1. MOTIVATION AND BACKGROUND
The Design-Oriented Analysis (D-OA) Paradigm

1A. FETs AND BJTs ARE CCDs
Field-Effect Transistors and Bipolar Junction Transistors are Charge-Controlled Devices
Both can be represented by the same small-signal equivalent circuit model

2. LOW ENTROPY EXPRESSIONS
The Key to D-OA

3. NORMAL AND INVERTED POLES AND ZEROS
How to choose the gain at any frequency as the Reference Gain

4. AN IMPROVED FORMULA FOR QUADRATIC ROOTS
The Conventional Formula suffers from two congenital defects

5. APPROXIMATIONS AND ASSUMPTIONS
How to build Low Entropy Expressions with minimum work

6. PRODUCTS AND SUMS OF FACTORED POLE-ZERO EXPRESSIONS
Doing the Algebra on the Graph

7. THE I/O IT:
The Input/Output Impedance Theorem
How to find them directly from the Gain, thereby saving almost two-thirds of the work

8. NDI AND THE EET:
Null Double Injection and the Extra Element Theorem
How to find the contribution of a particular element to the transfer function

9. THE DT AND THE CT:
The Dissection Theorem and the Chain Theorem
How to find the gain of a multistage amplifier as the product of separately calculated low entropy factors

10. BASIC FEEDBACK
An Improved Formula expresses the closed-loop gain G in terms of only two quantities, the Specification G_∞ and the Loop Gain T

11. NDI AND THE GFT:
Null Double Injection and the General Feedback Theorem
How to identify and include nonidealities in a third quantity, the Null Loop Gain T_n

12. DNTI AND THE 2EET:
Double Null Triple Injection and the Two Extra Element Theorem
A short and easy way to find the poles and zeros of a circuit containing two reactances

13. DNTI AND THE 2GFT:
Double Null Triple Injection and the Two General Feedback Theorem
Why two injected test signals are needed in the general case
