Functional enrichment analysis (FEA)

Today's webinar

PART 1

PART₂

Background and statistical concepts

- Introduction to functional enrichment analysis
- Key statistical concepts
- FEA workflow

Functional enrichment analysis in practice

- Platforms and tools for FEA
- Tool choice considerations

Part 1

Background and statistical concepts

Functional enrichment analysis

Functional enrichment analysis is a broad term that refers to various methods used to extract biological or functional insights from lists of biomolecules.

Identify biological functions, pathways, or molecular mechanisms that are significantly associated with a subset of biological molecules, such as those that are differentially expressed in a particular condition.

Synonyms

- Enrichment analysis
- Pathway analysis
- Pathway enrichment analysis
- Functional annotation analysis
- Functional enrichment analysis

FEA workflow

FEA at a glance: Mouse diet experiment

Functional enrichment analysis: When?

Post-differential expression analysis

- Transcriptomics (eg high-fat diet vs. low-fat diet)
- Proteomics (eg tumor tissue vs. healthy tissue)
- Lipidomics (eg disease vs. healthy state)
- Metabolomics (eg diabetic vs. non-diabetic patients)
- Epigenomics (eg smokers vs. non-smokers)

Functional enrichment analysis: Why?

Once a large-scale omics study undertaken

THE UNIVERSITY OF

- Summarise long list of many significant genes/proteins
- Extract meaningful bi
- Hypothesis generatio

Monitor systems by observing the behaviour in the order of 100s and 10^6 molecules per experiment Results in the order of 10^2 - 10^4 features, as a list

🛒 MONASH

Australian

BioCommons

Dysregulation of DNA repair mechanisms is a key driver in tumor progression in this specific cancer subtype.

Functional enrichment analysis: How?

Data captured from an -omics study

- List of features
- Background set
- Ranked list
- Gene sets

Concepts

- Gene list
- Gene set
 - GO Term (Apoptotic process genes involved in programmed cell death)
 - KEGG Pathway (MAPK signaling pathway genes involved in cell proliferation, differentiation, and survival)
 - Reactome Pathway (Mitochondrial protein import genes that help in importing proteins into mitochondria)
 - Hallmark Gene Sets (HALLMARK_HYPOXIA genes involved in the cellular response to low oxygen levels)
 - Transcription Factor Targets (TP53_TARGETS genes regulated by the tumor suppressor TP53)
 - Cell-Type Specific Gene Sets (Neurogenesis gene set genes that control the formation of neurons during brain development)
- P-value and false discovery rate (FDR)
- Regulation
- Background set
- ID mapping
- Annotation database

Types of enrichment analysis

Ten Years of Pathway Analysis: Current Approaches and Outstanding Challenges

Purvesh Khatri 🖾, Marina Sirota, Atul J. Butte 🖾

Published: February 23, 2012 • https://doi.org/10.1371/journal.pcbi.1002375

Types of enrichment analysis

- Over Representation Analysis (ORA)
 - Modular Enrichment (WGCNA)
 - Cell-Specific ORA
- Gene Set Enrichment Analysis (GSEA)
 - Pre-ranked GSEA
 - ssGSEA
- Topology-based Pathway Analysis (TPA)
 SPIA
 - TopologyGSEA

*Note: **TPA** is not covered in our workshop.

- Requires good understanding of network biology and pathway topology
- Needs high-quality pathway topology information (detailed pathway data), which might not be always available for all organisms or conditions
- ORA and GSEA have been mostly used by researchers

Why/when ORA/GSEA? Or both?

	ORA	GSEA
Inputs	Predefined gene list (e.g., DEGs, gene modules)	Full ranked gene list ordered by some sort of statistical method
Cutoffs	Requires cutoffs (logFC, p-value)	No cutoffs needed
Statistical methods	Fishers' Exact test, Hypergeometric test	Permutation tests like Kolmogorov–Smirnov (K-S) test to calculate p values
Outputs	Enriched terms with p values or FDR	Enrichment scores (ES) per gene set, normalised enrichment scores (NES), p values or FDR
Pros	Simple, computationally efficient, easier interpretation	Captures subtle effects and coordinated trends across all features
Cons	Missing subtle yet biologically important patterns, independence assumption of genes	Rank bias, gene set size bias, complex statistical framework, computationally intensive (depends on permutations)
Research question	Which biological pathways are over-represented in genes upregulated in response to a specific drug treatment?	Is there enrichment of genes involved in immune response pathways across the entire ranked gene list in patients with a specific disease?

Statistics overview - ORA

 $P = \frac{(a+b)!(c+d)!(a+c)!(b+d)!}{a!b!c!d!N!} = 7.34e-54$

THE UNIVERSITY OF

Australian **BioCommons MONASH** University

$$P(X = k) = rac{\binom{K}{k}\binom{N-K}{n-k}}{\binom{N}{n}}$$
 = 7.52e-54

Statistics overview - GSEA

1. Calculating enrichment score (ES)

- Walk down the ranked list of genes L, increment the running sum by $\sqrt{((N-N_h)/N_h)}$ and decrement it by $\sqrt{(N_h/(N-N_h))}$, similar to the Kolmogorov-Smirnov

2. Permutations

- Randomly assign phenotype labels to samples, re-order genes, re-compute the ES of a gene set to generate a null distribution of ES.
- Using this null, compute an empirical, nominal *p* value for any observed ES
- 3. Normalising enrichment score (NES)
- Adjust for variation in gene set size
- 4. Multiple hypothesis testing
 - False Discovery Rate(FDR)
 - Family-Wise Error Rate (FWER)

- Mitochondria
- MAP kinase signalling pathway
- Cell cycle control

Pathways in Biology

Biological pathways are series of interconnected biochemical reactions or molecular events that occur within cells, tissues, organs, or entire organisms.

These pathways describe the flow of biological information, matter, or energy that leads to specific biological outcomes.

- Metabolic Pathways
- Genetic Pathways
- Signal Transduction Pathways
- Immune Response Pathways
- Cell Cycle Pathways

Pathways in Biology

Gene Ontology: tool for the unification of biology

The Gene Ontology Consortium*

Genomic sequencing has made it clear that a large fraction of the genes specifying the core biological functions are shared by all eukaryotes. Knowledge of the biological role of such shared proteins in one organism can often be transferred to other organisms. The goal of the Gene Ontology Consortium is to produce a dynamic, controlled vocabulary that can be applied to all eukaryotes even as knowledge of gene and protein roles in cells is accumulating and changing. To this end, three independent ontologies accessible on the World-Wide Web (http://www.geneontology.org) are being constructed: biological process, molecular function and cellular component.

Directed Acyclic Graph (DAG)

GO classes (terms) are

composed of a definition, a label, a unique identifier, and several other elements.

This reflect the fact that:

- biosynthetic process is a subtype of metabolic process
- a hexose is a subtype of monosaccharide

GO Domains

Molecular Function	Molecular-level activities performed by gene products.	An example of GO annotation: human		
(MF)	<u>catalytic activity</u> and <u>transporter activity;</u> adenylate cyclase activity or <u>Toll-like receptor binding</u> .	molecular function oxidoreductase activity,		
	GO molecular functions are often appended with the word "activity" (a <i>protein kinase</i> would have the GO molecular function <i>protein kinase activity</i>).	the biological process oxidative phosphorylation, and the cellular component mitochondrial intermembrane space.		
Cellular Component	A location, relative to cellular compartments and structures.			
(CC)	<u>cellular anatomical entities</u> , includes cellular structures such as the <u>plasma membrane</u> and the <u>cytoskeleton</u> , as well as membrane-enclosed cellular compartments such as the <u>mitochondrion</u>			
Biological Process	The larger processes, or 'biological programs' accomplished by multiple molecular activities.	Note: a biological process is not equivalent to a pathway.		
(BP)	<u>DNA repair</u> or <u>signal transduction</u> . pyrimidine nucleobase biosynthetic process or glucose transmembrane transport	https://geneontology.org/docs/ontology-documentation

Functional enrichment analysis in practice

FEA workflow

Graphical or command line interface

- FEA can be performed via:
 - Graphical user interface (GUI) web or desktop application
 - R statistical programming language
- Key considerations:
 - Type of analysis (ORA, GSEA)
 - Database integration
 - Ease of use
 - Which species you are studying

FEA tools published 2001-2021 by platform Xie et al 2021

Web platforms for FEA

Key advantages for using web platforms include:

- Simple user interface
- Database integration

Key disadvantages:

- Limited visualisation flexibility
- 'Black box' can affect reporting and reproducibility
- Not available to all species
- Data security

Common pitfalls

- Most web platforms for ORA do not emphasise the option for provision of background gene list
- Can be difficult to obtain details sufficient for reporting and reproducibility

Urgent need for consistent standards in functional enrichment analysis

Abstract

Gene set enrichment tests (a.k.a. functional enrichment analysis) are among the most frequently used methods in computational biology. Despite this popularity, there are concerns that these methods are being applied incorrectly and the results of some peer-reviewed publications are unreliable. These problems include the use of inappropriate background gene lists, lack of false discovery rate correction and lack of methodological detail. To ascertain the frequency of these issues in the literature, we performed a screen of 186 open-access research articles describing functional enrichment results. We find that 95% of analyses using over-representation tests did not implement an appropriate background gene list or did not describe this in the methods. Failure to perform p-value correction for multiple tests was identified in 43% of analyses. Many studies lacked detail in the methods section about the tools and gene sets used. An extension of this survey showed that these problems are not associated with journal or article level bibliometrics. Using seven independent RNA-seq datasets, we show misuse of enrichment tools alters results substantially. In conclusion, most published functional enrichment studies suffered from one or more major flaws, highlighting the need for stronger standards for enrichment analysis.

https://doi.org/10.1371/journal.pcbi.1009935

R programming language for FEA

Key **advantages** for using R:

- Saved code provides thorough reproducibility
- Dedicated FEA packages available to simplify analysis
- High flexibility and parameter control
- Comprehensive plot options
- Can be used for non-model species which lack available web databases
- Can be performed offline, for maximum data security

HE UNIVERSITY OF

Key disadvantage:

- Steeper learning curve
- Can be slower than native web tools (external database calls depend on your local internet speed)

Integrated development environments for R

- IDEs help simplify working in R
- Popular choices include:
 - RStudio
 - VS Code
 - Jupyter Notebook

Tool choice will impact results

- Like any statistical analysis, small changes in method can lead to different results
- All analysis tools are doing things slightly differently, eg
 - Different underlying statistical analysis method
 - Different databases
 - Different database versions
 - Different P value adjustment method
 - Different default parameters
 - Your gene list processing and arbitrary filtering choices will also impact results

Different input filtering affects results

jvenn: Bardou et al 2014 data: Pezzini et al 2016

g:Profiler over-representation analysis of GO terms

Different tools running on the same database can also give different results

Tool	g:Profiler	Reactome
Statistical test	Hypergeometric	Hypergeometric
Padj cutoff	Default (0.05)	Default (0.05)
FDR method	Default (g:SCS)	Default (BH)
Background	Default (annotated genes)	Default (?)

jvenn: Bardou et al 2014 data: Pezzini et al 2016

Different tools running on the same database can also give different results

jvenn: Bardou et al 2014 data: Pezzini et al 2016

THE UNIVERSITY OF

How to manage conflicting results

This can make it hard to know which results to trust

If you:

- Apply robust methods
- Use sensible parameter choices
- Interpret your results in their biological context

"We believe the right attitude on the functional enrichment analysis is to treat it as a **guidance** to filter and rank pathways and processes, but **not to religiously believe in the absolute numbers**"

<u>Metascape, 2019</u>

the results will be as valid as any other regardless of which platform you use

Robust and reproducible methods

To ensure robust methods, keep these things in mind:

Use the **right gene list:** Pre-filter (eg P*adj*) for ORA, don't filter but sort (eg fold change) for GSEA Choose **actively maintained tools:** Those that are regularly updated and use the latest databases

Use the **right background**:

Always reduce the genes to the list of those that are detectable in the experiment (eg expressed in your tissue, present on your microarray...) to avoid bias

Use **adjusted P value** to account for multiple testing, never raw P value

Report all methodological

details in your methods to ensure reproducibility, eg:

- Tool and tool version
- DB and DB version
- Filter thresholds
- Padj method
- Optional parameters applied
- Include background gene list
- Copy of R code/link to repository

UNIVERSITY OF

Validating FEA results

- Cross-check findings with existing biological knowledge
 - Are the enriched pathways relevant to your tissue type or biological condition?
- Validate results with independent datasets or alternative methods
 - Consistent significant enrichment across multiple methods supports validity
- Reduce redundancy in terms (eg through REVIGO for GO terms) to help highlight the most relevant processes
- Explore FEA workflow benchmarking, a complex but worthy topic, eg GSEABenchmarkeR (Geistlinger at al 2020)
- Where possible, use laboratory validation (e.g., qPCR, Western blotting, knockout studies)

5 things to remember when doing FEA

1. ORA and GSEA are different statistical analyses, and their inputs differ!

GSEA: Kolmogorov-Smirnov test, requires a ranked yet unfiltered gene list

ORA: Hypergeometric or Fisher's Exact test, requires a filtered unranked gene list and experimental background gene list

2. Always correct for multiple testing!

Never unadjusted P values

3. Different analysis methods will return different results!

This is expected and OK, as long as your methods are robust, sensible and reproducible. All results should be validated!

4. Ensure reproducibility!

Record all methodological details

5. Interpret your results in their biological context!

Functional categories are often broad and redundant. Use the FEA results as a guide, not the end point. Use visualisations to make sense of it all. Validate!
