be related to study treatment.

Study 5077US/0049 Patient 0014/004 placebo

Withdrawal: Back Pain

This narrative concerns a 29-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of back pain-left side (MedDRA: back pain) on Day 2 of randomized treatment to placebo that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took the final dose of study medication on Day 19 and the event of back pain resolved four days later.

The patient had a relevant medical history of current back pain, headaches, joint pain, and neck pain. No relevant medications were given prior to or during the study treatment. The screening visit physical examination revealed decreased strength upper extremity bilateral,

decreased breath sounds, and tender hypogastrium. The final visit physical exam was unremarkable.

The investigator considered the back pain to be related to study treatment.

Study 5077US/0049 Patient 0014/007 600 mg

Withdrawal: Sedation

This narrative concerns a 22-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of sedation on Day 3 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 17 and the sedation resolved two days later.

The patient had non-serious adverse events of fatigue and hypersomnia both starting on Day 3 and ending two days after the patient took her last dose of study medication. Both of these events were considered by the investigator to be severe in intensity and related to study treatment. Other non-serious adverse events included throat tightness (Day 7 to two days after the last dose of study medication; moderate in intensity), tremor (Day 4 to two days after last dose of study medication; moderate in intensity), orthostatic hypotension (Day 3 to two days after last dose; severe in intensity), and tension (Day 15 to two days after last dose; severe in intensity), all judged by the investigator to be related to study treatment. Because of these adverse events, the dose of study medication was reduced from four tablets daily to three tablets daily on Day 14, to two tablets daily from Day 9 through Day 12, and Day 15, and to one tablet daily on Day 8 and Day 17. No study medication was taken on Day 13 or Day 16. The patient had no relevant medical history. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0014/012 600 mg

Withdrawal: Akathisia

This narrative concerns a 55-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of akathisia on Day 3 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The study medication was held on Day 5. From Day 9 to Day 28 the dose was reduced due to akathisia. The patient took her final dose of study medication on Day 28 and the akathisia resolved two days later.

The patient had a relevant medical history of loss of consciousness (past) and tremors in the hands and head (current). Before entering the study, the patient was treated with clonazepam (KLONOPIN®, Roche) 1 mg/day for sleep and ibuprofen for muscle pain, which were discontinued prior to study treatment. Acetaminophen / aspirin / caffeine (EXCEDRIN®, Bristol-Myers) was taken as needed for migraines and aspirin was taken as needed for muscle pain. These medications started prior to study entry and continued during the study. Also during the study, the patient was given propranolol 40 mg/day and acetaminophen / pseudoephedrine / diphenhydramine hydrochloride (BENADRYL®, Pfizer Consumer) 10 mg/day for akathisia. Propranolol was started on Day 15 and was continuing at the time of the site personnel's last contact with the subject. Acetaminophen / pseudoephedrine / diphenhydramine hydrochloride (BENADRYL®, Pfizer Consumer) was given on Day 19 and Day 20. The screening and final physical examination revealed fine tremors in the hands and neck.

The investigator considered the akathisia to be related to study treatment.

Study 5077US/0049 Patient 0015/003 300 mg

Withdrawal: Sedation

This narrative concerns a 54-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of excessive sedation (MedDRA: sedation) on Day 1 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 7 and the sedation resolved three days later.

The patient had no relevant medical history. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0018/003 600 mg

Withdrawal: Sedation

This narrative concerns a 27-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of sedated (MedDRA: sedation) on Day 4 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment, and the patient took her last dose of

study medication on Day 12. The sedation had not resolved at the time of the site personnel's last contact with the patient, three days after the last dose of study treatment.

The patient had a non-serious adverse event of dizziness on Day 2 that was considered by the investigator to be moderate in intensity and related to study treatment; dizziness resolved on Day 2. The patient had a non-serious adverse event of lethargy on Day 4, which was considered by the investigator to be moderate in intensity and related to study treatment. The lethargy had not resolved as of the site personnel's last contact with the patient. The patient's medical history revealed kidney stones, migraines, obesity, and seasonal allergies. The patient did not take any relevant concomitant medications before entering the study. Sumatriptan succinate (IMITREX®, GlaxoSmithKline) 50 mg/day and naproxen sodium (ALEVE®, Bayer Consumer) 275 mg/day were given for migraine headaches prior to the patient starting study medication. These medications were not given during study treatment. No additional medications were taken during the study. The screening and final visit physical examinations revealed obesity.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0018/007 600 mg

Withdrawal: Deep Vein Thrombosis

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0018/013 600 mg

Withdrawal: Akathisia

This narrative concerns a 44-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of akathisia on Day 2 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment and the patient took his last dose of study medication on Day 4. The akathisia resolved two days after the patient took his last dose of study medication.

The patient had a non-serious adverse event of sedation on Day 2 that was considered by the investigator to be moderate in intensity and related to study treatment. This event resolved two days after the patient took his last dose of study medication. The patient also had a non-serious adverse event of headache starting two days after the patient took his last dose of study medication and ending one day later. This event was considered by the investigator to be moderate in intensity and related to study treatment. The patient's medical history revealed allergies to codeine, diphenhydramine, ibuprofen, and hydrocodone bitartrate / acetaminophen (VICODIN®, Abbott). The medical history also included past alcohol abuse, current contact dermatitis, current headaches, and current insomnia. Before entering the study, the patient

was treated with acetaminophen / diphenhydramine (EXCEDRIN® PM, Bristol-Myers Squibb) for insomnia, which was ongoing as of the site personnel's last contact with the patient. During the study, aspirin was given to treat increased intensity of headaches. No additional medications were taken during the study. The screening physical examination revealed contact dermatitis. The final visit physical examination was unremarkable.

The investigator considered the akathisia to be related to study treatment.

Study 5077US/0049 Patient 0019/004 300 mg

Withdrawal: Irritability

This narrative concerns a 32-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of irritability on Day 29 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took her last dose of study medication on Day 42. This event was not resolved at the time of last patient contact, one day after the final dose of study medication.

The patient had a relevant medical history of anxiety. The patient's screening and final visit physical examinations were unremarkable. The patient did not take any relevant concomitant medications prior to, or during the study. On Day 2 of randomized treatment, the patient had a non-serious adverse event of abnormal dreams that was considered by the investigator to be moderate in intensity and related to study treatment. On Day 18 the patient had a non-serious adverse event of mania that was considered by the investigator to be severe in intensity and not related to study treatment. These adverse events were not resolved at the time of last patient contact, one day after the final dose of study medication.

The investigator considered the irritability to be related to study treatment.

Study 5077US/0049 Patient 0019/014 300 mg

Withdrawal: Lethargy and Balance Impaired NOS

This narrative concerns a 24-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of lethargy on Day 2 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The patient also had a non-serious adverse event of equilibrium problems (not due to orthostatic hypotension) (MedDRA: balance impaired NOS) on Day 4 of randomized treatment that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to these events. The patient took his last dose of study medication on Day 4. Lethargy and

balance impaired NOS were ongoing at the time of last patient contact, ten days after the final dose of study medication.

The patient had a current medical history of diarrhea, influenza, and stomach cramps. The patient's screening and final visit physical examinations were unremarkable. The patient did not take any relevant concomitant medications prior to or during the study. On Day 2 of randomized treatment, the patient had non-serious adverse events of dysarthria and flat affect, which were both considered by the investigator to be moderate in intensity and related to study treatment. These events were ongoing at the time of last patient contact, ten days after the final dose of study medication.

The investigator considered the lethargy and balance impaired NOS to be related to study treatment.

Study 5077US/0049 Patient 0019/024 600 mg

Withdrawal: Dizziness (lightheaded), Confusional state, Somnolence, Tooth disorder NOS, Dyspnoea (difficulty breathing,) Dyspnoea (shortness of breath), Limb discomfort NOS, Dizziness (dizziness), Dysphagia, and Bruxism

This narrative concerns a 26-year-old white man with bipolar II disorder.

The patient had non-serious adverse events of lightheaded (not due to orthostatic hypotension) (MedDRA: dizziness), confusion (MedDRA: confusional state), drowsy (MedDRA: somnolence), weird feeling in teeth (MedDRA: tooth disorder NOS), difficulty breathing (MedDRA: dyspnoea), and shortness of breath (MedDRA: dyspnoea) all on Day 2 of randomized treatment to 600 mg that were each considered by the investigator to be severe in intensity. On Day 3 the patient had uncomfortable feeling in legs and arms (MedDRA: limb discomfort NOS) that was considered by the investigator to be severe in intensity. On Day 6 of randomized treatment, the patient had dizziness (not due to orthostatic hypotension) (MedDRA: dizziness), difficulty swallowing (MedDRA: dysphagia), and bruxism which were considered by the investigator to be severe, moderate, and moderate in intensity, respectively. The investigator withdrew study treatment due to these events. The patient did not return his blister card. The patient's last dose of study medication was estimated to be Day 9 based on the number of doses dispensed. On Day 8 the adverse events listed above resolved.

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient did not take any relevant concomitant medications prior to or during the study.

The investigator considered the non-serious adverse events listed above to be related to study treatment.

Study 5077US/0049 Patient 0019/027 300 mg

Withdrawal: Lethargy, Dysarthria, Balance Impaired NOS, and Sedation

This narrative concerns a 26-year-old hispanic woman with bipolar II disorder.

The patient had non-serious adverse events of lethargy, slurred speech (MedDRA: dysarthria), and problems with equilibrium (MedDRA: balance impaired NOS) on Day 2 of randomized treatment to 300 mg that were considered by the investigator to be severe in intensity. The patient had a non-serious adverse event of excessive sedation (MedDRA: sedation) on Day 2 of randomized treatment that was considered by the investigator to be mild in intensity. The investigator withdrew study treatment due to these events. On Day 3 the patient took her last dose of study treatment. Two days after the patient's last dose, the dysarthria, balance impaired NOS, and sedation resolved. Five days after the patient's last dose, the lethargy resolved.

The patient had a non-serious adverse event of sinus headache starting one day prior to study treatment and ending on Day 1. The patient did not take any relevant concomitant medications prior to the study. During the study, the patient was given pseudoephedrine hydrochloride (SUDAFED®, Pfizer) for sinus headache. The patient had a relevant medical history of chronic ear infections. The patient's screening and final visit physical examinations were unremarkable.

The investigator considered the lethargy, dysarthria, balance impaired NOS, and sedation to be related to study treatment.

Study 5077US/0049 Patient 0019/031 600 mg

Withdrawal: Sedation, Paraesthesia, Paraesthesia, and Joint stiffness

This narrative concerns a 47-year-old white man with bipolar II disorder.

The patient had non-serious adverse events of sedation, tingling in arms (MedDRA: paraesthesia), tingling in legs (MedDRA: paraesthesia), and tightness in joints (not due to Extrapyramidal Syndrome) (MedDRA: joint stiffness). The sedation began on Day 1 of randomized treatment to 600 mg and was considered by the investigator to be severe in intensity. The paraesthesia (of the arms), paraesthesia (of the legs), and the joint stiffness began on Day 2 of randomized treatment and were considered by the investigator to be moderate in intensity. The investigator did not judge the events to be significant enough to warrant the withdrawal of study treatment. However, the patient elected to discontinue study treatment due to these events. On Day 4 the patient took his last dose of randomized treatment. That same day, the paraesthesia (of the arms), paraesthesia (of the legs), and the joint stiffness resolved. One day after the patient's last dose of study treatment, the sedation resolved.

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient did not take any relevant concomitant medications prior to or during the study.

The investigator considered the sedation, paraesthesia (of the arms), paraesthesia (of the legs), and joint stiffness to be related to study treatment.

Study 5077US/0049 Patient 0019/035 600 mg

Withdrawal: Sedation, Restless Legs Syndrome, and Hypomania

This narrative concerns a 34-year-old white woman with bipolar II disorder.

The patient had non-serious adverse events of sedation, restless legs at night not due to Extrapyramidal Syndrome (EPS) (MedDRA: restless legs syndrome), and hypomania on Days 3, 17, and 25 respectively, of randomized treatment to 600 mg. These events were considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to these events. On Day 30 the patient took her last dose of study treatment. Eight days after the patient's last dose, the sedation, restless legs syndrome, and hypomania resolved.

The patient had a medical history of tension headaches. The screening and final visit physical examinations were unremarkable. Before entering the study, the patient was not taking any medications. During the study the patient took acetaminophen (TYLENOL®, McNeil Consumer) for tension headache. On Day 8 of randomized treatment the subject had a non-serious adverse event of anger that was considered by the investigator to be severe in intensity and related to study treatment. This event was ongoing at the time of last patient contact, eight days after the final dose of study medication.

The investigator considered the sedation, restless legs syndrome, and hypomania to be related to study treatment.

Study 5077US/0049 Patient 0019/039 300 mg

Withdrawal: Lethargy, Disturbance In Attention, Paranoia, Suspiciousness, Dyspnoea, Balance Impaired NOS, Akathisia, Disorientation, Anxiety, and Panic Disorder NOS

This narrative concerns a 35-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of lethargy on Day 1 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The patient also had non-serious adverse events of decreased concentration (MedDRA: disturbance in attention), paranoia, suspiciousness, shortness of breath (MedDRA: dyspnoea), decreased equilibrium (not due to orthostatic hypotension) (MedDRA: balance impaired NOS), akathisia (not due to Extrapyramidal Syndrome) (MedDRA: akathisia), disorientation, anxiety, and panic disorder symptoms (MedDRA: panic disorder NOS) that all began on Day 3 of

randomized treatment. The investigator judged the disturbance in attention, paranoia, suspiciousness, dyspnoea, balance impaired NOS, and disorientation to be mild in intensity. The investigator judged the akathisia, anxiety, and panic disorder NOS to be moderate in intensity. The investigator did not judge these events to be significant enough to warrant the patient's withdrawal, however the patient elected to discontinue study treatment due to these adverse events. The patient took his last dose of study treatment on Day 3 of randomized treatment. One day after the patient's last dose, the lethargy, disturbance in attention, paranoia, suspiciousness, dyspnoea, balance impaired NOS, disorientation, anxiety, and panic disorder NOS resolved. Thirty-three days after the discontinuation of study treatment, the akathisia resolved.

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient did not take any medications prior to, or during the study.

With the exception of the non-serious adverse event of disorientation, the investigator considered the adverse events described above to be related to study treatment.

Study 5077US/0049 Patient 0019/042 600 mg

Withdrawal: Irritability

This narrative concerns a 27-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of irritability on Day 12 of randomized treatment to 600 mg that was considered by the investigator to be mild in intensity. The investigator did not consider the irritability to be significant enough to warrant discontinuation; however the patient elected to withdraw from study treatment due to the irritability. The patient took her last dose of study medication on Day 14, and the irritability resolved one day later.

The patient had a current medical history of migraine and tension headaches. The patient's screening and final visit physical examinations were unremarkable. The patient did not take any relevant concomitant medications prior to, or during the study. Other non-serious adverse events reported by the patient included sedation (moderate intensity, attributed to study medication, beginning on Day 2 and ongoing at the final visit), tremor (moderate intensity, attributed to study medication, beginning on Day 11 and resolving on Day 15), and lethargy (moderate intensity, attributed to study medication, beginning on Day 12 and resolving on Day 15).

The investigator considered the irritability to be related to study treatment.

Withdrawal: Conversion Disorder

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0022/025 600 mg

Withdrawal: Restless Legs Syndrome

This narrative concerns a 46-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of restless leg syndrome (worsening) "not due to [Extrapyramidal Syndrome] EPS" (MedDRA: restless legs syndrome) on Day 2 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient took her last dose of study medication on Day 7. Two days after the patient's last dose of study medication the restless legs syndrome resolved.

The patient had a relevant medical history of restless leg syndrome. The patient's screening and final visit physical examinations were unremarkable. Before entering the study, the patient took lorazepam (ATIVAN®, Wyeth Ayerst) for bipolar 3 mg/day from twenty days to nineteen days before the first dose, 2 mg/day from eighteen days to fifteen days before the first dose, and 1 mg/day from fourteen days to eleven days before the first dose. During the study, the patient took lorazepam (ATIVAN®, Wyeth Ayerst) 3 mg/day from Day 1 to Day 8.

The investigator considered the restless legs syndrome to be not related to study treatment.

Study 5077US/0049 Patient 0022/035 300 mg

Withdrawal: Somnolence

This narrative concerns a 20-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of somnolence on Day 2 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to somnolence. The patient took her last dose of

study treatment on Day 5 of randomized treatment, and the somnolence resolved one day later.

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient did not take any relevant medications prior to or during the study.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0022/038 600 mg

Withdrawal: Somnolence

This narrative concerns a 39-year-old white man with bipolar I disorder.

The patient had two non-serious adverse events of somnolence during randomized treatment to 600 mg that were considered by the investigator to be mild in intensity. The patient's first episode of somnolence began on Day 5 of randomized treatment. Beginning on Day 12, the investigator decreased the patient's daily dose of study treatment by one tablet due to the somnolence. The first episode of somnolence resolved on Day 22. The second episode of somnolence began on Day 37. The investigator withdrew study treatment due to the somnolence. The patient took his last dose of study treatment on Day 41. The somnolence resolved one day after the patient's last dose of study treatment.

The patient's medical history was unremarkable. The screening and final visit physical examinations revealed a mild bilateral hand tremor. The patient did not take any relevant medications prior to or during the study.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0022/058 600 mg

Withdrawal: Somnolence

This narrative concerns a 43-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of somnolence on Day 2 of randomized treatment to 600 mg that was considered by the investigator to be mild in intensity. Beginning on Day 15, the patient's daily dose of study treatment was reduced to three tablets. The patient continued to have somnolence throughout the dose reduction. The investigator withdrew study treatment due to this event. The patient took his last dose of study medication on Day 31, and the somnolence resolved three days later.

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient did not take any relevant medications prior to or during the study.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0022/062 600 mg

Withdrawal: Somnolence

This narrative concerns a 63-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of somnolence on Day 1 of randomized treatment to 600 mg that was considered by the investigator to be mild in intensity. The investigator withdrew study treatment due to this event. The patient took his last dose of study treatment on Day 16 of randomized treatment. One day after the patient took his last dose of study treatment the somnolence resolved.

The patient's relevant medical history included sleep apnea for which he required treatment during the study with loratadine (CLARITIN®, Schering) 10 mg/day on Days 9 and 10, diphenhydramine hydrochloride 25 mg/day starting on Day 11 and ongoing as of the last contact with the patient, three days after the last dose of study treatment, and oxymetazoline hydrochloride on Days 11 through 15. Prior to the study, the patient had been treated for bipolar disorder with modafinil (PROVIGIL®, Cephalon), nefazodone hydrochloride (SERZONE®, Bristol-Myers Squibb), clonazepam, lithium, and oxcarbazepine (TRILEPTAL®, Novartis). During the study, supplemental treatment with lorazepam was prescribed for bipolar disorder from seven days before the first dose of study treatment through Day 10. The screening and final visit physical examinations were unremarkable.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0023/023 600 mg

Withdrawal: Dizziness, Sweating Increased, and Sedation

This narrative concerns a 35-year-old white woman with bipolar II disorder.

The patient had non-serious adverse events of dizzy (not due to postural hypotension) (MedDRA: dizziness), sweating (MedDRA: sweating increased), and sedation on Day 2 of randomized treatment to 600 mg that were considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to dizziness. However, the patient decided to withdraw from study treatment due to sweating increased and sedation as well as the dizziness. The patient took her last dose of study treatment on Day 3. The events of dizziness, sweating increased, and sedation resolved two days later.

The patient's medical history and screening and final visit physical examinations were unremarkable. The patient did not take any relevant concomitant medications prior to or during the study.

The investigator considered the dizziness, sweating increased, and sedation to be related to study treatment.

Study 5077US/0049 Patient 0023/029 600 mg

Withdrawal: Sedation, Dry Mouth, and Dizziness

This narrative concerns a 46-year-old hispanic woman with bipolar II disorder.

The patient had non-serious adverse events of sedation, dry mouth, and dizziness (not due to postural hypotension) (MedDRA: dizziness) on Day 2 of randomized treatment to 600 mg that were each considered by the investigator to be severe in intensity. On Day 3 the patient discontinued study treatment as a result of these events. The investigator determined the sedation, dry mouth, and dizziness to be significant enough to warrant the patient's withdrawal from the study. Three days after the patient's last dose of study treatment, these non-serious adverse events resolved.

The patient's medical history and screening visit physical examination were unremarkable. The final visit physical examination was not done. The patient did not take any medications prior to or during the study.

The investigator considered the sedation, dry mouth, and dizziness to be related to study treatment.

Study 5077US/0049 Patient 0023/044 300 mg

Withdrawal: Restless Legs Syndrome

This narrative concerns a 44-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of restless legs (not due to Extrapyramidal Syndrome) (MedDRA: restless legs syndrome) on Day 5 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took her last dose of study medication on Day 25. The event of restless legs syndrome had not resolved at the time of the last patient contact, three days after the last dose of study medication.

The patient had a relevant past medical history of spondylolisthesis (surgical repair). The patient's screening and final visit physical examinations were unremarkable. Before entering the study the patient was taking venlafaxine hydrochloride (EFFEXOR® XR, Wyeth) 150 mg/day and lamotrigine (LAMICTAL®, GlaxoSmithKline) 200 mg/day. Both of these medications were discontinued six days prior to baseline. The patient did not take any relevant concomitant medications during the study.

The investigator considered the restless legs syndrome to be related to study treatment.

Study 5077US/0049 Patient 0026/005 600 mg

Withdrawal: Sedation

This narrative concerns a 57-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of sedation on Day 1 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. On Day 7 treatment was withdrawn for this event. Six days after the discontinuation of study treatment the sedation resolved.

The patient had a relevant current medical history of head tremor and insomnia, and a relevant past medical history of loss of consciousness. The screening physical examination revealed a mild head tremor. The final visit physical examination showed the mild head tremor to be resolved. The patient did not take any relevant concomitant medications during the study. Before entering the study, the patient had been treated with paroxetine hydrochloride (PAXIL®, GlaxoSmithKline) for depression. The patient took 20 mg/day from approximately seven years before study treatment to eight days before study treatment and 10 mg/day from seven days before study treatment to five days before study treatment. During the study, the patient had non-serious adverse events of dry mouth, dizziness, dyspnoea, and irritability. These events started on Day 1 of randomized treatment and resolved six days after the discontinuation of study treatment. The investigator judged these events to be related to study treatment.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0026/009 600 mg

Withdrawal: Dizziness

This narrative concerns a 43-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of dizzy (not due to postural hypotension) (MedDRA: dizziness) on Day 3 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. On Day 4, the patient discontinued study treatment as a result of the dizziness; however, the investigator did not judge the event significant enough to warrant withdrawal. The non-serious adverse event of dizziness resolved one day after the last dose of study treatment.

The patient's medical history and screening and final visit physical examinations were unremarkable. During the study the patient had non-serious adverse events of headache and vision blurred that began on Day 3 of study treatment and resolved one day after the last dose of study treatment. These events were considered by the investigator to be severe in intensity and related to study treatment. Before entering the study, the patient had been taking

topiramate (TOPAMAX®, Ortho-McNeil) 600 mg/day for bipolar. This medication was discontinued nine days prior to the first dose of study treatment. Topiramate (TOPAMAX®, Ortho-McNeil) 200 mg/day was restarted one day after the last dose of study treatment.

The investigator considered the dizziness to be related to study treatment.

Study 5077US/0049 Patient 0026/010 300 mg

Withdrawal: Nausea and Vomiting NOS

This narrative concerns a 31-year-old white man with bipolar I disorder.

The patient had non-serious adverse events of nausea and emesis (MedDRA: vomiting NOS) on Day 2 of randomized treatment to 300 mg. The investigator considered the nausea to be severe in intensity, and the vomiting to be moderate in intensity. The investigator discontinued study treatment for these events. The patient took his last dose of study treatment on Day 5. Two days after the discontinuation of study treatment, the non-serious adverse events of nausea and vomiting NOS resolved.

The patient's medical history and screening and final visit physical examinations were unremarkable. The subject did not take any concomitant medications prior to or during the study.

The investigator considered the nausea and vomiting NOS to be related to study treatment.

Study 5077US/0049 Patient 0026/027 placebo

Withdrawal: Convulsions NOS

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0026/028 placebo

Withdrawal: Major Depressive Disorder NOS, Acute Psychosis

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0028/007 600 mg

Withdrawal: Drug Abuser NOS

This narrative concerns a 22-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of drug abuse (methamphetamine) (MedDRA: drug abuser NOS) on Day 38 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The patient used methamphetamine on Day 38. The event was resolved on that same day. The patient returned to the clinic one day after the final dose of study medication and was withdrawn from the study due to the illicit drug use. The final dose of study medication was taken on Day 41.

On Day 39, the patient had a non-serious adverse event of panic attack, which was considered by the investigator to be severe in intensity and not related to study drug. In an attempt to control the panic attack, the patient took an overdose of 8 tablets of study medication on Day 39 of randomized treatment. This overdose was reported as a serious adverse event (non-accidental overdose) and was considered by the investigator to be moderate in intensity and not related to study treatment (see separate narrative). The patient had non-serious adverse events of nausea and vomiting NOS on Day 39, which were considered by the investigator to be severe in intensity and related to study drug. The patient had a relevant past medical history of polysubstance abuse. No relevant medications were taken prior to study treatment. During the study, the patient was treated with 50 g of activated charcoal and 20 MEQ of potassium chloride (KCL) on Day 39 for treatment of non-accidental overdose of study medication. The screening and final visit physical examinations were unremarkable.

The investigator considered the illicit drug use (drug abuser NOS) to be not related to study treatment.

Study 5077US/0049 Patient 0028/023 600 mg

Withdrawal: Suicide Attempt

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0028/025 600 mg

Withdrawal: Libido Decreased and Flat Affect

This narrative concerns a 27-year-old white man with bipolar I disorder.

The patient had non-serious adverse events of decreased libido (MedDRA: libido decreased) and flat affect. Libido decreased began on Day 1 and flat affect began on Day 3 of randomized treatment to 600 mg. Both events were considered by the investigator to be severe in intensity. The investigator determined that the libido decreased was severe enough to warrant withdrawal of study treatment. The patient determined that the flat affect also contributed to his decision to withdraw from study treatment. The patient's last dose of study treatment was taken on Day 12. Both adverse events resolved one day after the patient's final dose of study treatment.

The patient had a non-serious adverse event of fatigue starting on Day 3 and ending one day after the patient's final dose of study medication. This event was considered by the investigator to be severe in intensity and not related to study treatment. The patient had a relevant past medical history of Wolf Parkinson White syndrome, and a relevant current medical history of hay fever, headaches, and insomnia. Before entering the study, the patient had been treated with melatonin 2 mg/day for insomnia and divalproex sodium (DEPAKOTE®, Abbott) 1000 mg/day for bipolar disorder, which were discontinued one day and fifteen days prior to study treatment, respectively. No relevant concomitant medications were given during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the libido decreased to be related to study treatment and the flat affect to be not related to study treatment.

Study 5077US/0049 Patient 0028/031 placebo

Withdrawal: Hallucination, Auditory

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0028/045 300 mg

Withdrawal: Suicidal Ideation, Bipolar I Disorder

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0029/008 600 mg

Withdrawal: Syncope

This narrative concerns a 22-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of fainting (not due to orthostatic hypotension) (MedDRA: syncope) on Day 4 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator decided to reduce the dose of study medication due to the syncope. However, the patient decided to withdraw from study treatment as a result of this event. The syncope resolved on Day 4. The patient took her final dose of study medication on Day 5.

The patient had a non-serious adverse event of dizziness starting on Day 3 and ending one day after the patient took her final dose of study medication. The patient also had a non-serious adverse event of dyspnoea starting on Day 4 and ending one day after the patient took her final dose of study medication. Dizziness was considered by the investigator to be severe in intensity and related to study treatment. Dyspnoea was considered by the investigator to be

moderate in intensity and related to study treatment. The patient had a relevant current medical history of headaches, endometriosis, lower right quadrant tenderness, and iron deficient anemia. No relevant medications were given prior to or during the study treatment. The screening visit physical examination revealed lower right quadrant tenderness. The final physical exam was unchanged.

The investigator considered the syncope to be related to study treatment.

Study 5077US/0049 Patient 0029/012 600 mg

Withdrawal: Somnolence

This narrative concerns a 39-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of groggy in A.M. (MedDRA: somnolence) on Day 4 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. Beginning on Day 15, the patient's dose of study medication was reduced from 4 to 3 tablets per day. On Day 23, no study medication was taken. The patient took her final dose of study medication on Day 35. The event resolved three days after the patient's final dose of study medication.

The patient had no relevant medical history. No relevant medications were given prior to the study treatment. During the study, the patient was given lorazepam 1 mg/day for anxiety from Day 4 through Day 14. The screening and final visit physical examinations were unremarkable.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0029/015 600 mg

Withdrawal: Sedation

This narrative concerns a 45-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of sedation on Day 2 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment as a result of this event. The patient was not compliant with dosing from Day 8 to Day 10. The patient took 3 of 4 prescribed tablets on Day 8 and 2 of 4 prescribed tablets on Days 9 and 10. The patient took her final dose of study medication on Day 10. The event resolved five days after the patient's final dose of study medication.

The patient had no relevant medical history. Before entering the study, the patient had been treated with zaleplon (SONATA®, King) for insomnia. During the study, the patient was given zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 5 mg/day for insomnia (bipolar

disorder) and lorazepam (ATIVAN®, Wyeth Ayerst) 2 mg/day for anxiety (bipolar disorder). These medications were started six days prior to treatment and were continuing at the final study visit. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0029/038 placebo

Withdrawal: Anxiety

This narrative concerns a 61-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of anxiety on Day 2 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. The investigator did not determine that this event was significant enough to warrant withdrawal; however, the patient considered this event significant enough to warrant withdrawal from study treatment. The patient took his final dose of study medication on Day 7. The event resolved one day after the patient's final dose of study medication.

The patient had no relevant medical history. Before entering the study, the patient had been treated with St. John's Wort for depression. No concomitant medications were given during study treatment. The screening visit physical examination was unremarkable. A final visit physical exam was not performed.

The investigator considered the anxiety to be related to study treatment.

Study 5077US/0049 Patient 0029/039 placebo

Withdrawal: Dissociative Disorder NOS

This narrative concerns a 30-year-old hispanic woman with bipolar I disorder.

The patient had a non-serious adverse event of dissociative episode (MedDRA: dissociative disorder NOS) on Day 12 of randomized treatment to placebo that was considered by the investigator to be moderate in intensity. The event of dissociative disorder NOS resolved on that same day. The investigator did not consider the event significant enough to warrant withdrawal of study treatment. However, the patient decided to withdraw study treatment as a result of this event. The patient took her final dose of study medication on Day 13.

The patient had no relevant medical history. No relevant medications were given prior to the study treatment. During the study, the patient was given zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 10 mg/day, as needed, for worsening of insomnia. The screening and final visit physical examinations were unremarkable, except for a facial scar.

The investigator considered the dissociative disorder NOS to be not related to study treatment.

Study 5077US/0049 Patient 0030/024 600 mg

Withdrawal: Dry Mouth

This narrative concerns a 30-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of dry mouth on Day 3 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The investigator determined that this event was severe enough to warrant withdrawal from study treatment. The patient took her final dose of study medication on Day 5. The event resolved one day after the patient's final dose of study medication.

The patient had a non-serious adverse event of gingival infection that started four days prior to study treatment and was continuing as of the site personnel's last contact with the subject, three days after the patient's final dose of study medication. The patient had no relevant medical history. No relevant medications were given prior to study treatment. During the study, the patient was given penicillin 250 mg/day for a gingival infection starting four days prior to study treatment and continuing at the time of the site personnel's last contact with the subject. The screening and final visit physical examinations were unremarkable.

The investigator considered the dry mouth to be related to study treatment.

Study 5077US/0049 Patient 0030/025 600 mg

Withdrawal: Delusion NOS

This narrative concerns a 63-year-old black woman with bipolar I disorder.

The patient had a non-serious adverse event of delusional thinking (MedDRA: delusion NOS) on Day 36 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment as a result of this event. The patient took her final dose of study medication on Day 39. The event had not resolved at the time of the site personnel's last contact with the patient, one day after the last dose of study treatment.

The patient had no relevant medical history. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the delusion NOS to be not related to study treatment.

Study 5077US/0049 Patient 0031/010 600 mg

Withdrawal: Sedation

This narrative concerns a 37-year-old Italian/Native American woman with bipolar II disorder.

The patient had a non-serious adverse event of daytime sedation (MedDRA: sedation) on Day 1 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 14. The event had not resolved at the time of the site personnel's last contact with the subject, two days after the last dose of study treatment.

The patient also had a non-serious adverse event of hypersomnia starting on Day 1. This event was also continuing as of the site personnel's last contact with the subject. The investigator reduced the study dose due to this event. The dose was reduced from 4 tablets to 3 tablets per day from Day 9 to Day 14. Hypersomnia was considered by the investigator to be moderate in intensity and related to study treatment. The patient had a medical history of current pneumonia and current stomach aches. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0031/015 600 mg

Withdrawal: Sedation, Vision Blurred, Dizziness, and Constipation

This narrative concerns a 27-year-old white woman with bipolar II disorder.

The patient had non-serious adverse events of daytime sedation (MedDRA: sedation), blurred vision (MedDRA: vision blurred), lightheadedness not due to postural hypotension (MedDRA: dizziness), and constipation. Constipation started on Day 2 of randomized treatment to 600 mg and was considered by the investigator to be mild in intensity. Sedation, vision blurred, and dizziness started on Day 4 and were considered by the investigator to be moderate in intensity. The investigator withdrew study treatment as a result of the sedation. The patient felt that the events of vision blurred, dizziness, and constipation also contributed to the decision to withdraw treatment. The patient took her final dose of study medication on Day 6 and the events of sedation, vision blurred, dizziness, and constipation ended four days later.

The patient did not have any relevant medical history. No relevant medications were taken prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation, vision blurred, dizziness, and constipation to be related to study treatment.

Study 5077US/0049 Patient 0031/020 300 mg

Withdrawal: Chronic Lymphocytic Leukaemia NOS

This narrative concerns a 44-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of chronic lymphocytic leukemia (MedDRA: chronic lymphocytic leukaemia NOS) on Day 17 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient took his final dose of study medication on Day 22. The event was continuing as of the patient's last study visit, one day after the last dose of study treatment.

The patient had no relevant medical history. No relevant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the chronic lymphocytic leukaemia NOS to be not related to study treatment.

Study 5077US/0049 Patient 0031/029 300 mg

Withdrawal: Nausea

This narrative concerns a 24-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of nausea on Day 4 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator reduced the dose of study medication for this event. The patient took 2 tablets of study medication on Day 11 and Day 12 and 3 tablets on Day 13 and Day 14. The patient decided to withdraw from study treatment as a result of this event and took his final dose of study medication on Day 14. The event of nausea ended six days later.

The patient had a non-serious adverse event of coordination abnormal NOS starting on Day 4 and ending six days after the patient took his last dose of study medication. The investigator considered this event mild in intensity and related to study treatment. Non-serious adverse events of akathisia and vision blurred started on Day 2 and were considered by the investigator to be mild in intensity and related to study treatment. The event of vision blurred ended two days after the patient took his last dose of study medication and akathisia ended one day later. The patient had a relevant medical history of a past concussion, current toothache, and current migraines. No relevant medications were given prior to or during the

study treatment. The screening visit physical examination was unremarkable. The final visit physical exam was not performed.

The investigator considered the nausea to be related to study treatment.

Study 5077US/0049 Patient 0033/006 300 mg

Withdrawal: Loss of Libido

This narrative concerns a 38-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of loss of libido on Day 3 of randomized treatment to 300 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment for this event. The patient reported that he stopped study medication after the dose on Day 9; however, study medication use for the second study week could not be confirmed because the patient did not return the week 2 blister card. For data collection purposes, the last dose of study medication was estimated to be Day 16, based on the total number of prescribed doses available on the week 2 blister card. The loss of libido was ongoing at the time of the patient's final visit, five days after the estimated last dose of study medication.

The patient had non-serious adverse events of dyspnoea, speech disorder, and palpitations starting on Day 2 and ongoing at the patient's final visit. The patient did not take his Day 7 dose of study treatment due to these events. The dyspnoea and speech disorder were considered by the investigator to be mild in intensity and related to the study treatment. The palpitations were considered by the investigator to be moderate in intensity and related to the study treatment. The patient did not have any relevant medical history. The screening and final visit physical examinations were unremarkable. The patient was not taking any medications prior to or during randomized treatment.

The investigator considered the loss of libido to be related to study treatment.

Study 5077US/0049 Patient 0033/009 600 mg

Withdrawal: Headache

This narrative concerns a 46-year-old white woman with bipolar II disorder.

The patient had a non-serious adverse event of more severe headaches (MedDRA: headache) on Day 2 of randomized treatment to 600 mg that was considered by the investigator to be severe in intensity. The patient discontinued study treatment and withdrew from the study on Day 7. The patient did not return for study visits after the baseline visit and did not return the blister card with unused medication. In the Case Report Form for this study, treatment

duration was entered as nine days, the maximum possible exposure from the single blister card that was dispensed. The headache was ongoing as of Day 7.

The patient had a non-serious adverse event of insomnia that started seven days before the baseline visit and was ongoing when she withdrew from the study. This event was considered by the investigator to be moderate in intensity and not related to the study treatment. The patient had a medical history of asthma, chronic bronchitis, and headaches. The screening physical examination was unremarkable. The final visit physical examination was not performed. Before entering the study, the patient was not taking any medications. During the study, the patient was given zolpidem tartrate (AMBIEN®, Sanofi-Synthelabo) 5 mg/day for insomnia.

The investigator considered the headache to be related to study treatment.

Study 5077US/0049 Patient 0033/010 placebo

Withdrawal: Ectopic Pregnancy

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0034/002 300 mg

Withdrawal: Somnolence

This narrative concerns a 55-year-old white man with bipolar I disorder.

The patient had a non-serious adverse event of daytime drowsiness (MedDRA: somnolence) on Day 2 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took his final dose of study medication on Day 21 and the event resolved four days later.

The patient had a non-serious adverse event of insomnia starting six days prior to baseline and ending on Day 1. This event was considered moderate in intensity and was considered not related to study treatment. The patient had a non-serious adverse event of influenza like illness starting on Day 12 and ending on Day 16. This event was considered mild in intensity and was not considered related to study treatment. The patient had a non-serious adverse event of bronchitis NOS starting on Day 17 and ending six days after the final dose of study medication. This event was considered mild in intensity and was considered not related to study treatment. The patient had no relevant medical history. Before entering the study, the patient was treated with divalproex sodium (DEPAKOTE®, Abbott) 1000 mg/day and venlafaxine hydrochloride (EFFEXOR®, Wyeth) 150 mg/day for bipolar disorder. During the study, the patient was treated with acetaminophen (TYLENOL®, McNeil Consumer) 325 mg/day and tussin 2 tsps/day for flu symptoms, and amoxicillin/ clavulanate potassium

(AUGMENTIN® XR, GlaxoSmithKline) 325 mg/day and guaifenesin 200 mg/day for bronchitis. The screening and final visit physical examinations were unremarkable.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0035/013 300 mg

Withdrawal: Restlessness and Anxiety

This narrative concerns a 28-year-old white woman with bipolar II disorder.

The patient had non-serious adverse events of restlessness not due to EPS (MedDRA: restlessness) and anxiety beginning on Day 5 of randomized treatment to 300 mg that were considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to these events. Per study medication records, the patient reported that she stopped taking study medication due to these adverse events; however, her final dose of study medication was taken on Day 3, two days prior to the onset of restlessness and anxiety. Restlessness and anxiety resolved four days after onset, six days after the final dose of study medication.

The patient had no relevant medical history. Before entering the study, the patient was treated with carbamazepine (TEGRETOL®, Novartis) 500 mg/day for mood stabilization, risperidone (RISPERDAL®, Janssen) 4 mg/day for psychosis, and acetaminophen / pseudoephedrine / diphenhydramine hydrochloride (BENADRYL®, Pfizer Consumer) 50 mg/day for insomnia, all of which were discontinued prior to study treatment. The patient re-started these medications one day after taking her final dose of study medication. These medications were continuing as of the final study visit, four days after the final dose of study medication. The screening physical examination was unremarkable. A final visit physical examination was not performed.

The investigator considered the restlessness and anxiety to be related to study treatment.

Study 5077US/0049 Patient 0035/015 300 mg

Withdrawal: Sedation

This narrative concerns a 33-year-old hispanic woman with bipolar II disorder.

The patient had a non-serious adverse event of extreme sedation (MedDRA: sedation) on Day 1 of randomized treatment to 300 mg that was considered by the investigator to be severe in intensity. The investigator withdrew study treatment due to this event. The patient took her final dose of study medication on Day 5 and sedation resolved one day later.

The patient had a relevant medical history of asthma and weather allergies. No concomitant medications were given prior to or during the study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation to be related to study treatment.

Study 5077US/0049 Patient 0036/002 600 mg

Withdrawal: Mania

This narrative concerns a 32-year-old white woman with bipolar I disorder.

The patient had a non-serious adverse event of mania on Day 22 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The patient continued to have mania with moderate intensity through Day 25. On Day 26, the intensity of mania increased to severe. The patient returned for a study visit on Day 28 and the investigator withdrew study treatment. The final dose of study medication was taken on Day 27 and the event of mania resolved four days later.

The patient had a non-serious adverse event of somnolence from Day 1 through Day 28. This event was considered by the investigator to be severe in intensity and related to study treatment. The patient had a relevant medical history of intermittent migraine headaches and intermittent non-specific headaches. No relevant medications were taken prior to or during study treatment. The screening and final visit physical examinations were unremarkable.

The investigator considered the mania to be related to study treatment.

Study 5077US/0049 Patient 0036/007 600 mg

Withdrawal: Sedation and Urinary Incontinence

This narrative concerns a 35-year-old white woman with bipolar I disorder.

The patient had non-serious adverse events of sedation and intermittent urinary incontinence secondary to sedation (MedDRA: urinary incontinence) during randomized treatment to 600 mg. The patient had sedation on Day 8 through Day 10 and Day 12 through Day 13 with intensities of severe and moderate, respectively. The patient had urinary incontinence on Day 9 through Day 12 with an intensity of moderate. The subject began taking a reduced dose of study medication on Day 9 and stopped the study medication on Day 13 due to sedation. Urinary incontinence resolved on Day 12 and sedation resolved on Day 13. The investigator determined that sedation and urinary incontinence warranted withdrawal of the patient from the study treatment.

The patient had a non-serious adverse event of hypoaesthesia (intermittent numbness in both legs) starting on Day 1 and ending on Day 4 that was considered by the investigator to be

moderate in intensity and not related to the study treatment. The patient had a non-serious adverse event of somnolence starting on Day 5 and ending on Day 8 with an intensity of moderate. The somnolence was considered by the investigator to be related to the study treatment. The patient had a relevant medical history of intermittent migraine headaches and seasonal allergies. Before entering the study, the patient had been treated with venlafaxine hydrochloride (EFFEXOR®, Wyeth) 150 mg/day for bipolar depression for approximately 3 months and acetaminophen / pseudoephedrine (TYLENOL SINUS®, McNeil Consumer) as needed for seasonal allergies. During the study the patient was given acetaminophen / chlorpheniramine / pseudoephedrine (SINUTAB® MAXIMUM STRENGTH SINUS ALLERGY, Pfizer Consumer) for seasonal allergies on Day 4. The screening and final visit physical examinations were unremarkable.

The investigator considered the sedation and urinary incontinence to be related to study treatment.

Study 5077US/0049 Patient 0039/028 600 mg

Withdrawal: Suicidal Ideation

See Serious Adverse Event narrative section regarding withdrawal for this event.

Study 5077US/0049 Patient 0039/043 600 mg

Withdrawal: Drug Abuser NOS

This narrative concerns a 20-year-old white man with bipolar II disorder.

The patient had a non-serious adverse event of drug abuse with cocaine (MedDRA: drug abuser NOS) on Day 25 of randomized treatment to 600 mg that was considered by the investigator to be moderate in intensity. The investigator withdrew study treatment due to this event. The patient did not return his last study medication blister card. The patient's last dose of study medication was estimated to be Day 37 based on the number of doses dispensed. The adverse event of drug abuser NOS was not resolved at the time of the patient's last study visit on Day 37, twelve days after the onset of the event.

The patient had a relevant past medical history of alcohol and cocaine abuse. The screening physical examination was unremarkable. The final visit physical examination was not performed. The patient did not take any relevant concomitant medications prior to or during the study.

The investigator considered the drug abuser NOS to be not related to study treatment.

Study 5077US/0049 Patient 0039/052 300 mg

Withdrawal: Somnolence

This narrative concerns a 37-year-old black woman with bipolar II disorder.

The patient had a non-serious adverse event of drowsiness (MedDRA: somnolence) on Day 4 of randomized treatment to 300 mg that was considered by the investigator to be mild in intensity. The investigator withdrew study treatment due to this event. The patient failed to take some or all of her study medication on half of the study days (Days 3, 5, 6, 7, 10, and 12). The patient took her last dose of study medication on Day 13. The event of somnolence was ongoing as of the patient's last study visit, one day after the final dose of study medication.

The patient had a relevant medical history of insomnia, non-insulin dependent diabetes mellitus, and obesity. The patient's screening and final visit physical examinations were unremarkable. No relevant medications were taken prior to or during the study.

The investigator considered the somnolence to be related to study treatment.

Study 5077US/0049 Patient 0041/010 placebo

Withdrawal: Mania

See Serious Adverse Event narrative section regarding withdrawal for this event.
