TABLES TO FACILITATE THE COMPUTATION OF THE PROBABLE ERRORS OF THE CHIEF CONSTANTS OF SKEW FREQUENCY DISTRIBUTIONS.

By A. RHIND. B.Sc., Biometric Laboratory, University College, London.

THE general theory of the probable errors of the constants of skew frequency distributions was originally given with illustrations by Pearson and Filon, *Phil. Trans.* Vol. 191, A (1898), pp. 229—311. The values there deduced depend on the form of special frequency curve adopted, and involve considerable arithmetical work for each individual case. In these frequency investigations the fundamental constants are the well-known β_1 and β_2. Every frequency character expressible in terms of β_1 and β_2 can have its probable error determined, provided we know the probable errors of β_1 and β_2 and the correlation in deviations between β_1 and β_2. General expressions for the probable errors (or the S.D.'s Σ_{β_1}, Σ_{β_2}) of β_1 and β_2 as well as the correlation $R_{\beta_1\beta_2}$ of deviations in β_1 and β_2, together with the probable error of the criterion (or its S.D. $=\Sigma_K$) were first given by Pearson, *Phil. Trans.* Vol. 198, A (1902). These involve a knowledge of β_6, β_5, β_4 and β_3*, further constants of the distribution which can only be found if the numerical values of μ_5, μ_6, μ_7 and μ_8 have been in some way determined. Now it has been shown that with the total frequencies usual in practice these high moments are subject to very large percentage errors†, rendering their use extremely undesirable, even if we could overcome our natural repugnance to the great labour of calculating them.

But we have to bear in mind that the *exact* value of a probable error is not usually desired. What we more often require is a rough determination of its

---

* $\beta_3=\mu_3\mu_5/\mu_2^4$, $\beta_4=\mu_6/\mu_2^3$, $\beta_5=\mu_7\mu_3/\mu_2^5$, $\beta_6=\mu_8/\mu_2^4$.

magnitude in order that we may appreciate whether a certain quantity is or is not really significant. Accordingly it had been the practice of the Biometric Laboratory, if a frequency was only moderately a-normal, to use the values of the higher β's in determining probable errors, which would flow from the assumption of normality; if on the other hand the distribution had values of β_1 and $\beta_2 - 3$ differing a good deal from zero, to assume that the higher moments might be obtained from a skew distribution of Type III. (i.e. a distribution for which $2\beta_2 - 3\beta_1 - 6 = 0$). The justification of such hypotheses lies in the fact that if our data are to be of much value, the probable errors must themselves be small, hence in calculating these errors it is legitimate to insert into the formulae for them values for the β's that only differ from their true values by small quantities. Such insertion can only introduce second order, and therefore for our purposes usually unimportant, changes in the probable error. This point is emphasised when we remember the large percentage errors of the high β's. For example, it is usual to take the probable error of a standard deviation $\sigma = \cdot 67449\, \sigma/\sqrt{2n}$, but its true value $= \cdot 67449 \dfrac{\sigma}{\sqrt{2n}} (1 + \frac{1}{2}\eta)^{\frac{1}{2}}$; the former really results from assuming the kurtosis, $\eta = \beta_2 - 3$, to have the value zero of the normal curve. There are very few arguments made from probable error which would be seriously affected if the probable error were altered by 25 per cent. of its value, or if η took values from $-\cdot 875$ to $1\cdot 125$, i.e. we might give β_2 any value between $2\cdot 125$ and $4\cdot 125$ to get in practice a sufficiently close result.

Now the object of the present paper is to extend this idea by applying a method of determining β_3, β_4, β_5 and β_6 still more exact than the methods indicated above. It is well-known that the frequency curves in common use are deduced from the integral of

$$\frac{1}{y}\frac{dy}{dx} = \frac{ax+b}{c_0 + c_1 x + c_2 x^2},$$

and that this really assumes the condition that the coefficients of higher terms in the denominator on the right, e.g. c_3, c_4, etc., are all zero. These conditions involve a finite difference relation between the successive moments, first published in 1903[*], and enable us to determine any higher moment from the first three μ_2, μ_3 and μ_4. Such a finite difference momental equation actually exists for all probability frequency distributions of the hypergeometrical series type, which cover so wide a range of chance problems.

It is practically impossible to determine in a large percentage of cases whether the higher moments do or do not within their probable errors obey this finite difference relation, for the reason above stated, i.e. the high values of their probable errors. The present tables assume that they do; in other words β_3, β_4,

---

[*] *Biometrika*, Vol. II., p. 281.

β_3 and β_6 are calculated from β_1 and β_2, on the assumption that the values of them obtained from the finite difference momental formula are sufficiently accurate to use in Pearson's formulae for Σ_{β_1}, Σ_{β_2}, $R_{\beta_1\beta_2}$ and Σ_{sk}, etc.

The following are the finite difference β-formulae used:

$$\beta_n\,(\text{even}) = (n+1)\left\{\frac{\beta_{n-1}}{2} + \left(1+\frac{\alpha}{2}\right)\beta_{n-2}\right\}\Big/\left(1-\frac{n-1}{2}\alpha\right),$$

$$\beta_n\,(\text{odd}) = (n+1)\left\{\frac{\beta_1}{2}\beta_{n-1} + \left(1+\frac{\alpha}{2}\right)\beta_{n-2}\right\}\Big/\left(1-\frac{n-1}{2}\alpha\right),$$

where $\alpha = (2\beta_2 - 3\beta_1 - 6)/(\beta_2 - 3)$.

The process of calculation adopted was as follows:

Fundamental values of β_1, β_2 were adopted; these are indicated in Table VI., and the resulting values of β_3, β_4, β_5, β_6 calculated by the above formula were then found to seven figures. These are tabulated to six figures as they may be of service for the determination of other constants as occasion arises.

The values of κ_2 for the different values of β_1 and β_2 being known, it was seen that a very simple diagram would permit of a statistician ascertaining at once from his values of β_1 and β_2 the type of his frequency distribution. In fact this diagram brings out very suggestively the normal curve "point" (G), the Types II., III., V. and VII.* "lines" and the Types I., IV. and VI. "areas" of occurrence. By aid of this diagram and a reasonable consideration of the probable errors of his β_1 and β_2 the statistician can readily determine within what limits he is justified in using any special type of frequency curve for given data.

The following values of analytic constants for the fundamental values were then found $\sqrt{N}\Sigma_{\beta_1}$ (Table I.), $\sqrt{N}\Sigma_{\beta_2}$ (Table II.), $R_{\beta_1\beta_2}$ (Table III.), and intermediate values deduced by interpolation. It is believed that these interpolated values recorded to two places of decimals only are amply sufficient for the practical uses to which these tables will be put.

From these tables were found, again using interpolation, the probable errors of the two chief desired physical constants: (i) *d*, the distance from mean to mode or the modal divergence, and (ii) *Sk*, the skewness of the distribution. In Table IV. we have the values of $\sqrt{N}\,\Sigma_d/\sigma$ and in Table V. the values of $\sqrt{N}\,\Sigma_{sk}$ provided. The actual quantities tabled in Tables I., II., IV. and V. are such that when multiplied by $\cdot67449/\sqrt{N}$ we obtain immediately the required probable errors. The value of this numerical factor can at once, however, be extracted from Winifred Gibson's Tables for computing probable errors†.

---

* It is convenient to call $y = y_0\left(1+\frac{x^2}{a^2}\right)^{-m}$ Type VII., see *Biometrika*, Vol. IV., p. 174.

† *Biometrika*, Vol. IV., p. 385.

In the actual construction of the tables fundamental values of β_1 and β_2 were taken covering the usual range of these quantities in actual practice. The tables are, however, limited by certain considerations, which are not without suggestiveness for theoretical frequency discussions. Along a certain line, indicated in our diagram, β_6 becomes infinite. But this is statistically impossible. Hence, either we never get frequency distributions having such values of β_1 and β_2, or if we do the finite difference moment formula cannot approximate in such cases to the true state of affairs, and we must introduce an additional coefficient c_3 into the denominator of the right-hand side of the fundamental differential equation. The discussion and classification of such curves are now in hand. On the diagram the areas where they are absolutely needful are marked *Heterotypic.*

It is believed that the diagrams and tables now published will prove extremely useful to the biometrician. Having determined his β_1 and β_2, he will be able to see at a glance whether his frequency distribution may be safely treated by the usual types or is heterotypic. If it be one of the usual types, he will know at once how to classify it. Next an examination of Tables I., II., III. and IV., or such examination with a short interpolation, will give him with sufficient practical accuracy the probable errors of β_1, β_2, the modal divergence (d) and the skewness (Sk). Should other and more elaborate probable errors be required, they will be deducible from Tables I., II. and III., or by using Table VI., for all the usually desired constants depend upon the quantities therein tabulated.

The two diagrams represent, (A), a practical working diagram covering the customary range of β_1 and β_2 and, (B), a diagram on a small scale showing the whole nature of the distribution of the type curves from the theoretical standpoint.

The upper part of either diagram is bounded by the line $4\beta_2 - 3\beta_1 = 0$, because it has been shown that β_2 is of necessity $> \frac{3}{4}\beta_1$[*]. The normal curve is represented by a point $\beta_1 = 0$, $\beta_2 = 3$ marked G on the diagram.

The transition Types III. and V. are given by values of β_1, β_2 on the line

$$2\beta_2 - 3\beta_1 - 6 = 0,$$

and on the cubic

$$\beta_1 (\beta_2 + 3)^2 = 4 (4\beta_2 - 3\beta_1)(2\beta_2 - 3\beta_1 - 6),$$

respectively.

Type II. is a particular case of Type I. for $\beta_1 = 0$, and Type VII. a particular case of Type IV. for $\beta_1 = 0$; they are thus represented by portions of the vertical running through the "normal point" G. While the upper boundary of the diagram lies in the U-curve part of Type I., to be discussed below, the lower boundary is fixed by the line $8\beta_2 - 15\beta_1 - 36 = 0$ along which the finite difference moment formula first fails. This matter needs a little consideration.

Asymptote of Cubic
Asymptote of Biquadratic

The equation to Type IV. is

$$y = y_0 \left\{1 + \frac{x^2}{a^2}\right\}^{-\frac{1}{2}(r+2)} e^{-\nu \tan^{-1}(x/a)},$$

with the reduction formula*

$$\mu_{n+1} = \frac{n}{r-n}\left(\frac{a^2\mu_{n-1}}{\cos^2\phi} - 2a\tan\phi\,\mu_n\right),$$

where $\tan\phi = \nu/r$ and $r = 6(\beta_2 - \beta_1 - 1)/(2\beta_2 - 3\beta_1 - 6)$. It is clear that when $r = n$, μ_{n+1} becomes infinite. Now the probable errors of β_1 and β_2 require us to go as far as μ_8. Hence r must be greater than 7 if we are to use this formula, and this gives us at once the limiting line

$$8\beta_2 - 15\beta_1 - 36 = 0.$$

Of course the difference formula would also fail for μ_5, μ_6 or μ_7, if r were equal to 4, 5 or 6. But all the resulting lines lie outside the above line, which is all we need take into account. The failure of the difference formula is easily seen if we remember that

$$\frac{1}{y}\frac{dy}{dx} = \frac{a_0 + a_1 x}{c_0 + c_1 x + c_2 x^2}$$

leads at once for this type to

$$\int_{-\infty}^{+\infty} x^n (a_0 + a_1 x)\, y\, dx = \int_{-\infty}^{+\infty} (c_0 + c_1 x + c_2 x^2)\, x^n\, dy$$

or

$$N(a_0\mu_n + a_1\mu_{n+1}) = -N(c_0 n\mu_{n-1} + c_1(n+1)\mu_n + c_2(n+2)\mu_{n+1})$$
$$+ \left[y(c_0 x^n + c_1 x^{n+1} + c_2 x^{n+2})\right]_{-\infty}^{+\infty}.$$

The difference formula above follows from supposing the term between brackets to vanish at the limits.

But this it will not do unless

$$\left[\frac{x^{n+2}}{(a^2 + x^2)^{\frac{1}{2}(r+2)}}\right]_{x=\infty} = 0,$$

or if a be finite, unless r be $> n$, or to apply present results $r > 7$.

Of course for any real data μ_8 may become large, but it cannot actually become infinite. Fairly good fits—owing to the agreement of the first four moments—may be found even near the line $8\beta_2 - 15\beta_1 - 36 = 0$, but if we want to get the probable errors of β_1 and β_2 in this neighbourhood, it is best to calculate the higher moments and β_3, β_4, β_5 and β_6 from the actual data. Outside this line

---

* See *Biometrika*, Vol. II., p. 281.

we have marked the area as *Heterotypic*, because theoretically we need to introduce further terms into the denominator of our expression, i.e. to use c_3.

We now pass to a consideration of the subtypes of Type I. The equation is[*]

$$y = y_0\left(1 + \frac{x}{a_1}\right)^{m_1}\left(1 - \frac{x}{a_2}\right)^{m_2},$$

where m_1 and m_2 are roots of the quadratic

$$m^2 - m(r-2) + \epsilon - r + 1 = 0$$

and

$$r = 6(\beta_2 - \beta_1 - 1)/(3\beta_1 - 2\beta_2 + 6),$$

$$\epsilon = \frac{r^2}{4 + \frac{1}{4}\beta_1(r+2)^2/(r+1)}.$$

Now m_1 and m_2 will either be both positive or both negative if $\epsilon - r + 1$ is positive, or the curve $\epsilon - r + 1 = 0$ separates the area of J-curves or modeless curves from the area of modal curves (I_1 curves) and the area of anti-modal curves or U-curves.

$\epsilon - r + 1 = 0$ is the biquadratic

$$\beta_1(8\beta_2 - 9\beta_1 - 12)/(4\beta_2 - 3\beta_1) = (10\beta_2 - 12\beta_1 - 18)^2/(\beta_2 + 3)^2.$$

This biquadratic was traced by expressing it in the form:

$$\beta_1 = 4(1 + 2\alpha)^2(2 + \alpha)/(2 + 3\alpha),$$

and then finding β_1 for a series of values of α and determining β_2 from the equation

$$\alpha = (2\beta_2 - 3\beta_1 - 6)/(\beta_2 + 3).$$

Within the loop of the biquadratic all curves are J-curves, and the term "skewness" loses its essential meaning. Within this area, it will be noticed, our tables do not give the probable error of the skewness or of the modal divergence. Above this loop and up to the line $4\beta_2 - 3\beta_1 = 0$, we are in the range of U-curves and the skewness signifies the ratio to the standard deviation of the distance from mean to anti-mode. Below the loop we are in the customary Type I. area with m_1 and m_2 both positive.

Our second Diagram, B, shows what becomes of the biquadratic limiting the J-shaped curves. It first meets the Type III. line, and at this point Type III. curves become J-curves[†] and cease to have a true mode distinct from the asymptote value. The biquadratic then passes into the Type VI. area and Type VI. curves become J-curves beyond this. It never crosses, however, into

---

Type IV. area, for the cubic which bounds Type IV. asymptotes to the vertical line $\beta_1 = 32$, and the biquadratic asymptotes to the vertical line $\beta_1 = 50$ as shown on the diagram.

Of course much of Diagram B extends beyond the values of β_1 and β_2 that we are familiar with in actual frequency distributions. For practical purposes Diagram A drawn to a much larger scale suffices, and guides the statistician to the appropriate type and to the probable errors. Nevertheless Diagram B will indicate many points of much theoretical interest, and serves to show where failure in curve fitting is likely to arise.
