UNDERSTANDING DEEP ATLANTIC ECOSYSTEMS

Species distribution models under future climate scenarios

ATLAS 3rd General Assembly 2018, Mallorca

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 678760 (ATLAS). This output reflects only the author's view and the European Union cannot be held responsible for any use that may be made of the information contained therein.

PRESENCE RECORDS

OCEAN BIOGEOGRAPHIC
INFORMATION SYSTEM

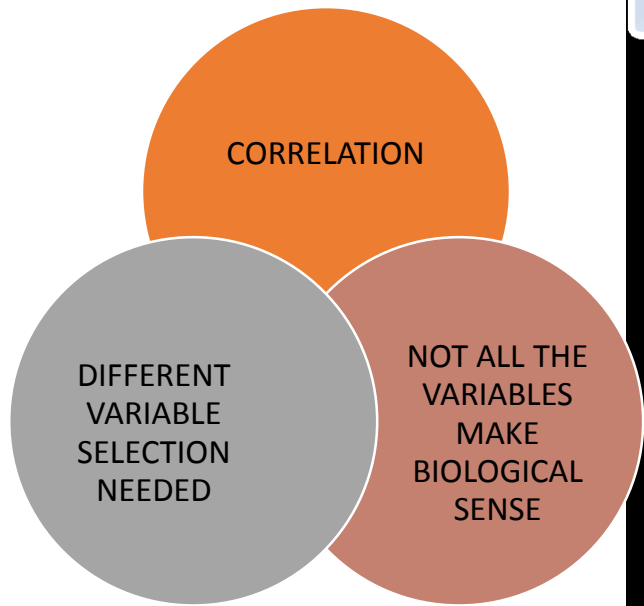

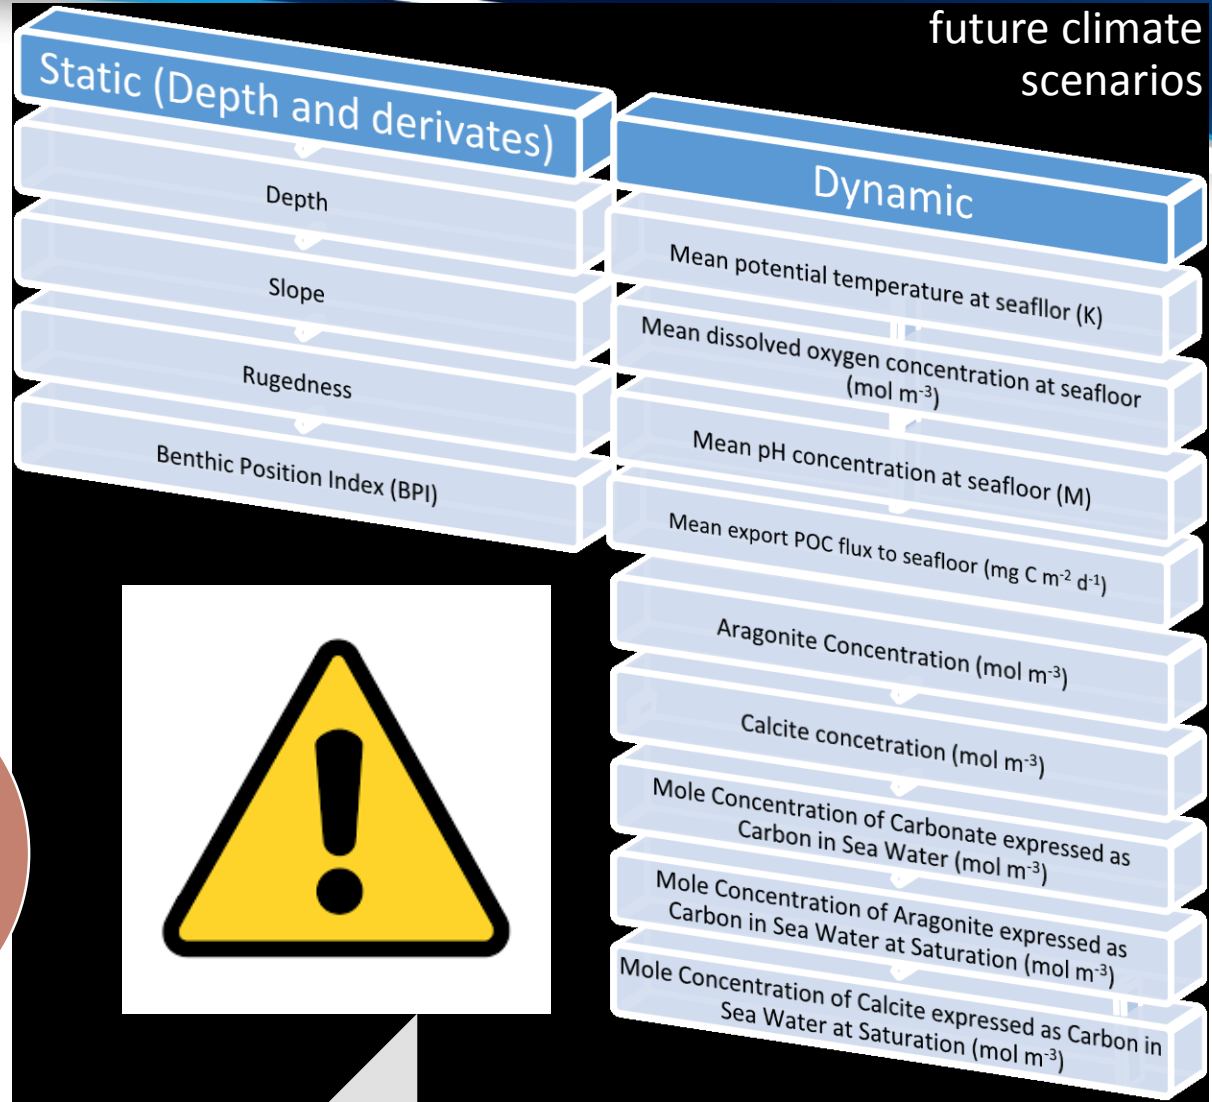

- OBIS is a global open-access data and information clearing-house on marine biodiversity for science, conservation and sustainable development.
- Include a huge number of presence records but:
 - Not all of them are in the studied area (North Atlantic)
 - Not all of them can be trust
 - Filtering (using depth)

CONCLUSIONS

1. According to our results corals will suffer severe reductions in the availability of suitable habitat for the period 2081-2100 (close to 100 % for the 3 species of Alcyonacea analysed). The effect on fishes will be highly dependant of the species
2. The 6 fish species analysed showed a polar shift in its distribution whereas changes in depth did not show any clear trend. Corals did not show a clear trend with Latitude or depth.
3. Species distribution model are useful and promising tools to predict how climate change will affect to the deep sea ecosystems. However, at the moment there are still important limitations which greatly reduce the liability of these models:
 1. Presence records bias
 2. Uncertainty in environmental variables (present and especially future)
 3. Lack of important explanatory variables
 4. Coarse resolution
5. Because of all the these limitations caution have to be exercise when interpreting these results
