Contrail Management – Now!

Prof. Dr.-Ing. **Dieter Scholz**, MSME, HAW Hamburg

Date: Thursday, 20 June 2024, 18:00 CET

Location: HAW Hamburg, Berliner Tor 5, Hörsaal 01.10

Flying is booming and with it the CO₂ emissions. It is not easy to decarbonize aviation. Whether electric drives, e-fuels, or green hydrogen, so far there is **no convincing** climate-friendly option for **propulsion in air transport**. And now? In addition to **drastic flight restrictions**, there is another way forward. Flights just need to be rerouted to **fly a little higher or lower**. Why? Large passenger and cargo jets are flying at an altitude of around 11000 m. In these regions water vapor condenses with soot from the engine exhaust to ice crystals forming **contrails behind the aircraft**. They can remain visible for many hours, when humidity is high. Especially at dawn, dusk and at night contrails are warming, because they act like panes of glass in a greenhouse (see picture). **CO₂** from aircraft fuel accounts for only **one third** of the warming effect measured in equivalent CO₂. In contrast, **contrails** can cause **more than half** of the equivalent CO₂. Experts in various fields of aviation explain unanimously that **contrail management could start now!** How is it done? Who knows what? Who is prepared? Who is against it?

NANO vom 8. Mai 2024: Kondensstreifen sind Klimakiller

Die Luftfahrtindustrie wird die Klimaziele krachend verfehlen. Neben dem CO₂ Ausstoß, der durch den weltweiten Luftverkehr verursacht wird, haben auch Kondensstreifen eine klimaschädliche Wirkung. Lösungsansätze gibt es bereits.

Problem Kondensstreifen

Kondensstreifen sind anthropogene, also vom Menschen gemachte Wolken. Sie haben einen wärmenden Effekt, weil sie die Wärmestrahlung, die von der Erde ausgeht, daran hindert, ins Weltall zu gelangen. Kondensstreifen sind ein wichtiger Faktor bei der Klimaschädlichkeit von Flugzeugen. Doch wie lassen sich diese Kondensstreifen vermeiden?

Climate Goals of the EU? => **Drastic Reduction of Flights?**

1.) 2019: The EU's "**Green Deal**":
"In 2050, net greenhouse gas emissions should no longer be released".

2.) 2020: The European climate targets for 2030 were defined under the motto "**Fit for 55**". This is the interim goal of the Green Deal:
"Greenhouse gas emissions are to be reduced by 55% compared to 1990 – i.e. only 45% of the 1990 value. This value is to be achieved by 2030."

<https://doi.org/10.48441/4427.225>

The 55% reduction compared to 1990 means a reduction of more than 80% for aviation by 2030, i.e. by about 13.5% per year. Fuel consumption has so far been reduced by 1.5% annually through operational measures and technology. **Air traffic would therefore have to shrink permanently by 12% per year from now on for the next 6 years** based on 2024 traffic numbers.

TAB Study: Climate-Friendly Aviation

Prof. Dr. Dieter Scholz (HAW Hamburg) was involved in the TAB Short Study No. 6 as an expert and interview partner.

The short study "Innovative Propulsion Systems and Fuels for more Climate-Friendly Aviation" was approved by the Committee on Education, Research and Technology Assessment and published on 8 May 2024 by the Office of Technology Assessment at the German Bundestag (TAB):
Homepage: [Link](#), [Archive](#).

Study: <https://doi.org/10.5445/IR/1000170399>

The interview with Prof. Scholz: <https://doi.org/10.48441/4427.1517>

The study identifies the following fields of action for policymakers, among others

- 1) => **Optimization of flight routes to reduce emissions (avoidance of warming contrails)** <=
- 2) Better support for consumers in choosing more climate-friendly alternatives: More transparency through "climate labels": a) Comparison of aircraft b) Comparison of airlines, b) Comparison of flight routes compared also to other means of transport.
- 3) Use of book-and-claim concepts (certificates for the use of Sustainable Aviation Fuel, SAF).
- 4) Reduction of the aromatic content in kerosene.
- 5) Adjustment of the taxation of aviation by levying a kerosene tax.
- 6) Business jets: Due to a significant increase in flights, combined with disproportionate climate-damaging emissions: Taxation or inclusion in emissions trading.

Controversy about Monitoring, Reporting, and Verification (MRV)

EU plans exemption for long-haul flights from emissions monitoring

Reuters, 19.06.2024

The EU is apparently backing down on the planned monitoring of non-CO2 emissions by airlines. This was actually supposed to be mandatory for all flights. But international resistance is heavy - as the EU has already found out.

FINANCIAL TIMES

Airlines lobby against EU plan to monitor non-CO₂ emissions

Plane to see

Why is the monitoring of contrails from planes causing controversy?

Their most recent delay tactic has been to oppose the mere monitoring of these contrails. As part of a major reform of the EU's carbon pricing scheme for aviation, lawmakers decided it was time to start monitoring contrail pollution. That scheme will be put in place by 2025. By 2028 the EU must introduce measures to reduce contrail pollution.

But legacy airlines and their political friends are pushing back. The powerful airline lobby IATA and its membership of legacy carriers are opposed to the EU monitoring contrails on long distance flights – which they mostly operate and which cause most of the contrails. Others claim fitting humidity sensors on their jets or reporting some data would be ruinously expensive. We have had 25 years of fear, uncertainty and doubt. There is no time to waste before we start monitoring these emissions.

Downwash

<https://skybrary.aero/sites/default/files/bookshelf/660.pdf>

Wake vortices spread laterally away from the aircraft and descend approximately 500 ft to 900 ft at distances of up to five miles behind it. These vortices tend to descend at approximately 300 ft to 500 ft per minute during the first 30 seconds. This is equal to a **descent speed of 2 m/s**.

The downwash at the horizontal tail is with about 20 m/s much higher and decreases with increasing distance from the aircraft. (<http://hoou.ProfScholz.de>, Eq. 11.29)

Aircraft	Max Gross Weight (w) 1b	Span (b) ft	Airspeed (V) ft/sec	Vortex Spacing (b') ft	Vortex Sink Rate (w) ft/min	Vortex Radius (r) ft	Max Vertical Velocity (less w) (V _z) ft/min

Troposphere: Laps rate, $L = 0.0065 \text{ K/m}$

$$L = \frac{\Delta T}{\Delta H} \quad \Delta H = \frac{\Delta T}{L}$$

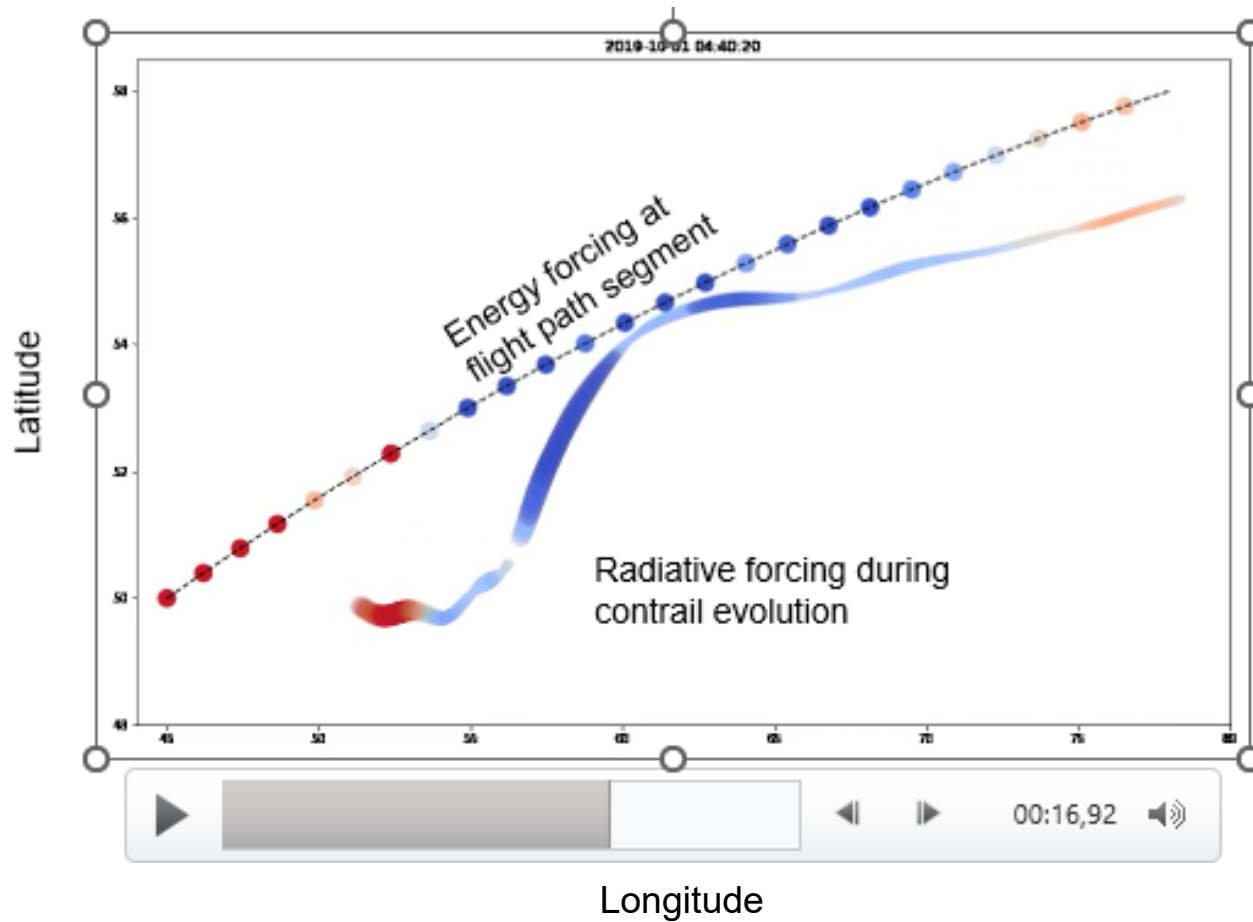

$$V = \frac{\Delta H}{\Delta t} \quad \Delta t = \frac{\Delta H}{V} = \frac{\Delta T}{V \cdot L}$$

$$\frac{\Delta t}{\Delta T} = \frac{1}{V \cdot L} = \frac{1}{3.2 \cdot 0.0065} \frac{\text{s}}{\text{K}}$$

$$= \underline{\underline{48 \text{ s/K}}}$$

It takes about 48 s for the contrail to sink so far to get into air that is 1 °C warmer. At this temperature vapor pressure over ice is higher and lets the ice sublimate ("dry") faster.

Exhaust Gas Mixing in Ambient Air

Graphical representation of the Schmidt-Appleman criterion analysis. When the mixing line (representing mixing of engine exhaust and ambient air) crosses the water saturation line, a contrail will form. As the mixture continues to cool and water deposits as ice, the mixing may cease in ice supersaturated conditions (shaded orange) where a contrail will persist.

NOPPEL, F., SINGH, R., 2007. Overview on Contrail and Cirrus Cloud Avoidance Technology. In: Journal of Aircraft, vol. 44, no. 5.

Available from: <https://doi.org/10.2514/1.28655>

via

BREAKTHROUGH ENERGY, 2023. Contrails & Climate Change. Archived at: <https://perma.cc/YT8Q-V3KW>

Schmidt-Appleman Criterion for Contrail Formation

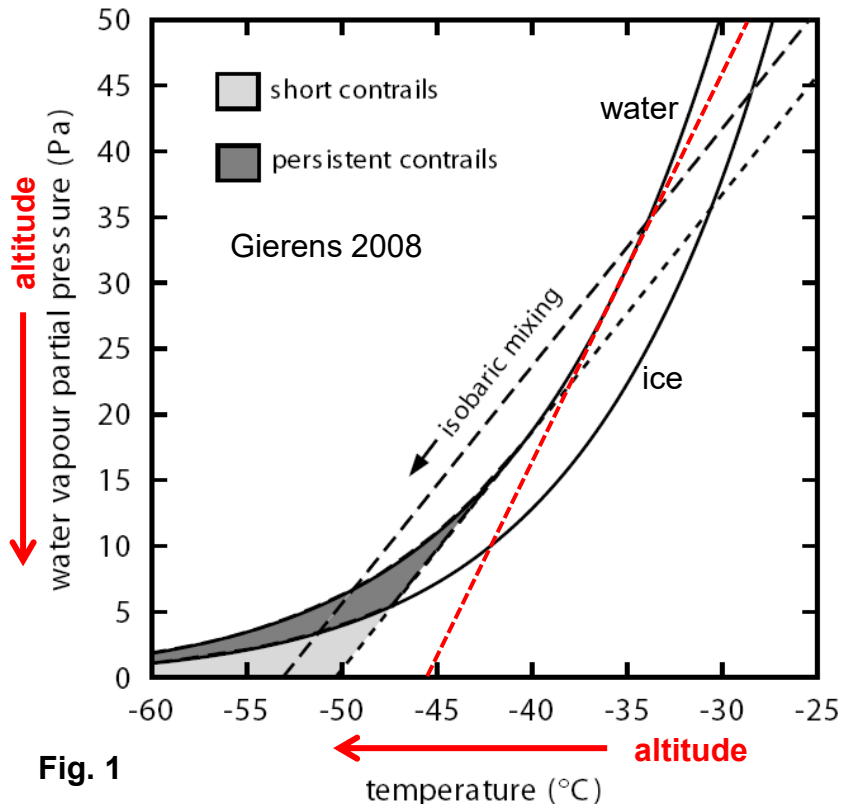

Fig. 1

G is the slope of the dotted line.

The dotted line is tangent to the water saturation line.

The mixing process is assumed to take place isobarically, so that on a T - e diagram the mixing (phase) trajectory appears as a straight line (e is the partial pressure of water vapour in the mixture, T is its absolute temperature, see Fig. (1)). The slope of the phase trajectory, G (units Pa/K), is characteristic for the respective atmospheric situation and aircraft/engine/fuel combination. G is given by

$$G = \frac{EI_{H_2O} p c_p}{\epsilon Q (1 - \eta)}$$

where ϵ is the ratio of molar masses of water and dry air (0.622), $c_p = 1004$ J/(kg K) is the isobaric heat capacity of air, and p is ambient air pressure. G depends on fuel characteristics (emission index of water vapour, $EI_{H_2O} = 1.25$ kg per kg kerosene burnt; chemical heat content of the fuel, $Q = 43$ MJ per kg of kerosene), and on the overall propulsion efficiency η of aircraft. Modern airliners have a propulsion efficiency (η) of approximately 0.35.

G is the slope of the red dotted line with increased slope.

The point on the line tangent to the water saturation line is shifted to the right (to higher temperatures).

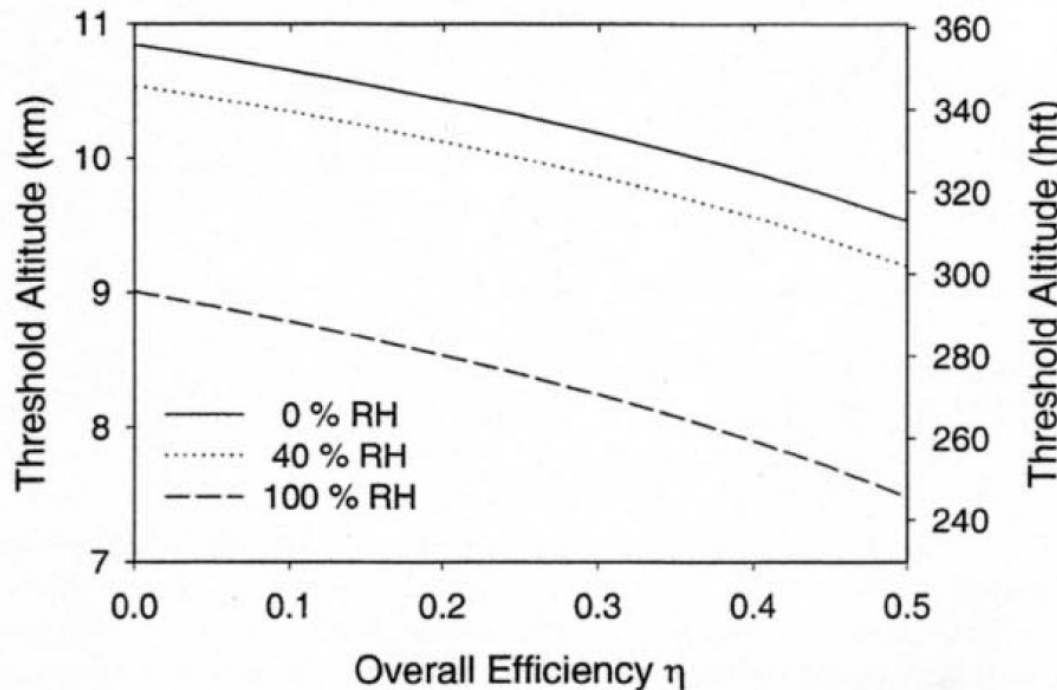

GIERENS, Klaus, LIM, Limg, ELEFATHERATOS, Kostas, 2008. A Review of Various Strategies for Contrail Avoidance. In: The Open Atmospheric Science Journal, 2008, 2, 1-7. Available from: <https://doi.org/10.2174/1874282300802010001>

Effect of the Propulsion Efficiency

Propulsion efficiency

$$\eta = FV / (m_f Q)$$

m_f : fuel flow
 F: thrust

A lower efficiency, η means a smaller slope, G which is tangent to the water saturation line further left (at lower temperatures or increase altitude).

A lower efficiency, η results in more heat losses and a warmer plume, which needs lower temperatures (at higher altitudes) for condensation to form the contrail.

Schumann, 2000, <https://doi.org/10.2514/2.2715>, Open Access: <https://elib.dlr.de/9281>

Heating Value Q, Emission Index EI, and Slope G

fuel	Q [MJ/kg]	EI _{H₂O} [kg/kg]	EI _{H₂O} /Q [kg/MJ]	G _{H₂} /G _{Jet-A1}
H2	120	8,94	0,0745	2,58
Jet –A1	43	1,24	0,0288	

The slope G of the dotted line is 2,58 times steeper in case of LH2 combustion. This means: **Contrails more often** and **also at lower altitudes**.

2,58 times more water vapor is produced with LH2 combustion compared to kerosene combustion (for the same energy used).

Calculating Saturation Pressure with the Magnus Equation

The saturation vapor pressure for water vapor in the pure phase (absence of air) can be calculated using the Magnus formula recommended by the WMO. This formula has the advantage that it requires only three parameters and is reversible. However, more accurate formulas exist. The ones shown here have an accuracy (standard deviation) of $\pm 0.3\%$ over water and $\pm 0.5\%$ over ice.

Over flat water surfaces

$$E_w(t) = 6,112 \text{ hPa} \cdot \exp\left(\frac{17,62 \cdot t}{243,12 \text{ }^\circ\text{C} + t}\right) \quad \text{für} \quad -45 \text{ }^\circ\text{C} \leq t \leq 60 \text{ }^\circ\text{C}$$

Over flat ice surfaces

$$E_i(t) = 6,112 \text{ hPa} \cdot \exp\left(\frac{22,46 \cdot t}{272,62 \text{ }^\circ\text{C} + t}\right) \quad \text{für} \quad -65 \text{ }^\circ\text{C} \leq t \leq 0 \text{ }^\circ\text{C}$$

WMO, 2018. Measurement of Meteorological Variables. In: Guide to Instruments and Methods of Observation, Annex 4.B Formulae for the Computation of Measures of Humidity. Archived at:

The Tangent Mixing Line of the Schmidt-Appleman Criterion

Determination of the straight line in the Schmidt-Appleman criterion. We only know the slope, G of the straight line

$$f(t) = G t + G_0$$

$f(t)$ is the tangent to $E_w(t)$. At the point of contact, the slope of $E_w(t)$ and $f(t)$ must be the same. $E_w(t)$ is differentiated with respect to t and set equal to G .

$$E_w(t)' = \frac{dE_w(t)}{dt} = G$$

This gives the temperature t_{SAC} at the point of contact (details on next page). The temperature t_{SAC} is the highest temperature at which a contrails can form. Furthermore, $E_w(t) = f(t)$ at point of contact. From this we obtain G_0 .

$$G_0 = E_w(t) - G t$$

The Tangent Mixing Line of the Schmidt-Appleman Criterion

$$E_w(t) = a \cdot e^{\frac{bt}{c+t}}$$

$$\frac{dE_w(t)}{dt} = a \cdot e^{\frac{bt}{c+t}} \cdot \frac{b(c+t) - bt}{(c+t)^2}$$

$$= a \cdot e^{\frac{bt}{c+t}} \cdot \frac{bc + bt - bt}{(c+t)^2}$$

$$\frac{dE_w(t)}{dt} = \frac{abc \cdot e^{\frac{bt}{c+t}}}{(c+t)^2}$$

$$\stackrel{!}{=} G$$

$$f(t) = G \cdot t + G_0$$

Magnus formula for saturation water vapor pressure over a flat water surface

$$a = 6.112 \text{ hPa}$$

$$b = 17.62$$

$$c = 243.12 \text{ }^\circ\text{C}$$

This equation can be solved for t with the *Solver* in Excel

$$\frac{abc \cdot e^{\frac{bt}{c+t}}}{(c+t)^2} - G = 0$$

The temperature, t is where $E_w(t)$ and $f(t)$ touch. This temperature is call t_{SAC} . It is the highest temperature for contrails to form.

SAC stands for Schmidt-Appleman Criterion.

Schmidt-Appleman Criterion (Scholz)

Schmidt-Appleman Criterion, Zoom In (Scholz)

Constructing the Schmidt-Appleman Diagram

An aircraft flies at altitude, H and air temperature, t .
 At what relative humidity, φ does it show contrails?

$$G \cdot t + G_0 = \rho \cdot E_w(t)$$

$$\rho = \frac{G \cdot t + G_0}{E_w(t)}$$

Exact solution of this equation with Excel's *Solver*.

Results need to be limited, if:

$$G t + G_0 < 0 \Rightarrow \varphi < 0\% \text{ (not defined)}$$

$$t > t_{SAC} \Rightarrow \varphi > 100\% \text{ (not defined)}$$

Schmidt-Appleman Diagram and the ISA (Scholz)

Contrails form down or left of the respective humidity lines.

The International Standard Atmosphere (light gray) shows:

- Conditions exist for contrails to form even with relative humidity of 0%.
- At 100% relative humidity contrails can form down to 27000 ft (but not below this altitude).

Schmidt-Appleman Diagram, Application (Scholz)

An aircraft flies at altitude, H and air temperature, t .

The red cross shows: There is one relative humidity, ϕ at which the aircraft starts to show contrails!

If the relative humidity is less than ϕ , it must be colder, or the same low temperature must occur at lower altitudes.

Contrails form down or left of the respective humidity lines. See black arrow.

Minimum Relative Humidity for Persistent Contrails

Ice crystals tend to sublimate (go directly from the solid to the gas phase) or dry up, if the air is dry enough. The blue line shows the relative humidity, above which ice does not sublimate anymore and contrails are persistent.

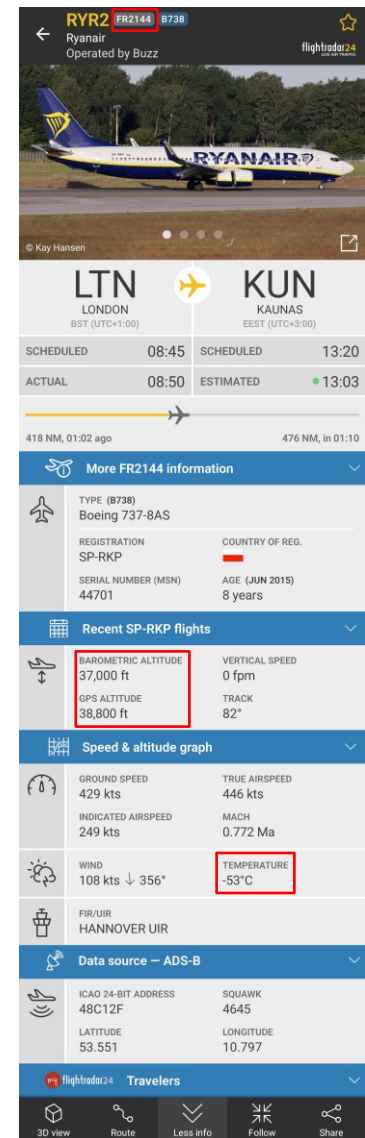

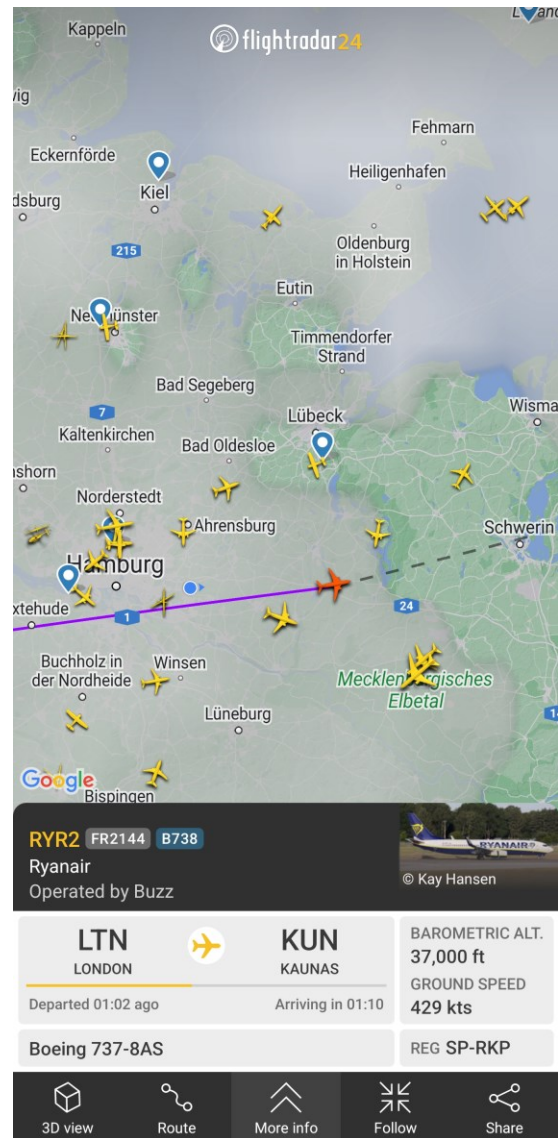

Contrail

Prediction & Observation

BRIEGERT, Finn, 2024. *Aircraft Contrails – Observation and Prediction*. Project. Hamburg University of Applied Sciences, Aircraft Design and Systems Group (AERO). Available from: <https://nbn-resolving.org/urn:nbn:de:gbv:18302-aero2024-03-14.019>

Observation & Prediction

At 10:53 AM, on September 3, a Boeing 737-8AS, registration SP-RKP, was flying eastbound. This plane left a persistent contrail. The aircraft was at a GPS altitude of 38800 ft (FL 370). The outside temperature was -53 °C.

EGGW

EYKA

Relative Humidity

Relative humidity at FL340: 100%
 Relative humidity at FL390: 100%

Interpolated relative humidity at FL370:
 100% (trivial here).

Aircraft Data

Obtained in the project with: <https://flightradar24.com>
 Free data: <https://globe.adsbexchange.com>

Evaluation of the Schmidt-Appleman Diagram

The red cross is far left of the blue line (100% relative humidity).

A contrail is expected to form.

Definition of the Persistence Factor, R

This project defines a factor that can be used to see whether a contrail is persistent or not. This factor is called the **persistence factor**.

$$R = \frac{\text{relative humidity of ambient air}}{\text{relative humidity for saturation with respect to ice}} = \frac{RH}{RH_{min}} \quad (3.1)$$

The relative humidity of the ambient air is divided by the relative humidity for saturation with respect to ice (the theoretical relative humidity for a persistent contrail). However, it is unlikely that $R = 1$ is sufficient for a persistent contrail in reality. A somewhat higher factor is probably necessary.

This project starts with this hypothesis:

- $R < 0.5$ no contrail,
- $R = 0.5 \dots 1.3$ transient contrail,
- $R > 1.3$ persistent contrail.

The persistence factor, R is the same as the **relative humidity with respect to ice, RH_i** .

$RH_i > 100\%$ is called **supersaturation**.

Evaluation of the Schmidt-Appleman Criterion

Minimum relative humidity for given temperature for persistent contrails to form.

If above the blue line persistent contrails are expected to form. Here

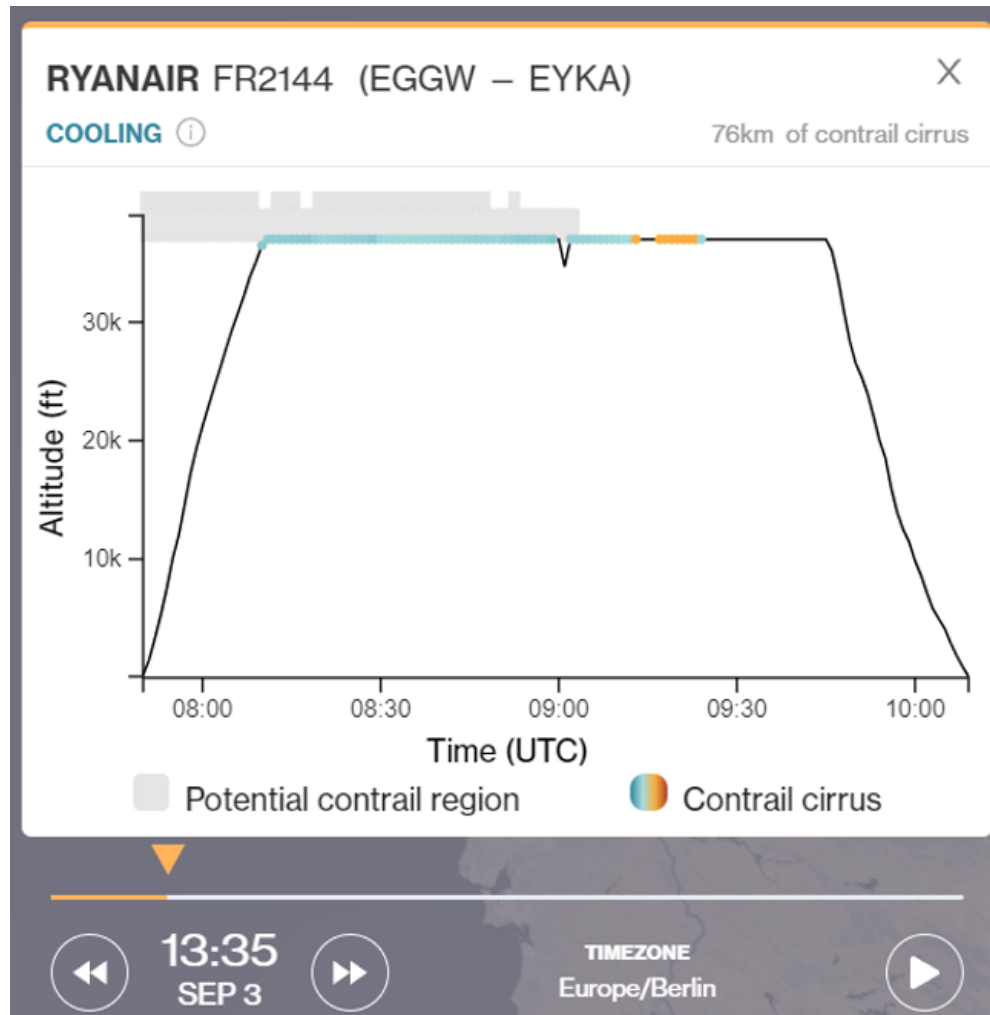

$R = 100\% / 60.2\% = 1.66 \Rightarrow$ persistent contrail (survival longer than 5 min.)

Weather Observation, Satellite Image

<https://windy.com>

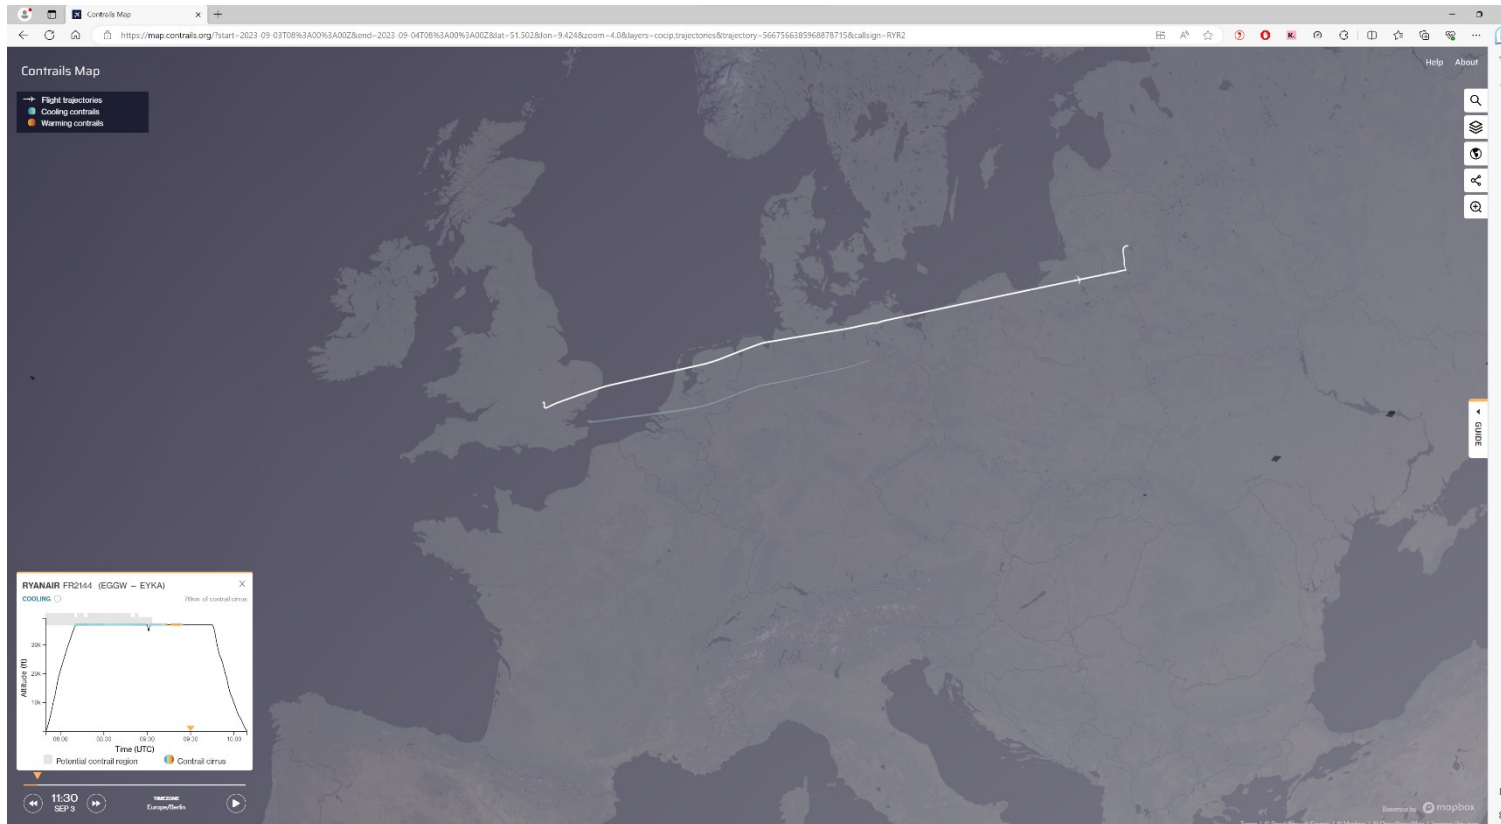

The Flight on contrails.org

AT 10:53 (08:53 UTC), the flight is passing just at the lower edge of a region with Potential Contrail Coverage (PCC).

At this time of the day (daytime) and the sky only partially covered with clouds, the **contrail is cooling**.

The Flight on contrails.org

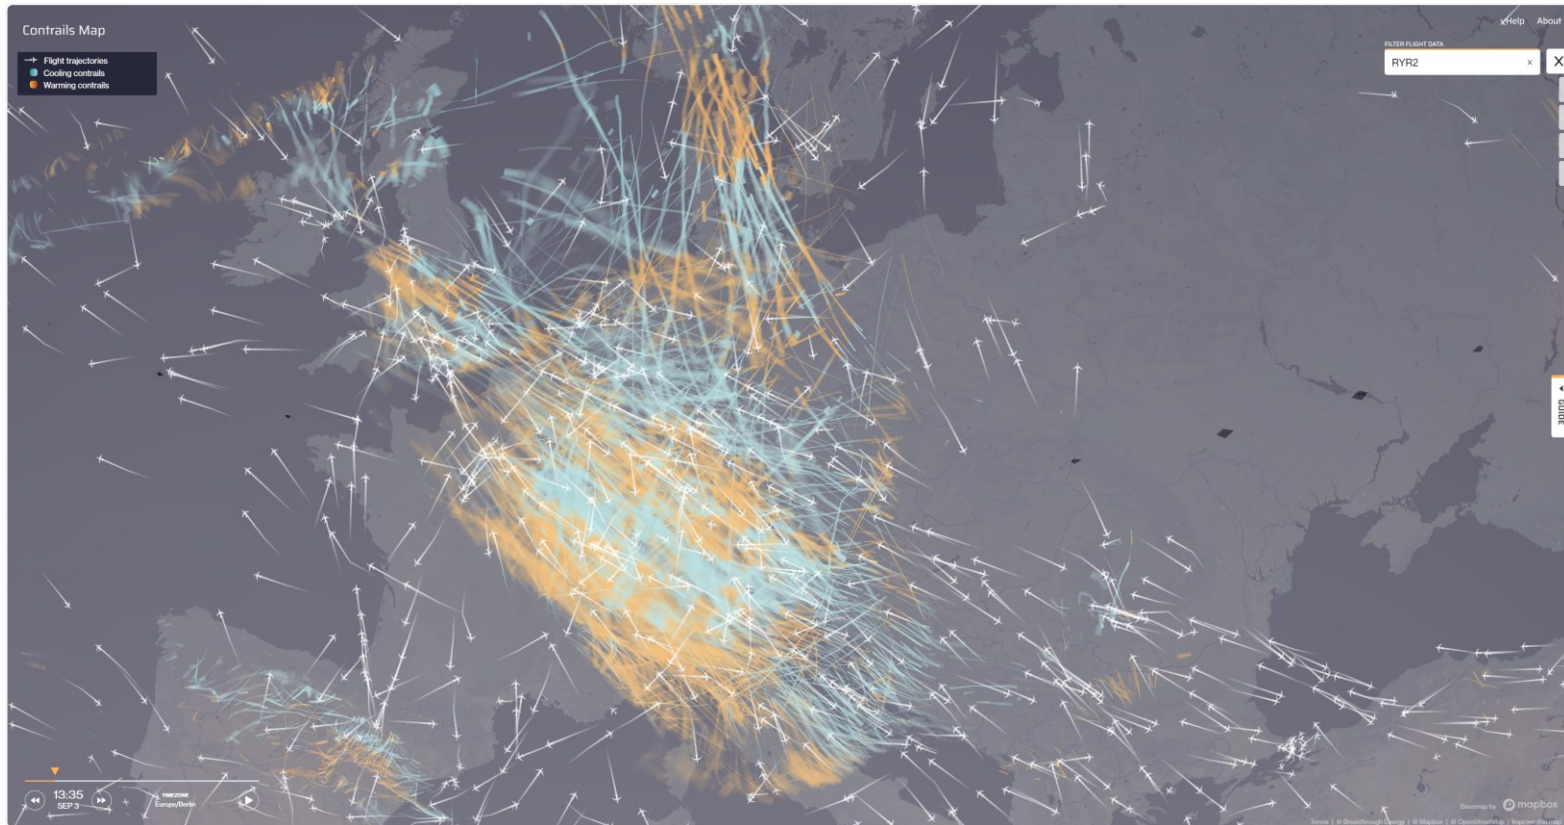

09:30 UTC: In a wind from the north (356° , 108 kt) the cooling contrail (blue) is drifting to the south.

The Flight on contrails.org

11:35 UTC: The contrail has drifted further south.

All Flights on contrails.org at 2023-09-03

11:35 UTC: All flights covered by contrails.org at this day and time. Some contrails are warming, some are cooling.

Observation & Prediction – Summary of 6 Flight

Prediction and Observation of Contrails														
Aircraft	Registration	Date	Time	Geo Alt.	Geo Alt.	Baro Alt.	Baro Alt.	Pressure	Temp.	RH	RH_min	R = RH / RHmin	Prediction	Observation

Systematic of Cooling and Warming Contrails

	C/SKC	D/N	R/NR	⇒ W/C/I	
1.	C	D	R	I	C: cloud (ovc)
2.	C	D	NR	I	SKC: sky clear
3.	C	N	R	I	D: day
4.	C	N	NR	I	N: night
5.	SKC	D	R	I	R: reflective
6.	SKC	D	NR	C	NR: non-reflective
7.	SKC	N	R	W	W: warming
8.	SKC	N	NR	W	C: cooling
					I: indifferent
					ovc: overcast

Reason:

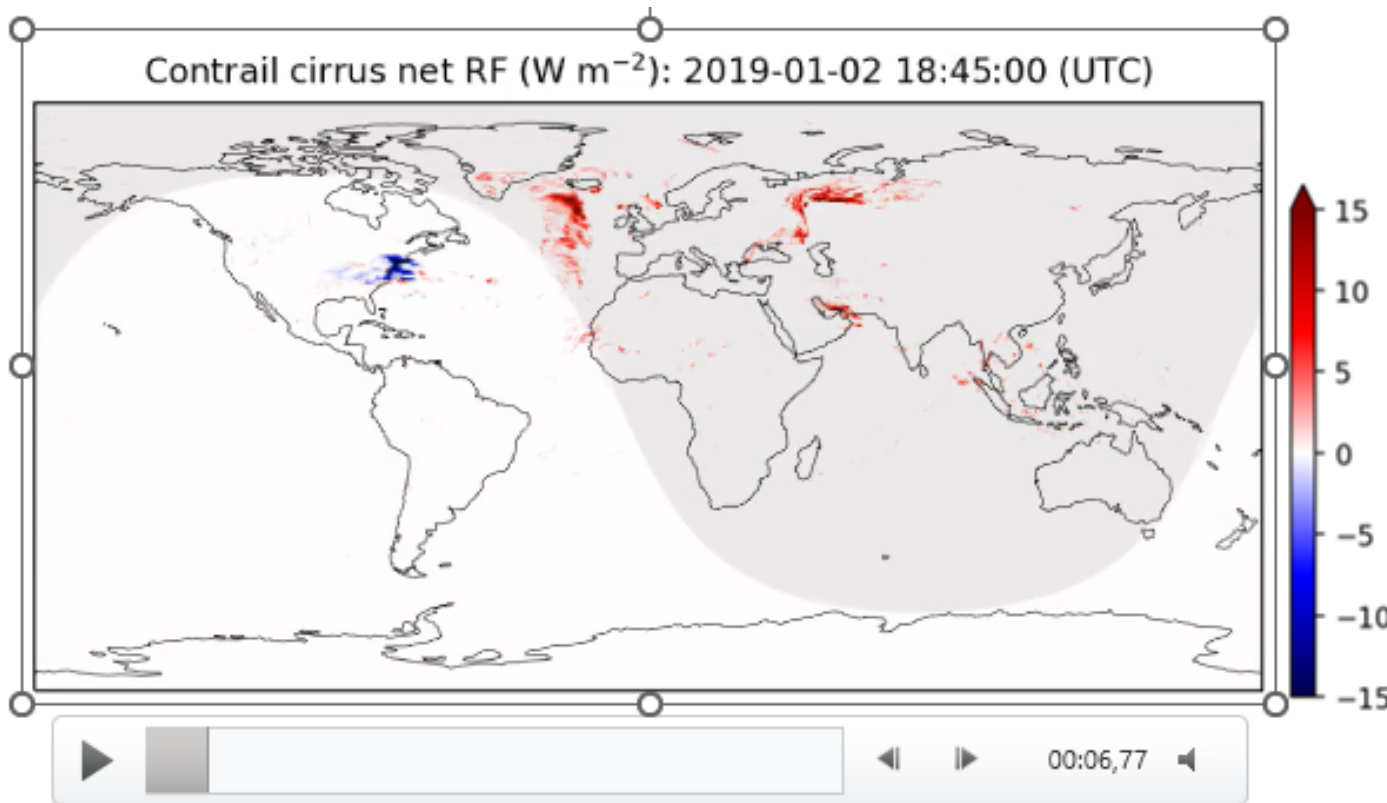

1. to 4. : Clouds are present, contrail does not make difference

5. : Surface is reflective, (reflective contrail — " —)

6. : NR e.g. ocean "swallows" sun's radiation, contrail precludes this

7. to 8. : No radiation from the sun. Reflection back to earth of long wavelength radiation due to contrail is important.

Prediction of Regions with Contrails and Their Energy Forcing

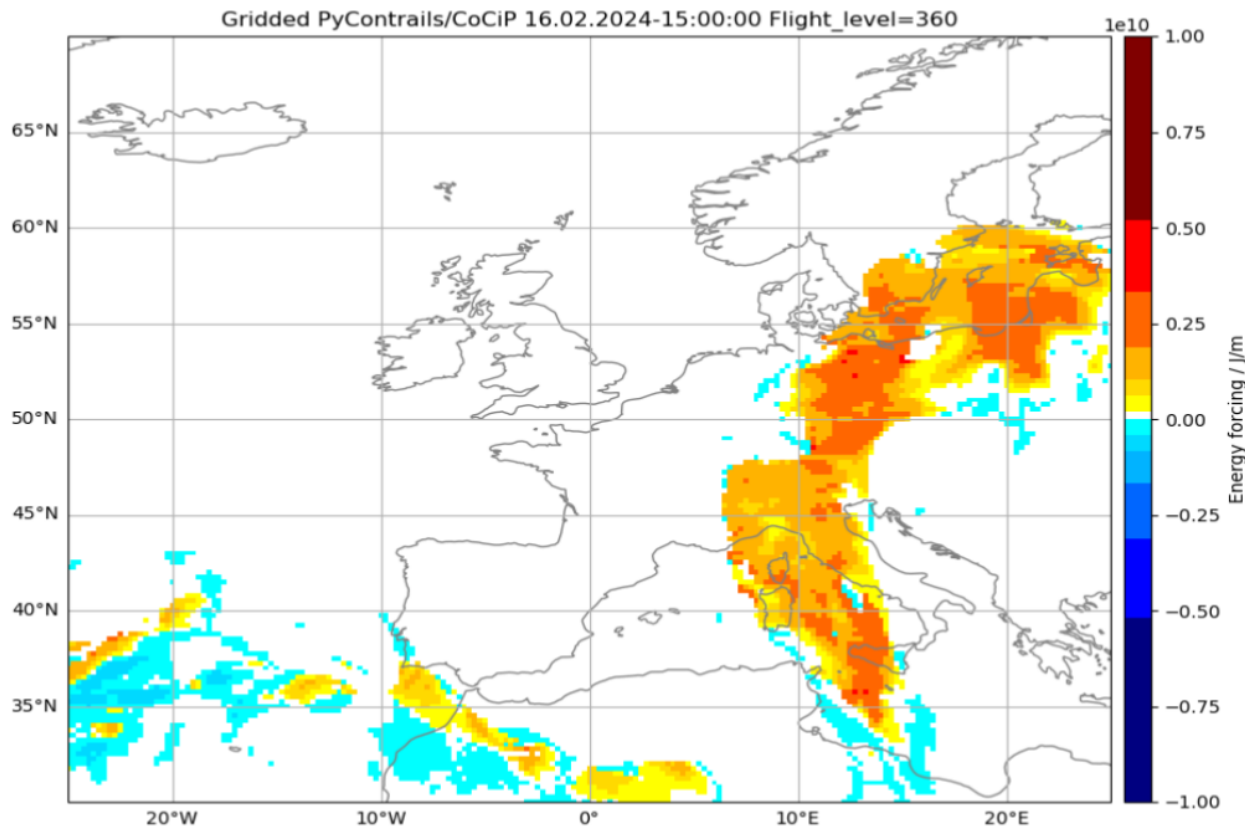

One moment in time from a video showing radiative forcing, RF of contrails in W/m^2 . During the night, all contrails are warming. During the day, some contrails are cooling.

Portion of contrail climate warming avoided by re-routing 5% of planes

<\$0.5

Average cost of avoiding warming equivalent to one tonne of CO₂

Days

Time it takes to get the full cooling effect of avoiding contrails

<https://contrails.org/science>

5% Planes Re-Routed

The best available data indicates a kind of “super-Pareto principle” at play, where tweaking only a few flight paths would eliminate almost all of contrails-induced warming. In practice, this means that just 1 in 20 flights would need to fly over, under, or around areas of the sky predicted to produce harmful contrails.

Better yet properly implemented, these adjustments would be cheap: Our studies show a fleet-average cost of roughly \$5.00 per flight, or less than \$0.50 per tonne of CO₂ equivalent warming avoided.

<https://contrails.org>

- **Forecast Input**
Weather forecasts, satellite images, flight locations, and other data are fed into contrail forecast models
- **Modeling**
Models determine where harmful contrails are likely to occur and compare these predictions with observations
- **Flight Planning**
Flight planners calculate the fastest route with the lowest fuel consumption accounting for contrail impact in their flight plan
- **Verification**
Ground-, air-, and satellite observations verify contrail avoidance and feed back into forecasting models to improve accuracy

Tactical versus Strategic Contrail Avoidance

Tactical avoidance

Adjust flight trajectory en-route to avoid contrails as they are observed

Based on contrail “nowcast”

- Issue real-time guidance
- Restrict avoidance to maneuvers within fuel burn limits
- ATC responsiveness

Long-term vision:

Convergence of concepts:

- Strategic elements to support fuel burn planning
- Tactical elements to maximize precision of guidance

Strategic avoidance

Flight trajectories are planned to avoid expected contrails along the route

Based on contrail forecast

- Reliable forecast of PCC regions
- Minimal deviation flightplan vs. flown trajectory
- ATC clearance

SATAVIA CEO, Dr. Adam Durant: "As a software solution incorporating the excellent and decades-mature atmospheric science available to us, contrail management provides the airline sector with an immediate and tangible option to reduce the climate impact of flying. With the incentive provided by Gold Standard Certified Mitigation Outcome Units (CMOUs), **aviation could reduce its non-CO2 impact by perhaps 50% before 2030**. All we need is a willingness to adopt this approach, which importantly doesn't require any changes to regulation and **could be deployed at scale today**."

FlightKeys

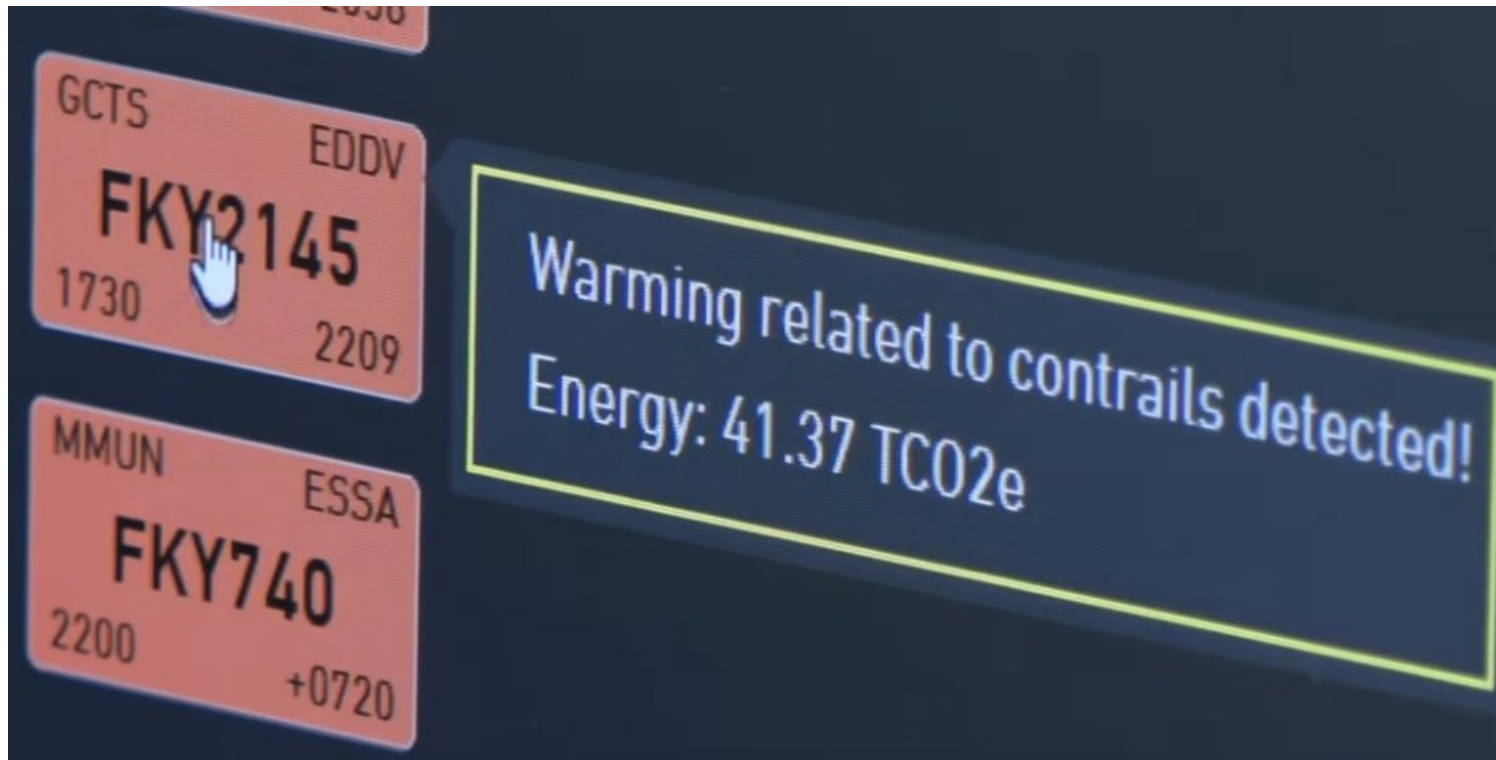

The screenshot displays the FlightKeys flight planning system "5D". The interface is dark-themed and organized into several functional areas:

- Top Panel:** Shows the current flight plan for TUI, with a time slider set to UTC: 12 Mar 14:27. It includes buttons for DEPARTURE and DESTINATION, and a search icon.
- Aircraft type Panel:** Lists available aircraft types such as B38M and B738, along with their respective flight numbers and status indicators.
- Main Flight Plan Grid:** A large grid of flight plan options, each represented by a colored box containing flight numbers and aircraft types. Some boxes are highlighted in yellow or red.
- Right Panel (Flight Plan Details):** Provides a detailed view of the selected flight plan (TUI6BM). It includes:
 - Flightplan:** Shows flight data such as FPP (0 TUI), COST INDEX (5), TRIP TIME (04:57), TRIPFUEL (12153), and DELAY (-00:00).
 - Flight Data:** Lists flight numbers (EDDV, GCTS, TUI6BM) and routes (RW09R - VAXEV1G, RW07 - KONBA4G).
 - Fuels:** Displays fuel consumption metrics like TRIP (12153), CONT% (365), and FRES (1119).
 - Masses:** Shows mass data including DOM (43150), PLD (16388), and ZFM (59538).
 - Flight Progress:** A table showing the flight path with columns for TIME, FUEL, AWY, POINT, ETO, FL, FOB, PETO, PF0B, POS, ATO, AFL, AFOB, SRC, and ADSB.
 - Map:** A map view showing the flight route from EDDV (Hannover) to LISBON, with various waypoints and altitudes.
 - Profile/NOTAM/MET/Route/DEST2/ETOPS/RMK(3):** A list of NOTAMs and other relevant information for the flight.
- Bottom Panel:** Contains several status and alert boxes, such as "CFMU Status OK!", "CREW CHANGED", "New enroute weather available!", and "Destination airport EDDS unsuitable".

Latest CO2 Data

May 2024: 426.90 ppm
 May 2023: 424.00 ppm
 Last updated: Jun 05, 2024

Mauna Loa, Hawaii

Recent Monthly Mean CO₂ at Mauna Loa Observatory

Atmospheric CO₂ at Mauna Loa Observatory

<https://gml.noaa.gov/ccgg/trends>

Base: Pre-industrial (1850-1900), 280 ppm, temperature change: 0 °C

Latest CO2 Data and Climate Sensitivity

2.5 ppm/year

Climate sensitivity is a key measure in climate science and describes how much Earth's surface will warm for a doubling in the atmospheric carbon dioxide (CO₂) concentration. In other words, due to an increase from 280 ppm to 560 ppm (plus 280 ppm).

3 °C (+/- 1.5) °C / 280 ppm
3.0 °C / 280 ppm = 0.0107 °C/ppm
≈ 0.01 °C/ppm

https://en.wikipedia.org/wiki/Climate_sensitivity

Latest Temperature Data

2023:

Tracking breaches of the 1.5°C global warming threshold

<https://climate.copernicus.eu/tracking-breaches-150c-global-warming-threshold>

2.5 ppm/year

Calculating the climate sensitivity from 424 ppm – 280 ppm = 144 ppm:

$$1.5 \text{ }^\circ\text{C} / 144 \text{ ppm} = 0.01042 \text{ }^\circ\text{C/ppm}$$

Additional 0.5 °C need 144 ppm/3 = 48 ppm. Hence:

2.0 °C threshold after further 48 ppm or after 48/2.5 years = 19 years

2023 + 19 => 2.0 °C threshold reached in 2042

May 2024: 426.90 ppm

(2020-09-21)

Airbus, 2023/2024: No Hydrogen Flight Demonstrator Launched

Introducing #ZEROe, 2020-09-21, https://youtu.be/525YtyRi_Vc. Left to right: Jean-Brice Dumont (Executive Vice President Engineering, Airbus), Glenn Llewelyn (Vice President Head of Zero Emission Aircraft, Airbus), Grazia Vittadini (Chief Technology Officer, Airbus. Left Airbus in April 2021).

Airbus, 2024: Zero-Emission Aircraft with Fuel Cell by 2035 (???)

"It has been three years since we revealed an aircraft concept 100% powered by hydrogen fuel cells. Since then, we have **adhered to our initial timeline and made tremendous progress. The recent success of powering on the iron pod system at 1.2 megawatts is a crucial step towards our goal of putting a hydrogen-powered aircraft in the skies by 2035."** Glenn Llewellyn, Vice President of ZEROe Aircraft at Airbus (16 January 2024)

<https://web.archive.org/web/20240116140238/https://www.airbus.com/en/newsroom/stories/2024-01-first-zeroe-engine-fuel-cell-successfully-powers-on>

"This report assessed every public climate target which the international aviation industry set itself since 2000.

We found that all but one of over 50 separate climate targets has either been missed, abandoned or simply forgotten about.

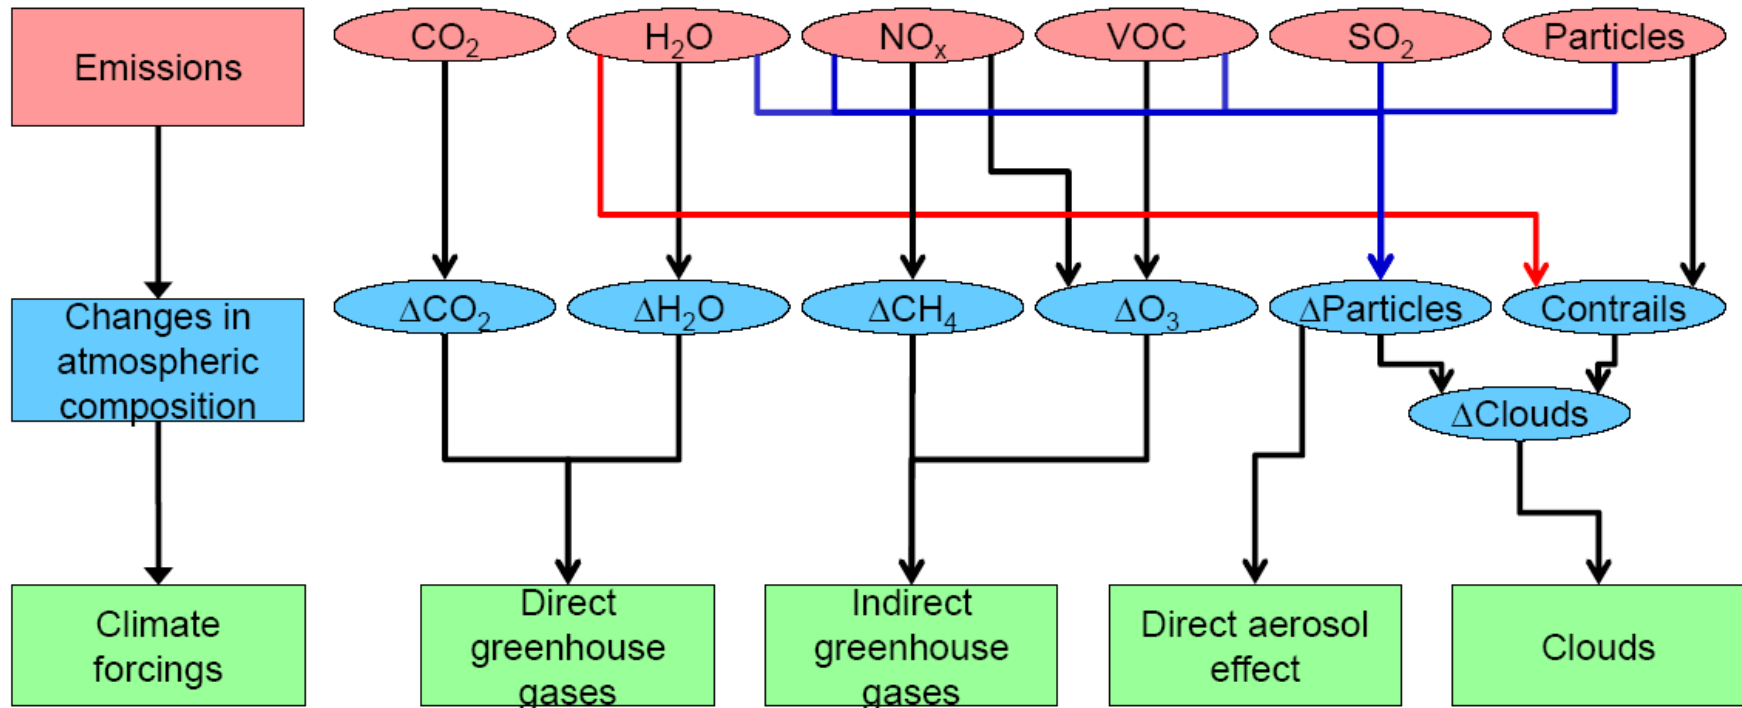

Overall, the industry's attempts to regulate its emissions and set its own targets suffered from a combination of unclear definitions, shifting goalposts, inconsistent reporting, a complete lack of public accountability and, in some cases, [goals] being quietly dropped altogether."

Contrail Radiative Forcing (CRF) as a Function of Fuel Flow (ff)

The quadratic regression (right) fits amazingly well. However, from the small number of aircraft tested, no such general law may be derived.

The climate model by SCHWARTZ 2009, which calculates AIC effects only based on contrail length (flight distance) was extended to include fuel burn (in kg/km) into the equation. Fuel burn enters optical depth linearly!

SCHWARTZ, Emily, KROO, Ilan M., 2009. *Aircraft Design: Trading Cost and Climate Impact*. 47th AIAA Aerospace Sciences Meeting including The New Horizons Forum and Aerospace Exposition, 05.01.-08.01.2009, Orlando, Florida, AIAA 2009, No.1261. Available from: <https://doi.org/10.2514/6.2009-1261>

Calculating Altitude-Dependent Equivalent CO2 Mass

E.g.: $CF_{midpoint,AIC}(h) = \frac{SGTP_{contrails,100}}{SGTP_{CO_2,100}} \cdot s_{contrails}(h) + \frac{SGTP_{cirrus,100}}{SGTP_{CO_2,100}} \cdot s_{cirrus}(h)$

$$s_{contrails}(h) = s_{cirrus}(h) = s_{AIC}(h)$$

Forcing Factor $s = f(h)$

- The curves go along with the ICAO Standard Atmosphere (ISA) applicable for average latitudes. With a first approximation, the curves could be adapted to other latitudes by stretching and shrinking them proportionally to the altitude of the tropopause.
- The curves from SVENSSON 2004 (Fig. 1) show similar shapes. However, the importance of AIC is not yet as distinct.

SVENSSON, Fredrik, HASSELROT, Anders, MOLDANOVA, Jana, 2004. Reduced Environmental Impact by Lowered Cruise Altitude for Liquid Hydrogen-Fuelled Aircraft. In: *Aerospace Science and Technology*, Vol. 8 (2004), Nr. 4, pp. 307–320. Available from: <https://doi.org/10.1016/j.ast.2004.02.004>

EI_NOx = 0.0145 kg/kg

h = 36000 ft

Standard split of CO2,eq:

1/6 = 1/6 = 16.7% from NOx
 2/6 = 1/3 = 33.3% from CO2
 3/6 = 1/2 = 50.0% from AIC

Relative Contributions to Global Warming

LEE, D.S., et al., 2020. The Contribution of Global Aviation to Anthropogenic Climate Forcing for 2000 to 2018. In: Atmospheric Environment, vol. 211 (2021), art. 17834. Available from: <https://doi.org/10.1016/j.atmosenv.2020.117834>

This can be compared to equivalent CO₂ at peak AIC ("33548 ft") according to the model by SCHWARTZ 2009 due to

- 54.7% AIC
- 23.6% CO₂
- 21.7% NO_x

Aviation-Induced Cloudiness (AIC) – Share Depends on Integration Time

LEEMÜLLER, 2022. Climate Optimized Flight Routes – The Path from Research to Operations. Hamburg Aerospace Lecture Series (DGLR, RAeS, VDI, ZAL, HAW Hamburg), Hamburg, Germany, 2022-11-24. Zenodo. <https://doi.org/10.5281/zenodo.7396325>

Aviation-Induced Cloudiness: Contrail Cirrus & Persistent Contrails

Cirrus/Contrails = 4.0

(b) Aviation forcing components, of which aviation-induced cloudiness (AIC) account for more than half.

(c) Breakdown of AIC radiative forcing into contrail cirrus and persistent contrails.

KÄRCHER, Bernd, 2018. Formation and Radiative Forcing of Contrail Cirrus. In: *Nature Communications*, vol. 9, art. 1824. Available from: <https://doi.org/10.1038/s41467-018-04068-0>

Calculating Altitude-Dependent Equivalent CO2 Mass

<https://doi.org/10.7910/DVN/DLJUUK>

SCHWARTZ 2009 and 2011

- At **41000 ft**, AIC is low. Equivalent CO2 is now dominated by NOx.
- Equivalent CO2 mass peaks at "**peak AIC**" (**33548 ft**) due to contrails and contrail cirrus.
- At lower altitudes (**24000 ft**) very little equivalent CO2 is produced. NOx effects and AIC are low. CO2 dominates.
- At very low altitudes (**18000 ft**) the forcing factor for CH₄ and O_{3L} is getting so large that it dominates the forcing factor of the warming O_{3S}. NOx is now **slightly cooling**.

New Technologies & Fuels

Calculating Maximum Range for Battery–Electric Flight: **Range too Short!**

$$e_{bat} = \frac{E_{bat}}{m_{bat}} \quad L = W = m_{MTO} g \quad E = \frac{L}{D} \quad D = \frac{m_{MTO} g}{E}$$

$$P_D = DV = \frac{m_{MTO} g}{E} V = P_T = P_{bat} \eta_{prop} \eta_{elec} \quad V = \frac{R}{t}$$

$$P_{bat} = \frac{E_{bat}}{t} = m_{bat} e_{bat} \frac{V}{R}$$

$$m_{bat} e_{bat} \frac{V}{R} \eta_{elec} \eta_{prop} = \frac{m_{MTO} g}{E} V$$

$$R = \frac{m_{bat}}{m_{MTO}} \frac{1}{g} e_{bat} \eta_{elec} \eta_{prop} E$$

$$\eta_{elec} = 0.9; \quad \eta_{prop} = 0.8$$

○ : realistic parameters

- e_{bat} : specific energy
- E_{bat} : energy in battery
- E : glide ratio (aerodynamic efficiency)
- L : lift
- D : drag
- W : weight
- V : flight speed
- R : range
- t : time
- g : earth acceleration
- P : power
- η : efficiency (prop : propeller)

Question:

The EU is calling for 70% **Sustainable Aviation Fuel (SAF)** by 2050 (a blend of 70% SAF and 30% kerosene). Let's assume SAFs "produce around 80 percent less CO₂" (Airbus).

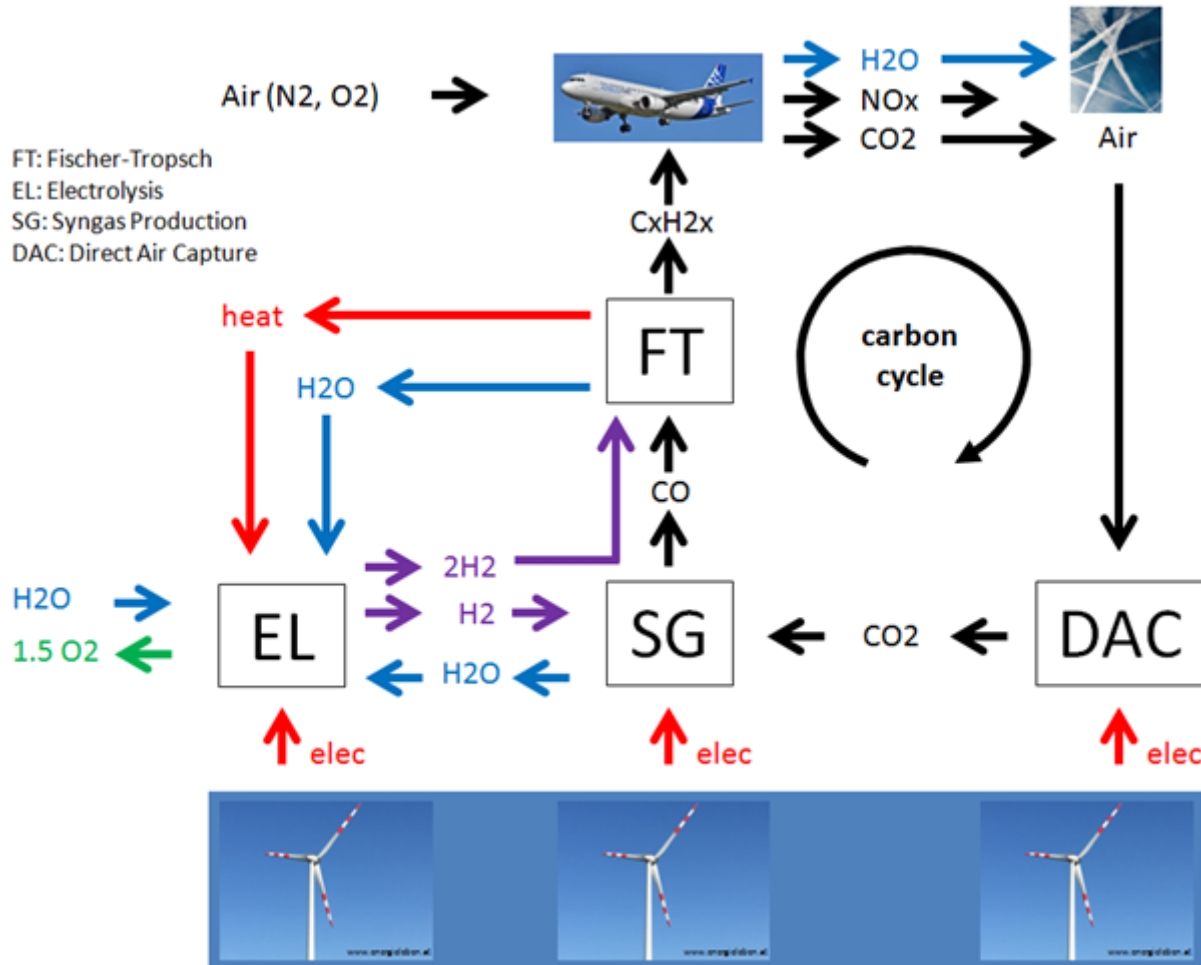

- a) To what percentage are CO₂ emissions left?
- b) It is estimated that **aviation will have grown by a factor of 2.9 by 2050**.
Based on this: How much more CO₂ will be emitted in 2050 compared to today?

Answer:

a) The 70% SAF are 35% from biofuel (CO₂-efficiency 80%) hence as good as $0.8 \cdot 35\% = 28\%$. The other 35% are from e-fuel, which may be considered to have a CO₂-efficiency of 100%. Together SAF is as good as 63%. The fuel in the tank is producing CO₂ as 37% of the kerosene before.

b) Due to traffic growth, the 37% become $37\% \cdot 2.9 = 107\%$. This means **CO₂ emission in 2050 are increased(!) by about 7% compared to today** (despite the ambitious introduction of SAF).

The Carbon Cycle of Sustainable Aviation Fuel (SAF, E-Fuel)

- **SAF need DAC** (Direct Air Capture) to **compensate for CO_2** ("carbon cycle")
- In addition: SAF and BioFuel need **more DAC** to compensate for the global warming effect due to
 - **NOX** and
 - **H_2O (AIC)**

Production of synthetic kerosene (e-fuel) with power-to-liquid (PtL). Taking CO_2 from the air (Direct Air Capture, DAC) enables a carbon cycle.

Refueling One A350 Once per Day with SAF (E-Fuel): 53 of the Largest Wind Power Plants (4.6 MW each) Are Needed!

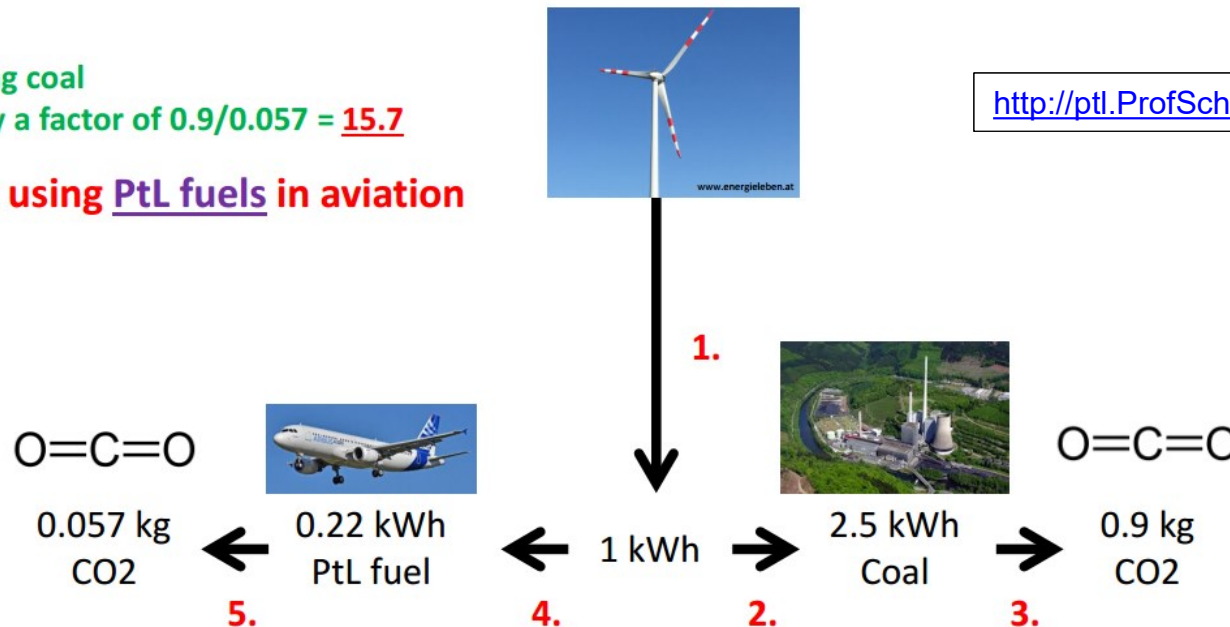

Airbus A350-900
 Tank Volume: 138 m³
 Fuel Mass: 110.4 t (800 kg/m³)
 Energy: 4747.2 GJ (43 MJ/kg)
 One E-160 per day: 89.4 GJ SAF
 (Capacity Factor: 0.5, $\eta_{PTL} = 0.45$)
53 E-160 required !

Best: Use Renewable Energy to Replace Coal Power Plants

Substituting coal
is better by a factor of $0.9/0.057 = 15.7$

The idea using PtL fuels in aviation

<http://ptl.ProfScholz.de>

- 1.) 1 kWh of renewable energy ...
- 2.) ... can replace 2.5 kWh lignite in coal-fired power plants (efficiency 40%);
- 3.) This corresponds to 0.9 kg of CO2 (0.36 kg of CO2 for 1 kWh of energy from lignite *).
- 4.) ... converted into Sustainable Aviation Fuel (SAF) only 0.22 kWh remain (efficiency: 70% electrolysis, 32% Fischer-Tropsch), 99% transport; <https://perma.cc/BJJ6-5L74>
- 5.) which save only 0.057 kg of CO2 (0.26 kg of CO2 for 1 kWh of kerosene *).

* UBA, 2016: CO2 Emission Factors for Fossil Fuels. <https://bit.ly/3r8avD1>

Best: Use Renewable Energy to Replace Coal Power Plants

Substituting coal
is better by a factor of $0.9/0.14 = 6.3$

The idea using LH2 in aviation

<http://ptl.ProfScholz.de>

- 1.) 1 kWh of renewable energy ...
- 2.) ... can substitute 2,5 kWh of coal (lignite, brown coal) in a coal power plant (efficiency of a coal power plant: 40%) this is
- 3.) ... equivalent to 0.9 kg CO2 (0.36 kg CO2 for 1 kWh of energy burning lignite*)
- 4.) ... but if used in an aircraft it generates LH2 with energy of 0.6 kWh (efficiencies: 70% electrolysis, 83% liquefaction & transport)
- 5.) LH2 aircraft consume (say) 10% more energy (higher operating empty mass, more wetted area); so a kerosene aircraft needs ...
- 6.) only 0.55 kWh, which can be substituted. This is equivalent to 0.14 kg CO2 (0.26 kg CO2 for 1 kWh of energy burning kerosene*).
- 7.) Note: Not considered is that hydrogen aircraft may come with higher non-CO2 effects than kerosene aircraft.

* UBA, 2016. CO2 Emission Factors for Fossil Fuels. Available from: <https://bit.ly/3r8avD1>

Climate & Statistics

"Contribution of global aviation in 2011 was calculated to be **3.5%** of the net anthropogenic Effective Radiative Forcing (ERF)."
