

Description of the dataset

The Oldenburg Hearing Health Repository (OHHR) provides a publicly accessible dataset that can be used to advance hearing health research. It includes a constellation of data collected from 581 participants (aged 18–86 years; 255 female; *Mean age = 67.31 years*; *SD = 11.93*) between 2013 and 2015 at the Hörzentrum Oldenburg in collaboration with 'Hearing4ALL' Excellence Cluster.

All the different data types are listed below:

Subjective Measures

- Home Questionnaire
- SF-12 Health Survey
- Technology Readiness Questionnaire
- Anamnesis

Audiological Tests

- Pure Tone Audiometry
- Adaptive Categorical Loudness Scaling
- Digit Triplet Test (Speech Reception Threshold in Noise: Screening)
- Göttingen Sentence Test (Speech Reception Threshold in Noise)

Cognitive Measures

- DemTect
- WortSchatz

Demographic Information

- Socio-Economic Data
- Scheuch-Winkler Index (calculated)

Supporting Documentation

MethodsDescription.rtf: Provides detailed explanations of data type and collection procedures.

data.zip/metadata: Includes schema and description files for all data tables.

A supporting paper of the same name detailing the dataset and methodologies will be published and made publicly available soon.

Data Table Overview

Table Name	Description	Procedure	Hardware/Software Used	Special Considerations
Home Questionnaire (HQ)	Comprehensive self-reported data on hearing history, general health, lifestyle, and media consumption habits. The HQ also includes the SF-12 Health Survey and the Technological Readiness Questionnaire (see details below)	Participants completed an 11-page questionnaire independently at home and returned it electronically	Paper-based; completed electronically and returned via email	Data cross-verified during face-to-face interview
Short Form Health Survey (12 items)	A 12-item survey assessing physical and mental health, yielding two scores: Physical Health Score (PSC) and Mental Health Score (MSC)	Participants self-reported physical and mental health limitations through 12 standardized questions.	Part of the HQ; raw scores converted into standardized T-values (M=50, SD=10)	Concise version of the 36-item survey, efficiently capturing health-related quality of life in physical and mental domains
Technological readiness Questionnaire	12-item questionnaire measuring willingness and confidence in adopting modern technology	Participants rated their technology readiness across three subscales: Competence, Acceptance, and Control	Part of the HQ	Focuses on adaptability and engagement with modern technology, especially among older adults
Socio Economic Status	Information on demographics (age, gender, native language) and socio-economic factors (education, occupation, income)	Derived from clinical interviews and the HQ, covering household composition and living situation	Manual entry during the clinical interview and HQ	-

<p>Scheuch Winkler Index</p>	<p>Socio-economic status (SES) quantified using education, occupation, and net income scores</p>	<p>Points assigned for education, occupation, and income (3.0–21.0); scores categorized into low, medium, and high SES group</p>	<p>Manual scoring based on standardized SWI guidelines</p>	<p>Reflects health disparities and socio-economic influences on health outcomes within German society</p>
<p>Anamnesis (face-to-face interview)</p>	<p>Medical history, hearing loss progression and tinnitus, hearing aid use, and family history were discussed in a structured interview</p>	<p>Data gathered via face-to-face structured interviews conducted by experts at the laboratory</p>	<p>Clinical interview</p>	<p>Interview ensured accuracy and addressed any ambiguities in self-reported HQ responses</p>
<p>Pure Tone Audiometry</p>	<p>Hearing thresholds for air and bone conduction (125–8000 Hz) and Uncomfortable Loudness Levels (UCL) at key frequencies (500, 1000, 2000, 4000 Hz) for both ears separately</p>	<p>Conducted in an acoustically shielded booth using the method of limits (5-dB step size). UCL measured by increasing tone levels in 5-dB steps, with participants indicating when sounds became uncomfortably loud</p>	<p>Siemens Unity II audiometer, Sennheiser HDA200 headphones, RadioEar B71 bone conduction transducer</p>	<p>Tests conducted without Hearing Aids (HA) for standardization</p>

<p>Adaptive Categorical Loudness Scaling</p>	<p>It evaluates subjective loudness perception, particularly diagnosing loudness recruitment in individuals with sensorineural hearing loss.</p>	<p>Stimuli at 1500 and 4000 Hz presented adaptively to each ear; participants rated loudness on an 11-point scale</p>	<p>Sennheiser HDA 200 headphones; lab software for adaptive loudness scaling.</p>	<p>Efficient testing with minimal trials; loudness functions fitted using standard methods; no pretest phase required; also conducted without HA</p>
<p>Göttingen Sentence Test</p>	<p>Sentence matrix test assessing speech recognition thresholds (SRT) in noise using 20 meaningful (3-7 word) sentences</p>	<p>Sentences presented in goenose (matches speech material characteristics); speech level adjusted adaptively to calculate the 50%-SRT.</p>	<p>Free-field loudspeakers in a sound-attenuated cabin; Oldenburg Measurement Applications (OMA) for noise calibration.</p>	<p>Noise set at 65 dB SPL, increased to 80 dB SPL for severe impairments. Conducted without HA</p>
<p>Digit Triplet Test</p>	<p>Speech-in-noise test using a list of 27 digit triplets to measure SRT</p>	<p>Participants heard digit triplets in background noise, with speech levels adjusted adaptively to determine the 50%-SRT.</p>	<p>Free-field loudspeakers in a sound-attenuated cabin; Oldenburg Measurement Applications (OMA) for noise calibration.</p>	<p>Noise set at 65 dB SPL, increased to 80 dB SPL for severe impairments. Conducted without HA</p>

<p>Dementia Detection Test (DemTect)</p>	<p>Screening tool for detecting mild cognitive impairment and dementia, assessing immediate and delayed recall of verbal information, working memory, language and number processing, and executive functioning</p>	<p>Five subtests: Word List, Number Conversion, Semantic Fluency, Digit Span, and Delayed Recall. Age-based scoring adjustments applied for people over 60 years</p>	<p>Administered manually by experts in the laboratory</p>	<p>Highly sensitive for detecting MCI. Tests conducted with HA for regular users. Reliable across test-retest scenarios</p>
<p>Vocabulary Size Test (Wortschatztest; WST)</p>	<p>Proxy for crystallized intelligence, assessing verbal intelligence and language comprehension, with applications in dementia tracking</p>	<p>Participants identified real words among five similar non-words across 40 word recognition tasks of increasing difficulty</p>	<p>Administered manually by experts in the laboratory</p>	<p>High reliability ($r = 0.95$); results correlate with education and vocational qualifications but are largely age-independent. Normed for ages 20–90 years</p>
