Data set: data base

- Campaign: ground-based Observational Support of the Fermi Gamma-ray Space Telescope @ Steward Observatory.
- Since October 2008.
- Data public at campaign website.
- Over 60 targets and 7900 observations (in 2015).
- This work: 5030 flux calibrated spectrum of 27 objects.

Data set: instrumentation

Steward Observatory

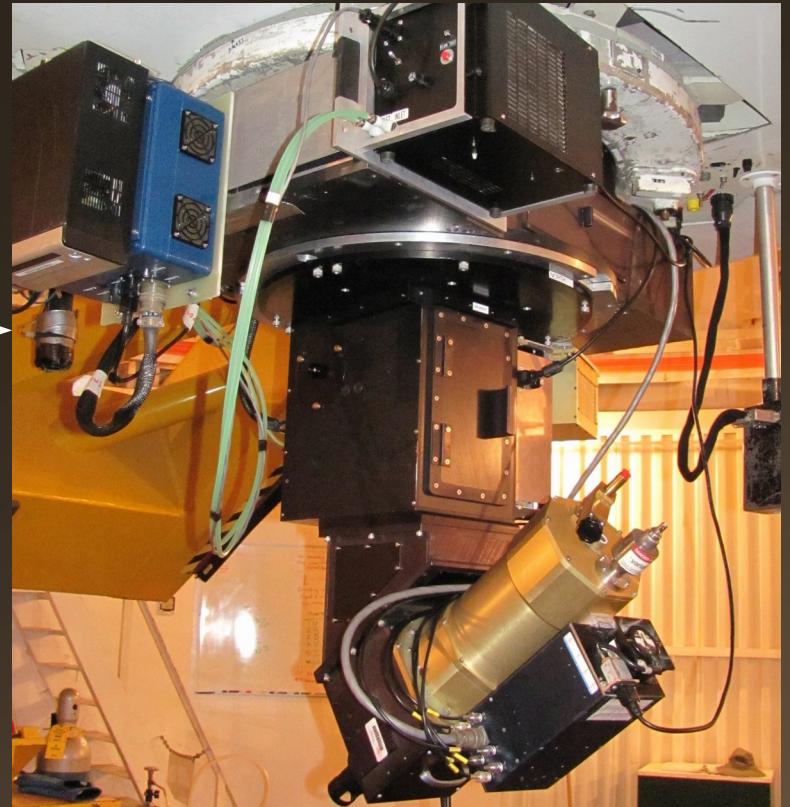

- 2.3m Bok Telescope

- 1.54m Kupier Tel.

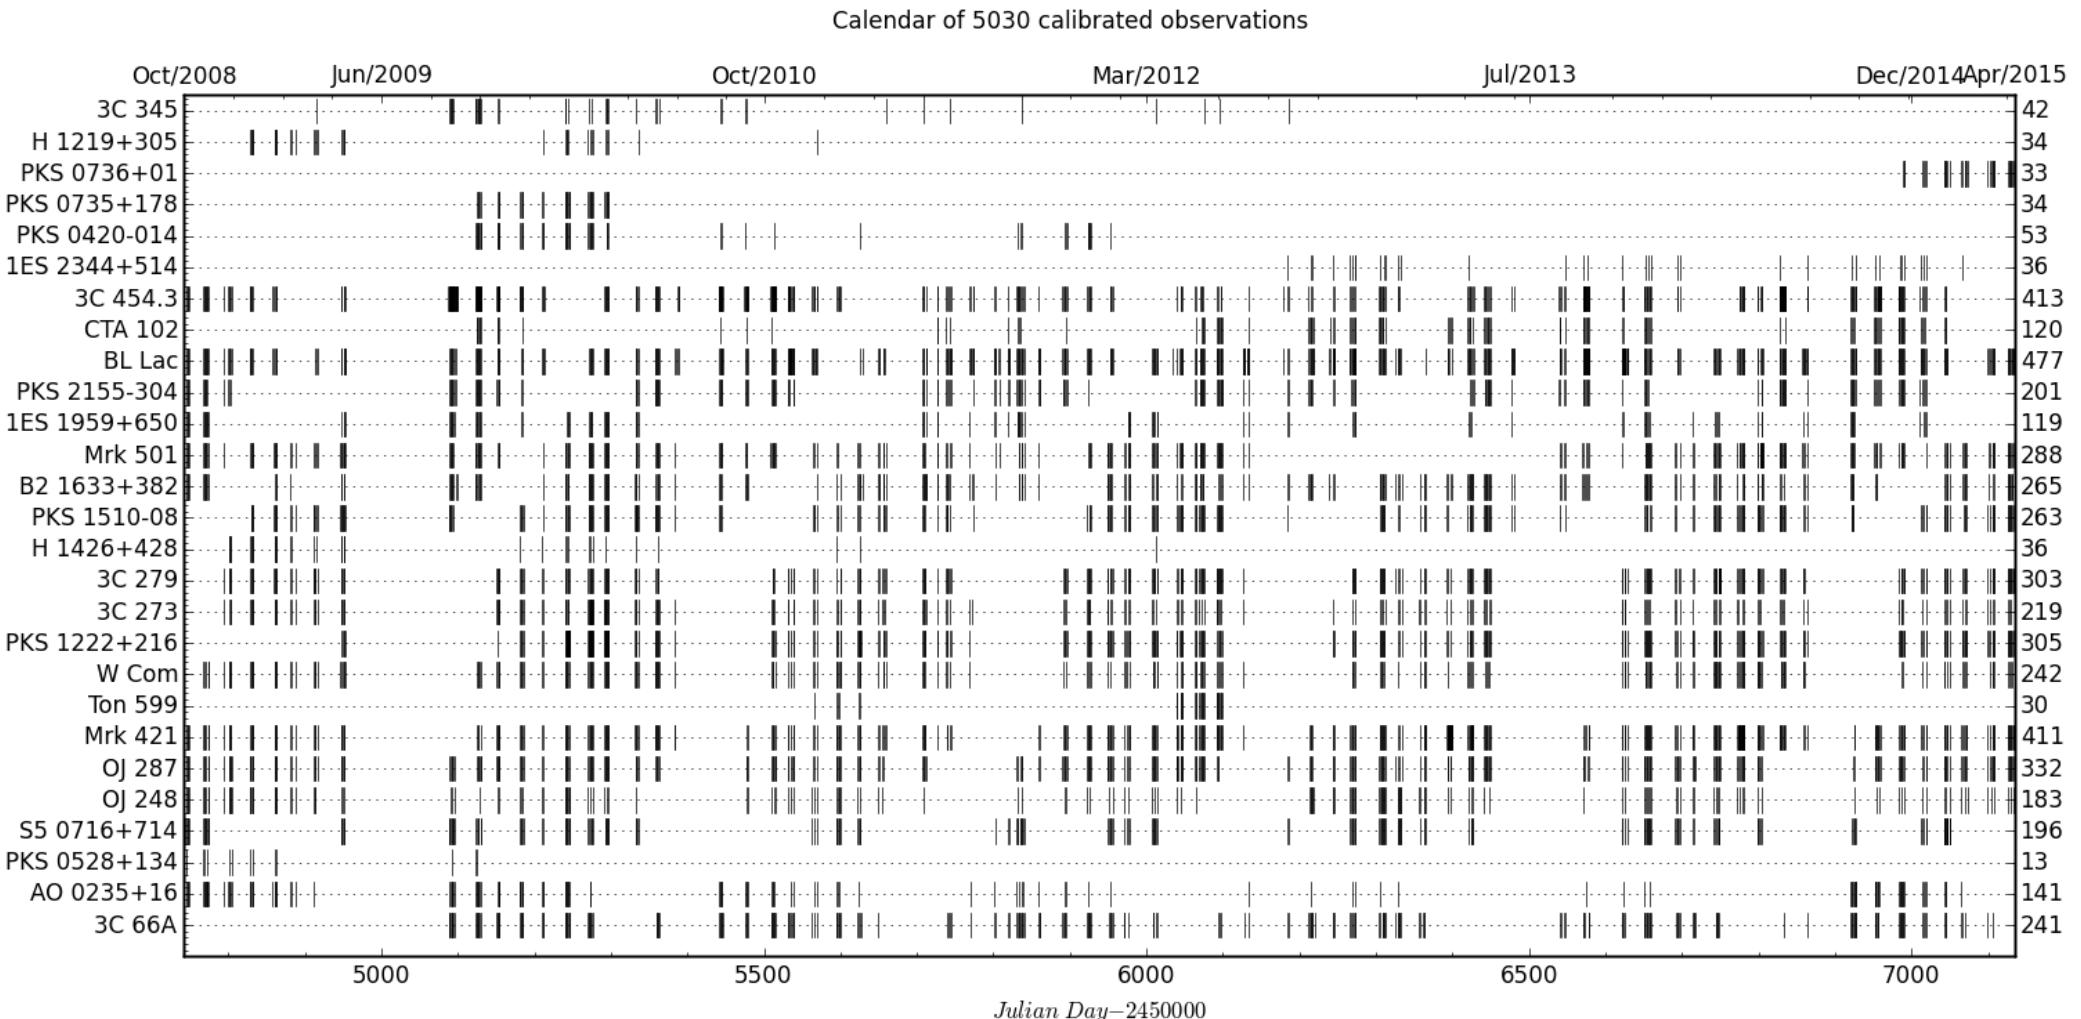

(Smith et al., 2009)

- SPOL Spectropolarimeter
Spectral resolution: 4-15 Å

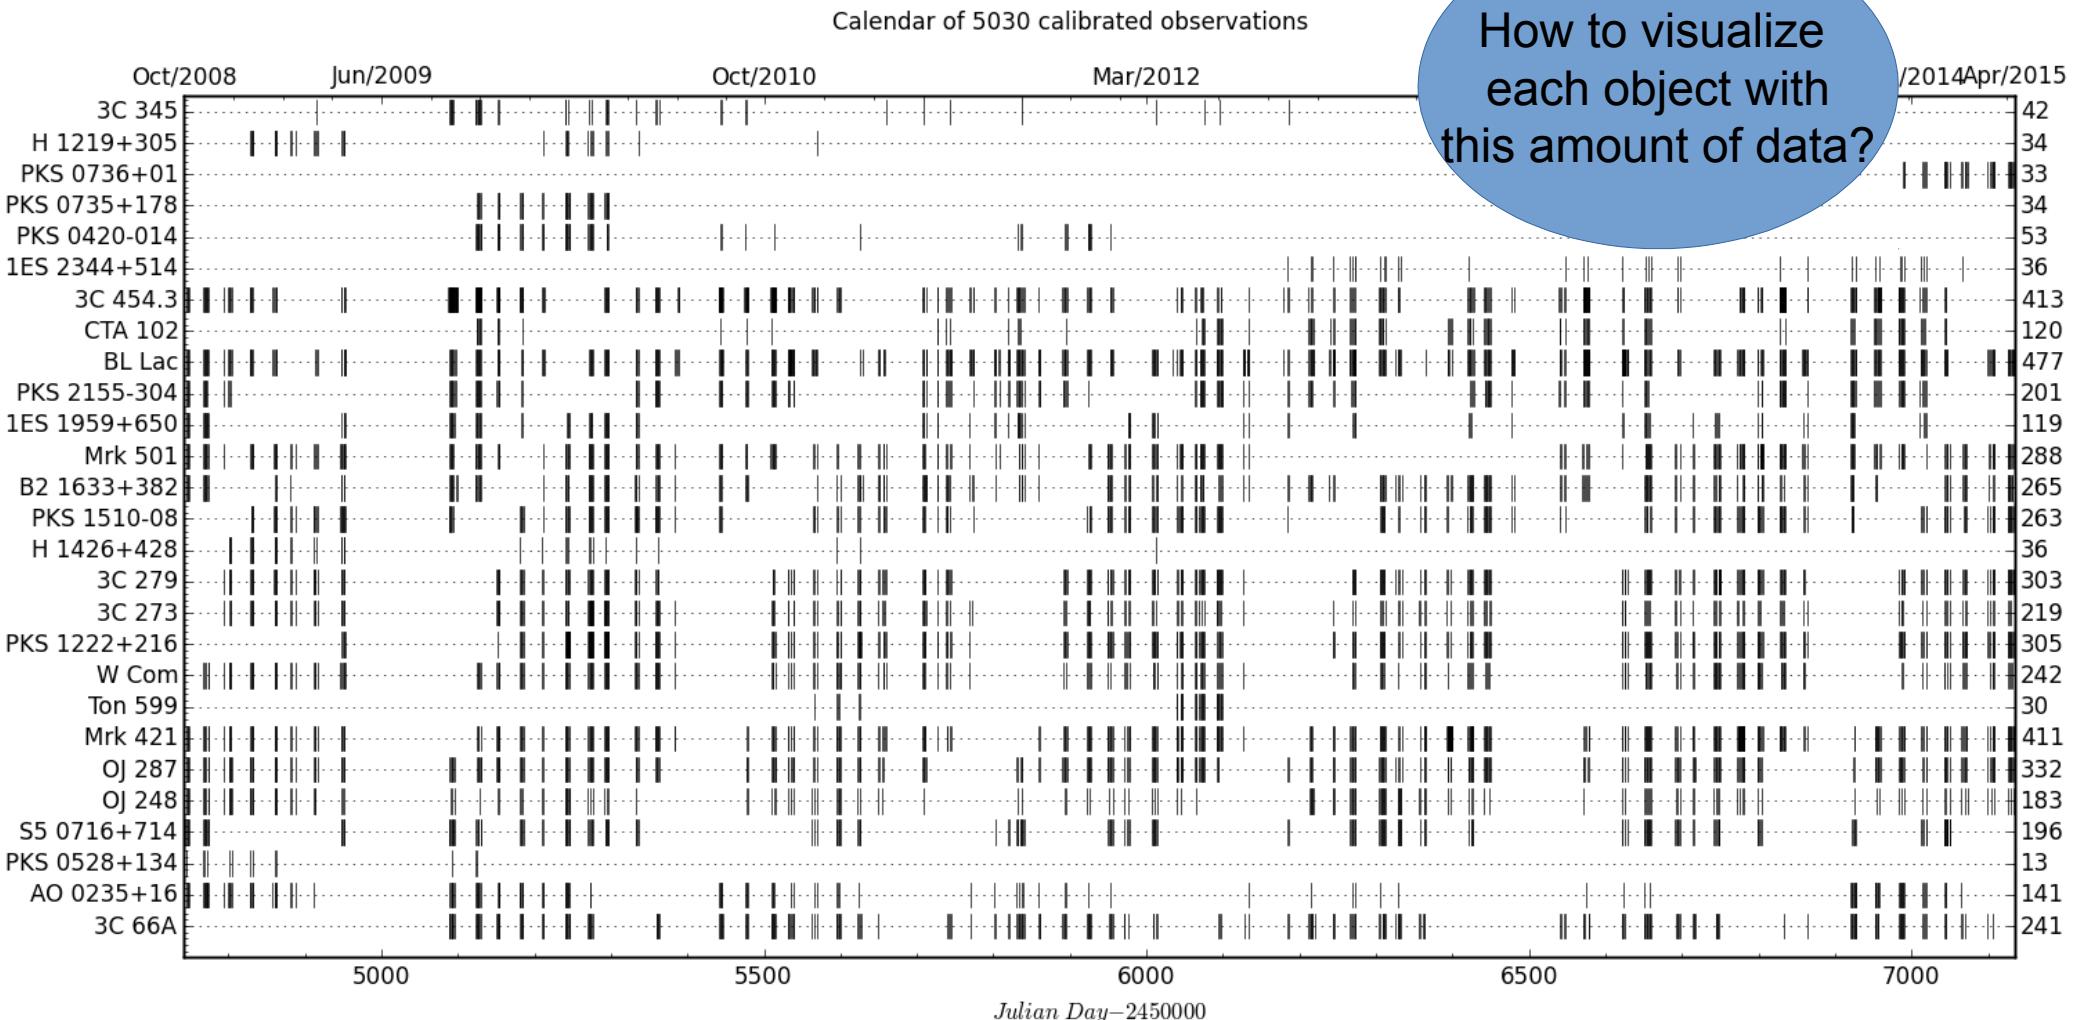

Data set: data base

- Observing Blazars since 2008.

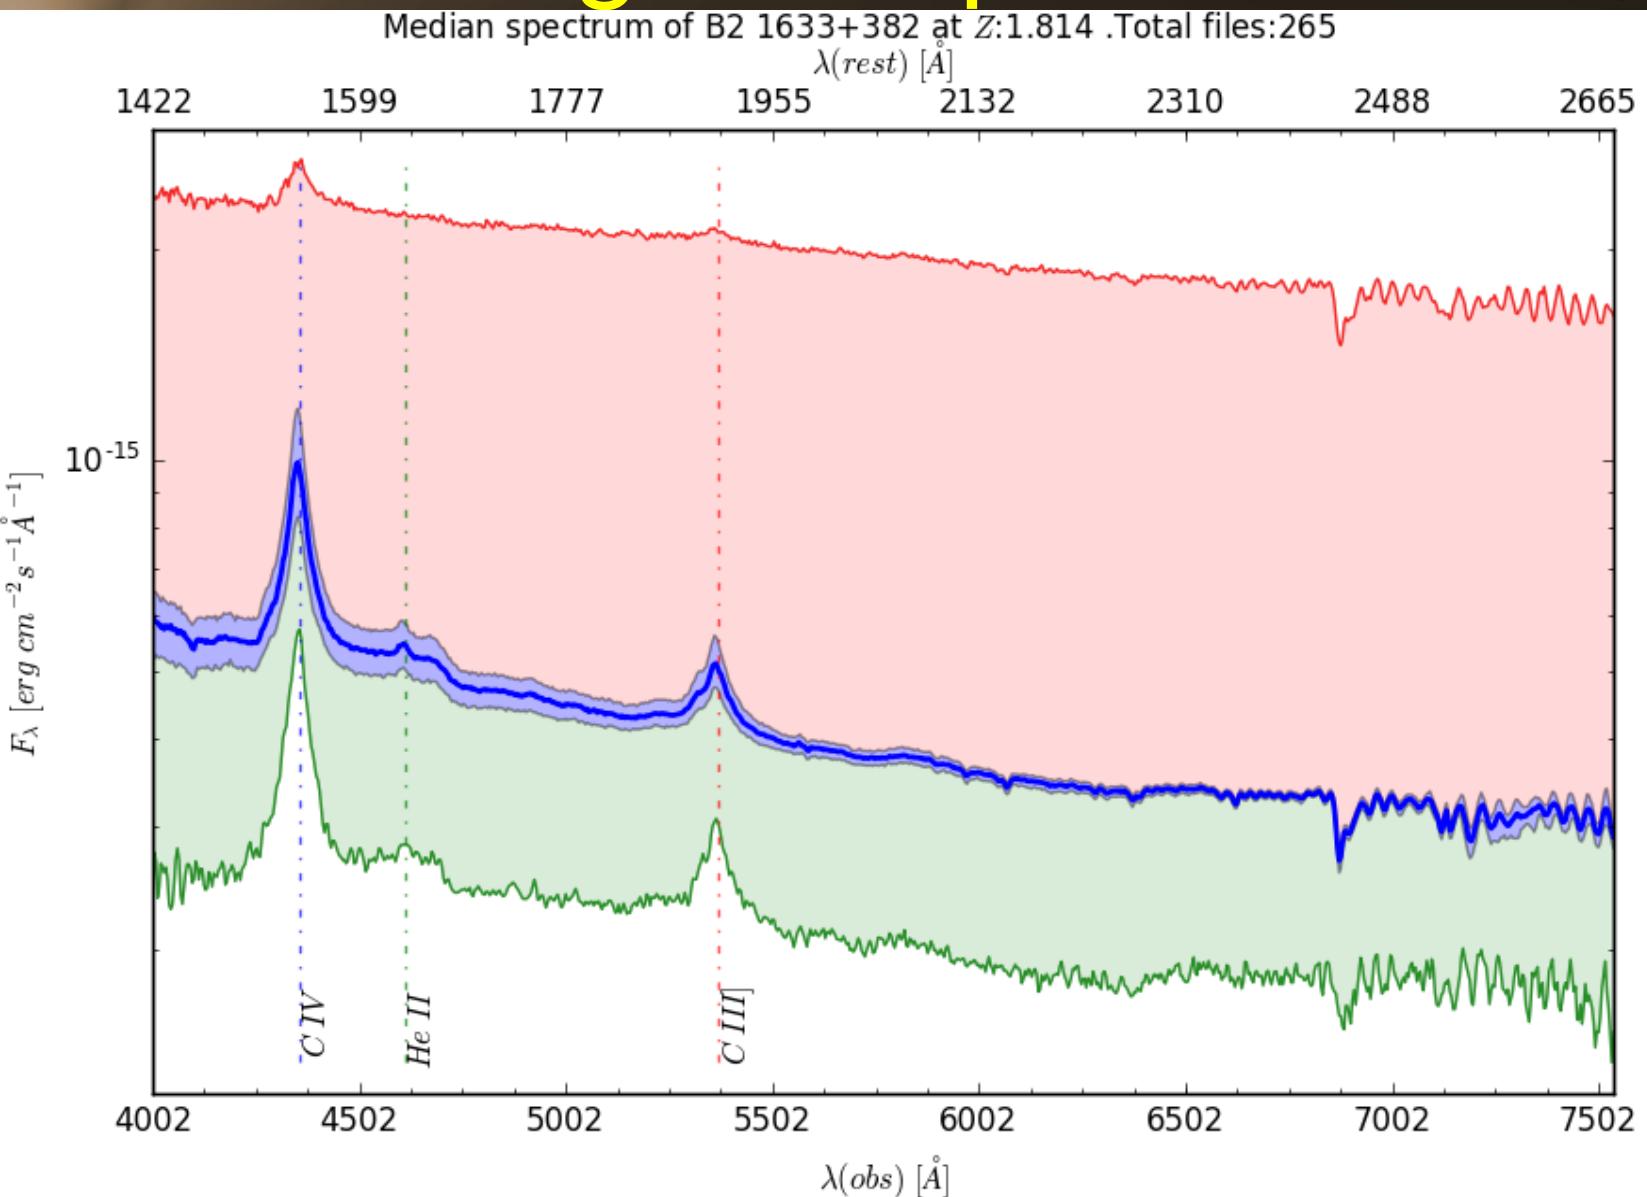

Data set: data base

- Observing Blazars since 2008.

Classification

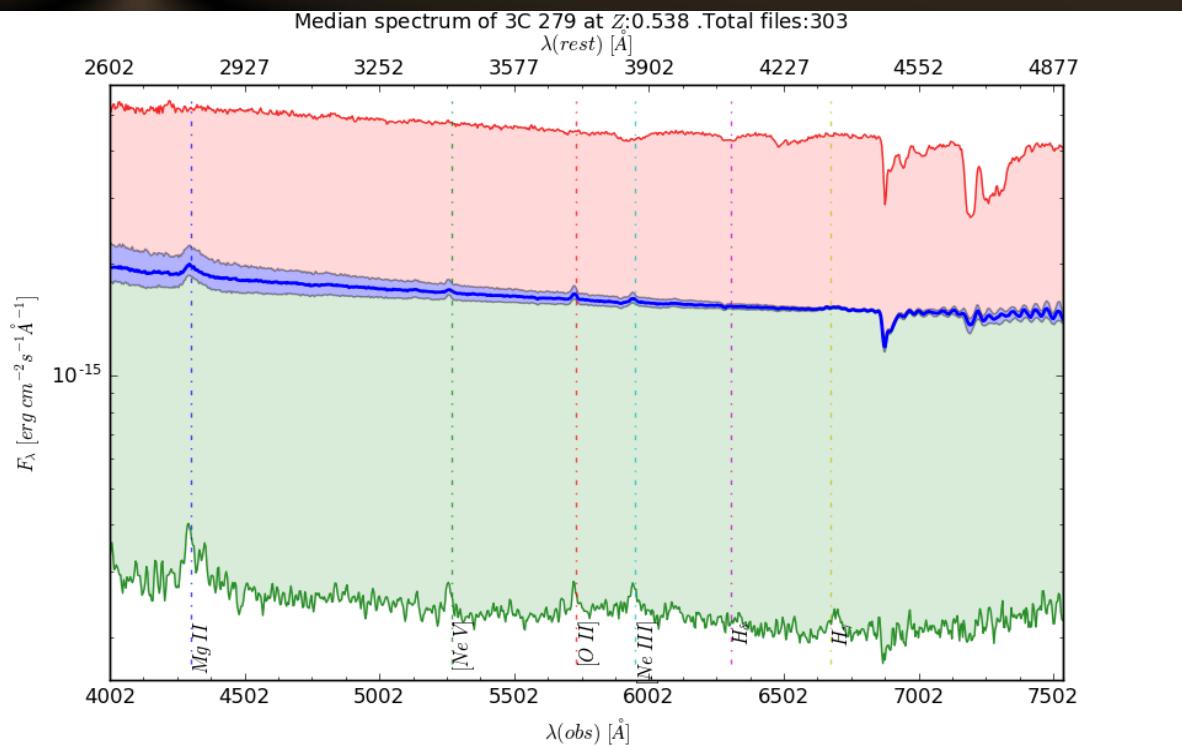

- Traditional Classification: $\text{EW} < 5(1+z)\text{\AA}$
(eg. Stickel et al. 1991; Stocke et al. 1991).
- Spectral shape characterized from median spectrum.
 - BL-Lacertae: no emission lines or $\text{EW}[\text{rest}] < 5\text{\AA}$.
 - FSRQ: prominent emission lines.
 - Stellar population dominated: absorption lines

Classification: BL-Lacertae

Spectroscopic study of Blazars

Outline:

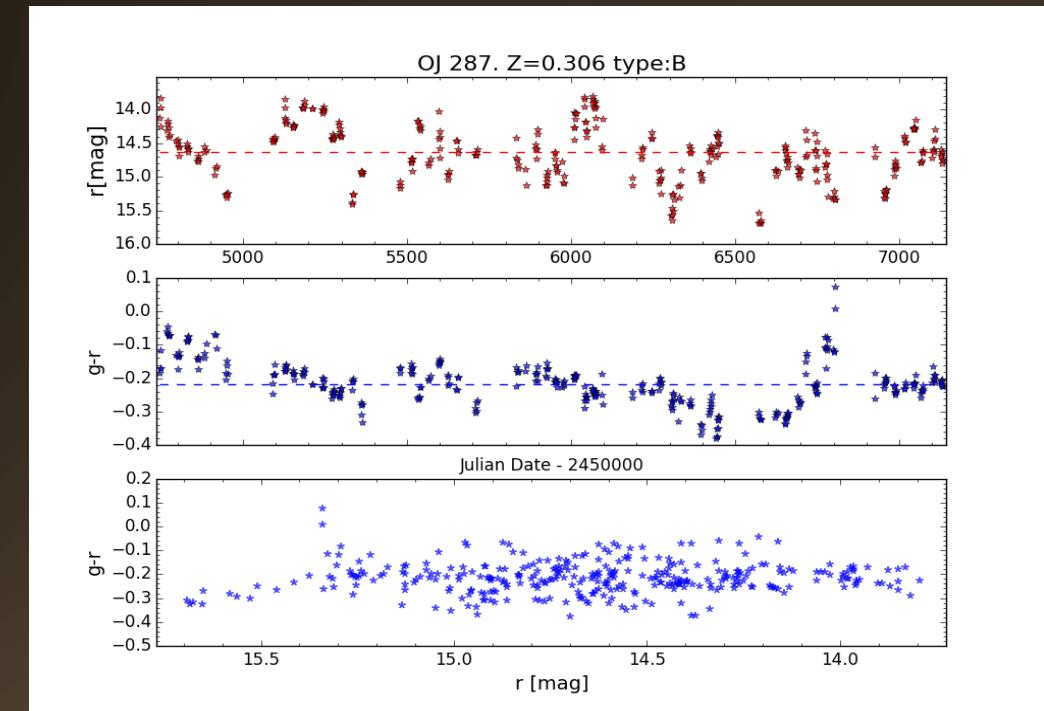

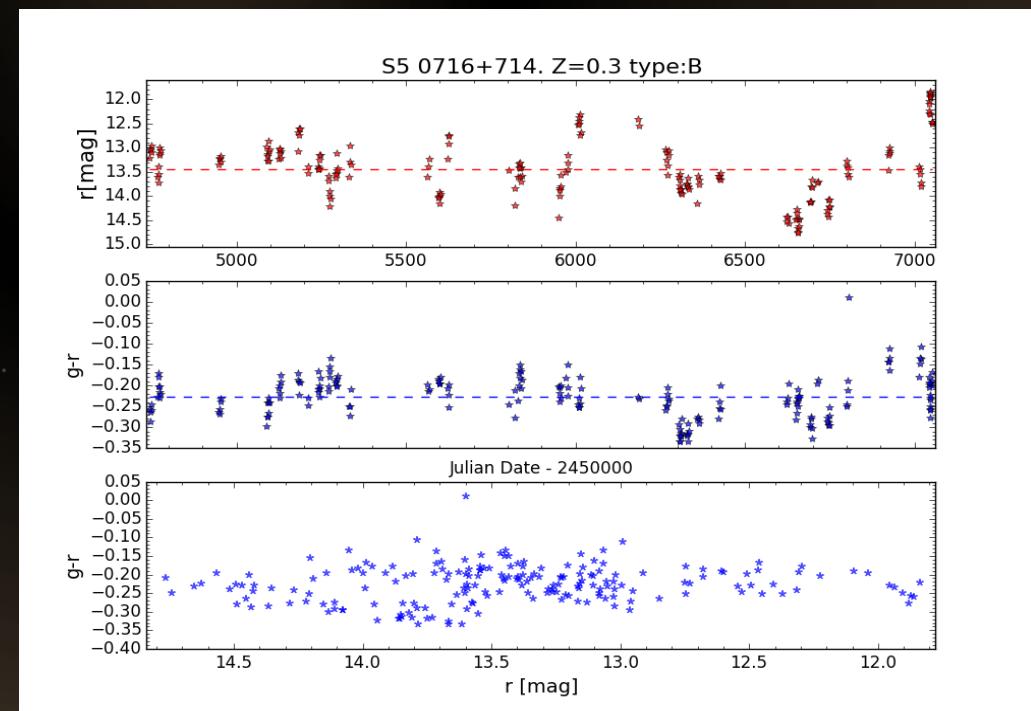

- Introduction
- Data set
- Classification
- Color-magnitude diagrams
- NMF
- Spectral measurements
- Summary of results

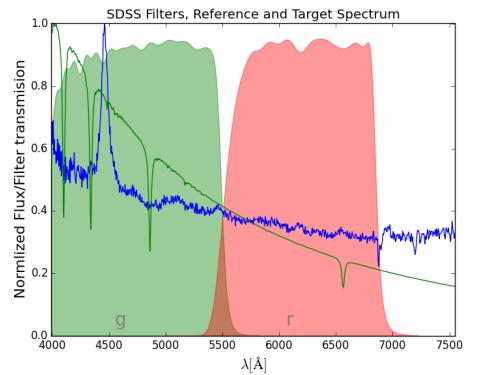

Color-magnitude diagrams

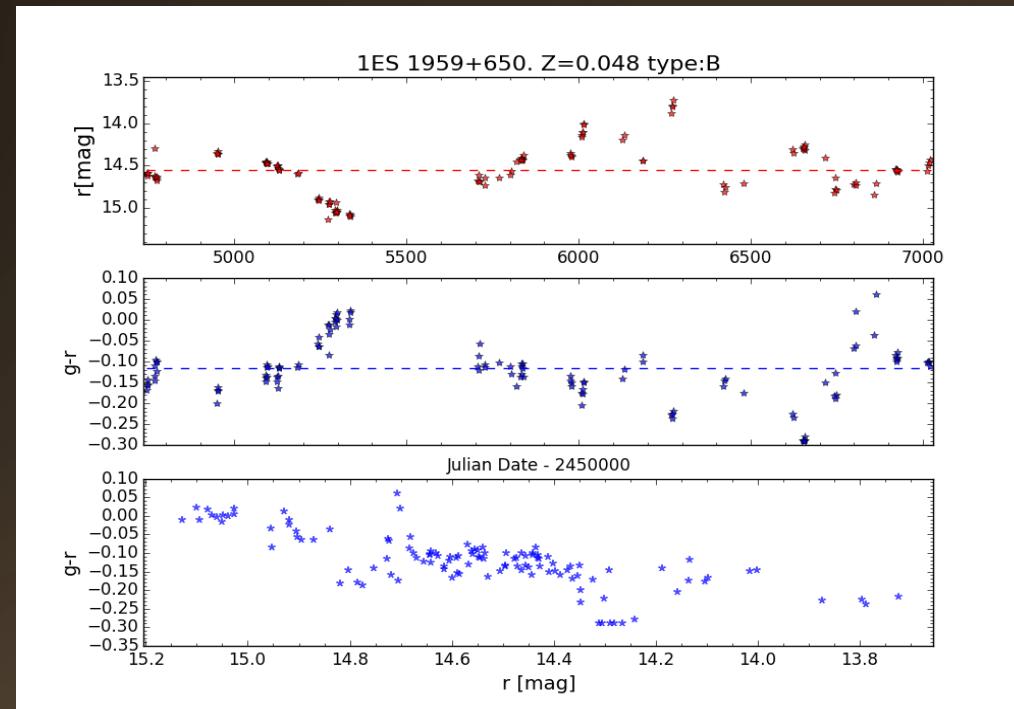

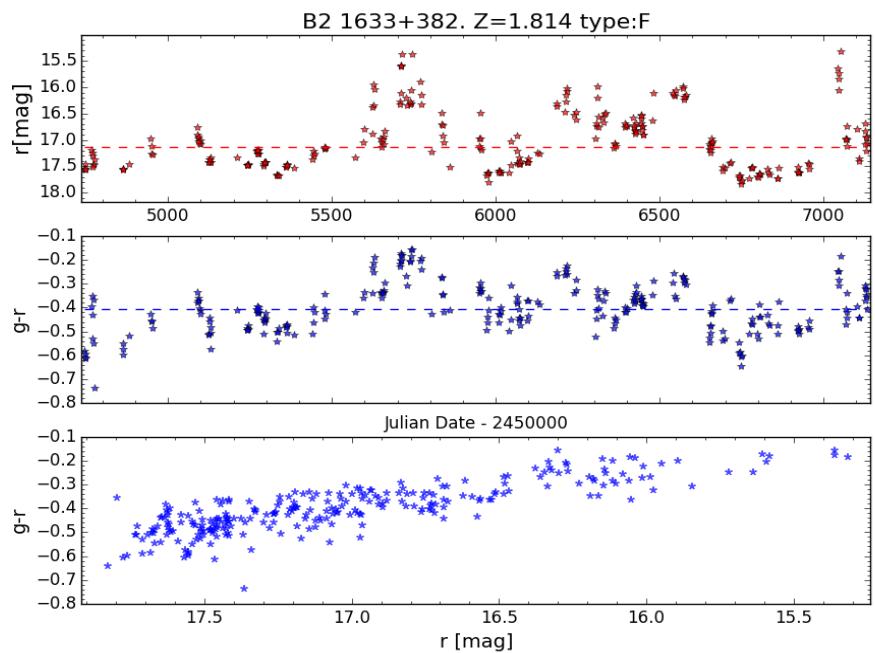

- No Color-magnitude correlation \rightarrow constant spectral shape

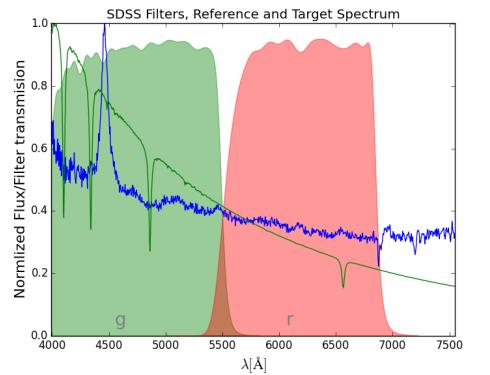

Color-magnitude diagrams

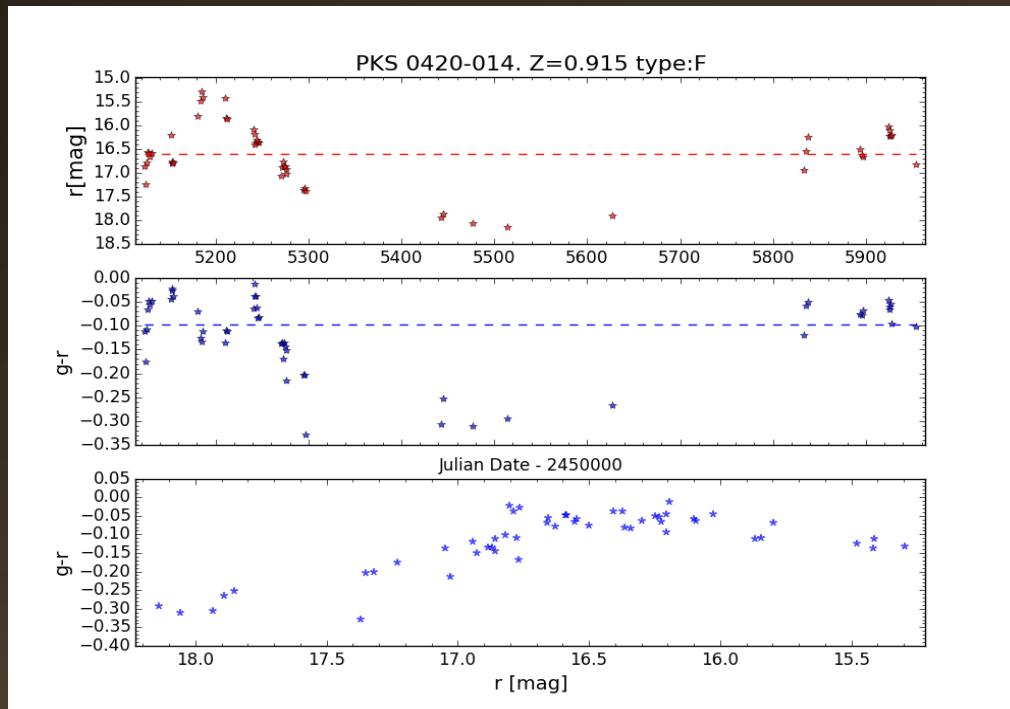

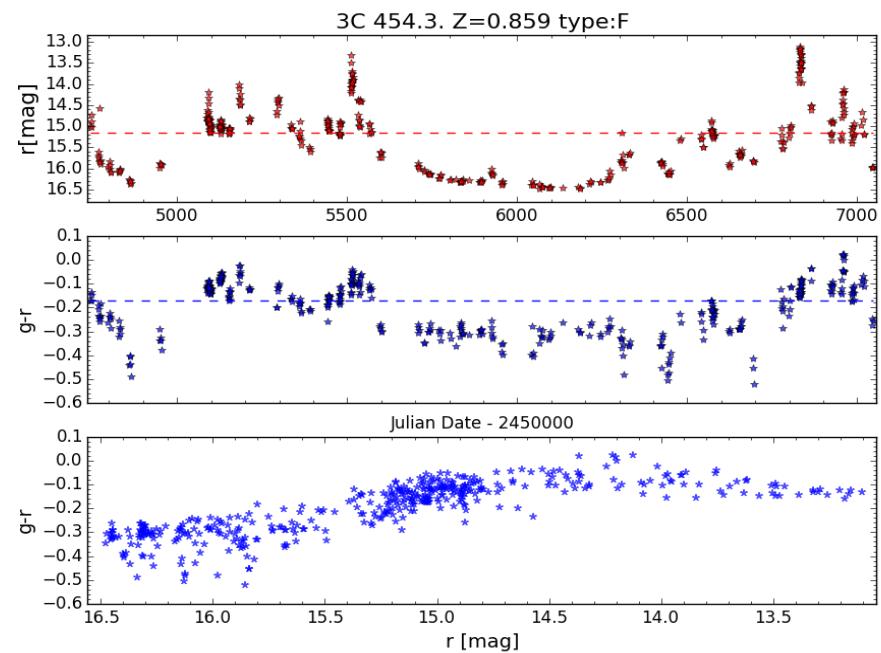

- Color-magnitude correlation → spectral shape variation.

Color-magnitude diagrams

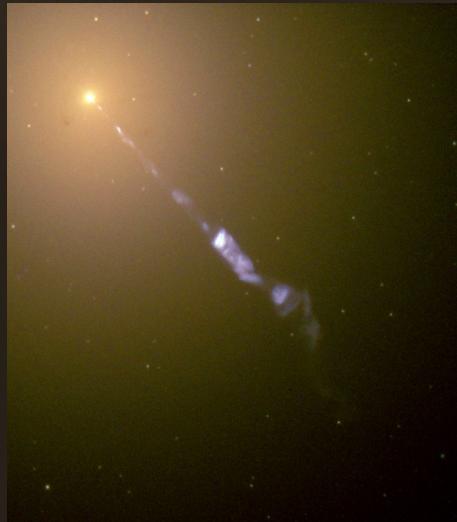

- Color-magnitude correlation
- Inflection magnitude (eg.Raiteri et al., 2012; Villata et al., 2006)

NMF: Non Negative Matrix Factorization (PCA-like)

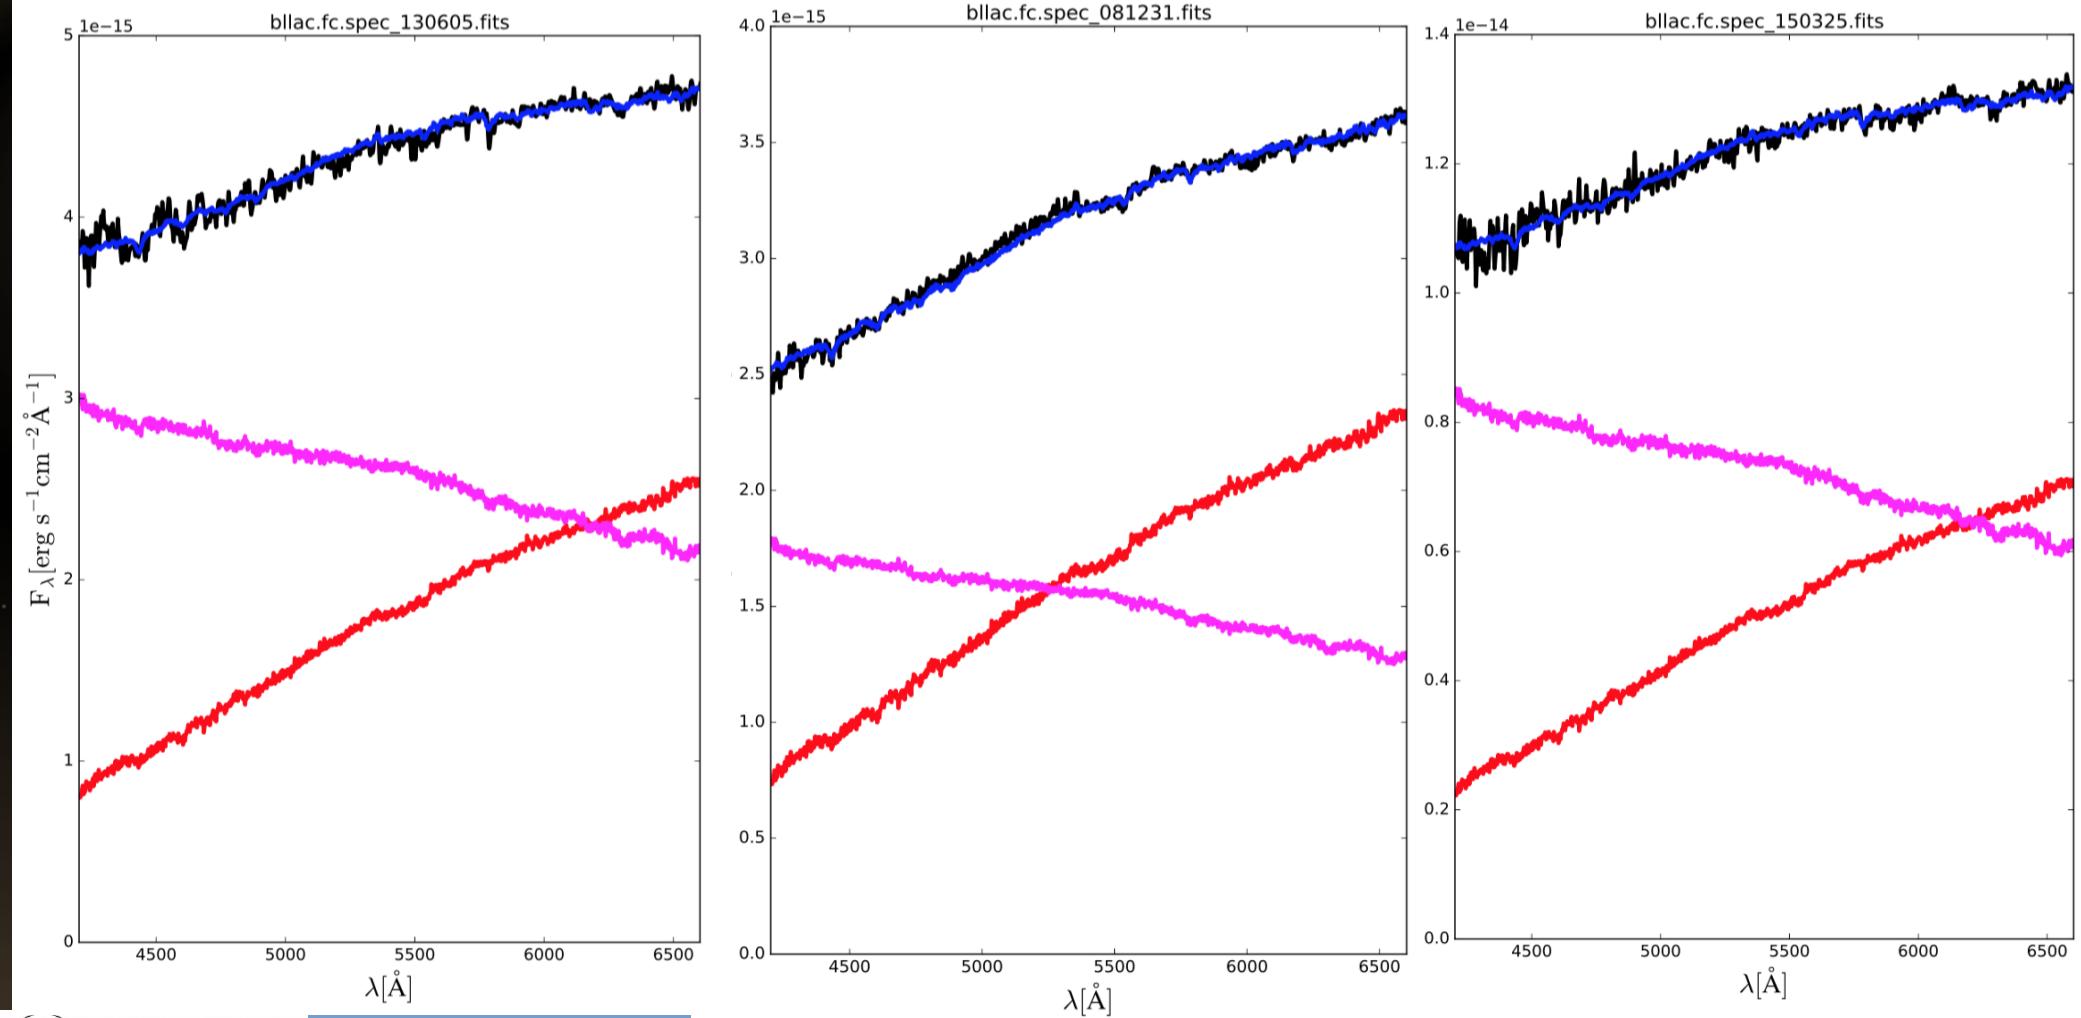

- An objective method for characterize spectral components
- Based in: Jean-P. Brunet, Pablo Tamayo, Todd R. Golub and Jill P. Mesirov. Metagenes and molecular patterns in cancer revealed by non-negative matrix factorization. In Proceedings of the National Academy of Sciences of the USA, 101(12): 4164-4169, 2004.
- Used for genetic correlation
 - Leukemia
 - Medulloblastoma
 - Central Nervous System Tumors

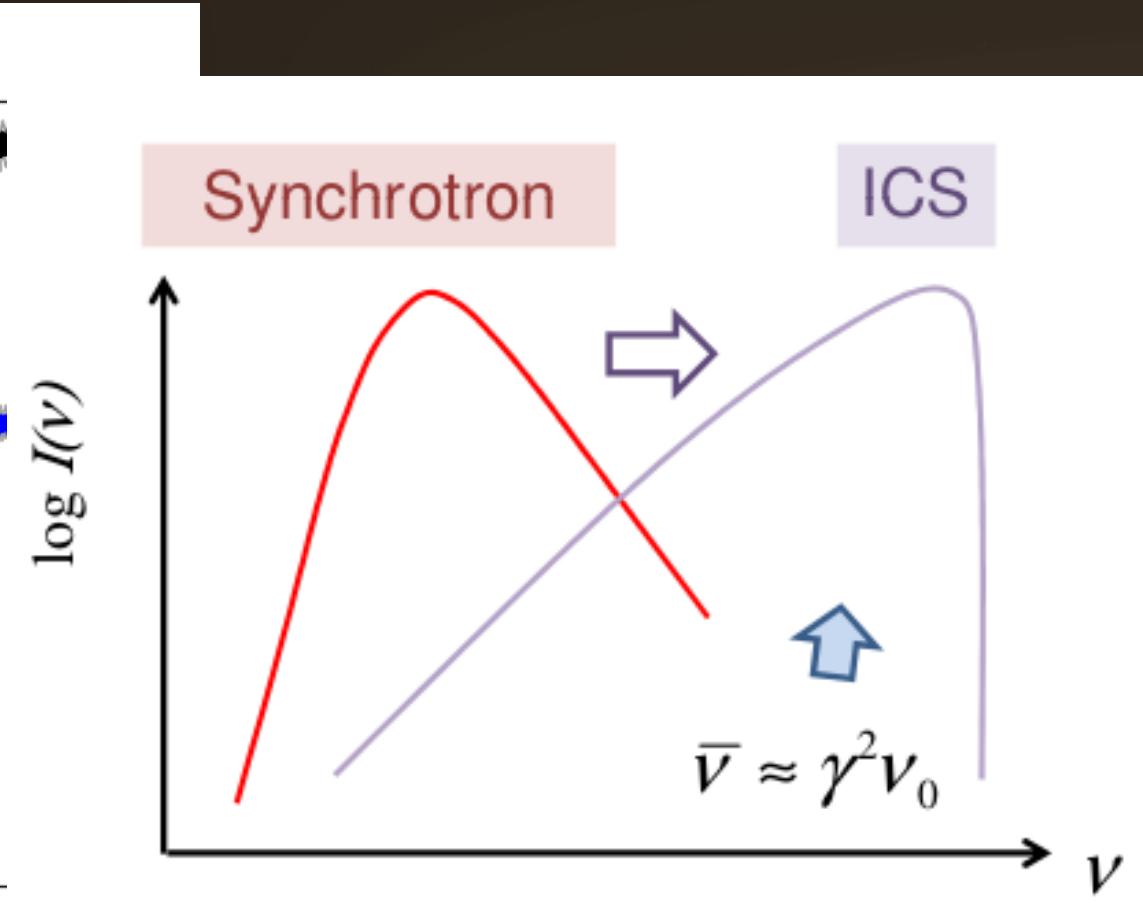

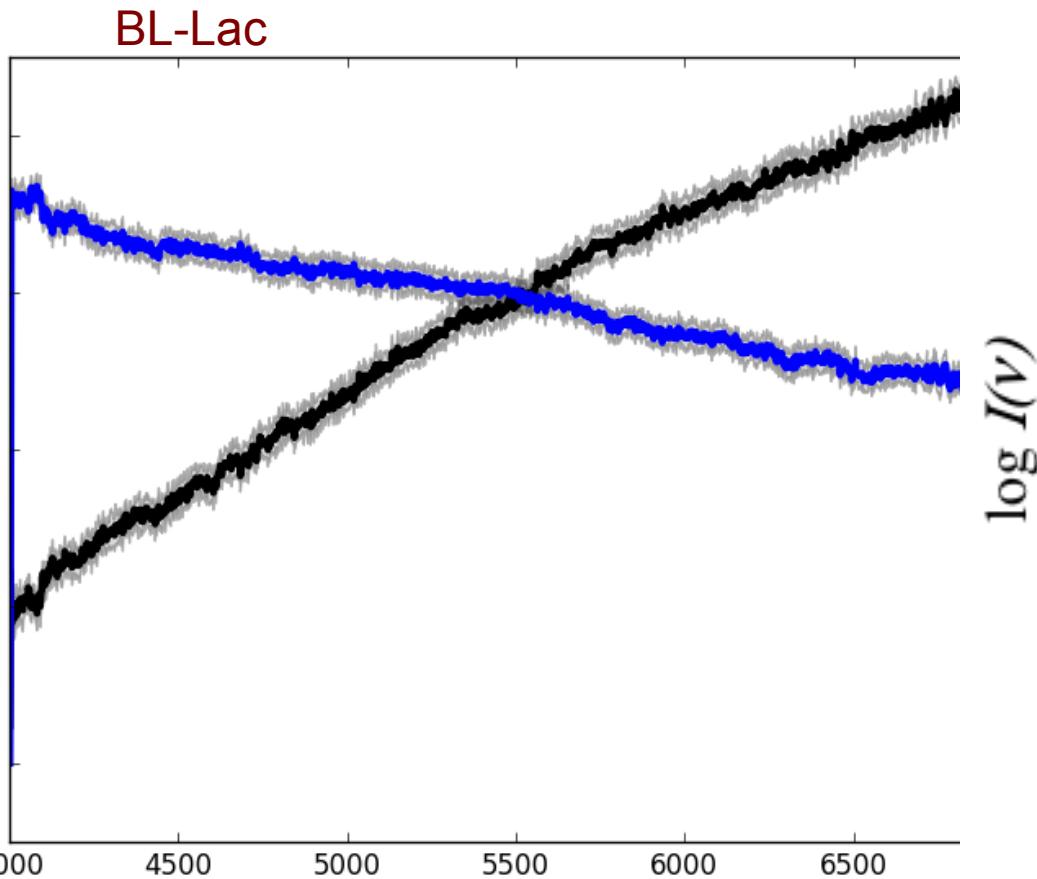

NMF: Non Negative Matrix Factorization

NMF: Non Negative Matrix Factorization

Spectral measurements: Iron template

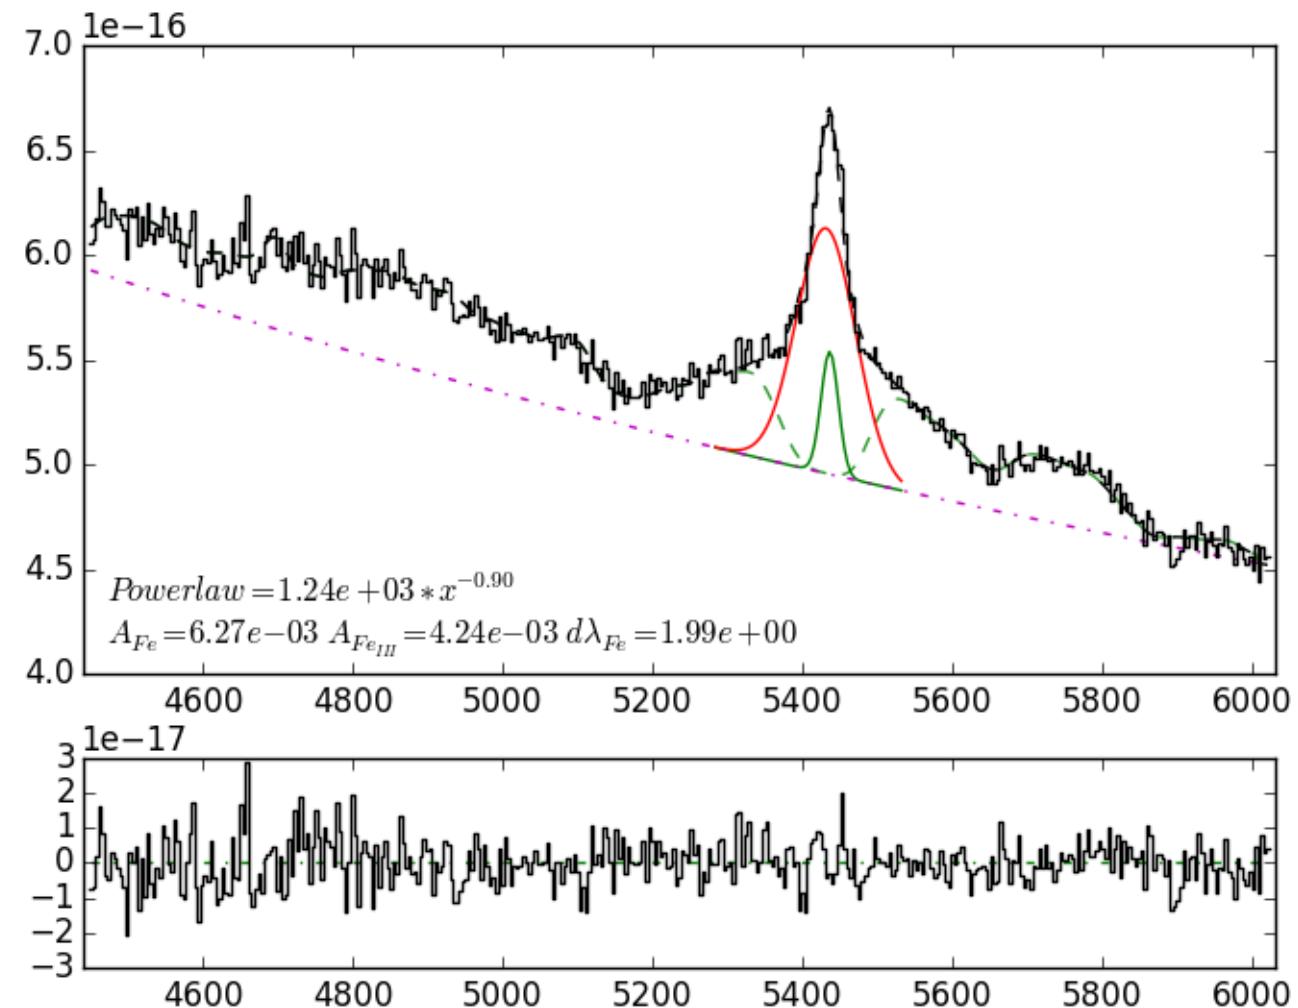

Continuum

+

Iron template

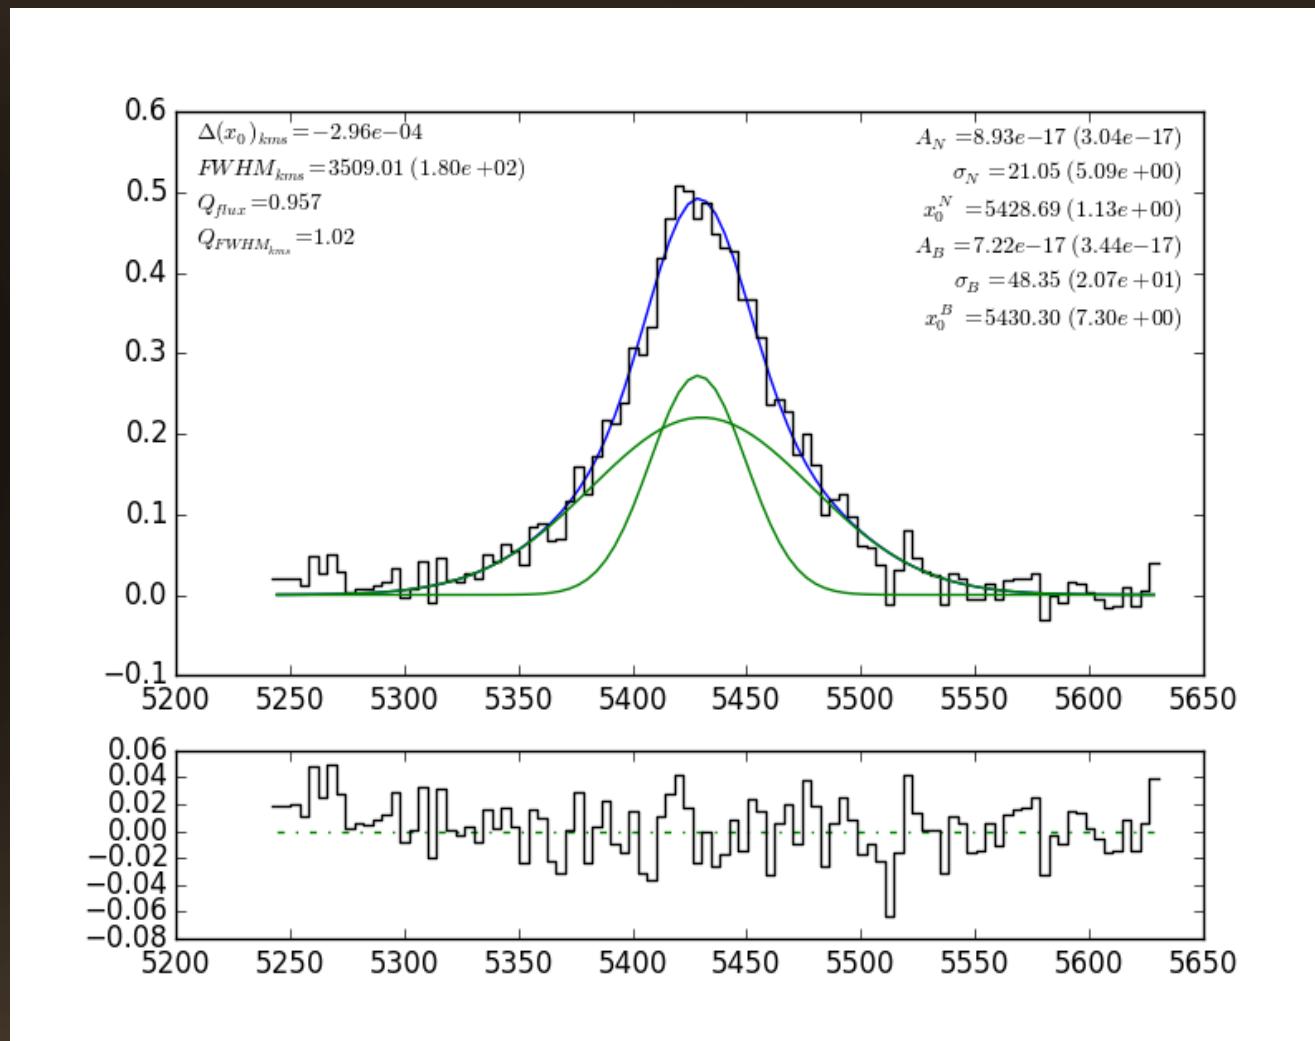

(Vestergaard, M. & Wilkes, B. J. 2001)

Fitted at once

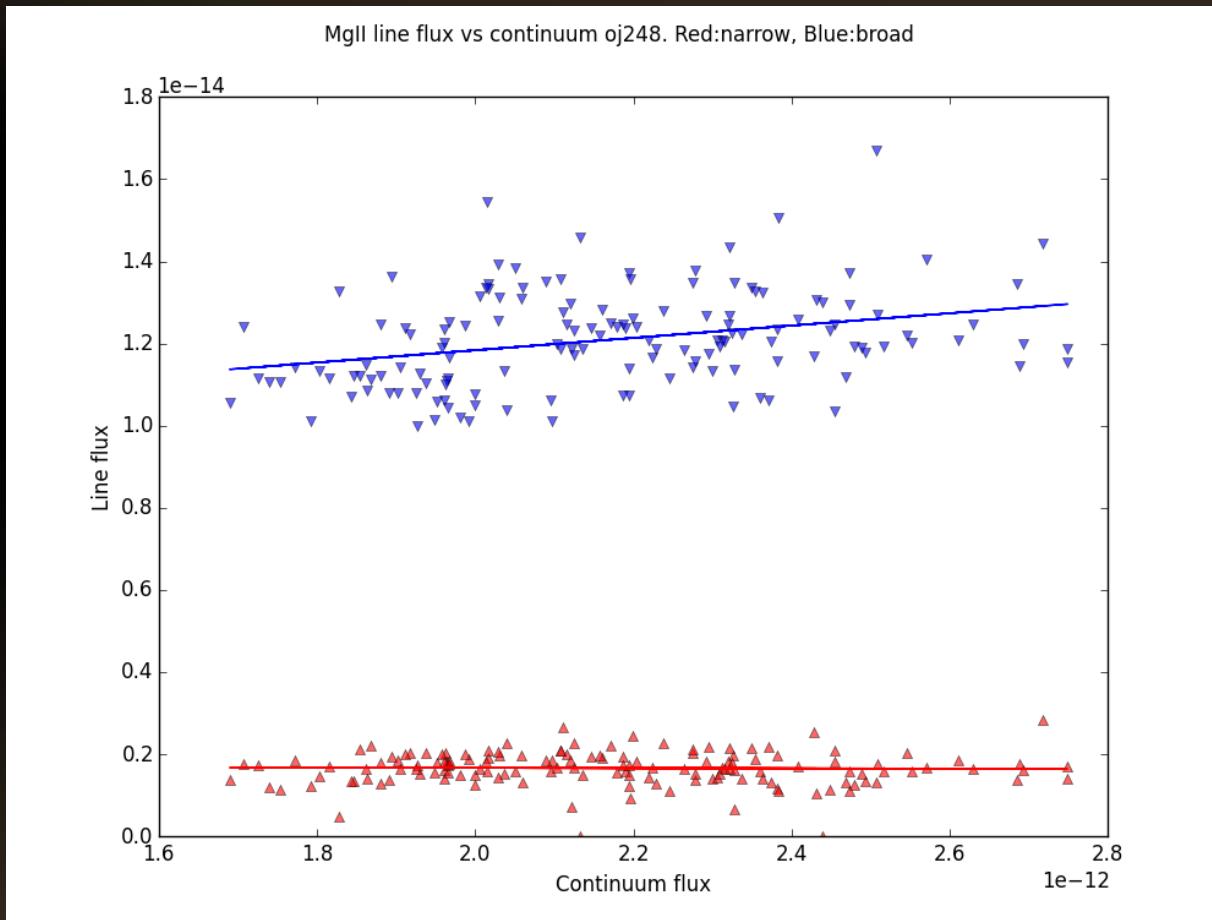

Spectral measurements: Line fit.

- 2 Component modeling + direct measurement.
- Boundary conditions for narrow line: [800, 2000] km/s
(McLure & Dunlop, 2004)
- Noise impact (Monte Carlo)

Results: Correlation broad line – continuum at low activity

Results: BLR size

- Delay in broad line-continuum flux → size.
- Discrete Correlation Function (Edelson & Krolik, 1988).
- No clear correlation was found.
- More observations needed to determine line-continuum delay.
- This technique might be successful with low NTD objects

Black hole mass measurements

$$\log \left(\frac{M_{\bullet,vir}}{M_{\odot}} \right) = a + b \times \log \left(\frac{\lambda L_{\lambda}}{10^{44} erg s^{-1}} \right) + 2 \times \log \left(\frac{FWHM}{km~s^{-1}} \right)$$

- Virial mass estimation.
 - From continuum:
 - (a, b)[cont] = (0.505, 0.62) \leftrightarrow Vestergaard & Osmer, 2009
 - From line luminosity:
$$\lambda L_{\lambda} \rightarrow L_{MgII}$$
 - (a, b)[line] = (1.70, 0.63) \leftrightarrow Shen et al., 2011

Ionizing continuum

- Line luminosity give a non collimated continuum estimation:

$$\log \left(\frac{L_{pred}^{cont}[3000\text{\AA}]}{erg\ s^{-1}} \right) = (1,016 \pm 0,003) \times \log \left(\frac{L_{Mg\ II}}{erg\ s^{-1}} \right) + (1,22 \pm 0,011)$$

Shen et al. (2011) calibration for radio quiet objects

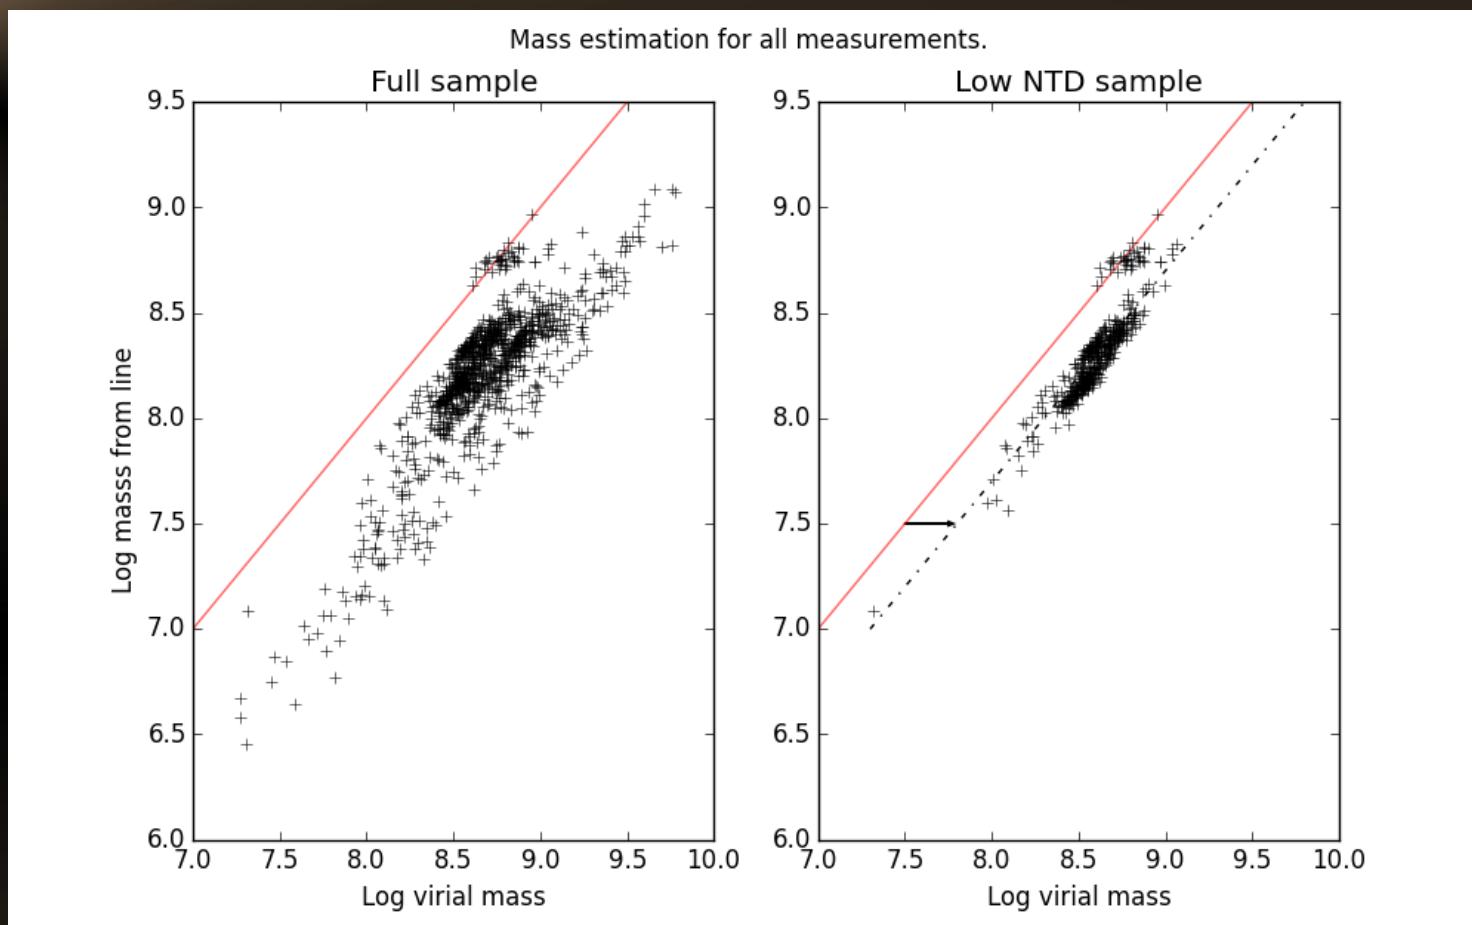

- Non-Thermal Dominance (NTD):

$$L[\text{obs}] / L[\text{pred}]$$

(Shaw et al., 2013)

NTD=1 → Disk luminosity dominated
NTD > 1 → Jet contribution

Results: Black hole mass

Mass from lines underestimated in 0.30 dex.

Results: Accretion rate

- Quasi-isotropic thermal luminosity (Urry & Padovani, 1995)
- Bolometric thermal luminosity: $L[\text{pred}] \rightarrow L[\text{bol}]$

$$L_{\text{bol}}/L_{3000} = 5,15$$

(Richards et al., 2006)

- Virial mass estimation:
 - $L[\text{pred}] \rightarrow (a,b)[\text{cont}] \rightarrow L[\text{Edd}]$

$\langle L[\text{bol}] / L[\text{Edd}] \rangle = 0.4$ for FSRQ

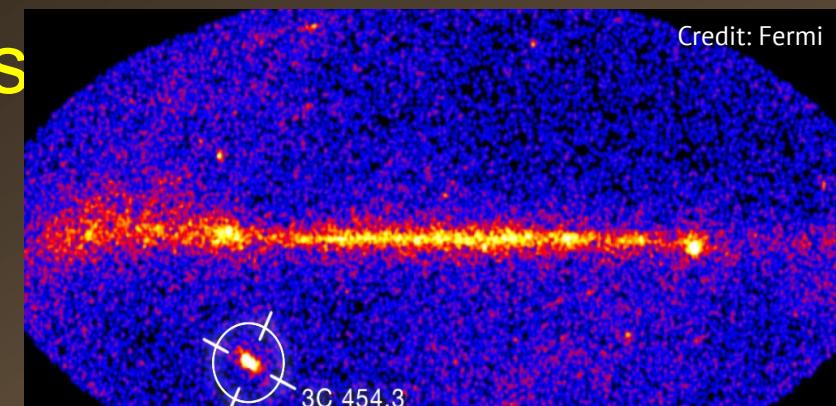

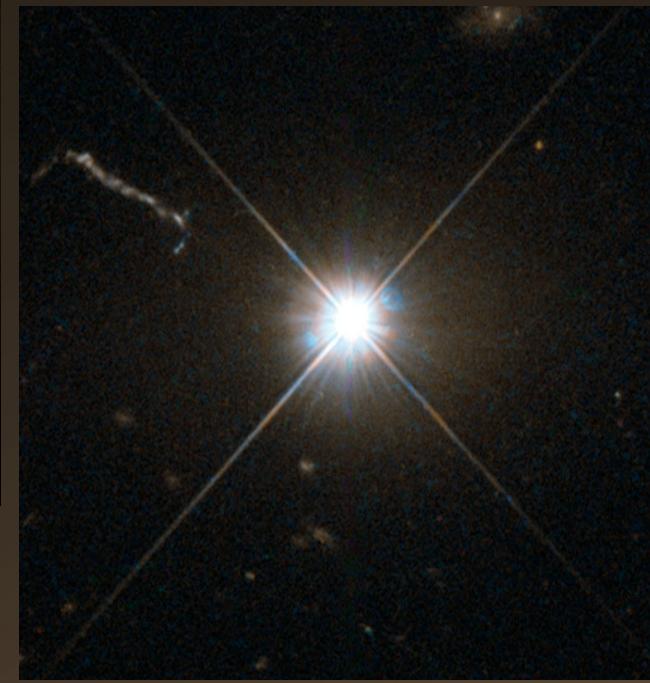

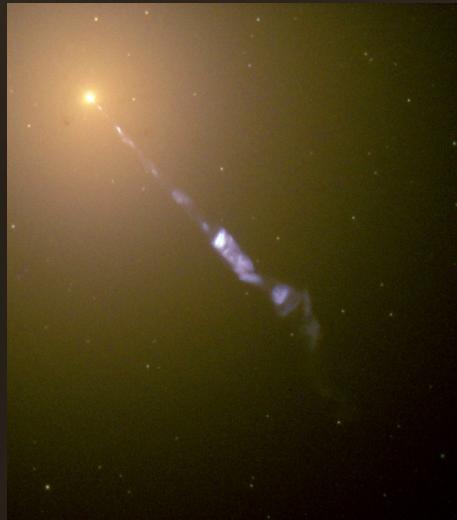

$\langle L[\text{bol}] / L[\text{Edd}] \rangle = 0.2$ for BL-Lac

- FSRQ are more active accretors (Ghisellini et al. 2011)

Spectroscopic study of Blazars

Outline:

- Introduction
- Data set
- Classification
- Color-magnitude diagrams
- Spectral measurements
- Summary of results

Summary of results

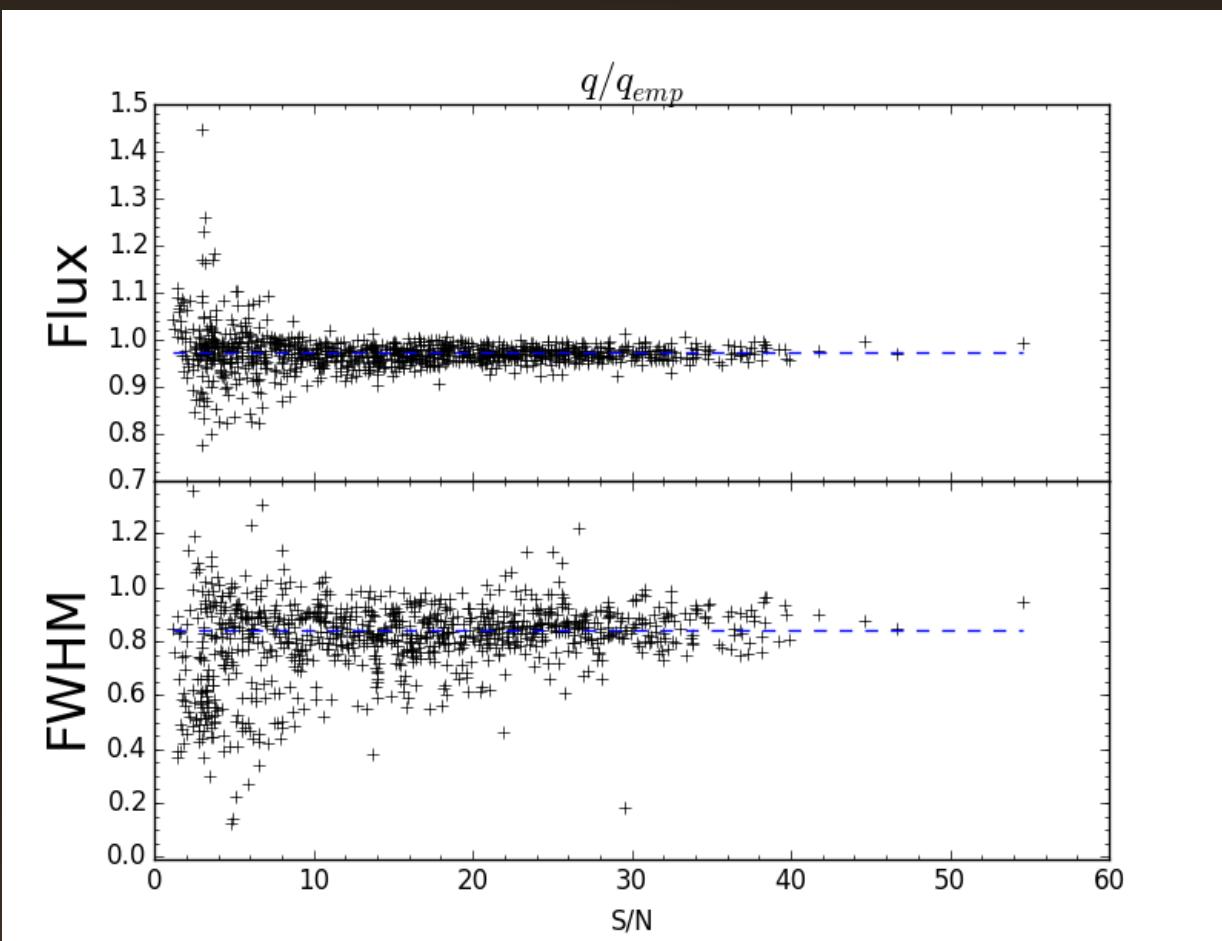

- Different behavior in VIS range
 - Flux variation → Constant color
 - Flux variation → Color variation
 - Redder when brighter
 - Bluer when brighter
 - Both
- Inflection magnitude → Changes on dominant source radiation.
- NMF show good component estimation, reproduces fairly well the spectrums and tow component objects are correlated with color measurements.

Summary of results

- Mass estimators have to be used carefully when only few spectra are available.
- NTD can be used for quantify the goodness of mass estimation.
- BLR shape may not be spherical at all.
- FSRQ are more active accretors.
- Broad component – continuum flux correlation at short time scales rather than narrow component.

Spectral measurements: Goodness of measurements.

- Quality factor
- Improve for
- S/N > 10
- Low confidence in FWHM

NO?Classification: High energy flux

- Galaxy population objects produces lower energy at GeV rather than FSRQ
