# A Comprehensive Methodology for Image Recognition Utilizing Machine Learning and Computer Vision: Automation of the Harvesting Process

Abstract: This study aims to investigate the machine learning techniques implemented in image recognition technology for the identification and classification of oil palm fruit ripeness. The accurate determination of fruit ripeness is crucial for optimizing harvest time and improving oil yield. The palm oil industry is one of the major plantations in Malaysia. The harvesting process of oil palm fruit was conducted with traditional methods by relying on manual inspection, which can be subjective and inconsistent. Plus, it required several workers. A model of image recognition was developed using machine learning algorithms and computer vision to automate the harvesting process and overcome the shortage of labor issues. Implementing this technology in the field could lead to more consistent harvests and higher-quality oil production. Several machine learning models were developed, trained, and tested for their ability to classify the ripeness stages. The findings suggest the trending techniques in implementing image recognition which can provide a reliable and efficient tool for assessing oil palm fruit ripeness.

Keywords: Palm Oil Fruit Ripeness Classification, Image Recognition, Machine Learning, Deep Learning

## I. INTRODUCTION

As one of the main sources that can be used as an eating oil, chemical, and energy product, the palm oil industry is no exception to being one of the rapidly growing industries due to the high yield and cost-effectiveness of palm oil compared

to other vegetable oils. The palm oil industry is a global powerhouse, playing a critical role in the agricultural sector and the world economy. Derived from the fruit of the oil palm tree (*Elaeis guineensis*), palm oil is a versatile vegetable oil commonly found in a wide range of products, including food, cosmetics, and biofuels. Malaysia, as the world's second-largest producer and exporter of palm oil after Indonesia, highlights the significant economic impact of this industry on the country [1].

The palm oil industry in Malaysia faces various challenges, including issues related to sustainability, labor practices, and social aspects. Challenges such as unsustainable practices forced labor, and the need for sustainable development to meet international market demands are prevalent [2]. In August 2023, plantations reported a total worker shortage of 41,733, reflecting a 24% decrease since December 2022. This reduction is attributed to the government's deOcision to lift the freeze, permitting plantation companies to hire foreign workers [3].

To maintain the sustainability of this industry, Fourth Industrial Revolution (IR 4.0) technologies like big data analysis and artificial intelligence (AI) may be adopted in the harvesting process of oil palm fruit to increase efficiency and overcome the labor shortage issue. IR 4.0 was first introduced at the Hanover Fair by Germany as a concept that integrates technology-driven manufacturing processes with information and communication technologies, aiming to enhance the country's competitive edge in the manufacturing sector [4]. In the 2024 Budget, the Malaysian government has proposed expanding automation tax incentives to include the plantation commodities sector. This initiative aims to boost productivity and lessen reliance on foreign labor by promoting mechanization and automation [3].

## II. LITERATURE REVIEW

## A. Artificial Intelligence

Artificial intelligence (AI) refers to a machine or computer system's ability to simulate and execute tasks typically requiring human intelligence, including logical reasoning, learning, and problem-solving [5]. Machine algorithms are extensively utilized in areas such as natural language processing, speech recognition, facial recognition, computer vision, and many other prediction systems [6]. Based on [7] reviewing the article, machine learning can be broadly divided into three categories which are supervised learning, unsupervised learning, and reinforcement learning.

## A Comprehensive Methodology for Image Recognition Utilizing Machine Learning and Computer Vision: Automation of the Harvesting Process

Meanwhile, based on the technical analysis article [6], there are additional categories which are semi-supervised learning and deep learning.

- Supervised Learning: this involves training a model with labeled data, allowing it to make predictions or classify new data. This approach applies to both classification and regression tasks.
- Unsupervised Learning: this involves analyzing and interpreting data without labeled examples, to uncover patterns and structures within the data. This approach assists in solving problems like clustering and dimensionality reduction.
- Reinforcement in Learning: this involves learning from feedback received from the environment, allowing machines to autonomously develop optimal strategies for behavior.
- Semi-supervised Learning: this involves training a model with a mix of labeled and unlabeled data. It uses the labeled data for initial guidance and employs the unlabeled data to improve the model's performance.
- Deep Learning: this approach addresses complex, large-scale, and intangible problems. It involves feature extraction and pattern recognition using multi-layer neural networks. It also assists efficiency in data processing and analysis.

Referring to the categories above, image recognition is assumed to fall between unsupervised learning and deep learning. This section reviews the application of machine learning algorithms in the image recognition model using different techniques and tools.

## **B. Image Recognition**

Image recognition and machine learning are closely intertwined, with machine learning playing a pivotal role in advancing image recognition technology. Machine learning techniques are extensively utilized in image recognition tasks such as feature extraction, classification, segmentation, and object recognition [8]. Image recognition and image classification are closely related tasks in the field of computer vision. While image classification involves categorizing images into predefined classes, image recognition goes beyond identifying and interpreting the contents within images, encompassing tasks like object recognition and image analysis [9]. Image recognition is the process of identifying and detecting objects or features within a digital image or video. This can include recognizing objects such as cars and cats, identifying faces, detecting scenes like a beach or cityscape, and understanding activities such as running or jumping. Machine algorithms can learn from and process large volumes of data through deep learning and other technologies, greatly improving the accuracy of image recognition [10].

## C. Oil Palm Fruit Ripeness

The ripeness of palm oil fruit is currently assessed through manual visual inspection by estate workers, which can lead to inconsistent and inaccurate grading of the fruit [11]. The harvesting process of palm fruit involves several steps to ensure the good quality of the product. The Smallholder Oil Palm Handbook, published online by SN International Development Organization and Wageningen University in 2016, stated that there are 9 steps required in harvesting palm fruit and 4 of the steps are significant in identifying the quality of fresh fruit bunch (FFB).

The 4 significant steps are: (1) identifying ripe bunches by visual inspection. Ripe bunches are identified by the presence of loose fruits on the ground or stuck behind frond butts on the trunk, (2) harvesting the bunch by cutting the frond according to the palm age, (3) cutting the bunch stalk and (4) collecting the harvested bunches using wheelbarrow or bicycle with buckets. Human labor is necessary for harvesting and sorting fresh fruit bunches (FFBs), and more workers need to be trained to accommodate the demands of larger plantations or growing industries [12] because it is conducted manually. However, after the pandemic, Malaysia faced a labor shortage crisis due to the slow entry of migrant workers.

Implementation of image recognition to classify the FFBs' ripeness is one of the ways to increase the efficiency of the oil palm fruit harvesting process and overcome the labor shortage issue.

## **III. IMAGE RECOGNITION TECHNIQUES**

## A. Data Pre-processing

Before implementing image recognition techniques, data collected as datasets must undergo data pre-processing. Pre-processing of images is an essential step that significantly impacts the effectiveness of the classifier algorithm [12]. During image pre-processing, the training images were labeled according to their maturity level, and some images were resized to reduce their computational size.

Image acquisition is the term used for collecting raw data, which is the first step in the workflow of image recognition. Images of FFBs were captured using a smartphone camera under sunlight during the study [13]. Capturing images is not restricted to smartphone cameras, it can be sourced from digital cameras, scanners, or other imaging devices.

Image segmentation is the process where an image is partitioned into multiple segments to simplify the image and make it difficult to analyze. The objective of applying segmentation to the image is to identify the variants and boundaries within an image. There are several methods for image segmentation such as thresholding, clustering algorithms, pixel grouping, and others. Image cropped using python and going through image segmentation process. The k-means clustering algorithm is used to segment the image [13]. Image preprocessed using the segmentation method with a threshold (remove background), resizing, and cropping [14]. Background removal is necessary to avoid the model misclassifying the image.

Image augmentation is a technique used to increase the diversity of an image dataset by applying various transformations to the original images. Image augmentation techniques will be implemented to induce variations to the dataset, such as horizontal and vertical flip, rotation, crop, zoom, and shear [15]. Fig. 1 shows the workflow of data pre-processing for image recognition.

[Fig.1: Workflow of Data Pre-Processing] (source: [12, 13])

# **B.** Feature Extraction

This step is crucial in image processing and computer vision as it extracts meaningful information from the image [12]. As shown in Fig. 2, there are a lot of features that can be extracted from an image for example color, texture, edge, size, and more. Hue measurement has shown to be a good discriminator to determine the ripeness stage based on color analysis for oil palm fruits compared to RGB (Red, Green, Blue) technique or CIExy values [13]. Color, texture, and shape features are commonly used to describe and determine the maturity level of FFB [12].

RGB is the common technique for color extraction where it consists of 3 color channels: red, green, and blue [16]. Meanwhile, feature extraction using L\*a\*b must perform color conversion based on L or luminance or brightness values from 0, which means dark or black, to L = 100, which means light or white. The a\* component describes the colors red and green, and the b\* component describes the colors blue and yellow [17].

[Fig.2: Feature Extraction Techniques] (source: [15])

# C. Fruit Ripeness Classification

The Malaysian Palm Oil Board (MPOB) has categorized palm fruit ripeness into four groups: Unripe, underripe, ripe, and overripe (MPOB, 2003). Artificial neural networks (ANN) and convolutional neural networks (CNN) are two types of deep learning methods used in many applications in fruit classification. SG (Savitzky-Golay) filter is one of the preprocessing techniques, which is applied to hyperspectral images to reduce the spectral noises significantly [18].

Previous researchers conclude that the CNN algorithm is more effective in classifying images than the ANN algorithm [19]. ResNet50 is the most popular pre-trained model used for image classification while YOLOv3 is for object detection [11] Genetic Algorithm (GA) is applied to the baseline model to get the optimal learning rate hyperparameter [20]. Based on the [21] study, several variations of the YOLOv4 model are evaluated to compare their performance in the task of FFB detection: YOLOv4-CSP and YOLOv4-tiny.

The images were labeled using "ClassifAI" an open-source data annotation platform. ResNet50 or known as Residual Neural Network is a pre-trained DL model from the ImageNet database that can classify images into 1000 object categories [11]. Both ResNet50 and YOLOv3 used hyperparameters with different numbers of epochs, image size, and batch size.

YOLO (You Only Look Once) is a single-stage object detection model that performs detection in a single pass, starting with YOLOv1 with 24 Convolution layers, improvements in YOLOv2 and YOLOv3 that uses Darknet-19 and Darknet-53 also able to detect 9.000 objects, and lastly YOLOv4 which focuses on improving performance from previous models with some term such as BoS (Bag of Specials) and BoF (Bag of Freebies) [20]. YOLO was first introduced in 2015, then YOLOv2 in 2016, YOLOv3 in 2018, and YOLOv4 in 2020. Table I summarizes the advantages and limitations of the classifier techniques that were used in previous research while Table II shows the classification of FFBs ripeness with different types of machine learning models conducted by previous researchers.

Table 1: List of Advantages and Limitations of	Classifier Techniques
Tuble It List of Hat and ges and Linnautons of	

Classifier techniques	Advantage	Limitation
ResNet50	Used for image classification	The images are sorted into different folders according to their category
YOLO	Used for real-time object detection	The location of the palm oil object needs to be labeled from the image
MobileNetv2	Offers more efficient memory usage for mobile application	Designed for implementation on mobile devices
EfficientDet	Single-shot object detector	Relies on EfficientNet
Support Vector Machine	Find the optimal hyperplane that separates data points of different classes with maximum margin.	Less effective when classes overlap and are not well-separated

Abdulrazak et al., 2020	-	-	Ripe, immature	Color	CNN	96%

#### **Table 2: List of Related Studies Techniques**

#### **IV. MODEL PERFORMANCE EVALUATION**

Performance evaluation is conducted to measure the model's accuracy with no overfitting issue. Commonly, data will be divided into training, testing, and validation. ResNet50 model performance is evaluated based on precision, recall, and F1-score value while YOLOv3 is measured based on mean average precision (mAP). Precision is the number of positive class predictions; recall is the number of correct positive class predictions made of all correct positive cases in the dataset and the F1-score provides a single score that addresses both precision and recall concerns in a single number [21]. K-fold cross-validation is another ML technique used to evaluate the classifier model performance. The k-fold cross-validation aims to select training and testing datasets to have ANN models with higher accuracy [18].

#### V. TOOLS AND FRAMEWORK

Image recognition relies on a combination of tools and frameworks designed to identify and classify objects within images with high accuracy. Key components include deep learning libraries such as TensorFlow, which provide the necessary infrastructure to build and train neural networks. Frameworks like YOLO offer essential image processing functions, enabling tasks like object detection and image transformation [22]. Integration tools like Keras simplify the construction and training of neural networks, making advanced image recognition accessible even to those with limited deep learning expertise. Table III shows a list of the tools and frameworks used in previous studies to implement image recognition. 
 Table 3: List of Tools and Framework for Image

 Recognition

Tool and framework	Functionality
Google Collaboratory	Free cloud-based Jupyter Notebook called Google Collab offers applications for deep
	learning and machine learning. High-level, interpreted programming
Python	language known for its simplicity and readability.
TensorFlow	Open-source ML framework provides a comprehensive, flexible ecosystem of tools, libraries, and community resources.
Keras	Open-source software library that provides a Python interface for artificial neural networks
SoftMax	The mathematical function used in ML for classification tasks within neural networks.
SQLite3	Open-source, serverless, zero-configuration, transactional SQL database engine.
DarkLabel	Annotating images by generating txt files with the same name in the image data.

#### VI. RELATED STUDIES

Other than palm fruit ripeness classification, there are several studies conducted on the classification of different categories of fruits. Apple, orange, banana, and other fruit groups are among the first to be examined for classification. Subsequently, eight categories of fruits were considered, including pomegranate, orange, banana, and five different types of red apples [23]. A CNN model was developed using the stochastic gradient algorithm and Adam optimizer to process the fruit images and classify them.

Published By: Blue Eyes Intelligence Engineering and Sciences Publication (BEIESP) © Copyright: All rights reserved.

The model's accuracy was 96.88% after 40 iterations of training on the dataset.

Another image recognition model was developed using CNN, RNN, and LSTM while the performance was evaluated using SVM and ANFIS [24]. RNN is a recurrent neural network where elements are building an organized association between the node edges. It is a part of ANN. LSTM is long short-term memory where it provides extra memory cells to combine with the RNN to classify the images of the fruits.

#### VII. CONCLUSION

Image recognition model development involves various types of machine learning and deep learning algorithms. The implementation required several techniques to ensure the images captured were interpreted correctly by validating the model's accuracy. Image acquisition, pre-processing, feature extraction, classifier design, and classification decision are the significant steps to conduct image recognition. The current technology that is commonly used in the experiment of image detection is the YOLO framework.

## A Comprehensive Methodology for Image Recognition Utilizing Machine Learning and Computer Vision: Automation of the Harvesting Process

# **AUTHORS PROFILE**

Nadia Adibah Rajab is currently a postgraduate student of a Master's Degree at Universiti Teknologi Malaysia (UTM), Department of Materials Manufacturing and Industrial Engineering. Her research project concerns data analysis for the application of image recognition in the palm plantation industry. She graduated with a Bachelor's

Degree in Computer Science majoring in Software Engineering from the same university. Previously, she worked as a process validation engineer at PharmEng Technology Sdn. Bhd.

Dr. Nor Asmaa Alyaa Nor Azlan is a senior lecturer at Universiti Tektology Malaysia (UTM), specializing in Data Analytics, Data Science, and Industrial Engineering. She serves as the Deputy Head of the Industrial and Systems Engineering Research Group (ISERG). She is an Associate Research Fellow at the Automotive

Development Centre (ADC), Institute for Vehicle Systems and Engineering. Previously, she worked as a Machine Learning Engineer at Intel Technology Sdn. Bhd. and as a Procurement Engineer at Honda Malaysia Sdn. Bhd. She holds a PhD in Operations Research (Manufacturing Engineering) from Universiti Teknikal Malaysia Melaka (UTeM), where she also earned her Bachelor's degree in Manufacturing Engineering (Manufacturing Management) and a Master's in Industrial Engineering. Her research focuses on academic-industry collaboration in predictive and prescriptive analytics, machine learning, and deep learning. She is also actively involved in consulting, offering expertise in data science, analytics, and programming language training.

Prof. Dr. Wong Kuan Yew holds a Ph.D. from the University of Birmingham, U.K., and is currently a Professor at Universiti Teknologi Malaysia (UTM), Skudai, where he leads the Industrial and Systems Engineering Research Group (ISERG). He is also a Chartered Engineer and a Fellow of the British Computer

Society. His expertise spans multiple fields: knowledge management, supply chain management, manufacturing, genetic algorithms, data envelopment analysis, and sustainability. Additionally, his work focuses on mathematical optimization, computer simulation, engineering management, environmental systems, and expert systems, with a notable specialization in ant colony optimization algorithms.

Prof. Ir. Dr. Adi Saptari previously served as a lecturer in the Faculty of Manufacturing Engineering at Universiti Teknikal Malaysia Melaka (UTeM) before transitioning to President University in Bekasi, Indonesia, where he is now part of the Faculty of Engineering. Before his academic career at UTeM, he worked in the Department of

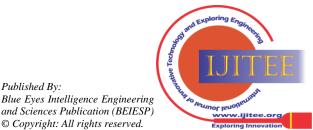

Manufacturing Management focusing on areas such as optimization. (linear and non-linear programming), human factors (ergonomics), and technology management. He holds a Bachelor's degree from the Bandung Institute of Technology, Indonesia, a Master's degree from Ohio University, USA, and a Doctorate from Case Western Reserve University, USA. His areas of expertise include optimization (linear and non-linear), human factors (ergonomics), and technology management.

Prof. Ts. Dr. Effendi Mohamad has been a lecturer at the Faculty of Manufacturing Engineering, Universiti Teknikal Malaysia Melaka (UTeM), since 2005. Before joining academia, he held various engineering roles at NEC Semiconductors Sdn. Bhd., Perodua Sales Sdn. Bhd., and ST Microelectronics Sdn. Bhd., specializing in

industrial and process engineering. He earned his Bachelor's degree in Manufacturing Engineering from the University of Malaya, Kuala Lumpur, and his Master's degree in Manufacturing Management from Coventry University, United Kingdom. He completed his PhD in Intelligent Structures and Mechanics Systems Engineering at the University of Tokushima, Japan. Prof. Effendi has also been a visiting professor and scholar at institutions such as Tokushima University, Japan, and Universitas Brawijaya, Indonesia. Currently, he is a professor at UTeM, actively engaged in research and consulting with various manufacturing organizations.
