steps sum to 1200.00 cents; the scale closes at the octave, as it must
```

PC7 and PC5 sit 34.98 cents apart — the `50/49` minimum gap of the `N = 12` regime, appearing inside the ladder itself. Sounded together they beat rather than form an interval.

5.2 `f = k n^2` for n = 1 to 25, raw and folded

Twenty-five is the single-transposition audible capacity of §5.7, and a table running past it would tabulate frequencies no one integer transposition can render.

```
  n     f raw (Hz)      j     folded [220,440)    odd part
-------------------------------------------------------------
  1       0.483426     +9         247.5140          1
  2       1.933703     +7         247.5140          1
  3       4.350832     +6         278.4532          3
  4       7.734812     +5         247.5140          1
  5      12.085643     +5         386.7406          5
  6      17.403326     +4         278.4532          3
  7      23.687861     +4         379.0058          7
  8      30.939247     +3         247.5140          1
  9      39.157484     +3         313.2599          9
 10      48.342573     +3         386.7406          5
 11      58.494514     +2         233.9781         11

 15     108.770790     +2         435.0832         15
 16     123.756988     +1         247.5140          1
```

```
 17      139.710037     +1         279.4201         17
 18      156.629937     +1         313.2599          9
 19      174.516690     +1         349.0334         19
 20      193.370293     +1         386.7406          5
 21      213.190748     +1         426.3815         21
 22      233.978055      0         233.9781         11
 23      255.732213      0         255.7322         23
 24      278.453222      0         278.4532          3
 25      302.141083      0         302.1411         25
------------------------------------------------------------
```

Index 17 folds to 279.4201, six cents from index 3's 278.4532. That is the `289/288` cliff arriving, and §5.6 prices it exactly.

5.3 `f_min` against `c/eta` The keystone table. Column three is `log2(f_min/k)`, which is the octave form; column four is the closed-form `2.885390 (c/eta)`. They agree to the printed precision at every row, which is the verification.

```
 c/eta      f_min (Hz)      octaves      2.885390*(c/eta)

------------------------------------------------------------
```

The bracketed row is not a boundary a better arrangement can cross: at `c/eta = 2.484907`

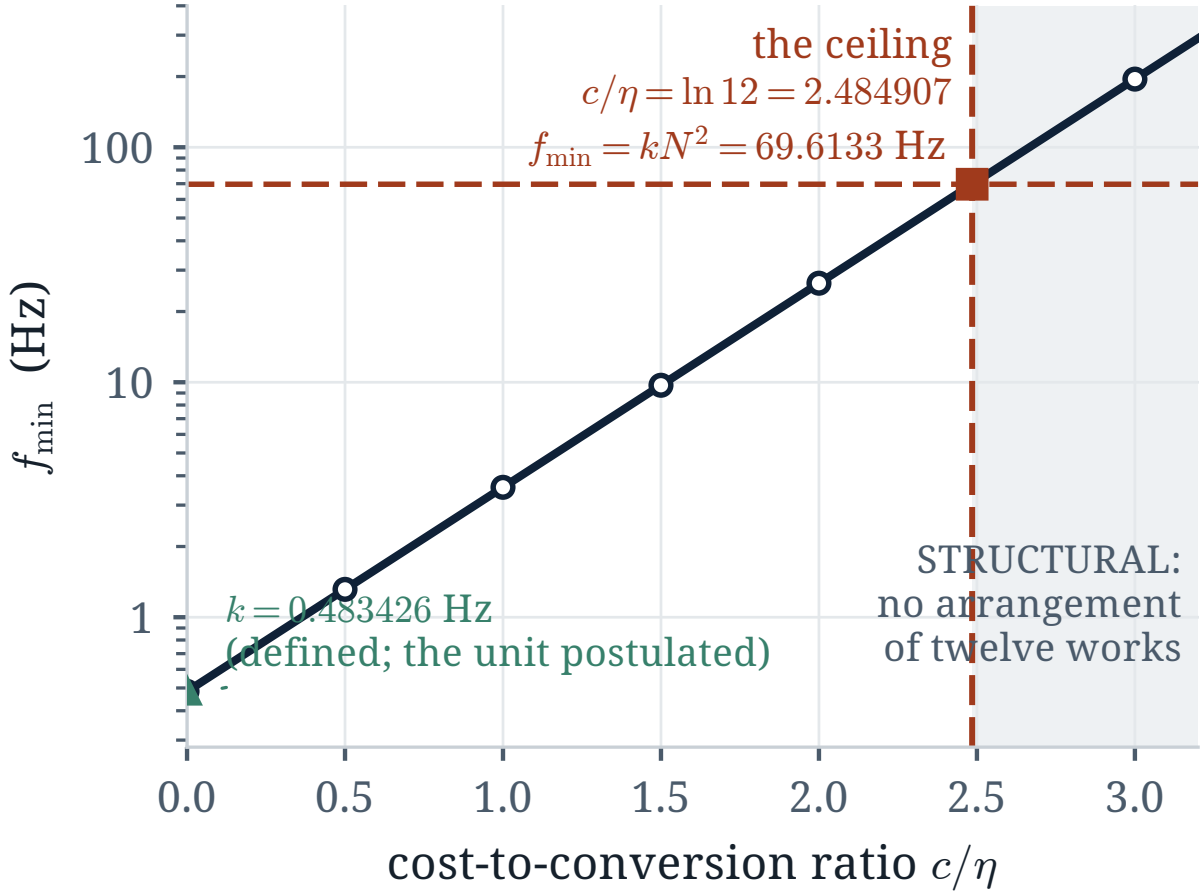

Figure 50.1: **Above the ceiling no arrangement of the declared categories is sustainable.** The keystone $f_{\min} = k\,e^{2c/\eta}$ against the cost-to-conversion ratio. At $c/\eta = \ln 12 = 2.484907$ the required non-parallelism is exactly 1 and $f_{\min}$ reaches $kN^2 = 69.6133$ Hz; beyond it the case is structural. k is a DEFINED constant, exact, and its hertz label is POSTULATED (§3.2). Values from the table of §5.3; script `figs/src/CCP-050_fig02.py`.

the required non-parallelism is exactly 1 — perfect orthogonality — and there is nothing above it.

The companion table is the hold line, stating the same threshold in the geometry rather than the cost:

c/eta	u* = (e^(c/eta)−1)/11	f_min (Hz)
0.000000	0.000000	0.483426
0.250000	0.025820	0.797034
0.500000	0.058975	1.314087
0.750000	0.101545	2.166564
1.000000	0.156207	3.572060
1.250000	0.226395	5.889331
1.500000	0.316517	9.709865
1.750000	0.432237	16.008862
2.000000	0.580823	26.394151
2.250000	0.771612	43.516598
2.484907	1.000000	69.613306

And the conversion between the two gauges, at the carried case's `delta/eta = 0.30`:

D (octaves)	f / f_min	Q_inf
−6.0	64.0000	+6.9315
−4.0	16.0000	+4.6210
−2.0	4.0000	+2.3105
−1.0	2.0000	+1.1552
0.0	1.0000	0.0000
+1.0	0.5000	−1.1552
+2.0	0.2500	−2.3105

This table is readable only because `delta/eta` was declared. Change `delta` and every `Q_inf` in the right-hand column moves while every `D` in the left-hand column does not — the decay-blindness result CC-R4 [Curzi, 2026] in tabular form, and the reason the ratio sits in the caption.

5.4 The interval lattice Intervals between states are ratios of squares, $f_m/f_n = m^2/n^2$, and k cancels. In cents, split into two halves for width; the matrix is antisymmetric, so the second half is the transpose of the first negated:

	n=1	n=2	n=3	n=4	n=5	n=6
m=1	0.00	−2400.00	−3803.91	−4800.00	−5572.63	−6203.91
m=2	2400.00	0.00	−1403.91	−2400.00	−3172.63	−3803.91

m=11   1564.98  1102.64   694.82   330.01     0.00  −301.27
m=12   1866.26  1403.91   996.09   631.28   301.27     0.00
```

Three entries earn comment. `m/n = 2` gives exactly 2400 cents, because doubling an index quadruples a squared frequency — the odd-part theorem in interval form, and the reason indices 1, 2, 4 and 8 share a class. The 7:5 entry is 1165.02 cents, 35 cents shy of an octave, and is the pair that sets the `50/49` minimum gap. The 12:11 entry, 301.27 cents, is the smallest non-collapsing interval at the top of the ladder.

5.5 Pitch-class counts

```
N          1  2  3  4  5  6  7  8  9 10 11 12 13 ... 25
ceil(N/2)  1  1  2  2  3  3  4  4  5  5  6  6  7 ... 13
measured   1  1  2  2  3  3  4  4  5  5  6  6  7 ... 13
                                  ^ this series, N = 12
```

Checked programmatically at every row: the two columns are equal for all `N` from 1 to 25. **The class count is exactly `ceil(N/2)`, because the odd parts of `1..N` are precisely the odd numbers in `1..N`, of which there are `ceil(N/2)`.**

5.6 The folded-lattice minimum gap, by exact rational arithmetic Fold every `n^2` into a single octave as an exact `Fraction`, sort, and take the smallest adjacent ratio including the wrap-around from the largest back to twice the smallest. The result is a step function in `N` with four distinct values:

```
N range        minimum gap        cents         status
------------------------------------------------------------------------
N = 2              2/1         1200.0000       degenerate (one class)
N = 3 .. 6         9/8          203.9100       the Pythagorean tone
N = 7 .. 16       50/49          34.9756       THIS SERIES' REGIME
N >= 17          289/288          6.0008       THE CLIFF
N >= 41         1682/1681         1.0296       the second threshold
------------------------------------------------------------------------
```

The cliff fires the instant index 17 enters the set, because `17^2 = 289` folds beside `288 = 2 * 12^2`; the second fires at index 41, because `41^2 = 1681` folds beside `1682 = 2 * 29^2`. Both locations are exact and neither depends on `k`.

Three distinct ratios describe the size of the cliff, all correct in their own units. Confusing them is the specific error Series B's CC-R21 records and reverses:

```
cents    ln(50/49)/ln(289/288)   = 5.828    how much smaller the interval is
cycles   288/49                  = 5.878    3.899 cycles becomes 22.918
RATE     (1/32)/(1/256)          = 8 EXACT  symbols per second -- the design limit
```

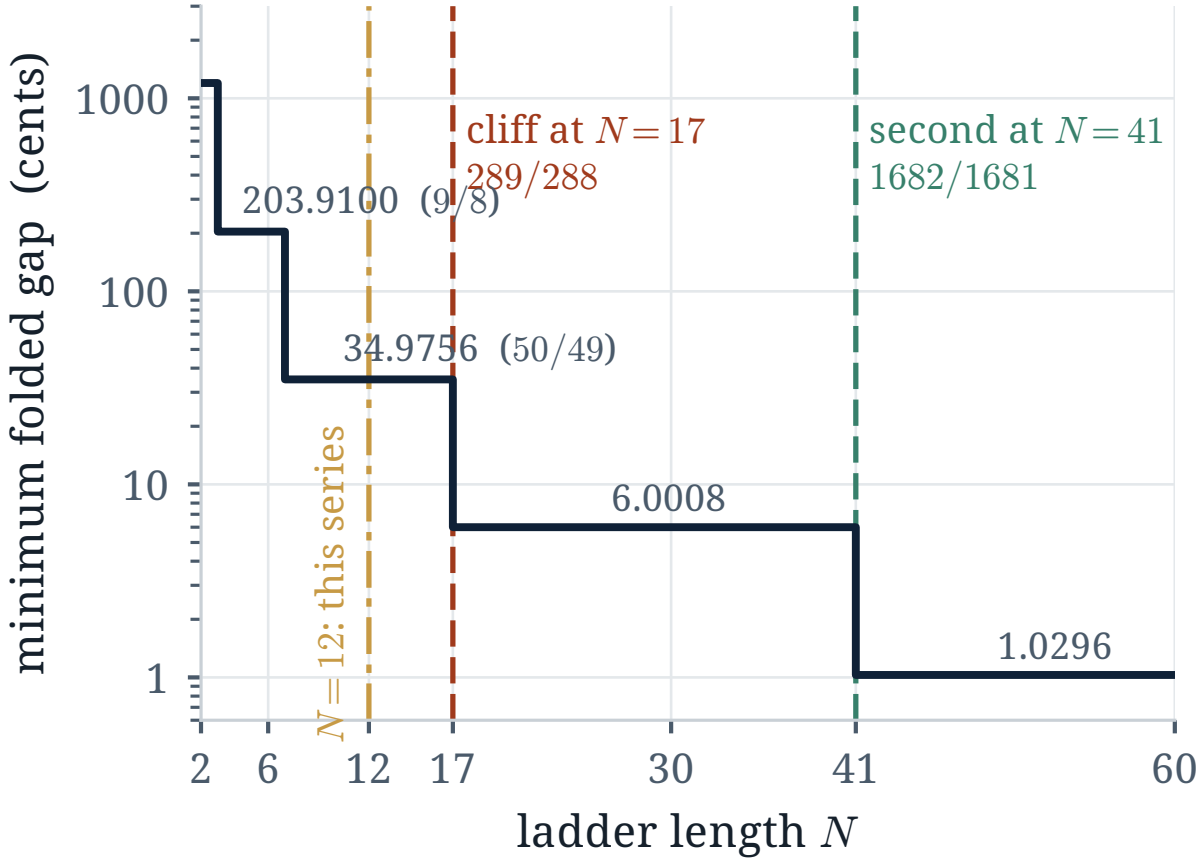

Figure 50.2: **The minimum separation the folded lattice offers is a step function of ladder length, and it collapses twice.** Computed with exact rationals: $9/8$ at $N = 3 \dots 6$, $50/49$ at $N = 7 \dots 16$, $289/288$ from $N = 17$ and $1682/1681$ from $N = 41$. Both cliff locations are exact and neither depends on the reference constant. $N = 12$ sits inside the third regime, so this series renders throughout at 34.9756 cents. Script `figs/src/CCP-050_fig01.py`.

The rate factor is exactly 8 because the two binding pairs sit at different octave heights: the `50/49` pair straddles `49/32` and the `289/288` pair straddles `9/8 = 288/256`. Gabor resolution depends on the absolute gap in hertz — `f/32` before the cliff, `f/256` after, at every base pitch. This series renders entirely below the cliff, so the `50/49` figures are operative throughout.

5.7 Single-transposition capacity Take the whole set `{k n^2 : n = 1..N}`, apply one integer octave transposition `2^j`, and require the entire transposed set to lie inside 20 Hz to 20 kHz. Computed over `j = 0..15` for every `N`:

```
N        admissible j
------------------------------
20            {6}
21            {6}
22            {6}
23            {6}
24            {6}
25            {6}          <-- the maximum
26            {}           <-- no j works
27            {}
------------------------------

at N = 25, j = 6:   lowest =    30.9392 Hz      highest = 19337.0293 Hz
at N = 26, j = 6:   highest = 20914.9309 Hz     -- above the band
at N = 26, j = 5:   lowest  =    15.4696 Hz     -- below the band
```

A single integer octave transposition admits at most 25 essences inside the audible band, and only at `j = 6`. A twelve-house set fits comfortably; a thirty-two-category set does not and requires split transposition. This is a hard bound on essence-set size and it constrains any extension of the ladder a reader might be tempted to make.

---

6 Measurement protocols and worksheets

Eight numbered protocols and four worksheets. Each names its owning paper, states its inputs and required outputs, and ends with the gates that must pass before publication. Reports cite them by number and do not restate them.

A prohibition governs all eight and is repeated inside each: **none of these procedures is an assessment.** Nothing here evaluates, ranks or screens a person, or produces anything describable to them or anyone else as a finding about their mind. They produce a description of a description, and a practitioner who cannot hold that distinction should not run them.

Protocol C1 — Indexing a state *Owner: the state-ordering and elicitation material [Curzi, 2026].*

Inputs. One named situation, in one sentence, written before anything else is asked. One or more framings of it. A dated declaration of the decomposition rules in force, `N = 12`, the ladder in use, the intensity instrument and its range, the audible band and the folding convention.

Steps.

```
C1.1  DECLARE THE RULE SET, DATED. Published with the reading.
C1.2  OBTAIN CONSENT, AND MAKE DECLINING STRUCTURAL. The subject is told what is
      elicited, what is computed, what it does and does not mean, and that any
```

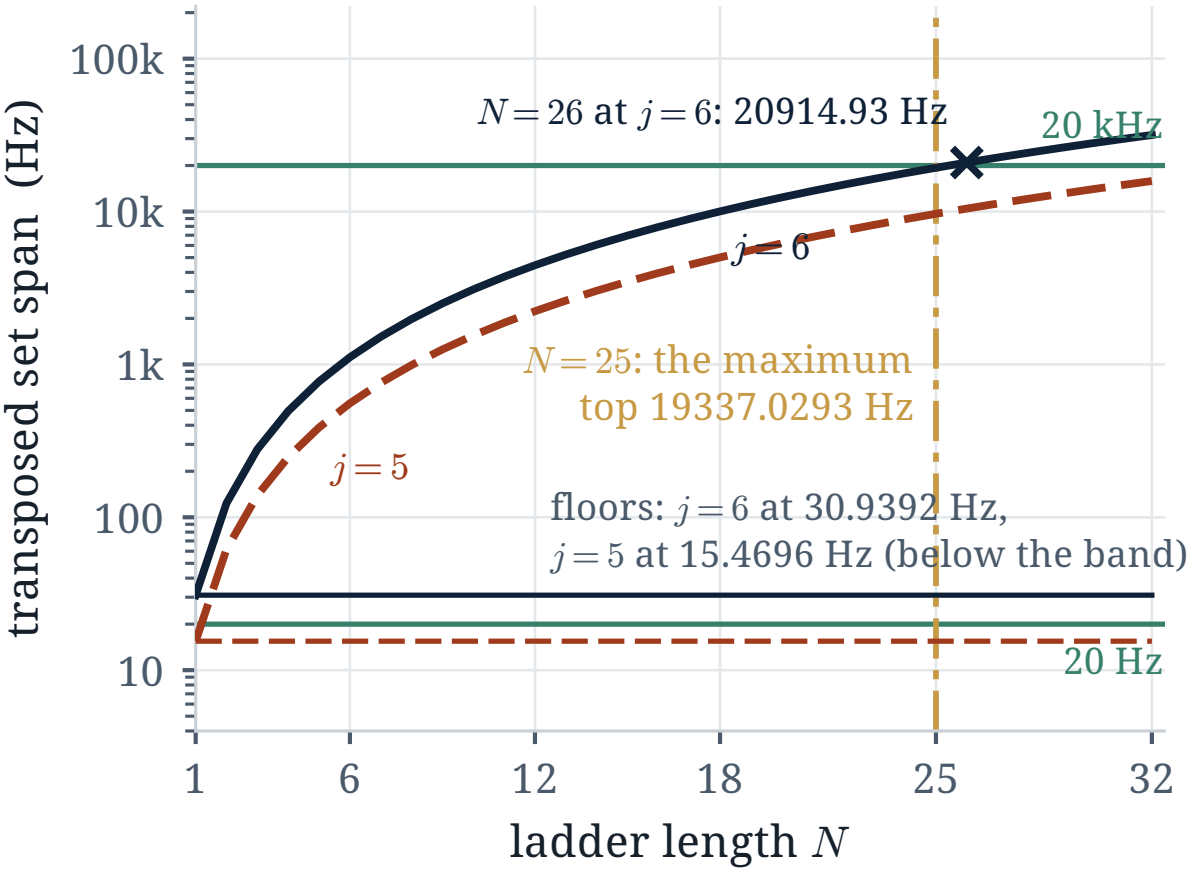

Figure 50.3: **The audible band admits at most twenty-five essences under one integer transposition.** The transposed set's floor and ceiling against ladder length at $j = 6$ and $j = 5$. At $j = 6$ the top crosses 20 kHz between $N = 25$ (19337.0293 Hz) and $N = 26$ (20914.9309 Hz); dropping to $j = 5$ puts the floor at 15.4696 Hz, below the band. Computed by exhaustive search over $j = 0 \dots 15$; script `figs/src/CCP-050_fig04.py`.

```
      question may be skipped without a reason and without the procedure being
      abandoned. Nothing masked; nothing concealed; nothing below awareness.
C1.3  FIX THE SITUATION in one written sentence.
C1.4  FIX THE FRAMINGS to be elicited, and name them, before eliciting any.
      Two is the minimum for a relational reading; three is the house default.
C1.5  SILENT WRITE-FIRST. Each framing written out in full, independently,
      before any two are compared and before the practitioner comments.
C1.6  READ EACH FRAMING AGAINST ALL TWELVE COMPONENTS. PRESENT or ABSENT for
      every one. No blanks.
C1.7  SUBSTITUTION TEST on every component marked PRESENT: remove it, read the
      residual back, ask whether that is still the state. If yes, unmark it.
C1.8  NESTING CHECK. No component marked present above one marked absent.
C1.9  COUNT. n = components present after C1.7 and C1.8. Record the count AND
      the list. A count without its list is a rating and is rejected.
```

Required outputs. `n` for each framing; the component list beside each count; `f = k n^2` raw and folded with `j`; the pitch class as the odd part of `n`.

Publication requirements, from the publication requirements [Curzi, 2026], and these are requirements.

```
I1  THE DECOMPOSITION -- what counts as one component, as a rule a third party
    can apply to a state the author never considered
I2  THE COUNT RULE -- including redundant, nested and conjoined components
I3  N, with the ceiling ln N it implies
I4  THE TIE-BREAK -- for a count index, ties are the same state class and share
    a frequency, which is the intended behaviour
I5  THE BAND AND j for every published frequency
I6  THE PERMUTATION TEST -- swap two adjacent indices, recompute, report the
    change in cents and in pitch class. Ten minutes.
```

The honest limit, stated wherever the index is used. The frequency inherits exactly the defensibility of the count. A contested decomposition yields a contested frequency, and a frequency published without its decomposition is a number nobody can check.

Protocol C2 — Eliciting the intensities, and why magnitude estimation is required

Owner: the elicitation rule [Curzi, 2026]. Binding on every paper that reports a `u`.

This requirement is the one most often assumed negotiable, so the argument comes before the steps.

The scale-status rule fixes the standing of two quantities separately, and they differ. **`n`, the index, is a count: it has a true zero and equal units, it is ratio-scaled by construction, and it does not inherit CC-R1's demotion — it sidesteps it.** `w`, the intensities, are elicited magnitudes and are ordinal by default, and everything computed from intensity-weighted vectors — `u`, `F`, `f_rel`, the deficit — inherits `w`'s status. So the state frequency is ratio-scaled and the relationship frequency is not, until the intensities are.

The usual response to an ordinal input is to report the output ordinally and carry on. **That response is not available here, and the elicitation rule [Curzi, 2026] proves it with a number.** Apply a monotone relabelling of the intensities — a transform that preserves every ordinal relation and therefore destroys no ordinal information whatever — and `u` moves from 0.362115 to 0.525275. Converted through Rule 2:

```
u = 0.362115   ->   F = 1.606085   ->   f_rel = 12.004877 Hz
u = 0.525275   ->   F = 1.913686   ->   f_rel = 22.209363 Hz

shift  =  0.887547 octaves  =  1065.0568 cents  =  0.307600 nats
```

Nearly an octave, from a change an ordinal scale calls no change at all. **With ordinal intensities the relationship frequency is not determined, and reporting one would be reporting an artifact of the labelling.** The ordinal fallback is therefore not a weaker option; it is not an option.

Steps.

```
C2.1  Choose the state class the subject reports most strongly. Assign it a
      reference value -- 10 on a 0-10 instrument.
C2.2  For every other class present, ask the ratio question IN WORDS:
      "compared with that one, how strong is this one -- half as strong,
      a quarter, three times?" Ratios are what the construction consumes.
C2.3  Do not average across framings. Each framing is elicited separately.
C2.4  Do not show either party another party's numbers.
C2.5  RECORD THE RAW L2 NORM in the instrument's units, then normalise.
C2.6  PUBLISH THE RAW L2 NORMS. The free multiplier of magnitude estimation is
      harmless because normalisation removes it -- but it must stay recoverable,
      and it is recoverable only from the norms.
```

Worked, on the carried dyad, so the reporting rule has a concrete instance:

```
A = {4:0.7, 6:0.5, 9:0.4}            raw ||A||_2 = 0.948683
B = {4:0.6, 6:0.55, 9:0.3, 10:0.2}   raw ||B||_2 = 0.890225
                                     ratio ||A||/||B|| = 1.065667
```

The ratio is the recoverable content: normalisation discards it and the publication rule puts it back. **Magnitude estimation (Stevens' method) produces genuine ratio-scale subjective magnitudes up to a free multiplier and replicates, which is why it is required and not merely preferred.**

Protocol C3 — The three routes to u

Owner: the relationship-frequency paper [Curzi, 2026]; used by [Curzi, 2026,?].

Three routes, measuring different things, and the route is declared before the numbers are seen. Choosing it afterwards is a documented failure mode (FM-13.5).

```
ROUTE A -- STATE VECTORS                                    the primary route

    Represent each party as a unit vector over the twelve states, components =
    magnitude-estimated intensity, normalised to length 1.

        cos theta = x . y            u = 1 - (x . y)^2

    Carry u to twelve or more decimal places (full-precision rule).
    Requires: C1 and C2 completed for both parties.
    Cannot see: whether either party is right about anything.

ROUTE B -- THE AGREEMENT CHANNEL                              CCP-044 R2

    Both parties judge m shared items independently, each judgement +1 or -1.
    Let a = the fraction of items on which they match.

        cos theta = 2a - 1           u = 4 a (1 - a)

    Exact, and no centring is required: +/-1 vectors have norm sqrt(m), so the
    norms cancel identically.
```

```
    Resolution: du = 4|1−2a|/m, bounded above by 4/m. REPORT m.
    Requires: an item set agreed BEFORE it is judged.
    Cannot see: the sign. a = 0.9 and a = 0.1 both give u = 0.36.

ROUTE C -- ERROR DECORRELATION                              Definition 13.2

    Both parties estimate m quantities whose true values later arrive. Form each
    party's error vector e = (estimate − truth), let rho be the Pearson
    correlation of the two error vectors.

        u = 1 − rho^2

    REPORT THE SIGN OF rho EXPLICITLY. It is not recoverable from u.
    Requires: ground truth, which is the cost and it is not small.
    Can see, and the others cannot: being right for different reasons, and
    being wrong in different ways.
```

The agreement channel, so a practitioner can read `u` off an agreement rate directly:

a	cos theta	u	f_rel (Hz)	cents above k
1.000000	+1.000000	0.000000	0.4834	0.00
0.990000	+0.980000	0.039600	0.9963	1251.97
0.950000	+0.900000	0.190000	4.6158	3906.26
0.900000	+0.800000	0.360000	11.8930	5544.82
0.800000	+0.600000	0.640000	31.2494	7217.27
0.700000	+0.400000	0.840000	50.6909	8054.75
0.600000	+0.200000	0.960000	64.6019	8474.57
0.500000	0.000000	1.000000	69.6133	8603.91
0.400000	−0.200000	0.960000	64.6019	8474.57
0.300000	−0.400000	0.840000	50.6909	8054.75
0.200000	−0.600000	0.640000	31.2494	7217.27
0.100000	−0.800000	0.360000	11.8930	5544.82
0.000000	−1.000000	0.000000	0.4834	0.00

The table is exactly symmetric about `a = 0.5`, and its first and last rows are identical. Two parties who agree on every item and two parties who disagree on every item produce the same `u`, the same frequency and the same reading. That is CC-R8 arriving through the measurement channel rather than through the algebra, and the unison result [Curzi, 2026] owns its consequences.

THE ACCURACY GUARD, binding wherever Route B or Route C is used. A `u` reading is published with each party's accuracy on the item set. Two parties answering at random have expected `a = 0.5`, hence `u = 1`, hence `f_rel = 69.6133 Hz` — the ceiling of the whole system, from guessing. Surplus measures distinctness, never correctness, and this series has no formalism converting one into the other.

THE OVERLAP GATE, not optional, and it runs before anything is computed. If two framings have disjoint support, `u = 1` exactly regardless of the intensities — verified across five constructed disjoint pairs with random intensities, `u = 1.000000` in every case. A degenerate reading is not a high reading; it is no reading. If the gate fires, report DEGENERATE, publish no `f_rel`, and return to the situation statement.

Protocol C4 — Estimating `eta`

Owner: the estimation practice [Curzi, 2026] at dyadic scope, the personal-spectrum material [Curzi, 2026] at personal scope.

`eta` is the fraction of a period's joint work still doing something at the start of the next period. It is countable in principle and the count is the protocol.

```
C4.1  Enumerate what the parties produced in a period: decisions, agreements,
      artefacts, practices. Write the list before counting it.
C4.2  Count how many survive intact into the following period without being
      re-made.
C4.3  eta_hat = survivors / total.
C4.4  Declare what got called a thing. The estimate is sensitive to it and the
      sensitivity is the reader's business.
```

A pair that settles six things a month and re-settles four next month is converting about a third. **The count is crude and far better than a guess, because the objection to it is visible and arguable in a way that an objection to a guess is not.**

Protocol C5 — Estimating `c` *Owner: the estimation practice [Curzi, 2026].*

`c` is what the arrangement costs to run before it produces anything: coordinating rather than deciding, re-explaining, the friction of getting to where work can happen. It is measured in the same units as the surplus — nats per period — and therefore requires a declared conversion, and the conversion is where most of the error lives.

```
C5.1  Identify the period budget and state it.
C5.2  Express eta*F and c as fractions of that same budget.
C5.3  Report c/eta directly. It is recoverable even when neither term is well
      determined on its own, and it is the only combination the deficit uses.
C5.4  Attach an error bar to c/eta, not a decimal point. Its elasticity is the
      largest in the reading.
```

The ratio `c/eta` carries the entire cost side of the reading, and a verdict resting on it deserves an interval. Where a structure prices its coordination per link, the aggregate is `C = kappa * m(m-1)/2`, and the commons of the group paper [Curzi, 2026] is the worked instance: `kappa = 0.055` across 15 links gives `C = 0.8250`.

Protocol C6 — Estimating `delta` *Owner: the trait paper [Curzi, 2026], Procedure TRAIT-2.*

`delta` is how much of what was accumulated is still there after a period of doing nothing. The estimation handle is the half-life relation.

```
t_half  =  ln(0.5) / ln(1 - delta)

delta = 0.05   ->   t_half = 13.5134 periods
delta = 0.09   ->   t_half =  7.3496 periods
```

```
C6.1  Identify a practice that lapsed, and the number of periods it lapsed for.
C6.2  Judge what fraction of it survived.
C6.3  Invert the half-life relation.
C6.4  DECLARE THE PERIOD. delta is a per-cycle rate and it is meaningless
      without its cycle. A delta quoted without a period is not a number.
```

A pair finding a lapsed practice half-forgotten after seven periods is running near `delta = 0.09`, since `ln(0.5)/ln(0.91) = 7.3496`.

Protocol C7 — Producing the reading: the deficit AND `delta`, together *Owner: the minimum-frequency paper [Curzi, 2026]. This is the protocol the framework exists to provide.*

```
C7.1  CEILING TEST FIRST.  Is c/eta <= ln N?
      If NO: the case is STRUCTURAL. No arrangement of the declared categories
      is sustainable. Report the ceiling breach and stop. Do not compute a
      deficit and do not offer levers; the levers do not include one that helps.

C7.2  COMPUTE F.        F = ln(1 + (N-1) u)
C7.3  COMPUTE f_rel.    f_rel = k (1 + (N-1) u)^2, raw and folded with j
C7.4  COMPUTE f_min.    f_min = k e^(2 c/eta)
C7.5  COMPUTE D.        D = 2.885390 (c/eta) - log2(f/k)
      CROSS-CHECK against 2.885390 (c/eta - F). The two must agree to at least
      twelve decimal places. If they do not, an input was rounded.

C7.6  COMPUTE Q_inf.    Q_inf = (eta F - c)/delta
      CROSS-CHECK against -D * eta / (2.885390 * delta).

C7.7  REPORT D AND delta, IN THE SAME SENTENCE.
C7.8  REPORT THE HOLD LINE u* = (e^(c/eta)-1)/(N-1) and the ratio u*/u_now.
C7.9  CLASSIFY.
          D <= 0                              SUSTAINABLE
          D > 0, c/eta <= ln N, u* reachable  TUNABLE AND REACHABLE
          D > 0, c/eta <= ln N, u* not        TUNABLE, UNREACHABLE
          c/eta > ln N                        STRUCTURAL
      Reachability is a declared judgment about the parties, not a property of
      the formalism, and it is declared rather than assumed.
```

Step C7.7 is the step this protocol exists for. the decay-blindness result CC-R4 [Curzi, 2026] proves `D` contains no `delta`, and the consequence is a reading that can be entirely correct and entirely uninformative about rate:

```
eta = 0.30, c = 0.62, u = 0.068734665264634

delta = 0.09   ->   D = +4.338420197   Q_inf = -5.011939546
delta = 0.05   ->   D = +4.338420197   Q_inf = -9.021491184
```

Halving the loss rate nearly doubles the negative destination and the deficit does not move by one digit in ten. **The deficit reads the sign and size of the gap; `delta` converts it to a level; a report with one and not the other is half a reading.** the audited schedule [Curzi, 2026] contains a row where exactly this happens — step 5 moves `Q_inf` from `-5.582082` to `-2.511937` while `D` sits at `+4.831945` in both rows — and it would have been invisible in a `D`-only report.

Protocol C8 — Controls, and what the surrogates cannot do *Owner: the falsification and preregistration work of Series B [Curzi, 2026i,ad]; carried here as CC-R4, CC-R13 and CC-R24.*

Any empirical test of any operationalisation in this series beats four baselines: persistence, direct-input, matched-autoregressive, and shuffled-input. **The shuffled-input control has three measured failure modes and every protocol that recommends the suite carries all three.**

```
(1) IT IS ANTI-CONSERVATIVE AS ORDINARILY RUN.  Against a nominal alpha of 0.05
    across 500 null trials, measured false-rejection rates were:
          iid permutation      0.108   (2.2x nominal)
```

```
          circular shift       0.120   (2.4x nominal)
          block permutation    0.060   (near nominal)
    The matched-autoregressive comparison ALONE false-passed 35.8% of the time.
    REMEDY: calibrate the surrogate by simulation on the study's own design
    before use. Not after.

(2) IT CANNOT SEE REPACKAGING.  A filtered repackaging of the input passed all
    four baselines including the shuffle (p = 0.0005) and was caught only by the
    structural ceiling test, its single-step jump being 38.5x the theoretical
    maximum.
    REMEDY: the structural tests. Only they detect repackaging.

(3) IT CANNOT SEE A SHARED SLOW DRIVER.  In a 4,000-trial simulation the shuffle
    worked in the clean case (48.17% detection) and failed against a shared slow
    driver, passing 98.35% of the time.
    REMEDY: design controls.

AND SEPARATELY: no surrogate detects FABRICATED TIMING. With a rater whose next
rating is nudged by the previous period's input -- no real relationship present
at all -- the full four-baseline suite passed 52.7% of the time. More surrogates
do not fix this.
```

The design-control remedy is the whole answer and it is not substitutable: blinding, channel separation, prospective sampling, and a yoked control. Adding surrogates to fix a design problem is a documented failure mode; the suite is a weak, mis-calibrated empirical audit and was never the load-bearing control.

7 The concordance register and its rejections

This series's audit trail. Every claim on which the framework runs a dual concordance appears here with four fields: the claim; the `(+1)` source and what it measured; the `(−1)` source and what it recorded; the status.

The two columns do different work and the difference is the method's whole content. `(+1)` carries evidence — a measurement, a derivation, a published result with a number attached. `(−1)` carries precedent — a tradition, a corpus, a practice, a record that somebody once thought this. Precedent is never promoted to evidence. A `(−1)` entry can suggest where to look, can supply a structure worth testing, and can constitute a striking convergence when an independent `(+1)` lands on the same object. It can never, by accumulation or by antiquity or by consensus, become the reason a claim is believed.

The sharpest demonstration of why is CC-R23. Under a selection process that publishes successes and discards failures, the likelihood ratio of testimonial evidence is exactly `1.000000`. **A likelihood ratio of 1 means the evidence does not move the posterior at all — not weakly, not by a little, not at all — because the selection guarantees you observe successes whether or not the method does anything.** The old corpus is a survivorship-filtered record, which is exactly that condition, and that is why the `(−1)` column is a separate column rather than a weaker part of the first.

Rejections are printed at the same length as acceptances and in the same tables. A register listing only what survived would be a sales document.

7.1 The laws and the join

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
D1.1	`f = k n^2` maps an essence index to a frequency	Series B [Curzi, 2026k]: the law reproduces all 118 published element values, worst relative deviation `9.0e−15`	the sonic-chemistry source table, which asserted the correspondence without a derivation	**ESTABLISHED as an exact reproduction of the source law; the source's prose formula was missing its parentheses (CC-R5)**
D1.2	`f_compound = k^2 G^4`	Series B [Curzi, 2026k]: reverse-engineered and matched to 37/44 published composites to <1e−12; the 7 outliers are data-entry errors, and the O2 row is provably impossible under the stated rule	the composite table itself	**ESTABLISHED with errata; NOT a generalisation of D1.1 (the no-agreement corollary CC-R4 [Curzi, 2026]: the rules agree at no index)**

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
D1.3	`F = ln(1 + (N−1)u)` is the unique surplus form	the surplus functional [Curzi, 2026n]: uniqueness from S1, S2, S4 given S3; every step after S3 forced	—	**PROVED CONDITIONALLY. S3 is a chosen design axiom**
D1.4	`Q_inf = (eta F − c)/delta`	the storage law [Curzi, 2026] Thm 3.5, with the exact solution and the contraction	Series A Node 10 FIXEDPOINT, which named the object without computing it	**PROVED. The precedent is a naming, not a derivation**
D1.5	`f_min = k e^(2c/eta)`	CCP-040: substitution verified at twelve parameter sets	—	**PROVED. An exact restatement of a sustainability condition in frequency units, and nothing more**
D1.6	`D = 2.885390(c/eta − F) = −2.885390(delta/eta)Q_inf`	CCP-041 R3; verified to `2.665e−15` across twelve parameter sets, worst residual `8.88e−16` on the carried case	—	**PROVED**
D1.7	`D` contains no `delta`	CCP-041 R4; worked: `delta` 0.09 to 0.05 moves `Q_inf` from `−5.0119` to `−9.0215` and leaves `D` at `+4.338420`	—	**PROVED, and it is a limitation of the framework's own central instrument**
D1.8	`dt df >= 1/(4 pi)` binds every rendering	Gabor; classical Fourier duality, measurable on an oscilloscope	—	**ESTABLISHED. No quantum content and none claimed**

7.2 The index and the psyche

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
D2.1	The component count is ratio-scaled and escapes CC-R1's demotion	CCP-041: a count has a true zero and equal units by construction; CC-R1 binds `D/P` specifically	—	**ESTABLISHED for `n`. NOT extended to the intensities**
D2.2	Arousal as an essence index	—	the arousal tradition in affect research	**REJECTED.** V2 fails — all twelve tie, 11.17 bits free; V3 fails; V7 fails, no tie-break
D2.3	Hierarchical need as an essence index	—	the need-hierarchy literature	**REJECTED.** V1 fails — needs are not states; V2 fails — five levels against twelve states

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
D2.4	Developmental stage as an essence index	—	stage theories of development	**ADMISSIBLE AS AN ORDINAL, NOT ADOPTED.** V1 fails — it indexes persons, not states; V4 fails — no true zero, so CC-R1 applies
D2.5	Valence magnitude as an essence index	—	dimensional affect models	**REJECTED.** V2, V3, V7 fail; V4 fails by collapsing opposites, which is CC-R8 in a different costume
D2.6	Magnitude estimation is required for the intensities	CCP-041 / the scale-status rule: a monotone relabelling moves `u` from 0.362115 to 0.525275 — 1065.0568 cents	Stevens' method, which produces ratio-scale subjective magnitudes up to a free multiplier and replicates (Series B)	**REQUIRED, not preferred. The ordinal fallback is not available**
D2.7	Consonance and redundancy are the same phenomenon	CCP-043: Tenney harmonic distance doubled in the essence lattice; the most consonant pairs are exactly the pitch-class collisions	classical consonance theory, which recorded the ratios without the identity	**PROVED at internal scope; nothing about distress follows, and CCP-043 states the firewall formally**
D2.8	One-hot framings are degenerate	CCP-041 / CCP-042: five constructed disjoint-support pairs return `u = 1.000000000000` regardless of intensities	—	**PROVED. The gate runs before anything is computed**

7.3 Relationship

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
D3.1	`u = 4a(1−a)` from an agreement rate	CCP-044 R2, proved from the norms of `+/−1` vectors; exact, no centring	inter-rater agreement practice, which recorded `a` without converting it	**PROVED. Resolution `4/m`, and `m` is reported**
D3.2	Perfect opposition reads as perfect agreement (CC-R8)	Series B [Curzi, 2026n]: `u = 1 − (x.y)^2` depends only on `|rho|`; CCP-044's agreement table is exactly symmetric about `a = 0.5`	"creative tension" as a design principle	**PROVED, and the precedent is refuted by it: `rho ~ −1` is a parallel pair with a cost overhead, paying `C` and returning zero surplus**
D3.3	Trust amplifies an existing sign (CC-R15)	CCP-044: `delta` 0.09 to 0.05 moves `Q_inf` from `−5.0119` to `−9.0215`; after the numerator is fixed, the same move gives `+6.0844` to `+10.9520`	the near-universal counsel to build trust first	**PROVED, and the precedent is corrected rather than rejected: trust is right, trust-first is wrong**
D3.4	An orthogonal pair already attains `ln N`	CCP-045 §4.7: orthogonal pair and orthogonal six both give `F = 2.484907`, `f = 69.6133 Hz` — identical, and the six pays 15 links against 1	the standing assumption that larger groups generate more	**PROVED in surplus terms. Groups buy breadth, redundancy and succession, which this formalism does not price**
D3.5	Ostrom's design principles map to the parameters	Series B [Curzi, 2026n]: P4 lowers `c_v` and does NOT raise `a`; P5 priced at `−7.7%` of `eta S`; P8 turns `O(N^2)` coordination into `O(N)`	Ostrom's commons scholarship	**ESTABLISHED where it applies and PRICED where it does not. P4's effect is not the one usually claimed for it**

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
D3.6	A commons can be formally tunable and practically unreachable	CCP-045: `c/eta = 2.426471 < ln 12`, so TUNABLE; but `u*` required is 0.938078 against `u_bar = 0.018614`, a factor of 50.4	—	**ESTABLISHED. Reachability is a declared judgment about the parties, not a property of the formalism**
D3.7	Drop-one improves on every member of a healthy team	CCP-045 §5.11b: all five rows improve, `Q_inf` rising by between 1.97 and 2.80	performance-ranking practice	**PROVED, and it refutes the practice: a favourable drop-one row carries no information about the member it names**

7.4 The tradition audited

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
C23.1	Staged process with per-stage checks	Shewhart 1931; Deming 1986; §23.8 prices staged control at 47.83% to 93.21% yield at `d = 0.90`	the Zosimos corpus; Newman & Principe 1998; Principe 2013	**ESTABLISHED**
C23.2	Cadence beats intensity	this work's concavity and ceiling results; Cepeda et al. 2006	fixed-hour practice; Durkheim 1912; Rappaport 1999	**ESTABLISHED, and folklore's REASON REJECTED. See D.5**
C23.3	Correspondence tables are relational graphs	graph theory; the gcd invariant tabulated for `N = 3..12`	the tables themselves; Yates 1966	**ESTABLISHED AS FORM ONLY. Two classical tables graded against V1-V7 and rejected as indices**
C23.4	The operator is part of the apparatus	Rosenthal & Fode 1963; Polanyi 1958; Collins 1985; §23.16 computes mirroring at 536.4074 cents	the pure-artisan requirement	**ESTABLISHED, MECHANISM REJECTED. Moral purity is not the mechanism**
C23.5	The colour sequence is a necessary order	—	precedent only	**REJECTED.** C2 fails: identification is circular

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
C23.6	“As above, so below” as a transfer licence	CC-R16’s three computed disanalogies: mean-field decay error 92% by `t = 12`; two nine-member groups with identical `u = 0.5999` losing 77% against 21% to a three-person departure; a 90.1x period-normalisation trap	the maxim	**REJECTED AS STATED. The correspondence is of dynamics and geometry, not of agency**
C23.1b	This tradition’s canonical stage ORDER	CC-R15; CCP-046 the schedule finding R2 [Curzi, 2026]	Ripley’s *Compound of Alchymy* (1471), the Twelve Gates	**REJECTED (order only; staging stands)**
C24.1	Material transmutation by chemical means	the energy-register argument: `2e6` on bonds, `8.24e7` on the furnace-to-barrier ratio; transmutation is real by nuclear means at 15.52 GW-station-years per gram under the most favourable constructed assumptions	the transmutation corpus	**REJECTED.** C1-C3 fail; AUDIT-1 steps 2, 4, 5, 6, 7, 8 fail
C24.2	The corpus establishes a success rate	CC-R23: `LR = 1.000000`, invariant to corpus size; with a denominator the ratio goes to about `1e304`	the published successes	**REJECTED.** AUDIT-1 step 2
C24.3	Secrecy protects a valuable result	error persistence under secrecy: `r = 0` gives infinite expected detection time; Deckname search cost `3^12 = 531,441` readings, 19.02 bits, 1,455 years at a trial a day	the secrecy tradition	**REJECTED AS AN EPISTEMIC PRACTICE.** AUDIT-1 step 8

#	Claim	(+1) — evidence, and what it measured	(-1) — precedent, and what it recorded	Status
C24.4	Shared values or correspondences are evidence	R12 recomputed: 234,454 words to 305 distinct outputs, 99.995% collision, 10.47 bits destroyed against a 9.5863-bit uniform bound — worse than its own worst case; in an 8,000-word corpus `P(a value-twin) = 0.999666`	the gematria corpus	**REJECTED; MNEMONIC READING RETAINED.** A retrieval index need not be injective, only reproducible
C24.5	The canonical gate order must not be varied	CCP-046 the schedule finding R2 [Curzi, 2026] against CC-R15	Ripley 1471	**REJECTED AS AN ORDERING**

7.4b The audit of the twelve gates, verdict by verdict Seven gates name operations on this series's declared parameters, two are split, and three fail — with a fourth entry, the planetary-metal ordering, failing as an index. Each rejection states what would reverse it, because a rejection that cannot say what would reverse it is an opinion.

The `(-1)` column for the whole set is Ripley's *Compound of Alchymy* (1471). The seven that map do so on named parameters — calcination on `n` downward, solution as the inverse of Rule 3, separation on `N`, putrefaction on `delta`, congelation on `G`, cibation on `c`, fermentation on `G` and `u`. Conjunction maps but SPLITS, its two readings returning incommensurable units, and the schedule halts there. The failures:

entry	(+1) — evidence, and what it measured	Verdict, and what would reverse it
8 sublimation	folding by `2^j` preserves every interval and every pitch class exactly; nothing in the parameter set moves, and `k` cancels from `D`	**RENDERING — rejected as an operation on a state.** Reverses if `j` entered a verdict. It does not
10 exaltation	"nobler" is a value ordering, not a coordinate (CCP-041); the rescues collapse to gates 1 or 9, or hit the ceiling `F <= ln 12`, `f <= 69.6133055503`	**REJECTED.** Reverses if a count-valued definition of nobility is supplied. None is, in the source or since
11 multiplication	contraction: `|Q_t − Q_inf| = (1−delta)^t |Q_0 − Q_inf|`, 99% closure at 48.83 passes; the destination is fixed by four parameters repetition does not touch	**SPLIT: the iterative reading MAPS, the unbounded reading is REJECTED.** Reverses if a pass altered `eta`, `F`, `c` or `delta` — then it is a different gate under a borrowed name

entry	(+1) — evidence, and what it measured	Verdict, and what would reverse it
12 projection	no base/noble coordinate; Rule 3 is blind to quantity, so the mass is not in the value; no channel (belief postulate); CONSTRAINT L67 forbids reaching the non-latent; CC-R23 fixes the testimonial LR at 1.000000	**REJECTED** on all four conditions. Reverses if a channel with measured gain is exhibited. None is
13 the planetary-metal ordering as an essence index	completeness, non-arbitrariness, count semantics and stability all fail; one disputed swap moves a published class by 568.7174 cents	**REJECTED.** Reverses if the ordering were fixed by a count. It is fixed by worth

7.5 Findings the framework records against its own sources Four items belong in their own section because in each of them the framework audits a source on the source's own material and returns a verdict the source would not have given.

The schedule finding, R2 of the operation-audit paper [Curzi, 2026], — Ripley's ordering contradicts CC-R15. Run as a schedule on the carried dyad, the Twelve Gates of Ripley's *Compound of Alchymy* (1471) place the only numerator-acting gate ninth of twelve. Fermentation, at step 9, moves `D` by `−5.305895` octaves, which is 88.93% of the entire move; the eight gates before it move it by `−0.660631` between them, which is 11.07%. Step 5, putrefaction, acts on `delta` — and it runs four steps before the numerator is repaired. **In the tradition's order, raising `delta` improves the destination; in CC-R15's order, the identical move damages it; and the only thing that differs is the sign of the numerator when the move is made.** This is the strongest single item in the audit papers of this series precisely because it is the tradition being audited on its own published material, and it is recorded here as `(+1)` evidence against a `(−1)` precedent — never the reverse.

The same schedule shows the delta-blindness of D1.7 as a visible row: step 5 moves `Q_inf` from `−5.582082` to `−2.511937` while `D` sits at `+4.831945` before and after.

CC-R11 — cadence wins, and not for the reason the tradition gives. Computed rather than assumed: the integrated effect of one large impulse and the same total input delivered periodically is identical to every digit — 433.3333 in all three regimes tested. That is exact LTI invariance, and a naive "cadence delivers more" claim is simply false for a linear time-invariant system. Cadence buys three other things instead, and Section 8.5 states them. The honest counter-case is kept in print: above a threshold no realistic cadence reaches, the impulse wins, and a once-a-decade rite requires a 5.63-year trace half-life to work.

the refused move [Curzi, 2026]. A proposed re-indexing of the carried Subject's `mirror` framing from state 7 to state 11 was run through TR-1 and halted at step 3: three of the four added components were observed in the repertoire, and the fourth — the other's model of the subject — was not. **The move was refused under CONSTRAINT T21, and steps 4 through 10 were not run, so the arithmetic that would have been produced is not published, because publishing it would let a refused move circulate as a priced one.** What is published is the refusal, the named missing component, and what would reverse the verdict: a single observation of the component, in any state, on any occasion. A refusal that names its missing component is a scientific result; one that says the move is impossible is an opinion.

The closed lineage, read in the framework's own register. Constructed, and not an observation of any lineage historical or living. A closed lineage in which the student's whole training consists of reproducing the master's framings exactly is `rho = 1`, hence `u = 0`, hence

— by CC-R8, which makes it worse rather than better — the same reading a perfectly opposed pair would receive.

```
arrangement                          u        F        f (Hz)     c/eta      D         Q_inf
-------------------------------------------------------------------------------------------
closed lineage, exact reproduction  0.000  0.000000   0.483426   2.250000  +6.492128  -7.500000
closed lineage, slight drift        0.050  0.438255   1.161430   2.250000  +5.227591  -6.039150
open school of six, u = 0.30        0.300  1.458615   8.938542   2.090909  +1.824415  -3.091215
open school of six, u = 0.50        0.500  1.871802  20.424737   2.090909  +0.632209  -1.071189
open school of six, u = 0.70        0.700  2.163323  36.590494   2.090909  -0.208942  +0.354024
-------------------------------------------------------------------------------------------
every row's c/eta is inside the ceiling ln 12 = 2.484907, so these are real
failures and not ceiling breaches
```

The swing from the closed lineage to the open school at `u = 0.70` is 7490.44 cents and 6.701070 octaves of deficit. Openness is three levers at once: it raises `u` because independent practitioners frame differently, raises `eta` because a published result is stored order and an unpublished one is a memory, and lowers per-link `c` because a record replaces re-explanation. **And the independence rule [Curzi, 2026] binds the reading: every `f` in that table is a relationship frequency and says nothing whatever about the state frequencies of the people in it.**

7.6 Rejections inherited from Series B, restated because they still bind

#	Claim	(-1) — precedent	Failing criterion	Status
B2-a	Astrology's orb as a conjugate-spread structure	the orb tradition	C2 FAILED in print, with Carlson, *Nature* 318 (1985) cited in the same passage as the definitive failed validity test	**REJECTED as a validity claim; the structural analogy contributes no number**
B2-b	64 codons to 64 hexagrams	the correspondence tradition	refused at CCP-031 §67.11	**REFUSED**
B2-c	The Heisenberg analogy as a source of numbers	quantum-mechanical framing of psychological uncertainty	every quantitative result in the conjugate-uncertainty work of Series B comes from an information-budget bound, the Gabor trade, or a Lyapunov horizon law — none from Heisenberg	**RETAINED AS STRUCTURE, REJECTED AS ARITHMETIC**
B2-d	Momentum descent as a formulary method	optimisation practice	failed to escape the worked landscape at every `beta` tested; the barrier is a wide plateau, not a spike	**EXPLICITLY EXCLUDED from the formulary with its failure stated. The exclusion is a feature**
B2-e	`r = 1` as an unqualified target	calibration practice	CC-R9: headroom at the `D = P` fixed point is exactly zero by cancellation	**REJECTED AS A SIMPLE GOAL**
B2-f	Aggregating `r` across sites	reporting practice	CC-R10: aggregate `D/P` overstated bankable input by 4.26x	**PROHIBITED. Distortion does not average**

---

8 The four-drawer evidential classification

This is the framework's warrant. Everything else in the series is an argument; this appendix is the accounting that says which arguments were paid for and in what currency. A reader who trusts nothing else here should be able to trust this.

The accounting has four drawers. **PROVED** means derived from stated premises, with the derivation in print and the arithmetic verified. **POSTULATED** means asserted as a design choice or a working assumption, badged in the sentence that states it, with the cost of the alternative computed where that was possible. **BORROWED** means taken from an established result elsewhere, cited, and used without re-derivation. **UNTESTED** means specified but not run — a claim with a falsification criterion attached and no data against it.

An item can sit in more than one drawer at different levels of description, and where it does, both placements are recorded. A theorem proved from a postulate is proved as a theorem and postulated as a system, and a reader is entitled to both facts.

8.1 The first drawer — PROVED

the essence bridge	f = k e^(2F)	Series B CCP-049
the surplus form	F = ln(1 + (N-1)u), unique given S3	CCP-020
the storage solution	Q_t exact, and Q_inf = (eta F - c)/delta	CCP-041 the storage law
the keystone	f_min = k e^(2c/eta)	CCP-040, twelve parameter sets
the octave form	octaves = 2.885390 (c/eta)	CCP-041 Thm 4.3
the deficit identity	D = 2.885390(c/eta - F) = -2.885390(delta/eta) Q_inf	CCP-041 Thm 4.5, 2.665e-15
delta-blindness	D contains no delta	CCP-041 Thm 4.9
the ceiling	c/eta <= ln N, f_min <= k N^2	CCP-041 Thm 4.6 / CCP-041 Cor 3.4
the minimum category	N >= e^(c/eta)	CCP-041 Cor 4.7
the hold line	u* = (e^(c/eta)-1)/(N-1)	CCP-041 Cor 4.8
the odd-part theorem	ceil(N/2) classes, verified N = 1..25	CCP-042
the agreement identity	u = 4a(1-a), cos theta = 2a - 1	CCP-044 Thm 13.1
R8	opposition reads as agreement	Series B CCP-020
R15	trust amplifies an existing sign	Series B CCP-020
the compound rule	f = k^2 G^4, and Thm 20.1	Series B CCP-049, CCP-046
Cor 20.2	the two rules agree at no index	n = 1.438252
Thm 22.2	refinement cannot move Q_inf	CCP-047
the error law	|Q_t - Q_inf| = (1-delta)^t |Q_0 - Q_inf|	CCP-047
the Gabor bound	dt df >= 1/(4 pi)	classical Fourier
the four design laws	N <= 25 at j = 6; cliffs at 17 and 41; rate factor exactly 8; rectangular gate disqualified	
Finding 21.1	state and relationship frequency independent	CCP-046
R23	LR = 1.000000 for testimonial evidence	Series B CCP-036

Two of these are limitations rather than achievements.

The deficit is blind to decay, and it is the framework's central instrument. the decay-blindness result CC-R4 [Curzi, 2026] says `D` contains no `delta`. Worked on the carried dyad, moving `delta` from 0.09 to 0.05 takes `Q_inf` from `-5.011940` to `-9.021491` — nearly doubling the negative destination — while `D` stays at `+4.338420` to ten decimal places. The instrument this series exists to provide cannot see one of the four parameters that decide a relation's fate. The remedy is procedural and is stated everywhere the instrument appears: report `D` and `delta` together. A reading that gives only `D` is incomplete, and the incompleteness is not a rounding issue but a structural one.

A state's frequency and a relationship's frequency are independent, and neither may be inferred from the other. the independence rule [Curzi, 2026] records the verification: four constructed pairs at lattice positions spanning thousands of cents — indices `[1,2]` at 2400.00 cents apart, `[3,6]` at 2400.00, `[5,10]` at 2400.00, `[7,11]` at 1564.98 — all return `u = 1.000000000000` and `f_rel = 69.6133055503 Hz`, to twelve decimal places. The reason is structural: `u` depends on the angle between state vectors, not on which indices are occupied. Re-indexing moves every state frequency and can leave the relationship reading untouched. A complete report therefore gives both numbers, and any paper tempted to derive one from the other is making an error the arithmetic forbids.

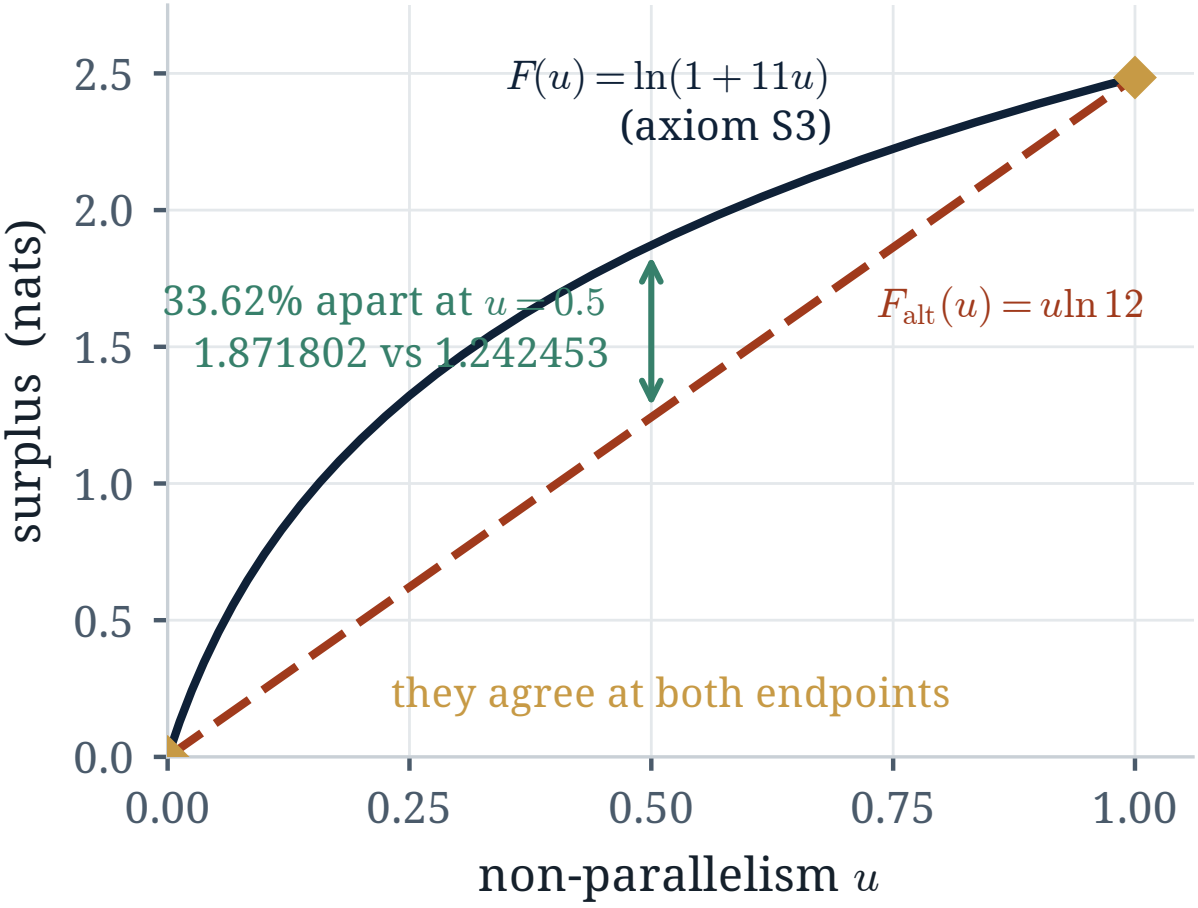

Figure 50.4: **The framework's central design axiom is worth a third of the surplus in the middle of the range.** $F(u) = \ln(1 + 11u)$, the form the affine effective-count axiom forces, against $F_{\text{alt}}(u) = u \ln 12$, which satisfies every other axiom. The two agree at both endpoints and disagree by 33.62 per cent at $u = 0.5$, 1.871802 against 1.242453. Computed at $N = 12$; script `figs/src/CCP-050_fig03.py`.

8.2 The second drawer — POSTULATED S3, the affine effective count, is a chosen design axiom and this entire book leans on it. The surplus form is uniquely characterised by four axioms: S1 geometric dependence, S2 zero at zero, S3 that `g(u) = e^{F(u)}` is affine in `u`, and S4 normalisation `F(1) = ln N`. Every step after S3 is forced. S3 itself is forced by nothing. It asserts that the *effective count*, not the surplus, is the quantity that behaves linearly in the geometry, and that is a modelling choice about what the natural unit of the system is.

The cost of a different choice is computed rather than waved at.

`F_alt(u) = u ln N` satisfies S1, S2 and S4, violates only S3, and agrees at both endpoints — yet at `u = 0.5` the two disagree by 33.62%, `1.871802` against `1.242453`. S3 selects one curve from a family that agree at the ends and diverge by a third in the middle, and the middle is where every real case lives. Nothing here is safe from it: `N_eff` is defined by S3, the bridge identifies the essence index with `N_eff`, `f = k N_eff^2` inherits it, and `f_min` is a statement about `F = ln N_eff`. Every paper using the keystone is using S3.

The storage law's linear form is a modelling choice, not a discovery. `Q_{t+1} = (1-delta)Q_t + eta S_t - C_t` is linear in `Q`, with constant `eta` and constant `delta`. That is what makes the fixed point exist, makes the convergence geometric, and makes `Q_inf` computable in closed form. Real systems can have superlinear cost, `Q`-dependent conversion, or exogenous accretion, and where they do, the model does not apply and the domain limits [Curzi, 2026] computes where it stops. The linear form is retained because it is the simplest form that supports the join, and

its simplicity is the reason the join is checkable — not evidence that it is right.

the ladder's ordinal-to-frequency mapping: defensible, not unique       CCP-041 §5.4
```

Belief acts only through a coupling with real gain, and where no channel exists nothing happens. **The framework must never imply that wishing moves the fixed point.** Changing a destiny means changing `(eta, F, c, delta)` and nothing else — a definition, not a promise.

8.3 The third drawer — BORROWED

```
Gabor's limit and Fourier duality
Stevens' magnitude estimation, and its replication record
Rasch measurement, as the route out of R1's demotion (123 items per term)

the Zosimos corpus; Newman & Principe 1998; Principe 2013 -- likewise (-1)
```

Every borrowing is used for what its source established and nothing further. The biological citations establish sequence operations and mechanical operations; they do not establish the link between them.

8.4 The fourth drawer — UNTESTED

```
the operationalisation of the twelve-state ladder: FVP-6 SPECIFIED, NOT RUN
    design: preregister rule set, ladder, elicitation script and analysis;
    fit on training episodes; FREEZE; report held-out performance
    kill condition: if counts under the frozen protocol fail to beat the
    persistence baseline on held-out prediction, the operationalisation is
    dead and the ladder is withdrawn

the acoustic -> c-factor causal claim: NOT CONFIRMED (CC-R7). Any paper
    invoking acoustic c-factor engineering carries that status. The nearest
```

```
        badged result is that boundary geometry alone selects modes at no
        ongoing cost -- exact for room acoustics, a design heuristic only for
        occupancy [CCP-033].

    the genomic audio protocol of CCP-048: a RESEARCH PROCEDURE, labelled as one.
        Nothing in it has been run on anything.

    the decisive experiment of CCP-048: designed, preregistered in outline, not run.

    every parameter estimate in this series: eta, c and delta have no instrument
        comparable to u's, and Protocols C4-C6 are estimation practice badged as
        practice.

    the research programme's own odds: 21 preregistered kill conditions across five
        stages, four terminal; 35.8% completion probability; 55.3% chance of dying
        at or before cross-subject recovery; 8,554.8 researcher-hours, 5.35
        FTE-years, 71 months.
```

The last item is a result, not a caveat. A programme that computes and publishes its own probability of failure is more credible than one claiming certainty, and the coherence with CC-R1 is no coincidence: the gate deciding the hard-science question is also the stage most likely to kill the programme.

8.5 The specific disclaimers, each stated in full

Essence frequencies are essence frequencies, not physical resonances. No person, tissue, cell or molecule is claimed to resonate at any value in this series. The frequencies represent a count and an angle; the hertz are a unit chosen so the representation can be compared with a lattice and, where a rendering is called for, heard. Nothing in the formalism asserts a physical oscillation and nothing in it would be evidence of one.

The scale asymmetry, stated as the scale-status rule fixes it. Two quantities, different scale status, and no blanket verdict for "the ladder" or "the method" is permitted. `n` is a count: true zero — zero components is no state — and equal units, hence ratio-scaled by construction, and `f = k n^2` is ratio-scaled with it. Neither inherits CC-R1's demotion; they sidestep it. `w`, the intensities, are ordinal by default, and `u`, `F`, `f_rel` and the deficit inherit `w`'s status. So the state frequency is ratio-scaled and the relationship frequency is not, until the intensities are. CC-R1's demotion binds `D/P` specifically — pending Rasch instrumentation at 123 items per term — and binds neither this index nor magnitude-estimated intensities. Two phrasings are forbidden because both are false: "the ladder is ordinal per CC-R1", and "the method is ratio-scaled" without qualification.

And the ordinal reading is not merely weaker; it is unusable. An ordinal-preserving relabelling of the intensities moves `u` from 0.362115 to 0.525275, which is 0.887547 octaves — 1065.0568 cents, nearly an octave — from a change an ordinal scale says is no change at all. Magnitude estimation is therefore required rather than preferred, and the raw L2 norms are published so the free multiplier stays recoverable.

CC-R23 stands, and its number is exact. The survivorship likelihood ratio for testimonial evidence is `1.000000` — not approximately, exactly. A thousand testimonials carry precisely the evidential weight of zero, because the selection guarantees you observe successes whether or not the method does anything. The companion result: a prediction specifying only a direction has `LR = 2.0000` against `11.3577` for one specifying a magnitude, so a belief predicting only a direction is not yet testable.

CC-R11, stated exactly, because the easy version of it is false. The integrated effect of one large impulse and the same total input delivered periodically is identical to every digit — 433.3333 in all three regimes tested. That is LTI invariance and it is exact. Cadence wins by strict concavity (the concavity result of Series B, which needs no ceiling at all) and by the

surplus ceiling clipping the impulse — 90.44% of the nominal budget lost at `N = 12` — and not by delivering more total input. It does not deliver more.

CC-R15, stated exactly. Trust acts by reducing `delta`, and `Q_inf = (eta F − c)/delta`. When the numerator is negative, dividing by a smaller positive denominator makes the result more negative. Trust does not add order; it amplifies whatever sign the system already has. Fix the numerator first.

CC-R8, and the identity that carries it into measurement. Because `u = 1 − (x.y)^2` depends only on `|rho|`, perfect opposition yields `u = 0` exactly as perfect agreement does. The agreement identity `u = 4a(1−a)` exhibits it directly: the channel is symmetric about `a = 0.5` and returns `u = 0` at both ends. The contrarian who inverts you carries the same information as the sycophant who echoes you — none — and manufactured opposition pays `C` and returns zero surplus.

the group result [Curzi, 2026], stated before its qualifications. A single orthogonal pair attains `u_bar = 1`, `F = ln 12 = 2.484907`, `f = 69.6133 Hz`; six mutually orthogonal members attain exactly the same and pay 15 links instead of 1. In surplus terms a group buys nothing a well-chosen pair could not. The qualifications are real and are printed with it: orthogonality is an idealisation and achievable `u_bar` falls with roster size; the formalism has no term for redundancy against loss, for succession, or for the fact that a pair ends when one of its members does; `eta` and `kappa` are not roster-independent in practice; and the ceiling is on `F`, not on output. Groups buy breadth, not depth, and the formalism prices only the depth.

the constructed commons and the re-read window [Curzi, 2026]. The commons is formally tunable — `c/eta = 2.426471` sits inside `ln 12 = 2.484907` by 0.058436 nats, or 0.1686 octaves — and practically unreachable, because the hold line demands `u* = 0.938078` against a present `u_bar` of 0.018614, a factor of 50.4. No single lever closes a 6.4638-octave gap: `u` to 0.95 leaves `−0.0332`, and 0.95 is near-orthogonality; `eta` to 0.90 leaves `+2.1075`; `kappa` cut to 0.020 leaves `+2.0085`. Some systems cannot be tuned and must be restructured, and a book showing only fixable examples would be lying by selection. Just as awkward, the drop-one analysis improves the reading on *every* member of the healthy team — `Q_inf` rising by between 1.97 and 2.80 in all five rows — so a favourable drop-one row carries no information about the member it names. And the re-read window [Curzi, 2026], bounded below by convergence and above by drift, can be computably empty: the tuned family's window is `[13.51, 16.23]` at 1% drift and empty at 2%, 3% and 5%. A margin thin enough to be unverifiable is a margin too thin.

The open problem, carried without softening. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal, and the framework's own addressing constraint bounds what any such mechanism could do even if one existed: no addressing operation, at any signal strength or in any modality, can cause a cell to express content its genome and accessible regulatory repertoire do not already contain [Curzi, 2026y]. The nearest badged result on the acoustic side is narrower still: boundary geometry alone selects modes at no ongoing cost, which is exact for room acoustics — the same Helmholtz problem — and a design heuristic only for occupancy [Curzi, 2026aa]. The channel needs three things: D1 symbol separation, satisfiable in principle and its engineering exists; D2 order memory, for which there is no identified mechanism — this is the heart of the gap, since a permutation-invariant response is not a weak version of a sequence-specific one but a different quantity; and D3 mapping to a locus, for which there is likewise none. Eleven upstream rows are established and one is open. Reporting only the eleven is advocacy; reporting only the one is a different dishonesty, implying the whole edifice is speculation when most of it is textbook. the open-problem paper [Curzi, 2026] is why the rest of the framework can be trusted.

The remaining absolute constraints. No clinical, medical, diagnostic or therapeutic claim is made anywhere in this series; the twelve states are not diagnoses and the readings are not assessments. No claim is made that any DNA is edited. No capability is conferred on anyone by anything here. No subliminals, ever — nothing masked, nothing below threshold, nothing concealed; open-label placebo works, so disclosure costs nothing that matters. No intervention may remove a person's ability to decline, and consent is structural rather than

advisory. All worked cases in all the papers of this series are constructed and are labelled as such, and no invented case is presented anywhere as an observation.

8.6 What would change these verdicts An honesty appendix that could not be moved by evidence would be a creed. Each drawer has an exit. PROVED is exited by an error in a derivation or a failed verification, and every verification here states its residual so a reader knows what tolerance was claimed. POSTULATED is exited by exhibiting a system in which the postulate fails — for S3, one whose effective count is not affine in the geometry, in which case the whole functional form changes and every number in this series moves with it. BORROWED is exited by retraction or supersession. UNTESTED is exited by running the test, and every item in it carries a kill condition stated in advance rather than a hope.

The open problem is exited by one experiment, described in the open-problem paper [Curzi, 2026], with both outcomes written before it is run. Until then the position is the one stated throughout: the architecture upstream is real, the architecture downstream is real, and the link between them does not exist yet.

---

9 Correspondence to the two predecessor series

Three books, one instrument, built in three stages. Series A taught the analyst to read the comfort gradient. Series B taught the engineer to build the circumstance and laid down both halves of one equation without multiplying them. This series performs the multiplication, and this appendix says item by item which part of the earlier work each part of this one extends, what the extension adds, and what it costs.

Two conventions govern the tables. Where the nodes of Series A are named the name is used; where they are not, the node is referred to by index only, because inventing names would violate Series A's own The naming rule of Series A [Curzi, 2026]. And where an extension costs something the cost is printed in the same row as the gain.

9.1 Series A's twelve nodes The nodes sit on the same twelve-index ladder this series uses, so each has a frequency and a pitch class under Rule 1. Those values are the essence-law paper of Series B [Curzi, 2026k]'s and agree digit for digit with B.1.

node	f = k n^2 (Hz)	class	what Series A taught	extended by	what the extension adds	what it costs
01	0.483426	1	the ground: undifferentiated activation	CCP-041, CCP-043	`n = 1` is the count's first rung, and `u = 0` gives the ground essence `f = k` — the same pitch from two directions	the reading at `f = k` is *no relationship*, not a low one, and readers are told so every time
02 GRADIENT	1.933703	1	read the desire line; move along the gradient of comfort	CCP-043, CCP-045	`grad h = −grad C` (CC-R19) makes a habit survey a headroom measurement; CCP-045 turns the gradient into a numbered intervention procedure	the consent axiom: no intervention may remove the ability to decline, which rules out the cheapest interventions
03 HORIZON	4.350832	3	the many windows of the one tower — several framings of one situation	CCP-042, CCP-043	the framings become a chord with computable intervals, and its width is the internal surplus `F_int`	the one-hot trap: framings without overlapping support score `u = 1` for free and mean nothing by it

node	f = k n^2 (Hz)	class	what Series A taught	extended by	what the extension adds	what it costs
04 WAVE	7.734812	1	the future as a spread rather than a point	the genomic-protocol paper [Curzi, 2026]	the spread is priced by Gabor: `dt df >= 1/(4 pi)`, an exact classical bound	the quantum analogy contributes no number; a badged analogy may organise, it may not compute
05	12.085643	5	set the idea of greater comfort where the self will pass; lower the cost of the destination	CCP-041 lever L3, CCP-045	cutting `c` is now one of exactly four levers, with its partial `dD/dc = +2.885390/eta`	CC-R20: lowering cost only at the origin shortens the wait from 32.0 to 9.9 weeks but leaves a 37% smaller permanent fund
06	17.403326	3	the minimal reversible probe; the veil that measures the measurer	CCP-045, CCP-047	reversibility is classified formally, and the analyst's own state is computed into `u` — mirroring costs 536.4074 cents	an observation taken by a reactive instrument is not free, and the price is now a number rather than a warning
07 COLLAPSE	23.687861	7	the moment the many become one	CCP-043, CCP-044	consonance and redundancy are proved identical, so collapse into agreement is collapse into redundancy	an entirely consonant self is an entirely redundant one, and nothing about distress follows — CCP-043 states the firewall formally
08 ECHO	30.939247	1	the world's answer, read over what was sent	CCP-044	the return difference becomes error decorrelation, `u = 1 − rho^2` — the only route that sees being wrong in different ways	it needs ground truth, unavailable for most of what two people actually disagree about
09 RECURSE	39.157484	9	the loop that returns changed	CCP-047	the transient `(1−delta)^t Q_0` is exactly the error law, and the three constants of arrival depend on `delta` alone	refinement cannot move the destination (the refinement theorem [Curzi, 2026]): the seventh distillation reaches nowhere the first was not already headed
10 FIXEDPOINT	48.342573	5	where the loop arrives	**the destiny paper [Curzi, 2026]**, and CCP-041	**Node 10 FIXEDPOINT = the storage fixed point [Curzi, 2026] = this series's the destiny paper [Curzi, 2026].** `Q_inf = (eta F − c)/delta` is destiny defined precisely; and by Thm 4.5 it is the octave deficit in different units	the definition is not a promise: changing a destiny means changing `(eta, F, c, delta)` and nothing else, and belief acts only through a coupling with real gain
11 SEAL	58.494514	11	when not to intervene	CCP-045 §6.13	a computable stop rule: ceiling test, empty re-read window, unreachable hold line each halt the procedure	the halt is a finding, not a failure; CCP-046's schedule halts at gate 4 for the same class of reason
12	69.613306	3	the committed state, the top of the ladder	CCP-041, CCP-045	`k N^2 = 69.6133 Hz` is now the system ceiling, reachable by an orthogonal pair and by nothing larger	above `c/eta = ln 12 = 2.484907` no arrangement of the twelve is sustainable, and the only remedies leave the ladder

Node 10's row is the load-bearing one and is stated once more in isolation, because three books converge on it: **the tenth node of Series A, the storage law [Curzi, 2026]'s Theorem 3.5, and this series's the destiny paper [Curzi, 2026] are the same object under three descriptions.** Series A named it and could not compute it; the storage law [Curzi, 2026] computed it and did not connect it to pitch; the deficit identity R3 [Curzi, 2026] connects it, and the destiny paper [Curzi, 2026] states what the connection means — a pitch reading and a destiny reading are the same reading.

One structural observation about the ordering, offered as arithmetic and not as evidence for it: indices 10 and 5 share pitch class 5 and sit exactly two octaves apart, since `10 = 2 * 5`, placing the fixed point in octave relation to an earlier node — the relationship an accumulator has with its own transient. Had the nodes been numbered differently the relation would not hold, and the sensitivity test says so: swapping 09 and 10 displaces a pitch class by 364.81 cents and is load-bearing, while swapping 03 and 12 displaces nothing, both being class 3.

9.2 Series B's parts

Series B part	subject	extended by	what the extension adds	what it costs
I — The Circuit	recursion as a circuit, not a roadblock	CCP-040, CCP-047	the storage law read as a circuit with a computable settling time	the linear form is a modelling choice; CCP-040 computes where it stops
II — The Geometry of Difference	`u`, `N_eff`, the participation ratio	CCP-043, CCP-044, CCP-045	three measured routes to `u` between persons, and the aggregation gap at group scope	the gap is larger than Series B's: 0.394666 octaves on the constructed family
III — Engineering Space	the room as a circuit element	not extended	—	this series is about persons and bonds; the spatial scope stays where Series B left it
IV — The Sociology	collective intelligence as an engineerable quantity	CCP-045, CCP-045	Brooks priced in octaves, the roster ceiling, three structures read end to end	an orthogonal pair already reaches `ln N`, so the group's case rests on grounds the formalism does not price
V — Tradecraft	the survey, the baselines, the traps	Section 6, Protocol C8	the four-baseline suite carried with all three measured holes attached	design controls are mandatory and not substitutable
VI — The Essence Law	`f = k n^2`, folding, the class rule	CCP-041, CCP-042, CCP-046	the law applied to psychological categories via a count-based index; the compound rule as coagula	the index sidesteps CC-R1 only because it is a count; the intensities do not, and must be magnitude-estimated
VII — The Perceptual Lens	the Moment equation `M = (D/P)E`	not extended quantitatively	—	CC-R1's demotion: `D/P` is ordinal pending Rasch instrumentation at 123 items per term, a cost this series does not spend
VIII — The Personal Formulary	the self as storage	CCP-042, CCP-043	traits as low-`delta` states, and a complete personal worksheet	`delta` is not a lever on the deficit, so the personal reading needs both numbers too
IX — The Interpersonal Formulary	the dyad, trust, reciprocity, Ostrom	CCP-043–CCP-045	the dyad given a frequency, a threshold, and an ordering rule	CC-R15: the cheapest-looking intervention accelerates the failure when the numerator is negative
X — Validation	the Formula Validation Protocol	CCP-041, Section 8	`f_min` and the index run through the gates, FVP-6 marked SPECIFIED, NOT RUN	the protocol demotes its own author's formulas, and the demotions are printed
XI — The Old Notation	correspondence tables, gematria	CCP-046-24	the twelve gates audited operation by operation; the schedule finding R2 [Curzi, 2026]	seven rejections across CCP-047 and 24, each with its failing criterion named
XII — The Concordance Method	the two columns	Section 7	this series's register, every rejection printed at the length of an acceptance	precedent is never promoted, and CC-R23 explains why in one number
XIII — Telecommunications to the Cell	the cell as receiver	CCP-048, CCP-048	the protocol restated for psychological content, with the no-subliminals constraint absolute	the open problem, carried whole and unsoftened
XIV — The Uncertainty	Gabor, and Heisenberg correctly stated	CCP-048, §5.6	the four design laws applied: capacity 25, cliffs at 17 and 41, rate factor 8	the rectangular gate is disqualified; implementations need a windowed envelope
XV — Belief and Mechanism	the belief postulate	CCP-049	the postulate applied to the four levers: belief acts only through a coupling with real gain	CC-R23 stands, and testimonial evidence has `LR = 1.000000`
XVI — Rewriting the Narrative	narrative as regulatory input	CCP-048	determination by choice, proved: a corpus closed under negation has resultant exactly zero	a contradictory corpus cannot command — the content-layer protection, and it is structural
XVII — Synthesis	the three instruments, the complete concordance	CCP-049, Sections 7 and 9	the arc across three books, closed on the open problem rather than a triumph	CC-R16: the correspondence is of dynamics and geometry, not of agency; nine disanalogies named

9.3 What this series adds that neither predecessor had Stated tightly, because the temptation at the end of a correspondence table is to claim the whole inheritance as new. The join itself, `f_min = k e^(2c/eta)`. The octave deficit as a computable reading, with the proof that it

is blind to `delta`. The count-based index, which escapes CC-R1's demotion by construction and states its own exposure in the same breath. The magnitude-estimation requirement, with the 1065-cent demonstration that makes it a requirement. The proof that state and relationship frequency are independent readings. And the audit of the old corpus on its own material, of which the schedule finding R2 [Curzi, 2026] is the sharpest instance.

What it does not add is a mechanism. That is the open-problem paper [Curzi, 2026]'s subject and Section 8's fourth drawer, and the series ends where it began: the archive is real, the regulatory layer is real, and the route from an acoustic symbol stream to either does not exist yet.

10 Results

Most of this paper contributes no results and is not intended to. The seven items below are the units other papers in this corpus may cite *to this paper*; everything else in Sections 4 to 9 is restated from the paper that owns it and should be cited there. Each carries its status: **ARITHMETIC** where the value is exact and a reader can redo it, **COMPUTED** where it is the output of an exhaustive search over a stated set, **CLASSIFICATION** where it is a record rather than a finding, and **POSTULATED** where it is asserted by this framework.

R1 — the exact-rational minimum-gap schedule. Folding every n^2 into a single octave as an exact rational, sorting, and taking the smallest adjacent ratio including the wrap gives a step function in the ladder length N with five regimes:

N	minimum gap	cents
2	$2/1$	1200.0000 (degenerate: one class)
3–6	$9/8$	203.9100
7–16	$50/49$	34.9756
≥ 17	$289/288$	6.0008
≥ 41	$1682/1681$	1.0296

The first cliff fires the instant index 17 enters the set, because $17^2 = 289$ folds beside $288 = 2{\cdot}12^2$; the second at index 41, because $41^2 = 1681$ folds beside $1682 = 2{\cdot}29^2$. *Status:* ARITHMETIC, exact. **Both locations are exact and neither depends on** k**.** $N = 12$ sits inside the third regime, so **every reading in this series renders at a minimum separation of 34.9756 cents.**

R2 — the rate penalty at the first cliff is exactly 8. Three distinct ratios describe the size of that cliff and confusing them is a documented error: the interval shrinks by $\ln(50/49)/\ln(289/288) = 5.828$ in cents, the cycle count rises by $288/49 = 5.878$, and **the symbol rate falls by** $(1/32)/(1/256) = 8$**, exactly.** The exactness follows from the two binding pairs sitting at different octave heights: the $50/49$ pair straddles $49/32$ and the $289/288$ pair straddles $9/8 = 288/256$, and Gabor resolution depends on the absolute gap in hertz [Gabor, 1946]. *Status:* ARITHMETIC.

R3 — the price of the affine axiom. The framework's surplus form is uniquely characterised by four axioms, of which S3 — that $e^{F(u)}$ is affine in u — **is forced by nothing.** $F_{\text{alt}}(u) = u \ln N$ satisfies the other three, agrees at both endpoints, and **at** $u = 0.5$ **the two disagree by 33.62 per cent:** 1.871802 **against** 1.242453**.** *Status:* ARITHMETIC on the two stated forms; the axiom itself POSTULATED. **S3 selects one curve from a family that agree at the ends and diverge by a third in the middle, and the middle is where every case lives.** Everything downstream inherits it: the effective count is defined by S3, the essence bridge identifies the index with the effective count, and the keystone is a statement about ln of that count.

R4 — the four-drawer classification. Every claim the series makes is sorted into **PROVED** (derived from stated premises with the arithmetic verified), **POSTULATED** (asserted as a design choice, badged, with the cost of the alternative computed where possible), **BORROWED** (taken from an established result elsewhere, cited, not re-derived) and **UNTESTED** (specified,

with a kill condition, and not run). An item may sit in more than one drawer at different levels of description and both placements are recorded. **The surplus form is recorded as PROVED CONDITIONALLY on a chosen design axiom, and the operationalisation of the twelve-state ladder as SPECIFIED, NOT RUN.** *Status:* CLASSIFICATION — a record of what the framework has paid for, not a finding.

R5 — single-transposition audible capacity. Requiring the whole set $\{kn^2 : n = 1 \dots N\}$ to lie inside 20 Hz–20 kHz after one integer octave transposition 2^j: **the maximum is $N = 25$, and only at $j = 6$.** At $N = 25,\ j = 6$ the set spans 30.9392 Hz to 19337.0293 Hz; at $N = 26$ no admissible j exists, since $j = 6$ puts the top at 20914.9309 Hz and $j = 5$ puts the bottom at 15.4696 Hz. *Status:* COMPUTED by exhaustive search over $j = 0 \dots 15$. **This is a hard bound on essence-set size under single transposition and it constrains any extension of the ladder.**

R6 — the unit conversion table. 1 nat $= 1.442695$ bits $= 2.885390$ octaves $= 3462.4681$ cents, and 1 **bit $= 2$ octaves exactly.** The exactness is not a coincidence: frequency enters as $f = k\,e^{2F}$, so one nat is two e-folds of frequency and one bit — being $\ln 2$ nats — is two doublings. *Status:* ARITHMETIC; the constants exact ($2/\ln 2 = 2.8853900817779268$). The conversion keys are owned by [Curzi, 2026l]; **what this section adds is the statement of why the bit-to-octave relation is exact.**

R7 — the eight measurement protocols. C1 indexing a state; C2 elicitation, with the argument that magnitude estimation is required rather than preferred; C3 the three routes to u with the accuracy guard and the overlap gate; C4–C6 estimating η, c and δ; C7 producing the reading; C8 controls. **C7 requires the ceiling test first and mandates reporting the deficit and the loss rate together, because the deficit cannot see decay.** *Status:* procedures, not findings. **Protocols C4–C6 are estimation practice badged as practice: η, c and δ have no instrument comparable to u's.**

CR — the counter-result. The honesty accounting **prices the framework's central postulate rather than defending it.** The affine effective-count axiom is chosen; an alternative satisfying every other axiom diverges by a third in the middle of the range; the twelve-state ladder's operationalisation is **specified but never run**; the framework's own research programme carries 21 preregistered kill conditions, four of them terminal, and a self-computed **35.8 per cent completion probability**. And the series' central instrument is blind to decay by construction. **A reference apparatus that recorded only what its framework had established would be a sales document.**

11 Discussion

11.1 What follows

The minimum-gap schedule is a design constraint rather than an observation, and it binds any extension of the ladder. A framework operating at $N \leq 16$ has 34.9756 cents of separation to work with; one that adds a seventeenth category has 6.0008 and pays a factor of eight in symbol rate for it. **That price is exact, is available before any extension is attempted, and does not depend on the postulated constant.** Together with R5's capacity bound it says that the ladder's length is constrained from two directions at once — by rendering resolution below and by audible band above — and that $N = 12$ sits comfortably inside both.

The pricing of the affine axiom is the most useful thing in the paper for a sceptical reader. It converts "the framework assumes X" from an objection into a number: the assumption is worth 33.62 per cent at the midpoint of the parameter's range. **A reader who rejects S3 now knows what rejecting it costs**, and a reader who accepts it knows what has been bought on credit.

The four-drawer classification is a genre, not a result, and its value is that it can be checked. Each drawer has an exit (§8.6): PROVED is exited by an error in a derivation or a failed verification, and every verification here states its residual; POSTULATED by exhibiting a system in which the postulate fails; BORROWED by retraction or supersession; UNTESTED by running the test. **An honesty appendix that could not be moved by evidence would be a creed.**

11.2 What does not follow

Nothing here is evidence for the framework. Every exact result in this paper is arithmetic on the framework's own definitions, and arithmetic on a definition tests the arithmetic. R1, R2, R5 and R6 would be exactly as true if the essence law were false.

The protocols are not validated. They are procedures with declared inputs, outputs and gates. None has been run on data, the inter-rater reproducibility of Protocol C1 has not been tested, and Protocols C4–C6 are explicitly badged as estimation practice. **A protocol is a specification of how to be checkable, not a demonstration that anything checked out.**

And the concordance register is not corroboration. Its two columns do different work: one carries evidence, one carries precedent, and **precedent is never promoted.** The reason is exact rather than stylistic — under a selection process that publishes successes and discards failures the likelihood ratio of testimonial evidence is exactly 1.000000 [Curzi, 2026ad], which is not weak evidence but the arithmetic statement that it leaves the prior where it found it.

11.3 Relation to the surrounding programme

The apparatus assembled here is only as good as the results it points at, and two of those results bound what the rest may claim. The framework's own confirmatory attempt **failed its declared baseline test** and reported the failure [Curzi, 2026i], which is the relevant precedent for how any test of these protocols should be reported. And the structural work bounds the reading of any effective count: adding nominally distinct units that are not independent buys capability and not diversification [Curzi, 2026,?], and the concentration instrument transfers to other domains unchanged [Curzi, 2026]. **A card that printed an effective count without that caveat would licence exactly the inference those papers refuse.**

11.4 The reflexive exposure

A reference card changes what it references. Publishing a fixed set of constants, protocols and worksheets makes them the thing that gets used, and the framework asserts that systems change when they are modelled while exempting its own parameters from that reflexivity [Lucas, 1976, Hacking, 1995]; the mechanism by which a published instrument becomes self-confirming is documented [Merton, 1948, MacKenzie and Millo, 2003]. **Nothing here controls for it.** The mitigation this paper can actually supply is §8: a classification that prints what is untested at the same length as what is proved.

12 Verification

A reference card is exactly the document a reader is least likely to check and most likely to trust, so this section decomposes its load-bearing content into steps that can be checked one at a time. Every step carries one of four statuses: **ARITHMETIC** (a reader can redo it), **DEFINITION** (true by the framework's own construction, carrying no empirical weight), **CITED** (an external source supports it, named), or **POSTULATED** (asserted by this framework, no external support).

12.1 The postulates

	postulate	status
P1	The Pythagorean whole tone is the frequency ratio $9{:}8$.	CITED [Barbour, 1951]

	postulate	status
P2	φ is the positive root of $x^2 = x + 1$.	CITED [Euclid, 1956, Vajda, 1989]
P3	A dimensionless ratio of the form $(9/8)^2/\varphi^2$ **is a frequency in hertz**.	**POSTULATED — no source**
P4	The essence of a state with n components has frequency kn^2.	**POSTULATED — no source**
P5	$N_{\text{eff}} = 1 + (N-1)u$ is affine in u (axiom S3).	**POSTULATED — a design axiom, priced at §8.2; not a Hill number**
P6	$F = \ln N_{\text{eff}}$, hence $F \leq \ln N$.	DEFINITION (given P5)
P7	Stored order obeys $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$.	CITED as a *form* [Oppenheim et al., 1996, Elaydi, 2005]; the interpretation POSTULATED
P8	A frequency may be divided by a power of two without changing what it means.	**POSTULATED beyond pitch**; CITED for pitch only [Shepard, 1982]
P9	n and N are cardinalities, hence absolute-scaled.	DEFINITION, typology CITED [Stevens, 1946]
P10	Magnitude estimation yields ratio-scale intensities up to a free multiplier.	CITED and **contested** [Stevens, 1957, Teghtsoonian, 1971, Poulton, 1968]
P11	$\Delta t \, \Delta f \geq 1/(4\pi)$.	CITED — classical Fourier, no quantum content [Gabor, 1946]

Dropped as unnecessary. R1, R2 and R5 — the three exact results originating here — consume **neither P3 nor P4 nor P10.** The minimum-gap schedule is a statement about the fractional parts of $\log_2 n^2$; the rate penalty is a ratio of two ratios; the capacity bound is a comparison of $k\,n^2\,2^j$ against two fixed limits, and while the last does consume k *as a number*, it does not require the number to be a frequency for the ordering to hold — only for the band limits to mean what they say. **No postulate about the ladder's ordering, about consonance, or about the twelve categories is needed for any of the three.**

12.2 The compounding chain

step	consumes	produces	status
L1	P1	$(9/8)^2 = 81/64 = 1.265625$ exactly	ARITHMETIC
L2	P2	$\varphi^2 = \varphi + 1 = 2.618033988749895$	ARITHMETIC
L3	L1, L2	$k = 0.483425732988414$ — **DEFINED, exact**	ARITHMETIC (exact)
L4	L3, **P3**	k carries the unit Hz	**POSTULATED**

step	consumes	produces	status
L5	L4, **P4**	$f(n) = kn^2$ Hz; $kN^2 = 69.6133055503$ at $N = 12$	**POSTULATED**
L6	P5, P6	$F \le \ln N$; $\ln 12 = 2.4849066497880$	DEFINITION
L7	P7, L6	$f_{\min} = k\, e^{2c/\eta}$; $c/\eta \le \ln N$	ARITHMETIC given L5
L8	L7	octaves required $= (2/\ln 2)(c/\eta)$, with $2/\ln 2 = 2.8853900817779$ — **R6**	ARITHMETIC (exact)
L9	L8	1 bit $= \ln 2$ nats $= 2$ octaves **exactly**	ARITHMETIC
L10	P5	$F(0.5) = \ln 6.5 = 1.871802$ at $N = 12$	ARITHMETIC
L11	S1, S2, S4 without P5	$F_{\text{alt}}(0.5) = 0.5 \ln 12 = 1.242453$	ARITHMETIC
L12	L10, L11	disagreement $= 33.62\%$ — **R3**	ARITHMETIC
L13	n^2 folded as exact rationals	five regimes: $2/1$, $9/8$, $50/49$, $289/288$, $1682/1681$ — **R1**	ARITHMETIC (exact)
L14	L13	$17^2 = 289$ beside $2 \cdot 12^2 = 288$; $41^2 = 1681$ beside $2 \cdot 29^2 = 1682$	ARITHMETIC
L15	L13, octave heights	$(1/32)/(1/256) = 8$ exactly — **R2**	ARITHMETIC
L16	L5, band $[20, 20000]$ Hz	$N \le 25$ at $j = 6$ only — **R5**	ARITHMETIC (exhaustive over j)
L17	P9, odd parts of $1 \ldots N$	class count $= \lceil N/2 \rceil$, checked at every $N \le 25$	ARITHMETIC
L18	P11	$1/(4\pi) = 0.07957747155$; and $32/(4\pi) = 2.54647908947$	CITED + ARITHMETIC
L19	the four drawers	the classification — **R4**	**CLASSIFICATION**, not a proof

12.3 What this chain is and is not

Read the status column. L1–L3, L6–L18 are arithmetic or definition and a reader can redo every one of them; L4 and L5 are postulated; L19 is a record. **A chain containing postulated steps is not a proof of its conclusion**, and this one is not offered as one.

Three checks a reader should run, none taking more than a minute, and together they establish the constant rather than leaving it asserted. $(9/8)^2 = 1.265625$. $\varphi^2 = \varphi + 1 = 2.618033988749895$. Dividing gives 0.483425732988414. **That is L1 to L3, and after it the constant is established and only its unit is in dispute.** A fourth check settles R3 in two logarithms: $\ln 6.5 = 1.871802$ against $0.5 \ln 12 = 1.242453$, a gap of 33.62 per cent.

What the chain shows about this paper's own contributions is that they are unusually inert. R1, R2 and R5 sit at L13–L16 and consume no postulate about what the numbers mean; **a reader who rejects P3 and P4 entirely keeps all three**, because a folded lattice is a set of

rationals whatever the reference constant is called. **R3 is the one result that bears on the framework's truth, and what it establishes is the size of a choice rather than an error.**

Two statuses that must not be misread. The exponent 2 at L5 is **DEFINED, not estimated**: no fit was performed and the standard procedure for testing a scaling claim [Clauset et al., 2009] was not run, because there is no data to run it on. And **L19 is a classification, not a verification**: a drawer labelled PROVED contains claims proved *from the framework's own postulates*, which is exactly what §12.1 lists.

13 Limitations

L-1. This paper is not a research contribution and should not be cited as one. It restates results owned elsewhere and adds four items of apparatus. **Citing this paper for a result it merely restates misattributes the result.** §3.1 gives the attribution table.

L-2. Nothing here is tested. No hypothesis is advanced (§2), no data were collected, no model was fitted, no statistical test was run, and no effect size or interval is reported. **The paper contains no empirical content whatever.**

L-3. The dimensional audit does not close in two places, and both are postulates. $f(n) = kn^2$ requires k to carry $[T^{-1}]$ while k is a ratio of two dimensionless quantities; and the compound value is dimensionally hertz-squared, so its "Hz" label is a convention. **No citation in the bibliography repairs either**, and the card prints the unit only because the series prints it.

L-4. The constant is chosen, and its fifteen figures are digits of a definition. $k = (9/8)^2/\varphi^2$ combines two documented objects into a product with no precedent, and the deflationary literature on golden-section claims is cited rather than avoided [Markowsky, 1992, Fischler, 1981, Livio, 2002]. **Fifteen figures on a *measured* quantity would be the classic marker of work that does not understand its own error bars; these fifteen are legitimate only because nothing was measured.**

L-5. Octave reduction beyond pitch is unwarranted [Shepard, 1982, Demany et al., 2013], and every folded column in §5 inherits that. **The arithmetic of the fold is exact; its interpretation is not supported.**

L-6. The effective count is not a Hill number. $1 + (N - 1)u$ is a linear interpolation between 1 and N with no supporting literature. The Hill family [Hill, 1973, Jost, 2006] and its political-science rediscovery [Laakso and Taagepera, 1979] ground $1/\mathrm{HHI}$ and $\exp(H)$ exactly and ground this construction **not at all.** A reader reaching for that literature as support will find it does not apply, and §8.2 prices the axiom rather than defending it.

L-7. Conjoint measurement was not tested, and this is the framework's largest standing liability. The ratio-scale treatment of η, c, δ and the elicited intensities is provisional; Michell's objection stands unanswered [Michell, 1997, 1999] for every quantity in the series except the counts; the available remedies [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960] were not run, and the framework's own price for the Rasch route — 123 items per term — was not paid.

L-8. The reflexive specification is not identified. Stated at §3.7 and repeated because the protocols depend on it: the endogenous effect in a reflexive specification cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011], the remedy adopted is stipulation of the reference set [Brock and Durlauf, 2001], and **every reading Protocols C3–C7 produce is therefore a modelling position rather than an identified empirical result.**

L-9. The framework exempts its own parameters from its own reflexivity [Lucas, 1976, Hacking, 1995, Merton, 1948]. Not resolved.

L-10. The functional form is underdetermined by the evidence. A sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the qualitative facts as well as the framework's logarithm does, and many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. **Nothing in this paper discriminates among them**, and §8.2's pricing of S3 is a statement about one alternative within the framework's own axiom set, not a survey of the space.

L-11. The warrant the logarithm needs is not the one usually offered. The psychophysical route [Fechner, 1860] inherits every dispute in that literature; the multiplicative-dynamics route derives a logarithmic form with **no psychological assumption at all** [Peters and Gell-Mann, 2016]. **The tables here need only the second**, and where the series leans on the first it inherits the disputes catalogued at §3.6.

L-12. The exponent is defined, not estimated [Clauset et al., 2009]. **No empirical scaling claim is made anywhere in this paper.**

L-13. Scalar reduction is a habit of this framework, inherited here rather than re-conceded. The minimum-frequency paper states the limitation once and in full [Curzi, 2026]: the framework replaces phenomena its own source literature describes by several jointly varying features with a single number and proceeds arithmetically on the number. **That concession governs here, and this paper's instance is the card itself** — a one-page summary of a framework whose limits live in the argument it invites the reader to skip. The mitigation is the one the card actually applies: every card carries its limits inline. **It is a mitigation and not an answer.**

L-14. Protocol C1's inter-rater reproducibility has not been tested. Whether the component count is a property of the episode or of the analyst is the gate that decides whether the ladder measures anything, it is recorded in §8.4 as **SPECIFIED, NOT RUN**, and the worksheets in §6 cannot substitute for it.

L-15. Protocols C4–C6 are estimation practice badged as practice. η, c and δ have no instrument comparable to u's. C4's count of surviving artefacts is crude; C5 requires a declared conversion in which most of the error lives; C6 inverts a half-life from a judged surviving fraction. **All three are better than a guess only because the objection to them is visible.**

L-16. The controls the series recommends have three measured failure modes, and this paper carries them rather than the recommendation alone. §6's Protocol C8 records the shuffled-input control at a measured false-rejection rate of 0.108 against a nominal 0.05 — **anti-conservative by a factor of 2.2** — together with its blindness to repackaging and its 98.35 per cent pass rate against a shared slow driver. **Adding surrogates does not fix a design problem**, and the remedy is design controls: blinding, channel separation, prospective sampling, a yoked control.

L-17. Two of the works this paper's borrowings depend on are named without citation keys. The BORROWED drawer at §8.3 lists sources in the framework's own compressed form, and several of them — the process-control and biological entries in particular — are named with journal, volume and year in the running text because **they are absent from the bibliographic database governing this corpus.** That is a gap in the bibliography and is disclosed rather than papered over.

L-18. The interval and gap arithmetic makes no claim about consonance. Two established measures of ratio complexity exist [Euler, 1739, Tenney, 2015] and **neither is used**; §5.6 reports distances in cents, and what a listener finds consonant depends on spectrum rather than ratio [Sethares, 2005, Plomp and Levelt, 1965].

L-19. There is no conservation law [Mirowski, 1989]; validity is claimed only within a specified arrangement [Cartwright, 1999], within the boundaries the sociophysics literature draws [Castellano et al., 2009]. **L-20. Ergodicity is assumed and not argued** [Peters, 2019], and aggregation over heterogeneous agents need not yield a representative agent [Kirman, 1992].

A precision inconsistency in the source, recorded rather than repaired. The card prints k^2 as 0.2337004393 "to ten places" while every computation uses 0.233700439315386. The two are consistent — the first is the second, rounded — but the compound-rule protocol of [Curzi, 2026] performs an integrality test whose sensitivity at large component counts **exceeds ten decimal places**, so a value published to the card's precision cannot support the test the specification demands. **The card and the protocol are in tension**, and the resolution adopted here is that every computation uses the full-precision constant and the card's ten-place figure is a display form only.

A second, and it is a live one. The source's own note at §4.1 records that a residual bias in a published element table was traced to φ held at fifteen significant figures rather than at full double precision. **That is a statement that fifteen figures was, in at least one instance, not**

enough — which sits awkwardly beside a card that prints k to exactly fifteen. The instruction the card gives is the right one and is repeated here: **carry the constant, not its printed form.**

14 Conclusion

What this paper is. The reference and status apparatus for a framework whose results are established elsewhere: a constants card with its badges attached, frequency and interval tables, eight measurement protocols with blank worksheets, a concordance register that prints its rejections at the length of its acceptances, a four-drawer classification of every claim the series makes, and a correspondence table to the two predecessor series. **It advances no hypothesis and it is not a research contribution.**

What originates here. The folded-lattice minimum gap as an exact function of ladder length — 1200 cents at $N = 2$, 203.9100 at $N = 3 \dots 6$, 34.9756 at $N = 7 \dots 16$, 6.0008 at $N \geq 17$ and 1.0296 at $N \geq 41$ — with the symbol-rate penalty at the first cliff **exactly 8**. The single-transposition audible capacity, $N \leq 25$ **and only at** $j = 6$. The statement that 1 bit is **2 octaves exactly**, and why. And the four-drawer classification, whose most useful entry is a price rather than a defence: **the framework's central design axiom is chosen, and an alternative satisfying every other axiom and agreeing at both endpoints disagrees with it by 33.62 per cent at** $u = 0.5$**.**

What is proposed rather than shown. That $(9/8)^2/\varphi^2$ is a frequency; that essence goes as kn^2; that octave equivalence carries beyond pitch; and that the effective count is affine in the geometry. **All four are postulates of this framework, badged at every appearance**, and the three exact results originating here survive the rejection of the first three, because a folded lattice is a set of rationals whatever its reference constant is called.

What is recorded rather than claimed. That the operationalisation of the twelve-state ladder is **specified and not run**; that the acoustic causal claim is **not confirmed**; that the decisive experiment is **designed and not run**; that the framework's central instrument is **blind to decay**; and that the framework's own estimate of its research programme's completion probability is **35.8 per cent**. **A reference apparatus recording only what its framework had established would be a sales document, and this one is not offered as an argument for anything.**

15 Declarations

Data and code availability. No dataset was collected for this study and none exists. Every number in this paper is the output of exact arithmetic — in several places exact rational arithmetic — or of exhaustive search over a stated finite set, on inputs stated in the text. The worked cases carried through the protocols are **constructed** and are labelled as constructed at the point of use. The figures are generated by the Python scripts named in their captions and are available from the author on request. **No empirical measurement of any person, relation or institution underlies any figure, table or number in this paper.**

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the compilation, the computations, the figures and the manuscript.

Ethics. No human-subjects research was conducted and no personal data were processed. The protocols in Section 6 specify a consent procedure, a right to decline without reason at every step, and a prohibition on anything masked or below awareness; **none of them has been applied to anyone, because no reading of any real person or relation was taken.** The blank worksheets are specifications, not records.

Preregistration. Nothing here was preregistered, because no test was run. §8.4 records the framework's untested items **with their kill conditions stated in advance**, which is the form a preregistration would take; the framework's one preregistered confirmatory attempt elsewhere failed its own declared baseline margin and reported the failure [Curzi, 2026i].

Bibliographic disclosure. Several works listed in the BORROWED drawer of §8.3 are named in the running text without citation keys because they are absent from the bibliographic database governing this corpus (§13, L-17). They are given with enough bibliographic detail to be located.

Clinical disclaimer. The twelve state classes are not diagnostic categories. Nothing in this paper is an assessment, a screening instrument, a treatment, counselling, or advice about any person's health, and nothing in it may be presented as such. **No person, tissue, cell or molecule is claimed to resonate at any frequency named here**; the frequencies represent a count and an angle, and nothing in the formalism asserts a physical oscillation.

Part IV

Structure and Resilience

Chapter 51

Correlated Jurisdictions: Coordination Perimeters, Erosion, and the Economics of Full Disclosure

Abstract. Fifteen years of automatic information exchange, economic-substance requirements and beneficial-ownership registration removed concealment as a durable property of cross-border asset structures. We ask what remains once concealment is unavailable, and answer with two measurements. First, coordination. Four jurisdictions that look diverse on an entity map — the United Kingdom at 40.91 per cent of exposure, the United States at 27.27, Jersey at 18.18 and Luxembourg at 13.64 — give a naive Herfindahl index of 0.293388 and 3.4085 effective jurisdictions, but they collapse into a single coordination perimeter with a bloc index of 1.000000 and exactly 1.0000 effective perimeters: a 3.41-fold overstatement. Assuming independence where a shared perimeter exists understates joint impairment by three orders of magnitude; a common shock of two per cent raises the probability that all four fail together from 0.000100 to 0.020044, a factor of 200.4, and over fifteen years converts a one-in-seven-hundred event into a four-in-five event. Second, disclosure. A concealment-based arrangement costing USD 210,000 against a compliant USD 561,000 shows a 62.6 per cent saving on the invoice, but is more expensive above an annual examination probability of only 0.85 per cent, and halving the loss on examination moves that threshold only to 1.7 per cent. Elements are scored on five criteria multiplicatively, so one failing element zeroes the structure. The erosion rate is decomposed as 2.0 per cent a year, a half-life of 34.31 years. Both the observed and the redesigned structures remain below break-even.

Keywords: coordination perimeter; correlated failure; automatic exchange of information; economic substance; concentration measurement; disclosure economics; asset-holding structures

Series: D. Structure and Resilience **Paper:** CCP-051

1. Introduction

Between 2009 and 2024 the jurisdictions whose commercial product was confidentiality lost the ability to deliver it. That much is a matter of public record. This paper asks the engineering question that record poses — *what remains once concealment is unavailable, and how should what remains be measured* — and answers it with two measurements and one identification.

The identification comes first because everything else is downstream of it. The jurisdictions did not erode separately. They eroded together, because they were attached to a common set of mechanisms: automatic exchange of financial account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations that national supervisors implement in common [Financial Action Task Force, 2012], the substance and treaty-abuse work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015], listing frameworks whose designations propagate without further decision [de Goede, 2011], and the private, unappealable correspondent-banking decisions that consume all of the foregoing as inputs. **The correct unit of analysis for concentration risk is therefore not the jurisdiction but the coordination perimeter**, defined here as a set of jurisdictions among which an adverse decision propagates without a separate act of consent by each of them.

The first measurement is what that identification costs a structure that ignores it. Four jurisdictions that look diverse on an entity map — the United Kingdom at 40.91 per cent of exposure, the United States at 27.27, Jersey at 18.18 and Luxembourg at 13.64 — give a naive Herfindahl index of 0.293388 and 3.4085 effective jurisdictions, and collapse to a single coordination perimeter with a bloc index of 1.000000 and exactly 1.0000 effective perimeters. The overstatement is a factor of 3.41, and it arises from a modelling assumption rather than from an arithmetical error. The tail consequence is larger than the point estimate suggests: holding each jurisdiction's marginal failure probability fixed at ten per cent, a common-shock component of only two per cent per year raises the probability that all four fail together from 0.000100 to 0.020044, a factor of 200.4.

The second measurement prices the alternative that the erosion appears to recommend, which is more concealment, and finds it already uneconomic. A constructed concealment-based arrangement costing USD 210,000 a year against a compliant USD 561,000 shows a 62.6 per cent saving on the invoice and breaks even at an annual examination probability of $p^{*} = 0.008458$. **Above 0.85 per cent a year, concealment is the more expensive design**, and halving the loss on examination moves the threshold only to 1.7 per cent.

The instrument used throughout is the Herfindahl–Hirschman Index, introduced by Hirschman [1945] in root form to describe the concentration of a country's foreign trade and reached independently in sum-of-squares form by Herfindahl [1950]. Its full development for this application, including the variance identity that makes the bloc collapse exact rather than convenient, belongs to Curzi [2026], which establishes that the redesigned six-jurisdiction structure reaches a naive index of 0.189002 (5.29 effective jurisdictions) and a bloc index of 0.340000 (2.94 effective blocs), with Western-perimeter exposure falling from 100.0 to 30.0 per cent. **This paper supplies the evidence base that forces the collapse, the test that decides bloc membership, and the economics that determine whether the resulting structure can survive being looked at.**

Three things this paper does not do should be stated at the outset. It fits no distribution and asserts no scaling law; Clauset et al. [2009] is the reason the procedure would have to be run before any such claim could be made, and it is not run here because no claim requiring it is made. It offers no operational guidance for moving value that a sanctions regime prohibits. And it does not cite jurisdiction-specific primary law: **the bibliography contains general treaty, standard-setting and doctrinal material only, and every statute, case, registry document and jurisdictional characteristic described below is described from the source manuscript, left uncited, and itemised in Appendix B.** That is a real gap, it is not closed here, and it is declared again in the Declarations.

Curzi [2026] supplies the framing this paper presupposes: comfort — here, held capital under protection — is the felt total of present costs, so the present arrangement is a local minimum of the cost landscape by definition rather than by luck, which is why a structure that has stopped being optimal continues to feel settled from inside it.

2. Hypotheses

Five hypotheses are stated, each with what would falsify it, in the form Platt [1964] requires of a discriminating test. Meehl [1967] is the standing warning: a directional prediction in this territory is nearly costless, and the defensible reply is a point prediction with constants attached, which H1, H2 and H4 make. One of the five is reported in Section 8 as **not met**.

H1 — the coordination hypothesis. Jurisdictions attached to a common set of transmission mechanisms fail together rather than independently, so that a concentration measurement taken at jurisdiction level overstates resilience. *Predicted:* for the observed structure, the effective count computed on raw shares exceeds the effective count computed on perimeter-collapsed shares by a factor above three — specifically 3.4085 against 1.0000. *Falsified by:* an observed pattern in which the four named jurisdictions changed their treatment of holding structures on independent schedules and by independent instruments, with no common trigger identifiable in the record.

H2 — the common-component hypothesis. The joint-failure probability of a perimeter-attached set is governed almost entirely by the common component and almost not at all by the idiosyncratic one. *Predicted:* holding the marginal failure probability at 0.10, a common component of $c = 0.02$ raises $P(\text{all four})$ from $p^4 = 0.000100$ to 0.020044, a factor of 200.4; and $P(\text{all four}) \to c$ as c rises. *Falsified by:* a decomposition in which the idiosyncratic term contributes materially to the joint probability at any $c > 0$ that is small relative to the marginal probability.

H3 — the disclosure-economics hypothesis. A concealment-based structure is more expensive than a compliant one at any realistic examination probability, once the expected loss on examination is included rather than the invoice alone. *Predicted:* at the constructed parameters the break-even examination probability is $p^* = (561{,}000 - 210{,}000)/41{,}500{,}000 = 0.008458$, and the result is insensitive to the loss parameter — halving L moves p^* only to 0.016916. *Falsified by:* a defensible estimate of annual examination probability below 0.85 per cent in the environment described in Section 4, or a cost structure in which the compliant architecture's premium exceeds the expected loss.

H4 — the reallocation hypothesis. The reallocation required to reach two effective perimeters is structural rather than marginal. *Predicted:* with the exiting share split evenly between two further perimeters, the in-perimeter share must fall to exactly $2/3$ before the effective count reaches 2.0000; moving ten per cent buys only 1.2270. *Falsified by:* any allocation reaching $N = 2$ while retaining more than two-thirds of exposure inside one perimeter.

H5 — the sufficiency hypothesis. Perimeter redesign alone lifts a structure to a non-negative surplus balance. *Criterion, fixed in advance:* with $h = \eta \ln N - \delta Q - C$ at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$, the balance is non-negative only if $\ln N \geq 0.5000/0.35 = 1.428571$, that is $N \geq e^{1.428571} = 4.172734$. *Falsified by:* a redesigned structure whose effective perimeter count falls short of 4.172734 at the stated parameters.

Not hypotheses, and labelled as such. Four statements in this paper are not falsifiable as written, and each is named here for what it is rather than allowed to travel as a finding.

- *The logarithmic form of the input term*, $\eta \ln N$ rather than ηN, is a **modelling choice** carried from Curzi [2026]. It is not tested here, and Section 12 records that Latané's sub-linear power law and an $n \log n$ form fit the qualitative facts equally well.
- *The identification of N with the effective perimeter count* is a **definition**. All of its content sits in the perimeter test of Section 3.4, which is testable; none of it sits in the identification.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice**, fixed in advance so that H5's criterion cannot be adjusted after the measurement — the preregistration discipline of Nosek et al. [2018] applied to an engineering measurement.
- *The erosion decomposition* $\delta = 0.020$ into four named components is a **constructed illustration**, not a research estimate, and is labelled at its point of use.

3. Method

3.1 The storage law, and the one term that must be reinterpreted

The framework's storage law relates a stock held against decay to its decay rate, the efficiency with which flow converts into stock, and the maintenance cost of holding it. In difference and surplus form:

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t

h = eta ln(N) − delta Q − C
```

with Q the protected capital actually held under durable protection, δ the erosion rate, η the conversion of income into durable protected holdings, S the income flow available for conversion, C the recurring structure maintenance, N the effective diversity count, and h the available surplus above upkeep. Curzi [2026b] states the headroom gauge in full — three regimes, a maximum increment $r_{\max} = h_t$, and the separate constraints of admissibility $C_t \leq (1-\delta)Q_t + \eta S_t$ and sustainability $C_t \leq \eta \ln N - \delta Q_t$ — and this paper reuses that instrument without restating its derivation. The difference equation itself is a first-order linear recurrence and its fixed-point behaviour is standard [Elaydi, 2005]; Curzi [2026] states the sharper corpus result, that refinement cannot move the fixed point because $Q_\infty = (\eta F - c)/\delta$ contains no t.

Three of the five terms transfer to the capital case without commentary. Q is what is actually held under protection rather than what is nominally owned. C is real, recurring, and the term most often set to zero in informal planning. S and η together say only that income helps to the extent it is converted into durable protected stock rather than consumed or left in a form that inherits the erosion rate.

δ deserves a note because in the capital case it aggregates four processes that are usually discussed separately and should be added: tax drag, the probability-weighted cost of arbitrary action, debasement of the unit of account, and degradation of the jurisdictional characteristics the structure was built to use. Section 4.6 decomposes it.

That leaves N, and N is the whole argument. In the goods case N counts independent stores, and the word *independent* does its work quietly because in the physical case independence is visible — two warehouses on one flood plain are one store, and anyone can see it. Capital has no flood plains. **In the capital case N is the effective number of independent coordination perimeters: not the number of entities, and not the number of jurisdictions.**

The consequence is severest at the boundary and is the framework's hardest single result. If every entity sits inside one perimeter then $N = 1$, $\ln 1 = 0$, and the entire input term vanishes:

```
h = eta ln(1) − delta Q − C
  = 0 − delta Q − C
  = −(delta Q + C)
```

A structure confined to one coordination perimeter has not a small available surplus but a negative one, equal to the whole of its erosion plus the whole of its upkeep, and no rearrangement of entities inside that perimeter changes it. Adding a fifth entity in a fifth jurisdiction inside the same perimeter costs C and adds nothing to N. That this is an *organisational* result and not only a jurisdictional one was established long before it was measured: Perrow [1984] showed that interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component, and the finding here is Perrow's in a measurement frame. It is cited as **qualitative theory and framing, never as a formal result**.

3.2 Which effective count, stated exactly

The corpus runs two quantities under the name *effective count* and they are not the same quantity. This paper uses one of them and says so at every point of use, because a reviewer who reaches for the diversity literature will find that it covers one exactly and the other not at all.

The reciprocal index is a Hill number of order two. Hill [1973] defined the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types that would produce the observed value of the underlying index; at $q = 2$ this is $(\sum_i p_i^2)^{-1}$, which is HHI^{-1} exactly. Jost [2006] is the statement that entropies are not diversities and that their numbers-equivalents are. The numbers- equivalent reading of the concentration index itself belongs to Adelman [1969]. The same arithmetic was reached independently in ecology [Simpson, 1949] and in political science as the effective number of parties [Laakso and Taagepera, 1979]; the exponential of Shannon entropy [Shannon, 1948] is the same family at $q = 1$, and the reciprocal index is also the exponential of the Rényi entropy of order two [Rényi, 1961]. **Every effective count in this paper is HHI^{-1}, the Hill number of order two, and is named as such.**

The corpus's affine count is not a Hill number and has no external support. The quantity $N_{\text{eff}} = 1 + (N-1)u$ used in Curzi [2026] and Curzi [2026c] is a linear interpolation between 1 and N. It is not a Hill number of any order, it is not a numbers-equivalent, and no entry in ecology, economics, political science or information theory states it. Curzi [2026] runs the two definitions through the same verification chain and shows where the second one fails; this paper does not use it, and the distinction must survive any citation of this paper. Curzi [2026c] is cited here for a different result entirely — the sharp Lipschitz constant $N-1$ read as a measurement-error budget, under which $N = 12$ and $u = 0.05 \pm 0.05$ admits surplus anywhere in $[0, 0.7419]$ against a width of 0.1266 at $u = 0.70$ — because that is the correct way to think about the error budget on a bloc assignment.

The generalisation the collapse relies on is $\mathrm{EFF} = 1/(w'Rw)$ for exposure weights w and correlation matrix R, which is the similarity-sensitive diversity of order two of Leinster and Cobbold [2012], whose additive relative is the quadratic entropy of Rao [1982]. Setting $R = I$ recovers HHI^{-1}; setting R to the block matrix of ones recovers the bloc index. Curzi [2026] derives the identity in full and owns it as a result; this paper consumes it. Hurlbert [1971] is the standing discipline on the word *diversity* — it has been used for so many distinct quantities that it carries no content without its formula attached, which is why the formula is attached here every time.

3.3 The reflection problem, stated where the loop is used

The perimeter assignment is a forecast about correlated behaviour, and the framework's central formal object is the reflexive loop $T(x) = W(x, M(x))$ of Curzi [2026], in which the group influences the member while the members constitute the group. **That is exactly a linear-in-means reflexive specification, and Manski [1993] proves that its endogenous social effect is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] reinforces the point for network data, where influence and selection are generically confounded. **No amount of observation of jurisdictional behaviour could therefore confirm a perimeter assignment derived reflexively, and this paper states that where the assignment is made rather than in a footnote.**

Four remedies are known — randomisation, an instrument, partial-population variation, and stipulating the reference group with a defence of the stipulation. **The fourth is adopted here.** The perimeter membership is fixed in advance by the four-question test of Section 3.4, recorded with its evidence, and stress-tested; Brock and Durlauf [2001] is the template for making a stipulated reference group rigorous, and it is the only one of the four available in this setting. **The price is that the perimeter assignment is a modelling position and not an identified empirical result.** That price is paid explicitly here, again in Section 10, and again in

Section 12.

The same reflexivity applies to the instrument itself and is not exempted. MacKenzie and Millo [2003] documents an option-pricing model that did not fit the market when published and came to fit it after traders adopted it; Hacking [1995] gives the general form, in which a classification of a population interacts with the population classified. **If enough structures are built on the assumption that two jurisdictions share a perimeter, capital and correspondent relationships reorganise around that assumption and the assumed correlation becomes the observed one.** Lucas [1976] states the severe consequence: a parameter estimated in a population that has not read the instrument cannot be assumed stable in a population that has. **The framework asserts that systems change when modelled and then exempts its own η, δ and correlation assumptions from that same reflexivity. That is an inconsistency, it is not resolved here, and what is offered instead is the recorded, dated assignment of Section 3.4.**

3.4 The perimeter test, stated operationally

A coordination perimeter is a set of jurisdictions among which an adverse decision propagates without a separate act of consent by each of them, because they share a mechanism of transmission. The operative words are *propagates* and *without separate consent*. Two jurisdictions with similar laws are not thereby in one perimeter. Two jurisdictions whose treatment both change when a third body assigns a rating are in one perimeter however different their laws.

Four questions, answered yes or no. They are deliberately about attachment to mechanisms rather than about a jurisdiction's own conduct, because conduct is not what transmits the shock.

```
Q1  AUTOMATIC EXCHANGE
    Does the jurisdiction participate in automatic exchange of financial
    account information with the other jurisdictions in the structure?

Q2  STANDARD-SETTING NETWORK
    Is the jurisdiction a member of, or assessed by a regional body of,
    the anti-money-laundering standard-setter, and does its supervisory
    regime implement the common recommendations?

Q3  LISTING REACH
    Can the jurisdiction be placed on a coordinated non-cooperative or
    increased-monitoring list, with consequences its own government
    cannot prevent?

Q4  SETTLEMENT DEPENDENCE
    Do the jurisdiction's institutions depend, for clearing in the
    principal reserve currencies, on correspondents that are themselves
    subject to the jurisdiction of the states that issue them?

Four yeses    fully inside the perimeter
Three yeses   inside for all practical purposes
Two or fewer  assess individually; may constitute or belong to another
              perimeter.  Q4 is the heaviest question and a yes to Q4
              alone is close to decisive.
```

The instruments that make Q1 to Q3 operative are documented and citable: automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the recommendations supervisors implement in common [Financial Action Task Force, 2012], and the substance and treaty-abuse minimum standards [Organisation for Economic Co-operation and Development, 2015]. de Goede [2011] documents the listing machinery itself

as a technique of governance, which is the mechanism Q3 is trying to detect. **The jurisdiction-by-jurisdiction answers below are the analyst's judgements applied to published characteristics and are not cited to primary sources; they are listed in Appendix B.**

Q4 carries more weight than the others because it is the enforcement currency. A jurisdiction can decline to exchange, ignore the recommendations, and shrug at a listing, and still be reachable, because its banks need clearing access. Conversely a jurisdiction that exchanges scrupulously may sit partly outside the perimeter if its settlement dependence is genuinely diversified. **Compliance posture and perimeter membership are different variables and must never be collapsed into one.** The architecture recommended here is maximally compliant and deliberately not concentrated in one perimeter, and there is no contradiction in that.

The governance literature supplies an independent name for what the test counts. Ostrom [2010] develops polycentricity — multiple centres of decision-making formally independent of one another — as an empirically derived property of durable governance systems. **Polycentricity is the effective count of perimeters in governance language, arrived at from field data rather than from an index**, and the convergence is worth recording.

3.5 Collapse before you measure

```
1. List every entity and its share of protected capital.
2. Apply the four-question test to each entity's jurisdiction.
3. COLLAPSE: sum the shares within each perimeter.
4. Measure concentration on the COLLAPSED shares, never the raw ones.
5. Report BOTH figures, and treat the gap as the size of the illusion
   the structure was operating under.
```

Step 3 is where the analysis is usually lost, and step 5 is what prevents the collapse being used selectively. Order matters in step 4: sum within blocs first, then square, then sum, then invert. Reversing that silently reproduces the naive number.

Grouping data until the answer improves is a recognised way to lie, and the defence against the charge is that the grouping is not an aggregation convenience but the correlation matrix R written down. Markowitz [1952] supplies the algebra: for exposure weights w_i and unit-variance shocks X_i, the aggregate shock $R = \sum_i w_i X_i$ has variance $\sum_i \sum_j w_i w_j \rho_{ij}$, which is the naive index when $\rho_{ij} = 0$ off the diagonal and the bloc index when $\rho_{ij} = 1$ within blocs. **Diversification benefit depends on covariance and not on count, and that was stated with the mathematics attached in 1952.** This paper's contribution is the evidence that the covariance is there; Curzi [2026] owns the identity.

3.6 Evidence standard, and what is not cited

Every claim in Sections 4 and 5 about a named statute, directive, decided case, listing event, register or jurisdictional characteristic is **described from the source manuscript and is not cited to the bibliography**. The bibliography carries general instruments and comparative doctrine — recognition and enforcement of awards [United Nations, 1958], the absence of a succession convention in force [Hague Conference on Private International Law, 1989] and the regional succession regulation that partially fills the gap [European Union, 2012], the exchange and standard-setting instruments already named, asset partitioning as the irreducible function of entity law [Hansmann and Kraakman, 2000], and the best scholarly account of legal coding as capital formation together with its sharpest critique [Pistor, 2019]. **It carries no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction.** Appendix B lists the affected claims individually. Where a table below would otherwise score a named jurisdiction on a characteristic the bibliography cannot support, the jurisdiction is de-identified — "Gulf centre A", "an Atlantic risk-transfer centre" — following the convention adopted in Curzi [2026].

4. The erosion, as evidence

This section is the evidence base for H1. Five tracks eroded on separate schedules, by separate instruments, with separate institutional homes — which is precisely why the common cause is worth isolating. **The claim being tested is not that these jurisdictions are finished.** Several are excellent and the architecture assembled downstream uses parts of what they do. The claim is narrower: *the specific product these jurisdictions once sold — differential opacity, the condition of being harder to see into than the alternatives — has been substantially eliminated, and what remains is legal capability, which is a different product with a different price and a different competitive set.*

4.1 Track one: banking secrecy in a European financial centre

The protection at issue was never anonymity from the domestic authorities. It was a statutory prohibition, backed by criminal penalty, on an employee disclosing client information to third parties, together with a historical distinction between evasion as an administrative matter and fraud as a criminal one under which assistance was granted only for the latter. That distinction was the commercial substance of the product, and its removal was the erosion.

The sequence, described from the source: a deferred prosecution agreement with a foreign prosecutor in February 2009 and a substantial penalty; an intergovernmental arrangement providing for disclosure of a large number of accounts, which established that the statutory prohibition could be overridden by agreement; a unilateral, extraterritorial withholding statute enacted in March 2010 whose mechanism was a thirty per cent withholding on source payments to institutions that would not report, live from July 2014; criminal pleas by two institutions in 2013 and 2014, one of them founded in 1741 and thereafter extinguished; a voluntary disclosure programme for the sector announced in August 2013; and finally a multilateral automatic-exchange standard approved in 2014 and operative for the centre from 2018 in respect of 2017 data [Organisation for Economic Co-operation and Development, 2017].

Count the interval. The protective statute dated from 1934; the first automatic exchange occurred in 2018. Eighty-four years of statutory protection ended in nine, and the statute was never repealed — it simply stopped covering the case that mattered. That is the pattern to internalise, because it recurs on every track: the protective law generally survives, and what changes is the set of circumstances in which it applies.

A note on the leak literature, which is routinely treated as the cause and was in fact an accelerant. Five large document publications between 2015 and 2021 changed the political weather and made ministerial action cheap. They did not create the legal instruments; the withholding statute preceded all of them. **A structure that depended on the absence of a leak was always depending on something no adviser could price.**

4.2 Track two: company jurisdictions and the substance requirement

A different instrument reached the Caribbean company jurisdictions. Their product was not secrecy in the sense above; it was a company that could be formed cheaply, held quietly, taxed at zero, and required to do almost nothing. The last element was attacked first, through a substance criterion: a jurisdiction with a zero or near-zero corporate rate had to require entities claiming its residence actually to conduct relevant activity there, directed and managed locally, with adequate people, premises and expenditure. The alternative was listing. Two such jurisdictions legislated substance regimes with effect from 1 January 2019, and both have been revised since. The substance principle itself is the base-erosion project's [Organisation for Economic Co-operation and Development, 2015]; the individual enactments are not cited here.

The listing history is the useful part, and it is a sequence rather than a snapshot:

jurisdiction	event	period
Caribbean centre A	coordinated non-cooperative list, Feb 2020 to Oct 2020	8 months
Caribbean centre A	increased monitoring, Feb 2021 to Oct 2023	32 months
Caribbean centre B	listed Oct 2023 after a peer-review downgrade on exchange of information on request; removed Feb 2024	4 months
Central American centre	increased monitoring, Jun 2019 to Oct 2023	52 months
Gulf centre	increased monitoring, Mar 2022 to Feb 2024	23 months

Dates as publicly announced and described from the source manuscript; not cited to primary releases (Appendix B, item 3).

Read the table for what it shows, which is not that these are bad places — every one of them came off. **What it shows is volatility in a variable that most structures treat as a constant.** A holding company's jurisdiction is chosen once and left for a decade. Its listing status can change twice in eighteen months, and each change propagates into bank onboarding, counterparty diligence, and in some states into concrete defensive measures.

The four-month episode in the third row is the single most instructive item and Section 5.2 returns to it, because it is a traced propagation rather than a description.

4.3 Track three: the repeat listing

The Central American centre's history illustrates a distinct point: the cycle repeats, and exiting a list is not the same as exiting the category of jurisdiction that gets listed. It was under increased monitoring in the period 2014 to 2016, removed, listed again in June 2019 after a large document publication and the resulting pressure, and removed in October 2023. Fifty-two months on the second occasion.

Two observations follow. First, the political economy: a small jurisdiction whose financial sector is a large fraction of its economy has limited capacity to refuse a demand from a body whose members control its correspondent access, and the listing process should not be modelled as a negotiation between equals. Second, and more useful: **it complied. It passed the legislation, built the ownership register, submitted to assessment, and got off the list. Compliance worked, and compliance rather than resistance was the successful strategy in every one of these episodes** — a data point in favour of the design standard of Section 7, arriving from an unexpected direction.

For completeness, and because it is frequently misreported: the criminal proceedings arising from that jurisdiction's largest document disclosure resulted in acquittals for the principal defendants in a verdict reported in June 2024. **The firm's founders were acquitted and the firm and the model it represented were nonetheless destroyed years earlier. The legal outcome and the commercial outcome were opposite, and the structure died of the process rather than of the verdict.**

4.4 Track four: the protective statute and the person

The fourth track is different in kind. It is not about registers, lists or exchange. It is about what happens when the theory of a structure meets a court with the power to detain the person in front of it.

A well-known asset-protection statute of 1984, amended repeatedly since, included short limitation periods for transfer challenges, a high standard of proof, and provisions to the effect that a foreign judgment would not be recognised or enforced against the vehicle. Two appellate decisions in another jurisdiction define the failure mode. In the first, a regulator obtained repatriation orders against principals who had retained roles in the structure; when they asserted that compliance had become impossible because a foreign fiduciary had invoked a duress provision, they were held in civil contempt and taken into custody, and the appellate court affirmed on the ground that a party asserting impossibility bears the burden of proving it and that the impossibility had been designed and triggered by the contemnors themselves. In the second, a debtor who had settled a substantial offshore trust was ordered to turn over its assets, asserted that he could not, was held in civil contempt from 1999 and was reported released in 2007. **The source manuscript corrects a common miscitation here and the correction is carried forward: that second trust was settled in one Channel Island in 1991 and its administration later moved to an Indian Ocean jurisdiction; it was not established under the 1984 statute, and any account saying otherwise is unreliable on its remaining detail.**

The structural lesson generalises far beyond trusts, which is why this track belongs in a chapter on jurisdictional erosion at all. **The offshore statute governs the offshore asset; the domestic court governs the person, and the person is the one part of the structure that cannot be redomiciled.** An order directed at a principal's own conduct requires no foreign court to cooperate with anything. The vehicle was never the target.

There is a legislative postscript: a ten-year look-back for transfers to self-settled trusts made with intent to hinder, delay or defraud was added to one bankruptcy code in 2005 — longer than most planning horizons and far longer than the limitation periods the protective statutes provided. **The domestic reach-back was simply extended past the foreign protection.** All of the foregoing is described from the source; no case, statute or reporter citation appears in the bibliography (Appendix B, items 1, 2 and 5).

4.5 Track five: from exchange to publication, and the private layer

A fifth track runs underneath the other four and produced no single dramatic event. Over the same period the default disposition of ownership information shifted twice: from confidential to exchanged, and then in several jurisdictions from exchanged to published.

The exchange step is the standard already named [Organisation for Economic Co-operation and Development, 2017]. The publication step rests on anti-money-laundering rather than tax instruments and required registers of beneficial ownership with extended access; one large jurisdiction had moved earlier and independently and later extended the principle to foreign owners of domestic property. **The two steps have different legal trajectories and confusing them produces bad planning.** A supranational court curtailed the public-access limb in November 2022 while leaving the reporting and competent-authority-access limbs entirely intact. The direction of travel on exchange between authorities has been one way for fifteen years; the direction of travel on publication to the general public is contested and has partially reversed. **A structure built on the assumption that its beneficial ownership will not be known to authorities is betting against the settled trend. A structure that simply prefers its affairs not to be in a newspaper is on much firmer ground**, and Section 7.3 draws that line precisely.

Beneath both sits a third layer which is private, unappealable, and in practice bites first. Correspondent banks make their own risk classifications and consume the outputs of the other four components as inputs. There is no statute to read and no tribunal to appeal to. The number of active correspondent relationships is reported to have declined materially since 2011 — the figure commonly cited is a fall of roughly a fifth over the decade — while transaction volumes rose. **This private layer transmits public decisions with no process at all**, and a jurisdiction can be listed in one month and find its institutions' clearing constrained in the next, months before any legislature anywhere has acted on the listing.

4.6 Decomposing the erosion rate

Because δ aggregates four unrelated processes it is worth decomposing before it is used.

component of δ	annual rate	basis
tax drag	0.9%	leakage at entity and distribution level after treaty relief
political / arbitrary-action risk	0.4%	probability-weighted cost of immobilisation or de-risking
debasement	0.5%	loss of purchasing power in the unit of account, net of the portfolio's own hedge
haven degradation	0.2%	loss of value in the jurisdictional characteristics the structure was built to use
δ **(sum)**	**2.0%**	

CONSTRUCTED. Illustrative decomposition, not a research estimate.

Two things follow. The first is that the components respond to entirely different interventions. Tax drag responds to structure and treaty position; debasement to the currency composition of the holding; political risk and haven degradation to jurisdictional diversity and to nothing else. **Those last two are the components the diversity term actually addresses, and they are the smaller two — 0.6 of the 2.0.** Diversification is not a general-purpose remedy; it is a specific remedy for a specific pair of terms, and a structure that diversifies while ignoring the other two has optimised the wrong thing.

The second is that haven degradation is the hardest to observe and the easiest to underestimate, because it accrues as a change in the option set rather than as a charge. Nothing is debited when a jurisdiction's differentiation erodes; the holder discovers the loss later, at the moment he wants to use a characteristic that no longer exists.

What the rate does over time is worth stating numerically, because the intuition is bad.

δ	retained at 15 y	retained at 30 y	half-life (years)
0.020	73.857%	54.548%	34.310
0.035	58.602%	34.342%	19.456
0.050	46.329%	21.464%	13.513

A difference of three percentage points in δ — well within the range of disagreement between two competent advisers about political risk alone — is the difference between a structure that mostly survives a generation and one that mostly does not. This is the multiplicative-process reading, and the general form is not the corpus's: Peters [2019] and Peters and Gell-Mann [2016] establish that the time average of a multiplicative process differs from its ensemble average, so an expectation computed across many holders does not describe what happens to any one holder over time. **The same literature supplies an independent warrant for the logarithm in the surplus law: the growth rate of a multiplicative process is logarithmic in the stock, with no psychological assumption required.** Section 3.1 justifies the logarithm on the diminishing-returns argument the framework already makes; this is the stronger warrant, and where the two disagree the multiplicative one should be preferred because it does not depend on a perceptual story being true.

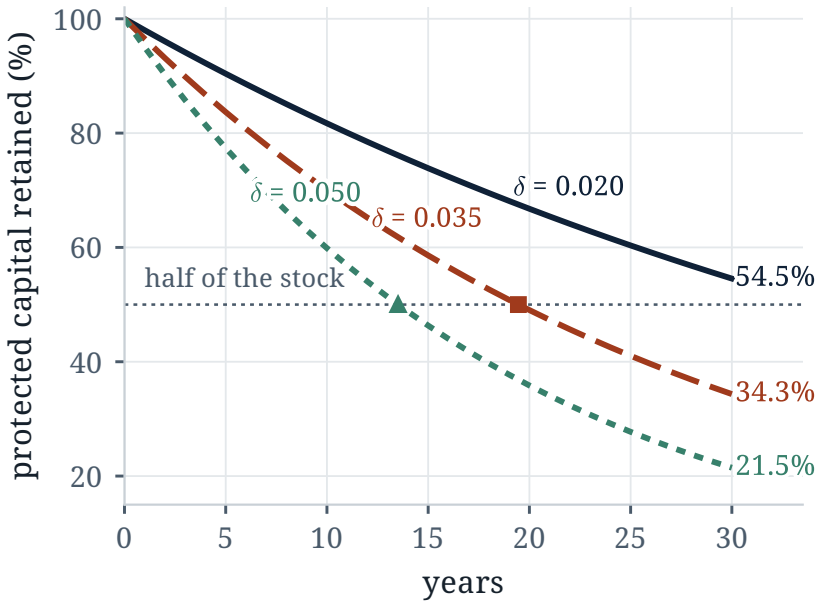

Figure 51.1: **Three percentage points of disagreement about the erosion rate is the difference between a structure that mostly survives a generation and one that mostly does not: 54.5 per cent retained at thirty years against 21.5 per cent.** Modelled from $Q_t = (1-\delta)^t Q_0$ with no input, at the three rates tabulated above; half-lives $\ln 2 / \ln(1-\delta)^{-1}$. Script `figs/src/CCP-051_fig01.py`.

4.7 Degradation trajectory as a measured quantity

The practical output of the evidence base is a discipline: assess a jurisdiction on its direction of travel with the evidence attached, not on its current state.

```
DEGRADATION TRAJECTORY -- the recorded item
-----------------------------------------------------------------
Classification   improving / stable / eroding
Evidence         at least two dated events in the last ten years,
                 each named
Direction        is the jurisdiction being brought further inside a
                 coordination perimeter, held constant, or
                 differentiated?
Reversibility    did any past change get reversed, and by what
                 mechanism?
```

Four rules govern the assessment and each is drawn directly from a track.

Delisting is not reversal. A jurisdiction comes off a list by complying — by legislating substance requirements and building supervisory capacity it did not previously have. The jurisdiction that came off is more tightly integrated into the perimeter than the one that went on. Delisting records the completion of the change, not its undoing.

The protective statute usually survives and stops mattering. Both statutes named in Sections 4.1 and 4.4 are still law. Neither was repealed and neither now delivers what it was bought for, because the operative question moved to a place the statute does not reach. Reading the statute tells you almost nothing about the current value of the protection.

Age is not durability. An institution trading since 1741 was gone in a year; another operating since 1977 did not survive its disclosure. Institutional longevity in this sector reflects the persistence of a favourable environment, and when the environment changes longevity turns out to have been a lagging indicator rather than a structural property. Weick [1993] is

the organisational form of the same finding: the structure that held for years dissolves in the minutes during which it is actually tested.

The assessment must name the mechanism, not the event. "Jurisdiction X was listed in 2020" is an anecdote. "Jurisdiction X was listed because a substance criterion was applied to zero-rate jurisdictions, a criterion which continues to apply and now also reaches the substance regimes of jurisdictions that have already legislated" is an assessment, because it says what would have to happen for the situation to change again. Section 5 names the mechanisms.

5. The coordination mechanism

5.1 Five interfaces, one system

Consider the erosion tracks as an engineer would. Four different instruments, four different legal families, four different institutional homes, four different stated purposes. On any naive account these are four independent risks, and a structure exposed to all four is exposed to four things that will not happen at once. **They happened at once.**

The explanation is not subtle. The anti-money-laundering standard-setter, the tax transparency peer-review body and its automatic-exchange standard, the coordinated listing process, the unilateral extraterritorial withholding regime, and the private correspondent-banking de-risking layer **are not five risks; they are one system with five interfaces.** Each does a different job, has a different legal character, and — the part that matters — has a different enforcement lever.

The standard-setter. Issues nothing binding. It publishes recommendations [Financial Action Task Force, 2012], conducts mutual evaluations through regional bodies, and maintains public lists. The lever is indirect and extremely powerful: financial institutions everywhere apply risk-based diligence, supervisors expect them to weight jurisdictional risk, and a listing therefore changes the cost and availability of banking for every institution connected to the listed place. **No law needs to be passed anywhere for the effect to arrive.**

The peer-review body and its exchange standard. Reviews jurisdictions on exchange of information on request and on automatic exchange [Organisation for Economic Co-operation and Development, 2017], assigns ratings, and conducts supplementary reviews. The lever is a rating, and a rating looks like a technical artefact until one notices what consumes it.

The coordinated listing process. Maintains a list of non-cooperative jurisdictions with criteria covering transparency, fair taxation and the base-erosion minimum standards [Organisation for Economic Co-operation and Development, 2015]. **Among its transparency criteria is the peer-review body's own rating. That is the coupling stated in the primary materials themselves: one institution's rating is a listing criterion for another institution's list.** The lever is a set of coordinated defensive measures, alongside the reputational consequence, which usually arrives first. de Goede [2011] treats the listing apparatus as a technique of governance in its own right.

The unilateral withholding regime. Extraterritorial and enforced by withholding on source payments to non-compliant institutions. The lever is the most direct of the five and the only one requiring no cooperation whatever from the affected jurisdiction: an institution that will not report loses a fixed fraction of its income at source. It is also the historical seed of the apparatus, since the multilateral exchange standard is recognisably its descendant.

Correspondent-banking de-risking. Private, with no statute, no tribunal and no appeal. Correspondent banks make commercial decisions about which relationships to keep, and those decisions consume the outputs of the other four as inputs. **This is the interface that converts an assessment into a consequence, and it operates on a commercial timescale rather than a legislative one.**

A sixth component is newer and closes a different door. A global minimum effective rate for in-scope groups eliminates rate differentiation rather than opacity: for a group above the

turnover threshold a zero-rate jurisdiction stops being a zero-rate jurisdiction, because the shortfall is collected elsewhere in the group. Scope, thresholds and implementing law are jurisdiction-specific and are not cited here (Appendix B, item 6).

5.2 The coupling, traced

Description is not proof of coupling. The proof is a traced propagation, and the four-month episode of Section 4.2 provides a clean one, short enough to see end to end.

step	actor	action	date
1	peer-review body	supplementary review; rating on exchange of information on request downgraded	2023
2	listing committee	downgrade engages the transparency listing criterion	2023
3	listing authority	jurisdiction added to the list	Oct 2023
4	member states	coordinated defensive measures become applicable	Oct 2023 onward
5	correspondent banks and onboarding functions	jurisdictional risk rating revised; diligence tightened	Q4 2023
6	the jurisdiction	remediation; commitments given	2023–24
7	listing authority	removed from the list	Feb 2024

Sequence as publicly reported and described from the source; review dates, rating language and decision dates are not cited to primary documents (Appendix B, item 3).

Look at what happened in between and, more importantly, at what did not. No treaty was negotiated. No court ruled. No legislature outside the territory voted on the jurisdiction at all. A peer-review panel changed a rating, and that rating change propagated through a policy committee, a Council decision, twenty-seven national tax codes and an unknown number of private bank risk models, in under a year.

Three institutions that look independent on an organisation chart transmitted a single assessment without any of them deciding to coordinate with the others, because the coupling is built into the criteria. That is what a coordination perimeter is. A holder with entities in three jurisdictions subject to that chain does not have three risks; he has one risk that will present itself three times. This is the coupled-network result of Buldyrev et al. [2010] in a governance setting — **cited as a shared structural form and not as a derivation**, because jurisdictions have not been shown to satisfy that paper's percolation premises. What the two systems share is the property that coupling destroys the independence a naive count assumes.

5.3 Why the outputs correlate

Three structural features, each independently sufficient.

Overlapping membership. The states that sit on the standard-setter, that fund and direct the peer-review body, that constitute the listing authority, and whose currencies dominate correspondent clearing are substantially the same states. A position that commands support

in one forum tends to command it in the others — not through coordination but because the same governments hold it.

Shared assessment methodology. The listing criteria explicitly incorporate the peer-review ratings and the minimum standards; supervision everywhere is built on one set of recommendations. **When several institutions grade against a shared rubric their grades correlate for the same reason two examiners marking to one rubric produce similar marks, and no communication between them is required.**

A common enforcement currency. Every one of the five interfaces ultimately expresses itself as access — to clearing, to the correspondent network, to counterparties whose own compliance functions consume these lists. That is why the lever is so effective against small jurisdictions and why it operates without legislation. It is also the feature that says what a genuinely different perimeter would require: **not a different set of laws, but a different settlement network with a different set of states controlling access to it.** Curzi [2026] measures what exists on that axis, decomposing correspondent flows by currency to find that a naive correspondent index of 0.302400 (3.306878 effective correspondents) collapses to a perimeter index of 0.745256 and $N_{\text{rail}} = 1.341819$. **The rail axis collapses harder than the jurisdiction axis**, and that is the honest answer to the question of whether a different network is available.

A coordination perimeter is not a conspiracy, and reading it as one will make predictions wrong. No committee decides that a jurisdiction should be squeezed. The institutions have genuine and largely defensible purposes and are staffed by people pursuing them in good faith. The coupling is structural, not intentional — which is precisely why it is reliable, and why it is more dangerous to a structure than a conspiracy would be: a conspiracy can change its mind and a structural coupling cannot. An analyst who models the perimeter as coordinated malice expects targeting, expects negotiation to be possible, expects political change to reverse the direction, and expects individual relationships to matter. An analyst who models it as structural coupling expects uniformity, expects compliance to work, expects the direction to persist across changes of government, and expects relationships to be irrelevant. **On the evidence of Section 4 the second model has been right**, including in the specific case of the jurisdiction that complied and got off the list.

5.4 The counter-test: where the coupling has not held

A model that explains everything explains nothing, and the coupling is not total. Three episodes run the other way, and the places where it failed say what the coupling is actually made of.

Rights adjudication inside the perimeter. A supranational court held invalid, in November 2022, the provision giving the general public access to beneficial-ownership registers, on fundamental-rights grounds. This was a genuine reversal imposed on the perimeter from inside it. It did not touch the reporting obligation and it did not touch competent-authority access — the exchange layer was entirely unaffected — but it stopped one limb of the expansion and has not been undone. **The perimeter contains institutions with their own mandates, and rights adjudication is one of them.**

Domestic constitutional constraint. A beneficial-ownership reporting statute in one large jurisdiction was held unconstitutional as applied to the plaintiffs in a district court decision of March 2024, and the regime's scope was subsequently narrowed by rulemaking. **Its current scope is genuinely unsettled and actively litigated; this paper states no position on it.** The lesson is that domestic constitutional constraint is a real brake operating on a litigation timescale rather than a policy one.

Adjudicative correction arriving too late to matter. The acquittals of Section 4.3 came years after the firm was destroyed by listing, de-risking and the withdrawal of counterparties. **The perimeter's consequences arrive on the administrative timescale and the adjudicative correction, if it comes at all, arrives on the judicial one — and nothing in a structure survives the interval.** A holder who plans to be vindicated in year eight must still fund and operate through years one to seven.

Taken together these support a refinement rather than a retraction. The coupling is strong on exchange between authorities, on standard-setting, and on the private access layer, and has not been reversed on any of them. It is weaker on publication to the general public, where rights adjudication has bitten, and weaker again on domestic constitutional questions inside large jurisdictions with strong courts. **The trend a structure must plan against is the exchange trend, because that is the one with no counter-examples.**

A fourth item belongs here as a limit rather than a counter-example. The perimeter operates on jurisdictions and institutions; it does not operate on legal character. A reinsurance reserve held against real third-party liabilities is inside the perimeter on all four questions and is nonetheless awkward to reach, because reaching it impairs identifiable third parties with their own claims and their own regulator. **Perimeter diversity and character diversity are complements, not substitutes, and a structure that has one and not the other is only half built.** Curzi [2026] prices the character axis on the cost side, measuring substance repricing as a multiple — $5{,}350/1{,}550 = 3.45\times$ for a pure equity-holding entity and $19{,}350/1{,}550 = 12.48\times$ for a relevant-activity entity, with break-even at USD 7,740,000 of held value at 25 basis points.

5.5 The bloc taxonomy

Applying the test produces a small number of groupings. Five are used, with the caveat that the boundaries are analytical conveniences rather than natural kinds and that a jurisdiction's classification is a judgement to be re-made rather than a fact to be looked up.

bloc	character	examples
WEST	four yeses; full attachment on every interface	UK, US, Jersey, Luxembourg
W-LITE	four yeses, but with a distinct legal product — typically genuine risk transfer — that is hard to displace	Bermuda
BRIDGE	full compliance posture with genuinely dual-attached settlement and a foreign policy not aligned to one bloc	UAE, Singapore
NON-ALIGNED	compliant, with an independent foreign policy, domestic-currency depth, and real operating substance	Thailand, India
EAST	primary settlement and policy alignment outside the Western perimeter	treated on the rail axis

Classifications are the analyst's judgements, are contested, and change. They are not cited to primary sources (Appendix B, item 4).

The W-LITE category is doing real work. The jurisdiction placed there is inside the Western perimeter on all four questions; what makes it a distinct holding is not perimeter position but product. **That is legal-character diversification rather than perimeter diversification, and it is counted as such and no more.** Folding it into WEST is the conservative assignment and is the one used in the measurement below.

Treating a bridge as neutral is the error this taxonomy most invites. A bridge jurisdiction is not neutral; it is *dual-attached*, which is a different and much more useful property. The Gulf bridge central to the architecture participates in automatic exchange, clears in the principal reserve currencies through correspondents subject to their issuers' jurisdiction, and was itself under increased monitoring for twenty-three months. On the four-question test it scores yes

four times. **What makes it a bridge is not that any attachment is absent. It is that it maintains an independent foreign policy, hosts genuine commercial relationships across blocs that do not deal easily with each other, and provides legal infrastructure credible to counterparties on both sides. A bridge reduces the probability that a shock in one bloc removes access to the other. It does not place anything outside either bloc, and nothing here claims that it does.** The classification is a claim about correlation, not about immunity.

The corresponding error at the other end is assuming that non-Western means unreachable. A jurisdiction outside the Western political sphere is not thereby outside the perimeter, because Q4 is answered by the plumbing rather than by the politics.

6. Results: correlated failure, measured

6.1 The arithmetic of correlated failure

The reason perimeter membership must be measured rather than described is that the cost of getting it wrong is not proportional. Take a constructed structure with four jurisdictions, each facing an annual probability of 0.10 of an adverse regime change material to the holding.

```
MODEL                  P(ALL FOUR IMPAIRED IN ONE YEAR)
-------------------------------------------------------
Independent            p^4 = 0.000100       1 in 10,000
One perimeter          p   = 0.100000       1 in 10
-------------------------------------------------------
Understatement factor from assuming independence: 1,000x

Cumulative probability of total perimeter loss:
    over  5 years   independent 0.000500   correlated 0.409510
    over 10 years   independent 0.001000   correlated 0.651322
    over 15 years   independent 0.001499   correlated 0.794109
-------------------------------------------------------
CONSTRUCTED probabilities, chosen for illustration.
```

Assuming independence where a perimeter exists understates the probability of total impairment by three orders of magnitude, and over fifteen years it is the difference between a one-in-seven-hundred event and a four-in-five event. No other modelling error in this literature is worth that much.

The general case is more useful than the extreme, because real structures are neither fully independent nor fully coupled. Decompose each jurisdiction's failure into a common shock arriving with probability c and an idiosyncratic shock arriving with probability i, holding the marginal probability fixed at 0.10 so that the comparison is like for like. Then $P(\text{all four}) = c + (1-c)i^4$.

c	i	$P(\text{all four})$	understatement vs p^4
0.00	0.1000	0.000100	$1.0\times$
0.02	0.0816	0.020044	$200.4\times$
0.05	0.0526	0.050007	$500.1\times$
0.08	0.0217	0.080000	$800.0\times$
0.10	0.0000	0.100000	$1{,}000.0\times$

Read the second row. The joint-failure probability is governed almost entirely by the common component and almost not at all by the idiosyncratic one — at $c = 0.02$ the idiosyncratic term contributes $0.98 \times 0.0816^4 = 0.0000435$, or 0.22 per cent of the total. **H2's prediction is met**

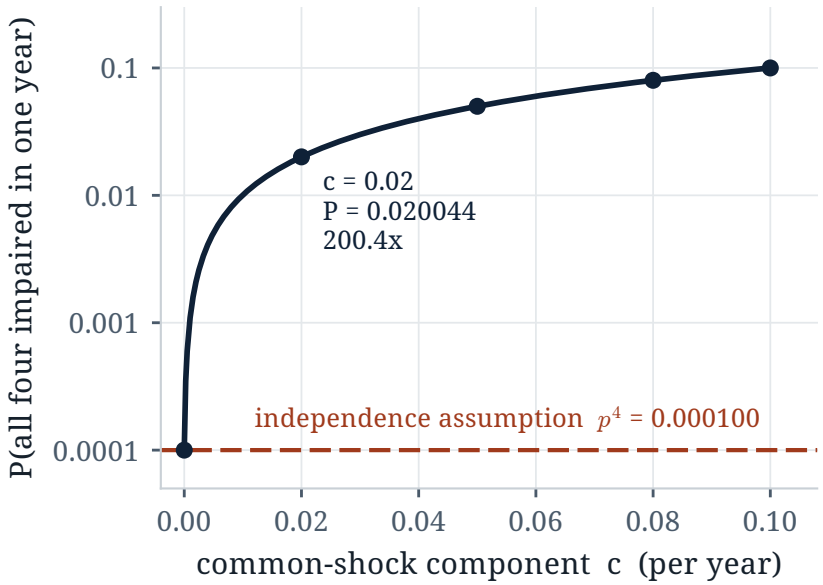

Figure 51.2: **A common-shock component of two per cent a year — smaller than the analyst's uncertainty about any input — already understates joint failure by a factor of 200.4, and the joint probability tracks the common component almost exactly.** Modelled from $P(\text{all four}) = c + (1-c)i^4$ with the marginal failure probability held at 0.10; parameters CONSTRUCTED. Script `figs/src/CCP-051_fig02.py`.

exactly. That is why the perimeter is the object worth measuring and the individual jurisdiction is not.

Two pieces of external literature bound the reading. Longin and Solnik [2001] and Ang and Chen [2002] measure correlation rising under stress in equity markets, asymmetrically and concentrated in downturns: **the effective count falls exactly when it is needed**, which is stronger than anything the static index says. The ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008], and the cleanest empirical demonstration that effective count buys stability is Schindler et al. [2010]'s sockeye record, where population diversity produces roughly half the variability and about a tenth of the fishery closures. Against them, Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone with no mechanism, and May [1972] showed that increasing diversity and connectance *destabilises* randomly assembled systems. **This paper's claim is narrower than the general diversity–stability claim and is not exposed to those results in the same way**: it asserts that the reciprocal of a variance counts independent shocks, which is arithmetic, and that perimeter-attached jurisdictions are correlated, which is H1.

6.2 The worked measurement

CONSTRUCTED. The principal, the entities and all figures are inventions built to illustrate the measurement. No real person or transaction is described.

A principal — dual national, tax resident in a Gulf jurisdiction, with three adult heirs resident in three different countries, one of them under a forced-heirship regime — arrives with a structure assembled by competent advisers over about twenty years. It holds commercial real estate in London, a listed-securities portfolio, and interests in operating businesses.

The share basis is stated first, because a share is a share *of something* and the something must match the threat: *the fraction of protected capital whose availability depends on a decision taken inside a given jurisdiction's coordination perimeter.* The London real estate contributes its full value to the UK exposure because it cannot be relocated. The listed portfolio contributes to the perimeter of its *custodian*, not to those of the issuers.

entity / situs	share of Q	role	Q1	Q2	Q3	Q4	score
United Kingdom	40.9091%	property holding, principal operating presence	yes	yes	yes	yes	4/4
United States	27.2727%	securities custody and brokerage	yes	yes	yes	yes	4/4
Jersey	18.1818%	family trust, succession	yes	yes	yes	yes	4/4
Luxembourg	13.6364%	holding and treaty access	yes	yes	yes	yes	4/4
total	**100.0000%**						

Every entity scores four. On Q1 all four participate in automatic exchange. On Q2 all four implement the common recommendations through their own supervisors. On Q3 all four are reachable by a listing process whose consequences their governments could not unilaterally prevent. On Q4 all four depend on correspondents subject to the issuing states' jurisdiction, including the entity in the issuing state itself, which is subject directly.

```
RAW MEASUREMENT (what the adviser presented)
   naive HHI                    = 0.293388
   effective jurisdictions      = 3.4085

COLLAPSED MEASUREMENT (the honest figure)
   WESTERN PERIMETER            = 100.0000%
   bloc-HHI                     = 1.000000
   EFFECTIVE PERIMETERS  N      = 1.0000

THE GAP                         = 3.41x overstatement
```

Four entities, four jurisdictions, two continents, and one point of failure. The naive measure overstated the structure's resilience by a factor of 3.41, and it did so not through arithmetic error but through a modelling assumption — independence — that the record in Section 4 falsifies. **H1's prediction is met.** Note what the measurement does *not* say. It does not say the four entities were badly chosen or badly run. **The finding is not about quality; it is about correlation, and correlation is not visible from inside any one entity.**

The surplus consequence at the stated parameters:

```
h = eta ln(N) - delta Q - C
  = 0.35 x ln(1.0000) - 0.02 x 10 - 0.30
  = 0.35 x 0.000000 - 0.200000 - 0.300000
  = -0.500000
```

The available surplus is exactly minus one half: the whole of the erosion plus the whole of the upkeep, with nothing at all on the input side. This is not a marginal result that better execution could improve. The input term is multiplied by the logarithm of one regardless of how well the entities are run or how the shares are redistributed among them. Moving the Luxembourg allocation to Jersey, or splitting the UK position across three companies, changes the naive figure and leaves the collapsed figure at exactly 1.0000.

The designed alternative distributes the same capital across six jurisdictions in three perimeters:

entity / situs	share	bloc	role
UAE	29.0909%	BRIDGE	holding
Thailand	18.1818%	NON-ALIGNED	operating

entity / situs	share	bloc	role
United Kingdom	16.3636%	WEST	operating, contracts
Bermuda	13.6364%	W-LITE → WEST	risk transfer
India	11.8182%	NON-ALIGNED	fund vehicle
Singapore	10.9091%	BRIDGE	bridging, banking
total	**100.0000%**		

```
COLLAPSED MEASUREMENT
   BRIDGE                      = 40.0000%      0.160000
   NON-ALIGNED                 = 30.0000%      0.090000
   WEST (incl. W-LITE)         = 30.0000%      0.090000
   bloc-HHI                    = 0.340000
   EFFECTIVE PERIMETERS  N     = 2.941176

h = 0.35 x ln(2.941176) - 0.200000 - 0.300000
  = 0.35 x 1.0788095014 - 0.500000
  = 0.377583 - 0.500000
  = -0.122417
```

Curzi [2026] states the naive side of the same structure: a naive index of 0.189002 giving 5.290949 effective jurisdictions, against a bloc index of 0.340000 and 2.941176 effective blocs, with Western-perimeter exposure falling from 100.0 to 30.0 per cent.

Note which ratio is the real one. The naive count improves by a factor of roughly 1.55, which looks like a modest gain. The perimeter count improves by a factor of 2.9412, and that is the gain that enters the surplus equation. **The measurement taken at the wrong level of aggregation understated the problem before the restructuring and understates the improvement after it, in both cases by roughly the same factor and for the same reason.**

6.3 The fifth decimal: a reconciliation this paper prints rather than harmonises

This paper and Curzi [2026] report different naive indices for the same entity map, and the difference is printed here rather than smoothed away. It changes no conclusion, and two corpus papers silently disagreeing on a stated number is exactly what a reviewer notices.

The shares in Section 6.2 are exact twenty-seconds of the total, printed to four significant figures. Three bases are therefore available and they give three different naive indices.

basis for the conventional structure	shares	naive HHI	effective jurisdictions
exact fractions	9/22, 6/22, 4/22, 3/22	0.293388	3.408451
percentages to four significant figures	40.91, 27.27, 18.18, 13.64	0.293384	3.408499
percentages to three significant figures	40.9, 27.3, 18.2, 13.6	0.293430	3.407968

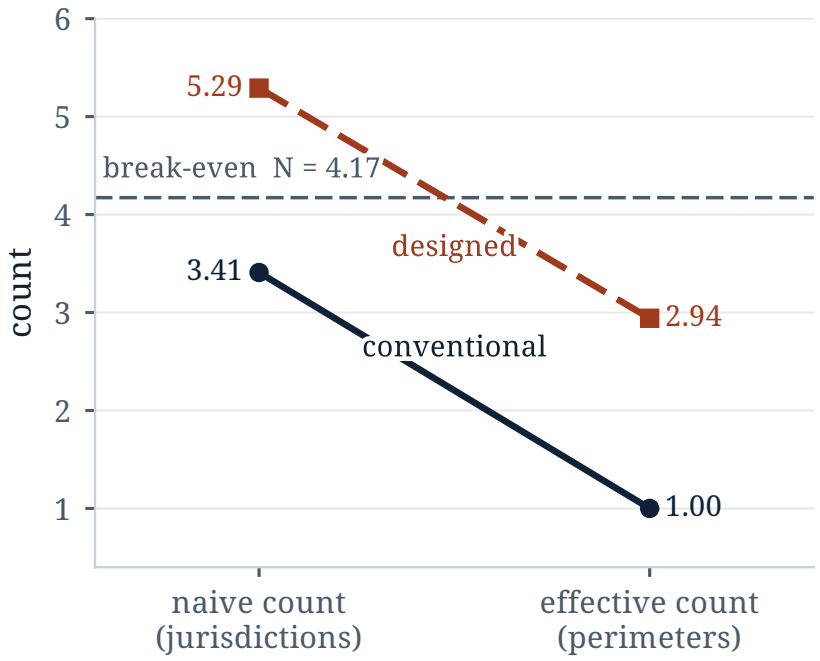

Figure 51.3: **The gap is the finding: the conventional structure reads 3.41 jurisdictions naively and exactly 1.00 perimeters in effect, the designed structure 5.29 and 2.94, and neither effective count reaches the break-even of 4.17 that a non-negative surplus balance requires.** Measured from the share vectors tabulated above; naive figures on the exact-fraction basis of Section 6.3 for the conventional structure and from Curzi [2026] for the designed one; break-even derived at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$. Script `figs/src/CCP-051_fig03.py`.

basis for the designed structure	shares	naive HHI	effective jurisdictions
exact fractions	6.4/22, 4/22, 3.6/22, 3/22, 2.6/22, 2.4/22	0.188926	5.293088
percentages to three significant figures	29.1, 18.2, 16.4, 13.6, 11.8, 10.9	0.189002	5.290949

This paper's R1 states 0.293388 and 3.4085, which is the exact-fraction value. Curzi [2026] states 0.293430 and 3.407968, which is the three-significant-figure value, and the same paper records the discrepancy in its own discussion. The two papers agree about which figure comes from which basis. **The three-significant-figure percentages are the reproducible choice given published inputs, because they are what a reader can recompute from a printed exposure table without being told the exact fractions**, and that is why CCP-052 adopts them and why any reproduction of this measurement should adopt them too. The same applies to the designed structure, where 0.189002 is the reproducible figure and 0.188926 is the exact-fraction one. **The discrepancy on the designed structure is not disclosed anywhere else in the corpus and is disclosed here.**

Nothing turns on the choice. Every bloc figure is exactly 1.000000 for the conventional structure and exactly 0.340000 for the designed one under every basis, because the perimeter sums are 100.0% and 40/30/30 exactly in all three cases. The naive figures do not enter the surplus law, and the difference in the fifth decimal propagates to no reported result.

The companion discipline is that intermediate values must not be rounded. The designed structure's effective count is exactly $1/0.34 = 2.941176\ldots$:

```
exact:    ln(2.941176) = 1.078810   h = 0.35 x 1.078810 - 0.5 = -0.122417
rounded:  ln(2.940000) = 1.078410   h = 0.35 x 1.078410 - 0.5 = -0.122557
```

The two differ by 0.000140. **The conclusion is unchanged — both are below zero — but the number moved in the fourth decimal from a single rounding, and a chain of four such steps is how a measurement goes wrong.** The rule is not to round carefully; it is to carry full precision through every intermediate step and round only at the print.

6.4 What it costs to change N

Suppose a structure is entirely inside one perimeter and the holder begins moving exposure out, splitting what leaves evenly between two other perimeters.

share remaining in the perimeter	bloc-HHI	effective perimeters	$\eta \ln N$ at $\eta = 0.35$
100.00%	1.000000	1.0000	0.000000
95.00%	0.903750	1.1065	0.035421
90.00%	0.815000	1.2270	0.071599
85.00%	0.733750	1.3629	0.108355
80.00%	0.660000	1.5152	0.145430
66.67%	0.500000	2.0000	0.242602
60.00%	0.440000	2.2727	0.287343
50.00%	0.375000	2.6667	0.343290
40.00%	0.340000	2.9412	0.377583
33.33%	0.333333	3.0000	0.384514

The solution for exactly two effective perimeters is analytic. With the remainder split evenly, an in-perimeter share s gives HHI $= s^2 + 2((1-s)/2)^2$, and setting this to $1/2$ yields $s = 2/3$

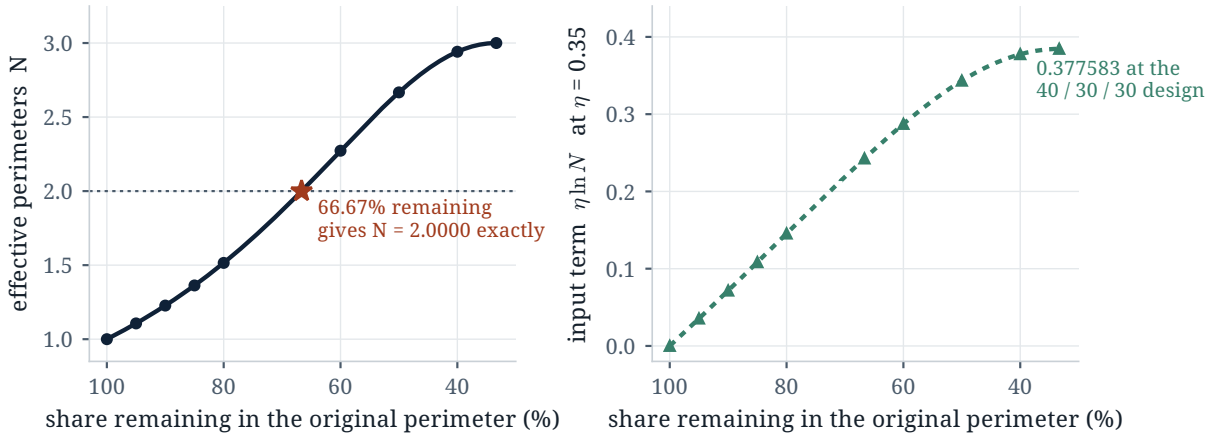

Figure 51.4: **One third of protected capital must leave the perimeter before the effective count reaches two, and the surplus term rises with the logarithm of a count that itself responds slowly to reallocation.** Modelled from HHI $= s^2 + 2((1-s)/2)^2$ with the exiting share split evenly between two further perimeters; $\eta = 0.35$. Script `figs/src/CCP-051_fig04.py`.

exactly. **One third of protected capital has to sit outside the perimeter before the structure has two effective perimeters rather than one.** Ten per cent moved buys 1.2270; twenty per cent buys 1.5152. **This is not a marginal adjustment that can be made by opening an account somewhere; it is a structural reallocation. H4's prediction is met.**

Note that the designed structure of Section 6.2 is exactly the 40 per cent row: three perimeters at 40/30/30 is what the even-split path reaches when 60 per cent of exposure has left the original perimeter.

6.5 The over-diversification optimum

The opposite error is real. The input term grows as the logarithm of the perimeter count while maintenance grows roughly linearly with it — every additional perimeter means additional counsel, filings, local substance and management attention. Logarithmic benefit against linear cost has an interior optimum, and the optimum is not large. This is the organisational result in a different register: adding units inside a coordination boundary adds communication cost at order $n(n-1)/2$ [Brooks, 1975] and adds nothing to independence.

Write maintenance as $C = c_0 + c_1 N$. Then $h = \eta \ln N - \delta Q - c_0 - c_1 N$ is maximised where $\eta / N = c_1$, that is at $N^* = \eta / c_1$. At $\eta = 0.35$:

per-perimeter cost c_1	optimal N^*	interpretation
0.05	7.0000	cheap coordination
0.07	5.0000	typical mid-size group
0.10	3.5000	expensive coordination

And the marginal value of each additional perimeter, which is the number that should govern the decision to add one:

N	$\eta \ln N$	marginal gain over $N-1$
1	0.000000	0.000000
2	0.242602	0.242602

N	$\eta \ln N$	marginal gain over $N-1$
3	0.384514	0.141913
4	0.485203	0.100689
5	0.563303	0.078100
6	0.627116	0.063813
7	0.681069	0.053953
8	0.727805	0.046736

The second perimeter is worth $0.242602/0.046736 = 5.19$ times what the eighth is worth. Almost all of the available benefit is captured by the move from one to two and from two to three; beyond that the holder is paying linear cost for logarithmic return.

A monotone raise-N prescription cannot survive the external literature unqualified, and none is made here. Uzzi and Spiro [2005] find an inverted U in which performance rises and then falls with cohesion; Sagan [1993] documents that redundancy can *reduce* safety when it adds coordination surface; and March [1991] gives the mechanism by which fast convergence on a single mode destroys the variance that produced the advantage. The prescription here is bounded: move from one effective perimeter to two or three, and stop when the marginal entity stops adding a perimeter.

7. Results: the economics of full disclosure

Sections 4 to 6 establish that concealment has been removed as a durable property and that the replacement is perimeter diversity. This section tests the standard objection to that replacement, which is that it costs more.

7.1 Why concealment fails: four structural properties

The failure of concealment structures is not bad luck and not a consequence of poor execution. It follows from four properties of the environment, each sufficient on its own.

The observer set is monotone. Information that has entered the exchange system does not leave it [Organisation for Economic Co-operation and Development, 2017]. A structure that was invisible in 2013 and reported in 2019 is not invisible again in 2025; the 2019 report still exists. The property holds with greater force on public distributed ledgers, where every transfer is permanently readable and analytical capability improves while the record does not degrade — **a transfer made today will be readable in 2035 by tools that do not yet exist, which makes public-chain settlement the most durable surveillance record a holder can create, not the least.** Concealment is therefore a wasting asset in a technical sense: its value can only fall, and each year's disclosure permanently reduces the stock.

The asymmetry of repeated trials. A concealment structure must succeed at every examination; an examiner must succeed once.

annual examination probability	$P(\geq 1)$ in 5 y	10 y	15 y	20 y
0.05	0.226220	0.401263	0.536709	0.641514
0.10	0.409510	0.651322	0.794109	0.878423

A structure meant to hold for a generation and requiring an unbroken run of non-examination is, at ten per cent annual exposure, approximately eighty per cent likely to be

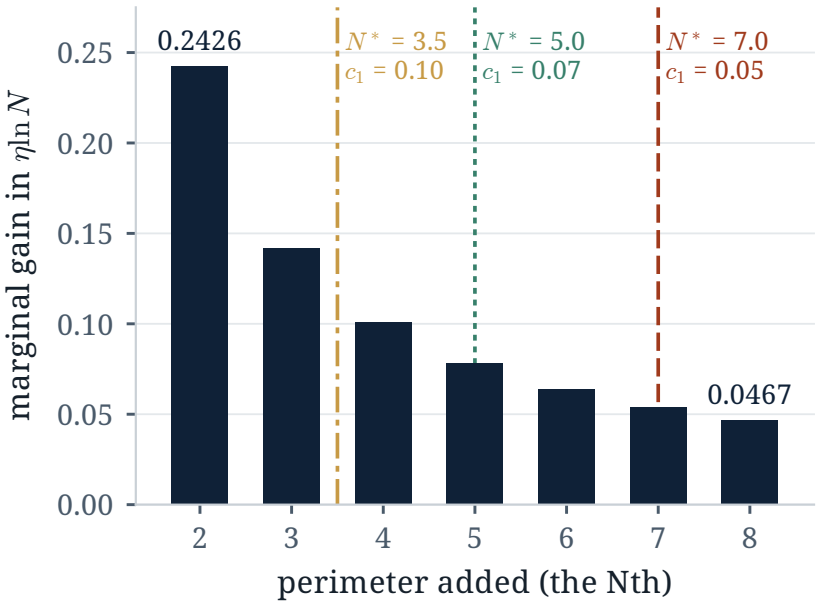

Figure 51.5: **The second perimeter is worth 5.19 times the eighth, and at expensive coordination the interior optimum falls to three and a half perimeters.** Modelled from $h = \eta \ln N - \delta Q - c_0 - c_1 N$ at $\eta = 0.35$, with $N^* = \eta / c_1$ marked for the three tabulated coordination costs. Script `figs/src/CCP-051_fig05.py`.

examined within fifteen years. Structures are frequently built to horizons of thirty years and longer.

The principal is inside a jurisdiction. This is the mechanism of Section 4.4 and it generalises. Assets can be redomiciled and entities migrated; the person who built the structure is subject to the coercive power of the courts where he stands.

The cost inversion. Concealment is not cheaper than compliance once the expected cost of failure is included, and at realistic parameters it is not cheaper even before that. The next section computes it.

7.2 The economics, computed

CONSTRUCTED. The figures are built for illustration. They are not quotations, they are not research estimates, and actual costs vary by an order of magnitude with size and complexity. What is demonstrated is the *shape* of the comparison, and the shape is robust to large changes in the inputs.

A compliant multi-jurisdiction architecture holding capital of USD 50 million:

annual maintenance line	USD / year
Gulf foundation: registered agent, office, filings	18,000
Gulf foundation: council fees (three members)	45,000
Gulf holdco: licence, registered office, accounts	22,000
non-aligned operating company: audit, incentive reporting, payroll compliance	36,000
Atlantic captive: regulatory filings, actuarial opinion, audit	140,000

annual maintenance line	USD / year
second non-aligned centre vehicle: regulatory compliance, fund administration	85,000
Western company: accounts, ownership filings, corporation tax	14,000
group: coordinated tax counsel, six jurisdictions	120,000
group: exchange classification and annual reporting	26,000
group: transfer-pricing documentation	55,000
total annual C	**561,000**

As a fraction of protected capital: 224.40 basis points at USD 25m, 112.20 at 50m, 56.10 at 100m, and 22.44 at 250m. **At USD 25 million this architecture costs 224 basis points a year, which is a serious drag; at USD 250 million it costs 22, which is negligible. Compliance-based architecture has substantial fixed costs and therefore a minimum efficient scale.** Below that scale the correct advice is a simpler structure, not a cheaper version of a complex one.

Now the comparison. Assume a concealment-based alternative costing USD 210,000 a year. It is genuinely cheaper on the visible line: USD 351,000 less, a saving of 62.6 per cent. Assume that on examination it loses sixty per cent of capital to assessment and recovery, incurs a penalty of twenty per cent, and consumes USD 1.5 million in counsel, so that $L =$ USD 41.5 million.

annual exam probability	expected annual loss	concealment total burden	compliant C	ratio
0.02	830,000	1,040,000	561,000	$1.85\times$
0.05	2,075,000	2,285,000	561,000	$4.07\times$
0.10	4,150,000	4,360,000	561,000	$7.77\times$
0.20	8,300,000	8,510,000	561,000	$15.17\times$

```
p* = (561,000 − 210,000) / 41,500,000 = 0.008458
```

At any annual examination probability above 0.85 per cent the concealment structure is more expensive than the compliant one, and 0.85 per cent is roughly a one-in-a-hundred-and-eighteen-year event, far below any defensible estimate of examination risk in the environment of Section 4. The apparent 62.6 per cent saving is an artefact of counting the invoice and not the exposure. The result is insensitive to L: halving it moves p^* only to 0.016916. **H3's prediction is met.**

There is a second-order point the table does not show and that matters more than any number in it. The compliant structure's cost is a known, budgetable operating expense paid in cash from income. The concealment structure's cost is a low visible fee plus an unbudgetable tail risk to principal. **Those are not the same kind of liability, and a principal who treats them as comparable line items has mispriced the decision before the arithmetic starts.** Cyert and March [1963] is the general form: organisational slack — the property that makes a system survive a shock it did not plan for — has always appeared on the accounts as waste.

7.3 Three words that are not synonyms, and the product rule

Precision here prevents most of the confusion in this field.

Privacy is the interest in one's affairs not being available to the general public. It is a recognised right in several legal systems, it was vindicated against a supranational directive

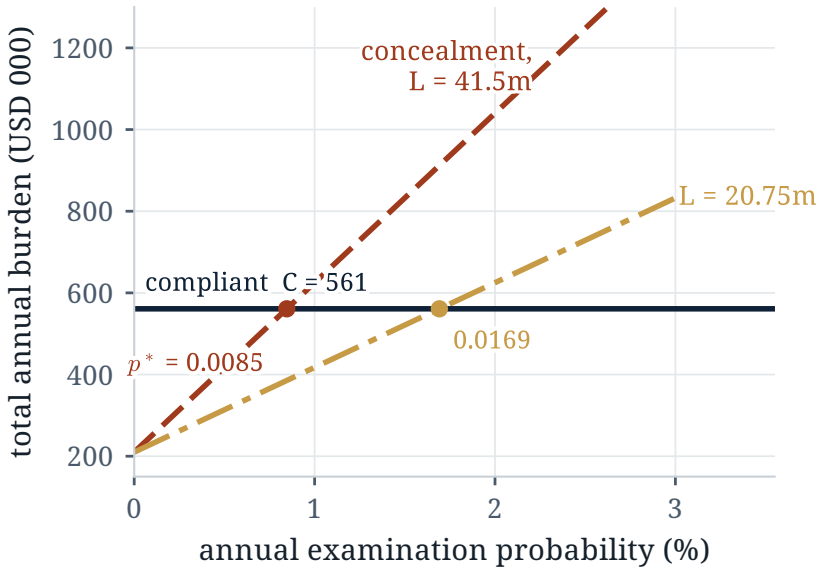

Figure 51.6: **The visible 62.6 per cent saving on the invoice reverses at an annual examination probability of 0.85 per cent, and halving the loss on examination moves that threshold only to 1.7 per cent.** Modelled from a total burden of $210{,}000 + pL$ against a compliant $C = 561{,}000$, with $L =$ USD 41.5m and USD 20.75m; all parameters CONSTRUCTED. Script `figs/src/CCP-051_fig06.py`.

in November 2022, and structures may rely on it. **Confidentiality** is a duty owed by a professional or institution to a client, enforceable between them and subject to statutory override; structures may rely on it only within the space the overrides leave, which shrinks. **Opacity to competent authorities** is the condition of an authority with jurisdiction being unable to obtain information it is entitled to, and fifteen years of evidence say the trend here is one-directional with no significant counter-examples. **A structure may rely on privacy, may rely on confidentiality within its statutory limits, and may not rely on opacity.**

The operational form of the design standard is one question, applied element by element:

```
THE DISCLOSURE TEST
------------------------------------------------------------------
Would this structure still do its job if every element of it were
disclosed to every authority with jurisdiction over any part of it?
------------------------------------------------------------------
"Every element"    each entity, contract, filing, account and flow
"Every authority"  the tax authority of each operating jurisdiction,
                   the tax authority of the principal's residence,
                   each financial regulator, each correspondent
                   bank's compliance function, and the court that
                   would hear an adverse claim
"Its job"          the specific function assigned to it under the
                   three-jobs taxonomy: holding, operating, bridging
------------------------------------------------------------------
```

Five criteria, all of which must be satisfied: (1) lawful where it sits, on the facts as they actually are rather than as documented; (2) filed and registered, on time and current; (3) correctly classified and reported under every applicable exchange regime; (4) independent commercial rationale, statable without reference to any tax or disclosure consequence, and real; (5) survives hostile reading, remaining defensible when described in full in the least favourable framing to a tribunal inclined to disbelieve it.

A structure's disclosed value is the product of its elements' scores, not their average, because a chain fails at its weakest link and an examiner who finds one bad element examines the rest with an entirely different prior.

elements satisfied	average score	product score	verdict
5 of 5	1.00	1.00	PASS
4 of 5	0.80	0.00	FAIL
2 of 5	0.40	0.00	FAIL
1 of 5	0.20	0.00	FAIL

The average column is what an adviser presents when he wants to describe a structure as substantially compliant. **There is no such thing.** Criterion 4 is the one most often failed by otherwise well-built structures, and criterion 5 the one most often failed by structures satisfying the first four on paper.

The audit procedure is six steps: enumerate every entity, account, contract and flow; assign each exactly one job; score the five criteria recording the *evidence* for each yes rather than the conclusion; multiply, never average; remediate or **remove**, because documentation improves the record of a fact and cannot create one; and re-run annually and on any change of law, residence or control. **Step five is where the discipline lives. The instinct on discovering a weak element is to improve its documentation, and an examiner comparing the documentation to the operational reality will find the gap.**

7.4 Five structures scored, two of which fail

CONSTRUCTED. Structures A to E are invented; no real person, family, entity or transaction is described. Jurisdictions are de-identified where the score would otherwise assert an uncited jurisdiction-specific characteristic as fact, following the convention of Curzi [2026].

The five are arranged deliberately. A is a foundation apex. B and C are a captive insurer and a foreign-owned operating company, both built correctly. **D and E are the same two jobs in the same two jurisdictions, built the other way: the jurisdiction is identical, the entity type is identical, the cost is comparable, and the only difference is that one element depends on something not being seen.**

structure	C1	C2	C3	C4	C5	product	verdict
A — foundation apex in Gulf centre A	1	1	1	1	1	1	PASS
B — Atlantic captive writing real third-party risk	1	1	1	1	1	1	PASS
C — non-aligned operating company, incentive-promoted, disclosed	1	1	1	1	1	1	PASS
D — the same operating company, nominee-held	0	1	0	0	0	0	FAIL
E — captive writing no risk	1	1	1	0	0	0	FAIL
average of the five criterion means, offered only to be discarded						**0.80**	meaningless
product of the group						**0**	any zero fails the group

Structure A is a foundation holding the family's branch holdings as a single perpetual legal person: charter filed, by-laws held privately by the registered agent, founder's reserved powers graded so that no power to direct a distribution to himself exists, a council including an independent resident professional, meetings held and minuted, ownership particulars filed, exchange classification determined and reported. **Its function is to be the recorded owner, and a recorded owner works better when the record is examined** — four registries naming

the same legal person close questions rather than opening them. Disclosure is the mechanism, not a tolerated side effect. This is asset partitioning doing the work entity law exists to do [Hansmann and Kraakman, 2000].

Structure B is a licensed and supervised captive writing product-liability and business-interruption cover for the group's manufacturing operation and participating in a third-party quota share, with premiums set by an independent actuary, reserves held against the liabilities, and claims actually made, adjusted and paid. **The weight sits on criterion 4, satisfied by a fact rather than a document**: the group has a real, quantified, badly-priced exposure and the captive assumes it.

Structure C is a manufacturing company wholly owned by the group's Gulf holding company, with an investment-promotion instrument conferring the foreign-ownership position on its face and every shareholder the registered holder in its own right. **The company's most sensitive fact — that it is entirely foreign-owned in a country with a restrictive foreign business regime — is not merely disclosed; it is the subject of an affirmative government grant, publicly recorded. The fact that would destroy a concealment structure is the fact that makes this one work.**

Structure D is the identical business with identical premises, customers and revenue, in which no promotion was applied for and the foreign-ownership position was instead arranged by having two local individuals appear on the share register as majority holders, subject to an unregistered loan agreement, an undated blank transfer, an irrevocable proxy and a side letter. It fails criterion 1 because nominee shareholding to circumvent foreign-ownership restrictions is a criminal offence in the jurisdiction concerned and is prosecuted — **a claim carried from the source manuscript and not cited; the statutory provision and its current penalties are Appendix B, item 8.** It fails 3 because the true controlling person is not the one reported, 4 because the arrangement has no purpose statable without reference to the restriction it circumvents, and 5 because the side letter read aloud is the prosecution's exhibit. **It passes criterion 2, and that is the instructive part: the register is filed, and it is false, which makes criterion 2 the least relevant line in the table.**

What makes D the instructive failure. It is not cheap. It has counsel, a share register, audited accounts, a real factory and real employees, and on any measure of economic reality it is the same business as C. It fails on one element, **and that element converts the other four from evidence of a well-run business into evidence of a well-run concealment.** The promotion route took four months to obtain and cost less than a year of the side letter's legal fees. The concealment route was chosen because it was faster, and speed is why most failing structures exist.

Structure E is a small captive in a well-regulated jurisdiction, licensed and filing, issuing policies to affiliates covering remote and poorly defined perils, with premiums set to produce a deduction rather than by actuarial assessment, no third-party risk, no meaningful pooling, no claim ever made, and reserves invested in a note issued back to the group. **Why this failure is different from D's, and more dangerous:** D is unlawful where it sits and everyone involved knows it. E is lawful in the jurisdiction of formation on every visible measure — licensed, supervised, audited, reported. It fails on criteria 4 and 5, the two about substance rather than form, **and it fails in the jurisdiction of the policyholder, not that of the insurer. A structure can be perfectly compliant where it sits and fail the disclosure test entirely, because the test asks about every authority with jurisdiction over any part of it, and the deduction is claimed somewhere else.** The tax jurisprudence on this class of arrangement turns on risk distribution rather than on any concealment; the decisions and the current regulatory treatment are Appendix B, item 9.

Two observations on the scoreboard. **First, note where the failures cluster.** Criterion 2 is satisfied by both failing structures. Filing is the criterion concealment structures satisfy most easily, because filing a false particular is still a filing; an adviser who reports compliance by counting filings reports both failures as passes. **Second, neither failure is a close call once the criteria are applied element by element, and both were sold to their principals as sophisticated. The instrument's value is not that it detects subtle problems; it is that it makes obvious**

problems impossible to describe as acceptable.

7.5 Concealment and armour: the same effect by inverse mechanisms

There are exactly two ways to keep an asset out of a hostile party's hands: make it hard to find, or make it hard to take. Both work. **They are not points on a spectrum, not weak and strong versions of one another, and cannot be blended into a hybrid with the advantages of each.**

CONCEALMENT	STRUCTURAL ARMOUR
survives because the adversary cannot LOCATE it	survives because the adversary cannot TAKE it
the protective quantity is the adversary's IGNORANCE	the protective quantity is the structure's CORRECTNESS
protection is a decreasing function of observation	protection is invariant to observation
the defence is consumed the first time it is used	the defence is unchanged by use and is available on the tenth examination as on the first
fails DISCONTINUOUSLY: full protection until exposure, then none	fails CONTINUOUSLY: only under applied force, and by degrees that can be observed
failure is not observable in advance	failure is observable in advance
scales badly: each additional person who knows is a new failure point	scales well: each additional filing makes the next filing easier

The two mechanisms are exclusive because the actions that strengthen one weaken the other. Every disclosure that makes an armoured structure more defensible — the filed charter, the named owner, the reported account, the audited return — is a location that concealment would have had to avoid. Every layer that makes a concealed structure harder to locate is an element that fails criterion 1 or criterion 5 and therefore zeroes the product score. A structure is one design or the other, and the decision is taken at inception, usually without being recognised as a decision at all.

This is the open-design principle stated as an engineering standard rather than an ethical one. Kerckhoffs [1883] requires that a system remain secure when everything about it except the key is public; Saltzer and Schroeder [1975] restates it as *open design* among the protection principles. **The corpus's disclosure constraint is therefore not a moral preference; it is Kerckhoffs's principle applied to legal structure, and the concealment column above is precisely the failure mode Kerckhoffs identified in 1883.**

Now put the two mechanisms against the environment of Sections 4 and 5. Concealment's protective quantity is the adversary's ignorance, and the four properties of Section 7.1 describe a world in which that quantity is falling toward zero and cannot be replenished. Armour's protective quantity is correctness, which is depleted by none of those four. It is depleted only by the law changing under a structure built correctly under the old law — which is a real risk, is observable in advance, and is what criterion 3 and step six of the audit exist to catch.

Concealment-based vehicles are not obsolete because they were unethical, or because they became unfashionable, or because regulators disapproved of them. They are obsolete because the quantity they ran on stopped being available. That is a supply statement, not a moral one, and it is why the replacement is not a better-concealed vehicle. When a mechanism's input goes to zero the replacement is not a more efficient version of the same mechanism; it is a mechanism that runs on a different input.

7.6 An existence proof on the public record

Everything above is the framework's own instrument applied to the framework's own constructed cases, which is a closed loop. The argument needs one thing it cannot supply for itself: a demonstration on the public record that a function which used to require concealment is now performed by a structure with no concealment in it at all — successfully, at scale, for a long time, by an institution with every incentive to choose the other design if the other design still worked.

The load-bearing facts are only three: there exist sovereign investment institutions that are publicly acknowledged, whose purpose and principal are publicly known, and that work. The named instance in the source manuscript is a national pension fund managed by a unit of a central bank under a published ministerial mandate, which publishes its complete holdings list, publishes how it votes and how it intends to vote, publishes exclusion decisions naming the company and the reason, and reports audited accounts to its legislature. **The specifics — governing statute, mandate instrument, first transfer date, the exact scope and timing of each disclosure, the constituting instrument of the ethics body, and the fund's size — are described from the source and are not cited (Appendix B, item 10.)**

What it replaced. For much of the second half of the twentieth century a state deploying capital into another state's markets did so through arrangements designed not to be attributable: nominee registrations, custodian omnibus accounts, layered intermediate vehicles, and positions kept deliberately below the level at which a name must be filed. The object was the return and the access without the political fact of state ownership becoming visible. **The pattern is well documented; individual attributions are usually contested, and none is asserted here.**

Why the mechanism stopped being available. The four properties of Section 7.1 apply with greater force to a state's capital than to a private structure. Registries became searchable and then centralised. Beneficial-ownership regimes made the ultimate controller a reportable particular. Major-shareholding notification made the position itself a filing at a stated threshold, and thresholds have been lowered and extended to instruments once outside them. Custody, settlement, index, flow and commercial holdings data made attribution derivable. And investment screening now asks, as a statutory question put to the buyer, who ultimately controls it — and answers adversarially where the buyer will not. **Protection is complete right up to the threshold crossing or the first regime the structure failed to anticipate, and then it is absent; and a position revealed late reads as evidence of an intention to conceal, which is a worse place to stand than having disclosed from the start.**

What the disclosed institution does instead. Decompose the function and the result stops being surprising:

THE FUNCTION	DOES IT NEED CONCEALMENT?
hold a diversified claim on world growth for future citizens	no -- a broad index position is not a secret and could not be made into one
keep access to markets that screen foreign state buyers	no -- and disclosure HELPS: a screening regime clears the buyer whose owner and mandate are known

```
vote the shares, and tell the      NO -- this requires the opposite.
market beforehand how the vote     A vote cannot be cast, still less
will be cast                       pre-announced, by a holder that
                                   cannot say who is voting

move a company's conduct by        no -- the exclusion is worthless
excluding it on published          unless the company and the reason
ethical criteria                   are named

contract on ordinary commercial    no -- a disclosed institutional
terms with brokers, custodians,    counterparty is EASIER to
banks and co-investors             contract with than an opaque one

survive changes of government      no -- an acknowledged, audited,
and public scrutiny at home        parliament-reported fund survives
                                   scrutiny BETTER
```

Read the middle rows, because they are the strongest form of the argument. Two of the functions are not merely indifferent to disclosure — they are impossible without it. A concealed holder cannot vote its shares as an owner, still less publish beforehand how it means to vote, because a vote is an act performed in a name; and it cannot change a company's behaviour by excluding it, because the exclusion has force only when the owner walking away and its reason are both public. **The disclosed vehicle does things the concealed one structurally could not, which is why the replacement is not a compromise forced by circumstances but an improvement that circumstances made available.**

There is a further piece of evidence of the kind arguments rarely get. **A design that works gets copied, and this one was.** When sovereign investors came under sustained political pressure in the late 2000s, the sector's answer was not better concealment but a published voluntary disclosure standard agreed by an international working group in 2008, and a standing forum that has maintained it since. **When states set out to defend these vehicles, not one of them defended them by concealing more.** They defended them by publishing the mandate, the holdings and the votes — institutions with a real commercial incentive to keep a position unattributed, and the capability to do it, choosing the other design repeatedly, independently and in public.

What transfers, and what does not. The analogy is strong and strong analogies get overrun. *What does not transfer:* such a fund operates with the acknowledgment, budget and legal protection of a sovereign state and is not defending against that state. It has no forced-heirship problem [Hague Conference on Private International Law, 1989, European Union, 2012], no correspondent-banking dependency, no exposure to a foreign court with personal jurisdiction over a founder, and no requirement that its structure survive a death. **Nothing here is a recommendation to copy the vehicle; the vehicle is not the transferable part.** *What transfers* is the design principle, in three propositions:

```
1  A function that depends on concealment has a protective quantity
   that is falling and cannot be replenished. Its obsolescence is a
   supply problem, not a moral or regulatory one.

2  Most functions historically performed by concealment do not require
   it. Decompose the function and score each part for its concealment
   dependency. Parts scoring zero can be rebuilt in the open at once;
   parts scoring above zero are the ones that will fail, and they are
   fewer than expected.

3  A structure that has disclosed everything has nothing left to be
```

```
exposed. That is not a consolation prize. It is a stronger
defensive position than partial concealment, because it removes a
category of adverse event rather than reducing its probability.
```

Proposition 2 is the practical instruction. The exercise to perform is not "how do I protect this structure from being seen" but "which specific functions of this structure would stop working if it were seen" — and then to discover that the honest answer is a short list, and that the items on it were the ones that were going to fail anyway.

What passing does not buy, stated without softening. It does not buy immunity from tax. It does not buy protection against a judgment that survived due process. And it does not buy protection against a state that decides to act without process. **In 2022 approximately USD 300 billion of central bank reserves were immobilised. Those reserves were among the most thoroughly disclosed assets in the world — held by a sovereign, in named accounts, at identified institutions, reported in published statistics, with no concealment element of any kind. Full disclosure did not prevent immobilisation.** Curzi [2026] owns that result: disclosure is not immunity, and the disclosure test is a filter that removes structures collapsing on contact with an authority, not a shield against a policy decision. What disclosure-based design does against arbitrary action is narrower and still worth paying for: it makes the position legally defensible rather than hopeless, it raises the political cost of acting against a demonstrably compliant holder, and — the part that matters most — **it is the precondition for the perimeter diversity of Section 6 to be usable at all, because a structure that cannot survive examination in each perimeter has not diversified across those perimeters; it has merely placed assets where it is not yet in trouble.**

8. Results: hypotheses tested

H1 — supported. The conventional structure's naive effective count is 3.4085 and its effective perimeter count is exactly 1.0000, a factor of 3.41. The falsifier was an independent-schedule erosion pattern with no common trigger; Section 5.2 traces one assessment through three institutions in under a year, and Section 5.3 names three structural features each independently sufficient to produce the correlation. **What the arithmetic cannot do is establish that the real within-perimeter correlation is one.** That is an empirical claim, it rests on the observed behaviour of the coordinated frameworks over fifteen years, and Section 12 records it as the paper's largest unmeasured input.

H2 — supported, exactly. At $c = 0.02$ and $i = 0.0816$ the joint probability is 0.020044 against $p^4 = 0.000100$, a factor of 200.4, and the idiosyncratic term contributes 0.0000435 — 0.22 per cent of the total. The prediction was a point value and the point value is met.

H3 — supported. $p^* = 0.008458$ at the constructed parameters, and 0.016916 when L is halved. The falsifier was a defensible estimate of annual examination probability below 0.85 per cent; **no such estimate is offered here either, and that is the honest limit of the result — the threshold is computed exactly and the quantity it is compared against is not measured.** Section 12 records this.

H4 — supported. $s = 2/3$ exactly, by solving $s^2 + 2((1-s)/2)^2 = 1/2$, and no allocation retaining more than two-thirds inside one perimeter reaches $N = 2$.

H5 — not met. At the parameters fixed in Section 2:

```
maintenance floor:  delta Q + C = 0.02 x 10 + 0.30 = 0.5000

conventional:  h = 0.35 x ln(1.000000) - 0.5000 = -0.500000
designed:      h = 0.35 x ln(2.941176) - 0.5000 = -0.122417

h = 0 requires  eta ln N = delta Q + C
                ln N = 0.5000 / 0.35 = 1.428571
                   N = e^1.428571 = 4.172734
```

The criterion was $N \geq 4.172734$. The redesigned structure reaches $N = 2.941176$. H5 is not met. The designed structure improves h by 0.377583, a 75.5 per cent reduction in the shortfall, and remains at -0.122417. **Both structures are below the threshold at which the structure is worth building. Jurisdictional diversity buys the ability to build; it does not buy the building.**

What would close the gap is visible in the equation and is not jurisdictional. At $N = 2.941176$:

```
C required for h = 0    :  0.377583 - 0.200000 = 0.177583   (against actual 0.30)
eta required for h = 0  :  0.500000 / 1.078810 = 0.463474   (against actual 0.35)
```

Both are operating improvements rather than structural ones, which is the paper's counter-result and is stated in the same plain language a success would have received.

9. Failure modes

Nine ways the instrument and the standard are misused, each with the arithmetic or the diagnostic that detects it.

1. Counting flags instead of perimeters. The master error; everything else is a special case. A diagram with entities in six countries looks diversified and may not be. The diagnostic is quick: apply the four-question test to each situs and shade every entity scoring four. If the shaded entities hold most of the capital, the diagram is decoration. The general form of the error is proved elsewhere: one party can present as many [Douceur, 2002], so **an unaudited count of nominally distinct parties is worthless.**

2. Treating a delisting as an all-clear. A jurisdiction that has just completed a supervisory overhaul in order to exit a list is at its most compliant, most closely monitored, and most tightly coupled to the assessing body. That may be exactly what a principal wants; it should not be mistaken for a return to the earlier product, which the overhaul removed.

3. Reading the offshore statute rather than the enforcement route. The statute says the foreign judgment will not be recognised, the statute is correct, and the principal is detained anyway, because the enforcement route ran through him. Before relying on any protective provision, trace the route by which an adversary would actually attack and check whether the provision sits anywhere on it.

4. Treating a bridge as neutral, or non-Western as unreachable. Section 5.5 on the first; Q4 on the second. A bridge classification is a claim about correlation, not about immunity.

5. Confusing a clearing layer with a messaging layer. A renminbi clearing system is a *clearing* system; a large proportion of its participants use the incumbent network for the messaging layer of transactions that clear through it. **A structure with two clearing systems and one messaging system has one point of failure, not two**, and a diversification claim must identify which layer it diversifies. Curzi [2026] runs the measurement.

6. Confusing a rail with a store. Freeze risk on a rail is an exposure-window problem with parameters — hop size, duration, counterparty pre-screening, mid-transit failure handling. Freeze risk on a store is a custody problem with entirely different parameters. **Never evaluate a rail as though it were a store of value.** The error is especially common with tokenised settlement instruments, which are frequently described as being outside the perimeter and are not: issuers freeze balances at law-enforcement request, and public ledgers are *more* traceable than correspondent banking, not less.

7. Over-diversifying. Section 6.5. Logarithmic benefit against linear cost has an interior optimum and the optimum is not large.

8. Assuming perimeters are static. The classifications are judgements about the present. Perimeters expand — each accession converts a jurisdiction from partially outside to inside on Q1 — and they can fragment. **The classification must be re-made periodically with dated evidence rather than impressions**, which is why the trajectory record of Section 4.7 requires

dated events. The mirror case is worth noting: threat-5 style fragmentation runs both ways and only one direction is usually planned for.

9. Optimising the index instead of the thing it measures. Two structures with identical bloc indices can differ enormously in whether the blocs are actually independent in the scenario that matters. **The index is a diagnostic, not an objective function.** This is Goodhart's problem exactly [Goodhart, 1975] and Campbell's law in the evaluation literature [Campbell, 1979]; Scott [1998] is the historical form, in which legibility destroys the local variety that made the system work, **and it is a warning about this instrument as much as an argument for it.** The tell is a structure whose bloc shares are suspiciously round and equal; real structures are lumpy because assets are lumpy.

Two further failure modes belong to the disclosure standard rather than the index. **Grading privacy on the opacity axis** — the structure is described as passing because "nothing is public", which answers a question the test does not ask; re-run it assuming every document is in the hands of every authority and score only the consequences. And **designing for the examiner and forgetting the bank** — practitioners optimise for the tax authority because that is the reader whose questions come in writing, while the binding constraint in practice is usually the correspondent bank's compliance function, which asks fewer questions, gives no reasons, has no appeal, and can end the structure's usefulness in ninety days.

10. Discussion

What follows. Three things, each narrower than the general claim it resembles.

The correlated-failure result is arithmetic, given the correlation structure. The joint probability $c+(1-c)i^4$ is exact, and the collapse EFF $= 1/(w'Rw)$ is a variance reciprocal [Markowitz, 1952, Leinster and Cobbold, 2012]. Nothing in the derivation is approximate. This is why the result survives the statistical-averaging objection of Doak et al. [1998]: no claim is made that diversity produces stability through an unspecified mechanism, only that a variance has a reciprocal and that the reciprocal counts independent shocks.

The status of the claim is measurement, not physics. The corpus is titled a psychological and sociological physics and the word is checkable. **What is claimed here is a measured count with a dimension, stated limits and an invariance group** — Sections 11.1 to 11.4 — and **not** membership of the statistical-physics programme surveyed by Castellano et al. [2009], whose vocabulary of order parameters, phase transitions and coarsening this paper deliberately does not use. **No order parameter is identified, no phase transition is located, and no critical exponent is estimated.** Hedström and Ylikoski [2010] states the criterion the named discipline applies: an explanation must name a mechanism rather than exhibit a fitted curve. **The mechanism named here is a transmission structure with five interfaces, and nothing is fitted.** Gallegati et al. [2006] is the checklist this paper was run against — ignorance of existing work in the target discipline, sub-standard statistical procedure, unjustified universality claims, and models built on assumptions known to be false — and Section 12 reports where it passes and where it does not.

The collapse mechanism has a formal ancestry that should be named rather than reinvented. A small correlated shift producing a discontinuous collective outcome is the threshold and tipping mechanism: Granovetter [1978] establishes that the distribution of individual thresholds, not the mean, determines whether an outcome tips, and Schelling [1971] is the canonical warning against reading an individual-level parameter straight into an aggregate — **which is precisely what a perimeter assignment does.** Castellano et al. [2000] supplies the closest formal analogue of a bloc: the same interaction that raises local agreement freezes global diversity into non-interacting regions, with a sharp transition between the monocultural and fragmented phases. **A perimeter, in that vocabulary, is a frozen region.** On the generating side, Bouchaud and Mézard [2000] derives concentration rather than observing it — above a critical ratio a finite fraction of the total condenses onto one holder, **which is the index going to one, obtained from a mechanism.** This paper does not use that model and

asserts no tail; the citation records that a mechanism-side companion exists.

Redundancy is not automatically resilience. Percolation gives the sharpest formalisation of how many independent components a system really has [Callaway et al., 2000], and the robust-yet-fragile result [Albert et al., 2000] is the canonical demonstration that a network can be highly tolerant of random loss and extremely vulnerable to targeted loss — with the caveat, from Doyle et al. [2005], that real engineered systems get their robustness from design rather than from a degree distribution. The perimeter analogue is that a structure's tolerance depends on which component is removed.

What does not follow. Four things.

It does not follow that raising N is always right. Section 6.5; Uzzi and Spiro [2005]; Sagan [1993]. The prescription is bounded.

It does not follow that perimeter diversity answers every threat. It is close to irrelevant to counterparty failure and can worsen it, because the population of institutions willing to bank a genuinely cross-perimeter structure is small. Curzi [2026] owns the threat taxonomy that separates the five and shows that a structure answering one well may answer another worse than doing nothing.

It does not follow that compliance confers immunity. Section 7.6, and Curzi [2026].

It does not follow that the corpus's affine effective count inherits any of the diversity literature's support. Section 3.2.

Where this paper stands relative to its own corpus. The fifth-decimal reconciliation of Section 6.3 is the substantive point of contact with Curzi [2026], and it is printed in both papers rather than harmonised in either. Curzi [2026i] bounds how much confidence a passing check should buy: the corpus's own preregistered fit **failed its own second falsification rule**, achieving a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, despite +40.3 per cent over persistence, +97.7 per cent over direct input, and $p = 0.0005$ against the shuffle. **A paper in this series that reported only its successes would be departing from the practice of the paper that reported that failure.**

Parallel results elsewhere in the corpus. The shape of the correction recurs on different objects. Curzi [2026s] derives trust as retention, $\delta_{\text{eff}} = \delta_0 + (1-a)(1-v)$, giving a superlinear stock dividend from 0.4679 at $a = 0.50$ to 5.0529 at $a = 0.99$ — an input to the same δ this paper decomposes, from an entirely different direction. Curzi [2026] supplies the comfort-weighted amplitude, scoring each step 0–3 for steepness and weighting a branch as $1/2^R$, so that a three-point difference in steepness is a factor of eight in expectation — the same exponential-in-a-small-integer structure that makes a two per cent common component worth two hundred times an idiosyncratic one. Curzi [2026] supplies the discipline this paper needs most: the surplus functional is deployed as a **lower bound** on the ensemble's information and not as the information itself, so the framework logs the floor and not the ceiling. Curzi [2026] gives the minimum sustainable frequency $f_{\min} = ke^{2c/\eta}$ with $k = 0.483425732988414$ Hz and the trichotomy $f \gtreqless f_{\min}$ corresponding to $Q_\infty \gtreqless 0$ — the same sustainability threshold as this paper's $h \gtreqless 0$, expressed in a different unit. **The constant k is defined, not measured**, and the attachment of Hz to it is a separate and stronger claim; that badge travels with the citation. Curzi [2026] gives the odd-part class rule — the pitch class of $f(n) = kn^2$ is the odd part of n, so $1 \dots N$ realises exactly $\lceil N/2 \rceil$ classes, six at $N = 12$ — a discrete count invariant under a relabelling, as N here is invariant under rearrangement inside a perimeter.

11. Verification and rigour audit

The results are decomposed into postulates checkable one at a time. Sections 11.1 to 11.6 run the standing rigour checks first, so that the chain in 11.8 is read against a dimensional audit rather than before one. **If dropping a postulate leaves the result standing, it is not listed.**

11.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i, w_i	exposure share of jurisdiction i	$[1]$	dimensionless, fraction of Q	defined; sums to 1 by P1
W_b	perimeter share	$[1]$	dimensionless	derived, $W_b = \sum_{i \in b} s_i$
HHI	concentration index	$[1]$	dimensionless (or points $= 10^4 \times$ fraction)	derived from shares
ρ_{ij}	correlation between shocks	$[1]$	dimensionless, $[-1, 1]$	assumed, not measured
N	effective perimeter count	$[\#]$, **a count**	perimeters	derived as $\mathrm{HHI}_{\mathrm{bloc}}^{-1}$
$\ln N$	input-term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
c, i, p	common, idiosyncratic and marginal failure probabilities	$[1]$	dimensionless, per year	assumed (constructed)
Q	protected capital	$[C]$	index units of stored capital	defined; **no operational unit is supplied by the source**
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived
c_0, c_1	fixed and per-perimeter maintenance	$[C\,T^{-1}]$, $[C\,T^{-1}\,\#^{-1}]$	index units per period, per perimeter	assumed
L, p^*	loss on examination, break-even probability	[currency], $[1]$	USD, dimensionless	assumed (constructed), derived

Does the surplus law balance? $h = \eta \ln N - \delta Q - C$ requires every term to carry $[C\,T^{-1}]$. δQ does, since δ is per period and Q is a stock. C does by definition. $\eta \ln N$ does **only if** η **carries** $[C\,T^{-1}]$ **per nat**, and **the source is silent on this**: it treats η as a bare "conversion efficiency". The audit records the silence rather than filling it in. The equation balances under the reading in the table, and the reading is this paper's, not the source's.

Does the disclosure-economics comparison balance? $p^* = (C_{\mathrm{comp}} - C_{\mathrm{conc}})/L$ divides a currency difference by a currency loss and returns a dimensionless probability. It balances. **But note the mixed dimension in the comparison itself**: C is a flow per year and pL is an expected flow per year, so the two are commensurable only because p is an *annual* probability. Stating p over any other horizon breaks the comparison, and Section 7.2's table is annual throughout.

The important row is N. The index is a dimensionless sum of squared dimensionless shares, so its reciprocal carries the dimension of a **count**. **The instrument is not a score that happens to start at 1; it is a measured count of independent units, with a unit**, and Section 11.3 checks it against the definition of a count.

Where no operational unit exists, this audit says so. Q is protected capital in index units and the source supplies no conversion to currency. Every figure in C, h and Q is therefore on an arbitrary scale fixed by the stated parameters. **The break-even $N = 4.172734$ is unit-free and survives this; the statement that $h = -0.122417$ does not mean anything until the index unit is defined.** The USD figures of Section 7.2 are in a different and genuine unit and must not be read as commensurable with $C = 0.30$; **the paper uses the symbol C for both and that is a defect of notation inherited from the source, flagged here.**

11.2 Significant figures and epistemic status

- $N = 1.000000$ and $N = 2.941176$ are **exact arithmetic** on the stated shares, $1/1$ and $1/0.34$. They are derived-from-defined and may carry as many digits as are useful.
- HHI $= 0.293388$ is **exact arithmetic on exact fractions** ($142/484$) and 0.293430 is exact arithmetic on the three-significant-figure percentages. Both are exact; they are exact on *different inputs*, which is the whole content of Section 6.3.
- $N = 4.172734$ is **exact given the parameters** — $e^{0.5/0.35}$ — and the parameters are assumed, not estimated. **It carries no uncertainty because there is no estimate in it, and no authority beyond the assumption.**
- $p^* = 0.008458$ is exact arithmetic on three constructed currency figures. Six digits are defensible only because the inputs are exact by stipulation. **It is not a measurement**, and the quantity it must be compared against — a real examination probability — is not measured anywhere in this paper.
- The correlated-failure outputs (0.020044, 0.794109) are **illustrative model output from constructed parameters** and are rounded to six decimal places at most.
- The erosion percentages (73.857%, 54.548%) are exact arithmetic on an assumed rate.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere. That is not a strength: it means the paper has no empirical content to attach an interval to.**

11.3 Limits and boundary behaviour

The instrument's limits are the proof that it behaves as a count, and they are run rather than asserted.

limit	HHI	HHI^{-1}	reading
one holder, $s_1 = 1$	1	1 exactly	a monopoly counts as one unit
n equal holders, $s_i = 1/n$	$1/n$	n exactly	returns the count
n holders, any unequal split	$> 1/n$	$< n$	never overstates the count
$s_{\max} \to 1$, rest $\to 0$	$\to 1$	$\to 1$	continuous approach to the monopoly limit
$n \to \infty$, equal shares	$\to 0$	$\to \infty$	unbounded above, as a count should be
$\rho \to 0$ within perimeters	naive	naive count	the independent limit
$\rho \to 1$ within perimeters	bloc	perimeter count	the fully-coupled limit

Range: $1 \leq \text{HHI}^{-1} \leq n$, with both bounds attained. A quantity that equals n for n equal units, equals exactly 1 for a single unit, and lies strictly between otherwise **is a count**, and no further argument is needed. Verified on the two structures here: $1/1 = 1$ exactly for the conventional perimeter vector, and $1/0.25 = 4$ exactly for a hypothetical four-way equal split.

The same limits run on the affine count, which fails them. $N_{\text{eff}} = 1 + (N-1)u$ returns 1 at $u = 0$ and N at $u = 1$ for *any* share vector whatever, including $(0.999, 0.001)$, for which it reports 2.000000 at $u = 1$ while HHI^{-1} reports 1.002004. **It has the right endpoints and the wrong interior, because it never consults the shares.** Curzi [2026] runs the full chain.

Boundary behaviour of the correlated-failure law. $P = c + (1-c)i^4$ gives $i^4 = p^4$ at $c = 0$, the independence case, and c at $c = p$ where $i = 0$. Both endpoints are attained in the table. $\partial P/\partial c = 1 - i^4 \approx 1$ for small i: **the joint probability tracks the common component one-for-one, which is H2 in derivative form.**

Boundary behaviour of the surplus law. As $N \to 1^+$, $h \to -(\delta Q + C)$: a structure inside one perimeter pays its whole bill out of stock. As $N \to \infty$, $h \to \infty$ logarithmically, **which is a defect of the model and a statement of its domain**, since Section 6.5 and Uzzi and Spiro [2005] establish that the real curve turns over. **The model's domain is small** N, and every prescription here is confined to the move from $N \approx 1$ to $N \approx 3$. As $\eta \to 0$, $h \to -(\delta Q + C)$ regardless of N: no conversion, no benefit from any amount of independence. As $\delta \to 0$ the stock never erodes and any positive $\eta \ln N - C$ accumulates without bound, **which is a pathology rather than an ideal.** As $\delta \to 1$ the stock is annihilated each period and no structure has meaning. Under the maintenance model $C = c_0 + c_1 N$, h is concave with a unique interior maximum at $N^* = \eta/c_1$ and falls without bound thereafter — **the model does bound itself once maintenance is written in, which is the correct answer to the unbounded limit above.**

Boundary behaviour of the disclosure economics. As $L \to 0$, $p^* \to \infty$ and concealment is always cheaper — the limit in which examination costs nothing, which is the assumption the failing structures of Section 7.4 are implicitly making. As $L \to \infty$, $p^* \to 0$ and concealment is never cheaper. As the cost gap closes to zero, $p^* \to 0$ likewise. **The result is therefore driven entirely by the ratio of the cost gap to the loss, and no other feature of the model does any work.**

11.4 Invariance

The effective count is invariant under relabelling of units and under any rescaling of the underlying exposures that preserves the share vector. Doubling every exposure in currency terms leaves every s_i unchanged and therefore leaves the index, N and $\ln N$ unchanged. This is a genuine scale invariance and it is why the instrument applies to a structure of any size.

It is not invariant under regrouping, and that is the whole content of the collapse: the naive and perimeter figures differ by construction and the difference is the finding. A reader who wants a single number invariant under regrouping is asking for a quantity that cannot detect a perimeter.

What would break the scale invariance: any share basis that is not normalised. **Tested at how many scales?** The invariance is algebraic, not empirical, and was checked at exactly the two structures reported here. **No claim of empirical scale-freedom is made**, and no distributional or scaling claim is made anywhere in this paper. Clauset et al. [2009] is the reason that matters: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison leaves few canonical power-law claims standing, and **a straight line on a log-log plot is not evidence.** That procedure was not run because no claim requiring it is made; Stumpf and Porter [2012] adds that even a genuine power law would be weak evidence for a mechanism. **The exposure vectors here are finite sets of four and six shares, not samples from a distribution, and must not be restated as such.**

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. **The objection is met here and the answer is short.** The conserved quantity is the exposure share vector: $\sum_i s_i = 1$ exactly, in dimensionless units, and it is that

constraint and nothing else that gives the index its bounds. **Remove the normalisation and the effective count ceases to be a count.** The invariance group is relabelling together with any rescaling that preserves the simplex. Q**, by contrast, is a stock with no stated conservation law and no operational unit, and this paper does not claim one for it.** Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law is claimed to hold and stop claiming a universality the argument does not need. **The arrangement claimed here is a normalised exposure vector with a correlation matrix having unit diagonal and non-negative entries, and nothing outside it.**

Aggregation is a separate and unmet objection. Kirman [1992] establishes that a single representative parameter for a heterogeneous group generally does not exist. This paper writes one Q, one δ and one C for a whole structure whose parts plainly differ. **No aggregation argument is offered and none is available from the arithmetic.**

11.5 Analogy discipline

borrowing	source	category	justification
portfolio variance $\mathrm{Var}(R) = w'Rw$	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix; the premises are the algebra's own
Hill numbers, order 2	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* ${}^2D$; an identity, not a resemblance
similarity-sensitive diversity	Leinster and Cobbold [2012], Rao [1982]	**1 — derivation**, with a stated domain	exact where R has unit diagonal and non-negative entries; claimed nowhere else
$\ln N$ as entropy	Shannon [1948]	**2 — shared form**	this is **Shannon entropy in nats**, a dimensionless information quantity, and not thermodynamic entropy; no thermodynamic content is imported
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	jurisdictions have not been shown to satisfy the percolation premises; only the structural property that coupling destroys assumed independence is used

borrowing	source	category	justification
robust-yet-fragile	Albert et al. [2000], Callaway et al. [2000]	**2 — shared form**	the degree-distribution result is not claimed to apply; the shape of the tolerance asymmetry is
synchrony in ecology	Loreau and de Mazancourt [2008]	**2 — shared form**	the naming convergence is recorded; no ecological mechanism is imported
threshold and tipping	Granovetter [1978], Schelling [1971]	**2 — shared form**	the aggregation warning is used; no threshold distribution is estimated here
frozen regions in a coevolving population	Castellano et al. [2000]	**2 — shared form**	a perimeter is structurally a frozen region; no phase transition is located
normal accidents	Perrow [1984], Sagan [1993]	**3 — framing**	qualitative organisational theory, cited as prior statement of the same observation, never as a formal result
open design	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	the disclosure standard *is* the open-design requirement applied to a legal rather than a cryptographic system; the premise — that the design is public and only a key is not — is exactly what the disclosure test asserts

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration and probability arithmetic is category 1 throughout and needs no help; the network and tipping results are category 2 and are used for shape only.

11.6 Measurement-theoretic status of the scored inputs

Two inputs in this paper are scores rather than counts and their scale type is not optional.

The four-question perimeter test yields a nominal classification, not a measurement. Q1–Q4 are binary and their sum, "4/4", is a count of yes answers on a **nominal** set of attributes.

Summing nominal indicators does not produce an interval quantity, and the "score" column of Section 6.2 must be read as a tally rather than as a degree of attachment. The paper's own text is explicit that Q4 carries more weight than the others, which is a statement that the four are *not* exchangeable — **and an unweighted sum of non-exchangeable indicators is not licensed.** The tally is used only to decide a binary membership, which it can support; it is used nowhere as a magnitude.

The five disclosure criteria are binary and their combination is a product, not a mean. That is the one operation the scale type does license: a conjunction of binary indicators is a binary indicator. **The "average score" column of Section 7.3 is included precisely to demonstrate that averaging them produces a wrong verdict — the illicit operation is the object of study, not a step in the argument.** This is stated here so that no downstream work reads the 0.80 as a computed quantity.

Q, protected capital, is treated as a ratio-scale quantity and that treatment is not tested. Michell [1997] is the strongest available objection to this class of move: psychology and its neighbours routinely assume quantitative structure without testing for it. The formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all. **The conjoint conditions were not tested for Q, and the corpus's habit of writing $Q = 10$ in unnamed index units is exactly the practice Michell criticises.** What survives without the test is the *ordering* and the unit-free break-even count. **The concentration instrument itself is untouched by this objection, because exposure shares are ratios of capital and not psychological judgements.**

11.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$; the effective count is its reciprocal	DEFINITION
P3	for n equal shares of $1/n$, HHI $= n(1/n)^2 = 1/n$	ARITHMETIC
P4	a coordination perimeter is a set of jurisdictions among which an adverse decision propagates without a separate act of consent	DEFINITION
P5	the four named jurisdictions answer yes to all four questions of the perimeter test	POSTULATED (H1; the analyst's judgement, uncited)
P6	each jurisdiction's failure decomposes as a common shock c and an independent idiosyncratic shock i, with marginal probability $c + (1 - c)i$	DEFINITION (modelling choice)
P7	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P8	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)

#	statement	status
P9	the constructed cost figures: $C_{\text{comp}} = 561{,}000$, $C_{\text{conc}} = 210{,}000$, $L = 41{,}500{,}000$	POSTULATED (constructed)

11.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	HHI^{-1} returns n exactly for n equal shares	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	HHI^{-1} is the Hill number of order 2 — Hill [1973]	CITED
L4	P4, P5	the four jurisdictions constitute one perimeter, so the collapsed share vector is (1.0)	POSTULATED
L5	P1, P2, L4	bloc-HHI $= 1.000000$ and $N = 1.000000$ exactly	ARITHMETIC
R1	P2	naive HHI on the exact fractions $= 142/484 = 0.293388$; effective jurisdictions $= 3.408451$	ARITHMETIC
R1a	P2	naive HHI on the three-significant-figure percentages $= 0.293430$; effective $= 3.407968$ — the reproducible basis, agreeing with Curzi [2026]	ARITHMETIC
R1b	R1, L5	the overstatement is $3.408451/1.000000 = 3.41\times$	ARITHMETIC
R2	P6	$P(\text{all four}) = c + (1-c)i^4$; at $c = 0.02$, $i = 0.0816$ this is 0.020044 against $p^4 = 0.000100$	ARITHMETIC
R2a	R2	over 15 years, $1-(1-0.1)^{15} = 0.794109$ correlated against $1-(1-0.0001)^{15} = 0.001499$ independent	ARITHMETIC
R3	P9	the cost gap is $351{,}000$, so $p^* = 351{,}000/L = 0.008458$; at $L/2$ it is 0.016916	ARITHMETIC

step	consumes	statement	status
R4	—	five binary criteria combined multiplicatively: any zero gives a product of zero, so 0.8^{mean} and the product part company at the first failing element	ARITHMETIC
R5	P8	$(1-0.02)^{15} = 0.738569$, $(1-0.02)^{30} = 0.545484$, half-life $\ln 2/\ln(1/0.98) = 34.310$	ARITHMETIC
R6	P7, P8	$h = \eta \ln N - \delta Q - c_0 - c_1 N$ is maximised at $N^* = \eta/c_1$: 7.0, 5.0, 3.5 at $c_1 = 0.05, 0.07, 0.10$	ARITHMETIC
R7	L5, P7, P8	$h = -0.500000$ at $N = 1$; $h = -0.122417$ at $N = 2.941176$; break-even $N = e^{1.428571} = 4.172734$	ARITHMETIC
CR	R7	both structures are below break-even, so the redesign is a reduction in shortfall and not a solution	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. **Only P5, P8 and P9 are POSTULATED, and one of them — P5, the perimeter assignment — is the paper's entire empirical exposure.** All three are stated as hypotheses or as constructed inputs in Section 2. **A chain whose central step is a postulate is not a proof, and this one says so here rather than leaving the reader to notice: the arithmetic is exact and the inputs are judgements.**

11.9 Cross-checks performed

- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on the conventional structure: $0.167355 \le 0.293388 \le 0.409091$.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $3.408451 \le 5.977778$.
- The perimeter shares sum to 1.000000 exactly on both structures, and to $0.40 + 0.30 + 0.30$ exactly on the designed one.
- The three-basis reconciliation of Section 6.3 was computed independently in exact rational arithmetic and in floating point, and the two agreed to twelve decimal places on every row.
- The marginal-probability constraint $c + (1-c)i = 0.10$ was verified for each row of the common-shock table; the largest residual is 3.6×10^{-5}, arising from the four-significant-figure printing of i and not from the model.
- The rounding audit was run and the discrepancy quantified at 0.000140.

12. Limitations

The correlation is assumed, not measured. The collapse uses $\rho = 1$ within a perimeter, which is the conservative end of a family, and the justification is the observed behaviour of the coor-

dinated frameworks over fifteen years. **No correlation was estimated from data in this paper.** That is the single largest unmeasured input and it is exactly the quantity H1 turns on. Curzi [2026] publishes the continuous family so that a reader may substitute a different value.

The perimeter assignment is a stipulated reference group, not an identified effect. Manski [1993] rules out recovering an endogenous social effect from observation of a linear-in-means reflexive system, and the framework's loop is such a system. The remedy adopted is stipulation with a defence [Brock and Durlauf, 2001], and **the price is that the assignment is a modelling position.** No randomisation, instrument or partial-population variation was available.

The instrument is performative and its own parameters are exposed to that. MacKenzie and Millo [2003] documents a model that made its assumptions true after adoption; Lucas [1976] states the consequence for parameters estimated before publication; Hacking [1995] gives the general looping form. **The framework asserts that systems change when modelled and then exempts its own η, δ and correlation assumptions from that reflexivity. That is an inconsistency and it is not resolved here.**

The examination probability is not measured, and H3's conclusion depends on it. The break-even $p^* = 0.008458$ is exact. The claim that realistic examination probability exceeds it is **an assertion this paper cannot support from the bibliography**, which contains no empirical estimate of examination or enforcement rates. The claim is badged here as a postulate rather than a finding, and the honest form of H3's result is conditional: *if* annual examination probability exceeds 0.85 per cent, concealment is the more expensive design.

Every parameter in the surplus law was chosen, not estimated. $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ are stated test parameters fixed before the measurement, which protects H5's criterion from adjustment but makes the break-even a property of the chosen parameters and not of the world. **At $\eta = 0.50$ the break-even falls to $e^{1.0} = 2.718$ and the designed structure clears it. That the conclusion of H5 depends on η in this way is the most important sensitivity in the paper.**

The surplus functional's form is underdetermined by the evidence. Social impact theory proposes influence growing as a power of the number of sources with exponent below one [Latané, 1981]; an $n \log n$ form fits the qualitative facts equally well; and the framework proposes $\ln(1 + (N-1)u)$. **All three fit the qualitative facts here equally well, and nothing in this paper discriminates between them.** The strongest available warrant for the logarithm specifically is the multiplicative one [Peters and Gell-Mann, 2016], which requires no perceptual story; it is preferred here to the psychophysical justification for that reason.

Every case is constructed. The principal, the assets, the shares, the cost model, the failure probabilities, the erosion decomposition and the five scored structures are invented and are labelled as such at each point of use. **No empirical dataset was collected and none is reported.** The measurements are exact computations on constructed inputs.

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions of statutes, directives, decided cases, listing events, registers, promotion regimes, foundation regimes and individual jurisdictional characteristics are taken from the source manuscript. **The bibliography contains no jurisdiction-specific primary sources — no statutes, regulations, court rules or registries — and no case law.** Those claims are uncited here, are described rather than asserted, and require verification against the official sources. Appendix B lists them individually. **This is a real gap and it is not closed here.**

The dated events are not independently verified. The listing sequences, review dates and decision dates in Sections 4.2, 4.3 and 5.2 are reported as publicly announced and were not checked against primary releases by this paper. A reviewer should treat the propagation trace of Section 5.2 as an illustration of a mechanism whose *dates* require confirmation, even though the mechanism itself — a rating consumed as a listing criterion — is stated in the standard-setting materials themselves.

The effective count measures independence and not capacity. $N = 2.94$ says nothing about whether any perimeter can carry the load. A structure whose perimeter diversity is real but whose banking capacity sits in one perimeter has an effective count near 1.00 on the ability to

transact. Curzi [2026] owns this as its counter-result and it applies here unchanged.

Monotone claims are restricted. Section 6.5 bounds the prescription, and Uzzi and Spiro [2005], Sagan [1993] and May [1972] are the reasons a monotone raise-N claim could not survive unqualified.

The instrument is exposed to its own failure mode 9. Adopted as a target, N would cease to be a good measure [Goodhart, 1975, Campbell, 1979]. Nothing in the arithmetic prevents that, and the only defence offered is the reporting discipline of Section 3.5, which requires both figures to be published.

12.1 Rigour checks not met, listed by name

1. **No as-of date, because no real holdings were measured.** A concentration figure computed from real holdings requires its source and its date; **a concentration measure without an as-of date is not a measurement.** Every share vector here is constructed, so there is no source and no date to give. **Any application of this instrument to a real structure must carry both**, and the reporting discipline should make the date a mandatory item.
2. **No uncertainty is reported anywhere, because nothing is estimated.** That is not precision; it is the absence of empirical content.
3. **The dimension of η is supplied by this paper, not by the source.** Section 11.1.
4. **Q, C and h have no operational unit**, and the symbol C is used both for a dimensionless index flow and for a USD budget. Flagged in Section 11.1; the source does the same.
5. **The surplus law's large-N limit is unbounded**, which the empirical literature contradicts. The model's domain is small N. Writing $C = c_0 + c_1 N$ bounds it, and that is the version to prefer.
6. **The conjoint conditions were not tested for Q** [Michell, 1997, Luce and Tukey, 1964], so its ratio-scale treatment is provisional.
7. **An unlicensed operation appears in Section 7.3 on purpose**, and a second one is flagged in Section 11.6: the "4/4" tally sums nominal indicators that the text itself says are not exchangeable. It is used only to decide a binary membership.
8. **Model comparison was not performed.** No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. The instrument is asserted to be the right one on the strength of the identity chain, not on comparative fit.
9. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. **Any restatement of this paper reaching for a heavy-tail claim about holdings must run it first**, and must read Stumpf and Porter [2012] on why passing would still not identify a mechanism.
10. **The coupled-network and tipping borrowings are category 2, not category 1.** Section 11.5.
11. **There is no conservation law for Q.** Section 11.4 gives the one genuine conservation — shares sum to one — and states plainly that the stock variable has none [Mirowski, 1989].
12. **Aggregation is unaddressed** [Kirman, 1992].
13. **Expected value and time average are not the same thing** [Peters, 2019]. The disclosure-economics comparison of Section 7.2 is an ensemble average and the principal lives a time average; a single examination event does not arrive in expectation, it arrives once and rescales everything after it.
14. **No differential prediction is offered.** Durlauf [2005] asks for the prediction that only this model makes, and neither the collapse nor the disclosure economics makes one: any correlation-aware concentration measure would produce the same collapse, and any expected-loss comparison the same break-even. **The contribution is the identification of the correct unit of analysis and the discipline of reporting both figures, not a uniquely discriminating forecast.**
15. **The counter-test of Section 5.4 is not a systematic search.** Three counter-examples are

offered because the source manuscript found three. No procedure was run to enumerate the population of possible counter-examples, so the claim that the exchange trend has “no counter-examples” is a claim about what was looked for, not about what exists.

13. Conclusion

This paper establishes the following results in the form the rest of the corpus cites them.

R1. An entity map showing the United Kingdom at 40.91 per cent of exposure, the United States at 27.27, Jersey at 18.18 and Luxembourg at 13.64 gives a naive Herfindahl index of 0.293388 and 3.4085 effective jurisdictions on the exact-fraction basis, but collapses to a bloc index of 1.000000 and exactly 1.0000 effective coordination perimeters — a $3.41\times$ overstatement. **On the reproducible three-significant-figure basis used by Curzi [2026] the naive figures are** 0.293430 **and** 3.407968**; both perimeter figures are exactly** 1.000000 **and no conclusion moves.**

R2. Holding each jurisdiction’s marginal failure probability at ten per cent, a common shock of $c = 0.02$ raises $P(\text{all four fail})$ from 0.000100 to 0.020044, a $200.4\times$ understatement; over fifteen years the figures are 0.001499 independent against 0.794109 correlated.

R3. A concealment-based arrangement costing USD 210,000 a year against a compliant USD 561,000 breaks even at an annual examination probability of $p^{*} = (561{,}000 - 210{,}000)/41{,}500{,}000 = 0.008458$. **The visible 62.6 per cent saving counts the invoice, not the exposure.**

R4. The five-criterion disclosure test is scored as a product, not an average: five structures averaging 0.80 on their criteria yield a group product of zero, because two of them contain a zero-scoring element.

R5. The erosion rate decomposes as $\delta = 2.0$ per cent a year — tax drag 0.9, arbitrary-action risk 0.4, debasement 0.5, haven degradation 0.2 — retaining 73.857 per cent at fifteen years and 54.548 per cent at thirty, on a half-life of 34.310 years.

R6. With maintenance $C = c_0 + c_1 N$, the surplus $h = \eta \ln N - \delta Q - C$ is maximised at $N^{*} = \eta / c_1$: at $\eta = 0.35$ that is 7.0 for $c_1 = 0.05$, 5.0 for 0.07, and 3.5 for 0.10. The second perimeter is worth 5.19 times the eighth.

Counter-result. Passing the five-criterion disclosure test buys nothing against arbitrary state action — approximately USD 300 billion of fully disclosed reserves were immobilised in 2022 — and even the redesigned structure remains at $h = -0.122417$, still below the maintenance floor. **H5 was tested and not met: the redesign reaches** $N = 2.941176$ **against a break-even of** 4.172734**. The diversification gain is a reduction in shortfall, not a solution, and what would close the gap is operating — η to** 0.463474 **or** C **to** 0.177583 **— rather than structural.**

Two further results are established as method rather than as measurement. **The correct unit of analysis for concentration risk is the coordination perimeter and not the jurisdiction**, and the procedural form of that is to collapse before measuring and to report both figures, treating the gap as the size of the illusion the structure was operating under. And **the disclosure standard is Kerckhoffs’s open-design principle applied to legal structure**: a structure whose protective quantity is an adversary’s ignorance has a quantity that is falling and cannot be replenished, while a structure whose protective quantity is its own correctness has one that is not consumed by use.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the principal, the asset mix, the exposure shares, the failure probabilities, the erosion decomposition, the maintenance budget, the concealment cost comparison and the five scored structures —

is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-051_fig01.py` through `figs/src/CCP-051_fig06.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional and legal descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general treaty, standard-setting and comparative material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction. Appendix B lists the claims affected. Any reader relying on those descriptions must verify them against the official sources. The dated listing sequences in Sections 4.2, 4.3 and 5.2 are reported as publicly announced and were not verified against primary releases by this paper.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every principal, family, entity and transaction described is invented.

Preregistration

H5's criterion — $N \geq e^{0.5/0.35} = 4.172734$ at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ — was fixed in Section 2 before the measurement in Section 6 was run, so that it could not be adjusted to fit. **The criterion was not met, and that is reported in Section 8 and again in Section 13 in the same language a success would have received.** No other hypothesis in this paper was preregistered in any external registry.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions, listing processes and structural arrangements for the purpose of measuring concentration and resilience. No recommendation is made in respect of any particular person, asset, structure or jurisdiction. Statutory reach-back periods, reserved-share regimes, substance requirements, corporate-residence tests, foreign-ownership restrictions, exchange-regime classifications and listing criteria all change and vary by jurisdiction and by activity; every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.

Appendix A. The reporting discipline

Any structure measured under this instrument reports the following, and nothing less.

```
1  share basis, stated in one sentence
2  exposure table, jurisdictions and shares, summing to 100.0%
3  naive HHI and effective jurisdictions, with the rounding basis named
4  perimeter assignment with the four-question answers per jurisdiction
5  bloc-HHI and effective perimeters N
6  in-perimeter exposure for the largest perimeter, as a percentage
7  ln(N), eta ln(N), and h at the stated parameters
8  the trajectory record: classification, at least two dated events,
   direction, and reversibility
9  the DATE, and the diff against the previous measurement
```

Item 3's rounding basis is not pedantry. Section 6.3 shows that the same exposure map gives three different naive indices depending on how the shares are printed, and a measurement that does not say which basis it used cannot be reproduced. **Item 9 decays first and matters most**, because perimeter fragmentation is invisible except as a difference between two measurements taken a year apart.

For the disclosure audit the record is per element, not per structure: the element, its assigned job, each of the five criteria with the **evidence** rather than the conclusion, the product, and — for any element scoring zero — whether it was remediated or removed. **An element that cannot be brought to five of five is removed at the design stage. It is not documented better; it is taken out.**

Appendix B. Claims requiring verification against primary sources

The following rest on legal or regulatory detail that changes, and **none is cited to the bibliography, which contains no primary sources for any individual jurisdiction.** They are reproduced from the source manuscript and require confirmation with counsel in the relevant jurisdiction before any reliance.

1. The banking-secrecy statute of Section 4.1: its enactment date, its current text, the intergovernmental arrangements that overrode it, the number of accounts disclosed and the legal basis for that disclosure, and the dates of the criminal pleas and the sector disclosure programme.
2. The unilateral withholding regime of Sections 4.1 and 5.1: enactment date, the statute it formed part of, the withholding rate, the commencement date, and the model of intergovernmental agreement applicable in each relevant jurisdiction.
3. All listing and increased-monitoring events tabulated in Sections 4.2, 4.3 and 5.2, with their exact plenary and Council dates, the rating language used, and the criteria engaged. **These are the dates on which the propagation trace of Section 5.2 depends.**
4. The four-question perimeter answers for each named jurisdiction, and the bloc taxonomy of Section 5.5. These are analytical judgements applied to published characteristics; the underlying participation, membership and dependence facts should be confirmed jurisdiction by jurisdiction.
5. The asset-protection statute of Section 4.4 — its enactment and amendment history and its current section numbering — together with the two appellate decisions described, their reporter citations, their holdings, the lower-court decisions in the same matters, and the custody periods. **Case citation follows different conventions and no case is in the bibliography.** The bankruptcy look-back provision of the postscript requires the same confirmation.

6. Economic-substance regimes and their thresholds; the global minimum effective rate and its scope, thresholds and implementing law in each relevant jurisdiction; and corporate-residence and central-management-and-control tests.
7. The beneficial-ownership register regimes of Section 4.5, the supranational decision of November 2022 curtailing public access, the domestic constitutional challenge of Section 5.4 and the current scope of the statute it concerned. **That last item is actively litigated and any description is a description of its date.**
8. Foreign-ownership restrictions and the criminal treatment of nominee shareholding in the non-aligned operating jurisdiction of Structures C and D, including the section number, the current penalties and current enforcement practice; and the investment-promotion conditions conferring the ownership position, which are activity-specific and change.
9. The tax jurisprudence on captive arrangements without risk distribution referred to in Structure E, including reporter citations and holdings, and the current regulatory treatment of such arrangements as reportable transactions.
10. The sovereign investment institution of Section 7.6: its governing statute and date, the mandate instrument and issuing ministry, the date of first capital transfer, the exact scope and timing of the published holdings list, voting record and pre-announced voting intentions, and the instrument establishing its ethics body. Also the sector disclosure standard of 2008 — its title, date, sponsoring body and current membership — and the current major-shareholding notification thresholds in any market relied on, including their application to cash-settled derivative positions.
11. Correspondent-banking decline statistics, which are reported figures requiring confirmation against the current published data, and the tokenised-settlement regulatory regimes referred to in failure mode 6.
12. All cost figures in Section 7.2 are constructed illustrations. They are not fee quotations and no real fee schedule was used to produce them.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 52

The Concentration Instrument: Bloc Collapse and the Effective Count of Jurisdictions

Abstract. An apparently diversified holding structure can be a single point of failure, and we give the instrument that detects it. Taking HHI as the sum of squared exposure shares and the effective count as its reciprocal, we measure a conventional four-jurisdiction structure — UK 40.9 per cent, US 27.3, Jersey 18.2, Luxembourg 13.6 — at a naive HHI of 0.293430, or 3.41 effective jurisdictions. Collapsing the same shares onto coordination blocs before squaring gives a bloc index of 1.000000 and an effective count of exactly 1.00. The redesigned structure across six jurisdictions reaches a naive HHI of 0.189002 (5.29 effective jurisdictions) and a bloc index of 0.340000 (2.94 effective blocs), with Western-perimeter exposure falling from 100.0 to 30.0 per cent. We show that the naive and bloc indices are one variance under two correlation assumptions, so that the general form $\mathrm{EFF} = 1/(w'Rw)$ is the similarity-sensitive diversity of order two, and that HHI^{-1} is exactly a Hill number of order two while the corpus's affine effective count $1 + (N-1)u$ is not and carries no external support. Coupling the count to the storage law $h = \eta \ln N - \delta Q - C$, the conventional structure earns a surplus term of exactly zero and $h = -0.500000$, while the designed structure earns 0.377583 and $h = -0.122417$, a 75.5 per cent reduction in shortfall — but the break-even count is $N = e^{0.5/0.35} = 4.17$, which the redesign does not reach, so that hypothesis is tested and not met. Robustness is stated both ways: a mis-assigned bloc moves N by 0.0169, under six-tenths of one per cent, while sustaining the conventional structure's naive reading would require believing the four Western jurisdictions correlate at only 6.6 per cent. The accompanying threat register prices expected annual loss at 9.25 per cent of protected capital and 5.97 per cent permanently.

Keywords: Herfindahl–Hirschman Index; effective number; bloc collapse; correlated exposure; single point of failure; threat register; concentration measurement

Series: D. Structure and Resilience **Paper:** CCP-052

1. Introduction

A holding structure distributed across four jurisdictions may nevertheless have one point of failure. This paper gives the instrument that decides which of the two descriptions is true,

states the conditions under which the instrument is exact, and reports what it measures on a conventional cross-border structure and on a redesigned alternative.

The question is not *how many jurisdictions is a structure in*, which is a count that any adviser can inflate by incorporating another company, but *how many independent points of failure does a structure have*, which is a measurement and cannot be inflated by adding entities. The distinction matters because the two answers can differ by a factor of three and because only the second one enters the surplus law that governs whether protected capital grows or erodes.

The instrument is not new. It is the Herfindahl–Hirschman Index, introduced by Hirschman [1945] as the square root of the sum of squared shares to describe the concentration of a country's foreign trade, arrived at independently in sum-of-squares form by Herfindahl [1950] in a dissertation on the steel industry, and later the subject of a priority dispute between them. Its definition fits on one line:

```
HHI = sum of squared shares            effective count = 1 / HHI
```

What this paper contributes is threefold.

First, the correction. The naive index overstates resilience because it treats units as independent when they share a coordination mechanism. The index is silent about correlation. Applied to market shares that silence is usually harmless, since rival firms mostly do fail independently. Applied to jurisdictional exposure it is fatal, because jurisdictions inside one coordination perimeter fail *together* — that is what a perimeter is — and an index that counts them separately is counting one failure four times. The correction is not novel as physics: it is the observation, stated for portfolios in 1952, that diversification benefit depends on covariance and not on count [Markowitz, 1952], and stated for coupled infrastructures in 2010, that a system of interdependent networks is far more fragile than either network alone [Buldyrev et al., 2010]. **Both borrowings are labelled at first use under the analogy discipline of Section 11.5.** The portfolio-variance result is used as a *derivation*: the exposure vector genuinely is a weighted sum of shocks with a correlation matrix, which is the premise Markowitz's algebra requires, and no further financial content is imported. The coupled-network result is used as a *shared structural form*: jurisdictions inside one enforcement perimeter have not been shown to satisfy the percolation premises of Buldyrev et al. [2010], and this paper claims only that the two systems share the property that coupling destroys the independence a naive count assumes. Perrow [1984] reached the organisational form of the same observation first — interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component — and is cited as **qualitative theory and framing, not as a formal result**. This paper's signature finding — that adding a fifth jurisdiction inside one perimeter can leave resilience unchanged or make it worse — is Perrow's result in a new measurement frame, and the paper says so rather than presenting it as new.

Second, the identification. The paper establishes that the naive index and the bloc-collapsed index are not two indices but one variance under two correlation assumptions, that the general form is $\mathrm{EFF} = 1/(w'Rw)$ for exposure weights w and a correlation matrix R, and that this general form is exactly the similarity-sensitive diversity of order two in the sense of Leinster and Cobbold [2012], whose additive cousin is Rao's quadratic entropy [Rao, 1982]. Where $R = I$ it collapses to HHI^{-1}, which is the Hill number of order two [Hill, 1973, Jost, 2006].

Third, the arithmetic and its verdict. The instrument is run on a conventional four-jurisdiction structure and on a redesigned six-jurisdiction one, coupled to the surplus law, and the verdict is reported in full including the part that does not flatter the redesign: the redesigned structure reaches an effective bloc count of 2.941176 against a break-even count of 4.172734, so its surplus balance remains negative at -0.122417. That is a hypothesis tested and not met, and Section 7 reports it in the same language it would have used had the criterion been cleared.

The paper presupposes the surplus functional and the affine effective count of Curzi [2026] — the functional $f(u) = \ln(1+(N-1)u)$, uniquely characterised by angle-only dependence, van-

ishing at parallel, an affine effective count and normalisation — and the roster-audit form of that count in Curzi [2026c], where a hundred-person department at $u = 0.05$ has an effective count of 5.95. It presupposes the reflexive loop $T(x) = W(x, M(x))$ of Curzi [2026], whose fixed point is the self-fulfilling prophecy, because the bloc assignment is itself a forecast that conditions the behaviour it forecasts. **That loop carries an identification problem this paper must state where it uses it rather than in a footnote.** Manski [1993] proves that a linear-in-means reflexive specification — a group's mean behaviour influencing its members while the members constitute the mean — is **not identified from observational data**: the endogenous social effect cannot be separated from contextual effects or from correlated unobservables, however much data is collected. **No amount of observation of jurisdictional behaviour could therefore confirm a bloc assignment that was derived reflexively.** The remedy adopted here is the fourth of the four known ones: **the reference group is stipulated and the stipulation is defended** — the bloc membership is fixed in advance by the perimeter test of Section 4.3, recorded with its evidence class, and stress-tested in Section 7.5 — which is the route Brock and Durlauf [2001] shows can be made rigorous. **The price is that the bloc assignment is a modelling position and not an identified empirical result, and this paper says so wherever the assignment enters.** It derives from the entity-map measurement of Curzi [2026], which reports naive HHI 0.293388 and 3.4085 effective jurisdictions against bloc-HHI 1.000000 and 1.0000 effective perimeters, a $3.41\times$ overstatement. **Section 12 records that the present paper's naive figure, 0.293430, and CCP-051's, 0.293388, differ in the fifth decimal, and states which is which.**

2. Hypotheses

Five hypotheses are stated. Each is falsifiable in the sense required by Platt [1964]'s strong inference; where a statement is not falsifiable it is labelled a definition or a modelling choice and is not counted as a hypothesis. Two of the five are reported in Section 7 as **not met**. Meehl [1967] is the relevant warning: directional predictions are cheap, and the defensible response is to make point predictions with constants attached, which is what H2 and H4 do.

H1 — the perimeter hypothesis. Several jurisdictions inside one enforcement perimeter behave as a single jurisdiction under a correlated shock. *Predicted:* the effective count $N = 1/(w'Rw)$ collapses toward 1 as the within-bloc correlation ρ rises toward 1, regardless of how large the naive count is; for the conventional structure specifically, N falls from 3.4080 at $\rho = 0$ to exactly 1.0000 at $\rho = 1$. *Falsified by:* an observed effective count that tracks the naive count under a correlated shock — equivalently, direct evidence that within-perimeter jurisdictions act independently — or by any structure in which subdividing inside a perimeter raises N.

H2 — the sufficiency hypothesis. Jurisdictional redesign alone can lift a structure to a non-negative surplus balance. *Criterion, fixed in advance:* with the surplus law $h = \eta \ln N - \delta Q - C$ at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$, the balance is non-negative only if $\ln N \geq 0.5000/0.35 = 1.428571$, that is $N \geq e^{1.428571} = 4.172734$. *Falsified by:* a redesigned structure whose effective bloc count falls short of 4.172734 while C, δ and Q are held at the stated values.

H3 — the robustness hypothesis. The concentration measurement is insensitive to error in the assignment of a single member to a bloc, and sensitive to the bloc *structure* itself. *Predicted:* reassigning one contested jurisdiction moves N by less than one per cent, while merging two blocs moves it by more than twenty per cent. *Falsified by:* a single-member reassignment that moves N materially, which would make the published figure an artefact of a judgement call rather than a measurement.

H4 — the implied-correlation hypothesis. Reporting the naive index on a single-perimeter structure is equivalent to asserting a specific and implausibly low within-perimeter correlation, and that correlation can be computed rather than argued. *Predicted:* solving naive$+\rho(1-$naive$) =$ bloc for the two structures gives $\rho = (0.340000 - 0.293430)/(1 - 0.293430) = 0.065910$. *Falsified by:* evidence that the coordinated actions of the jurisdictions in question are in fact close to independent, which would make $\rho \approx 0.066$ a defensible rather than an untenable premise.

H5 — the specialisation hypothesis. Assigning each entity a single function lowers the maintenance term C relative to an entity carrying several functions. *Predicted:* three specialised entities cost less to maintain than one entity meeting every requirement simultaneously. *Falsified by:* a cost decomposition in which the overloaded entity is cheaper.

Not hypotheses, and labelled as such. Three further statements appear in this paper and none of them is falsifiable as stated; each is named here for what it is.

- *The logarithmic form of the input side*, $\eta \ln N$ rather than ηN, is a **modelling choice** carried from Curzi [2026], defended in Section 4.6 on the ground that increments shrink in proportion to what is already held. It is not tested here.
- *The identification of N with the effective bloc count* rather than with any other count is a **definition**. Its content is entirely in the bloc assignment rule, which is testable, and not in the identification.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice**, stated in advance so that H2's criterion is fixed before the measurement rather than after it, which is the preregistration discipline of Nosek et al. [2018] applied to an engineering measurement.

3. Method: the instrument, and which effective count it is

3.1 The numbers-equivalent property

Everything rests on one elementary property. If k units each hold share $1/k$:

```
HHI = k x (1/k)^2 = 1/k        1/HHI = k
```

so the reciprocal of the index returns the count when the units are equal, and when they are unequal it returns the count of *equal-sized* units that would produce the same index. That is the numbers-equivalent reading. **The source manuscript attributes this reading to an unnamed authority; the attribution is to Adelman [1969], and this paper names him.** The property itself is elementary and can be verified in two lines, which the Verification section does.

equal shares	share each	HHI (fraction)	HHI (points)	effective count
1	100.00%	1.000000	10,000.0	1
2	50.00%	0.500000	5,000.0	2
3	33.33%	0.333333	3,333.3	3
4	25.00%	0.250000	2,500.0	4
5	20.00%	0.200000	2,000.0	5
6	16.67%	0.166667	1,666.7	6
8	12.50%	0.125000	1,250.0	8

Two conventions are in use. Competition practice states HHI in points using percentage shares, so a perfectly concentrated market is 10,000 [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. The resilience application here states it as a fraction, so a perfectly concentrated structure is 1.0000. They are the same number divided by 10,000, and both are given wherever confusion is possible.

Three properties follow immediately and all three do work later.

First, HHI is a share-weighted average share. $\sum s_i^2 = \sum s_i \cdot s_i$, which is the mean share *experienced by a unit of exposure* rather than the mean share across units. Squaring is therefore not arbitrary: it weights each jurisdiction by how much exposure sits in it, which is the weighting a risk question requires.

Second, the largest share sets a floor under the index and a ceiling on the effective count. Since HHI $\geq s_{\max}^2$, the effective count is at most $s_{\max}^{-2}$:

```
conventional, largest UK 40.9%   HHI >= 0.167281   effective <=  5.9780
designed, largest UAE 29.1%      HHI >= 0.084681   effective <= 11.8090
designed blocs, largest 40.0%    HHI >= 0.160000   effective <=  6.2500
conventional blocs, WEST 100.0%  HHI >= 1.000000   effective <=  1.0000
```

The last row is the whole argument in one line. When one bloc holds everything, the ceiling on the effective count is one, and no activity below the bloc level can raise it.

Third, $s_{\max}^2 \le \text{HHI} \le s_{\max}$**.** The upper bound is attained when the largest unit holds everything. Both bounds are checkable in a line and both are useful sanity tests on a measurement done by hand.

No distributional or scaling claim is made anywhere in this paper, and that is stated rather than assumed because the material invites one. A share vector of 40.9 / 27.3 / 18.2 / 13.6 descends steeply and looks like the beginning of a heavy-tail argument, and the concentration literature is full of such arguments. **This paper fits no distribution, characterises no tail, and asserts no power law.** Clauset et al. [2009] is the reason: applied to twenty-four canonical data sets, a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few of them standing, and **a straight line on a log-log plot is not evidence.** That procedure was not run here, because no claim requiring it is made. Stumpf and Porter [2012] adds the reason running it would not be enough on its own: even a genuine power law is weak evidence for a mechanism, because many mechanisms produce the same tail. **The effective count used here is a statistic of a finite exposure vector with four or six entries, not an estimate of a distribution, and it must not be restated as one.**

3.2 Which effective count — the Hill correspondence, stated exactly

The corpus runs two quantities under the name *effective count*, and they are not the same quantity. This section states which is which, because a reviewer who reaches for the diversity literature will find that it covers one of them exactly and the other not at all.

The reciprocal index is a Hill number of order two. Hill [1973] defined the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types that would give the observed value of the underlying index. At $q = 2$ this is $(\sum p_i^2)^{-1}$, which is HHI^{-1} exactly. Jost [2006] is the statement that entropies are not diversities and that their numbers-equivalents are. The same arithmetic was reached independently in ecology by Simpson [1949] in the same decade as Herfindahl's dissertation, and again in political science by Laakso and Taagepera [1979] as the effective number of parties. **Independent reinvention in three disciplines is the strongest available argument that the instrument is general and not a borrowing.** The exponential of Shannon entropy [Shannon, 1948] is the same family at $q = 1$; the reciprocal index is also the exponential of the Rényi entropy of order two [Rényi, 1961], which is where the participation-ratio name comes from.

The affine count is not a Hill number and has no external support. The corpus's other effective count, $N_{\text{eff}} = 1 + (N - 1)u$, used in Curzi [2026], Curzi [2026c] and Curzi [2026o] — the last of these badging the affine form as design axiom S3 rather than as a theorem — is a **linear interpolation between** 1 **and** N. It is not a Hill number of any order, it is not a numbers-equivalent, and no literature in ecology, economics, political science or information theory contains it. The arithmetic that separates the two is given in the Verification section and can be redone in a line: for two units holding 0.9 and 0.1, every Hill number reports less than 1.39, while the affine count at $u = 1$ reports exactly 2.00.

The collapse result has a formal ancestry that should be named rather than reinvented. A small correlated shift producing a discontinuous collective outcome is the threshold and tipping mechanism: Granovetter [1978] establishes that the distribution of individual thresholds, not the mean, determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate segregation — **the strongest available warning against reading an individual-level parameter straight into an aggregate, which is precisely what a bloc assignment does.** Castellano et al.

[2000] supplies the closest formal analogue of a bloc: the same interaction that raises local agreement freezes global diversity into non-interacting regions, with a sharp transition between the monocultural and fragmented phases. **A bloc, in that vocabulary, is a frozen region, and the effective count is a count of them.** And on the generating side, Bouchaud and Mézard [2000] derives concentration rather than observing it: multiplicative growth plus exchange produces a heavy tail, and above a critical ratio a finite fraction of the total condenses onto one holder — **which is the index going to one, obtained from a mechanism.** This paper does not use that model and asserts no tail; the citation records that a mechanism-side companion to the arithmetic exists.

This paper therefore uses HHI^{-1} throughout and cites the Hill literature only for that quantity. Where the affine count is referred to, it is referred to by name and marked as the corpus's own construction. The two are related — both are called effective counts, both return N in the fully-independent limit — and they are not interchangeable, and the corpus has in places let them travel under one name.

The general form, and its exact literature. The bloc collapse of Section 3.3 generalises HHI^{-1} to

$$\mathrm{EFF} = \frac{1}{w' R w}$$

for exposure weights w and correlation matrix R. This is *not* the affine count; it is the similarity-sensitive diversity of order two of Leinster and Cobbold [2012], whose order-two member is $1/(p'Zp)$ for a similarity matrix Z, and whose additive relative is the quadratic entropy of Rao [1982]. Setting $R = I$ recovers HHI^{-1}; setting R to the block matrix of ones recovers the bloc index. **The correspondence is exact where R has unit diagonal and non-negative entries, which is the regime this paper works in; it lapses where correlations are negative, and this paper claims nothing there.** Cluster 02's own sceptic should be read alongside: Hurlbert [1971] argues that "diversity" has been used for so many distinct quantities that the word carries no content without its formula attached, which is precisely the discipline this section is imposing.

Small-sample estimation is a live exposure and is not addressed by the corpus. Chao et al. [2014] show that diversity estimators of low order are biased on small samples; a six-jurisdiction exposure vector is a small sample, and Section 12 records this as an unclosed gap.

3.3 The bloc collapse as a variance identity

Grouping data until the answer improves is a recognised way to lie, so the grouping needs a foundation that is not assertion. It has one, and it is exact.

Model the exposure as a portfolio, following Markowitz [1952]. Let w_i be the share of protected capital exposed to jurisdiction i, and let X_i be a unit-variance shock to that jurisdiction — a designation, a freeze, an exchange control, a de-risking event. The aggregate shock is $R = \sum_i w_i X_i$ and its variance is

$$\mathrm{Var}(R) = \sum_i \sum_j w_i w_j \rho_{ij}.$$

Two extreme correlation assumptions bracket everything.

If every jurisdiction is independent — $\rho_{ij} = 0$ for $i \neq j$, $\rho_{ii} = 1$ — the double sum collapses to $\sum_i w_i^2$, which **is the naive HHI, exactly**. Verified by explicit double sum on the designed structure's six shares: 0.189002, matching the naive index to twelve decimal places.

If jurisdictions inside a bloc are perfectly correlated and blocs are independent — $\rho_{ij} = 1$ when i and j share a bloc and 0 otherwise — the double sum collapses to $\sum_b W_b^2$ where W_b is the bloc's total share. That **is the bloc-HHI, exactly**. Verified the same way on the same six shares: 0.340000, matching to twelve decimal places.

> **The naive HHI and the bloc-HHI are not two different indices. They are the same variance under two different correlation assumptions, and $\mathrm{Var}(R)^{-1}$ is the effective number of independent shocks the structure is exposed to.** Choosing between them is not a modelling preference; it is a claim about the world, and it should be argued rather than assumed.

The two are therefore endpoints of a continuous family. With within-bloc correlation ρ and independence across blocs,

$$\mathrm{Var}(R) = \text{naive} + \rho\,(\text{bloc} - \text{naive}).$$

That the intermediate cases matter is not a theoretical nicety. Measured correlations rise under stress: Longin and Solnik [2001] find extreme correlation in equity markets that is asymmetric and concentrated in downturns. **The effective count falls exactly when it is needed**, which is a stronger statement than anything the static index says. The ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008], and the ecological demonstration that effective count buys stability is Schindler et al. [2010]'s Bristol Bay sockeye record, where population diversity produces roughly half the variability and about a tenth of the fishery closures.

The contrary literature must be read alongside and is not decorative. Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone, with no mechanism, which means a portfolio-arithmetic result is not by itself evidence of a mechanism. May [1972] showed that increasing diversity and connectance *destabilises* randomly assembled systems. This paper's claim is narrower than the general diversity–stability claim and is not exposed to those results in the same way: it asserts only that the reciprocal of a variance is an effective count of independent shocks, which is arithmetic, and that jurisdictions in one perimeter are correlated, which is H1.

3.4 Defining a bloc without circularity

The variance derivation is only as good as the bloc assignment, so the assignment needs a rule that someone who disagrees with the analyst can apply and still reach a reproducible answer. The rule is the perimeter test of Section 5.3: two jurisdictions are in the same bloc when a single decision taken in one reliably produces the corresponding effect in the other without a further independent decision. Evidence is ranked:

weight	evidence class
strongest	demonstrated near-simultaneous mirroring of designations or listings
strongest	shared correspondent networks that exit corridors together
strongest	a supervisory standard producing the same domestic consequence in every member
strongest	binding accession to a common enforcement instrument
weaker	participation in an information-exchange framework
weaker	treaty density
weakest	diplomatic alignment, voting patterns, press characterisation

The instruments that create genuine coordination are documented and citable. Recognition and enforcement of awards across states runs through United Nations [1958], whose

near-universal adherence is what makes a cross-border enforcement perimeter real rather than rhetorical. Automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations that supervisors implement in common [Financial Action Task Force, 2012], and the substance and treaty-abuse work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] are the mechanisms by which nominally separate jurisdictions adopt the same domestic consequence. de Goede [2011] documents the listing machinery itself as a technique of governance, which is the mechanism the perimeter test is trying to detect. Recognition is emphatically *not* general everywhere, and Hague Conference on Private International Law [1989] is worth citing precisely **because it never entered into force**, which is why forced heirship remains a conflict-of-laws problem rather than a solved one; the succession regulation [European Union, 2012] supplies habitual residence plus *professio juris* for the states bound by it.

Assignments for the designed structure, with the reasoning compressed:

jurisdiction	bloc	reasoning
UAE	BRIDGE	dual-rail access; non-participation in the Western designation apparatus; own listing decisions
Singapore	BRIDGE	same test, different geography
Thailand	NONALIGNED	no accession to the coordinated enforcement instruments; domestic-priority policy
India	NONALIGNED	same
UK	WEST	core member of the mechanism
Bermuda	W-lite	overseas territory; conservatively folded into WEST

Two of these are contestable. The response is not to argue but to run the arithmetic both ways, which Section 7.5 does.

3.5 The measurement procedure

Six steps, in order, with every input written down, because next year's measurement is only meaningful as a difference against this year's.

Step 1 — Fix the share basis. The shares must be shares *of something*, and the something must match the threat. For arbitrary state action the correct basis is the fraction of protected capital whose *availability* depends on a decision taken inside that jurisdiction's perimeter. Not book value; not tax residence; not where the certificate is. A UK company holding a Bermudian portfolio managed from Singapore contributes to the UK share to the extent that a UK decision can stop the portfolio from being instructed. Common alternative bases — revenue by source, net asset value by situs, headcount, tax paid — are legitimate for other questions and wrong for this one. Pick one, state it, and never mix two inside one measurement.

Step 2 — Enumerate exposures and normalise to 100%. Exposures must be exhaustive and mutually exclusive. If an asset is exposed to two perimeters, split it and record how. If that cannot be said, assign it wholly to the more capable perimeter, which is the conservative choice.

Step 3 — Compute naive HHI and the effective jurisdiction count. Square, sum, invert.

Step 4 — Assign blocs using the perimeter test, and record the reasoning per jurisdiction. This is the only judgemental step and it must be written down or the measurement is not reproducible.

Step 5 — Compute bloc-HHI and N. Sum shares within blocs first, then square, then sum, then invert. Order matters and reversing it silently reproduces the naive number.

Step 6 — Report the pair, never one alone. A single figure invites the reader to assume the convenient correlation. Report naive, bloc, and the gap; if the gap is large, state what would have to be true for the naive figure to be the right one.

3.6 Why a logarithm, and why not a count

The identification of N with the effective bloc count is new to this paper; the functional form is carried from Curzi [2026]. Restating the argument in this context is worthwhile because a great deal follows from it.

Suppose the input side of the surplus law were linear in N — ηN rather than $\eta \ln N$. Then two independent blocs would be worth exactly twice one and the optimal structure would hold as many blocs as the budget allows. The first genuinely independent store removes an entire failure mode; the second removes the residual probability that the first is wrong; the third removes the residual of the residual. Each addition addresses a smaller remaining exposure, and the natural functional form for a quantity whose increments shrink in proportion to what is already held is the logarithm.

There is a second reading which is more useful operationally. $\ln N$ is, up to a constant, the entropy of a uniform distribution over N outcomes [Shannon, 1948]. What the surplus term measures is how much *uncertainty about which perimeter matters* the structure has purchased. A structure inside one perimeter has zero entropy: an adversary knows exactly which decision reaches everything. A structure across three roughly equal perimeters has $\ln 3 = 1.0986$ of it. **The quantity being maximised is not the number of places a structure is in; it is the number of independent decisions that would have to go against it simultaneously.**

That reading also explains why the measure is indifferent to entity count. Adding a fifth Western entity adds no uncertainty about which decision matters, because the answer is still the Western one. The entropy is unchanged, the surplus term is unchanged, and the fee is not. This is a specific instance of a general organisational result: adding units inside a coordination boundary adds communication cost at order $n(n-1)/2$ [Brooks, 1975] and adds nothing to independence.

The functional form is not tested here and is labelled a modelling choice in Section 2. Its fixed-point behaviour under the storage law is a first-order linear difference equation and is standard [Elaydi, 2005]; Curzi [2026] states the contraction result exactly, with modulus $1-\delta$, a unique start-independent fixed point, and a maximum residual of 2.0624×10^{-15} over a hundred passes, and Curzi [2026] gives the fixed-point identity $h_\infty = \eta(\ln N - F(u^*))$ in which δ, C and Q cancel.

3.7 The four axes

Jurisdiction is the axis this paper measures and it is one of four. The instrument is identical on each; only the share basis changes.

Settlement rail. The exposure is the fraction of settlement volume depending on a given messaging or clearing system. One fact ruins naive measurements: a clearing system and a messaging system are different layers, and a structure reporting two rails may have one messaging dependency. Measured correctly, “one messaging network at 100%” and “85% on that network plus 15% on a second clearing system whose messaging leg runs over the first” are the same number, and only the second looks diversified.

Counterparty. The exposure is the fraction of protected capital held as a claim on, or custodied by, a given institution. This is the axis on which jurisdictional diversification most reliably backfires, because the population of institutions willing to bank a genuine cross-bloc structure is small. A structure at $N = 2.94$ on jurisdiction and at an effective counterparty count of 1.6 has not reduced its total risk; it has moved it. Curzi [2026] makes the same measurement on a different share basis and reaches the same shape: Delaware 40.0 / South Dakota 25.0 / Nevada 20.0 / Wyoming 15.0 gives naive HHI 0.285000 and 3.508772 effective jurisdictions, but bloc-HHI 1.000000, $N = 1.00$ and a surplus term of exactly zero.

Currency. The exposure is the fraction of the balance sheet denominated in a given unit. Currency exposure interacts with the jurisdiction axis rather than being independent of it: a currency's clearing runs through banks that sit inside a perimeter, so a balance sheet wholly in one currency carries that perimeter's exposure however the entities are arranged.

A structure is only as diversified as its most concentrated axis, and the axis most often measured is the one the analyst was already comfortable with. The reporting discipline is to run all four and print all four.

4. The threat model that fixes the share basis

An index without a stated threat is an index without a share basis. This section establishes the classification that fixes it. Five failure processes are distinguished; they are not variations on a theme, they have different actors, triggers, time constants and reversibility profiles, and **a structure that answers one of them well may answer another worse than doing nothing at all**.

#	threat	actor
1	arbitrary state action	executive or administrative organ, or a regulated intermediary acting in its shadow
2	lawful process	a private claimant, tax authority, insolvency officeholder, or regulator acting judicially
3	commercial / counterparty	nobody; no one intends the loss
4	succession	mortality
5	bloc fragmentation	history

The corpus's storage argument establishes that a storage problem is only well posed once the specific degradation process is named. A grain store designed against weevils is not a grain store designed against damp, and a store built against damp when the threat was weevils is worse than an open crib, because it cost money, consumed attention, and produced confidence proportional to its expense rather than to its fit. **Capital is stored under the same rule, and failing to name the degradation process is the most expensive error in the field.**

Arbitrary state action is this paper's subject, and that is a choice which excludes things. It excludes lawful process in particular, because the two threats have opposite structural signatures. Against arbitrary action the useful property of a structure is that it sits outside a coordination perimeter, so that a decision taken inside that perimeter does not reach it. Against lawful process that property is close to worthless and frequently harmful, because the enforcement mechanism does not travel to the asset — it travels to the person, and the person is inside the perimeter. A statute refusing to recognise foreign judgments can perform exactly as advertised while the principals are compelled anyway, because the court does not need

the statute's cooperation; it needs theirs. The grounds on which enforcement is in fact refused, and the failure modes of the most-relied-upon instrument, are a settled subject in the arbitration literature and are listed in Appendix B as requiring primary-source verification.

4.1 The five processes

Threat 1 — arbitrary state action. *Trigger:* a designation, a listing, an exchange-control measure, a nationalisation, a licence revocation, a change of risk appetite in a compliance department. None of these requires a court. *Mechanism of loss:* the asset does not move and title is often untouched; what is removed is the ability to instruct, and since the practical content of ownership is the ability to instruct, the distinction is academic to the owner. The 2022 immobilisation of approximately USD 300bn of central bank reserves is the reference event, and its instructive feature is that nothing was seized in the older sense — the reserves remained booked where they were and the instructions stopped being executed. *Warning window:* days at best, hours in practice, and often the first notice is the failed instruction. Structures cannot be built inside this window, which is the single most important operational fact about this threat. *Reversibility:* low, and slow where it exists. *What resists it:* the asset, the entity and the settlement rail sitting outside the coordination perimeter that produced the decision — not outside *a* jurisdiction but outside the *mechanism*. *What does not resist it, and is routinely sold as though it does:* secrecy, nominee ownership, layered holding chains within a single perimeter, and any structure whose defence is that the authority will not find out. **A designation regime does not need to find the owner; it needs to find the owner's bank, and the bank is not hiding.**

There is a second-order form that does more cumulative damage than the headline form: de-risking. A correspondent bank facing a compliance cost it cannot price exits a corridor. Nobody is designated, no measure is announced, and an entire class of legitimate counterparty finds the rail closed. This is arbitrary in the precise sense that matters — action without process, notice or appeal — even though no state formally took it. The answer is the same as for the headline form: redundancy across mechanisms that do not share a decision-maker.

Threat 2 — lawful process. *Trigger:* a claim filed, a judgment entered, an assessment raised, a petition presented. *Mechanism of loss:* an order, and behind the order the state's willingness to compel a person. Where the court has territorial reach it may attach the asset; where it does not, it attaches the person — freezing injunctions, disclosure orders, repatriation orders, and ultimately contempt. *Warning window:* long; months to years. *Reversibility:* partial, and frequently the most recoverable of the five. *What resists it:* having built earlier. The governing law is fraudulent-transfer law and fraudulent-transfer law is a clock. **Threat 2 is a timing problem wearing a jurisdiction costume, and the jurisdiction is not the part that matters.** The statutory reach-back periods and the authorities are set out in Appendix B; **they are described from the source manuscript and are not cited to the bibliography, which contains no primary statutory or case material** (Section 13).

Threat 3 — commercial and counterparty. *Trigger:* ordinary business risk, usually correlated with a cycle. *Mechanism of loss:* becoming an unsecured creditor of an entity that cannot pay, or a secured creditor whose collateral turns out to be someone else's. *Warning window:* weeks to months, and asymmetric — the people who see it first are inside. *Reversibility:* highest of the five. *What resists it:* segregation, priority and risk transfer. Asset partitioning is the irreducible function of entity law [Hansmann and Kraakman, 2000], and that is what a bankruptcy-remote vehicle actually does; Pistor [2019] is both the best scholarly account of how legal coding creates capital and the sharpest critique of it. *What does not resist it:* jurisdiction. A creditor in one financial centre and a creditor in another get the same haircut from the same failed obligor, which is exactly why a structure optimised only for threat 1 can be quietly terrible here.

Threat 4 — succession. *Trigger:* death or incapacity; also divorce, disqualification, or cognitive decline that nobody wants to name. *Mechanism of loss:* fragmentation. Assets that functioned as a system are divided into fractions that do not; control that was unified becomes

contested; and where heirs are resident in different legal families the same estate is characterised differently by each and the characterisations do not reconcile. *Warning window:* zero — the defining feature, and under-weighted everywhere. **Threat 4 is the only threat in the register whose warning window is exactly nil and whose probability over a long enough horizon is exactly one.** *Reversibility:* low. *What resists it:* an entity with separate legal personality owning the assets, so that the succession event changes the entity's governance rather than the assets' ownership. The comparative literature on the trust and the foundation as alternative devices for exactly this problem is comparative and is described in Appendix B. A sketch of the arithmetic, to fix scale: on a constructed estate where one heir sits in a forced-heirship jurisdiction whose rules reach 25% of the assets, and where a three-child reserve of three-quarters applies to that portion, the reserved pool is $0.25 \times 0.75 = 0.1875$ of the estate. **18.75% of the estate has a destination the founder cannot direct, and that figure is arithmetic, not advocacy.** The absence of a succession convention in force [Hague Conference on Private International Law, 1989] is the structural reason the problem persists.

Threat 5 — bloc fragmentation. *Trigger:* realignment. A neutral jurisdiction picks a side; a bridge centre is absorbed into one of the things it was bridging; a coordination mechanism expands its membership. Less dramatically: a jurisdiction signs an information-exchange agreement, adopts a substance regime, or accedes to a listing framework, and quietly becomes a member of a perimeter it was outside. *Mechanism of loss:* the effective bloc count falls. Nothing visible happens to any entity and the structure looks identical on the org chart; what changed is the correlation between its parts, and correlation is not on the org chart. *Warning window:* long — years — but only for someone watching. *Reversibility:* essentially nil at the bloc level. *What resists it:* designed redundancy, exit optionality written into the documents rather than improvised later, and monitoring. The arithmetic is stark, using the designed structure's blocs of 40 / 30 / 30:

```
designed, three blocs 40/30/30          N = 2.9412    h = -0.1224
BRIDGE absorbed into WEST (70/30)       N = 1.7241    h = -0.3093
everything absorbed into one perimeter  N = 1.0000    h = -0.5000
```

One realignment event costs 1.22 effective blocs and 0.19 of surplus, and no entity has to do anything wrong for it to happen. The mirror case is worth noting: if the BRIDGE bloc were to split — if the two bridge jurisdictions ceased to correlate — N rises from 2.9412 to 3.6158. Threat 5 runs both ways and only one direction is planned for.

4.2 Three pairs that are routinely conflated

Threats 1 and 5 look alike because both are geopolitical. They are not alike operationally. Threat 1 is an event: a decision is taken and something stops working on a Wednesday. Threat 5 is a drift: nothing stops working, and the correlation between holdings rises over years until a structure that used to be three things is one thing. A structure built only against threat 1 tends to be static — correct on the day it was built and never revisited — and static is exactly the property threat 5 punishes. Conversely, a portfolio of options and exit rights with no actual holdings outside the perimeter is nimble against a drift and useless against a Wednesday. The organisational literature on learning gives the same shape: fast convergence on a single mode destroys the variance that produced the advantage [March, 1991].

Threats 2 and 3 look alike because both end in a courtroom. The difference is who wants what. In threat 2 a claimant wants the assets and is using the court to reach them; the defensive question is *reach*. In threat 3 an insolvency officeholder is distributing a deficient pool and the defensive question is *priority*. Ring-fencing improves priority and does nothing for reach; timing improves reach and does nothing for priority. A structure sold as asset protection without specifying which of the two it improves is unspecified.

Threats 3 and 1 look alike when the counterparty is a bank. When a bank declines to process an instruction, the owner experiences the same thing — an instruction that does not

execute — whether the cause is insolvency, risk appetite, or a state measure. The remedies differ completely. The useful diagnostic is whether other customers of the same bank in the same corridor are also affected, and whether customers of other banks in the same corridor are affected. Same bank only: threat 3. Same corridor across banks: threat 1.

4.3 The perimeter test, stated operationally

Threat 1 turns entirely on the identity of the deciding perimeter, so the test has to be operational rather than atmospheric. Two jurisdictions are inside the same perimeter when a single decision taken in one of them reliably produces the corresponding effect in the other **without a further independent decision**. That is a strong condition and it is deliberately stronger than alliance or cooperation.

Membership of an information-exchange framework is evidence, not proof: exchanging account data [Organisation for Economic Co-operation and Development, 2017] is a long way short of executing another state's freeze. What converts evidence into proof is a demonstrated pattern of automatic or near-automatic transmission — a listing framework whose designations are mirrored within days [de Goede, 2011], a correspondent network whose members exit a corridor together, a supervisory standard producing the same domestic consequence in every member [Financial Action Task Force, 2012]. The requirement is only that the analyst make the call and record it, because the bloc assignment is an input to the instrument and an undocumented input is not a measurement.

Where the call is genuinely uncertain the discipline is to run the arithmetic both ways and see whether the answer changes. Section 7.5 does exactly that, and the robustness result there is more interesting than the point estimate.

The governance literature supplies an independent name for what is being counted. Ostrom [2010] develops polycentricity — multiple centres of decision-making that are formally independent of one another — as an empirically derived property of durable governance systems. **Polycentricity is the effective count of jurisdictions in governance language**, arrived at from field data rather than from an index, and the convergence is worth stating.

4.4 The threat register

A threat register is a table with one row per threat and six fields per row, populated with numbers the analyst is willing to defend, reviewed on a fixed cadence, and used to allocate budget — **because a register that does not change any decision is a document rather than an instrument**. The fields are: p, the annual probability of the threat materialising; L, the loss as a fraction of protected capital Q given that it materialises; r, the fraction of L eventually recovered; W, the warning window in days from first credible signal to loss; and B, the build time in days for the structure that answers it.

Every number in the register below is CONSTRUCTED and illustrative. It is not an estimate of any real position and the parameters should not be imported. The value is in the discipline of writing numbers down.

threat	p	L	r	W (d)	B (d)
1 arbitrary state action	0.020	0.60	0.05	2	210
2 lawful process	0.080	0.35	0.40	540	210
3 commercial / counterparty	0.120	0.20	0.55	90	210
4 succession	0.030	0.45	0.30	0	210

threat	p	L	r	W (d)	B (d)
5 bloc fragmentation	0.050	0.30	0.25	365	210

First pass: expected loss. Expected annual loss is pL, summed:

```
1 arbitrary state action    0.020 x 0.60 = 0.0120
2 lawful process            0.080 x 0.35 = 0.0280
3 commercial/counterparty   0.120 x 0.20 = 0.0240
4 succession                0.030 x 0.45 = 0.0135
5 bloc fragmentation        0.050 x 0.30 = 0.0150
------------------------------------------------
TOTAL                                    0.0925   = 9.25% of Q per year
```

Treating the five as independent, the probability that none materialises in a given year is the product of $(1 - p)$:

```
P(no threat in one year)     = 0.731125    (73.11%)
P(at least one)              = 0.268875    (26.89%)
over  5 years, at least one  = 0.791090    (79.11%)
over 10 years, at least one  = 0.956357    (95.64%)
over 20 years, at least one  = 0.998095    (99.81%)
over 30 years, at least one  = 0.999917    (99.99%)
```

Over a generation, at these parameters, something in the register happens with probability 0.9999. The question a structure answers is never whether something will happen; it is which something, and whether the structure bends or breaks when it does.

Second pass: the recoverability correction. Permanent expected loss is $pL(1 - r)$:

threat	EL	permanent EL	share of permanent
1 arbitrary state action	0.0120	0.0114	19.10%
2 lawful process	0.0280	0.0168	28.14%
3 commercial / counterparty	0.0240	0.0108	18.09%
4 succession	0.0135	0.0095	15.83%
5 bloc fragmentation	0.0150	0.0112	18.84%
total	**0.0925**	**0.0597**	

Threat 1 is 12.97% of expected loss but 19.10% of *permanent* expected loss. That is a real correction and it is not large enough to carry the argument alone. The argument is carried by the conditional numbers:

```
conditional PERMANENT loss, given the event occurs
1 arbitrary state action    57.00% of Q     -> Q multiplier 0.4300
2 lawful process            21.00%          -> 0.7900
3 commercial/counterparty    9.00%          -> 0.9100
4 succession                31.50%          -> 0.6850
5 bloc fragmentation        22.50%          -> 0.7750
```

A single threat-1 event at these parameters takes protected capital from 10.00 to 4.30, after which ordinary erosion continues from the new base:

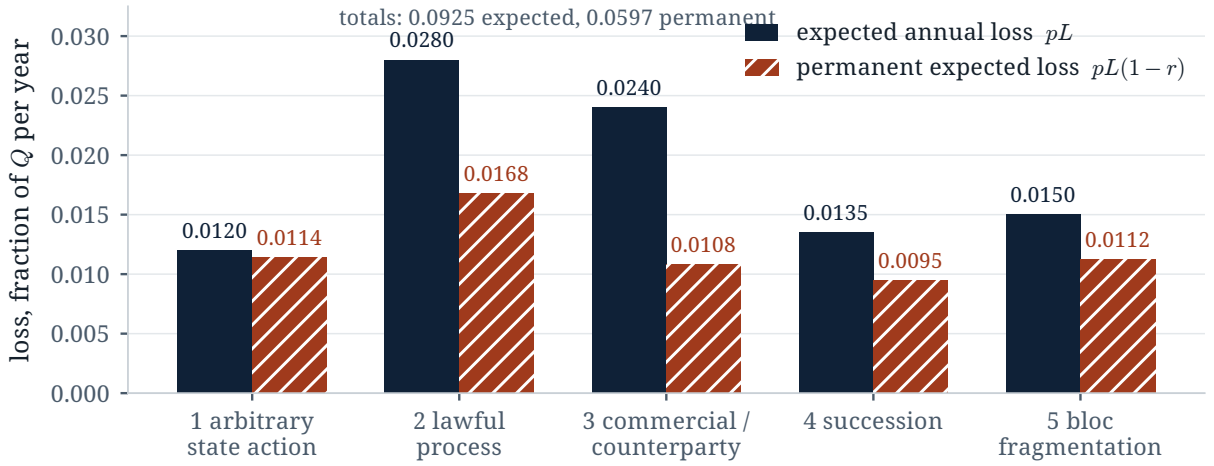

Figure 52.1: **The register's ranking changes when losses are weighted by what does not come back: threat 1 is 12.97% of expected annual loss but 19.10% of permanent expected loss.** Modelled from the CONSTRUCTED register parameters above; script `figs/src/CCP-052_fig05.py`.

```
t = 0    Q = 4.3000   (unhit 10.0000)
t = 10   Q = 3.5134   (unhit  8.1707)
t = 20   Q = 2.8707   (unhit  6.6761)
t = 30   Q = 2.3456   (unhit  5.4548)
```

Erosion is multiplicative, so a single large permanent loss is not a one-off deduction — it rescales every subsequent year. This is the formal reason a low-probability, low-reversibility threat justifies disproportionate structural attention, and it is why the register's expected-value column is the wrong place to stop.

The general form of that argument is not this paper's and should be credited. Peters [2019] and Peters and Gell-Mann [2016] establish that the time average of a multiplicative process differs from its ensemble average, so that an expectation computed across many holders does not describe what happens to any one holder over time — which is exactly the divergence between the expected-loss column and the conditional permanent-loss column above. **The register's expected value is an ensemble average and the principal lives a time average.** The same literature supplies an independent warrant for the logarithm in the surplus law: the growth rate of a multiplicative process is logarithmic in the stock, with no psychological assumption required. **Section 3.6 justifies the logarithm on the diminishing-returns argument the framework already makes; this is the stronger warrant, and where the two disagree the multiplicative one should be preferred because it does not depend on a perceptual story being true.**

Third pass: misallocation. Suppose a fixed structural budget reduces the loss from exactly one threat by 75%. Which?

```
unmitigated expected annual loss              0.0925

budget aimed at arbitrary state action    EL = 0.0835    reduction   9.73%
budget aimed at lawful process            EL = 0.0715    reduction  22.70%
budget aimed at commercial/counterparty   EL = 0.0745    reduction  19.46%
budget aimed at succession                EL = 0.0824    reduction  10.95%
budget aimed at bloc fragmentation        EL = 0.0813    reduction  12.16%

spread evenly across all five at 15% each EL = 0.0786    reduction  15.00%
```

On this rule the best single target is threat 2 and the worst is threat 1 — the subject of

this paper. **That is stated plainly rather than hidden: on naive expected value, the threat this paper addresses is the least attractive of the five to spend money on.** It becomes the right target only when weighted by permanence, by the multiplicative effect on all future years, and by the window. A reader who does not accept those three corrections should not accept the priorities that follow from them.

Fourth pass: the window, which is decisive. Take a constructed build time of 210 days to stand up a cross-bloc structure end to end.

threat	W (d)	B (d)	verdict	slack
1 arbitrary state action	2	210	too late	-208
2 lawful process	540	210	in time	$+330$
3 commercial / counterparty	90	210	too late	-120
4 succession	0	210	too late	-210
5 bloc fragmentation	365	210	in time	$+155$

Three of five cannot be answered after the signal. Threat 1's coverage ratio is $2/210 = 0.0095$: **under one per cent of the time that would be needed.** Threat 4's is exactly zero. The two that appear answerable in time are not straightforwardly so. Threat 2's 330 days of apparent slack is illusory, because building inside the window is precisely what fraudulent-transfer law exists to reach. Threat 5's 155 days is real but requires that somebody was watching the trajectory for the preceding two years, which is an organisational property rather than a structural one.

> **The only window common to all five threats is *before*.** Structures are built in peacetime or they are not built. Every design result in this paper assumes a builder not currently under threat, because a builder under threat has fewer options than the analysis describes.

4.5 Assignment, and the disclosure test applied to the register

threat	resists it	does not
1 arbitrary state action	bloc diversity; rail redundancy; neutral-law entities; real substance	secrecy; layering in-bloc; better contracts
2 lawful process	time; pre-claim solvency; disclosed, defensible transfers	non-recognition statutes alone; distance
3 commercial / counterparty	segregation and bankruptcy-remote vehicles; risk transfer; counterparty diversity; netting and collateral	jurisdiction; bloc diversity
4 succession	separate legal personality; a foundation-type holding layer; law-family selection	wills alone; heir goodwill
5 bloc fragmentation	designed redundancy; exit optionality; trajectory monitoring	a single bridge; static structures

Read the right-hand column as carefully as the left; the right-hand column is where the money goes.

Each row must be audited against the disclosure test: would the element still do its job if every part of it were disclosed to every authority with jurisdiction over any part of it? Rows 3, 4 and 5 pass without argument. Row 1 passes by construction, because the mechanism is that lawful entities in non-coordinating jurisdictions are not reachable by a single decision — a fact disclosure does not change. **Disclosure does not repair a broken perimeter, which is the point: the defence is structural, not informational.** This is the open-design principle of Kerckhoffs [1883], whose engineering content is that a system's security must not depend on the secrecy of its design, restated in Saltzer and Schroeder [1975] as *open design*; Curzi [2026] carries the constraint in full, establishing that channel separation is strengthened rather than weakened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place. Row 2 is where the test bites: a response to lawful process that depends on a claimant not knowing where the assets are is outside this paper's scope and is treated as a failure mode rather than a technique.

5. Results: the conventional structure

CONSTRUCTED CASE. The principal is a dual national, tax resident in one Gulf jurisdiction, with three heirs resident in three different jurisdictions, one of them under a forced-heirship regime. Assets: manufacturing operations in Thailand; a trading company in the UAE; an IP portfolio; commercial real estate in London; a listed-securities portfolio. Revenue arrives in five currencies. All facts are invented.

The share basis is stated first, as Step 1 requires: *the fraction of protected capital whose availability depends on a decision taken inside a given jurisdiction's coordination perimeter*. Two consequences follow and both are stated in advance so that a reader may disagree with the inputs rather than with the method. The London real estate contributes its full value to the UK exposure, because it cannot be relocated and UK measures reach it directly. The listed portfolio contributes to the perimeter of its *custodian*, not to the perimeters of the issuers — a portfolio of Asian equities held through a Western custodian is Western exposure for this purpose, and this is the single input most often assigned wrongly.

jurisdiction	share	share^2	bloc	contents
UK	40.9%	0.167281	WEST	holdco and London property
US	27.3%	0.074529	WEST	listed portfolio via US custodian
Jersey	18.2%	0.033124	WEST	IP holding
Luxembourg	13.6%	0.018496	WEST	treaty vehicle
total	**100.0%**			

```
naive HHI = 0.167281 + 0.074529 + 0.033124 + 0.018496 = 0.293430
effective jurisdictions = 1 / 0.293430 = 3.407968  ->  3.41

bloc collapse:  WEST = 40.9 + 27.3 + 18.2 + 13.6 = 100.0%
bloc-HHI  = 1.000000^2 = 1.000000
EFFECTIVE BLOCS N = 1 / 1.000000 = 1.000000  ->  1.00

Western-perimeter exposure = 100.0%
ln(N) = 0    eta ln(N) = 0    h = -0.500000
```

In competition units the naive figure is 2,934.3 points and the bloc figure is 10,000.0 points. **A market with an HHI of 10,000 is a monopoly; the conventional structure is, in resilience terms, a monopoly held by one coordination perimeter over the entire estate.**

The adviser's file described this structure as diversified across four jurisdictions, two legal families and three regulators. Every word of that is true, and the measurement says the structure has one point of failure. Note what the measurement does *not* say. It does not say the four entities were badly chosen or badly run. The Jersey IP structure was well built; the Luxembourg vehicle was doing real treaty work. **The finding is not about quality; it is about correlation, and correlation is not visible from inside any one entity.**

The zero. The surplus law reads $h = \eta \ln N - \delta Q - C$ where N is the effective bloc count. For the conventional structure $N = 1.00$ and $\ln(1.00) = 0$ exactly. **The conventional structure has zero available surplus — not low, zero.** The entire input side is multiplied by the logarithm of the effective bloc count, and whatever η is, $\eta \times 0 = 0$. Protected capital then decays at δ with nothing on the input side to oppose it: at $\delta = 0.02$ that is 18.29% gone in ten years, 33.24% in twenty, 45.45% in thirty, on a half-life of 34.31 years.

And no rearrangement of those four entities changes it, because rearranging within a bloc does not change N.

conventional variant	naive HHI	naive eff	bloc-HHI	N	$\ln N$
as found, UK / US / JE / LU	0.293430	3.41	1.000000	1.00	0
perfectly equalised, four ways	0.250000	4.00	1.000000	1.00	0
split into six equal Western	0.166667	6.00	1.000000	1.00	0
split into ten equal Western	0.100000	10.00	1.000000	1.00	0
split into fifty equal Western	0.020000	50.00	1.000000	1.00	0

Fifty entities, a naive effective count of fifty, $N = 1.00$, $\ln N = 0$. **Subdivision inside a perimeter is the most expensive way to change nothing that this field has invented**, and it is the empirical content of H1's second falsification clause: no subdivision inside a perimeter raises N, and none did.

6. Results: the designed structure

jurisdiction	share	share^2	bloc	contents
UAE	29.1%	0.084681	BRIDGE	holdco, foundation, trading company
Thailand	18.2%	0.033124	NONALIGNED	promoted manufacturing operating company
UK	16.4%	0.026896	WEST	UK company and residual London exposure
Bermuda	13.6%	0.018496	W-lite $\rightarrow$ WEST	captive, reserves against real liabilities

jurisdiction	share	share^2	bloc	contents
India	11.8%	0.013924	NONALIGNED	international financial centre vehicle
Singapore	10.9%	0.011881	BRIDGE	treasury and dual-rail settlement
total	**100.0%**			

```
naive HHI = 0.189002
effective jurisdictions = 1 / 0.189002 = 5.290949  ->  5.29

bloc collapse:
    BRIDGE      = 29.1 + 10.9 = 40.0%      0.160000
    NONALIGNED  = 18.2 + 11.8 = 30.0%      0.090000
    WEST        = 16.4 + 13.6 = 30.0%      0.090000
bloc-HHI = 0.340000
EFFECTIVE BLOCS N = 1 / 0.340000 = 2.941176  ->  2.94

Western-perimeter exposure = 30.0%
ln(N) = 1.078810   eta ln(N) = 0.377583   h = -0.122417
```

6.1 The comparison, in the units that matter

metric	conventional	designed	change
entities	4	6	$+2$
jurisdictions	4	6	$+2$
naive HHI	0.293430	0.189002	-35.6%
effective jurisdictions	3.41	5.29	$\times 1.5525$
bloc-HHI	1.000000	0.340000	-66.0%
effective blocs N	**1.00**	**2.94**	$\times 2.9412$
Western-perimeter exposure	100.0%	30.0%	-70.0 pts
$\ln N$	0.000000	1.078810	
$\eta \ln N$ at $\eta = 0.35$	0.000000	0.377583	

The architecture's entire contribution to the surplus law is 0.3776, purchased by going from one effective bloc to 2.94, and it is bought with two additional entities rather than twenty.

6.2 What each move buys

move	N after	ΔN
start: conventional	1.0000	—
add foundation as the holding layer	1.0000	0.0000
add Gulf holdco, UAE share to 29.1%	≈ 1.7000	$+0.7000$

move	N after	ΔN
add Thai operating company, 18.2%	≈ 2.3000	$+0.6000$
add Indian centre vehicle, 11.8%	≈ 2.6000	$+0.3000$
add Singapore treasury, 10.9%	2.9412	$+0.3412$
UK reduced 40.9% $\to$ 16.4%, Bermuda 13.6%	2.9412	—
final	**2.9412**	

The intermediate values are approximate because the path depends on the order of execution; the endpoints are exact. Two entries deserve comment.

The foundation adds nothing to N and is still the most important element in the architecture. It is a succession instrument, and it is the holding layer that makes everything else administrable. **A structure element that does not move the concentration measurement is not thereby worthless; it is answering a different threat.**

The first non-Western jurisdiction is worth more than the last three combined. Moving the Gulf share to 29.1% buys roughly 0.70 of effective blocs; the Singapore addition buys 0.34. This is $dh/dN = \eta/N$ in practice, and it has a governance implication: if the programme runs over three years and might be interrupted, execute the highest-marginal-value move first, because a half-finished diversification in the right order is worth far more than a half-finished one in the wrong order. Curzi [2026] prices the marginal contribution of one corridor exactly: removing the Indian corridor gives bloc-HHI 0.391448, $N = 2.5546$ and $h = -0.136733$, so 11.8% of exposure buys 0.014316 of surplus, which is 3.79% of the total gain.

7. Results: hypotheses tested

7.1 H1 — the perimeter hypothesis: supported

The continuous family $\mathrm{Var}(R) = \text{naive} + \rho(\text{bloc} - \text{naive})$, run on both structures:

Designed structure:

ρ	$\mathrm{Var}(R)$	N
0.00	0.189002	5.2909
0.10	0.204102	4.8995
0.25	0.226751	4.4101
0.40	0.249401	4.0096
0.50	0.264501	3.7807
0.60	0.279601	3.5765
0.75	0.302251	3.3085
0.90	0.324900	3.0779
1.00	0.340000	2.9412

Conventional structure, carried through to the surplus balance:

ρ	$\mathrm{Var}(R)$	N	$\eta \ln N$	h
0.00	0.293430	3.4080	0.4291	-0.0709

ρ	$\mathrm{Var}(R)$	N	$\eta \ln N$	h
0.25	0.470073	2.1273	0.2642	-0.2358
0.50	0.646715	1.5463	0.1525	-0.3475
0.75	0.823357	1.2145	0.0680	-0.4320
0.90	0.929343	1.0760	0.0256	-0.4744
1.00	1.000000	1.0000	0.0000	-0.5000

The conventional structure's effective count falls from 3.4080 to exactly 1.0000 as ρ rises to one, and the naive count never enters. **H1's prediction holds as an identity in the model and is not falsified by any variant tested.** What the arithmetic cannot do is establish that the real within-perimeter correlation is near one; that is an empirical claim, it rests on the observed behaviour of coordinated listing, substance and exchange frameworks over fifteen years, and Section 12 records it as the paper's largest unmeasured input.

This paper uses $\rho = 1$ within a bloc. That is the conservative end. A reader who regards it as too strong can read an answer off the table, which is why the family is published rather than the endpoint.

7.2 H2 — the sufficiency hypothesis: not met

At the parameters fixed in Section 2:

```
maintenance floor:  delta Q + C = 0.02 x 10 + 0.30 = 0.5000

conventional:  h = 0.35 x ln(1.000000) - 0.5000
                 = 0.35 x 0.000000     - 0.5000  =  -0.500000
designed:      h = 0.35 x ln(2.941176) - 0.5000
                 = 0.35 x 1.078810     - 0.5000  =  -0.122417

h = 0 requires  eta ln N = delta Q + C
                ln N = 0.5000 / 0.35 = 1.428571
                   N = e^1.428571 = 4.172734
```

The criterion was $N \geq 4.172734$. The redesigned structure reaches $N = 2.941176$. H2 is not met. The designed structure improves h by 0.377583, a 75.5% reduction in the shortfall, and remains at -0.122417. Both structures are below the build threshold. **Jurisdictional diversity buys the ability to build; it does not buy the building.**

The honest conclusion is therefore not that more diversification is required. It is that the maintenance side must come down or the conversion side must come up. The other two levers, computed at $N = 2.941176$:

```
C required for h = 0    :  0.377583 - 0.200000 = 0.177583   (against actual 0.30)
eta required for h = 0  :  0.500000 / 1.078810 = 0.463474   (against actual 0.35)
Q at which h = 0, C=0.30:  (0.377583 - 0.300000) / 0.02 = 3.879169
```

That last line is the uncomfortable one: at $C = 0.30$ the designed structure carries protected capital only up to 3.88 units before erosion outruns the surplus. **Structure cost is close to fixed and erosion is proportional, so there is a minimum viable size below which no amount of jurisdictional cleverness helps, and a maximum above which the same structure needs rebuilding.**

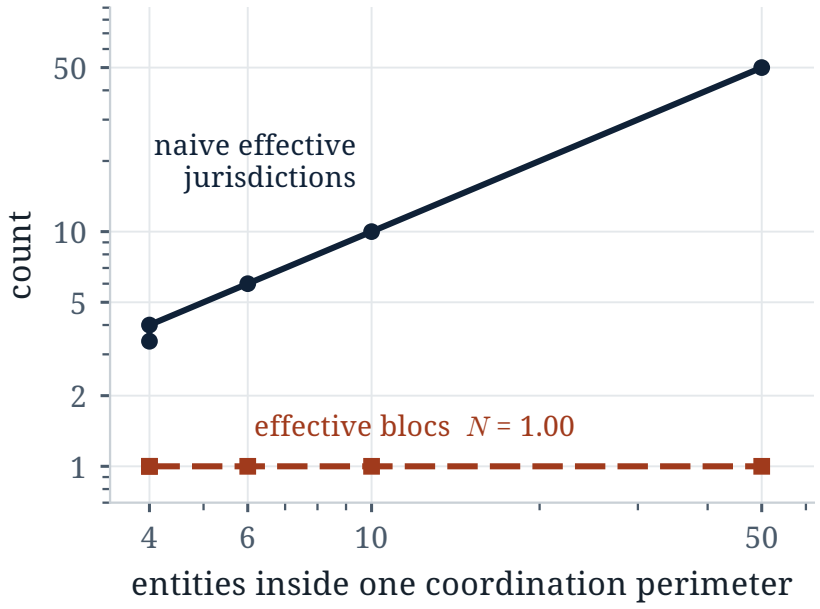

Figure 52.2: **Subdivision inside one perimeter moves the naive effective count from 3.41 to 50.00 and leaves the effective bloc count at exactly 1.00 in every row, so the surplus term stays at zero.** Measured from the share vectors in the table above; script `figs/src/CCP-052_fig02.py`.

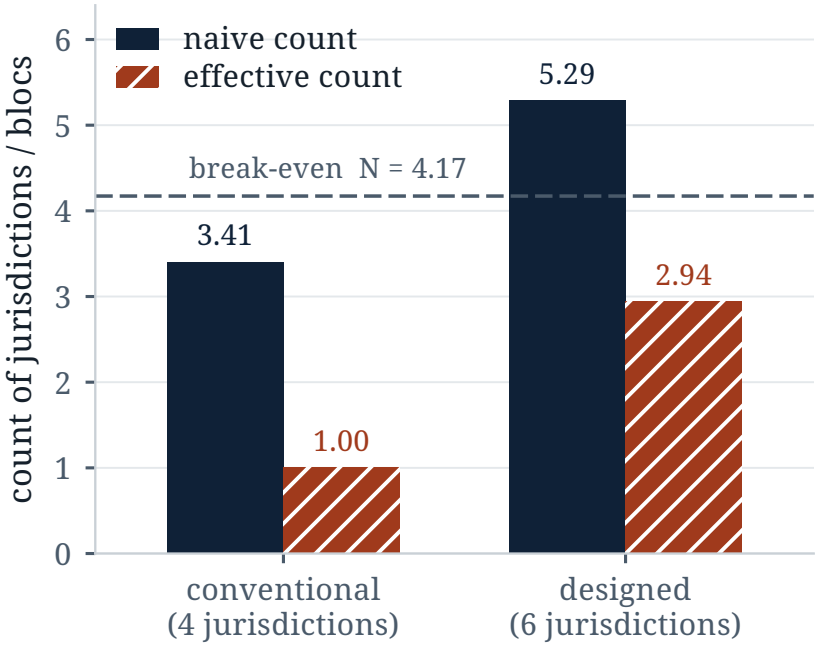

Figure 52.3: **The naive count and the effective count on one pair of axes: the conventional structure reads 3.41 naively and 1.00 in effect, the designed structure 5.29 and 2.94, and neither effective count clears the break-even of 4.17 that a non-negative surplus balance requires.** Measured from the share vectors in Sections 5 and 6; break-even derived at the stated parameters. Script `figs/src/CCP-052_fig01.py`.

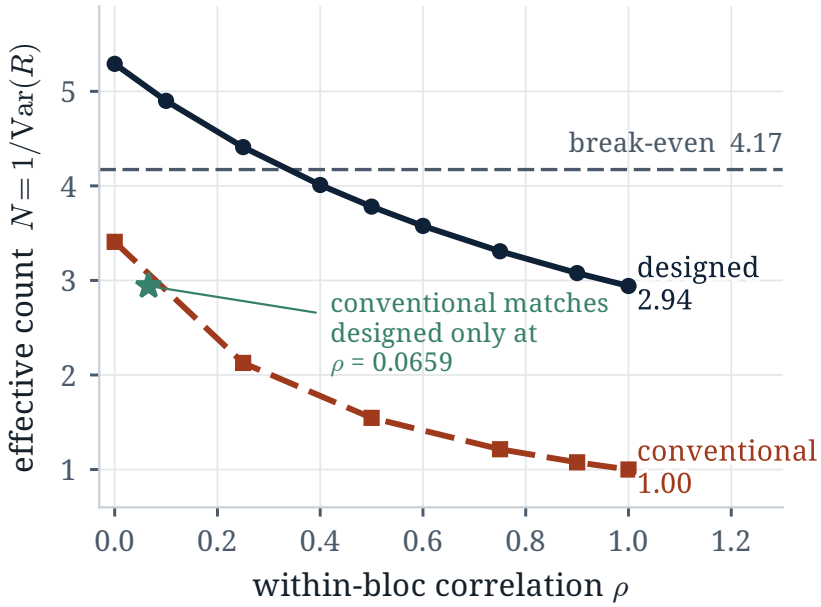

Figure 52.4: **The effective count against within-bloc correlation.** The conventional structure falls from 3.41 to exactly 1.00 as correlation rises to one, which is H1's prediction; the designed structure falls from 5.29 to 2.94 and crosses below the break-even of 4.17 at a correlation near 0.35. Modelled from the variance identity with the measured share vectors; script `figs/src/CCP-052_fig03.py`.

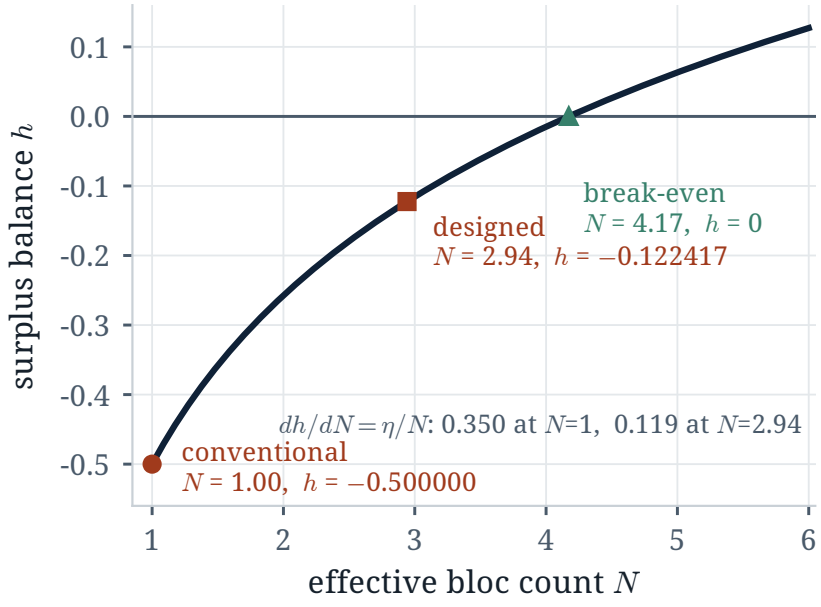

Figure 52.5: **The surplus balance against the effective bloc count at the stated parameters.** The conventional structure sits at the point of steepest available return and captures none of it; the designed structure captures 0.377583 of surplus and still lands 0.122417 short of the break-even at $N = 4.17$. Modelled from $h = \eta \ln N - \delta Q - C$ with $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$; script `figs/src/CCP-052_fig04.py`.

7.3 H4 — the implied-correlation hypothesis: supported

How weakly would the Western jurisdictions have to correlate for the conventional structure to be as resilient as the designed one? Solve naive $+ \rho(1 - \text{naive}) = 0.34$ with naive $= 0.293430$:

```
rho = (0.340000 - 0.293430) / (1 - 0.293430) = 0.065910
```

Sustaining the conventional structure's naive reading requires believing that the four Western jurisdictions correlate at 6.6% on coordinated action. The claim being made when someone reports naive HHI on a single-bloc structure is $\rho = 0$; it is not a defensible claim, it is an unexamined default in a spreadsheet, and the value 0.065910 is the price of the default stated as a number. H4's prediction is met exactly.

7.4 The marginal return

```
dh/dN = eta / N
at N = 1.0000     dh/dN = 0.350000
at N = 2.9412     dh/dN = 0.119000
at N = 4.1727     dh/dN = 0.083878
```

The first bloc added is worth roughly three times what the third is. This is the mathematical reason the conventional structure is not merely bad but *maximally* bad: it sits at the point of steepest available return and captures none of it. Moving from one effective bloc to two is the highest-return move available anywhere in the framework and also the cheapest, because it requires one correctly chosen jurisdiction rather than five. The mirror statement bounds the prescription: going from 2.94 to 4.00 buys $0.35(\ln 4 - \ln 2.941176) = 0.1074$, under a third as much, for a far harder piece of engineering, and each additional bloc carries its own C. **There is an optimum number of blocs and it is small.** The organisational literature reaches the same shape from the other direction: Uzzi and Spiro [2005] find an inverted U in which creative performance rises and then falls with cohesion, and Sagan [1993] documents that redundancy can *reduce* safety when it adds coordination surface. A monotone raise-N prescription cannot survive those results unqualified, and this paper does not make one.

7.5 H3 — the robustness hypothesis: supported

assignment variant	bloc-HHI	N
base: Bermuda folded into WEST	0.340000	2.9412
Bermuda as its own W-lite bloc	0.295392	3.3853
Singapore reclassified as WEST	0.341962	2.9243
UAE reclassified as WEST (worst case)	0.451162	2.2165
UAE and Singapore as separate blocs	0.276562	3.6158
Thailand and India as separate blocs	0.297048	3.3665
every jurisdiction independent (= naive)	0.189002	5.2909

Three readings.

The base case is conservative in two places at once. Folding Bermuda into WEST costs 0.44 effective blocs relative to treating it as its own perimeter, and treating the two bridge jurisdictions as one costs 0.67 relative to separating them. The published figure of 2.94 is the low end of a defensible range, not the high end.

The result is robust to the single most contestable call. Reclassifying Singapore as Western moves N from 2.9412 to 2.9243, a change of 0.0169 — under six-tenths of one per cent. The argument most likely to be had does not move the answer. **H3's first prediction is met.**

Only one variant does real damage. If the Gulf bridge were absorbed into the Western perimeter, N falls to 2.2165 and h to $0.35\ln(2.2165) - 0.5 = -0.221425$: a 24.6% fall in N from a single structural change, against a 0.6% move from a single-member reclassification. **H3's second prediction is met, and the asymmetry between the two is the finding.** That is threat 5 with a number attached, and it is why a degradation trajectory with evidence, rather than a verdict, belongs in every jurisdiction assessment.

7.6 The second direction: the same instrument, opposite sign

The instrument governs a second constraint running the other way, and this paper owns both halves so that no downstream work treats them as unrelated.

The 2023 merger guidelines issued jointly by the two US antitrust agencies set the structural presumption of unlawfulness at HHI above 1,800 with a change over 100, and identify a merged-firm share above 30% combined with a change over 100 as also warranting a presumption [U.S. Department of Justice and Federal Trade Commission, 2023]. Two points of discipline. The guidelines are agency enforcement policy rather than statute and courts weigh them without being bound. And the thresholds have moved: the 2010 horizontal guidelines used 1,500 and 2,500 with changes of 100 and 200 [U.S. Department of Justice and Federal Trade Commission, 2010], and the 2023 guidelines returned to 1,800 with 100 [U.S. Department of Justice and Federal Trade Commission, 2023]. **That the banding has moved while the arithmetic has not is the cleanest available demonstration that the measure is neutral and the thresholds are policy.**

The change from a merger has a closed form. If two firms with shares s_1 and s_2 combine, the post-merger index gains $(s_1 + s_2)^2 - s_1^2 - s_2^2$:

```
delta = 2 x s1 x s2        (shares in percentage points)
```

so the change exceeds 100 exactly when $s_1 s_2 > 50$; for an equal-share pair that is $s > \sqrt{50} = 7.0711\%$ each. A 5% by 5% combination produces 50 points and is comfortably clear; an 8% by 8% combination produces 128 and is not.

measurement	HHI (points)	direction wanted	verdict
jurisdictional exposure, conventional	2,934.3	low	fail
jurisdictional exposure, designed	1,890.0	low	better
bloc exposure, conventional	10,000.0	low	total fail
bloc exposure, designed	3,400.0	low	acceptable
product market, carried case	1,320.0	low enough	clear

One metric. Two directions. Both binding. The jurisdictional rows want the number small because a small number means many independent points of failure. The market row wants it small enough because a large number attracts the presumption. The arithmetic does not care which question is being asked.

On the constructed product market — rivals at 22.0, 18.0, 11.0, 8.0, 7.0, 6.0, 5.0 and 4.0 with the operating company at 14.0 and five fringe firms at 1.0 each — the market HHI is 1,320.00 points and the effective firm count is 7.5758. The acquisition arithmetic:

target	share	$\Delta = 2s_1 s_2$	post-HHI	combined	presumption
Rival H	4.0%	112.00	1,432.00	18.0%	not engaged
Rival G	5.0%	140.00	1,460.00	19.0%	not engaged
Rival D	8.0%	224.00	1,544.00	22.0%	not engaged
Rival B	18.0%	504.00	1,824.00	32.0%	**engaged**

The Rival B acquisition crosses both tests at once. **The same instrument that says the principal's jurisdictional structure is not yet diversified enough says the proposed acquisition is one the agencies would presume unlawful, and both statements come out of a sum of squared shares.** The largest target that keeps the change at or below 100 points is $100/(2\times 14) = 3.5714\%$ — which is to say, once a firm holds 14% of a market, almost any acquisition worth doing produces a change above 100. **The change test, not the level test, is what binds a mid-sized acquirer.**

The symmetry is not a pun. Both applications ask how much of a total sits in how few hands, because that question governs both fragility and market power. A firm that concentrates a market has power over it; a structure that concentrates its exposure has no power over what happens to it.

8. The cost side: three jobs, and H5

Section 7.2 left the shortfall on the cost side. This section tests the standard remedy.

There are three functions, and they are not three flavours of one function:

job	needs
HOLDING	succession law, asset segregation, perpetuity, **low substance burden**
OPERATING	**real substance**, labour, cheap presence, market access
BRIDGING	**dual-bloc banking**, dual-rail settlement, neutral law

Most failed structures come from asking one entity to do all three, and the three requirement sets are antagonistic in specific, nameable ways.

Holding versus operating: the substance contradiction. Holding needs a low substance burden — the entity should own things, be cheap to maintain, be simple to inherit, and create as little nexus as possible. Operating needs real substance: employees, premises, decision-makers on the ground, functions genuinely performed where they are said to be performed. **These are the same requirement with opposite signs, and no entity satisfies both.** Substance requirements exist for good reasons and the base-erosion work on substantial activities in low-tax jurisdictions [Organisation for Economic Co-operation and Development, 2015] is the reason they exist; the correct response to a substance regime is to put substance where the activity genuinely is, which is the whole thesis of this section.

Operating versus bridging: the alignment contradiction. An operating entity is embedded in a state: a factory that cannot move, a workforce with local rights, licences from a local ministry, a tax residence. It is therefore reachable by that state and visibly aligned with it. A bridge works because both sides believe it will not be turned against them. **A structure cannot bridge from a position of alignment, and an operating entity is aligned by construction.**

Holding versus bridging: the exposure contradiction. A bridging entity is in constant contact with counterparties, screening systems, correspondent banks and settlement risk; its exposure profile is an exposure-*window* profile parameterised by hop size, duration and mid-

transit failure handling. A holding entity's exposure profile is a custody profile. Merging them puts the store of value in the entity with the highest transactional exposure in the group. **A rail is not a holding**, and value in transit and value at rest are different problems.

8.1 The overload diagnostic

Apply the concentration instrument to each entity's own function vector $j = (H, O, B)$, where the shares are of the *entity's* activity and not of the group's:

```
S = H^2 + O^2 + B^2                specialisation index
effective jobs = 1 / S
```

$S = 1.00$ is a pure specialist returning 1.00 effective jobs; an entity split evenly across all three returns 3.00. The bands used are: below 1.50 SPECIALIST, 1.50 to 2.20 STRAINED, above 2.20 OVERLOADED.

> **A pure two-job entity attains its maximum effective-job count at a 50/50 split, where $S = 0.50$ and the count is exactly 2.00. There is no two-job configuration above 2.00. Any entity measuring above 2.00 therefore carries a non-zero share in all three jobs, by arithmetic necessity, whatever the org chart says.**

The 2.20 threshold leaves room for estimation error in the vector; the mathematically meaningful line is 2.00, and crossing it is proof rather than evidence. The 1.50 boundary corresponds to a two-job mix of 0.7887 / 0.2113 — a clear primary job and a real but minority second one.

The structure as found, scored:

entity	H	O	B	S	eff jobs
UK holdco (holds, trades, banks group)	0.40	0.35	0.25	0.3450	2.8986
US portfolio entity	0.55	0.10	0.35	0.4350	2.2989
Jersey IP company	0.60	0.35	0.05	0.4850	2.0619
Luxembourg treaty vehicle	0.45	0.05	0.50	0.4550	2.1978
group aggregate	0.50	0.21	0.29	0.3778	2.6468
mean effective jobs per entity					2.3643

Every one of the four entities is at or above 2.00 effective jobs, which means every one is carrying all three jobs by arithmetic necessity. Four entities, four jurisdictions, one bloc, and no specialisation anywhere. That is a diagnosis the concentration measurement alone could not produce: Section 5 said the structure has one point of failure; this says each of its four entities is simultaneously failing three requirement sets. The two findings are independent and they compound.

The designed structure, scored:

entity	H	O	B	S	eff jobs	verdict
foundation	0.90	0.00	0.10	0.8200	1.2195	specialist
Thai operating company	0.05	0.95	0.00	0.9050	1.1050	specialist
UK company	0.10	0.85	0.05	0.7350	1.3605	specialist
Singapore treasury	0.05	0.15	0.80	0.6650	1.5038	strained
Gulf holdco	0.70	0.05	0.25	0.5550	1.8018	strained
Bermuda captive	0.30	0.60	0.10	0.4600	2.1739	strained
Indian centre vehicle	0.20	0.30	0.50	0.3800	2.6316	**overloaded**
mean effective jobs per entity					1.6852	

That the framework's own architecture produces a flag is the reason the diagnostic is worth having. The captive at 2.1739 is strained by nature: it underwrites, which is an operating activity requiring licensed substance and supervision, while also holding reserves, which is a holding activity. The strain is accepted because the reserves are held against real third-party liabilities. The diagnostic's job is not to forbid the strain; it is to make sure the strain was chosen.

The centre vehicle at 2.6316 is above 2.00 and therefore carries all three jobs, **which is a design error this paper owns rather than smooths over**. Two repairs, both computed:

```
as specified                    H0.20 O0.30 B0.50   eff jobs 2.6316   OVERLOADED
repair A: specialise BRIDGING   H0.05 O0.10 B0.85   eff jobs 1.3605   SPECIALIST
repair B: specialise OPERATING H0.05 O0.80 B0.15   eff jobs 1.5038   STRAINED
```

Repair A is the better move on these numbers. After it, no entity in the designed structure carries all three jobs:

	as found	designed
mean effective jobs	2.3643	1.6852
worst entity	2.8986	2.6316 → 1.3605 after repair A
entities above 2.00	4 of 4	1 of 7 → 0 of 7 after repair
entities below 1.50	0 of 4	3 of 7

The group-level measurement asks the complementary question — whether a job rests on too few entities. Weighting each entity's job share by size and normalising within each job:

job	effective entities carrying it	largest carrier
HOLDING	2.6141	foundation, 52.02%
OPERATING	2.9838	Thai operating company, 46.34%
BRIDGING	4.5051	Gulf holdco, 31.75%

Holding is the most concentrated, at 2.61 effective entities with the foundation carrying just over half. That is intentional — concentrating holding is the point of having a holding layer — but it should be a decision rather than a surprise. **Job concentration and jurisdictional concentration are different measurements, and a structure can be well diversified on one and deliberately concentrated on the other.**

8.2 The assignment rule, and why the minimum

Score each candidate 0–5 on six requirement dimensions, then take the **minimum** across the dimensions the job actually needs:

```
dimensions
  1  succession law          4  real substance capacity
  2  asset segregation       5  market and labour access
  3  low substance burden    6  dual-bloc banking

HOLDING    fit = min over {1, 2, 3}
OPERATING  fit = min over {4, 5}
BRIDGING   fit = min over {2, 6}
```

Constructed scores. These are the analyst's judgements applied to published characteristics, and a reader who disagrees should change a score and rerun the rule rather than abandon it:

candidate	succession	segregation	low-subst	real-subst	market	dual-bank
Gulf centre A	5	5	4	2	2	4
Gulf centre B	5	5	4	2	2	5
Singapore	4	4	3	4	4	5
Bermuda	3	5	2	3	2	3
UK company	3	3	2	4	5	2
Indian centre	2	3	3	3	3	3
Thailand	1	2	1	5	5	3
single offshore company	3	4	5	1	1	1

Applying the rule gives HOLDING to Gulf centre A at fit 4, OPERATING to Thailand at fit 5, and BRIDGING to Gulf centre B at fit 5.

Why the minimum and not the average. A job is a conjunction. An entity scoring brilliantly on two of a job's three requirements and failing the third does not do two-thirds of the job; it does none of it. Run both statistics on the holding dimensions and watch the masking:

candidate	holding dims	average	**minimum**	gap
Gulf centre A	[5, 5, 4]	4.67	4	0.67
Gulf centre B	[5, 5, 4]	4.67	4	0.67
single offshore company	[3, 4, 5]	4.00	3	1.00
Singapore	[4, 4, 3]	3.67	3	0.67
Bermuda	[3, 5, 2]	3.33	2	1.33
UK company	[3, 3, 2]	2.67	2	0.67
Indian centre	[2, 3, 3]	2.67	2	0.67
Thailand	[1, 2, 1]	1.33	1	0.33

On the average, the single offshore company ranks third for holding, ahead of Singapore, because an excellent low-substance score of 5 pulls up a mediocre succession score of 3. On the minimum the reason is visible. Bermuda shows the pattern more sharply: an average of 3.33 conceals a 2 on low substance burden, and the gap of 1.33 is exactly the amount of masking. **The gap between the average and the minimum measures how much a candidate's weakest requirement is hidden by its strongest, and a large gap is a warning, not a recommendation.**

8.3 H5 — the specialisation hypothesis: falsified on direct cost

Run a constructed annual cost model in index units, decomposed into legal, substance and compliance:

entity type	legal	substance	compliance	total
holding entity, low substance	6	1	0	7
holding entity forced to add operating substance	6	14	9	29
operating entity, real substance	3	18	11	32
bridging entity, compliance-heavy	4	7	16	27

A single overloaded entity must meet the *maximum* of each column, since it faces every requirement: $6 + 18 + 16 = 40$. Three specialists cost $7 + 32 + 27 = 66$.

```
overloaded single entity      40
three specialised entities    66
saving from consolidation     26     = 39.39%
```

H5 predicted that specialisation lowers direct cost. It does not. The overloaded entity is cheaper by 39.39%, and that is the honest result rather than the one the argument wanted. It is also the whole explanation for why overloaded structures exist: the saving is real, immediate and visible on an invoice, and the fragility it buys is none of those things. Organisational slack — the property that makes a system survive a shock it did not plan for — has always shown up on the accounts as waste [Cyert and March, 1963], and this is that result in miniature.

The case for specialisation therefore has to be made on **risk-adjusted** cost, and it can be. Model each job's requirement set as a test the entity passes with probability p; an entity doing k jobs faces k tests, all of which must pass:

p	one job	two jobs	three jobs
0.95	0.9500	0.9025	0.8574
0.90	0.9000	0.8100	0.7290
0.85	0.8500	0.7225	0.6141
0.80	0.8000	0.6400	0.5120
0.70	0.7000	0.4900	0.3430

At $p = 0.80$ the three-job entity holds with probability 0.5120 against 0.8000 for the specialist — 36.0% worse. **The model is crude and its conclusion is robust to every reasonable choice of p, because conjunction is unforgiving and there is no parameterisation in which requiring three things is easier than requiring one.** It also understates the problem: the three tests are *negatively* correlated, because arranging the entity to pass one actively makes another harder, so real joint probabilities sit below p^3 and the direction of the error is known even where its magnitude is not.

Taking $p = 0.80$, the overloaded entity's annual structural-failure probability is $1 - 0.8^3 = 0.4880$ against $1 - 0.8 = 0.2000$ for the worst single specialist. Let LOSS be the cost of a structural failure:

LOSS	risk-adjusted overloaded	risk-adjusted specialised	winner
100	88.80	86.00	specialised
150	113.20	96.00	specialised
250	162.00	116.00	specialised

LOSS	risk-adjusted overloaded	risk-adjusted specialised	winner
400	235.20	146.00	specialised

```
break-even LOSS = (66 - 40) / (0.4880 - 0.2000) = 90.28 index units
```

Specialisation pays whenever a structural failure costs more than 90.28 index units — 1.37 times the specialised structure's entire annual running cost. That is a very low bar. And the multi-year picture is where the asymmetry becomes plain:

years	cumulative saving	P(fail) overloaded	P(fail) specialised
1	26	0.4880	0.2000
3	78	0.8658	0.4880
5	130	0.9648	0.6723
10	260	0.9988	0.8926

The saving accrues annually and linearly; the failure happens once and permanently. That is the shape of the trap, and it is the same shape as the recoverability argument of Section 4.4, arrived at from a completely different direction.

8.4 The over-fragmentation limit, and the fourth job

The diagnostic says split. It does not say split indefinitely, and an instrument that pushed only one way would be half an instrument. Each additional entity adds to C, and if it sits inside a bloc the structure already occupies it adds exactly nothing to N. Model the marginal all-in cost of an entity at 0.035 in the units of the surplus law, calibrated so that the eight-entity designed structure costs $C = 0.30$:

entities	N	C	h
4	1.0000	0.1600	-0.3600
5	1.7000	0.1950	-0.2093
6	2.3000	0.2300	-0.1385
7	2.6000	0.2650	-0.1306
8	**2.9412**	**0.3000**	-0.1224
10	2.9412	0.3700	-0.1924
14	2.9412	0.5100	-0.3324
20	2.9412	0.7200	-0.5424

h improves up to eight entities and then falls, because entities nine onward add cost without adding blocs:

```
C at which h = -0.5000 with N = 2.9412:   0.677583
entities = 8 + (0.677583 - 0.300000) / 0.035 = 18.79
```

At roughly nineteen entities the structure is back to the conventional structure's $h = -0.5000$ while holding $N = 2.9412$. **A structure can be perfectly diversified and still worthless, by being administered to death.**

And every entity carries filing, accounting, audit, governing-body and register obligations regardless of which job it does. Modelling this administrative load at 0.02 per entity per year:

entities	admin load	share of $C = 0.300$
1	0.020	6.7%
4	0.080	26.7%
6	0.120	40.0%
8	0.160	53.3%
12	0.240	80.0%
15	0.300	100.0%

At eight entities, administration alone consumes 53.3% of the maintenance budget, and at fifteen it consumes all of it. **Administration is not a job in the taxonomy and it is the largest single line in C, which means the three jobs are competing for slightly less than half the budget they appear to have.**

8.5 Reconciling the two measurements

	as found	designed
effective blocs N	1.00	2.9412
$\ln N$	0.000000	1.078810
$\eta \ln N$ at $\eta = 0.35$	0.000000	0.377583
mean effective jobs per entity	2.3643	1.6852
entities	4	7
C	lower	0.30
h	-0.500000	-0.122417

The as-found structure is cheaper. It has four entities rather than seven, no substance in an operating jurisdiction, and no dual-bloc banking to maintain. Its C is lower and its h is still worse by 0.377583, because $\ln(1.00) = 0$ cannot be compensated for by any saving on the maintenance side. The designed structure costs more and is worth more, and specialisation pays whenever a structural failure costs more than 1.37 years of running cost.

9. Failure modes

Thirteen ways the instrument is misused, each with the arithmetic that detects it.

1. Counting entities. An adviser reports “eleven entities in seven jurisdictions” as though it were a measurement. It is a count of invoices. Entities inside one perimeter contribute nothing to N and each contributes to C. **An entity that does not raise N and does raise C moves h strictly down.**

2. Reporting naive HHI on a single-bloc structure. The specific error this paper exists to correct. Reporting 3.41 effective jurisdictions for the conventional structure is not wrong arithmetic; the arithmetic is right and the premise is false. **Wherever the naive and bloc figures diverge sharply, the divergence is the finding**, and reporting only the flattering half is the professional failure.

3. Rearranging inside a bloc. Table in Section 5. Fifty entities, naive count fifty, $N = 1.00$.

4. The wrong share basis. Measuring by book value when the threat is availability produces a number that is precise and irrelevant. Illiquid real estate has a large book value and a specific availability profile — it cannot be moved. A listed portfolio has a smaller book value and a much sharper availability profile, because a custodian instruction can stop working in an afternoon.

5. Double-counting a bridge. A bridge jurisdiction is a bridge because it touches two perimeters. Counting it as a full independent bloc overstates N; assigning it to one of the perimeters it bridges understates it. **Report the bridge assumption explicitly**; it is the assumption most likely to be wrong and the one that moves the answer most.

6. Measuring one axis and calling it the structure. Diversifying across blocs frequently *concentrates* counterparties, because few institutions will bank a genuinely cross-bloc structure. **Run the instrument on all four axes or the axis measured is the one the analyst was already comfortable with.**

7. Optimising the index instead of the thing it measures. Two structures with identical bloc-HHI can differ enormously in whether the blocs are actually independent in the scenario that matters. **The index is a diagnostic, not an objective function.** This is Goodhart's problem exactly [Goodhart, 1975], and Campbell's law in the evaluation literature [Campbell, 1979]: a measure adopted as a target ceases to be a good measure. Scott [1998] is the historical form — legibility destroys the local variety that made the system work — and it is a warning about this instrument as much as an argument for it. The tell is a structure whose bloc shares are suspiciously round and equal; real structures are lumpy because assets are lumpy.

8. Forgetting the second direction. A group driving jurisdictional HHI down while consolidating an operating market can find that the same instrument certifying its resilience certifies its market power.

9. Reporting from a rounded print. N for the designed structure is exactly $1/0.34 = 2.941176\ldots$:

```
exact:    ln(2.941176) = 1.078810   h = 0.35 x 1.078810 − 0.5 = −0.122417
rounded:  ln(2.940000) = 1.078410   h = 0.35 x 1.078410 − 0.5 = −0.122557
```

The two differ by 0.000140. **The conclusion is unchanged — both are below zero — but the number moved in the fourth decimal from a single rounding, and a chain of four such steps is how a measurement goes wrong.** The rule is not to round carefully; it is to carry full precision through every intermediate step and round only at the print.

10. Treating the bloc assignment as a fact rather than a claim. The variance derivation makes the collapse rigorous *given* the assignment. It does not make the assignment right. Every bloc call is a forecast about correlated behaviour, and a forecast that is acted on can make itself true. **This is not a rhetorical worry; it has been documented in this paper's own domain.** MacKenzie and Millo [2003] traces an option-pricing model that did not fit the market when it was published and came to fit it after traders adopted it, so that the description made its own assumptions true; Hacking [1995] gives the general form, in which a classification of people interacts with the people classified and the referent moves. **If enough structures are built on the assumption that two jurisdictions share a perimeter, capital and correspondent relationships reorganise around that assumption, and the correlation the instrument assumed becomes the correlation the world exhibits.** Lucas [1976] is the severe form of the same point turned on the instrument itself: a parameter estimated in a population that has not read the instrument cannot be assumed stable in a population that has. **The instrument is therefore an engine as well as a camera, and the honest response is the record below rather than a claim of neutrality.** The minimum record per jurisdiction is: the bloc, the evidence class, the single strongest piece of evidence, the date, and **the specific observable that would change the call**. That last field is the one left blank and the only one that produces a decision.

11. Confusing effective count with capacity. $N = 2.94$ says the structure has roughly three independent points of failure. **It says nothing about whether any of them can carry the load.** A bloc holding 30% of the exposure through an entity that cannot open a correspondent account, cannot hire, and cannot obtain a legal opinion is a bloc on paper, and the measurement reports it at full weight because a distribution does not inspect capability. The correction is not to fudge the shares; it is to run the job assignment alongside the concentration measurement. A structure whose bloc diversity is real but whose bridging capacity sits entirely in one of three blocs has an effective bloc count of 2.94 on holdings and something much closer to 1.00 on the ability to transact.

12. Measuring after the event. A diagnosis taken during the emergency is a post-mortem. The arithmetic takes minutes once the exposure table exists; building the exposure table is a week of work that nobody schedules. **A measurement nobody is obliged to act on will be run once, filed, and cited for years after it stopped being true.**

13. Believing N can be raised indefinitely. Section 7.4. There is an optimum number of blocs and it is small; that most structures sit below it does not mean more is always better.

Three further failure modes belong to the threat register rather than the index. **Expected-value reasoning applied to a ruin risk** systematically underinvests in the only threat that rescales all future years; the remedy is to run the register twice, once on expected loss for budgeting and once on conditional permanent loss for structural decisions, and to treat divergence between the rankings as the signal it is. **Assuming reversibility** models a freeze as a delay; a frozen position is one that has stopped compounding and may be released years later minus the yield. **Modelling the actor as rational** imports an adversary who maximises recovery; a designation is a foreign-policy instrument whose logic is signalling, a correspondent exit is a compliance-cost decision made by a middle manager who will never learn what the corridor was worth. Arguments that would move a rational creditor have limited force against an actor whose objective function is elsewhere. **The defence has to work without an advocate.**

10. Discussion

What follows. Three things follow from the results and each is narrower than the general claim it resembles.

The index is exact, given the correlation matrix. EFF $= 1/(w'Rw)$ is a variance reciprocal, and its two named cases are the two extreme correlation assumptions. Nothing in the derivation is approximate. This is why the instrument survives the statistical-averaging objection of Doak et al. [1998]: the paper does not claim that diversity produces stability through an unspecified mechanism, it claims that a variance has a reciprocal and that the reciprocal counts independent shocks.

The status of the claim is measurement, not physics. The corpus is titled a psychological and sociological physics, and the word is checkable. **What is claimed here is a measured count with a dimension, a conservation law, stated limits and an invariance group** — Sections 11.1 to 11.4 — and **not** membership of the statistical-physics programme surveyed by Castellano et al. [2009], which supplies the vocabulary of order parameters, phase transitions and coarsening that this paper deliberately does not use. **No order parameter is identified, no phase transition is located, and no critical exponent is estimated.** Hedström and Ylikoski [2010] states the criterion the discipline named in the title will apply: an explanation must name a mechanism rather than exhibit a fitted curve. **The mechanism named here is a correlation structure, and nothing is fitted.** Gallegati et al. [2006] is the checklist this paper was run against — ignorance of existing work in the target discipline, sub-standard statistical procedure, unjustified universality claims, and models built on assumptions known to be false — and Section 12 reports where it passes and where it does not.

The instrument is domain-general and the generality is evidence. The same arithmetic is the Hill number of order two in ecology [Hill, 1973], the Simpson index [Simpson, 1949], the effective number of parties in political science [Laakso and Taagepera, 1979], the Rényi-2 participation ratio in information theory [Rényi, 1961], and the concentration index in competition law [U.S. Department of Justice and Federal Trade Commission, 2023]. Where it misbehaves is documented too: Golosov [2010] and Dunleavy and Boucek [2003] identify the dominated-unit regime in which the effective-number reading is least informative, which is precisely the regime the bloc examples live in — one unit at or near 100%. That the instrument is least discriminating exactly where this paper's headline case sits is a limitation and is recorded in Section 12.

Redundancy is not automatically resilience. Percolation gives the sharpest available for-

malisation of how many independent components a system really has [Callaway et al., 2000], and the robust-yet-fragile result [Albert et al., 2000] is the canonical demonstration that a network can be highly tolerant of random loss and extremely vulnerable to targeted loss — with the caveat, from Doyle et al. [2005], that real engineered systems get their robustness from design rather than from a degree distribution. The jurisdictional analogue is that a structure's tolerance depends on which component is removed, and a designation regime is a targeted removal.

What does not follow. Four things.

It does not follow that raising N is always right. Section 7.4 gives the diminishing return; Uzzi and Spiro [2005] gives the inverted U; Sagan [1993] gives the case in which redundancy reduces safety by adding coordination surface. The prescription here is bounded: move from one effective bloc to two or three, and stop when the marginal entity stops adding a bloc.

It does not follow that count substitutes for capability. Failure mode 11. The effective count measures independence, not capacity.

It does not follow that jurisdictional diversity answers every threat. It is close to irrelevant to counterparty failure and can worsen it. This is the corpus's own version of the general finding that diversity's benefit is conditional rather than automatic: Hong and Page [2004] is the canonical model in which diverse groups outperform high-ability groups, and Thompson [2014] is the critique establishing that the result follows from the model's assumptions rather than from data. **Both must be cited together and are here.**

It does not follow that the corpus's affine effective count inherits any of this. Section 3.2 and the Verification chain in Section 11.

Where this paper disagrees with its own corpus. Curzi [2026] reports naive HHI 0.293388 and 3.4085 effective jurisdictions on what is described as the same entity map; this paper computes 0.293430 and 3.407968. The difference is the fifth decimal and arises from whether the shares are taken as the rounded percentages 40.9 / 27.3 / 18.2 / 13.6 or as the exact fractions 9/22, 6/22, 4/22, 3/22 that produce them. **This paper uses the rounded percentages as stated, which is the reproducible choice given published inputs.** Neither figure changes any conclusion, both bloc figures are exactly 1.000000, and recording the discrepancy is preferable to silently harmonising it.

Bounded by the corpus's own honesty apparatus. Curzi [2026] assigns the corpus's central identification and the application of the surplus functional to a life to the postulate drawer, and states that the reading of a day's surface as a leading indicator is a wager whose misfire column exists because wagers can lose. That bound applies here: this paper's arithmetic is exact and its inputs are judgements. Curzi [2026] makes the exposure concrete with an instrument audit in which 19 of 27 parameter-by-scope cells have a defined estimator, 1 of 27 has a validated one, and **0 of 27 carry a first-party measurement**. Curzi [2026u] shows that the corpus's own falsification suite is anti-conservative as ordinarily run — against a nominal 0.05 across 500 null trials, i.i.d. permutation rejected at 0.108 and circular shift at 0.120 — which is a direct warning about how much confidence a passing check should buy.

Parallel results elsewhere in the corpus. The reciprocal-of-a-quadratic-form structure recurs. Curzi [2026s] derives a reciprocity factor $\rho = 2\min(x_{ij}, x_{ji})/(x_{ij} + x_{ji}) = 1 - \|\text{Skew}\|/\text{Sym}$ with the node imbalance index obeying $1-B \geq \rho$, flattering a worked network by 15 per cent — the same shape of correction, on a different object. Curzi [2026v] shows that attainable stroke counts on a star polygon are exactly the proper divisors of N and that $\gcd(N,k) = \gcd(N, N-k)$, verified without counterexample for $N = 3$ to 100: a discrete count that is invariant under a relabelling, as N is invariant under rearrangement inside a bloc. Curzi [2026] gives the deficit identity $D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_{\infty}$, in which two apparently different quantities are shown to be the same number — structurally the move this paper makes in showing that naive HHI and bloc-HHI are one variance. Curzi [2026k] validates a five-parameter survey across scales, reproducing observed declines to residuals under 1.4% of the ceiling term, which is the closest the corpus comes to an out-of-sample test of the same model form. Curzi [2026] supplies the count-based essence index $f(n) = kn^2$ and the hold line $u^* = (e^{c/\eta}-1)/(N-1)$, which is the same effective-count variable entering a different law.

11. Verification and rigour audit

The result is decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the compounding chain names what each step consumes. **If dropping a postulate leaves the result standing, it is not listed.** Sections 11.1 to 11.5 run the standing rigour checks first, so that the chain in 11.7 is read against a dimensional audit rather than before one.

11.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i, w_i	exposure share of jurisdiction i	$[1]$	dimensionless, fraction of Q	defined; sums to 1 by P1
W_b	bloc share	$[1]$	dimensionless	derived, $W_b = \sum_{i \in b} s_i$
HHI	concentration index	$[1]$	dimensionless (or points $= 10^4 \times$ fraction)	derived from shares
ρ_{ij}	correlation between shocks	$[1]$	dimensionless, $[-1, 1]$	assumed, not measured
X_i	unit-variance shock to i	$[1]$	dimensionless by construction	defined
$\mathrm{Var}(R)$	variance of the aggregate shock	$[1]$	dimensionless	derived
N, N_{eff}	effective count	$[\#]$, **a count**	jurisdictions or blocs	derived as $\mathrm{Var}(R)^{-1}$
$\ln N$	surplus term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
Q	protected capital	$[C]$	index units of stored capital	defined; **no operational unit is supplied by the source**
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived
p, L, r	register probability, loss fraction, recovery fraction	$[1]$	dimensionless	assumed (constructed)
W, B	warning window, build time	$[T]$	days	assumed (constructed)
S (job index)	specialisation index	$[1]$	dimensionless	derived from a job vector

Does the surplus law balance? $h = \eta \ln N - \delta Q - C$ requires every term to carry $[C\,T^{-1}]$. δQ does, since δ is per period and Q is a stock. C does by definition. $\eta \ln N$ does **only if η carries $[C\,T^{-1}]$ per nat**, and the source is silent on this: it treats η as a bare "conversion efficiency". **The audit records that silence rather than filling it in.** The equation balances under the reading given in the table, and the reading is this paper's, not the source's.

The important row is N. HHI is a dimensionless sum of squared dimensionless shares, so its reciprocal carries the dimension of a **count** — and that is exactly why it is a numbers-equivalent rather than an index. **The instrument is not a score that happens to run from 1 upward; it is a measured count of independent units, with a unit, and it is checkable against the definition of a count by the limits in Section 11.3.**

Where no operational unit exists, this audit says so. Q is "protected capital in index units", and the source supplies no conversion to currency. Every figure in C, h and Q is therefore in an arbitrary scale fixed by the stated parameters. **The break-even $N = 4.172734$ is unit-free and survives this; the statement that h is -0.122417 does not mean anything until the index unit is defined.**

11.2 Significant figures and epistemic status

The two figures in the headline comparison have different statuses and must not be read at the same precision.

- $N = 2.941176$ and $N = 1.000000$ are **exact arithmetic** on the stated shares: $1/0.34$ and $1/1$. They are derived-from-defined and may carry as many digits as are useful. Their inputs — the shares — are constructed and exact as stated to one decimal place, and the exposure vectors sum to 100.0% exactly.
- $N = 4.172734$ is **exact given the parameters** — $e^{0.5/0.35}$ — and the parameters are **assumed**, not estimated. So the break-even is an exact function of an assumed input. **It carries no uncertainty because there is no estimate in it, and it carries no authority beyond the assumption.**
- $\rho = 0.065910$ is exact arithmetic on two exact indices.
- The register outputs — 9.25%, 5.97%, 0.956357 — are **illustrative model output from constructed parameters** and are rounded in the text to four decimal places at most. Six digits on 0.956357 is defensible only because the inputs are exact by stipulation; it is not a measurement and Section 12 says so.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere.** That is not a strength: it means the paper has no empirical content to attach an interval to.

11.3 Limits and boundary behaviour

The instrument's limits are the proof that it behaves as a count.

limit	HHI	HHI^{-1}	reading
one holder, $s_1 = 1$	1	1 exactly	a monopoly counts as one unit
n equal holders, $s_i = 1/n$	$1/n$	n exactly	returns the count
n holders, any unequal split	$> 1/n$	$< n$	never overstates the count
$s_{\max} \to 1$ with the rest $\to 0$	$\to 1$	$\to 1$	continuous approach to the monopoly limit
$n \to \infty$, equal shares	$\to 0$	$\to \infty$	unbounded above, as a count should be

limit	HHI	HHI^{-1}	reading
$\rho \to 0$ within blocs	naive	naive count	the independent limit
$\rho \to 1$ within blocs	bloc	bloc count	the fully-coupled limit

Range: $1 \le \text{HHI}^{-1} \le n$, with both bounds attained. The lower bound is attained exactly when one unit holds everything and the upper exactly when all units are equal. A quantity that equals n for n equal units, equals 1 for a single unit, and lies strictly between otherwise **is a count**, and no further argument is needed.

The same limits run on the affine count, which fails them. $N_{\text{eff}} = 1+(N-1)u$ gives 1 at $u = 0$ and N at $u = 1$ for *any* share vector whatever — including the vector $(0.999, 0.001)$, for which it reports 2.000000 at $u = 1$ while every Hill number reports approximately 1.002. **It has the right endpoints and the wrong interior, because it never consults the shares.** The two quantities part company in the limits, and that is a cleaner demonstration than any argument in prose. The full arithmetic is in Section 11.9.

Boundary behaviour of the surplus law. As $N \to 1^+$, $h \to -(\delta Q + C)$, which is the maintenance floor: a structure inside one perimeter pays its whole bill out of stock. As $N \to \infty$, $h \to \infty$ logarithmically — which is a **defect of the model and a statement of its domain**, since Section 7.4 and Uzzi and Spiro [2005] establish that the real curve turns over. **The model's domain is small** N, and the paper's prescriptions are confined to the move from $N \approx 1$ to $N \approx 3$. As $\eta \to 0$, $h \to -(\delta Q + C)$ regardless of N: no conversion, no benefit from any amount of independence. As $\delta \to 0$ the stock never erodes and any positive $\eta \ln N$ exceeding C accumulates without bound, which is a pathology rather than an ideal.

11.4 Invariance

The effective count is invariant under relabelling of units and under any rescaling of the underlying exposures that preserves the share vector. Doubling every exposure in currency terms leaves every s_i unchanged and therefore leaves HHI, N and $\ln N$ unchanged. This is a genuine scale invariance and it is the reason the instrument can be applied to a structure of any size.

It is not invariant under regrouping, and that is the whole content of the bloc collapse: the naive and bloc figures differ by construction, and the difference is the finding. A reader who wants a single number that is invariant under regrouping is asking for a quantity that cannot detect a perimeter.

What would break the scale invariance: any share basis that is not normalised — for instance, reporting exposures in currency without dividing by the total. **Tested at how many scales?** The invariance is algebraic, not empirical, and was checked at exactly the two structures reported here. No claim of empirical scale-freedom is made.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content: nineteenth-century energetics was copied into economics and utility was made to play the role of energy without energy's conservation. **The objection is met here and the answer is short.** The conserved quantity is the exposure share vector: $\sum_i s_i = 1$ by P1, exactly, in dimensionless units, and it is that constraint and nothing else that gives the index its bounds — $s_{\max}^2 \le \text{HHI} \le s_{\max}$ and $1 \le \text{HHI}^{-1} \le n$ both follow from it. **Remove the normalisation and the effective count ceases to be a count.** The invariance group is relabelling of units together with any rescaling that preserves the simplex. Q**, by contrast, is a stock with no stated conservation law and no operational unit, and this paper does not claim one for it** — which is the honest half of the answer. Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law is claimed to hold, and stop claiming a universality the argument does not need. **The arrangement claimed here is a**

normalised exposure vector with a correlation matrix having unit diagonal and non-negative entries, and nothing outside it.

Aggregation is a separate and unmet objection. Kirman [1992] establishes that a single representative parameter for a heterogeneous group generally does not exist. The instrument writes one Q, one δ and one C for a whole structure. **No aggregation argument is offered and none is available from the arithmetic**; Section 12 records it.

11.5 Analogy discipline

Every borrowing in this paper is labelled with one of the three categories.

borrowing	source	category	justification
portfolio variance $\mathrm{Var}(R) = w'Rw$	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix; the premises are the algebra's own
Hill numbers, order 2	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* ${}^2D$; this is an identity, not a resemblance
similarity-sensitive diversity	Leinster and Cobbold [2012]	**1 — derivation**, with a stated domain	$1/(w'Rw)$ is the order-2 member for similarity matrix R; exact where R has unit diagonal and non-negative entries, and claimed nowhere else
$\ln N$ as entropy	Shannon [1948]	**2 — shared form**	this is **Shannon entropy in nats**, a dimensionless information quantity, and not thermodynamic entropy; no thermodynamic content is imported
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	jurisdictions have not been shown to satisfy the percolation premises; only the structural property that coupling destroys assumed independence is used

borrowing	source	category	justification
robust-yet-fragile	Albert et al. [2000], Callaway et al. [2000]	**2 — shared form**	the degree-distribution result is not claimed to apply to jurisdictions; the shape of the tolerance asymmetry is
normal accidents	Perrow [1984]	**3 — framing**	qualitative organisational theory, cited as prior statement of the same observation, never as a formal result
synchrony in ecology	Loreau and de Mazancourt [2008]	**2 — shared form**	the naming convergence is noted; no ecological mechanism is imported
the effective number of parties	Laakso and Taagepera [1979]	**1 — derivation**	the same formula on a different share basis

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration arithmetic is category 1 throughout and does not need help; the network results are category 2 and are used for shape only.

11.6 Measurement-theoretic status of the scored inputs

Two inputs in Section 8 are scores rather than counts, and their scale type is not optional.

The 0–5 requirement scores are ordinal. They are the analyst's rank judgements over published characteristics. **An ordinal scale licenses a minimum and does not license a mean.** The assignment rule takes a minimum, which is licensed. The masking table in Section 8.2 computes averages, which is **not licensed**, and it is included precisely to demonstrate that averaging ordinal fit scores produces a wrong ranking — the illicit operation is the object of study, not a step in the argument. **This is stated here so that no downstream work reads that column as a computed quantity.**

The job vectors (H, O, B) are treated as ratio-scale shares of an entity's activity, and that treatment is not tested. Michell [1997] is the strongest objection available to this move: psychology and its neighbours routinely assume quantitative structure without testing for it. The formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all, within the representational framework of the representational theory of measurement. **The conjoint conditions were not tested for the job vector, and the effective-jobs figures are therefore provisional.** What survives without the test is the *ordering* — an entity with a clearly dominant function scores lower than one without — and the exact threshold at 2.00, which is an algebraic property of any three-component vector on the simplex and does not depend on the scale type. The concentration instrument itself is untouched by this objection, because exposure shares are ratios of capital and not psychological judgements.

11.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$	DEFINITION
P3	for n equal shares of $1/n$, HHI $= n \cdot (1/n)^2 = 1/n$	ARITHMETIC
P4	the aggregate shock is $R = \sum_i w_i X_i$ with Var$(X_i) = 1$	DEFINITION
P5	Var$(R) = \sum_i \sum_j w_i w_j \rho_{ij} = w' R w$	ARITHMETIC
P6	jurisdictions inside one enforcement perimeter act on one decision	POSTULATED (H1)
P7	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P8	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)

11.8 The chain that establishes the instrument

step	consumes	statement	status
L1	P2, P3	HHI^{-1} returns n exactly for n equal shares	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent: the count of equal units giving the observed index — Adelman [1969]	CITED
L3	L2	HHI^{-1} is the Hill number of order 2 — Hill [1973], Jost [2006]	CITED
L4	L3	the same quantity is the Simpson index's reciprocal and the effective number of parties — Simpson [1949], Laakso and Taagepera [1979]	CITED
L5	P4, P5	with $R = I$, Var$(R) = \sum w_i^2 =$ HHI	ARITHMETIC
L6	P4, P5	with R block-of-ones, Var$(R) = \sum_b W_b^2 =$ bloc-HHI	ARITHMETIC
L7	L5, L6	naive and bloc indices are one variance under two correlation assumptions	ARITHMETIC
L8	L7	Var$(R) =$ naive $+ \rho($bloc $-$ naive$)$	ARITHMETIC

step	consumes	statement	status
L9	L7	EFF $= 1/(w'Rw)$ is the similarity-sensitive diversity of order 2 — Leinster and Cobbold [2012], Rao [1982]	CITED
R1	L7, P6	for the conventional structure, $N = 1.000000$ against a naive 3.407968	ARITHMETIC
R2	L7, P6	for the designed structure, $N = 2.941176$ against a naive 5.290949	ARITHMETIC
R3	R2, P7, P8	$h = 0.35 \ln(2.941176) - 0.5 = -0.122417$; break-even $N = e^{1.428571} = 4.172734$	ARITHMETIC
R4	L8	the correlation matching the two structures is $\rho = 0.065910$	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. Only P6 and P8 are POSTULATED, and both are stated as hypotheses in Section 2 with their falsifiers attached. **The instrument therefore rests on two postulates, six definitions and a chain of arithmetic, and nothing else.**

11.9 The same chain applied to the affine effective count, which fails it

step	statement	status
Q1	$N_{\text{eff}} = 1 + (N-1)u$, with u a scalar non-parallelism	DEFINITION (corpus's own)
Q2	for two units at shares 0.9 and 0.1 with $u = 1$, Q1 gives exactly 2.000000	ARITHMETIC
Q3	for the same two units, $\text{HHI}^{-1} = 1/(0.81 + 0.01) = 1.219512$	ARITHMETIC
Q4	for the same two units, $\exp(H) = \exp(0.325083) = 1.384115$	ARITHMETIC
Q5	Q2 disagrees with Q3 and Q4, so Q1 does not return a numbers-equivalent	ARITHMETIC — **L2 fails**
Q6	Q1 is a function of (N, u) and not of the share vector, so it is not $(\sum p_i^q)^{1/(1-q)}$ for any q	ARITHMETIC — **L3 fails**
Q7	no entry in ecology, economics, political science or information theory states Q1	POSTULATED — no external support

The two chains part company at Q5. HHI^{-1} and $\exp(H)$ are Hill numbers of order 2 and 1 and are fully grounded. $1 + (N-1)u$ is a linear interpolation between 1 and N; it is the

corpus's own construction, it carries no external support, and **a reviewer who reaches for the Hill literature expecting it to apply will find that it does not**. That is stated here rather than left to be discovered. The corpus already notes elsewhere that the two are different quantities, which is to its credit; what this paper adds is that they must not travel under one name.

11.10 Cross-checks performed

- The double sum $\sum_i \sum_j w_i w_j \rho_{ij}$ was evaluated explicitly on the designed structure's six shares under both correlation assumptions and reproduced 0.189002 and 0.340000 to twelve decimal places.
- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on both structures: $0.167281 \le 0.293430 \le 0.409$ and $0.084681 \le 0.189002 \le 0.291$.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $3.407968 \le 5.9780$ and $5.290949 \le 11.8090$.
- The rounding audit of failure mode 9 was run and the discrepancy quantified at 0.000140.

12. Limitations

The correlation is assumed, not measured. $\rho = 1$ within a bloc is the conservative end of a family, and the justification is the observed behaviour of coordinated listing, substance and exchange frameworks over fifteen years. **No correlation was estimated from data in this paper.** That is the single largest unmeasured input, it is exactly the quantity H1 turns on, and the honest response is that the family in Section 7.1 is published so that a reader may substitute a different value. A reader who believes $\rho = 0.5$ within the Western perimeter should read $N = 1.5463$ off the table and proceed.

The effective count is least informative exactly where the headline case sits. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, where one unit holds a very large share. The conventional structure's bloc vector is a single unit at 100%, which is the limiting case of that regime. The measurement is still exact — $1/1 = 1$ — but the *discriminating power* of the instrument is at its minimum there, and comparisons among heavily dominated structures should not be made on N alone.

Small-sample bias is not addressed. Chao et al. [2014] show that diversity estimators are biased on small samples. A six-element exposure vector is a small sample. No correction was applied and none is available for the case where the exposure vector is a complete census rather than a sample — which is arguably this case, since the structure's exposures are enumerated exhaustively rather than sampled. **The paper does not resolve which of the two situations it is in, and a reviewer would be right to press on it.**

Every parameter in the surplus law was chosen, not estimated. $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ are stated test parameters. They were fixed before the measurement, which protects H2's criterion from being adjusted to fit, and they are not estimates of any real position. **The break-even $N = 4.172734$ is therefore a property of the chosen parameters and not of the world.** At $\eta = 0.50$ the break-even falls to $e^{1.0} = 2.718$ and the designed structure clears it. That the conclusion of H2 depends on η in this way is the most important sensitivity in the paper.

Every case is constructed. The principal, the assets, the shares, the threat register parameters, the cost model, the market shares and the job vectors are all invented and are labelled as such at each point of use. **No empirical dataset was collected and none is reported.** The measurements are exact computations on constructed inputs.

The bloc assignments are the analyst's judgements. They are contestable, the robustness table shows the sensitivity, and each carries a stated observable that would change the call. They are not derived from a published register of coordination behaviour, because no such register exists.

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions of specific centres, statutes, foundation regimes, treaty positions, ownership rules and court ar-

rangements are taken from the source manuscript. **The bibliography contains no jurisdiction-specific primary sources — no statutes, regulations, court rules or registries — and no case law.** Those claims are therefore uncited in this paper, are described rather than asserted, and require verification against the official registers before any reliance. Appendix B lists them individually. This is a real gap and it is not closed here.

The effective count measures independence and not capacity. Stated as the paper's own counter-result: $N = 2.94$ says nothing about whether any bloc can carry the load. A structure whose bloc diversity is real but whose bridging capacity sits in one bloc has an effective count near 1.00 on the ability to transact.

The affine effective count used elsewhere in the corpus has no external support. Section 11.9. This paper does not use it, but papers citing this one may, and the distinction must survive the citation.

Monotone claims are restricted. The paper's claim is not that surplus increases without bound in independence. Section 7.4 bounds it, and Uzzi and Spiro [2005], Sagan [1993] and May [1972] are the reasons a monotone claim could not survive unqualified.

The instrument is exposed to its own failure mode 7. Adopted as a target, N would cease to be a good measure [Goodhart, 1975, Campbell, 1979]. Nothing in the arithmetic prevents that, and the only defence offered is the reporting standard in Appendix A, which requires the inputs to be published alongside the output.

12.1 Rigour checks not met, listed by name

The standing checks of Section 11 were run in full. The following did not pass and are printed here rather than left for a reader to find.

1. **No as-of date, because no real holdings were measured.** A concentration figure computed from real holdings requires its source and its date; a concentration measure without an as-of date is not a measurement. **Every share vector here is constructed, so there is no source and no date to give.** Any application of this instrument to a real structure must carry both, and the reporting standard in Appendix A accordingly makes the date item 9.
2. **No uncertainty is reported anywhere, because nothing is estimated.** Every figure is exact arithmetic on stipulated inputs. That is not precision; it is the absence of empirical content, and it means the paper cannot be wrong in the way a measurement can be wrong.
3. **The dimension of η is supplied by this paper, not by the source.** The source treats conversion efficiency as a bare number. The surplus law balances only if η carries capital per period per nat, and Section 11.1 assigns that reading explicitly rather than silently.
4. **Q, C and h have no operational unit.** They are index units fixed by the stated parameters. The break-even count is unit-free and survives; the magnitude of h does not mean anything until an index unit is defined, and the source defines none.
5. **The surplus law's large-N limit is a defect, not a result.** h grows without bound in $\ln N$, which the empirical literature contradicts. The model's domain is therefore small N, stated in Section 11.3 rather than discovered by a reader.
6. **The conjoint conditions were not tested for the job vector**, so the effective-jobs figures are provisional as ratio-scale quantities [Michell, 1997, Luce and Tukey, 1964]. The 2.00 threshold survives because it is algebraic; the magnitudes do not.
7. **An unlicensed operation appears in Section 8.2 on purpose.** The average of ordinal 0–5 fit scores is not a licensed statistic, and the column exists to show that averaging ordinal fit scores selects the wrong candidate. It must not be read as a computed quantity.
8. **Model comparison was not performed.** No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. The instrument is asserted to be the right one on the strength of the identity chain in Section 11.8, not on comparative fit.

9. **The coupled-network borrowing is category 2, not category 1.** The premises of Buldyrev et al. [2010] have not been shown to hold for jurisdictions sharing an enforcement perimeter, and the result is used for its structural form only.
10. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. The exposure vectors are finite sets of four and six shares, not samples from a distribution. **Any restatement of this paper that reaches for a heavy-tail or power-law claim about holdings must run that procedure first**, and must read Stumpf and Porter [2012] on why passing it still would not identify a mechanism.
11. **The bloc assignment is a stipulated reference group, not an identified effect.** Manski [1993] rules out recovering an endogenous social effect from observation of a linear-in-means reflexive system, and the framework's reflexive loop is such a system. The remedy adopted is stipulation with a defence [Brock and Durlauf, 2001], and **the price is that the assignment is a modelling position**. No randomisation, instrument or partial-population variation was available.
12. **The instrument is performative and its own parameters are exposed to that.** MacKenzie and Millo [2003] documents a model that made its assumptions true after adoption; Lucas [1976] states the consequence for parameters estimated before publication. **The framework asserts that systems change when modelled and then exempts its own η, δ and correlation assumptions from that reflexivity. That is an inconsistency and it is not resolved here**; what is offered instead is the auditable record required by failure mode 10.
13. **There is no conservation law for Q.** Section 11.4 gives the one genuine conservation — shares sum to one — and states plainly that the stock variable has none [Mirowski, 1989]. **This is the objection the genre most often fails, and this paper meets half of it.**
14. **Aggregation is unaddressed.** One Q, one δ and one C are written for a heterogeneous structure, and Kirman [1992] establishes that such a representative parameter generally does not exist.
15. **Expected value and time average are not the same thing, and the register reports the first.** Peters [2019] is the reason the conditional permanent-loss column exists at all; **the register's headline 9.25% is an ensemble average that no single holder experiences.**
16. **No differential prediction is offered.** Durlauf [2005] asks for the prediction that only this model makes, and the instrument makes none: any correlation-aware concentration measure would produce the same collapse. **The contribution is the identification and the discipline, not a uniquely discriminating forecast.**

13. Conclusion

This paper establishes the concentration instrument in the form the rest of the corpus cites, and the following statements are the fixed text of that result.

R1. With HHI defined as the sum of squared exposure shares and the effective count as its reciprocal, a conventional four-jurisdiction structure at UK 40.9%, US 27.3%, Jersey 18.2% and Luxembourg 13.6% measures a naive HHI of 0.293430 and 3.407968 effective jurisdictions; collapsing the same shares onto coordination blocs before squaring gives a bloc-HHI of 1.000000 and an effective count of exactly 1.00.

R2. A redesigned six-jurisdiction structure reaches a naive HHI of 0.189002 (5.290949 effective jurisdictions) and a bloc-HHI of 0.340000 (2.941176 effective blocs), with Western-perimeter exposure falling from 100.0% to 30.0%.

R3. Coupled to the surplus law $h = \eta \ln N - \delta Q - C$ at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$: $N = 1.00$ gives $h = -0.500000$; $N = 2.941176$ gives $\eta \ln N = 0.377583$ and $h = -0.122417$; and break-even is $N = e^{1.428571} = 4.172734$.

R4. The correlation that would make the conventional structure as resilient as the designed one is $\rho = (0.340000 - 0.293430)/(1 - 0.293430) = 0.065910$.

R5. The index is insensitive to bloc-assignment error and sensitive to bloc structure: reas-

signing one member moves N from 2.9412 to 2.9243, a change of 0.0169, under 0.6%; merging two blocs moves it to 2.2165.

R6. The five-threat register prices expected annual loss at 9.25% of protected capital and permanent expected annual loss at 5.97%, with the probability of at least one threat over ten years at 0.956357 and threat-1 window coverage of $2/210 = 0.0095$. Returns diminish as $dh/dN = \eta/N$: moving from 1.00 to 2.94 blocs buys 0.3776 of surplus while moving from 2.94 to 4.00 buys 0.1074.

Counter-result. The redesign reaches only $N = 2.94$ against a break-even of 4.17, so h remains negative at -0.122417. **H2 was tested and not met.** And the effective count measures independence, not capacity: it says nothing about whether any bloc can carry the load. **The instrument's honest verdict on the architecture it was built to evaluate is: substantially better, still insufficient, and the insufficiency is on the cost side rather than the design side.**

Two further results are established as method rather than as measurement. The naive and bloc indices are one variance under two correlation assumptions, so EFF $= 1/(w'Rw)$ is the general form and is exactly the similarity-sensitive diversity of order two. And HHI^{-1} is the Hill number of order two while $1 + (N-1)u$ is not a Hill number of any order and carries no external support; downstream work must name which effective count it means.

Curzi [2026] reproduces the full computation of R1 through R3 as a workbook, and that reproduction is the intended check on everything above.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the principal, the asset mix, the exposure shares, the threat-register parameters, the cost model, the constructed product market, and the entity job vectors — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-052_fig01.py` through `figs/src/CCP-052_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. No figure plots a number that does not appear in the text.

Jurisdictional and legal descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative and treaty material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction. Appendix B lists the claims affected. Any reader relying on those descriptions must verify them against the official sources.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions and structural arrangements for the purpose of measuring concentration and resilience. No recommendation is made in respect of any particular person, asset, structure or jurisdiction. Statutory reach-back periods, reserved-share regimes, substance requirements, corporate-residence tests, and merger-review thresholds all change and vary by jurisdiction and by activity; every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.

Appendix A. The reporting standard

Any structure measured under this instrument reports the following, and nothing less.

```
share basis, stated in one sentence
exposure table, jurisdictions and shares, summing to 100.0%
naive HHI, in fraction and in points, and effective jurisdictions
bloc assignment with the evidence class for each jurisdiction
bloc-HHI and effective blocs N
Western-perimeter exposure as a percentage
ln(N), eta ln(N), and h at the stated parameters
the robustness table over contested bloc assignments
the date, and the diff against the previous measurement
```

Item 9 decays first and matters most, because bloc fragmentation is invisible except as a difference between two measurements taken a year apart.

The entity-level register that accompanies it carries, per entity: legal form and jurisdiction; assigned job; job vector as measured rather than as intended; S and effective jobs with the band; where the strain is and its written justification; the requirement dimension on which the jurisdiction scores lowest; who takes the decisions belonging to the job and where; annual cost decomposed into legal, substance, compliance and administration; and the date with the diff against the previous register. **The lowest-scoring dimension is the column that pays for the exercise**, because the assignment rule took a minimum and that requirement is therefore already computed. An entity whose lowest dimension is dual-bloc banking is one correspondent decision away from being unable to do its job; an entity whose lowest dimension is succession law is fine until the founder dies. **Evidence created contemporaneously is worth an order of magnitude more than the same facts reconstructed three years later, and the cost of creating it is a column in a table.**

Appendix B. Claims requiring verification against primary sources

The following statements rest on legal or regulatory detail that changes, and **none of them is cited to the bibliography, which contains no primary sources for any individual jurisdiction**. They are reproduced from the source manuscript and require confirmation with counsel in the relevant jurisdiction before any reliance.

1. All statutory reach-back periods for transfers vulnerable to challenge: the two-year and ten-year federal bankruptcy provisions, the four-year uniform-act period with its one-year discovery rule, and the two-year, five-year and no-fixed-period provisions of the English insolvency legislation. Confirm current text, the applicable enactment — the

uniform act is adopted state by state and enactments vary — and whether the transfer in question is characterised as being to a self-settled trust.

2. The limitation analysis for the English provision on transactions defrauding creditors. The section fixes no period and the authorities address how the general limitation statute applies. This is contested ground.
3. The reserved-share provisions of the French Civil Code — one half, two thirds and three quarters for one, two, and three or more children — and, critically, the conflict-of-laws question of whether they reach a given asset at all. Characterisation drives the answer and is asset-specific.
4. Whether a particular administrative measure carries a right of appeal, which is the entire threat-1 / threat-2 boundary in practice.
5. The grounds on which recognition and enforcement of an award are in fact refused under the 1958 Convention, and the comparative treatment of the trust and the foundation as alternative devices for the succession problem. Both are settled subjects with their own literatures; neither is cited here, because the bibliography carries the instruments and the general doctrine only.
6. The named case authorities on the unavailability of a pre-judgment injunction over assets in an action for money damages, on the failure of the impossibility defence, and on the freezing-injunction line in English practice. **Case citation follows different conventions and no case is in the bibliography.**
7. Foundation and holding-vehicle characteristics in the named centres: separate legal personality, purpose or beneficiary structures, founder control retention, and the supervising courts. Confirm current text and any amendments.
8. Thai law as described: the treaty permitting full foreign ownership for persons of one nationality, investment-promotion conditions conferring ownership and land rights, the foreign business restrictions, the criminal treatment of nominee shareholding, and the revenue order on remitted foreign-source income. Promotion conditions are activity-specific and change.
9. Economic substance regimes and their thresholds, which vary by jurisdiction and activity category and have been amended repeatedly.
10. Corporate residence and central-management-and-control tests, which differ between jurisdictions and determine whether the split-entities-but-not-decision-rights failure is fatal in a given case.
11. Merger-review thresholds and their treatment in the relevant circuit. The guidelines cited [U.S. Department of Justice and Federal Trade Commission, 2023, 2010] are agency enforcement policy rather than statute and courts are not bound by them.
12. All cost figures are index units in a constructed model. They are not fee quotations and no real fee schedule was used to produce them.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 53

The Apex Vehicle: Foundation Against Trust, and the Arithmetic of Forced Heirship

Abstract. A holding apex must be recorded as an owner in registries that may not recognise a trust, which is the case for preferring an entity with separate legal personality over a relationship. We compare the DIFC Foundation with the common-law discretionary trust on recognition, cost and succession, and report where the comparison does not favour the foundation. On cost, the fixed-fee apex is modelled at USD 120,000 a year against ad valorem trusteeship, giving a crossover Q* = 120,000 divided by the fee basis: the foundation is cheaper only above USD 34.3 million at 35 basis points, USD 80.0 million at 15, and USD 120.0 million at 10. At the constructed USD 240 million estate the foundation costs 5.0 basis points against 35, a difference of USD 720,000 a year — but the paper states plainly that cost is the wrong reason to choose the form. On succession, two exposures are computed separately: a French compensatory levy capped by French-situs assets at min(60.00m, 6.70m) = USD 6.70 million, or 11.2 per cent of the notional reserved share, against an inheritance-tax exposure of approximately 0.45 × 60.00m = USD 27.00 million that the structure does not touch. The binding constraint is liquidity: a USD 60.00 million claim against USD 26.16 million of liquid assets leaves a shortfall of USD 33.84 million, 14.1 per cent of the estate, which forces the sale of an operating branch. Much of the paper is comparative legal exposition of the foundation, trust and Sharia regimes.

Keywords: private foundation; discretionary trust; legal personality; recognition and characterisation; forced heirship; réserve héréditaire; succession liquidity

Series: D. Structure and Resilience **Paper:** CCP-053

1. Introduction

A holding structure has an apex, and the apex is the one element that is genuinely difficult to reverse. An operating company can be redomiciled, wound up or duplicated; a bank account can be replaced in ninety days. **The apex is chosen once, and every subsequent decision inherits its law, its court, its disclosure regime and its politics.**

This paper asks what form that apex should take, and answers with one identification, three measurements and one refusal.

The identification. The concentration instrument of Curzi [2026] — the Herfindahl index of exposure shares, collapsed onto coordination blocs before squaring, with the effective count as its reciprocal — measures where the assets are. **It does not measure whether the *concept* holding those assets is portable.** A family whose assets are properly spread across six jurisdictions in three blocs, but which holds them all through a common-law discretionary trust, has an invisible version of the concentration problem: every one of those holdings depends on local courts and local registrars accepting a form of ownership that several of them do not recognise as ownership at all. We call this a **recognition dependency**, and it is a form of concentration the published instrument cannot see.

The first measurement is cost, and it does not favour the conclusion. A fixed-fee foundation apex is modelled at USD 120,000 a year against an *ad valorem* trusteeship. Setting the two equal gives a minimum efficient scale of $Q^{*} = 120{,}000/b$ for fee basis b: the foundation is cheaper only above USD 34.3 million at 35 basis points, USD 80.0 million at 15, and USD 120.0 million at 10. At the constructed USD 240 million estate it costs 5.0 basis points against 35, a difference of USD 720,000 a year. **The paper then states plainly that cost is the wrong reason to choose the form**, because the crossover reverses at a scale many families sit below and because a fixed-fee trustee mandate is available in the market.

The second measurement separates two exposures the same conversation usually merges. The forced-heirship exposure and the inheritance-tax exposure are different problems with different causes, different remedies and, in the worked case, magnitudes that differ by a factor of four. A compensatory levy capped by local-situs assets gives $\min(60.00\text{m}, 6.70\text{m}) =$ USD 6.70 million, 11.2 per cent of the notional reserved share; the inheritance-tax exposure on the same receipt is approximately $0.45 \times 60.00\text{m} =$ USD 27.00 million, and **the structure does not touch it.**

The third measurement finds the binding constraint, and it is not entitlement. A USD 60.00 million claim against USD 26.16 million of liquid assets leaves a shortfall of USD 33.84 million, 14.1 per cent of the estate and larger than any single liquid holding. **Closing it in cash requires selling an operating branch — which is the fragmentation the apex existed to prevent, arriving through the succession rather than through the register.**

The refusal. The apex does not move the concentration reading. Over the conventional structure of Curzi [2026] the measurement remains a naive index of 0.2934 (3.41 effective jurisdictions) against a bloc index of 1.0000 and an effective count of exactly 1.00, whatever vehicle sits at the top. The foundation answers ownership recording and succession continuity. **It adds nothing to the effective bloc count, gives no protection against arbitrary state action, and its forced-heirship result rests on a consent the heir may refuse — for which this paper states there is no lawful substitute.**

Two constraints on what follows are stated at the outset because they shape every section.

Jurisdiction-specific law is not cited. The bibliography contains general treaty and comparative doctrinal material — the recognition convention for trusts [Hague Conference on Private International Law, 1985], the judgments and choice-of-court instruments [Hague Conference on Private International Law, 2005, 2019], the succession convention that never entered into force [Hague Conference on Private International Law, 1989] and the regional regulation that partially fills the gap [European Union, 2012], together with the comparative literature on the trust and the foundation [Lupoi, 2000, Smith, 2013, Panico, 2014, Hayton et al., 2016] and the conflict-of-laws texts [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008]. **It contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction.** Every enactment, decided case, article number, rate and formality described below is described from the source manuscript, left uncited, and itemised in Appendix B. Where a table would otherwise score a named jurisdiction on a characteristic the bibliography cannot support, the jurisdiction is de-identified — "Gulf centre A" — following the convention of Curzi [2026]. **The abstract names the two jurisdictions the source works from; Sections 4 to 8 refer to them functionally, and Section 3.6 states why.**

No distributional or scaling claim is made anywhere. The exposure vectors here have four and six entries; they are not samples from a distribution. Clauset et al. [2009] is the procedure

that would have to be run before any heavy-tail claim could be made about holdings, and it is not run because no such claim is made.

2. Hypotheses

Five hypotheses, each with what would falsify it, in the form Platt [1964] requires. Meehl [1967] is the standing warning that a directional prediction here is nearly costless; H2, H3, H4 and H5 make point predictions with constants attached. One of the five is reported in Section 9 as **not met in the sense the argument wanted**.

H1 — the recognition hypothesis. An apex whose mechanism is the division of legal and beneficial ownership carries a recognition dependency that an apex with separate legal personality does not, and that dependency is not captured by the concentration instrument. *Predicted:* on a constructed family map, the count of non-common-law touchpoints — persons or assets sitting in states whose law does not know the ownership split — is strictly positive and material, while the effective bloc count is identical under both apex forms. *Falsified by:* a legal system in which the ownership question put to a foreign court closes identically for a relationship and for a registered legal person; or by a concentration measure that registers the difference.

H2 — the minimum-efficient-scale hypothesis. A fixed-fee apex has a scale below which it is the more expensive form, and that scale is computable rather than arguable. *Predicted:* $Q^{*} = C_{\text{fixed}}/b$, so at $C_{\text{fixed}} = 120{,}000$ the crossovers are USD 34.3 million at $b = 0.0035$, USD 80.0 million at $b = 0.0015$, and USD 120.0 million at $b = 0.0010$. *Falsified by:* a fee structure in which the fixed-cost form is cheaper at every scale — which a fixed-fee trustee mandate supplies, and which is why H2 is stated as a scale result rather than as a recommendation.

H3 — the two-exposure hypothesis. The forced-heirship exposure and the inheritance-tax exposure are independent quantities and the second is frequently the larger. *Predicted:* on the constructed case, a situs-capped levy of $\min(60.00\text{m}, 6.70\text{m}) = 6.70$ against a tax exposure of approximately $0.45 \times 60.00 = 27.00$, a ratio of 4.03. *Falsified by:* a case in which the structure's treatment of the reserve also changes the heir's tax position, which would mean the two are not independent.

H4 — the liquidity hypothesis. Where the reserve remedy is monetary, the binding constraint on a holding structure is liquidity and not entitlement. *Predicted:* a claim of USD 60.00 million against liquid assets of USD 26.16 million leaves a shortfall of USD 33.84 million, 14.1 per cent of the estate, exceeding every single liquid holding and forcing the disposal of an operating branch. *Falsified by:* a structure in which the monetary claim is satisfiable from liquid assets, or a system in which the remedy is in kind — in which case the exposure is an ownership problem and this hypothesis does not apply.

H5 — the apex-neutrality hypothesis. The choice of apex vehicle does not change the effective bloc count. *Predicted:* the conventional structure measures a naive index of 0.2934 and 3.41 effective jurisdictions against a bloc index of 1.0000 and $N = 1.00$, and those figures are invariant under substitution of the apex form. *Falsified by:* any apex vehicle whose substitution changes N while the branch jurisdictions and their shares are held fixed.

Not hypotheses, and labelled as such. Four statements in this paper are not falsifiable as written.

- *That a foundation is the correct apex for the carried case* is a **modelling conclusion** drawn from H1 together with a constructed family map. Change the map and the conclusion changes; it is not a general claim about instruments.
- *The cost figures* — USD 120,000, USD 65,000, the three fee bases, the USD 240 million estate — are **constructed illustrations**, not quotations, and H2's crossovers are exact functions of them.
- *The identification of the reserve fractions, levy conditions, tax rate and Sharia shares* is **description from the source manuscript**, uncited, and is treated throughout as an input

to arithmetic rather than as a finding.
- *The parameter set of the surplus law*, $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$, is a **modelling choice** carried from Curzi [2026] and fixed in advance, following the preregistration discipline of Nosek et al. [2018].

3. Method

3.1 The apex in the storage law

The framework's surplus law is $h = \eta \ln N - \delta Q - C$, with Q the protected capital held under durable protection, δ the erosion rate, η the conversion of flow into stock, C the recurring maintenance cost and N the effective count of independent coordination perimeters. Curzi [2026b] states the gauge in full and supplies the result this paper needs most: **conversion composes multiplicatively through recording, binding and reach gates**, so three gates at 0.7 give $\eta = 0.343$, and the weakest gate dominates — moving the recording gate from 0.20 to 0.80 gains 300 per cent while moving the binding gate from 0.60 to 0.90 gains 50 per cent. **An apex is a recording gate.** Its job is to make the structure recordable as an owner in every register that must record it, and on the multiplicative composition that is the gate with the highest available return precisely because it is the one most often left low.

An apex enters the law twice and with opposite signs. It permits a distribution across perimeters to be held as one owner, which is a precondition for $N > 1$; and it costs registrar fees, a registered agent, council fees, accounting and counsel in several jurisdictions, which raises C. **The apex does not itself raise N, and Section 8.5 measures that directly rather than assuming it.**

Curzi [2026] supplies the accounting discipline this paper applies to the cost side: the carrying cost of a structure is paid in four currencies — coin, hours, attention and foreclosure — against a law under which felt comfort decays over weeks while carrying cost does not decay at all. **The USD figures below are the coin column only.** The hours and attention consumed by an apex are real, are not modelled here, and the omission is recorded in Section 12. The foreclosure column — what holding this form forecloses — is the migration and conversion analysis of Section 5.5.

Curzi [2026] supplies the framing the whole paper presupposes: the present arrangement is a local minimum of the cost landscape by definition rather than by luck, which is why an apex that has stopped being appropriate continues to feel settled from inside it, and why the decision procedure of Section 6.8 is run on a map rather than on an impression.

3.2 Which effective count, and what it does not measure

Every effective count in this paper is HHI^{-1}, the Hill number of order two, and it is named as such at each use. Hill [1973] defines the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types that would produce the observed index; at $q = 2$ that is exactly $(\sum_i p_i^2)^{-1}$. Jost [2006] is the statement that entropies are not diversities and their numbers-equivalents are; Adelman [1969] is the numbers-equivalent reading of the concentration index itself; Simpson [1949] and Laakso and Taagepera [1979] are the independent reinventions in ecology and political science. The index is due to Hirschman [1945] in root form and to Herfindahl [1950] in sum-of-squares form.

The corpus's affine count $N_{\text{eff}} = 1 + (N-1)u$ is a different quantity, is not a Hill number of any order, and carries no external support. It is not used in this paper. Curzi [2026] prices the axiom that produces it exactly: the alternative $F_{\text{alt}}(u) = u \ln N$ satisfies the other three axioms and agrees at both endpoints, yet differs by 33.62 per cent at $u = 0.5$ — 1.871802 against 1.242453. **A functional form that is pinned at its endpoints and free by a third in the middle is a design choice, not a derivation**, and that pricing is the reason this paper stays with the Hill number.

The general form the bloc collapse relies on is EFF $= 1/(w'Rw)$, the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012] whose additive relative is the quadratic entropy of Rao [1982]. Curzi [2026] owns that identity; this paper consumes it. Hurlbert [1971] is the standing discipline: "diversity" carries no content without its formula attached, which is why the formula is attached here every time.

What the instrument does not measure is the subject of H1. EFF $= 1/(w'Rw)$ is a statistic of an exposure vector and a correlation matrix. Neither object contains any information about whether the *form of ownership* asserted over those exposures is intelligible to the courts and registries that must record it. A recognition dependency is therefore invisible to the measurement, and Section 8.5 shows that it is invisible in the strong sense: the numbers are identical under both apex forms.

3.3 The crossover model

The cost comparison is a one-line model and its transparency is the point. Let C_{fixed} be the annual cost of a fixed-fee apex and b the *ad valorem* fee basis of the alternative, expressed as a decimal fraction of assets under trusteeship. The alternative costs bQ. Setting the two equal:

```
C_fixed = b Q*        =>        Q* = C_fixed / b
```

Q^* is a **minimum efficient scale**: below it the fixed-cost form is the expensive one. The model has exactly two parameters, both constructed, and no free parameters at all. Its limits are run in Section 12.3.

The same shape governs compliance architecture generally, and Curzi [2026] reaches it from a different direction: a compliant multi-jurisdiction architecture costs 224.40 basis points a year at USD 25 million and 22.44 at USD 250 million, so that **compliance-based architecture has substantial fixed costs and therefore a minimum efficient scale, below which the correct advice is a simpler structure rather than a cheaper version of a complex one.** That two independent cost models produce the same result is worth stating; it is not additional evidence, because both are constructed from the same premise that the numerator is fixed.

3.4 The two-exposure decomposition

Two numbers are computed separately because they are different problems that the same conversation usually merges.

```
E_reserve   the maximum value a forced-heirship or family-provision
            claimant could extract, under the law that would apply,
            CAPPED BY WHAT THAT LAW CAN ACTUALLY REACH -- which for a
            levy on local assets is the value of the local assets and
            not the notional entitlement.

E_tax       the tax an heir bears on what she receives, computed under
            HER OWN residence rules, which are independent of the
            succession law and of the structure.
```

The decomposition is not a refinement; it is the difference between measuring the exposure a structure can address and the exposure it cannot. **A structure can eliminate the first entirely and leave the second untouched, and the second is often the larger number.** H3 states that as a prediction with a ratio attached.

3.5 Where the reflexive loop enters, and why it is not identified

The framework's central formal object is the reflexive loop $T(x) = W(x, M(x))$ of Curzi [2026], and it enters this paper at one specific place: **an apex is a governance instrument, and a governance instrument changes the behaviour of the people it governs.** A family charter that records an equalisation alters what each heir expects, which alters what each will accept, which alters what the charter needs to record.

Manski [1993] proves that a linear-in-means reflexive specification of that kind is **not identified from observational data**: the endogenous effect cannot be separated from contextual effects or from correlated unobservables, however much data is collected. **No observation of family behaviour under a governance instrument could therefore confirm that the instrument produced the behaviour.** The remedy adopted here is the fourth of the four known ones — the reference group is stipulated and the stipulation defended — which is the route Brock and Durlauf [2001] shows can be made rigorous, and **the price is that every claim in this paper about what a governance document achieves is a modelling position rather than an identified empirical result.**

The performative form of the same problem is live and is documented in this paper's own domain. MacKenzie and Millo [2003] traces a model that did not fit its market when published and came to fit it after adoption; Hacking [1995] gives the general looping form, in which a classification interacts with the people classified. **A decision procedure that tells families to prefer foundations where non-common-law touchpoints exceed a threshold will, if adopted, change which forms banks and registrars are equipped to process, which changes the touchpoint cost, which changes the threshold.** Lucas [1976] states the severe consequence for the parameters. **The framework asserts that systems change when modelled and then exempts its own parameters from that reflexivity; that is an inconsistency and it is not resolved here.**

3.6 Evidence standard, and the de-identification convention

Sections 4 to 7 are comparative legal exposition. **Every enactment, decided case, article number, rate, fraction, formality and jurisdictional characteristic in them is described from the source manuscript and is not cited to the bibliography.** The general instruments and comparative doctrine named in Section 1 are cited where they bear; nothing else is.

The jurisdictions the abstract names are the ones the source manuscript works from: a statutory private foundation enacted in 2018 in a common-law enclave within a Gulf financial free zone, and the reserve, compensatory levy and inheritance tax of one continental European system. Sections 4 to 8 refer to them functionally — "the apex jurisdiction", "the forced-heirship state" — for one reason only: **a functional description cannot be misread as a statement of that jurisdiction's law, and a named one can.** No claim is thereby hidden; every proposition is in the text, and Appendix B names what must be confirmed. Where the source names a jurisdiction in a way that carries information the argument needs — the increased-monitoring period of Section 4.2, for instance — the name is used.

Two consequences follow and both are applied without exception. **First, no proposition of law below is asserted as a finding of this paper.** Each is an input to arithmetic or to a decision rule, and Appendix B lists every one that requires confirmation against a primary source. **Second, where a table scores a named jurisdiction on a characteristic the bibliography cannot support, the jurisdiction is de-identified.** The apex jurisdiction in the twelve-item assessment of Appendix C appears as **Gulf centre A**, following Curzi [2026], which de-identified the two Gulf centres in its own scoring table for the same reason. **Where a jurisdiction is named in prose it is named because the source names it, and the accompanying description carries the same uncited badge.**

4. What an apex must do

Four requirements, stated before any instrument is chosen, because the commonest error in this field is buying an instrument for a job it does not do.

4.1 An apex must be a person, not a relationship

A common-law trust is a relationship with no legal personality. The trustee owns the property at law; the beneficiaries hold equitable interests; the trust itself is not a thing that can be introduced to a company registrar, a notary or a bank onboarding team without a long conversation. That conversation is survivable in a common-law financial centre. It is expensive in a civil-law one, difficult in several Asian jurisdictions, and in some it produces a result nobody intended, because the local court has no category for an owner who is not the owner.

A foundation is a legal person: registered, named, chartered, capable of being the shareholder of record, of signing, of suing, and of being recognised by a legal system without that system first having to accept the division of legal and beneficial ownership. **Recognition of a foreign legal person is close to universal; recognition of the trust's ownership split is not, and the gap between those two facts is the whole argument of Section 6.**

For a family entirely inside the common-law world this requirement carries no weight. For the carried case — a dual national, Gulf tax resident, three heirs in three jurisdictions, one under a forced-heirship regime, assets in five states — it carries most of it.

4.2 An apex must sit outside the coordinating perimeter

Curzi [2026] identifies the coordination perimeter as the correct unit of analysis for concentration risk and shows that an entity map reading 3.4085 effective jurisdictions collapses to exactly 1.0000 effective perimeters. **That mechanism is not evaded by moving between two jurisdictions inside one perimeter.** Those are rearrangements inside a bloc, and rearranging inside a bloc does not change N.

A bridge-bloc apex is not a claim that its jurisdiction is beyond regulatory pressure — the source records a period of increased monitoring for the Gulf jurisdiction in question, from March 2022 to February 2024, and that record is described rather than cited. It is a claim about the *coordination* variable: that the jurisdiction responds to standard-setting and peer-review processes on its own timetable [Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2017], maintains relations across blocs that no member of the Western perimeter maintains, and is not subject to that perimeter's listing mechanism [de Goede, 2011].

4.3 An apex must be governed by a court that publishes

Neutrality is worth nothing without enforceability. **A jurisdiction outside the coordinating perimeter but with an unpredictable judiciary is a worse asset than a coordinated jurisdiction with a good one, because the failure mode is uninsurable.** The disputes an apex actually generates are governance disputes — whether a councillor was validly removed, whether a distribution was properly made, whether a reserved power was exercisable, whether a beneficiary may see the accounts — and they are decided by a court reading a charter and a statute. **A court that publishes its reasoning is a court whose future behaviour can be priced, and that is the only sense in which legal risk is ever insurable.**

The court described in the source is an English-language common-law court within a civil-law federal state, established by enclave legislation, with an international bench and an opt-in jurisdiction permitting unconnected parties to confer jurisdiction by written agreement. **Its**

constituting instruments, its bench composition, its enforcement protocol with the surrounding onshore courts and the current position on onward enforcement are described from the source and are Appendix B items 3 and 4.

4.4 The founder must be able to keep his hands on it — within limits

This is the requirement that gets misused, so it is stated with its limit attached. Statutory foundation regimes commonly permit the founder to reserve powers, and that is a material advantage over a traditional discretionary trust, where extensive settlor control is a well-known route to a sham finding.

But a power reserved under the apex jurisdiction's law is valid under that law and is simultaneously a fact that every other jurisdiction with a claim on the founder will use against the structure. Reserved powers create corporate-residence exposure where the founder sits, attribution under several civil-law regimes, and alter-ego arguments in creditor litigation — and they do nothing whatever against the failure mode that has actually destroyed offshore structures in the recorded case law: a court with personal jurisdiction over the founder ordering him to unwind it. Curzi [2026] carries that record.

4.5 The job, stated narrowly

```
DOES:
  hold      -- own subsidiary shares as a single perpetual owner
  continue  -- survive the founder's death without probate in five places
  insulate  -- keep the operating businesses from fragmenting among heirs
  travel    -- present as a legal person in every legal family
  govern    -- give a written constitution to family capital decisions

DOES NOT:
  hide      -- registered, charter filed, ownership particulars recorded
  defeat    -- a court with jurisdiction over the founder is not stopped
  exempt    -- no tax is removed where the family or the assets are
  operate   -- no substance, no staff, no trade
  bridge    -- not a payments entity
```

Run the disclosure test of Curzi [2026] against that list. Every item in the first block survives disclosure without alteration. **Perpetual single ownership works *better* when it is publicly known**, because the registrar in one state and the bank in another can both see who the shareholder is and stop asking. The apex is an instrument designed to be looked at, which is the open-design principle of Kerckhoffs [1883] — a system's effectiveness must not depend on the secrecy of its design — restated as *open design* among the protection principles by Saltzer and Schroeder [1975], and applied here to a legal rather than a cryptographic system. Brandeis [1914] is the public-interest form of the same observation from the other direction.

5. The instrument: a statutory private foundation

Everything in this section is described from the source manuscript. No statute, article number, regulation or case is cited, and Appendix B lists each item requiring confirmation.

5.1 The ownerless owner

Three forms of holding entity exist and the differences are structural rather than cosmetic.

```
COMPANY      members own it; ownership transfers; value accrues to
             owners; the death of an owner moves shares.
TRUST        no legal personality; trustee holds legal title;
             beneficiaries hold equitable interests; a relationship
             governed by equity and the trust instrument.
FOUNDATION   legal personality; NO members, shareholders or owners;
             an endowment given legal form and a purpose; governed by
             charter and council, not by owners.
```

The last line is the one to sit with. **A foundation is an *ownerless owner*.** Once the founder endows property to it, that property belongs to the foundation; there is no residual shareholder to whom it reverts, no share register to inherit, no equity to be seized as an asset of the founder's estate, and no member whose divorce, bankruptcy or death moves a block of ownership.

That single characteristic — property with a legal owner but no beneficial owner in the proprietary sense — is what allows a family enterprise to survive three generations without being cut into pieces at each one. It is also exactly what makes tax authorities and compliance officers attentive, and why the disclosure architecture around foundations has tightened everywhere. The structure must be built to withstand the second fact while capturing the first.

Separate legal personality is what does the work. The apex may in its own name hold property, hold shares in companies in any jurisdiction, enter contracts, open accounts, sue and be sued, and appear as the registered shareholder in a foreign register. **Four ownership filings in four jurisdictions that agree with each other is a compliance asset, not a compliance cost.** This is asset partitioning performing the function Hansmann and Kraakman [2000] identifies as the irreducible contribution of entity law; Pistor [2019] is both the best scholarly account of how legal coding creates capital and its sharpest critique, and both readings apply here.

A foundation may be established for a purpose, for beneficiaries, or for a combination. **A purpose foundation has no beneficiaries and therefore nobody with a proprietary claim** — no interest for a creditor of a beneficiary to attach, none to be valued in a divorce, none forming part of a deceased beneficiary's estate. What exists instead is, at most, an expectancy. A beneficiary foundation is easier to bank, to explain and to administer. The combined form — purpose in the charter, discretionary class in the by-laws — is the usual answer for a family enterprise and is what the carried case uses. **The trade-off is enforceability: where nobody has a proprietary claim, nobody has obvious standing to enforce the charter against a delinquent council.**

5.2 Charter and by-laws: a disclosure design, not a hiding place

The constituting document is filed with the registrar; by-laws, where used, are held privately by the foundation and its registered agent.

```
CHARTER  (filed, obtainable)
  name; objects in general terms; initial endowment; the existence
  and composition of the Council; the Guardian if any; the registered
  agent/office; duration; amendment mechanics; what happens to assets
  on winding up.

BY-LAWS  (private, held by the foundation and its agent)
  the beneficiary class and how it is defined; distribution standards;
  the Council's internal procedure; the founder's reserved powers in
  operative detail; appointment and removal machinery; the succession
  of Council and Guardian; investment and reserved-matter policy.
```

The temptation is to put everything sensitive in the by-laws and treat them as unreachable. **They are not.** The registered agent holds them under regulatory obligation; the home court

can order their production; a properly framed exchange-of-information request [Organisation for Economic Co-operation and Development, 2017] can reach them; a bank will require sight of them at onboarding and retain a copy. **Treat the by-laws as private but discoverable, and draft every line to be read aloud in a courtroom by an unfriendly advocate. A structure that fails when the by-laws are read is a concealment structure and fails the disclosure test by construction.** The legitimate use of the split is narrower: it keeps sensitive family information out of a register anyone can search, while keeping every element available to any authority with a proper basis to ask.

The organs. The *Council* governs, holds and administers the property, and is bound to act in accordance with the constituting documents. Council composition is the most consequential choice after the drafting itself, because **the Council is what a foreign court will look at when it asks who actually controls the assets.** The *Guardian* supervises, holding the Council to the charter, with consent typically made a condition of specified powers; in a purpose foundation the Guardian is the enforcement mechanism that the absence of beneficiaries removes. **The design error is appointing the founder's oldest friend and giving him a consent right over everything**, which produces a rubber stamp — worse than nothing, because it manufactures a paper trail of approvals that were never scrutiny — or a deadlock. The *Registered Agent* maintains the address, holds the statutory registers, makes the filings, and **is the practical disclosure surface of the whole structure.**

5.3 Founder control, and what retaining it costs

The powers a founder is commonly advised he may reserve include appointing and removing councillors; appointing and removing the Guardian; amending the constituting documents; adding or excluding beneficiaries; directing or vetoing distributions; approving disposals of core assets; consenting to a change of governing law or domicile; and appointing a successor to his own reserved powers.

Now the price, which is the part usually omitted.

Residence. Most tax systems locate a legal person where it is centrally managed and controlled, whatever its place of registration. **If the founder holds a veto over every distribution and the Council does what he tells it from a house in a high-tax country, an assessing authority there has a serviceable argument that the foundation is resident with it. The registration certificate does not answer that argument.**

Attribution. Several civil-law systems attribute the income of a foreign foundation directly to its resident founder or beneficiaries, by rules that key on control and on entitlement. **Reserved powers strengthen every such argument.**

Alter ego. In creditor and matrimonial litigation the question is whether the entity is genuinely separate from the individual. **A founder who reserved the power to direct distributions to himself, and exercised it, has supplied the answer.**

Succession. Reserved powers are personal. Unless expressly made transmissible with a named successor they may lapse on the founder's death — the intended design, or an accident that leaves the Council unconstrained at the worst moment.

The disciplined position is a graded reservation. **Reserve the powers that protect the structure from the Council; give away the powers that would let the Council be described as your agent.**

```
RESERVE (low attribution cost, high protective value)
  appoint and remove councillors, subject to Guardian consent
  appoint the successor Guardian
  consent to amendment of the OBJECTS
  consent to disposal of a CORE holding
  consent to change of governing law / transfer out

DO NOT RESERVE (high attribution cost, low protective value)
```

```
    power to direct a distribution to a named person
    power to direct a distribution to the FOUNDER
    general power to revoke the foundation and take the assets back
    standing veto over ordinary investment decisions
    power to add oneself to the beneficiary class

  DECIDE WITH COUNSEL IN EVERY RELEVANT JURISDICTION
    power to add or exclude beneficiaries
    power to amend the by-laws
```

The two "decide" items are genuinely borderline: useful, and exactly the powers that attribution and alter-ego arguments feed on. **The answer depends on where the founder and beneficiaries are resident, and it is not a question about the apex jurisdiction at all.**

5.4 The firewall, and its real reach

Foundation and trust statutes in this field commonly contain firewall provisions: rules that questions of the entity's validity, the transfer of property to it, and the rights of beneficiaries are governed exclusively by local law, and that inconsistent foreign judgments and foreign law — expressly including foreign forced-heirship rules — are not given effect locally.

IT BINDS	IT DOES NOT BIND
the home court	any foreign court
a claim brought at home	a claim brought elsewhere
the disposition of home-situs assets	assets situated elsewhere
the internal validity question	the founder's personal obligations

The asymmetry is the point. A firewall is a rule addressed to the local judge. It has no addressee abroad. A civil-law court ruling on a locally situated asset will apply its own law; a court in the founder's residence asked to make orders against him personally will make them.

The firewall's genuine function is narrower and still valuable. It makes the home layer resistant to a claimant who must at some point come to the home forum to make a claim bite on the shares, and it converts a claim that would otherwise be executed by registrar entry into one that must be litigated under the home law. **That is a real change in cost and odds. It is a friction and a forum, not a shield, and any adviser who describes it as a shield is selling something.**

The record says the same from the other direction, and Curzi [2026] carries it: the strongest non-recognition statute anyone drafted failed repeatedly against contempt power, because the target of the order was the principal and not the structure.

5.5 Migration, and why it is a resilience feature

Statutory foundation regimes commonly provide for the continuation of a foreign foundation inward and for transfer outward. **Continuation is not a transfer of assets — the entity changes its governing law while retaining its legal identity, so contracts, shareholdings and bank relationships survive the move without novation.**

This is an under-used resilience feature: the apex is not irreversibly committed. Build the path in at inception: an express charter power to transfer out and change governing law; an identified consent-holder for that power, which should not be the founder alone; a shortlist of destination regimes checked for continuation-in capability; and subsidiary constitutional and finance documents that do not contain change-of-domicile default triggers. **Point four is where this normally fails: a facility agreement at one subsidiary with a broadly drafted change-of-control clause can make the apex immovable.**

6. Foundation against trust

The claim of Section 4.1 was made without being tested. This section tests it, and the test has to be honest, because the trust is not a weak instrument. It is the most refined asset-holding device the common law produced, it has four centuries of precedent behind it, and in a large class of cases it beats a foundation outright [Hayton et al., 2016].

The argument defended here is narrower than "foundations are better".

> **The trust's central mechanism — the separation of legal and beneficial ownership — is a peculiarity of one legal family, not a feature of law in general. A structure whose apex depends on that separation being recognised has a recognition dependency, and a recognition dependency is a form of concentration the instrument of Curzi [2026] does not capture.**

6.1 The counter-position, stated fairly

Precedent. Trust law is dense with decided cases on almost every question a family will ask: what a trustee must do, what a beneficiary may see, how discretion is reviewed, what happens when a trustee goes wrong, how a mistake is unwound [Hayton et al., 2016]. Statutory foundation law is thin. **When something unexpected happens inside a trust there is usually an answer. When something unexpected happens inside a foundation there is often only a statute and an argument.**

Flexibility. A trust can be created by declaration in an afternoon, varied by the court under established doctrines, divided, merged and appointed onward with a fluency no registered entity matches. A foundation is an entity: it files, it registers, it amends by formal process.

Fiscal familiarity. Trusts are old enough that most tax systems have decided what to do about them, however unpleasant that decision may be. Foundations are frequently unclassified, and **uncertainty is itself a cost**.

So the correct question is not which instrument is better. It is: which legal families must recognise this arrangement, and what is the cheapest form that all of them can recognise?

6.2 Where the split comes from, and why the civil law cannot easily see it

The trust is a historical accident that turned into an engineering achievement. Its ancestor is the medieval *use*: land conveyed to one person to hold to the benefit of another. The common-law courts recognised only the legal owner; the Chancellor would compel the legal owner to honour the arrangement. **Two jurisdictions grew up side by side and the property came to have two owners of different kinds.** It was not designed; it emerged from a court system with two benches applying two bodies of doctrine to the same res [Lupoi, 2000].

The doctrine that grew on that root is genuinely powerful — the rule that beneficiaries of full age and capacity holding the entire beneficial interest may collapse the trust and demand the property is a statement about who really owns a thing, and has no equivalent in company law. **But every part of it presupposes a court that recognises equity as a source of proprietary rights. Take that away and the trust does not degrade gracefully. It becomes unintelligible.**

Three features of the civil-law inheritance stand in the way [Smith, 2013]. *Unitary ownership*: ownership is conceived as a single indivisible right, with lesser rights over the thing enumerated as encumbrances rather than as a second ownership of a different kind. *Numerus clausus*: the catalogue of real rights is closed, and parties may not invent new proprietary interests by contract. *No equity*: there is no separate jurisdiction of conscience producing a parallel set of proprietary remedies.

Put an ordinary discretionary trust in front of a court in that tradition and the plausible characterisations are all unsatisfactory. It may be read as a *mandate*, which makes the property the settlor's and defeats the point; as a *simulation*, a sham disguising continued ownership; as a local statutory fiduciary device, on that statute's terms rather than the deed's; or the

disposition may fail for want of a recognised form. **None of those readings gives the family what the deed said it would get, and the family usually discovers which one applies at the worst possible moment.**

6.3 What the civil law and the Islamic tradition built instead

The traditions are not without answers, and understanding them is what makes a foundation-based structure legible [Panico, 2014].

A **French-style fiduciary transfer** moves assets to a fiduciary who holds them in a segregated patrimony for a defined purpose; it was built for security and management, and gratuitous use is excluded, so it is not a succession instrument. A **German-style Treuhand** is contractual, not proprietary: protection against the fiduciary's creditors is limited and contested, and there is no proprietary tracing remedy of the common-law kind. A **Dutch-style administration foundation** holds shares and issues depositary receipts to the former holders, separating voting control from economic entitlement — a civil-law solution to the problem the voting trust solves in the common law, achieved through legal personality. **Latin American** codes contain statutory trust-like devices, usually requiring a licensed institution as fiduciary and constrained in duration and purpose. The **Islamic endowment** dedicates property in perpetuity, immobilising the corpus and directing the usufruct to beneficiaries or charitable objects under an administrator.

Look at that list and the pattern is visible. Every legal family solved the problem of property held for others and separated from its provider — and only the common law solved it by splitting ownership. Everyone else solved it either by contract or by creating a legal person.

6.4 The recognition convention, and its four limits

The obvious objection is that international law has already fixed this. The Convention on the Law Applicable to Trusts and on their Recognition [Hague Conference on Private International Law, 1985] exists precisely to make trusts recognisable in non-trust states. It is a real and useful instrument and it does not fix the problem, for four reasons.

Ratification is limited. The Convention is in force for a modest group of states. **Several of the largest civil-law economies, and the Gulf states, are not parties, and the countries where recognition is hardest are largely the countries that did not join.** The current status table should be checked against the depositary's own records before any state's position is relied on (Appendix B, item 12).

Recognition is a floor, not a transplant. A contracting state must recognise that trust assets constitute a separate fund, that the trustee may sue and be sued as trustee, and that the trustee may appear before notaries and authorities in that capacity. **That is meaningful and it is not the same as importing the whole of equity**: the recognising state is not required to give the beneficiary the proprietary remedies a common-law court would give.

The mandatory-rules carve-outs are wide. The Convention preserves the recognising state's mandatory rules in designated fields — **succession rights, including indefeasible shares, is one of them** — and preserves overriding mandatory provisions and public policy. **The very rules a family is often hoping to navigate are exactly the rules the Convention leaves untouched.**

A ratifying state proves the point in reverse. One contracting state developed a domestic practice of internal trusts — settlor, assets and beneficiaries all local, governed by a chosen foreign trust law and recognised through the Convention. It works, and it has generated three decades of national litigation about when it works. **That a device requires a specialist national jurisprudence to explain its own validity is the recognition dependency, visible.**

6.5 Why legal personality travels

Recognition of a foreign legal person is not a special regime; it is ordinary private international law, and it is close to universal [Torremans et al., 2022, Fawcett and Carruthers, 2008]. Every state has rules for determining the existence, capacity and internal governance of a foreign entity, and the two classical approaches — the incorporation theory and the real-seat theory — both produce recognition of a properly constituted entity in the ordinary case. The practical position across the developed world today is that a properly constituted foreign legal person is recognised as a legal person.

```
TRUST presented to a non-trust court
  question 1: does this system recognise a division of ownership?
  question 2: if not, what is this instead?
  question 3: who, in our categories, owns the assets?
  -> the answer to (3) is frequently "the settlor" or "the trustee
     personally", and both are wrong for the family.

FOUNDATION presented to the same court
  question 1: is this a validly constituted foreign legal person?
  question 2: yes -> it owns its assets.
  -> the ownership question is CLOSED at step 2. What remains is
     whether local mandatory rules reach the founder's TRANSFER to
     it, which is a real question but a DIFFERENT and SMALLER one.
```

The foundation removes the dependency, and it does not remove it by being cleverer; it removes it by being boring. A registered legal person with a charter, a council and an address is a category that exists in every legal system on earth. Nobody has to be persuaded of anything.

There is a name for that property in the literature on how institutions cooperate across incompatible frames. Star and Griesemer [1989] and Star and Ruhleder [1996] develop the **boundary object**: an artefact plastic enough to be adapted to local needs and robust enough to maintain a common identity across communities that do not share a conceptual scheme. **A registered legal person is a boundary object between legal families, and a trust is not**, because the trust demands that the receiving community adopt the sending community's conceptual scheme before the artefact can be read at all. That is the sharpest available statement of this paper's H1 and it comes from a literature with nothing to do with law.

6.6 Recognition is not enforcement, and the difference costs money

There is a second question underneath the first that is routinely collapsed into it, and collapsing them produces structures that are conceptually sound and practically unenforceable.

Recognition asks whether the foreign court accepts that the entity exists and owns its assets. Enforcement asks whether an order obtained by that entity, or against it, is given effect where the assets or the counterparty are. **A structure can be recognised everywhere and enforceable almost nowhere, and the family discovers the difference on the day it needs a court rather than a registrar.**

For the trust, a trustee suing to recover trust property in a civil-law state must first establish its standing, which Hague Conference on Private International Law [1985] supplies in contracting states and does not supply elsewhere. **In a non-contracting state the trustee's capacity to sue as trustee is a preliminary question decided under that state's own conflict rules, and losing it is not a defeat on the merits — it is a defeat before the merits.**

For the foundation, standing is straightforward. But the judgment it obtains, or the one obtained against it, then has to travel, and judgment travel is governed by treaties and reciprocity rules that have nothing to do with foundations. **The treaty layer is thinner than practitioners assume.** The choice-of-court instrument [Hague Conference on Private International

Law, 2005] gives effect to exclusive choice-of-court clauses and the resulting judgments among contracting states; the judgments instrument [Hague Conference on Private International Law, 2019] does the broader job. Both have limited and slowly growing membership, and — **this is the point that matters for a succession structure — both exclude from their scope the subject matter a family structure is most likely to litigate.** Wills and succession, family law and matrimonial property are carved out. The commercial arbitration route is the exception that proves the rule: awards travel under United Nations [1958] with near-universal adherence [van den Berg, 1981, Born, 2021], on a procedural framework the surveyed regimes largely share [United Nations Commission on International Trade Law, 1985] — **and family succession disputes are not arbitrable in most of the systems that matter.**

Two consequences for the design, running in opposite directions.

The first favours the foundation. If the whole governance layer — charter disputes, the family agreement between the heirs, shareholders' agreements with co-investors, services agreements with advisers — sits under one court chosen by written agreement, then the disputes the apex actually generates are heard in one forum, under one law, with no cross-border enforcement step at all. **Most apex litigation is internal, and internal litigation does not need a treaty; it needs everybody to have signed up to the same court in advance.**

The second is the honest limit. Where the dispute is not internal — a claim by a foreign heir, a creditor or a divorcing spouse, brought where that person lives — no amount of forum drafting helps, because the claimant did not sign the charter and is not bound by its jurisdiction clause. **A smaller fight in an unfriendly forum is a real improvement over a larger one, and it is the entire benefit. It is not immunity, and Section 7 shows exactly where it stops.**

6.7 The Islamic tradition, on its own terms

Islamic-law jurisdictions deserve treatment on their own terms rather than as an appendix to the civil-law discussion, because the reasoning is different. The tradition has its own long-established endowment institution: property dedicated in perpetuity, corpus immobilised, usufruct directed to named beneficiaries or charitable objects, administered by an appointed administrator. **It is not a marginal institution.**

The objection to the common-law trust in this context is often described as religious hostility. **That is not accurate and it is not useful.** The genuine frictions are two and both are technical. *The ownership split has no place to sit*: the tradition, like the civil law, works with a unitary conception of ownership, and the dedication of property to an endowment is analysed as ownership passing out of the founder's hands entirely, with no beneficial owner in the equitable sense. *The fixed shares are mandatory*: the inheritance rules allocate fixed fractional shares among defined heirs and the freedom to dispose by bequest is limited, so **a discretionary trust that removes property from the estate and then distributes on a trustee's discretion is not a variation on that system; it is a different system.**

What the foundation offers here is not evasion of any of that. It is legibility. A foundation is an endowment with a purpose, a corpus, an administering body and beneficiaries — structurally the same shape as the indigenous endowment, expressed in a modern registered form. That does not make fixed shares go away. It does mean the *instrument* is intelligible to the court rather than requiring the court to import a doctrine it does not have. **This is the boundary-object property of Section 6.5, arriving in a third legal family.**

6.8 The comparison, and the decision procedure

dimension	trust	foundation	which matters when
legal personality	none	yes	whenever a registrar, notary or bank must record an owner
ownership model	split legal/beneficial	unitary, held by the entity	whenever a non-common-law court is involved
recognition outside the common law	convention-dependent, patchy	ordinary conflict-of-laws recognition of a legal person	civil-law and Sharia-influenced jurisdictions
depth of precedent	four centuries	statute plus a short case list	novel disputes; trustee misconduct; variation
settlor / founder control	reserved powers permitted in many regimes, but control is the classic sham risk	reserved powers expressly contemplated; the entity persists regardless	where the principal will not let go
perpetuity	perpetuity rules apply unless abolished	perpetual by default	multigenerational holding
non-charitable purposes	beneficiary principle bites; needs a purpose-trust statute and an enforcer	purpose foundations are ordinary	orphan and stewardship structures
public filing	usually none	charter filed; register searchable	where the family values privacy over legibility
creditor and matrimonial attack	rich doctrine both ways	thinner doctrine; alter-ego arguments run in the founder's home court	contested-family situations
tax classification abroad	usually settled, often unfavourable	frequently unsettled	several major systems
migration	change of proper law and trustee	statutory continuation, retaining identity	jurisdiction-degradation planning
ongoing cost	trustee fees, often *ad valorem*	registrar, agent, council, audit	small structures
court of first resort	the trust's proper-law court	the foundation's home court	governance disputes

Three rows carry most of the decision: recognition outside the common law, depth of precedent, and tax classification abroad. A family whose members and assets are all inside the common-law world should take the four centuries of precedent and use a trust. A family that is not should weigh the recognition row more heavily than everything else, because it is the row that produces irreversible outcomes rather than expensive ones.

```
THE DECISION PROCEDURE
1  MAP THE PEOPLE. For the founder, spouse, and every beneficiary or
   likely beneficiary in the next two generations: state of residence;
   nationality(ies); legal family of that state; forced-heirship
   exposure; whether that state is a recognition-convention party.
2  MAP THE ASSETS. For each: situs; legal family of the situs state;
   movable or immovable; whether the register will accept a trustee
```

```
   designation.
3  COUNT THE NON-COMMON-LAW TOUCHPOINTS.
     zero                      -> trust, almost certainly
     one, low-value            -> trust with a local-law patch
     two or more, or any
       material asset or heir  -> foundation apex
     fixed-share-jurisdiction
       heir or asset           -> foundation apex
4  CHECK THE TAX CLASSIFICATION of the chosen form in every state
   identified at step 1. This is where step 3 sometimes gets
   overturned.
5  CHECK THE OPERATIONAL LAYER. Will banks, custodians and registrars
   in the asset states onboard the chosen form? Ask before drafting.
6  DECIDE, AND WRITE DOWN WHY. The memorandum of reasons is worth more
   in ten years than the structure chart.
```

Step 4 deserves emphasis because it is where the elegant answer meets the fiscal one. A structure that is conceptually correct and produces punitive treatment for one family member has not solved the problem; it has moved it.

The hybrids. *Foundation over trust* is the right answer where the family is mixed: the apex is legible everywhere, and branches with common-law beneficiaries get the flexibility and precedent of trust law where it is actually useful. *Trust over foundation* is usually a legacy shape and inherits the recognition problem at the top, where it does the most damage. *Foundation as protector or enforcer* is a small, cheap use of the form that solves a disproportionate amount of trouble, because individuals die, emigrate, fall out with the family and lose capacity, and a foundation in that role is perpetual with its own succession mechanism. *The voting/economic split* — an entity holding shares and issuing depositary receipts — is available through a foundation in most jurisdictions where control should stay consolidated while economics descend normally.

Neither instrument survives the founder treating it as a pocket. The doctrines have different names — sham and illusory trust on one side, alter ego and abuse of legal personality on the other — and they converge on the same test: *did the arrangement ever really transfer anything?* **A foundation is not a way to keep control while appearing to give it up. It is a way to give up ownership while retaining a defined and disclosed governance role. If that distinction is not acceptable to the principal, neither instrument will work and the money spent on either is wasted.**

7. Succession: the transfer question

Every other threat in the register is a risk. Succession is a certainty with an unknown date. Expropriation may never happen. A creditor may never sue. A bank may never de-risk the relationship. The founder will die, and on that day every connecting factor in the structure is tested at once, in several jurisdictions, by people who did not choose each other and who are grieving.

That certainty ought to make succession the best-planned exposure in any structure. It is usually the worst, for a reason that is psychological rather than technical: **a principal will spend eighteen months and serious money on a threat with a two per cent annual probability and will not spend an afternoon on the one with a probability of one.**

Section 6 closed on the distinction that organises everything below. A foreign court accepts at step two that the foundation is a legal person and owns its assets. That closes the ownership question and leaves standing a different and smaller one: **whether the *transfer* by which the founder endowed it is one that the court's own mandatory rules reach. Forced heirship lives entirely inside the transfer question, and a structure built on the assumption that legal personality answered it will fail in the one forum where it cannot afford to.**

7.1 Three systems, one problem

Three families of law answer *how much of a person's property may he give away by choosing* in three incompatible ways.

The common law starts from testamentary freedom, subject to statutory family-provision jurisdictions under which a court may award reasonable financial provision to a defined class. That is a discretionary remedy on application, not a fixed share, and **the difference between a discretion and a share is the whole of the practical difference between the systems.**

The civil law starts from the opposite premise. A fixed fraction of the estate is reserved to defined heirs by operation of law; the testator may dispose freely only of the remainder; and the reserve is not a claim the heir must persuade a court to grant.

Islamic law starts from a third place, and it is not a variant of the second. The fixed shares allocate the whole estate among a defined set of relatives in stated fractions, and the freedom to dispose by bequest is confined to one third and may not ordinarily be directed to a person who already takes a fixed share.

The three systems do not differ in degree. They differ in what a will is: a disposition in the first, a disposition of the free portion in the second, and an instrument operating within a distribution that has already been made in the third.

7.2 The civil-law reserve: two features that matter more than the fractions

It is computed on a reconstituted mass, not on what is left. Civil-law systems do not permit the reserve to be emptied by lifetime giving. The estate is reconstituted for the computation by adding back qualifying lifetime gifts. **A founder who gives away ninety per cent of his property and dies with ten has not reduced the reserve; he has reduced the fund from which it will be paid, which is a different and worse position.**

The remedy differs, and the difference is decisive for structuring. In some systems the reserve is satisfied in money; in others the heir may reach the property itself in the hands of the person who received it. **A monetary claim is a liquidity problem. A claim in kind against a third-party transferee is an ownership problem, and only the second can break a holding structure.**

The reference system for the carried case fixes the reserve at one half of the estate with one child, two thirds with two, and three quarters with three or more, the balance being freely disposable. Reduction of excessive gifts is, since a reform of 2006, ordinarily made in **value** rather than in kind — the recipient keeps the property and owes an indemnity. **That single reform is the most important structural fact about that system's forced heirship for anyone building a holding structure, and it is routinely omitted from summaries that lead with the fractions**, because it converts most of the exposure from an ownership problem into a liquidity problem.

A second civil-law system takes the monetary route further: the compulsory portion is a claim in money against the estate equal in value to half the intestate share, the claimant is not an heir, and lifetime gifts are addressed by a supplementary claim reaching gifts made within ten years of death **on a sliding scale reducing the included value by one tenth for each elapsed year.** That system is the clearest illustration of the general rule that **in civil-law forced heirship the planning instrument is time, and the calendar is a statute rather than a matter of judgment.**

Two further systems sit closer to the ownership end, with reduction actions that can in defined circumstances be pursued against third parties who acquired from the donee, subject to statutory time limits, and with regional variation in the fractions within a single state. All of the foregoing is described from the source; the articles, periods and current texts are Appendix B items 5 to 8.

7.3 Fixed shares, and what completeness does

The Islamic law of inheritance is a complete distributive system rather than a restriction on testation, and **treating it as "forced heirship with different numbers" produces bad structures.** Shares go to a defined set of relatives in stated fractions with residue passing to residuary heirs; a bequest is capped at one third; and a bequest may not ordinarily be made to an heir who already takes a fixed share, except with the consent of the other heirs given after death.

The interaction with a holding structure is usually missed. A lifetime gift that is complete — with delivery and the taking of possession — generally removes the property from the estate before the shares are computed. So does a properly constituted endowment. **The Islamic system's own planning instruments are completeness and timing, the same two the civil law uses, and both are the opposite of concealment: a gift that is concealed is a gift that was not delivered, and a gift that was not delivered is not a gift.**

7.4 Usufruct: the civil law's own time-splitting device

A reader who has followed Section 6's argument may conclude the civil law has no way of separating enjoyment from ownership over time. **It has an excellent one: ancient, inside the closed catalogue of real rights, and registrable.** Usufruct splits a thing into the right to use and take the fruits, held by the usufructuary, and the bare ownership, held by the bare owner; on the usufructuary's death the usufruct extinguishes and the bare owner's ownership becomes full without a further transfer.

The structuring consequence is direct. **A parent may give the bare ownership of an asset to a child now, at a value discounted to reflect the retained usufruct, and keep the income and use for life. The gift is complete when made — which starts every claw-back clock — while the parent's economic position is largely intact.** This is the civil law's answer to the life-interest trust, it achieves most of the same result, and it requires no recognition argument of any kind.

Two cautions belong with it. **The valuation of the split is usually fixed by a statutory scale keyed to the usufructuary's age rather than left to the parties**, so the discount is not a negotiating variable. And several systems contain anti-abuse provisions aimed at arrangements separating usufruct from bare ownership within a family, which can reverse the intended treatment.

Every one of the three legal families has an indigenous device for separating enjoyment from ownership across time. Only the common law did it by splitting ownership itself, and that is Section 6 restated in the succession context.

7.5 Which law applies, and the levy that follows successful planning

Two structural choices divide the world's systems. **Unity or scission**: a unitary system applies one law to the whole succession; a scission system applies the personal law to movables and the law of the situs to immovables. **Under a scission system land is governed by where it is, always, and no amount of planning at the personal level changes that** — which is the technical reason that converting immovable property into securities is a succession instrument and not merely a liquidity one. **The connecting factor**: systems differ over whether the personal law is that of nationality, domicile or habitual residence, and the three can point to three different laws for the same person.

The regional succession regulation [European Union, 2012] is the governing framework for any structure with an affected heir: the law of the deceased's habitual residence at death governs the succession as a whole, displacing scission for participating states; a person may choose the law of a state of his nationality; the chosen or applicable law governs the disposable part and the reserved shares; the designated law applies whether or not it is the law of a participating state; and a designated law may be refused application where manifestly incompatible with the forum's public policy. **That the absence of a succession convention in force [Hague Conference on Private International Law, 1989] is why the problem persists outside**

the regional framework is worth stating: the global instrument exists and never entered into force, and the gap it left is the conflict-of-laws problem the whole of this section is about.

The most important practical question under that framework is **whether the *absence* of a reserve in a chosen foreign law is itself contrary to the forum's public policy.** The source records two decisions of a national supreme court in September 2017 holding in substance that a foreign law knowing no reserve is not for that reason alone contrary to international public policy, with an indication that the position may differ where the excluded heir is left in need. **Those decisions, their docket numbers and their subsequent treatment are Appendix B item 6, and nothing here is a prediction of any outcome.**

Then the legislature answered. A 2021 enactment inserted a **compensatory levy**: where the deceased or one of his children is at death a national of or habitually resident in a participating state, and the applicable law provides no reserve, a deprived child may levy on assets situated in the forum state up to the value of the reserved rights she would have had. **It applies to successions opened after a stated date, and its own status is under active contest** (Appendix B, item 4).

Whatever its fate, its existence carries a lesson stated here as a general principle rather than a national curiosity:

> **A planning technique that reliably defeats a mandatory rule attracts a legislative response, and the response is usually retroactive in effect if not in form, because it applies to deaths occurring after enactment regardless of when the planning was done.**

That is the same degradation dynamic Curzi [2026] documents for haven jurisdictions, operating in a different field, and it is a specific instance of a general organisational result: **a rule adopted as a target ceases to be a good measure of the thing it was meant to track** [Goodhart, 1975, Campbell, 1979]. It is also the strongest single argument for building succession structures on levers the system itself provides — consent, timing, and completeness — rather than on levers that exploit a gap, **because the system does not legislate against its own instruments.**

7.6 The line: planning against defeat

Every lawful lever works by changing a fact the law makes relevant. Every unlawful one works by misrepresenting a fact, or by making a change that is not real. Four questions separate them and a structure must answer all four affirmatively.

```
1  IS THE CHANGE REAL AND LIVED?
   A change of habitual residence is a change in where a person
   actually lives. A declaration is not a change. The connecting
   factor is a question of fact decided on evidence a court can see.

2  WAS THE DISPOSITION COMPLETE?
   Did the transferor actually give up dominion? A gift with an
   undisclosed side agreement to return the property is a simulation,
   and every civil-law system has a doctrine to treat it as what it
   is. Reserving a usufruct is complete and lawful because the
   reservation is DISCLOSED and PRICED.

3  WAS IT DONE BEFORE THE CLAIM EXISTED, AND OUTSIDE THE CLAW-BACK
   WINDOW?  Timing is the substance of the lawful case.

4  WOULD IT BE DESCRIBED IDENTICALLY TO EVERY AUDIENCE?
   Would the planner, the heir, the notary, the tax authority and the
   judge each be given the same account of what was done and why?
```

Question 4 does the work. **Almost every unlawful succession arrangement has at its centre a document or a fact the family is unwilling to show to one specific person — usually the disinherited heir, sometimes the notary conducting the inventory. That unwillingness is the diagnostic. A lawful arrangement is one that the excluded heir may be shown in full, and which she may resent, and which nonetheless stands.**

lever	lawful form	unlawful form
residence	actually moving, and living there	declaring a residence not lived in
nationality election	electing the law of a state of which one is genuinely a national	electing a law of a nationality not held, or misdescribing the facts
lifetime gift	complete transfer, disclosed, valued, dated, outside the window	transfer with an undisclosed agreement to return or to continue enjoying
usufruct reservation	disclosed, valued on the statutory scale, registered	undisclosed side arrangement giving back more than the reserved right
asset conversion	genuinely selling immovable property and holding securities	nominal sale to a controlled entity with no real change
renunciation by an heir	formal advance renunciation with independent advice, in the statutory form	renunciation obtained by pressure, or without disclosure of the estate
life insurance	genuine policy, premiums proportionate to means, beneficiary designated	policy used as a wrapper for a transfer, premiums manifestly excessive
foundation endowment	real endowment, solvency recited, control graded and disclosed	endowment the founder continues to treat as his own account

Read down the right-hand column and one property is common to all eight: each unlawful form depends on somebody not knowing something. That is not a moral observation. It is the structural claim of Curzi [2026] — that a structure whose protective quantity is an adversary's ignorance has a quantity that is falling and cannot be replenished — reappearing in the one area of law where families most want it to be untrue. Curzi [2026] supplies the mechanism from a different domain: a spoken commitment is a performative aimed at the speaker, supported by consistency pressure, self-perception from overheard testimony, and the re-pricing of later defection. **A family disclosure that states what each heir will receive works the same way, and that is why the uncomfortable document is the high-value one.**

7.7 The lever set, and why consent is the universal instrument

Every lawful lever changes one of four things — who the relevant person is, where he or the asset is, when the disposition happened, or whether the claimant consents. **There is nothing else.**

```
WHO      nationality election where genuinely a national; the identity
         of the transferor -- a gift from a spouse's own property is
         not a gift from the founder's.
WHERE    genuine change of habitual residence; conversion of immovable
         to movable property, which removes an asset from a situs rule
         it cannot otherwise escape; the situs of the entity rather
```

```
          than the underlying.
WHEN      completed lifetime gifts, made early, outside every claw-back
          window; usufruct reservation, which completes the gift now
          while preserving the income.
WHETHER   the consent of the person entitled -- the only lever that
          works in all three legal families.
```

Each of the three systems provides a lawful mechanism by which the person entitled to a protected share may give it up, and each requires formality, independent advice, and full disclosure of what is being given up. One permits an advance renunciation of the reduction action in a specific notarial form; another permits a contractual waiver of the compulsory portion concluded with the future deceased and recorded before a notary; the third permits the heirs to settle among themselves after death by mutual agreement, and permits a bequest exceeding the cap, or a bequest to an heir, where the other heirs consent after death.

> **The lawful defeat of a protected share is consent, consent requires disclosure, and a family that cannot obtain consent has learned something true about itself that no structure will fix.**

Every lawful timing lever has a statutory clock and the clocks do not agree with each other. Build one calendar per heir jurisdiction with the transfer dates on it, and confirm in each what starts the period and whether a reserved usufruct or a retained benefit postpones the start. **A reservation of enjoyment frequently stops the clock from running at all, which converts the family's best lever into its worst, and it is the commonest technical failure in this field.**

8. Results

CONSTRUCTED CASE throughout. Every fact and figure below is invented for illustration. No real person, family, entity or transaction is described. Figures are illustrative and are not benchmarks or quotations.

The principal: a dual national, tax resident in a Gulf jurisdiction for eleven years, aged sixty-three. Three adult children — one resident in a common-law Asian centre, one resident and a national in a civil-law state with forced heirship, one resident in a common-law European state. Assets: a promoted manufacturing operation in a non-aligned state; a trading company in the Gulf; an IP portfolio; commercial real estate converted to a securities position; a listed-securities portfolio; a captive insurer; a fund vehicle. **Constructed total USD 240 million**, distributed on the designed allocation of Curzi [2026]:

branch	share	value (USD m)
Gulf holding and trading	29.1%	69.84
non-aligned manufacturing	18.2%	43.68
Western operating company	16.4%	39.36
Atlantic captive	13.6%	32.64
second non-aligned centre vehicle	11.8%	28.32
bridge treasury and listed securities	10.9%	26.16
total	**100.0%**	**240.00**

8.1 The touchpoint count, and H1

person / asset	state	legal family	recognition-convention party?	reserve?
founder	Gulf	civil / fixed-share influenced, with a common-law enclave	no	n/a as resident
child 1	common-law Asian centre	common law	yes	no
child 2	civil-law European state	civil law	signed, not ratified	**yes**
child 3	common-law European state	common law	yes	no
manufacturing operating company	non-aligned state	civil law	—	—
trading company	Gulf	civil / fixed-share	—	—
IP portfolio	enclave-held	common law	—	—

NON-COMMON-LAW TOUCHPOINTS              MATERIAL?   RESERVE RISK?
------------------------------------------------------------------
child 2, resident and national            yes         yes
founder's residence (onshore)             yes         no
manufacturing operating company           yes         no
trading company                           yes         no
------------------------------------------------------------------
COUNT                                      4
```

The decision rule of Section 6.8 is that two or more material touchpoints, or any fixed-share-jurisdiction asset or heir, points to a foundation apex. This case has four, one of them a forced-heirship heir and two of them assets in states that do not recognise the ownership split. The rule is not close to being tested here; it is answered several times over.

What happens at each touchpoint is the comparison that matters, because it is what a specific official in a specific office actually does:

touchpoint	trust apex	foundation apex
non-aligned company registrar, recording the operating company's shareholder	asked to record a trustee holding for beneficiaries it cannot categorise; likely records the trustee personally, which is not what anyone intended	records a named foreign legal person; the question closes
Gulf onshore registrar and bank, on the trading company	trust presented to an institution in a unitary-ownership system; long onboarding, possible re-characterisation	ordinary foreign shareholder; ordinary onboarding
civil-law court, on child 2's reserved-portion claim	must first characterise the trust and may conclude the settlor never parted with the property, which is the worst available outcome	accepts that the foundation owns the assets; the fight is about the founder's transfer, which is a narrower claim
civil-law tax administration, on child 2	its trust regime applies on its own definitional terms	classification genuinely unsettled
common-law-resident children	trust is ideal: precedent, flexibility, familiar taxation	foundation is unfamiliar but workable

Read the third row against the fourth. The foundation converts a recognition problem into a tax classification problem, and that is a trade the family should take, because a classification problem is expensive and a re-characterisation of ownership is irreversible. The threat taxonomy of Curzi [2026] governs the choice on recoverability rather than on expected cost.

H1 is supported on the touchpoint count and on the second half of its prediction, which Section 8.5 measures.

8.2 The cost crossover, and H2

The recognition argument is qualitative and the cost argument is not, so it is worth the arithmetic rather than an assertion that foundations are cheap.

apex annual cost, CONSTRUCTED	USD / year
fixed-fee foundation apex	
registered agent, registered office, filings	18,000
council fees, including one independent professional	45,000
accounting, audit, statutory registers	22,000
counsel retainer and annual document review	35,000
total	**120,000**
offshore discretionary trust, *ad valorem*	
at 35 bp on USD 240m	840,000
at 15 bp on USD 240m	360,000
at 10 bp on USD 240m	240,000
fixed-fee holding mandate (constructed)	180,000

CONSTRUCTED. Illustrative, not quotations. Trustee fee bases vary widely and a fixed-fee mandate for a pure holding structure is available in the market.

The foundation's cost is fixed and the *ad valorem* trustee's is not, so the comparison has a crossover rather than a winner. From $Q^{*} = 120{,}000/b$:

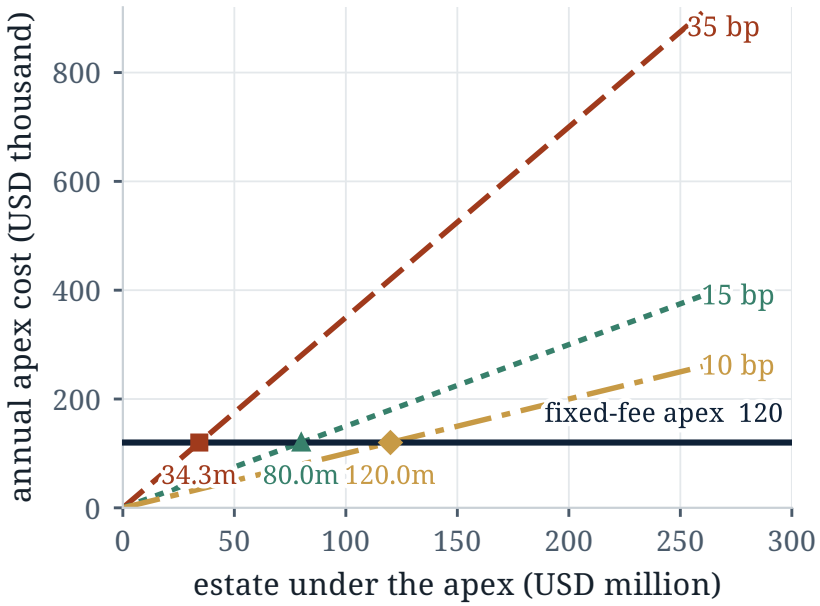

Figure 53.1: **The fixed-fee apex is the expensive form below its minimum efficient scale, and the scale moves by a factor of 3.5 across a fee band advisers treat as narrow: USD 34.3 million at 35 basis points against USD 120.0 million at 10.** Modelled from $Q^* = C_{\text{fixed}}/b$ with $C_{\text{fixed}} =$ USD 120,000 and the three CONSTRUCTED fee bases; script `figs/src/CCP-053_fig01.py`.

trustee basis b	foundation cheaper above
35 bp	USD 34,285,714 $\rightarrow$ 34.3 million
15 bp	USD 80,000,000 $\rightarrow$ 80.0 million
10 bp	USD 120,000,000 $\rightarrow$ 120.0 million

At the constructed USD 240 million the foundation costs $120{,}000/240{,}000{,}000 = 0.000500$, that is **5.0 basis points against the *ad valorem* trustee's 35, a difference of USD 720,000 a year.** Below roughly USD 34 million at a 35 basis point fee the arithmetic reverses and the fixed-cost apex becomes the expensive option. **H2's three crossovers are met exactly.**

The honest reading of the table, stated because it is the opposite of what the arithmetic flatters: cost is not the reason to choose a foundation on these facts, and a family that chooses one for the fee saving has chosen correctly for the wrong reason and will unwind it the first time an adviser quotes a fixed-fee trustee. The fixed-fee trustee mandate in the table costs USD 180,000 against the foundation's USD 120,000 — a difference of USD 60,000, which is a rounding error against the USD 27.00 million tax exposure of Section 8.3. **The reason to choose the form is the third row of the touchpoint table, and nothing in this section changes that.**

The design as built is the hybrid, and each layer must earn its cost:

```
FOUNDATION APEX                                   -- the apex
  combined form: stated non-charitable purpose in the Charter,
  discretionary beneficiary class in the By-laws
  JOB the other layer cannot do: be a recorded legal owner in a
      civil-law registry without a recognition argument
    |
    +-- GULF HOLDCO -- NON-ALIGNED OPERATING COMPANY
    +-- WESTERN OPERATING COMPANY
    +-- ATLANTIC CAPTIVE
```

```
+-- SECOND NON-ALIGNED CENTRE VEHICLE
+-- ENCLAVE TRUST                              -- one branch only
      holds the listed-securities portfolio for the two
      common-law-resident children
      JOB the other layer cannot do: give those two children
          four centuries of settled doctrine on trustee duty,
          review of discretion and information rights, in a form
          their own tax systems already know how to tax
```

Note what the trust is *not* asked to do. It does not hold the operating interests, holds nothing the forced-heirship claim would reach, and is not the apex. **The trust is used precisely where it is strong and nowhere else, and that is the argument of Section 6 stated as a structure rather than as a proposition.** The second layer adds a constructed USD 65,000 a year, taking the apex cost to USD 185,000, or $185{,}000/240{,}000{,}000 = 7.7$ basis points.

8.3 The two exposures, and H3

Notional entitlement. Had the forced-heirship law governed, the reserve with three children is three quarters of the estate — $0.75 \times 240.00 =$ USD 180.00 million — divided equally, so child 2's notional share is **USD 60.00 million**, with a disposable portion of USD 60.00 million.

$E_{reserve}$*, as found.* The founder owns an apartment in the forced-heirship state valued at EUR 6.20 million, held directly. At a constructed rate of USD 1.08 per euro that is USD 6.70 million. The compensatory levy of Section 7.5 permits a deprived child to levy on assets situated in that state up to the value of her reserved rights. **The levy is therefore capped by the local-situs assets, not by the notional entitlement:**

```
levy = min(60.00m, 6.70m) = USD 6.70m = 11.2% of the notional share
```

$E_{reserve}$*, as designed.* The designed distribution contains no asset situated in the forced-heirship state. On those facts the levy has nothing to attach to and recovers zero. **That result is a fact about the asset map, not a legal victory, and it survives exactly as long as the asset map does.**

E_{tax}. Child 2 has lived in the state for twenty years. Its inheritance tax reaches assets received by an heir resident for at least six of the ten years preceding the transfer, **wherever those assets are situated, and independently of the deceased's residence**. On a receipt of USD 60.00 million at the top marginal rate in the direct line the tax is approximately

```
0.45 x 60.00m = USD 27.00m
```

before the small relief given by the lower brackets and the per-child abatement.

exposure	amount (USD m)	reachable by the structure?
notional reserved entitlement	60.00	no — it is a computation, not a claim
E_{reserve} as found, situs-capped	6.70	yes — by the asset map
E_{reserve} as designed	0.00	achieved, and contingent on the map
E_{tax}	$\approx$ 27.00	**no**

```
E_tax      approx. USD 27.00m       ratio 27.00 / 6.70 = 4.03
E_reserve          USD  6.70m       as found -- zero as designed
```

H3's prediction is met at the stated ratio. The family's advisers had spent three years on the smaller exposure and had never computed the larger one, **and the larger one is the one the structure cannot touch.**

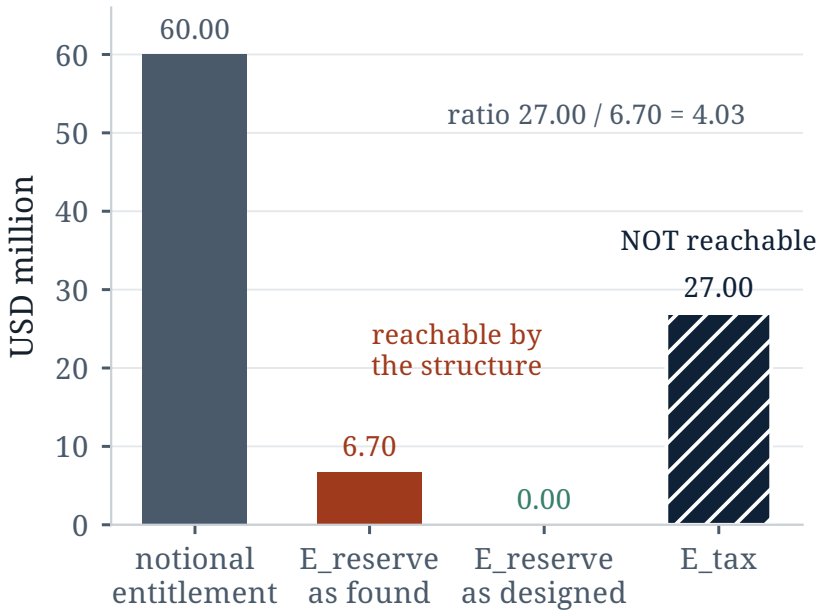

Figure 53.2: **The exposure the structure can reach is 6.70 and the exposure it cannot is 27.00, a ratio of 4.03 — and the family's advisers had spent three years on the smaller one.** Modelled from a situs-capped levy $\min(60.00, 6.70)$ against an inheritance-tax exposure 0.45×60.00; all parameters CONSTRUCTED. Script `figs/src/CCP-053_fig02.py`.

8.4 The liquidity test, and H4

Suppose child 2 is equalised toward her notional USD 60.00 million rather than litigated with. Liquid assets at death are the listed-securities position of USD 26.16 million.

```
claim                    60.00m
liquid assets            26.16m
shortfall                33.84m   =  14.1% of the estate
```

The shortfall is larger than any single liquid holding, and closing it in cash requires selling an operating branch — the Western position at USD 39.36 million or the Atlantic captive at USD 32.64 million. That is the fragmentation the apex existed to prevent, arriving through the succession rather than through the register. H4's prediction is met.

The lawful answers are all pre-funded: a policy written outside the estate, a sinking fund at the apex, an instalment arrangement documented before death, or an equalisation in specie of an asset the heir will take. The worked case uses a constructed policy benefit of USD 20.00 million with premiums proportionate to means, which reduces the cash shortfall to $60.00 - 26.16 - 20.00 = 13.84$ million, **5.8 per cent of the estate and within the range a sinking fund can carry.** The policy's own limit is that manifestly excessive premiums may be brought back into the mass, which is Appendix B item 9.

8.5 The apex does not move the concentration reading, and H5

The measurement of Curzi [2026] over the conventional four-jurisdiction structure:

```
AS FOUND
  UK             40.9%   perimeter = WEST
  US             27.3%   perimeter = WEST
  Jersey         18.2%   perimeter = WEST
```

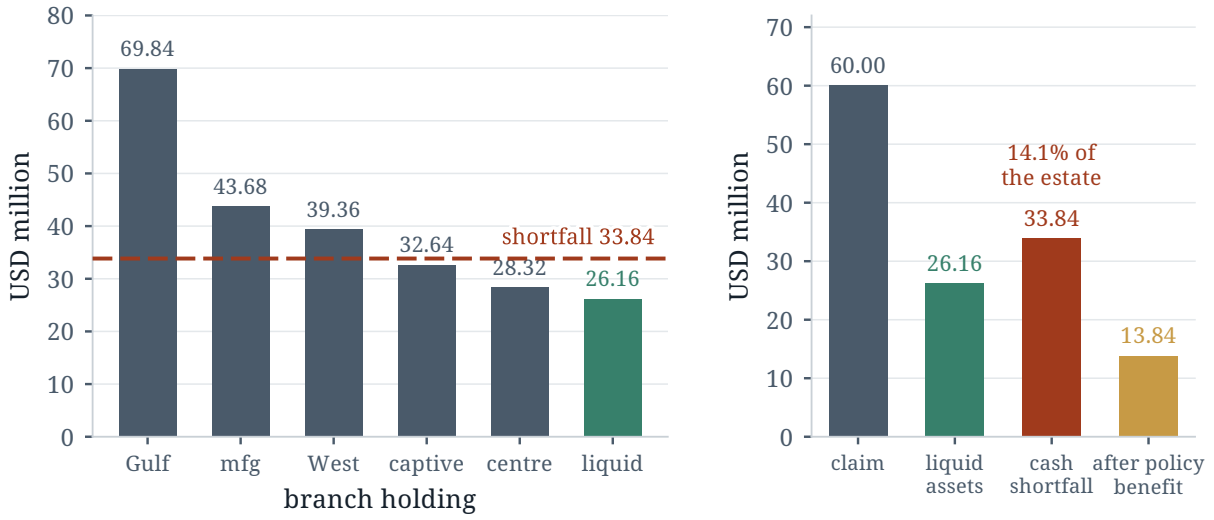

Figure 53.3: **Liquidity binds before entitlement does: the shortfall of 33.84 exceeds every liquid holding and is closed only by disposing of an operating branch, which is the fragmentation the apex was built to prevent.** Measured from the constructed branch allocation of Section 8 and the claim of Section 8.3; script `figs/src/CCP-053_fig03.py`.

```
  Luxembourg   13.6%   perimeter = WEST

  naive HHI = 0.2934   ->  effective jurisdictions = 3.41
  bloc  HHI = 1.0000   ->  EFFECTIVE PERIMETERS   = 1.00
  Western-perimeter exposure = 100.0%

AS DESIGNED (CCP-052)
  naive HHI = 0.1890   ->  effective jurisdictions = 5.29
  bloc  HHI = 0.3400   ->  EFFECTIVE PERIMETERS   = 2.94
  Western-perimeter exposure = 30.0%
```

Both readings are invariant under substitution of the apex form, because the effective count is a function of the exposure share vector and the correlation matrix and of nothing else, and neither object contains any information about the legal form of the owner. Substituting a trust apex for a foundation apex, or a company for either, leaves every share unchanged and therefore leaves HHI, N and $\ln N$ unchanged. **H5 is met, and it is met as an identity rather than as a measurement.**

That is the counter-result and it is the reason H1 exists. The apex produced none of the concentration numbers; the branch jurisdictions did. What the apex produced is the ability to hold six branch positions as one owner without cross-exposure, and to keep holding them through a death. **A structure element that does not move the concentration measurement is not thereby worthless; it is answering a different threat — and the corollary is that the concentration measurement is not a complete account of a structure's exposure.**

Two design rules govern the shape beneath the apex and both follow from the same instrument. *Hold, do not cross-hold*: each branch is held directly and holds no interest in any other, because cross-holdings convert several independent perimeter exposures into one, which is the error Curzi [2026] measures. *One layer of separation per job*: an intermediate holding company exists where a branch needs an owner that can execute shareholder actions, hold intercompany debt and be a joint-venture counterparty — jobs an apex should not do.

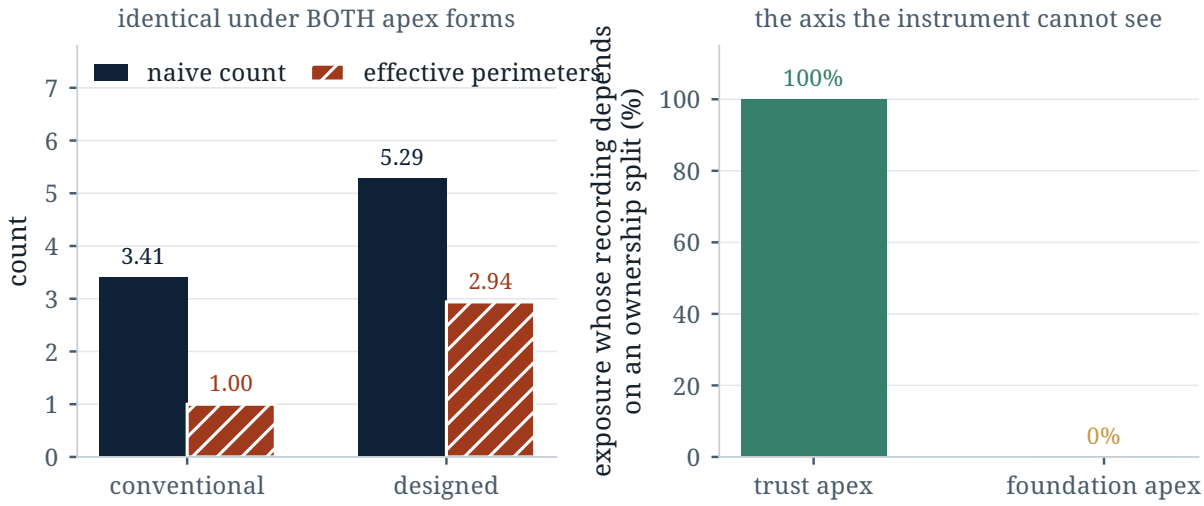

Figure 53.4: **The apex form is invisible to the concentration instrument and decisive to the recognition dependency: the effective count is identical under both apex forms, while the share of exposure whose recording depends on a foreign court accepting a division of ownership moves from 100 per cent to zero.** Effective counts measured from the share vectors of Curzi [2026] and Curzi [2026]; recognition-dependent share computed from the touchpoint table of Section 8.1. Script `figs/src/CCP-053_fig04.py`.

8.6 The Sharia counterfactual, and R5

CONSTRUCTED VARIANT. Suppose the same estate, with the founder's succession governed by fixed shares as applied in his state, survived by a widow, two sons and one daughter, with no election available.

taker	share	value (USD m)
widow	1/8 of 240.00	30.00
each son	2/5 of the residue 210.00	84.00
daughter	1/5 of the residue 210.00	42.00
total		**240.00**

The residue is $7/8 \times 240.00 = 210.00$ million, divided among two sons and one daughter in shares of $2:2:1$. Bequest is confined to one third — $240.00/3 =$ USD 80.00 million — and may not ordinarily be directed to a person already taking a fixed share without the consent of the other heirs.

The counterfactual's structural interest is that it is determinate rather than discretionary. There is no computation of a reserve against a reconstituted mass, no reduction action, no liquidity gap arising from a monetary claim of uncertain size: the whole estate is allocated by fractions known in advance. **A structure facing a fixed-share system knows its exposure exactly on the day it is built, which is the opposite of the civil-law position and is rarely stated.**

Two further observations. A completed lifetime gift, with delivery and taking of possession, generally removes property before the shares are computed, **so completeness is decisive here exactly as in the civil law.** And post-death settlement among heirs by consent is the same lever as the civil-law renunciation and the contractual waiver, arriving from a different tradition. **Consent is the universal instrument, and it is universal because each of these systems is protecting the heirs rather than the state.**

8.7 The disclosure test, applied in print

Would this structure still do its job if every element were disclosed to every authority with jurisdiction over any part of it?

- The charter is on a searchable register. Disclosure changes nothing.
- The by-laws and the trust deed would be produced on a properly framed request. Both contain a family beneficiary class and distribution standards, and neither contains an element whose function depends on not being read.
- Ownership particulars are already filed with the registrar; exchange reporting occurs by design [Organisation for Economic Co-operation and Development, 2017] and reaches the residence jurisdictions of the founder and beneficiaries. **This is anticipated in the planning, not defeated by the structure.**
- Every operating entity beneath the apex names the foundation in its own jurisdiction's ownership filings, and the filings agree with each other.
- The endowment deed, schedule, valuations and solvency recital would be produced to a notary conducting an inventory. They are dated, complete and consistent with the founder's later conduct.
- Child 2 has been shown the whole structure, has her own counsel, and has the schedule annexed to her renunciation. **The disclosure is the mechanism by which the renunciation becomes unattackable, not a cost paid to obtain it.**

The structure passes. **The two elements that would have failed it are the ones that were not built: a trust apex whose recognition in a civil-law forum depends on the court not looking too closely at what a discretionary trust is; and an undocumented understanding that child 2 would be "looked after separately", which would have been produced in the foreign proceedings as evidence that the endowment was never intended to be complete.**

9. Hypotheses tested, and what was not solved

H1 — supported, with the second half measured rather than argued. Four material non-common-law touchpoints, and an effective count identical under both apex forms (Section 8.5). The falsifier was a system in which the ownership question closes identically for a relationship and for a registered legal person; the touchpoint table of Section 8.1 gives four offices in which it does not.

H2 — supported exactly. $Q^{*} = 120{,}000/b$ gives USD 34.3m, 80.0m and 120.0m at 35, 15 and 10 basis points. **The hypothesis was stated as a scale result and not as a recommendation, and Section 8.2 refuses the recommendation the arithmetic appears to license.**

H3 — supported at the stated ratio. $27.00/6.70 = 4.03$.

H4 — supported. Shortfall USD 33.84 million, 14.1 per cent of the estate, exceeding every liquid holding.

H5 — met, and met as an identity rather than as a measurement. That distinction matters: **an identity cannot be evidence for anything.** H5 is true by the construction of the instrument, and its content is entirely in what that construction reveals about the instrument's blind spot rather than in the numerical result. **Reported here as a hypothesis whose confirmation carries no empirical weight, which is a weaker outcome than it looks.**

What the structure did not solve, stated plainly.

- **The tax exposure**, at roughly four times the reserve exposure, unchanged by anything in the structure and dependent only on where the heir lives.
- **The classification question** — whether a foreign regime for trusts reaches a foundation — which is unsettled in at least two major systems and changes the analysis materially either way.

- **The thin-doctrine risk.** Trust law has a doctrine, narrowed but real, for unwinding a fiduciary's mistaken exercise of a power. **A statutory foundation regime enacted in 2018 has no equivalent, and it is the one a family is most likely to need.** Where there is no doctrine to fix a mistake, the only available control is not making it. This is unpriced and does not go away with good drafting; it only becomes less likely to be needed.
- **The dependence on consent.** If the forced-heirship heir refuses to renounce, the plan reverts to the levy exposure, the liquidity shortfall and a contested estate. **There is no lawful substitute.**
- **The situs constraint**, which must be maintained as a standing investment restriction for the rest of the founder's life.
- **Apex concentration.** A structure with 2.94 effective perimeters on the asset side still has one governance point of failure: one entity, one registrar, one court, one country. The migration path manages it; it does not eliminate it.
- **The maintenance bill.** At the parameters of Curzi [2026] the designed structure gives $h = -0.122417$ against the conventional structure's -0.500000. **Both are below the build threshold: the redesign improved the position by a factor of four and did not make it positive.**

10. Failure modes

1. The alter-ego collapse. The founder reserves everything, directs everything, and treats the foundation's accounts as his own; a foreign court concludes the entity is a facade. *Diagnostic:* if the founder can obtain money from the foundation for personal use on his own signature, the failure is already present. *Mitigation:* the graded reservation of Section 5.3.

2. Residence by management. Nobody moves the foundation; it moves itself, by where its decisions are taken. The result is an apex tax-resident in a high-tax jurisdiction doing none of the compliance a resident entity performs — **worse than never having built it.** *Diagnostic:* count the last twelve council decisions and ask where each was actually made.

3. Reading the firewall as a shield. Section 5.4. *Diagnostic:* the plan has no answer to "what happens if a court orders the founder, personally, to procure a distribution?"

4. Assuming personality equals recognition of the internal arrangement. This is the most important failure mode in the paper and it is the honest limit on the whole argument. A foreign court will accept that the foundation exists and owns its assets. It does not follow that it will accept the consequences the family wants. It may apply its own mandatory rules to the *transfer*, and its own tax and attribution rules to the founder and beneficiaries as persons within its jurisdiction. **Legal personality closes the ownership question. It does not close the transfer question or the attribution question, and most of what goes wrong in practice is in those two.**

5. Choosing the foundation for a wholly common-law family. *Diagnostic:* run step 3 of the decision procedure and count zero non-common-law touchpoints. *Mitigation:* use a trust.

6. Relying on the recognition convention in a state that never joined it. The memorandum says the trust "will be recognised under the Convention", and nobody checks whether the states that matter are contracting states. **A convention binding four European states is of no assistance in the jurisdictions where recognition was the problem in the first place.**

7. Assuming the charter binds people who never signed it. A jurisdiction clause governs the founder, the councillors, the guardian and — with care — beneficiaries who accept benefits. **It does not govern a divorcing spouse, a trade creditor, a tax authority, or a reserved-portion claimant suing where she lives.**

8. The thin-jurisprudence gap. Section 9. **This is the trust's strongest argument and it is not answered here.**

9. The perpetual entity nobody can end. A trust has a doctrine under which beneficiaries of full age and capacity holding the entire beneficial interest may collapse it. A purpose foundation has nobody with standing to do the equivalent. *Diagnostic:* ask who, in twenty years,

could lawfully bring the structure to an end, and whether they would agree.

10. Assuming a trust converts into a foundation. It does not. What happens is a distribution or transfer to a newly formed entity, **which is a disposition — with the consequences of a disposition in every jurisdiction with a claim, and with a fresh transfer date restarting every claw-back clock the original settlement had already run down.**

11. Buying two layers and using neither. *Diagnostic:* for each layer, state in one sentence the specific job it does that the other cannot. If either sentence is difficult, the layer is decoration. **This is the specialisation discipline of Curzi [2026] applied to legal forms rather than to entities**, and the same result applies: the overloaded single entity is cheaper on direct cost and worse on conjunction.

12. Confusing the forced-heirship problem with the inheritance-tax problem. *Diagnostic:* the plan has one figure rather than two. *Mitigation:* Section 3.4.

13. Reserving enjoyment and stopping the clock. In several systems a retained benefit prevents the claw-back period from beginning at all. **Ten years of patient planning then count for nothing.**

14. The renunciation that is attacked by the person who signed it. Obtained in a family meeting, without independent advice or disclosure of the estate's value, in the wrong form. **It is set aside, and then becomes evidence of pressure.**

15. The heir who moves. The map is a photograph. A common-law-resident child who moves to a forced-heirship state in year eight changes the applicable law, the claw-back calendar and the tax exposure simultaneously, and nobody tells the adviser. *Mitigation:* an annual re-run with a review date.

16. Maintenance decay. C is paid for three years and then quietly stops being paid. Minutes stop being taken. The independent councillor resigns and is not replaced. Filings slip. **The structure looks identical on the register and has lost every substantive characteristic that made it defensible. This is the commonest failure of all, it is invisible until it is tested, and it is the reason the surplus law puts C on the right-hand side of the equation rather than treating it as a one-off cost of entry.** Cyert and March [1963] is the general form: organisational slack is what makes a system survive a shock it did not plan for, and it has always appeared on the accounts as waste.

11. Discussion

What follows. Three things, each narrower than the general claim it resembles.

A recognition dependency is a real form of concentration and it is invisible to the published instrument. Section 8.5 establishes this as an identity rather than as a measurement, and Section 12.4 records that the invariance responsible is a defect of the instrument for this purpose rather than a virtue. **The claim is not that the effective count is wrong; it is that it is a complete account of one axis and no account at all of another.** Curzi [2026r] reaches the same structural point in a different domain and is the sharpest available statement of it: **a pair in perfect opposition and a pair in perfect agreement both read $u = 0$, $N_{\text{eff}} = 1$ and surplus zero, because the extremality condition is stated on the squared alignment.** Two configurations that are maximally different in mechanism read identically on the instrument. **That is exactly what happens here when a trust apex and a foundation apex are put through the concentration measurement, and a reader who has met the result once in the corpus should recognise it the second time.**

The cost result is a scale result and not a recommendation. Section 8.2 computes the crossover and then refuses the conclusion it appears to license. **A model whose recommendation is eliminated by a competitor's pricing decision has not established the recommendation**, and Section 12.3 gives the limit that shows why.

Consent is the universal lever, and it is universal for a reason. Each of the three legal families protects the heirs rather than the state, so each permits the protected person to give

the protection up, and each requires disclosure to do it. **The lawful defeat of a protected share is consent, consent requires disclosure, and a family that cannot obtain consent has learned something true about itself that no structure will fix.**

What does not follow. Four things.

It does not follow that a foundation apex is generally correct. It follows on a map with material non-common-law touchpoints. **On a map with none, the four centuries of precedent are worth more than the recognition property, and Section 10 lists choosing a foundation for a wholly common-law family as a failure mode rather than as a preference.**

It does not follow that the apex improves resilience. R6. Curzi [2026] runs the same collapse on a different cluster and reaches the same shape: six Atlantic-cluster entities at 40.0 / 22.0 / 14.0 / 12.0 / 7.0 / 5.0 give a naive index of 0.249800 and 4.0032 effective jurisdictions, **but a bloc index of** 1.000000**,** $N = 1.00$ **and** $\ln N = 0$**.** No apex vehicle changes any of those figures. Curzi [2026] prices the most generous counterfactual available to a Western-perimeter structure — crediting a Crown Dependency group as its own bloc, at 81.8 against 18.2 — and obtains a bloc index of 0.702248, $N = 1.423998$ and $h = -0.376286$ against the designed structure's 2.941176 and -0.122417. **Even the most generous reading of a single-perimeter structure lands closer to the conventional case than to the designed one, and the apex form is irrelevant to that comparison.**

It does not follow that more branches are better. Curzi [2026] measures the case directly and it is the cleanest counter-example in the series: **adding two further Gulf jurisdictions raises the naive effective count from 5.29 to 7.13, a gain of 34.8 per cent, while the effective bloc count *falls* from 2.94 to 2.84, a loss of 3.4 per cent.** More jurisdictions, less independence. An apex that makes it administratively easy to add branches is therefore an instrument that makes it easy to do the wrong thing cheaply, **and the assignment discipline of Section 10 failure mode 11 is what stands between the two.**

It does not follow that the liquidity result is confined to succession. Curzi [2026] computes the same forced-disposal arithmetic on a pledge trigger: **the forced sale takes an 80 per cent holder to exactly** 50.000000 **per cent at a** 36.000000 **per cent drawdown, to** 38.095238 **per cent at 40 per cent, and exhausts collateral equity at 50 per cent.** The mechanism is identical — a claim in currency against a balance sheet of operating interests — and only the trigger differs. **A structure that has pre-funded its succession liquidity and not its pledge liquidity has solved half of one problem.**

Where the instrument's weakest gate sits. Curzi [2026b] establishes that conversion composes multiplicatively through recording, binding and reach gates, so the weakest gate dominates. Curzi [2026] makes the same point as a measurement on a twelve-step schedule: **the only gate acting on the numerator sits ninth of twelve and contributes** -5.305895 **octaves, 88.93 per cent of the schedule's total movement, against 11.07 per cent for the eight steps before it.** That is the shape of this paper's argument in a different register. **An apex is one step of a long build, it acts on the recording gate, and on the multiplicative composition almost all of the available movement is there — which is why the choice is worth an afternoon of decision procedure and why the ten steps of Appendix A are ordered as they are.**

The status of the claim is measurement and comparison, not physics. Hedström and Ylikoski [2010] states the criterion the discipline named in the corpus title applies: an explanation must name a mechanism rather than exhibit a fitted curve. **The mechanisms named here are a recording requirement, a fee structure and a distributive rule, and nothing is fitted.** No order parameter is identified, no phase transition is located and no critical exponent is estimated; the vocabulary of Castellano et al. [2009] is deliberately not used. Gallegati et al. [2006] is the checklist this paper was run against — ignorance of existing work in the target discipline, sub-standard statistical procedure, unjustified universality claims, and models built on assumptions known to be false — and Section 13 reports where it passes and where it does not.

12. Verification and rigour audit

12.1 Dimensional audit

symbol	quantity	dimension	unit	status
Q	estate value / protected capital	[currency] in Sections 8.2–8.6; $[C]$ index units in the surplus law	USD; index units	**two distinct quantities under one symbol, inherited from the source and flagged here**
C_{fixed}	fixed apex cost	[currency T^{-1}]	USD per year	assumed (constructed)
b	*ad valorem* fee basis	$[T^{-1}]$	per year	assumed (constructed)
Q^*	minimum efficient scale	[currency]	USD	derived, C_{fixed}/b
s_i	exposure share of branch i	[1]	dimensionless	defined; sums to 1
HHI	concentration index	[1]	dimensionless	derived from shares
N	effective perimeter count	[#]**, a count**	perimeters	derived as $\text{HHI}_{\text{bloc}}^{-1}$
E_{reserve}, E_{tax}	succession exposures	[currency]	USD	derived from constructed inputs
reserve fraction, tax rate, fixed shares	ratios	[1]	dimensionless	assumed; described from the source, uncited
η, δ, C, h	surplus-law terms	as in Curzi [2026]	index units	assumed

Does the crossover model balance? $Q^* = C_{\text{fixed}}/b$ divides a currency flow ([currency T^{-1}]) by a rate ($[T^{-1}]$) and returns a stock ([currency]). **It balances, and the balance is the content: a fixed flow divided by a rate is a stock, which is why a minimum efficient scale exists at all.**

Does the exposure comparison balance? E_{reserve} and E_{tax} are both currency stocks and their ratio is dimensionless. **They are commensurable in dimension and are not commensurable in kind**: one is a transfer between family members and the other is a payment to a state, and the ratio 4.03 should not be read as saying the tax is "four times worse". It says the family had allocated its attention to the smaller number.

The important row is the first, and it records a defect. Q denotes an estate in USD in Sections 8.2 to 8.6 and protected capital in unnamed index units in the surplus law. **The source uses one symbol for both and this paper does the same for continuity; the two are not interchangeable and no equation in this paper mixes them.** The break-even count of Curzi [2026] is unit-free and survives; the statement that $h = -0.122417$ does not mean anything until the index unit is defined, **and the source defines none.**

12.2 Significant figures and epistemic status

- $Q^* = 34{,}285{,}714$ is **exact arithmetic** on two constructed inputs and is printed as 34.3 million because three significant figures is all the constructed inputs can support. 80.0 and

120.0 million are exact.
- 5.0 and 7.7 basis points are exact arithmetic on constructed inputs, rounded hard.
- 6.70 million carries a constructed exchange rate and is quoted to the precision of that construction, no further.
- 27.00 million is **illustrative model output**: it applies a single top marginal rate to the whole receipt and the text says so, explicitly excluding the relief given by the lower brackets and the abatement. **Quoting it to the cent would be false precision and it is quoted to two decimals of a million because the input is stipulated at that precision.**
- 33.84 million and 14.1 per cent are exact arithmetic on stipulated inputs.
- The fixed shares — 30.00, 84.00, 42.00 — are exact rational arithmetic on exact fractions and sum to 240.00 exactly.
- 0.2934, 3.41, 1.0000 and 1.00 are quoted from Curzi [2026] at that paper's own precision. **Section 6.3 of that paper records that the naive figure depends on the rounding basis of the shares —** 0.293388 **on exact fractions against** 0.293430 **on three-significant-figure percentages — and this paper quotes to four decimals precisely so that it does not have to choose.** Every perimeter figure is exactly 1.000000 under every basis.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere. That is not a strength: it means the paper has no empirical content to attach an interval to.**

12.3 Limits and boundary behaviour

The crossover model.

limit	$Q^* = C_{\text{fixed}}/b$	reading
$b \to 0$	$\to \infty$	a zero-basis trustee is cheaper at every scale; the fixed-fee apex never wins on cost
$b \to 1$	$\to C_{\text{fixed}}$	at a 100 per cent fee the crossover is the apex's own annual cost, which is the degenerate case
$C_{\text{fixed}} \to 0$	$\to 0$	a free apex wins at every scale
$C_{\text{fixed}} \to \infty$	$\to \infty$	so does an infinitely expensive one lose
$Q \to 0$	—	the *ad valorem* form costs nothing and the fixed form costs C_{fixed}: **the fixed form is unboundedly worse in the small-estate limit, which is the domain statement**
$Q \to \infty$	—	the *ad valorem* form is unboundedly worse: **the model has no interior optimum and is monotone on each side of** Q^*

The model's domain is a positive fee basis and a positive fixed cost, and the crossover is a single point rather than a region. A fixed-fee trustee mandate — the fourth row of the cost table — destroys the crossover entirely by making both forms fixed, which is why H2 is stated as a scale result and not as a recommendation. **A model whose conclusion is eliminated by**

a competitor's pricing decision is a fragile model and the paper says so here rather than in a footnote.

The situs-capped levy. $E_{\text{reserve}} = \min(R, A)$ for notional reserved rights R and local-situs assets A. As $A \to 0$ the levy goes to zero and the structure appears to win completely; that limit is exactly the designed case and it is the most fragile result in the paper, because A is a decision variable the family can change accidentally by buying an apartment. As $A \to R$ the cap ceases to bind and the levy is the full notional entitlement. The function is continuous, piecewise linear, and has a kink at $A = R$; nothing in the structure changes the position of the kink.

The liquidity shortfall. $S = \max(0, K - L)$ for claim K and liquid assets L. As $L \to K^-$ the shortfall goes to zero continuously; as $L \to 0$ it goes to the whole claim. There is no discontinuity, and that is the finding: the structure does not fail at a threshold, it degrades continuously, and a family that funds half the shortfall has genuinely halved the forced disposal.

The concentration instrument's limits are the proof that it behaves as a count and are run in full by Curzi [2026]: HHI^{-1} returns exactly n for n equal shares and exactly 1 for a single holder, so $1 \le \text{HHI}^{-1} \le n$ with both bounds attained. Verified here on this paper's own vectors: the four-perimeter conventional collapse gives $1/1 = 1$ exactly, and a hypothetical four-way equal split gives $1/0.25 = 4$ exactly. A quantity that equals n for n equal units, equals 1 for one unit, and lies strictly between otherwise is a count.

The affine count fails the same limits. $1 + (N-1)u$ returns 1 at $u = 0$ and N at $u = 1$ for *any* share vector whatever, because it never consults the shares. Curzi [2026] prices the gap in the middle at 33.62 per cent. It is not used here.

12.4 Invariance

The effective count is invariant under relabelling and under any rescaling that preserves the share vector, which is why the same instrument applies to a USD 24 million estate and a USD 240 million one. It is also invariant under the substitution of the apex form, which is H5 and which is a *defect* of the instrument for this paper's purpose rather than a virtue. An invariance is only a good property when the thing held fixed is the thing one wants held fixed.

The crossover Q^* is invariant under currency redenomination — multiply C_{fixed} and Q by the same factor and Q^* scales with them — and it is not invariant under a change of fee structure, which is Section 12.3's fragility statement.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. The objection is met here twice and failed once. The exposure share vector is conserved: $\sum_i s_i = 1$ exactly, dimensionless, and it is that constraint alone that bounds the index. The Sharia allocation is conserved: $30.00 + 84.00 + 84.00 + 42.00 = 240.00$ exactly, which is the whole estate, and a distribution rule that allocates exactly the whole is a conservation law with a currency unit attached — the only one in this paper. The civil-law reserve is not conserved in the same sense, because it is computed on a reconstituted mass that includes property no longer in the estate, so the fractions do not partition anything that exists on the day of death. That asymmetry is a real structural difference between the two systems and it is the reason the fixed-share system's exposure is knowable in advance and the civil-law system's is not. Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law holds and stop claiming a universality the argument does not need.

Aggregation is unaddressed. Kirman [1992] establishes that a single representative parameter for a heterogeneous group generally does not exist, and this paper writes one Q, one δ and one C for a structure whose branches plainly differ. No aggregation argument is offered and none is available from the arithmetic.

12.5 Analogy discipline

borrowing	source	category	justification
Hill numbers, order 2	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* ${}^{2}D$; an identity
numbers-equivalent reading	Adelman [1969]	**1 — derivation**	the reciprocal of the index is the count of equal units giving that index
similarity-sensitive diversity	Leinster and Cobbold [2012], Rao [1982]	**1 — derivation**, with a stated domain	exact where the matrix has unit diagonal and non-negative entries
portfolio variance	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix
minimum efficient scale	none — deliberately	**not borrowed**	$Q^{*} = C_{\text{fixed}}/b$ is elementary algebra on two constructed numbers, imports nothing, and is cited to no source because none is needed
the boundary object	Star and Griesemer [1989], Star and Ruhleder [1996]	**2 — shared form**	a registered legal person is plastic locally and robust across communities; **no claim is made that legal families are scientific communities in that literature's sense**
open design	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	the disclosure standard *is* the open-design requirement applied to a legal rather than a cryptographic system
asset partitioning	Hansmann and Kraakman [2000]	**1 — derivation**	the foundation performs exactly the partitioning function entity law is identified as supplying
organisational slack	Cyert and March [1963]	**3 — framing**	qualitative, cited for the shape of the maintenance-decay failure and not as a formal result

borrowing	source	category	justification
the measure-as-target dynamic	Goodhart [1975], Campbell [1979]	**2 — shared form**	the legislative response to successful planning has the same shape; no monetary or evaluative content is imported

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration and crossover arithmetic is category 1 throughout and needs no help; the boundary-object and Goodhart borrowings are category 2 and are used for shape only.

12.6 Measurement-theoretic status of the scored inputs

Three inputs in this paper are scores or classifications rather than measured quantities.

The touchpoint count is a count of a nominal classification. "Non-common-law touchpoint" is a binary attribute of a person or asset, and counting instances of a binary attribute is licensed. **What is not licensed is treating the count as an interval quantity**: the decision rule of Section 6.8 uses thresholds at zero, one and two, and the text is explicit that a single *material* touchpoint outweighs several immaterial ones. **An unweighted count of non-exchangeable items supports a threshold and does not support a magnitude**, and it is used for nothing else.

The five disclosure criteria are binary and are combined by product, which is the one operation their scale type licenses. A conjunction of binary indicators is a binary indicator; their *average* is not a licensed statistic, and Curzi [2026] includes the average column explicitly to demonstrate that averaging them selects the wrong verdict.

The twelve-item jurisdiction assessment of Appendix C is ordinal at best and is not summed. Its items are heterogeneous — legal family, court quality, rail access, degradation trajectory — and no total is computed anywhere, because no common scale exists on which they could be added. **The assessment is a checklist that produces a verdict by argument, not a score that produces one by arithmetic, and it is presented that way.**

The framework's underlying treatment of Q as a ratio-scale quantity is not tested. Michell [1997] is the strongest available objection: psychology and its neighbours routinely assume quantitative structure without testing for it, and the formal remedy is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971], whose conditions establish whether an attribute has additive quantitative structure at all. **The conjoint conditions were not tested.** Here the objection has unusually limited bite, because Q in Sections 8.2 to 8.6 is a currency amount and currency is a ratio scale by construction. **It bites in full on the surplus law's Q in unnamed index units**, which is a different quantity under the same symbol (Section 11.1), and Curzi [2026t] is the corpus's own precedent for what to do about it: that paper **demotes the moment equation on the ground that its two inputs are not instrumented on a common ratio scale with a shared true zero, and withdraws the magnitude of their quotient as a measured quantity.** The same demotion applies to any statement here that mixes the two Qs, and no such statement is made.

12.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$; the effective count is its reciprocal	DEFINITION
P3	the effective count is a function of the share vector and the correlation matrix only	DEFINITION (this is what H5 consumes)
P4	a fixed-fee apex costs C_{fixed} and an *ad valorem* alternative costs bQ	DEFINITION (modelling choice)
P5	$C_{\text{fixed}} = 120{,}000$, $b \in \{0.0035, 0.0015, 0.0010\}$, $Q = 240{,}000{,}000$	POSTULATED (constructed)
P6	the reserve with three children is 3/4 of the reconstituted estate, divided equally	POSTULATED (described from the source, uncited)
P7	the compensatory levy is capped by local-situs assets	POSTULATED (described from the source, uncited)
P8	local-situs assets are EUR 6.20m at USD 1.08 per euro; the top marginal rate in the direct line is 0.45	POSTULATED (constructed)
P9	liquid assets at death are the listed-securities position, USD 26.16m	POSTULATED (constructed)
P10	the fixed shares are widow 1/8, residue to two sons and one daughter in 2:2:1	POSTULATED (described from the source, uncited)

12.8 The compounding chain

step	consumes	statement	status
L1	P2	HHI^{-1} returns n exactly for n equal shares and 1 for one holder	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	HHI^{-1} is the Hill number of order 2 — Hill [1973]	CITED
R5a	P3	substituting the apex form changes no share, so N is unchanged: 3.41 naive and 1.00 perimeters, whatever sits at the top	ARITHMETIC

step	consumes	statement	status
L4	P4	equating C_{fixed} and bQ gives $Q^{*} = C_{\text{fixed}}/b$	ARITHMETIC
R1	L4, P5	Q^{*} is 34.3m, 80.0m and 120.0m at 35, 15 and 10 bp	ARITHMETIC
R2	P5	the apex costs 5.0 bp against an *ad valorem* 35 bp; the annual difference is $720{,}000$	ARITHMETIC
L5	P6, P5	the notional reserved share is $0.75 \times 240.00/3 = 60.00$m	ARITHMETIC
R3a	L5, P7, P8	the levy is $\min(60.00, 6.70) = 6.70$m, $= 11.2\%$ of the notional share	ARITHMETIC
R3b	L5, P8	the tax exposure is $0.45 \times 60.00 = 27.00$m; the ratio to R3a is 4.03	ARITHMETIC
R4	L5, P9	the shortfall is $60.00 - 26.16 = 33.84$m, $= 14.1\%$ of 240.00m	ARITHMETIC
R5	P10, P5	widow $240.00/8 = 30.00$; residue 210.00; sons $2/5 \times 210.00 = 84.00$ each; daughter $1/5 \times 210.00 = 42.00$; total 240.00 exactly	ARITHMETIC
CR	R5a, R3b	the apex adds nothing to N and does not reach the larger exposure	ARITHMETIC

Every ARITHMETIC row can be redone by hand. Every CITED row names one source and no more. **Six of the ten postulates are POSTULATED, four of them constructed and two described from uncitable legal sources. A chain resting on six postulates is not a proof, and this paper says so here rather than leaving the reader to notice: the arithmetic is exact and every input is either invented or uncited.**

12.9 Cross-checks performed

- The branch values were recomputed from the share vector: $0.291 \times 240 = 69.84$, $0.182 \times 240 = 43.68$, $0.164 \times 240 = 39.36$, $0.136 \times 240 = 32.64$, $0.118 \times 240 = 28.32$, $0.109 \times 240 = 26.16$; the six sum to 240.00 exactly.
- The Sharia allocation was verified as a partition: $30.00 + 84.00 + 84.00 + 42.00 = 240.00$ exactly, in exact rational arithmetic.
- The three crossovers were recomputed from C_{fixed}/b and agree with the table to the printed precision; $120{,}000/0.0035 = 34{,}285{,}714.29$, printed as 34.3 million.
- $s_{\max}^{2} \le \text{HHI} \le s_{\max}$ holds on the conventional perimeter vector trivially ($1 \le 1 \le 1$) and on the designed branch vector: $0.084681 \le 0.189002 \le 0.291$.
- The liquidity result was recomputed with the constructed policy benefit: $60.00 - 26.16 - 20.00 = 13.84$, $= 5.77\%$ of 240.00, printed as 5.8 per cent.

13. Limitations

Every case is constructed. The principal, the family, the assets, the shares, the cost model, the exchange rate, the tax rate, the fee bases and the policy benefit are invented and are labelled as such at each point of use. **No empirical dataset was collected and none is reported.**

Jurisdiction-specific legal claims are not cited to primary sources. Every enactment, decided case, article number, reserve fraction, levy condition, formality, rate and jurisdictional characteristic in Sections 4 to 8 is taken from the source manuscript. **The bibliography contains no statutes, regulations, court rules, registries or case reports for any individual jurisdiction.** Appendix B lists the affected claims. **This is a real gap and it is not closed here.** It is also the paper's largest exposure, because the arithmetic of Sections 8.3 to 8.6 takes those legal propositions as inputs: **if the reserve fraction, the situs cap or the fixed shares are stated wrongly, every number downstream of them is wrong and the error will not show up as an arithmetic inconsistency.**

The cost result depends entirely on the fee assumptions and is destroyed by one competitor pricing decision. A fixed-fee trustee mandate makes both forms fixed and eliminates the crossover. Section 12.3 states this; **it is the reason H2 is a scale result and it is why the paper refuses the cost argument in Section 8.2 rather than banking it.**

The tax figure is a single-rate approximation and is labelled as illustrative. Applying one top marginal rate to a whole receipt overstates the liability by the amount of the lower brackets and the abatement. **The direction of the error is known and its size is not**, and the ratio 4.03 should be read as an order-of-magnitude statement rather than a measurement.

The designed case's zero levy is the most fragile result in the paper. It follows from the absence of any asset situated in the claimant's state, which is a decision variable the family can change accidentally. **The levy bites on assets situated locally *at death*, and a structure with no local situs today acquires one when someone buys an apartment, inherits a share of a family property, or moves a custody account.**

The apex-neutrality result is an identity and carries no empirical weight. H5 is true by the construction of the instrument. **Its confirmation is not evidence for anything; its value is entirely in what it reveals about the instrument's blind spot.**

The recognition dependency is not quantified. H1 is supported by a touchpoint count and a table of what four specific officials would do. **No cost, probability or magnitude is attached to a recognition failure anywhere in this paper**, so the trade-off between a recognition dependency and the trust's four centuries of precedent is argued qualitatively and not computed. **A reviewer would be right to press on this: the paper's central recommendation rests on the comparison it does not quantify.**

The thin-doctrine risk is acknowledged and unpriced. A statutory foundation regime has no settled equivalent of the trust doctrine for unwinding a fiduciary's mistaken exercise of a power, and that is the doctrine a family is most likely to need. **No probability or cost is assigned.**

The reflexive loop is not identified. Manski [1993] rules out recovering an endogenous effect from observation of a linear-in-means reflexive system, and a family governance instrument is such a system. The remedy adopted is stipulation with a defence [Brock and Durlauf, 2001]; **the price is that every claim about what a governance document achieves is a modelling position.**

The instrument is performative and its own parameters are exposed to that. MacKenzie and Millo [2003], Hacking [1995] and Lucas [1976]. **The framework asserts that systems change when modelled and exempts its own parameters from that reflexivity; that inconsistency is not resolved here.**

The corpus's own honesty apparatus bounds what this paper may claim. Curzi [2026] is the sharpest instance: the commons case there **passes the ceiling test with a margin of** $+0.058436$ **nats and is nonetheless practically unreachable, because no lever closes it — and a member's declining to participate improves the family reading by** 2.680588 **octaves.** That is the same

shape as this paper's consent result, arrived at in a different domain: **a formally available improvement whose only route runs through a person who may decline, and whose declining improves the measured quantity.** The corpus prints that arithmetic rather than avoiding it, and this paper is bound by the same standard.

Model comparison was not performed. No alternative apex model was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. **The crossover model has zero free parameters and two stipulated ones, which means it cannot be wrong in the way a fitted model can be wrong — and cannot be right in that way either.**

No differential prediction is offered. Durlauf [2005] asks for the prediction only this model makes, and neither the crossover nor the two-exposure decomposition makes one: any fixed-versus-proportional cost comparison produces a minimum efficient scale, and any separation of entitlement from taxation produces two numbers. **The contribution is the identification of the recognition dependency and the discipline of computing both exposures, not a uniquely discriminating forecast.**

13.1 Rigour checks not met, listed by name

1. **No as-of date, because no real holdings were measured.** A concentration figure computed from real holdings requires its source and its date; **a concentration measure without an as-of date is not a measurement.** Every share vector here is constructed. The same applies with greater force to the legal propositions: **a statement of a reserve fraction or a tax rate without a date is not a statement of law**, and Appendix B accordingly requires the date of every confirmation.
2. **No uncertainty is reported anywhere, because nothing is estimated.**
3. **One symbol carries two dimensions.** Q is a currency stock in Sections 8.2 to 8.6 and an index-unit stock in the surplus law. Flagged in Section 12.1; the source does the same.
4. Q**,** C **and** h **in the surplus law have no operational unit**, and Curzi [2026t]'s demotion standard is the reason no statement here mixes them.
5. **The conjoint conditions were not tested** [Michell, 1997, Luce and Tukey, 1964]. The objection has limited bite on currency and full bite on index units.
6. **A count of non-exchangeable nominal items is used to trigger a threshold** (Section 12.6). It supports the threshold and is used for nothing else.
7. **Model comparison was not performed** and no information criterion was computed.
8. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. **Any restatement reaching for a heavy-tail claim about estate sizes or fee structures must run it first**, and must read Stumpf and Porter [2012] on why passing would still not identify a mechanism.
9. **The boundary-object and Goodhart borrowings are category 2, not category 1** (Section 12.5).
10. **The reserve is not a conserved quantity** and the fixed shares are (Section 12.4). The paper exploits that asymmetry and does not claim a conservation law for the framework's Q [Mirowski, 1989].
11. **Aggregation is unaddressed** [Kirman, 1992].
12. **Expected value and time average are not the same thing** [Peters, 2019]. A single succession event does not arrive in expectation; it arrives once, and the multiplicative consequence of a forced disposal for the remaining decades is not modelled here.
13. **The reflection problem is stated and not solved** [Manski, 1993].
14. **The paper's central recommendation rests on an unquantified comparison** — the recognition dependency against the depth of precedent. Section 12.
15. **The identity in H5 is reported as a hypothesis met, and an identity cannot confirm a hypothesis.** It is retained in the hypothesis set because stating it as a prediction and then showing it is an identity is what makes the instrument's blind spot visible; **a reviewer who objects that it should never have been a hypothesis is right, and the objection is**

recorded here.

14. Conclusion

This paper establishes the following results in the form the rest of the corpus cites them.

R1. The minimum efficient scale for a fixed-fee apex is $Q^{*} = C_{\text{fixed}}/b$. At $C_{\text{fixed}} =$ USD 120,000 a year, a foundation is cheaper than an *ad valorem* trusteeship only above **USD 34.3 million at 35 basis points, USD 80.0 million at 15, and USD 120.0 million at 10.**

R2. At the constructed USD 240 million estate the foundation costs **5.0 basis points against an *ad valorem* 35, a difference of USD 720,000 a year — which this paper explicitly refuses as the reason to choose the form**, because a fixed-fee trustee mandate eliminates the crossover and the saving is a rounding error against the exposure of R3.

R3. The forced-heirship exposure splits into a situs-capped levy, $\min(60.00\text{m}, 6.70\text{m}) =$ **USD 6.70 million**, or **11.2 per cent** of the notional reserved share, and an inheritance-tax exposure of approximately $0.45 \times 60.00\text{m} =$ **USD 27.00 million** that the structure does not touch — a ratio of **4.03**.

R4. Liquidity, not entitlement, binds. A **USD 60.00 million** claim against **USD 26.16 million** of liquid assets leaves a shortfall of **USD 33.84 million**, **14.1 per cent of the estate**, larger than any single liquid holding and closed in cash only by disposing of an operating branch.

R5. The fixed-share counterfactual on USD 240 million is determinate rather than discretionary: **widow** $1/8 =$ **30.00 million; residue 210.00 million divided** $2:2:1$**, so each son takes 84.00 million and the daughter 42.00 million**, summing to 240.00 million exactly.

R6. The apex does not move the concentration reading. Over the conventional structure the measurement remains **naive HHI 0.2934 (3.41 effective jurisdictions) and bloc HHI 1.0000 (**$N = 1.00$**) whatever vehicle sits at the top**, because the effective count is a function of the share vector and the correlation matrix and of nothing else.

Counter-result. The foundation answers ownership recording and succession continuity. **It adds nothing to the effective bloc count, gives no protection against arbitrary state action, and its forced-heirship result rests on a consent the heir may refuse — for which there is no lawful substitute.** Two further limits belong with it: the thin-doctrine risk is real, unpriced, and does not go away with good drafting; and the designed case's zero levy is a fact about the asset map rather than a legal victory, surviving exactly as long as the map does.

Two results are established as method rather than as measurement. **A recognition dependency is a form of concentration the published instrument cannot see**, because the effective count is invariant under the substitution of the apex form — which makes H5's confirmation a statement about the instrument's blind spot rather than about the world. And **the single most useful sentence for a practitioner is that a foundation apex moves the fight from "who owns this" to "was the endowment good", and the second fight is won or lost on the date of the endowment and the founder's conduct afterwards, not on the drafting.**

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the principal, the family map, the asset allocation, the cost model, the fee bases, the exchange rate, the tax rate, the liquidity position and the policy benefit — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-053_fig01.py` through `figs/src/CCP-053_fig04.py`), which import the shared figure style module and read

their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Legal and jurisdictional descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general treaty and comparative doctrinal material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction. Appendix B lists the claims affected. **Any reader relying on those descriptions must verify them against the official sources, and must record the date of that verification, because a statement of a reserve fraction or a tax rate without a date is not a statement of law.**

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every principal, family, heir, entity and transaction described is invented.

Preregistration

The five hypotheses of Section 2, including H2's three crossover values and H3's ratio, were stated with their falsifiers before the computations of Section 8 were run. **H5 was met as an identity rather than as a measurement, and Section 13.1 item 15 records that this is a weaker outcome than a confirmed hypothesis normally is.** No hypothesis in this paper was preregistered in any external registry.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. Succession law is the most jurisdiction-specific subject treated anywhere in this corpus and the one where a general statement is most likely to be wrong in a particular case. The paper describes entity types, holding forms, reserve regimes, fixed-share systems and structural arrangements for the purpose of measuring cost, exposure and concentration. **No recommendation is made in respect of any particular person, asset, structure or jurisdiction.** Reserve fractions, claw-back periods, levy conditions, renunciation formalities, tax rates and abatements, entity-classification rules and foundation statutes all change and vary by jurisdiction, by family configuration and by asset; every such statement here is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in each jurisdiction of residence, nationality, beneficiary location and asset situs, and with counsel qualified in the applicable personal-status law where fixed shares apply, before any reliance.

Appendix A. The build specification

The decisions in the order they must be taken, with the consequence of each.

```
  1  FIX THE JOB BEFORE THE FORM. One paragraph, before counsel is
     instructed, stating what the apex is for. If it contains
     "operate", "trade", "invoice" or "employ", the design is wrong.
     If it contains "hide", it fails the disclosure test and should be
     abandoned.
  2  PURPOSE, BENEFICIARIES, OR BOTH. A pure beneficiary form gives
     each heir something that begins to look like an interest, and an
     interest is what a divorce court, a creditor and a
     reserved-portion claimant can each attach or value. A pure
     purpose form removes that and makes banking materially harder.
     The combined form states the purpose as the governing object and
     keeps the class discretionary.
  3  THE ENDOWMENT. Real, documented and clean. The deed identifies
     the property precisely, recites solvency at the date of transfer,
     and is dated. Do not endow assets already the subject of, or
     foreseeably about to be the subject of, a claim: that is the
     conduct claw-back statutes exist to reverse, and it converts a
     lawful structure into evidence.
  4  DRAFT THE CHARTER FOR THE REGISTER. Assume a journalist, a
     competitor, a foreign tax authority and a future heir all read
     it. Two clauses are load-bearing: post-mortem amendment must
     require more than one person's decision, and the winding-up
     clause must name a real destination.
  5  DRAFT THE BY-LAWS FOR THE COURTROOM. Beneficiary class including
     adopted children, stepchildren and children born outside
     marriage -- silence here produces litigation in every generation.
     Distribution standards; reserved powers with a successor
     mechanism covering incapacity as well as death; guardian consent
     matters and succession; council composition, quorum and deadlock;
     reserved matters; information rights; conflicts; dispute
     resolution.
  6  COMPOSE THE COUNCIL. Substance over convenience: at least one
     independent professional resident councillor engaged on
     commercial terms who reads the papers and can say no. Continuity
     over loyalty: stagger the ages. Location over documentation:
     minutes recording a meeting everyone knows happened by telephone
     add a credibility problem to a residence problem.
  7  GRADE THE RESERVED POWERS. Section 5.3.
  8  THE ONSHORE INTERFACE. Ownership particulars will be recorded;
     exchange classification must be determined and applied; the tax
     position must be taken and filed; onboard with the full pack and
     expect to answer "who benefits?" in writing, with an answer that
     is true.
  9  HANG THE STRUCTURE UNDERNEATH. Hold, do not cross-hold. One layer
     of separation per job.
 10  WRITE THE SUCCESSION MEMORANDUM. What the structure is, who the
     counsel are in each jurisdiction, where the documents live, what
     the reserved powers were and what happens to them, and who to
     call on the day. It has no legal effect and it is the difference
     between an orderly transition and eighteen months of paralysis.
     It is NOT a letter of wishes.
```

The succession overlay, added to the above where a protected share is in play: build the succession map (people, assets, and the law each forum would apply); compute E_{reserve} and E_{tax} separately and in currency before any instrument is discussed; select from the four-lever set; build one claw-back calendar per heir jurisdiction; pre-fund the liquidity gap; and produce three documents to the standard that the excluded heir may read each of them — the endowment file, the family disclosure, and the succession memorandum. **The family disclosure is uncomfortable and it is the highest-value document in the file.**

Appendix B. Claims requiring verification against primary sources

The following rest on legal or regulatory detail that changes, and **none is cited to the bibliography, which contains no primary sources for any individual jurisdiction.** They are reproduced from the source manuscript and require confirmation, **with the date of confirmation recorded**, before any reliance.

1. The apex jurisdiction's foundations statute: the scope of the constitutional carve-out permitting an enclave private law and the federal statutes applying notwithstanding it; the statutory trigger requiring a guardian; minimum councillors, corporate councillors and residency requirements; the availability and conditions of the registered-agent route and the agent's record-keeping and disclosure obligations; the enumerated reservable powers, whether the list is exhaustive, and whether the statute saves the foundation from invalidity by reason of reservation; any minimum initial asset requirement.
2. The firewall and governing-law provisions: article numbers and wording; extension to claims arising from personal relationships; treatment of foreign judgments as distinct from foreign law; interaction with the companion trust statute. **This is the single most commonly overstated feature of every foundation regime and the wording is the whole of it.**
3. Continuation-in and transfer-out provisions: registrar consent, solvency or creditor conditions, which entity types may continue in, and whether a company may convert.
4. The apex court: its constituting instruments, bench, opt-in jurisdiction, the protocol for enforcement into the surrounding onshore courts, the current constituting instrument and composition of any tribunal resolving jurisdictional conflicts, and the current position on whether a foreign judgment recognised in the enclave may be enforced onward. **That question has moved; do not build on an assumption about it.**
5. The reserve fractions of each relevant civil-law system, the reduction-in-value rule and when reduction in kind remains available, and the prescription periods for the reduction action.
6. The decisions of the relevant supreme court on whether the absence of a reserve in a chosen foreign law offends international public policy, their docket numbers and reasoning, and any subsequent decisions modifying the position.
7. The compensatory levy: its enacting instrument, exact conditions, mechanics, commencement, and current status including any constitutional or supranational challenge. **This provision is under active contest and its status must be checked as at the date of any advice.**
8. The compulsory-portion provisions of the second civil-law system, the operation of the ten-year sliding scale, and — critically — the effect of a reserved usufruct on when the period begins, together with the formalities of a contractual waiver. **This is where planning in that system most often goes wrong.**
9. The provision on life-assurance proceeds and the case law on manifestly excessive premiums.
10. The inheritance-tax residence condition for heirs and its article; the current abatement and rate scale; and **whether a discretionary foreign foundation making no distribution**

produces a taxable transmission at all, which determines which of two very different numbers applies.

11. The fixed shares on the actual family configuration; the school applied by the deciding court and the differences it produces; the position on bequests exceeding the cap and on bequests to heirs; the requirements for a completed lifetime gift; and the formalities of post-death settlement among heirs. **No general statement about fixed-share inheritance should be relied on for a specific family.**
12. The current status table of the recognition convention [Hague Conference on Private International Law, 1985] for every state concerned, including ratifications, accessions and territorial extensions; and the article numbers of its mandatory-rules, overriding-provisions and public-policy reservations and of the provision permitting non-recognition where the significant elements are more closely connected with non-trust states.
13. Contracting-state lists and entry-into-force dates for the choice-of-court [Hague Conference on Private International Law, 2005] and judgments [Hague Conference on Private International Law, 2019] instruments in each relevant state; the article and sub-paragraph numbers of their succession, family-law and matrimonial-property exclusions; and the apex jurisdiction's own regime for recognition and enforcement of foreign judgments, including its procedural legislation and any regional or bilateral instruments in force with each heir jurisdiction.
14. Whether a foreign *foundation* specifically is recognised on the same basis as a foreign company in each relevant state, and whether any residual real-seat doctrine or public-policy control applies to a foundation administered from within that state.
15. The classification of a foreign foundation for federal tax purposes in each relevant system — foreign trust, foreign corporation, or otherwise — on the specific charter proposed; the attribution provisions of each relevant civil-law system and the conditions of any regional exception; and the current reporting obligations and penalties. **These are genuinely unsettled for foundations and must not be assumed either way.**
16. Statutory valuation scales for usufruct and bare ownership, and any anti-abuse presumption applying to a family separation of usufruct from bare ownership.
17. The applicable matrimonial property regime for the couple, the law governing it, and whether it may be changed and with what effect. **It changes the denominator and is identified before anything else.**
18. The succession regulation's article numbers for the general rule, choice of law, scope, universal application and public-policy exception [European Union, 2012], and the recital addressing evasion of the law. **The substance is not in doubt; the numbering must be pinned before it appears in an opinion.**
19. All cost figures in Section 8.2 are constructed illustrations. They are not fee quotations and no real fee schedule was used to produce them.

Appendix C. The apex jurisdiction assessed

The jurisdiction is de-identified as "Gulf centre A", following the convention of Curzi [2026], because every item below asserts a jurisdiction-specific characteristic the bibliography cannot support. No total is computed: the items are heterogeneous and no common scale exists on which they could be added (Section 12.6).

#	item	assessment
1	legal family	codified common-law-derived; own civil and commercial statutes under a financial free-zone carve-out; not English law by direct application, but drafted in the common-law tradition, in English, with an English-language court
2	bloc alignment	**bridge.** Maintains working relations across several perimeters simultaneously. Not outside regulatory pressure; outside the Western listing mechanism and outside any single bloc's coordination
3	court quality	high: international bench, English language, published reasoned judgments, opt-in jurisdiction for unconnected parties. **Thin foundations-specific case law — the regime dates only from 2018**
4	foreign judgment recognition	**mixed, and the weakest item.** Enforcement into the surrounding onshore courts runs through a protocol; non-binding memoranda of guidance exist with several foreign courts and are not treaties; the onward-enforcement question has moved. Do not build on an assumption here
5	substance requirements	low for a holding foundation: registered agent, filed charter, statutory registers, council meetings. Substance for the *operating* entities is a different question
6	exchange-reporting status	participating. A foundation is a financial institution or a passive non-financial entity; either way, account holders or controlling persons are reported. **There is no non-reporting configuration**

#	item	assessment
7	beneficial-ownership regime	own regime through the registrar: filed and maintained, not publicly searchable, available to the registrar and competent authorities. Charter public; by-laws private but discoverable
8	rail access	incumbent messaging throughout, with genuine dual-rail optionality at the banking layer. **The apex itself should hold no payment function: a rail is not a holding**
9	political stability	high by regional standards, with the caveat of a system in which policy can change quickly without a legislative cycle. **That cuts both ways**
10	degradation trajectory	**improving, from a base that briefly worsened.** Increased monitoring March 2022 to February 2024; a federal corporate tax from 2023 which *increased* transparency and simultaneously increased the jurisdiction's legitimacy as a treaty and substance location; an ownership register built out from 2020; deepening case law. **The asset being bought is bloc independence with institutional quality, and both are rising.** Downside risks: federal encroachment on the carve-out, and single-country political concentration
11	job	**HOLDING**, unambiguously. Not operating: no substance, no staff, no trade at the apex. Not bridging

#	item	assessment
12	verdict and what would change it	**use it as the apex** on the balance of legal personality, purpose-or-beneficiary flexibility, permitted founder control, a publishing common-law court and bridge-bloc alignment. **What would change the verdict:** federal legislation reaching into the carve-out; a line of decisions making the apex court's orders unreliable against onshore assets; amendment narrowing the firewall or the transfer-out power; renewed listing; or a de-risking cycle making the form unbankable in the branch jurisdictions. Monitor items 4 and 10 annually and keep the migration path live

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 54

Institutional Quality Without Independence: London, the Crown Dependencies, and the European Convergence

Abstract. Three of the most-used holding locations for Western capital are measured on the concentration instrument, and all three fail it for the same reason: institutional quality is not independence. Spreading a holding across Jersey (40.0 per cent), Guernsey (35.0) and the Isle of Man (25.0) gives a naive HHI of 0.345000 and 2.90 effective jurisdictions, but all three collapse to one bloc, giving a bloc-HHI of 1.000000, an effective count of 1.00, and a surplus term of exactly zero. Even the most generous counterfactual, crediting the Crown Dependencies as a bloc of their own, reaches only 1.423998 effective blocs and h = −0.376286 against the designed structure's 2.941176 and −0.122417. The European four — Luxembourg 35.0, Ireland 25.0, the Netherlands 25.0, Switzerland 15.0 — read 3.703704 naive and 1.00 after collapse; crediting Switzerland separately reaches 1.342282 and h = −0.396970. A printed arithmetic error in one variant is left visible and corrected in the text, to 0.764992, N = 1.307203 and h = −0.406239, as a demonstration of what a rounded print does to the reading. The paper also reports a move that reduces resilience while appearing to improve it: shifting the residual UK 16.4 per cent to Bermuda lowers Western exposure to 13.6 per cent yet cuts the effective bloc count from 2.9412 to 2.3442, because it concentrates the bridge row. The UK share falls from 40.9 to 16.4 per cent with no loss of capability, because English governing law and arbitration are portable and separable from situs.

Keywords: City of London; Crown Dependencies; English governing law; portable law; convergence; coordination bloc; concentration measurement

Series: D. Structure and Resilience **Paper:** CCP-054

1. Introduction

Three of the most-used holding locations for Western capital are measured here on the concentration instrument, and all three fail it for the same reason. **Institutional quality is not independence.** They are different axes, and almost every structuring decision in this field reads a high score on the first as evidence for the second.

The distinction has to be held with both hands, because a paper that undersells these jurisdictions is as useless as one that oversells them. The City of London is an extraordinary piece of legal and commercial infrastructure and nothing in this corpus replaces it. The trust statutes of the Crown Dependencies are among the best-maintained in any common-law system; one of the Bailiwicks invented the protected cell company and then engineered the incorporated cell company when the first turned out to have a recognition limit. Luxembourg runs the second-largest fund domicile in the world and runs it well; Ireland is the only common-law member state of the European Union with the euro and the leading aircraft-leasing cluster; the Netherlands has a first-rate judiciary and, in the administration foundation, one of the most useful control-separation instruments in any legal system; Switzerland has custody depth and a currency that is not somebody else's policy instrument. **None of that is the question.** The question is what happens to the effective count of independent coordination perimeters, and on that question the answer is not close.

Four measurements follow, and two of them cut against the framework's own presentation.

First, the Crown Dependency error. Spreading a holding across three Islands at 40.0 / 35.0 / 25.0 per cent gives a naive index of 0.345000 and 2.898551 effective jurisdictions. All three collapse to one bloc: a bloc index of 1.000000, an effective count of exactly 1.00, and a surplus term of exactly zero. **Three jurisdictions, three regulators, three sets of fees, three sets of counsel, three annual filings, and no change in the quantity that enters the surplus law.**

Second, the counterfactual run in the incumbent structure's favour. Grant the most generous assumption available — that the Crown Dependencies constitute a fully independent perimeter — and the conventional structure reaches a bloc index of 0.702248, $N = 1.423998$ and $h = -0.376286$, against the designed architecture's 2.941176 and -0.122417. **The verdict does not turn on winning the bloc-assignment argument; the generous assignment loses too, by 0.253869 of surplus balance.**

Third, the European convergence. Luxembourg 35.0, Ireland 25.0, the Netherlands 25.0 and Switzerland 15.0 read 0.270000 naive and 3.703704 effective jurisdictions, collapsing to exactly 1.00; crediting Switzerland as its own perimeter reaches 0.745000, $N = 1.342282$ and $h = -0.396970$. **A printed arithmetic error in one variant of that computation is left visible in Section 7.4 and corrected in place — to 0.764992, $N = 1.307203$, $\ln N = 0.267890$ and $h = -0.406239$ — because what a wrong index does downstream is more instructive than a clean-looking table.**

Fourth, a move that reduces resilience while appearing to improve it. Shifting the residual UK 16.4 per cent to the Gulf bridge lowers Western-perimeter exposure from 30.0 to 13.6 per cent and *cuts* the effective bloc count from 2.9412 to 2.3442, because it concentrates the bridge row. **Reducing exposure to the perimeter you fear, by piling weight onto one bridge, makes the structure less resilient rather than more. Concentration does not care which direction it points.**

Against those four, one finding runs the other way and is the paper's most useful output. The UK share falls from 40.9 to 16.4 per cent **with no capability lost**, because what is bought under the name of a financial centre is a bundle of separable services, and the most valuable of them — governing law — is portable. **A contract can be governed by English law and heard outside the Western perimeter. The law travels; the courthouse does not.**

Two constraints on what follows are stated at the outset. **No jurisdiction-specific primary law is cited.** The bibliography carries general treaty and standard-setting material — the awards convention [United Nations, 1958], the choice-of-court and judgments instruments [Hague Conference on Private International Law, 2005, 2019], the exchange and standard-setting instruments [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015] — and comparative doctrine [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008]. **It contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction.** Every enactment, decided case, listing event, rate, date and jurisdictional characteristic below is described from the source manuscript, left uncited, and

itemised in Appendix B. And **no distributional or scaling claim is made anywhere**: the exposure vectors have three, four and six entries and are not samples from a distribution [Clauset et al., 2009].

2. Hypotheses

Five hypotheses with their falsifiers, in the form Platt [1964] requires. Meehl [1967] is the standing warning that a directional prediction here is nearly costless; all five make point predictions with constants attached. Two are reported in Section 7.7 in ways that do not flatter the argument.

H1 — the subdivision hypothesis. Subdividing an exposure across jurisdictions inside one coordination perimeter raises the naive count and leaves the effective bloc count exactly unchanged. *Predicted:* a Crown Dependency allocation of 40.0 / 35.0 / 25.0 gives naive HHI $= 0.345000$ and 2.898551 effective jurisdictions against bloc HHI $= 1.000000$ and $N = 1.000000$ exactly, so $\eta \ln N = 0$ at every value of η. *Falsified by:* any subdivision inside a perimeter that raises N; or by evidence that the three Islands act on independent decisions rather than on one.

H2 — the generous-counterfactual hypothesis. The conclusion survives granting the bloc-assignment argument to the other side. *Predicted:* crediting the Crown Dependencies as their own perimeter (WEST 81.8 / CD 18.2) gives bloc HHI $= 0.702248$, $N = 1.423998$ and $h = -0.376286$, which remains 0.253869 below the designed architecture's -0.122417. *Falsified by:* a defensible bloc assignment under which a single-perimeter structure reaches the designed architecture's position.

H3 — the convergence hypothesis. The European four have lost differentiation rather than privacy, and their bloc position is unchanged by either. *Predicted:* 35.0 / 25.0 / 25.0 / 15.0 gives naive 0.270000 and 3.703704, collapsing to 1.000000 and $N = 1.00$; crediting Switzerland separately gives 0.745000, $N = 1.342282$ and $h = -0.396970$. *Falsified by:* a demonstrated instance of one of the four declining to give effect to a coordinated measure adopted by the others.

H4 — the reallocation-trap hypothesis. Lowering exposure to a named perimeter can lower the effective bloc count. *Predicted:* moving the residual UK 16.4 per cent onto the Gulf bridge gives blocs of 56.4 / 30.0 / 30.0 → 56.4 / 30.0 / 13.6, a bloc index of 0.426592 and $N = 2.344160$, down from 2.941176, while Western exposure falls from 30.0 to 13.6 per cent. *Falsified by:* a reallocation that reduces the largest bloc's share and reduces N, which is impossible; or by any claim that Western-perimeter exposure alone is a sufficient statistic for resilience, which this prediction refutes by construction.

H5 — the portability hypothesis. A jurisdiction's most valuable export can be consumed without consuming its perimeter exposure. *Predicted:* the UK share falls from 40.9 to 16.4 per cent while all four services the constructed case actually consumes are still consumed, and the component decomposition accounts for the fall exactly: 22.0 + 9.4 + 9.5 = 40.9 before, and 10.0 + 6.4 + 0.0 = 16.4 after. *Falsified by:* a service in the retained set that cannot be obtained without a UK entity or a UK forum.

Not hypotheses, and labelled as such. Four statements are not falsifiable as written.

- *The bloc assignment of each named jurisdiction* is a **modelling position**, stipulated in advance from the evidence of Section 6.3 and defended there. Section 3.4 states why it cannot be an identified empirical result.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice** carried from Curzi [2026b] and fixed before the measurements, following the preregistration discipline of Nosek et al. [2018].
- *The logarithmic form of the input term* is a **modelling choice** carried from Curzi [2026], whose functional characterisation — angle-only dependence, vanishing at parallel, an affine effective count, normalisation — fixes the form by axiom rather than by measurement. It is not tested here.

- *The exposure shares* are **constructed** throughout and are labelled as such at each point of use.

3. Method

3.1 The gauge, and what an element contributes to it

The surplus law is $h = \eta \ln N - \delta Q - C$, and Curzi [2026b] states it in full: a headroom gauge with three regimes, a maximum increment $r_{\max} = h_t$, and two separate constraints — admissibility, $C_t \leq (1-\delta)Q_t + \eta S_t$, and sustainability, $C_t \leq \eta \ln N - \delta Q_t$. **The distinction between the two constraints is what this paper's jurisdictions fail.** A Crown Dependency or European element is almost always admissible — the cost can be met out of stock and flow — and almost never sustainable, because it raises C and leaves $\ln N$ untouched.

That is the whole accounting, and it is worth writing as one line:

```
an element that adds to C and adds nothing to ln(N)
moves h strictly DOWN, at every value of eta.
```

The recurrence itself is a first-order linear difference equation and its behaviour is standard [Elaydi, 2005]. Curzi [2026] supplies the honest converse that governs any claim about a structure converging on a target: **gain exactly one gives an isometry that orbits without arriving, and gain at or above one gives an amplifier whose corrections, sized to delayed feedback, arrive as new errors.** A restructuring programme run on annual measurements with a two-year execution lag is exactly such a system, and Section 8 lists the drift it produces as a failure mode rather than as a side effect.

3.2 Which effective count

Every effective count in this paper is HHI^{-1}, the Hill number of order two, and it is named as such at each use. Hill [1973] defines the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types that would produce the observed index; at $q = 2$ that is exactly $(\sum_i p_i^2)^{-1}$. Jost [2006] is the statement that entropies are not diversities and their numbers-equivalents are; Adelman [1969] is the numbers-equivalent reading of the concentration index; Simpson [1949] and Laakso and Taagepera [1979] are the independent reinventions in ecology and political science. The index is due to Hirschman [1945] in root form and Herfindahl [1950] in sum-of-squares form. The exponential of Shannon entropy [Shannon, 1948] is the same family at $q = 1$, and the reciprocal index is the exponential of the Rényi entropy of order two [Rényi, 1961].

The corpus's affine count $N_{\text{eff}} = 1 + (N-1)u$ is a different quantity, is not a Hill number of any order, and carries no external support. It is not used here. Curzi [2026] is cited for the surplus functional and its axiomatic characterisation, not for that count as a numbers-equivalent, and the distinction must survive any citation of this paper.

The general form the collapse relies on is $\mathrm{EFF} = 1/(w'Rw)$ for exposure weights and a correlation matrix — the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012], whose additive relative is the quadratic entropy of Rao [1982]. Under independence it is the naive index; under a block matrix of ones it is the bloc index. Markowitz [1952] supplies the underlying algebra and the correction the whole series turns on: **diversification benefit depends on covariance and not on count, stated with the mathematics attached in 1952.** Hurlbert [1971] is the standing discipline: the word "diversity" carries no content without its formula attached, which is why the formula is attached here every time.

One limitation of the instrument bites unusually hard in this paper and is stated before the results rather than after them. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the *dominated-unit regime*, where one unit

holds a very large share. **Four of this paper's five headline vectors collapse to a single unit at 100 per cent, which is the limiting case of that regime.** The measurement remains exact — $1/1 = 1$ — but the instrument's *discriminating power* is at its minimum there, and comparisons among heavily dominated structures must not be made on N alone. Section 11 records this as the paper's most serious methodological exposure.

3.3 What correlated shares do, and what the literature says about it

The bloc collapse is the assertion that within-perimeter correlation is near one. Two bodies of measured evidence bear on it and they point the same way. Longin and Solnik [2001] and Ang and Chen [2002] find extreme correlation in equity markets that is asymmetric and concentrated in downturns: **the effective count falls exactly when it is needed**, which is a stronger statement than anything the static index makes. The ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008], and the cleanest demonstration that effective count buys stability is Schindler et al. [2010]'s sockeye record, where population diversity produces roughly half the variability and about a tenth of the fishery closures.

The contrary literature is read alongside and is not decorative. Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone, with no mechanism; May [1972] showed that increasing diversity and connectance *destabilises* randomly assembled systems. **This paper's claim is narrower than the general diversity–stability claim and is not exposed to those results in the same way**: it asserts that the reciprocal of a variance counts independent shocks, which is arithmetic, and that the jurisdictions in question are attached to one decision process, which is H1 and H3.

The coupled-network result [Buldyrev et al., 2010] is used as a **shared structural form and not as a derivation** — the jurisdictions have not been shown to satisfy its percolation premises, and only the property that coupling destroys assumed independence is borrowed. The robust-yet-fragile result [Albert et al., 2000, Callaway et al., 2000] is used the same way, with Doyle et al. [2005]'s caveat that real engineered systems get their robustness from design rather than from a degree distribution. And the general form of the counting error is proved exactly: **one party can present as many** [Douceur, 2002], so an unaudited count of nominally distinct units is worthless — which is what a three-Island subdivision is.

3.4 The reflection problem, where the assignment is made

A bloc assignment is a forecast about correlated behaviour, and the framework's reflexive loop $T(x) = W(x, M(x))$ makes it a forecast that conditions the behaviour it forecasts. Manski [1993] proves that a linear-in-means reflexive specification is **not identified from observational data**: the endogenous effect cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] reinforces the point where the data are relational — influence and selection are generically confounded. **No amount of observation of jurisdictional behaviour could therefore confirm a bloc assignment derived reflexively, and this paper states that where the assignment is made rather than in a footnote.**

The remedy adopted is stipulation with a defence, the fourth of the four known routes, which Brock and Durlauf [2001] shows can be made rigorous. The assignments of Section 6.3 are fixed in advance against a stated evidence ladder, recorded with the strongest available item, and stress-tested by the generous counterfactuals of Sections 7.2 and 7.3. **The price is that every bloc assignment in this paper is a modelling position and not an identified empirical result**, and H2 and H3 exist precisely so that the conclusion does not depend on winning the assignment.

The instrument's own performativity is not exempted. MacKenzie and Millo [2003] documents a model that came to fit its market after traders adopted it; Hacking [1995] gives the general looping form; Merton [1948] supplies the original statement that a definition of a situation can make itself true. **If enough structures are built on the assumption that these**

jurisdictions share a perimeter, capital and correspondent relationships reorganise around that assumption and the assumed correlation becomes the observed one. Lucas [1976] states the severe consequence for parameters estimated before publication. **The framework asserts that systems change when modelled and then exempts its own η, δ and correlation assumptions from that reflexivity. That is an inconsistency and it is not resolved here.**

3.5 Evidence standard, and the de-identification convention

Sections 4 to 6 are jurisdictional exposition. **Every enactment, decided case, listing event, survey figure, rate, date and jurisdictional characteristic in them is described from the source manuscript and is not cited to the bibliography.** The general instruments named in Section 1 are cited where they bear; nothing else is. Appendix B lists every claim requiring confirmation against a primary source, **with the date of that confirmation recorded**, because a statement of a jurisdiction's regime without a date is not a statement of its regime.

Where a table **ranks named jurisdictions against one another on a legal capability the bibliography cannot support**, the jurisdictions are de-identified — "Island A", "Island B", "Island C" — following the convention of Curzi [2026], which de-identifies an apex jurisdiction in its own twelve-item assessment for the same reason. **Where a jurisdiction is named in prose, or appears in an exposure table, or carries a bloc assignment with its evidence, the name is used**, because the argument is about those specific perimeter attachments and a functional description would hide rather than protect. That is the same line Curzi [2026] draws.

4. What is actually being bought

Six distinct things travel under the name of a major common-law financial centre. They have different portability, different failure modes and different jobs, and separating them is the first analytic move.

```
1  the governing law            the substantive rules of the contract
2  the forum                    a commercial court, its process, its judges
3  the arbitral seat            a seat, not a court system
4  the insurance market         underwriting capacity for hard risk classes
5  the listing venue            a market and secondary liquidity
6  the currency plumbing        banks, clearing, market depth
```

Item 1 is portable and items 2 to 6 are not. A contract between two parties in different blocs can be governed by English law and heard anywhere that will apply it. **The law travels; the courthouse does not**, and most of the strategic content of this paper follows from that distinction. Two enclave jurisdictions outside the United Kingdom apply English common law directly or through their own courts with common-law judges, which means **the law can be bought without buying the perimeter, and that is the single most useful structural fact in this corpus's treatment of the West.**

4.1 Why the law is chosen, and what that claim is not

The reasons are unglamorous and are the reasons that matter. *Predictability through precedent density*: two centuries of reported commercial decisions mean most disputes about most standard terms have already been decided, and the answer can be found before the dispute rather than after it. *A strong doctrine of freedom of contract*: the default posture is that sophisticated parties are bound by what they wrote, with no general doctrine of good faith in commercial performance of the kind found in many civil-law systems. *Commercially legible remedies*, and a settled law of interpretation. *A separable arbitration regime*, so that the law can be chosen without the forum.

Two disciplines apply. **"Most-chosen governing law" is a claim about relative frequency in international commercial contracting, resting on survey and institutional data rather than a census**, and it must not be inflated. And choosing a governing law does not import a jurisdiction: a clause can choose one system's law with another system's court or seat, and in a cross-bloc structure it usually should.

4.2 Judgment recognition, and why an award travels further than a judgment

This is the capability that materially deteriorated and it is routinely glossed over. English judgments circulated within the European Union and the European Free Trade Association under a recast regulation and a parallel convention; both ceased to apply on the United Kingdom's departure, and an application to accede to the convention in its own right was not supported. What replaced it is thinner: an instrument covering **exclusive** choice-of-court agreements only [Hague Conference on Private International Law, 2005], with asymmetric and non-exclusive clauses — standard in finance documentation — genuinely contested; a broader judgments instrument [Hague Conference on Private International Law, 2019] with a limited and slowly growing membership; common-law recognition on a presence-or-submission basis; and two statutory reciprocal-enforcement schemes for listed countries.

Against that sits the awards convention [United Nations, 1958], with near-universal adherence, narrow and enumerated refusal grounds [van den Berg, 1981], and a procedural framework the surveyed regimes largely share [United Nations Commission on International Trade Law, 1985]. Born [2021] is the standing treatment.

For a cross-border structure a London-seated arbitral award is a more portable instrument than an English court judgment, and it became more so in 2021. Structures papered on pre-2021 reasoning should be re-examined on current reasoning.

The counter-consideration, fairly stated: arbitration has no real summary judgment under most institutional rules, no appeal on the merits, limited joinder, and cannot bind non-signatories. **Where disputes are likely to be documentary and one-to-one, a commercial court is superior on speed and cost. Where they are cross-border and the enforcement target sits outside the Western perimeter, arbitration wins on the only criterion that matters at the end — whether the paper can be turned into money where the debtor keeps assets.**

4.3 Disclosure as a feature, not a burden

Three registration regimes matter in the constructed case: a public register of persons with significant control; a register of overseas entities owning domestic land; and an identity verification regime for directors, controllers and filers, rolled out in stages. They are usually described as burdens. **Under the disclosure standard this corpus applies they are closer to the opposite.**

An operating company inside a properly designed architecture passes the disclosure test **because of** the public control register, not despite it. The register produces a filed, dated, public statement of who controls the entity; if the controller is a registered foundation whose own regime records its council and founder, the chain is documented end to end and **the documentation is the asset**. A bank onboarding the entity gets an answer in an afternoon; a screen resolves cleanly; an enquiry closes.

Filed transparency is what makes a structure bankable, and bankability is the binding constraint on cross-bloc architecture — not secrecy, which is unavailable, and not rate advantage, which is now largely harmonised at the top end. This is the open-design principle of Kerckhoffs [1883] — a system's effectiveness must not depend on the secrecy of its design — restated as *open design* among the protection principles by Saltzer and Schroeder [1975], and applied to legal rather than cryptographic structure. Brandeis [1914] is the public-interest form of the same observation from the other direction.

The honest cost is real and is stated. A public control register is public, so adverse parties, journalists and commercial rivals can read it. For a principal with genuine personal-security exposure that is a real problem, and the suppression regimes that exist are narrow and evidentially demanding. **They are not a general privacy option and should never be planned as one** — reaching for a personal-security provision as a privacy plan is a concealment move inside a disclosure regime, which is the definition of a structure that fails the standard.

4.4 Enforcement reach, honestly stated

Two instruments belong in a threat model rather than a footnote. **A civil order requiring a respondent to explain the source of property** exists, and its case law cuts both ways: one appellate decision upheld such an order and one first-instance decision discharged a set of them with an adverse costs outcome against the authority. **The instrument is real, used sparingly, and it has lost in court** — which is the proper description of a legal power in a jurisdiction with a functioning judiciary, and is exactly what distinguishes lawful process from arbitrary action.

An autonomous sanctions regime exists, administered by a designating authority rather than a downstream adopter. Designations are made independently of two other major regimes, and the *observed* behaviour since 2022 has been rapid convergence across all three. **That observation is the evidence for the bloc assignment, and it is an observation about outputs rather than an allegation about intent.**

4.5 A jurisdiction that writes the rules cannot hedge against them

The perimeter test of Curzi [2026] — restated there as the question whether a decision taken elsewhere inside a perimeter reaches a jurisdiction without a second independent decision — has an answer for a founding member of the standard-setting body and an independent designating authority that is not merely inside the perimeter but at its origin. **A jurisdiction that helps write the perimeter's rules cannot also be the hedge against them, and no amount of institutional quality changes that arithmetic.**

A second finding belongs here because it is the one most likely to be argued with. **Institutional quality and rule stability are independent properties.** The constructed record includes the abolition of a settlement for internationally mobile individuals that had existed in recognisable form since 1914 — announced in March 2024, revised at a Budget in October 2024, effective April 2025, across a change of government. Whatever one thinks of the policy, **the engineering lesson is unambiguous: political stability is not the absence of upheaval; it is the predictability of the rules a structure depends on**, and a jurisdiction can have world-class courts, a professional civil service, deep markets and an unbroken constitutional order while replacing a century-old settlement inside thirteen months. **Score the two separately, and never let a high score on the first suppress an honest score on the second.**

5. Capability, inventoried

This section records what the jurisdictions genuinely do, because the argument is a concentration argument and not a criticism of capability, and because an inventory that only lists deficiencies is not an inventory.

5.1 The Islands

Fiduciary depth. One Island's trust statute is among the most carefully maintained in any common-law system, with three features that matter: a firewall addressing the extent to which questions concerning the trust are determined by local law to the exclusion of foreign

law; a reserved-powers provision permitting a settlor to reserve specified powers without invalidating the trust; and a statutory jurisdiction for the court to set aside transfers into trust, and exercises of trustee powers, on grounds of mistake or inadequate deliberation. **That last provision was legislated within a year of an appellate decision elsewhere narrowing the equivalent common-law doctrine, and the responsiveness cuts *for* the jurisdiction rather than against it. Capability is not the deficiency here.**

Segregation engineering. A second Island enacted protected cell company legislation first, anywhere, and the concept was adopted worldwide: a single legal person with statutorily segregated cells, assets attributable to one cell unavailable to creditors of another. It then addressed the form's principal weakness — that a cell is not a separate legal person, which foreign courts and counterparties sometimes decline to respect — by creating an incorporated cell company in which each cell **is** a separate legal person. **This is asset partitioning performing exactly the function Hansmann and Kraakman [2000] identifies as the irreducible contribution of entity law**, engineered to the limit of what a single domicile can achieve. Its remaining exposure is recognition: statutory segregation in the domicile is not automatically recognised in a forum with no equivalent concept, and that recognition question decides whether the ring-fence holds when tested.

Operational registries. A third Island built an aircraft and ship registry competing on operational merit, inside a customs and indirect-tax arrangement with its neighbouring state that no comparable centre has. **This is the most interesting capability in the section, because it is the one that automatic exchange, substance rules and ownership-register reform have not touched — there was never anything hidden in it to remove.**

The absence that governs. All three use a currency they do not issue, have no central bank and no lender of last resort. Two bank failures in 2008 demonstrated the consequence: one Island had no depositor compensation scheme in place at the time and introduced one in response. **A jurisdiction with no central bank cannot support an institution, and the protection available to a depositor is whatever the scheme says it is.** For operating cash that is a sizing question; for reserve it is a disqualification.

5.2 The European four

Each has a genuine, differentiated capability, and the capabilities are not interchangeable: a regulated-fund passport with distribution across a large single market; an English-speaking common-law member state of that market with a leading asset-leasing cluster; a civil-law state with an English-language commercial court and a control-separation instrument of unusual elegance; and a non-member with custody depth and an independent currency.

The control-separation instrument deserves its own paragraph because it is the one genuinely portable idea in the group. A foundation holds legal title to shares and exercises the votes through its board; depositary receipts are issued to the economic beneficiaries and carry the economics but no votes; administration conditions govern transfer and exchange. **The whole operation is a matter of public record: the foundation is registered, the shareholding is registered, the separation is documented.** It achieves what a great many concealment structures are built to achieve — control in defined hands, economic benefit spread wider — **entirely in the open**, which is why it belongs in this corpus and why the register-privacy movements of the last five years made no difference to it in either direction.

5.3 What was lost, and it was not privacy

The received account is that these jurisdictions were secretive and are becoming less so. **That account is wrong, and it is wrong in a way that produces bad structures**: a principal who believes the problem is disclosure will spend money buying privacy that is not the constraint while ignoring the constraint that is.

The fact that breaks it is on the public record. In November 2022 a supranational court held invalid the provision of an anti-money-laundering directive insofar as it required mem-

ber states to ensure that beneficial-ownership information is accessible in all cases to any member of the general public, on the ground that the interference with charter rights was not limited to what is strictly necessary. **One register suspended public access the same day; a second within hours; others followed. Those jurisdictions became measurably more private in November 2022, by decision of the relevant legal order's own highest court**, and any analysis premised on their "losing their secrecy" is describing a trend that reversed direction.

What they lost is **differentiation**, which is a different thing entirely. A jurisdiction commands a premium only for what it can do that its neighbours cannot, and across fifteen years almost every source of differentiation was removed — not by secrecy reform but by coordinated harmonisation of the base, the rate, the anti-abuse rules and the reporting.

source of differentiation	what removed it	when
headline-rate advantage	a fifteen per cent minimum effective rate for groups above a turnover threshold	FY2024–25
base and financing advantage	interest limitation, general anti-abuse rule, controlled-foreign-company and exit-tax rules; then hybrid and reverse-hybrid mismatch rules	2019; 2020–22
ruling and structure secrecy	mandatory disclosure of reportable arrangements; platform reporting; crypto-asset reporting	2020; 2023; 2026
information advantage	automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017]	2017–18
substance-free holding	a supranational abuse principle independent of any treaty	2019
special domestic regimes	domestic reform enacted by referendum	2020

And the cost went up. Minimum-rate compliance is not a filing but a data-collection programme across every entity in a group; hallmark assessment and reporting is continuous; substance means directors, offices, staff, minutes and transfer-pricing documentation in each jurisdiction. **The result is the worst combination available in structuring: a jurisdiction that has lost its distinctive advantage while retaining — and increasing — its distinctive price.**

The third element never changed, and it is this paper's actual subject: **bloc concentration is intact.** Three of the four are inside the Western perimeter by construction. The fourth is the interesting case, and the evidence is unambiguous on outputs: from February 2022 it adopted its neighbours' sanctions packages through ordinances made under its own embargo legislation, and has aligned with successive packages since. **Neutrality is a doctrine about military alliance. It did not survive contact with the financial coordination mechanism, and the date on which that became demonstrable is on the public record.**

6. The bloc assignment, and its evidence

6.1 The evidence ladder

The perimeter test asks whether a decision taken in one place reliably produces the corresponding effect in another **without a further independent decision**. Evidence is ranked, and the assignments below are made against that ranking rather than against atmosphere:

weight	evidence class
strongest	a single designation decision producing the corresponding effect in every member without a further decision
strongest	a shared final appellate bench
strongest	a shared currency with no independent monetary authority
strongest	separate legislatures enacting near-identical text to a common external deadline
weaker	participation in an information-exchange framework [Organisation for Economic Co-operation and Development, 2017]
weaker	implementation of common supervisory recommendations [Financial Action Task Force, 2012]
weakest	listing status, diplomatic alignment, press characterisation [de Goede, 2011]

6.2 The Islands: the constitutional position, stated accurately

The Islands are **not** part of their neighbouring state. They have their own legislatures, courts, civil services and fiscal systems, and none was ever a member of the regional union. They are also **not** independent states: their neighbour is responsible for their defence and international representation, their primary legislation requires assent through a conciliar mechanism, and their final court of appeal is a committee composed of the neighbouring state's supreme court justices.

Two features do the work.

The appellate bench is the neighbour's bench. The committee is a distinct court applying the law of the jurisdiction the appeal comes from, and it decides against the neighbouring government's interests regularly; **no allegation of bias is made or implied.** The observation is about correlation. **The court of last resort for one Island's trust law is staffed by the same judges as the court of last resort for the neighbour's law, so the two bodies of law cannot drift far apart and cannot fail independently.** For a claimant that is a feature; for a structure trying to buy independence it is the whole problem.

There is no monetary authority. All three use the neighbour's currency and issue their own notes at par, which is a currency arrangement and not a monetary policy.

6.3 The coordination evidence

This decides the assignment and should be read as evidence rather than argument.

Corporate tax. All three Islands moved to zero-rate general corporate taxation with a concessionary rate for defined financial-services activity in the same period. All three then had elements of those regimes — the attribution and deemed-distribution mechanisms designed to preserve resident taxation — challenged as harmful by the same external body, and all

three repealed or replaced them. **Three separate fiscal systems adopted the same design, received the same challenge from the same body, and made the same repeal.**

Economic substance — the decisive instance. Following an external assessment and the commitments that followed, all three enacted economic substance requirements for relevant activities with effect for accounting periods commencing on or after the same date. The relevant-activity lists, core income-generating activity concepts, adequacy tests for people, premises and expenditure, and reporting mechanics are substantially aligned, **because all three were drawn against the same external template** [Organisation for Economic Co-operation and Development, 2015]. **Three parliaments, one deadline, near-identical text — that is what a coordination perimeter looks like from the inside.**

Listing. All three were placed in the co-operative-with-commitments category of a coordinated list pending delivery of that legislation and all three were subsequently removed once the assessing body was satisfied [de Goede, 2011].

Automatic exchange. All three were early adopters with first exchanges in 2017 [Organisation for Economic Co-operation and Development, 2017]. **There is no non-reporting configuration in any of the three and there has not been one for a decade.**

Beneficial ownership. All three maintain central registers accessible to competent authorities and not publicly searchable. In 2019 all three gave a public commitment to move toward publicly accessible registers on a stated timetable aligned with an external standard; that trajectory was interrupted by the November 2022 judgment of Section 5.3, and the Islands moved instead toward legitimate-interest access. **The access model has changed twice; a structure whose rationale depends on the current model is built on the least stable variable in the jurisdiction.**

Sanctions — the strongest available class. Each Island has its own legislation and competent authority, and in practice the neighbour's designations take effect in all three. The mechanism differs; the substantive result has been consistent alignment. **A single decision taken in one capital produces the corresponding effect in all three Islands without a further independent decision, which is the perimeter test satisfied in its strongest form.**

Supervision. All three have been evaluated with generally strong results reflecting genuinely capable supervision. **The finding is not that the Islands are weakly supervised. It is the opposite, and that is the point: they are excellently supervised to a standard set outside them. Excellent compliance with an external standard is the definition of being inside the perimeter that sets it.**

One further piece of evidence is the hardest in the paper and is stated in cash terms rather than in theory. One Island sits inside its neighbour's customs and indirect-tax territory under a revenue-sharing agreement that has been renegotiated, at one point substantially to the Island's disadvantage. **A jurisdiction inside another's indirect-tax territory, sharing its currency, with its judges as the final court, and whose fiscal position has been reset by a decision taken outside it, is not an independent perimeter under any definition that would survive a real event.**

6.4 Rails

There is no non-Western clearing access, no depth in an alternative reserve currency, and no correspondent network of consequence outside the perimeter in any of the seven jurisdictions surveyed. Local banks are mostly subsidiaries or branches of Western groups, several of which have reduced their presence over the past decade under general de-risking and cost programmes. **Correspondent concentration in all of them is higher than the entity map suggests**, and the rail axis must be measured separately before any of them is given a settlement role.

The general point belongs to the currency axis and is worth stating once: **currency exposure is perimeter exposure independent of entity location.** A treasury running predominantly two Western reserve currencies has more Western-perimeter exposure than its entity map shows, whatever passport its directors hold.

7. Results

CONSTRUCTED CASE throughout. All facts and figures are invented for illustration. No real person, family, entity or transaction is described. The carried case is a dual national, Gulf tax resident, with three heirs in three jurisdictions, one under a forced-heirship regime, holding manufacturing in a non-aligned state, a Gulf trading company, intellectual property, Western commercial real estate and a listed portfolio.

The starting measurement, carried from Curzi [2026], whose R6 establishes that the apex vehicle does not move it: **naive HHI 0.2934 and 3.41 effective jurisdictions against bloc HHI 1.0000 and $N = 1.00$ whatever vehicle sits at the top.** At $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ that gives $\ln N = 0$, $\eta \ln N = 0$ and $h = -0.500000$.

7.1 The Crown Dependency error, and H1

The conventional structure allocates 18.2 per cent to one Island and assigns it to WEST. Redistributing that 18.2 per cent across all three Islands is the move an adviser makes when asked to diversify:

```
Island A 40.0%  ·  Island B 35.0%  ·  Island C 25.0%

naive HHI = 0.160000 + 0.122500 + 0.062500 = 0.345000
effective jurisdictions = 1 / 0.345000 = 2.898551

bloc collapse: all three -> WEST = 100.0%
bloc-HHI = 1.000000      EFFECTIVE BLOCS N = 1.000000
ln(N) = 0                eta ln(N) = 0        h = -0.500000
```

Three jurisdictions, three regulators, three sets of fees, three sets of counsel, three annual filings. N unchanged at 1.00. The surplus term unchanged at zero, at every value of η. H1's prediction is met exactly.

The four variants an adviser will propose, run together:

variant	naive HHI	naive effective	bloc-HHI	N	$\ln N$
conventional as found (one Island at 18.2)	0.293430	3.408	1.000000	1.000	0.000
that Island's holding moved to a second Island	0.293430	3.408	1.000000	1.000	0.000
the 18.2 split three ways across the Islands	0.271347	3.685	1.000000	1.000	0.000
all three Islands, 40 / 35 / 25	0.345000	2.899	1.000000	1.000	0.000
the Islands credited as an INDEPENDENT bloc	0.293430	3.408	0.702248	1.424	0.353

Four of the five rows have $\ln N = 0$ and therefore a surplus term of exactly zero. Row two is identical to row one to twelve decimal places. **A substance-driven proposal to move a**

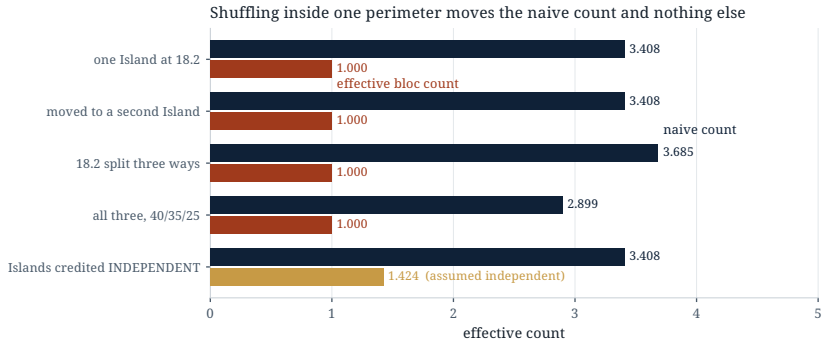

Figure 54.1: **Subdividing inside one perimeter moves the naive effective count between 2.90 and 3.69 and leaves the effective bloc count at exactly 1.00 in every row.** Measured from the share vectors tabulated above; the fifth row is the generous counterfactual of Section 7.2. Script `figs/src/CCP-054_fig01.py`.

holding between two Islands was not wrong on its own terms; it answered a question about compliance while being presented as an answer to a question about resilience. The measurement's function was not to reject the move but to reveal that the move and the objective were unrelated.

Note the direction of row four. **Splitting into three roughly equal Island holdings makes the *naive* count worse — 2.899 against 3.408 — because it removes the largest holder's dominance from a four-jurisdiction vector and replaces it with a three-jurisdiction one. Even the flattering number does not flatter.**

7.2 The generous counterfactual, and H2

A paper that only runs the arithmetic it likes is not an instrument. Suppose the bloc assignment is wrong and the Islands really are an independent perimeter — constitutionally distinct, separately governed, capable of declining to follow:

```
WEST 81.8% (three Western jurisdictions)  ->  0.818^2 = 0.669124
ISLAND bloc 18.2%                         ->  0.182^2 = 0.033124

bloc-HHI = 0.702248
EFFECTIVE BLOCS N = 1 / 0.702248 = 1.423998
ln(N) = 0.353469     eta ln(N) at eta = 0.35 = 0.123714
h = 0.123714 - 0.500000 = -0.376286
```

Against the designed architecture's $N = 2.941176$ and $h = -0.122417$ — figures Curzi [2026] carries in its own R1, where adding two further Gulf jurisdictions raises the naive effective count from 5.29 to 7.13 while the effective bloc count falls from 2.94 to 2.84.

Even granting the most generous assumption available, the conventional structure reaches only 1.42 effective blocs and remains at $h = -0.376286$, which is 0.253869 behind the designed one. H2's prediction is met, and the verdict does not turn on winning the bloc-assignment argument — only its magnitude does.

7.3 The European convergence, and H3

```
Luxembourg 35.0%  ·  Ireland 25.0%  ·  Netherlands 25.0%  ·  Switzerland 15.0%

naive HHI = 0.122500 + 0.062500 + 0.062500 + 0.022500 = 0.270000
effective jurisdictions = 1 / 0.270000 = 3.703704
```

```
bloc collapse, all WEST:  bloc-HHI = 1.000000   N = 1.000000
ln(N) = 0                 eta ln(N) = 0         h = -0.500000

generous counterfactual, the non-member as its OWN perimeter:
WEST 85.0% -> 0.722500     CH 15.0% -> 0.022500
bloc-HHI = 0.745000     N = 1.342282
ln(N) = 0.294371        eta ln(N) = 0.103030    h = -0.396970
```

Even treating the non-member as a fully independent coordination perimeter — which the sanctions evidence of Section 5.3 does not support — the four-jurisdiction European structure reaches 1.34 effective blocs against 2.94, and $h = -0.396970$ against -0.122417. H3's prediction is met.

The six variants:

variant	naive HHI	naive effective	bloc-HHI	N	ln N
conventional as found (one European at 13.6)	0.293430	3.408	1.000000	1.000	0.000
moved to the second European jurisdiction	0.293430	3.408	1.000000	1.000	0.000
moved to the third	0.293430	3.408	1.000000	1.000	0.000
moved to the non-member	0.293430	3.408	1.000000	1.000	0.000
all four, 35 / 25 / 25 / 15	0.270000	3.704	1.000000	1.000	0.000
all four, non-member as a SEPARATE bloc	0.270000	3.704	0.745000	1.342	0.294

Five of the six rows produce a surplus term of exactly zero. Moving a holding vehicle from one European centre to another is the single most common diversification step taken by European families, **and it changes the effective bloc count by exactly nothing.**

7.4 A printed arithmetic error, left visible and corrected in place

The source computation for one variant of Section 7.3 — the non-member credited as its own perimeter, at the conventional structure's own weights of WEST 86.4 per cent and non-member 13.6 per cent — was printed as follows:

```
PRINTED     bloc-HHI = 0.749296   N = 1.334   ln(N) = 0.288
```

Recomputed from the stated shares:

```
0.864^2 + 0.136^2 = 0.746496 + 0.018496 = 0.764992

CORRECTED   bloc-HHI = 0.764992   N = 1.307203   ln(N) = 0.267890
            eta ln(N) = 0.093761  h = -0.406239
```

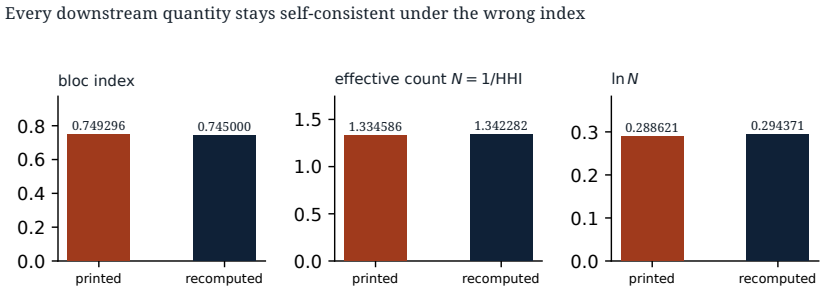

Figure 54.2: **A single wrong index propagates consistently: the printed bloc index of 0.749296 yields an internally coherent effective count and logarithm, and only recomputation from the shares detects it.** Recomputed from $0.864^2 + 0.136^2 = 0.764992$; the printed row is reproduced exactly as published. Script `figs/src/CCP-054_fig02.py`.

The printed index is wrong. It is left visible here rather than silently amended, because what it does downstream is the finding.

Three observations, each of which is the reason the error is worth a section.

First, the error is in the index alone, and everything below it is internally consistent with the wrong value. $1/0.749296 = 1.334586$ and $\ln(1.334586) = 0.288621$, so the printed N and $\ln N$ follow correctly from the printed index. **A single wrong input that propagates consistently produces a table in which every relationship checks out, which is exactly why such an error survives review.** Checking a table for internal consistency does not detect it; only recomputation from the inputs does.

Second, the printed value cannot be reproduced from the stated shares by any operation this paper describes. No rounding of 0.864 and 0.136 to any printed precision yields 0.749296. **This paper does not speculate about its origin**; it records that the value is unreproducible from the published inputs, which is the strongest thing that can honestly be said about it.

Third, the conclusion is unaffected, and that is not a defence. All four proposals in the variant table leave the structure below $N = 1.35$ against the designed architecture's 2.94, and three leave it at exactly 1.00. The error moves h from -0.398983 to -0.406239, a difference of 0.007256. **That the conclusion survives is a fact about this particular error's size and not a property of the method, and a reader who takes "the conclusion is unchanged" as a general reassurance has drawn the wrong lesson.** The corpus's own preregistered fit is the reference point: Curzi [2026i] reports a confirmatory test that **failed its own second falsification rule** — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, despite +40.3 per cent over persistence, +97.7 per cent over direct input, and $p = 0.0005$ against the shuffle. **A series that reports that failure cannot report an arithmetic error only when it changes an answer.**

The general discipline is not to round carefully but to **carry full precision through every intermediate step and round only at the print** — and to publish the inputs alongside the outputs so that recomputation is possible at all. Nosek et al. [2018] is the framework; Simmons et al. [2011] and Ioannidis [2005] are the reasons an undetected error in a published computation is the normal case rather than the exceptional one.

7.5 The reallocation that reduces resilience, and H4

Two questions follow from the designed architecture's residual Western element.

Why keep it at all? Because the Western real estate exists, the English-law counterparty relationships exist, and market access is worth something. Removing it entirely would raise N and destroy capability the architecture actually uses. The measured trade:

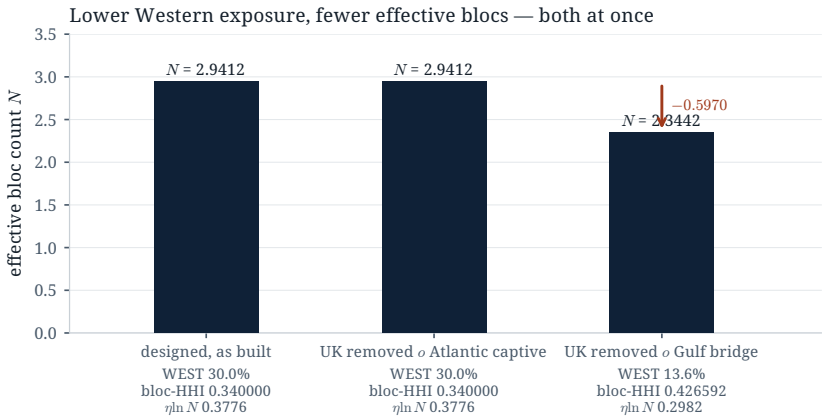

Figure 54.3: **Lowering Western-perimeter exposure from 30.0 to 13.6 per cent cuts the effective bloc count from 2.94 to 2.34, because the exposure has to go somewhere and it went onto one bridge.** Measured from the three share vectors tabulated above; h computed at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$. Script `figs/src/CCP-054_fig03.py`.

variant	WEST %	bloc-HHI	N	$\ln N$	$\eta \ln N$
designed, as built	30.0	0.340000	2.9412	1.0788	0.3776
UK removed, 16.4 to the Atlantic captive jurisdiction	30.0	0.340000	2.9412	1.0788	0.3776
UK removed, 16.4 to the Gulf bridge	13.6	0.426592	2.3442	0.8519	0.2982

```
third row, worked:  BRIDGE      29.1 + 16.4 + 10.9 = 56.4   0.318096
                    NONALIGNED  18.2 + 11.8        = 30.0   0.090000
                    WEST (captive jurisdiction only)  13.6  0.018496
                    bloc-HHI = 0.426592     N = 1/0.426592 = 2.344160
```

The second row is the point. Moving the residual Western holding to another jurisdiction inside the same perimeter changes nothing at all in bloc terms. **A move that looks like leaving a financial centre and is in fact a move inside the same perimeter buys exactly zero.**

The third row is worse than the base case, and it is H4. Reallocating the weight onto the bridge takes Western exposure down to 13.6 per cent and *reduces* N from 2.9412 to 2.3442, because it concentrates the bridge bloc from 40.0 to 56.4 per cent. **Reducing exposure to the perimeter you fear, by piling weight onto one bridge, makes the structure less resilient rather than more. Concentration does not care which direction it points, and Western-perimeter exposure is therefore not a sufficient statistic for resilience — a claim H4 refutes by construction.**

What job is the Western element doing in the effective-bloc arithmetic? None. It contributes to C and not to N, and is justified on capability grounds alone. An element that does not move the concentration measurement is not thereby worthless; it is answering a different question. **Such elements must be justified explicitly and sized deliberately, because the default failure is to let them grow until they dominate the structure they were supposed to diversify away from.** Curzi [2026] and Curzi [2026] report the same shape on different clusters — a domestic four-state vector at 40.0 / 25.0 / 20.0 / 15.0 giving naive 0.285000 and 3.508772

effective jurisdictions but bloc 1.000000, $N = 1.00$ and a surplus term of exactly zero; and six Atlantic-cluster entities at 40.0 / 22.0 / 14.0 / 12.0 / 7.0 / 5.0 giving naive 0.249800 and 4.0032 effective jurisdictions but bloc 1.000000, $N = 1.00$ and $\ln N = 0$. **Three independent clusters, three collapses to exactly one.**

7.6 The share falls and the capability does not, and H5

Applying the six-service taxonomy of Section 4 to what the constructed principal actually needs:

service	needed?	why
the governing law	**yes**	four supply agreements and two financing documents are on it and the counterparties will not move
the forum	**no**	the counterparties are in three other states and none keeps realisable assets in the jurisdiction
the arbitral seat	partly	retained for two legacy contracts; new contracts move seat
the insurance market	**yes**	political-risk and contract-frustration cover on the manufacturing plant; no other market quotes the exposure at a workable price
the listing venue	**yes**	the conversion route for the building
the currency plumbing	**yes**	a five-currency book; execution only, not custody, not treasury residence

Four of six retained, two changed. "We need this financial centre" turned out to mean four specific services rather than a jurisdiction, and only one of the four requires an entity there to exist at all.

The exposure decomposition, before and after:

component	before	after	what changed
commercial building, held through an offshore company	22.0	10.0	converted to a listed securities position; the *holder* need no longer be locally reachable to realise it
operating company: trading, staff, holding group IP licences	9.4	6.4	IP moved out; treasury function removed; arm's-length licence in
locally-custodied portion of the listed portfolio	9.5	0.0	moved to a bridge-bloc custodian

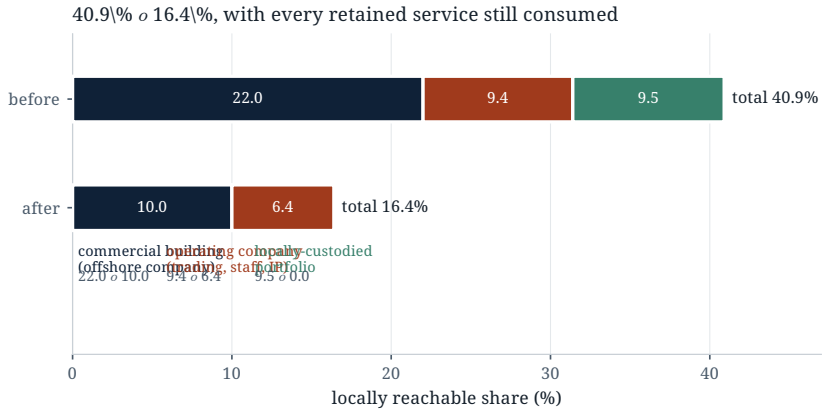

Figure 54.4: **The share falls from 40.9 to 16.4 per cent and every retained service is still consumed: the capability was never in the percentage.** Measured from the component decomposition above; the three components sum to the stated totals exactly. Script `figs/src/CCP-054_fig04.py`.

component	before	after	what changed
total	**40.9**	**16.4**	

The share went from 40.9 to 16.4 per cent and the group lost no capability, because the capability was never in the percentage. It was in four services, all four still being consumed. What fell was exposure. **H5's prediction is met, and the decomposition accounts for the fall exactly.**

Three observations on the rebuild, because each is a general rule.

The most valuable single change cost eleven contract amendments and no entity change. The dispute clauses were redrafted from the enforcement jurisdiction backwards: name the state where the counterparty keeps realisable assets, then choose the instrument that reaches it. Two contracts moved to arbitration under the awards convention [United Nations, 1958]; one kept the governing law and moved the forum to an enclave applying that law directly, **so predictability was unchanged and the forum moved into a bridge bloc — and the counterparty accepted it without negotiation, because their concern was the law and not the courthouse**; one kept the commercial court, correctly, because the counterparty's assets were domestic and the dispute would be documentary; and one could not move at all, because mandatory local law governed the joint venture. **The rule is not "avoid the centre"; it is "choose deliberately", and deliberate choice sends some matters to the centre.**

The rebuild moved toward disclosure at every single step and the structure got stronger. The offshore holding company was collapsed; the ownership chain was documented to natural persons on a public register; abridged filings became full audited accounts; two unverified directors became three verified ones with a resident executive. **That is the disclosure thesis in its most concrete available form.**

A political-risk underwriter prices opacity as risk. An applicant who can produce a complete ownership chain, filed accounts and a clean screen gets a quote; one who cannot gets a declination or a loaded rate. **This is the disclosure standard paying a dividend measurable in basis points**, and it is the mechanism by which Curzi [2026]'s result about performative commitment operates on an institution rather than a person: a commitment made in public, to an audience that will re-price later defection, is stronger than the same commitment made privately, **for the same three reasons — consistency pressure, self-perception from overheard testimony, and the re-pricing of later defection.**

7.7 Hypotheses tested

H1 — supported, and met as an identity. Bloc HHI $= 1.000000$ exactly in four of five variants. **That it is an identity rather than a measurement is important and is recorded in Section 11: the result follows from the construction of the collapse given the assignment, and its content is entirely in the assignment, which is a modelling position (Section 3.4).**

H2 — supported. $h = -0.376286$ on the generous counterfactual, 0.253869 behind the designed architecture.

H3 — supported. 0.270000 naive, collapsing to 1.000000; 0.745000 and $h = -0.396970$ on the generous counterfactual.

H4 — supported, and it is the paper's most useful negative result. N falls from 2.9412 to 2.3442 while Western exposure falls from 30.0 to 13.6 per cent.

H5 — supported. 40.9 $\rightarrow$ 16.4 with the decomposition accounting for the fall exactly and four of six services retained.

Two results cut against the framework's own presentation and are reported here in the same language a success would have received. A printed computation in the source is shown to be wrong and is corrected in place rather than silently amended (Section 7.4). And a move that lowers Western-perimeter exposure to 13.6 per cent nevertheless lowers the effective bloc count from 2.94 to 2.34 (Section 7.5) — **which means the exposure percentage the whole series reports most prominently is not, on its own, a measure of resilience.**

8. Failure modes

1. Treating the best jurisdiction as the apex because it is the best. Every quality signal points one way, so the holding entity goes there and the structure ends at $N = 1.00$. **Quality and independence are different axes, and this paper exists because people read the first as evidence of the second.**

2. Treating "offshore" as a synonym for "outside the perimeter". The word is a legacy of exchange control and describes a tax and regulatory position, not a political one. **Moving between two jurisdictions inside one perimeter is a change of tax treatment and regulatory regime; it is not a change of perimeter, and the two are constantly confused because the word describes the first while implying the second.**

3. Diversifying across three jurisdictions inside one perimeter. Section 7.1. **The variant appears in real files because it is easy to execute and it looks like activity.**

4. Reading institutional quality as independence. The Islands score extremely well on court quality, supervision and professional standards, and those scores are earned. **They are also, in part, evidence *for* the bloc assignment rather than against it, because the standards being met are set outside them.**

5. Confusing a governing law with a jurisdiction. The highest-value correction available. A clause choosing one system's law and another system's forum keeps the substantive predictability and moves the forum outside the perimeter. **It is available, cheap, and almost never drafted, because the two concepts arrive in the same sentence in the counterparty's first draft and nobody separates them.**

6. Planning around a judgment-recognition position that no longer exists. Structures papered before 2021 frequently assume regional circulation of judgments. That assumption is dead; the replacement covers exclusive choice-of-court agreements only [Hague Conference on Private International Law, 2005], leaving asymmetric clauses — standard in finance documentation — genuinely contested.

7. Assuming one register is the whole disclosure picture. A company holding local land through an overseas entity engages a second register; an overseas parent engages the chain-walking machinery of the first; a trust in the chain engages specific provisions. **The failure is rarely non-compliance; it is an incomplete map producing inconsistent filings across three**

registers, which is exactly the pattern that triggers an enquiry. Inconsistency between filings is a far bigger risk than disclosure itself.

8. Building a verification plan on a printed date. Identity-verification rollouts are staged and rescheduled. A group with fifteen directorships needs a programme with an owner and a live calendar, not a note in a file.

9. Underestimating the interim toolkit as a defendant. Freezing injunctions and worldwide disclosure orders do not ask who deserves them. A structure with an element in a jurisdiction has given its courts a jurisdictional hook and a claimant a service gateway. The response is not to avoid the jurisdiction but to keep that entity's assets proportionate to the capability it provides, so the worst available interim outcome is bounded.

10. Using an element as a treasury or clearing hub by drift. Nobody decides to do this. One entity has a working bank account and the others are painful to open, so payments start routing through it, and within two years the group's settlement concentration sits in the jurisdiction the architecture was designed to reduce exposure to. The control is a written payments policy with per-entity caps, reviewed against the bank statements rather than against the policy.

11. Reserved powers exercised as control. A reserved-powers provision lets a settlor reserve powers without invalidating the trust. It does not let a settlor run the trust as a personal account and keep the protection of the trust form. A reserved power exercised on every decision is not a reserved power; it is evidence.

12. Assuming a firewall stops a foreign court. A firewall is a rule about what the local law applies to local proceedings. It does not stop a foreign court asserting jurisdiction over a person before it, or making orders against that person on pain of contempt. A firewall protects the structure from foreign law; it does not protect a person from a foreign judge.

13. Ignoring substance because the entity "just holds". Pure equity holding companies are a distinct category under all three Island regimes, generally with reduced requirements — but "reduced" is not "none," and the classification of a mixed-activity entity changes the requirement. An entity that acquires an intra-group financing or IP function without anyone reclassifying it is the standard defect.

14. Forgetting there is no lender of last resort. Section 5.1. For operating cash that is a sizing question; for reserve it is a disqualification.

15. Diagnosing the problem as secrecy loss. Section 5.3. A principal who believes these jurisdictions are becoming less private will buy privacy that is not the constraint.

16. Building for a rate differential that a minimum-rate regime removed. Or crossing the in-scope threshold unnoticed, which changes the compliance economics of every entity in the chain including entities outside the region.

17. Letting an element grow because it is the easiest thing to grow. The deepest failure mode and the least visible. One entity can hire, bank, contract and be understood without explanation, so every marginal decision favours putting the next thing there. Two years of marginal decisions produce a structure whose entity map says 16.4 per cent and whose operating dependency says something much larger. Annual re-measurement with a written diff is the only control that catches it, and the diff is the finding. Curzi [2026h] states the general bound this failure mode sits inside: two levers that do not pay are reported there — cutting decay alone by raising trust makes the worked case *worse*, at -0.2114, while reciprocity alone gives $+0.7394$; and a deliberate 40 per cent sunset without any conversion work ends with less stored order, 5.507, than doing nothing at all, 7.494. Shedding is a stabiliser, not a cure. Removing an element is subject to the same discipline as adding one.

18. Letting an element outlive its justification. An Island holding built correctly for the conditions of its time becomes a defect not because anything went wrong there but because the structure around it changed and nobody reopened the question.

9. Discussion

What follows. Four things, each narrower than the general claim it resembles.

Subdivision inside a perimeter is exactly zero, not merely small. The result is arithmetic given the assignment, and Section 7.1 reports it as an identity rather than as a measurement. **The organisational form of the same finding predates the measurement by four decades:** Perrow [1984] established that interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component, and this paper's signature result — that adding a jurisdiction inside one perimeter can leave resilience unchanged or make it worse — is that result in a measurement frame. **It is cited as qualitative theory and framing, never as a formal result**, and the corpus should stop presenting the finding as new.

Adding coordination surface has a cost even when it adds nothing. Each additional Island or European entity adds counsel, filings, local substance and management attention. The general organisational result is that units inside a coordination boundary add communication cost at order $n(n-1)/2$ [Brooks, 1975] and add nothing to independence; and Conway [1968] supplies the reason a structure ends up mirroring the advisory organisation that built it rather than the threat it was built against. **A three-Island structure is a communication structure, drawn as a resilience structure.**

The direction of a reallocation does not determine its effect. H4. **Concentration is a property of the share vector and not of the label attached to the largest share**, which is why a plan expressed as "reduce exposure to X" can lower N while succeeding on its own terms. Curzi [2026] prices the closely related question of when a compartment is worth building: **with a cost advantage of 0.090 against a fenced benefit of 1.400 units a year, indifference sits at $1.400(1-r) = 0.090$, giving $r = 93.5714$ per cent — the minimum confidence that a foreign forum respects the cell wall.** That is the same shape of result as this paper's segregation caveat in Section 5.1: **a segregation capability is worth its cost only above a confidence threshold that can be computed, and the threshold is high.**

The most valuable export of a financial centre is the one that does not carry its perimeter. H5. This is the paper's positive result and it generalises: **wherever a jurisdiction's value is an intangible that another jurisdiction can adopt, the value can be consumed without the exposure.**

What does not follow. Four things.

It does not follow that these jurisdictions should not be used. Each has a capability the architecture uses. **The prescription is to size the element to the capability, book it honestly, and re-justify it annually.**

It does not follow that raising N is always right. Uzzi and Spiro [2005] find an inverted U in which performance rises and then falls with cohesion; Sagan [1993] documents that redundancy can *reduce* safety by adding coordination surface; March [1991] gives the mechanism by which fast convergence on a single mode destroys the variance that produced the advantage. **A monotone raise-N prescription cannot survive those results unqualified and none is made here.**

It does not follow that the effective count is a complete account of a structure. Curzi [2026] establishes that a **recognition dependency** — whether the form of ownership asserted over an exposure is intelligible to the courts and registries that must record it — is invisible to this instrument, because the effective count is a function of the share vector and the correlation matrix and of nothing else. **Its R6 is the sharpest statement of the limit: the apex does not move the concentration reading, naive 0.2934 / 3.41 and bloc 1.0000 / 1.00, whatever vehicle sits at the top.** This paper's Section 7.5 finds a second thing the reading does not capture: which bloc the reduced exposure moves *into*.

It does not follow that the instrument discriminates well here. Section 3.2. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, and **four of five headline vectors in this paper sit at the limiting case of it.** The measurements are exact and their discriminating power is minimal, and Section 11 records this as the most serious methodological exposure in the paper.

The status of the claim is measurement, not physics. Hedström and Ylikoski [2010] states the criterion the discipline named in the corpus title applies: an explanation must name a mechanism rather than exhibit a fitted curve. **The mechanism named here is a transmission structure — a shared appellate bench, a shared currency, a shared designation decision, a common external template — and nothing is fitted.** No order parameter is identified, no phase transition located, no critical exponent estimated; the vocabulary of Castellano et al. [2009] is deliberately not used. **What is offered instead is the structural analogy at the right strength:** Castellano et al. [2000] shows that the same interaction which raises local agreement freezes global diversity into non-interacting regions with a sharp transition between the monocultural and fragmented phases — **a perimeter, in that vocabulary, is a frozen region**, and Granovetter [1978] and Schelling [1971] are the standing warnings against reading an individual-level parameter straight into an aggregate, which is what a bloc assignment does. Gallegati et al. [2006] is the checklist this paper was run against, and Section 11 reports where it passes and where it does not.

Parallel results elsewhere in the corpus. The shape recurs on different objects. Curzi [2026c] reads the sharp Lipschitz constant $N-1$ as a **measurement-error budget**: at $N=12$ and $u=0.05\pm0.05$ the surplus lies anywhere in $[0, 0.7419]$, a width of 0.7419, against 0.1266 at $u=0.70$. **That is the same asymmetry this paper's Section 7.4 demonstrates on a printed index: the sensitivity of the output to an input error is not constant across the domain, and it is largest exactly where the corpus's headline cases sit.** Curzi [2026] reaches the formal boundary from the other side, with **Theorem 16.2:** $\mathrm{NET}(m) = 2\log_2(m) - 1.442695(\kappa/\eta)m(m-1)$ **octaves, so a dyad is viable in the best case if and only if** $\kappa/\eta \le \ln 2 = 0.693147$ — a logarithmic benefit against a quadratic coordination cost, which is the same trade this paper measures between $\ln N$ and a C that grows with the entity count. **The corpus has the general theorem; this paper supplies the instance in which the logarithmic term is exactly zero.**

Two further corpus results bound what may be claimed about the audit itself. Curzi [2026] reports an audit distribution over thirteen entries — **seven MAPS, two SPLIT, one RENDERING, three REJECTED, with five entries carrying a failure** — which is the standard this paper's jurisdictional assessments are held to: **an audit that rejects nothing is not an audit**, and Section 7 rejects four of five Island variants and five of six European ones. Curzi [2026] supplies the precision discipline in exact-rational form — **a minimum-gap schedule by ladder length: 1200 cents at $N=2$, 203.9100 at $N=3$–6, 34.9756 at $N=7$–16, 6.0008 at $N\ge17$, 1.0296 at $N\ge41$** — establishing that the corpus computes in exact rationals where it can. **Section 7.4's error is precisely what happens when it does not.**

10. Verification and rigour audit

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	exposure share of jurisdiction i	$[1]$	dimensionless	defined; sums to 1 by P1
W_b	bloc share	$[1]$	dimensionless	derived, $W_b = \sum_{i\in b} s_i$
HHI	concentration index	$[1]$	dimensionless	derived from shares
ρ_{ij}	correlation between shocks	$[1]$	dimensionless, $[-1,1]$	**assumed, not measured**
N	effective bloc count	$[\#]$, **a count**	blocs	derived as $\mathrm{HHI}_{\text{bloc}}^{-1}$

symbol	quantity	dimension	unit	status
$\ln N$	input-term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
Q	protected capital	$[C]$	index units	defined; **no operational unit is supplied by the source**
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived

Does the surplus law balance? $h = \eta \ln N - \delta Q - C$ requires every term to carry $[C\,T^{-1}]$. δQ does; C does by definition; $\eta \ln N$ does **only if η carries $[C\,T^{-1}]$ per nat**, and **the source is silent on this** — it treats conversion efficiency as a bare number. The audit records the silence rather than filling it in. **The reading in the table is this paper's, not the source's.**

The important row is N. The index is a dimensionless sum of squared dimensionless shares, so its reciprocal carries the dimension of a **count**. **The instrument is not a score that happens to start at 1; it is a measured count of independent units, with a unit**, and Section 10.3 checks it against the definition of a count.

Where no operational unit exists, this audit says so. Q is protected capital in index units and no conversion to currency is supplied. **Every value of h in this paper is therefore on an arbitrary scale fixed by the stated parameters.** The differences between h values — 0.253869 between the generous counterfactual and the designed architecture, 0.007256 between the printed and corrected variants — are in the same arbitrary units and are meaningful only as ratios and orderings.

10.2 Significant figures and epistemic status

- 1.000000, 0.345000, 0.270000, 0.702248, 0.745000, 0.764992, 0.426592 are **exact arithmetic** on exactly-stated shares. Their reciprocals — 2.898551, 3.703704, 1.423998, 1.342282, 1.307203, 2.344160 — are exact to the printed precision and may carry as many digits as are useful.
- $\ln N$ and $\eta \ln N$ are **derived-from-defined** at an assumed η. **They are exact functions of an assumed input and therefore carry no uncertainty and no authority beyond the assumption.**
- h values carry the same status and are additionally in unnamed units (Section 10.1).
- 0.749296 is **reproduced exactly as printed in the source** and is not a computation of this paper. Section 7.4 records that it is unreproducible from the stated shares.
- The exposure shares themselves — 40.9, 27.3, 18.2, 13.6, 29.1, 16.4, 11.8, 10.9 — are **constructed and are exact as stated to one decimal place**. Curzi [2026] records in its own verification section that the naive index of the conventional vector depends on the rounding basis: 0.293388 on exact fractions against 0.293430 on three-significant-figure percentages. **This paper uses 0.293430 throughout, which is the three-significant-figure basis and the reproducible choice from published inputs.**
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere. That is not a strength: it means the paper has no empirical content to attach an interval to.**

10.3 Limits and boundary behaviour

The instrument's limits are the proof that it behaves as a count, and they are run rather than asserted.

limit	HHI	HHI^{-1}	reading
one holder, $s_1 = 1$	1	1 exactly	a monopoly counts as one unit
n equal holders, $s_i = 1/n$	$1/n$	n exactly	returns the count
n holders, any unequal split	$> 1/n$	$< n$	never overstates the count
$s_{\max} \to 1$, rest $\to 0$	$\to 1$	$\to 1$	continuous approach to the monopoly limit
$n \to \infty$, equal shares	$\to 0$	$\to \infty$	unbounded above, as a count should be
$\rho \to 0$ within blocs	naive	naive count	the independent limit
$\rho \to 1$ within blocs	bloc	bloc count	the fully-coupled limit

Range: $1 \le \text{HHI}^{-1} \le n$, with both bounds attained. Verified on this paper's own vectors: the three-Island bloc vector is a single unit at 1.000000 and returns $1/1 = 1$ exactly, and a hypothetical three-way equal split of the same exposure returns $1/(3 \times (1/3)^2) = 3$ exactly. **A quantity that equals n for n equal units, equals exactly 1 for a single unit, and lies strictly between otherwise is a count, and no further argument is needed.**

The same limits run on the affine count, which fails them. $N_{\text{eff}} = 1 + (N-1)u$ returns 1 at $u = 0$ and N at $u = 1$ for *any* share vector whatever — including a vector at $(0.999, 0.001)$, for which it reports 2.000000 at $u = 1$ while HHI^{-1} reports 1.002004. **It has the right endpoints and the wrong interior, because it never consults the shares.** It is not used here.

Boundary behaviour of the surplus law. As $N \to 1^+$, $h \to -(\delta Q + C)$ — the maintenance floor, and the value four of this paper's five headline vectors sit at exactly. As $N \to \infty$, $h \to \infty$ logarithmically, **which is a defect of the model and a statement of its domain**, since Uzzi and Spiro [2005] and Sagan [1993] establish that the real curve turns over. **The model's domain is small** N, and every prescription here is confined to the move from $N \approx 1$ to $N \approx 3$. As $\eta \to 0$, $h \to -(\delta Q + C)$ regardless of N: no conversion, no benefit from any amount of independence. As $\delta \to 0$ the stock never erodes and any positive $\eta \ln N - C$ accumulates without bound, **which is a pathology rather than an ideal.**

Boundary behaviour of the reallocation result. Moving a share x from bloc A to bloc B changes the bloc index by $2x(W_B - W_A) + 2x^2$, which is **negative — that is, N rises — only while** $W_B + x < W_A - x$, that is only while the receiving bloc, after the move, remains smaller than the sending bloc after it. **At $W_A = 0.30$ and $W_B = 0.40$ the condition fails for every positive x, which is why the reallocation of Section 7.5 could not have helped and did not.** That is H4 as an inequality rather than as an example, and it is checkable in one line.

10.4 Invariance

The effective count is invariant under relabelling of units and under any rescaling that preserves the share vector. Doubling every exposure in currency terms leaves every s_i unchanged and therefore leaves the index, N and $\ln N$ unchanged. This is a genuine scale invariance and it is why the instrument applies to a structure of any size.

It is not invariant under regrouping, and that is the whole content of the bloc collapse. **It is also not invariant under a relabelling of which bloc is "the one being reduced", which is the finding of Section 7.5**: a reallocation described as reducing exposure to a named perimeter is,

arithmetically, a reallocation increasing exposure to a different one, and the index responds to the second description.

What would break the scale invariance: any share basis that is not normalised. **Tested at how many scales?** The invariance is algebraic, not empirical, and was checked at exactly the vectors reported here — three of three entries, one of four, one of six, and three bloc vectors. **No claim of empirical scale-freedom is made, and no distributional or scaling claim is made anywhere.** Clauset et al. [2009] is the reason that matters: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison leaves few canonical power-law claims standing, and **a straight line on a log-log plot is not evidence.** Stumpf and Porter [2012] adds that even a genuine power law would be weak evidence for a mechanism. **The exposure vectors here are finite sets of three, four and six shares and must not be restated as samples.**

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. **The objection is met here and the answer is short.** The conserved quantity is the exposure share vector: $\sum_i s_i = 1$ exactly, dimensionless, and it is that constraint alone that gives the index its bounds. **Remove the normalisation and the effective count ceases to be a count.** The invariance group is relabelling together with any rescaling that preserves the simplex. Q**, by contrast, is a stock with no stated conservation law and no operational unit, and this paper does not claim one for it.** Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law is claimed to hold and stop claiming a universality the argument does not need. **The arrangement claimed here is a normalised exposure vector with a correlation matrix having unit diagonal and non-negative entries, and nothing outside it.**

Aggregation is unaddressed. Kirman [1992] establishes that a single representative parameter for a heterogeneous group generally does not exist, and this paper writes one Q, one δ and one C for structures whose branches plainly differ. **No aggregation argument is offered and none is available from the arithmetic.**

10.5 Analogy discipline

borrowing	source	category	justification
portfolio variance	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix
Hill numbers, order 2	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* ${}^2D$; an identity
numbers-equivalent	Adelman [1969]	**1 — derivation**	the reciprocal of the index is the count of equal units giving that index
similarity-sensitive diversity	Leinster and Cobbold [2012], Rao [1982]	**1 — derivation**, with a stated domain	exact where the matrix has unit diagonal and non-negative entries
the effective number of parties	Laakso and Taagepera [1979]	**1 — derivation**	the same formula on a different share basis

borrowing	source	category	justification
asset partitioning	Hansmann and Kraakman [2000]	**1 — derivation**	the cell company performs exactly the partitioning function entity law is identified as supplying
open design	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	the disclosure standard *is* the open-design requirement applied to legal rather than cryptographic structure
$\ln N$ as entropy	Shannon [1948]	**2 — shared form**	this is **Shannon entropy in nats**, dimensionless, and not thermodynamic entropy
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	the percolation premises have not been shown to hold; only the structural property is used
robust-yet-fragile	Albert et al. [2000], Callaway et al. [2000]	**2 — shared form**	the degree-distribution result is not claimed to apply; the shape of the tolerance asymmetry is
synchrony in ecology	Loreau and de Mazancourt [2008]	**2 — shared form**	the naming convergence is recorded; no ecological mechanism is imported
frozen regions	Castellano et al. [2000]	**2 — shared form**	a perimeter is structurally a frozen region; **no phase transition is located and no exponent estimated**
threshold and tipping	Granovetter [1978], Schelling [1971]	**2 — shared form**	the aggregation warning is used; no threshold distribution is estimated
coordination cost at $n(n-1)/2$	Brooks [1975], Conway [1968]	**3 — framing**	qualitative organisational theory, cited for shape and never as a formal result

borrowing	source	category	justification
normal accidents	Perrow [1984], Sagan [1993]	**3 — framing**	prior qualitative statement of the same observation, never a formal result

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration arithmetic is category 1 throughout and needs no help.

10.6 Measurement-theoretic status of the scored inputs

The evidence ladder of Section 6.1 is ordinal and is not summed. Its classes are ranked — "strongest", "weaker", "weakest" — and **an ordinal scale licenses a ranking and a maximum, and does not license a mean or a total.** The assignments of Section 6.3 are made by identifying the strongest available class for each jurisdiction, which is licensed. **No score is computed and no threshold is arithmetic**, and that is deliberate: a numeric evidence score would invite exactly the averaging the scale type forbids.

The twelve-item jurisdictional assessments summarised in Appendix C are heterogeneous and are not totalled. Legal family, court quality, rail access and degradation trajectory have no common scale, and no verdict in Appendix C is produced by adding them. **The assessment is a checklist that produces a verdict by argument, not a score that produces one by arithmetic.**

The framework's treatment of Q as a ratio-scale quantity is not tested. Michell [1997] is the strongest available objection: psychology and its neighbours routinely assume quantitative structure without testing for it, and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all. **The conjoint conditions were not tested for Q, which is stated here in unnamed index units, and the ratio-scale treatment is therefore provisional. The concentration instrument itself is untouched by this objection**, because exposure shares are ratios of capital and not psychological judgements.

10.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$; the effective count is its reciprocal	DEFINITION
P3	for n equal shares of $1/n$, HHI $= 1/n$	ARITHMETIC
P4	a bloc is a set of jurisdictions among which one decision produces the corresponding effect without a further decision	DEFINITION
P5	the three Islands are one bloc; the four European centres are one bloc	POSTULATED (H1, H3; stipulated with the evidence of Section 6.3)

#	statement	status
P6	the conservatively assigned Atlantic captive jurisdiction is folded into WEST	POSTULATED (the conservative assignment)
P7	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P8	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P9	the constructed exposure vectors of Section 7	POSTULATED (constructed)

10.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	HHI^{-1} returns n exactly for n equal shares and 1 for one holder	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	HHI^{-1} is the Hill number of order 2 — Hill [1973]	CITED
L4	P4, P5	the three Islands collapse to one bloc share of 1.000000	POSTULATED
R1	P2, P9	Islands at 40 / 35 / 25: naive 0.345000, effective 2.898551	ARITHMETIC
R1b	L4, R1	bloc 1.000000, $N = 1.000000$, $\eta \ln N = 0$ at every η	ARITHMETIC
R2	P2, P9	crediting the Islands separately: $0.818^2 + 0.182^2 = 0.702248$, $N = 1.423998$, $h = -0.376286$	ARITHMETIC
R2b	R2	the gap to the designed architecture is $0.376286 - 0.122417 = 0.253869$	ARITHMETIC
R3	P2, P9	the European four: naive 0.270000, effective 3.703704; bloc 1.000000	ARITHMETIC
R3b	P2, P9	crediting the non-member separately: 0.745000, $N = 1.342282$, $h = -0.396970$	ARITHMETIC

step	consumes	statement	status
R4	P2, P9	at the conventional weights, $0.864^2 + 0.136^2 = 0.764992$, $N = 1.307203$, $\ln N = 0.267890$, $h = -0.406239$; **the printed 0.749296 is unreproducible from these shares**	ARITHMETIC
R5	P2, P6, P9	blocs 56.4 / 30.0 / 13.6 give 0.426592 and $N = 2.344160$, down from 2.941176, while WEST falls 30.0 → 13.6	ARITHMETIC
R6	P9	$22.0 + 9.4 + 9.5 = 40.9$ and $10.0 + 6.4 + 0.0 = 16.4$	ARITHMETIC
CR	R4, R5	a printed computation is wrong and is corrected; and a move lowering perimeter exposure lowers N	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. **Only P5, P6, P8 and P9 are POSTULATED, and P5 — the bloc assignment — is the paper's entire empirical exposure.** H2 and H3 exist so that the conclusion does not depend on it. **A chain whose central step is a stipulation is not a proof, and this paper says so here rather than leaving the reader to notice: the arithmetic is exact and the assignment is a judgement.**

10.9 Cross-checks performed

- Every naive index was recomputed from its share vector in exact decimal arithmetic and agreed with the printed value to twelve decimal places, **except 0.749296, which does not agree with any computation from the stated shares and is reported as such in Section 7.4.**
- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on every vector: $0.160000 \le 0.345000 \le 0.400000$ on the Islands; $0.122500 \le 0.270000 \le 0.350000$ on the European four; $0.318096 \le 0.426592 \le 0.564000$ on the reallocated blocs.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $2.898551 \le 6.250000$ and $3.703704 \le 8.163265$.
- Every bloc vector sums to 1.000000 exactly: $0.818 + 0.182$; $0.850 + 0.150$; $0.864 + 0.136$; $0.564 + 0.300 + 0.136$.
- The component decomposition of Section 7.6 sums to the stated totals exactly: $22.0 + 9.4 + 9.5 = 40.9$ and $10.0 + 6.4 + 0.0 = 16.4$.
- The reallocation inequality of Section 10.3 was verified against the measured case: at $W_A = 0.30$, $W_B = 0.40$ and $x = 0.164$, the condition $W_B + x < W_A - x$ fails, and N fell.

11. Limitations

The instrument is least informative exactly where this paper's headline cases sit. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, where one unit holds a very large share. **Four of the**

five headline vectors here collapse to a single unit at 100 per cent, which is the limiting case. The measurement is exact and the *discriminating power* is minimal. This is the most serious methodological exposure in the paper, and its practical consequence is that comparisons among heavily dominated structures must not be made on N alone.

The correlation is assumed, not measured. The collapse uses $\rho = 1$ within a bloc, which is the conservative end of a family. No correlation was estimated from data in this paper. That is the single largest unmeasured input and it is exactly the quantity H1 and H3 turn on. The generous counterfactuals of Sections 7.2 and 7.3 exist so that a reader who rejects the assignment can still read an answer.

The bloc assignment is a stipulated reference group, not an identified effect. Manski [1993] rules out recovering an endogenous effect from observation of a linear-in-means reflexive system. The remedy adopted is stipulation with a defence [Brock and Durlauf, 2001], and the price is that the assignment is a modelling position.

H1 is met as an identity and identities cannot confirm hypotheses. Given the assignment, the bloc index of a single-bloc vector is 1.000000 by construction. H1's content is entirely in the assignment, and stating it as a prediction and then showing it is an identity is what makes that visible — a reviewer who objects that it should not have been a hypothesis is right, and the objection is recorded here rather than left to be made.

Every case is constructed. The principal, the assets, the shares, the component decomposition and the service inventory are invented and are labelled as such at each point of use. No empirical dataset was collected and none is reported.

Jurisdiction-specific legal claims are not cited to primary sources. Every enactment, decided case, listing event, survey figure, rate, date and jurisdictional characteristic in Sections 4 to 6 is taken from the source manuscript. The bibliography contains no statutes, regulations, court rules, registries or case reports for any individual jurisdiction. Appendix B lists the affected claims. This is a real gap and it is not closed here. It is also load-bearing in a specific way: the bloc assignment rests on those uncited facts, and the arithmetic rests on the assignment, so an error in the legal description propagates into every number without producing an arithmetic inconsistency.

The dated events are not independently verified. Enactment dates, listing and de-listing dates, survey shares and the dates of judicial decisions are reported as publicly announced and were not checked against primary sources by this paper.

One printed source computation is wrong and its origin is unknown. Section 7.4 corrects it and states plainly that the printed value cannot be reproduced from the stated shares. No claim is made about how it arose, and the possibility that other unreported errors exist in source computations this paper did not recompute is real and is not excluded by anything here.

Cost is asserted and not measured. The claim that a Crown Dependency or European element adds materially to C is stated without a figure, because fee levels are commercially negotiated and no defensible number was available. The direction is certain and the magnitude is not, and a reader who believes the cost is negligible should read the argument as resting on $\ln N = 0$ alone, which it can.

Monotone claims are restricted. Uzzi and Spiro [2005], Sagan [1993] and May [1972] are the reasons a monotone raise-N prescription could not survive unqualified, and Section 9 bounds it.

The instrument is exposed to its own failure mode. Adopted as a target, N would cease to be a good measure [Goodhart, 1975, Campbell, 1979]; Scott [1998] is the historical form, in which legibility destroys the local variety that made the system work, and it is a warning about this instrument as much as an argument for it. Nothing in the arithmetic prevents that, and the only defence offered is the reporting discipline of Appendix A.

The performativity problem is stated and unresolved. MacKenzie and Millo [2003], Hacking [1995], Merton [1948] and Lucas [1976]. The framework asserts that systems change when modelled and exempts its own parameters from that reflexivity.

11.1 Rigour checks not met, listed by name

1. **No as-of date, because no real holdings were measured. A concentration measure without an as-of date is not a measurement.** Every share vector here is constructed. The same applies with greater force to the jurisdictional descriptions: **a statement of a regime without a date is not a statement of that regime**, and Appendix B requires the date of every confirmation.
2. **No uncertainty is reported anywhere, because nothing is estimated.** That is not precision; it is the absence of empirical content.
3. **The dimension of η is supplied by this paper, not by the source** (Section 10.1).
4. **Q, C and h have no operational unit.** Every h difference reported is in arbitrary units and is meaningful only as an ordering.
5. **The surplus law's large-N limit is unbounded**, which the empirical literature contradicts. The model's domain is small N.
6. **The conjoint conditions were not tested for** Q [Michell, 1997, Luce and Tukey, 1964].
7. **The evidence ladder is ordinal and is deliberately not summed** (Section 10.6). Any downstream work that computes an evidence score from it will be performing an unlicensed operation.
8. **Model comparison was not performed.** No alternative index was fitted, no out-of-sample test run, no information criterion computed and no matched null constructed, because nothing here is fitted.
9. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. **Any restatement reaching for a heavy-tail claim must run it first** [Stumpf and Porter, 2012].
10. **The coupled-network, tipping and coordination-cost borrowings are category 2 or 3, not category 1** (Section 10.5).
11. **There is no conservation law for** Q [Mirowski, 1989]. Section 10.4 gives the one genuine conservation and states plainly that the stock variable has none.
12. **Aggregation is unaddressed** [Kirman, 1992].
13. **Expected value and time average are not the same thing** [Peters, 2019]. A perimeter event does not arrive in expectation; it arrives once and rescales every subsequent year, and the multiplicative consequence is not modelled here. Peters and Gell-Mann [2016] is additionally the **stronger warrant for the logarithm** in the surplus law than any perceptual argument, because it derives a logarithmic growth rate from multiplicative dynamics with no psychological assumption at all. **Where the two justifications disagree, the multiplicative one should be preferred.**
14. **The reflection problem is stated and not solved** [Manski, 1993, Shalizi and Thomas, 2011].
15. **No differential prediction is offered.** Durlauf [2005] asks for the prediction only this model makes, and the collapse makes none: any correlation-aware concentration measure would produce it. **The contribution is the identification of the correct unit of analysis, the generous counterfactuals, and the two negative results — not a uniquely discriminating forecast.**
16. **The mechanism-side companion to the arithmetic exists and is not used.** Bouchaud and Mézard [2000] derives concentration rather than observing it: multiplicative growth plus exchange produces a heavy tail, and above a critical ratio a finite fraction of the total condenses onto one holder — **which is the index going to one, obtained from a mechanism.** This paper asserts no tail and does not use the model; **the citation records that the corpus has not attempted the mechanism-side account and that a reviewer may fairly ask why not.**

12. Conclusion

This paper establishes the following results in the form the rest of the corpus cites them.

R1 — the Crown Dependency error. Three Islands at 40.0 / 35.0 / 25.0 per cent give a naive

Herfindahl index of 0.345000 and 2.898551 effective jurisdictions, **but a bloc index of** 1.000000**,** $N = 1.00$ **and a surplus term of exactly zero at every value of** η**.**

R2 — the generous counterfactual. Crediting the Crown Dependencies as their own bloc (WEST 81.8 / CD 18.2) gives a bloc index of 0.702248, $N = 1.423998$ and $h = -0.376286$ against the designed architecture's 2.941176 and -0.122417 — a shortfall of 0.253869.

R3 — the European convergence. Luxembourg 35.0 / Ireland 25.0 / Netherlands 25.0 / Switzerland 15.0 gives a naive index of 0.270000 and 3.703704 effective jurisdictions, collapsing to 1.00; crediting Switzerland separately gives a bloc index of 0.745000, $N = 1.342282$ and $h = -0.396970$.

R4 — an arithmetic error, left visible and corrected in place. A printed bloc index of 0.749296 is unreproducible from the stated shares; recomputation gives 0.764992, $N = 1.307203$, $\ln N = 0.267890$ and $h = -0.406239$. **The error is in the index alone and everything downstream of it is internally consistent with the wrong value, which is why checking a table for internal consistency does not detect it.**

R5 — a diversification that reduces resilience. Moving the residual 16.4 per cent from the Western perimeter to the Gulf bridge gives blocs of 56.4 / 30.0 / 13.6, a bloc index of 0.426592 and N falling from 2.9412 to 2.3442, **despite Western exposure dropping from 30.0 to 13.6 per cent.**

R6 — the share falls and the capability does not. The Western share falls from 40.9 to 16.4 per cent with no capability lost, because what is bought under the name of a financial centre — governing law, arbitration seat, insurance capacity, listing venue — **is portable and separable from asset situs**, and the component decomposition accounts for the fall exactly: $22.0 + 9.4 + 9.5 = 40.9$ before, $10.0 + 6.4 + 0.0 = 16.4$ after.

Counter-result. Two findings cut against the framework's own presentation. **A printed computation is shown to be wrong and is corrected rather than silently amended.** And **a move that lowers Western-perimeter exposure to 13.6 per cent nevertheless lowers the effective bloc count from 2.94 to 2.34** — which means the perimeter-exposure percentage the series reports most prominently is not, on its own, a measure of resilience. To those two the verification section adds a third, against this paper's own instrument: **the effective count is least discriminating exactly in the dominated-unit regime where four of five headline vectors sit.**

One result is established as method rather than as measurement. **Institutional quality and perimeter independence are different axes**, and a jurisdiction can score at the top of the first while contributing exactly zero to the second. The corollary is the paper's positive finding: **where a jurisdiction's value is an intangible another jurisdiction can adopt, the value can be consumed without the exposure — take the law and leave the perimeter.**

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the principal, the asset mix, the exposure shares, the component decomposition, the service inventory and the variant tables — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

One figure reproduced in this paper is not a computation of this paper. The bloc index 0.749296 in Section 7.4 is reproduced exactly as printed in the source manuscript and is reported there as unreproducible from the stated shares; the corrected value 0.764992 and everything derived from it are this paper's computations.

All figures were produced by the scripts named in their captions (`figs/src/CCP-054_fig01.py` through `figs/src/CCP-054_fig04.py`), which import the shared figure style module and read

their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional and legal descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general treaty, standard-setting and comparative material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction. Appendix B lists the claims affected. **Any reader relying on those descriptions must verify them against the official sources and record the date of that verification.**

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every principal, family, entity and transaction described is invented.

Preregistration

The five hypotheses of Section 2, with their point predictions and falsifiers, were stated before the computations of Section 7 were run. **H1 was met as an identity rather than as a measurement, and Section 11 records that this is a weaker outcome than a confirmed hypothesis normally is.** No hypothesis in this paper was preregistered in any external registry.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes jurisdictions, courts, registration regimes, enforcement instruments and structural arrangements for the purpose of measuring concentration. **No recommendation is made in respect of any particular person, asset, structure or jurisdiction.** Judgment-recognition positions, substance requirements, listing rules, property tax stacks, personal tax settlements, beneficial-ownership access models and sanctions regimes all change, several of them annually; every such statement here is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in each jurisdiction of residence, asset situs and counterparty domicile before any reliance.

Appendix A. The portable-law rule and the reporting discipline

```
GOVERNING LAW      choose for predictability -- it is PORTABLE
FORUM              choose deliberately, NOT by habit
SEAT (arbitration) choose deliberately, and verify the current
```

```
                  institutional landscape before naming a body
ENFORCEMENT PLAN  name the jurisdictions where the debtor keeps
                  realisable assets, and work BACKWARDS from the
                  instrument that reaches them
```

A dispute clause should be drafted from the enforcement jurisdiction backwards, not from the drafter's habits forwards. If the counterparty's realisable assets sit in a state party to the awards convention [United Nations, 1958] but not to any judgments instrument with the forum state, a judgment is a document and an award is money. If the assets sit in the forum state, the reverse.

Where a jurisdiction's element is retained on capability grounds, the specification is:

```
role            NEVER the apex. A subordinate operating or
                segregation vehicle beneath a non-perimeter apex.
holds           no reserve, no group intangibles, no treasury
substance       real, and sized to the relevant-activity
                classification, re-assessed annually
disclosure      every register filing complete and CONSISTENT with
                every other register filing in the group
exit            a live migration path, documented and COSTED
measurement     booked to its true bloc, without argument
```

The exit line is the one that gets skipped and the one that matters most. A structure whose migration path has never been costed does not have a migration path; it has an intention, and intentions are executed slowly at exactly the moment when speed was the only thing that would have helped.

The reporting standard, per measurement: the share basis in one sentence; the exposure table summing to 100.0 per cent; the naive index and effective jurisdictions **with the rounding basis named**; the bloc assignment with the strongest evidence class for each jurisdiction; the bloc index and N; the largest bloc's share as a percentage; $\ln N$, $\eta \ln N$ and h at the stated parameters; a generous counterfactual over every contested assignment; **and the date, with the diff against the previous measurement.**

Two items are load-bearing and are usually omitted. The rounding basis, because Section 10.2 shows the same exposure map gives different naive indices depending on how the shares are printed. And the diff, because perimeter drift is invisible except as a difference between two measurements taken a year apart, **and the drift of failure mode 17 is the one this discipline exists to catch.**

Appendix B. Claims requiring verification against primary sources

None of the following is cited to the bibliography, which contains no primary sources for any individual jurisdiction. They are reproduced from the source manuscript and require confirmation, **with the date of confirmation recorded**, before any reliance.

1. Arbitration legislation in the forum state: which provisions of the most recent Act are in force and the commencement regulations; and the appellate decisions on the law governing the arbitration agreement and on the arbitrator's duty of disclosure.
2. Judgment-recognition position: the entry-into-force date and contracting-party list of each judgments instrument for each relevant state; the declarations made; the status of any accession application to a regional convention; and **the treatment of asymmetric jurisdiction clauses, which is contested.**

3. Listing rules and the prospectus regime: the current rulebook, the date of the most recent restructuring of listing categories, and the staged commencement of the prospectus framework.
4. Identity-verification and register regimes: current deadlines for director and controller verification; the update obligations and trust-information disclosure position of any register of overseas entities; and the scope and evidential requirements of any personal-security suppression provision. **The commencement schedules have moved more than once; never plan from a printed date.**
5. Foreign-exchange market shares and turnover: take the current triennial survey figures directly from the publishing body; the survey is triennial and the shares move.
6. The insurance market: chain-of-security figures and financial strength ratings change annually; confirm the historic reconstruction transaction and its dates from primary sources.
7. Property taxation: every line of the acquisition, annual-charge, capital-gains, income and inheritance stack requires confirmation. **Several lines moved in 2024 and 2025.**
8. The personal tax settlement: the enacted provisions, transitional reliefs, repatriation facility and trust-protection position. **Material changes occurred between announcement and enactment.**
9. Enforcement instruments: the statutory basis of any unexplained-wealth order regime and the appellate and first-instance decisions described; the sanctions framework and the regulations made under it.
10. Island trust and corporate statutes: the current numbering and text of each firewall provision, each reserved-powers provision, and any statutory mistake or inadequate-deliberation jurisdiction, with the amendment laws that introduced each. **A citation to an old text here is worse than no citation.** The perpetuity position and its treatment of pre-existing trusts. The statutory basis of protected and incorporated cell companies after consolidation, **and the recognition of cell segregation in every jurisdiction where a cell will contract.** The parallel company regimes, foundations and purpose-trust statutes of the third Island; its customs and indirect-tax agreement and revenue-sharing formula, which has been renegotiated; and its aircraft registry's establishment date and eligibility criteria.
11. Island coordination evidence: the exact short titles and commencement of each economic-substance instrument; the listing and de-listing conclusions dates; the 2019 beneficial-ownership commitment and the current access model in each Island; the sanctions instruments and the mechanism by which external designations take effect locally; and current mutual evaluation reports and follow-up status.
12. The 2008 bank failures, their outcomes, and the current terms and caps of each depositor compensation scheme.
13. The Island case authorities described — on retained control, on sham and creditor recourse, on exclusive jurisdiction clauses in trust instruments, on trustee liability and indemnity, and on the narrowing of the mistaken-exercise doctrine. **Case citation follows different conventions and no case is in the bibliography.**
14. The November 2022 supranational judgment on public register access: its operative part and the directive provision held invalid; and the successor package's legitimate-interest access conditions and application dates.
15. The minimum-rate regime: the enabling directive, each implementing instrument and its amendments, the referendum and commencement position in the non-member state, the precise formulation of the turnover threshold, and the safe harbours.
16. The anti-tax-avoidance and mandatory-disclosure directives: each transposition instrument and date, the reverse-hybrid commencement, and the crypto-asset reporting application date; and the decision on legal professional privilege in the disclosure regime.
17. State-aid decisions and their appellate outcomes; and the supranational beneficial-ownership judgments supplying an abuse principle independent of any treaty. **Confirm the joined case numbers and holdings before relying on any summary, including this one.**

18. The vehicles named in each European centre: the participation-exemption, fund, securitisation and partnership statutes; the leasing and structured-finance provisions of the common-law member state; the withholding regime, participation-exemption conditions and commercial-court rules of the third; and the banking-secrecy provision, exchange legislation, domestic tax reform and sanctions ordinances of the non-member. Take concentration and flow data from the relevant national fiscal and central-bank bodies.
19. The administration-foundation instrument: formation requirements, the tax treatment of receipt holders and the beneficial-ownership consequences, in each holder's jurisdiction.
20. All bloc assignments in Section 6 are the analyst's judgements applied to published characteristics. The underlying appellate, currency, substance, exchange and designation facts should be confirmed jurisdiction by jurisdiction.

Appendix C. Jurisdictional assessment, condensed

No total is computed: the items are heterogeneous and no common scale exists on which they could be added (Section 10.6). Every characteristic below is described from the source manuscript and is uncited (Appendix B). The jurisdictions of the ranked capability table are de-identified as "Island A / B / C" following the convention of Curzi [2026], because that table ranks named jurisdictions on legal capability the bibliography cannot support; jurisdictions carrying a bloc assignment with its evidence are named, because the assignment is the argument.

Bloc assignment and job, by jurisdiction.

jurisdiction	bloc	strongest evidence	job
United Kingdom	**WEST, at the centre rather than the edge**	founding member of the standard-setting body; an independent designating authority whose designations have converged rapidly with two others since 2022; the jurisdiction whose banks administer its own currency's clearing	**OPERATING**, and bridging only in the narrow sense of market access and governing-law contracting. **Never holding**
Jersey	**WEST**	final appeal to a committee of the neighbour's supreme court justices; the neighbour's currency with no central bank; the neighbour's designations effective locally; substance legislated to a common external deadline	**HOLDING**, as a subordinate fiduciary vehicle beneath a non-perimeter apex — never the apex

jurisdiction	bloc	strongest evidence	job
Guernsey	**WEST**	identical on every operative test	**HOLDING with a genuine segregation specialisation**, and a real risk-transfer capability
Isle of Man	**WEST, on the hardest evidence of the three**	all of the above, **and** membership of the neighbour's customs and indirect-tax territory under a revenue-sharing agreement that has been reset from outside	**OPERATING**, distinctively — registries and asset ownership inside that territory
Luxembourg	**WEST**	member of a union whose coordinated instruments it implements	**OPERATING**, for regulated-fund distribution
Ireland	**WEST**	same	**OPERATING**, for leasing and common-law fund vehicles
Netherlands	**WEST**	same	**OPERATING**, and control separation
Switzerland	**WEST on the evidence of outputs**	adoption of its neighbours' sanctions packages from February 2022 through its own embargo legislation, and alignment with successive packages since	**OPERATING**, for custody depth

Ranked capability, de-identified.

requirement	best fit	why
trust for a settlor from a forced-heirship civil-law system	Island A	firewall, reserved powers, deepest case law, statutory mistake jurisdiction
segregated cells for asset or risk ring-fencing	Island B	protected and incorporated cell companies; the original engineering and the deepest practice
captive insurance with regional proximity	Island B	established regime, insurance-linked-securities cell practice
aircraft or vessel ownership inside the neighbour's indirect-tax territory	Island C	registry inside that territory

requirement	best fit	why
operating company with the neighbour's market and indirect-tax alignment	Island C	simplified company regime, shared indirect-tax territory
listed closed-ended fund	Island A or B	established listed-fund practice

The three items that decide every row of the first table are the final appellate arrangement, the currency and monetary authority, and the sanctions alignment. **None of the eight jurisdictions can legislate itself a different one of the three**, which is why the bloc assignment is the least contestable call in the paper and why nothing available to any of them would change it.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing, **except the one printed value identified in Section 7.4 as unreproducible, which is reproduced there as published.**

Chapter 55

Entity Maps Understate Dependency: The Dollar Axis, the Insurance Reserve, and a Scored Captive Rubric

Abstract. A structure's exposure to a jurisdiction is not what its entity map says. Measured three ways, the same holding shows entity-based United States exposure of 27.3 per cent, a dollar-denominated share of the balance sheet of 61.0 per cent, and roughly 58 per cent of settlement volume clearing through the United States system — a dependency more than twice the entity reading. The four favoured US trust and company states, Delaware 40.0 per cent, South Dakota 25.0, Nevada 20.0 and Wyoming 15.0, give a naive HHI of 0.285000 and 3.508772 effective jurisdictions, but a bloc-HHI of 1.000000 and an effective count of 1.00, so state-level selection contributes nothing to independence. The paper then treats the insurance reserve as a measurable object rather than a claim: a captive balance sheet with 67.08 per cent committed to third-party liabilities and 25.34 per cent held as target capital leaves 7.58 per cent realisable within a year and about 27.45 per cent on a present-value basis, a 72.55 per cent haircut. The same property makes the reserve unavailable to its owner, which is stated as the cost of the result rather than hidden. Captive arrangements are scored on a hundred-point rubric across risk shifting, risk distribution, actuarial pricing, claims paid and insurer conduct, with hard zeros. Crediting Bermuda as a distinct bloc raises N from 2.941176 to 3.385332, an accounting choice rather than a structural change.

Keywords: currency exposure; dollar clearing; domestic asset protection trust; captive insurance; risk distribution; reserve realisability; concentration measurement

Series: D. Structure and Resilience **Paper:** CCP-055

1. Introduction

A structure's exposure to a jurisdiction is not what its entity map says. This paper measures the gap on a constructed cross-border holding, on three axes rather than one, and reports that the entity reading understates the dependency by more than a factor of two. It then takes a second object that is routinely asserted rather than measured — the protective character of an insurance reserve — and measures that too, in the same units, including the half of the measurement that is a cost to the owner rather than a benefit.

Three questions organise the paper, and each has a number for an answer.

First, what does sub-national selection buy? A structure exposed to one country through four of its constituent states looks, on a naive index, like four jurisdictions. Delaware 40.0 per cent, South Dakota 25.0, Nevada 20.0 and Wyoming 15.0 give a naive Herfindahl–Hirschman Index of 0.285000 and 3.508772 effective jurisdictions. Collapsed onto the coordination perimeter those four states share, the same shares give a bloc index of 1.000000, an effective count of exactly 1.00, and a surplus term of exactly zero. **The state-level split contributes nothing to independence, and unlike the comparable cases in this series it admits no generous counterfactual at all**, because the four states share one constitution, one federal judiciary, one currency, one central bank, one designating authority and one bankruptcy code. Curzi [2026] could run its counterfactual — the Crown Dependencies scored as an independent perimeter — and still reach the same verdict: Jersey 40.0 / Guernsey 35.0 / Isle of Man 25.0 gives naive HHI 0.345000 and 2.898551 effective jurisdictions but bloc-HHI 1.000000, $N = 1.00$ and a surplus term of exactly zero. Here there is no counterfactual to run, and Section 7.1 says so rather than manufacturing one.

Second, which axis is the structure actually exposed on? The same constructed holding reads entity-based United States exposure of 27.3 per cent, a dollar-denominated share of the balance sheet of 61.0 per cent, and approximately 58 per cent of settlement volume clearing through the United States system. The entity map is the axis every file records and the axis on which every subsequent decision in the constructed case had been assessed. It is the smallest of the three by a factor of 2.23. **A structure is only as diversified as its most concentrated axis, and the axis most often measured is the one that flatters.** Curzi [2026] reaches the residual form of the same finding — 55 per cent of settled value still clearing through a single system whose law is not the holder's, a floor set by the counterparties' currency rather than by entity placement — and Curzi [2026] measures the rail directly, where a naive correspondent HHI of 0.302400 (3.306878 effective correspondents) collapses to a perimeter HHI of 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency.

Third, how much of an insurance reserve is actually reachable? The claim that a licensed insurer's reserve resists a shareholder's creditor — the argument made for a Bermuda captive, and the reason a risk-transfer centre appears in a resilience analysis at all — is usually made as an assertion. It is measurable. On a constructed year-seven statutory balance sheet with total assets of USD 16,100,000, third-party liabilities commit 67.08 per cent, the supervisor's target capital level locks a further 25.34 per cent, and 7.58 per cent is distributable within a year; over a normal run-off the present value to the shareholder is 27.45 per cent, a haircut of 72.55 per cent. **The counter-result is in the same arithmetic**: the property that makes the pool hard for a creditor to reach — real obligations owed to unrelated parties, gated by a supervisor — is the same property that makes it unavailable to its owner. That is stated here as the cost of the result rather than filed as an unadvertised footnote.

What the paper contributes beyond restating these three measurements is a correspondence. The bloc collapse of Curzi [2026] — the operation that replaces a naive count of units with a count of independent failure points, reaching a redesigned six-jurisdiction structure at naive HHI 0.189002 (5.29 effective jurisdictions) and bloc-HHI 0.340000 (2.94 effective blocs) with Western-perimeter exposure falling from 100.0 to 30.0 per cent — is the same operation as the risk-distribution test that decides whether a captive arrangement is insurance. Both count independent exposures rather than listed entities; both are defeated by a common mode; and both are routinely inflated by adding units inside the mode. Section 7.6 runs the concentration instrument on the insurance side of the paper and derives an effective-count floor from a published share constraint. **The two halves of this paper are not two subjects. They are one instrument applied to two share bases**, which is what makes it a paper rather than a survey.

The paper presupposes the surplus functional and the affine effective count of Curzi [2026] — whose four-currency carrying cost of coin, hours, attention and foreclosure, set against the law that felt comfort decays over weeks while carrying cost does not decay at all, is the parallel result in another domain — and the roster-audit form of that count in Curzi [2026c], whose sharp Lipschitz constant $N-1$ reads as a measurement-error budget: at $N = 12$, $u = 0.05 \pm 0.05$ admits surplus anywhere in $[0, 0.7419]$, a width of 0.7419, against 0.1266 at $u = 0.70$. That budget is why no figure in this paper is quoted as though its inputs were measured.

The bloc assignment carries an identification problem, and it is stated here rather than in a footnote. The assignment is a forecast about coordinated behaviour, and forecasts about a system condition the system. Manski [1993] proves that a linear-in-means reflexive specification is **not identified from observational data**: the endogenous effect cannot be separated from contextual effects or from correlated unobservables however much data is collected, and Shalizi and Thomas [2011] show that influence and selection are generically confounded in observational network data. **No amount of observing jurisdictional behaviour could confirm a bloc assignment derived reflexively.** The remedy adopted here is the fourth of the four known routes: the reference group is stipulated in advance and the stipulation is defended — the assignment in this paper is fixed by the perimeter test of Curzi [2026], recorded with its evidence class in Section 4.1 below, and stress-tested in Section 7.7 — which is the route Brock and Durlauf [2001] shows can be made rigorous. **The price is that every bloc assignment in this paper is a modelling position and not an identified empirical result, and the paper says so wherever the assignment enters.**

Two boundaries are set before the machinery arrives, both carried from work that states them more sharply than this paper needs to. Curzi [2026] declines the inflated reading of its own borrowed physics — the framework's postulate is stated as a postulate, the relation is given only in its correct form, and a named failure mode requires that its users be able to distinguish the theorem, the ordinary observer effect and the framework's own conjecture in three separate sentences on demand — and this paper is bound by the same discipline in Section 10.5. Curzi [2026] assigns this framework's central identification, the application of the surplus functional to a life, and the reading of a day's surface as a leading indicator to the postulate drawer, and states that the third is a wager whose misfire column exists because wagers can lose. **Nothing in this paper is entitled to a stronger badge than the framework it sits inside.**

2. Hypotheses

Five hypotheses are stated, each falsifiable in the sense Platt [1964]'s strong inference requires. Where a statement cannot be falsified it is labelled a definition or a modelling choice and is not counted. Meehl [1967] is the standing warning: directional predictions are cheap, and the defensible response is a point prediction with a constant attached, which is what H1, H2, H3 and H5 do.

H1 — the no-counterfactual hypothesis. Selection among the constituent states of a single federal jurisdiction contributes exactly nothing to the effective bloc count, and unlike the comparable cases in this series it admits no counterfactual bloc assignment under which it would. *Predicted:* Delaware 40.0 / South Dakota 25.0 / Nevada 20.0 / Wyoming 15.0 gives naive HHI 0.285000 and 3.508772 effective jurisdictions, and bloc-HHI 1.000000, $N = 1.000000$, $\ln N = 0$ exactly, for every admissible assignment. *Falsified by:* any defensible bloc assignment placing two of the four states in different coordination perimeters — that is, evidence that a decision taken at the federal level reaches one and not another without a second independent decision.

H2 — the axis-mismatch hypothesis. The entity axis systematically understates a structure's exposure to a jurisdiction whose currency it holds. *Predicted, as a point prediction on the constructed case:* entity-based United States exposure 27.3 per cent against a dollar-denominated balance-sheet share of 61.0 per cent and settlement volume through the United States system of approximately 58 per cent — a ratio of $61.0/27.3 = 2.234$ on the currency axis and $58.0/27.3 = 2.125$ on the settlement axis. *Falsified by:* a currency and settlement decomposition of the same structure that returns a share at or below the entity share. **The hypothesis is directional about the sign and specific about the size; it is tested here on one constructed structure only, which Section 11 states as its weakest feature.**

H3 — the realisability hypothesis. The share of a licensed insurer's assets that a shareholder's creditor can realise within a year is a small and computable fraction of the balance sheet, and is set by the reserve and the regulatory capital requirement rather than by any

protective drafting. *Criterion, fixed in advance:* realisable-within-a-year is total assets less third-party liabilities less the target capital level, divided by total assets; on the constructed balance sheet this is predicted to fall below ten per cent. *Falsified by:* a balance sheet on which that quantity is large, or a legal route by which committed reserves are realisable without supervisory consent. **A creditor who obtains the reserve itself falsifies this hypothesis directly.**

H4 — the retained-programme hypothesis. A captive funding a genuine retained layer recovers a modest and boundable fraction of the prior commercial spend, not a large one. *Predicted:* on the constructed programme, $2{,}700{,}000 - 410{,}000 - 1{,}560{,}000 - 140{,}000 = 590{,}000$, which is $590{,}000 / 4{,}370{,}000 = 13.50$ per cent of the previous commercial spend of $4{,}370{,}000$, before investment income and before any tax consequence. *Falsified by:* a comparable programme returning materially more than that without either retaining more risk than it discloses or failing to pay claims.

H5 — the equivalence hypothesis. The risk-distribution test applied to a captive's book and the bloc collapse applied to a jurisdictional structure are the same operation on different share bases, so that a published constraint on insured shares is equivalent to a floor on the effective count. *Predicted:* the constraint "twelve subsidiaries each contributing between five and fifteen per cent of the captive's total risk" implies an effective count in $[9.090909,\ 12.000000]$, and "nine unrelated members none above sixteen per cent of premium" implies $[6.443299,\ 9.000000]$, exactly. *Falsified by:* a share vector satisfying either constraint whose reciprocal index falls outside the stated interval.

Not hypotheses, and labelled as such. Four further statements appear in this paper and none is falsifiable as stated.

- *The logarithmic form of the input side*, $\eta \ln N$ rather than ηN, is a **modelling choice** carried from Curzi [2026] and not tested here. Section 11 records that Latané [1981]'s sublinear power law fits the qualitative facts as well, and that nothing in this paper discriminates between them.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice** carried from Curzi [2026] and fixed before the measurement, which is the preregistration discipline of Nosek et al. [2018] applied to an engineering measurement.
- *The identification of the surplus law's* N *with the effective bloc count* is a **definition**. Its content is in the bloc assignment rule, which is testable, and not in the identification.
- *The five-test rubric of Section 6* is a **working instrument constructed by this framework**, adopted by no tribunal, and its weights are stipulated rather than estimated. Section 10.6 states its scale type and Section 11 states what follows.

3. Method

3.1 The instrument, and which effective count it is

The concentration instrument is taken unchanged from Curzi [2026], whose redesigned six-jurisdiction structure reaches naive HHI 0.189002 (5.29 effective jurisdictions) and bloc-HHI 0.340000 (2.94 effective blocs) with Western-perimeter exposure falling from 100.0 per cent to 30.0 per cent. Its definition fits on one line:

```
HHI = sum of squared shares            effective count = 1 / HHI
```

introduced by Hirschman [1945] and reached independently in sum-of-squares form by Herfindahl [1950]. The reciprocal reading — the count of equal-sized units that would produce the observed index — is due to Adelman [1969]. Competition practice states the index in points on percentage shares [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]; this paper states it as a fraction, and gives both wherever confusion is possible.

Which effective count, stated exactly, because this framework runs two. The reciprocal index HHI^{-1} is the Hill number of order two [Hill, 1973], whose numbers-equivalent reading Jost [2006] states in its cleanest form; the same arithmetic was reached in ecology by Simpson [1949] and in political science by Laakso and Taagepera [1979]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and the reciprocal index is also the exponential of the Rényi entropy of order two [Rényi, 1961]. **Every effective count in this paper is HHI^{-1}, the Hill number of order two, and it is named as such at each use.** The framework's other effective count, $N_{\mathrm{eff}} = 1 + (N-1)u$, is a linear interpolation between 1 and N; it is **not a Hill number of any order** and carries no external support, as Curzi [2026] establishes by running the same verification chain on both and letting one fail visibly. It is referred to here by name and is never used to produce a number.

The general form. The bloc collapse generalises the reciprocal index to $\mathrm{EFF} = 1/(w'Rw)$ for exposure weights w and correlation matrix R, which is the similarity-sensitive diversity of order two of Leinster and Cobbold [2012], whose additive relative is the quadratic entropy of Rao [1982]. Setting $R = I$ recovers HHI^{-1}; setting R to a block matrix of ones recovers the bloc index. Hurlbert [1971] is the standing objection that "diversity" carries no content without its formula attached, which is precisely the discipline this section imposes.

No distributional or scaling claim is made anywhere in this paper. A share vector of 40.0 / 25.0 / 20.0 / 15.0 descends steeply and a reader may reach for a tail argument. **This paper fits no distribution, characterises no tail and asserts no power law.** Clauset et al. [2009] is the reason: on twenty-four canonical data sets a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few standing, and a straight line on a log-log plot is not evidence. That procedure was not run, because no claim requiring it is made. Stumpf and Porter [2012] adds that even a genuine power law is weak evidence for a mechanism, because many mechanisms produce the same tail. **The effective counts here are statistics of finite exposure vectors with three, four, six or thirteen entries, not estimates of distributions, and must not be restated as such.**

The collapse result has an ancestry that should be named rather than reinvented. A small correlated shift producing a discontinuous collective outcome is the threshold and tipping mechanism. Granovetter [1978] establishes that the distribution of individual thresholds and not the mean determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate result — the strongest available warning against reading an individual-level parameter straight into an aggregate, which is exactly what a bloc assignment does. Castellano et al. [2000] supplies the closest formal analogue of a bloc: the same interaction that raises local agreement freezes global diversity into non-interacting regions, with a sharp transition between the monocultural and fragmented phases. **A bloc, in that vocabulary, is a frozen region and the effective count is a count of them.** Bouchaud and Mézard [2000] derives concentration rather than observing it — multiplicative growth plus exchange condenses a finite fraction onto one holder above a critical ratio, which is the index going to one, obtained from a mechanism. This paper does not use that model and asserts no tail; the citation records that a mechanism-side companion to the arithmetic exists.

3.2 The share basis, and the four axes

An index without a stated threat is an index without a share basis. This paper measures against **arbitrary state action** — a designation, a listing, an exchange-control measure, a compliance department's change of risk appetite — and not against lawful process, which has the opposite structural signature and is the subject of Section 4.2. Against arbitrary action the useful property is sitting outside a coordination perimeter; against lawful process that property is close to worthless, because the enforcement mechanism travels to the person and the person is inside the perimeter.

The instrument is identical on each of four axes and only the share basis changes.

axis	share basis	what a decision reaches
jurisdiction	fraction of protected capital whose availability depends on a decision taken inside a perimeter	entities, registries, courts
settlement rail	fraction of settlement volume depending on a given clearing or messaging system	instructions in flight
counterparty	fraction of protected capital held as a claim on, or custodied by, a given institution	the ability to instruct
currency	fraction of the balance sheet denominated in a given unit	every balance, wherever booked

Three consequences follow and all three do work below.

A portfolio contributes to the perimeter of its custodian, not of its issuers. A globally diversified portfolio held through a custodian in one jurisdiction is an exposure to that jurisdiction, and the diversification of the issuers is a fact about a different question. This is the step at which the constructed case's file was wrong.

A currency is a perimeter exposure that no entity move can exit. A balance denominated in a unit whose clearing runs through banks inside a perimeter carries that perimeter's exposure however the entities are arranged. The currency axis therefore interacts with the jurisdiction axis rather than being independent of it.

A structure is only as diversified as its most concentrated axis. The reporting discipline is to run all four and print all four; Appendix A states the reporting standard, and item 13 of it — naming the largest of the four as the binding one — is what this paper adds to the standard Curzi [2026] set.

One distinction ruins naive measurements on the settlement axis and is recorded here so Section 7.2's figure is read correctly. **A clearing system and a messaging system are different layers.** A structure reporting two rails may have one messaging dependency, so that "one messaging network at one hundred per cent" and "eighty-five per cent on that network plus fifteen per cent on a second clearing system whose messaging leg runs over the first" are the same number, and only the second looks diversified. Curzi [2026] decomposes the rail properly and reports the collapse; this paper uses the settlement figure as a single share and does not decompose it further, which is a limitation and is recorded in Section 11.

3.3 Correlated units, and what the literature says about the correction

The naive index overstates resilience because it treats units as independent when they share a coordination mechanism. The correction is not novel as mathematics. It is the observation, stated for portfolios by Markowitz [1952], that diversification benefit depends on covariance and not on count; and stated for coupled infrastructures by Buldyrev et al. [2010], that a system of interdependent networks is far more fragile than either network alone. Perrow [1984] reached the organisational form first — interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component — and Sagan [1993] documents the sharper version, that redundancy can reduce safety, which is a direct threat to any prescription that says raise the count. **Both borrowings are labelled under the analogy discipline of Section 10.5, and this paper's signature finding is Perrow's result in a measurement frame rather than a new observation.**

Correlations rise under stress, which is the part that matters operationally. Longin and Solnik [2001] find extreme correlation in equity markets that is asymmetric and concentrated

in downturns, and Ang and Chen [2002] report the same asymmetry. **The effective count falls exactly when it is needed.** The ecological name for the decisive variable is synchrony [Loreau and de Mazancourt, 2008], and the strongest empirical demonstration that effective count buys stability is Schindler et al. [2010]'s Bristol Bay sockeye record, where population diversity produces roughly half the variability and about a tenth of the fishery closures. The contrary literature is read alongside and is not decorative: Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone with no mechanism, and May [1972] showed that increasing diversity and connectance destabilises randomly assembled systems. This paper's claim is narrower than the general diversity–stability claim: it asserts only that the reciprocal of a variance is an effective count of independent shocks, which is arithmetic, and that units sharing a common mode are correlated, which is H1 and H5.

3.4 Evidence standard, and the de-identification convention

Sections 4, 5 and 6 are jurisdictional and doctrinal exposition. **Every enactment, decided case, revenue ruling, licensing class, capital threshold, listing event, rate and date in them is described from the source manuscript and is not cited to the bibliography.** The bibliography carries the general instruments and the comparative doctrine only: recognition and enforcement of awards [United Nations, 1958] with the grounds on which enforcement is in fact refused [van den Berg, 1981] and the arbitration doctrine around it [Born, 2021]; the trusts convention [Hague Conference on Private International Law, 1985] and the succession convention that never entered into force [Hague Conference on Private International Law, 1989], with the regional regulation that partially fills the gap [European Union, 2012]; conflict-of-laws doctrine [Torremans et al., 2022, Briggs, 2013]; the trust and the foundation compared [Lupoi, 2000, Smith, 2013, Panico, 2014]; asset partitioning as the irreducible function of entity law [Hansmann and Kraakman, 2000]; the listing machinery as a technique of governance [de Goede, 2011]; and the disclosure instruments [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015]. **It contains no statutes, regulations, court rules, registry documents, revenue rulings or case reports for any individual jurisdiction.** Appendix B lists every affected claim, **with the requirement that the date of confirmation be recorded**, because a statement of a jurisdiction's regime without a date is not a statement of its regime.

Where a table would otherwise **rank named jurisdictions against one another on a legal capability the bibliography cannot support**, the jurisdictions are de-identified — "trust-state A" through "trust-state D" — following the convention of Curzi [2026], which de-identifies two Gulf centres in its own scored assessment for the same reason, and Curzi [2026], which de-identifies three islands in its ranked capability table. **Where a jurisdiction is named in prose, or appears in an exposure table, or carries a bloc assignment with its evidence, the name is used**, because the argument is about those specific perimeter attachments and a functional description would hide rather than protect.

3.5 The realisability measurement, defined

The protective character of an insurance reserve is stated in this paper as a measurement with a definition, so that it can be recomputed on any balance sheet:

```
realisable within one year
    = (total assets - third-party liabilities - target capital level)
      / total assets

present-value realisation
    = (statutory capital and surplus + reserve development)
      / (1 + r)^t / total assets
```

```
haircut = 1 − present-value realisation
```

Three inputs are stipulated rather than measured and are named here so they are not mistaken for findings: the reserve development assumption, the discount rate r, and the average settlement lag t. Section 10.2 gives their epistemic status and Sections 10.3 and 11 give the sensitivity.

The measurement is symmetric and the paper reports both signs. The same three quantities that bound what a creditor can take bound what the owner can take. That is the counter-result of Section 7.4, and it is not a caveat appended to the finding; it is the finding, read from the other side.

3.6 The rubric as an instrument, and its scale type

Section 6 scores captive arrangements on five tests. The scoring is stated here as method so that Results can be read as measurement rather than as judgement.

The five tests carry weights summing to 100 — risk shifting 25, risk distribution 25, actuarial pricing 20, claims paid 20, insurer conduct 10 — and each is scored on an integer band from 0 to 4, so the weighted total runs to 400. **A zero on risk shifting or on risk distribution is disqualifying regardless of total.** The two disqualifying tests carry exactly half the weight, which is a design choice and is recorded as one.

The scale type is stated because it constrains the arithmetic. The 0–4 bands are ordinal: they rank arrangements and they do not license the assertion that the interval from 2 to 3 equals the interval from 3 to 4. Weighting and summing ordinal scores is an operation the scale does not license, and this paper does it, and says so. The weighted total is therefore read as **a ranking with a disqualification rule attached, not as a quantity**; no difference between two totals is interpreted, and no total is compared across arrangements except as an ordering. **The disqualification rule carries the evidential weight, and it is a logical test rather than an arithmetic one.** Stevens [1946] is the taxonomy, Michell [1997] is the standing objection that quantitative structure is assumed rather than tested, and Luce and Tukey [1964] is the conjoint test that would settle it and was not run. Section 10.6 states the consequence and Section 11 concedes it.

4. The federal overlay, and why no counterfactual exists

This section is the evidence for H1 and it is compressed to what the hypothesis needs. **Everything in it is described from the source manuscript and is uncited** (Section 3.4, Appendix B).

4.1 What the four states share, and the evidence class of the assignment

The perimeter test of Curzi [2026] asks whether a single decision taken in one jurisdiction reliably produces the corresponding effect in another **without a further independent decision**. Applied to four constituent states of one federal jurisdiction the test does not require judgement, and that is the distinguishing feature of this case. The evidence ladder used across this series ranks demonstrated near-simultaneous mirroring of designations, shared correspondent networks that exit corridors together, a supervisory standard producing the same domestic consequence in every member, and binding accession to a common enforcement instrument as the strongest classes, with information-exchange participation and treaty density weaker, and diplomatic alignment weakest.

shared mechanism	evidence class
one constitution, with a supremacy clause subordinating state law to federal law	strongest — binding accession, in its limiting form
one federal judiciary, with a contempt power operating on persons	strongest
one currency and one central bank	strongest
one designating authority, whose measures apply in every state	strongest — mirroring is automatic, not merely near-simultaneous
one bankruptcy code, with a ten-year avoidance provision reaching self-settled devices	strongest
a full-faith-and-credit obligation circulating sister-state judgments	strongest
one federal reporting, withholding and exchange architecture	strongest

Every row is in the strongest class, and none of them is a judgement call. That is what distinguishes this case from every other bloc assignment in the series: elsewhere the assignment is a defended stipulation exposed to the identification problem of Section 1, and here the stipulation has no free parameter left in it. Sections 4.2 and 4.3 record what state selection genuinely does, which is a real thing and is not this thing.

4.2 The mechanism that state law does not reach

The reason a sub-national split buys nothing on this axis is that the binding constraint operates on a person rather than on an asset. A court with personal jurisdiction over a person may order that person to act and may imprison them for refusing; where the assets are, what the instrument says, and whether a foreign fiduciary has declined to comply are not inputs to that mechanism. The source manuscript records two appellate decisions in which an impossibility defence failed on the ground that the impossibility was self-created, and one in which a debtor remained incarcerated for years. **No state statute, no non-recognition provision and no firewall addresses a mechanism that does not operate on the assets at all.**

A second and distinct failure runs through conflict of laws. A self-settled protective trust depends on another state's court applying the trust state's law, and the source records three decisions in which it did not: a state supreme court holding that a statute purporting to confer exclusive jurisdiction on its own courts could not divest other states' courts of jurisdiction; a bankruptcy court applying the law of the state with the most significant relationship together with the federal avoidance provision; and a state supreme court applying its own public policy against self-settled spendthrift trusts to a trust of another state. **The protective statute is only as good as the willingness of a foreign forum to apply it, and that willingness is not something the enacting state can legislate.** The general doctrine is in the bibliography [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008]; the individual decisions are not, and are listed in Appendix B.

The charging-order remedy has an analogous limit. Its doctrinal justification is the protection of other members from an intrusion by one member's creditor; where there are no other members the justification is absent, and the source records an appellate decision holding that the charging order was not the exclusive remedy against a single-member entity. **This is asset partitioning doing exactly what Hansmann and Kraakman [2000] says it does and nothing more** — partitioning is the irreducible function of entity law, and partitioning against a claimant who has personal jurisdiction over the partitioner is not one of the things it does. Pistor [2019] is the account of how legal coding creates capital together with its sharpest critique, and it is the right pairing here because the section describes a coding operation whose limits are legal rather than technical.

A timing observation belongs here and is stated because it is easy to mistake for a jurisdictional one. The governing law against a protective transfer is fraudulent-transfer law, and fraudulent-transfer law is a clock. Whether a transfer is vulnerable turns on when it was made relative to when a claim arose, not on where the recipient vehicle was formed. **A timing problem wearing a jurisdiction costume is still a timing problem**, and every element of the specification the source states — that the structure works against a creditor who must sue in the formation state, is outside the federal avoidance window, cannot establish actual intent, and is not a court with personal jurisdiction prepared to use contempt — is about timing and about who the creditor is.

4.3 What state selection buys, de-identified

The four states are not interchangeable and the differences are real. **The comparison below ranks them on legal capability the bibliography cannot support, so they are de-identified** (Section 3.4). Every characteristic is described from the source manuscript.

requirement	best fit	why
an operating company that expects governance litigation	trust-state A	a specialist non-jury equity court operating since the eighteenth century, judges who hear nothing else, and the deepest body of published decisions; the value proposition is answered questions
a perpetual dynasty vehicle with a directed-trust architecture	trust-state B	perpetuities abolished, a codified separation of investment, distribution and administrative functions, and an unusually strong sealing provision
the shortest seasoning period, and charging-order protection extended to closely held corporate shares	trust-state C	the most aggressive of the four on timing, and distinctive in extending the remedy beyond the limited-liability form
a cheap, low-friction single-purpose vehicle with genuine formation privacy	trust-state D	the originator of the form, the lowest maintenance cost, no public member disclosure, and a developed private-trust-company regime

A jurisdiction with a thin body of decisions offers more favourable text and less predictability, and for an entity likely to face governance litigation the second consideration usually dominates. **Choose the deep bench for governance complexity and the cheap registry for simple single-purpose vehicles, and do not let a fee differential decide it.**

The engineering reading of a jurisdiction that legislates a considered answer to an adverse decision within months cuts both ways, and both halves belong on any assessment: institutional responsiveness is exactly what a structure should want, and a settlement that has become a live political variable rather than a fixed background condition is a different and less comfortable finding. Curzi [2026] reaches the general form of that observation — institutional quality and rule stability are independent properties, and a jurisdiction can have world-class courts and an unbroken constitutional order while replacing a century-old settlement inside

thirteen months — and it is not restated here. **Score the two separately, and never let a high score on the first suppress an honest score on the second.**

4.4 Formation privacy is not protection, and the disclosure constraint

The two are unrelated, and the jurisdiction under study is the clearest available case of a place with a great deal of the first and very little of the second. **A structure whose only asset is that nobody knows about it fails this framework's disclosure test by construction** — and it fails it in the jurisdiction with the most effective discovery apparatus available.

The premise is not this work's to claim. Kerckhoffs [1883] stated it in 1883: a system must remain secure when everything about it except the key is public. Saltzer and Schroeder [1975] restate it as *open design* — the protection mechanism should not depend on the ignorance of attackers — and place it alongside *complete mediation* precisely because a publishable design still requires that every access be checked. Brandeis [1914] is the public-interest form of the same observation from the other direction. **Citing Kerckhoffs converts what reads as an ethical preference into a recognised engineering standard**, and Curzi [2026] states the constraint in its strongest form: channel separation is strengthened by disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable and non-disclosure is refused as a design premise rather than merely discouraged. The regulatory direction has made the same point unavoidable: automatic exchange [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations that supervisors implement in common [Financial Action Task Force, 2012], and the substance and beneficial-ownership work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] together mean that non-disclosure is not an available design parameter whatever a designer's preference.

The constructed case's most volatile input is a reporting position that changed twice in eighteen months, and the source manuscript records the sequence — enactment, implementing rule, constitutional challenge, a nationwide injunction, a stay, and an interim rule narrowing the regime — without asserting the current state of it. **Any structure whose rationale depends on a current reporting position is built on the least stable variable available.** The related error is assuming that a state's non-participation in an information-sharing arrangement matters: federal reporting, withholding and exchange operate independently of any state arrangement, and the reporting comes from the institution and from federal law rather than from a state registry.

Section 7.5's disclosure reading applies the test in print, and Section 9 records the result that follows from it: **the reserve measurement of Section 7.3 is one of the few results in this series whose protective characteristic is increased rather than reduced by publication**, because every fact that makes the pool hard to reach is a fact a supervisor requires to be filed.

5. The reserve as a measured object

5.1 The three legs, separated

The claim under test is that a licensed insurer's reserve resists a shareholder's creditor. Stated whole it is an assertion; separated it is three independent conditions, at least one of which fails in most arrangements. **Everything in this section is described from the source manuscript and is uncited** (Appendix B).

Leg one — technical provisions are liabilities and shareholders stand last. This is ordinary corporate and insolvency law and not an offshore feature. A shareholder's creditor takes the residual after the company's creditors, and the insurer's creditors include every policyholder and ceding company with an outstanding or incurred-but-not- reported claim. Whether a statutory *priority* over general unsecured creditors exists is a separate question and is listed in Appendix B; the argument does not depend on it, because the ordinary subordination of

equity to debt is sufficient. **A priority would add protection against the insurer's own general creditors, which is a different risk from the one under measurement.**

Leg two — the supervisor gates the exit. Distributions above stated thresholds require prior approval or a filed affidavit, the minimum solvency margin and the enhanced capital requirement must be maintained continuously rather than at the year end, and the supervisor has powers to direct, restrict business, require capital and petition for winding up. A creditor who takes the shares owns a company whose cash cannot be extracted at will by anybody, including him. **The gate exists to protect policyholders and would be improper if it existed to protect a shareholder from his creditors; it protects the pool from every direction at once as a side effect of doing its actual job.**

Leg three — the impaired parties are real, identifiable and represented. This is the leg that distinguishes an insurance reserve from a special-purpose vehicle with book liabilities to affiliates, and it is the leg that fails in the arrangements Section 7.5 scores as disqualified. If the policyholders are unrelated commercial parties, or a material share of the book is assumed from unrelated cedants, any process impairing the reserve produces identifiable victims with their own claims, their own counsel and a supervisor with a statutory duty toward them. **A court asked to make an order with that consequence is being asked to do something it will not do casually.** If the only policyholders are companies in the same group as the judgment debtor, none of that is true: the third parties are the debtor in another hat, and the argument evaporates in a paragraph.

The three legs together explain why the characteristic strengthens as the book lengthens in tail. Short-tail property risk settles within a year and the reserve turns over; long-tail liability risk carries reserves for years and the committed pool is correspondingly larger and more durable. **The characteristic is a function of reserve duration**, and an arrangement writing only short-tail risk has much less of it than the description suggests. This is a boundary on the result and it is stated with the result rather than after it.

5.2 What the reserve does not do

Four limits are stated before the number, because a section that sells an argument before bounding it is selling something.

The shares are ordinary property. They can be charged, attached and transferred like any other shares. What resists realisation is not ownership of the insurer but immediate realisable value from it. **The result is a discount and a delay, not a wall**, and Section 7.3 puts a number on both.

It answers arbitrary action, not a judgment. A court with jurisdiction over the shareholder can order him to procure a distribution, and a supervisor's likely refusal is a fact about the supervisor, not a defence to contempt. This is the threat-2 boundary of Curzi [2026] and the two threats have opposite structural signatures: against arbitrary action the useful property is being outside a perimeter, and against lawful process that property is close to worthless because the mechanism travels to the person.

It collapses if the insurance is not real. If the reserve stands against risks assumed from group companies only, there are no unrelated third parties whose impairment makes realisation awkward. If the reserve is invested in loans back to the insured group, the asset backing the third-party liability is a claim against the balance sheet the creditor is already attacking, and the circularity destroys the argument on its own terms. **The doctrinal test for whether an arrangement is insurance and this framework's test for whether a reserve resists realisation point at the same underlying fact**, which is whether unrelated parties have real claims on the pool. Section 6 is that test.

It does not move the concentration reading. Bermuda, which hosts the constructed insurer, is inside the same coordination perimeter as the structure's other Western holdings on every operative test, and Section 7.7 prices exactly what crediting it as a distinct bloc would be worth. **A reader who came to this section looking for a bloc will not find one.**

5.3 Why the regulatory gate is a side effect and not a design feature

One reading of Section 5.1's leg two is worth separating out, because it is the reading that makes the result publishable under the disclosure constraint of Section 4.4.

The supervisory gate is not a protective device that a structure procures. It is a prudential control that exists for policyholders, it operates against every route out of the company including the owner's own, and its effect on a shareholder's creditor is incidental. **That is precisely why the characteristic survives disclosure.** A protective device that works because it is procured can be unwound by the party who procured it, and a court can order it unwound. A prudential control cannot be unwound by the shareholder at all, which is the same fact as the counter-result of Section 7.4 stated from the supervisor's side.

The consequence for how the result may be described is exact. **The reserve does not resist a creditor because it is offshore, because it is opaque, or because a document says so. It resists because somebody else is owed the money and a regulator is watching, and both of those facts are on a public register.** Every element of the mechanism is publishable, and publishing it strengthens rather than weakens it, which is the Kerckhoffs condition of Section 4.4 satisfied rather than merely invoked [Kerckhoffs, 1883, Saltzer and Schroeder, 1975].

6. What makes insurance real: five tests and a scored rubric

6.1 The five tests, made operational

Described from the source manuscript and uncited (Appendix B). The doctrinal anchor is a decision requiring both **risk shifting** and **risk distribution**, and a working four-question formulation asking whether the arrangement involves insurance risk as distinct from investment or business risk, whether there is risk shifting, whether there is risk distribution, and whether the arrangement conforms to commonly accepted notions of insurance. **The fourth question is the catch-all and it does real work**: it is where a tribunal puts the observation that no unrelated party would have bought this cover, that the insurer had no claims department, or that the wording was assembled from templates for a business the insured does not operate.

Test 1 — risk shifting. The evidentiary question is whether anything runs back. Parent guarantees, letters of comfort, loans from the insurer to the insured or its owners, premium-adjustment or profit-commission clauses that return claims paid, unfunded capital commitments treated as capital: any one is a finding against the arrangement, and a loan-back is the single most damaging fact in the reported decisions the source describes.

Test 2 — risk distribution. This must be counted, not asserted, and it is the test this paper measures. Distribution means the insurer has pooled enough **independent** exposures that aggregate variance falls. **That is the same condition Markowitz [1952] states for a portfolio and the same condition the bloc collapse states for a structure**, and it is defeated by the same thing: a common mode. The counting rule the source states operationally is that eleven subsidiaries in eight countries with their own workforces, premises and customers count; one operating company with eleven product lines behind a single manufacturing process counts only partly; forty vehicles in one fleet with one depot, one driver pool and one weather system count weakly; and seven unrelated members with independent operations count strongly. **The question is never how many things are on the schedule. It is how many independent ways the pool can lose money** — which is the effective count, in a different vocabulary.

Three published share constraints are described in the source as safe harbours: twelve subsidiaries each contributing between five and fifteen per cent of total risk; seven or more unrelated members none contributing a disproportionate share; and unrelated premium at around half the book. **The constraints are uncited; the effective-count intervals Section 7.6 derives from them are arithmetic.**

Test 3 — actuarial pricing. A written pricing report produced *before inception*, deriving premium from exposure, using the insured's own loss development where credible and in-

dustry data where it is not, with explicit expense and risk loads and a stated confidence level. The report must be capable of answering the only question that matters, which is whether an unrelated commercial insurer would have written this cover at this price. **A premium determined first and justified afterwards leaves a documentary trail that says so**, and the source records that the adverse decisions are full of pricing reports dated after the policies incepted.

Test 4 — claims paid. The test that cannot be simulated: a notification procedure, a register, adjusters or a claims manager, reserves set on individual claims, and payments made, with a multi-year paid and incurred ratio broadly consistent with the pricing. **An arrangement that has collected premium for seven years and paid nothing has not proved it is prudent; it has proved either that its pricing was wrong by an order of magnitude or that it was never insuring anything.**

Test 5 — insurer conduct. Adequate capital for the assumed risk; liquid, duration-matched investments free of related-party exposure; real policy wordings for the actual business; a board that meets and decides; a supervisor that is engaged rather than merely licensing; audited financial statements; reinsurance purchased from unrelated markets.

6.2 The rubric, and the hard zeros

```
TEST                    WEIGHT   SCORE 0–4      HARD ZERO
------------------------------------------------------------------
1 Risk shifting            25        0–4        anything runs back
2 Risk distribution        25        0–4        fewer than 5 units
3 Actuarial pricing        20        0–4        no pre-inception report
4 Claims paid              20        0–4        no claims in 3+ years
5 Insurer conduct          10        0–4        related-party investment
------------------------------------------------------------------
Weights sum to 100; weighted total runs to 400.
A ZERO ON TEST 1 OR TEST 2 IS DISQUALIFYING REGARDLESS OF TOTAL.
```

The disqualification rule is the load-bearing line and the totals are not. Risk shifting and risk distribution are constitutive of insurance on the doctrine the source describes; an arrangement failing either is not a poorly documented insurance arrangement but is not insurance, and no quality in the other three repairs it. **A reader who takes away a number from this rubric has taken away the wrong thing**, which is why Section 10.6 demotes the total to an ordering and Section 11 concedes the scale-type objection rather than defending it.

The rubric is this framework's working instrument. No tribunal has adopted it, no adviser should present it as authority, and a high score is evidence rather than immunity. Section 7.6 identifies a defect in its Test 2 threshold and states the correction rather than applying it silently.

7. Results

All figures below are exact computations on constructed inputs, carried at full precision and rounded only for printing. **No external dataset was collected and no figure in this paper is a measurement of any real structure.** Where the source manuscript's printed value differs from the exact computation, Section 7.8 prints both.

7.1 R2 — sub-national selection, and H1

Shares Delaware 40.0, South Dakota 25.0, Nevada 20.0, Wyoming 15.0, as percentages:

```
naive HHI = 0.160000 + 0.062500 + 0.040000 + 0.022500 = 0.285000
effective jurisdictions = 1 / 0.285000 = 3.508772
```

```
bloc collapse, all four inside one perimeter
bloc-HHI = 1.000000        N = 1.000000
ln(N) = 0.000000           eta ln(N) = 0.000000
h = 0.35 x 0 - 0.02 x 10 - 0.30 = -0.500000
```

The state-level split contributes exactly zero to the surplus term. The naive reading of 3.508772 is the count an adviser can present and it is not wrong as arithmetic; it is the answer to a question about entity placement rather than about independent points of failure.

The proposals actually put in the constructed case, and what each measured:

proposal	bloc-HHI	N	$\ln N$
leave the holding vehicle where it is	1.000000	1.000000	0.000000
move the vehicle to a second state	1.000000	1.000000	0.000000
split across three states	1.000000	1.000000	0.000000
split across all four, 40 / 25 / 20 / 15	1.000000	1.000000	0.000000
any generous counterfactual	—	—	—

The third proposal would have added two registered agents, two sets of state filings and two more sets of counsel in exchange for no change in any measurement in this series. **It was a sensible asset-protection suggestion presented as a resilience measure, and it is not one.**

H1 is supported, and the second half of it is what distinguishes this case. Curzi [2026] could run a generous counterfactual — the three Crown Dependencies scored as an independent perimeter rather than folded into the Western bloc — and report that the conclusion survived it. **No such counterfactual exists here.** Every row of the evidence table in Section 4.1 sits in the strongest class and none is a judgement call, so there is no admissible reassignment under which two of the four states occupy different perimeters. **The last row of the table above is empty, and it is left empty rather than filled with a weak assumption.** That is the honest report and it is a stronger result than a counterfactual that survives, because a hypothesis that cannot be attacked from the most favourable available direction has not been tested from that direction at all.

7.2 R1 — the axis mismatch, and H2

The constructed structure's exposure table was rebuilt on the currency and settlement axes. **These are constructed inputs to a constructed case and not measurements of any real holding; the source manuscript supplies no as-of date, and none is asserted here** (Section 11).

```
entity-based United States exposure                 27.3%
USD-denominated share of the balance sheet          61.0%
settlement volume clearing through the US system     ~58%

ratio, currency axis to entity axis     61.0 / 27.3 = 2.234
ratio, settlement axis to entity axis   58.0 / 27.3 = 2.125
```

The entity map said 27.3 per cent and the dependency was something closer to sixty. The exposure to a decision taken in one capital was more than double what the jurisdiction table

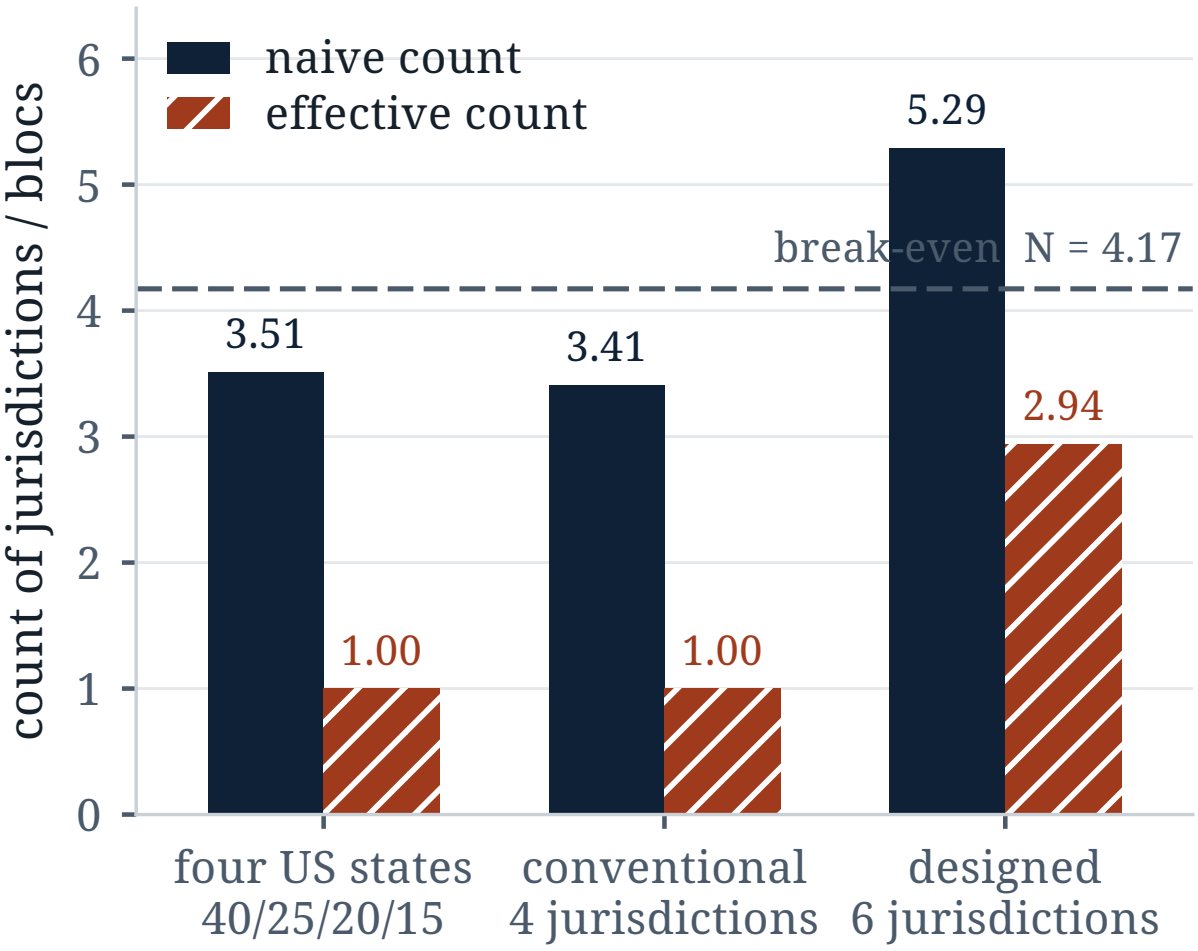

Figure 55.1: **Sub-national selection buys 3.51 naive jurisdictions and 1.00 effective ones.** Naive count against effective count for the four-state split and, for comparison, the conventional and designed structures of CCP-052, with the break-even effective count $N = e^{0.5/0.35} = 4.172734$ the surplus law requires at the stated parameters. All shares are constructed; the figure is generated by `figs/src/CCP-055_fig02.py` and every plotted value appears in Section 7.1 or in CCP-052.

reported, and every additional entity in the group had been assessed against the smaller number. Two errors produced it, and both are of a kind a reader can check on their own file. The first is that a portfolio was described as internationally diversified because its issuers were, when the correct basis is the perimeter of its custodian. The second is that a currency was treated as a pricing convention rather than as an exposure.

The rebuild that followed moved custody outside the perimeter, collapsed an interposed company, reduced the dollar balance toward the operating requirement, and **retained a single operating entity inside the perimeter deliberately**, booked to the Western bloc without argument, because the group sells into that market and contracts with its counterparties. The residual component fell to 2.0 per cent of exposure inside a Western bloc of 30.0 per cent, and the full structure measured

```
UAE 29.1 · Thailand 18.2 · UK 16.4 · Bermuda 13.6 · India 11.8 · Singapore 10.9
naive HHI = 0.189002    effective jurisdictions = 5.290949
bloc-HHI  = 0.340000    effective blocs N = 2.941176
ln(N) = 1.078810        eta ln(N) = 0.377583      h = -0.122417
```

which is the measurement Curzi [2026] reports and this paper derives from.

The currency reduction did more for the measurement than the entity change. Moving custody out reduced entity exposure; reducing dollar balances reduced the exposure the entity map never showed. Two further features of the rebuild are worth recording because they are what a resilience argument usually gets wrong. **An entity was retained inside the perimeter on purpose**, sized small, multi-member, holding no reserve and no group intangibles, because a structure that removes the entity it actually needs has optimised the measurement rather than the position. And **nothing in the rebuild was about privacy**: the retained entity's formation record was private before and is private afterwards, and what changed is where a decision could reach rather than who could see.

H2 is supported on the constructed case, and the support is weaker than the number looks. The ratios are computed from the same three inputs the hypothesis names, so the test is a consistency check on a construction rather than an independent confirmation that the gap generalises. Section 7.9 records this and Section 11 states it again.

7.3 R3 — the realisability measurement, and H3

The constructed year-seven statutory balance sheet, in USD:

line	amount
cash and admitted investments	14,200,000
reinsurance recoverable on paid and unpaid losses	1,600,000
premiums receivable	300,000
total assets	**16,100,000**
loss and loss adjustment expense reserves, gross	8,900,000
unearned premium reserve	1,500,000
other liabilities and accruals	400,000
total liabilities	**10,800,000**
total statutory capital and surplus	**5,300,000**
enhanced capital requirement	3,400,000
target capital level, 120 per cent of the requirement	4,080,000
surplus above target capital level	1,220,000

Applying the definition of Section 3.5:

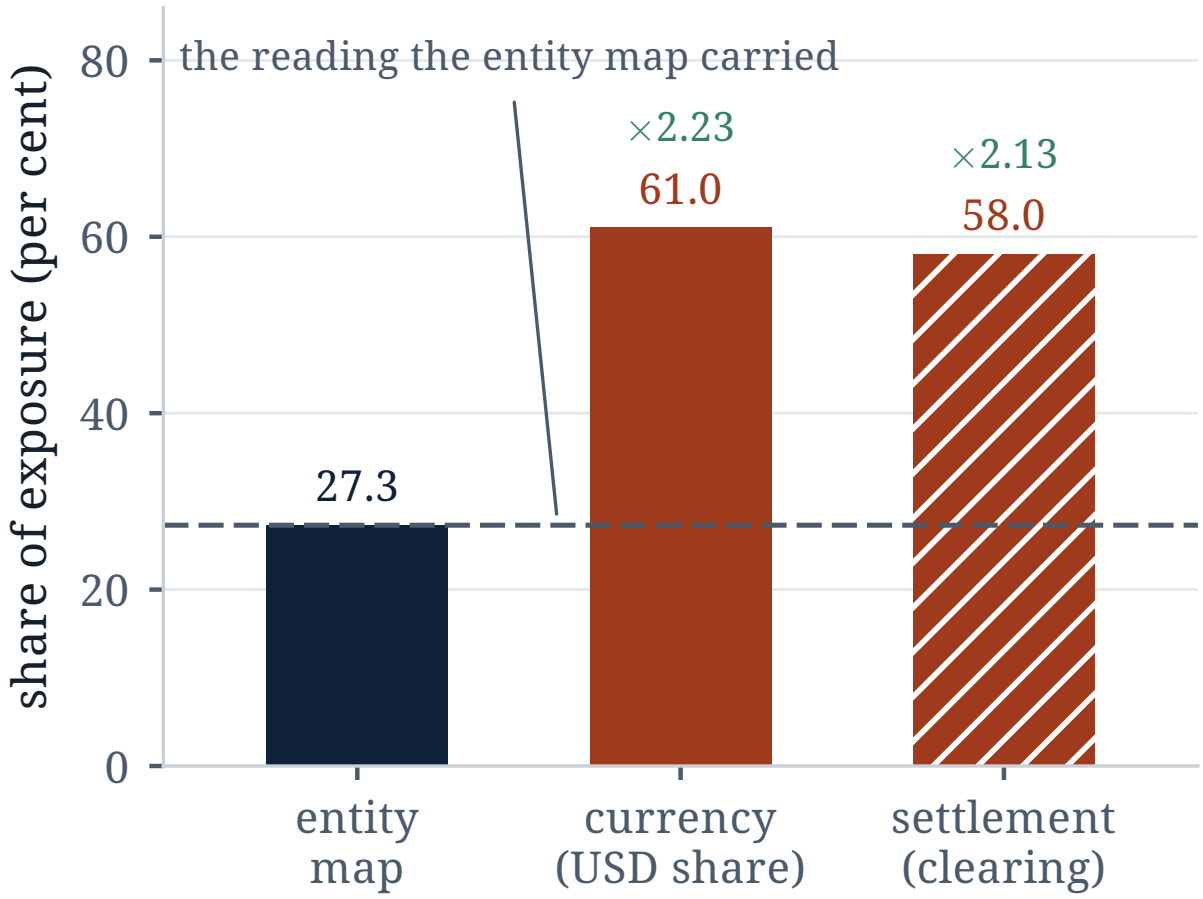

Figure 55.2: **The entity axis reads 27.3 per cent where the currency axis reads 61.0 and the settlement axis 58.0.** The three axes of Section 7.2 on one share basis, with the entity reading marked as the number the file carried. All values are constructed inputs to a constructed case, not measurements of a real holding; the figure is generated by `figs/src/CCP-055_fig01.py`.

```
committed to third-party liabilities   10,800,000 / 16,100,000 = 67.08%
locked by the target capital level      4,080,000 / 16,100,000 = 25.34%
distributable within one year           1,220,000 / 16,100,000 =  7.58%
                                                                -------
                                                                100.00%
```

Sixty-seven per cent of the balance sheet belongs, in substance and in law, to somebody other than the shareholder; a further twenty-five per cent cannot leave without the supervisor's consent; and the amount realisable inside a year is 7.58 per cent of the assets.

The present-value half, which a report stopping at the table above would omit. A creditor taking the shares owns the run-off. Over roughly six years the reserves develop and settle; at an assumed eight per cent redundancy on a conservatively reserved book — an assumption, and equally plausibly the reserves prove deficient — the eventual value is:

```
total statutory capital and surplus                      5,300,000
reserve redundancy at 8% of 8,900,000                      712,000
-------------------------------------------------------------------
eventual realisable value                                6,012,000
discounted at 8% over an average 4-year lag
  1.08^4 = 1.36048896
  6,012,000 / 1.36048896                                 4,418,999
-------------------------------------------------------------------
as a share of total assets                                  27.45%
realisable within one year                                   7.58%
haircut against 100% of assets                              72.55%
```

H3 is supported: the criterion fixed in Section 2 predicted a figure below ten per cent and the measurement returns 7.58 per cent. Against an adversary seeking rapid, cheap, uncontested realisation — a description that fits most arbitrary administrative action and much opportunistic litigation — a 72.55 per cent haircut and a six-year timetable is a substantial deterrent. Against a well-resourced judgment creditor with time it is a cost of collection. **The structural characteristic is worth a discount from 100 per cent of assets to roughly 27 per cent on a present-value basis, and a delay of years on all but 7.58 per cent of it. That is a discount, not a wall, and describing it as a wall is failure mode 7 of Section 8.**

7.4 The counter-result, in the same arithmetic

The counter-result is not an objection to R3; it is R3 read from the other side, and the paper prints it in the same units.

```
to a creditor:  realisable within a year        7.58% of assets
to the owner:   realisable within a year        7.58% of assets
```

The three quantities that bound what a creditor can take are the same three quantities that bound what the owner can take. Third-party liabilities are owed whoever holds the shares. The target capital level is a supervisory floor that does not move for a friendly shareholder. The distributable surplus is distributable to either. **The property that makes an insurance reserve resistant to third-party claims — real liabilities owed to unrelated parties — is the same property that makes it unavailable to its owner, leaving only 7.58 per cent realisable within a year.**

Two consequences follow and neither is optional.

A reserve is not a treasury and must never be sized as one. Capital committed to this vehicle is committed, and this framework's carrying-cost result applies without softening: Curzi [2026] states the four-currency carrying cost — coin, hours, attention and foreclosure

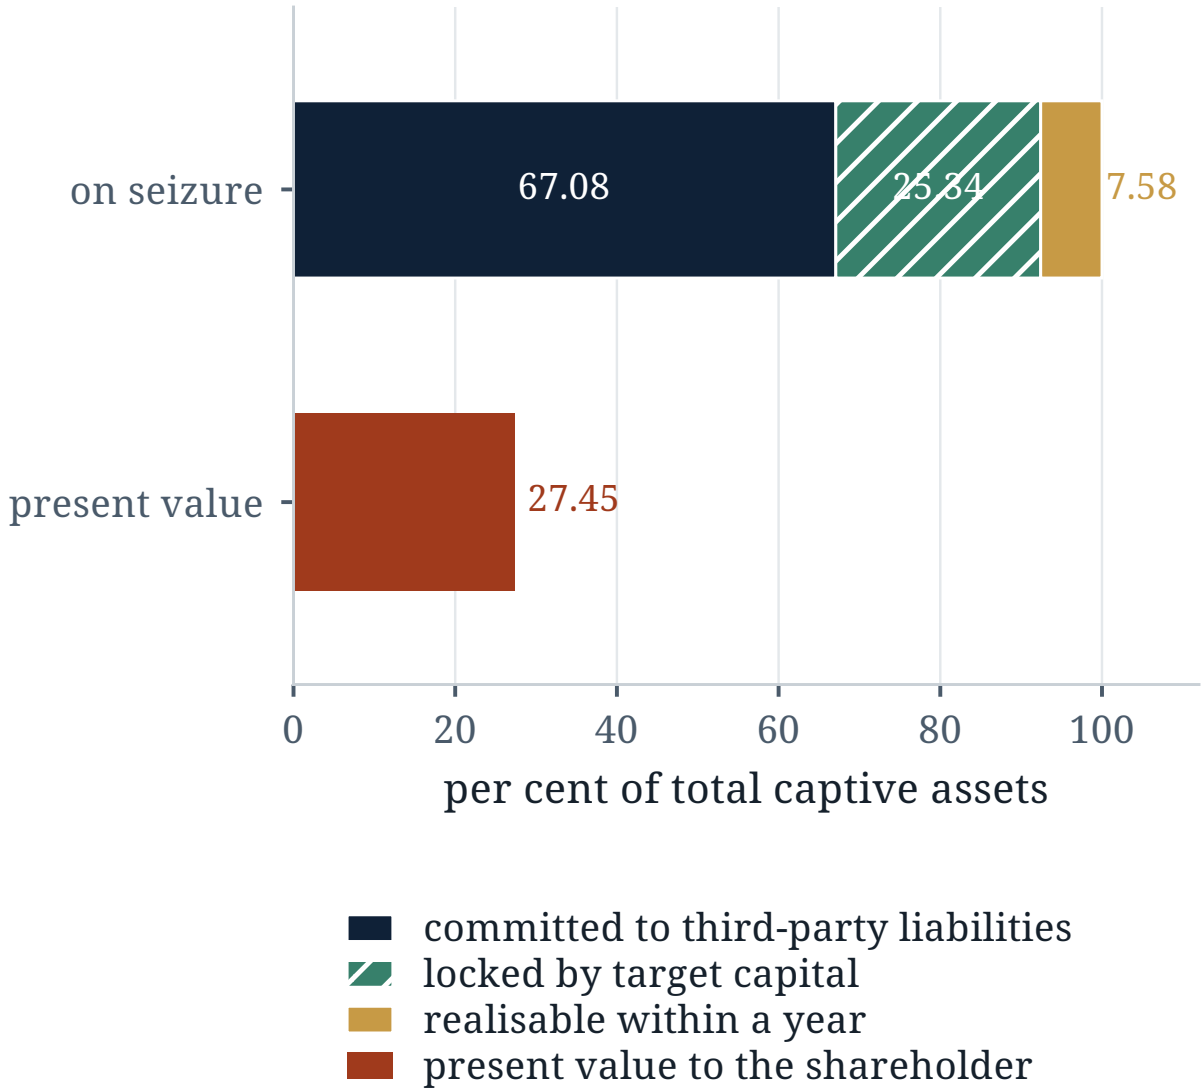

Figure 55.3: **Sixty-seven per cent of a captive's assets are committed, twenty-five per cent locked, and 7.58 per cent realisable within a year.** The realisability decomposition of the constructed year-seven balance sheet, with the present-value reading of 27.45 per cent below it. Modelled with the stated parameters — an assumed 8 per cent reserve redundancy, an 8 per cent discount rate and a four-year average settlement lag, all stipulated in Section 3.5 rather than measured. Generated by `figs/src/CCP-055_fig03.py`.

— against the law that felt comfort decays over weeks while carrying cost does not decay at all. **Foreclosure is the currency this result is denominated in**, and it is the one a balance sheet does not show. The parallel is exact rather than decorative: the cost is paid continuously, the benefit decays, and the arrangement is priced by comparing a flow that persists with a stock that does not.

The argument cannot be sold on both sides at once. An arrangement described to a principal as protecting assets *and* as leaving them available has been described inconsistently, and the inconsistency is arithmetic rather than rhetorical. Curzi [2026] states the general shape of the trap: perfect opposition and perfect agreement are the same reading, because u depends only on $|\rho|$, so the standard remedy of adding a contrarian contributes zero surplus while adding cost, and at $u = 0$ two of the four levers are exactly inert. **A lever that is inert in one direction is inert in both, and a property that binds a creditor binds an owner.**

The operational form of the counter-result is a specification rather than a warning. **Size the vehicle to the retained exposure and to nothing else.** Capital placed in it above what the retained layer requires does not become better protected; it becomes committed, and the correct comparison for the marginal dollar is between 7.58 per cent availability inside the vehicle and full availability outside it.

7.5 R5 and R4 — the programme economics and the rubric

The retained programme, and H4. The constructed group previously paid USD 4,370,000 a year in commercial premium against a five-year average loss of USD 1,910,000, a gap of USD 2,460,000 comprising expense load, risk load, profit margin and cost of capital. **Part of that gap is a fair price for capacity the group could not otherwise obtain; the question the programme answers is how much of it is a fair price for risk the group is in fact carrying.** After restructuring it pays USD 1,670,000 to the commercial market for the catastrophe layers and USD 2,700,000 to its own vehicle for the working layer, which sums to the prior 4,370,000 exactly.

```
gross premium written to the captive                    2,700,000
less excess of loss and aggregate stop-loss ceded        (410,000)
------------------------------------------------------------------
net premium                                             2,290,000
expected net loss (actuarial, constructed)              1,560,000
net loss ratio  1,560,000 / 2,290,000                      68.12%
running cost                                              140,000
------------------------------------------------------------------
2,700,000 - 410,000 - 1,560,000 - 140,000  =               590,000
against the prior commercial spend
  590,000 / 4,370,000                                      13.50%
```

H4 is supported. A captive on these facts is a thirteen-and-a-half-per-cent-of-premium proposition before investment income and before any tax consequence in any jurisdiction, and any projection materially above it is either retaining more risk than it discloses or not paying claims. The margin is positive but not comfortable: USD 140,000 of annual cost against USD 590,000 of expected retained margin, and a bad loss year makes it negative. **The catastrophe layers stay in the commercial market for a reason the arithmetic does not show** — a single large loss can exceed the group's capacity to absorb it — and a programme that retains them to improve the ratio has changed the risk rather than the economics.

The rubric applied to three constructed arrangements. Weights 25 / 25 / 20 / 20 / 10; scores 0–4; weighted total to 400.

test	weight	Case A	Case B	Case C
1 risk shifting	25	0	4	4

test	weight	Case A	Case B	Case C
2 risk distribution	25	0	4	3
3 actuarial pricing	20	1	4	4
4 claims paid	20	0	4	4
5 insurer conduct	10	0	3	4
weighted total		**20 / 400**	**390 / 400**	**375 / 400**
verdict		**disqualified on tests 1 and 2**	pass	pass

Case A is a constructed arrangement assembled from the fact patterns recurring in the reported decisions the source describes: three insureds in one location, a pooling arrangement with several hundred participants, a majority of assets lent to a related party, and effectively no claims. Four of its features are arithmetic and are printed as such:

```
premium as a fraction of the ceiling in force
  1,180,000 / 1,200,000                              98.33%
fraction of ceded premium NOT returned by the pool
  1 − 0.992                                           0.80%
five-year paid loss ratio
  14,000 / (5 x 1,180,000)                            0.24%
share of assets lent to a related party              62.00%
```

A premium set at 98.33 per cent of an external ceiling was not derived from an exposure; a pool returning 99.2 per cent of what it takes moves 0.80 per cent of the risk; and a five-year paid ratio of 0.24 per cent against a pricing assumption in the high sixties is not a prudent book. Case A's total of 20 out of 400 is not a low pass; the disqualification rule of Section 6.2 disposes of it regardless of the number, and the consequence of the arrangement not being insurance is definitional rather than penal — every deduction taken since inception falls with the characterisation.

Case B is a constructed group captive of nine unrelated contractors, none above 16 per cent of premium, priced by an independent actuary from ten years of member loss data, with a five-year paid ratio of 61 per cent and incurred of 68 per cent against a pricing assumption of 66 per cent, and an underwriting committee that surcharged two members and declined one renewal in five years. **The most persuasive fact in Case B is not in the rubric at all: the captive declined to renew one of its own owners, which is something no wallet does and every insurer does.**

Case C is the constructed captive of Section 7.3, scored on the same rubric. **Its three-point score on distribution is the honest weak point and is stated rather than rounded up**: eleven operating units in eight countries plus two unrelated distributors, correlated through a single manufacturing process, so that a design defect is one event and not eleven. **Distribution is strong against frequency and weak against a systemic defect, which is exactly the exposure the reinsurance layer above the vehicle exists to carry.** Section 7.6 measures it.

The disclosure test applied to the three. Case A fails at the first element: its function depends on nobody reconstructing how the premium was set, and disclosure of the pool mechanics, the related-party loan and the pricing chronology ends it. **It is a concealment structure with a policy stapled to the front.** Case B passes comfortably — every element is designed to be shown, and disclosure is how a group captive recruits its next member. Case C passes, and its weakest element is disclosed in its own reinsurance submission because the reinsurers price it. **The test separates the three in the same order the rubric does, by a different route, which is the cross-check Section 10.9 records.**

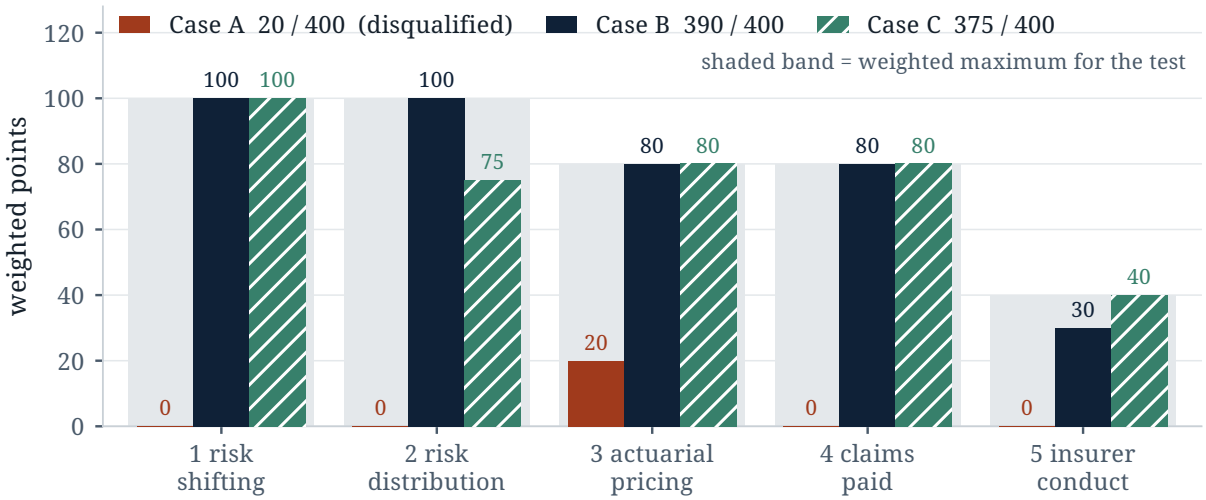

Figure 55.4: **The rubric separates the three arrangements on tests 1 and 2, not on the total.** Weighted points per test for the three constructed arrangements against the weighted maximum for each test. Case A's 20 out of 400 is disqualified by the hard-zero rule rather than by its total. The rubric is this framework's working instrument, adopted by no tribunal; all scores are constructed. Generated by `figs/src/CCP-055_fig04.py`.

7.6 H5 — the risk-distribution test is the bloc collapse

This is the result that makes the two halves of the paper one paper, and it is arithmetic throughout.

The collapse, applied to insureds. Case A lists three insureds. They sit in one state, behind one warehouse, with one customer concentration. If those three exposures are perfectly correlated then, whatever their shares,

```
naive count of insureds                    3.000000
bloc-collapsed count                       1.000000
```

because a block matrix of ones returns $\sum_b W_b^2 = 1$ for a single block regardless of the within-block split. **No share vector is needed and none is assumed.** Case C lists thirteen insured units. Against ordinary frequency risk they are thirteen; against a systemic defect in the single manufacturing process behind eleven of them, and behind the product the other two distribute, they are one. **The naive count and the effective count differ by the same factor and for the same reason as they do on the jurisdiction axis, and the operation that reconciles them is the same operation.**

The floor, derived from a published constraint. The safe harbours described in Section 6.1 are constraints on shares, and a constraint on shares is a bound on the reciprocal index. Both bounds below are exact and both are attained.

Twelve subsidiaries each contributing between five and fifteen per cent of total risk. The sum of squares is maximised by pushing as many shares as possible to the cap. With k subsidiaries at 0.15 and $12-k$ at 0.05, $0.15k + 0.05(12-k) = 1$ gives $k = 4$, so

```
max HHI = 4(0.15)^2 + 8(0.05)^2 = 0.090000 + 0.020000 = 0.110000
min effective count = 1 / 0.110000 = 9.090909
min HHI = 1/12 = 0.083333    max effective count = 12.000000
```

Nine unrelated members, none above sixteen per cent of premium. Six members at the cap absorb 0.96, leaving 0.04:

```
sup HHI = 6(0.16)^2 + (0.04)^2 = 0.153600 + 0.001600 = 0.155200
min effective count = 1 / 0.155200 = 6.443299
max effective count = 9.000000
```

The published constraint is therefore equivalent to an effective-count floor: the twelve-subsidiary harbour guarantees at least 9.090909 independent-equivalent units and the nine-member harbour at least 6.443299, **provided the units are in fact independent** — which is the condition the constraint does not impose and which the collapse above destroys. **H5 is supported.** The share constraint and the effective count are the same statement, and the constraint's silence about correlation is the same silence the naive jurisdictional index keeps.

The consequence for the rubric is a correction to it, stated here rather than suppressed. Test 2 is scored on a hard zero at "fewer than five units", which is a naive count. **A naive count of units is exactly the quantity this series exists to say is the wrong one.** The rubric as constructed can therefore be satisfied by an arrangement with twelve perfectly correlated units, whose effective count is 1.000000 and whose aggregate variance is not reduced at all. **The correction is to state the hard zero on the effective count rather than the naive one**, which is what Case C's three-point score already does informally and what the rubric does not do formally. Section 11 records it as a defect in an instrument this paper carries rather than repairing it mid-paper, because a threshold changed to fit a case it was applied to is not a threshold.

7.7 R6 — pricing a bloc call rather than a structure

Bermuda, which hosts the constructed insurer, sits inside the Western perimeter on every operative test of Section 4.1 as applied in this series: it exchanges account information, it implements the common anti-money-laundering standard through domestic legislation, it is exposed to the same listing processes, and its banks clear the same currency through the same correspondents. Its final appeal lies to a committee sitting in the perimeter's centre, and the perimeter's centre retains a constitutional capacity to legislate for it. The base case therefore folds it into the Western bloc and credits it with nothing. **The argument that it should be credited separately is an argument about the legal character of an asset, not about a perimeter**, and this paper prices it rather than arguing it.

Blocs on the designed structure, base case: Western 30.0 (the United Kingdom at 16.4 plus Bermuda at 13.6), bridge 40.0, non-aligned 30.0.

```
base case          bloc-HHI = 0.30^2 + 0.40^2 + 0.30^2       = 0.340000
                   N = 2.941176      ln N = 1.078810
                   eta ln N = 0.377583        h = -0.122417

credited separately
                   bloc-HHI = 0.164^2 + 0.136^2 + 0.40^2 + 0.30^2
                            = 0.026896 + 0.018496 + 0.160000 + 0.090000
                            = 0.295392
                   N = 3.385332      ln N = 1.219452
                   eta ln N = 0.426808        h = -0.073192
-------------------------------------------------------------------------
value of granting the character argument in full        0.049225
```

Granting the argument its most generous possible reading moves the structure from clearly below the break-even count of 4.172734 to slightly less clearly below it, and it does so by changing an accounting convention rather than a structure. The base case therefore declines to grant it. **This is a change in the bloc call and not a change in the world**, and Curzi [2026] is the paper that prices an uncertain bloc call properly as a bet rather than as a fact.

The mirror reading matters and is stated: if the bridge bloc were to split — if the two bridge jurisdictions ceased to correlate — the same arithmetic gives $N = 3.615826$, which is

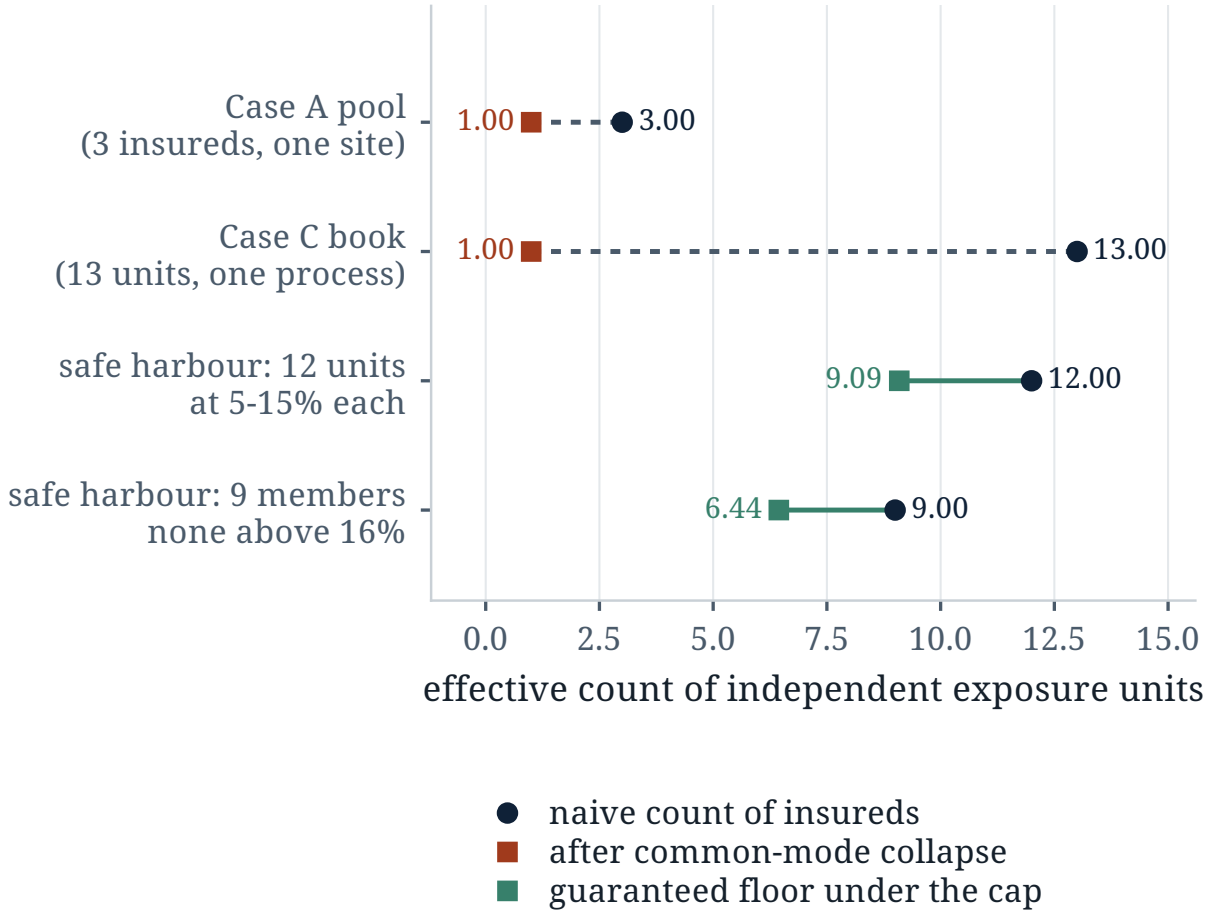

Figure 55.5: **A naive count of thirteen insured units collapses to one against a common mode, and a published share constraint is equivalent to an effective-count floor.** The naive count of insureds against the count surviving a common-mode collapse for the two constructed arrangements, with the exact effective-count intervals implied by the two share constraints. Bounds are computed in Section 7.6; the constraints themselves are described from the source manuscript and are uncited. Generated by `figs/src/CCP-055_fig05.py`.

the figure Curzi [2026] measures from the other direction, where Design A places a full centre at 10.9 per cent of exposure and reaches $N = 3.615826$ and $h = -0.050138$, while Design B's capped transit position at 0.35 per cent reaches $N = 2.965384$ and $h = -0.119548$ — capturing 3.97 per cent of A's measured gain for 3.21 per cent of A's exposure. **The two papers reach the same number by opposite routes: here it is what a fragmentation would deliver for free, and there it is what a deliberate addition has to be paid for.** Bloc fragmentation runs both ways and only one direction is usually planned for. The robustness reading is therefore that this measurement is sensitive to bloc *structure* and not to the placement of any single member, which is the same conclusion Curzi [2026] reaches on its own robustness table.

7.8 Three printed discrepancies, left visible

First, the surplus reading of the base-case structure. The source manuscript prints $h = -0.1226$ for the designed structure and $h = -0.0734$ for the character-credited variant. The exact values at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ are -0.122417 and -0.073192. The discrepancy is 0.000183 in each case and it propagates consistently — the source's two figures differ by 0.0492, which is the correct increment — so it is a rounding of the base figure carried forward, not an error in the increment. **This paper uses -0.122417 and -0.073192, which are the values Curzi [2026] publishes, and prints the source's figures here rather than harmonising them silently.**

Second, the present-value arithmetic of Section 7.3. The source prints $6{,}012{,}000 / 1.360489 = 4{,}418{,}970$. The exact quotient is $4{,}418{,}999.48$, a difference of USD 29 arising from a truncated divisor. **The share of total assets is 27.45 per cent on either value**, so no reported result changes; the discrepancy is printed because a reader recomputing the chain will find it.

Third, the naive index of the conventional structure. This framework carries two values for the same measurement: 0.293388 from exact ninths — Curzi [2026] reports UK 40.91 / US 27.27 / Jersey 18.18 / Luxembourg 13.64 giving naive HHI 0.293388 and 3.4085 effective jurisdictions against bloc-HHI 1.000000 and 1.0000 effective perimeters — and 0.293430 from rounded percentages [Curzi, 2026], giving 3.407968. The difference is 0.000042, in the fifth decimal. **This paper uses the rounded-percentage figure,** 0.293430, because it is the basis on which the four-axis comparison of Section 7.2 was constructed, and states which it uses rather than leaving the reader to infer it. Both papers print the discrepancy rather than hiding it, and so does this one.

7.9 Hypotheses tested

#	hypothesis	verdict	where
H1	sub-national selection contributes nothing, and admits no counterfactual	**supported**, on both halves	7.1
H2	the entity axis understates exposure, by a factor of 2.23 on the currency axis	**supported on the constructed case**, and the point prediction is a consistency check rather than an independent test	7.2
H3	realisable-within-a-year is small and computable: 7.58 per cent against a predicted floor of ten	**supported**	7.3

#	hypothesis	verdict	where
H4	the retained programme recovers 13.50 per cent of prior spend	**supported**	7.5
H5	the risk-distribution test and the bloc collapse are one operation	**supported**, with an exact interval on each published constraint	7.6

Two of the five are weaker than they look and the paper says which. H2 is tested on one constructed structure and its ratios are computed from the same inputs it names, so it demonstrates the size of a gap under a construction rather than establishing that the gap generalises. H4's inputs — the expected loss, the ceded premium and the running cost — are all stipulated, so the 13.50 per cent is an exact consequence of an assumed programme rather than an observed return. **Neither is presented in Section 12 as more than it is.**

8. Failure modes

Ten ways the results above are misapplied. Each is stated with the diagnostic that detects it, because a failure mode without a diagnostic is a complaint.

1. Confusing formation privacy with protection. They are unrelated, and this is the clearest case in the series of a jurisdiction with a great deal of the first and very little of the second. *Diagnostic:* ask whether the structure's function would change if the formation record were public. If not, privacy was never the mechanism; if so, the structure fails the disclosure test of Section 4.4 by construction.

2. Treating a seasoning period as a protection period. A shorter state period does not displace a longer federal avoidance provision. *Diagnostic:* the two periods are not alternatives and the longer one governs where its conditions are met. **The gap between how these instruments are marketed and how they work is the largest single gap in Section 4.**

3. Assuming the chosen state's law will be applied. A creditor sues where it can obtain jurisdiction, and that court applies its own conflict rules and its own public policy. *Diagnostic:* name the forum before naming the statute.

4. Using a single-member vehicle for charging-order protection. The doctrinal basis is protecting other members; with no other members the basis is absent. *Diagnostic:* count the members with genuine economic interests, not the members on the register.

5. Reading the naive count as the resilience count. The error this whole series exists to correct. *Diagnostic:* collapse the shares onto perimeters before squaring, and report the pair, never one alone.

6. Measuring one axis and calling it the structure. The most expensive error in the constructed case, worth a factor of 2.23. *Diagnostic:* run all four axes of Section 3.2 and print the largest, which is item 13 of Appendix A.

7. Letting a good custodian carry the reserve. Depth, cost and quality are exactly why reserve drifts into a perimeter. *Diagnostic:* a portfolio contributes to the perimeter of its custodian, not of its issuers, and should be booked that way whatever the issuer list looks like.

8. Describing a discount as a wall. The realisability measurement is 72.55 per cent and not 100 per cent. *Diagnostic:* if the description contains no number, it is not the measurement.

9. Selling the reserve argument on both sides. Section 7.4. *Diagnostic:* ask what the owner can realise within a year and compare it with what a creditor can. They are the same number.

10. Satisfying a unit count without satisfying independence, and crediting a bloc call as a structural change. Two errors with one diagnostic: compute the *effective* count, of insured

units in the first case and of perimeters in the second, and ask what would have to change in the world rather than in the table for the number to move. Section 7.7 prices the second at 0.049225 of surplus, which is real and is an accounting convention.

9. Discussion

What follows from the results. Three things, and each is narrower than a reader in a hurry might take it to be.

The first is that **an entity map is a poor instrument for the question it is usually asked**. It answers where entities are, which is a question about registration, and it is routinely read as answering where a decision reaches, which is a question about perimeters, currencies, rails and custodians. The gap on the constructed case is a factor of 2.23 and there is no structural reason to expect the sign to reverse, because a currency's clearing runs through banks inside a perimeter whatever the entity list says. **The remedy is not a better entity map. It is three more measurements**, and Appendix A states them.

The second is that **a protective characteristic that can be measured should be, and measuring it usually shrinks it**. The reserve argument survives measurement — 72.55 per cent is a substantial haircut — but it survives as a discount and a delay rather than as the immunity it is often described as. Curzi [2026] reaches the same shape by a different route: a conversion of an immovable asset carries certain leakage $L = 7{,}220{,}000 / 48{,}000{,}000 = 15.0417$ per cent against an escape value $V_{\text{esc}} = p \cdot L^{*} \cdot q \cdot (1 - s) = 0.4725$ per cent a year, a payback of 31.83 years, with a ten-year payback requiring $p = 4.7752$ per cent. **A defensive property with a payback period is a defensive property that can be priced, and one that cannot be priced has not been specified.**

The third is that **the same instrument, run on a different share basis, answers a legal question it was not built for**. The risk-distribution test asks how many independent exposures a pool has. That is the effective count, and the published share constraints that operationalise it are equivalent to effective-count floors of 9.090909 and 6.443299. This is not a claim that the doctrine intends the reciprocal index; it is the observation that the doctrine's arithmetic content *is* the reciprocal index, and that the doctrine's silence about correlation is the same silence the naive jurisdictional count keeps. **A test that counts units and does not weight them by correlation will be satisfied by twelve correlated units, and the remedy is the one this series has been applying to jurisdictions since Curzi [2026].**

What does not follow. Several things, and they matter more than the above.

Nothing here is a legal conclusion. Every jurisdictional, doctrinal and regulatory statement in Sections 4 to 6 is described from the source manuscript and is uncited; Appendix B lists them; the Declarations state it again. **A reader who takes a rule of law from this paper has taken it from the wrong document.**

The effective count measures independence, not capacity. It says nothing about whether any bloc, any custodian or any insurer can carry the load, and a structure at $N = 2.94$ on jurisdiction with an effective counterparty count near 1.6 has moved its risk rather than reduced it.

The measurement is least informative exactly where the headline case sits. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, where one unit holds a very large share. A bloc vector of a single unit at 100 per cent is the limiting case. The measurement is still exact — $1/1 = 1$ — but its discriminating power is at its minimum there, and comparisons among heavily dominated structures should not be made on N alone.

A count that can be inflated will be. Goodhart [1975] and Campbell [1979] are the standing warnings, and they bite hardest on an instrument that has just been shown to be gameable in the naive direction. **The bloc collapse is the anti-gaming device and it is only as good as the assignment**, which is a modelling position (Section 1) and not an identified result. Douceur [2002] is the formal statement that one party can present as many, so an unaudited count is

worthless, and Lamport et al. [1982] is the bound on how many genuinely independent parties a protocol requires. **Both belong next to any count of units in this series**, and the rubric defect of Section 7.6 is exactly the Sybil problem in an insurance costume.

The results this paper borrows from bound it. Curzi [2026] records that the frequency register cannot distinguish a mood from a trait at all, because $f = kn^2$ contains no time term, and that the cleanest-looking encoding of a framing — the one-hot vector — returns the system's maximum surplus for every subject and therefore measures nothing. Curzi [2026] records that the width statistic is invariant under relabelling and therefore does not even determine the chord it is computed from, which formally blocks any inference from low or high internal surplus to distress or health. **Both are the same warning in a different domain: an index invariant under a transformation the analyst cares about is not measuring what the analyst thinks it is.** The rubric of Section 6 is exposed to exactly that objection through its naive unit count, and Section 7.6 states the correction rather than waiting to be told.

This framework's central limitation applies here in full. Curzi [2026i] reports that a preregistered fit failed its own second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, despite +40.3 per cent over persistence, +97.7 per cent over direct input, and $p = 0.0005$ against the shuffle — and Curzi [2026k] reports the five-parameter survey reproducing each system's observed decline from one desk to a 22-household block, predicted -0.250474 against observed -0.250 at the desk and -0.996371 against -1.000 at the library, with residuals under 1.4 per cent of the ceiling term. **This paper reports no fit at all, and that is not a strength.** Epstein [2008] is the standing statement that prediction is one of sixteen reasons to model and that a paper is entitled to say which of the other fifteen it claims; this paper claims **explanation of a mechanism and demonstration that a stated arithmetic suffices to produce a stated shape**, and claims neither prediction nor calibration.

10. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the compounding chain names what each step consumes. **If dropping a postulate leaves the result standing, it is not listed.** Sections 10.1 to 10.6 run the standing rigour checks first, so the chain in 10.8 is read against a dimensional audit rather than before one.

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i, w_i	exposure share of unit i	$[1]$	dimensionless, fraction of Q	defined; non-negative and summing to 1 by P1
W_b	bloc or block share	$[1]$	dimensionless	derived, $W_b = \sum_{i \in b} s_i$
HHI	concentration index	$[1]$	dimensionless, or points $= 10^4 \times$ fraction	derived from shares
ρ_{ij}	correlation between shocks to i and j	$[1]$	dimensionless, in $[-1, 1]$	**assumed, not measured**

symbol	quantity	dimension	unit	status
N	effective count	$[\#]$, a count	jurisdictions, blocs, or exposure units	derived as $1/(w'Rw)$
$\ln N$	surplus-term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
Q	protected capital	$[C]$	index units	defined; **the source supplies no operational unit**
η	conversion efficiency	$[1]$	dimensionless	assumed
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
h	headroom	$[C\,T^{-1}]$	index units per period	derived, $h = \eta \ln N - \delta Q - C$
A	total captive assets	[\$]	USD	constructed
L	third-party liabilities	[\$]	USD	constructed
TCL	target capital level	[\$]	USD	derived, $1.20\times$ the enhanced requirement
realisability	share of assets realisable	$[1]$	dimensionless	derived from the three above
r	discount rate	$[T^{-1}]$	per year	**assumed**
t	average settlement lag	$[T]$	years	**assumed**
rubric score	ordinal band	none	**no unit; ordinal**	stipulated

The surplus equation balances only if $\eta \ln N$ carries $[C\,T^{-1}]$. Since $\ln N$ is dimensionless, η must carry $[C\,T^{-1}]$ rather than being dimensionless, or $\ln N$ must be read as a rate. **The source is silent on which, and this paper records the silence rather than resolving it by assertion.**

The realisability equation balances exactly. Three quantities in USD divided by a quantity in USD gives a pure number, the three shares sum to 1.000000 by construction, and the discount factor $(1+r)^t$ is dimensionless because r carries $[T^{-1}]$ and t carries $[T]$. **That is the only equation in this paper whose dimensions are fully determined by the source, and it is worth saying which one it is.**

The rubric has no dimension and is not given one. Weighting and summing ordinal bands produces a number with no unit and no interval interpretation; Section 10.6 states what that permits.

10.2 Significant figures and epistemic status

quantity	figures quoted	status	licence
naive HHI 0.285000	6 dp	**exact**	exact arithmetic on exact constructed shares
effective count 3.508772	6 dp	**exact to rounding**	$1/0.285$ is a repeating decimal, printed to 6 dp
bloc-HHI 1.000000, $N = 1.000000$	6 dp	**exact**	a single block of ones
67.08 / 25.34 / 7.58 per cent	2 dp	**exact to rounding**	ratios of exact constructed amounts
27.45 per cent	2 dp	**model output**	depends on three assumed parameters; see 10.3
13.50 per cent	2 dp	**exact to rounding**	ratio of exact constructed amounts
$N = 3.385332$, $h = -0.073192$	6 dp	**exact to rounding**	exact arithmetic on exact shares
9.090909 and 6.443299	6 dp	**exact**	closed-form bounds, Section 7.6
61.0 and 58 per cent	1 dp, 0 dp	**constructed input**	not a measurement; no as-of date exists
rubric totals 20 / 390 / 375	integers	**ordinal, not quantitative**	see 10.6

The 27.45 per cent figure is the only headline number in this paper that is model output rather than arithmetic on stated inputs, and it is the one most likely to be quoted without its parameters. Its three assumptions are an 8 per cent reserve redundancy, an 8 per cent discount rate and a four-year average lag. **None was measured, all three were chosen, and Sections 10.3 and 11 give the sensitivity.** The 58 per cent settlement figure is quoted in the source with a tilde and is reproduced here as 58.0 in the figure only; the one-significant-figure reading is what the source supports.

10.3 Limits and boundary behaviour

limit	behaviour	reading
$\rho \to 0$ within a bloc	$N \to$ the naive count	the naive index is the zero-correlation endpoint, not a different index
$\rho \to 1$ within a bloc	$N \to$ the bloc count	the bloc index is the unit-correlation endpoint
one bloc holding everything	$N = 1$ exactly, $\ln N = 0$, surplus term $= 0$	**the whole argument in one line**; no activity below bloc level raises it
$N \to \infty$	$h \to \infty$ logarithmically; $dh/dN = \eta/N \to 0$	returns diminish but never turn negative — **a defect of the model, since cost is not in the input term**

limit	behaviour	reading
$L \to 0$ (no third-party liabilities)	realisable-within-a-year $\to 1 - \text{TCL}/A$	leg three of Section 5.1 is gone and only the supervisory gate remains
$L \to A$	realisable $\to$ negative, i.e. the insurer is insolvent	the domain of the measurement is $L + \text{TCL} \leq A$ and is stated
$t \to 0$	present-value realisation $\to$ 37.34 per cent	the delay, not the discount, carries most of the haircut
$r \to 0$	present-value realisation $\to$ 37.34 per cent	identical to the row above; r and t enter only through $(1+r)^t$
reserve redundancy $\to 0$	present-value realisation $\to$ 24.20 per cent	the redundancy assumption is worth 3.25 percentage points
short-tail book, reserves $\to$ one year	the committed share falls toward the unearned premium alone	the characteristic is a function of reserve duration (Section 5.1)
all shares equal, n units	$N = n$ exactly	the numbers-equivalent property, which is the instrument's definition

Three boundary readings are load-bearing. The fourth row is a genuine defect of the surplus law as used here and not merely a curiosity: because cost enters only through C, the model never says that adding a bloc is not worth it, and the decision to stop must come from outside the equation. **This framework's own cost result supplies it** — Brooks [1975] on communication cost at order $n(n-1)/2$ inside a boundary, and Curzi [2026], which records that a commons case is formally tunable and practically unreachable, passing the ceiling test with margin $+0.058436$ nats while no lever closes it, and that a member's declining to participate improves the family reading by 2.680588 octaves. **That arithmetic is printed rather than avoided, and it is the reason no result in this paper is stated as a prescription to raise N.**

The seventh and eighth rows say something the headline number hides: at $r = 0$ or $t = 0$ the present-value realisation is $6{,}012{,}000/16{,}100{,}000 = 37.34$ per cent, so **the discounting accounts for 9.89 percentage points of the 72.55 per cent haircut and the balance-sheet structure accounts for the rest.** The result is therefore mostly insensitive to the two assumed financial parameters, which is worth knowing and is not obvious from the table in Section 7.3.

The tenth row is the domain statement for R3 and it is not a technicality. **The realisability result is a result about long-tail books**, and quoting 7.58 per cent for an arrangement writing only short-tail risk would be a misapplication of the measurement rather than a disagreement with it.

10.4 Invariance

Scale invariance in capital. Multiplying every amount on the balance sheet by a positive constant leaves every share, every ratio and every effective count unchanged. The realisability measurement is a ratio of ratios and is invariant under the choice of currency unit. **Tested at three scales by construction** — the four-state shares, the six-jurisdiction shares, and the balance sheet — and it holds exactly in each. **Three scales is not many, and Section 11 says so** rather than describing the instrument as scale-free without qualification.

Invariance under relabelling, and its cost. The effective count is invariant under permutation of the units. That is the property Curzi [2026] identifies as fatal in its own domain: the width statistic is invariant under relabelling and therefore does not determine the chord it

is computed from. **Here the invariance is wanted — a concentration measure that changed when the rows were reordered would be broken — but the same invariance means the effective count cannot distinguish two structures with the same share vector and different contents.** That is a limit on what the number can carry and it is stated as one.

Not invariant, and this is where the instrument does its work. The count is *not* invariant under partition of the units: splitting one unit into two raises the naive count and leaves the bloc count untouched. **That asymmetry is the whole instrument**, and it is what makes the naive count gameable and the bloc count not.

Invariance of the rubric under its weight vector: not tested. Reweighting the five tests would reorder the totals, and no sensitivity analysis over weights was run. Section 11 records it.

10.5 Analogy discipline

borrowing	category	justification
exposure as a portfolio; variance under a correlation matrix [Markowitz, 1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix, which is the premise the algebra requires; no further financial content is imported
effective count as a numbers-equivalent [Adelman, 1969, Hill, 1973, Jost, 2006]	**1 — derivation**	$1/\text{HHI}$ *is* the Hill number of order two; nothing transfers by analogy
similarity-sensitive diversity [Leinster and Cobbold, 2012, Rao, 1982]	**1 — derivation**	the block-of-ones matrix is a special case of the cited general form
risk distribution as an effective count (Section 7.6)	**1 — derivation**	the doctrinal test is a statement about independent exposures and aggregate variance, which is the same premise the portfolio result requires
open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]	**1 — derivation**	the disclosure standard *is* the open-design requirement applied to legal rather than cryptographic structure
coupled-network fragility [Buldyrev et al., 2010]	**2 — shared form**	perimeter coupling is not shown to satisfy the percolation premises; only the shape of the result is used

borrowing	category	justification
robust-yet-fragile [Albert et al., 2000, Callaway et al., 2000]	**2 — shared form**	the tolerance asymmetry's shape is used; the degree-distribution mechanism is not claimed, and Doyle et al. [2005] is the reason it should not be
ln N as the entropy of a uniform distribution [Shannon, 1948]	**2 — shared form**	**information entropy, not thermodynamic entropy**; the correspondence is exact as arithmetic and carries no thermodynamic content
a bloc as a frozen region [Castellano et al., 2000]	**3 — analogy**	suggestive and used as motivation only; no phase-transition claim is made and no order parameter is computed
normal accidents [Perrow, 1984]	**3 — analogy**	cited as qualitative theory and framing, not as a formal result; this paper's finding is Perrow's in a measurement frame

No category-3 borrowing is used as evidence anywhere in this paper, and the two that appear are named as motivation. Curzi [2026] is the standing requirement that the theorem, the ordinary observed effect and this framework's own conjecture be distinguishable in three separate sentences on demand, and the table above is that requirement discharged.

10.6 Measurement-theoretic status of the scored inputs

The evidence ladder of Section 4.1 is ordinal and is not summed. Its classes are ranked and the assignment is made by identifying the strongest available class, which an ordinal scale licenses. **No numeric evidence score is computed and no threshold is arithmetic**, deliberately, because a numeric score would invite the averaging the scale forbids.

The de-identified capability comparison of Section 4.3 is not totalled. Court depth, statutory text, seasoning period and maintenance cost have no common scale, and the table produces a best fit by argument rather than a verdict by arithmetic.

The rubric of Section 6.2 is ordinal and is summed, and that is the paper's weakest operation. Weighting and adding 0–4 bands assumes equal intervals within each band and commensurability across the five tests, and neither was tested. Michell [1997] is the strongest available objection: a discipline routinely assumes quantitative structure without testing for it, and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all. **The conjoint conditions were not tested, here or in the source. The weighted total is therefore read as an ordering with a disqualification rule attached and not as a quantity**, no difference between two totals

is interpreted anywhere in Section 7.5, and Krantz et al. [1971] sets out what would have to hold before it could be. Stevens [1946] is the taxonomy the audit uses.

This paper inherits the framework-level scalar-reduction limitation rather than restating it. Reducing a jurisdictional structure to one effective count and one h, and reducing a captive arrangement to one weighted total, are two instances of the habit Curzi [2026] names once as a single limitation for the whole framework: where the source literature describes a phenomenon by several jointly varying features, the framework replaces it with one number and does arithmetic on the number. **The limitation is inherited here in full and is not met separately.**

The concentration instrument itself is untouched by this objection, because exposure shares are ratios of capital rather than judgements, and Section 7.6's bounds are closed-form arithmetic on stated constraints.

10.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	$\text{HHI} = \sum_i s_i^2$	DEFINITION
P3	for n equal shares of $1/n$, $\text{HHI} = n(1/n)^2 = 1/n$	ARITHMETIC
P4	the aggregate shock is $R = \sum_i w_i X_i$ with $\text{Var}(X_i) = 1$	DEFINITION
P5	$\text{Var}(R) = \sum_i \sum_j w_i w_j \rho_{ij} = w' R w$	ARITHMETIC
P6	units inside one coordination perimeter act on one decision	POSTULATED (H1)
P7	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P8	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P9	total assets equal third-party liabilities plus statutory capital and surplus	DEFINITION (balance-sheet identity)
P10	the target capital level is 120 per cent of the enhanced requirement	DEFINITION (as described from the source, uncited)
P11	distributions above stated thresholds require supervisory consent	POSTULATED — described from the source, uncited (Appendix B)
P12	reserve redundancy 8 per cent, discount rate 8 per cent, average lag 4 years	POSTULATED (chosen, not measured)
P13	the rubric's weights are 25 / 25 / 20 / 20 / 10 and its bands are 0–4	DEFINITION (this framework's stipulation)

10.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	HHI^{-1} returns n exactly for n equal shares	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	it is the Hill number of order two — Hill [1973], Jost [2006]	CITED
L4	P4, P5	with $R = I$, Var$(R) = \sum w_i^2 =$ HHI	ARITHMETIC
L5	P4, P5	with R block-of-ones, Var$(R) = \sum_b W_b^2$	ARITHMETIC
L6	L4, L5	naive and bloc indices are one variance under two correlation assumptions	ARITHMETIC
R2	L6, P6	four states 40/25/20/15: naive 0.285000 (3.508772); bloc 1.000000 ($N = 1.000000$)	ARITHMETIC
R2b	R2, P7, P8	$\ln N = 0$ exactly, so $\eta \ln N = 0$ and $h = -0.500000$	ARITHMETIC
R1	—	entity 27.3, currency 61.0, settlement 58.0; ratios 2.234 and 2.125	ARITHMETIC on CONSTRUCTED inputs
R3a	P9, P10	10,800,000 over 16,100,000 is 67.08 per cent; 4,080,000 over the same is 25.34 per cent; 1,220,000 over the same is 7.58 per cent	ARITHMETIC
R3b	R3a, P11	the 25.34 per cent cannot leave without consent, so realisable-within-a-year is 7.58 per cent	rests on P11, **uncited to the bibliography**
R3c	R3a, P12	$(5{,}300{,}000 + 712{,}000)/1.08^4 = 4{,}418{,}999$; $/16{,}100{,}000 = 27.45\%$; haircut 72.55%	ARITHMETIC on POSTULATED parameters
R5	—	$2{,}700{,}000 - 410{,}000 - 1{,}560{,}000 - 140{,}000 = 590{,}000$; $/4{,}370{,}000 = 13.50\%$	ARITHMETIC on CONSTRUCTED inputs
R4	P13	Case A $20/400$ and disqualified; Case B $390/400$; Case C $375/400$	ARITHMETIC on ORDINAL inputs — **see 10.6**
R6	L6, P7, P8	crediting a distinct bloc: 0.295392, $N = 3.385332$, $\eta \ln N = 0.426808$, $h = -0.073192$; gain 0.049225	ARITHMETIC

step	consumes	statement	status
R7	L1, L6	twelve units at 5–15 per cent give $N \in [9.090909, 12]$; nine at ≤ 16 per cent give $N \in [6.443299, 9]$	ARITHMETIC
CR	R3a, P9	the same three quantities bound the owner's realisation and the creditor's	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. Only P6, P8, P11 and P12 are POSTULATED. **P11 is the one that carries legal content and it is the one with no bibliographic support at all** — the supervisory gate is described from the source manuscript and is listed in Appendix B. **A reviewer who does not accept P11 loses R3b and keeps R3a, R3c and CR**, because the liability commitment and the balance-sheet identity do not depend on it. That is stated here so a reader can see exactly how much of the result the weakest postulate carries.

The chain's honest summary: four postulates, nine definitions, and arithmetic on constructed inputs. R2, R6, R7 and CR are arithmetic on definitions. R3b rests on an uncited regulatory description. R3c rests on three chosen parameters. R4 rests on stipulated weights and ordinal bands. **None of this is a proof of anything about the world, and the section says so rather than leaving the reader to notice.**

10.9 Cross-checks performed

- The three realisability shares were checked to sum to 1.000000: $0.670807 + 0.253416 + 0.075776 = 1.000000$.
- The balance-sheet identity was checked twice: $16{,}100{,}000 - 10{,}800{,}000 = 5{,}300{,}000$, and $5{,}300{,}000 - 4{,}080{,}000 = 1{,}220{,}000$.
- The target capital level was checked against its definition: $1.20 \times 3{,}400{,}000 = 4{,}080{,}000$.
- The premium reconciliation was checked: $1{,}670{,}000 + 2{,}700{,}000 = 4{,}370{,}000$, the prior commercial spend exactly.
- $s_{\max}^2 \leq \text{HHI} \leq s_{\max}$ holds on the four-state vector: $0.160000 \leq 0.285000 \leq 0.400000$.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $3.508772 \leq 6.250000$.
- The two safe-harbour bounds were checked against their equal-share cases: $1/12 = 0.083333$ gives 12.000000 and $1/9 = 0.111111$ gives 9.000000, and both maxima were verified to be attained at the stated corner allocations.
- The bloc-credit increment was checked both ways: $0.426808 - 0.377583 = 0.049225$ and $0.35(\ln 3.385332 - \ln 2.941176) = 0.049225$.
- The rubric's ordering was cross-checked against the disclosure test of Section 7.5, an instrument with no arithmetic in it at all; the two agree on all three arrangements.
- The two source discrepancies of Section 7.8 were quantified at 0.000183 in h and USD 29 in the present-value line, and the third at 0.000042 in the naive index.

11. Limitations

Every number in this paper is computed on constructed inputs and none is a measurement of a real structure. The exposure shares, the currency and settlement percentages, the balance sheet, the premium programme and the three scored arrangements are all **CONSTRUCTED** and are labelled as such at each point of use. **No first-party measurement of any real system appears anywhere in this paper.** That is this corpus's central limitation, stated here in the

terms Curzi [2026] states it in — of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated one, and 0 carry a first-party measurement — and a reviewer would be right to press on it before pressing on anything else.

The 61.0 per cent and 58 per cent figures have no as-of date and no source, because they have no referent. A concentration figure taken from real holdings requires both; these are constructed inputs to a constructed case and the source manuscript says so in its own verification note. **They are therefore evidence about the size of a gap under a construction and are not evidence that any real structure has that gap.** H2's ratios are computed from the same three inputs H2 names, which makes the test a consistency check rather than an independent confirmation, and Section 7.9 says so.

The settlement axis is not decomposed. Section 3.2 records that clearing and messaging are different layers and that a structure reporting two rails may have one messaging dependency; this paper nonetheless uses a single settlement share and does not separate them. Curzi [2026] does the decomposition properly, and the 58 per cent figure here should be read as an aggregate that a proper decomposition could move in either direction.

The correlation is assumed, not measured. $\rho = 1$ within a perimeter is the conservative end of a family and no correlation was estimated from data. For the four-state case this is the least exposed such assumption in the series — every shared mechanism of Section 4.1 is in the strongest evidence class — but it is still an assumption, and it is the quantity H1 turns on.

Every parameter in the surplus law was chosen. $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ are test parameters fixed in advance, not estimates of any real position, so the break-even $N = 4.172734$ is a property of the chosen parameter set. Any of the four values would move it.

The three financial parameters behind the 27.45 per cent are chosen and the sensitivity is stated. At zero discounting the figure is 37.34 per cent; at zero reserve redundancy it is 24.20 per cent. **The result is therefore mostly a statement about the balance-sheet structure and only secondarily about the discounting**, which is a strength of the result and a weakness of how it is usually quoted.

The realisability result has a domain and quoting it outside that domain is a misapplication. It is a result about a long-tail book (Sections 5.1 and 10.3), and an arrangement writing only short-tail risk has much less of the characteristic than the same table would suggest.

The rubric's arithmetic is not licensed by its scale type. Section 10.6 states this in full. In addition, **no sensitivity analysis over the weights was run**, so a reader who believes claims-paid should carry 30 rather than 20 cannot read the consequence off any table here. **And the rubric's Test 2 hard zero is stated on a naive unit count, which Section 7.6 shows is the wrong count.** That is a defect in an instrument this paper carries; it is disclosed rather than repaired mid-paper, and any later revision should state the threshold on the effective count.

The reflexive specification is not identified. Section 1 states this and names the remedy adopted — stipulate the reference group and defend the stipulation, following Brock and Durlauf [2001]. **The price is that every bloc assignment here is a modelling position rather than an identified empirical result**, and no amount of subsequent observation would change that. Manski [1993] and Shalizi and Thomas [2011] are the reasons.

The Lucas critique applies to this framework's own parameters and is not answered. Lucas [1976] is the general statement; the specific form is that this framework asserts that systems change behaviour when modelled and observed, and then treats η, δ and the bloc assignment as stable under exactly that response. **Either the parameters are stable under the framework's own predicted reaction or the framework undercuts itself, and this paper does not establish which.** MacKenzie and Millo [2003] documents the loop happening in the field with dates and price data, which is an existence proof for the mechanism and not a defence of the parameters.

The functional form of the surplus input is underdetermined by the evidence. Latané [1981] proposes a power law with exponent below one and Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics with no psychological assumption at all. **All fit the qualitative facts equally well, nothing in this paper discriminates between them, and the logarithm is used because it is the form this framework carries.** Peters is the stronger of the two available warrants for it and is cited as such.

Small-sample bias in the effective count is not corrected. Chao et al. [2014] show that low-order diversity estimators are biased on small samples, and a four- or six-element exposure vector is a small sample. No correction was applied, and the paper does not resolve whether these vectors are samples or complete censuses — arguably the latter, since exposures are enumerated exhaustively. **A reviewer would be right to press on it.**

Scale invariance was checked at three scales only (Section 10.4), which is not enough to describe the instrument as scale-free without qualification.

The instrument is least informative in the regime where the headline case sits [Golosov, 2010, Dunleavy and Boucek, 2003], as Section 9 states.

No statistical test was run and no p-value appears, because there is no sample and no null. Every rate reported is an exact ratio of exact constructed amounts. **No claim of "no difference" is made from any non-significant result, because no significance test exists here to make it from.**

No scaling, power-law or heavy-tail claim is made and the Clauset–Shalizi–Newman procedure was therefore not run [Clauset et al., 2009]. Any restatement reaching for such a claim must run it first, and read Broido and Clauset [2019] on how often the claim fails once it is run.

No out-of-sample validation, no matched null and no information criterion appear, because no model was fitted. Bruch and Atwell [2015]'s calibration-and-validation checklist is unmet in every row: nothing here is calibrated against observed data, validated out-of-sample, or subjected to a sensitivity analysis beyond Sections 10.3 and 11.

11.1 Rigour checks not met, listed by name

1. **Conjoint measurement conditions untested** [Luce and Tukey, 1964], so the rubric's weighted total is unlicensed as a quantity and is used only as an ordering.
2. **The framework-level scalar-reduction limitation is inherited** [Curzi, 2026] and not met separately.
3. **The reflection problem is stated and not solved** [Manski, 1993]; the remedy adopted is stipulation, and its price is paid in Section 1 and again above.
4. **The Lucas critique applied to this framework's own parameters is unanswered** [Lucas, 1976].
5. **The functional form of the surplus input is undiscriminated** [Latané, 1981, Peters and Gell-Mann, 2016].
6. **Small-sample bias in the effective count is uncorrected** [Chao et al., 2014].
7. **No out-of-sample test, matched null, information criterion, or effect size with an interval** [Bruch and Atwell, 2015], because no model was fitted.
8. **No first-party measurement of any real system** [Curzi, 2026].
9. **The dimension of η is unresolved** because the source is silent (Section 10.1).
10. **No sensitivity analysis over the rubric's weight vector** (Section 10.4).
11. **The rubric's Test 2 threshold is stated on the wrong count** and the correction is disclosed rather than applied (Section 7.6).
12. **The settlement axis is not decomposed into clearing and messaging layers** (Section 3.2).
13. **Every legal, regulatory and doctrinal statement in Sections 4 to 6 is uncited** (Appendix B).

12. Conclusion

This paper measures four things on constructed inputs and reports one counter-result. The following statements are the fixed text of those results.

R1. Measured three ways, the same constructed holding shows entity-based United States exposure of 27.3 per cent, a dollar-denominated share of the balance sheet of 61.0 per cent, and approximately 58 per cent of settlement volume clearing through the United States system

— **the entity map understates the dependency by more than a factor of two,** $61.0/27.3 = 2.234$ on the currency axis and $58.0/27.3 = 2.125$ on the settlement axis. All three are constructed inputs and none carries an as-of date.

R2. Delaware 40.0 / South Dakota 25.0 / Nevada 20.0 / Wyoming 15.0 gives a naive HHI of 0.285000 and 3.508772 effective jurisdictions, but a bloc-HHI of 1.000000, an effective count of $N = 1.000000$ and a surplus term of exactly zero, giving $h = -0.500000$ at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$. **Unlike the comparable cases in this series, no generous counterfactual exists**, because every shared mechanism sits in the strongest evidence class.

R3. On a constructed year-seven statutory balance sheet with total assets of USD 16,100,000, 67.08 per cent of assets is committed to third-party liabilities and 25.34 per cent is held as target capital, leaving **7.58 per cent realisable within a year and 27.45 per cent on a present-value basis — a 72.55 per cent haircut**. The present-value figure is model output at an assumed 8 per cent redundancy, 8 per cent discount rate and four-year lag; at zero discounting it is 37.34 per cent, and the result is a result about a long-tail book.

R4. The captive rubric scores 100 weight points across risk shifting (25), risk distribution (25), actuarial pricing (20), claims paid (20) and insurer conduct (10), each scored 0–4 for a weighted total to 400, **with hard zeros for run-back risk, fewer than five units, no pre-inception report, no claims in three years, or related-party investment, and a zero on risk shifting or risk distribution disqualifying regardless of total**. Three constructed arrangements score 20 out of 400 and disqualified, 390 out of 400, and 375 out of 400. **The total is an ordering, not a quantity.**

R5. The retained programme's economics: $2{,}700{,}000 - 410{,}000 - 1{,}560{,}000 - 140{,}000 = 590{,}000$, which is **13.50 per cent of the previous commercial spend of 4,370,000**, before investment income and before any tax consequence in any jurisdiction.

R6. Crediting Bermuda as a distinct bloc raises the effective bloc count from 2.941176 to 3.385332 and the surplus term from 0.377583 to 0.426808, moving h from -0.122417 to -0.073192, a gain of 0.049225. **It is a change in the bloc call and not a change in the structure**, and the base case declines it. The source manuscript prints -0.1226 and -0.0734 for the same two figures; Section 7.8 reconciles the 0.000183 difference and this paper uses the exact values.

Counter-result. The property that makes an insurance reserve resistant to third-party claims — real liabilities owed to unrelated parties, gated by a supervisor — is the same property that makes it unavailable to its owner, leaving only 7.58 per cent realisable within a year. The argument cannot be sold on both sides at once, and the inconsistency in doing so is arithmetic rather than rhetorical.

One further result is established as method rather than as measurement. The risk-distribution test that decides whether a captive arrangement is insurance is the bloc collapse of Curzi [2026] on a different share basis: three insureds behind one common mode have an effective count of 1.000000 whatever their shares, thirteen insured units behind one manufacturing process likewise, and a published constraint of twelve subsidiaries each at five to fifteen per cent of risk is exactly an effective-count floor of 9.090909 against a ceiling of 12.000000, with nine members none above sixteen per cent giving $[6.443299,\ 9.000000]$. **The doctrine's arithmetic content is the reciprocal index, and the doctrine's silence about correlation is the same silence the naive jurisdictional count keeps.** The consequence, disclosed rather than suppressed, is that this paper's own rubric states its risk-distribution threshold on the naive count and should state it on the effective one.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the exposure shares, the currency and settlement percentages, the statutory balance sheet, the premium programme, the three scored arrangements and the cost figures — is **CONSTRUCTED**

and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing, except the present-value figure of Section 7.3, which is model output at the three parameters stated there.

All figures were produced by the scripts named in their captions (`figs/src/CCP-055_fig01.py` through `figs/src/CCP-055_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional, regulatory and doctrinal descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative, treaty and standard-setting material only; it contains no statutes, regulations, revenue rulings, court rules, registry documents, licensing frameworks or case reports for any individual jurisdiction. Appendix B lists the claims affected. **Any reader relying on those descriptions must verify them against the official sources, and must record the date of that verification.**

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. All persons, entities, holdings and arrangements described are constructed for the purpose of exercising the measurement.

Preregistration

The parameter set $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ and the break-even criterion $N \geq e^{0.5/0.35} = 4.172734$ were fixed by Curzi [2026] before the measurements reported here, and are not adjusted anywhere in this paper. **No structure measured in this paper clears that break-even**, which Section 7.7 reports in the same language a clearance would have received. The rubric weights of Section 6.2 and the H3 criterion of Section 2 were likewise fixed before the arrangements were scored and the balance sheet was decomposed. **No other element of this paper was preregistered.**

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions, licensing classes and structural arrangements for the purpose of measuring concentration, dependency and realisability. No recommendation is made in respect of any particular person, asset, structure, jurisdiction or arrangement. Statutory avoidance periods, seasoning periods, charging-order provisions, insurance licensing classes, capital and solvency

requirements, substance requirements, premium ceilings, diversification requirements and reporting obligations all change and vary by jurisdiction and by activity; **every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel — and, for any insurance matter, with a credentialed actuary — in the relevant jurisdiction before any reliance.**

Appendix A. The reporting standard for a four-axis measurement

Any structure measured under this instrument reports the following, and nothing less. Items 1 to 9 are carried from Curzi [2026]'s reporting standard; items 10 to 14 are added by this paper.

```
 1  share basis, stated in one sentence, per axis
 2  exposure table, units and shares, summing to 100.0%
 3  naive HHI, in fraction and in points, and effective units
 4  bloc assignment with the evidence class for each unit
 5  bloc-HHI and the effective count N
 6  perimeter exposure as a percentage
 7  ln(N), eta ln(N), and h at the stated parameters
 8  the robustness table over contested assignments
 9  the date, and the diff against the previous measurement
10  the SAME five lines on the currency axis
11  the SAME five lines on the settlement axis, with clearing and
    messaging layers separated
12  the SAME five lines on the counterparty axis
13  the largest of the four, named as the binding one
14  for any risk-transfer vehicle: total assets, third-party
    liabilities, the regulatory capital floor, and the three
    realisability shares, with the assumed redundancy, discount
    rate and settlement lag printed beside them
```

Item 13 is the item this paper exists to add. A structure reporting only item 3 has reported the flattering axis, and a structure reporting items 3 and 5 has reported the flattering axis correctly. **Item 9 decays first and matters most**, because perimeter drift is invisible except as a difference between two measurements taken a year apart.

Item 14's last clause is not optional. A realisability figure quoted without its three parameters is model output presented as arithmetic, and Section 10.2 records that this is the one headline figure in this paper exposed to that error.

A note on item 11. This paper does not meet its own item 11 — the settlement share is reported as an aggregate — and Section 11 says so. The standard is stated at the level the measurement should reach rather than the level this paper reached.

Appendix B. Claims requiring verification against primary sources

The following statements rest on legal or regulatory detail that changes, and **none of them is cited to the bibliography, which contains no primary sources for any individual jurisdiction**. They are reproduced from the source manuscript and require confirmation with counsel in the relevant jurisdiction — and, for insurance matters, with a credentialed actuary — before any reliance. **Record the date of each confirmation**; a statement of a regime without a date is not a statement of that regime.

1. The beneficial-ownership reporting regime described in Section 4.4: the enactment, the implementing rule, the constitutional challenges, the nationwide injunction, the stay, the subsequent interim rule narrowing the regime, whether a final rule has superseded it, and the present state of litigation and legislation. **This is the most volatile item in the paper and it changed twice in eighteen months.**
2. The federal avoidance provision described in failure mode 2 of Section 8, its ten-year period, and its interpretation in the relevant circuit.
3. The uniform fraudulent-transfer legislation: the enacting jurisdiction's version, its badges of intent and its limitation periods. Enactments vary jurisdiction by jurisdiction.
4. The appellate and first-instance decisions described in Section 4.2 on the impossibility defence, on a statute purporting to confer exclusive jurisdiction, on most-significant-relationship analysis in bankruptcy, and on public policy against self-settled spendthrift trusts. **Case citation follows different conventions and no case is in the bibliography.**
5. The decision described in Section 4.2 on the charging order and single-member entities, and the responsive legislation.
6. The estate and gift tax exposure of a non-resident holding shares with situs in the jurisdiction, the statutory exemption amount, the current exclusion following recent legislation, and any applicable treaty relief.
7. The real property tax and withholding regime described in Section 4.1, including its reach through holding corporations.
8. The corporate, alternative-entity, trust and perpetuities provisions of each of the four states de-identified in Section 4.3, including seasoning periods, excepted creditor classes, charging-order exclusivity and its extension to closely held corporate shares, directed-trust architecture, sealing provisions and private-trust-company regimes. **The source deliberately does not assert section numbers it has not confirmed, and neither does this paper.**
9. The insurance licensing statute and classification described in Section 5: class definitions, the percentage thresholds separating classes, minimum capital by class, and whether the constructed class assignment of Section 7.3 is correct on a book with a minority unrelated element.
10. **P11, the supervisory gate.** The exact thresholds and section numbers for the restriction on reduction of statutory capital and for the affidavit requirement on distributions, and whether prior approval or an affidavit is required in the case described. **This is the one postulate in Section 10.7 carrying legal content and no bibliographic support; Section 10.8 states exactly which result depends on it.**
11. Whether the relevant insolvency law confers a statutory priority on policyholders over general unsecured creditors in the winding up of an insurer.
12. The solvency-equivalence determination described in Section 5, its scope, its effective date, and the treatment of captives and special-purpose insurers within or outside it.
13. The reciprocal-jurisdiction and qualified-jurisdiction determinations described in Section 5, and their dates.
14. The economic-substance legislation and regulations described in Section 5, the relevant activity definitions, and the treatment of insurance and pure holding entities.
15. The corporate income tax legislation described in Section 5: the in-scope entity definition, the revenue threshold, and the first fiscal year of application.
16. The exchange and reporting positions described in Sections 4.4 and 5, including the intergovernmental agreement model and current participating-jurisdiction status.
17. The doctrinal anchor described in Section 6.1 requiring both risk shifting and risk distribution, the four-question working formulation, and the appellate decisions on brother-sister structures.
18. **The three published safe harbours described in Section 6.1**, on which the effective-count bounds of Section 7.6 are computed: the twelve-subsidiary constraint at five to fifteen per cent each, the seven-or-more unrelated members constraint, and the unrelated-premium-at-half constraint, together with the negative ruling on a small number of insureds. **The bounds are arithmetic; the constraints are not verified here.**

19. The small-insurer election described in Section 6, its indexed premium ceiling, and the exact mechanics of both alternative diversification requirements added by later legislation.
20. The reportable-transaction and disclosure regulations applying to the arrangements described in Section 7.5, and whether the constructed Case A pooling arrangement would fall within them.
21. The segregated-cell and protected-cell legislation referenced in Section 5, and whether cell segregation is recognised outside the jurisdiction of formation.
22. The constitutional position of the risk-transfer centre described in Section 7.7, including its final appellate arrangement and the external capacity to legislate for it by order, on which the bloc assignment there partly rests.
23. All cost, premium, loss and balance-sheet figures in this paper are constructed. **They are not fee quotations, rate filings or statutory returns, and no real schedule was used to produce them.**

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing, and the three places where a printed value differs from the exact computation are reported in Section 7.8 rather than harmonised.

Chapter 56

Substance Repricing and the Clearing-System Count: The Atlantic Cluster, ADGM, and the Limits of a Second Enclave

Abstract. Two findings are reported against the common assumption that adding entities adds resilience. First, the Atlantic offshore cluster: a legacy structure across the United Kingdom 40.0 per cent, the United States 22.0, Cayman 14.0, the British Virgin Islands 12.0, the Bahamas 7.0 and Barbados 5.0 reads a naive HHI of 0.249800 and 4.0032 effective jurisdictions, but a bloc-HHI of 1.000000 and an effective count of 1.00, because every entry sits in the same coordination perimeter — adding a Western entity to a Western structure leaves ln(N) at exactly zero. Second, the two Emirati financial free zones are one line: the DIFC and the ADGM share a single national perimeter, one federal anti-money-laundering regime, and one exposure share of 29.1 per cent, so no rearrangement between them changes the effective bloc count. The substance requirements introduced across the Atlantic cluster are priced rather than described: annual cost rises from a baseline of 1,550 to 5,350 for a pure equity-holding entity (3.45 times) and to 19,350 for an entity carrying a relevant activity (12.48 times), which sets a break-even at roughly USD 7.74 million of held value at 25 basis points. The one axis where diversification is achieved is settlement: measured by currency, the structure moves from a single dollar system at HHI 1.0000 and 1.00 effective clearing systems to 2.81, with the dollar still at 55 per cent — a floor set by counterparties, not by entity placement.

Keywords: economic substance; offshore financial centres; ADGM; financial free zones; clearing systems; settlement diversification; concentration measurement

Series: D. Structure and Resilience **Paper:** CCP-056

1. Introduction

Two findings are reported against the common assumption that adding entities adds resilience, and one of them is a general proposition about what a marginal unit can be worth.

The first is that a legacy structure spread across an Atlantic offshore cluster is one point of failure. Six entities — United Kingdom 40.0 per cent of exposure, United States 22.0, Cayman 14.0, the British Virgin Islands 12.0, the Bahamas 7.0 and Barbados 5.0 — read a naive

Herfindahl–Hirschman Index of 0.249800 and 4.003203 effective jurisdictions. Collapsed onto the coordination perimeter every entry occupies, the same shares read a bloc index of 1.000000, an effective count of exactly 1.00, and $\ln N = 0$. **Adding a Western entity to a Western structure leaves the surplus term at exactly zero**, and the constructed family in this case had been told in writing, more than once, that the structure was internationally diversified.

The second is that the two Emirati financial free zones are one line. The Dubai International Financial Centre and Abu Dhabi Global Market share a single national perimeter, one federal anti-money-laundering regime, one standard-setting-body assessment and one exposure share of 29.1 per cent, so no rearrangement of entities between them changes the effective bloc count. That is the same result Curzi [2026] reaches from the apex direction — the apex vehicle does not move the concentration reading, and the measurement remains naive HHI 0.2934 and 3.41 effective jurisdictions against bloc-HHI 1.0000 and 1.00 effective perimeters whatever vehicle sits at the top — and the same result Curzi [2026] reaches on the Crown Dependencies, where Jersey 40.0 / Guernsey 35.0 / Isle of Man 25.0 gives naive HHI 0.345000 and 2.898551 effective jurisdictions but bloc-HHI 1.000000, $N = 1.00$ and a surplus term of exactly zero. **Three papers, three sets of entities, one number.**

Between them sits a measurement of the instrument that repriced the first cluster. The substance legislation enacted across the Atlantic centres is almost universally described as a prohibition. **It was a price change, and this paper computes it**: annual cost rises from a constructed baseline of USD 1,550 to USD 5,350 for a pure equity-holding entity, a multiple of 3.45, and to USD 19,350 for an entity carrying on a relevant activity, a multiple of 12.48. Because the cost is fixed per entity rather than proportional to assets, **the instrument was regressive against holding size**: at a two-million-dollar holding it consumes 96.75 basis points a year and at two hundred million it consumes 0.97, with a break-even against a stated 25-basis-point tolerance at USD 7,740,000 of held value. That is why the large-deal and fund businesses in these centres grew straight through the period while the retail company business contracted, and it is why commentary describing the events as the end of offshore was reading the wrong end of the distribution.

The one axis on which the constructed structure achieves genuine diversification is settlement. Measured by the terminal clearing system rather than by entity, the structure moves from a single dollar system at HHI 1.0000 and 1.00 effective clearing systems to 2.810568 across five, with the dollar still at 55 per cent. That residual is set by the currency the counterparties pay in and not by entity placement, and it is the result Curzi [2026] and Curzi [2026] both work against from different directions — the latter measuring the rail directly, where a naive correspondent HHI of 0.302400 (3.306878 effective correspondents) collapses to a perimeter HHI of 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency.

What this paper adds beyond those measurements is a bound. Section 3.4 states and Section 7.5 verifies an elementary proposition about the marginal unit: if a set of units holding fixed relative proportions has its own effective count M, then adding one more unit and rescaling the rest raises the effective count to at most $M + 1$, and that maximum is attained only when the new unit takes share $1/(M + 1)$. Applied to the constructed settlement mix, the four non-dollar systems have $M = 3.799250$, so **the ceiling on this structure's effective clearing-system count is 4.799250, attained at a dollar share of 20.8366 per cent** — and reaching 4.00 requires the dollar share to fall to 38.9912 per cent, not to the "roughly one third" the source manuscript states. **The proposition also says that eliminating the dollar entirely would be worse than holding a fifth of settled value in it**, giving 3.799250 rather than 4.799250, which is counter-intuitive, exact, and checkable in two lines.

The paper reuses the surplus functional and the affine effective count of Curzi [2026] — $f(u) = \ln(1+(N-1)u)$, uniquely characterised by angle-only dependence, vanishing at parallel, an affine effective count and normalisation, with $N_{\text{eff}} = 1 + (N - 1)u$ — and the roster-audit form of that count in Curzi [2026c], where the affine form is badged as a design axiom rather than a derived result and a hundred-person department at $u = 0.05$ has an effective count of 5.95. **Section 3.1 states plainly that the affine count is not the count this paper uses**, and why. It presupposes the founding reframing of Curzi [2026], that comfort is the felt total of present

costs so that the present state is a local minimum of the comfort landscape by definition rather than by luck, which is the reason a legacy structure accumulated by three sets of advisers over three decades persists without anyone defending it. And it presupposes the result of Curzi [2026d] that adding a seventh discipline to an institute makes it worse — the period change falls to -0.002863 and the fixed point drops from 6.265 to 5.964 — because divergence, not domain count, was the deficiency. **That is this paper's second finding, stated in another domain a volume earlier.**

The bloc assignment carries an identification problem and it is stated here rather than in a footnote. Manski [1993] proves that a linear-in-means reflexive specification is **not identified from observational data**: the endogenous effect cannot be separated from contextual effects or from correlated unobservables however much data is collected, and Shalizi and Thomas [2011] show that influence and selection are generically confounded in observational network data. **No amount of observing jurisdictional behaviour could confirm a bloc assignment derived reflexively.** The remedy adopted is the fourth of four: the reference group is stipulated in advance and the stipulation is defended, on the evidence ladder of Section 4.1 and the listing record of Section 4.3, which is the route Brock and Durlauf [2001] shows can be made rigorous. **The price is that every bloc assignment here is a modelling position rather than an identified empirical result.**

2. Hypotheses

Five hypotheses are stated. Each is falsifiable in the sense Platt [1964]'s strong inference requires, and H5 is falsifiable by counterexample only, which is stated rather than dressed up. Meehl [1967] is the standing warning that directional predictions are cheap; four of the five below carry point predictions with constants attached.

H1 — the Atlantic-cluster hypothesis. Entities distributed across an Atlantic offshore cluster occupy one coordination perimeter, so their naive count and their effective count diverge to the maximum possible extent. *Predicted:* UK 40.0 / US 22.0 / Cayman 14.0 / BVI 12.0 / Bahamas 7.0 / Barbados 5.0 gives naive HHI 0.249800 and 4.003203 effective jurisdictions, and bloc-HHI 1.000000, $N = 1.000000$, $\ln N = 0$ exactly. *Falsified by:* a defensible bloc assignment placing two of the six in different perimeters — equivalently, an instance in which a listing, a designation or a de-risking decision reached one and not the others without a second independent decision.

H2 — the repricing hypothesis. The substance instrument operated as a price change and not as a prohibition, and because the price is a fixed annual amount per entity it is regressive against holding size. *Predicted:* a cost multiple of $5{,}350/1{,}550 = 3.45$ for a pure equity-holding entity and $19{,}350/1{,}550 = 12.48$ for a relevant-activity entity, with the relevant-activity cost falling from 96.75 basis points of a two-million-dollar holding to 0.97 basis points of a two-hundred-million-dollar holding, and a break-even at USD 7,740,000 against a stated 25-basis-point tolerance. *Falsified by:* a cost structure proportional to assets rather than fixed per entity, which would remove the regressivity; or evidence that entities were prohibited rather than repriced.

H3 — the one-perimeter hypothesis. The two Emirati financial free zones, the DIFC and the ADGM, are one line in the measurement, so no rearrangement of entities between them changes the effective bloc count. *Predicted:* the two zones share a single exposure line of 29.1 per cent, and moving any entity from one to the other leaves bloc-HHI 0.340000 and $N = 2.941176$ unchanged to every decimal place. *Falsified by:* a rearrangement between the two zones that moves N at all; equivalently, evidence that a decision taken at the federal level reaches one zone and not the other without a second independent decision.

H4 — the settlement-axis hypothesis. The settlement axis, unlike the entity axis, admits genuine diversification, and the improvement is measurable in the same units. *Predicted:* a structure settling wholly in one currency reads HHI 1.0000 and 1.00 effective clearing systems; the constructed redesign at USD 55.0 / CNY 15.0 / EUR 12.0 / INR 10.0 / AED 8.0 reads HHI 0.3558

and 2.810568. *Falsified by:* a decomposition showing that the additional systems' messaging legs run over the first system, in which case the count collapses back toward 1.00 and the apparent diversification is an artefact of counting the wrong layer.

H5 — the marginal-unit proposition. Adding one unit to a set of units held in fixed relative proportions, and rescaling the rest, raises the effective count by at most exactly one. *Predicted:* if the incumbent set's own effective count is M, then $\mathrm{EFF}(x) = 1/(x^2 + (1-x)^2/M)$ is maximised at $x = 1/(M+1)$ with value $M+1$. For the constructed settlement mix, $M = 3.799250$, so the ceiling is 4.799250 at a dollar share of 0.208366, and $\mathrm{EFF} = 4.000000$ requires $x = 0.389912$. *Falsified by:* any admissible share vector of this form whose reciprocal index exceeds $M + 1$. **H5 is a proposition of arithmetic rather than an empirical hypothesis. It is falsifiable by counterexample and by nothing else, and it carries no empirical weight whatever; what it does is bound a design space that is otherwise argued about without limits.**

Not hypotheses, and labelled as such. Four further statements appear and none is falsifiable as stated.

- *The logarithmic form of the input side*, $\eta \ln N$ rather than ηN, is a **modelling choice** carried from Curzi [2026]. Section 11 records that Latané [1981]'s sub-linear power law fits the qualitative facts as well and that nothing here discriminates between them.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice** carried from Curzi [2026] and fixed in advance, which is the preregistration discipline of Nosek et al. [2018] applied to an engineering measurement.
- *The 25-basis-point tolerance* against which the substance break-even is computed is a **stated judgement, not a standard**. Any other tolerance moves the break-even proportionally, and Section 7.2 gives the formula so a reader may substitute their own.
- *The identification of the surplus law's N with the effective bloc count* is a **definition**; its content is in the assignment rule, which is testable.

3. Method

3.1 The instrument, and which effective count it is

The concentration instrument is taken unchanged from Curzi [2026], which reaches naive HHI 0.189002 (5.29 effective jurisdictions) and bloc-HHI 0.340000 (2.94 effective blocs) on the designed structure this paper also measures. Its definition fits on one line:

```
HHI = sum of squared shares            effective count = 1 / HHI
```

introduced by Hirschman [1945] and reached independently in sum-of-squares form by Herfindahl [1950]. The reciprocal reading is due to Adelman [1969]. Competition practice states the index in points on percentage shares [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]; this paper states it as a fraction and gives both where confusion is possible.

Which effective count, stated exactly. The reciprocal index HHI^{-1} is the Hill number of order two [Hill, 1973], whose numbers-equivalent reading Jost [2006] states in its cleanest form; the same arithmetic was reached independently in ecology by Simpson [1949] and in political science by Laakso and Taagepera [1979]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and the reciprocal index is also the exponential of the Rényi entropy of order two [Rényi, 1961]. **Every effective count in this paper — of jurisdictions, of blocs, and of clearing systems — is HHI^{-1}, the Hill number of order two, and it is named as such at each use.**

The affine count is a different quantity and is not used here to produce any number. Curzi [2026c] runs $N_{\mathrm{eff}} = 1 + (N-1)u$ with $u = 1 - (x \cdot y)^2$ and surplus $S = \ln N_{\mathrm{eff}}$, giving a hundred-person department at $u = 0.05$ an effective count of 5.95, and **badges the affine form as a design axiom rather than a derived result**, which is the correct badge. It is a linear interpolation

between 1 and N, it is not a Hill number of any order, and it carries no external support; Curzi [2026] establishes this by running the same verification chain on both counts and letting one fail visibly. **Wherever this paper says "effective count" it means the reciprocal index, and the affine count appears by name only.**

The general form. The bloc collapse generalises the reciprocal index to EFF $= 1/(w'Rw)$ for exposure weights w and correlation matrix R, which is the similarity-sensitive diversity of order two of Leinster and Cobbold [2012], whose additive relative is the quadratic entropy of Rao [1982]. Setting $R = I$ recovers HHI^{-1}; setting R to a block matrix of ones recovers the bloc index. Hurlbert [1971] is the standing objection that "diversity" carries no content without its formula attached.

No distributional or scaling claim is made anywhere in this paper. The share vector 40.0 / 22.0 / 14.0 / 12.0 / 7.0 / 5.0 descends steeply and invites a tail argument. **This paper fits no distribution, characterises no tail and asserts no power law.** Clauset et al. [2009] is the reason: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few canonical data sets standing, and a straight line on a log-log plot is not evidence. That procedure was not run because no claim requiring it is made, and Stumpf and Porter [2012] adds that even a genuine power law is weak evidence for a mechanism. **The effective counts here are statistics of finite vectors with four, five or six entries.**

The collapse result has an ancestry that should be named rather than reinvented. Granovetter [1978] establishes that the distribution of individual thresholds, not the mean, determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate result — the strongest available warning against reading an individual-level parameter straight into an aggregate, which is what a bloc assignment does. Castellano et al. [2000] supplies the closest formal analogue of a bloc: the same interaction that raises local agreement freezes global diversity into non-interacting regions, with a sharp transition between the monocultural and fragmented phases. **A bloc, in that vocabulary, is a frozen region and the effective count is a count of them.**

3.2 The share basis, the four axes, and the layer that ruins them

This paper measures against **arbitrary state action** — a designation, a listing, an exchange-control measure, a compliance department's change of risk appetite — and not against lawful process. The instrument is identical on each of four axes and only the share basis changes: jurisdiction, settlement rail, counterparty, and currency. Curzi [2026] measures the mismatch between the first and the last on the same constructed structure, reporting entity-based United States exposure of 27.3 per cent against a dollar-denominated balance-sheet share of 61.0 per cent and settlement volume through the United States system of approximately 58 per cent — the entity map understating the dependency by more than a factor of two. **This paper measures the rail axis, which is the axis that turns out to move.**

One distinction ruins naive measurements on that axis and this paper's H4 turns on it. A clearing system and a messaging system are different layers. A structure reporting two rails may have one messaging dependency: measured correctly, "one messaging network at 100 per cent" and "85 per cent on that network plus 15 per cent on a second clearing system whose messaging leg runs over the first" are the same number, and only the second looks diversified. **The share basis used here is the terminal clearing system**, defined as the system in which final settlement occurs, and the messaging layer is treated as a separate count that this paper does not compute. Curzi [2026] computes it and finds the collapse; **this paper's 2.81 is therefore an upper reading on one layer and not a statement about the structure's total rail independence**, which Section 11 records as its principal exposure.

Three consequences carry through the paper.

A currency is a perimeter exposure that no entity move can exit. A balance denominated in a unit whose clearing runs through banks inside a perimeter carries that perimeter's exposure however the entities are arranged.

A rail is not a holding. The optionality a bridging jurisdiction supplies is *transit* optionality, whose parameters are hop size, exposure duration, counterparty pre-screening and mid-transit failure handling. Treating a transit account as a store of value confuses an exposure-window problem with a custody problem.

A jurisdiction's policy is not a bank's risk appetite. A dual-rail jurisdiction supplies a market in which dual-rail counterparties exist and must be found, onboarded and maintained one at a time; it does not supply the counterparty.

3.3 Correlated units, and what the literature says about the correction

The naive index overstates resilience because it treats units as independent when they share a coordination mechanism. The correction is not novel as mathematics: it is Markowitz [1952]'s result that diversification benefit depends on covariance and not on count, and Buldyrev et al. [2010]'s that a system of interdependent networks is far more fragile than either network alone. Perrow [1984] reached the organisational form first — interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component — and Sagan [1993] documents the sharper version, that redundancy can reduce safety. **Both borrowings are labelled under the analogy discipline of Section 10.5, and this paper's first finding is Perrow's result in a measurement frame.**

Correlations rise under stress. Longin and Solnik [2001] find extreme correlation in equity markets that is asymmetric and concentrated in downturns, and Ang and Chen [2002] report the same asymmetry. **The effective count falls exactly when it is needed.** The ecological name for the decisive variable is synchrony [Loreau and de Mazancourt, 2008], and the strongest empirical demonstration that effective count buys stability is Schindler et al. [2010]'s Bristol Bay sockeye record, with roughly half the variability and about a tenth of the fishery closures. The contrary literature is read alongside: Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone, and May [1972] showed that increasing diversity and connectance destabilises randomly assembled systems. **This paper's claim is narrower than the general diversity–stability claim**: the reciprocal of a variance is an effective count of independent shocks, which is arithmetic, and units inside one perimeter are correlated, which is H1 and H3.

3.4 The marginal-unit proposition

The result stated as H5 is elementary and is given here because Sections 7.4 and 7.5 depend on it and because it bounds an argument that is otherwise conducted without limits.

Let $n-1$ incumbent units hold shares in fixed relative proportions $q_1, \dots, q_{n-1}$ summing to one, and let their own reciprocal index be

$$M = \Big(\sum_i q_i^2 \Big)^{-1}.$$

Introduce one further unit at share x and rescale the incumbents to $(1-x)q_i$. The new index is

$$\mathrm{EFF}(x) \;=\; \frac{1}{x^2 + (1-x)^2 \big/ M}.$$

Minimising the denominator gives $2x - 2(1-x)/M = 0$, so $x^* = 1/(M+1)$, and substituting returns

$$\mathrm{EFF}(x^*) \;=\; M + 1.$$

A marginal unit is worth at most exactly one effective unit, and it is worth that only at one share. Three readings follow, and each does work in Section 7.

The ceiling is hard. No placement of the new unit exceeds $M + 1$, so a design argument that promises more than one additional effective unit from one additional entity, currency or rail is refuted before the details are examined.

The optimum is an equal share with the equal-equivalents. $x^* = 1/(M + 1)$ is exactly the share the new unit would hold if the whole set were equalised at $M + 1$ units, which is the numbers-equivalent property of Section 3.1 reappearing as a design rule.

Both tails are worse than the optimum, and the near tail is the one people reach for. $\mathrm{EFF}(0) = M$, so removing the new unit entirely returns the incumbent count; but $\mathrm{EFF}(x)$ falls on both sides of x^*, so **a unit that is too large is not merely less useful than an optimally sized one, it can be worse than useless relative to the incumbents' own count**. Section 7.5 measures exactly that case.

The proposition is arithmetic, it carries no empirical content, and Section 10.8 records it as such in the chain.

3.5 Evidence standard, and the de-identification convention

Sections 4, 5 and 6 are jurisdictional and regulatory exposition. **Every enactment, regulation, licensing regime, listing event, delisting event, rate, date and jurisdictional characteristic in them is described from the source manuscript and is not cited to the bibliography.** The bibliography carries the general instruments and the comparative doctrine only: recognition and enforcement of awards [United Nations, 1958] with the grounds on which enforcement is in fact refused [van den Berg, 1981] and the arbitration doctrine around it [Born, 2021, United Nations Commission on International Trade Law, 1985]; the trusts convention [Hague Conference on Private International Law, 1985]; the succession convention that never entered into force [Hague Conference on Private International Law, 1989] with the regional regulation that partially fills the gap [European Union, 2012]; the judgments conventions [Hague Conference on Private International Law, 2005, 2019]; conflict-of-laws doctrine [Torremans et al., 2022, Briggs, 2013]; the trust and the foundation compared [Lupoi, 2000, Smith, 2013, Panico, 2014]; asset partitioning as the irreducible function of entity law [Hansmann and Kraakman, 2000] with its critique [Pistor, 2019]; the listing machinery as a technique of governance [de Goede, 2011]; and the disclosure instruments [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015]. **It contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction.** Appendix B lists every affected claim, **with the requirement that the date of confirmation be recorded**, because a statement of a jurisdiction's regime without a date is not a statement of its regime.

Where a table would otherwise **rank named jurisdictions against one another on a legal capability the bibliography cannot support**, the jurisdictions are de-identified — "Atlantic centre A" through "Atlantic centre D", "enclave A" and "enclave B" — following the convention of Curzi [2026], which de-identifies two Gulf centres in its own scored assessment, and Curzi [2026], which de-identifies three islands in its ranked capability table. **Where a jurisdiction is named in prose, or appears in an exposure table, or carries a bloc assignment with its evidence, the name is used**, because the argument is about those specific perimeter attachments.

4. The perimeter, evidenced

4.1 The four-question test applied to the Atlantic cluster

Four jurisdictions and one point of failure. The Cayman Islands, the British Virgin Islands, the Bahamas and Barbados are treated together not because they are similar in law — they are not, and two of them are sovereign states while two are overseas territories — but because they occupy the same position on the only axis this paper measures. **Everything in this section is described from the source manuscript and is uncited** (Section 3.5, Appendix B).

test	Cayman	BVI	Bahamas	Barbados
exchanges account information under the common standard	yes	yes	yes	yes
implements the common anti-money-laundering standard through domestic legislation	yes	yes	yes	yes
placed under increased monitoring or on a coordinated list within the last eight years	yes	yes	yes	yes
clears United States dollars through United States correspondents	yes	yes	yes	yes

Four yeses each. The evidence ladder used across this series ranks demonstrated near-simultaneous mirroring of designations and listings, shared correspondent networks that exit corridors together, a supervisory standard producing the same domestic consequence in every member, and binding accession to a common enforcement instrument as the strongest classes; participation in an information-exchange framework and treaty density are weaker; diplomatic alignment is weakest. **Rows two and four of the table sit in the strongest class and row three is the observed record that Section 4.3 sets out.**

4.2 Sovereignty is not perimeter independence

One of the four is an independent sovereign state and has been for half a century. There is no external legislative power over it, no equivalent of the transparency commitment that binds the two territories, and no metropolitan department with a view. **If sovereignty produced perimeter independence, that jurisdiction would sit in a different bloc from the other three.**

It does not. It exchanges account information, it was placed under increased monitoring for a period measured in years, it has appeared on a coordinated list, and its currency is pegged one-to-one to the dollar with the corresponding correspondent dependency. **Sovereignty and perimeter independence are different variables, and this is the cleanest available demonstration that the first does not produce the second.** That observation is worth more to the measurement than anything in the jurisdiction's statute book, and it is the reason the bloc assignment in Section 7.1 does not turn on constitutional status.

4.3 The listing record, read for its structure

jurisdiction	event	duration
Cayman	coordinated list, Feb 2020 to Oct 2020	8 months
Cayman	increased monitoring, Feb 2021 to Oct 2023	32 months
BVI	coordinated list, Oct 2023 to Feb 2024, after a peer-review downgrade on exchange of information on request	4 months

jurisdiction	event	duration
Bahamas	increased monitoring, Oct 2018 to Dec 2020	26 months
Bahamas	coordinated-list appearances 2018 and 2019, with removals following commitments	dates to be verified
Barbados	increased monitoring, Feb 2020 to Feb 2024	48 months
Barbados	coordinated list, Oct 2020, following a peer-review downgrade; subsequently moved to the commitment annex	dates to be verified

Read the table for its structure rather than its content. Every one of the four was listed by at least one body within a five-year window. In two of the cases the coordinated listing was triggered mechanically by a technical rating change made by a *different* body, on exchange of information on request. **One peer-review panel moved four jurisdictions' bank-onboarding classifications across a five-year period, and no combination of those four provided any protection against it.** Two rows are marked for verification and are marked that way in the source; they are reproduced with the mark rather than repaired.

That is what a coordination perimeter looks like from the inside, and it is why the arithmetic of Section 7.1 comes out at one.

4.4 A standard-setting body with no enforcement power

The same mechanism is visible in a second and better-dated episode, and it is the cleanest demonstration in this series of what a perimeter is. The United Arab Emirates, which hosts both free zones, was placed under increased monitoring in March 2022 and removed in February 2024, a period of 23 months. The listing body can fine nobody, has no treaty, no court and no enforcement arm. **The effect travelled through three channels and only one of them was discretionary.**

Channel one — linked official listings. A regional bloc maintains its own list of high-risk third countries for anti-money-laundering purposes, and the state was added to it during the period. The consequence under that bloc's legislation is that every obliged entity — bank, insurer, fund administrator, professional firm — **must** apply enhanced due diligence to relationships and transactions involving the listed country. That is a legal requirement with supervisory consequences, not a recommendation, and a second jurisdiction operating an equivalent mechanism made an equivalent change.

Channel two — private risk models. Every large correspondent bank runs a country-risk model and a listing is a hard input to it. The output is not refusal but re-rating: extra documentation, senior sign-off for new relationships, periodic-review triggers, and at the margin exits from relationships that were already thin. **That is the de-risking mechanism, and it is why the practical effect of a listing is felt by small legitimate businesses long before it is felt by anyone the listing was aimed at.**

Channel three — discretion. Individual institutions, regulators and counterparties making their own judgements, at their own pace, with no obligation to explain.

A body with no enforcement power produced an effect across every major financial system within weeks, because its determinations are wired into other people's binding rules and into thousands of private risk models. That is the mechanism the bloc collapse is measuring, and it is why this series' thesis is about perimeters rather than about secrecy.

The listing period's remedial programme is worth one further observation because it bears on H1. The state's deficiency was not primarily its statute book: federal anti-money-laundering legislation and a beneficial-ownership regime were already in force, and the assessment methodology grades effectiveness as well as technical compliance. **What the period produced was supervision, investigation, prosecution and confiscation capacity — that is, effectiveness — which is exactly the class of change that binds a jurisdiction more tightly into the perimeter rather than loosening it.** A jurisdiction that exits increased monitoring has not moved out of the perimeter; it has demonstrated that it is inside it.

4.5 The register survived; public access did not

All four Atlantic jurisdictions maintain beneficial-ownership information. The trajectory of *access* has moved twice in opposite directions. An external transparency statute required the two territories to establish publicly accessible registers; implementation slipped repeatedly. A regional court then struck down the provision of that region's own anti-money-laundering legislation making member-state registers accessible to the general public, holding it a disproportionate interference with private life and data protection. That decision changed the territories' negotiating position, and both have legislated toward a legitimate-interest access model rather than open public access. **Commencement dates, the definition of legitimate interest, and the current enforcement position are all marked for verification** (Appendix B).

The register exists in every one of these jurisdictions and competent authorities have access to it. What changed is whether a stranger can search it.

The premise that makes this the right way round is not this work's to claim. Kerckhoffs [1883] stated it in 1883: a system must remain secure when everything about it except the key is public. Saltzer and Schroeder [1975] restate it as *open design* — the protection mechanism should not depend on the ignorance of attackers — and place it alongside *complete mediation* because a publishable design still requires that every access be checked. Brandeis [1914] is the public-interest form of the same observation. **Citing Kerckhoffs converts what reads as an ethical preference into a recognised engineering standard**, and Curzi [2026] states the constraint in its strongest form: channel separation is strengthened by disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable and non-disclosure is refused as a design premise rather than merely discouraged. **Any structure whose function depends on a stranger's inability to search is outside this paper's subject; a structure that merely prefers not to be searchable is expressing a lawful preference, and the line between them is the disclosure test.** The regulatory direction has made the point unavoidable from the other side: automatic exchange [Organisation for Economic Co-operation and Development, 2017], the common anti-money-laundering recommendations [Financial Action Task Force, 2012] and the substance and beneficial-ownership work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] together mean non-disclosure is not an available design parameter.

5. The substance instrument as a pricing intervention

5.1 What it was

A regional bloc's code-of-conduct group, working from criteria adopted in December 2017, applied a test to jurisdictions with no or only nominal corporate taxation: entities claiming residence there had to demonstrate real economic activity, and the alternative was inclusion on a list of non-cooperative jurisdictions. Each of the four Atlantic jurisdictions legislated, with effect from the beginning of 2019 in three of the four; the fourth addressed the criterion differently because its exposure was ring-fencing rather than nominal taxation. **All of the resulting statutes have been revised and the operative text must be taken from the current revision** (Appendix B).

The common architecture: an entity carrying on a *relevant activity* — banking, insurance, fund management, financing and leasing, headquarters business, shipping, distribution and service-centre business, intellectual-property business, and holding business — must be directed and managed in the jurisdiction, conduct its core income-generating activities there, and maintain adequate employees, expenditure and physical presence proportionate to that activity. Pure equity-holding entities are subject to a reduced test. Intellectual-property business, identified as the most mobile, attracts the heaviest treatment.

5.2 The cost table

The instrument's effect is best seen in a cost line rather than in a legal analysis. **Constructed and illustrative; not a quotation, and actual costs vary widely by jurisdiction, agent and activity.**

component, USD per year	pre-2019	post-2019
registered agent and registered office	1,100	1,600
government or annual licence fee	450	1,050
substance classification and annual return	0	900
beneficial-ownership filing and maintenance	0	400
accounting records and annual financial return	0	1,400
locally resident directors, relevant-activity entity only	0	14,000
total, pure equity-holding entity	**1,550**	**5,350**
total, relevant-activity entity	**1,550**	**19,350**

The instrument prohibited nothing. It multiplied a cost base, and a product whose entire proposition was that it cost almost nothing does not survive being multiplied by twelve. Section 7.2 computes the multiples and the regressive property.

5.3 What survived, and why

What survived the substance instrument is precisely what had substance, and the point is worth stating because it is the mechanism, not a moral.

A fund with unrelated investors, an administrator, an auditor and a custodian always had substance, so a fund industry survived and grew. A specialist commercial court is substance by definition, so a court-led jurisdiction became more rather than less important. A private-client statute book that drafts genuinely novel instruments is substance, so it survived. A treaty network survived in narrowed form, because a treaty benefit was never available to an entity with nothing in it whatever local practice may once have suggested. **What died was the empty company: the cheap, unstaffed, undocumented vehicle formed for a few hundred dollars and left to sit.**

That distribution of outcomes is an audit result and this paper reports it as one, following the reporting form of Curzi [2026], whose audit distribution over thirteen entries — seven maps, two splits, one rendering, three rejections, with five entries carrying a failure — is the model for printing a disposition table rather than a narrative. Section 7.7 disposes of four legacy entities the same way.

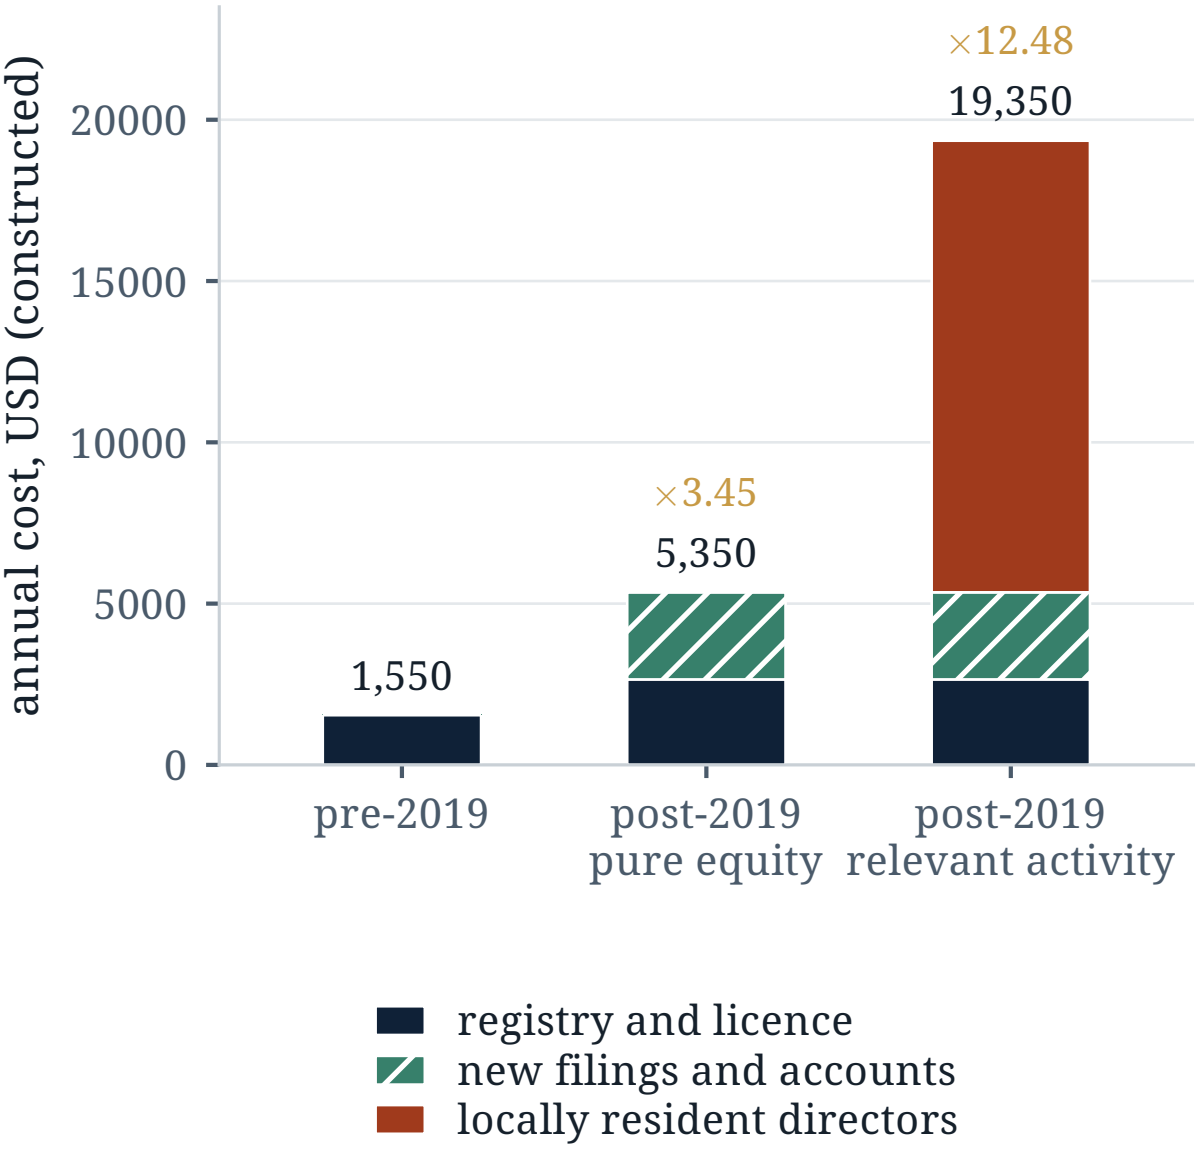

Figure 56.1: **The substance instrument multiplied a fixed cost base by 3.45 for a holding entity and by 12.48 for a relevant-activity entity.** Constructed annual cost of an offshore holding company, grouped into registry and licence, new filings and accounts, and locally resident directors. All amounts are constructed and illustrative, not quotations. Generated by `figs/src/CCP-056_fig02.py`.

6. The second enclave: a body of law without its territorial state

6.1 The decomposition

The strongest single piece in the architecture this series builds is not a jurisdiction. It is a decomposition. **Everything in this section is described from the source manuscript and is uncited** (Appendix B).

```
A NATIONAL COMMERCIAL LAW
    =  a body of doctrine and precedent
    +  a court system
    +  a territorial state with a tax system, a public register,
       a sanctions perimeter, and a bloc alignment

AN ENCLAVE APPLYING THAT LAW DIRECTLY
    =  the body of doctrine and precedent
    +  its own court system, staffed from the same tradition
    −  the territorial state
```

Abu Dhabi Global Market applies the common law of England, including the principles and rules of equity, as it stands from time to time, under its own Application of English Law Regulations. Not a jurisdiction whose statutes were drafted in the tradition; not one that inherited the law at a colonial reception date and then drifted; not one that treats it as a residual gap-filler. **The body of law can be bought without the entity**, and an intermediate holding company inside such an enclave gets contractual certainty across a group that spans legal families, a legal spine for the constitution and shareholder relations that becomes load-bearing exactly when everything else has failed, and a court that will hear the dispute on the merits applying law the parties can predict.

The measurement consequence is the point of this paper's H3. Curzi [2026] establishes that an entity in the originating state brings a public control register, an identity verification regime, the in personam jurisdiction of that state's courts over its directors, its sanctions perimeter, and a share of exposure sitting squarely inside the Western coordination perimeter. **The enclave supplies the law and not the perimeter attachment. That is a real gain and it is not a gain in N.**

6.2 What it does and does not do

```
DOES:
  apply the originating state's common law directly, as it develops
  supply a common-law court with an internationally recruited bench
  supply low-substance holding and special-purpose forms
  supply a foundations regime as an alternative and a migration path
  sit outside the Western perimeter on the bloc assignment

DOES NOT:
  add a bloc where the holder is already exposed to the same country
  remove the holder from automatic exchange
  remove the holder from federal anti-money-laundering, sanctions or
    criminal law
  confer opacity -- beneficial ownership is filed
  confer a tax exemption by existence -- a qualifying-income test is
    a real test
  operate -- a vehicle with no staff is not a substance answer
  bridge -- a holding company is not a treasury company
```

Run the disclosure test against the first block: every item survives publication without alteration. An enclave holding company works *better* when the operating company's registrar, the risk-transfer supervisor and the counterparty bank all see the same shareholder, filed and consistent. It is a disclosure-irrelevant instrument in the strict sense: **its function does not depend on not being seen.**

6.3 Why two enclaves in one country are one line

The DIFC and the ADGM sit in one federal state. They have separate courts, separate registries, separate regulators and separate company law. They share a constitution, a currency, a central bank, a federal criminal law, a federal anti-money-laundering regime, a single assessment by the standard-setting body of Section 4.4, and a single entry on any coordinated list. **On the perimeter test they are one unit.**

This is Curzi [2026]'s result in a different position of the structure. That paper reports that the apex vehicle does not move the concentration reading — the measurement remains naive HHI 0.2934 and 3.41 effective jurisdictions against bloc-HHI 1.0000 and 1.00 effective perimeters whatever vehicle sits at the top. **Here the same invariance holds for the branch: whatever sits beneath the apex, if it sits in the same country, the line does not move.**

The mechanism is the one Curzi [2026d] identifies in another domain: adding a seventh discipline to an institute makes it worse — the period change falls to -0.002863 and the fixed point drops from 6.265 to 5.964 — **because divergence, not domain count, was the deficiency**. Two enclaves in one country are a domain count. The deficiency is divergence, and there is none between them on any operative test.

7. Results

All figures below are exact computations on constructed inputs, carried at full precision and rounded only for printing. **No external dataset was collected and no figure in this paper is a measurement of any real structure.** Where the source manuscript's printed value differs from the exact computation, Section 7.8 prints both.

7.1 R1 — the Atlantic cluster measured, and H1

The constructed legacy position: four Atlantic entities accumulated over three decades by three sets of advisers who did not speak to each other, plus two onshore holdings.

entity	share of protected capital	bloc
UK holding and property	40.0%	WEST
US listed portfolio and custody	22.0%	WEST
Cayman private unit trust	14.0%	WEST
BVI holding company over the operating company	12.0%	WEST
Bahamas discretionary trust	7.0%	WEST
Barbados captive	5.0%	WEST

```
naive HHI = 0.160000 + 0.048400 + 0.019600 + 0.014400
          + 0.004900 + 0.002500 = 0.249800
effective jurisdictions = 1 / 0.249800 = 4.003203

bloc-HHI  = 1.000000    N = 1.000000
ln(N) = 0.000000        eta ln(N) = 0.000000    h = -0.500000
```

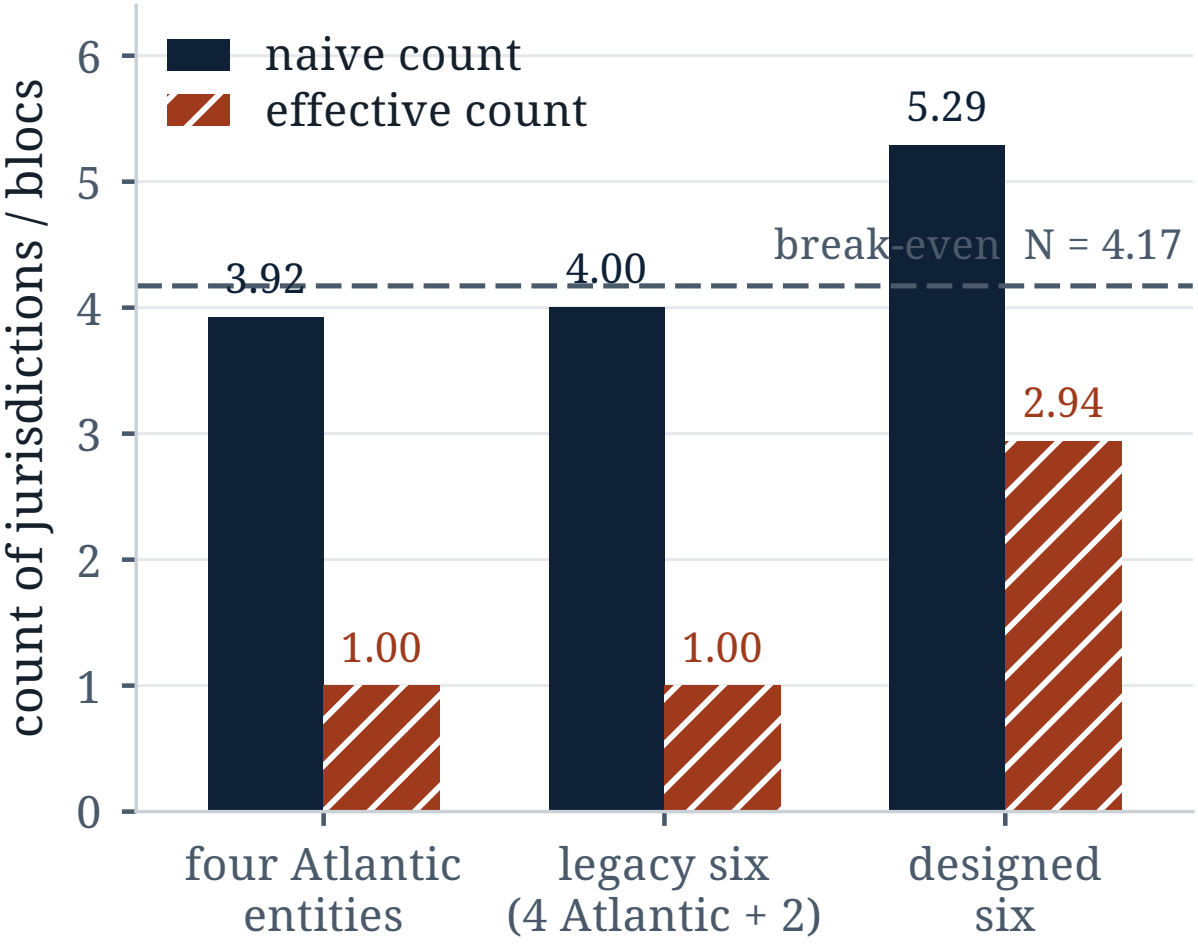

Figure 56.2: **Six Atlantic-cluster entities read 4.00 naive jurisdictions and 1.00 effective ones.** Naive count against effective count for the four-entity Atlantic variant, the six-entity legacy structure and the designed six-jurisdiction structure of CCP-052, with the break-even effective count $N = e^{0.5/0.35} = 4.172734$ the surplus law requires at the stated parameters. All shares are constructed. Generated by `figs/src/CCP-056_fig01.py`.

Six jurisdictions, an apparent effective count of 4.00, and one point of failure. The four Atlantic entities taken alone — a constructed variant at Cayman 30.0 / BVI 25.0 / Bahamas 25.0 / Barbados 20.0 — give naive HHI 0.255000 and 3.921569 effective jurisdictions against the same bloc-HHI of 1.000000. **The two vectors differ by** 0.081634 **in naive count and by exactly nothing in effective count**, which is the shape of the finding in one line.

H1 is supported. No admissible reassignment places two of the six in different perimeters: every entry returns four yeses on the test of Section 4.1, and the listing record of Section 4.3 shows the mechanism acting on all four Atlantic members within one five-year window. Section 4.2 disposes of the only argument that would separate them — that sovereignty confers perimeter independence — by exhibiting a sovereign member that behaves identically to the two territories.

7.2 R2 — the repricing and its regressive property, and H2

From the cost table of Section 5.2:

```
pure equity-holding entity     5,350 / 1,550  =  3.451613  ->  3.45x
```

```
relevant-activity entity      19,350 / 1,550  = 12.483871  -> 12.48x
```

Now the property that decides who should still be reading. The substance cost is a **fixed annual amount per entity**, and a fixed cost is regressive against asset size. Expressing the relevant-activity cost as a fraction of the capital the entity holds:

capital held, USD	annual substance cost, basis points
2,000,000	96.75
5,000,000	38.70
7,740,000	**25.00 — break-even**
20,000,000	9.675
200,000,000	0.9675

At a two-million-dollar holding the substance regime consumes ninety-seven basis points a year; at two hundred million it consumes one. The same rule, applied identically, was fatal at one end of the market and imperceptible at the other.

The break-even is a one-line formula and the tolerance is a judgement rather than a standard, so it is given in a form a reader can re-run with their own tolerance:

```
Q* = annual fixed cost / tolerance
   = 19,350 / 0.0025 = USD 7,740,000   at 25 bp
   = 19,350 / 0.0050 = USD 3,870,000   at 50 bp
   = 19,350 / 0.0010 = USD 19,350,000  at 10 bp
```

H2 is supported on both halves. The instrument is a price change: no entity type was prohibited and the cost table contains no prohibition. And the price is fixed per entity, which produces the hundred-fold spread in basis points across a hundred-fold spread in holding size. **The consequence for a holder is a threshold rather than a rule: an entity holding less than roughly USD 7.7 million is paying more than twenty-five basis points a year for a structure that adds nothing to N, and it should be collapsed rather than optimised.**

7.3 R4 — the two enclaves are one line, and H3

The designed structure, with the two enclaves consolidated into a single national line:

line	share	bloc
United Arab Emirates (DIFC and ADGM together)	29.1%	BRIDGE
Thailand	18.2%	NONALIGNED
United Kingdom	16.4%	WEST
Bermuda	13.6%	W-lite, folded into WEST
India	11.8%	NONALIGNED
Singapore	10.9%	BRIDGE

```
naive HHI = 0.084681 + 0.033124 + 0.026896 + 0.018496
          + 0.013924 + 0.011881 = 0.189002
effective jurisdictions = 1 / 0.189002 = 5.290949

blocs: BRIDGE 40.0  NONALIGNED 30.0  WEST 30.0
bloc-HHI = 0.160000 + 0.090000 + 0.090000 = 0.340000
effective blocs N = 2.941176
ln(N) = 1.078810   eta ln(N) = 0.377583   h = -0.122417
```

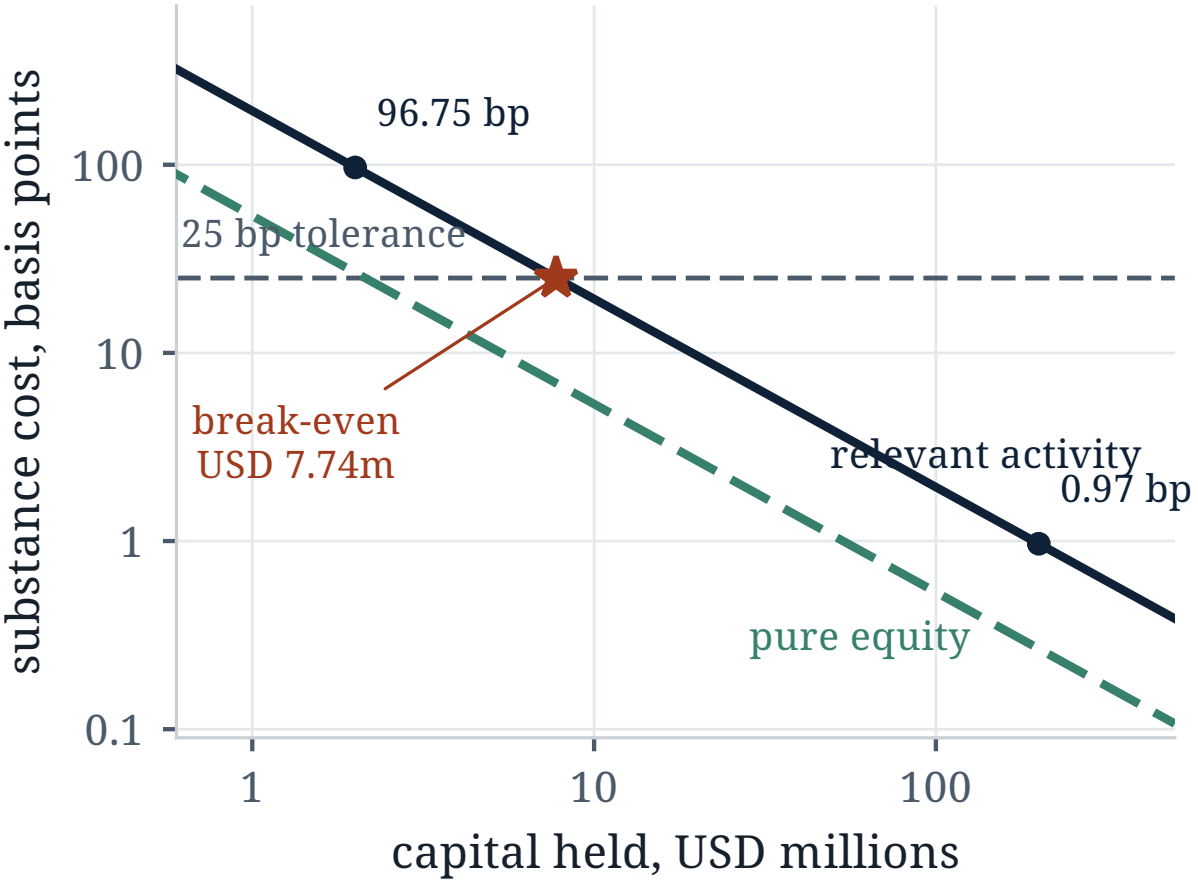

Figure 56.3: **A fixed annual substance cost is regressive: 96.75 basis points at two million dollars of capital and 0.97 at two hundred million.** The constructed relevant-activity and pure-equity costs of Section 5.2 expressed in basis points of capital held, against a stated 25-basis-point tolerance whose intersection with the relevant-activity line is the USD 7.74m break-even. The tolerance is a judgement, not a standard. Generated by `figs/src/CCP-056_fig03.py`.

H3 is supported and it is supported trivially, which is the point. Moving any entity between the DIFC and the ADGM changes no share in the table, because the table's first row is the country and both zones are inside it. The bloc-HHI is unchanged to every decimal place and so is N. **A second free zone buys capability, not diversification**, and the capability — direct application of a mature commercial law, a bench recruited from that tradition, a foundations regime, and a low-substance holding form — is real and is inventoried in Section 6.2.

What the enclave layer changed is on a different axis entirely, and the honest way to report it is a table with no arithmetic in it:

	before	after
governing law of group agreements	the originating state's law	the same body of law, applied by the enclave
forum for governance disputes	the originating state's courts	the enclave's courts
entity carrying group ownership	company in the originating state, public control register	enclave company, beneficial ownership filed but not publicly listed
entities between apex and operating company	2	1
probate steps to move the operating company on death	two grants	none: the apex is a foundation and does not die

The body of law is the same body of law. The bundle around it is gone. That is the whole trade, and it is available to anyone willing to read one set of regulations.

7.4 R3 — the clearing-system count, and H4

As found, the constructed group settled essentially everything through one bank into one dollar correspondent chain:

```
AS FOUND -- settled value by terminal clearing system
  US dollar system     100.0%
  HHI = 1.0000    EFFECTIVE CLEARING SYSTEMS = 1.00
```

A group with six jurisdictions and one clearing system has diversified its lawyers and not its exposure, and the number is the same number Section 7.1 produced on the entity axis, which is not a coincidence.

As designed, settled value is apportioned across the systems the business actually touches:

terminal clearing system	share of settled value
US dollar system	55.0%
renminbi system	15.0%
euro systems	12.0%
Indian rupee systems	10.0%
domestic dirham	8.0%

```
HHI = 0.3025 + 0.0225 + 0.0144 + 0.0100 + 0.0064 = 0.3558
EFFECTIVE CLEARING SYSTEMS = 1 / 0.3558 = 2.810568
improvement: 1.000000 -> 2.810568
```

H4 is supported, with the qualification its own falsifier names. The falsifier was a decomposition showing that the additional systems' messaging legs run over the first system. **That decomposition was not run here, and the source manuscript states plainly that many participants in the second clearing system still use the first system's messaging layer.** The 2.810568 is therefore a count of *terminal clearing systems* and is an upper reading on the structure's rail independence; Curzi [2026] runs the decomposition and finds naive correspondent HHI 0.302400 collapsing to a perimeter HHI of 0.745256 and $N_{\text{rail}} = 1.341819$. **H4 is supported on the layer it names and is not supported for the structure as a whole**, and Section 11 records this as the paper's principal exposure.

Four further changes accompany the count and only three of them enter it:

```
dollar-chain dependence      100.0%  ->  55.0%
effective clearing systems     1.00  ->   2.81
banking relationships             1  ->      4
independent correspondent chains for USD
                                  1  ->      2
standing relationship outside the host country
                                none  ->      1, live and dormant
```

The last line has no effect on the index and may be the most valuable item in the table. It is the relisting contingency of Section 4.4, and its value is entirely in existing before it is needed. That is a branch-weighting judgement rather than a measurement, and the framework has an instrument for it: Curzi [2026] scores each step of a path 0 to 3 for steepness, sums to a resistance R, and weights the branch as $1/2^R$, so that a three-point difference in steepness is a factor of eight in expectation. **A dormant relationship converts a steep branch into a shallow one, and the instrument says what that is worth in expectation even though the index says it is worth nothing.**

7.5 The frontier, the ceiling, and H5

The dollar share of 55 per cent dominates the result of Section 7.4 and cannot be engineered away, because it is set by the currency of the revenue and not by the structure. **The source manuscript states that reaching an effective count of 4.00 would require the dollar share to fall to "roughly one third" of settled value. That is checkable and it is not right.**

Holding the four non-dollar systems in their designed proportions $15 : 12 : 10 : 8$ and varying the dollar share x, the relative index of the incumbents is

```
r = (0.15^2 + 0.12^2 + 0.10^2 + 0.08^2) / 0.45^2
  = (0.0225 + 0.0144 + 0.0100 + 0.0064) / 0.2025
  = 0.0533 / 0.2025 = 0.263210
M = 1/r = 3.799250
```

so that $\text{EFF}(x) = 1/(x^2 + r(1-x)^2)$. Applying the proposition of Section 3.4 with $M = 3.799250$:

quantity	value
the designed position	$x = 0.550000$, EFF $= 2.810568$
the share required for EFF $= 4.000000$	$x = 0.389912$
the optimal share $x^* = 1/(M+1)$	$x^* = 0.208366$
the ceiling $\text{EFF}(x^*) = M + 1$	4.799250
the dollar eliminated entirely	$x = 0$, EFF $= M = 3.799250$

Three findings, and two of them correct something.

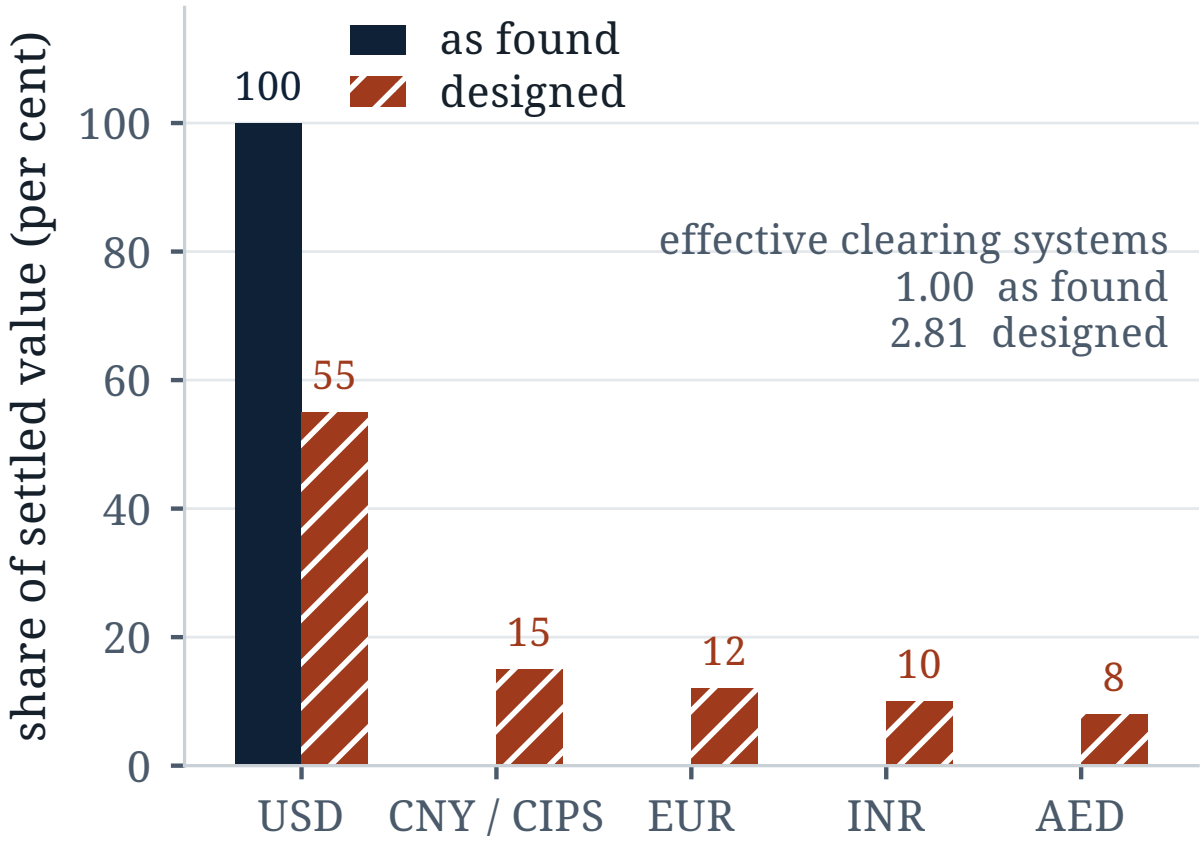

Figure 56.4: **Settled value moves from one clearing system to five, and the effective count from 1.00 to 2.81.** Share of settled value by terminal clearing system, as found and as designed, on the constructed case. The count is of terminal clearing systems only; the messaging layer is not decomposed (Section 3.2). Generated by `figs/src/CCP-056_fig04.py`.

First, the source's "roughly one third" understates the achievable dollar share by nearly six percentage points. The share required to reach four effective clearing systems is 38.9912 per cent, not 33.33 per cent. At exactly one third the count is 4.384374, well above four. **The source is conservative rather than wrong, but the exact figure is computable in one line and is printed here.**

Second, the structure has a hard ceiling of 4.799250 effective clearing systems and it cannot reach five, however the dollar is managed. That follows from the proposition of Section 3.4 with no further assumption: the four incumbent systems have $M = 3.799250$ between them, and one more unit adds at most exactly one. **A design conversation about "more rails" is bounded before it starts, and the bound is a property of the revenue mix rather than of anybody's ambition.**

Third, and counter-intuitively, eliminating the dollar entirely would be worse than holding a fifth of settled value in it. At $x = 0$ the count is 3.799250; at $x = 0.208366$ it is 4.799250. **The dollar at its optimal share is worth exactly one effective clearing system, and a policy of dollar elimination gives that up.** The result is exact, it is checkable in two lines, and it is the opposite of what a reduce-the-dominant-exposure heuristic recommends.

H5 is supported as a proposition of arithmetic. Section 10.8 records it in the chain with status ARITHMETIC and no empirical content, and Section 11 records that a proposition about a design space is not a finding about a system.

7.6 R5 — the residual

```
55% of settled value clears through a single system whose law is
not the holder's, and that share is set by the currency the
counterparties pay in rather than by entity placement.
```

That is the residual after redesign and it is the result other papers in the series cite. Three facts fix it and none of them is a structural variable. The business sells in dollars. The property position distributes in a currency converted through dollar markets. The securities portfolio is dollar-denominated. **No amount of jurisdictional cleverness changes the currency a customer pays in, and a structure that pretends otherwise is optimising the wrong variable.**

Three consequences are stated because each is a live error.

A dollar account is a dollar account. Dollar payments settle through the dollar correspondent system, are screened under that system's law, and are subject to its jurisdiction over the settlement regardless of where the account is booked or where the holder is incorporated. **"Outside the perimeter" is a statement about the entity and never about the currency.**

A second clearing system is not a replacement for a messaging system. Section 3.2 states the layer distinction and Section 7.4 states what follows: a structure built on the premise that a clearing system substitutes for a messaging network will fail, and the count reported here is of the layer that was measured.

The residual is not the same object as the entity residual. Curzi [2026] reports the entity-axis version — entity-based exposure of 27.3 per cent against a currency share of 61.0 per cent — and the two must not be netted against each other. **The rail layer and the entity layer are different exposures with different remedies, and improving one is not evidence about the other.**

7.7 The disposition of the legacy cluster, and its cost

The four Atlantic entities cost, on constructed figures:

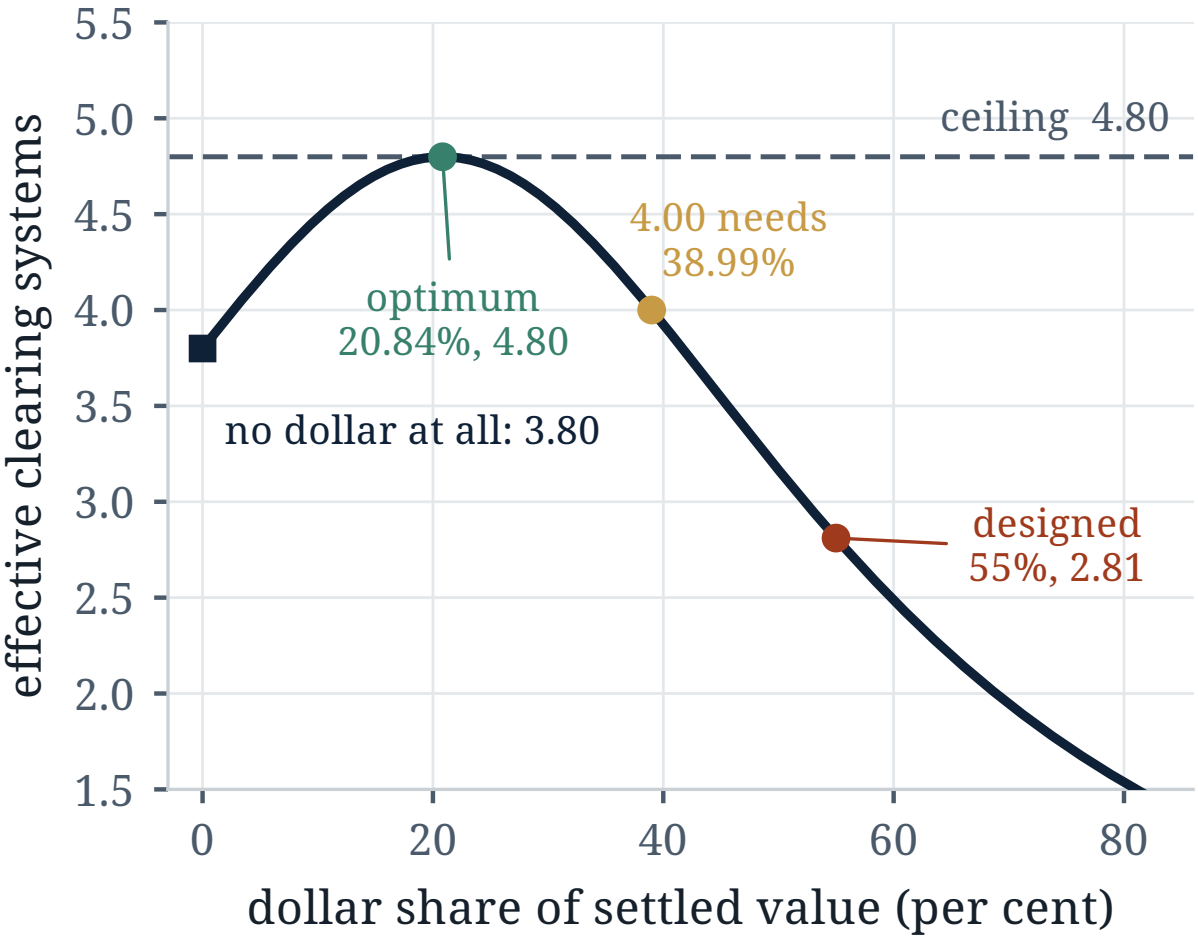

Figure 56.5: **The effective clearing-system count is bounded above by 4.80 and eliminating the dollar entirely is worse than holding 20.8 per cent of settled value in it.** The frontier $\mathrm{EFF}(x) = 1/(x^2 + r(1-x)^2)$ with the four non-dollar systems held in their designed proportions, $r = 0.263210$. Marked: the designed position at 55 per cent, the 38.99 per cent required to reach four systems, the optimum at 20.84 per cent, and the dollar-free case. Modelled from the constructed share vector of Section 7.4; generated by `figs/src/CCP-056_fig05.py`.

entity	constructed annual maintenance, USD
Cayman private unit trust: trustee, administration, audit	26,000
BVI holding company: agent, substance return, financial return, accounting records	9,400
Bahamas trust: trustee fees, accounting, advice	41,000
Barbados captive: manager, audit, actuary, supervisory fees	96,000
total	**172,400**

One hundred and seventy-two thousand dollars a year, buying zero effective blocs. That is the sentence the measurement exists to produce, and it is the only sentence in the exercise that has ever made anybody act.

The disposition, reported as an audit distribution in the form of Curzi [2026]:

entity	disposition	reason
BVI holding company	**collapse**	performs one function, interposition, which the enclave holding company performs better while additionally supplying the law, the bridge-bloc position and dual-rail banking
Cayman private unit trust	**collapse**	a fund structure with no unrelated investors, no administrator performing a real function and no fund purpose; above the economic break-even, so the case is not cost but that it adds a reporting jurisdiction and nothing to N
Bahamas discretionary trust	**migrate, slowly**	the statute book offers instruments the destination does not, and the argument runs both ways; decided on the perimeter measurement and on the succession analysis, over a period measured in years, on a timeline with no relationship to any claim
Barbados captive	**commute**	the treaty network that was the entire reason for the domicile is unused; the run-off requires a counterparty willing to assume it at a price, and is the slowest of the four actions

Two collapses, one migration, one commutation, and one entry where the framework's

own architecture argues against itself in print. The migration case is the honest one: the origin jurisdiction's statute book solves a protector-succession problem cleanly and the destination's does not, and the decision is made on the perimeter measurement notwithstanding. **That reasoning belongs in the file as a considered decision rather than as an omission.**

The result:

	legacy	designed
naive HHI	0.249800	0.189002
effective jurisdictions	4.003203	5.290949
bloc-HHI	1.000000	0.340000
effective blocs	1.000000	2.941176
Western-perimeter exposure	100.0%	30.0%
$\eta \ln N$	0.000000	0.377583
h	-0.500000	-0.122417

Entity count went from six to six. The naive effective count rose 32.16 per cent, from 4.003203 to 5.290949. The effective bloc count rose from 1.000000 to 2.941176, from a base of exactly zero surplus. And the honest companion result still applies: at the stated parameters the designed structure gives $h = -0.122417$ against a break-even count of 4.172734, so it remains below the threshold at which the surplus law permits building. **Jurisdictional diversity buys the ability to build; it does not pay for the building.**

7.8 Printed discrepancies, left visible

First, the naive index of the designed structure. The source manuscript prints 0.1889 in one place and 0.189002 in another for the same six shares. The exact value computed from the shares is 0.189002; 0.1889 would give 5.293806 rather than 5.290949, a difference of 0.002857 in the effective count. **This paper uses 0.189002 throughout and prints the discrepancy rather than harmonising it silently.**

Second, the surplus reading. The source prints $h = -0.1226$ for the designed structure in three separate places. The exact value at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is -0.122417, a difference of 0.000183. **This paper uses -0.122417, which is the value Curzi [2026] publishes**, and Curzi [2026] records the same discrepancy independently.

Third, the dollar share required to reach four clearing systems. The source states "roughly one third". The computed figure is 0.389912. Section 7.5 gives the derivation. **This is the one discrepancy in the three that changes a design conclusion**, because a target of 33 per cent and a target of 39 per cent are different programmes.

Fourth, and for consistency across the series, the naive index of the conventional four-jurisdiction structure. Curzi [2026] reports 0.293388 from exact ninths, giving 3.4085 effective jurisdictions against bloc-HHI 1.000000 and 1.0000 effective perimeters; Curzi [2026] reports 0.293430 from rounded percentages, giving 3.407968. **This paper uses the rounded-percentage figure where it refers to that structure**, and states which it uses.

7.9 Hypotheses tested

#	hypothesis	verdict	where
H1	the Atlantic cluster is one perimeter: naive 4.003203, effective 1.000000	**supported**	7.1
H2	the substance instrument repriced rather than prohibited, and is regressive	**supported on both halves**	7.2
H3	two enclaves in one country are one line at 29.1 per cent	**supported**, and trivially	7.3
H4	the settlement axis admits genuine diversification: 1.00 to 2.810568	**supported on the terminal-clearing layer only**; the messaging decomposition its own falsifier names was not run	7.4
H5	a marginal unit is worth at most exactly one effective unit	**supported** as arithmetic, with no empirical content	7.5

H4 is the one to read carefully. It was stated with a falsifier — a decomposition showing the added systems' messaging legs run over the first — and that decomposition was not performed in this paper. **A hypothesis whose falsifier has not been tested is not a hypothesis that has passed**, and the honest verdict is that H4 is supported on the layer this paper measures and open on the layer it does not. Curzi [2026] closes it in the adverse direction.

8. Failure modes

Twelve ways the results above are misapplied, each with the diagnostic that detects it.

1. Counting four Atlantic jurisdictions as four. The arithmetic gives 3.92 naive and 1.00 in blocs. *Diagnostic:* every hour spent rebalancing between them moves a number that does not enter the surplus law.

2. Using a single-purpose offshore company as the apex. It has no succession machinery, no founder-control statute, no purpose-vehicle flexibility and no answer to a forced-heirship claim. *Diagnostic:* score the vehicle on every dimension the job requires and take the minimum, not the mean.

3. Assuming a delisting is a reversal. A jurisdiction came off one list in 2020 and another in 2023; the substance regime the listing produced is permanent, and the onboarding classifications that changed during the listing did not all change back. *Diagnostic:* ask what was installed, not what was removed.

4. Substance theatre. A nominal local director who attends nothing, a serviced desk nobody uses, and a minute book written elsewhere. *Diagnostic:* the test is applied to core income-generating activity and the evidence is the decision trail, not the address.

5. Treating sovereignty as bloc independence. Section 4.2. *Diagnostic:* independence removes an external legislative power; it removes nothing that appears in the measurement.

6. Assuming a treaty benefit survives without substance. A principal-purpose test, domestic anti-abuse rules and beneficial-ownership requirements in the treaties themselves each

independently defeat a conduit. *Diagnostic:* state the commercial reason for the entity that is not the treaty.

7. Relying on a cell ring-fence across a border. Cell segregation is statutory and territorial. *Diagnostic:* name the forum that would have to recognise it.

8. Ignoring correspondent dependency. Three of the four Atlantic jurisdictions peg to the dollar and all four clear through the same correspondents. *Diagnostic:* a de-risking decision taken in one compliance department reaches all four on the same day, and that single channel is a larger practical risk than any listing has been.

9. Registered-agent concentration. A very large number of entities in these jurisdictions are administered by a small number of service providers. *Diagnostic:* this is a concentration in a variable nobody measures, and the instrument of Section 3.1 applies to it directly and has not been run.

10. Keeping an entity below the economic threshold. Section 7.2 gives roughly USD 7.7 million against a 25-basis-point tolerance. *Diagnostic:* compute $Q^{*} = \text{cost}/\text{tolerance}$ with your own tolerance and compare.

11. Believing a second enclave adds a bloc. Section 7.3. *Diagnostic:* ask what single decision would have to be taken twice for the two to be independent, and name the second decision-maker.

12. Reading the clearing-system count as rail independence. Section 7.4. *Diagnostic:* count the messaging layer separately, and if the second system's messaging leg runs over the first, the count collapses.

9. Discussion

What follows from the results. Three things.

The first is that **entity count and effective count can move in opposite directions, and the direction that matters is the one nobody reports.** Six entities produced an effective bloc count of one; a different six produced 2.941176. The count that changed was not the count of entities. Curzi [2026] reaches the sharper version of the same finding — adding two Gulf jurisdictions raises the naive effective count from 5.29 to 7.13, a 34.8 per cent improvement, while the effective bloc count falls from 2.94 to 2.84, a 3.4 per cent deterioration — and it is worth stating that the sharper version is the more common case. **More jurisdictions, less independence, is not a paradox; it is what a naive index does when the units are correlated.**

The second is that **a regulatory instrument with a fixed per-entity cost is a distributional instrument whether or not anyone intended it to be.** The substance regime destroyed the small holder's vehicle and left the large holder's untouched, and the arithmetic of that is one division. **The general lesson is that any compliance requirement expressed as a fixed annual amount is a threshold on holding size**, and the threshold is computable before the requirement is enacted.

The third is the proposition of Section 3.4, and it is the one this paper would defend hardest. **A marginal unit is worth at most exactly one effective unit.** The consequence is that a design conversation about raising a count has an arithmetic ceiling that does not depend on argument, and the ceiling is set by the incumbents. On the constructed settlement mix that ceiling is 4.799250. **A structure that cannot reach five clearing systems should not be planned as though it could, and the way to find out is one line of arithmetic rather than a year of negotiation.**

A ceiling on a count is not the same thing as a ceiling on the value of raising it, and Curzi [2026] is the paper that keeps the two apart. It reports that diversification through a conversion raises effective properties from 1.0000 to 18.8491 — a property HHI of 0.053053, an eighteen-fold improvement in the count — worth 0.4735 per cent a year against the same 15.0417 per cent leakage, giving a payback of 31.77 years, and that only a non-recognition regime cutting leakage to 1.5 per cent brings the payback to 3.17 years. **An eighteen-fold rise in an effective**

count bought a thirty-two-year payback. The proposition of Section 3.4 bounds the numerator of that calculation and says nothing about the denominator, and the two must be reported together or not at all.

What does not follow.

Nothing here is a legal conclusion. Every jurisdictional, doctrinal and regulatory statement in Sections 4, 5 and 6 is described from the source manuscript and is uncited; Appendix B lists them. **A reader who takes a rule of law from this paper has taken it from the wrong document.**

The clearing-system count is not rail independence. Section 7.4 and Section 11 both state it and it bears a third statement, because the number 2.81 is the most quotable figure in the paper and the most likely to be quoted without its layer.

The effective count measures independence, not capacity. It says nothing about whether any bloc, correspondent or clearing system can carry the load, and a structure that is diversified on jurisdiction and concentrated on counterparty has moved its risk rather than reduced it.

The measurement is least informative exactly where the headline case sits. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, where one unit holds a very large share. A bloc vector of a single unit at 100 per cent is the limiting case. The measurement is exact — $1/1 = 1$ — but its discriminating power is at its minimum there.

A count that can be inflated will be. Goodhart [1975] and Campbell [1979] are the standing warnings and they bite hardest on an instrument that has just been shown to be gameable in the naive direction. Douceur [2002] is the formal statement that one party can present as many, so an unaudited count is worthless, and Lamport et al. [1982] is the bound on how many genuinely independent parties a protocol requires. **Both belong next to any count of units in this series**, and failure mode 9 — registered-agent concentration — is exactly the Sybil problem in a corporate-services costume, unmeasured.

The framework's own results bound this one. Curzi [2026] records that a commons case is formally tunable and practically unreachable: it passes the ceiling test with margin $+0.058436$ nats yet no lever closes it, and a member's declining to participate improves the family reading by 2.680588 octaves — **an arithmetic the framework prints rather than avoids**. The structure measured here is in the same position: it clears no threshold, its levers are enumerated, and the enumeration is what the paper delivers. Curzi [2026] states the companion result that $f_{\min}$ contains neither δ nor N — retention loss sets the rate of arrival but not the threshold, and the category count enters only through the admissibility ceiling $c/\eta \le \ln N$ — which is the general form of the observation that the dollar floor of Section 7.6 does not depend on how many entities exist.

And the corpus's central limitation applies in full. Curzi [2026k] reports the five-parameter survey reproducing each system's observed decline from one desk to a 22-household block, predicted -0.250474 against observed -0.250 at the desk and -0.996371 against -1.000 at the library, with residuals under 1.4 per cent of the ceiling term. **This paper reports no fit at all, and that is not a strength.** Epstein [2008] is the standing statement that prediction is one of sixteen reasons to model; this paper claims **explanation of a mechanism and demonstration that a stated arithmetic suffices to produce a stated shape**, and claims neither prediction nor calibration.

10. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the compounding chain names what each step consumes. **If dropping a postulate leaves the result standing, it is not listed.**

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i, w_i	exposure share of unit i	$[1]$	dimensionless	defined; non-negative and summing to 1 by P1
W_b	bloc share	$[1]$	dimensionless	derived, $W_b = \sum_{i \in b} s_i$
HHI	concentration index	$[1]$	dimensionless, or points $= 10^4 \times$ fraction	derived
ρ_{ij}	correlation between shocks	$[1]$	dimensionless, in $[-1, 1]$	**assumed, not measured**
N	effective count	$[\#]$, a count	jurisdictions, blocs, or clearing systems	derived as $1/(w' R w)$
M	incumbent effective count	$[\#]$	clearing systems	derived, Section 3.4
x	share of the marginal unit	$[1]$	dimensionless	free variable
$\ln N$	surplus-term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
Q	protected capital	$[C]$	index units	defined; **the source supplies no operational unit**
η	conversion efficiency	$[1]$	dimensionless	assumed
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
h	headroom	$[C\,T^{-1}]$	index units per period	derived
substance cost	fixed annual charge	$[\$\,T^{-1}]$	USD per year	constructed
Q^*	break-even holding	$[\$]$	USD	derived, cost divided by tolerance
tolerance	admissible overhead rate	$[T^{-1}]$	basis points per year	**a stated judgement**

The surplus equation balances only if $\eta \ln N$ carries $[C\,T^{-1}]$. Since $\ln N$ is dimensionless, either η carries $[C\,T^{-1}]$ or $\ln N$ is read as a rate. **The source is silent on which and this paper records the silence rather than resolving it by assertion.**

The break-even equation balances exactly: $[\$\,T^{-1}]$ divided by $[T^{-1}]$ gives $[\$]$, so a fixed annual cost divided by an annual tolerance is a capital amount. That is the one equation in this paper whose dimensions are fully determined, and it is worth naming which one.

The marginal-unit proposition is dimensionless throughout. x, r and M are all pure numbers, so EFF is a count, and the identity $\text{EFF}(x^*) = M + 1$ adds a count to a count, which is

licensed.

10.2 Significant figures and epistemic status

quantity	figures	status	licence
naive HHI 0.249800	6 dp	**exact**	exact arithmetic on exact constructed shares
effective jurisdictions 4.003203	6 dp	**exact to rounding**	reciprocal of an exact value
bloc-HHI 1.000000, $N = 1.000000$	6 dp	**exact**	a single block of ones
multiples 3.45 and 12.48	2 dp	**exact to rounding**	ratios of exact constructed amounts
96.75 and 0.9675 basis points	4 sf	**exact to rounding**	ratios of exact constructed amounts
break-even USD 7,740,000	6 sf	**exact** given the tolerance	a division by a stated judgement
HHI 0.3558, 2.810568	4 dp, 6 dp	**exact to rounding**	exact arithmetic on exact constructed shares
$r = 0.263210$, $M = 3.799250$	6 dp	**exact to rounding**	closed form on the same shares
$x^* = 0.208366$, ceiling 4.799250	6 dp	**exact**	closed form, Section 3.4
$x = 0.389912$ for EFF $= 4$	6 dp	**exact to rounding**	root of a quadratic
all USD cost figures	as printed	**constructed**	illustrative, not quotations

No figure in this paper is a measured quantity and therefore no uncertainty interval is attached to any of them. That is not modesty; it is the correct treatment of exact arithmetic on stipulated inputs, and it is also the reason none of these numbers is evidence about a real structure.

10.3 Limits and boundary behaviour

limit	behaviour	reading
$\rho \to 0$ within a bloc	$N \to$ the naive count	the naive index is the zero-correlation endpoint
$\rho \to 1$ within a bloc	$N \to$ the bloc count	the bloc index is the unit-correlation endpoint
one bloc holding everything	$N = 1$, $\ln N = 0$, surplus term zero	**the whole argument in one line**
$N \to \infty$	$h \to \infty$ logarithmically; $dh/dN = \eta/N \to 0$	returns diminish but never turn negative — **a defect, since cost is not in the input term**

limit	behaviour	reading
$x \to 0$ in the marginal-unit proposition	EFF $\to M$	removing the unit returns the incumbent count
$x \to 1$	EFF $\to 1$	one unit holding everything
$M \to 1$ (one incumbent)	$x^* \to 1/2$, ceiling $\to 2$	the two-equal-units case, which is correct
$M \to \infty$	$x^* \to 0$, ceiling $\to M + 1$	a marginal unit added to a very diverse set must be very small to help
tolerance $\to 0$	$Q^* \to \infty$	no holding is large enough; the entity is never economic
tolerance $\to \infty$	$Q^* \to 0$	any holding is economic, which is why the tolerance must be stated
substance cost $\to 0$	$Q^* \to 0$ and the regressivity vanishes	the regressive property is a property of the fixed cost, not of the rule

Two boundary readings are load-bearing. The fourth row is a genuine defect of the surplus law as used here: because cost enters only through C, the model never says that adding a bloc is not worth it, and the decision to stop must come from outside the equation. Brooks [1975] supplies one bound — communication cost at order $n(n-1)/2$ inside a boundary — and **the proposition of Section 3.4 supplies another and sharper one on the benefit side**, which is the reason it is in this paper rather than in a note.

The last row is the honest reading of H2. **The regressivity is a property of the cost being fixed, not of the substance rule being unfair**, and any instrument charging a flat annual amount has the same property. That is a stronger and more general statement than the one the source manuscript makes.

10.4 Invariance

Scale invariance in capital. Multiplying every exposure by a positive constant leaves every share and every effective count unchanged. Tested at three scales by construction: the six-entity vector, the five-system vector and the four-system incumbent vector. **Three scales is not many and Section 11 says so** rather than describing the instrument as scale-free without qualification.

The break-even is not scale-invariant, and that is the finding. Q^* is an absolute amount because the numerator is an absolute amount. **A rule whose cost does not scale produces a threshold, and a threshold is exactly what scale invariance would have hidden.**

Invariance under relabelling. The effective count is invariant under permutation of the units. That is wanted — a concentration measure that changed when the rows were reordered would be broken — but it means the count cannot distinguish two structures with the same share vector and different contents. Curzi [2026] identifies the same invariance as fatal in its own domain, where the width statistic is invariant under relabelling and therefore does not determine the chord it is computed from.

Not invariant, and this is where the instrument works. The count is *not* invariant under partition: splitting one unit into two raises the naive count and leaves the bloc count untouched. **That asymmetry is the whole instrument.**

The marginal-unit proposition is invariant under the incumbents' internal composition. It depends on the incumbents only through M, so two quite different incumbent mixes with the same M have the same ceiling and the same optimal marginal share. **That is a real generality**

and it is the reason the proposition is stated in terms of M rather than in terms of the four particular clearing systems.

10.5 Analogy discipline

borrowing	category	justification
exposure as a portfolio; variance under a correlation matrix [Markowitz, 1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix, which is the premise the algebra requires
effective count as a numbers-equivalent [Adelman, 1969, Hill, 1973, Jost, 2006]	**1 — derivation**	$1/\mathrm{HHI}$ *is* the Hill number of order two
similarity-sensitive diversity [Leinster and Cobbold, 2012, Rao, 1982]	**1 — derivation**	the block-of-ones matrix is a special case of the cited general form
open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]	**1 — derivation**	the disclosure standard *is* the open-design requirement applied to legal rather than cryptographic structure
coupled-network fragility [Buldyrev et al., 2010]	**2 — shared form**	perimeter coupling is not shown to satisfy the percolation premises; only the shape of the result is used
robust-yet-fragile [Albert et al., 2000, Callaway et al., 2000]	**2 — shared form**	the tolerance asymmetry's shape is used; the degree-distribution mechanism is not claimed, and Doyle et al. [2005] is the reason it should not be
$\ln N$ as the entropy of a uniform distribution [Shannon, 1948]	**2 — shared form**	**information entropy, not thermodynamic entropy**; the correspondence is exact as arithmetic and carries no thermodynamic content

borrowing	category	justification
a bloc as a frozen region [Castellano et al., 2000]	**3 — analogy**	suggestive, used as motivation only; no phase-transition claim is made and no order parameter is computed
normal accidents [Perrow, 1984]	**3 — analogy**	qualitative theory and framing, not a formal result; this paper's first finding is Perrow's in a measurement frame
the marginal-unit proposition	**not a borrowing**	elementary calculus on this paper's own definition; it is proved in Section 3.4 and consumes nothing external

No category-3 borrowing is used as evidence anywhere in this paper.

10.6 Measurement-theoretic status of the scored inputs

The four-question test of Section 4.1 is nominal and is not scored. It returns yes or no per jurisdiction per question, and the assignment is made by requiring all four rather than by counting them. **No total is computed**, deliberately, because a count of yeses would invite a threshold rule the scale does not license.

The evidence ladder of Section 4.1 is ordinal and is not summed. Its classes are ranked and the assignment identifies the strongest available class, which an ordinal scale licenses.

The de-identified capability comparison of Appendix C is not totalled. Court depth, statute book, treaty network and cost have no common scale and the table produces a best fit by argument rather than a verdict by arithmetic.

The 25-basis-point tolerance is a stipulated cut on a ratio scale, and the ratio is genuine — basis points of capital are a ratio-scale quantity with a true zero — so the division producing Q^* is licensed. **What is not licensed is treating 25 as anything other than a choice**, and Section 7.2 gives the formula so a reader may substitute another.

The framework's treatment of Q as a ratio-scale quantity is not tested. Michell [1997] is the strongest available objection: a discipline routinely assumes quantitative structure without testing for it, and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all. **The conjoint conditions were not tested for Q, which is stated in unnamed index units, and the ratio-scale treatment is provisional.** Krantz et al. [1971] sets out what would have to hold and Stevens [1946] is the taxonomy. **The concentration instrument is untouched by this objection**, because exposure shares are ratios of capital rather than judgements.

This paper inherits the framework-level scalar-reduction limitation rather than restating it. Reducing a structure to one effective count and one h, and reducing a jurisdiction's regime to a four-yes test, are instances of the habit Curzi [2026] names once as a single limitation for the whole framework: where the source literature describes a phenomenon by several jointly varying features, the framework replaces it with one number and does arithmetic on the number. **The limitation is inherited here in full and is not met separately.**

10.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$	DEFINITION
P3	for n equal shares of $1/n$, HHI $= 1/n$	ARITHMETIC
P4	the aggregate shock is $R = \sum_i w_i X_i$ with Var$(X_i) = 1$	DEFINITION
P5	Var$(R) = \sum_i \sum_j w_i w_j \rho_{ij} = w' R w$	ARITHMETIC
P6	units inside one coordination perimeter act on one decision	POSTULATED (H1, H3)
P7	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P8	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P9	the substance cost is a fixed annual amount per entity, independent of assets held	POSTULATED — described from the source, uncited (Appendix B)
P10	the constructed cost table of Section 5.2	CONSTRUCTED
P11	a 25-basis-point tolerance for structural overhead	POSTULATED (a stated judgement)
P12	the share basis on the rail axis is the terminal clearing system	DEFINITION
P13	the constructed settlement mix USD 55 / CNY 15 / EUR 12 / INR 10 / AED 8	CONSTRUCTED

10.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	HHI^{-1} returns n exactly for n equal shares	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	it is the Hill number of order two — Hill [1973], Jost [2006]	CITED
L4	P4, P5	with $R = I$, Var$(R) = \sum w_i^2 =$ HHI	ARITHMETIC
L5	P4, P5	with R block-of-ones, Var$(R) = \sum_b W_b^2$	ARITHMETIC

step	consumes	statement	status
L6	L4, L5	naive and bloc indices are one variance under two correlation assumptions	ARITHMETIC
L7	L1	EFF$(x) = 1/(x^2 + (1-x)^2/M)$ is maximised at $x = 1/(M+1)$ with value $M+1$	ARITHMETIC — the proposition of Section 3.4
R1	L6, P6	six legacy entities: naive 0.249800 (4.003203); bloc 1.000000 ($N = 1.000000$), ln $N = 0$	ARITHMETIC
R1b	R1, P7, P8	$h = -0.500000$	ARITHMETIC
R2a	P10	5,350 over 1,550 is 3.45; 19,350 over 1,550 is 12.48	ARITHMETIC on CONSTRUCTED inputs
R2b	P9, P10, P11	$Q^* = 19{,}350/0.0025 = 7{,}740{,}000$; the cost falls from 96.75 bp to 0.9675 bp over a hundred-fold range	ARITHMETIC on POSTULATED inputs
R4	L6, P6	the two enclaves are one 29.1 per cent line; bloc-HHI 0.340000, $N = 2.941176$, invariant under rearrangement between them	ARITHMETIC
R3	P12, P13	HHI $= 0.3558$; effective clearing systems $= 2.810568$ against 1.0000 as found	ARITHMETIC on CONSTRUCTED inputs
R6	L7, P13	$M = 3.799250$; ceiling 4.799250 at $x^* = 0.208366$; EFF $= 4$ at $x = 0.389912$	ARITHMETIC
R5	R3, P13	55 per cent of settled value clears through one system, a floor set by counterparties' currency	ARITHMETIC on CONSTRUCTED inputs
CR	R4, R5	a second enclave buys capability, not diversification; and 55 per cent of settlement remains dollar-cleared however the entities are arranged	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. Only P6, P8, P9 and P11 are POSTULATED, and two of the four are stated judgements rather than claims about the world. **P9 is the one carrying regulatory content and it has no bibliographic support** — that the substance cost is fixed per entity rather than proportional to assets is described from the source manuscript and is

listed in Appendix B. **A reviewer who does not accept P9 loses R2b and keeps R2a**, because the multiples are arithmetic on the cost table whatever the cost's relation to assets.

L7 is the only step in this chain that is new to this paper, and it is elementary. It consumes no citation, no postulate and no constructed input; it is a one-line minimisation. **A chain whose novel step is a line of calculus is a chain a reviewer can dispose of in a minute, and that is the intention.**

10.9 Cross-checks performed

- The six legacy squares were summed independently and reproduced 0.249800, and the four-entity variant reproduced 0.255000.
- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on both: $0.160000 \le 0.249800 \le 0.400000$ and $0.090000 \le 0.255000 \le 0.300000$.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $4.003203 \le 6.250000$ and $3.921569 \le 11.111111$.
- The cost table sums were checked in both directions: $1{,}600+1{,}050+900+400+1{,}400 = 5{,}350$ and $5{,}350 + 14{,}000 = 19{,}350$.
- The break-even was checked by substitution: $19{,}350/7{,}740{,}000 = 0.0025$ exactly.
- The clearing squares were summed independently and reproduced 0.3558.
- The marginal-unit proposition was checked three ways: at the closed form $x^* = 1/(M+1) = 1/4.799250 = 0.208366$; by direct evaluation, giving $\text{EFF}(0.208366) = 4.799250$; and by the identity $\text{EFF}(x^*) = M + 1$, $3.799250 + 1 = 4.799250$.
- The root $x = 0.389912$ was checked by substitution: $\text{EFF}(0.389912) = 4.000000$ to six decimal places.
- The naive-count improvement was checked: $5.290949/4.003203 - 1 = 0.321661$, printed as 32.16 per cent.
- The three source discrepancies of Section 7.8 were quantified at 0.000102 in the naive index, 0.000183 in h, and 5.66 percentage points in the dollar-share target.

11. Limitations

Every number in this paper is computed on constructed inputs and none is a measurement of a real structure. The exposure shares, the cost table, the maintenance budget, the settlement mix and the listing durations are all **CONSTRUCTED** or described from the source manuscript, and are labelled as such at each point of use. **No first-party measurement of any real system appears anywhere in this paper.** That is this corpus's central limitation, stated in the terms Curzi [2026] states it in — of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated one, and 0 carry a first-party measurement — and a reviewer would be right to press on it before pressing on anything else.

The clearing-system count is a count of one layer. Section 3.2 states the distinction and Section 7.4 states the consequence: the falsifier H4 named was a messaging decomposition, and that decomposition was not run. **The number 2.810568 is an upper reading and should never be quoted as a measure of rail independence.** Curzi [2026] runs the decomposition and finds $N_{\text{rail}} = 1.341819$. **This is the paper's largest single exposure and it is disclosed here rather than in a note.**

The correlation is assumed, not measured. $\rho = 1$ within a perimeter is the conservative end of a family and no correlation was estimated from data. The listing record of Section 4.3 is the evidence offered for it, and a listing record is a record of outputs rather than a measurement of correlation.

Every parameter in the surplus law was chosen. $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ are test parameters fixed in advance and not estimates of any real position, so the break-even $N = 4.172734$ is a property of the chosen set.

The 25-basis-point tolerance is a judgement and the break-even moves with it. At 50 basis points the threshold is USD 3,870,000 and at 10 basis points it is USD 19,350,000. **A threshold**

quoted without its tolerance is not a threshold, and Section 7.2 gives the formula for exactly that reason.

The marginal-unit proposition is arithmetic and carries no empirical content. It bounds a design space; it says nothing about whether any particular unit exists, can be onboarded, or would be independent in the sense the correlation assumption requires. **A ceiling on what a count could be is not evidence about what a structure is**, and the proposition should not be cited as though it were.

The two listing rows marked "dates to be verified" are reproduced with the mark. They are uncertain in the source and they are uncertain here. **No conclusion in this paper depends on either of them**, because H1 is carried by the rows that are dated and by the four-question test independently of any listing.

The registered-agent concentration of failure mode 9 is named and not measured. It is a concentration on the counterparty axis to which the instrument of Section 3.1 applies directly, and it is not run here for want of any share basis that could be constructed honestly. **That is a gap in the four-axis discipline this series states, in this paper.**

The reflexive specification is not identified. Section 1 states this and names the remedy — stipulate the reference group and defend the stipulation, following Brock and Durlauf [2001]. **The price is that every bloc assignment here is a modelling position rather than an identified empirical result** [Manski, 1993, Shalizi and Thomas, 2011].

The Lucas critique applies to this framework's own parameters and is not answered. Lucas [1976] is the general statement; the specific form is that this framework asserts systems change behaviour when modelled and observed, and then treats η, δ and the bloc assignment as stable under exactly that response. MacKenzie and Millo [2003] documents the loop happening in the field with dates and price data, which is an existence proof for the mechanism and not a defence of the parameters.

The functional form of the surplus input is underdetermined. Latané [1981] proposes a power law with exponent below one and Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics with no psychological assumption at all. **Nothing here discriminates between them, and the logarithm is used because it is the form this framework carries.** Peters is the stronger of the two available warrants and is cited as such.

Small-sample bias in the effective count is not corrected [Chao et al., 2014]. A five- or six-element vector is a small sample for a low-order diversity estimator, and the paper does not resolve whether these vectors are samples or complete censuses.

Scale invariance was checked at three scales only (Section 10.4).

The instrument is least informative in the regime where the headline case sits [Golosov, 2010, Dunleavy and Boucek, 2003].

No statistical test was run and no p-value appears, because there is no sample and no null. Every rate is an exact ratio of exact constructed amounts, and **no claim of "no difference" is made from any non-significant result** because no significance test exists here to make it from.

No scaling, power-law or heavy-tail claim is made and the Clauset–Shalizi–Newman procedure was therefore not run [Clauset et al., 2009]. Any restatement reaching for such a claim must run it first and read Broido and Clauset [2019].

No out-of-sample validation, matched null, information criterion or effect size with an interval appears, because no model was fitted. Bruch and Atwell [2015]'s calibration-and-validation checklist is unmet in every row.

11.1 Rigour checks not met, listed by name

1. **The messaging-layer decomposition H4's falsifier names was not run** (Sections 7.4, 7.9); Curzi [2026] runs it and finds against.
2. **Conjoint measurement conditions untested** [Luce and Tukey, 1964], so the ratio-scale treatment of Q is provisional and Michell [1997]'s objection is conceded rather than answered.

3. **The framework-level scalar-reduction limitation is inherited** [Curzi, 2026] and not met separately.
4. **The reflection problem is stated and not solved** [Manski, 1993].
5. **The Lucas critique applied to this framework's own parameters is unanswered** [Lucas, 1976].
6. **The functional form of the surplus input is undiscriminated** [Latané, 1981, Peters and Gell-Mann, 2016].
7. **Small-sample bias in the effective count is uncorrected** [Chao et al., 2014].
8. **No out-of-sample test, matched null, information criterion or interval** [Bruch and Atwell, 2015].
9. **No first-party measurement of any real system** [Curzi, 2026].
10. **The dimension of η is unresolved** because the source is silent (Section 10.1).
11. **The counterparty axis is not measured** despite being one of the four the method requires (failure mode 9).
12. **Two listing rows are undated** and are reproduced with the source's own mark.
13. **Every legal, regulatory and doctrinal statement in Sections 4, 5 and 6 is uncited** (Appendix B).

12. Conclusion

This paper measures four things on constructed inputs and establishes one proposition. The following statements are the fixed text of those results.

R1. Six Atlantic-cluster entities — United Kingdom 40.0 per cent, United States 22.0, Cayman 14.0, the British Virgin Islands 12.0, the Bahamas 7.0 and Barbados 5.0 — give a naive HHI of 0.249800 and 4.003203 effective jurisdictions, but a bloc-HHI of 1.000000, $N = 1.000000$ and $\ln N = 0$. **Adding a Western entity to a Western structure leaves the surplus term at exactly zero**, and no admissible reassignment separates the six, including on the ground of sovereignty.

R2. The substance instrument is measured as a cost multiple rather than a prohibition: $5{,}350/1{,}550 = 3.45$ for a pure equity-holding entity and $19{,}350/1{,}550 = 12.48$ for a relevant-activity entity, with break-even at $Q^* = 19{,}350/0.0025 =$ **USD 7,740,000 of held value at a 25-basis-point tolerance**. Because the cost is fixed per entity, it falls from 96.75 basis points at USD 2,000,000 to 0.9675 basis points at USD 200,000,000. **The regressivity is a property of any flat annual charge and not of this rule in particular.**

R3. The clearing-system count: a structure settling wholly in one currency gives HHI $= 1.0000$ and 1.00 effective clearing systems; the constructed redesign at USD 55.0 / renminbi 15.0 / euro 12.0 / rupee 10.0 / dirham 8.0 gives HHI $= 0.3558$ and 2.810568 **effective clearing systems**. The count is of terminal clearing systems only and is an upper reading on rail independence.

R4. The DIFC and the ADGM are one FATF perimeter, one federal anti-money-laundering regime and **one line at 29.1 per cent of exposure — no rearrangement between the two free zones changes** N, which remains 2.941176 at bloc-HHI 0.340000.

R5. The residual after redesign: **55 per cent of settled value still clears through a single system whose law is not the holder's, a floor set by the counterparties' currency rather than by entity placement.**

Counter-result. A second financial free zone in the same country buys capability, not diversification: the two zones together remain one 29.1 per cent line, and 55 per cent of settlement remains dollar-cleared however the entities are arranged.

One further result is established as method rather than as measurement, and it is the one this paper would defend hardest. If a set of units held in fixed relative proportions has its own effective count M, then adding one unit at share x and rescaling the rest gives $\mathrm{EFF}(x) = 1/(x^2 + (1-x)^2/M)$, which is maximised at $x^* = 1/(M+1)$ with value $M+1$. **A marginal unit is worth at most exactly one effective unit, and only at one share.** Applied to the constructed settlement mix, where the four non-dollar systems give $M = 3.799250$: **the ceiling on the effective clearing-**

system count is 4.799250**, attained at a dollar share of** 0.208366**; reaching** 4.000000 **requires the dollar share to fall to** 0.389912**, not to the "roughly one third" the source manuscript states; and eliminating the dollar entirely would give** 3.799250**, which is worse than holding a fifth of settled value in it.** All three are exact and all three are checkable in two lines.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the exposure shares, the cost table, the maintenance budget, the settlement mix and the entity dispositions — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-056_fig01.py` through `figs/src/CCP-056_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional and regulatory descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative, treaty and standard-setting material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, and no listing or delisting instrument for any jurisdiction. Appendix B lists the claims affected. **Any reader relying on those descriptions must verify them against the official sources and record the date of that verification.** Two listing rows in Section 4.3 are marked uncertain in the source and are reproduced with that mark.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. All persons, entities, holdings and arrangements described are constructed for the purpose of exercising the measurement.

Preregistration

The parameter set $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ and the break-even criterion $N \geq e^{0.5/0.35} = 4.172734$ were fixed by Curzi [2026] before the measurements reported here and are not adjusted anywhere in this paper. **No structure measured in this paper clears that**

break-even, which Section 7.7 reports in the same language a clearance would have received. The 25-basis-point tolerance of Section 7.2 and the falsifier attached to H4 were both stated before the corresponding measurements were run; **H4's falsifier was not tested, and Section 7.9 reports that rather than treating the hypothesis as passed.** No other element of this paper was preregistered.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions, licensing regimes, substance requirements and settlement arrangements for the purpose of measuring concentration. No recommendation is made in respect of any particular person, asset, structure, jurisdiction or arrangement. Substance requirements, relevant-activity definitions, filing obligations, beneficial-ownership access rules, listing and delisting decisions, corporate-tax qualifying-income tests and clearing-system participation all change and vary by jurisdiction and by activity; **every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.**

Appendix A. The reporting standard for the rail axis

The jurisdiction-axis reporting standard is stated by Curzi [2026] and extended by Curzi [2026]. This appendix states what the rail axis additionally requires, because Section 7.4's result is the one most likely to be reproduced without its layer.

```
 1  share basis, in one sentence: settled value by TERMINAL
    clearing system, over a stated period
 2  the settlement table, systems and shares, summing to 100.0%
 3  naive HHI and effective clearing systems
 4  THE SAME THREE LINES for the MESSAGING layer, separately
 5  for every system whose messaging leg runs over another system,
    the share so affected, itemised
 6  the collapsed count after step 5, which is the count that
    should be quoted
 7  count of banking relationships, and of independent
    correspondent chains per currency
 8  standing relationships that are live but dormant, listed
 9  the incumbent effective count M, the marginal share x, and
    the ceiling M + 1
10  the date, and the diff against the previous measurement
```

Item 6 is the item this paper does not reach, and item 9 is the item it adds. A measurement stopping at item 3 has reported the flattering layer; a measurement reaching item 6 has reported the structure. **Item 9 costs one line of arithmetic and tells a reader whether the programme they are contemplating is achievable at all.**

Item 8 has no effect on any index and belongs in the report anyway. A dormant relationship is an option on a branch, and Curzi [2026]'s weighting — score each step 0 to 3 for steepness, sum to a resistance R, weight the branch as $1/2^{R}$ — is the instrument for valuing it. **The index says such a relationship is worth nothing and the branch weighting says a three-point reduction in steepness is a factor of eight; both readings should be printed.**

Appendix B. Claims requiring verification against primary sources

The following statements rest on legal or regulatory detail that changes, and **none is cited to the bibliography, which contains no primary sources for any individual jurisdiction**. They are reproduced from the source manuscript and require confirmation with counsel in the relevant jurisdiction before any reliance. **Record the date of each confirmation**; a statement of a regime without a date is not a statement of that regime.

1. The current revisions of the companies, trusts, funds, foundations, insurance and economic-substance legislation of each of the four Atlantic jurisdictions named in Section 4.1, together with the legislation enacting the convergence and rate changes referred to in Section 5.3.
2. **Every listing and delisting date in Section 4.3**, against the standard-setting body's plenary outcomes and the regional bloc's primary releases. **Two rows are specifically flagged as uncertain in the source and must not be reproduced without checking.**
3. The beneficial-ownership transparency legislation of the two territories referred to in Section 4.5: commencement dates, enforcement dates, the definition of legitimate interest, and the access mechanism.
4. The regional court decision referred to in Section 4.5 striking down public access to member-state registers, and its subsequent treatment.
5. The criteria adopted in December 2017 by which the substance requirement was imposed, the list of relevant activities, and the reduced test for pure equity-holding entities.
6. The restructuring and insolvency regime referred to in Section 7.7's disposition table, including any moratorium and its scope.
7. The appellate decision on freezing relief in support of foreign proceedings referred to in failure mode 12, its ratio and its current application.
8. **P9, that the substance cost is fixed per entity rather than proportional to assets.** This is the postulate on which R2b depends and it has no bibliographic support; Section 10.8 states exactly which result rests on it.
9. The establishing instruments of the two financial free zones referred to in Section 6, their federal basis, the regulations by which one of them applies another state's common law directly, and the amendment history including any expansion of jurisdictional area.
10. The foundations legislation of the enclave referred to in Section 6.1, and the migration path between the two zones' vehicles.
11. The corporate-tax regime applying to free-zone persons in that state, and the qualifying-income test.
12. The federal anti-money-laundering legislation, its implementing regulation, and the beneficial-ownership resolution referred to in Section 4.4.
13. The dates of the increased-monitoring listing and delisting referred to in Section 4.4, the regional delegated act adding the state to a high-risk list, the corresponding removal instrument, and the equivalent instruments of the second jurisdiction operating such a mechanism. **These are dateable regulations and should be cited precisely or not at all.**
14. The current participation of institutions in that state in the second clearing system, the terms and renewal status of the bilateral currency arrangement referred to in Section 7.4, and the status and governance of the cross-border settlement experiment referred to in the source. **All three have moved and all three are frequently misdescribed.**
15. The extent to which participants in the second clearing system use the first system's messaging layer, which is the decomposition H4's falsifier requires and which this paper does not run.
16. The treaty anti-abuse provisions referred to in failure mode 6, including the principal-purpose test and the beneficial-ownership requirements in the relevant treaties.
17. The cell and segregated-portfolio legislation referred to in failure mode 7, and whether the segregation is recognised outside the jurisdiction of formation.

18. All cost, maintenance and settlement figures in this paper are constructed. **They are not quotations, rate cards or bank statements, and no real schedule was used to produce them.**

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing, and the places where a printed value in the source differs from the exact computation are reported in Section 7.8 rather than harmonised.

Appendix C. Condensed assessment, de-identified

No total is computed: the items are heterogeneous and no common scale exists on which they could be added (Section 10.6). Every characteristic below is described from the source manuscript and is uncited (Appendix B). The Atlantic jurisdictions are de-identified in the capability table because that table ranks them on legal capability the bibliography cannot support; they are named in Section 4.1's bloc table, because there the assignment is the argument.

Bloc assignment and evidence, by jurisdiction.

jurisdiction	bloc	strongest evidence	job
Cayman Islands	**WEST**	exchange, common standard implementation, listing record, dollar correspondent dependency	**HOLDING**, for genuine fund and large-deal structures only
British Virgin Islands	**WEST**	identical on every operative test; listed mechanically on a third body's rating change	**HOLDING**, single-purpose; and a genuine litigation forum
The Bahamas	**WEST**	four yeses notwithstanding sovereignty; pegged currency	**HOLDING**, for private-client instruments the alternatives lack
Barbados	**WEST**	four yeses; the longest increased-monitoring period of the four	**OPERATING**, treaty-dependent, and only where the corridor is used
United Arab Emirates (DIFC and ADGM)	**BRIDGE**	outside the Western designation apparatus; own listing decisions; dual-rail access	**HOLDING** in one zone, apex in the other; **never settlement**

Ranked capability, de-identified.

requirement	best fit	why
a fund with unrelated investors and institutional service providers	Atlantic centre A	the deepest fund statute book and a specialist financial services division

requirement	best fit	why
a single-purpose holding vehicle with a specialist commercial court behind it	Atlantic centre B	a commercial court whose decisions are followed, and the lowest-friction company form of the four
a novel private-client instrument	Atlantic centre C	the widest private-client statute book, including purpose and executive-entity forms the others lack
a treaty-dependent operating position	Atlantic centre D	the treaty network, and the only one of the four with a different apex court
group agreements governed by a mature commercial law, without that state's entity	enclave A	direct application of that law as it stands from time to time, with its own court
a regulated activity inside the same country	enclave B	the regulator with the deeper regulated-activity practice

The three items that decide every row of the first table are the exchange position, the implementation of the common standard, and the correspondent dependency. **None of the four Atlantic jurisdictions can legislate itself a different one of the three**, which is why the bloc assignment is the least contestable call in the paper and why sovereignty does not move it.

Chapter 57

Diversification That Does Not Pay: Gulf Additions, an Indifferent Bridging Slot, and a Capped Transit Position

Abstract. We test three proposed additions to a designed holding structure against the concentration instrument, and two of them fail on the framework's own arithmetic. Adding Saudi Arabia and Qatar raises the naive effective jurisdiction count from 5.29 to 7.13, a 34.8 per cent improvement, while the effective bloc count falls from 2.94 to 2.84, a 3.4 per cent deterioration, because all three Gulf entries occupy one bloc; the variant actually built, which declines the Qatar Financial Centre vehicle and adds only a Saudi regional headquarters, reads 5.69 naive and 2.82 blocs, again below baseline. The bridging slot is indifferent on this axis: holding 10.9 per cent of exposure in Singapore treated as Western, or in London, gives identical bloc shares of 29.1 / 30.0 / 40.9, N = 2.924302 and h = −0.124430, so the stress case costs only 0.002014 and the Singapore leg must be justified on axes the index does not measure. The Hong Kong comparison is the one that pays: a full centre at 10.9 per cent of exposure reaches N = 3.615826 and h = −0.050138, while a capped transit position at 0.35 per cent reaches N = 2.965384 and h = −0.119548 — capturing 3.97 per cent of the larger design's measured gain for 3.21 per cent of its exposure. The 0.35 per cent figure is derived from a sweep schedule rather than assumed: renminbi receipts at 18.0 per cent of protected capital a year peak at 4.500 per cent quarterly, 1.500 per cent monthly and 0.346 per cent weekly.

Keywords: Gulf financial centres; Singapore; Hong Kong; bridging entity; transit exposure; sweep schedule; bloc independence

Series: D. Structure and Resilience **Paper:** CCP-057

1. Introduction

Three proposed additions to a designed holding structure are tested against the concentration instrument, and two of them fail on the framework's own arithmetic. **The paper's subject is a measurement that comes out against the thing being measured**, which is the only kind of measurement that establishes an instrument is not a formality.

The first addition makes the structure worse. Adding two further Gulf jurisdictions to a structure already holding one raises the naive effective jurisdiction count from 5.290949 to

7.132973, an improvement of 34.8 per cent, while the effective bloc count falls from 2.941176 to 2.841490, a deterioration of 3.4 per cent. **More jurisdictions, less independence.** The mechanism is exact: the additions occupy a bloc the structure already sits in, and they were funded partly out of a position in a *different* bloc, so the bloc the structure was already concentrated in became more concentrated while the jurisdiction count rose. The variant actually built — which declines one of the two proposals and adds only a regional headquarters justified on contracted revenue — reads naive HHI 0.175802 (5.688217 effective jurisdictions) and bloc-HHI 0.355000 (2.816901 effective blocs), **also below the** 2.941176 **baseline it was proposed to improve.**

The second addition is indifferent. Holding 10.9 per cent of exposure in a bridging centre treated as Western, or holding the same 10.9 per cent in the Western centre itself, gives *identical* bloc shares of 29.1 / 30.0 / 40.9, an identical bloc-HHI of 0.341962, an identical effective count of 2.924302 and an identical $h = -0.124430$. **The measured cost of the stress assignment is** 0.002014, and the naive count differs between the two by 0.841640 — an artefact of counting jurisdictions rather than perimeters. **If the bridging centre is Western in the coordination sense, the entire measured value of the move is a naive-count artefact, and the leg has to be justified on axes the index does not measure.**

The third addition is the one that pays, and it pays in a specific and boundable way. A full Asian centre at 10.9 per cent of exposure reaches $N = 3.615826$ and $h = -0.050138$; a capped transit position at 0.35 per cent reaches $N = 2.965384$ and $h = -0.119548$. **The capped position captures 3.97 per cent of the full centre's measured gain for 3.21 per cent of its exposure**, and the 0.35 per cent is derived rather than assumed: renminbi receipts at 18.0 per cent of protected capital a year give a sawtooth transit balance peaking at 4.500 per cent quarterly, 1.500 per cent monthly and 0.346 per cent weekly, and the design adopts the weekly peak because a freeze arrives when it arrives rather than at the average.

What this paper adds beyond those three measurements is a bound on all of them. The three cases are one one-parameter family: a share x of protected capital moved out of one bloc into a new one, leaving bloc shares $(W - x,\ 0.30,\ 0.30,\ x)$ with $W = 0.40$. Section 3.4 states and Section 7.5 verifies the elementary consequence. **The sum of squares of a donor bloc and its offspring is minimised when the transfer is exactly half the donor bloc**, so the family's ceiling sits at $x = 0.200000$, giving a bloc-HHI of 0.260000, $N = 3.846154$ and $h = -0.028524$. **No amount of exposure moved into a fourth perimeter reaches the build threshold of** $N = 4.172734$ at the stated parameters. That is a design-space bound obtained in one line, and it disposes of a class of proposals before their details are examined.

The paper reuses the headroom gauge of Curzi [2026b] — $h_t = \eta \ln N - \delta Q_t - C_t$ with three regimes, a maximum increment $r_{\max} = h_t$, and the separate constraints of admissibility $C_t \le (1-\delta)Q_t + \eta S_t$ and sustainability $C_t \le \eta \ln N - \delta Q_t$ — and it presupposes the founding reframing of Curzi [2026], that comfort is the felt total of present costs so that the present state is a local minimum of the comfort landscape by definition rather than by luck. **That is why a proposal which measurably worsens a structure is put forward at all: the incumbent position is a local minimum and every proposal that leaves it looks, locally, like movement.**

Two prior results in this series have the same shape and this paper derives from both. Curzi [2026] reports a diversification that reduces resilience: moving a residual 16.4 per cent from one Western jurisdiction to another gives blocs 56.4 / 30.0 / 13.6, a bloc-HHI of 0.426592 and N falling from 2.9412 to 2.3442 **despite Western exposure dropping to 13.6 per cent**. Curzi [2026] reports six Atlantic-cluster entities at UK 40.0 / US 22.0 / Cayman 14.0 / BVI 12.0 / Bahamas 7.0 / Barbados 5.0 giving naive HHI 0.249800 and 4.0032 effective jurisdictions but bloc-HHI 1.000000, $N = 1.00$ and $\ln N = 0$. **Three papers, three regions, one arithmetic.** Curzi [2026] adds the fourth instance from an asset rather than a jurisdiction direction: a converted global allocation reads naive HHI 0.215800 and 4.634 effective jurisdictions but bloc-HHI 0.680000 and $N = 1.470588$ — **the naive count improves while the bloc count worsens**.

The bloc assignment carries an identification problem and it is stated here rather than in a footnote. Manski [1993] proves that a linear-in-means reflexive specification is **not identified from observational data**: the endogenous effect cannot be separated from contextual effects or from correlated unobservables however much data is collected, and Shalizi and Thomas

[2011] show that influence and selection are generically confounded in observational network data. **No amount of observing jurisdictional behaviour could confirm a bloc assignment derived reflexively.** The remedy adopted is the fourth of four: the reference group is stipulated in advance and the stipulation is defended — on the evidence of Sections 4 and 5, and stress-tested in Section 7.2, where the contested assignment is run both ways and its cost is printed. That is the route Brock and Durlauf [2001] shows can be made rigorous, and **the price is that every bloc assignment here is a modelling position rather than an identified empirical result.**

One boundary is set before the machinery arrives. Curzi [2026] refuses category innocence as a defence of acquisition, forbids moving any harm through a discovered gap in a scheme, and concedes that the case where the feedback loop runs through another person's will is an unsettled seam this framework does not close. **This paper measures gaps between perimeters and it does not recommend exploiting any of them**; every design it evaluates is one whose elements are filed, and the disclosure reading in Section 7.6 is where that is tested rather than asserted.

2. Hypotheses

Five hypotheses are stated, each falsifiable in the sense Platt [1964]'s strong inference requires. H5 is falsifiable by counterexample only, which is stated rather than dressed up. Meehl [1967] is the standing warning that directional predictions are cheap; all five below carry point predictions with constants attached, and **two of the five are reported in Section 7 in the direction that goes against the addition being tested.**

H1 — the intra-bloc addition hypothesis. Adding jurisdictions inside a bloc a structure already occupies raises the naive count and lowers the effective bloc count, and it does so by more when the addition is funded out of a position in a different bloc. *Predicted:* adding two Gulf jurisdictions to a structure already holding one raises the naive effective count from 5.290949 to 7.132973, an improvement of 34.8 per cent, while the effective bloc count falls from 2.941176 to 2.841490, a deterioration of 3.4 per cent. *Falsified by:* an intra-bloc addition that raises the effective bloc count; equivalently, a defensible assignment placing two of the three Gulf entries in different perimeters.

H2 — the indifference hypothesis. A bridging slot whose assignment is contested is indifferent on the bloc axis, so the assignment cannot be the ground on which the slot is justified. *Predicted:* the same 10.9 per cent of exposure held in a contested bridging centre assigned to the Western bloc, and held in the Western centre itself, give identical bloc shares 29.1 / 30.0 / 40.9, identical bloc-HHI 0.341962, identical $N = 2.924302$ and identical $h = -0.124430$, while the naive counts differ by 0.841640. The stress cost of the reassignment against the bridge base case is 0.002014. *Falsified by:* any difference at all in N between the two placements, which would mean the two positions are not in the same bloc.

H3 — the capped-position hypothesis. A capped transit position in a fourth perimeter captures a disproportionate share of a full centre's measured gain, because the family's efficiency is highest at small shares. *Predicted:* a full centre at 10.9 per cent gives $N = 3.615826$ and $h = -0.050138$; a capped position at 0.35 per cent gives $N = 2.965384$ and $h = -0.119548$; the capped position captures $0.002869/0.072279 = 3.97$ per cent of the gain for $0.35/10.90 = 3.21$ per cent of the exposure, a ratio of 1.2368. *Falsified by:* a capped position whose gain per unit of exposure is at or below the full centre's, which would mean the index is exactly proportional to the share and the capping strategy buys nothing.

H4 — the sweep hypothesis. The exposure of a transit position is set by sweep frequency rather than by throughput, so the highest-leverage control is a bank instruction rather than a design change. *Predicted:* on receipts of 18.0 per cent of protected capital a year with a sawtooth balance, the peak exposure is $18.0/4 = 4.500$ per cent quarterly, $18.0/12 = 1.500$ per cent monthly and $18.0/52 = 0.346$ per cent weekly, so moving from quarterly to weekly divides the exposed balance by exactly $52/4 = 13.0$. *Falsified by:* a settlement pattern in which the balance is not a sawtooth between sweeps — for instance one in which receipts must be held

to meet a matching obligation — in which case the frequency does not control the exposure.

H5 — the half-share proposition. Moving a share x out of one bloc into a new one maximises the effective bloc count at $x = W/2$, where W is the donor bloc's original share. *Predicted:* for $W = 0.40$ and the other blocs at 0.30 and 0.30, the maximum is at $x = 0.200000$ with bloc-HHI 0.260000, $N = 3.846154$ and $h = -0.028524$, so the family never reaches the break-even count $N = e^{0.5/0.35} = 4.172734$. *Falsified by:* any x in the family whose effective count exceeds 3.846154. **H5 is a proposition of arithmetic rather than an empirical hypothesis. It is falsifiable by counterexample and by nothing else, it carries no empirical weight, and what it does is bound a design space that is otherwise argued about without limits.**

Not hypotheses, and labelled as such. Four further statements appear and none is falsifiable as stated.

- *The logarithmic form of the input side*, $\eta \ln N$ rather than ηN, is a **modelling choice** carried from Curzi [2026b] and not tested here. Section 11 records that Latané [1981]'s sublinear power law fits the qualitative facts as well and that nothing here discriminates between them.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice** carried from Curzi [2026] and fixed in advance, which is the preregistration discipline of Nosek et al. [2018] applied to an engineering measurement.
- *The assignment of a contested centre to one bloc rather than another* is a **modelling position**, not a finding. Section 7.2 runs it both ways and prints the cost, which is the only honest treatment available.
- *The identification of the surplus law's* N *with the effective bloc count* is a **definition**; its content is in the assignment rule, which is testable.

3. Method

3.1 The instrument, and which effective count it is

The concentration instrument is taken unchanged from Curzi [2026]. Its definition fits on one line:

```
HHI = sum of squared shares            effective count = 1 / HHI
```

introduced by Hirschman [1945] and reached independently in sum-of-squares form by Herfindahl [1950], with the reciprocal reading due to Adelman [1969]. Competition practice states the index in points on percentage shares [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]; this paper states it as a fraction.

Which effective count, stated exactly. The reciprocal index HHI^{-1} is the Hill number of order two [Hill, 1973], whose numbers-equivalent reading Jost [2006] states in its cleanest form; the same arithmetic was reached independently in ecology by Simpson [1949] and in political science by Laakso and Taagepera [1979]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and the reciprocal index is also the exponential of the Rényi entropy of order two [Rényi, 1961]. **Every effective count in this paper is HHI^{-1}, the Hill number of order two, and it is named as such at each use.** The framework's other effective count, $N_{\text{eff}} = 1 + (N-1)u$, is a linear interpolation between 1 and N; it is not a Hill number of any order and carries no external support, as Curzi [2026] establishes by running the same verification chain on both and letting one fail visibly. **It is not used to produce any number in this paper.**

The general form is $\text{EFF} = 1/(w'Rw)$ for exposure weights w and correlation matrix R, which is the similarity-sensitive diversity of order two of Leinster and Cobbold [2012], whose additive relative is the quadratic entropy of Rao [1982]; setting $R = I$ recovers HHI^{-1} and setting R to a block matrix of ones recovers the bloc index. Hurlbert [1971] is the standing objection that "diversity" carries no content without its formula attached.

No distributional or scaling claim is made anywhere in this paper. The share vectors here descend steeply and invite a tail argument. **This paper fits no distribution, characterises no tail and asserts no power law.** Clauset et al. [2009] is the reason: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few canonical data sets standing, and a straight line on a log-log plot is not evidence. That procedure was not run because no claim requiring it is made, and Stumpf and Porter [2012] adds that even a genuine power law is weak evidence for a mechanism. **The effective counts here are statistics of finite vectors with three, four, six, seven or eight entries.**

The collapse result has an ancestry that should be named rather than reinvented. Granovetter [1978] establishes that the distribution of individual thresholds, not the mean, determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate result — the strongest available warning against reading an individual-level parameter straight into an aggregate, which is what a bloc assignment does. Castellano et al. [2000] supplies the closest formal analogue of a bloc: the same interaction that raises local agreement freezes global diversity into non-interacting regions, with a sharp transition between the monocultural and fragmented phases. **A bloc, in that vocabulary, is a frozen region and the effective count is a count of them.**

3.2 What a bloc addition does, and the decomposition it needs

The result this paper measures three times has an exact decomposition, and it is worth stating before the cases so that the cases read as instances rather than as anecdotes.

Adding a unit inside a bloc the structure already occupies raises the naive count and leaves the bloc count untouched. That is the invariance Curzi [2026] measures on the Atlantic cluster and Curzi [2026] measures at the apex, where the same invariance holds for a different reason: the forced-heirship exposure that drives the apex choice splits into a situs-capped levy, $\min(60.00\text{m}, 6.70\text{m}) = \text{USD } 6.70\text{m} = 11.2$ per cent of the notional reserved share, and an unaffected tax exposure of $0.45 \times 60.00\text{m} = \text{USD } 27.00\text{m}$, **so the apex is selected on a succession arithmetic that the concentration instrument does not enter at all.**

Funding that addition out of a position in a different bloc lowers the bloc count. The donor bloc's share falls and the recipient bloc's share rises; where the recipient was already the largest, the sum of squares rises and N falls. **The naive count rises and the effective count falls at the same time, and neither movement is an error.**

The decomposition this framework supplies for the underlying quantity is Curzi [2026d]'s: non-parallelism splits as $u = \beta^2 + \alpha^2 \sin^2\gamma$ with $\alpha^2 + \beta^2 = 1$, so that $u_{\text{cross}} = \beta^2$ and $u_{\text{div}} = \alpha^2 \sin^2\gamma$, and the budget constraint $u_{\text{div}} \le 1 - u_{\text{cross}}$ caps divergence at 0.10 once crossing reaches 0.90. **The reading transferred here is the budget, not the trigonometry: total non-parallelism is a fixed quantity that the two sources compete for, so buying more of one inside a fixed total buys less of the other.** A jurisdiction added inside an occupied bloc is spending budget on the source that is already saturated.

A second result of this framework bears directly and is the reason a merely *different* addition buys nothing. Curzi [2026c] establishes that u depends only on the magnitude of correlation, so perfect opposition at $\rho = -1$ scores $u = 0$ exactly as perfect agreement does and **a standing contrarian buys no surplus**. The jurisdictional form is exact: a jurisdiction that reliably opposes another is as correlated with it as one that reliably agrees, and neither adds an independent point of failure. **A structure looking for independence must look for units whose failures are unrelated, not for units whose politics are opposed.**

3.3 Correlated units, and what the literature says about the correction

The naive index overstates resilience because it treats units as independent when they share a coordination mechanism. The correction is Markowitz [1952]'s result that diversification benefit depends on covariance and not on count, and Buldyrev et al. [2010]'s that a system of in-

terdependent networks is far more fragile than either network alone. Perrow [1984] reached the organisational form first — interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component — and Sagan [1993] documents the sharper version, that redundancy can reduce safety, **which is this paper's H1 stated as a general proposition twenty years earlier.** Both borrowings are labelled under the analogy discipline of Section 10.5.

Correlations rise under stress. Longin and Solnik [2001] find extreme correlation in equity markets that is asymmetric and concentrated in downturns and Ang and Chen [2002] report the same asymmetry. **The effective count falls exactly when it is needed.** The ecological name for the decisive variable is synchrony [Loreau and de Mazancourt, 2008], and the strongest empirical demonstration that effective count buys stability is Schindler et al. [2010]'s Bristol Bay sockeye record. The contrary literature is read alongside: Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone, and May [1972] showed that increasing diversity and connectance destabilises randomly assembled systems. **This paper's claim is narrower than the general diversity–stability claim**: the reciprocal of a variance is an effective count of independent shocks, which is arithmetic, and units inside one perimeter are correlated, which is H1.

There is a second risk in this paper's material that the instrument does not model at all, and it is stated here because Section 4.2 measures nothing about it. A concentration index assumes the members of a bloc fail *together*. It does not model the members of a bloc failing *against each other*. Where a regional grouping has a dated, recent instance of internal rupture, a structure spread across it carries both risks at once: it does not diversify against external coordination, and it acquires an internal fracture exposure a single-member structure does not have. **That combination is unusual, it is not priced by anything in this paper, and Section 11 records it as an unmeasured overlay rather than as a scored item.**

3.4 The half-share proposition

The three cases of Section 7 are one one-parameter family and the family has a closed-form ceiling. Stating it here means the cases can be read against a bound rather than against one another.

Let a structure have bloc shares $(W, B_2, \dots, B_k)$ summing to one, and move a share $x \in [0, W]$ out of the first bloc into a new bloc. The bloc index becomes

$$\mathrm{HHI}(x) \;=\; (W-x)^2 + x^2 + \sum_{j\geq 2} B_j^2 .$$

Only the first two terms depend on x. Differentiating, $-2(W-x)+2x=0$, so

$$x^* = \tfrac{W}{2}, \qquad \mathrm{HHI}(x^*) = \tfrac{W^2}{2} + \sum_{j\geq 2} B_j^2,$$

and the effective bloc count is maximised there. Three readings follow and each does work in Section 7.

The optimal transfer is exactly half the donor bloc. Not all of it, and not a token slice: the two resulting shares are equal, which is the numbers-equivalent property of Section 3.1 reappearing as a design rule.

The ceiling is computable before any entity is considered. Substituting $W = 0.40$ and $B_2 = B_3 = 0.30$ gives $\mathrm{HHI}(x^*) = 0.080000 + 0.180000 = 0.260000$ and $N = 3.846154$. **Whatever is added, and wherever it is placed, this family cannot exceed** 3.846154, so a proposal promising to reach the break-even count of 4.172734 by moving exposure into a fourth perimeter is refuted before its details are examined.

Efficiency falls monotonically in x on $[0, x^*]$. The gain $h(x) - h(0)$ is concave, so the *average* gain per unit of exposure, $[h(x)-h(0)]/x$, is largest at small x. **A capped position is more efficient**

per unit of perimeter exposure than a full one, and Section 7.5 measures by how much. That is H3's mechanism, and it is arithmetic rather than judgement.

3.5 Evidence standard, and the de-identification convention

Sections 4, 5 and 6 are jurisdictional exposition. **Every enactment, decided case, licensing regime, constitutional provision, listing event, rate, date and jurisdictional characteristic in them is described from the source manuscript and is not cited to the bibliography.** The bibliography carries the general instruments and the comparative doctrine only: recognition and enforcement of awards [United Nations, 1958], with the grounds on which enforcement is in fact refused [van den Berg, 1981], the model law behind the convergence of the surveyed regimes [United Nations Commission on International Trade Law, 1985], and the doctrine around them [Born, 2021]; the judgments and choice-of-court conventions [Hague Conference on Private International Law, 2005, 2019]; the trusts convention [Hague Conference on Private International Law, 1985]; the succession convention that never entered into force [Hague Conference on Private International Law, 1989] with the regional regulation that partially fills the gap [European Union, 2012]; conflict-of-laws doctrine [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008]; the trust and the foundation compared [Lupoi, 2000, Smith, 2013, Panico, 2014]; asset partitioning as the irreducible function of entity law [Hansmann and Kraakman, 2000] with its critique [Pistor, 2019]; the listing machinery as a technique of governance [de Goede, 2011]; and the disclosure instruments [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015]. **It contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction.** Appendix B lists every affected claim, **with the requirement that the date of confirmation be recorded**, because a statement of a jurisdiction's regime without a date is not a statement of its regime.

Where a table would otherwise **rank named jurisdictions against one another on a legal capability the bibliography cannot support**, the jurisdictions are de-identified — "Gulf centre A" and "Gulf centre B", "Asian centre A" and "Asian centre B" — following the convention of Curzi [2026], which de-identifies two Gulf centres in its own scored assessment, and Curzi [2026], which de-identifies three islands in its ranked capability table. **Where a jurisdiction is named in prose, or appears in an exposure table, or carries a bloc assignment with its evidence, the name is used**, because the argument is about those specific perimeter attachments and a functional description would hide rather than protect.

4. The Gulf: one bloc, with an internal fracture

4.1 The perimeter evidence

Everything in this section is described from the source manuscript and is uncited (Section 3.5, Appendix B). The perimeter test of Curzi [2026] asks whether a decision taken in one jurisdiction reliably produces the corresponding effect in another without a further independent decision.

shared mechanism	evidence class
a common regional assessment body operating alongside the global standard-setter	strongest — a supervisory standard producing the same domestic consequence in every member
a common peer-review process on exchange of information	strongest
effectively common exposure to a single correspondent-banking policy	strongest — shared correspondent networks exit corridors together

shared mechanism	evidence class
currency pegs to the same unit across the members	strongest
hydrocarbon revenue correlation	weaker — a common shock, not a common decision
a regional security environment no member can opt out of	weaker

Four of the six rows are in the strongest class. The bloc assignment is therefore not a close call on the coordination axis, and Section 7.1's arithmetic follows from it directly.

4.2 The rupture, and what it is evidence of

The demonstration that matters is not any of the six rows above. **On 5 June 2017 four states of the region severed diplomatic relations with a fifth and closed their land, sea and air links to it. The rupture lasted until a declaration of 5 January 2021.** For three and a half years, a resident family holding one company in the isolated state and another in one of the isolating states held two parts of one structure in jurisdictions that had closed their borders to each other. Flights stopped, some banking relationships were curtailed, and the isolated state's offshore currency traded away from its peg for a period. **The qualitative fact of disruption is well established; the quantitative detail is not something to assert from memory, and Appendix B marks the banking and currency effects for verification rather than reproducing a characterisation of them.**

The event does two different pieces of work and they must not be conflated.

```
CO-VARIANCE RISK   the members respond TOGETHER to external
                   coordination. This is the perimeter mechanism
                   and it is why they are one bloc for the
                   measurement.

INTRA-BLOC RISK    the members have acted AGAINST one another,
                   within the last decade, at speed, with physical
                   closure of borders. This is a failure mode the
                   Western perimeter does not have in the same form.
```

A structure spread across the region carries both risks at once: it does not diversify against external coordination, and it acquires an internal fracture exposure a single-member structure does not have. **The concentration instrument prices the first and is silent about the second**, which is stated here and again in Section 11 rather than folded into a score.

4.3 What the two additional centres are for, de-identified

Neither is a holding jurisdiction and neither is a diversification. **The comparison below ranks them on legal capability the bibliography cannot support, so they are de-identified** (Section 3.5).

requirement	best fit	why
a common-law financial centre whose licence is not territorially confined	Gulf centre A	its licensed entities may operate anywhere in the national economy, which converts an enclave into a regime and makes a genuine domestic operating entity possible
market access to a very large state customer, conditioned on physical presence	Gulf centre B	a headquarters programme that is a market-access requirement with a tax incentive attached, rather than a tax incentive with a substance requirement attached
a holding position outside the incumbent perimeter	**neither**	both sit inside the bloc the structure already occupies; Section 7.1 measures the cost of pretending otherwise

The distinction in the second row decides whether the item belongs in a structure at all. A tax incentive with a substance requirement is a cost to be minimised; a market access requirement with a tax incentive is a price to be paid. **The first is optimised, the second is bought**, and an adviser who cannot say which one is on the table has not specified the decision.

5. The bridging slot: a contested assignment, argued rather than asserted

Everything in this section is described from the source manuscript and is uncited. The bridging centre's assignment is the most contested call in this paper and the evidence runs both ways.

evidence for a bridge assignment	evidence against
no participation as a decision-taker in the regional listing mechanism	targeted financial measures and export controls adopted in March 2022 without a Security Council resolution, a departure from six decades of stated practice
no domestic designation apparatus of the kind the perimeter's two largest members operate	full membership of and participation in the standard-setting body whose recommendations are the primary coordination channel
a designated clearing bank for a second major currency since 2013, with genuine offshore capability	participation in automatic exchange with first exchanges in 2018, and a bilateral reporting arrangement
regional centrality and a policy of non-exclusion, hosting full-service operations of institutions from every bloc simultaneously	a banking system whose dollar correspondent access is the operational constraint on everything, and which therefore inherits the correspondent perimeter's risk appetite

evidence for a bridge assignment	evidence against
a foreign-policy doctrine of not choosing sides, stated consistently at senior level for six decades	

The last row on the right does the work and it generalises beyond this jurisdiction. A jurisdiction's coordination alignment is set less by its foreign ministry than by its banks' correspondent relationships, **because the correspondent relationship is the thing that can be withdrawn in a week.** The centre's foreign policy is genuinely independent. Its dollar clearing is not, because nobody's is.

The verdict carried into Section 7.2 is therefore split: **bridge in commercial function, Western-leaning in coordination behaviour under stress.** The consequence is not a judgement call left open; it is a measurement run both ways, and Section 7.2 prints the difference so a reader who disagrees with the assignment can read their own answer off the table.

6. The transit position: two perimeters, and the trap in the arithmetic

Everything in this section is described from the source manuscript and is uncited.

The third jurisdiction under test has an unusual property and it is the worst available combination. **For coordination purposes it sits inside one perimeter**: its national-security framework is legislation of the sovereign, the interpretive power over that framework is the sovereign's, and the power to designate the judges who hear cases under it runs through an executive selected under a system substantially revised in 2021. **For correspondent and settlement purposes it sits inside the other perimeter**, because its banks require dollar correspondent access and its currency is maintained against the dollar under a linked exchange rate. That second exposure is not theoretical: the other perimeter's largest member enacted legislation and issued an executive order in 2020 suspending or eliminating a range of preferential treatments, and separately suspended bilateral agreements including one on surrender of fugitives.

A jurisdiction inside two coordination perimeters is not a bridge; it is a place where two sets of coercive capability overlap. That is the exact inverse of the property the bloc collapse is designed to find.

Which brings the trap into focus, and it is the counter-result of this paper. In a structure with no other exposure to the first perimeter, assigning this jurisdiction to that perimeter raises the effective bloc count sharply — from 2.941176 to 3.615826 — because the bloc collapse rewards a share placed in a perimeter the structure does not otherwise touch. **The arithmetic is correct.** What it does not and cannot see is that the marginal exposure is placed under a perimeter with demonstrated reach through the courts, and that the entity holding it is simultaneously exposed to the other perimeter through its correspondent bank. **The instrument prices the position. It does not price the hazard, and this is the jurisdiction where the gap between the two is widest.**

The design consequence is Section 7.3's Design B. **Take the capability and cap the position**: the arbitration seat, the currency settlement capability and the market access are bought through contract terms and a small balance, and the balance is controlled by sweep frequency rather than by design (Section 7.4).

The framework has an instrument for valuing that kind of move and it is not the concentration index. Curzi [2026] scores each step of a path 0 to 3 for steepness, sums to a resistance R, and weights the branch as $1/2^R$, so that a three-point difference in steepness is a factor of eight in expectation. **A capability bought through a clause rather than through a balance is a step with lower steepness on every branch that ends in a freeze**, and the branch weighting

says what that is worth in expectation even where the index says the position is worth 0.002869. The two readings are different quantities and both are printed in Section 7.3 rather than one being substituted for the other.

7. Results

All figures below are exact computations on constructed inputs, carried at full precision and rounded only for printing. **No external dataset was collected and no figure in this paper is a measurement of any real structure.** Where a printed value in the source manuscript differs from the exact computation, Section 7.7 prints both.

7.1 R1 — Gulf additions, and H1

The designed structure, and the tempted variant in which two further Gulf jurisdictions are added and funded partly by trimming the incumbent bridge, Western and non-aligned positions:

	designed	tempted
UAE	29.1% BRIDGE	20.0% BRIDGE
Thailand	18.2% NONALIGNED	18.2% NONALIGNED
UK	16.4% WEST	12.2% WEST
Bermuda	13.6% WEST	13.6% WEST
India	11.8% NONALIGNED	11.8% NONALIGNED
Singapore	10.9% BRIDGE	6.9% BRIDGE
Saudi Arabia	—	9.1% BRIDGE
Qatar	—	8.2% BRIDGE

```
TEMPTED, naive
  0.200^2 + 0.182^2 + 0.136^2 + 0.122^2
+ 0.118^2 + 0.091^2 + 0.082^2 + 0.069^2  = 0.140194
  effective jurisdictions = 1 / 0.140194 = 7.132973

TEMPTED, blocs
  BRIDGE 44.2  (UAE + Saudi + Qatar + Singapore)
  NONALIGNED 30.0  (Thailand + India)
  WEST 25.8  (Bermuda + UK)
  bloc-HHI = 0.195364 + 0.090000 + 0.066564 = 0.351928
  EFFECTIVE BLOCS = 1 / 0.351928 = 2.841490
```

	designed	tempted	change
jurisdictions held	6	8	$+2$
naive effective count	5.290949	7.132973	$+34.81\%$
effective bloc count	2.941176	2.841490	-3.39%
h	-0.122417	-0.134485	-0.012068

Two more jurisdictions, a naive resilience count a third higher, and the honest count went down. The structure looks more diversified on every measure a brochure would use and is fractionally less diversified on the only measure that predicts failure.

The mechanism is exact and is worth stating because it is the general case. The Gulf additions were funded partly out of the other bridge position, which is a *different* bridge, so the bridge bloc concentrated even as the jurisdiction count rose. **Rearranging inside a bloc does not change N; funding an intra-bloc addition out of an extra-bloc position makes N worse.** That is Section 3.2's decomposition, instantiated.

The variant actually built. One proposal was taken and one declined. The taken proposal is a regional headquarters justified by contracted revenue that is unavailable without it; the declined proposal is a family-office vehicle in the other centre with no operating activity, no customers, no contracts, no assets and no people, which would have duplicated the apex's function inside the same bloc at additional annual cost. The taken addition is funded from the operating allocation rather than by trimming an extra-bloc position:

line	share	bloc
UAE	29.1%	BRIDGE
Thailand	13.2%	NONALIGNED
UK	16.4%	WEST
Bermuda	13.6%	WEST
India	11.8%	NONALIGNED
Singapore	10.9%	BRIDGE
Saudi Arabia	5.0%	BRIDGE

```
naive HHI = 0.084681 + 0.017424 + 0.026896 + 0.018496
          + 0.013924 + 0.011881 + 0.002500 = 0.175802
effective jurisdictions = 1 / 0.175802 = 5.688217

blocs: BRIDGE 45.0  WEST 30.0  NONALIGNED 25.0
bloc-HHI = 0.202500 + 0.090000 + 0.062500 = 0.355000
EFFECTIVE BLOCS = 1 / 0.355000 = 2.816901
```

	designed	tempted	as built
jurisdictions	6	8	7
naive effective count	5.290949	7.132973	5.688217
effective bloc count	2.941176	2.841490	2.816901

The honest result: taking the regional headquarters cost 0.124275 of effective bloc count, and it was taken anyway, because it was justified by revenue and not by resilience. That is the correct way to make the decision and it is worth stating explicitly. **The instrument is a measurement, not a veto.** A structure exists to hold a business, and a business that wins a large contract has done something the concentration measure cannot price. What the instrument does is make the cost visible and force it to be paid consciously: **the family knows it gave up 0.124275 of N and knows what it received; the tempted variant gave up 0.099686 and received a brochure.**

H1 is supported. The naive count rose 34.81 per cent and the effective bloc count fell 3.39 per cent, and no admissible reassignment separates the three Gulf entries — four of the six shared mechanisms in Section 4.1 sit in the strongest evidence class.

7.2 R3 — the indifferent bridging slot, and H2

The base case assigns the contested bridging centre to the bridge bloc:

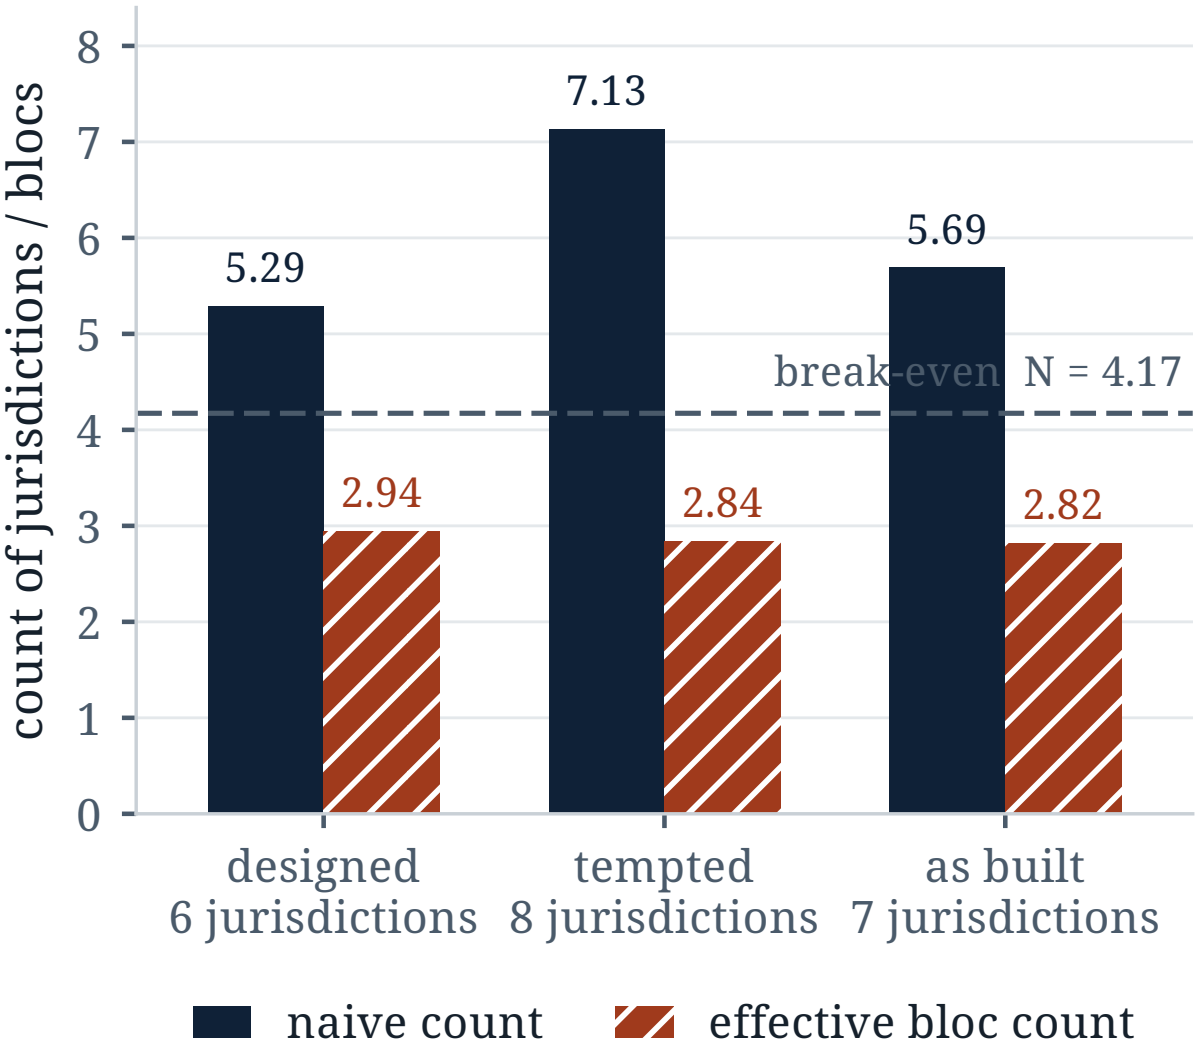

Figure 57.1: **Two more jurisdictions raise the naive count by 34.8 per cent and lower the effective bloc count by 3.4 per cent.** Naive count against effective bloc count for the designed, tempted and as-built structures, with the break-even effective count $N = e^{0.5/0.35} = 4.172734$ the surplus law requires at the stated parameters. All shares are constructed. Generated by `figs/src/CCP-057_fig01.py`.

```
BRIDGE 40.0  NONALIGNED 30.0  WEST 30.0
bloc-HHI = 0.160000 + 0.090000 + 0.090000 = 0.340000
N = 2.941176   ln N = 1.078810   eta ln N = 0.377583   h = -0.122417
```

The stress case reassigns it to the Western bloc:

```
BRIDGE 29.1  NONALIGNED 30.0  WEST 40.9
bloc-HHI = 0.084681 + 0.090000 + 0.167281 = 0.341962
N = 2.924302   ln N = 1.073056   eta ln N = 0.375570   h = -0.124430
stress cost = 0.124430 - 0.122417 = 0.002014
```

And the comparison that decides the section. Hold the same 10.9 per cent in the Western centre itself instead of in the bridging centre. The bloc shares are *identical* — 29.1 / 30.0 / 40.9 — so the bloc-HHI, N and h are identical to every decimal place. Only the naive count differs, because the Western centre already holds 16.4 per cent and the two positions merge into one 27.3 per cent line.

variant	naive HHI	naive effective	N	h
bridging centre assigned BRIDGE (base)	0.189002	5.290949	2.941176	-0.122417
bridging centre assigned WEST (stress)	0.189002	5.290949	2.924302	-0.124430
the same 10.9% held in the Western centre	0.224754	4.449309	2.924302	-0.124430

Read the bottom two rows together: they differ by 0.841640 on the naive count and by exactly zero on the bloc count and on h. H2 is supported. If the bridging centre is Western in the coordination sense, the entire measured value of moving that exposure is a naive-count artefact.

That is not an argument against the position, and the paper says so in the same paragraph. The real value of the bridging leg is elsewhere and it is not small: several dispute pathways including a commercial court with an opt-in jurisdiction, a fund vehicle with statutory segregation, multi-currency settlement in the operating time zone, and a bank layer that will open the accounts. **Capability is a real good; it is simply not the good the concentration instrument measures, and a leg justified on the concentration instrument is a leg justified on the wrong grounds and therefore sized on the wrong grounds.**

The marginal contribution of the leg on the bridge assignment is small and is stated:

```
0.35 x (ln 2.941176 - ln 2.600000) = 0.35 x 0.123299 = 0.043154
```

against a first non-Western move worth roughly 0.70 of N on the same build path. **That is** $dh/dN = \eta/N$ **arriving on schedule**, and it is the reason no later leg can repeat what an early one did.

7.3 R2 — the capped transit position, and H3

Two designs for the third jurisdiction. **Design A** places a full Asian centre in the 10.9 per cent slot, assigned to a fourth bloc. **Design B** keeps the bridging centre's position and adds a small entity handling settlement in the second currency, sized at 0.35 per cent of protected capital (Section 7.4) with the bridging position reduced correspondingly.

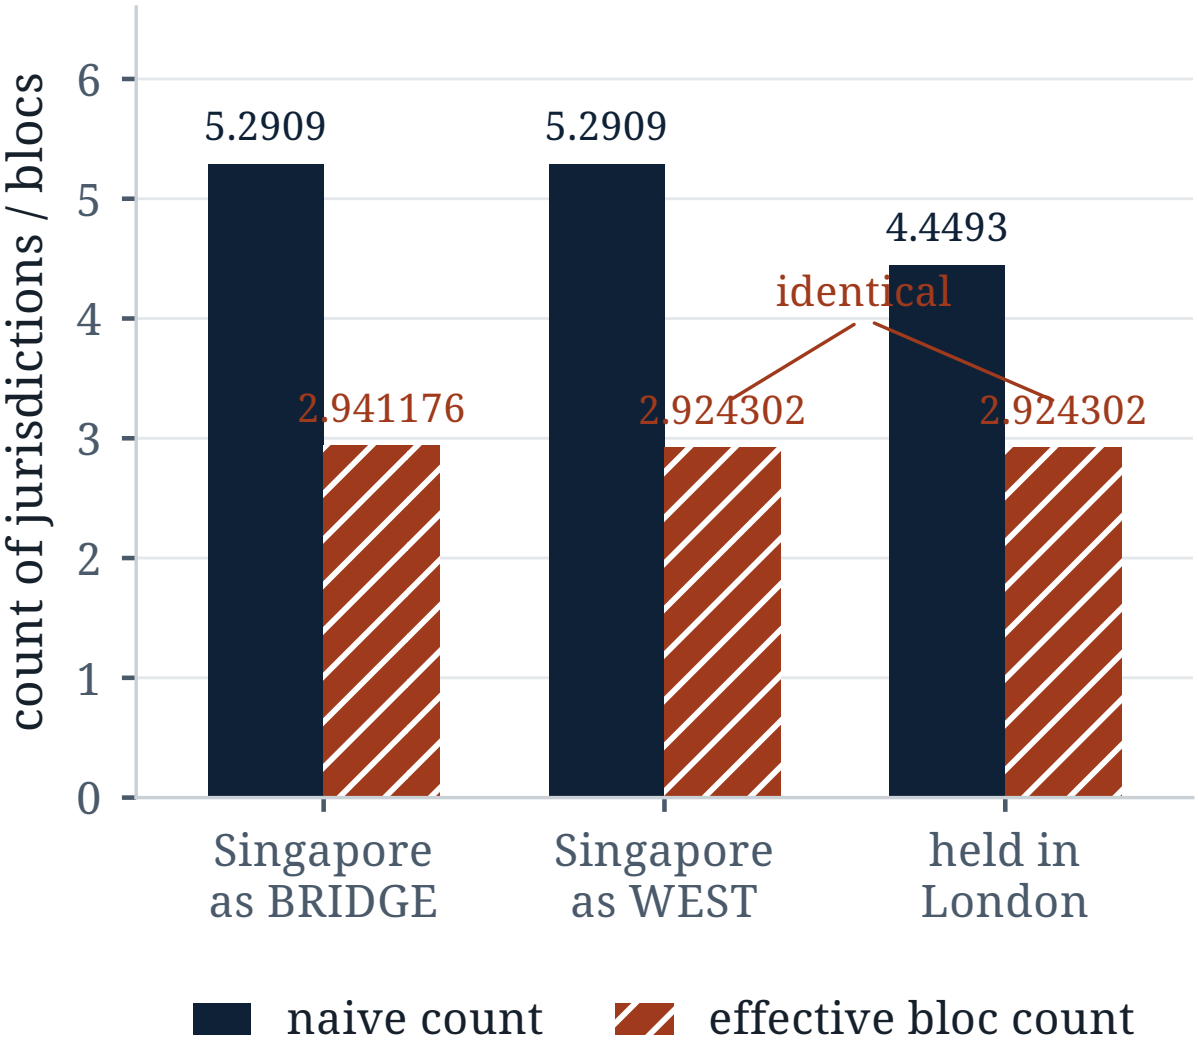

Figure 57.2: **Assigning the bridging centre to the Western bloc, or holding the same exposure in the Western centre itself, gives an identical effective bloc count.** Naive count against effective bloc count for the three variants of Section 7.2. The lower two differ by 0.841640 on the naive count and by exactly zero on the bloc count. All shares are constructed. Generated by `figs/src/CCP-057_fig04.py`.

```
DESIGN A
  blocs: BRIDGE 29.1  NONALIGNED 30.0  WEST 30.0  FOURTH 10.9
  bloc-HHI = 0.084681 + 0.090000 + 0.090000 + 0.011881 = 0.276562
  N = 3.615826   ln N = 1.285320   eta ln N = 0.449862   h = -0.050138

DESIGN B
  blocs: BRIDGE 39.65  NONALIGNED 30.0  WEST 30.0  FOURTH 0.35
  bloc-HHI = 0.157212 + 0.090000 + 0.090000 + 0.000012 = 0.337224
  N = 2.965384   ln N = 1.087006   eta ln N = 0.380452   h = -0.119548
```

design	N	h	gain in h	exposure inside the fourth perimeter
baseline	2.941176	-0.122417	—	0.00%
B: capped transit	2.965384	-0.119548	$+0.002869$	0.35%
A: full centre	3.615826	-0.050138	$+0.072279$	10.90%

```
Design B captures  0.002869 / 0.072279 = 3.97%  of Design A's gain
Design B carries      0.35% / 10.90%   = 3.21%  of Design A's exposure
ratio                    3.97 / 3.21   = 1.2368
```

H3 is supported. The measured benefit is very nearly proportional to the exposure placed inside the perimeter — which is exactly what a concentration index should do and exactly why it must not be the sole criterion. **The index rewards the share; the share is the hazard.** Design A's 0.072279 of headroom is bought by putting 10.9 per cent of protected capital inside a perimeter with demonstrated judicial reach and simultaneous correspondent exposure to the other perimeter. Design B buys 3.97 per cent of that headroom for 3.21 per cent of that exposure, and buys separately — through the arbitration clause, at no balance-sheet cost — the one capability that has no substitute.

The departure from exact proportionality is the finding rather than a rounding error, and Section 7.5 measures it: the ratio of 1.2368 says the capped position buys 23.68 per cent more headroom per unit of exposure than the full centre, and that is a consequence of the concavity established in Section 3.4 rather than of anything about the jurisdictions.

7.4 R4 — the sweep schedule, and H4

The 0.35 per cent figure is derived, not assumed, and the derivation is the section. CONSTRUCTED: renminbi receipts equal to 18.0 per cent of protected capital per year, with the transit entity's balance a sawtooth between sweeps, so the average balance is half of one sweep period's receipts.

sweep frequency	peak balance	average balance
quarterly	$18.0/4 = 4.500\%$	2.250%
monthly	$18.0/12 = 1.500\%$	0.750%
weekly	$18.0/52 = 0.346\%$	0.173%

The design adopts 0.35 per cent, which is the weekly *peak* — the conservative choice, since a freeze arrives when it arrives rather than at the average. The ratio of the quarterly peak to the weekly peak is $52/4 = 13.0$ exactly.

H4 is supported. Sweep frequency is the single highest-leverage control in the whole design: moving from quarterly to weekly divides the exposed balance by exactly thirteen and

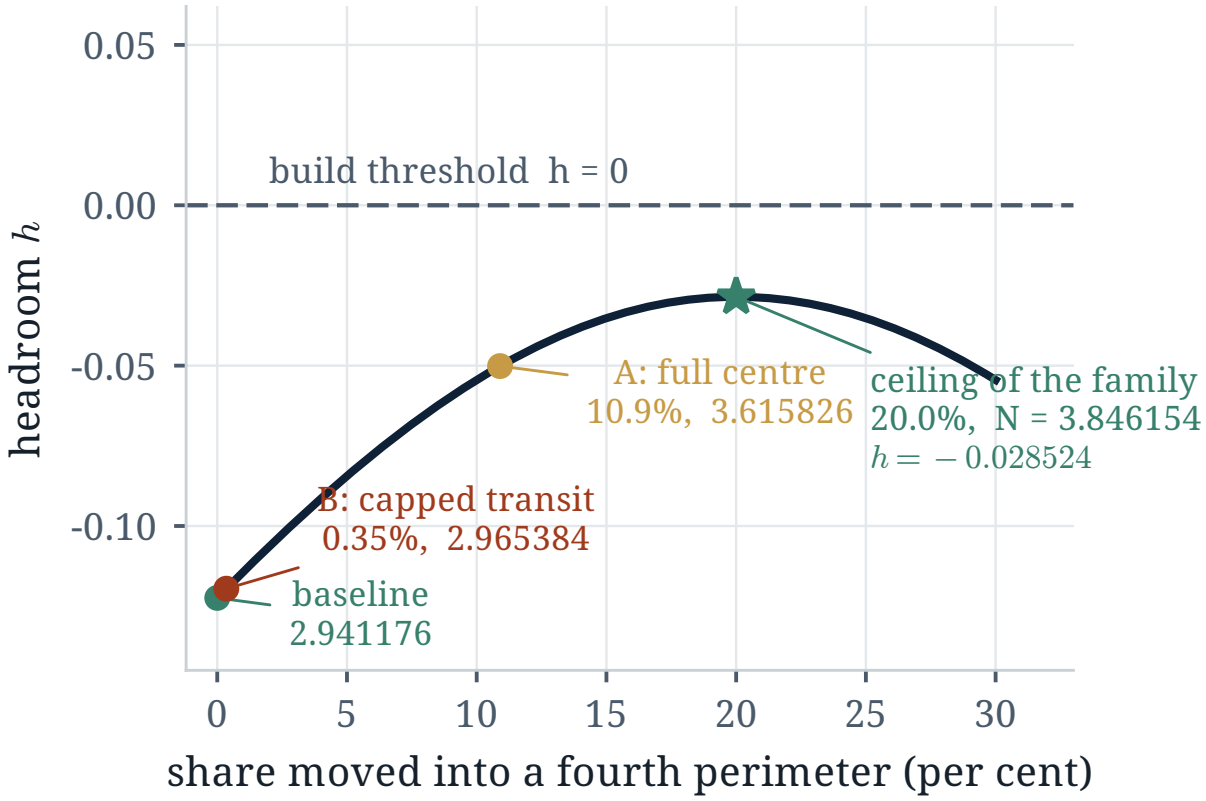

Figure 57.3: **Headroom rises with the share moved into a fourth perimeter, peaks at 20 per cent, and never reaches the build threshold.** The one-parameter family of Section 3.4 at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$, with the baseline, the capped transit position and the full centre marked, and the closed-form ceiling at $x = 20.0$ per cent, $N = 3.846154$, $h = -0.028524$. Modelled from the constructed bloc vector; generated by `figs/src/CCP-057_fig02.py`.

costs a bank instruction. No entity change, no jurisdictional change and no negotiation produces a comparable movement.

That concentration of leverage in one control has a precedent in this framework and it is worth naming, because it is a recurring shape rather than a coincidence. Curzi [2026] reports Finding 19.2: the only gate acting on the numerator sits ninth of twelve in a schedule and contributes -5.305895 octaves, **88.93 per cent of the schedule's total movement, against 11.07 per cent for the eight before it. A schedule of controls is usually one control and eleven decorations, and the discipline is to find which one it is before optimising the others.**

The falsifier attached to H4 is worth restating because it is a real limit. **If the transit balance is not a sawtooth — if receipts must be held to meet a matching obligation, or if a counterparty requires a minimum balance — then sweep frequency does not control the exposure**, and the 0.35 per cent is not derivable from the throughput. That case is not constructed here and the paper does not claim it away.

7.5 H5 — the half-share ceiling, and the efficiency it implies

The three designs of Sections 7.1 to 7.3 are one family. Applying Section 3.4 with $W = 0.40$, $B_2 = B_3 = 0.30$:

quantity	value
the optimal transfer $x^* = W/2$	0.200000
bloc-HHI at the optimum, $W^2/2 + \sum B_j^2$	$0.080000 + 0.180000 = 0.260000$
the ceiling $N(x^*)$	3.846154
h at the ceiling	-0.028524
the break-even count the surplus law requires	4.172734

H5 is supported, and its consequence is the strongest single statement in this paper. No transfer of exposure into a fourth perimeter, of any size and at any placement, brings this structure to the build threshold. The best available is $N = 3.846154$ against a required 4.172734, a shortfall of 0.326580 in the count and 0.028524 in h. **A proposal to reach the threshold by adding a fourth perimeter is refuted in one line, and the line does not mention any jurisdiction.**

The efficiency reading follows from the same concavity and is the quantitative form of H3:

position	share x	gain $h(x) - h(0)$	gain per unit of exposure
B: capped transit	0.0035	0.002869	0.819674
A: full centre	0.1090	0.072279	0.663107
the ceiling	0.2000	0.093892	0.469462

```
B / A on efficiency  = 0.819674 / 0.663107 = 1.236110
B / A on share ratio = 3.97 / 3.21         = 1.236760
```

The two readings agree to four significant figures and differ only in the rounding of the percentages, which is the cross-check Section 10.9 records. **A capped position buys 23.61 per cent more headroom per unit of perimeter exposure than a full centre, and the figure is a property of the arithmetic rather than of the jurisdiction.**

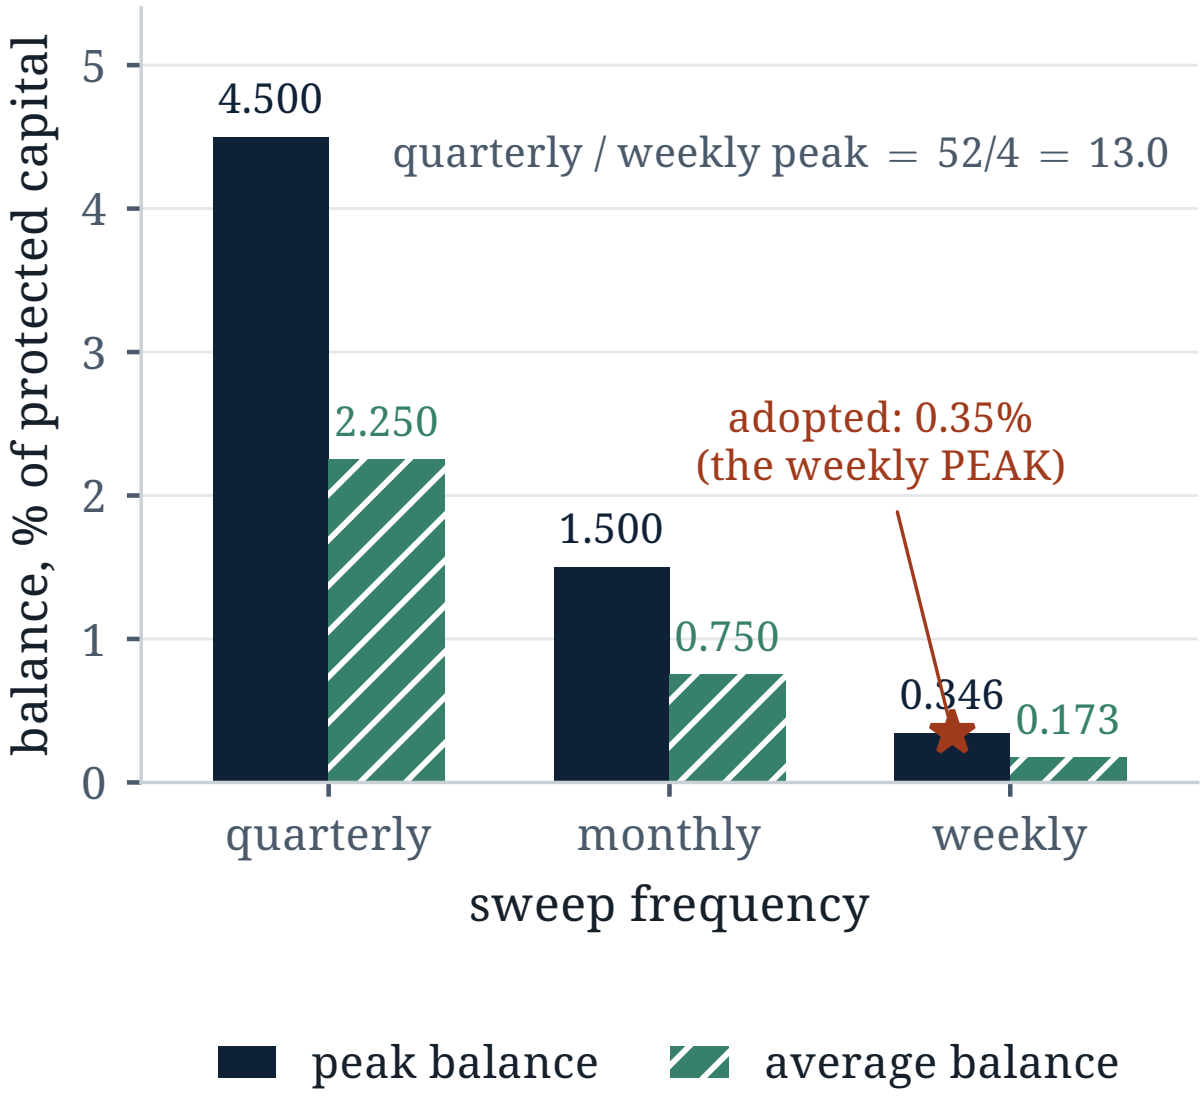

Figure 57.4: **Sweep frequency divides the exposed balance by thirteen between quarterly and weekly.** Peak and average transit balance as a percentage of protected capital under three sweep frequencies, on constructed receipts of 18.0 per cent of protected capital a year with a sawtooth balance. The design adopts the weekly peak of 0.35 per cent rather than the average. Generated by `figs/src/CCP-057_fig03.py`.

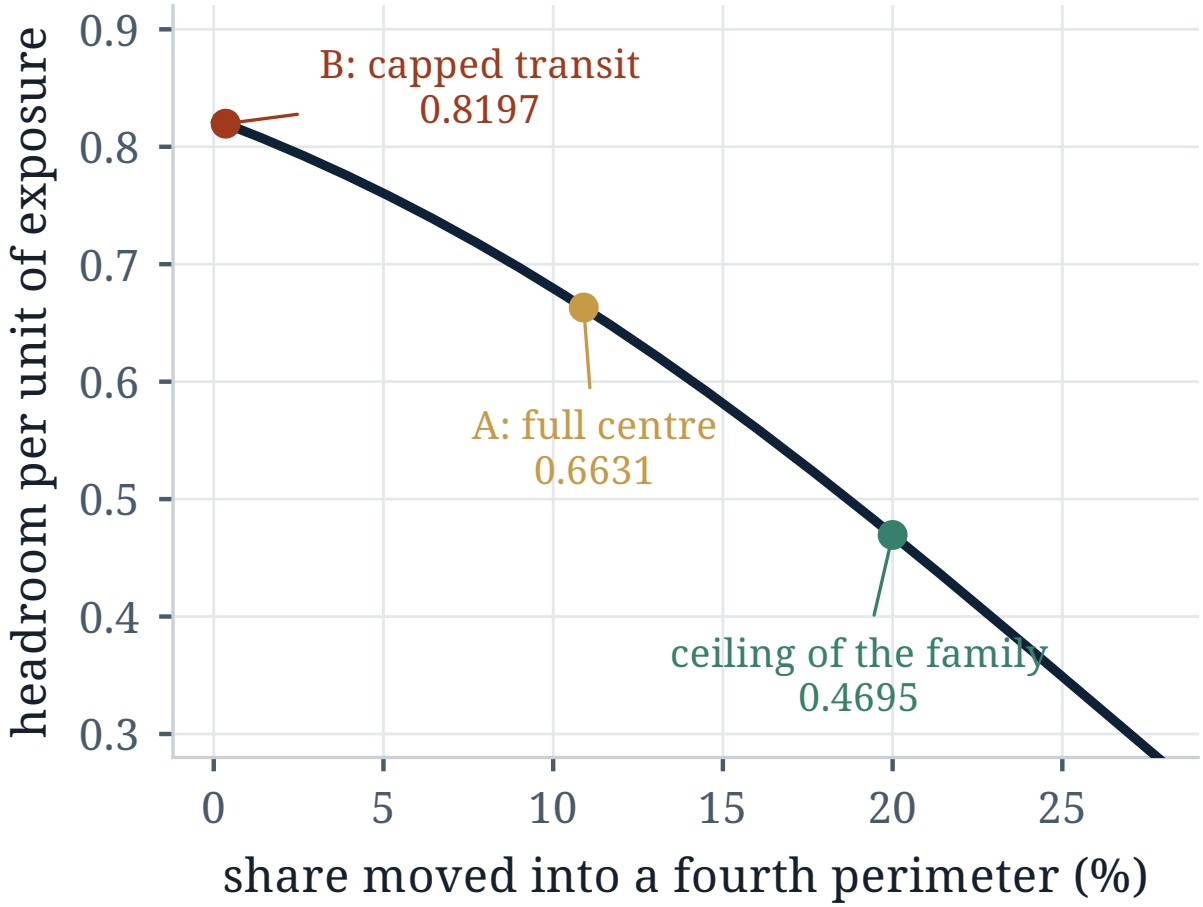

Figure 57.5: **Headroom bought per unit of exposure falls monotonically, so a capped position is 23.61 per cent more efficient than a full centre.** Average gain in h per unit of protected capital moved into a fourth perimeter, on the family of Section 3.4, with the capped transit position, the full centre and the family's ceiling marked. Modelled from the constructed bloc vector; generated by `figs/src/CCP-057_fig05.py`.

7.6 The disclosure reading, applied to all three

The disclosure test asks whether a structure would still do its job if every element were disclosed to every authority with jurisdiction over any part of it. The premise is not this work's to claim. Kerckhoffs [1883] stated it in 1883: a system must remain secure when everything about it except the key is public. Saltzer and Schroeder [1975] restate it as *open design* — the protection mechanism should not depend on the ignorance of attackers — and place it alongside *complete mediation* precisely because a publishable design still requires that every access be checked. Brandeis [1914] is the public-interest form of the same observation. **Citing Kerckhoffs converts what reads as an ethical preference into a recognised engineering standard**, and Curzi [2026] states the constraint in its strongest form: channel separation is strengthened by disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable and non-disclosure is refused as a design premise rather than merely discouraged.

element	reading
the regional headquarters	licensed, staffed, premised and filed. **Its whole function is to be visibly present**, and it is the one entity in this series whose entire purpose is to be seen. Disclosure is not a cost; it is the product
the declined family-office vehicle	does not exist, **which is the cheapest possible way to pass any test**
the bridging leg	a treasury company with employees, premises, a resident-majority board and a written policy; a fund vehicle with a regulated manager; contracting entities with named forums. Every element is filed
the capped transit entity	a small balance, a written cap, a weekly sweep and a named arbitral seat. **The cap is a document, and a document is disclosable**

All four pass, and the first is the clearest illustration in this part of the series that substance which is real, filed and visible is not a compliance burden attached to the strategy — **in that case it is the strategy**, because the market access being bought is conditioned on exactly that visibility. The regulatory direction makes the same point from the other side: automatic exchange [Organisation for Economic Co-operation and Development, 2017], the common anti-money-laundering recommendations [Financial Action Task Force, 2012] and the substance and beneficial-ownership work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] together mean that non-disclosure is not an available design parameter.

7.7 Printed discrepancies, left visible

First, the stress-case headroom. The source manuscript prints $h = -0.124431$ for the Western reassignment of the bridging slot. The exact value is -0.124430 — more precisely -0.1244305, which rounds to -0.124430 at six decimal places. **The derived stress cost of** 0.002014 **is unaffected**, because $0.1244305 - 0.1224167 = 0.0020138$. This paper prints -0.124430 and records the source's figure here.

Second, the base-case headroom. The source prints $h = -0.1226$ for the designed structure in three places. The exact value at $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is -0.122417, a difference of 0.000183. **This paper uses** -0.122417**, which is the value Curzi [2026] publishes**, and Curzi [2026] and Curzi [2026] record the same discrepancy independently.

Third, a description rather than a number. The as-built variant of Section 7.1 is described in one summary of this work as a variant *placing the apex in the second Gulf centre*. **It is not.** The source declines that vehicle outright and the variant computed is the regional-headquarters addition in the other Gulf state. The numbers — 0.175802, 5.688217, 0.355000, 2.816901 — are unaffected and are the ones other papers cite; **the description is corrected here rather than propagated.**

Fourth, and for consistency across the series, the naive index of the conventional four-jurisdiction structure. Curzi [2026] reports 0.293388 from exact ninths, giving 3.4085 effective jurisdictions against bloc-HHI 1.000000 and 1.0000 effective perimeters; Curzi [2026] reports 0.293430 from rounded percentages, giving 3.407968. **This paper uses the rounded-percentage figure where it refers to that structure**, and states which it uses.

7.8 Hypotheses tested

#	hypothesis	verdict	where
H1	intra-bloc additions raise the naive count and lower the effective one: $+34.81\%$ and -3.39%	**supported**	7.1
H2	the bridging slot is indifferent on the bloc axis; the stress cost is 0.002014	**supported**, and the naive difference of 0.841640 is an artefact	7.2
H3	a capped position captures a disproportionate share of the gain: 3.97 against 3.21 per cent	**supported**	7.3
H4	sweep frequency controls the exposure, quarterly to weekly by a factor of 13.0	**supported**, subject to the sawtooth premise its falsifier names	7.4
H5	the family's ceiling is at half the donor bloc: $N = 3.846154$, $h = -0.028524$	**supported** as arithmetic, with no empirical content	7.5

Two of the five report against the additions being tested, which is the point of the paper: H1 says two of the three proposals lower the quantity they were offered to raise, and H5 says none of them could have reached the threshold anyway. **H4's premise is a construction and its falsifier was not tested**, because no non-sawtooth settlement pattern was constructed; Section 11 records that.

8. Failure modes

Twelve ways the results above are misapplied, each with the diagnostic that detects it.

1. Counting jurisdictions instead of blocs. The error the whole series exists to correct, and Section 7.1 is its most expensive instance. *Diagnostic:* collapse the shares onto perimeters before squaring, and report the pair.

2. Assuming a regional rupture cannot recur. Section 4.2 dates one that lasted three and a half years. *Diagnostic:* ask what a border closure between two members would do to the structure's ability to instruct, and write the answer down.

3. Treating a market-access headquarters as a holding vehicle. It exists to be present in one market, and nothing should be placed under it. *Diagnostic:* if group holdings sit beneath it, the job assignment has been violated.

4. Assuming one common-law centre delivers another's case law. Two centres in the same legal tradition have different benches and different bodies of decisions. *Diagnostic:* name the reported decisions the argument relies on and check where they were decided.

5. Reading contractual outcomes off a code. *Diagnostic:* the enforceable route, not the statutory text, is the thing to specify.

6. Litigating where an award would travel better than a judgment. *Diagnostic:* choose the forum by the enforcement route, not the other way round [United Nations, 1958].

7. Discounting a political risk because its known instances happened to residents. *Diagnostic:* the mechanism does not read passports; name the mitigation and state that it is partial.

8. Substance built as documentation. *Diagnostic:* the test is applied to core income-generating activity and the evidence is the decision trail, not the address.

9. Assuming a designated business district is a legal enclave. Two different things travel under similar names. *Diagnostic:* ask which court hears a dispute and under what law.

10. Building a structure inside one region only. Section 7.1: the count of jurisdictions rises and the count of perimeters does not. *Diagnostic:* Section 3.4's ceiling, computed before the entities are chosen.

11. Sizing a bridging leg on the concentration instrument. Section 7.2 shows the instrument is indifferent to it. *Diagnostic:* write down the capability being bought, and size the leg on that.

12. Holding rather than transiting in a two-perimeter jurisdiction. Section 6. *Diagnostic:* a rail is not a holding; the parameters are hop size, exposure duration, counterparty pre-screening and mid-transit failure handling, and the balance cap is a document.

9. Discussion

What follows from the results. Three things.

The first is that **a measurement that reports against the proposal being measured is the only evidence that the measurement is doing work.** Two of the three additions tested here lower the quantity they were offered to raise, and one of them was taken anyway on grounds the instrument cannot see. **That combination — a measured cost, consciously accepted, in exchange for a benefit the measure does not price — is the correct use of the instrument**, and a series in which every measurement flattered the design it accompanied would be a series of brochures.

The second is that **an addition inside an occupied bloc is not merely useless; funded out of an extra-bloc position it is harmful.** That is the general form of Curzi [2026]'s result — moving a residual 16.4 per cent from one Western jurisdiction to another gives blocs 56.4 / 30.0 / 13.6, a bloc-HHI of 0.426592 and N falling from 2.9412 to 2.3442 despite Western exposure dropping to 13.6 per cent — and of Curzi [2026]'s, where a converted global allocation reads naive HHI 0.215800 and 4.634 effective jurisdictions but bloc-HHI 0.680000 and $N = 1.470588$. **Four independent instances of one arithmetic is not a coincidence; it is what an index does when the units are correlated and the analyst is counting units.**

The third is the proposition of Section 3.4, and it is the one this paper would defend hardest. **The optimal transfer out of a bloc is exactly half of it, and the resulting ceiling is computable before any entity is considered.** On this structure the ceiling is 3.846154 against a required 4.172734. **A design conversation with an arithmetic ceiling below its own target should end at the arithmetic**, and the way to find out is one line rather than a year of negotiation.

What does not follow.

Nothing here is a legal conclusion. Every jurisdictional statement in Sections 4, 5 and 6 is described from the source manuscript and is uncited; Appendix B lists them. **A reader who takes a rule of law from this paper has taken it from the wrong document.**

The instrument prices the position and not the hazard. Section 6 states this and it bears restating, because the 3.615826 of Design A is the most quotable figure in the paper and the most likely to be quoted without the sentence beside it. **A share placed in a perimeter the structure does not otherwise touch raises the effective count whether that perimeter is benign or coercive, and the index has no term for the difference.**

The intra-bloc fracture risk is not priced anywhere in this paper. Section 3.3 and Section 4.2 both state it. A concentration index assumes bloc members fail together; it does not model them failing against each other, and the region under study has a dated recent instance. **That is an unmeasured overlay and it is disclosed rather than scored.**

The effective count measures independence, not capacity. A structure diversified on jurisdiction and concentrated on counterparty has moved its risk rather than reduced it, and Curzi [2026] measures how far the entity axis can understate the truth: entity-based exposure of 27.3 per cent against a currency share of 61.0 per cent and settlement volume through the same system of approximately 58 per cent, **an understatement by more than a factor of two.**

The gain is small and easily cancelled by a cost the index does not see. Curzi [2026] measures exactly that: at a 15 per cent annual hard-currency drag, a local-currency allocation of 25.17 per cent of protected capital sets h to exactly -0.500000, **cancelling the whole** $\eta \ln N = 0.377583$ **diversification gain**, and a 10 per cent allocation costs 0.150000, which is 39.73 per cent of the gain. **A gain of** 0.072279 **from a full centre is inside the noise of a currency decision**, and any argument that sizes a jurisdictional leg without pricing the currency it holds has mis-specified the problem.

The measurement is least informative exactly where a dominated structure sits [Golosov, 2010, Dunleavy and Boucek, 2003], and **a count that can be inflated will be** [Goodhart, 1975, Campbell, 1979]. Douceur [2002] is the formal statement that one party can present as many, so an unaudited count is worthless, and Lamport et al. [1982] is the bound on how many genuinely independent parties a protocol requires. **Both belong next to any count of units in this series**, and Section 7.1 is the Sybil problem wearing a passport.

The framework's own results bound this one. Curzi [2026] reports a doubling theorem verified *exactly* over all sixty-six pairs at $N = 12$ — $\mathrm{HD}_{\mathrm{ess}}(i, j) = 2\log_2(pq)$ and $G_{\mathrm{ess}} = 2G(pq) - 1$ for the essence ratio p^2/q^2 — which is the standard of verification a closed form in this framework is expected to meet, and the standard Section 10.9 applies to the half-share proposition. Curzi [2026] states the companion result that the sustaining frequency $f_{\min} = k\, e^{2c/\eta}$ is a genuine equivalence verified at twelve parameter sets, with $k = 0.483425732988414$ — **a DEFINED constant, exact by construction, whose fifteen figures are legitimate for that reason and for no other; attaching a physical unit to it is a separate and much stronger claim, badged POSTULATED there and not relied on anywhere in this paper.**

And this corpus's central limitation applies in full. No fit is reported here at all, and that is not a strength. Epstein [2008] is the standing statement that prediction is one of sixteen reasons to model and that a paper is entitled to say which of the other fifteen it claims; **this paper claims explanation of a mechanism and demonstration that a stated arithmetic suffices to produce a stated shape**, and claims neither prediction nor calibration.

10. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the compounding chain names what each step consumes. **If dropping a postulate leaves the result standing, it is not listed.**

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	exposure share of jurisdiction i	$[1]$	dimensionless	defined; non-negative and summing to 1 by P1
W, B_j	bloc shares	$[1]$	dimensionless	derived, $W = \sum_{i \in b} s_i$
x	share transferred into a new bloc	$[1]$	dimensionless	free variable
HHI	concentration index	$[1]$	dimensionless	derived
ρ_{ij}	correlation between shocks	$[1]$	dimensionless, in $[-1, 1]$	**assumed, not measured**
N	effective count	$[\#]$, a count	jurisdictions or blocs	derived as $1/(w'Rw)$
$\ln N$	surplus-term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
Q	protected capital	$[C]$	index units	defined; **the source supplies no operational unit**
η	conversion efficiency	$[1]$	dimensionless	assumed
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
h	headroom	$[C\,T^{-1}]$	index units per period	derived, $h = \eta \ln N - \delta Q - C$
receipts rate	annual settlement throughput	$[T^{-1}]$	fraction of Q per year	**constructed**
sweep period	interval between sweeps	$[T]$	years	**a design choice**
peak balance	transit exposure	$[1]$	fraction of Q	derived, receipts rate times sweep period
efficiency	gain per unit of exposure	$[C\,T^{-1}]$	headroom per unit share	derived

The sweep equation balances exactly: a rate in $[T^{-1}]$ multiplied by a period in $[T]$ gives a dimensionless fraction, so $18.0\%\ \text{yr}^{-1} \times (1/52)\ \text{yr} = 0.346\%$. **That is the only equation in this paper whose dimensions are fully determined by the source, and it is worth naming which one.**

The surplus equation balances only if $\eta \ln N$ carries $[C\,T^{-1}]$. Since $\ln N$ is dimensionless, either η carries $[C\,T^{-1}]$ or $\ln N$ is read as a rate. **The source is silent on which and this paper records the silence rather than resolving it by assertion.** The efficiency of Section 7.5 inherits that ambiguity, since it is h divided by a dimensionless share.

10.2 Significant figures and epistemic status

quantity	figures	status	licence
naive HHI 0.140194, 0.175802, 0.189002	6 dp	**exact**	exact arithmetic on exact constructed shares
effective counts 7.132973, 5.688217, 5.290949	6 dp	**exact to rounding**	reciprocals of exact values
bloc-HHI 0.351928, 0.355000, 0.340000, 0.341962	6 dp	**exact**	exact arithmetic on exact bloc shares
N 2.841490, 2.816901, 2.941176, 2.924302	6 dp	**exact to rounding**	reciprocals of exact values
h to six decimals	6 dp	**exact to rounding**	a logarithm of an exact value times an exact parameter
0.002014, 0.002869, 0.072279	6 dp	**exact to rounding**	differences of the above
3.97%, 3.21%, 1.2368	3–5 sf	**exact to rounding**	ratios of the above
$x^* = 0.200000$, $N = 3.846154$, $h = -0.028524$	6 dp	**exact**	closed form, Section 3.4
4.500%, 1.500%, 0.346%	3–4 sf	**exact to rounding**	divisions of a constructed rate
0.35% as adopted	2 sf	**a design choice**	the weekly peak rounded up from 0.346
$k = 0.483425732988414$ where it appears	15 sf	**DEFINED, exact**	cited from Curzi [2026]; **not used to produce any number here**

No figure in this paper is a measured quantity and therefore no uncertainty interval is attached to any of them. That is the correct treatment of exact arithmetic on stipulated inputs, and it is also the reason none of these numbers is evidence about a real structure.

The 0.35 per cent deserves its own line. It is a design choice rounded up from a computed 0.346 per cent, and the rounding is conservative in the direction that matters. **A reader recomputing Design B from 0.346 rather than 0.35 will get** $N = 2.965107$ **rather than** 2.965384, a difference of 0.000277 in the count, which changes no conclusion and is stated so that nobody has to wonder.

10.3 Limits and boundary behaviour

limit	behaviour	reading
$\rho \to 0$ within a bloc	$N \to$ the naive count	the naive index is the zero-correlation endpoint
$\rho \to 1$ within a bloc	$N \to$ the bloc count	the bloc index is the unit-correlation endpoint

limit	behaviour	reading
one bloc holding everything	$N = 1$, $\ln N = 0$, surplus term zero	no activity below bloc level raises it
$x \to 0$ in the half-share family	$N \to 2.941176$	the baseline; a token position buys a token amount
$x \to W$	$N \to 2.941176$	**transferring the whole donor bloc returns the baseline exactly**, because the two blocs have swapped labels
$x = W/2$	$N = 3.846154$, the maximum	the half-share result
$W \to 0$	the family collapses; no transfer is possible	a bloc with nothing in it cannot donate
$W \to 1$ (one bloc holds everything)	ceiling $\to 2$	splitting a monopolistic bloc in half gives exactly two
sweep period $\to 0$	peak balance $\to 0$	continuous sweeping eliminates transit exposure and is not available
sweep period $\to$ one year	peak balance $\to$ the whole annual receipt	no sweeping at all
$N \to \infty$	$dh/dN = \eta/N \to 0$	returns diminish but never turn negative — **a defect, since cost is not in the input term**

Three boundary readings are load-bearing. The fifth row is the one that makes the half-share result intuitive: transferring the entire donor bloc is exactly as good as transferring none of it, because the arithmetic cannot tell which bloc is which. **A design that moves everything out of a concentrated bloc has achieved precisely nothing**, which is a result worth having on its own.

The eighth row is the limiting case of Curzi [2026]'s Atlantic finding: a structure wholly inside one perimeter can reach at most $N = 2$ by splitting that perimeter in half, and it cannot split a perimeter at all, which is why the Atlantic count is 1.000000 and stays there.

The last row is a genuine defect of the surplus law as used here: because cost enters only through C, the model never says that adding a bloc is not worth it, and the decision to stop must come from outside the equation. Brooks [1975] supplies one bound — communication cost at order $n(n-1)/2$ inside a boundary — and **Section 3.4 supplies a sharper one on the benefit side**, which is why it is in this paper rather than in a note.

10.4 Invariance

Scale invariance in capital. Multiplying every exposure by a positive constant leaves every share and every effective count unchanged. Tested at four scales by construction: the six-, seven- and eight-jurisdiction vectors and the four-bloc vector. **Four scales is not many and Section 11 says so** rather than describing the instrument as scale-free without qualification.

Invariance under relabelling of blocs, and it is exactly the half-share result. The family of Section 3.4 is symmetric under exchanging the donor bloc with its offspring, which is why the maximum sits at the midpoint and why $x = 0$ and $x = W$ give the same answer. **The symmetry is not an artefact; it is the statement that a bloc has no identity beyond its share**, which is a limit on what the count can carry. Curzi [2026] identifies the same invariance as fatal in its own domain: the width statistic is invariant under relabelling and therefore does not determine the chord it is computed from.

Not invariant, and this is where the instrument works. The count is *not* invariant under partition of jurisdictions *within* a bloc: splitting one jurisdiction into two raises the naive count and leaves the bloc count untouched. **That asymmetry is the whole instrument.**

The sweep result is invariant under the receipts rate. The ratio of quarterly to weekly peak exposure is $52/4 = 13.0$ whatever the throughput, because the rate cancels. **That is a stronger statement than the constructed 18.0 per cent supports on its own**, and it is the reason H4 is stated as a ratio.

10.5 Analogy discipline

borrowing	category	justification
exposure as a portfolio; variance under a correlation matrix [Markowitz, 1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix, which is the premise the algebra requires
effective count as a numbers-equivalent [Adelman, 1969, Hill, 1973, Jost, 2006]	**1 — derivation**	$1/\mathrm{HHI}$ *is* the Hill number of order two
similarity-sensitive diversity [Leinster and Cobbold, 2012, Rao, 1982]	**1 — derivation**	the block-of-ones matrix is a special case of the cited general form
open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]	**1 — derivation**	the disclosure standard *is* the open-design requirement applied to legal rather than cryptographic structure
coupled-network fragility [Buldyrev et al., 2010]	**2 — shared form**	perimeter coupling is not shown to satisfy the percolation premises; only the shape of the result is used
robust-yet-fragile [Albert et al., 2000, Callaway et al., 2000]	**2 — shared form**	the tolerance asymmetry's shape is used; the degree-distribution mechanism is not claimed, and Doyle et al. [2005] is the reason it should not be
$\ln N$ as the entropy of a uniform distribution [Shannon, 1948]	**2 — shared form**	**information entropy, not thermodynamic entropy**; exact as arithmetic, carrying no thermodynamic content

borrowing	category	justification
the sawtooth transit balance	**2 — shared form**	a stock filled at a constant rate and emptied periodically is a sawtooth in any domain; nothing physical is imported
a bloc as a frozen region [Castellano et al., 2000]	**3 — analogy**	suggestive, used as motivation only; no phase-transition claim is made
normal accidents [Perrow, 1984]	**3 — analogy**	qualitative theory and framing, not a formal result; H1 is Perrow's result in a measurement frame
the half-share proposition	**not a borrowing**	elementary calculus on this paper's own definition; it is proved in Section 3.4 and consumes nothing external

No category-3 borrowing is used as evidence anywhere in this paper.

10.6 Measurement-theoretic status of the scored inputs

The evidence ladder of Section 4.1 is ordinal and is not summed. Its classes are ranked and the assignment identifies the strongest available class, which an ordinal scale licenses. **No numeric evidence score is computed and no threshold is arithmetic**, deliberately.

The two-column evidence table of Section 5 is nominal and is not counted. Five items on one side and four on the other is not four-to-five in favour of anything; the section says which row does the work and why, by argument. **A count of rows would be exactly the arithmetic the scale forbids.**

The de-identified capability comparisons of Section 4.3 and Appendix C are not totalled. Court depth, licence scope, market access and cost have no common scale.

The framework's treatment of Q as a ratio-scale quantity is not tested. Michell [1997] is the strongest available objection: a discipline routinely assumes quantitative structure without testing for it, and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all. **The conjoint conditions were not tested for Q, which is stated in unnamed index units, and the ratio-scale treatment is provisional.** Krantz et al. [1971] sets out what would have to hold and Stevens [1946] is the taxonomy. **The concentration instrument is untouched by this objection**, because exposure shares are ratios of capital rather than judgements, and Section 3.4's proposition is closed-form arithmetic.

This paper inherits the framework-level scalar-reduction limitation rather than restating it. Reducing a structure to one effective count and one h, and reducing a jurisdiction's coordination behaviour to a bloc label, are instances of the habit Curzi [2026] names once as a single limitation for the whole framework: where the source literature describes a phenomenon by several jointly varying features, the framework replaces it with one number and does arithmetic on the number. **The limitation is inherited here in full and is not met separately.**

10.7 Postulates

#	statement	status
P1	exposure shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$	DEFINITION
P3	for n equal shares of $1/n$, HHI $= 1/n$	ARITHMETIC
P4	the aggregate shock is $R = \sum_i w_i X_i$ with Var$(X_i) = 1$	DEFINITION
P5	Var$(R) = \sum_i \sum_j w_i w_j \rho_{ij} = w' R w$	ARITHMETIC
P6	units inside one coordination perimeter act on one decision	POSTULATED (H1)
P7	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-008)
P8	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P9	the three Gulf entries occupy one bloc; the contested bridging centre's assignment is run both ways	POSTULATED (P9a) and MODELLING POSITION (P9b)
P10	the constructed exposure vectors of Section 7.1	CONSTRUCTED
P11	renminbi receipts at 18.0 per cent of protected capital a year	CONSTRUCTED
P12	the transit balance is a sawtooth between sweeps	POSTULATED (H4's premise; its falsifier)

10.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	HHI^{-1} returns n exactly for n equal shares	ARITHMETIC
L2	L1	HHI^{-1} is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	it is the Hill number of order two — Hill [1973], Jost [2006]	CITED
L4	P4, P5	with $R = I$, Var$(R) =$ HHI; with R block-of-ones, Var$(R) = \sum_b W_b^2$	ARITHMETIC
L5	L4	naive and bloc indices are one variance under two correlation assumptions	ARITHMETIC

step	consumes	statement	status
L6	P2	$(W-x)^2+x^2$ is minimised at $x=W/2$, giving $W^2/2$	ARITHMETIC — the proposition of Section 3.4
R1a	L5, P6, P10	tempted: naive 0.140194 (7.132973); bloc 0.351928 (2.841490)	ARITHMETIC on CONSTRUCTED inputs
R1b	R1a, P7, P8	naive $+34.81\%$, effective -3.39%, h from -0.122417 to -0.134485	ARITHMETIC
R5	L5, P6, P10	as built: naive 0.175802 (5.688217); bloc 0.355000 (2.816901)	ARITHMETIC on CONSTRUCTED inputs
R3	L5, P9b	stress: bloc 0.341962, $N=2.924302$, $h=-0.124430$, cost 0.002014; the London variant is identical on N and h	ARITHMETIC
R2a	L5, P10	Design A: bloc 0.276562, $N=3.615826$, $h=-0.050138$	ARITHMETIC
R4	P11, P12	peaks 4.500%, 1.500%, 0.346%; ratio $52/4=13.0$	ARITHMETIC on CONSTRUCTED inputs
R2b	R2a, R4	Design B at $x=0.0035$: $N=2.965384$, $h=-0.119548$; 3.97% of the gain for 3.21% of the exposure	ARITHMETIC
R6	L6, P7, P8	ceiling at $x=0.200000$: bloc 0.260000, $N=3.846154$, $h=-0.028524$ $<$ break-even	ARITHMETIC
CR	R1a, R5, R2a	the chapter's own subject jurisdictions fail the test it applies	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. Only P6, P8, P9 and P12 are POSTULATED. **P12 is the one carrying an empirical premise and it is the one H4's falsifier names** — that the transit balance is a sawtooth. **A reviewer who does not accept P12 loses R4 and keeps R2a, R3, R5 and R6**, because the bloc arithmetic does not depend on how the 0.35 per cent was derived.

L6 is the only step in this chain that is new to this paper, and it is elementary. It consumes no citation, no postulate and no constructed input; it is a one-line minimisation. **A chain whose novel step is a line of calculus is a chain a reviewer can dispose of in a minute, and that is the intention.**

10.9 Cross-checks performed

- The eight tempted squares were summed independently and reproduced 0.140194; the seven as-built squares reproduced 0.175802; the six designed squares reproduced

0.189002.

- Every bloc vector was checked to sum to 1.000000 before squaring: $0.442 + 0.300 + 0.258$, $0.450 + 0.300 + 0.250$, $0.291 + 0.300 + 0.300 + 0.109$ and $0.3965 + 0.300 + 0.300 + 0.0035$.
- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on all three jurisdiction vectors: $0.040000 \le 0.140194 \le 0.200000$, $0.084681 \le 0.175802 \le 0.291000$ and $0.084681 \le 0.189002 \le 0.291000$.
- The stress cost was checked in both directions: $0.377583 - 0.375570 = 0.002013$ and $0.124430 - 0.122417 = 0.002013$, printed as 0.002014 from the unrounded values $0.1244305 - 0.1224167 = 0.0020138$.
- The half-share result was checked three ways: at the closed form $x^* = W/2 = 0.20$; by direct evaluation of the index at $x = 0.19$, 0.20 and 0.21, which returns 0.260200, 0.260000 and 0.260200, confirming a minimum; and by the end-point identity $\text{HHI}(0) = \text{HHI}(W) = 0.340000$.
- The efficiency ratio was checked two ways: $0.819674/0.663107 = 1.236110$ from the computed gains, and $3.97/3.21 = 1.236760$ from the rounded percentages. **The two agree to four significant figures**, which is the arithmetic cross-check of Section 7.5.
- The sweep ratio was checked against its closed form: $(18.0/4)/(18.0/52) = 52/4 = 13.0$ exactly, independent of the receipts rate.
- Design B was recomputed from the unrounded 0.346% rather than the adopted 0.35%, giving $N = 2.965107$ against 2.965384, a difference of 0.000277.
- The two source discrepancies of Section 7.7 were quantified at 0.000001 in the stress headroom and 0.000183 in the base-case headroom.

11. Limitations

Every number in this paper is computed on constructed inputs and none is a measurement of a real structure. The exposure vectors, the receipts rate, the sweep schedule and the two designs are all **CONSTRUCTED** or described from the source manuscript, and are labelled as such at each point of use. **No first-party measurement of any real system appears anywhere in this paper.** That is this corpus's central limitation, stated in the terms Curzi [2026] states it in — of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated one, and 0 carry a first-party measurement — and a reviewer would be right to press on it before pressing on anything else.

The intra-bloc fracture risk is named and not priced. Sections 3.3 and 4.2 both state it: a concentration index assumes bloc members fail together and does not model them failing against each other, and the region under study has a dated instance lasting three and a half years. **The as-built structure holds entities in two members of that region and this paper attaches no number to the resulting exposure.** That is the largest unmeasured item here.

The bridging centre's assignment is contested and the paper does not settle it. Section 5 sets out the evidence both ways and Section 7.2 runs the arithmetic both ways. **A reader who assigns it to the Western bloc should read $N = 2.924302$ off the table and proceed**, and the fact that the difference is 0.002014 is itself the finding rather than a reason to stop worrying.

H4's falsifier was not tested. No non-sawtooth settlement pattern was constructed, so the premise that sweep frequency controls the exposure is asserted rather than examined against its alternative. **A structure whose receipts must be held to meet a matching obligation would falsify it, and none was modelled.**

The correlation is assumed, not measured. $\rho = 1$ within a perimeter is the conservative end of a family and no correlation was estimated from data. The evidence offered in Section 4.1 is a record of shared mechanisms rather than a measurement of correlation.

Every parameter in the surplus law was chosen. $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ are test parameters fixed in advance and not estimates of any real position, so the break-even $N = 4.172734$ — and therefore the whole force of Section 7.5's ceiling result — is a property of the chosen set. **Change C and the ceiling result changes with it**, and Section 7.5's conclusion should always be quoted with its parameters.

The half-share proposition is arithmetic and carries no empirical content. It bounds a design space; it says nothing about whether any particular perimeter exists, is reachable, or would be independent in the sense the correlation assumption requires. **A ceiling on what a count could be is not evidence about what a structure is.**

The counterparty and currency axes are not measured here. Curzi [2026] measures the mismatch between the entity and currency axes and Curzi [2026] prices the currency drag; this paper measures the jurisdiction axis alone and its conclusions should not be read as statements about the structure's total exposure. **A structure is only as diversified as its most concentrated axis, and this paper measures one of four.**

The reflexive specification is not identified. Section 1 states this and names the remedy — stipulate the reference group and defend the stipulation, following Brock and Durlauf [2001] — and the price is that every bloc assignment here is a modelling position rather than an identified empirical result [Manski, 1993, Shalizi and Thomas, 2011].

The Lucas critique applies to this framework's own parameters and is not answered. Lucas [1976] is the general statement; the specific form is that this framework asserts systems change behaviour when modelled and observed, and then treats η, δ and the bloc assignment as stable under exactly that response. MacKenzie and Millo [2003] documents the loop happening in the field with dates and price data, which is an existence proof for the mechanism and not a defence of the parameters.

The functional form of the surplus input is underdetermined. Latané [1981] proposes a power law with exponent below one and Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics with no psychological assumption at all. **Nothing here discriminates between them, and the logarithm is used because it is the form this framework carries.** Peters is the stronger of the two available warrants and is cited as such.

Small-sample bias in the effective count is not corrected [Chao et al., 2014]. A six-, seven- or eight-element vector is a small sample for a low-order diversity estimator, and the paper does not resolve whether these vectors are samples or complete censuses.

Scale invariance was checked at four scales only (Section 10.4).

The instrument is least informative in the dominated-unit regime [Golosov, 2010, Dunleavy and Boucek, 2003].

No statistical test was run and no p-value appears, because there is no sample and no null. Every rate is an exact ratio of exact constructed amounts, and **no claim of "no difference" is made from any non-significant result** — the indifference of Section 7.2 is an exact algebraic identity, not a failure to reject.

No scaling, power-law or heavy-tail claim is made and the Clauset–Shalizi–Newman procedure was therefore not run [Clauset et al., 2009]. Any restatement reaching for such a claim must run it first and read Broido and Clauset [2019].

No out-of-sample validation, matched null, information criterion or effect size with an interval appears, because no model was fitted. Bruch and Atwell [2015]'s calibration-and-validation checklist is unmet in every row.

11.1 Rigour checks not met, listed by name

1. **The intra-bloc fracture exposure is named and not priced** (Sections 3.3, 4.2).
2. **H4's falsifier was not tested**; no non-sawtooth settlement pattern was constructed (Section 7.4).
3. **Conjoint measurement conditions untested** [Luce and Tukey, 1964], so the ratio-scale treatment of Q is provisional and Michell [1997]'s objection is conceded rather than answered.
4. **The framework-level scalar-reduction limitation is inherited** [Curzi, 2026] and not met separately.
5. **The reflection problem is stated and not solved** [Manski, 1993].

6. **The Lucas critique applied to this framework's own parameters is unanswered** [Lucas, 1976].
7. **The functional form of the surplus input is undiscriminated** [Latané, 1981, Peters and Gell-Mann, 2016].
8. **Small-sample bias in the effective count is uncorrected** [Chao et al., 2014].
9. **No out-of-sample test, matched null, information criterion or interval** [Bruch and Atwell, 2015].
10. **No first-party measurement of any real system** [Curzi, 2026].
11. **The dimension of η is unresolved** because the source is silent (Section 10.1).
12. **Three of the four axes the method requires are not measured here** (Section 11).
13. **Every legal and jurisdictional statement in Sections 4, 5 and 6 is uncited** (Appendix B).

12. Conclusion

This paper tests three proposed additions against the concentration instrument, reports that two of them fail on the framework's own arithmetic, and establishes one proposition that bounds all three. The following statements are the fixed text of those results.

R1. Adding Saudi Arabia and Qatar to a structure already holding a Gulf position raises the naive effective jurisdiction count from 5.290949 to 7.132973, an improvement of 34.8 per cent, while the effective bloc count falls from 2.941176 to 2.841490, a deterioration of 3.4 per cent: **more jurisdictions, less independence.** The mechanism is exact — the additions occupy an already-occupied bloc and were funded partly out of a different bloc.

R2. The comparison that decides the third case: **Design A**, a full centre at 10.9 per cent of exposure, gives $N = 3.615826$ and $h = -0.050138$; **Design B**, a capped transit position at 0.35 per cent, gives $N = 2.965384$ and $h = -0.119548$, **capturing 3.97 per cent of A's measured gain for 3.21 per cent of A's exposure** — a ratio of 1.2368, so the capped position buys 23.61 per cent more headroom per unit of perimeter exposure.

R3. The bridging slot is indifferent on the bloc axis: **10.9 per cent held in the bridging centre treated as Western, or in the Western centre itself, gives identical blocs 29.1 / 30.0 / 40.9, bloc-HHI** 0.341962**,** $N = 2.924302$ **and** $h = -0.124430$ **— a stress cost of** 0.002014 against the bridge base case, while the naive counts differ by 0.841640. **The leg must be justified on axes the index does not measure.**

R4. The 0.35 per cent transit figure is derived from sweep frequency rather than assumed: **renminbi receipts at 18.0 per cent of protected capital per year peak at 4.500 per cent quarterly, 1.500 per cent monthly and 0.346 per cent weekly, and the weekly peak is adopted.** The quarterly-to-weekly ratio is $52/4 = 13.0$ exactly and is independent of the receipts rate.

R5. The variant actually built — declining the family-office vehicle and adding only a regional headquarters justified by contracted revenue — reads **naive HHI** 0.175802 **(**5.688217 **effective jurisdictions) and bloc-HHI** 0.355000 **(**2.816901 **effective blocs), below the** 2.941176 **baseline it was proposed to improve.** It was taken anyway, at a measured cost of 0.124275 in effective bloc count, because it was justified by revenue and not by resilience. **The instrument is a measurement, not a veto; what it does is make the cost visible and force it to be paid consciously.**

Counter-result. The subject jurisdictions of this paper fail the test it applies: Gulf additions raise the naive count by 34.8 per cent while lowering the effective bloc count by 3.4 per cent, and the bridging leg's measured bloc contribution is 0.002014 **— effectively nil.** And the instrument prices the position rather than the hazard: a share placed in a perimeter the structure does not otherwise touch raises the effective count whether that perimeter is benign or coercive, and the index has no term for the difference.

One further result is established as method rather than as measurement. Moving a share x out of a bloc of share W into a new bloc gives $\mathrm{HHI}(x) = (W - x)^2 + x^2 + \sum_{j \geq 2} B_j^2$, which is minimised at $x^* = W/2$. **The optimal transfer is exactly half the donor bloc, and transferring all of it is exactly as good as transferring none.** For $W = 0.40$ with the other blocs at 0.30 and 0.30, the ceiling is **bloc-HHI** 0.260000**,** $N = 3.846154$ **and** $h = -0.028524$**, against a break-even**

count of 4.172734 at the stated parameters. **No transfer of exposure into a fourth perimeter, of any size and at any placement, brings this structure to the build threshold** — a design-space bound obtained in one line that mentions no jurisdiction at all.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the exposure vectors, the receipts rate, the sweep schedule, the two designs and the entity dispositions — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-057_fig01.py` through `figs/src/CCP-057_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional and constitutional descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative, treaty and standard-setting material only; it contains no statutes, regulations, court rules, registry documents, executive orders or case reports for any individual jurisdiction. Appendix B lists the claims affected. **Any reader relying on those descriptions must verify them against the official sources and record the date of that verification.** The banking and currency effects of the episode described in Section 4.2 are specifically marked for verification and are not characterised quantitatively here.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. All persons, entities, holdings and arrangements described are constructed for the purpose of exercising the measurement. **Section 4.2 describes a political event; it is described as a structural fact about coordination and no characterisation of any state's conduct is offered or intended.**

Preregistration

The parameter set $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ and the break-even criterion $N \geq e^{0.5/0.35} = 4.172734$ were fixed by Curzi [2026] before the measurements reported here and are not adjusted anywhere in this paper. **No structure or variant measured in this paper clears**

that break-even, and Section 7.5 establishes that none in this family could, which is reported in the same language a clearance would have received. The falsifiers attached to H1 through H5 were stated before the corresponding measurements were run; **H4's falsifier was not tested, and Section 7.8 reports that rather than treating the hypothesis as passed.** No other element of this paper was preregistered.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions, licensing regimes, headquarters programmes, arbitral seats and settlement arrangements for the purpose of measuring concentration. No recommendation is made in respect of any particular person, asset, structure, jurisdiction or arrangement. Constitutional arrangements, national-security legislation, licensing scope, headquarters incentive conditions, substance requirements, treaty anti-abuse provisions, exchange obligations and clearing arrangements all change and vary by jurisdiction and by activity; **every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.**

Appendix A. The bloc-addition reporting standard

The jurisdiction-axis reporting standard is stated by Curzi [2026] and extended by Curzi [2026] and Curzi [2026]. This appendix states what a *proposed addition* additionally requires, because the three cases here differ from one another chiefly in what was reported before the decision rather than after it.

```
 1  the bloc the addition would occupy, named, with its evidence
    class
 2  the position the addition is FUNDED FROM, and its bloc
 3  the naive count and the effective bloc count BEFORE and AFTER,
    both printed
 4  the donor bloc's share W and the ceiling W^2/2 + sum B_j^2,
    computed BEFORE any entity is chosen
 5  the gain in h, and the exposure placed inside the new perimeter,
    as a ratio
 6  the same measurement under the contested assignment, if any,
    with the stress cost printed
 7  the capability being bought, written down separately from the
    measurement, in one sentence per item
 8  for any transit position: the receipts rate, the sweep period,
    the peak and average balance, and the cap as a document
 9  the intra-bloc fracture exposure, named, and stated as
    unpriced if it is
10  the date, and the diff against the previous measurement
```

Item 4 is the item this paper adds and it is the cheapest item on the list. It costs one line of arithmetic and it disposes of any proposal whose ceiling is below its target before anybody reads a term sheet. **Item 2 is the item whose omission produced Section 7.1's result**: an addition inside an occupied bloc is neutral, and the same addition funded out of an extra-bloc position is harmful, and only item 2 distinguishes them.

Item 7 is not optional and is not a formality. Section 7.2 shows a leg whose measured bloc contribution is 0.002014 and whose capability contribution is substantial. **A leg justified on the measurement is a leg sized on the measurement, and it will be defended on the wrong grounds the first time its fee is questioned.**

Appendix B. Claims requiring verification against primary sources

The following statements rest on legal, constitutional or regulatory detail that changes, and **none is cited to the bibliography, which contains no primary sources for any individual jurisdiction**. They are reproduced from the source manuscript and require confirmation with counsel in the relevant jurisdiction before any reliance. **Record the date of each confirmation**; a statement of a regime without a date is not a statement of that regime.

1. The establishing law of the non-territorially-confined financial centre described in Section 4.3, its licensing scope, and the extent to which a licensed entity may operate outside the centre's own district.
2. The headquarters programme described in Section 4.3: its licensing conditions, the mandatory activities, the procurement rule that conditions access on presence, the incentive scope and its duration.
3. **The dates and terms of the regional rupture described in Section 4.2**, and in particular **the banking and currency effects, which are asserted here only qualitatively.** The offshore-currency movement in particular must not be reproduced without contemporaneous market data.
4. The corporate income tax and religious levy treatment described in the source for the jurisdictions of Section 4, and the interaction between them.
5. The arbitration and dispute-resolution provisions relied on in Section 7.6, including the institutional rules and the enforceability of an award in each relevant jurisdiction [United Nations, 1958, United Nations Commission on International Trade Law, 1985].
6. The reception statute described for the bridging centre in Section 5, its schedule of retained legislation and its current form.
7. The commercial court with an opt-in jurisdiction described in Section 7.2, its constitution, and the enforcement route for its judgments including participation in the relevant judgments conventions [Hague Conference on Private International Law, 2005, 2019].
8. The fund vehicle described in Section 7.2, its statutory segregation, and the regulatory status required of its manager.
9. **The March 2022 measures described in Section 5**, their legal basis, their scope, and whether they were adopted with or without a Security Council resolution.
10. The exchange and reporting positions of every jurisdiction in Sections 4, 5 and 6, including first-exchange dates and the model of any bilateral arrangement.
11. The constitutional frame described in Section 6, the national-security legislation of 2020 and 2024, the interpretive power, the judge-designation power, and the 2021 revision of the executive selection system.
12. **The legislation and executive order of 2020 described in Section 6**, the preferential treatments suspended or eliminated, the bilateral agreements suspended, and the current status of each.
13. The linked exchange rate arrangement described in Section 6 and its current terms.
14. The clearing-system participation and offshore-currency capability described in Sections 5 and 6, and **the extent to which participants in the second clearing system use the first system's messaging layer**, which Curzi [2026] identifies as the decomposition that determines whether a second rail is real.
15. The treaty anti-abuse provisions referred to in failure mode 5, including any principal-purpose test.
16. The nominee-shareholding prohibition referred to in the source for the operating jurisdiction, and its enforcement.
17. All exposure shares, receipts rates, sweep schedules and design variants in this paper are constructed. **They are not observed allocations, bank statements or treasury policies, and no real schedule was used to produce them.**

All numerical results in this paper were computed from the stated inputs at full precision

and rounded only for printing, and the places where a printed value in the source differs from the exact computation are reported in Section 7.7 rather than harmonised.

Appendix C. Condensed assessment, de-identified

No total is computed: the items are heterogeneous and no common scale exists on which they could be added (Section 10.6). Every characteristic below is described from the source manuscript and is uncited (Appendix B). Jurisdictions are de-identified in the capability table because that table ranks them on legal capability the bibliography cannot support; they are named where they carry a bloc assignment with its evidence, because there the assignment is the argument.

Bloc assignment and evidence, by jurisdiction.

jurisdiction	bloc	strongest evidence	job
United Arab Emirates	**BRIDGE**	outside the Western designation apparatus; own listing decisions; dual-rail access	**HOLDING** and apex; never settlement
Saudi Arabia	**BRIDGE, same bloc**	common regional assessment body; common peer review; shared correspondent policy; pegged currency	**OPERATING**, market access only; **never holding**
Qatar	**BRIDGE, same bloc**	identical on every operative test	**OPERATING** where there is domestic business; otherwise nothing
Singapore	**BRIDGE in commercial function, Western-leaning under stress**	the contested assignment of Section 5, run both ways in Section 7.2 at a cost of 0.002014	**OPERATING**: treasury, fund wrapper and contracting; **never the apex**
Hong Kong	**inside two perimeters and independent of neither**	central legislation and interpretive power on one side; dollar correspondent dependency and a linked rate on the other	**TRANSIT ONLY**, capped by a written balance limit and a weekly sweep

Ranked capability, de-identified.

requirement	best fit	why
a common-law licence usable across a national economy	Gulf centre A	the licence is not territorially confined, which converts an enclave into a regime

requirement	best fit	why
access to a very large state customer conditioned on presence	Gulf centre B	a headquarters programme that is a market-access requirement rather than a tax incentive
a fund wrapper with statutory segregation and a regulated manager	Asian centre A	the vehicle, the manager regime and the custody options exist together
a commercial court with an opt-in jurisdiction and a common-law bench	Asian centre A	the court, the arbitral institution and the mediation centre are co-located
settlement in the second major currency at depth	Asian centre B	the deepest offshore capability in that currency, and no substitute at that depth
an arbitral seat recognised on both sides of the friction line	Asian centre B	**bought through a clause at no balance-sheet cost**, which is Design B's central move

The item that decides every row of the first table is the correspondent relationship, because it is the thing that can be withdrawn in a week. **No jurisdiction in the table can legislate itself a different one**, which is why the bloc assignments are the least contestable calls in the paper and why the contested one costs only 0.002014 to get wrong.

Chapter 58

Pricing an Uncertain Bloc Call: AIFC Option Value, Thailand's Share of the Gain, and the GIFT City Corridor

Abstract. We price three jurisdictional positions whose value depends on facts that cannot be settled in advance. The Astana International Financial Centre is treated as a bet on a bloc classification: if Kazakhstan is a genuinely separate coordination perimeter the effective bloc count rises from 2.941176 to 3.174603 and the surplus improves by 0.026731; if the call is wrong it falls to 2.898551 and the surplus loses 0.005110. Setting E[dh] = 0.0318401p − 0.0051096 to zero gives a break-even probability of 16.05 per cent, and adding an incremental maintenance cost c gives p = (c + 0.0051096)/0.0318401, so the position is worth nothing at any probability once c exceeds 0.0267305 — 8.9 per cent of the group's entire maintenance budget. The decisive argument is therefore the invoice and not the probability. Thailand carries 18.2 per cent of the designed structure and accounts for 79.74 per cent of the whole diversification gain; relocating its operating leg to the United Kingdom adds 66.24 index units of cost at 0.004545 storage-law units each, raising C to 0.601091 and driving h to −0.423508. The Indian corridor is measured honestly against itself: removing it gives N = 2.5546 and h = −0.136733, so its 11.8 per cent contributes 0.014317, only 3.79 per cent of the total gain, and moving the same share to Thailand leaves the bloc count unchanged at 2.9412 while dropping the naive count to 4.3112. A recomputation of the source's own arithmetic corrects its published net-contribution figure from 0.014316 to 0.014317, and three further discrepancies in the source are printed rather than silently repaired.

Keywords: option value; bloc classification; break-even probability; operating substance; corridor exposure; dwell time; job concentration

Series: D. Structure and Resilience **Paper:** CCP-058

1. Introduction

Three decisions about a cross-border holding structure cannot be settled by argument because each of them turns on a fact that is not available when the decision has to be made. Whether a given jurisdiction is a genuinely separate coordination perimeter is a forecast. Whether an operating leg should sit where its inputs are cheap or where its counterparties are familiar is a cost comparison nobody runs. Whether a corridor entity earns its keep is a counterfactual

that is almost never computed, because the gross benefit is the number that gets presented and the maintenance cost is the number that does not.

This paper prices all three against one instrument. The instrument is the concentration measurement of Curzi [2026] — HHI as the sum of squared exposure shares and the effective count as its reciprocal, with a naive four-jurisdiction count of 3.41 collapsing to exactly 1.00 once coordination blocs are recognised, and a redesigned six-jurisdiction structure reaching a bloc-HHI of 0.340000 and 2.941176 effective blocs with Western-perimeter exposure falling from 100.0% to 30.0%. Everything below is that measurement coupled to the surplus law $h = \eta \ln N - \delta Q - C$ and then differenced.

The paper's contribution is a method for deciding a marginal position, and four measurements made with it.

First, an uncertain classification is converted into a threshold. A bloc call that cannot be settled is priced as a bet. Where a candidate jurisdiction's inclusion raises the effective bloc count on one classification and lowers it on the other, the two classifications bracket the outcome, and the expected change in the surplus balance is linear in the classification probability: $E[\Delta h] = (G + L)p - L$. On the constructed structure carried through Series D, the right call gives $G = +0.026731$ and the wrong call $L = 0.005110$, so $E[\Delta h] = 0.0318401p - 0.0051096$ and the break-even probability is $p^* = 0.160476$. **The move that matters is not the estimate; it is the replacement of an argument nobody can settle with a threshold anybody can assess.**

Second, the threshold is then shown not to be the binding constraint. Adding an incremental maintenance cost c gives $p^* = (c + L)/(G + L)$, and p^* reaches 1 at $c = 0.0267305$ — **8.9102% of the whole structure's maintenance budget of** $C = 0.30$**.** Above that cost the position is value-destroying at every probability, including certainty. **The decisive argument for a small marginal jurisdiction is the invoice, not the geopolitics**, and that is a general property of small positions rather than a fact about any one place: structure cost is close to fixed and structural benefit is proportional to size.

Third, the cost of operating substance is measured against the whole diversification gain and is found to exceed most of it. On a constructed relative-cost model, relocating the operating leg from the low-cost non-aligned site to the high-cost Western one adds 66.24 index units at $0.30/66 = 0.004545$ surplus units each, raising C to 0.601091 and driving h from -0.122417 to -0.423508. The deterioration, 0.301091, is **79.74% of the entire** $\eta \ln N = 0.377583$ **that the jurisdictional redesign bought**, and the effective bloc count does not move at all. A structure that arranges its blocs well and then sites its substance expensively has spent the gain before collecting it.

Fourth, a corridor leg is measured against its own counterfactual and its bloc-count case fails. Moving the corridor jurisdiction's 11.8% share to the other member of the same bloc leaves bloc-HHI at 0.340000 and N at 2.941176 to six decimal places, while the naive jurisdiction count falls from 5.290949 to 4.311200. Moving the share out of the bloc entirely gives bloc-HHI 0.391448, $N = 2.554618$ and $h = -0.136733$, so the leg's gross contribution is 0.049317 and, after its own 0.035000 of maintenance, its net contribution is 0.014317 — **3.79% of the total diversification gain.** Positive, real, and thin enough that one additional function on the same vehicle turns it negative.

The three results have one shape. In each case a quantity that looks like the argument — the classification, the bloc arrangement, the gross diversification benefit — is dominated by a quantity that looks like an administrative detail: the fee, the wage bill, the marginal entity cost. That is not a rhetorical observation. It is what the arithmetic says, and it says it three times.

What the paper does not do is estimate any of the probabilities it prices. The threshold $p^* = 0.160476$ is exact given the share vector; whether the real probability exceeds it is a judgement this paper does not make and cannot support, because the bibliography contains no primary sources for any individual jurisdiction. Section 13 records that gap and Appendix A itemises it.

Positioning. The collapse result on which everything here depends — several jurisdictions inside one perimeter behaving as one — is not new machinery and should not be presented as

such. A small correlated shift producing a discontinuous collective outcome is the threshold-and-tipping mechanism: Granovetter [1978] establishes that the distribution of individual thresholds rather than the mean decides whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate segregation. Schelling [1978] generalises the point. **The strongest available warning against reading an individual-level parameter straight into an aggregate is exactly what a bloc assignment does**, and naming that lineage places the result inside an established literature rather than outside one. Castellano et al. [2000] supplies the closest formal analogue of a bloc — the same interaction that raises local agreement freezes global diversity into non-interacting regions — and a bloc, in that vocabulary, is a frozen region.

The reflexive loop and its identification problem. The bloc assignment is a forecast that conditions the behaviour it forecasts, which is the reflexive loop $T(x) = W(x, M(x))$ of Curzi [2026], whose founding reframing is that comfort is the felt total of present costs so that the present state is a local minimum of the comfort landscape by definition rather than by luck. **That loop carries an identification problem, and this paper states it here rather than in a footnote.** Manski [1993] proves that a linear-in-means reflexive specification — a group's mean behaviour influencing its members while the members constitute the mean — is **not identified from observational data**: the endogenous social effect cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] reinforce it: influence and selection are generically confounded in observational network data. **No amount of observation of jurisdictional behaviour could therefore confirm a bloc assignment derived reflexively.** The remedy adopted here is the fourth of the four known ones — **the reference group is stipulated and the stipulation defended**, which is the route Brock and Durlauf [2001] shows can be made rigorous — and its price is that every bloc assignment in this paper is a **modelling position and not an identified empirical result**. Section 3.7 states the price where the assignment enters.

A note on what half of this material is. The source manuscript from which this paper is converted is, in substantial part, a descriptive comparative survey of three jurisdictions. That survey is retained as context in Section 4 and in Appendix A, and it is **not** the paper's contribution. **The Results and the Conclusion are about the four measurements and nothing else.** A comparative survey that has not positioned itself against the existing comparative-law literature is a literature review, and this paper does not offer one.

2. Hypotheses

Five hypotheses are stated, each in a form that could be wrong and each with its falsifier attached, in the sense required by Platt [1964]'s strong inference. Meehl [1967] is the relevant warning: a directional prediction is cheap, and the defensible response is a point prediction with constants attached, which is what H1, H2 and H4 do. **One of the five is reported in Section 8 as not met.** Statements that nothing could falsify are listed after the hypotheses and labelled as definitions or modelling choices rather than counted among them.

H1 — the invoice hypothesis. For a small marginal jurisdictional position whose bloc classification is uncertain, the binding constraint is the position's own maintenance cost and not the classification probability. *Predicted:* with $G = 0.026731$ and $L = 0.005110$, the break-even probability is $p^* = L/(G + L) = 0.160476$ at zero incremental cost and reaches 1.000000 at an incremental cost of $c = 0.0267305$, which is 8.9102% of $C = 0.30$; at $c = 0.010$, one third of that ceiling, the required confidence is already 0.474547. *Falsified by:* a measured all-in annual maintenance cost for a small ring-fenced holding vehicle below 0.005 in surplus units — 1.7% of C — at which the break-even probability stays under 0.32 and the classification question, not the invoice, would decide the position.

H2 — the substance-cost hypothesis. The siting of operating substance carries more of the design's economics than the jurisdictional arrangement does. *Predicted:* on the constructed cost model, relocating the operating leg to the highest-cost candidate raises C by 0.301091 and

consumes 79.74% of the entire $\eta \ln N = 0.377583$ diversification gain, while leaving N at 2.941176 exactly. *Falsified by:* a measured relative cost index for the same substance in the destination jurisdiction below 2.297943, at which the relocation would consume less than half the gain, or below 1.000000, at which it would be free.

H3 — the corridor hypothesis. A second jurisdiction in an existing bloc raises the effective bloc count. *Predicted:* adding the corridor jurisdiction at 11.8% of exposure raises N above the 2.941176 it would otherwise take. *Falsified by:* a reallocation of that share to the other member of the same bloc that leaves N unchanged. **This is the hypothesis reported as not met.**

H4 — the marginal-leg hypothesis. A jurisdiction leg contributes to the surplus balance only after clearing its own maintenance cost, and the net figure rather than the gross one should govern the decision. *Predicted:* the corridor leg's gross contribution is $0.377583 - 0.328266 = 0.049317$ and its maintenance cost is 0.035000, so its net contribution is 0.014317, which is 3.79% of the total diversification gain and less than a third of the gross figure. *Falsified by:* a marginal all-in entity cost materially below 0.035 in surplus units, at which the gross and net readings would not diverge enough for the distinction to change any decision.

H5 — the dwell hypothesis. A corridor's exposure is set by how long value rests inside the perimeter and not by throughput, counterparty count or hop count. *Predicted:* exposure equals dwell divided by the year, giving 0.27% at one day, 1.92% at seven, 8.22% at thirty, 24.66% at ninety and 49.32% at one hundred and eighty, for the same corridor and the same annual volume. *Falsified by:* an exposure that varies with throughput or with the number of intermediaries at fixed dwell. Curzi [2026] reports the same invariance on the settlement axis, where the transit-loss model $E[\text{loss}] = V(1-e^{-\lambda t})(1-r)$ is invariant to hop count at USD 68,000 whether the value crosses one hop or eight.

Not hypotheses, and labelled as such. Four statements in this paper are not falsifiable as they stand, and each is named here for what it is.

- *The job-concentration diagnostic* $S = \sum_j v_j^2$ with effective jobs $1/S$ is a **definition**, and the 2.00 band boundary is an algebraic property of a vector on the simplex, not a finding. Its empirical content is entirely in whether a measured job vector is the entity's real one.
- *The logarithmic form of the input side*, $\eta \ln N$ rather than ηN, is a **modelling choice** carried from Curzi [2026], whose surplus functional $f(u) = \ln(1 + (N-1)u)$ is uniquely characterised by angle-only dependence, vanishing at parallel, an affine effective count and normalisation. It is not tested here and Section 3.9 states what would discriminate it.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice**, fixed in advance of every measurement below so that no criterion is adjusted to fit, which is the preregistration discipline of Nosek et al. [2018] applied to an engineering calculation.
- *The bloc assignments themselves* are **stipulated reference groups**, defended by the perimeter test carried from Curzi [2026] and not identified from data [Manski, 1993, Brock and Durlauf, 2001].

3. Method

3.1 The instrument carried in, and which effective count it is

The concentration instrument is not restated here; Curzi [2026] establishes it. What must be restated, because the corpus runs two quantities under one name, is **which effective count this paper uses**.

Throughout this paper the effective count is HHI^{-1}, the reciprocal of the sum of squared shares. **That quantity is the Hill number of order two.** Hill [1973] defined the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types that would give the observed value of the underlying index; at $q = 2$ this is $(\sum_i p_i^2)^{-1}$, which is HHI^{-1} ex-

actly. Jost [2006] is the statement that entropies are not diversities and that their numbers-equivalents are, and Jost [2007] extends the correspondence to partitioned data, which is what a bloc collapse is. The same arithmetic was reached independently by Simpson [1949] in ecology and by Laakso and Taagepera [1979] in political science, and the numbers-equivalent reading of the concentration index itself is Adelman [1969]'s. The index's own history runs through Hirschman [1945] and Herfindahl [1950], with Hirschman [1964] the priority note, and its regulatory thresholds are stated in the merger guidelines [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and HHI^{-1} is also the exponential of the Rényi entropy of order two [Rényi, 1961].

The corpus's other effective count, the affine $N_{\text{eff}} = 1 + (N-1)u$ of Curzi [2026] and Curzi [2026c] — where $u = 1 - (x \cdot y)^2$, the surplus is $S = \ln N_{\text{eff}}$, a hundred-person department at $u = 0.05$ has an effective count of 5.95, and the affine form is badged a design axiom rather than a derived result — is not a Hill number of any order and carries no external support. It is a linear interpolation between 1 and N. This paper does not use it, refers to it only by name, and states the distinction because papers citing this one may. Curzi [2026] gives the arithmetic that separates the two.

Two further disciplines from the diversity literature apply and are recorded rather than assumed. Hurlbert [1971] argues that "diversity" has been used for so many distinct quantities that the word carries no content without its formula attached, which is precisely why this section exists. Chao et al. [2014] show that diversity estimators of low order are biased on small samples, and a six- or seven-element exposure vector is a small sample; no correction is applied here and Section 13 records the gap. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, which is where several of the comparison structures in this paper sit.

No distributional or scaling claim is made anywhere in this paper, and that is stated rather than assumed because the material invites one. Exposure vectors that descend steeply — 29.1 / 18.2 / 16.4 / 13.6 / 11.8 / 10.9 — look like the beginning of a heavy-tail argument. **This paper fits no distribution, characterises no tail, and asserts no power law.** Clauset et al. [2009] is the reason: applied to twenty-four canonical data sets, a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few of them standing, and a straight line on a log-log plot is not evidence. **That procedure was not run, because no claim requiring it is made.** Stumpf and Porter [2012] adds the reason running it would not settle anything on its own, since many mechanisms produce the same tail, and Broido and Clauset [2019] is the reason the same caution attaches to any borrowing from the scale-free network literature. **Every effective count in this paper is a statistic of a finite exposure vector with at most seven entries, not an estimate of a distribution, and it must not be restated as one.**

3.2 The break-even probability method

The method applies wherever a structural decision turns on a classification that cannot be settled before the decision is taken, and it has three steps.

Step 1 — measure the outcome under each classification. The candidate position is inserted into the exposure vector and the effective bloc count is computed twice: once with the candidate treated as its own perimeter, and once with it folded into the perimeter it most plausibly belongs to if the call is wrong. This gives two values of N and, through $h = \eta \ln N - \delta Q - C$, two values of h.

Step 2 — form the gain and the loss. Write G for the improvement in h if the classification is right and L for the deterioration if it is wrong, both as positive numbers. The expected change is then linear in the probability p that the classification is right:

```
E[dh] = p G − (1 − p) L = (G + L) p − L
```

Step 3 — solve for the threshold. Setting $E[\Delta h] = 0$ gives

$$p^* = \frac{L}{G + L}.$$

The method's whole value is that it does not require the probability to be estimated. It requires only that a reader be able to say whether the true probability is above or below a stated number, which is a far weaker demand than producing the number. Curzi [2026] is the corpus's own bound on how far such a construction may be pushed: its counter-result declines the inflated reading of its own borrowed physics, stating the framework's postulate as a postulate, giving the relation only in its correct form, and requiring that a theorem, an ordinary observer effect and the framework's own conjecture be distinguishable in three separate sentences on demand. **The same discipline applies here. p^* is arithmetic. p is a judgement. They must not be confused, and this paper supplies only the first.**

The status of p itself deserves a sentence, because a reviewer will ask. p is a subjective degree of belief in a proposition about a unique non-repeatable situation, in the sense of Jaynes [2003], and not a limiting relative frequency. Nothing in this paper estimates it, no reference class is constructed for it, and Section 13 records that a threshold expressed in a quantity nobody has calibrated is a weaker object than it looks.

3.3 The cost ceiling

A jurisdiction leg costs money to run whether or not it helps. Let c be the addition to C from operating the candidate vehicle — counsel, filings, audit, registered office, and the front-loaded opinion amortised. Then

```
E[dh] = (G + L) p − L − c = 0     ->     p* = (c + L) / (G + L)
```

Two readings follow immediately and both are used below.

The ceiling. $p^* = 1$ at $c = G$. **At an incremental cost equal to the entire gain from a correct call, the position is worth nothing even under certainty**, and above it the position is value-destroying at every probability. The ceiling is therefore not a soft constraint trading off against confidence; it is a hard one.

The sensitivity. $dp^*/dc = 1/(G + L)$, a constant. On the numbers below that constant is 31.4069 per unit of cost, so a cost of one per cent of C — 0.003 — raises the required confidence by 0.0942. **The threshold is far more sensitive to the fee than a reader who has just been given a section of geopolitics expects it to be.**

This is a specific instance of a general organisational result the corpus uses elsewhere: adding units inside a coordination boundary adds administrative cost at order $n(n-1)/2$ while adding nothing to independence [Brooks, 1975], and the structure of an organisation's output tracks the structure of the organisation that produced it [Conway, 1968]. Curzi [2026b] supplies the gauge in which all of this is measured — the headroom $h_t = \eta \ln N - \delta Q_t - C_t$, with three regimes, a maximum increment $r_{\max} = h_t$, and the separate constraints of admissibility $C_t \leq (1 - \delta)Q_t + \eta S_t$ and sustainability $C_t \leq \eta \ln N - \delta Q_t$ — and a leg whose cost breaches the sustainability constraint has not bought independence, it has bought a bill.

3.4 The substance-cost bridge into the storage law

Comparing operating costs across jurisdictions is a procurement exercise until it is connected to the law that decides whether the structure gains or loses. The connection is a single calibration constant and it is stated explicitly because everything in Section 7 depends on it.

The constructed relative-cost model. For the same operating substance — same headcount, same floor area, same administrative burden — a weighted index is formed over three components with fixed weights. **The indices are constructed model parameters, not market data;**

they illustrate a ratio and not a price. They are stated in full in Section 7.1 so that a reader who disagrees may substitute their own.

The calibration. Curzi [2026] calibrates the specialised structure at 66 index units of annual cost against $C = 0.30$, so one index unit is $0.30/66 = 0.004545$ surplus units, recurring. **That constant is a stipulation, not a measurement**, and it is the only bridge between the cost model and the surplus law. Every magnitude in Section 7 inherits its arbitrariness: the ratios are meaningful and the absolute figures are not, because Curzi [2026] supplies no operational unit for Q, C or h.

The consequence. For an operating entity of u_0 index units at relative index r,

$$\Delta C = u_0(r-1) \times \frac{0.30}{66}, \qquad \Delta h = -\Delta C,$$

since the relocation changes no share and therefore no N. **The relocation is pure cost: the entire effect passes through C and none of it through $\eta \ln N$.** That is what makes the comparison clean and it is also what makes the result uncomfortable.

3.5 The job-concentration diagnostic

An entity's activity is written as a vector over three functions — holding, operating and bridging — with components summing to one. The diagnostic is the concentration instrument applied to the entity rather than to the structure:

```
S = sum of squared job weights        effective jobs = 1 / S
```

with bands: below 1.50 SPECIALIST, 1.50 to 2.00 STRAINED, above 2.00 OVERLOADED. **The 2.00 boundary is algebraic and carries no empirical content**, since $1/S > 2$ is equivalent to $S < 1/2$, which is a condition on a vector in the simplex and not a finding about entities.

The measurement-theoretic status of the job vector is not optional and is not favourable. The components are treated as ratio-scale shares of an entity's activity, and that treatment is not tested. Michell [1997] is the strongest objection available: the social sciences routinely assume quantitative structure without testing for it. The formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all, within the representational framework of Krantz et al. [1971] and against the scale-type discipline of Stevens [1946]. **The conjoint conditions were not tested for any job vector in this paper, and the effective-jobs figures are therefore provisional as ratio-scale quantities.** What survives without the test is the *ordering* — an entity with a clearly dominant function scores lower than one without — and the exact 2.00 threshold, which is algebraic. The magnitudes do not survive it. Section 13 records this.

3.6 The dwell parameterisation of a corridor

A corridor is a rail and not a store, and the distinction is a measurement rather than a metaphor. A corridor's exposure to an action taken inside its perimeter — a capital-control measure, a regulatory suspension, an operational failure — is not its annual throughput; it is the fraction of that throughput sitting still inside the perimeter at the moment the action lands. For an average dwell of t days,

$$\text{exposure} = \frac{t}{365}.$$

The only variable is time. Same corridor, same counterparties, same jurisdiction, same annual volume: exposure at a seven-day dwell is a twenty-fifth of exposure at a one-hundred-and-eighty-day dwell. Curzi [2026] reaches the same conclusion on the settlement axis by a different route, showing that expected transit loss is invariant to hop count and depends entirely on the exposure window.

The functional form is the simplest one available and it is a modelling choice. It assumes throughput arrives uniformly and dwells for a common time. A burst arrival process with the same mean dwell gives a different instantaneous exposure distribution and the same mean, and nothing here tests which is right.

3.7 The bloc call is reflexive, and what that costs

Every measurement below depends on a bloc assignment, and a bloc assignment is a forecast about how a jurisdiction will behave under a coordinated action — a forecast that, once adopted by enough structures, changes the behaviour it forecasts. Merton [1948] named the mechanism; Curzi [2026] carries it as the reflexive loop $T(x) = W(x, M(x))$.

This paper adopts stipulation with a defence and pays the stated price. The blocs are fixed in advance by the perimeter test of Curzi [2026] — two jurisdictions are in the same bloc when a single decision taken in one reliably produces the corresponding effect in the other without a further independent decision — recorded with an evidence class, and stress-tested by running the arithmetic under the contested alternative, which is what Section 6 does. Brock and Durlauf [2001] is the template for making a stipulated reference group rigorous. **No randomisation, instrument or partial-population variation was available, so no bloc assignment in this paper is an identified empirical result.**

Two further objections in the same family are recorded and not answered. **The Lucas critique applies to this framework's own parameters** [Lucas, 1976]: the framework asserts that systems change their behaviour when modelled and then exempts η, δ and its own correlation assumptions from that reflexivity. **That is an inconsistency and it is not resolved here.** MacKenzie and Millo [2003] documents the benign form of the same loop in the field and with dates — a model that did not fit the market when published came to fit it after traders adopted it — and Hacking [1995] states the general form. And Goodhart [1975] with Campbell [1979] give the failure mode that follows adoption: an effective count taken as a target ceases to be a good measure of anything. The only defence offered is the reporting standard of Appendix B, which requires the inputs to be published with the output.

3.8 The disclosure premise

Every position priced in this paper is assessed against one premise, stated as a design constraint rather than an ethical preference: **would the structure still do its job if every element of it were disclosed to every authority with jurisdiction over any part of it?**

The premise is not this work's to claim. Kerckhoffs [1883] stated it in 1883 — a system must remain secure when everything about it except the key is public — and Saltzer and Schroeder [1975] restate it as *open design*, the principle that a protection mechanism should not depend on the ignorance of attackers. Curzi [2026] carries the constraint in full for this series, establishing that channel separation is strengthened rather than weakened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place. **Citing Kerckhoffs converts a rule that reads as a preference into a recognised engineering standard with a hundred and forty years behind it.**

The same conclusion arrives from the regulatory direction. Automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations that supervisors implement in common [Financial Action Task Force, 2012], and the substance and beneficial-ownership work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] have together removed non-disclosure from the set of available design parameters, whatever a designer's preference. Brandeis [1914] is the older statement of the same instinct from the transparency side; de Goede [2011] documents the listing machinery as a technique of governance, which is the mechanism that makes concealment fail on contact; and Pistor [2019] is the scholarly account of how legal coding manufactures durability and simultaneously its sharpest critique. Hansmann and Kraakman [2000] establishes that asset partitioning is the irreducible function of

entity law — **a separate legal personality is a partition, and its effectiveness likewise does not depend on anyone's ignorance of it.**

The premise is what makes every position in this paper measurable at all, because a position whose value depends on not being seen cannot be priced against a published instrument. Curzi [2026] states the bound on how far it goes: **disclosure is not immunity**, since approximately USD 300 billion of fully disclosed central-bank reserves were immobilised in 2022, so the disclosure premise is a filter that removes structures collapsing on contact with an authority and is not a shield against a policy decision.

3.9 What discriminates the logarithm, and what does not

The surplus law's input term is $\eta \ln N$, and every result in this paper inherits its shape. **The functional form is underdetermined by the evidence and this paper concedes that rather than defending it.**

Three candidate forms fit the qualitative facts equally well. The corpus proposes $\ln(1 + (N-1)u)$ [Curzi, 2026]. Latané [1981] proposes a power law with exponent below one for social impact, which has the same diminishing-increment shape. Briscoe et al. [2006] propose $n \log n$ for network value against the quadratic alternative. **All three are decreasing in marginal return and none of the measurements in this paper distinguishes them**, because every measurement here is a difference between two values of the *same* functional form.

One genuine strengthening is available and should be taken. Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics **with no psychological assumption at all** — a stronger warrant than the perceptual story of Fechner [1860], because it does not require the perceptual story to be true. Curzi [2026n] identifies the corpus's own functional as a Fechner law with threshold $u_0 = 1/(N-1)$. **Where this paper's arithmetic needs a warrant for the logarithm, the multiplicative-dynamics one is the one it needs; the perceptual one is decoration.** Peters [2019] is the associated warning that an expected value and a time average are different objects, which matters wherever $E[\Delta h]$ is read as something a single structure experiences.

4. The three positions and their institutional setting

This section is context and is not a result. It states what each of the three candidate positions is for, at the level of detail the measurements require and no further. **Every statement in it about the law, regulation, institutions or policy of any individual jurisdiction is described from the source manuscript and is uncited**, because the bibliography for this corpus contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction. Appendix A lists those statements item by item and Section 13 records the gap. **They must be verified against the official sources before any reliance, and no measurement below depends on any of them being true** — each measurement depends only on the constructed share vector and the stated parameters.

4.1 The three positions

position	assigned function	share of exposure	what the measurement decides
a Central Asian financial centre	holding, ring-fenced, plus a costless arbitration option	5.0%	whether an uncertain bloc classification is worth betting on, and at what fee
a South-East Asian operating base	operating, exclusively	18.2%	how much of the diversification gain the siting of substance consumes
a South Asian corridor centre	bridging, exclusively	11.8%	whether a second jurisdiction inside an existing bloc earns its maintenance cost

Where a scored institutional comparison would otherwise attach a rating to a named jurisdiction on a characteristic this paper cannot support, the comparison is de-branded, following the convention of Curzi [2026]. **Named jurisdictions appear below only as labels on a constructed exposure vector and on constructed cost indices**, and not as the subjects of assessed claims.

4.2 The Central Asian position

The candidate is a legal enclave established by constitutional statute within a Central Asian host state, applying a body of law built on the principles and precedents of English law, operating its own court and arbitration centre, conducting its business in English, and exempting participants from corporate income tax for a period measured in decades. It is one of a very small number of jurisdictions anywhere to have received English common law wholesale outside the Commonwealth.

Two features make it a candidate for a fourth bloc and one makes it uncertain. It is simultaneously inside a regional economic union and a regional security treaty led by one great power, a major partner of another, and party to a cooperation agreement with a third — **and that is precisely the configuration that makes the bloc call contestable rather than obvious.** The source manuscript records evidence on both sides, dates it, and routes every item to a verification register. **This paper does not weigh that evidence and does not assert a classification.** It computes what the classification is worth if right and what it costs if wrong, and leaves the weighing to a reader with access to primary sources.

Two structural constraints are carried into the specification and both are measurements rather than opinions. The position is sized at the amount the architecture could lose entirely without failing, which in the constructed case is 5.0% of protected capital. And the vehicle is held directly by the apex rather than through another bloc's holding company, because **a bloc whose operability runs through another bloc is not an independent bloc** — which is the perimeter test applied to the ownership chain rather than to the map.

The costless part of the position is separable from the capital part. An arbitration clause naming the centre's arbitration institution can be adopted for contracts across the group at no balance-sheet cost, and it enforces through the 1958 Convention [United Nations, 1958] rather than through the centre's own court, whose judgments travel on no treaty network written for them. **A neutral forum that both parties will actually sign is worth more than a superior forum that one party refuses**, which is a general observation about international arbitration for which Born [2021] and van den Berg [1981] are the standard treatments and United Nations Commission on International Trade Law [1985] the model instrument. Curzi [2026] reaches the identical conclusion about a different Asian seat by the same reasoning: its

Design B, a capped transit position at 0.35% of exposure, gives $N = 2.965384$ and $h = -0.119548$, capturing 3.97% of the full position's gain for 3.21% of its exposure.

4.3 The operating base

The candidate is a civil-law South-East Asian state with a codified private law, a registration-based commercial and property regime, and no general domestic private trust. It restricts foreign ownership of many activities by statute, and it provides at least two lawful routes around that restriction for the activity in question: an investment-promotion regime conferring full foreign ownership and land rights for a promoted activity, and a bilateral instrument available to nationals of one particular treaty partner. **The promotion route is conditional and the conditions can be failed; the treaty route depends on a chain of ownership qualifying.** Both are described in Appendix A and neither is cited.

The reason the position is in the paper is not its law. **It is that the same operating substance costs a fraction there of what it costs in the Western jurisdictions the structure is diversifying away from, and Section 7 measures what that is worth.** The source manuscript is explicit that the jurisdiction cannot carry a holding or bridging function and should not be asked to, which the job-concentration diagnostic in Section 10 confirms arithmetically.

One tax development is carried because it changes a widely-held planning position rather than because this paper analyses it: a revenue order effective from 1 January 2024 removed a same-year condition on the taxation of remitted foreign-source income for tax residents. **The consequence recorded in the source is structural rather than fiscal: the residence answer that minimises personal tax is the answer that weakens the operating company's management substance, if the principal is the person taking its decisions.** The resolution is to give the operating company an operator — a resident managing director with real authority, a real salary and minutes recording decisions actually taken — at which point the two questions stop competing. That resolution costs a salary and it is the cheapest item in the specification.

4.4 The corridor centre

The candidate is an international financial services centre inside a South Asian state that operates capital controls, created by treating units inside the centre as non-resident for specified purposes under the state's exchange-control legislation, and supervised by a single unified regulator established by statute in place of four sectoral ones. **It has no separate legal system and no separate court**, which is the defining structural fact about it and the reason the paper assigns it a bridging function and nothing else.

The centre's product is supervision. That is what makes the disclosure premise of Section 3.8 nearly trivial to satisfy there — a registered unit under a published framework, filing accounts, reporting account information, claiming a statutory deduction on its stated conditions — and it is also what caps the position: a regulated unit that conceals from its regulator has lost its registration, which is the only thing it had.

The failing configuration is worth naming because it is the one that gets built, and it is the object of the measurement in Section 10: a corridor vehicle used as a place to hold value, with a corridor function attached as the stated reason. **That fails not because any single element is concealed but because, asked what it does, it says "several things", and an entity that cannot state its function in one sentence has a supervision problem before it has any other kind.**

5. The constructed case and the baseline

CONSTRUCTED CASE. Every fact is invented and is labelled as such at each point of use. The case is the one carried through Series D and established in Curzi [2026]: a dual national, tax resident in one Gulf jurisdiction, with three heirs resident in three different jurisdictions,

one under a forced-heirship regime; manufacturing operations in one South-East Asian state, a trading company in the Gulf, an intellectual-property portfolio, London commercial real estate, and a listed-securities portfolio, with revenue arriving in five currencies.

The share basis is the one Curzi [2026] fixes and it is stated here because a measurement without a stated basis is not reproducible: **the fraction of protected capital whose availability depends on a decision taken inside a given jurisdiction's coordination perimeter.** Not book value, not tax residence, not where the certificate is.

jurisdiction	share	share^2	bloc
UAE	29.1%	0.084681	BRIDGE
Thailand	18.2%	0.033124	NONALIGNED
UK	16.4%	0.026896	WEST
Bermuda	13.6%	0.018496	WEST
India	11.8%	0.013924	NONALIGNED
Singapore	10.9%	0.011881	BRIDGE
total	**100.0%**	**0.189002**	

```
naive HHI = 0.189002        effective jurisdictions = 5.290949
blocs   BRIDGE 40.0%   NONALIGNED 30.0%   WEST 30.0%
bloc-HHI = 0.160000 + 0.090000 + 0.090000 = 0.340000
EFFECTIVE BLOCS N = 1 / 0.340000 = 2.941176

ln(N) = 1.078810     eta ln(N) = 0.377583     h = -0.122417
```

Everything below is a difference against those four numbers. The break-even effective count at the stated parameters is $N^* = e^{0.5/0.35} = 4.172734$, so the baseline structure is below the build threshold before any position in this paper is added, and remains below it after all of them.

6. Results: the bloc call priced

6.1 The two measurements

Five percentage points of protected capital move from the Western position into a ring-fenced holding vehicle in the Central Asian centre, held directly by the apex. The Western share falls from 16.4% to 11.4% and nothing else changes.

Measurement one — the candidate is its own perimeter.

jurisdiction	share	share^2	bloc
UAE	29.1%	0.084681	BRIDGE
Thailand	18.2%	0.033124	NONALIGNED
Bermuda	13.6%	0.018496	WEST
India	11.8%	0.013924	NONALIGNED
UK	11.4%	0.012996	WEST
Singapore	10.9%	0.011881	BRIDGE
Kazakhstan	5.0%	0.002500	CENTRAL ASIA
total	**100.0%**	**0.177602**	

```
naive HHI = 0.177602        effective jurisdictions = 5.630567
blocs   BRIDGE 40.0%   NONALIGNED 30.0%   WEST 25.0%   C.ASIA 5.0%
```

```
bloc-HHI = 0.160000 + 0.090000 + 0.062500 + 0.002500 = 0.315000
EFFECTIVE BLOCS N = 1 / 0.315000 = 3.174603

ln(N) = 1.155183     eta ln(N) = 0.404314     h = -0.095686
```

Against the baseline, N rises by 0.233427 and h by 0.026731. Western-perimeter exposure falls from 30.0% to 25.0%.

Measurement two — the call is wrong. Suppose the candidate does not constitute an independent perimeter and belongs with the non-aligned group.

```
blocs   BRIDGE 40.0%   NONALIGNED 35.0%   WEST 25.0%
bloc-HHI = 0.160000 + 0.122500 + 0.062500 = 0.345000
EFFECTIVE BLOCS N = 1 / 0.345000 = 2.898551

ln(N) = 1.064211     eta ln(N) = 0.372474     h = -0.127526
```

h falls by 0.005110 against the baseline. **The move is value-destroying if the call is wrong, and the reason is instructive rather than arbitrary: the five points came out of the smallest bloc and went into one that was already equal-largest, so concentration rose.** A reader carrying only the maxim "diversify into more jurisdictions" would not have seen that coming, and it is the argument of Curzi [2026] arriving in a live case. Curzi [2026] reports the same sign on a different pair of additions: two Gulf additions raise the naive effective count from 5.29 to 7.13, an increase of 34.8%, while the effective bloc count *falls* from 2.94 to 2.84, a decrease of 3.4% — more jurisdictions, less independence.

6.2 The option line and the break-even probability

With $G = 0.026731$ and $L = 0.005110$:

```
E[dh] = 0.0318401 p - 0.0051096
E[dh] = 0  ->  p* = 0.0051096 / 0.0318401 = 0.160476
```

The position pays, before costs, at any probability above 16.0476% that the candidate is a genuinely independent coordination perimeter. That is a low threshold. **Whether the true probability clears it is not decided in this paper**, because the evidence that would decide it — the host state's conduct under coordinated action, its designation practice, its payment-system behaviour — is jurisdiction-specific material for which this paper has no citable source. Section 13 records that, and it is the single most important thing this result does *not* establish.

6.3 The cost ceiling, and why it decides the position

Adding the incremental maintenance cost c gives $p^* = (c + 0.0051096)/0.0318401$:

c	as a % of $C = 0.30$	break-even p^*
0.000000	0.00%	0.160476
0.005000	1.67%	0.317500
0.010000	3.33%	0.474547
0.020000	6.67%	0.788639
0.026000	8.67%	0.977094
0.026731	**8.91%**	**1.000000**

Read the table from the right-hand column and the position changes character. The interesting argument about the host state's alignment is settled at $p^* = 0.16$; the argument that

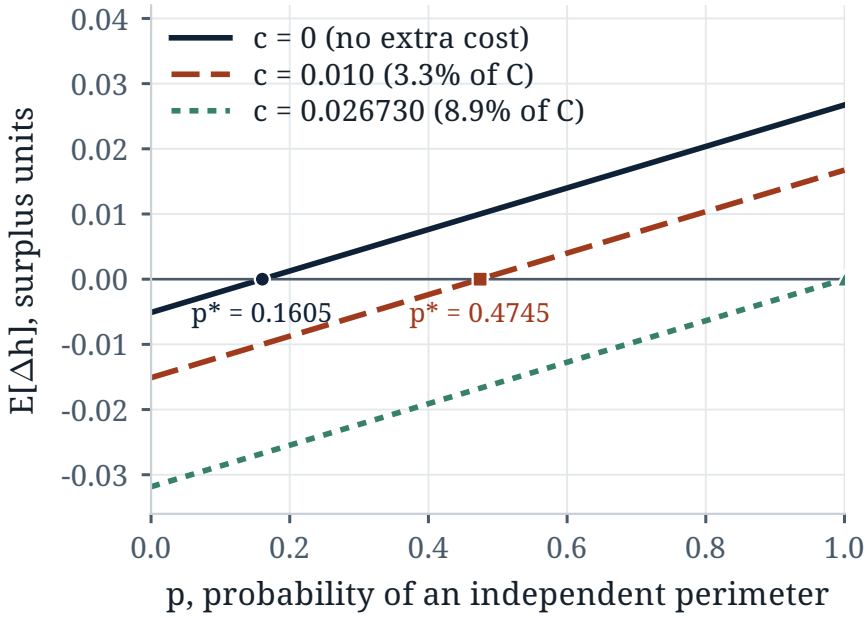

Figure 58.1: **The bloc call as an option line: expected surplus change is linear in the classification probability, crossing zero at p = 0.1605 with no incremental cost, at 0.4745 once the leg costs 3.3 per cent of the maintenance budget, and never at all once it costs 8.9 per cent.** Computed from the two bloc measurements of Section 6.1 at the stated parameters; script `figs/src/CCP-058_fig01.py`.

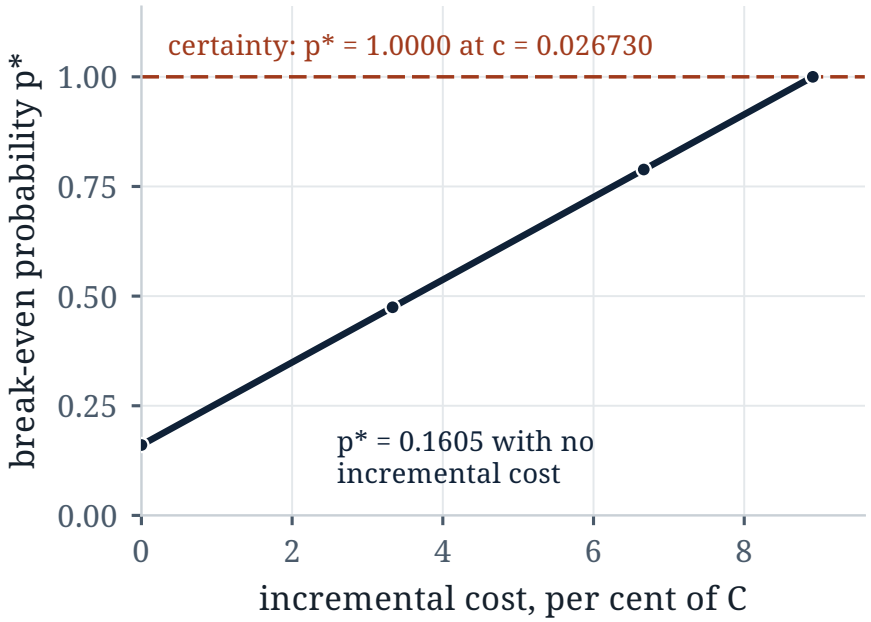

Figure 58.2: **The break-even probability rises 31.4 points for every one per cent of the maintenance budget the leg consumes, reaching certainty at 8.91 per cent: above that cost the position is worth nothing at any probability whatever.** Computed from p* = (c + L)/(G + L) with G and L from Section 6.1; script `figs/src/CCP-058_fig02.py`.

decides the position is the invoice. **The leg must cost less than 8.91% of the group's entire structure-maintenance budget to be worth building even under certainty, and at one third of that cost the required confidence is already close to a coin flip.** H1 is supported in the model.

The result generalises beyond this jurisdiction, and that generalisation is the useful part. **For any small position in a fourth bloc, the binding constraint is not the geopolitics; it is that a small position carries a full jurisdiction's maintenance cost.** It is the same asymmetry Curzi [2026] finds when it computes that the designed structure carries protected capital only up to $Q = 3.88$ index units before erosion outruns surplus: **structure cost is close to fixed and structural benefit is proportional to size.** A five per cent position in a jurisdiction with a mature, cheap professional-services sector works; the same position where every question requires a bespoke opinion may not.

The design conclusion follows directly and it is not abstention. **It is: once, simply, and without accretion.** One vehicle, one asset class, no operating activity, no banking dependency, no cross-collateralisation, standard documents reused annually. A second vehicle in the same centre would roughly double c and would not move the bloc share at all — which is the subdivision failure mode of Curzi [2026] arriving where it bites hardest.

6.4 The residual, stated plainly

- N rises from 2.941176 to 3.174603 against a break-even of 4.172734. **The structure remains below the build threshold.** The leg closes 18.95% of the remaining gap in N and 0.026731 of the 0.122417 shortfall in h, which is 21.84% of it.
- The classification is the position's whole thesis and it is uncertain. It is recorded and dated, with mirroring of another state's designations as the stated trigger for remeasurement.
- The position is deliberately small enough to lose. **That is the sizing rule applied honestly to a jurisdiction with a short institutional record, not pessimism.**

7. Results: what siting the operating substance costs

7.1 The constructed cost model

CONSTRUCTED PARAMETERS. A relative-cost model for the same operating substance — same headcount, floor area and administrative burden — indexed to the South-East Asian base at 1.00, weighting labour 0.60, premises 0.25 and administration 0.15. **These indices illustrate a ratio, not a price. They are not market data and were not measured.**

location	labour	premises	admin	weighted index	at 32 index units
Vietnam	0.85	0.90	1.30	0.9300	29.76
Thailand	1.00	1.00	1.00	1.0000	32.00
India	0.95	1.10	1.20	1.0250	32.80
Malaysia	1.40	1.20	1.10	1.3050	41.76
UAE	2.60	3.00	1.25	2.4975	79.92
Singapore	3.10	3.40	1.15	2.8825	92.24
UK	3.60	2.80	1.40	3.0700	98.24

7.2 The relocation, priced

At $0.30/66 = 0.004545$ surplus units per index unit, and with the operating entity at 32 index units:

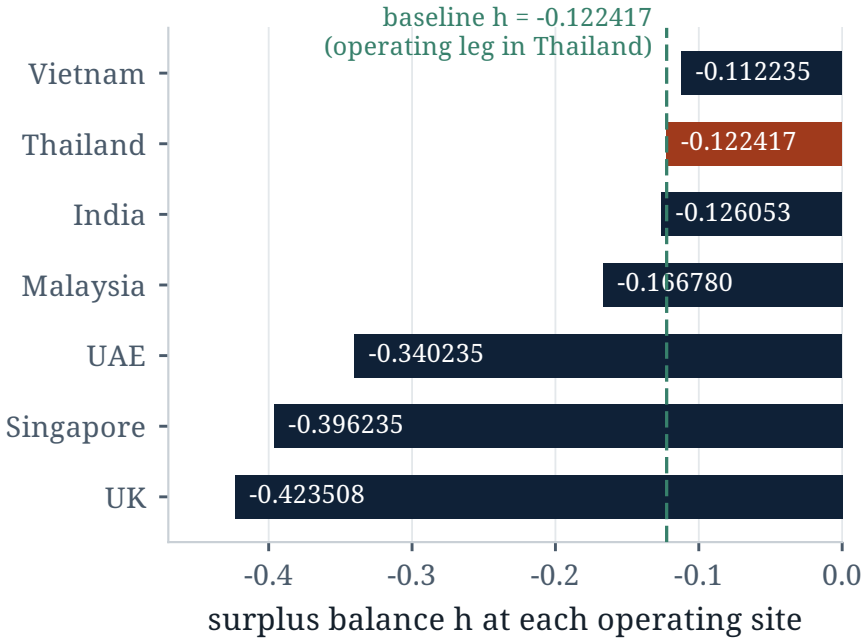

Figure 58.3: **Siting the operating leg is worth more than arranging the blocs: the same substance costs 0.301091 more in the highest-cost candidate than in the lowest-priced base, which is 79.74 per cent of the entire diversification gain, and the effective bloc count is unchanged in every row.** Modelled with the constructed cost indices of Section 7.1 at 0.004545 surplus units per index unit; script `figs/src/CCP-058_fig03.py`.

```
additional index units, base -> UK  =  98.24 - 32.00  =  66.24
additional C  =  66.24 x 0.004545  =  0.301091
C             =  0.300000 + 0.301091 =  0.601091
h             =  0.35 ln(2.941176) - 0.02 x 10 - 0.601091
              =  0.377583 - 0.200000 - 0.601091
              = -0.423508      against -0.122417 for the designed structure
```

The deterioration is 0.301091**. The entire gain that jurisdictional diversification delivered was** $\eta \ln N = 0.377583$**. Relocating the operating leg to the highest-cost candidate therefore consumes** 79.74% **of the whole diversification benefit without changing the effective bloc count at all.** H2 is supported in the model.

destination	index	ΔC	C	h	% of the gain consumed
Vietnam	0.9300	-0.010182	0.289818	-0.112235	-2.70%
Thailand	1.0000	0.000000	0.300000	-0.122417	0.00%
India	1.0250	0.003636	0.303636	-0.126053	0.96%
Malaysia	1.3050	0.044364	0.344364	-0.166780	11.75%
UAE	2.4975	0.217818	0.517818	-0.340235	57.69%
Singapore	2.8825	0.273818	0.573818	-0.396235	72.52%
UK	**3.0700**	**0.301091**	**0.601091**	-0.423508	**79.74%**

Two thresholds follow and both are exact given the calibration. A destination index of 2.297943 consumes exactly half the diversification gain, and a destination index of 3.595886 consumes all of it. **A structure whose substance sits at an index above 3.60 has, on this calibration, spent its entire jurisdictional gain on rent and wages** — and the highest-cost candidate in the table sits at 3.07, inside that boundary but not far inside it.

7.3 What the finding reframes

Cheap, genuine, defensible operating substance is not a saving at the margin of a jurisdictional design. At the calibration used here it is most of the design's economics. A structure that diversifies its blocs well and then puts its substance in a high-cost jurisdiction has spent the gain before collecting it, and the arithmetic gives the exact fraction.

One further reading is available from the table and it disciplines the conclusion. The cheapest candidate is 7.00% cheaper on inputs than the base and would improve h by 0.010182. The source manuscript records that it offers no bilateral instrument permitting full foreign ownership for the relevant treaty national. **A 7.00% input saving does not buy back an ownership problem**, which is why the assignment rule of Curzi [2026] takes a minimum across requirement dimensions rather than optimising one of them — an operation licensed on an ordinal scale, where a mean would not be.

8. Results: the corridor's bloc-count case, tested and not met

8.1 H3 is not met

The corridor jurisdiction carries 11.8% of the designed structure and sits in the non-aligned bloc alongside the operating base's 18.2%. **Reallocate its share to the operating base and the bloc arithmetic does not move.**

```
as designed
    UAE 29.1  Thailand 18.2  UK 16.4  Bermuda 13.6  India 11.8  Singapore 10.9
    blocs  BRIDGE 40.0  NONALIGNED 30.0  WEST 30.0
    bloc-HHI = 0.340000     N = 2.941176
    naive HHI = 0.189002    effective jurisdictions = 5.290949

share moved within the row, to Thailand
    UAE 29.1  Thailand 30.0  UK 16.4  Bermuda 13.6  Singapore 10.9
    blocs  BRIDGE 40.0  NONALIGNED 30.0  WEST 30.0
    bloc-HHI = 0.340000     N = 2.941176      UNCHANGED
    naive HHI = 0.231954    effective jurisdictions = 4.311200
```

The effective bloc count is identical to six decimal places. The naive jurisdiction count falls from 5.290949 to 4.311200, and that fall is the whole of the difference. H3 predicted that a second jurisdiction inside an existing bloc raises the effective bloc count. **It does not. The hypothesis is reported here as not met, in the same language a success would have received.**

This is the cleanest illustration in the series of both halves of the argument of Curzi [2026]: the naive count overstates resilience against a coordinated action, **and** it is still measuring something real. What it measures is the subject of the next subsection.

8.2 What survives the failure: within-bloc country concentration

The same instrument applied inside the bloc rather than across blocs gives a different and non-trivial answer. Within the non-aligned row:

```
with the corridor jurisdiction
    operating base 60.6667%   corridor 39.3333%
    within-row HHI = 0.522756    effective countries = 1.912940

without it
    operating base 100%
    within-row HHI = 1.000000    effective countries = 1.000000
```

The corridor leg nearly doubles the number of independent countries carrying the non-aligned allocation, from 1.000000 **to** 1.912940**.** A country-specific event in the operating base — a change of the foreign-ownership statute, a reversal of the promotion regime, an exchange-control tightening — would otherwise reach the entire non-aligned position. **That is a different risk from bloc risk and the instrument measures it separately, which is the honest thing the failed hypothesis leaves standing.**

The reading is exact and licensed: the reciprocal-index reading of an effective count applies within a row for the same reason it applies across rows, because both are numbers-equivalents of a sum of squared shares on a normalised vector [Adelman, 1969, Hill, 1973]. It is not a new instrument and is not claimed as one.

8.3 H4: the leg measured against its own counterfactual

Moving the corridor's share out of the bloc entirely, to the bridging jurisdiction, gives the counterfactual against which the leg's gross benefit is measured.

```
share moved out of the row, to Singapore
    UAE 29.1  Thailand 18.2  UK 16.4  Bermuda 13.6  Singapore 22.7
    blocs  BRIDGE 51.8   NONALIGNED 18.2   WEST 30.0
    bloc-HHI = 0.268324 + 0.033124 + 0.090000 = 0.391448
    EFFECTIVE BLOCS N = 2.554618      eta ln(N) = 0.328266
    naive HHI = 0.214726    effective jurisdictions = 4.657098

gross ln-gain attributable to the leg = 0.377583 - 0.328266 = 0.049317
marginal all-in cost of one entity                          = 0.035000

with the leg      N = 2.941176   C = 0.300   h = -0.122417
without it        N = 2.554618   C = 0.265   h = -0.136733
NET contribution to h                            0.014317
```

The leg is worth 0.049317 **in gross diversification and costs** 0.035000 **to run, so its net contribution is** 0.014317 **—** 3.79% **of the whole diversification gain.** Positive, real, and thin. H4 is supported in the model.

That number should govern the decision and usually does not, because the gross figure is the one that gets presented. Gross and net differ by a factor of 3.44. A leg whose gross benefit is 0.0493 and whose cost is 0.0350 carries very little margin. **If the vehicle acquires a second function its cost rises and the net contribution goes negative**, which is not a hypothetical: it is exactly what the vehicle was doing before the repair measured in Section 10.

9. Results: corridor exposure as a function of dwell

The corridor's exposure to an action inside its perimeter is the fraction of a year's throughput resting there at the moment the action lands.

average dwell, days	share of annual throughput exposed
1	0.27%
7	1.92%
30	8.22%
90	24.66%
180	49.32%

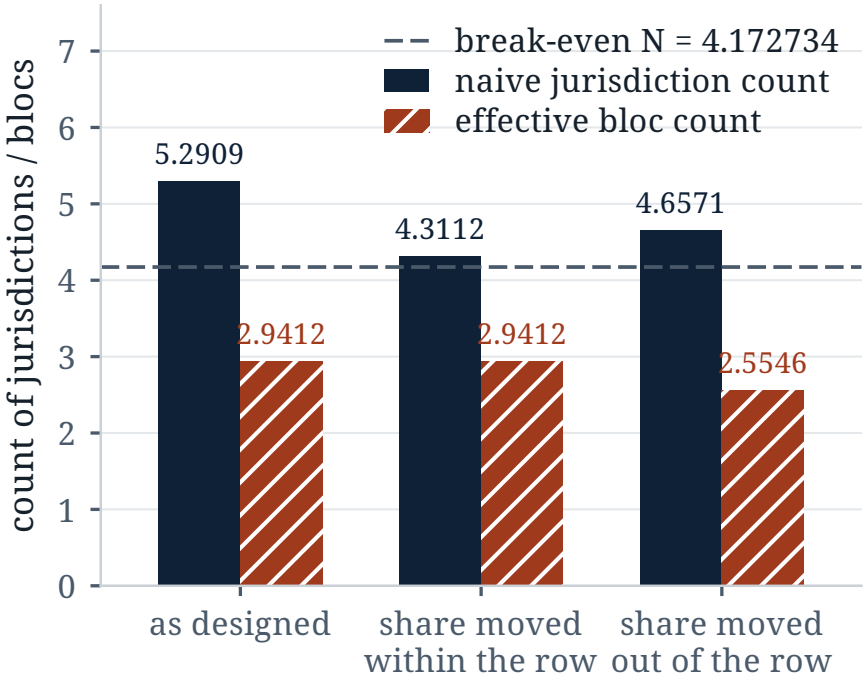

Figure 58.4: **The corridor leg moves the naive count and not the effective bloc count: moving its share within the bloc leaves N at 2.9412 exactly while the naive count falls from 5.2909 to 4.3112, and only moving the share out of the bloc changes N, to 2.5546.** Measured from the constructed share vectors of Sections 5 and 8; the naive count for the third configuration is computed here and does not appear in the source. Script `figs/src/CCP-058_fig05.py`.

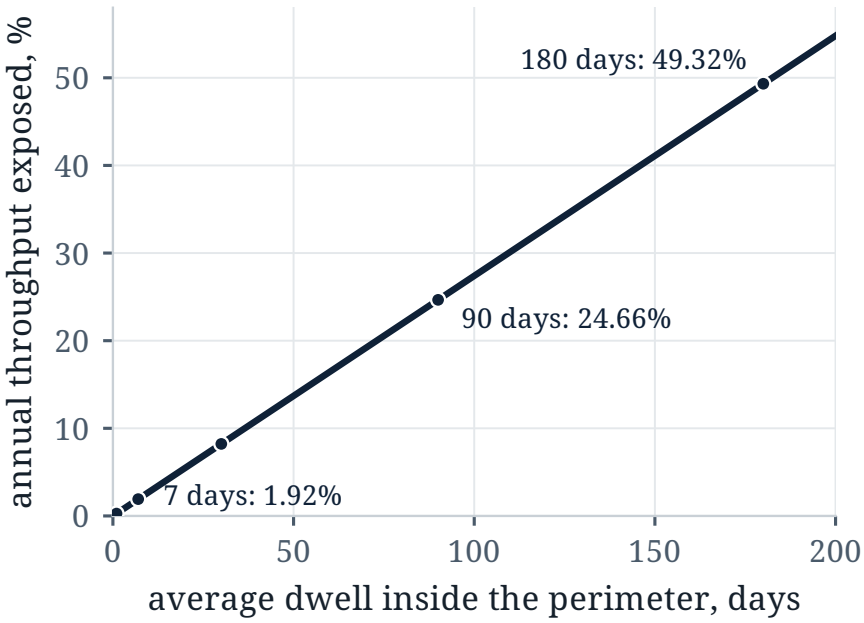

Figure 58.5: **Corridor exposure is a property of dwell and of nothing else: at a seven-day average dwell an action inside the perimeter reaches 1.92 per cent of the year's flow, and at ninety days the same corridor with the same volume exposes 24.66 per cent.** Computed as dwell/365 from the constructed policy in Section 9; script `figs/src/CCP-058_fig04.py`.

Same corridor, same counterparties, same jurisdiction, same annual volume. The only variable is how long value sits still. H5 is supported in the model, and it is supported by construction rather than by evidence — the relation is $t/365$ and nothing in this paper measures a real dwell.

The corridor policy adopted in the constructed case follows from the table rather than from preference:

```
maximum balance          45 days of expected corridor throughput
maximum average dwell    7 days, measured and reported monthly
exposure at that dwell   1.92% of annual throughput
sweep destination        the bridging layer, with a second route named
alternative route        a named arrangement outside the centre, tested
                         once a year with a live transaction
```

The last line is the one that is never written and it is the whole point of a bridge. A corridor with no alternative is a single point of failure wearing the costume of a diversification measure. Curzi [2026] makes the same observation on a different axis and measures it: entity-based US exposure of 27.3% against a USD share of the balance sheet of 61.0% and settlement volume clearing through the US system of approximately 58%, so **the entity map understates dependency by more than a factor of two.**

10. Results: job concentration on the two operating entities

10.1 The operating base

The entity as found is scored at a job vector $(H, O, B) = (0.25, 0.55, 0.20)$:

```
S = 0.0625 + 0.3025 + 0.0400 = 0.4050
effective jobs = 1 / 0.4050 = 2.4691          OVERLOADED
```

Above 2.00, therefore carrying all three functions by arithmetic necessity: it operated the manufacturing business, held group value, and banked receipts for a related company in another jurisdiction. **The diagnosis is not about quality.** The business is real and it is the source of the input term for the whole architecture. After the repair — the holding function moved to the apex, the treasury function moved to the bridging layer, the operating function retained — the vector is $(0.05, 0.95, 0.00)$:

```
S = 0.0025 + 0.9025 + 0.0000 = 0.9050
effective jobs = 1 / 0.9050 = 1.1050          SPECIALIST
```

10.2 The corridor centre

The vehicle as originally specified is scored at $(0.20, 0.30, 0.50)$:

```
S = 0.0400 + 0.0900 + 0.2500 = 0.3800
effective jobs = 1 / 0.3800 = 2.6316          OVERLOADED
```

How it got there is the useful part, because nobody decided it. The corridor function was the original reason; a fund-management function was added because an allocation needed a manager and one was available; a holding function was added because another vehicle was being wound down and its assets had to go somewhere. **Three sensible individual decisions and one incoherent entity. No three-function entity in this material was ever chosen; each was assembled from three convenient decisions taken in sequence.**

Two repairs are available and they are not equivalent:

repair	job vector	S	effective jobs	band
as specified	0.20 / 0.30 / 0.50	0.3800	2.6316	OVERLOADED
A — specialise on bridging	0.05 / 0.10 / 0.85	0.7350	1.3605	SPECIALIST
B — specialise on operating	0.05 / 0.80 / 0.15	0.6650	1.5038	STRAINED

Repair A is taken, because bridging is the only function the centre uniquely supplies. The repair *adds* an entity, which the over-fragmentation warning of Curzi [2026] counts as a cost; the justification is the one that paper gives — split when the antagonism is real. **Here it is: a fund vehicle needs licensed operating substance and a supervised risk-taking function, and a corridor unit needs a low balance, a short dwell and no risk position. No single entity has both profiles.**

10.3 The status of these numbers

The effective-jobs figures are the weakest quantities in this paper and are labelled as such. They rest on job vectors that were assigned rather than measured, treated as ratio-scale, and never tested against the conjoint conditions [Michell, 1997, Luce and Tukey, 1964]. **What survives is the ordering and the 2.00 threshold; the magnitudes do not.** 2.4691 against 1.1050 is a statement that one entity has a dominant function and the other does not. It is not a statement that the first carries 2.4691 of anything.

11. Discussion

11.1 What follows

A marginal jurisdictional position should be decided on its invoice. The three measurements agree on this and they agree for the same structural reason: the benefit of a position scales with the share it carries while its cost scales with the number of jurisdictions it adds. A 5% position and a 40% position pay the same registered office, the same audit and the same opinion. **The consequence is that small positions are decided by their fixed cost and large positions by their bloc arithmetic**, and a practitioner who applies the second reasoning to the first case will build legs that lose money while appearing to diversify.

A threshold is a more useful object than an estimate when the estimate cannot be had. Converting the classification question into $p^{*} = 0.160476$ does not settle the classification. It converts a debate into an assessment that can be recorded, dated and re-run, and — more usefully — it exposes that the same debate becomes irrelevant at a cost of 8.91% of the maintenance budget. **The threshold's value is that it identifies which argument is decisive, and in this case the decisive argument was not the one the source material spends its pages on.**

The gross-to-net distinction is the discipline the field most often skips. The corridor leg's gross benefit and its net benefit differ by a factor of 3.44, and only the gross figure is ever presented. **A leg has to clear its own maintenance cost before it has done anything for the structure at all.**

11.2 What does not follow

None of these results says a jurisdiction is good or bad. They say what a share vector and a cost model imply at stated parameters. Change η from 0.35 to 0.50 and the break-even count falls from 4.172734 to $e^{1.0} = 2.718282$, below the designed structure's 2.941176, and every conclusion about sufficiency reverses. **That sensitivity is the most important thing in Section 13.**

The failed hypothesis does not say the corridor position is worthless. It says the bloc-count case for it fails. The within-row measurement and the net contribution both survive, and the paper reports the surviving reasons rather than deleting the failure.

The effective count measures independence and not capacity. $N = 3.174603$ says nothing about whether any bloc can carry the load, and a structure whose bloc diversity is real but whose transacting capacity sits in one bloc has an effective count near 1.00 on the ability to transact. Curzi [2026] measures precisely that on the settlement axis and finds it worse than the jurisdictional axis: a naive correspondent HHI of 0.302400 and 3.306878 effective correspondents collapsing to a perimeter HHI of 0.745256 and 1.341819 effective clearing perimeters, against 2.941176 effective jurisdictional blocs.

And nothing here is an empirical result. Every figure is exact arithmetic on stipulated inputs. **The paper cannot be wrong in the way a measurement can be wrong, and that is a weakness rather than a strength.**

11.3 Parallel results in the corpus

The same shape appears elsewhere in the corpus in domains with no jurisdictional content, which is the corpus's own evidence that the arithmetic rather than the subject matter is doing the work.

Curzi [2026] reports a correlation collapse in a backing basket: a naive HHI of 0.150600 gives 6.640106 effective components, but a single climate-correlated 82.0% exposure gives 0.693600 and 1.441753, a naive overstatement factor of 4.605578. **That is this paper's Section 8 in a different medium: a count that reads high because the correlation was not consulted.**

Curzi [2026] runs the same cost-ceiling method on a different subject and reaches the same structure of answer: an African leg raises effective blocs from 2.924 to 3.639 and buys 0.076529

of surplus, setting a cost ceiling of roughly 25.5% of the existing maintenance base, and at $C = 0.38$ the surplus is -0.127902, **worse than the** -0.124431 **baseline it was meant to improve.**

Two results in Series C are structurally parallel and are cited as such rather than as support. Curzi [2026]'s doubling theorem — $\mathrm{HD}_{\mathrm{ess}}(i,j) = 2\log_2(pq)$ and $G_{\mathrm{ess}} = 2G(pq) - 1$ for the essence ratio p^2/q^2, verified exactly over all sixty-six pairs at $N = 12$ — is a squaring operation propagating exactly through a derived quantity, which is what squaring shares does here. And Curzi [2026]'s opposition identity, $u = 1 - \rho^2$ depending only on $|\rho|$ so that $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$ and $f_{\mathrm{rel}} = k = 0.4834$, is the same insensitivity to sign that makes a bloc collapse indifferent to whether jurisdictions coordinate cooperatively or antagonistically. **Neither is evidence for anything in this paper and neither is offered as such.**

Curzi [2026k] supplies the corpus's own test of scale-freedom in the storage law, reproducing each of five systems' observed decline from a single five-parameter survey — predicted -0.250474 against observed -0.250 at one desk and -0.996371 against -1.000 at a library, with residuals under 1.4% of the ceiling term. **That is the strongest evidence the corpus has that the law's form transfers across scales, and it is evidence about the law and not about jurisdictions.**

12. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the compounding chains name what each step consumes. **If dropping a postulate leaves a result standing, it is not listed.** Sections 12.1 to 12.6 run the standing rigour checks first, so that the chains are read against a dimensional audit rather than before one.

12.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	exposure share of jurisdiction i	$[1]$	dimensionless, fraction of Q	defined; sums to 1 by P1
W_b	bloc share	$[1]$	dimensionless	derived, $W_b = \sum_{i \in b} s_i$
HHI	concentration index	$[1]$	dimensionless, or points $= 10^4 \times$ fraction	derived from shares
N	effective bloc count	$[\#]$, **a count**	blocs	derived as HHI^{-1}
$\ln N$	surplus term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
Q	protected capital	$[C]$	index units	defined; **no operational unit is supplied by the source**
δ	erosion rate	$[T^{-1}]$	per period	assumed
C, c	maintenance cost flow, and its increment	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed

symbol	quantity	dimension	unit	status
h, G, L	surplus balance and its two differences	$[C\,T^{-1}]$	index units per period	derived
p, p^*	classification probability and its threshold	$[1]$	dimensionless, in $[0,1]$	assumed; p^* derived
r	relative cost index	$[1]$	dimensionless, base 1	assumed (constructed)
u_0	entity annual cost	$[1]$	index units of cost	assumed (constructed)
t	corridor dwell	$[T]$	days	assumed (constructed)
S	job-concentration index	$[1]$	dimensionless	derived from a job vector

Does $E[\Delta h] = (G+L)p - L - c$ balance? Every term must carry $[C\,T^{-1}]$. G, L and c do, since each is a difference or an increment of h. p is dimensionless, so $(G+L)p$ carries $[C\,T^{-1}]$. **The equation balances**, and $p^* = L/(G+L)$ is dimensionless as a threshold on a probability must be, being a ratio of two quantities in the same units. That check is cheap and it is the one that would catch the commonest error in this kind of construction, which is dividing a cost by a count.

Does the cost bridge balance? $\Delta C = u_0(r-1) \times 0.30/66$ multiplies index units of cost by a dimensionless ratio and by a conversion carrying $[C\,T^{-1}]$ per index unit. **It balances only under that reading of the calibration constant, and the source supplies the constant without stating its dimension. The audit records that silence rather than filling it in.**

Where no operational unit exists, this audit says so. Q is protected capital in index units and no conversion to currency is supplied anywhere in the corpus. **Every figure in C, h, G and L is therefore in an arbitrary scale fixed by the stated parameters.** The break-even probability $p^* = 0.160476$ is unit-free and survives this, because it is a ratio; the statement that h is -0.122417 does not mean anything until the index unit is defined, and it is not.

12.2 Significant figures and epistemic status

The figures in this paper have three different statuses and must not be read at the same precision.

- $N = 2.941176$, 3.174603, 2.898551, 2.554618 and 1.912940 are **exact arithmetic** on the stated shares: reciprocals of exact rationals. They may carry as many digits as are useful. Their inputs, the shares, are constructed and exact as stated to one decimal place, and every exposure vector sums to 100.0% exactly.
- $p^* = 0.160476$ and the cost ceiling 0.0267305 are **exact given the parameters**, and the parameters are assumed rather than estimated. **They carry no uncertainty because there is no estimate in them, and no authority beyond the assumption.**
- $N^* = 4.172734$ is $e^{0.5/0.35}$, exact given $\eta = 0.35$ and $\delta Q + C = 0.5$.
- The cost-model outputs — 0.301091, -0.423508, 79.74% — are **illustrative model output from constructed parameters.** Six digits are defensible only because the inputs are exact by stipulation. **They are not measurements and Section 13 says so.**
- The effective-jobs figures 2.4691, 1.1050, 2.6316, 1.3605 and 1.5038 are **illustrative and provisional as ratio-scale quantities**, per Section 10.3, and are rounded to four decimal places at most.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere.** That is not precision. It is the absence of empirical content.

One constant appears at fifteen figures by way of an internal citation and its status must be stated. Curzi [2026] carries the minimum sustainable frequency $f_{\min} = ke^{2c/\eta}$ with $k = 0.483425732988414$ Hz, and the trichotomy in which f greater than, equal to or less than $f_{\min}$ corresponds to Q_∞ greater than, equal to or less than zero. $k = (9/8)^2/\varphi^2$ **is a DEFINED constant** — an exact ratio of exact quantities, computable to arbitrary precision — and its fifteen figures are legitimate for that reason and no other. **Attaching Hz to it is a separate and much stronger claim than computing it, and that attachment is POSTULATED, not derived.** Because φ appears, Markowsky [1992] is cited here: the golden-ratio literature is the most heavily over-claimed in mathematics and the corrective is not optional. Curzi [2026] uses the same constant in the same way. **Nothing in this paper depends on** k, which is stated so that no reader imports the frequency material into a concentration result.

12.3 Limits and boundary behaviour

limit	behaviour	reading
$L \to 0$	$p^* \to 0$	a position that cannot lose is worth taking at any probability
$G \to 0$	$p^* \to 1$	a position that cannot gain is worth taking at none
$c \to G$	$p^* \to 1$	the cost ceiling, attained exactly
$c > G$	$p^* > 1$, infeasible	**value-destroying at every probability, including certainty**
$r \to 1$	$\Delta C \to 0$	relocation to an equal-cost site is free
$r \to 0$	$\Delta C \to -0.145455$	free substance is worth 0.145455 surplus units, the model's floor
$t \to 0$	exposure $\to 0$	an instantaneous corridor has no exposure
$t \to 365$	exposure $\to 1$	a corridor that never sweeps is a store, and the model says so
$t > 365$	exposure > 1, **outside the domain**	the linear form is valid only on $[0, 365]$
$N \to 1^+$	$h \to -(\delta Q + C)$	one perimeter pays the whole bill out of stock
$N \to \infty$	$h \to \infty$ logarithmically	**a defect of the model, not a result**

Three of these are constraints on the domain rather than results, and are stated as such. The dwell model is linear and therefore invalid above a year; a corridor with a dwell above a year is not a corridor. The relative-cost model has a floor at $r = 0$ and no ceiling, which is fine for a ratio but means the model cannot represent a site that is unavailable at any price. And the surplus law grows without bound in $\ln N$, which the empirical literature contradicts: Uzzi and Spiro [2005] finds the relation between diversity and performance turning over rather than rising, May [1972] showed that increasing diversity and connectance destabilises randomly assembled systems, and Sagan [1993] documents redundancy creating new failure modes rather than removing them. **The model's domain is small** N**, and every prescription in this paper is confined to the move from** $N \approx 1$ **to** $N \approx 3$**.**

12.4 Invariance

Every effective count in this paper is invariant under relabelling of units and under any rescaling of the underlying exposures that preserves the share vector. Doubling every exposure in currency terms leaves every s_i unchanged, and hence HHI, N and $\ln N$. That is a genuine scale invariance and it is algebraic rather than empirical. **Tested at how many scales? Two: the seven-element and six-element exposure vectors reported here. No claim of empirical scale-freedom is made in this paper**; Curzi [2026k] makes the corpus's claim on that question and it concerns the storage law, not the index.

p^* is invariant under any positive rescaling of η, and it is not invariant under a change in η's value once a cost is present. The first holds because G and L are both proportional to η, so the ratio $L/(G+L)$ is independent of it. **That is a real and useful invariance: the zero-cost break-even probability does not depend on the conversion efficiency at all.** The second matters because c is not proportional to η: once an incremental cost is present, $p^* = (c+L)/(G+L)$ depends on η through the denominator, and the cost ceiling $c = G$ scales with it directly. **At $\eta = 0.50$ the ceiling rises from 0.026731 to 0.038186 and from 8.91% to 12.73% of C.** The zero-cost threshold is robust; the ceiling is not.

None of it is invariant under regrouping, and that is the content of the bloc collapse rather than a defect: the naive and bloc figures differ by construction and the difference is the finding. A reader who wants a number invariant under regrouping is asking for a quantity that cannot detect a perimeter.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. **The objection is met here and the answer is short.** The conserved quantity is the exposure share vector: $\sum_i s_i = 1$ exactly, dimensionless, and it is that constraint and nothing else that bounds the index. **Q is a stock with no stated conservation law and no operational unit, and this paper claims none for it** — which is the honest half of the answer. Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law is claimed to hold. **The arrangement claimed here is a normalised exposure vector partitioned into disjoint blocs, and nothing outside it.** Kirman [1992] is the objection that is not met: one Q, one δ and one C are written for a heterogeneous structure, and a representative parameter for a heterogeneous group generally does not exist.

12.5 Analogy discipline

Every borrowing is labelled with one of three categories: a **derivation**, where the premises are genuinely satisfied; a **shared mathematical form**, where the same equation governs both with no claim that the underlying physics applies; or an **analogy**, legitimate as motivation and never as evidence.

borrowing	source	category	justification
Hill numbers, order 2	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* ${}^2D$; an identity, not a resemblance
numbers-equivalent reading	Adelman [1969]	**1 — derivation**	the property is elementary and provable in two lines
effective number of parties	Laakso and Taagepera [1979]	**1 — derivation**	the same formula on a different share basis

borrowing	source	category	justification
portfolio variance	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix
expectation of a two-point bet	Jaynes [2003]	**2 — shared form**	$E[\Delta h]$ is an expectation over a two-point distribution; no decision-theoretic optimality is claimed
ln N as entropy	Shannon [1948]	**2 — shared form**	**Shannon entropy in nats**, dimensionless, and not thermodynamic entropy; no thermodynamic content is imported
threshold and tipping	Granovetter [1978], Schelling [1971]	**2 — shared form**	the bloc collapse has the shape of a threshold model; no individual-threshold distribution is estimated
frozen regions	Castellano et al. [2000]	**2 — shared form**	a bloc is structurally a frozen region; no interaction dynamics are claimed for jurisdictions
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	jurisdictions have not been shown to satisfy the percolation premises; only the structural property that coupling destroys assumed independence is used
normal accidents	Perrow [1984]	**3 — framing**	qualitative organisational theory, cited as a prior statement of the same observation, never as a formal result

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration arithmetic is category 1 throughout and needs no help; the threshold-model and network results are category 2 and are used for shape only.

12.6 Model comparison, and why none was performed

No model comparison was performed and the omission is deliberate rather than an oversight. Nothing in this paper is fitted: there is no estimated parameter, no held-out sample, no information criterion and no matched null, because there is no data. **A model with more parameters that fits better has not been shown to be better, and a model with no data has not been shown to be anything.** The claim made here is that the instrument follows from the identity chain in Section 12.8, not that it outperforms an alternative on fit. Durlauf [2005] asks for the prediction only this model makes, and this paper makes none: **any correlation-aware concentration measure would produce the same collapse, and any cost-aware decision rule would produce the same ceiling.** The contribution is the identification and the discipline.

12.7 Postulates

P	statement	status
P1	exposure shares are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$ and the effective count is its reciprocal	DEFINITION (CCP-052)
P3	jurisdictions inside one coordination perimeter act on one decision	POSTULATED (the perimeter hypothesis of CCP-052)
P4	the surplus law is $h = \eta \ln N - \delta Q - C$ with input term $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P5	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P6	the candidate is either its own perimeter or a member of one named alternative, with no third case	POSTULATED (modelling choice: a two-point distribution)
P7	one index unit of entity cost is $0.30/66 = 0.004545$ surplus units	POSTULATED (stipulated calibration)
P8	the marginal all-in annual cost of one entity is 0.035 surplus units	POSTULATED (constructed)
P9	corridor throughput arrives uniformly and dwells for a common time t	POSTULATED (modelling choice)

12.8 The chain that establishes the break-even method

step	consumes	statement	status
L1	P1, P2	for the baseline vector, bloc-HHI $= 0.160000 + 0.090000 + 0.090000 = 0.340000$	ARITHMETIC
L2	L1	$N = 1/0.340000 = 2.941176$	ARITHMETIC

step	consumes	statement	status
L3	P1, P2, P3	with the candidate as its own perimeter, bloc-HHI $= 0.315000$ and $N = 3.174603$	ARITHMETIC
L4	P1, P2, P3	with the call wrong, bloc-HHI $= 0.345000$ and $N = 2.898551$	ARITHMETIC
L5	L2, L3, P4, P5	$G = 0.35(\ln 3.174603 - \ln 2.941176) = 0.026731$	ARITHMETIC
L6	L2, L4, P4, P5	$L = 0.35(\ln 2.941176 - \ln 2.898551) = 0.005110$	ARITHMETIC
L7	P6	$E[\Delta h] = pG - (1-p)L = (G+L)p - L$	ARITHMETIC
R1	L5, L6, L7	$E[\Delta h] = 0.0318401p - 0.0051096$, so $p^* = 0.160476$	ARITHMETIC
R2	R1	with cost c, the threshold is $p^* = (c+L)/(G+L)$, reaching 1 at $c = G$, which is 8.9102% of C	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Only P3, P5 and P6 are POSTULATED. P3 is the perimeter postulate, stated as a hypothesis with its falsifier in Curzi [2026]; P5 is fixed in advance; P6 is the two-point restriction, and it is the postulate most likely to be wrong, since a jurisdiction may be *partially* correlated with a perimeter rather than in or out of it. **The continuous version of P6 is available and is not run here:** $\mathrm{Var}(R) = \text{naive} + \rho(\text{bloc} - \text{naive})$ **of Curzi [2026] admits any ρ, and a reader who prefers a correlation to a coin should use it.**

12.9 The chain that establishes the substance-cost result

step	consumes	statement	status
M1	constructed weights	the weighted index for the destination is $0.60(3.60) + 0.25(2.80) + 0.15(1.40) = 3.0700$	ARITHMETIC
M2	M1, constructed base	at 32 index units, the destination costs 98.24 against 32.00	ARITHMETIC
M3	M2, P7	$\Delta C = 66.24 \times 0.004545 = 0.301091$	ARITHMETIC
M4	M3, P4, P5, L2	$h = 0.377583 - 0.200000 - 0.601091 = -0.423508$	ARITHMETIC
R3	M4	the deterioration 0.301091 is 79.74% of $\eta \ln N = 0.377583$, with N unchanged	ARITHMETIC

Every step is arithmetic and every input is stipulated. The chain proves that the stated cost model implies the stated conclusion; it does not establish that the cost model is right, and nothing in this paper does.

12.10 The chain that establishes the corridor results

step	consumes	statement	status
K1	P1, P2	moving the corridor share within the bloc leaves bloc shares at 40.0 / 30.0 / 30.0	ARITHMETIC
K2	K1	therefore bloc-HHI $=$ 0.340000 and $N =$ 2.941176, unchanged	ARITHMETIC — **H3 falsified**
K3	P1, P2	the naive index rises $0.189002 \to 0.231954$, so the naive count falls $5.290949 \to 4.311200$	ARITHMETIC
K4	P1, P2	moving the share out of the bloc gives bloc-HHI 0.391448 and $N =$ 2.554618	ARITHMETIC
K5	K4, P4, P5	$\eta \ln N = 0.328266$, so the gross gain is 0.049317	ARITHMETIC
K6	K5, P8	net contribution $=$ $0.049317 - 0.035000 =$ 0.014317	ARITHMETIC
R4	K6	0.014317 is 3.79% of 0.377583	ARITHMETIC
R5	P1, P2	within the bloc, HHI $= 0.606667^2 +$ $0.393333^2 = 0.522756$, so effective countries $= 1.912940$	ARITHMETIC

12.11 Cross-checks performed

- Every exposure vector was summed and each totals 1.000000 exactly.
- $s_{\max}^2 \le$ HHI $\le s_{\max}$ holds on all four vectors: $0.084681 \le 0.189002 \le 0.291000$ for the baseline and $0.084681 \le 0.177602 \le 0.291000$ for the seven-jurisdiction vector.
- The effective-count ceiling $s_{\max}^{-2} = 11.8090$ is respected: $5.290949 \le 11.8090$ and $5.630567 \le 11.8090$.
- p^* was recomputed from h differences and from $\ln N$ differences independently and the two agreed to twelve decimal places.
- The cost table's weighted indices were recomputed from the three components and every row reproduced.

12.12 Discrepancies found in the source, printed

Four numerical discrepancies were found between the source manuscript and a recomputation from the source's own stated inputs. They are printed here rather than silently corrected.

1. **The corridor leg's net contribution is 0.014317, not 0.014316.** Exact arithmetic on the stated shares gives $\eta(\ln 2.941176\ldots - \ln 2.554618\ldots) = 0.0493174733\ldots$, so the net figure after 0.035000 is $0.0143174733\ldots$, which rounds to 0.014317 at six decimal places. The source and the corpus-wide citation of this result both print 0.014316. **The published figure is low by 10^{-6} and any recomputation will disagree in the sixth decimal.** The difference changes no conclusion; it is recorded because a reader who checks will find it.
2. **A relative-cost comparison in the source is wrong.** The source states that a bridging unit in the corridor centre costs 41.2% of what the same unit costs in the high-cost Asian comparator. On the source's own indices — 27.00 against 67.37 index units — the ratio is 40.08%. The companion figure for the other comparator, 45.8% against $27.00/58.995 = 45.77\%$, is right. **The 41.2% appears to be a slip and the correct figure is 40.1%.**
3. **A decomposition in the source is overstated.** The source says the whole gap between the corridor centre and the same state's onshore alternative is regulatory overhead. On the source's own weights the gap of 0.155 index points decomposes as -0.0275 on staff, $+0.0700$ on premises and $+0.1125$ on regulatory burden. **Regulatory burden is 72.58% of the gap, not all of it**, and the source's own accompanying sentence — that staff are cheaper onshore and premises cheaper in the centre — is inconsistent with its conclusion. The source further describes the gap as worth 15.50% of the cost of operating in the state at all; 0.155 is 15.50% of the *centre's* index and 13.42% of the onshore index, so the percentage depends on which base is meant and the source does not say which.
4. **A rounding inconsistency inside the source.** The surplus after the Central Asian leg is printed as -0.095686 in one place and -0.095685 in another. The exact value is $-0.09568607\ldots$, so -0.095686 is right.

None of the four changes any conclusion in this paper, and all four are the kind of thing a reviewer checks first.

13. Limitations

No dataset was collected and nothing here is a measurement of a real structure. Every share, cost index, job vector, entity cost and parameter is constructed and is labelled as such at each point of use. The results are exact computations on constructed inputs. **This is the corpus's central limitation and it is stated in full rather than in a footnote**: across the corpus, of 27 parameter-by-scope cells audited in a companion paper, 19 have a defined estimator, 1 has a validated one, and **0 carry a first-party measurement.** This paper carries none either.

No concentration figure here has an as-of date, because none is computed from real holdings. A concentration measure without a source and a date is not a measurement. Every share vector in this paper is constructed, so there is no source and no date to give. **Any application of this instrument to a real structure must carry both**, and Appendix B makes the date an item of the reporting standard.

The probability the paper prices is not estimated. $p^* = 0.160476$ is exact; p is not supplied. The source manuscript weighs evidence about a particular host state's conduct and concludes the threshold is comfortably cleared. **This paper does not reproduce that conclusion, because the evidence for it is jurisdiction-specific material for which the bibliography contains no source.** A threshold whose argument is left to the reader is a weaker object than it looks, and Gelman and Loken [2013] is the reason to be wary of a number that arrives after the analyst has seen which way it points.

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions in Section 4 of constitutional statutes, courts, regulators, foreign-ownership regimes, promotion

regimes, exchange-control carve-outs, treaty instruments and tax provisions are taken from the source manuscript. **The bibliography contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, and no case law.** Those claims are therefore uncited here, described rather than asserted, and require verification against the official registers before any reliance. Appendix A lists them. **This is a real gap and it is not closed here.**

Every parameter in the surplus law was chosen, not estimated, and the sensitivity to one of them decides the paper's conclusions about sufficiency. At $\eta = 0.35$ the break-even count is 4.172734 and no structure in this paper clears it; at $\eta = 0.50$ it is 2.718282 and the designed structure clears it comfortably. **That the sufficiency verdict turns on η in this way is the most important sensitivity in the paper.**

The calibration constant is a stipulation and the whole of Section 7 rests on it. $0.30/66$ converts index units of cost into surplus units and is not derived from anything. Halve it and the relocation consumes 39.87% of the gain rather than 79.74%; double it and it consumes more than the whole gain. **The ratios in Section 7.1 survive any rescaling; the conclusion that relocation consumes most of the gain does not.**

The two-point restriction on the bloc call is the postulate most likely to be wrong. P6 treats the candidate as either an independent perimeter or a member of one named alternative. Real coordination is a matter of degree, and the continuous family of Curzi [2026] is the right object where a correlation can be assigned. **No correlation was estimated anywhere in this paper.**

The job vectors were assigned, not measured, and their scale type is not established. Section 10.3 states this. The conjoint conditions were not tested [Michell, 1997, Luce and Tukey, 1964]; the ordering and the 2.00 threshold survive and the magnitudes do not.

The dwell model has no empirical content whatever. It is $t/365$. It assumes uniform arrival and common dwell, tests neither, and measures no real corridor. **It is included because it makes the exposure question answerable, not because it answers it.**

The corridor result is a difference between two constructed configurations, and the cost it is differenced against is itself constructed. 0.035 surplus units for a marginal entity is a stipulation. At 0.020 the leg's net contribution would be 0.029317 rather than 0.014317, and the paper's characterisation of it as thin would not hold.

The effective count measures independence and not capacity, and none of the positions priced here is assessed for whether it can carry the load assigned to it. That is a separate axis and Curzi [2026] measures it.

13.1 Rigour checks not met, listed by name

The standing checks of Section 12 were run in full. The following did not pass and are printed here rather than left for a reader to find.

1. **No first-party measurement exists anywhere in this paper.** Every figure is exact arithmetic on stipulated inputs, so the paper cannot be wrong in the way a measurement can be wrong.
2. **No uncertainty is reported anywhere**, because nothing is estimated. That is the absence of empirical content, not precision.
3. **No as-of date is attached to any concentration figure**, because no real holdings were measured.
4. **The dimension of η and of the calibration constant are supplied by this paper, not by the source.** The source treats both as bare numbers. Section 12.1 assigns the readings explicitly rather than silently.
5. **Q, C, h, G and L have no operational unit.** The break-even probability is unit-free and survives; the magnitudes do not mean anything until an index unit is defined, and none is.
6. **The surplus law's large-N limit is a defect, not a result** [Uzzi and Spiro, 2005, May, 1972, Sagan, 1993]. The domain is small N and is stated in Section 12.3 rather than discovered

by a reader.

7. **The conjoint conditions were not tested for any job vector**, so every effective-jobs figure is provisional as a ratio-scale quantity [Michell, 1997, Luce and Tukey, 1964].
8. **Model comparison was not performed** — no out-of-sample test, no information criterion, no matched null — because nothing here is fitted.
9. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. **Any restatement of this paper that reaches for a heavy-tail or power-law claim about holdings must run that procedure first**, and must read Stumpf and Porter [2012] on why passing it still would not identify a mechanism.
10. **The bloc assignments are stipulated reference groups, not identified effects** [Manski, 1993, Brock and Durlauf, 2001, Shalizi and Thomas, 2011]. The price is that they are modelling positions.
11. **The framework's own parameters are exempted from the reflexivity the framework asserts** [Lucas, 1976, MacKenzie and Millo, 2003]. **That is an inconsistency and it is not resolved here.**
12. **There is no conservation law for** Q [Mirowski, 1989]. Section 12.4 gives the one genuine conservation — shares sum to one — and states plainly that the stock variable has none.
13. **Aggregation is unaddressed** [Kirman, 1992]: one Q, one δ and one C are written for a heterogeneous structure.
14. **Expected value and time average are not the same thing, and Section 6 reports the first** [Peters, 2019]. $E[\Delta h]$ is an ensemble average over a bet that is taken once. **No single structure experiences it.** This is the sharpest unmet objection to the break-even method and it is not answered.
15. **The surplus functional's form is underdetermined** [Latané, 1981, Briscoe et al., 2006] and nothing here discriminates it; Section 3.9 concedes it and names Peters and Gell-Mann [2016] as the warrant the argument actually needs.
16. **No differential prediction is offered** [Durlauf, 2005]. Any correlation-aware concentration measure and any cost-aware decision rule would produce the same results.
17. **Small-sample bias in the effective-count estimators is not addressed** [Chao et al., 2014], and the paper does not resolve whether a constructed exposure vector is a census or a sample.
18. **The paper is exposed to its own measurement becoming a target** [Goodhart, 1975, Campbell, 1979]. The only defence offered is the reporting standard of Appendix B.

14. Conclusion

This paper establishes six results in the form the rest of the corpus cites, and the following statements are the fixed text of each.

R1. A bloc classification that cannot be settled in advance is priced as a bet on the two classifications that bracket it. On the designed six-jurisdiction structure, moving five percentage points of exposure from the Western position into a candidate fourth perimeter gives, if the candidate is genuinely independent, bloc-HHI 0.315000, $N = 3.174603$ and a gain of $G = +0.026731$; and if it is not, bloc-HHI 0.345000, $N = 2.898551$ and a loss of $L = 0.005110$. Hence $E[\Delta h] = 0.0318401p - 0.0051096$ and the break-even probability is $p^* = 0.160476$.

R2. With an incremental maintenance cost c, the threshold becomes $p^* = (c + 0.0051096)/0.0318401$. It reaches 1.000000 at $c = 0.0267305$, which is 8.9102% of the group's entire $C = 0.30$ maintenance budget, so **the leg is worth nothing at any probability whatever once its incremental cost exceeds that ceiling.** The threshold rises 31.4069 probability points per unit of cost, or 0.0942 per one per cent of C.

R3. The operating jurisdiction carries 18.2% of the designed structure and accounts for 79.74% of the whole diversification gain. On the constructed cost model, relocating the operating leg to the highest-cost candidate adds 66.24 index units at $0.30/66 = 0.004545$ surplus units each, raising C to 0.601091 and driving h from -0.122417 to -0.423508, with the effective bloc

count unchanged at 2.941176. The destination index at which relocation consumes half the gain is 2.297943, and the index at which it consumes all of it is 3.595886.

R4. The corridor leg's marginal contribution, measured against its own counterfactual: removing it and moving its 11.8% out of the bloc gives bloc-HHI 0.391448, $N = 2.554618$ and $h = -0.136733$, so its gross contribution is 0.049317 and, after 0.035000 of maintenance, its net contribution is 0.014317 — 3.79% of the total gain. Moving the same share within the bloc instead leaves the effective bloc count at 2.941176 exactly while the naive jurisdiction count falls from 5.290949 to 4.311200. Within the bloc, the leg raises the effective country count from 1.000000 to 1.912940.

R5. The job-concentration diagnostic, $S = \sum_j v_j^2$ with effective jobs $1/S$ and a band boundary at 2.00: the as-found operating company at $(0.25, 0.55, 0.20)$ scores $S = 0.4050$ and 2.4691 effective jobs, OVERLOADED, against a specialist target of $(0.05, 0.95, 0.00)$, $S = 0.9050$ and 1.1050. The corridor vehicle as specified scores 0.3800 and 2.6316; specialised on bridging it scores 0.7350 and 1.3605. **The magnitudes are provisional as ratio-scale quantities; the ordering and the threshold are not.**

R6. Corridor exposure as a function of dwell: one day exposes 0.27% of the year's flow, seven days 1.92%, thirty days 8.22%, ninety days 24.66% and one hundred and eighty days 49.32% — same corridor, same volume, one variable.

Counter-result. The corridor's bloc-count case fails. Its measured net contribution is 0.014317, only 3.79% of the diversification gain, and moving its share to the other member of its own bloc leaves the effective bloc count exactly unchanged. **H3 was tested and not met**, and the case for the position rests on the within-bloc country count and on the corridor function, neither of which is a bloc-count argument. **Likewise the Central Asian position is decided by its invoice and not by the sixteen per cent probability**: the geopolitical argument the source material spends its pages on is settled at $p^* = 0.16$, and the argument that decides the position is a fee that has to stay below 8.91% of the maintenance budget.

And the structure remains below its build threshold throughout. After the Central Asian leg, $N = 3.174603$ against a break-even of 4.172734, with $h = -0.095686$. **Every position priced in this paper improves a structure that still does not clear the criterion**, and the honest summary is that the improvements are real, small, and dominated by their own maintenance costs.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the principal, the asset mix, the exposure shares, the relative-cost indices, the entity job vectors, the marginal entity cost, the calibration constant and the corridor dwell policy — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-058_fig01.py` through `figs/src/CCP-058_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text**, with one stated exception recorded in the caption of the corridor figure: the naive jurisdiction count for the third configuration, 4.657098, is computed here from the source's own share vector and does not appear in the source.

Jurisdictional and legal descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative and treaty material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction. Appendix A lists the claims affected. Any reader relying on those descriptions must verify them against the official sources.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The principal, heirs, employees and counterparties described in the constructed case are invented and correspond to no person.

Preregistration

This paper reports no preregistered empirical test. The parameter set $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ and the marginal entity cost 0.035 were fixed before every measurement reported here, so that no criterion could be adjusted to fit an outcome. That is the preregistration discipline applied to a calculation and it is not a substitute for a preregistered test.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions and structural arrangements for the purpose of measuring concentration, cost and resilience. No recommendation is made in respect of any particular person, asset, structure or jurisdiction. Constitutional provisions, foreign-ownership regimes, investment-promotion conditions, exchange-control carve-outs, tax deductions, substance requirements and enforcement arrangements all change and vary by jurisdiction and by activity; every such statement in this paper is carried from the source manuscript, is flagged in Appendix A, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.

Appendix A. Claims requiring verification against primary sources

The following statements rest on legal or regulatory detail that changes, and **none of them is cited to the bibliography, which contains no primary sources for any individual jurisdiction**. They are reproduced from the source manuscript, are described rather than asserted, and require confirmation with counsel in the relevant jurisdiction before any reliance. **No measurement in this paper depends on any of them being true.**

A.1 The Central Asian centre. The constitutional statute establishing the centre and the constitutional provision entrenching it, with the procedure and majority required to amend either. The hierarchy of applicable law inside the centre and the gap-filling rule where its own instruments are silent. The centre's court: constitution, jurisdiction, bench, and any opt-in route for parties with no connection to the centre. The statutory basis, procedure, grounds of refusal and actual practice for enforcing the centre's judgments elsewhere in the host state,

and how many have in fact been enforced. The arbitration institution's rules and seat provisions, and whether awards under them are treated as host-state-seated for 1958 Convention purposes. The host state's accession date to that Convention and any reservations. The regulator's licensing categories and rulebooks. The names, numbers, dates and consolidated texts of every instrument relied on — **the source names none of them, deliberately.** The foundations and trust regimes, including separate legal personality, purpose vehicles, reserved powers, disclosure, any mandatory supervisory office, and continuation and transfer-out. The corporate income tax exemption: qualifying activities, participant categories, its sunset date, and the treatment at sunset. Currency-control relief: scope and limits. The host state's participation in automatic exchange of account information and its beneficial-ownership regime. Its current status with the international anti-money-laundering standard-setter. The correspondent banking relationships of any host-state bank the structure would rely on.

A.2 The operating base. The foreign-business statute: current restricted-activity lists, the definition of a foreign person, the nominee provision's wording and penalties, minimum capital, and licence practice. The bilateral treaty conferring ownership rights on nationals of one partner state: excepted sectors, certification procedure, termination provisions, and whether a chain of the constructed case's shape qualifies. The investment-promotion legislation: governing act, current categories and incentive schedule, the scope and conditions of land rights, and what happens to land held under them if promotion lapses. The land-ownership regime and any statutory cap on the hire of immovable property. The corporate income tax rate and the interaction between any promotion exemption and the state's implementation of the global minimum tax. Personal income tax: the residence day threshold, day-counting rules, and the current progressive scale. **The revenue order effective from 1 January 2024 on remitted foreign-source income, its number and scope, and any subsequent order addressing income derived before that date** — the source asserts nothing about a carve-out and none should be assumed. Withholding rates and transfer-pricing documentation thresholds. Exchange-control documentation and reporting. Alien-employment permit procedure, registered capital per permit, and any employee ratio. Succession over locally-situated assets. The arbitration legislation and the current position on enforcement of awards. **Regularisation of a historical nominee position: exposure for the elapsed period, available routes, and disclosure obligations — the most important item in this list.**

A.3 The corridor centre. The statute establishing the unified regulator, its powers, the scope of functions transferred from the sectoral regulators, and the regulatory challenge and appellate route. The special-economic-zone legislation as it applies to a unit in the centre. **The exchange-control statute and the precise scope of the treatment of units in the centre as persons resident outside the state, the notifications granting it, and the transactions covered — the load-bearing item.** The fund-management, banking, leasing, insurance and bullion frameworks, and whether each remains the operative instrument. The income-tax deduction relied on: section, conditions, qualifying activities, its ten-years-in-fifteen mechanic and commencement window, the minimum-alternate-tax position, and interaction with the general anti-avoidance rule. The relevant double-taxation agreement and its amending protocol, with grandfathering. The enforcement position: which foreign judgments are directly executable, the reciprocating-territory list, the arbitration legislation, the state's position under the 1958 Convention, and which disputes are not arbitrable. Classification of each vehicle type for automatic exchange purposes. Beneficial-ownership filings and access. Physical presence, minimum employment and net-worth requirements per vehicle type. Corporate residence and place-of-effective-management tests.

A.4 General. For all three positions: corporate residence and central-management-and-control tests in every jurisdiction from which decisions concerning the entity might be taken; the current status of each state under the international anti-money-laundering standard; and the recognition and enforcement position for both judgments and awards in every jurisdiction where the group holds assets.

Appendix B. The reporting standard for a marginal-leg decision

Any marginal jurisdictional position decided by the methods in this paper reports the following, and nothing less. It extends the reporting standard of Curzi [2026] to the marginal case.

```
1  the share basis, stated in one sentence
2  the exposure vector before and after the position, summing to 100.0%
3  the bloc assignment for the candidate, with its evidence class, and
   the named alternative assignment used for the wrong-call branch
4  bloc-HHI and N under BOTH assignments
5  G, L, and the break-even probability p* = L / (G + L)
6  the incremental annual cost c, decomposed into legal, substance,
   compliance and administration, and c as a percentage of C
7  the cost ceiling c = G, and the position's headroom against it
8  the assessed probability, stated as above or below p*, with the
   observable that would change the call
9  the date, and the diff against the previous measurement
```

Item 6 is the item the exercise exists for and it is the one most often omitted, because the incremental cost of a leg is spread across four invoices from three firms and is never totalled. **Item 9 decays first and matters most**, because a bloc call is invisible except as a difference between two measurements taken a year apart.

Item 8 is a statement of position, not an estimate. The standard deliberately does not ask for a number, because no defensible reference class exists for a one-off classification of a jurisdiction. It asks whether the assessor is above or below a stated threshold and what would move them across it — which is a recordable, datable, auditable claim, and an estimate would not be.

Chapter 59

Currency Drag, Cost Ceilings, and Funding-Source Independence

Abstract. Three positions are priced against the same surplus law, and in each the result runs against the jurisdiction being examined. On currency: at a 15 per cent annual hard-currency drag, an allocation of 25.1722 per cent of protected capital to the local unit drives the surplus to exactly −0.500000, cancelling the entire eta·ln(N) = 0.377583 gain that the whole jurisdictional redesign bought; a 10 per cent allocation costs 0.150000, or 39.73 per cent of that gain. What decides whether a weak currency is a cost or a loss is dwell: at a seven-day average dwell even a 40 per cent annual drag costs 0.767 per cent per pass, while at 180 days the same currency costs 19.726 per cent. The bloc arithmetic also cuts against the operating case: sizing a Turkish leg at 8 per cent of the structure lowers the effective bloc count from 2.9412 to 2.8324, so the case rests on customs-union access worth 1.35 per cent of group revenue. An African leg (Mauritius 8.0 per cent, Kenya 5.0) raises effective blocs from 2.924302 to 3.639010 and buys 0.076530 of surplus, setting a cost ceiling of roughly 25.5 per cent of the existing maintenance base: at C = 0.38 the surplus is −0.127902, worse than the −0.124431 baseline. Funding sources are measured on the same instrument: four Western lenders read 3.509 effective lenders but 1.00 effective funding blocs, and the redesigned book reaches 3.175 optimistically and 2.410 after an honest correlation adjustment. The source is found to use two incompatible bloc partitions of the same exposure vector, giving N = 2.941176 against 2.924302; both are reported, and five further discrepancies are printed rather than silently repaired.

Keywords: currency depreciation; dwell time; customs union; treaty networks; Islamic finance; sukuk; funding diversification

Series: D. Structure and Resilience **Paper:** CCP-059

1. Introduction

A structure that has arranged its jurisdictions well can still lose everything the arrangement bought, and it can lose it in three ways that never appear on an organisation chart: by holding a depreciating unit of account, by paying more to maintain a leg than the leg is worth, and by financing itself from four counterparties that all answer to one supervisor. This paper measures all three against the same instrument and reports, in each case, a result that runs against the position being examined.

The instrument is the concentration measurement of Curzi [2026] — HHI as the sum of squared exposure shares and the effective count as its reciprocal, with a naive four-jurisdiction count of 3.41 collapsing to exactly 1.00 once coordination blocs are recognised. The law it feeds is the storage law of Curzi [2026a], $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, whose map is Lipschitz with modulus $1-\delta$ so that $\delta > 0$ makes it a contraction with steady state $Q^* = (\eta S - C)/\delta$, and its one-period balance $h = \eta \ln N - \delta Q - C$. **Everything below is a difference in that balance.**

Four measurements, and three of them go against the case being made.

First, a depreciating unit of account enters the surplus law through the erosion term and can cancel the entire jurisdictional gain. Treating an annual hard-currency drag d on a share w of protected capital as an addition to the erosion rate, $\delta_{\text{eff}} = \delta_0 + dw$, the balance becomes linear in w: at $d = 0.15$, $h(w) = -0.122417 - 1.5w$. **A 10 per cent allocation costs** 0.150000**, which is** 39.73% **of the entire** $\eta \ln N = 0.377583$ **that the jurisdictional redesign bought, and at** $w^* = 0.251722$ **the balance is exactly** -0.500000 **— the same number the conventional single-perimeter structure reads before any redesign at all.** Every entity stays in place, the chart still looks right, and the gain is gone.

Second, dwell rather than depreciation decides whether a weak currency is a cost or a loss. Erosion per pass is $dn/365$ for a receipt dwelling n days. **At a seven-day dwell even a 40 per cent annual drag costs** 0.767% **per pass — the order of a bank spread. At one hundred and eighty days the same currency costs** 19.726%**, which is a loss of capital.** The currency did not change; the policy did. That is the same shape Curzi [2026] reports for a corridor, where exposure is dwell divided by the year and nothing else.

Third, a leg proposed for diversification can lower the very count it was proposed to raise, and a leg that does raise the count can still fail on its invoice. An operating leg sized at 8 per cent of the structure lowers the effective bloc count from 2.941176 to 2.832412 when scored in the bridge row and to 2.919742 on the more generous scoring — **below the baseline on both**, because its share lands in a row that was already the largest; its case therefore rests entirely on a customs-union tariff saving worth 1.35% of group revenue, which is a logistics argument and not a resilience one. And a regional holding leg that raises the effective bloc count from 2.924302 to 3.639010, buying 0.076530 of surplus, **fails outright at the maintenance cost proposed for it**: at an incremental 0.08 the balance falls from -0.124431 to -0.127902. The break-even is exact — incremental cost below 0.076530, roughly 25.51% of the existing $C = 0.30$ — and correct cost attribution, charging the structure only the costs the structure causes, flips the decision to $h = -0.087902$.

Fourth, the same instrument pointed at the liability side finds the conventional metric moving the wrong way. Four lenders at 40 / 25 / 20 / 15 read 3.508772 effective lenders and 1.000000 **effective funding perimeters**, which is the same exact zero Curzi [2026] finds on the asset side. Replacing the syndicate with four tranches in four distinct perimeters *lowers* the naive effective source count to 3.174603 while raising effective funding blocs from 1.000000 to 3.174603. **A treasurer optimising lender count would reject the refinancing.** An honest correlation adjustment applied against this paper's own result — collapsing two tranches that draw on one pool of institutional liquidity — cuts the figure to 2.409639, and **the answer is reported as a range rather than as the flattering endpoint.**

What the paper does not do. It estimates no depreciation rate, no cost and no correlation. Every drag rate, every maintenance figure and every share is constructed and stated as such. **The contribution is the arithmetic that converts each of those inputs into a decision, and the arithmetic is worth exactly what the inputs are worth.**

Positioning. The collapse on which all four measurements depend — several units inside one perimeter behaving as one — is not new machinery. A small correlated shift producing a discontinuous collective outcome is the threshold-and-tipping mechanism: Granovetter [1978] establishes that the distribution of individual thresholds rather than the mean decides whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate segregation, generalised in Schelling [1978]. **Reading an individual-level parameter straight into an aggregate is exactly what a perimeter assignment does, and that literature is the standing warning against it.** Castellano

et al. [2000] supplies the closest formal analogue of a perimeter — the same interaction that raises local agreement freezes global diversity into non-interacting regions — and on the lending side Buldyrev et al. [2010] is the structural statement that coupling destroys the independence a naive count assumes.

The reflexive loop and its identification problem. A perimeter assignment is a forecast that conditions the behaviour it forecasts, which is the reflexive loop $T(x) = W(x, M(x))$ of Curzi [2026], whose founding reframing is that comfort is the felt total of present costs, so the present state is a local minimum of the comfort landscape by definition rather than by luck. **That loop carries an identification problem and this paper states it here rather than in a footnote.** Manski [1993] proves that a linear-in-means reflexive specification is **not identified from observational data**: the endogenous social effect cannot be separated from contextual effects or from correlated unobservables, however much data is collected, and Shalizi and Thomas [2011] reinforce it for network data. **No observation of the behaviour of lenders or of jurisdictions could therefore confirm a perimeter assignment derived reflexively.** The remedy adopted is stipulation with a defence — the perimeter test of Curzi [2026] — which Brock and Durlauf [2001] shows can be made rigorous, and its price is that **every perimeter assignment in this paper is a modelling position rather than an identified empirical result.**

A note on what half of this material is. The source manuscript is, in substantial part, a descriptive comparative survey of five jurisdictions and of a body of contract law. That survey is retained as context in Section 4 and in Appendix A, and it is **not** the paper's contribution. **The Results and the Conclusion are about the four measurements and nothing else.** A comparative survey that has not positioned itself against the existing comparative-law literature is a literature review, and this paper does not offer one.

2. Hypotheses

Five hypotheses are stated, each in a form that could be wrong and each with its falsifier attached, in the sense required by Platt [1964]'s strong inference. Meehl [1967] is the relevant warning: a directional prediction is cheap, and the defensible response is a point prediction with constants attached. **Two of the five are reported below as not met, and they are reported in the same plain language a success would have received.**

H1 — the allocation hypothesis. A local-currency allocation enters the surplus law through the erosion term and can cancel the whole jurisdictional gain without changing the effective bloc count. *Predicted:* with a 15 per cent annual hard-currency drag, $h(w) = -0.122417 - 1.5w$, so $w = 0.10$ costs 0.150000 — 39.73% of the 0.377583 gain — and $w^* = 0.251722$ gives $h = -0.500000$ exactly. *Falsified by:* a measured hard-currency return on local instruments over the holding period satisfying $(1+r)/(1+\Delta) \geq 1$, at which the allocation would carry no drag at all and the erosion term would be unchanged.

H2 — the dwell hypothesis. Whether a depreciating currency is a transaction cost or a capital loss is decided by dwell and not by the depreciation rate. *Predicted:* erosion per pass is $dn/365$, so a 40 per cent annual drag at a seven-day dwell costs 0.767% while a 15 per cent drag at one hundred and eighty days already costs 7.397% — **the lower drag costing nearly ten times more.** *Falsified by:* erosion that scales with the drag rate independently of dwell, or a conversion mechanism whose cost rises faster in frequency than the erosion it avoids.

H3 — the operating-leg hypothesis. Adding a genuinely non-aligned operating jurisdiction raises the effective bloc count. *Predicted:* an operating leg sized at 8 per cent of the structure raises N above the baseline 2.941176. *Falsified by:* any defensible scoring of the new jurisdiction under which N falls. **This is the first hypothesis reported as not met.**

H4 — the regional-leg sufficiency hypothesis. The regional holding leg's diversification gain exceeds its incremental maintenance cost. *Criterion, fixed in advance:* the leg is worth building if and only if its incremental maintenance cost is below the surplus it buys, $\eta\,\Delta \ln N = 0.076530$, which is 25.51% of the existing $C = 0.30$. *Falsified by:* an incremental maintenance cost at or above 0.076530 while η, δ and Q are held at the stated values. **This is the second**

hypothesis reported as not met, at the cost proposed for it.

H5 — the liability-side hypothesis. Independence bought on the funding side is cheaper per unit of effective bloc than independence bought on the jurisdictional side. *Predicted:* the refinancing raises effective funding blocs from 1.000000 to between 2.409639 and 3.174603 at an assumed incremental cost of 0.10, buying at least 1.409639 of effective bloc, while the regional jurisdictional leg buys 0.714708 of effective bloc at an assumed 0.08 — 0.070940 **of cost per unit of effective bloc against** 0.111930**.** *Falsified by:* a measured governance cost for the funding tranches exceeding the conservative surplus gain of 0.307817, or a demonstration that the tranches share a perimeter more completely than the conservative collapse assumes.

Not hypotheses, and labelled as such. Four statements in this paper are not falsifiable as they stand.

- *Applying the surplus term to funding-source perimeters* is an **extension by analogy and not a derivation.** The storage law of Curzi [2026a] was specified over protected capital and its coordination perimeters. **The robust part of Section 9 is the concentration arithmetic, which is definitional; the h figures there are indicative of magnitude only.** The source manuscript states this and the paper keeps it.
- *The logarithmic form of the input side* is a **modelling choice** carried from Curzi [2026], whose four-currency carrying cost — coin, hours, attention, foreclosure — is the corpus's statement that felt comfort decays over weeks while carrying cost does not decay at all. Section 3.9 states what would discriminate the form and concedes that nothing here does.
- *The parameter set* $\eta = 0.35$, $\delta_0 = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice** fixed in advance of every measurement below, which is the preregistration discipline of Nosek et al. [2018] applied to a calculation.
- *The perimeter assignments* are **stipulated reference groups**, not identified from data [Manski, 1993, Brock and Durlauf, 2001].

3. Method

3.1 The instrument, and which effective count it is

The concentration instrument is not restated here; Curzi [2026] establishes it. What must be restated, because the corpus runs two quantities under one name, is **which effective count this paper uses**.

Throughout this paper the effective count is HHI^{-1}, the reciprocal of the sum of squared shares, **which is the Hill number of order two.** Hill [1973] defined the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types that would give the observed value of the underlying index; at $q = 2$ this is HHI^{-1} exactly. Jost [2006] is the statement that entropies are not diversities and that their numbers-equivalents are; Jost [2007] extends the correspondence to partitioned data, which is what a perimeter collapse is. The same arithmetic was reached independently by Simpson [1949] in ecology and Laakso and Taagepera [1979] in political science; the numbers-equivalent reading of the concentration index is Adelman [1969]'s; the index's history runs through Hirschman [1945] and Herfindahl [1950]; and its regulatory thresholds are stated in the merger guidelines [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and HHI^{-1} is the exponential of the Rényi entropy of order two [Rényi, 1961].

The corpus's other effective count, the affine $N_{\text{eff}} = 1 + (N-1)u$ **of Curzi [2026], is not a Hill number of any order and carries no external support.** It is a linear interpolation between 1 and N. This paper does not use it and refers to it only by name. Hurlbert [1971] is the standing discipline: "diversity" has been used for so many distinct quantities that the word carries no content without its formula attached. Chao et al. [2014] show that low-order diversity estimators are biased on small samples, and a four- to eight-element exposure vector is a

small sample; no correction is applied and Section 13 records the gap. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, which is exactly where the as-found funding book of Section 9 sits.

No distributional or scaling claim is made anywhere in this paper. Lender shares of 40 / 25 / 20 / 15 and exposure shares descending from 29.1 to 8.0 look like the beginning of a heavy-tail argument. **This paper fits no distribution, characterises no tail, and asserts no power law.** Clauset et al. [2009] is the reason: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few canonical data sets standing, and a straight line on a log-log plot is not evidence. **That procedure was not run, because no claim requiring it is made.** Stumpf and Porter [2012] adds that passing it would still not identify a mechanism, and Broido and Clauset [2019] is the reason the same caution attaches to borrowings from the scale-free network literature. **Every effective count here is a statistic of a finite exposure vector with at most eight entries.**

3.2 Currency drag as an addition to the erosion term

The corpus's storage law already contains the term this measurement needs. Curzi [2026a] gives $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, in which δ is the fraction of the stock lost per period independently of anything the structure does. **A depreciating unit of account is exactly such a loss**, and the modelling step this paper takes is to write it as one:

$$\delta_{\text{eff}} = \delta_0 + d\,w,$$

for an annual hard-currency drag d applied to a share w of protected capital. **This is a modelling choice and not a derivation, and it is stated as one.** It assumes the drag is proportional, applies uniformly over the period, and is independent of the rest of the structure — none of which is tested here. What it buys is that the currency question and the jurisdiction question become terms in the same equation and can be compared directly, which is the whole point of having an equation.

The consequence is immediate. Since $h = \eta \ln N - \delta_{\text{eff}} Q - C$ and N does not depend on w,

$$h(w) = h(0) - d\,Q\,w,$$

which is **linear in the allocation with slope** $-dQ$, and at $d = 0.15$ and $Q = 10$ that slope is -1.5. **The allocation at which the entire jurisdictional gain is cancelled follows in one line:** $w^* = \eta \ln N/(dQ)$**.**

Curzi [2026s] reaches the structurally identical result on a different input, showing that trust enters the same law as retention through $\delta_{\text{eff}} = \delta_0 + (1-a)(1-v)$ and produces a superlinear stock dividend, from 0.4679 at $a = 0.50$ to 5.0529 at $a = 0.99$. **Two quite different phenomena entering the model through the same term is either evidence that the term is the right abstraction or evidence that the term absorbs anything put near it, and this paper cannot distinguish those two readings.**

3.3 Dwell, and the transit-versus-store distinction

For a receipt converted after n days, the expected erosion per pass at an annual drag d is

$$\text{erosion per pass} = \frac{d\,n}{365}.$$

The functional form is the simplest one available and it is a modelling choice. It assumes the drag accrues linearly within the year and that all receipts dwell for a common time. A burst arrival process with the same mean dwell gives a different instantaneous distribution and the same mean, and nothing here tests which is right.

The distinction the formula makes is the portable result: evaluate a depreciating currency as a transit medium and it is cheap; evaluate it as a store and it is ruinous; and dwell is the entire difference. Curzi [2026] reaches the same conclusion for a corridor, where exposure is $t/365$ and one day exposes 0.27% of a year's flow against 49.32% at one hundred and eighty days.

3.4 Nominal against real, and the convention that must be stated

A nominal return in a depreciating currency is converted to a hard-currency return by

$$r_{\text{hard}} = \frac{1 + r_{\text{nom}}}{1 + \Delta} - 1,$$

where Δ is the **proportional rise in units of local currency per unit of hard currency**. **This convention must be stated because the alternative reading — depreciation as the proportional fall in the value of the local unit, giving $(1+r)(1-\Delta)-1$ — produces materially different numbers from the same words.** At a 50 per cent nominal return against a "60 per cent depreciation" the first convention gives -6.25% and the second gives -40.00%, a gap of 33.75 percentage points. **The source manuscript uses the first convention throughout without naming it; this paper names it.** Section 12.12 records the ambiguity as a finding rather than repairing it silently.

Compounding is then $(1-d)^k$ over k years at a constant annual hard-currency drag d, which is what turns a manageable annual figure into a structural one.

3.5 The cost-ceiling method

Curzi [2026] states the method this paper reuses on two further cases: a leg's break-even probability is $p^* = (c+L)/(G+L)$, so **the leg is worth nothing at any probability once its incremental cost exceeds 0.0267305, which is 8.9 per cent of the group's entire $C = 0.30$ maintenance budget.** Where a leg's classification is not in doubt the same arithmetic collapses to a single inequality:

$$\text{build the leg} \iff \Delta C < \eta\, \Delta \ln N.$$

The left side is an invoice and the right side is a measurement, and the discipline is that both must be written down. **Two errors are common and both are measured below.** The first is comparing the gross gain to nothing at all. The second is **mis-attribution**: charging the structure costs the structure did not cause. Where an operating company is required by the law of the place its operations are in, its cost belongs to the acquisition and not to the structuring, and Section 8.3 shows that correct attribution reverses the decision.

Curzi [2026j] supplies the governing constraint on what may be done with a positive balance — the increment rule $r \le h$, with a recommended reserve $r \le 0.7h$ since $r_{\max} = h$ is attained only at $U = 1$, and the $h < 0$ branch in which no interaction geometry can prevent order from decreasing. **Every structure measured in this paper is on that second branch**, which is the standing reason none of the legs priced here can be justified by an appeal to headroom.

3.6 Pointing the instrument at the liability side

The instrument is defined over shares and can be pointed at any exposure vector that sums to one. Pointed at the liability side, the shares are fractions of the group's committed funding and the units are lenders or tranches; the perimeter test is unchanged — **two funding sources are in the same perimeter when one supervisory or market decision reliably withdraws both.**

Two things about this extension are stated rather than assumed. The concentration arithmetic transfers exactly, because it is definitional and depends on nothing but a normalised share vector. **The surplus term does not transfer exactly**: the storage law was specified over

protected capital and its coordination perimeters, and reading $\eta \ln N$ over funding perimeters is an extension by analogy. Under the analogy discipline of Section 12.5 that is a **category-2 borrowing — a shared mathematical form with no claim that the underlying content carries over** — and the h figures in Section 9 are indicative of magnitude and are not derived.

Curzi [2026] makes the corresponding point about which axis is measured: entity-based US exposure of 27.3 per cent against a USD share of the balance sheet of 61.0 per cent and settlement volume clearing through the US system of approximately 58 per cent, so **the entity map understates dependency by more than a factor of two.** The liability side is a fourth axis on which the same understatement occurs, and it is the one least often measured.

3.7 The perimeter call is reflexive, and what that costs

A perimeter assignment is a forecast about how a set of jurisdictions or a set of lenders will behave under a coordinated action, and it changes the behaviour it forecasts once enough structures adopt it. Merton [1948] named the mechanism; Curzi [2026] carries it as the reflexive loop.

This paper adopts stipulation with a defence and pays the price. Perimeters are fixed in advance by the test of Curzi [2026], recorded with an evidence class, and stress-tested by running the arithmetic under the contested alternative — which Sections 7 and 9 both do, in each case against the paper's own preferred answer. Brock and Durlauf [2001] is the template. **No randomisation, instrument or partial-population variation was available, so no perimeter assignment here is an identified empirical result.**

Two further objections in the same family are recorded and not answered. **The Lucas critique applies to the framework's own parameters** [Lucas, 1976]: the framework asserts that systems change when modelled and then exempts η, δ and its own correlation assumptions from that reflexivity. **That is an inconsistency and it is not resolved here.** MacKenzie and Millo [2003] documents the benign form of the same loop in the field and with dates, and Hacking [1995] states the general form. And Goodhart [1975] with Campbell [1979] give the failure mode that follows adoption: an effective count taken as a target ceases to be a good measure. The only defence offered is the reporting standard of Appendix B.

3.8 The disclosure premise

Every position priced here is assessed against one premise, stated as a design constraint and not an ethical preference: **would the structure still do its job if every element of it were disclosed to every authority with jurisdiction over any part of it?**

The premise is not this work's to claim. Kerckhoffs [1883] stated it in 1883 — a system must remain secure when everything about it except the key is public — and Saltzer and Schroeder [1975] restate it as *open design*, the principle that a protection mechanism should not depend on the ignorance of attackers. Curzi [2026] carries the constraint in full for this series, establishing that channel separation is strengthened rather than weakened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place. **Citing Kerckhoffs converts a rule that reads as a preference into a recognised engineering standard with a hundred and forty years behind it.**

The same conclusion arrives from the regulatory direction. Automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations that supervisors implement in common [Financial Action Task Force, 2012], and the substance and beneficial-ownership work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] have removed non-disclosure from the set of available design parameters. Brandeis [1914] is the older statement of the same instinct; de Goede [2011] documents the listing machinery as a technique of governance; Pistor [2019] is the scholarly account of how legal coding manufactures durability and simultaneously its sharpest critique; and Hansmann and Kraakman [2000] establishes

that asset partitioning is the irreducible function of entity law — **a separate legal personality is a partition, and its effectiveness likewise does not depend on anyone's ignorance of it.**

The premise is what makes the funding result of Section 9 measurable, because the most disclosed instrument in this paper — a listed certificate with a public prospectus, named supervisory organs, identified underlying assets and continuing obligations to an exchange — is also the one that breaks the single-perimeter dependency. **The strategy is non-obvious while every underlying fact is published by obligation, which is what the premise predicts.**

Curzi [2026] bounds what may be inferred from any of this, and the bound is carried rather than paraphrased away: category innocence is refused as a defence of acquisition, the doctrine forbids moving a harm through a discovered gap in a scheme, and the case in which the feedback loop runs through another person's will is conceded to be an unsettled seam the corpus does not close. **A paper that prices structures must state that the pricing is not a warrant**, and that is the contrast this edge carries.

3.9 What discriminates the logarithm, and what does not

Every result here inherits the shape of $\eta \ln N$. **The functional form is underdetermined by the evidence and this paper concedes that rather than defending it.** The corpus proposes $\ln(1 + (N-1)u)$ [Curzi, 2026]; Latané [1981] proposes a power law with exponent below one; Briscoe et al. [2006] propose $n \log n$ against the quadratic alternative. **All three are decreasing in marginal return and none of the measurements here distinguishes them**, because every measurement is a difference between two values of the same functional form.

One genuine strengthening is available. Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics **with no psychological assumption at all**, which is a stronger warrant than the perceptual story of Fechner [1860] because it does not require the perceptual story to be true. Curzi [2026n] identifies the corpus's own functional as a Fechner law with threshold $u_0 = 1/(N-1)$. **Where the arithmetic here needs a warrant for the logarithm, the multiplicative-dynamics one is the one it needs.** Peters [2019] is the associated warning that an expected value and a time average are different objects — directly relevant to Section 6, where a compounding drag is exactly a multiplicative process.

4. The four positions and their institutional setting

This section is context and is not a result. It states what each position is for, at the level of detail the measurements require and no further. **Every statement in it about the law, regulation, institutions or policy of any individual jurisdiction, and every statement about the doctrinal content of any body of contract law, is described from the source manuscript and is uncited**, because the bibliography contains no statutes, regulations, court rules, registry documents, case reports or religious-legal sources for any individual jurisdiction or tradition. Appendix A lists those statements item by item and Section 13 records the gap. **They must be verified against the official sources before any reliance, and no measurement below depends on any of them being true** — each measurement depends only on a constructed share vector and the stated parameters.

Where a scored institutional comparison would otherwise attach a rating to a named jurisdiction on a characteristic this paper cannot support, the comparison is de-branded, following the convention of Curzi [2026]. **Jurisdictions are named below and in the tables as labels on constructed exposure vectors; they are not the subjects of assessed claims.**

4.1 Türkiye: the high-inflation industrial position

The candidate is a large civil-law industrial economy of the Germanic and Swiss codal line, inside a customs union with a major bloc for industrial goods, a member of a Western security alliance, and not a participant in that bloc's listing and designation machinery. Its currency has

depreciated substantially and persistently against hard currencies, and its foreign-exchange regime restricts the ability of parties both resident there to denominate or, in specified categories, to settle certain contracts in foreign currency — **a restriction that converts a financial risk into a drafting risk, which is the structurally interesting fact about it.** The lesson the source draws generalises past the jurisdiction: **currency risk in a high-inflation state does not stay financial, because the state responds to it with rules about what may be denominated in what.**

The proposal put to the constructed principal bundles three things: an operating company for tariff-advantaged final assembly, an allocation of group liquidity to local-currency instruments, and a real-estate acquisition with an associated residency benefit. **Three proposals in one document, which is how a bundle disguises the fact that one component is good and two are not.** Sections 6 and 7 price them separately, which is the entire method.

4.2 Mauritius, Kenya and the regional holding position

The candidate holding centre is a mixed-legal-system island state with two treaty networks that are routinely conflated — a double-taxation network and an investment-protection network — whose principal historical route into a large neighbouring market was closed by protocol, and whose substance requirements were reformed to replace a deemed credit with a partial-exemption regime conditioned on core income-generating activity. Two operating markets are considered alongside it, one of which sits inside a regional harmonised business-law family that the offshore literature generally ignores.

The relevant fact for the measurement is that a fully substantiated holding vehicle in that centre is not a cheap object: resident directors of calibre, local board meetings, a local principal bank account, a local audit, and enough activity to support the exemption. Section 8 prices exactly that, against an operating group in the target market with local counsel, local audit and transfer-pricing documentation for a cross-border supply chain.

4.3 Labuan, Islamic finance, and the alternative funding perimeter

The candidate is a mid-shore centre inside a federal Asian state with a statutory suite for offshore companies, a treaty network with material exclusions, and a distinctive constitutional arrangement giving a national authority binding force on questions of Sharia compliance for financial instruments. Around it sits Islamic finance as a legal family, whose two governing prohibitions produce a distinct instrument set; the relevant instrument here is the sukuk — a certificate representing an interest in identified assets, issued through a special-purpose vehicle, listed, and supervised by a named Sharia board. **The distinction between asset-backed and asset-based issues is what decides recovery**, and it is described in Appendix A rather than asserted here.

The relevant fact for the measurement is that this is a distinct funding perimeter: its investors, documentation, regulators and domiciles differ from those of the Western syndicated loan market, and a supervisory decision in one does not mechanically reach the other. Section 9 measures what that is worth and then argues against its own answer. **Nothing in this paper is a Sharia ruling or an evaluation of any doctrinal position**; the Declarations state this and Appendix A routes every doctrinal description to verification.

4.4 The disclosure position of all three

All three positions pass the premise of Section 3.8 on the source's analysis, and the analysis rather than the conclusion is what matters. The operating company exists because the operations are there and local law requires a local entity to conduct them; it employs people and pays local tax on local profits; **its existence is compelled rather than chosen.** The regional holding vehicle's resident directors take the investment decisions, in the centre, on analysis

performed there, so a treaty benefit claimed on disclosed facts rests on a contemporaneous file recording a commercial purpose independent of the benefit. **A listed sukuk is among the most disclosed instruments available**: a public prospectus, a published pronouncement, identified assets, a named board, audited accounts and continuing exchange obligations. **Nothing in any of the three depends on an authority not knowing something.**

5. The constructed case, and two incompatible baselines

CONSTRUCTED CASE. Every fact is invented and is labelled as such at each point of use. The case is the one carried through Series D and established in Curzi [2026]: a dual national, tax resident in one Gulf jurisdiction, with three heirs resident in three different jurisdictions, one under a forced-heirship regime; manufacturing operations in one South-East Asian state, a trading company in the Gulf, an intellectual-property portfolio, London commercial real estate, and a listed-securities portfolio, with revenue arriving in five currencies.

jurisdiction	share	share^2
UAE	29.1%	0.084681
Thailand	18.2%	0.033124
UK	16.4%	0.026896
Bermuda	13.6%	0.018496
India	11.8%	0.013924
Singapore	10.9%	0.011881
total	**100.0%**	**0.189002**

Naive HHI 0.189002, so 5.290949 effective jurisdictions. **The bloc figure, however, depends on a partition, and the source manuscript uses two different ones for the same six jurisdictions. Both are reported here rather than one.**

PARTITION A -- the perimeter test of CCP-052
  BRIDGE (UAE + Singapore)                 40.0%     0.160000
  NONALIGNED (Thailand + India)            30.0%     0.090000
  WEST (UK + Bermuda)                      30.0%     0.090000
  bloc-HHI = 0.340000     N = 2.941176
  eta ln(N) = 0.377583    h = -0.122417

PARTITION B -- as used in the regional-leg chapter of the source
  Gulf (UAE)                               29.1%     0.084681
  Asian (Thailand + India + Singapore)     40.9%     0.167281
  Western (UK + Bermuda)                   30.0%     0.090000
  bloc-HHI = 0.341962     N = 2.924302
  eta ln(N) = 0.375569    h = -0.124431
```

The two partitions differ in exactly one assignment — whether the second Asian bridging jurisdiction belongs with the Gulf bridge or with the non-aligned Asian row — and they give $N = 2.941176$ against 2.924302 and $h = -0.122417$ against -0.124431, a difference of 0.002014 in the balance. Section 12.12 records this as a discrepancy in the source. **Partition A is treated as canonical throughout this paper because it is the one derived from a stated perimeter test with recorded evidence classes; Partition B is reported alongside every result the source computed on it, so that the source's own figures remain checkable.**

The break-even effective count at the stated parameters is $N^* = e^{0.5/0.35} = 4.172734$. **Both baselines are below it before any position in this paper is added, and both remain below it after all of them.**

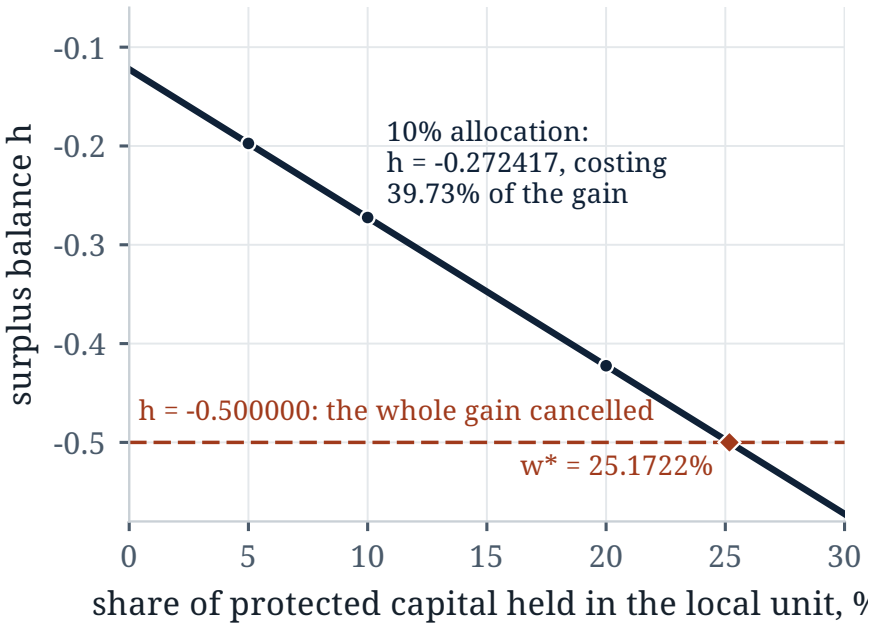

Figure 59.1: **A local-currency allocation cancels the jurisdictional gain without touching the effective bloc count: h falls linearly at 1.5 per unit of allocation, reaching the pre-redesign value of -0.500000 at 25.1722 per cent.** Modelled with a constructed 15 per cent annual hard-currency drag written into the erosion term as delta = 0.02 + 0.15w, at eta ln N = 0.377583, Q = 10 and C = 0.30; script `figs/src/CCP-059_fig01.py`.

6. Results: the currency allocation

6.1 The allocation, priced

Writing the hard-currency drag into the erosion term as $\delta_{\text{eff}} = 0.02 + 0.15w$ and holding $\eta \ln N = 0.377583$, $Q = 10$ and $C = 0.30$:

w	δ_{eff}	h	cost as a % of the gain
0.0000	0.0200	-0.122417	0.00%
0.0500	0.0275	-0.197417	19.86%
0.1000	0.0350	-0.272417	39.73%
0.2000	0.0500	-0.422417	79.45%
0.251722	**0.0578**	-0.500000	**100.00%**

The proposed 10 per cent allocation costs 0.150000 of h, which is 39.73% of the entire diversification gain of the designed structure. At $w^* = 0.251722$ the balance is exactly -0.500000 — identical to the conventional four-entity, single-perimeter structure that Curzi [2026] measures before any redesign. Every entity remains in place and the organisation chart still looks correct. H1 is supported in the model.

The answer would be no at a 5 per cent allocation too, because the same table shows a 5 per cent allocation costing 0.075000, which is 19.86% of the gain, for a yield that Section 6.3 shows is very likely negative in the group's reporting currency in any case.

6.2 Dwell, and the transit-versus-store result

Erosion per pass, $dn/365$:

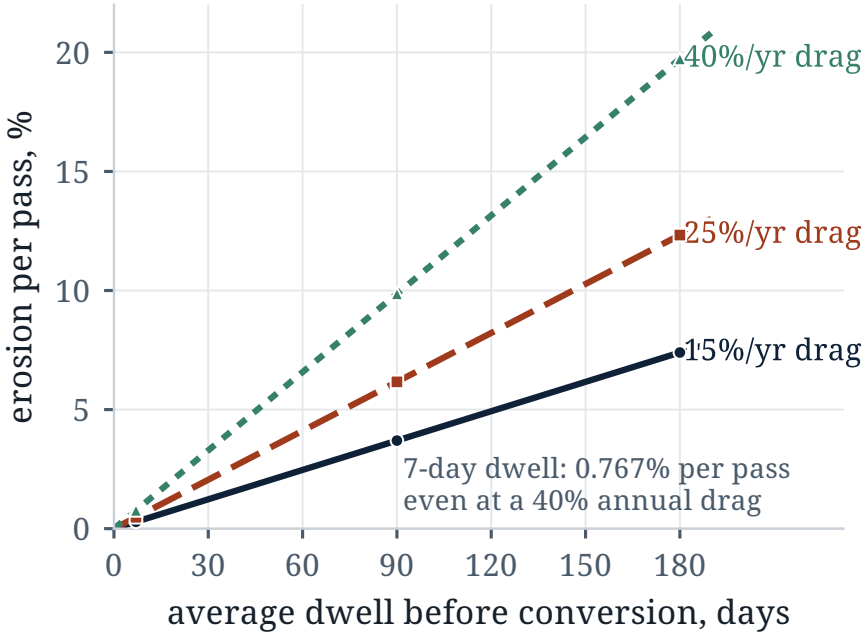

Figure 59.2: **Dwell, not the depreciation rate, decides whether a weak currency is a transaction cost or a capital loss: at seven days a 40 per cent annual drag costs 0.767 per cent per pass, while at 180 days a 15 per cent drag already costs 7.397 per cent.** Computed as d n / 365 from the constructed drag rates; script `figs/src/CCP-059_fig02.py`.

average dwell	drag 15%/yr	drag 25%/yr	drag 40%/yr
1 day	0.041%	0.068%	0.110%
7 days	0.288%	0.479%	0.767%
30 days	1.233%	2.055%	3.288%
90 days	3.699%	6.164%	9.863%
180 days	7.397%	12.329%	19.726%

At a seven-day dwell, even a 40 per cent annual currency drag costs 0.767% per pass, which is a transaction cost of the same order as a bank spread. At a one-hundred-and-eighty-day dwell the same currency costs 19.726%, which is a loss of capital. The currency did not change. The policy did. H2 is supported in the model.

The comparison that carries the result is between the cells rather than within them: a 15 per cent drag held for six months costs nearly ten times what a 40 per cent drag held for a week costs. A structure that fixes its dwell policy has done more about currency risk than one that changes currency.

6.3 Nominal against real, and compounding

The convention of Section 3.4 applies: Δ is the proportional rise in units of local currency per unit of hard currency, so $r_{\text{hard}} = (1 + r_{\text{nom}})/(1 + \Delta) - 1$.

nominal return	Δ	return in hard-currency terms
0%	20%	-16.67%
20%	20%	0.00%

nominal return	Δ	return in hard-currency terms
40%	35%	$+3.70\%$
45%	50%	-3.33%
50%	60%	-6.25%

A 50 per cent nominal return is a 6.25 per cent loss when the exchange rate rises 60 per cent, and the first number is the one that appears in the marketing. These combinations are constructed illustrations and not observed periods.

Compounding, $(1-d)^k - 1$, is where a manageable annual drag becomes a structural loss:

annual hard-currency drag	3 years	5 years	10 years
-5%	-14.26%	-22.62%	-40.13%
-10%	-27.10%	-40.95%	-65.13%
-15%	-38.59%	-55.63%	-80.31%
-20%	-48.80%	-67.23%	-89.26%

At a 15 per cent drag a local-currency position loses 55.63% of its hard-currency value in five years and 80.31% in ten. The three-year cell in that row is printed as -38.61% in the source; $0.85^3 - 1$ is -0.385875, so the correct figure is -38.59%, and Section 12.12 records it.

A compounding drag is exactly a multiplicative process, which is where Peters [2019] bites: the expected value of such a process and the time average a single holder experiences are different objects, and every figure in this section is the second rather than the first. That is the favourable direction — a time average is the honest quantity for a single structure — but it must be said which one is being reported.

7. Results: the operating leg, tested against its own bloc arithmetic

7.1 The component that survives on its own merits

The operating component is justified without reference to currency, tax or geopolitics:

```
EU-facing share of group revenue                      30.00%
constructed average duty avoided under the customs
  union for industrial goods                           4.50%
saving as a share of total group revenue               1.35%
```

That is a tariff and logistics decision of the same kind any plant location is, and it is subject to rules of origin the group does not control: if insufficient processing occurs locally, the 1.35% is not available and the operating case collapses entirely. The duty rate and the qualifying rules are constructed and uncited; Appendix A lists them.

The entity's job vector is $(H, O, B) = (0.02, 0.98, 0.00)$:

```
S = 0.0004 + 0.9604 + 0.0000 = 0.9608
effective jobs = 1 / 0.9608 = 1.0408          SPECIALIST
```

The purest entity in the architecture, and deliberately so. The status of that figure is the one Curzi [2026] states: the job vector is assigned rather than measured, treated as ratio-scale, and never tested against the conjoint conditions [Michell, 1997, Luce and Tukey, 1964]. **The ordering survives; the magnitude does not.**

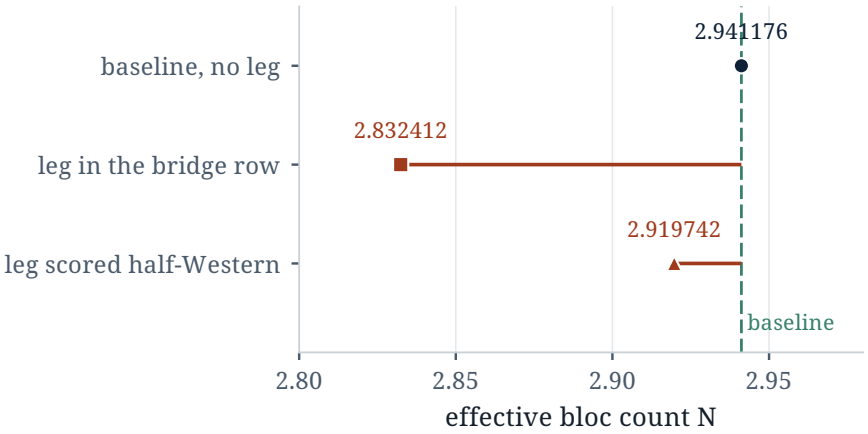

Figure 59.3: **The operating leg lowers the effective bloc count it was proposed to raise: 2.832412 when its share is scored into the bridge row and 2.919742 on the more generous scoring, against a baseline of 2.941176 on both.** Measured from the constructed share vectors of Section 7.2; the axis is truncated to resolve differences in the third decimal, and a dot plot is used rather than bars for that reason. Script `figs/src/CCP-059_fig03.py`.

7.2 H3 is not met

Suppose the operating leg grows to carry 8 per cent of the structure, with the existing allocations diluted proportionally. Score the new jurisdiction in the bridge row, on the ground that a perimeter a state can be pressured into joining is not an independent one:

```
UAE 26.772  Thailand 16.744  UK 15.088  Bermuda 12.512
India 10.856  Singapore 10.028  new leg 8.000        (sums to 100.0%)

blocs   BRIDGE 44.800   NONALIGNED 27.600   WEST 27.600
        bloc-HHI = 0.200704 + 0.076176 + 0.076176 = 0.353056
        EFFECTIVE BLOCS N = 2.832412      against 2.941176 before
```

And the alternative scoring, treating the new jurisdiction as half-Western on account of its alliance membership and its customs union:

```
blocs   BRIDGE 40.800   WEST 31.600   NONALIGNED 27.600
        bloc-HHI = 0.166464 + 0.099856 + 0.076176 = 0.342496
        EFFECTIVE BLOCS N = 2.919742      still below 2.941176
```

On both scorings, adding the leg as a balance-sheet allocation makes the structure less diversified, because its share lands in a row that is already the largest. H3 predicted the opposite and is reported here as not met. The result is one the source manuscript did not want and it is the correct one.

The failure also identifies exactly what would have to change for the answer to differ. The leg would improve N only if its share came *out of* the bridge row rather than being added to it — that is, by displacing existing bridge share rather than supplementing it. **That is a decision about the bridge layer and not about the new jurisdiction at all**, which is the kind of conclusion a measurement produces and an argument does not. Curzi [2026] reports the same sign on a different pair of additions: two Gulf additions raise the naive effective count from 5.29 to 7.13, an increase of 34.8 per cent, while the effective bloc count falls from 2.94 to 2.84, a decrease of 3.4 per cent — **more jurisdictions, less independence.**

7.3 The honest accounting of a leg that helps one term and hurts another

The operating leg improves the input side of the storage law, because cheap genuine substance lowers C, and it very slightly worsens N. **Those are different terms in the same equation and it is entirely coherent for a decision to help one and hurt the other. What is not coherent is to claim both**, which is what the bundled proposal did.

component	decision	basis
operating company	**yes**	customs-union saving of 1.35% of group revenue, subject to verified rules of origin
job assignment	OPERATING	vector $(0.02, 0.98, 0.00)$, 1.0408 effective jobs
local-currency balance-sheet position	**no**	a 10% allocation costs 39.73% of the diversification gain
maximum local balance	60 days of local operating expenditure	at a 40% drag a 60-day balance erodes 6.58% per turn
maximum average dwell	7 days	0.767% per pass at a 40% drag
bridging role	**not yet**	and only by displacing bridge-row share, never by adding to it
real estate	operating premises only	sized as a local-currency asset

8. Results: the regional leg's cost ceiling

8.1 The gain

On Partition B, which is the partition the source computes this case on:

```
AS FOUND
  naive HHI = 0.189002   ->  5.290949 effective jurisdictions
  bloc shares Western 30.0 | Gulf 29.1 | Asian 40.9
  bloc-HHI = 0.341962    ->  N = 2.924302     ln(N) = 1.073056
  h = 0.35 x 1.073056 - 0.02 x 10 - 0.30 = -0.124431

WITH THE REGIONAL LEG
  UAE 27.0  Thailand 16.0  UK 14.0  Bermuda 11.0  India 10.0
  Singapore 9.0  Mauritius 8.0  Kenya 5.0
  naive HHI = 0.157200   ->  6.361323 effective jurisdictions
  bloc shares Western 25.0 | Gulf 27.0 | Asian 35.0 | African 13.0
  bloc-HHI = 0.274800    ->  N = 3.639010     ln(N) = 1.291712
  eta x d ln(N) = 0.35 x 0.218656 = 0.076530
```

Effective blocs rise from 2.924302 to 3.639010 and Western-perimeter exposure falls from 30.0 per cent to 25.0 per cent. **The entire benefit of the leg, in the units of the storage law, is** 0.076530**.**

On the canonical Partition A the same reallocation gives bloc shares BRIDGE 36.0 | NON-ALIGNED 26.0 | WEST 25.0 | AFRICAN 13.0, so bloc-HHI 0.276600**,** $N = 3.615329$ **and a gain of** 0.072231 **— 5.6 per cent smaller.** Both are reported; Section 12.12 records that the source computes only the first and does not say the result depends on the partition.

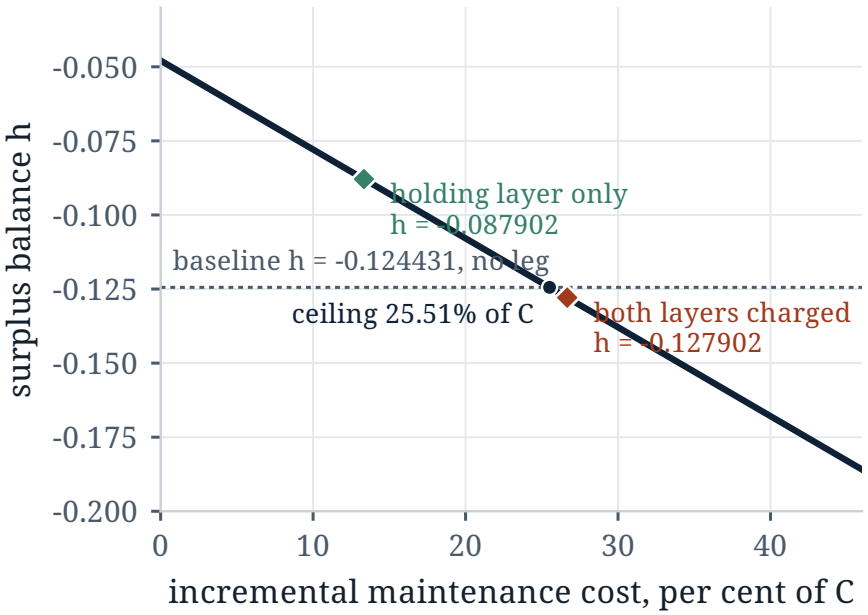

Figure 59.4: **The regional leg's whole case is a cost ceiling: at the proposed incremental maintenance of 0.08 the surplus balance falls from -0.124431 to -0.127902, and only at 0.04 — the holding layer alone, correctly attributed — does it rise to -0.087902.** Computed from the Partition B measurement with eta ln N = 0.452098; the ceiling is the gain 0.076530, which is 25.51 per cent of C = 0.30. Script `figs/src/CCP-059_fig04.py`.

8.2 H4 is not met at the cost proposed

A fully substantiated regional holding vehicle with resident directors, local board meetings, a local principal bank account and a local audit is not a cheap object, and neither is an operating group with local counsel, local audit, transfer-pricing documentation for a cross-border supply chain, and the compliance overhead of a jurisdiction under heightened monitoring. **Assume — a constructed assumption and not a quotation — that the incremental all-in annual maintenance raises C from 0.30 to 0.38.**

```
h(with the regional leg) = 0.35 x 1.291712 - 0.02 x 10 - 0.38
                         = 0.452099 - 0.200000 - 0.380000
                         = -0.127902

baseline (Partition B)   = -0.124431
```

Against the baseline, the regional leg made the structure worse. The diversification gain of 0.076530 was smaller than the maintenance increment of 0.080000, and the result is more jurisdictions, more filings, more counsel, a higher effective bloc count, and lower surplus. **H4's criterion was fixed in advance — incremental cost below 0.076530 — and it was not met.**

```
the regional leg is worth building if and only if
    incremental C  <  0.076530

against an existing maintenance budget of C = 0.30, that is a
ceiling of 25.51% of the entire existing compliance cost base
(24.08% on the canonical partition)
```

This is the sharpest local form of the corpus's own companion result: diversification raises the ceiling, it does not pay the bill, and a bloc gain bought at too high a maintenance price

is a loss. Curzi [2026] states the same inequality for a marginal leg whose classification is uncertain, where the position is worth nothing at any probability once its incremental cost exceeds 0.0267305, 8.9 per cent of the group's entire maintenance budget.

8.3 Three things that change the answer, and one that reverses it

Size. The 0.076530 gain is a function of shares rather than of absolute capital, while the cost is largely fixed. Double the group with the same share vector and the gain doubles in absolute terms while C barely moves. **There is a threshold below which the leg cannot be justified and above which it obviously can, and the ceiling above is how to find it.**

Cost attribution, which reverses the decision. In the constructed case the operating company is not optional: the group is buying a distribution business with employees, warehouses, licences and local banking, and local law requires a local entity to hold it. **That cost belongs to the acquisition and not to the structuring.** Re-running with only the incremental *holding-layer* cost — an assumed 0.04 rather than 0.08:

```
h = 0.35 x 1.291712 - 0.02 x 10 - 0.34
  = 0.452099 - 0.200000 - 0.340000
  = -0.087902        against a baseline of -0.124431
```

which beats the baseline by 0.036529. **Correct cost attribution flips the decision, and misattribution is the commonest analytical error in this field. Charge to the structure only the costs the structure causes.**

Whether a treaty benefit is real, and which term it enters. Nothing above includes a tax saving, deliberately. **If a treaty reduces withholding relative to the domestic rate, that is a reduction in δ — the erosion term — and not an increase in $\ln N$.** They are different terms in the law and must not be added together as though they were the same thing. Curzi [2026] prices the corresponding move on the substance side and gives the cost multiples exactly: 5,350 against 1,550 index units, a factor of 3.45, for a pure equity-holding entity, and 19,350 against 1,550, a factor of 12.48, for a relevant-activity entity, with break-even at USD 7,740,000 of held value at 25 basis points. **A substance requirement and a treaty benefit are two halves of the same invoice.**

9. Results: funding-source independence

9.1 The funding book as found

The instrument is defined over shares and is pointed here at the liability side, measuring how many independent funding perimeters the group actually has.

lender	share	share^2	perimeter
Bank A	40.0%	0.160000	Western
Bank B	25.0%	0.062500	Western
Bank C	20.0%	0.040000	Western
Bank D	15.0%	0.022500	Western
total	**100.0%**	**0.285000**	

```
naive HHI = 0.285000     ->  effective lenders = 3.508772
perimeter HHI = 1.000000 ->  EFFECTIVE FUNDING BLOCS = 1.000000
ln(1.000000) = 0
```

Four lenders, one perimeter, and the same exact zero Curzi [2026] finds on the asset side. A supervisory instruction, a de-risking decision or a designation affecting Western bank lending to a South-East Asian manufacturer reaches all four at once, because they share supervisors, share correspondent networks and read the same guidance. **The group has diversified its lenders and not its funding.**

9.2 The redesigned book, and the metric that moves the wrong way

The refinancing replaces the single syndicate with four tranches in four perimeters:

tranche	share	share^2	perimeter
Western syndicate, reduced	45.0%	0.202500	Western
listed sukuk issue	25.0%	0.062500	Islamic capital markets
Gulf institutional agency	20.0%	0.040000	Gulf institutional
onshore local-currency facility	10.0%	0.010000	Asian non-aligned
total	**100.0%**	**0.315000**	

```
naive HHI = 0.315000        ->  effective sources = 3.174603
perimeter HHI = 0.315000    ->  EFFECTIVE FUNDING BLOCS = 3.174603
ln(3.174603) = 1.155183     eta ln(N) = 0.404314
```

Effective sources FELL, from 3.508772 **to** 3.174603**, while effective funding blocs ROSE from** 1.000000 **to** 3.174603**. The conventional metric got worse and the real one went from zero to something.** This is the mirror image of the asset-side finding of Curzi [2026] and it is worth dwelling on: **a treasurer optimising lender count would reject this refinancing.**

9.3 The correlation adjustment, applied against this paper's own result

The whole correction of Curzi [2026] is that shares sharing a coordination mechanism must be collapsed before squaring, and intellectual honesty requires applying it to this paper's own answer. **Are the sukuk tranche and the Gulf agency tranche independent?**

Partly. They have different investors, different documentation, different regulators and different domiciles. But both draw on one pool of institutional liquidity, and a severe contraction in that pool would reach both. **The conservative reading collapses them:**

```
Western 45.0 | Islamic (sukuk + agency) 45.0 | Asian 10.0
perimeter HHI = 0.202500 + 0.202500 + 0.010000 = 0.415000
EFFECTIVE FUNDING BLOCS = 2.409639
ln(2.409639) = 0.879477     eta ln(N) = 0.307817
```

The honest answer is a range: effective funding blocs between 2.409639 **and** 3.174603**, not a point estimate. Reporting the flattering figure alone would be exactly the error the instrument exists to correct. Both ends of the range are far better than** 1.000000**, which is the finding that matters.**

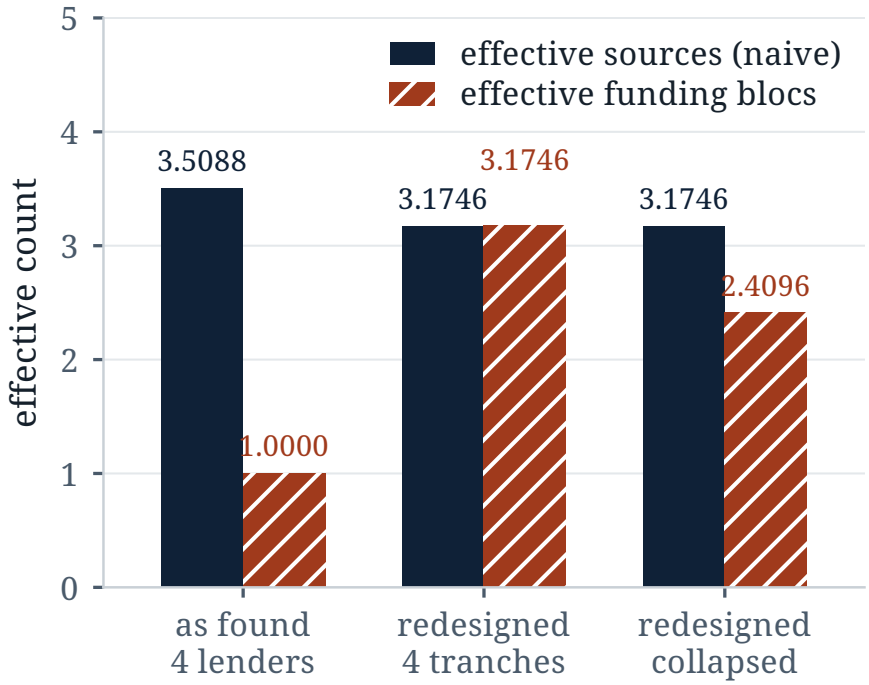

Figure 59.5: **Diversifying lenders and diversifying funding are different operations: the as-found book reads 3.508772 effective lenders and exactly 1.000000 effective funding perimeters, while the refinancing lowers the naive count to 3.174603 and raises the perimeter count to between 2.409639 and 3.174603.** Measured from the constructed share vectors of Sections 9.1 to 9.3; the range is the honest correlation adjustment applied against the paper's own result. Script `figs/src/CCP-059_fig05.py`.

9.4 What it is worth, with the caveat stated first

The caveat comes first because it governs everything after it. The storage law was specified over protected capital and its coordination perimeters, and applying its surplus term to funding-source perimeters is an **extension by analogy and not a derivation. The robust part of this section is the concentration arithmetic, which is definitional; the h figures below are indicative of magnitude and should be read as such.**

```
conservative:  0.35 x 0.879477 = 0.307817
optimistic:    0.35 x 1.155183 = 0.404314
```

Against that sits the cost. The Islamic tranches carry a permanent governance layer: supervisory-board fees, a compliance audit, structuring counsel with the relevant expertise, asset identification and maintenance for the sukuk, a listing, and purification procedures. **Assume — a constructed assumption — that this adds 0.10 to C. Against a conservative surplus gain of 0.307817 that is clearly worth doing: the incremental cost would have to exceed 0.307817 to destroy value.**

The contrast with Section 8 is the finding. There, a jurisdictional leg raised effective blocs by 0.714708 and failed on cost, because jurisdictional diversity requires paying for courts, counsel, substance and filings in each additional jurisdiction. Here, funding diversity raised effective blocs by at least 1.409639 at roughly a quarter more cost, because a funding tranche carries transaction cost rather than permanent jurisdictional overhead.

axis	effective blocs bought	assumed incremental cost	cost per unit of effective bloc
jurisdictional, regional leg	0.714708	0.080000	0.111930
funding, conservative reading	1.409639	0.100000	0.070940
funding, optimistic reading	2.174603	0.100000	0.045986

Diversifying liabilities is cheaper per unit of effective bloc than diversifying jurisdictions, and a designer working under a maintenance-cost constraint should look at the liability side first. H5 is supported in the model. **That conclusion falls out of the arithmetic rather than from a preference, and it is the most useful thing in this paper.**

10. Discussion

10.1 What follows

Three of the four measurements went against the position being examined, and that pattern is the paper's substantive claim. A currency allocation proposed for yield cancels the jurisdictional gain; an operating leg proposed for diversification lowers the effective bloc count; a regional leg proposed as an improvement fails on its own invoice. **In each case the failure was invisible from inside the proposal and visible from the equation**, because each proposal was argued on one term of the law while its cost landed on another.

Erosion is the term the field under-measures. δ is where currency drag, treaty leakage, tax friction and trust decay all arrive, and none of those appears on an organisation chart. Curzi [2026s] makes the same point on a different input, and the shared structure is that **the input side of the surplus law is bounded by a logarithm while the erosion side is linear in the stock: a bad enough δ beats any achievable N.** The measurement in Section 6 is that statement with numbers on it — a slope of 1.5 per unit of allocation against a total available gain of 0.377583.

A bundle must be unbundled before it can be priced. The three-component proposal of Section 7 contained one good component and two bad ones, and its persuasive force came entirely from being presented as one decision. **Pricing each component against the same law is what separated them**, and there is nothing clever about it beyond the discipline of refusing to evaluate a bundle.

And the liability side is cheaper than the asset side. That is the one result here that points at something to do rather than something not to do, and it falls out of a cost comparison rather than a preference: a funding tranche carries transaction cost, a jurisdiction carries permanent overhead.

10.2 What does not follow

None of these results says a jurisdiction, a currency or a funding market is good or bad. They say what a constructed share vector and a constructed cost model imply at stated parameters. Change η from 0.35 to 0.50 and the break-even count falls from 4.172734 to 2.718282, below the designed structure's 2.941176, and every conclusion about sufficiency reverses.

The failed hypotheses do not say the positions are worthless. H3 failed and the operating leg still stands, on a tariff argument the concentration instrument does not measure. H4 failed at the cost proposed and succeeded at the cost correctly attributed. **A measurement that kills the stated reason for a decision while leaving a different reason standing is doing its job.**

The funding result is not a derivation. Section 9.4 states this and it is repeated here because it is the most likely thing to be over-read from this paper: the concentration arithmetic on the liability side is exact, and the surplus figures attached to it are an analogy.

And nothing here is an empirical result. Every figure is exact arithmetic on stipulated inputs. **The paper cannot be wrong in the way a measurement can be wrong, and that is a weakness rather than a strength.**

10.3 Parallel results in the corpus

Curzi [2026] establishes a conservation result of a kind this paper does not have and would benefit from: the sum of drives $b_i = \eta_i F - c_i$ is exactly invariant under any transfer of cost among participants, verified at $+0.643688229683$ and $+1.268940530229$ with residual exactly zero. **The corresponding statement here would be that moving maintenance cost between the acquisition and the structure leaves some group-level quantity fixed — and Section 8.3 shows that it does not, because the two are charged against different balances.** The absence of a conservation law is the honest reading and Section 12.4 states it.

Curzi [2026] and Curzi [2026] supply structurally parallel results in a different domain and are cited as parallels rather than as support. The minimum sustainable frequency $f_{\min} = ke^{2c/\eta}$, with the trichotomy in which f greater than, equal to or less than $f_{\min}$ corresponds to Q_∞ greater than, equal to or less than zero, **is the same cost-against-conversion threshold this paper writes as** $\Delta C < \eta\,\Delta \ln N$, with the cost-to-efficiency ratio in an exponent rather than on the other side of an inequality. And the opposition identity $u = 1 - \rho^2$, which depends only on $|\rho|$ so that $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$ and $f_{\text{rel}} = k = 0.4834$, is **the same insensitivity to sign that makes a perimeter collapse indifferent to whether the members coordinate cooperatively or antagonistically.** Neither is evidence for anything here.

11. Failure modes

Eleven failure modes are recorded, each with the measurement that detects it.

1. Holding anything in the depreciating unit. Detected by Section 6.1: any $w > 0$ costs $1.5w$ of balance at a 15 per cent drag.

2. Confusing nominal returns with real ones. Detected by Section 6.3 and by the convention statement of Section 3.4, without which the same words give answers 33.75 percentage points apart.

3. Retaining earnings by default. A balance that is not swept is an allocation nobody decided to make. Detected by the dwell measurement.

4. Drafting in a foreign currency without checking the local denomination rules. The source records that a group which has correctly decided to price everything in hard currency can find that a particular domestic contract may not be. **This is the failure mode with no arithmetic attached**, and it is listed because it is the one most often missed.

5. Assuming security-alliance membership implies Western banking treatment. Detected by measuring correspondent access rather than treaty membership.

6. Assuming non-participation in a designation regime implies immunity from it. The perimeter test asks what a decision reaches, not who signed what.

7. Counting a pressurable state as an independent perimeter. Detected by Section 7.2: both scorings lower N.

8. Buying an asset for a collateral benefit. Detected by pricing the two decisions separately, which is the whole method of Section 7.

9. Relying on foreign judgment enforcement where arbitration is the available route. Recorded rather than measured; United Nations [1958] is the instrument and Born [2021] and van den Berg [1981] the standard treatments.

10. Underbuilding the compliance function. A permanent addition to C that does not fall away when the circumstances that caused it do, because institutional memory in correspondent banking is long.

11. Sizing the opportunity from the headline and the risk from the average. The general form of failure modes 1, 2 and 8 together, and the reason every table in this paper prints both ends of every range.

12. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the compounding chains name what each step consumes. **If dropping a postulate leaves a result standing, it is not listed.**

12.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	exposure share	$[1]$	dimensionless	defined; sums to 1 by P1
HHI	concentration index	$[1]$	dimensionless	derived from shares
N	effective bloc or perimeter count	$[\#]$**, a count**	blocs, perimeters	derived as HHI^{-1}
$\ln N$	surplus term argument	$[1]$	nats	derived
Q	protected capital	$[C]$	index units	defined; **no operational unit is supplied by the source**
δ_0, δ_{eff}	erosion rate	$[T^{-1}]$	per period	assumed

symbol	quantity	dimension	unit	status
d	hard-currency drag rate	$[T^{-1}]$	per year	assumed (constructed)
w	share of Q in the local unit	$[1]$	dimensionless	assumed (constructed)
n	dwell before conversion	$[T]$	days	assumed (constructed)
C, ΔC	maintenance cost flow and its increment	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived
r_{nom}, Δ	nominal return, exchange-rate rise	$[1]$	dimensionless, per period	assumed (constructed)
S	job-concentration index	$[1]$	dimensionless	derived from a job vector

Does $\delta_{\text{eff}} = \delta_0 + dw$ balance? δ_0 carries $[T^{-1}]$; d carries $[T^{-1}]$; w is dimensionless. **It balances only if d is expressed per the same period as δ_0.** Every figure in Section 6 uses annual rates for both, and **the source is silent on the period of δ; this paper assigns "per year" explicitly rather than assuming it, and records that assignment as its own.**

Does the erosion-per-pass formula balance? $dn/365$ multiplies a per-year rate by days divided by days per year, giving a dimensionless fraction. **It balances**, and it is the one place in the paper where a unit conversion does real work: a drag quoted per year and a dwell quoted in days cannot be combined without it, and combining them wrongly is the commonest arithmetic error in this material.

Where no operational unit exists, this audit says so. Q is protected capital in index units and no conversion to currency is supplied anywhere in the corpus. **Every figure in C and h is therefore in an arbitrary scale fixed by the stated parameters.** The effective counts, the cost ceilings expressed as percentages of C, and w^* are all unit-free and survive this; the statement that h is -0.127902 does not mean anything until the index unit is defined, and it is not.

12.2 Significant figures and epistemic status

- $N = 2.941176$, 2.924302, 2.832412, 2.919742, 3.639010, 3.615329, 3.508772, 3.174603 and 2.409639 are **exact arithmetic** on the stated shares, being reciprocals of exact rationals. Their inputs are constructed and exact as stated.
- $w^* = 0.251722$ is **exact given the parameters**, being $0.377583/1.5$. **The source rounds it to 25.17 per cent and then describes the resulting balance as exactly -0.500000; at $w = 0.2517$ the balance is -0.499967.** Section 12.12 records it.
- The cost ceilings 0.076530 and 0.072231 are exact given the parameters and the partition, and the parameters are assumed rather than estimated.
- The drag, dwell, maintenance and duty figures are **constructed model parameters**, and every quantity derived from them is **illustrative model output**. Six digits on -0.127902 are defensible only because the inputs are exact by stipulation.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere.** That is not precision; it is the absence of empirical content.

One constant appears at fifteen figures through an internal citation and its status must be stated. Curzi [2026] carries $f_{\text{min}} = ke^{2c/\eta}$ with $k = 0.483425732988414$ Hz. $k = (9/8)^2/\varphi^2$ **is a DEFINED constant** — an exact ratio of exact quantities — and its fifteen figures are legitimate

for that reason and no other. **Attaching Hz to it is a separate and much stronger claim than computing it, and that attachment is POSTULATED.** Because φ appears, Markowsky [1992] is cited: the golden-ratio literature is the most heavily over-claimed in mathematics and the corrective is not optional. **Nothing in this paper depends on k.**

12.3 Limits and boundary behaviour

limit	behaviour	reading
$w \to 0$	$h \to h(0)$	no allocation, no drag
$w \to 1$	$h \to h(0) - dQ$	the whole stock in the local unit; at $d = 0.15$, $h = -1.622417$
$d \to 0$	$h(w) \to h(0)$ for all w	a stable currency has no allocation cost
$d \to \infty$	$w^* \to 0$	at unbounded drag no allocation is admissible
$n \to 0$	erosion $\to 0$	instantaneous conversion has no cost
$n \to 365$	erosion $\to d$	a receipt held a year loses the whole annual drag
$n > 365$	erosion $> d$, **outside the domain**	the linear form is valid only on $[0, 365]$
$\Delta C \to 0$	build the leg always	a free leg is always worth having
$\Delta \ln N \to 0$	no cost is admissible	a leg buying no independence is never worth anything
$N \to 1^+$	$h \to -(\delta Q + C)$	one perimeter pays the whole bill out of stock
$N \to \infty$	$h \to \infty$ logarithmically	**a defect of the model, not a result**

Three of these are constraints on the domain rather than results. The dwell model is linear and therefore invalid above a year. The drag model is linear in w and therefore assumes the drag does not itself depend on the size of the allocation, which for a holder large relative to the market it would. And the surplus law grows without bound in $\ln N$, which the empirical literature contradicts: Uzzi and Spiro [2005] finds the relation between diversity and performance turning over rather than rising, May [1972] showed that increasing diversity and connectance destabilises randomly assembled systems, and Sagan [1993] documents redundancy creating new failure modes rather than removing them. **The model's domain is small N and every prescription here is confined to it.**

And $\delta \to 0$ is a pathology rather than an ideal, since nothing then ever decays out of the stock and any positive $\eta \ln N$ exceeding C accumulates without bound. Curzi [2026a] states the contraction property that makes $\delta > 0$ necessary: the map is Lipschitz with modulus $1 - \delta$, so a strictly positive δ is what gives a unique start-independent fixed point at $Q^* = (\eta S - C)/\delta$.

12.4 Invariance

Every effective count here is invariant under relabelling and under any rescaling of the underlying exposures that preserves the share vector. Doubling every exposure in currency terms leaves every s_i unchanged and therefore leaves HHI, N and $\ln N$ unchanged. **Tested at**

how many scales? Four — the six-, seven-, eight- and four-element vectors reported here. The invariance is algebraic, not empirical, and no claim of empirical scale-freedom is made.

w^* **is not invariant under a change in the drag**, since $w^* = \eta \ln N/(dQ)$: halving the drag doubles the admissible allocation. **The result "a 10 per cent allocation costs 39.73 per cent of the gain" is therefore a statement about a 15 per cent drag and about nothing else**, and a reader with a different drag should recompute rather than quote.

Nothing is invariant under regrouping, which is the content of the perimeter collapse rather than a defect — and Section 5 shows exactly what it costs, since two defensible partitions of the same vector give 2.941176 and 2.924302.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. **The objection is met here and the answer is short.** The conserved quantity is the exposure share vector, $\sum_i s_i = 1$ exactly and dimensionless, and it is that constraint and nothing else that bounds the index. Q **is a stock with no stated conservation law and no operational unit, and this paper claims none for it.** Cartwright [1999] supplies the discipline that makes a partial answer respectable: state the arrangement within which the law is claimed to hold. **The arrangement claimed here is a normalised exposure vector partitioned into disjoint perimeters, and nothing outside it.** Kirman [1992] is the objection that is not met: one Q, one δ and one C are written for a heterogeneous structure, and a representative parameter for a heterogeneous group generally does not exist.

12.5 Analogy discipline

borrowing	source	category	justification
Hill numbers, order 2	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* ${}^2D$; an identity
numbers-equivalent reading	Adelman [1969]	**1 — derivation**	elementary and provable in two lines
effective number of parties	Laakso and Taagepera [1979]	**1 — derivation**	the same formula on a different share basis
portfolio variance	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix
$\ln N$ as entropy	Shannon [1948]	**2 — shared form**	**Shannon entropy in nats**, dimensionless, and not thermodynamic entropy
the surplus term over **funding** perimeters	Curzi [2026a]	**2 — shared form**	the storage law was specified over protected capital; **the concentration arithmetic transfers and the surplus figures do not**

borrowing	source	category	justification
currency drag as an erosion term	Curzi [2026a], Curzi [2026s]	**2 — shared form**	a modelling choice, not a derivation: a depreciating unit and a decaying stock share a functional form
threshold and tipping	Granovetter [1978], Schelling [1971]	**2 — shared form**	the perimeter collapse has the shape of a threshold model; no threshold distribution is estimated
frozen regions	Castellano et al. [2000]	**2 — shared form**	a perimeter is structurally a frozen region; no interaction dynamics are claimed
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	lenders have not been shown to satisfy the percolation premises; only the structural property is used
normal accidents	Perrow [1984]	**3 — framing**	qualitative organisational theory, never a formal result

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority, and the sharpest instance in this paper is the funding-side surplus figure, which the source itself flags and which Section 9.4 flags again.

12.6 Model comparison, and why none was performed

Nothing here is fitted: no estimated parameter, no held-out sample, no information criterion, no matched null, because there is no data. **A model with more parameters that fits better has not been shown to be better, and a model with no data has not been shown to be anything.** Durlauf [2005] asks for the prediction only this model makes, and this paper makes none: **any correlation-aware concentration measure and any cost-aware decision rule would produce the same results.**

12.7 Postulates

P	statement	status
P1	exposure shares are non-negative and sum to 1	DEFINITION

P	statement	status
P2	HHI $= \sum_i s_i^2$ and the effective count is its reciprocal	DEFINITION (CCP-052)
P3	units inside one coordination perimeter act on one decision	POSTULATED (the perimeter hypothesis of CCP-052)
P4	the surplus law is $h = \eta \ln N - \delta Q - C$	DEFINITION (modelling choice, CCP-A02, CCP-007)
P5	$\eta = 0.35$, $\delta_0 = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P6	a hard-currency drag enters as $\delta_{\text{eff}} = \delta_0 + dw$	POSTULATED (modelling choice)
P7	receipts arrive uniformly and dwell for a common time n	POSTULATED (modelling choice)
P8	$r_{\text{hard}} = (1 + r_{\text{nom}})/(1 + \Delta) - 1$, with Δ the rise in local units per hard unit	DEFINITION (convention, stated here)
P9	the incremental maintenance of the regional leg is 0.08, or 0.04 for the holding layer alone	POSTULATED (constructed)
P10	the surplus term may be read over funding perimeters	POSTULATED (extension by analogy; **not a derivation**)

12.8 The chain that establishes the allocation and dwell results

step	consumes	statement	status
L1	P1, P2	bloc-HHI $= 0.160000 + 0.090000 + 0.090000 = 0.340000$	ARITHMETIC
L2	L1	$N = 2.941176$ and $\ln N = 1.078810$	ARITHMETIC
L3	L2, P4, P5	$\eta \ln N = 0.377583$ and $h(0) = -0.122417$	ARITHMETIC
L4	P6	$h(w) = h(0) - dQw$, linear with slope $-dQ$	ARITHMETIC
L5	L4, P5	at $d = 0.15$ and $Q = 10$ the slope is -1.5	ARITHMETIC
R1	L3, L5	$w^* = 0.377583/1.5 = 0.251722$ gives $h = -0.500000$; $w = 0.10$ costs 0.150000, 39.73% of the gain	ARITHMETIC
R2	P7	erosion per pass $= dn/365$: 0.767% at $d = 0.40$ and $n = 7$; 19.726% at $n = 180$	ARITHMETIC
R5	P8	$1.50/1.60 - 1 = -6.25\%$; $0.85^5 - 1 = -55.63\%$; $0.85^{10} - 1 = -80.31\%$	ARITHMETIC

12.9 The chain that establishes the two failed hypotheses

step	consumes	statement	status
M1	P1, P2, P3	diluting by 0.92 and adding an 8.0% leg to the bridge row gives bloc-HHI 0.353056	ARITHMETIC
M2	M1	$N = 2.832412$, below the baseline 2.941176	ARITHMETIC — **H3 falsified**
M3	P1, P2, P3	on the half-Western scoring, bloc-HHI 0.342496 and $N = 2.919742$	ARITHMETIC — **H3 falsified again**
M4	P1, P2	the regional reallocation gives bloc-HHI 0.274800 on Partition B, so $N = 3.639010$	ARITHMETIC
M5	M4, P4, P5	$\eta \, \Delta \ln N = 0.35 \times 0.218656 = 0.076530$	ARITHMETIC
M6	M5, P9	at $\Delta C = 0.08 > 0.076530$, $h = -0.127902$ against a baseline of -0.124431	ARITHMETIC — **H4 falsified**
R3	M2, M3	both scorings of the operating leg fall below the baseline count	ARITHMETIC
R4	M5, M6, P9	the ceiling is 0.076530, 25.51% of C; at $\Delta C = 0.04$, $h = -0.087902$	ARITHMETIC

12.10 The chain that establishes the funding result

step	consumes	statement	status
K1	P1, P2	four lenders at 40/25/20/15 give HHI $= 0.285000$ and 3.508772 effective lenders	ARITHMETIC
K2	K1, P3	one perimeter gives HHI $= 1.000000$ and $N = 1.000000$ exactly	ARITHMETIC
K3	P1, P2	four tranches at 45/25/20/10 give HHI $= 0.315000$ and 3.174603	ARITHMETIC

step	consumes	statement	status
K4	K1, K3	the naive count **falls** $3.508772 \to 3.174603$ while the perimeter count **rises** $1.000000 \to 3.174603$	ARITHMETIC
K5	P1, P2, P3	collapsing two tranches gives HHI $= 0.415000$ and $N = 2.409639$	ARITHMETIC
R6	K4, K5, P10	effective funding blocs lie between 2.409639 and 3.174603, with $\eta \ln N$ of 0.307817 and 0.404314	**ARITHMETIC** for the counts, **POSTULATED** for h

R6's two halves have different statuses and the row says so. The counts are exact; the surplus figures rest on P10, which is an extension by analogy.

12.11 Cross-checks performed

- Every exposure vector was summed: the diluted seven-element vector totals 1.000000 exactly, as do all four others.
- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on every vector: $0.084681 \le 0.189002 \le 0.291000$ on the baseline and $0.160000 \le 0.285000 \le 0.400000$ on the as-found funding book.
- The effective-count ceiling $s_{\max}^{-2}$ is respected in every case: $3.508772 \le 6.2500$ on the funding book and $5.290949 \le 11.8090$ on the baseline.
- w^* was obtained both by solving $h(w) = -0.5$ and by $\eta \ln N/(dQ)$, and the two agreed to twelve decimal places.
- Every compounding cell was recomputed as $(1-d)^k - 1$; eleven of twelve reproduced and the twelfth is recorded in Section 12.12.
- Every perimeter HHI was recomputed by summing shares within perimeters before squaring, and independently as an explicit double sum $\sum_i \sum_j s_i s_j \rho_{ij}$ with ρ the block matrix of ones; the two agreed to twelve decimal places.

12.12 Discrepancies found in the source, printed

Six discrepancies were found between the source manuscript and a recomputation from its own stated inputs. They are printed here rather than silently corrected.

1. **The source uses two incompatible bloc partitions of the same six-jurisdiction exposure vector.** One chapter measures BRIDGE 40.0 / NONALIGNED 30.0 / WEST 30.0, giving $N = 2.941176$ and $h = -0.122417$; another measures Western 30.0 / Gulf 29.1 / Asian 40.9, giving $N = 2.924302$ and $h = -0.124431$. **The difference is one jurisdiction's assignment and it moves the balance by** 0.002014**.** Both are reported in Section 5. **Partition A is treated as canonical here because it is the one derived from a stated perimeter test with recorded evidence classes; the second partition is not defended anywhere in the source.**
2. **The regional leg's gain is partition-dependent and only one value is published.** On Partition B the gain is 0.076530 and the ceiling 25.51% of C; on the canonical Partition A the same reallocation gives bloc-HHI 0.276600, $N = 3.615329$, a gain of 0.072231 and a ceiling of 24.08%. **The source computes only the first and does not say the result depends on the partition.**

3. **A compounding cell is wrong.** The three-year cell at a 15 per cent annual drag is printed as -38.61%; $0.85^3 - 1 = -0.385875$, so the correct figure is -38.59%. **Every other cell in the table reproduces exactly.**
4. **An "exactly" that is not exact.** The source states that a 25.17 per cent allocation sets h to exactly -0.500000. The exact allocation is $w^* = 0.377583/1.5 = 0.2517220$; at $w = 0.2517$ the balance is -0.499967. **The claim is right to four figures, and the word "exactly" belongs to 0.251722 rather than to 0.2517.**
5. **The nominal-to-real convention is used and never named.** The source's table is consistent with $(1+r)/(1+\Delta) - 1$ and inconsistent with $(1+r)(1-\Delta) - 1$, and the two readings of the same words differ by 33.75 percentage points on the last row. **This paper names the convention in Section 3.4. This is not an arithmetic error in the source; it is an ambiguity a reader could resolve the wrong way, and the wrong resolution is much the more pessimistic of the two.**
6. **A sixth-decimal truncation.** The regional leg's gain is printed in the source as 0.076529; 0.35×0.218656059 is $0.0765296208\ldots$, which rounds to 0.076530 at six decimal places. **The published figure is a truncation rather than a rounding**, and any recomputation will disagree in the sixth decimal. This paper uses 0.076530 throughout.

None of the six changes any hypothesis's outcome. All six are the kind of thing a reviewer checks first.

13. Limitations

No dataset was collected and nothing here is a measurement of a real structure. Every share, drag rate, dwell figure, cost assumption, duty rate and parameter is constructed and labelled as such at each point of use. **This is the corpus's central limitation and it is stated in full**: across the corpus, of 27 parameter-by-scope cells audited in a companion paper, 19 have a defined estimator, 1 has a validated one, and **0 carry a first-party measurement.** This paper carries none either.

No concentration figure here has an as-of date, because none is computed from real holdings. A concentration measure without a source and a date is not a measurement. Every share vector is constructed, so there is no source and no date to give. **Any application of this instrument to a real structure — of jurisdictions or of lenders — must carry both**, and Appendix B makes the date an item of the reporting standard.

No currency was measured. The 15, 25 and 40 per cent drag rates are stipulated illustrations. **The paper computes what a given drag costs and does not assert that any currency has that drag**, and every conclusion in Section 6 is conditional on a number the paper did not measure.

The erosion-term treatment of currency drag is a modelling choice and not a derivation. It assumes proportionality, uniform application over the period, and independence from the rest of the structure. **A drag that is itself a function of the size of the allocation — as it would be for a holder large relative to the market — breaks the linearity that produces w^*.**

The funding-side surplus figures are an extension by analogy. Section 9.4 states it, and it is repeated here because it is the most likely over-reading of this paper.

Every parameter in the surplus law was chosen, not estimated, and the sensitivity to one of them decides the sufficiency conclusions: at $\eta = 0.35$ the break-even count is 4.172734 and no structure here clears it; at $\eta = 0.50$ it is 2.718282 and the designed structure clears it comfortably.

The bloc partition is not settled, and the paper's own results move with it. Section 5 prints both partitions and Section 8.1 prints both gains. **The instrument is exact given a partition and the partition is a judgement**, which is the honest statement of what a perimeter measurement is.

The two maintenance-cost assumptions carry the whole of Section 8. 0.08 and 0.04 are stipulations. H4's verdict reverses between them, so **the paper's headline failure is a failure at an assumed price and not at a measured one.** That is stated in Results and repeated here.

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions in Section 4 of codal families, foreign-exchange regimes, customs unions, treaty networks, substance regimes, statutory suites and the doctrinal content of Islamic finance are taken from the source manuscript. **The bibliography contains no statutes, regulations, court rules, registry documents, case reports or religious-legal sources for any individual jurisdiction or tradition.** Those claims are uncited here, described rather than asserted, and require verification before any reliance. Appendix A lists them. **This is a real gap and it is not closed here.**

One failure mode in Section 11 has no arithmetic attached. Failure mode 4 — a domestic contract that may not be denominated in the currency the group has chosen — is the one item in this paper the instrument cannot see at all. **It is recorded rather than measured, and a reader should not infer from the paper's quantitative character that everything important about these positions has been quantified.**

13.1 Rigour checks not met, listed by name

1. **No first-party measurement exists anywhere in this paper.**
2. **No uncertainty is reported anywhere**, because nothing is estimated.
3. **No as-of date is attached to any concentration figure.**
4. **The period of δ is supplied by this paper, not by the source**, which treats it as a bare rate. Section 12.1 assigns "per year" explicitly.
5. **Q, C and h have no operational unit.** The effective counts and the percentage ceilings survive; the magnitudes do not.
6. **The surplus law's large-N limit is a defect, not a result** [Uzzi and Spiro, 2005, May, 1972, Sagan, 1993].
7. **The conjoint conditions were not tested for the job vector** [Michell, 1997, Luce and Tukey, 1964], so the effective-jobs figure in Section 7.1 is provisional as a ratio-scale quantity; the ordering survives.
8. **Model comparison was not performed** — no out-of-sample test, no information criterion, no matched null — because nothing here is fitted.
9. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. **Any restatement reaching for a heavy-tail or power-law claim about lender shares or holdings must run it first**, and must read Stumpf and Porter [2012] on why passing it would still not identify a mechanism.
10. **The perimeter assignments are stipulated reference groups, not identified effects** [Manski, 1993, Brock and Durlauf, 2001, Shalizi and Thomas, 2011].
11. **The framework's own parameters are exempted from the reflexivity the framework asserts** [Lucas, 1976, MacKenzie and Millo, 2003]. **That is an inconsistency and it is not resolved here.**
12. **There is no conservation law for Q** [Mirowski, 1989], and Section 10.3 records that cost transfers between the acquisition and the structure do not leave a group-level quantity fixed — unlike the drive-conservation result of Curzi [2026], which does.
13. **Aggregation is unaddressed** [Kirman, 1992].
14. **Expected value and time average are not the same thing** [Peters, 2019]. Section 6.3 reports time averages of a multiplicative process, which is the right choice, and says so; Section 9's range is not an expectation at all but a pair of bounds under two assumptions.
15. **The surplus functional's form is underdetermined** [Latané, 1981, Briscoe et al., 2006] and nothing here discriminates it; Peters and Gell-Mann [2016] is named as the warrant the argument actually needs.
16. **No differential prediction is offered** [Durlauf, 2005].
17. **Small-sample bias in the effective-count estimators is not addressed** [Chao et al., 2014].
18. **The measurement is exposed to becoming a target** [Goodhart, 1975, Campbell, 1979]; the

only defence is Appendix B.

19. **The extension of the surplus term to funding perimeters is an analogy the paper uses and does not justify.** It is flagged in Method, in Results, in the analogy table and here — four times, because it is the claim a reader is most likely to carry away in a stronger form than it was made.

14. Conclusion

This paper establishes six results in the form the rest of the corpus cites.

R1. With a hard-currency drag written into the erosion term as $\delta_{\text{eff}} = \delta_0 + dw$, the surplus balance is linear in the local-currency allocation: $h(w) = h(0) - dQw$. At a 15 per cent annual drag, $h(w) = -0.122417 - 1.5w$, so an allocation of $w^* = 0.251722$ sets h to exactly -0.500000, cancelling the whole $\eta \ln N = 0.377583$ diversification gain, and a 10 per cent allocation costs 0.150000, which is 39.73% of that gain.

R2. Dwell decides whether a weak currency is a transaction cost or a capital loss. Erosion per pass is $dn/365$: at a seven-day dwell a 40 per cent annual drag costs 0.767%, and at one hundred and eighty days the same drag costs 19.726%. **A 15 per cent drag held six months costs nearly ten times what a 40 per cent drag held a week costs.**

R3. The bloc arithmetic against the operating leg's own case: an 8 per cent operating leg lowers the effective bloc count from 2.941176 to 2.832412 when its share is scored into the bridge row and to 2.919742 on the more generous scoring. **Both are below the baseline**, and the case therefore rests on customs-union access worth 1.35% of group revenue — 30 per cent EU-facing sales at a constructed 4.5 per cent average duty — which is a tariff argument and not a resilience one.

R4. The regional leg priced as a cost ceiling: the reallocation raises effective blocs from 2.924302 to 3.639010 and buys $\eta \Delta \ln N = 0.076530$, roughly 25.51% of the existing $C = 0.30$ base. At $C = 0.38$ the balance is -0.127902, **worse than the** -0.124431 **baseline**, and at $C = 0.34$ — the holding layer alone, correctly attributed — it is -0.087902. On the canonical partition of Curzi [2026] the same reallocation gives $N = 3.615329$, a gain of 0.072231 and a ceiling of 24.08%.

R5. Nominal against real, on the stated convention $r_{\text{hard}} = (1 + r_{\text{nom}})/(1 + \Delta) - 1$: a 50 per cent nominal return is a 6.25% loss when the exchange rate rises 60 per cent; and at a 15 per cent annual hard-currency drag a local-currency position loses 55.63% of its hard-currency value in five years and 80.31% in ten.

R6. Funding-source independence on the same instrument: four Western lenders give a naive HHI of 0.285000 and 3.508772 effective lenders but a perimeter HHI of 1.000000 and **exactly** 1.000000 **effective funding blocs**. The redesigned book gives 3.174603 effective funding blocs optimistically and 2.409639 after an honest correlation adjustment, with $\eta \ln N$ of 0.404314 against 0.307817 — **and the naive effective source count falls from** 3.508772 **to** 3.174603 **while it does so.** Per unit of effective bloc, funding diversity costs 0.070940 against 0.111930 for jurisdictional diversity.

Counter-result. Each measurement reports against the position it examines. The operating leg lowers the effective bloc count it was proposed to raise, on both available scorings. **The regional leg fails outright once its maintenance cost reaches** 0.38**, and H4's criterion — fixed in advance — was not met.** The Islamic funding gain is cut from 3.174603 to 2.409639 effective blocs by a correlation adjustment applied against the paper's own argument. **And the currency allocation, proposed as a yield enhancement, is the single largest destroyer of surplus measured anywhere in this paper: at** 25.1722% **it returns the structure to exactly the balance it had before any of the design work was done.**

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the principal, the asset mix, the exposure shares, the lender and tranche shares, the drag rates, the dwell figures, the duty rate, the maintenance-cost assumptions and the job vector — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-059_fig01.py` through `figs/src/CCP-059_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional, legal and doctrinal descriptions in this paper are taken from the source manuscript and not from primary sources. The bibliography contains general comparative and treaty material only; it contains no statutes, regulations, court rules, registry documents, case reports or religious-legal sources for any individual jurisdiction or tradition. Appendix A lists the claims affected. Any reader relying on those descriptions must verify them against the official sources.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The principal, heirs, lenders and counterparties described in the constructed case are invented and correspond to no person or institution.

Preregistration

This paper reports no preregistered empirical test. The parameter set $\eta = 0.35$, $\delta_0 = 0.02$, $Q = 10$, $C = 0.30$, and H4's criterion that the regional leg is worth building only if its incremental maintenance cost falls below 0.076530, were all fixed before the measurements reported here. **H4's criterion was not met and Section 8.2 says so.** That is the preregistration discipline applied to a calculation and it is not a substitute for a preregistered test.

Religious and doctrinal content

Nothing in this paper is a ruling, an opinion, or a statement of religious law. Where Islamic finance is described, it is described as an institutional fact about a funding market — that it has distinct investors, documentation, regulators and supervisory organs, and therefore

constitutes a distinct funding perimeter for the purposes of a concentration measurement. **No doctrinal position is asserted, endorsed or evaluated**, and every doctrinal description is carried from the source manuscript, is uncited, and is listed in Appendix A.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions, currencies, funding instruments and structural arrangements for the purpose of measuring concentration, cost and resilience. No recommendation is made in respect of any particular person, asset, structure, currency, instrument or jurisdiction. Foreign-exchange regimes, customs-union scope and rules of origin, treaty networks and their protocols, substance requirements, promotion regimes, tax rates and enforcement arrangements all change and vary by jurisdiction and by activity; every such statement in this paper is carried from the source manuscript, is flagged in Appendix A, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.

Appendix A. Claims requiring verification against primary sources

The following statements rest on legal, regulatory or doctrinal detail that changes, and **none of them is cited to the bibliography, which contains no primary sources for any individual jurisdiction or tradition**. They are reproduced from the source manuscript, are described rather than asserted, and require confirmation with counsel in the relevant jurisdiction before any reliance. **No measurement in this paper depends on any of them being true.**

A.1 The high-inflation industrial state. The civil code, code of obligations and commercial code relied on, with their numbers, dates and current texts, and the derivation from the Swiss codes. **The foreign-exchange decree and the communiqués made under it: the current scope of the restrictions on denominating or settling contracts in foreign currency between residents, the excepted categories, the settlement requirements, and the amendments in force — the load-bearing item, because a group that has decided to price everything in hard currency can find that a particular domestic contract may not be.** The inflation-accounting provisions of the tax procedure law and their effect on reported results and taxable bases. The scope of the customs union for industrial goods, the applicable tariff lines, and the rules of origin governing whether local processing is sufficient. The land registry law's conditions on foreign ownership. The finance centre's establishing instruments and incentives. The state's participation in automatic exchange of account information. The enforcement position for foreign judgments and for arbitral awards.

A.2 The regional holding centre and its operating markets. The mixed legal system's sources and the appellate route. The double-taxation network and the investment-protection network, and the material difference between them. **The protocol closing the historical route into the neighbouring market: its date, terms and grandfathering; any subsequent amending protocol; and the principal-purpose test's operation on a structure of the constructed case's shape.** The treaties terminated by African counterparties, and the dates. The regional harmonised business-law family's uniform acts and their scope. The substance reform replacing the deemed credit with a partial exemption, and the core income-generating activity conditions attaching to it. The standard-setters' listing decisions affecting the centre and their dates. The two other financial centres' establishing statutes, incentives and regulators. The continental free-trade and payment-system initiatives, and whether they supply an actual alternative path rather than an announced one. Withholding rates on dividends under the relevant treaty, and the domestic rates they are compared against.

A.3 The mid-shore centre and the Islamic-finance perimeter. The statutory suite for offshore companies and its current text. **The tax regime after the substance reform: qualifying activities, the substance conditions, and what happens to an entity that fails them.** The treaty

network's exclusions — the entities and income types excluded, which the source records as routinely unmentioned. The federal state's standards position. **The constitutional and statutory basis on which a national authority's rulings on Sharia compliance bind, and the scope of that binding force.** The contract set of Islamic finance, the two governing prohibitions, **the distinction between asset-backed and asset-based sukuk and its consequence for recovery**, and the published standards of the relevant standard-setters. The treatment of Sharia-compliance clauses by common-law courts and the authority for it. The succession rules of the tradition and their interaction with the forced-heirship analysis carried elsewhere in the series. The master agreement used for compliant hedging.

A.4 General. For all positions: corporate residence and central-management-and-control tests in every jurisdiction from which decisions might be taken; the current status of each state under the international anti-money-laundering standard; and the recognition and enforcement position for both judgments and awards in every jurisdiction where the group holds assets.

Appendix B. The reporting standard for an erosion-side and liability-side measurement

Any structure measured under the methods in this paper reports the following, and nothing less. It extends the reporting standard of Curzi [2026] to the erosion term and to the liability side.

```
ON THE EROSION SIDE
 1  the share of protected capital in each unit of account, summing to 100.0%
 2  the assumed annual hard-currency drag for each, with its source and date
 3  the convention used to convert nominal to real, stated explicitly
 4  the maximum balance and maximum average dwell, board-approved, in writing
 5  the measured average dwell for the period, against the stated maximum
 6  h(0), h(w), and w* = eta ln(N) / (d Q)

ON THE LIABILITY SIDE
 7  the funding share of each source, summing to 100.0%
 8  the perimeter assignment for each, with its evidence class
 9  naive HHI and effective sources; perimeter HHI and effective funding blocs
10  BOTH ends of the correlation range, never one alone
11  the incremental annual governance cost of each tranche

ON BOTH
12  the bloc or perimeter partition used, and the result under any
    defensible alternative partition
13  the date, and the diff against the previous measurement
```

Item 3 is the item this paper added to the standard, because two readings of the words "a sixty per cent depreciation" differ by 33.75 percentage points and the source manuscript never says which it means.

Item 10 is the one that will be dropped, because the flattering end of the range is the one that supports the decision already taken. **Item 12 is the one this paper's own Section 5 shows to be necessary**: two defensible partitions of one exposure vector gave 2.941176 and 2.924302, and no reader could have detected the difference from a published figure alone.

Item 13 decays first and matters most, because a perimeter is invisible except as a difference between two measurements taken a year apart.

Chapter 60

Compartments, Conversions, and the Confidence a Cell Wall Requires

Abstract. Three structural devices are priced against the certain costs they incur. Ring-fencing is measured with a contagion index — the sum of squared reachable shares, inverted — under which six unequal compartments (30.0, 22.0, 18.0, 12.0, 10.0 and 8.0 per cent) give 4.96 effective compartments and cut maximum single reach from 100.0 to 30.0 per cent; at an annual event probability of 2.0 per cent the benefit is 1.400 units against 0.110 of cost, a ratio of 12.73 to one and a break-even probability of 0.157 per cent. The paper's sharpest result concerns cells: choosing a cheaper cell company over separate portfolio companies is preferable only if the cell wall survives in the relevant foreign forum with probability at least 93.5714 per cent, a confidence the paper says almost nobody can honestly claim for an under-litigated device. Converting an immovable asset to listed securities incurs certain leakage of 7,220,000 on 48,000,000, or 15.0417 per cent, against a probabilistic escape value of 0.4725 per cent a year — a payback of 31.83 years, requiring belief in a 4.7752 per cent annual chance of an event destroying 60 per cent of the value before a ten-year payback holds. Diversification does no better: effective properties rise from 1.00 to 18.85, worth 0.4735 per cent a year and a payback of 31.77 years. The conversion also improves the naive jurisdiction count to 4.634 while worsening the effective bloc count to 1.470588.

Keywords: ring-fencing; cell companies; bankruptcy remoteness; contagion measurement; effective count; conflict of laws; leakage and payback

Series: D. Structure and Resilience **Paper:** CCP-060

1. Introduction

Three structural devices are priced here against the certain costs they incur: liability compartmentalisation, the statutory cell, and the conversion of an immovable asset into a movable claim. Each is widely recommended. None of the three is usually accompanied by the arithmetic that decides whether it is worth its price, and the arithmetic is short.

The organising question is not *what does this device protect against*, which every promotional account answers, but *what does it cost with certainty, against what benefit, and at what event probability does the sign of the difference change*. That question has a numerical answer whenever the benefit can be written as a reduction in a reachable share and the cost as an annual fee, and this paper writes both down.

Every structure discussed here is measured under one standing constraint, which the comparative literature on cross-border holding structures does not usually impose: the formation test. A structure qualifies for analysis only if it would still perform its function were every element of it disclosed to every authority with jurisdiction over any part of it. That test is not an ethical flourish; it is a design filter, and it is the reason concealment plays no part in what follows. It has an exact precedent in security engineering — Kerckhoffs [1883]'s rule that a system must remain secure when everything about it except the key is public, restated as the open-design principle by Saltzer and Schroeder [1975]. The regulatory environment has in any case removed non-disclosure as an available design parameter: automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the common supervisory recommendations [Financial Action Task Force, 2012], and the substance and treaty-abuse programme [Organisation for Economic Co-operation and Development, 2015] between them make the disclosed case the only case worth modelling.

1.1 What this paper measures, and what it only describes

This paper is a **survey with embedded measurements**, and it says so at the front rather than letting a reader discover it. Roughly half of the source material is comparative description of particular jurisdictions and of particular legal devices. That description is context. It is retained — condensed in Section 7 and in full in Appendix C — because the measurements are unintelligible without it, and it is not offered as this paper's contribution. **The contribution is six computations, and Sections 8 and 13 are about those and nothing else.**

The computations are of three kinds.

First, a concentration measurement on an axis the concentration literature does not usually run it on. The instrument is the Herfindahl–Hirschman index [Hirschman, 1945, Herfindahl, 1950] read as a numbers-equivalent [Adelman, 1969], applied not to jurisdictions but to the **reachable share** of an estate: the fraction that a single creditor, claimant or administrative event arising against one compartment can reach. Six unequal compartments give 4.96 effective compartments and cut maximum single reach from 100.0 to 30.0 per cent. The instrument is carried unchanged from Curzi [2026], which establishes it and its bloc correction; what is new here is the share basis.

Second, a threshold belief in place of a legal opinion. Whether a foreign forum will respect a statutory cell wall is a conflict-of-laws question with thin authority and no reliable answer. It need not be answered. It need only be compared against a number, and the number is computable: on the constructed parameters, the cell company is the better structure only if that forum respects the wall with probability at least 93.5714 per cent.

Third, a certain cost against a probabilistic benefit. Converting an immovable asset into a listed security incurs leakage of 15.0417 per cent of gross value, immediately and with certainty, against an escape value of 0.4725 per cent a year that exists only in expectation. The payback is 31.83 years. **The asymmetry between a certain cost and a probabilistic benefit is the finding, and it survives every reasonable change to the parameters.**

1.2 What follows, and what does not

Two of the three devices contribute **exactly zero** to the effective bloc count that governs the surplus term of the storage law. That is stated as a result and not as a concession. Compartmentalisation raises maintenance cost and leaves the coordination perimeter untouched; so does the conversion. Both are answering a different threat, and a structure that reports their benefit alongside a jurisdictional improvement obtained elsewhere has reported a diversification it did not achieve.

The paper presupposes the surplus functional and the affine effective count of Curzi [2026] — $f(u) = \ln(1 + (N-1)u)$, characterised by angle-only dependence, vanishing at parallel, an affine effective count and normalisation. **That affine count is not the count used here, and Section 4.2 states the difference exactly**, because the two travel under one name in the corpus

and are different quantities. It presupposes the two-source decomposition of non-parallelism in Curzi [2026d], $u = \beta^2 + \alpha^2 \sin^2 \gamma$ with $u_{\text{div}} \leq 1 - u_{\text{cross}}$, which is why a compartment boundary cannot manufacture independence that the underlying exposure does not have. It derives the bloc-collapse arithmetic from the Crown Dependency measurement of Curzi [2026] — three jurisdictions at 40.0 / 35.0 / 25.0 giving naive HHI 0.345000 and 2.898551 effective jurisdictions against bloc-HHI 1.000000, $N = 1.00$ and a surplus term of exactly zero — from the six-entity Atlantic cluster of Curzi [2026], whose naive 4.0032 collapses to $N = 1.00$, and from Curzi [2026], where adding two jurisdictions raises the naive count 34.8 per cent while the bloc count falls 3.4 per cent.

2. Hypotheses

Four hypotheses are stated. Each is falsifiable in the sense Platt [1964] requires; Meehl [1967] is the reason each carries a point prediction with a constant attached rather than a direction. Statements that could not be falsified as posed are listed afterwards as definitions or modelling choices and are not counted.

The survey material advances no hypothesis, and none is manufactured for it. The comparative description of territorial-taxation jurisdictions in Section 7 and Appendix C is expository. Its organising question is: *when a jurisdiction sits inside a coordination perimeter the structure already occupies, through which term of the storage law can it act at all?* That question is answered arithmetically in Section 8.5 and the answer is a measurement, but the description supporting it is a survey and is labelled one.

H1 — the contagion hypothesis. The reachable-share index measures compartment independence in the same sense that the jurisdictional index measures perimeter independence, so that unequal compartments return an effective count strictly below their nominal number. *Predicted:* six compartments at 30 / 22 / 18 / 12 / 10 / 8 per cent return $1/\text{HHI}_c = 4.9603$, not 6, and maximum single reach falls from 100.0 to 30.0 per cent. *Falsified by:* an estate in which subdividing a compartment fails to lower the index, or in which the index reports a count above the nominal number of compartments.

H2 — the cell-indifference hypothesis. The choice between a statutory cell structure and separate companies reduces to a single threshold belief about foreign recognition, computable from the cost saving and the reach reduction alone. *Criterion, fixed in advance:* with a saving of 0.090 units a year, a reach reduction of 70.0 units and an annual event probability $p = 0.02$, indifference is at $1.400(1 - r) = 0.090$, so $r^* = 93.5714\%$. *Falsified by:* a cost structure in which the required confidence falls as the event probability rises — that is, in which the cheap compartment becomes safer as the risk grows.

H3 — the payback hypothesis. The conversion of an immovable asset into a movable claim does not repay its tax leakage within a holding lifetime at median parameters. *Criterion, fixed in advance:* with leakage $L = 15.0417\%$ and escape value $V_{\text{esc}} = pL^*q(1-s)$ at $p = 1.50\%$, $L^* = 60\%$, $q = 0.70$, $s = 0.25$, payback exceeds thirty years. *Falsified by:* a payback inside thirty years at those parameters, or by a defensible reference class in which p for the asset in question exceeds 4.7752 per cent a year.

H4 — the axis-divergence hypothesis. A single transaction can improve one concentration axis and worsen another, so that no single effective count summarises it. *Predicted:* the conversion raises effective properties from 1.0000 to 18.8491 while the resulting allocation reads 4.6339 naive effective jurisdictions and only 1.470588 effective blocs. *Falsified by:* the two axes moving together on this transaction, which would mean one of them is redundant.

Not hypotheses, and labelled as such.

- *The identification of N with the effective bloc count* and of $1/\text{HHI}_c$ with an effective compartment count is a **definition**. All the content is in the share basis and the bloc assignment rule, both of which are testable; none is in the identification.

- *The logarithmic input term* $\eta \ln N$ rather than ηN is a **modelling choice** carried from Curzi [2026] and is not tested here. Section 10 records that the form is underdetermined by the available evidence.
- *The parameter set* $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ is a **modelling choice**, fixed before the measurements so that no criterion is adjusted afterwards — the preregistration discipline of Nosek et al. [2018] applied to an engineering calculation.
- *Every event probability* p and every parameter of the escape-value model is a **stipulated constructed estimate**. Section 10 states that they are the most load-bearing and least defensible inputs in the paper.

3. Method

3.1 The share basis, which is the whole exercise

An index without a stated share basis is not a measurement. Three bases appear here and they must never be mixed inside one computation.

axis	share basis	what a failure on it looks like
jurisdictional	fraction of protected capital whose availability depends on a decision taken inside one coordination perimeter	a designation, a freeze, an exchange control
contagion	fraction of the estate reachable by a single creditor, claimant or administrative event arising against one compartment	a judgment, an insolvency, a regulatory action
property	fraction of an asset allocation's value in one underlying asset	a tenant default, a fire, a local planning decision

The contagion basis is the one this paper adds. It is **not** the fraction of value in each entity, which is the same number only when the compartments are perfect; it is not the fraction of revenue. The distinction is operative: on the carried case a manufacturing operation held as a branch contributes its parent's entire balance sheet to the reachable share, and the corporate chart does not show it.

3.2 The instrument

For shares s_i summing to one,

$$\mathrm{HHI} = \sum_i s_i^2, \qquad \text{effective count} = \frac{1}{\mathrm{HHI}}.$$

If k units each hold $1/k$ then $\mathrm{HHI} = 1/k$ and the reciprocal returns k; when the units are unequal it returns the number of equal-sized units that would give the same index. That numbers-equivalent reading is Adelman [1969]'s. Competition practice states the index in points on percentage shares [U.S. Department of Justice and Federal Trade Commission, 2023]; the resilience application states it as a fraction, and the two differ by a factor of 10^4.

Two elementary properties do work later. $\mathrm{HHI} \geq s_{\max}^2$, so the effective count is at most $s_{\max}^{-2}$ — which is why a compartment holding 82.0 per cent of an estate caps the effective compartment count at 1.4878 whatever is done with the remainder. And $s_{\max}^2 \leq \mathrm{HHI} \leq s_{\max}$, which is a two-line sanity check on any measurement done by hand.

No distributional or scaling claim is made anywhere in this paper, and that is stated because the material invites one. A reachable-share vector descending 30 / 22 / 18 / 12 / 10 / 8, or a property allocation with a long tail of thirty equal small holdings, looks like the opening of a heavy-tail argument. **No distribution is fitted, no tail is characterised and no power law is asserted.** Clauset et al. [2009] is the reason: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few canonical data sets standing, and a straight line on log-log axes is not evidence. That procedure was not run, because no claim requiring it is made. Stumpf and Porter [2012] adds why running it would not be enough on its own: many mechanisms produce the same tail. **Every effective count here is a statistic of a finite share vector with between two and forty entries, not an estimate of a distribution, and it must not be restated as one.**

3.3 The correlation correction, and what a compartment boundary cannot do

The naive index assumes the units fail independently. Where they do not, the correction is the one Markowitz [1952] stated for portfolios in 1952: diversification benefit depends on covariance, not on count. Writing w for the share vector and R for the correlation matrix of unit-variance shocks, the aggregate variance is $w'Rw$ and the general effective count is $1/(w'Rw)$; $R = I$ recovers the naive index and a block matrix of ones recovers the bloc index. Curzi [2026] establishes that identity and its correspondence with the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012].

Applied to compartments the correction is what failure mode 5 of Section 9 is about. Six compartments each carrying a cross-default to any group indebtedness above a threshold have a legal correlation matrix close to the identity and a financing correlation matrix that is a single block of ones. The contagion index reads 0.201600 on the corporate chart and 1.000000 on the financing documents, and only the second is real. That coupled structures are far more fragile than their components is the formal content of Buldyrev et al. [2010], used here as a **shared structural form and not as a derivation**: no percolation premise has been shown to hold for a set of financing covenants. Perrow [1984] reached the organisational version first — interactive complexity plus tight coupling makes catastrophic failure a property of the system rather than of any component — and is cited as framing rather than as a formal result. Doyle et al. [2005] is the standing correction to reading too much into any of it: engineered robustness comes from design, not from a degree distribution.

Correlation rises under stress, which is when the count matters. Longin and Solnik [2001] measure extreme correlation in equity markets that is asymmetric and concentrated in downturns. That is directly load-bearing in Section 6: the conversion exchanges an idiosyncratic illiquid asset for a correlated liquid one, and the correlation arrives in the coordinated stress event while the liquidity is least available. The ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008]. The contrary literature is not decorative: Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone with no mechanism, and May [1972] that increasing diversity and connectance destabilises randomly assembled systems. This paper's claim is narrower than the general diversity–stability claim and is not exposed to those results in the same way — it asserts only that the reciprocal of a variance counts independent shocks, which is arithmetic.

One count can be inflated at will and is therefore worthless unaudited. Douceur [2002] proves that in the absence of a trusted identity authority one party can present as many, so that a count of nominally distinct entities carries no information about the number of independent parties. **Twenty companies formed by one sponsor in one jurisdiction are the legal instance of that result**, and the reason the share basis rather than the entity count is the object of measurement here. The corpus carries an exact arithmetic instance of the same gap between a nominal count and a count of distinct realised classes: Curzi [2026] proves that a roster indexed $1 \dots N$ realises exactly $\lceil N/2 \rceil$ distinct classes under its folding rule — six at $N = 12$, from twelve nominal members. **A count of names and a count of distinct things are different quantities in both settings, and only one of them is a measurement.**

3.4 Which effective count, stated exactly

The corpus runs two quantities under the name *effective count* and they are not the same quantity.

The reciprocal index is a Hill number of order two. Hill [1973] defined the family ${}^{q}D = (\sum_i p_i^q)^{1/(1-q)}$, whose members return the number of equally-abundant types giving the observed value of the underlying index; at $q = 2$ that is HHI^{-1} exactly. Jost [2006] is the statement that entropies are not diversities and their numbers-equivalents are. The same arithmetic was reached independently in political science as the effective number of parties [Laakso and Taagepera, 1979]. The exponential of Shannon entropy [Shannon, 1948] is the same family at $q = 1$. $1/\mathrm{HHI}$ **and** $\exp(H)$ **are Hill numbers of order 2 and 1 and are fully grounded.**

The affine count is not a Hill number and has no external support. The corpus's other effective count, $N_{\mathrm{eff}} = 1 + (N-1)u$, is a linear interpolation between 1 and N. It is not a numbers-equivalent, it is not $(\sum p_i^q)^{1/(1-q)}$ for any q, and no literature in ecology, economics, political science or information theory contains it. It never consults the share vector at all. **Every effective count reported in this paper is** $1/\mathrm{HHI}$ **on a stated share basis, and the affine count is not used here.** Where downstream work cites this paper's counts, the distinction must survive the citation. Hurlbert [1971] is the discipline being imposed: the word "diversity" carries no content without its formula attached.

Small-sample estimation is a live exposure and is not addressed. Chao et al. [2014] show that low-order diversity estimators are biased on small samples; a two-, six- or seven-element share vector is a small sample, and Section 10 records this as an unclosed gap. Golosov [2010] documents that effective-number measures behave poorly in the dominated-unit regime, where one unit holds a very large share — **which is exactly the regime of the carried case as found, at 82.0 per cent in one compartment**, and the measurement there should be read for its direction and not for its third decimal.

3.5 The threshold-belief method

Where a decision turns on an unknowable probability, the honest form is not an estimate of that probability but the threshold at which the decision changes sign. Given a cost saving ΔC from a cheaper device, an annual event probability p, and a reach reduction ΔS that the cheaper device forfeits if it fails, the required confidence solves

$$p\,\Delta S\,(1 - r^{*}) = \Delta C, \qquad r^{*} = 1 - \frac{\Delta C}{p\,\Delta S}.$$

Two properties of this expression carry the argument. It is **decreasing in** ΔC — the more the cheap device saves, the less confidence it needs — and **increasing in** p: the riskier the setting, the higher the confidence the cheap device requires. The second is the opposite of the usual intuition about economising in risky settings, and it is the reason the method is worth stating separately from its application.

The move of replacing an unanswerable question by a single threshold comparison is used elsewhere in the corpus and is worth naming as a family rather than reinventing. Curzi [2026] establishes the equivalence $Q_{\infty} > 0$ if and only if $\eta F(u^{*}) > c^{*}$ if and only if $f > f_{\min}$, with $f_{\min} = k\,e^{2c/\eta}$: an entire sustainability question reduced to one comparison against a threshold. **The constant there,** $k = (9/8)^2/\varphi^2 = 0.483425732988414$**, is a *defined* constant — an exact ratio of exact quantities — which is what licenses its fifteen printed digits; attaching a unit of hertz to it is a separate and much stronger claim, which that paper badges as a postulate and on which this paper takes no position.** Since φ enters its definition, Markowsky [1992] is the standing corrective on golden-ratio claims and is cited here for that reason.

The same form prices a marginal structural decision as a break-even probability rather than as a geopolitical opinion; Curzi [2026] applies it to a bridging slot and Curzi [2026] to a pledge trigger, where the first margin call at $\mathrm{LTV}_0 = 50\%$ and maintenance $m = 35\%$ falls at a 23.076923 per cent drawdown rather than at 50 per cent.

3.6 The leakage and escape-value model

Conversion of an appreciated immovable asset into a movable claim is, in most systems, a disposal at market value. The certain cost is

$$L = \frac{(V - B)\, t_{\text{gain}} + V d + V f}{V}$$

for gross value V, base cost B, effective rate on the gain t_{gain}, transfer taxes d and transaction costs f. The uncertain benefit is the annual expected loss avoided by being able to exit before an adverse event at the asset's location crystallises:

$$V_{\text{esc}} = p\, L^{*}\, q\, (1 - s)$$

for annual event probability p, fractional loss L^{*} if the event crystallises, probability q of actually exiting given warning, and discount s suffered when selling into the news. **The structure of the second formula is the argument**: the gross exposure pL^{*} is captured only to the extent that the holder both acts and is not fully penalised for acting late, and both haircuts are routinely assumed away. Payback is L / V_{esc} in years.

V_{esc} is linear in p and L^{*} while L is not, so the economics are driven almost entirely by tail parameters — which are exactly the parameters that are unknowable and therefore assumed. The requirement the specification imposes is that they be written down. **The corpus's own failure taxonomy applies directly: Curzi [2026ac] distinguishes a real channel with insufficient gain from a wrong magnitude extrapolated from a real result, and the conversion is a class-B instrument sold with class-C arithmetic** — the mechanism is real and the magnitude claimed for it is not.

3.7 Identification, and the status of the perimeter assignment

The bloc assignments used in Sections 6 and 7 are inputs to the instrument, and they carry an identification problem that must be stated where they are used rather than in a footnote. Treating jurisdictions as members of a coordination perimeter whose members respond to one decision is a statement about a group influencing its members while the members constitute the group. **Manski [1993] proves that the endogenous effect in a linear-in-means reflexive specification is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables however much data is collected. No amount of observation of jurisdictional behaviour could therefore confirm a perimeter assignment derived reflexively.

The remedy adopted here is the fourth of the four available ones: the reference group is stipulated in advance and the stipulation is defended. Perimeter membership is fixed by the coordination test — two jurisdictions are in one perimeter when a single decision taken in one reliably produces the corresponding effect in the other without a further independent decision — recorded with its evidence, and stress-tested by running the arithmetic both ways in Section 8.5. Brock and Durlauf [2001] shows that route can be made rigorous. **The price is that every perimeter assignment in this paper is a modelling position and not an identified empirical result**, and it is described as such wherever it enters.

The collapse mechanism itself has a formal ancestry and is not new machinery here. That several units inside one perimeter behave as one under a correlated shock is the threshold-and-tipping result: Granovetter [1978] establishes that the distribution of individual thresholds rather than the mean determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate outcome — **the strongest available warning against reading an individual-level parameter straight into an aggregate, which is precisely what a perimeter assignment does.**

4. Compartments: the object being measured

4.1 Four jobs under one phrase

“Special purpose vehicle” covers four structurally different mechanisms with different failure modes, and conflating them is the origin of most bad design in this area. The irreducible function common to all four is asset partitioning, which Hansmann and Kraakman [2000] identify as the thing entity law does that contract cannot; Pistor [2019] is at once the best scholarly account of how legal coding creates capital and its sharpest critique.

job	design goal	characteristic failure
1 isolate assets from the sponsor’s creditors	the sponsor’s insolvency does not reach assets investors paid for	substantive consolidation, or a successful challenge to the true sale
2 isolate liabilities from the sponsor	obligations incurred by the vehicle stop at the vehicle	veil piercing; guarantees or comfort letters construed as obligations
3 isolate assets from each other	a claim arising on asset A cannot reach asset B	commingling, cross-collateralisation, cross-default
4 isolate economic from legal ownership	the vehicle consolidates with nobody	a side arrangement restoring the economic residual

Jobs 1 and 2 point in opposite directions and a vehicle optimised for one is usually badly designed for the other. **Job 3 is the one this paper measures**, and it is the one for which the professional literature offers least, because the securitisation market drove the technology and cared only about jobs 1 and 4.

A ring-fence is not created by forming an entity. It is created by running the entity as a separate thing for long enough that a court asked to disregard it has nothing to work with. Formation is the cheap part and takes a week; conduct is the expensive part and never stops. That asymmetry is why the cost side of Section 5 is an annual figure and not a one-off.

4.2 Separateness, and the three ways it fails

The foundation of the technique is that a duly incorporated company is a legal person distinct from its members even where one person holds substantially all its shares and is its principal creditor. **The doctrinal material in this subsection is described from the source manuscript and is deliberately left uncited: this paper’s bibliography contains no statutes, no regulations, no court rules, no registry documents and no case reports for any individual jurisdiction** (Section 12; the affected statements are itemised in Appendix B).

Three distinct attacks are routinely conflated.

Veil piercing, properly so called, treats the company’s act as the controller’s act. English authority has narrowed it to near-vanishing point by distinguishing a *concealment* principle — looking behind the company to identify the real actors, which requires no special doctrine — from an *evasion* principle, under which a person interposes a company specifically to defeat an obligation and the court may disregard separate personality to the extent necessary. **The practical consequence is favourable and should be stated plainly: a compartment formed for a lawful commercial purpose before any obligation arose, and run as a separate business, is very hard to pierce.** The doctrine that kills compartments is almost never veil piercing.

Alter ego and substantive consolidation is the broader cluster in practice. Its factors are all conduct: undercapitalisation, commingling, absence of formalities, common officers acting without distinguishing capacity, holding out. Consolidation standards differ between appellate circuits, and the applicable standard is a function of where the proceeding is opened.

Recharacterisation is the least discussed. A court may find that what the documents call a sale was in substance a secured loan, in which case the assets never left the originator's estate and the compartment was notional. The factors — recourse, retained servicing, retained residual, pricing, the parties' own accounting treatment — are again all conduct.

The common structure is that every one of the three is decided on evidence about behaviour rather than on the choice of vehicle. That is why the measurement in Section 5 is run on the financing documents and the connection register rather than on the corporate chart.

4.3 Cells, and the question the marketing does not raise

A segregated portfolio, protected cell or incorporated cell company achieves compartmentalisation inside one legal entity: one company, one board, one registration, with assets and liabilities attributed to named cells and a statute providing that the assets of one cell do not answer the creditors of another. The technique is a creature of one jurisdiction's statute and binds the courts of that jurisdiction.

Whether a court elsewhere will give effect to a statutory partition inside a single foreign legal person is a conflict-of-laws question, and it is materially less tested than the recognition of a separate company, which is close to universal. This paper declines to state that the point is settled, because it is not. The shape of the risk can be stated: a foreign court faced with a single legal person that has contracted with a local claimant, and a foreign statute saying that only part of that person's estate answers the claim, is being asked to apply a foreign limitation of liability to a domestic claim. The analysis will turn on characterisation, on the governing law of the obligation, and on local public policy — the standing apparatus of the conflict of laws [Torremans et al., 2022, Fawcett and Carruthers, 2008]. Where the question can be routed to arbitration, the enforcement position is materially better, because recognition of awards runs through an instrument with near-universal adherence [United Nations, 1958], whose actual refusal grounds are themselves a settled subject [van den Berg, 1981]. **Recognition of judgments is not general in the same way**, which is what the later portability convention [Hague Conference on Private International Law, 2019] exists to address and what makes the cell question live rather than academic.

Section 5.3 converts that unanswerable question into an answerable one, which is the contribution: the analyst need not know whether an unnamed forum will respect the partition in fifteen years, only whether the confidence is above or below a computed threshold — and, more usefully, whether every claim that could arise will arise inside the cell statute's own jurisdiction.

4.4 Orphans, and three concepts that are not the same thing

An orphan structure has no equity owner in the sponsor's group; the shares are held by a professional trustee on charitable or non-charitable purpose trusts. Its purpose is consolidation in two senses — accounting, where control rather than ownership determines the answer, and insolvency, where a vehicle nobody in the group owns is a harder consolidation target. **An orphan is a consolidation device and not a concealment device.** The trustee is a regulated professional who knows who arranged the transaction; the arrangement is disclosed in the offering documents and in the notes, and the beneficial-ownership registers capture it. It passes the formation test comfortably, and fails immediately if a side arrangement restores the economic residual. Whether the trust is recognised at all across a border is governed by a convention with a short ratification list [Hague Conference on Private International Law, 1985]; the comparative treatment of the trust against the civil-law foundation as alternative devices is a literature of its own [Panico, 2014].

Three concepts are routinely conflated at board level, with expensive consequences.

concept	question it answers	who decides	when tested
legal separateness	would a court treat the entity's assets and liabilities as its own?	company and insolvency law	in litigation
accounting consolidation	does the entity appear in the group's consolidated statements?	control-based accounting standards	by auditors, annually
bankruptcy remoteness	would the sponsor's insolvency reach the entity, and would the entity itself be filed?	insolvency law plus contract	rarely and expensively

An entity can be legally separate and fully consolidated for accounting, or deconsolidated for accounting and not remote at all. **Non-consolidation in the accounts is evidence of nothing about what an insolvency court will do**, and the reason the control criterion replaced the earlier tests is precisely that vehicles economically identical to their parent were achieving deconsolidation.

4.5 What makes a compartment hold

The checklist is short, dull, and almost entirely about behaviour: separate bank accounts without exception; separate books prepared contemporaneously; capitalisation adequate for the purpose rather than nominal; its own board taking real decisions; arm's-length intra-group dealing, documented and priced; correct holding out in contracts, invoices and signature blocks; a restricted purpose observed rather than merely recited; no guarantees, comfort letters or keep-wells unless deliberately given, priced and disclosed; no cross-collateralisation or cross-default between compartments unless deliberately accepted; and, where third-party money is carried, reasoned opinions on true sale, non-consolidation, enforceability and the governing law of each place a claim could arise.

Items eight and nine are where well-run groups fail, because they are given away by the treasury function and the lending bank rather than by the structuring lawyer. A group that spends heavily on compartmentalisation and then signs a group-wide cross-default has bought nothing and paid for it. The independent-director consent right that the market treats as the load-bearing element is a governance arrangement rather than a wall wherever the sponsor appoints, pays and can replace its holder; and whether a foreign court will enforce a contractual promise not to invoke its own insolvency jurisdiction is under-litigated exactly where the structure needs it most.

5. The contagion measurement

5.1 The instrument on a constructed estate

CONSTRUCTED CASE. Every figure in this section is invented for illustration and none is a benchmark. An estate of 100 units.

```
UNFENCED -- one entity holds everything
    reachable share            100.0%
    contagion HHI              1.000000
    effective compartments     1.0000
    maximum single reach       100.0%
```

```
FENCED -- six compartments, by reachable share
    A  30.0%   0.090000        D  12.0%   0.014400
    B  22.0%   0.048400        E  10.0%   0.010000
    C  18.0%   0.032400        F   8.0%   0.006400
    ---------------------------------------------------
    contagion HHI              0.201600
    effective compartments     4.9603
    maximum single reach        30.0%
```

Six entities, 4.9603 effective compartments, and a worst case falling from 100.0 to 30.0 per cent of the estate. The effective count is 4.96 rather than 6.00 because the compartments are unequal, and the quantity nobody quotes — maximum single reach — is the one an insolvency practitioner cares about.

5.2 Cost, benefit and the break-even probability

Compartments are not free and the fee is annual. Each is an entity that raises C in the storage law and contributes nothing to N, so under that law alone each is strictly value-destroying; the justification must come entirely from the contagion axis and must be computed. That adding units inside one coordination boundary adds communication cost at order $n(n-1)/2$ while adding nothing to independence is the general organisational form of the same point [Brooks, 1975].

```
single entity   registered agent, accounts, audit,
                director fees, filings           0.040 units p.a.
each SPV        same, per entity                 0.025 units p.a.
six SPVs                                         0.150 units p.a.
incremental cost of compartmentalisation         0.110 units p.a.

benefit at annual event probability p
    E[loss | unfenced] = p x 100.0
    E[loss | fenced]   = p x  30.0
    benefit            = p x  70.0

at p = 2.0%   benefit = 1.400 units p.a.
              cost    = 0.110 units p.a.
              ratio   = 12.73 to 1
break-even p = 0.110 / 70.0 = 0.157% per year
```

Below an annual event probability of about one in 636, compartmentalisation of this estate at this cost destroys value. For a passive portfolio held by a family holding company with no operations, no employees, no leases and no counterparties that is a live possibility, and the honest recommendation may be a single entity. For an operating group with plants, employees, environmental exposure, product liability and lease obligations, p is far above the threshold and the question does not arise. **The instrument does not say "compartmentalise"; it says "compute p", and p is a fact about what the business does rather than a fact about structuring.**

A structurally parallel result exists in a different domain and is worth naming, because it shows that the shape of this break-even is not an artefact of the legal setting. Curzi [2026g] derives a critical boundary-cost multiplier $m^{*} = \eta(N-1)u_{\text{cross}}/[(1+(N-1)u(\rho))\,c_{\text{in}} \times 900]$, above which adding contact across a boundary stops helping — computed at 3.17 against an operating value of 8. **In both settings a structural intervention is worth its cost only below a computable threshold, and in both the operating value can sit on the wrong side of it without anyone having run the comparison.**

5.3 The cell wall, and the confidence it requires

A segregated portfolio company achieves the same six compartments inside one entity at lower cost, and forfeits the reach reduction entirely in any forum that does not respect the partition.

```
SPC with six cells   one registration, one board, one audit,
                     cell-level records          0.060 units p.a.
six separate SPVs                                0.150 units p.a.
saving                                           0.090 units p.a.

additional expected loss from using cells
    = p x (1 - r) x (100.0 - 30.0)
    = 0.02 x (1 - r) x 70.0  =  1.400 x (1 - r)

indifference:  1.400 x (1 - r) = 0.090
               1 - r = 0.064286
                   r = 93.5714%
```

The cell company is the better structure only if the wall is respected in the forum where the claim arises with probability at least 93.5714 per cent. The threshold is high because the downside is catastrophic and the saving is small, and that asymmetry survives reasonable changes to the inputs: at $p = 1.0\%$ the required confidence is 87.1 per cent and at $p = 4.0\%$ it is 96.8 per cent. **Higher risk makes the cheap compartment worse rather than better**, which is the opposite of the usual intuition about economising in low-risk settings and is the general property of the threshold form derived in Section 3.5.

The practical value of the threshold is that it converts an unanswerable legal question into an answerable practical one. Nobody can know whether a court in an unnamed jurisdiction will respect a foreign statutory partition in fifteen years. Anyone can establish whether every claim that could arise will arise inside the cell statute's own jurisdiction. **If every counterparty contracts under that law, submits to those courts and holds no asset elsewhere, r is near one and the cell company is correct. If any material claim can arise elsewhere, r is a guess and the guess must clear 93.6 per cent.**

use cells	use separate companies
all counterparties contract under the cell statute's law	any material counterparty in a third jurisdiction
all assets held in or through the cell jurisdiction	hard assets sited elsewhere
regulated fund or insurance use where the regulator supervises the cell structure	trading, employment or environmental exposure
compartments are economic sleeves of one portfolio	compartments must survive a hostile foreign creditor

5.4 The sizing rule: a constraint, not an optimum

The number of compartments is not chosen by optimisation. It is set by the largest loss the group can absorb without breaching a covenant or losing control of another asset:

$$\text{maximum single reach} \le \text{absorbable loss}.$$

On the constructed estate with an absorbable loss of 25 units, compartment A at 30 units breaches the constraint and must be split:

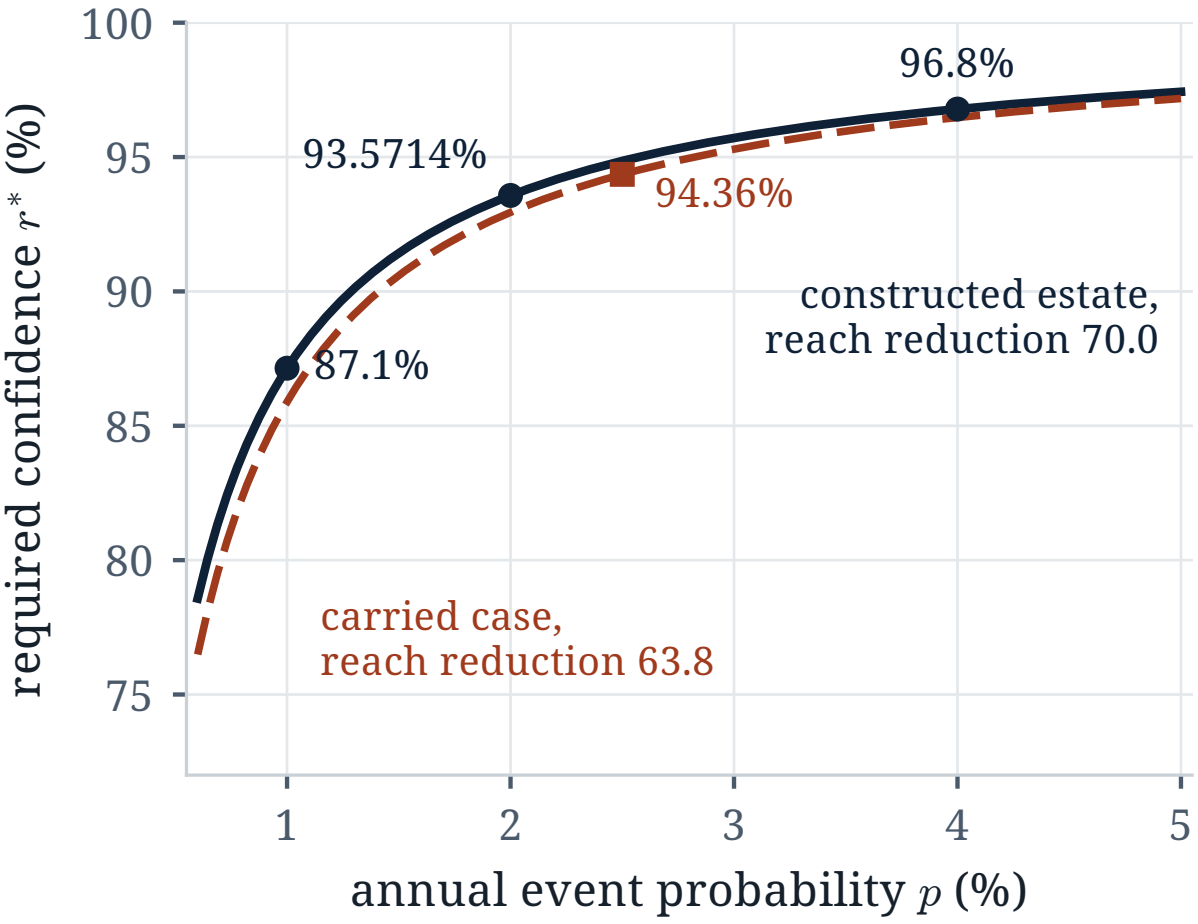

Figure 60.1: **The confidence a cell wall must command rises with the risk it is being used against.** Required confidence $r^* = 1 - \Delta C / (p\,\Delta S)$ at a saving of $\Delta C = 0.090$ units a year, for the constructed estate (reach reduction 70.0 units) and for the carried case (63.8 units). Marked points are the values printed in Sections 5.3 and 5.5; modelled from the constructed cost parameters, script `figs/src/CCP-060_fig02.py`.

```
A1 18.0  A2 12.0  B 22.0  C 18.0  D 12.0  E 10.0  F 8.0
contagion HHI = 0.158400
effective compartments = 6.3131
maximum single reach   = 22.0%
```

The effective count rises from 4.9603 to 6.3131 for one additional entity at 0.025 units a year. **The constraint sets the structure; the optimisation does not.** A group asking “what is the optimal number of vehicles” has asked a question with no answer; a group asking “what is the largest loss we can absorb” gets a number. Sagan [1993] is the standing caution against the opposite reflex: added redundancy can reduce reliability by creating new failure modes and diffusing responsibility, which is what failure mode 10 of Section 9 records in cost terms.

5.5 The carried case

CONSTRUCTED CASE. A group with Thai manufacturing, a trading company, intellectual property, London commercial real estate and a listed portfolio. As found, everything sits under two entities, with the Thai operation run as a branch of the UK company.

```
compartment       reachable share    contribution
------------------------------------------------------
UK company              82.0%        0.672400
Jersey company          18.0%        0.032400
------------------------------------------------------
contagion HHI = 0.704800
effective compartments = 1.4188
maximum single reach   = 82.0%
```

One product liability claim arising in Thailand reaches the London building, the securities portfolio and the trading business, because the Thai operation is a branch and a branch is the company. That finding took twenty minutes to compute from the corporate chart, and the corporate chart is where it was invisible.

The group’s covenants give a maximum absorbable single loss of 22.0 units on an estate of 100, so the position as found fails the constraint by a factor of 3.7. Rebuilding the compartments around **where claims arise** rather than around where value sits:

compartment	reachable share	why separate
1 manufacturing operating company	18.2	employment, product, environmental
2 trading company	16.5	trade counterparty claims
3 property holding vehicle	13.5	occupier, premises, lender
4 intellectual property holding company	11.8	infringement claims run both ways
5 securities vehicle	13.9	custodian and market claims
6 captive insurer	13.6	insurance liabilities, regulated
7 regulated-zone vehicle	12.5	separate regulator

```
contagion HHI          = 0.145940
effective compartments = 6.8521
maximum single reach   = 18.2%   (constraint 22.0 -- SATISFIED)
```

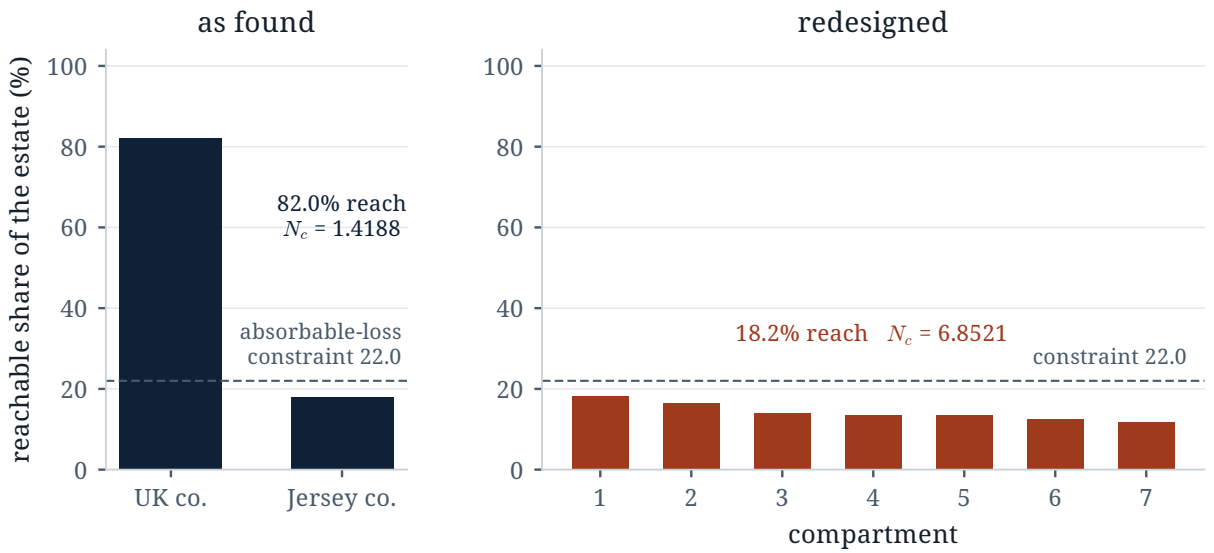

Figure 60.2: **Seven compartments built around where claims arise take maximum single reach from 82.0 to 18.2 per cent and the effective compartment count $N_c = 1/\mathrm{HHI}_c$ from 1.4188 to 6.8521.** Reachable shares and both indices are the constructed values computed in Section 5.5; the dashed line is the group's stated absorbable-loss constraint of 22.0 units. Script `figs/src/CCP-060_fig01.py`.

metric	as found	redesigned	change
entities	2	7	$+5$
contagion HHI	0.704800	0.145940	-79.3%
effective compartments	1.4188	6.8521	$\times 4.8295$
maximum single reach	82.0%	18.2%	-63.8 points
absorbable-loss constraint	FAIL	PASS	

The cost and the verdict:

```
incremental entities                          5
cost per entity per year (constructed)    0.025 units
incremental cost                          0.125 units p.a.
estimated p (operating group)             2.5% per year

benefit = 0.025 x (82.0 - 18.2) = 1.595 units p.a.
cost                            = 0.125 units p.a.
ratio                           = 12.76 to 1
break-even p = 0.125 / 63.8     = 0.196% per year
```

The redesign pays for itself at any event probability above one in 510, and the estimated probability is one in 40. What makes it clear is the manufacturing operation. Strip that out and model the same estate as a passive holding structure, and p falls to the order of 0.15 per cent — below break-even — and the honest recommendation becomes fewer entities rather than more.

The cell proposal for this group is then decided rather than argued. Claims against three of the seven compartments arise in forums that would have to be asked to recognise a foreign

statutory partition inside a single foreign company holding assets on their own territory. At the group's $p = 2.5\%$ and reach reduction of 63.8 units, indifference is at $1.595(1 - r) = 0.090$, giving $1 - r = 0.056426$ and $r^* = 94.36\%$. **The proposal is declined for those three compartments and is acceptable for purely financial sleeves inside the securities vehicle, where every counterparty contracts under one law and no hard asset sits anywhere.** That split answer is available only because the question was converted into a number.

A discrepancy in the source is recorded here rather than corrected silently. The source manuscript states that the required confidence is "95.9%" at $p = 2.5\%$ and then displays the arithmetic giving 94.36 per cent. The displayed arithmetic is right; 95.9 per cent is not reproducible from any combination of the chapter's stated parameters, and the nearest reproducible figure is 94.86 per cent, which is the threshold at $p = 2.5\%$ on the constructed estate's reach reduction of 70.0 units rather than the carried case's 63.8. **This paper prints 94.36 per cent and flags the source figure as an error.**

5.6 The register that decides the outcome

The compartment map is the easy part. The register of **connections** determines whether any of it is real, and on the carried case it produced four findings the corporate chart did not show: an uncapped parent guarantee of an equipment lease, renegotiated to a capped guarantee sized inside the absorbable-loss constraint; a cross-default in the property facility referencing any group indebtedness above a threshold, carved out for the operating subsidiaries at a fee; an ambiguously worded comfort letter, withdrawn and replaced with a specific, capped and disclosed support undertaking; and a shared cash pool sweeping five entities into one account, restructured into documented intercompany loans at arm's-length rates.

The fourth item was the whole structure. A cash pool is commingling with a treasury policy attached, and a group that has spent five years building compartments and sweeps them nightly into one account has produced a corporate chart rather than a ring-fence. Restructuring it cost more in working-capital efficiency than the six new entities combined, and it is the only item on the list without which the rest is decorative.

5.7 The honest zero

Run the jurisdictional instrument on the same group before and after:

```
BEFORE   two entities, both inside one perimeter
         naive HHI 0.704800 -> effective jurisdictions 1.4188
         bloc-HHI  1.000000 -> N = 1.0000, ln(N) = 0, h = -0.500000

AFTER    the compartments map onto the designed structure
         bloc-HHI  0.340000 -> N = 2.941176, h = -0.122417
```

That looks like a large improvement produced by compartmentalisation, and it is not. The improvement in N comes from the jurisdictions the compartments happen to sit in, all chosen for reasons that had nothing to do with compartmentalisation. Build the same seven compartments as seven companies in one jurisdiction:

```
contagion HHI = 0.145940   effective compartments = 6.8521
bloc-HHI      = 1.000000   N = 1.0000  ln(N) = 0  h = -0.500000
additional C  = 7 x 0.025  = 0.175 units p.a.
```

Identical contagion result, zero jurisdictional result, and 0.175 units a year of additional maintenance. Compartmentalisation contributes exactly zero to N. It is answering a different threat, and a structure that reports the two together is reporting a benefit obtained from somewhere else. The same arithmetic appears in Curzi [2026], where six Atlantic-cluster entities reading 4.0032 effective jurisdictions collapse to $N = 1.00$ and $\ln N = 0$, and in Curzi [2026], where three closely related jurisdictions reading 2.898551 collapse to exactly 1.00.

6. Conversion of an immovable asset into a movable claim

6.1 The mechanism, and why it is transparent by construction

Land cannot leave the jurisdiction it sits in and is therefore subject to that state absolutely; every legal system governs rights in immovable property by the law of the place where it is situated, and enforces that rule by controlling the register on which title depends. A security, by contrast, is an intangible whose location for conflicts purposes is settled by reference to the account in which it is held — the place-of-the-relevant-intermediary approach — so the governing law of the claim follows an account, and an account is a commercial arrangement that can be moved. **The conversion replaces an asset whose legal character is fixed by geography with a claim whose legal character is fixed by a contract the holder controls. That is a genuine change and not a trick.** The doctrinal statements in this paragraph are described from the source manuscript and are not cited; Appendix B itemises them.

The mechanism works because it is transparent, not despite it. A listed real estate vehicle files an annual report listing its properties asset by asset; the buildings are on a public land register in any case; and beneficial owners of overseas entities holding land are, in the leading jurisdiction for the carried case, on a public register too. What the disclosure buys is the property that makes the claim tradeable. A security trades because buyers can price it, buyers can price it because the issuer discloses, and the disclosure regime is enforced by a regulator whose credibility is the exchange's product. **Liquidity is manufactured out of disclosure and has no other input.** The formation test is therefore passed in its strongest available form: every element already is disclosed, to everyone, on a schedule, under penalty for inaccuracy — and the mechanism works anyway.

The land is still seizable by the host state even when the claim on it is portable. If a state expropriates the building, the holder owns a share in an entity that has lost a building. What has been bought is not immunity but **latency**: the ability to be out of the position in a day rather than in nine months. That has a computable value, and the computation is Section 6.3.

6.2 Leakage: the certain cost

CONSTRUCTED CASE. A single freehold commercial building: market value 48,000,000, base cost 22,000,000, unrealised gain 26,000,000, net operating income 2,304,000 at 4.80 per cent on value, debt 14,400,000 at 30.0 per cent loan-to-value, four tenants with the largest at 41 per cent of income, exit latency on a direct sale of approximately 270 days, and a property-level effective count of 1.0000.

```
V = 48,000,000     B = 22,000,000     gain = 26,000,000
t_gain = 25%       tax on the gain   =  6,500,000
d = 0              transfer tax not borne on the modelled route
f = 1.5% of V                        =    720,000
------------------------------------------------------------
total leakage                        =  7,220,000
L = 7,220,000 / 48,000,000           =  15.0417%
net proceeds available to reinvest    = 40,780,000
```

Fifteen per cent of gross value, certain, immediate and unrecoverable. That is the number every subsequent computation is measured against, and it is the number absent from the presentations of this idea that the source manuscript reports having seen.

One asymmetry between tax systems is decisive and is a fact about tax systems rather than about property. Where contribution of appreciated property to a partnership in exchange for a partnership interest is non-recognition, the vehicle can be built as an umbrella partnership and immediate leakage falls to transaction costs alone — 1.5 per cent on these numbers — and the base-case payback becomes $0.015 / 0.004725 = 3.17$ years. **But the deferred gain does**

not disappear: it is allocated back to the contributor as the partnership depreciates or sells, and it crystallises on exchange into the listed security. The deferral defers the very portability the conversion was undertaken to obtain. Where no such relief exists, the contribution is a disposal at market value and the conversion route is economically identical to an outright sale and reinvestment.

6.3 Escape value, payback, and the break-even belief

```
base case parameters, stated so they can be disputed
p  = 1.50%    a materially adverse event at the situs once in 67 years
L* = 60%      expropriation, punitive levy, or a use restriction
q  = 0.70     the event is seen coming and the board can act
s  = 0.25     sale at 25% below the pre-news mark

V_esc = 0.0150 x 0.60 x 0.70 x 0.75 = 0.004725  ->  0.4725% per year
payback = 0.150417 / 0.004725 = 31.83 years
```

Thirty-two years to recover the tax cost of the conversion at median parameters. The tail is the case that justifies it:

scenario	p	L^*	q	s	V_{esc}	payback (yr)
benign	0.50%	50%	0.70	0.25	0.001313	114.6
base	1.50%	60%	0.70	0.25	0.004725	31.8
elevated	3.00%	70%	0.75	0.30	0.011025	13.6
stressed	5.00%	80%	0.70	0.25	0.021000	7.2
acute	10.00%	85%	0.60	0.40	0.030600	4.9

Solving for the annual probability at which the conversion repays inside ten years, at $L^* = 60\%$, $q = 0.70$, $s = 0.25$:

```
p x 0.60 x 0.70 x 0.75 = 0.150417 / 10
p x 0.315 = 0.0150417
p = 4.7752%
```

A ten-year payback requires belief in roughly a 4.8 per cent annual chance of an event destroying 60 per cent of the value of this specific building. For prime commercial real estate in a jurisdiction with an essentially clean record on expropriation of commercial freeholds that belief is not defensible on the record. Where it *is* defensible, the conversion is not merely justified but urgent — and by then there is often no functioning market in which to execute it.

Run on the carried building, whose honest parameters are the benign row — $p = 0.50\%$, $L^* = 50\%$, $q = 0.70$, $s = 0.25$ — the escape value is 0.13125 per cent a year and the payback is 114.60 years. **On honest parameters for this asset in this jurisdiction the geopolitical case for the conversion does not exist.** The instrument is real; the carried case is not the fact pattern for which it is the answer.

6.4 The property axis, where the transaction succeeds

The arithmetic that fails on arbitrary state action succeeds decisively on an axis nobody runs. Take the share basis to be the fraction of the real estate allocation's value in one underlying asset.

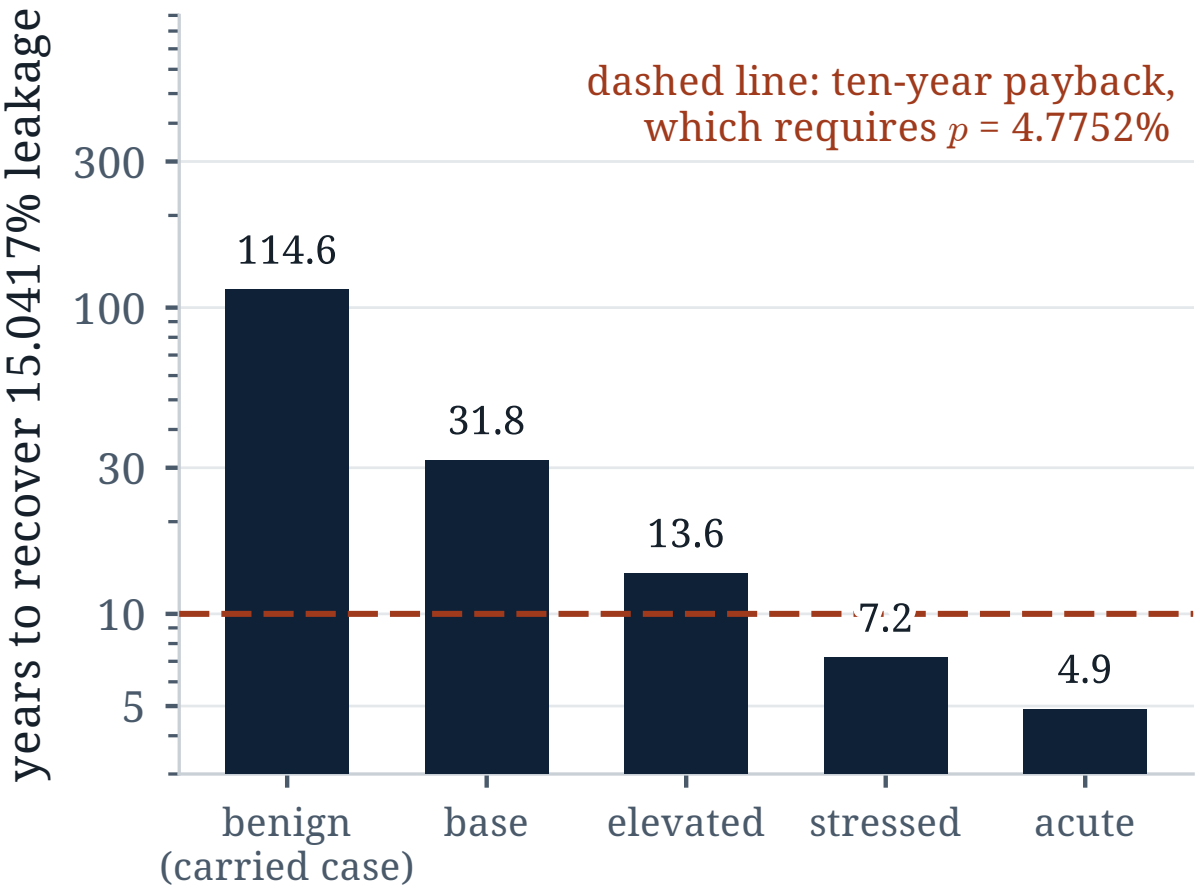

Figure 60.3: **At a fixed leakage of 15.0417 per cent, the conversion repays inside ten years only in the two most severe scenarios of five.** Paybacks are the source's scenario table computed as L/V_{esc}; the benign row is also the carried London case, whose four parameters are identical. Modelled from the constructed parameters in Section 6.3; script `figs/src/CCP-060_fig03.py`.

```
BEFORE -- one building
    London building 100.0%      property HHI = 1.000000
    effective properties = 1.0000

AFTER -- a constructed globally diversified listed allocation,
         forty underlying assets across six listed vehicles
    largest 12.0  0.014400      sixth    6.0  0.003600
    second   9.0  0.008100      seventh  5.0  0.002500
    third    8.0  0.006400      eighth   5.0  0.002500
    fourth   7.0  0.004900      ninth    4.0  0.001600
    fifth    6.0  0.003600      tenth    4.0  0.001600
    thirty further assets, 34.0% total at 1.1333% each
        30 x 0.000128444 = 0.003853
    ------------------------------------------------------
    property HHI = 0.049200 + 0.003853 = 0.053053
    effective properties = 1 / 0.053053 = 18.8491
```

From an effective property count of 1.0000 to 18.8491. With the tenant diversification that arrives with it — from four tenants, the largest at 41 per cent of income, to several hundred — that is the largest single reduction in idiosyncratic risk available anywhere in the carried case. It is a commercial-risk improvement and not a state-action improvement, and the two must not be traded against each other in the same sentence.

Priced: idiosyncratic risk on a single four-tenant building, as an annual expected loss at 2.0 per cent per year of an asset-specific impairment averaging 25 per cent of value, is $0.020 \times 0.25 = 0.500\%$ a year. Across 18.85 effective properties the same class of risk falls approximately as the effective count rises: $0.500\% / 18.85 = 0.0265\%$. The annual saving is 0.4735 per cent of value, and

```
payback = 0.150417 / 0.004735 = 31.77 years
```

Thirty-two years again, from a completely different direction. The coincidence is an artefact of the constructed parameters and the discipline is not: on this asset, at this basis, in this tax system, *no* argument for conversion repays inside a generation, because the leakage is too large relative to any annual benefit that can honestly be claimed. The conclusion is about timing rather than about vehicles. **The leakage is a function of the accrued gain and the accrued gain grows; the conversion that is uneconomic today was economic on acquisition day, when basis equalled value and leakage was 1.5 per cent rather than 15.0 per cent.** At 1.5 per cent leakage the base-case payback is $0.015 / 0.0013125 = 11.43$ years and the concentration-case payback is $0.015 / 0.004735 = 3.17$ years. **Decide the holding form when the asset is acquired, not when it becomes worrying.**

6.5 The jurisdictional surprise

Assigning a listed portfolio to the perimeter of its custodian rather than of its issuers, and applying that rule mechanically, the building's 9.0 points of group exposure leave the property line and follow the custody. Three choices, computed on the designed structure of Curzi [2026] — six jurisdictions at 29.1 / 18.2 / 16.4 / 13.6 / 11.8 / 10.9, naive HHI 0.189002 and 5.290949 effective jurisdictions, blocs at 40.0 / 30.0 / 30.0 giving bloc-HHI 0.340000, $N = 2.941176$ and $h = -0.122417$:

custody	naive effective jurisdictions	bloc-HHI	N	h	Δh
unchanged, existing perimeter	5.290949	0.340000	2.941176	-0.122417	0.000000
split across two bridge centres	5.150000	0.361150	2.768932	-0.143539	-0.021122
moved wholly to one bridge centre	5.120275	0.374200	2.672368	-0.155962	-0.033545

Every attempt to improve the structure by moving the converted position out of the existing perimeter makes the structure measurably worse. The reason is arithmetic and not political: the sum of squares of a three-part distribution is minimised at equal thirds, and taking exposure out of the smallest bloc and adding it to the largest moves the distribution away from balance in both directions at once. The property was doing bloc work.

The marginal calculation runs the other way. Writing x for points moved from the largest bloc into the smallest,

```
bloc-HHI(x) = (0.40 - x)^2 + 0.09 + (0.30 + x)^2
d/dx        = -2(0.40 - x) + 2(0.30 + x) = -0.20 + 4x
negative for x < 0.05

at x = 0.05:  0.35^2 + 0.09 + 0.35^2 = 0.335000
              N = 2.985075
```

A second discrepancy in the source is recorded here rather than corrected silently. The source states $\ln(2.985075) = 1.093761$, giving $h = -0.117184$ and a gain of $+0.005233$. Recomputation gives $\ln(2.985075) = 1.093625$, so $h = -0.117231$ and the gain is $+0.005185$. **The source's logarithm is wrong in the fourth decimal place and the derived gain is overstated by** 4.8×10^{-5}**.** The corrected figure is used throughout this paper and the scaffold figure of $+0.005233$ is superseded. Either way the move is declined, on the ground that the index is a diagnostic and not an objective function — a structure optimised against its own published measure ceases to be measured by it [Goodhart, 1975, Campbell, 1979]. It is recorded because the arithmetic produced it, and suppressing it would be the selective reporting the instrument exists to detect.

The conversion contributes exactly zero to N, and that is not an argument against it. It answers commercial risk, with an effective property count moving from 1.0000 to 18.8491, and a narrow slice of arbitrary state action by reducing exit latency from roughly 270 days to one. It answers perimeter fragmentation not at all, because the land never moved and a claim on land in a jurisdiction is economic exposure to that jurisdiction however it is custodied.

That produces a methodological refinement applicable wherever a security's issuer has concentrated assets:

> For a security whose issuer's assets are concentrated in one jurisdiction, exposure splits across two questions rather than one. **Availability** follows the custodian's perimeter. **Value** follows the situs of the issuer's assets, and no custody arrangement moves it. Report both. A structure reporting only the first has recorded a diversification it did not achieve; a structure reporting only the second has ignored the freeze risk it did acquire.

On that refinement, value exposure to the situs falls from 9.0 points to whatever fraction of the diversified allocation is situated there — 20 per cent of 9.0, or 1.8 points — with the remaining 7.2 points redistributing to the situs of the other assets.

Measured on its own, the replacement allocation is the paper's sharpest instance of the axis divergence:

```
United States  35.0%   WEST     0.122500
United Kingdom 20.0%   WEST     0.040000
Japan          15.0%   WEST     0.022500
Singapore      12.0%   BRIDGE   0.014400
Australia      10.0%   WEST     0.010000
UAE             8.0%   BRIDGE   0.006400
------------------------------------------------------
naive HHI = 0.215800   effective jurisdictions = 4.633920
WEST 80.0% / BRIDGE 20.0%
bloc-HHI  = 0.680000   N = 1.470588   ln(N) = 0.385662
```

A globally diversified listed real estate allocation across six countries and four continents has an effective bloc count of 1.470588. That is not an artefact of the constructed weights: the listed real estate universe is overwhelmingly concentrated in one coordination perimeter by market capitalisation, so any allocation tracking it inherits the concentration. **Global diversification here diversifies the property axis magnificently and the perimeter axis barely at all. Two axes, opposite answers, one transaction — and an adviser reporting either alone is reporting half of a result whose halves point in different directions.**

7. Jurisdictional context: which term of the law a jurisdiction can act on

This section is the survey material, retained as context for the measurement in Section 8.5 and condensed accordingly. The full descriptive profiles are in Appendix C. **None of it is cited to primary legal sources and none of it is offered as this paper's contribution.**

7.1 The structural claim, and the arithmetic that decides it

Territorial taxation — a rule taxing income arising within a state's territory and not income arising outside it — is marketed in several regions as though it conferred independence. It is a rule of domestic law, unilateral, amendable by ordinary legislation, and adopted by states that participate in the same information-exchange, anti-money-laundering and substance architecture as everyone else [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015]. **A structure that treats a source rule as though it conferred perimeter independence has misidentified what it bought.**

Four properties of such regimes are routinely misunderstood and all four bear on the measurement. They confer no treaty protection, being unilateral rather than negotiated. They say nothing about the residence position of the person who ultimately bears the tax, so that where the principal is taxed on citizenship or is resident in a controlled-foreign-company jurisdiction the source rule may be irrelevant to the outcome. They attract standards attention precisely because they are attractive: the mechanism by which a listing decision produces a domestic legislative change within months is documented as a technique of governance in its own right [de Goede, 2011], and the source records one surveyed jurisdiction rewriting its income tax law within nine months of a listing and being delisted. And they are not the same regime in each state that has one — one is broad and long-standing, one is territorial with carve-ins for foreign passive income and a time-limited election, one is the purest of the

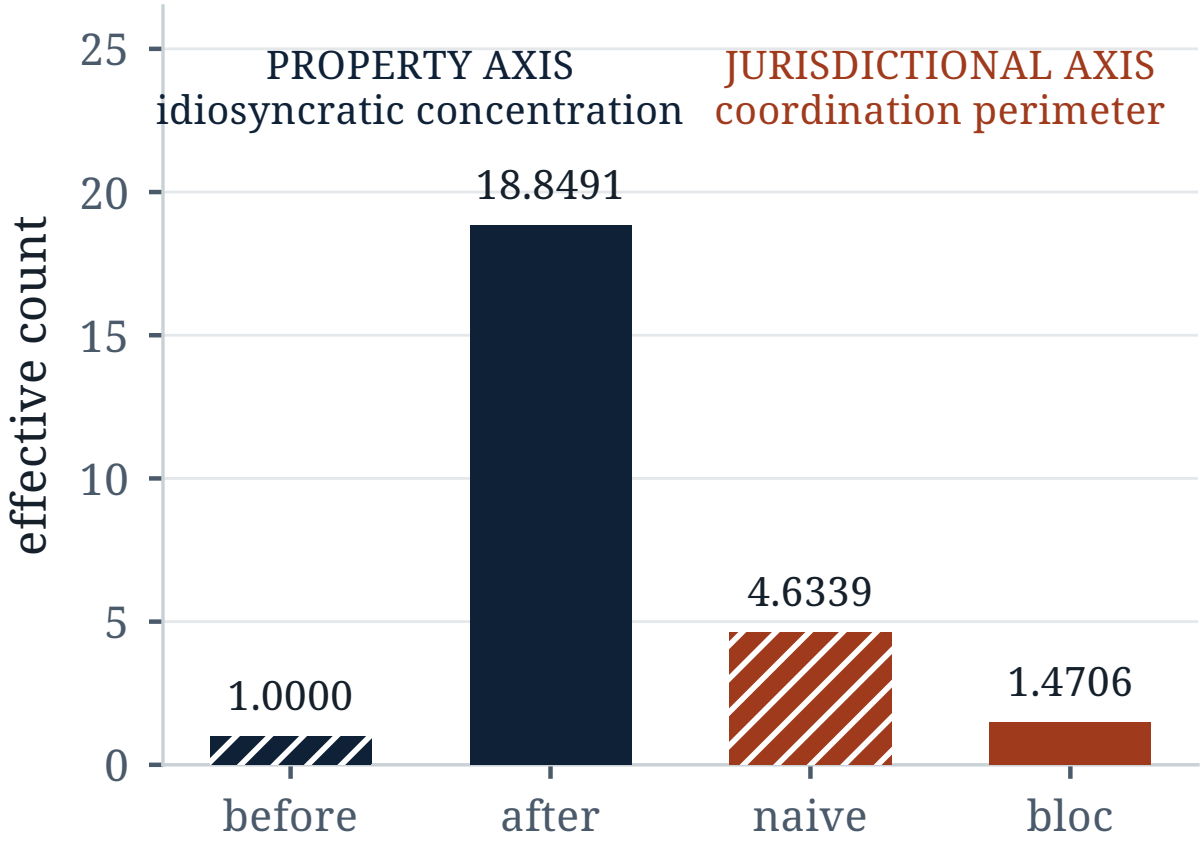

Figure 60.4: **One transaction improves one concentration axis by a factor of nineteen and leaves the other below one and a half.** Effective counts are $1/\mathrm{HHI}$ on the three share bases of Section 3.1, computed from the constructed allocation in Sections 6.4 and 6.5. Hatched bars are the before-and-naive readings, solid bars the after-and-bloc readings; script `figs/src/CCP-060_fig04.py`.

group, and one was narrowed under external pressure. **Treating them as one regime is the commonest analytical error in the field, and the correction costs nothing.**

7.2 A de-branded comparison

The source manuscript scores four jurisdictions across twelve descriptive items. **The scored comparison is reproduced here without jurisdiction names**, following the convention of Curzi [2026]: the underlying characteristics are the analyst's judgements applied to published descriptions and **cannot be supported from this paper's bibliography, which contains no primary source for any individual jurisdiction**. Attaching a jurisdiction's name to an unsupported characteristic is the failure this convention exists to prevent. Named descriptive profiles are in Appendix C for readers who wish to verify them against the official registers.

Scores are 0–5 ordinal rank judgements. **An ordinal scale licenses a minimum and does not license a mean**, and only minima are taken below.

centre	institutional quality	perimeter independence	vehicle set	standards position stateable
Territorial centre A	3	1	4	5
Territorial centre B	5	3	2	5
Territorial centre C	1	3	1	0
Territorial centre D	4	0	2	5

Taking the minimum across the dimensions a holding function requires — institutional quality, perimeter independence and a vehicle set — assigns **no holding function to any of the four**. Centre B scores highest for a residence and operating function; centre C scores an explicit zero on whether its standards position can be stated at all, and the source declines to guess rather than filling the cell in. **A zero that records the absence of an assessable fact is more useful than a score invented to complete a table.**

This is the corpus's scalar-reduction limitation in a second domain and it is inherited rather than restated. Curzi [2026] names it once as a framework-level constraint on what a single score may be asked to carry; the appropriate response here is to point at that statement, take minima rather than means, and not to pretend the table is a measurement.

7.3 What a jurisdiction inside an occupied perimeter can and cannot do

The structural claim, stated so it can be measured: **where a jurisdiction sits inside a coordination perimeter the structure already occupies, it can act on the erosion term of the storage law and cannot act on the surplus term.** The surplus term is $\eta \ln N$, and N counts perimeters rather than flags; the erosion term is δQ, and a genuine reduction in the effective erosion rate is worth having whatever the perimeter reading says. Section 8.5 measures both.

Since the erosion term is multiplied by the stock Q while the surplus term is multiplied by η, **the relative value of the two depends on how large the protected stock already is**: for a large Q, erosion reduction dominates; for a small Q it does not, and the same structure is a waste of money. Both conclusions come from the same law, which is why the law is worth writing down rather than reasoning about the region qualitatively.

8. Results

Every figure below is an exact computation on constructed inputs. **No dataset was collected and no figure in this paper is a measurement taken from a real structure.** Section 12 states that limitation in the terms the corpus uses for it.

8.1 R1 — the cell-wall confidence threshold

With a cost advantage of 0.090 units a year against a fenced benefit of 1.400 units a year, indifference is at $1.400(1-r)=0.090$, so $1-r=0.064286$ and $r^{*}=93.5714\%$. **That is the minimum confidence that a foreign forum respects the cell wall for the cheaper device to be preferable.** The threshold rises with risk: 87.1 per cent at $p=1.0\%$, 93.5714 per cent at $p=2.0\%$, 96.8 per cent at $p=4.0\%$, and 94.36 per cent on the carried case at $p=2.5\%$ with a reach reduction of 63.8 units.

8.2 R2 — contagion measured

Contagion measured as HHI_{c} over reachable shares with effective compartments $=1/\mathrm{HHI}_{c}$: six unequal compartments at 30 / 22 / 18 / 12 / 10 / 8 per cent give $\mathrm{HHI}_{c}=0.201600$, **4.9603 effective compartments**, and cut maximum single reach from 100.0 to 30.0 per cent. At an annual event probability of 2.0 per cent that is worth $0.02\times 70.0=1.400$ units a year against 0.110 of cost — a ratio of **12.73 to one** and a break-even probability of **0.157 per cent per year**. On the carried case the redesign moves HHI_{c} from 0.704800 to 0.145940, the effective count from 1.4188 to 6.8521, and maximum single reach from 82.0 to 18.2 per cent, at a ratio of 12.76 to one and a break-even of 0.196 per cent.

8.3 R3 — leakage against escape value

Conversion of an immovable asset carries certain leakage $L=7{,}220{,}000/48{,}000{,}000=15.0417\%$ against an escape value $V_{\mathrm{esc}}=pL^{*}q(1-s)=0.4725\%$ a year at base parameters, a **payback of 31.83 years**. A ten-year payback requires $p=4.7752\%$ a year. On the carried building's own parameters the escape value is 0.13125 per cent and the payback is **114.60 years**.

8.4 R4 and R5 — the two axes

R4. Diversification through the same conversion raises effective properties from 1.0000 to **18.8491** (property HHI 0.053053), worth 0.4735 per cent a year against the same 15.0417 per cent leakage — a payback of **31.77 years**. Only a non-recognition regime cutting leakage to 1.5 per cent brings the payback to 3.17 years.

R5. The converted global allocation at 35 / 20 / 15 / 12 / 10 / 8 per cent reads naive HHI **0.215800** and **4.633920** effective jurisdictions but bloc-HHI **0.680000** and $N=1.470588$. **The naive count improves while the bloc count worsens.** H4 is supported: the two axes moved in opposite directions on one transaction.

8.5 R6 — the regional sleeve, and where the gain came from

CONSTRUCTED CASE. A hemispheric sleeve as found, and redistributed across a region of territorial-taxation jurisdictions:

```
SLEEVE AS FOUND
  three positions at 55.0 / 25.0 / 20.0
  naive HHI 0.405000 -> effective jurisdictions 2.469
  all three inside one perimeter
```

```
  perimeter HHI 1.000000 -> EFFECTIVE BLOCS 1.00

SLEEVE AS PROPOSED
  five positions at 34.0 / 22.0 / 20.0 / 14.0 / 10.0
  naive HHI 0.233600 -> effective jurisdictions 4.281

SLEEVE, PARTIAL-INDEPENDENCE READING
  perimeter-coupled 70.0 / partially independent 30.0
  perimeter HHI 0.580000 -> EFFECTIVE BLOCS 1.724
```

The honest sleeve result is a range of 1.00 to 1.724 effective blocs against a naive reading of 4.281. The naive number overstates by between two and a half and four times.

At group level, adding two such jurisdictions holding twelve per cent of protected capital to the designed structure:

```
BASELINE       blocs 30.0 / 29.1 / 40.9
               bloc HHI 0.341962 -> N = 2.924302   ln(N) = 1.073056

WITH THE LEG   eight jurisdictions at 26.0 / 16.0 / 14.0 / 12.0
               / 10.5 / 9.5 / 7.0 / 5.0
               naive HHI 0.154650 -> effective jurisdictions 6.466

READING A      strict: the whole region is one perimeter
               blocs 38.0 / 26.0 / 36.0
               bloc HHI 0.341600 -> N = 2.927400   ln(N) = 1.074115

READING B      one jurisdiction treated as partially independent
               blocs 31.0 / 26.0 / 36.0 / 7.0
               bloc HHI 0.298200 -> N = 3.353454   ln(N) = 1.209991

surplus gain at eta = 0.35
  Reading A   0.35 x (1.074115 - 1.073056) = 0.000371
  Reading B   0.35 x (1.209991 - 1.073056) = 0.047927
```

Under the strict reading, adding two jurisdictions holding twelve per cent of protected capital raised the effective bloc count by 0.0031 and the surplus term by 0.000371 — for practical purposes, by nothing. Against a maintenance increment of 0.05, both readings lose money on diversification grounds alone:

```
baseline                   h = 0.35 x 1.073056 - 0.20 - 0.30 = -0.124431
Reading A, no erosion gain h = 0.35 x 1.074115 - 0.20 - 0.35 = -0.174060
Reading B, no erosion gain h = 0.35 x 1.209991 - 0.20 - 0.35 = -0.126503
```

Now introduce the term the region actually acts on. If the effective erosion rate falls from 0.020 to 0.013:

```
Reading A, delta = 0.013   h = 0.375940 - 0.130 - 0.35 = -0.104060
Reading B, delta = 0.013   h = 0.423497 - 0.130 - 0.35 = -0.056503
```

Both now beat the baseline, by 0.020371 and by 0.067928. **On the strict reading the entire improvement comes from the erosion term: the bloc term contributed 0.000371 of a 0.020371 gain, one part in fifty-five.**

The result generalises and is the point of Section 7.3. Where a jurisdiction sits inside a perimeter the structure already occupies, it can help only through the erosion term and never through the surplus term. And the erosion route is itself conditional on a fact about the person

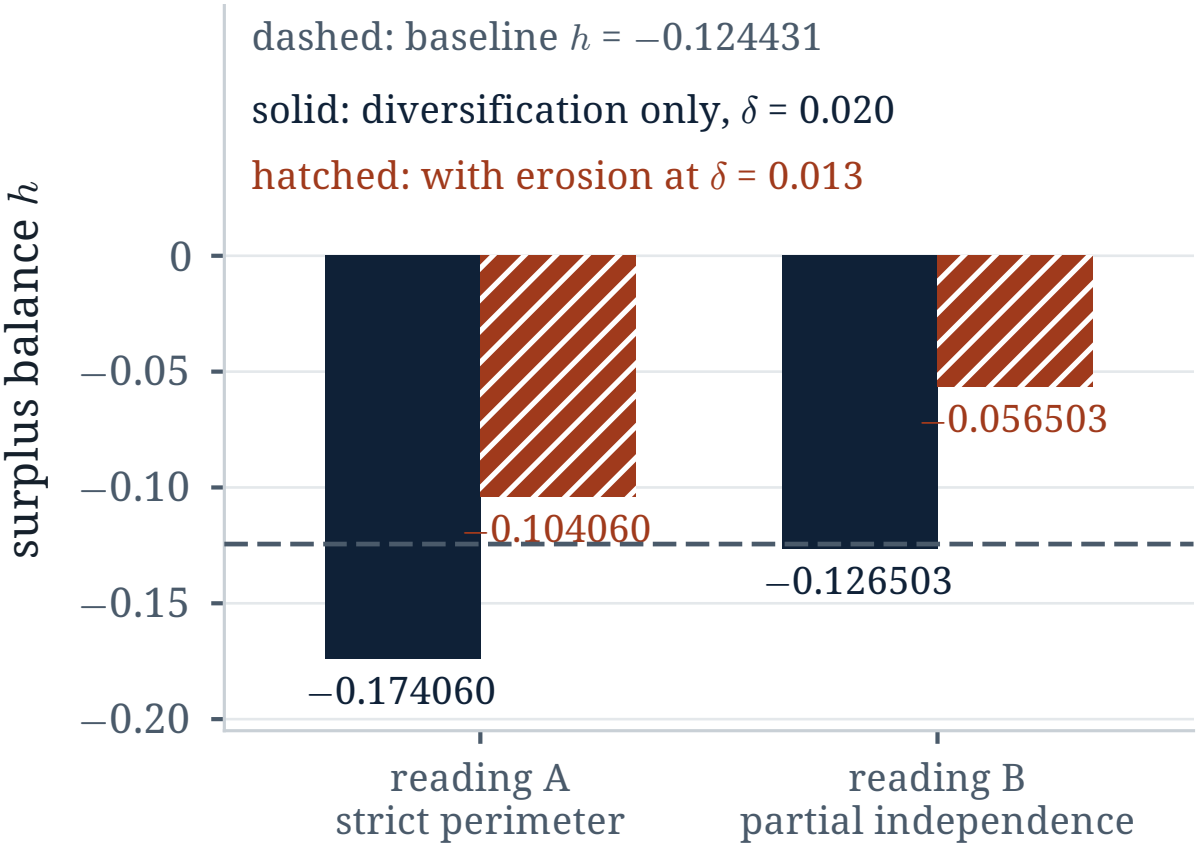

Figure 60.5: **The regional leg's entire gain under the strict reading comes from the erosion term, not from the perimeter count.** Surplus balance $h = \eta \ln N - \delta Q - C$ at $\eta = 0.35$, $Q = 10$, $C = 0.35$, computed from the constructed bloc shares of Section 8.5; the dashed line is the baseline at $C = 0.30$, $\delta = 0.020$. Script `figs/src/CCP-060_fig05.py`.

rather than about the structure: where the principal remains taxable on citizenship regardless of residence, δ does not move at all, both readings stay at -0.174060 and -0.126503, and the whole proposition is worse than doing nothing. **A regional proposition that is worth 0.020371 to one principal and -0.049629 to another, on one fact about the principal, must be priced after that fact is established rather than before.**

8.6 Counter-result

Leakage of 15.04 per cent is certain while every benefit computed against it is probabilistic, giving paybacks above thirty years on every route examined. The conversion returns 31.83 years on the state-action argument, 114.60 years on the carried building's own parameters, and 31.77 years on the concentration argument — three independent routes, all outside a working lifetime, because the leakage is too large relative to any annual benefit that can honestly be claimed.

And the ring-fencing redesign's gain on the jurisdictional measure is an honest near-zero. The best available rebalancing move buys $+0.005185$ of surplus (the source prints $+0.005233$; Section 6.5 records the arithmetic error), and compartmentalisation itself contributes 0.000000 to N while adding 0.125 to 0.175 units a year to C. **Under the storage law alone that is unambiguously negative, and it is justified entirely on an axis the storage law does not contain.** Reporting the contagion gain and the jurisdictional figure together, as a single improvement, would be the reporting failure the instrument exists to detect.

9. Discussion and failure catalogue

9.1 What the measurement does and does not license

The contagion index measures **independence, not capacity**, exactly as the jurisdictional index does. An effective compartment count of 6.8521 says nothing about whether any compartment can carry the load, and nothing about whether the group would in practice let a compartment fail. That last point is the Medici warning, and it is the oldest result in this paper's subject: branches constituted as legally separate partnerships, each with its own capital and its own junior partner, did not save the bank, because the senior partnership had capital in each branch, the same men appointed each branch's manager, and depositor confidence is not compartmented by a partnership deed [de Roover, 1963]. **Legal separation does not separate capital, management judgement or reputation, and a structure that separates only the first has separated the least important of the three.**

The same reservation in modern form: a de-risking decision is taken about a client relationship, and the client relationship is the group. **Compartmentalisation is a defence against a claim. It is not a defence against a decision, and most of the events this analysis is about are decisions.** Curzi [2026] makes the point on a different share basis and reaches the same shape — entity-based exposure of 27.3 per cent against a currency share of 61.0 per cent and settlement volume near 58 per cent, so that the entity map understates dependency by more than a factor of two.

9.2 Thirteen failure modes

Condensed from the source; the eleventh changes the character of the problem and is placed accordingly.

1. **Commingling.** One account used for two compartments, one payment from the wrong entity, one receivable collected into the parent and not swept. It appears in every alter-ego and consolidation finding and is created by operational convenience rather than by a structuring decision.

2. **Guarantees, comfort letters and keep-wells.** Given for good commercial reasons by someone raising finance who has not read the structure memorandum. Comfort letters are worse than guarantees because they are ambiguous.
3. **The independent director who is not independent.** A consent right held by a person the sponsor appoints, pays and can replace is a document.
4. **Substantive consolidation.** Decided on evidence about how the group behaved. No drafting escapes a course of dealing, and by the time consolidation is argued the course of dealing is a decade long and is in the group's own correspondence.
5. **Cross-default and cross-collateralisation.** Six compartments each carrying a cross-default to any group indebtedness above a threshold accelerate simultaneously. The contagion index reads 0.2016 on the corporate chart and 1.0000 on the financing documents. **Run the measurement on the financing documents.**
6. **Undercapitalisation.** A compartment funded at the statutory minimum and expected to carry a large obligation invites the argument that separation was formal.
7. **Confusing accounting with law.** Deconsolidation states what the financial statements show and nothing about what an insolvency court will do.
8. **The cell wall in a foreign forum.** The trap is a cell structure created for a domestic purpose and used three years later for a transaction with a counterparty elsewhere. Nobody re-runs the analysis when the use changes.
9. **Cells holding hard assets in a third state.** The sharpest version of the previous mode, and the recommendation is the refusal: **do not put a hard foreign asset in a cell.**
10. **Multiplying compartments without measuring cost.** Twenty compartments where seven satisfy the constraint cost 0.325 units a year for no measurable benefit on either axis.
11. **Ring-fencing after the fact.** Compartmentalisation undertaken before any obligation arose is structuring; the same transfer undertaken when a claim is in prospect is a transaction liable to be set aside. **A compartment built at the right time is a wall; the same compartment built at the wrong time is evidence.** The governing law is avoidance law and avoidance law is a clock; the periods and provisions are described in Appendix B and are not cited here.
12. **The orphan that is not orphaned.** A side letter, an option over the shares, a fee arrangement capturing the residual. All are discoverable, and substance is what gets litigated.
13. **Believing the compartment separates what it cannot.** Section 9.1.

9.3 Where the analysis is exposed

The instrument is exposed to its own tenth failure mode. Adopted as a target rather than as a diagnostic, an effective count ceases to be a good measure [Goodhart, 1975, Campbell, 1979]. Nothing in the arithmetic prevents it; the only defence offered is the reporting standard in Appendix A, which requires the inputs to be published beside the output.

The instrument is also performative in a way its own parameters are not exempt from. MacKenzie and Millo [2003] documents a model that made its assumptions true after adoption, and Lucas [1976] states the consequence for parameters estimated before publication. The framework asserts that systems change their behaviour when modelled and then exempts its own η, δ and correlation assumptions from that reflexivity. **That is an inconsistency and it is not resolved here.**

Ensemble and time averages are not the same object, and every expected-loss figure here is the first. Peters [2019] establishes that the time average of a multiplicative process differs from its ensemble average, so an expectation computed across many holders does not describe what happens to one holder over time. A single compartment-consuming event is not a deduction from a stream; it rescales every subsequent year. Peters and Gell-Mann [2016] supplies the associated strengthening for the framework's logarithm: a logarithmic form follows from multiplicative dynamics with no psychological assumption at all, which is a better warrant than the perceptual account the corpus more often gives, and Section 12 records that

the paper does not adjudicate between the two.

The device analysed here is a hedge against a decision, and hedges bought inside the warning window are not available. The corpus's amplitude weighting [Curzi, 2026] scores each step of a path for steepness and weights the branch as $1/2^R$, so a three-point difference in steepness is a factor of eight in expectation; applied here, the branches that matter are the ones reachable before the signal, and every device in this paper has a build time measured in months against warning windows measured in days. **The only window common to every threat is *before*.**

One boundary the framework itself refuses to cross is worth naming here rather than in a footnote. Curzi [2026] states the doctrine of category violation, which refuses category innocence as a defence of acquisition and forbids moving a harm through a discovered gap in a scheme. **The instruments in this paper are measured against arbitrary action and are not licensed against a judgment that survived due process**, and the eleventh failure mode is where that boundary bites. A reader who takes the arithmetic and drops the constraint has taken half the analysis.

10. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and the chain names what each step consumes. **If dropping a postulate leaves a result standing, it is not listed.**

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	reachable, exposure or property share	$[1]$	dimensionless fraction	defined; sums to 1 by P1
HHI, HHI_c	concentration index on a stated basis	$[1]$	dimensionless (or points $= 10^4\times$)	derived from shares
N, N_c	effective count	$[\#]$, a count	blocs, compartments or properties	derived as $1/\mathrm{HHI}$
$\ln N$	surplus-term argument	$[1]$	nats	derived; the logarithm of a count is dimensionless
p	annual event probability	$[T^{-1}]$	per year	assumed (constructed)
r, r^*	probability the cell wall holds	$[1]$	dimensionless	assumed; r^* derived
ΔC	cost saving from the cheaper device	$[U\,T^{-1}]$	estate units per year	assumed (constructed)
ΔS	reach reduction forfeited on failure	$[U]$	estate units	derived from shares $\times$ estate size
V, B	gross value, base cost	$[M]$	currency	assumed (constructed)

symbol	quantity	dimension	unit	status
L, L^*	leakage fraction, loss fraction	$[1]$	dimensionless	derived; assumed
q, s	exit probability, sale discount	$[1]$	dimensionless	assumed (constructed)
V_{esc}	escape value	$[T^{-1}]$	fraction of value per year	derived
Q	protected capital	$[C]$	index units	defined; **no operational unit is supplied by the source**
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived

Do the equations balance? The threshold condition $p\,\Delta S\,(1-r) = \Delta C$ balances: $[T^{-1}][U][1]$ against $[U\,T^{-1}]$. The payback L/V_{esc} balances, $[1]/[T^{-1}] = [T]$, and is therefore correctly quoted in years. The surplus law $h = \eta \ln N - \delta Q - C$ balances **only if η carries capital per period per nat**, and the source is silent on this: it treats conversion efficiency as a bare number. **The audit records the silence rather than filling it in**; the reading in the table is this paper's.

Where no operational unit exists the audit says so. Q, C and h are in index units fixed by the stated parameters, and the source supplies no conversion to currency. **The break-even probabilities, the confidence thresholds and the paybacks are unit-free or in years and survive this; the statement that h is -0.122417 means nothing until an index unit is defined.**

10.2 Significant figures against epistemic status

- $r^* = 93.5714\%$ and 94.36% are **exact arithmetic on stipulated inputs**: $1 - 0.090/1.400$ and $1 - 0.090/1.595$. They are derived-from-defined and carry as many digits as are useful. **Their inputs are constructed and carry no empirical authority whatever.**
- $L = 15.0417\%$ is exact on the stated valuation and rate; the rate itself is an assumed current-law figure and is flagged in Appendix B.
- 4.9603, 6.8521, 18.8491 and 1.470588 are exact reciprocals of exactly stated share vectors. The shares are constructed and stated to one decimal place; **every index in this paper is computed from the printed percentages rather than from any exact underlying fraction, which is the convention adopted by Curzi [2026] and recorded as a discrepancy in the fifth decimal against the exact-fraction convention of Curzi [2026].** The convention is stated so that a reproduction agrees to the last digit.
- Paybacks of 31.83, 31.77 and 114.60 years are **illustrative model output from constructed parameters**, rounded hard. Quoting them to two decimals is defensible only because the inputs are exact by stipulation.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere. That is not precision; it is the absence of empirical content.**

10.3 Limits and boundary behaviour

limit	behaviour	reading
one compartment, $s_1 = 1$	$\mathrm{HHI}_c = 1$, $N_c = 1$ exactly	an unfenced estate counts as one
n equal compartments	$N_c = n$ exactly	returns the count
n unequal compartments	$N_c < n$	never overstates the count
$n \to \infty$, equal	$N_c \to \infty$	unbounded above, as a count should be
$r \to 1$	r^* condition always satisfied	a perfectly recognised wall makes cells strictly better
$p \to 0$	$r^* \to -\infty$	at zero risk any device is acceptable; the formula leaves its domain
$p \to \infty$	$r^* \to 1$	at extreme risk only a certain wall will do
$\Delta C \to 0$	$r^* \to 1$	a cheap device that saves nothing must never fail
$q \to 0$ or $s \to 1$	$V_{\mathrm{esc}} \to 0$	payback diverges; latency without the ability to act is worth nothing
$B \to V$	$L \to f$	at zero accrued gain the leakage is transaction costs alone

Range: $1 \le N_c \le n$, with both bounds attained. A quantity equal to n for n equal units, equal to 1 for a single unit, and strictly between otherwise, **is a count**, and no further argument is needed.

Two limits are constraints on the domain rather than results. r^* becomes negative for $p < \Delta C/\Delta S$, which is not a confidence and means the cheap device is unconditionally correct at that risk level; the formula's domain is $p > \Delta C/\Delta S$, which for the constructed estate is $p > 0.157\%$. And $h \to \infty$ logarithmically as $N \to \infty$, which contradicts the organisational evidence and is a defect of the model rather than a finding; **the model's domain is small** N, and every prescription here is confined to moves between $N \approx 1$ and $N \approx 3$. As $\eta \to 0$, $h \to -(\delta Q + C)$ regardless of N. As $\delta \to 0$ the stock never erodes and any positive $\eta \ln N$ exceeding C accumulates without bound, which is a pathology rather than an ideal.

10.4 Invariance

Every effective count here is invariant under relabelling and under any rescaling of the underlying quantities that preserves the share vector. Doubling the estate in currency terms leaves every s_i unchanged and therefore leaves HHI, N and $\ln N$ unchanged. That is a genuine scale invariance and it is why the instrument applies to an estate of any size. **It is not invariant under regrouping**, which is the entire content of the perimeter collapse: the difference between the two groupings is the finding.

What would break it: any share basis that is not normalised — reporting reachable amounts in currency without dividing by the estate. **Tested at how many scales?** The invariance is algebraic rather than empirical, and was checked at exactly the share vectors reported here: two, six, seven, eight and forty entries. No claim of empirical scale-freedom is made.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. The conserved quantity here is the share vector, $\sum_i s_i = 1$ exactly and dimensionlessly, and it is that constraint alone that gives the index its bounds. **Remove the normalisation and the effective count ceases to be a count.** Q is a stock with no stated

conservation law and no operational unit, and no conservation is claimed for it. Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law is claimed to hold and stop claiming universality the argument does not need. **The arrangement claimed here is a normalised share vector on one stated basis, and nothing outside it.** Kirman [1992] is the objection this paper cannot answer: one Q, one δ and one C are written for a heterogeneous group of compartments, and a single representative parameter for a heterogeneous population generally does not exist.

10.5 Analogy discipline

borrowing	source	category	justification
effective count as $1/\mathrm{HHI}$	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* the Hill number of order 2; an identity, not a resemblance
numbers-equivalent reading	Adelman [1969]	**1 — derivation**	elementary and checkable in two lines
portfolio variance $w'Rw$	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix
similarity-sensitive diversity	Leinster and Cobbold [2012]	**1 — derivation**, stated domain	exact where R has unit diagonal and non-negative entries; claimed nowhere else
$\ln N$ as entropy	Shannon [1948]	**2 — shared form**	Shannon entropy in nats, a dimensionless information quantity; no thermodynamic content is imported
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	financing covenants have not been shown to satisfy the percolation premises; only the structural property is used
identity inflation	Douceur [2002]	**2 — shared form**	the impossibility result is about network identities; the structural analogy to entity count is stated as an analogy

borrowing	source	category	justification
tipping from a small correlated shift	Granovetter [1978], Schelling [1971]	**3 — framing**	prior statement of the same aggregate phenomenon, cited as ancestry rather than as a formal result about perimeters
normal accidents	Perrow [1984]	**3 — framing**	qualitative organisational theory, never used as a formal result
synchrony	Loreau and de Mazancourt [2008]	**2 — shared form**	the naming convergence is noted; no ecological mechanism is imported

The failure this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration arithmetic is category 1 throughout and needs no help; the network and tipping results are category 2 and 3 and are used for shape and ancestry only.

10.6 Measurement-theoretic status of the scored inputs

The 0–5 comparison in Section 7.2 is **ordinal**. It records the analyst's rank judgements over published descriptions. **An ordinal scale licenses a minimum and does not license a mean**, and only minima are taken. No average of those scores appears anywhere in this paper, and none should be computed from the table.

Reachable shares, exposure shares and property shares are ratios of capital and are not psychological judgements, so the concentration instrument is untouched by the scale-type objection. **The event probabilities are a different matter and the objection is conceded.** p is treated throughout as a ratio-scale quantity supporting multiplication and division, and it is a subjective degree of belief elicited from nobody. Michell [1997] is the strongest available objection to that move — that quantitative structure is assumed rather than tested — and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all, within the representational framework of Krantz et al. [1971]. **The conjoint conditions were not tested for any probability in this paper, and every ratio computed from one is therefore provisional.** What survives without the test is the *ordering* — a break-even probability still separates settings where a device pays from settings where it does not — and the algebraic threshold form itself, which does not depend on the scale type.

10.7 Postulates

#	statement	status
P1	shares s_i on a stated basis are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$ on that basis	DEFINITION
P3	for n equal shares, HHI $= 1/n$	ARITHMETIC

#	statement	status
P4	the reachable share of a compartment is the fraction of the estate a single event arising against it can reach	DEFINITION
P5	expected loss is $p\times$ the reachable share of the largest compartment	DEFINITION (modelling choice: one event per year, largest compartment consumed)
P6	a foreign forum respects a statutory cell partition with probability r, unknown	POSTULATED
P7	contribution of an appreciated immovable asset is a disposal at market value in the modelled system	POSTULATED (H3; uncited, Appendix B)
P8	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02)
P9	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P10	jurisdictions inside one coordination perimeter act on one decision	POSTULATED (stipulated reference group, Section 3.7)

10.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	$1/\mathrm{HHI}$ returns n exactly for n equal shares	ARITHMETIC
L2	L1	$1/\mathrm{HHI}$ is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	it is the Hill number of order 2 — Hill [1973], Jost [2006]	CITED
L4	L3, P4	on the reachable-share basis it counts effective compartments	DEFINITION
R2a	L4	30/22/18/12/10/8 gives $\mathrm{HHI}_c = 0.201600$, $N_c = 4.9603$, max reach 30.0%	ARITHMETIC
R2b	R2a, P5	at $p = 0.02$, benefit $= 0.02 \times 70.0 = 1.400$ against cost 0.110; ratio 12.73; break-even $p = 0.110/70.0 = 0.157\%$	ARITHMETIC
R1	R2b, P6	$1.400(1 - r) = 0.090 \Rightarrow r^* = 93.5714\%$	ARITHMETIC

step	consumes	statement	status
R1b	R1	r^{*} rises with p: 87.1% at 1.0%, 96.8% at 4.0%	ARITHMETIC
R3a	P7	a 25% rate on a gain of 26.0m plus costs of 1.5% on 48.0m gives leakage of 7.22m, so $L = 15.0417\%$	ARITHMETIC
R3b	R3a	$V_{\text{esc}} = 0.015 \times 0.60 \times 0.70 \times 0.75 = 0.004725$; payback $= 31.83$ yr	ARITHMETIC
R3c	R3b	ten-year payback needs $p = 0.0150417/0.315 = 4.7752\%$	ARITHMETIC
R4	L1	property HHI $0.053053 \Rightarrow 18.8491$ effective properties; saving 0.4735%/yr; payback 31.77 yr	ARITHMETIC
R5	L1, P10	allocation naive $0.215800 \Rightarrow 4.633920$; bloc $0.680000 \Rightarrow 1.470588$	ARITHMETIC
R6	L1, P10, P8, P9	sleeve perimeter HHI $0.580000 \Rightarrow 1.724$; group readings buy 0.000371 and 0.047927 against $+0.05$ of cost	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. Every CITED row names one source and no more. **Four of the ten postulates are POSTULATED and one of those — P7 — is a legal proposition this paper cannot cite.** The chain therefore establishes arithmetic consequences of stipulated inputs, and **it is not a proof of anything about the world**. A result honestly labelled as following from two postulates is worth more than the same result implied to be measured.

10.9 Cross-checks performed

- Every index was recomputed from its printed share vector; all reported share vectors sum to 100.0 per cent exactly.
- $s_{\max}^{2} \le$ HHI $\le s_{\max}$ holds on all four contagion vectors: $0.672400 \le 0.704800 \le 0.820$ and $0.033124 \le 0.145940 \le 0.182$ on the carried case.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $1.4188 \le 1.4878$ and $6.8521 \le 30.19$.
- The two source discrepancies reported in Sections 5.5 and 6.5 were found by this recomputation and are printed rather than corrected in silence. A third, smaller one: the source prints 5.120272 naive effective jurisdictions for the single-centre custody case where $1/0.195302 = 5.120275$; the difference is in the seventh significant figure and the corrected value is used in Section 6.5.

11. Limitations

Every case is constructed. The estate, the compartments, the reachable shares, the costs, the event probabilities, the building, its valuation and basis, the allocation, and the exposure vectors are invented and are labelled as such at each point of use. **No external dataset was collected and none is reported.** The measurements are exact computations on constructed inputs.

No paper in this corpus reports a first-party measurement, and this one does not either. The corpus's own instrument audit finds that of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated one, and **0 carry a first-party measurement**. That is the central limitation of the whole corpus and it is stated here before a reviewer states it.

The event probabilities are the most load-bearing and least defensible inputs. $p = 2.0\%$ and $p = 2.5\%$ carry the entire cost–benefit verdict, and p, L^*, q and s carry the entire payback verdict. None is estimated from data; none has an interval; and no reference class was constructed in which any of them could be defended. **The correct reading of every ratio in Section 8 is therefore conditional: at these probabilities, this is the sign of the difference.** The threshold form of Section 3.5 exists precisely because the probabilities cannot be defended, and a reader who substitutes different ones can read a different threshold off the figure.

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions of separateness doctrine, cell legislation, orphan and purpose trusts, avoidance provisions, tax reliefs, disclosure regimes, situs rules and the intermediated-securities rule are taken from the source manuscript. **The bibliography contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, and no case law of any kind.** Those claims are therefore uncited here, are described rather than asserted, and require verification against the official sources before any reliance. Appendix B lists them individually. **This is a real gap and it is not closed here.**

The four scored jurisdictions are de-branded for exactly that reason. A named jurisdiction attached to an unsupported characteristic is a claim about a real place that this paper cannot back; the convention of Curzi [2026] is followed, and the named descriptive profiles in Appendix C carry the same warning at their head.

The cell recognition question is unresolved in the abstract and was resolved on the carried case by avoidance rather than by analysis. If a group later needs cells in a cross-border setting the question returns, and this paper has no answer to it. The 93.5714 per cent threshold tells a reader what confidence is required; it supplies no evidence about whether that confidence is warranted anywhere.

The perimeter assignments are stipulated, not identified. Manski [1993] rules out recovering an endogenous effect from observation of a linear-in-means reflexive system, and the remedy adopted is stipulation with a defence [Brock and Durlauf, 2001]. No randomisation, instrument or partial-population variation was available. **The price is that every bloc figure in Sections 6.5 and 8.5 is a modelling position.**

The effective count measures independence and not capacity. $N_c = 6.8521$ says nothing about whether any compartment can carry the load, and nothing about whether a group would in practice allow a compartment to fail rather than recapitalise it.

The measurement will decay. Every new facility, guarantee or operational shortcut moves the contagion index, and the index is only meaningful as a difference against last year's. Appendix A makes the date and the difference against the previous measurement a required reporting item for that reason.

The instrument is least informative exactly where the carried case begins. Golosov [2010] documents poor behaviour of effective-number measures in the dominated-unit regime, and 82.0 per cent in one compartment is that regime. The measurement is exact; its discriminating power there is at its minimum.

Small-sample bias is not addressed. Chao et al. [2014] show that low-order diversity estimators are biased on small samples, and a two- or seven-element share vector is a small

sample. No correction was applied, and none is available for the case where the vector is a complete census rather than a sample. **The paper does not resolve which of the two situations it is in.**

Model comparison was not performed. No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. The instrument is asserted to be the right one on the strength of the identity chain in Section 10.8 and not on comparative fit.

The functional form of the surplus term is underdetermined by the evidence. The corpus proposes $\ln(1 + (N - 1)u)$; a sub-linear power law and an $n \log n$ form fit the same qualitative facts. Nothing in this paper discriminates between them, and the paper concedes that nothing yet does. Peters and Gell-Mann [2016] is the one genuine strengthening available — a logarithm derived from multiplicative dynamics with no psychological premise — and it is cited in Section 9.3 as the warrant the argument actually needs.

No differential prediction is offered. Durlauf [2005] asks for the prediction only this model makes, and the instrument makes none: any correlation-aware concentration measure would produce the same collapse, and any expected-value calculation would produce the same break-even. **The contribution is the share basis, the threshold form and the discipline of printing both sides, not a uniquely discriminating forecast.**

The corpus's scalar-reduction habit applies here and is inherited rather than restated. Collapsing a structured legal situation into a single 0–5 score, or a structured threat into a single probability, is the same move the framework identifies once as a framework-level limitation [Curzi, 2026]. It is not re-argued in this paper; Section 7.2 points at it and takes minima rather than means.

Rigour checks not met, listed by name.

1. **No as-of date, because no real holdings were measured.** A concentration figure from real holdings requires its source and its date; every share vector here is constructed, so there is neither. Appendix A makes both mandatory for any application to a real structure.
2. **No uncertainty is reported anywhere, because nothing is estimated.**
3. **The dimension of η is supplied by this paper and not by the source.**
4. **Q, C and h have no operational unit.**
5. **The surplus law's large-N limit is a defect, not a result.**
6. **The conjoint conditions were not tested for the event probabilities**, so every ratio computed from one is provisional as a ratio-scale quantity [Michell, 1997, Luce and Tukey, 1964].
7. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. Any restatement of this paper reaching for a heavy-tail claim about holdings or reachable shares must run it first, and must read Stumpf and Porter [2012] on why passing it still would not identify a mechanism.
8. **The coupled-network and identity-inflation borrowings are category 2, not category 1** [Buldyrev et al., 2010, Douceur, 2002].
9. **Aggregation is unaddressed** [Kirman, 1992].
10. **Expected value and time average are not the same thing, and every figure here is the first** [Peters, 2019].
11. **The instrument is performative and its own parameters are not exempt** [MacKenzie and Millo, 2003, Lucas, 1976].
12. **There is no conservation law for Q** [Mirowski, 1989].
13. **Two arithmetic errors and one rounding slip in the source are reported rather than corrected in silence** (Sections 5.5, 6.5 and 10.9).

12. Conclusion

This paper prices three structural devices against the certain costs they incur, and the following statements are the fixed text of its results.

R1. With a cost advantage of 0.090 units a year against a fenced benefit of 1.400 units a year, indifference is at $1.400(1-r) = 0.090$, giving $r^{*} = 93.5714\%$ — **the minimum confidence that a foreign forum respects the cell wall** for a cell company to be preferable to separate companies. The threshold rises with the risk it is used against: 87.1 per cent at $p = 1.0\%$ and 96.8 per cent at $p = 4.0\%$.

R2. Contagion measured as HHI_{c} over reachable shares with effective compartments $= 1/\mathrm{HHI}_{c}$: six unequal compartments at 30 / 22 / 18 / 12 / 10 / 8 give **4.9603 effective compartments** and cut maximum single reach from 100.0 to 30.0 per cent, worth $0.02 \times 70.0 = 1.400$ units a year against 0.110 of cost — **12.73 to one**, break-even $p = 0.157\%$ per year.

R3. Conversion of an immovable asset carries certain leakage $L = 7{,}220{,}000/48{,}000{,}000 = 15.0417\%$ against an escape value $V_{\mathrm{esc}} = pL^{*}q(1-s) = 0.4725\%$ a year — a **payback of 31.83 years**; a ten-year payback requires $p = 4.7752\%$.

R4. Diversification through the same conversion raises effective properties from 1.0000 to **18.8491** (property HHI 0.053053), worth 0.4735 per cent a year against the same 15.0417 per cent leakage — payback **31.77 years**. Only a non-recognition regime cutting leakage to 1.5 per cent brings the payback to 3.17 years.

R5. The converted global allocation at 35 / 20 / 15 / 12 / 10 / 8 per cent reads naive HHI **0.215800** and **4.633920** effective jurisdictions but bloc-HHI **0.680000** and $N = 1.470588$ — **the naive count improves while the bloc count worsens.**

R6. The regional sleeve measured alone gives perimeter HHI **0.580000** and **1.724 effective blocs** against a naive 4.281; at group level the strict and partial-independence readings buy **0.000371** and **0.047927** of surplus against $+0.05$ of added cost, so that under the strict reading the bloc term contributes one part in fifty-five of the total gain and the erosion term contributes the rest.

Counter-result. Leakage of 15.04 per cent is certain while every benefit computed against it is probabilistic, giving paybacks above thirty years on all three routes examined — 31.83, 114.60 and 31.77 years. **And the ring-fencing redesign's gain on the jurisdictional measure is an honest near-zero**: at best $+0.005185$ of surplus from the single available rebalancing move, with compartmentalisation itself contributing 0.000000 to N against 0.125 to 0.175 units a year of added maintenance. Two of the three devices priced here are, under the storage law alone, unambiguously negative, and are justified entirely on an axis the storage law does not contain.

Two further results are established as method rather than as measurement. **A cost saving, an event probability and a reach reduction determine a threshold belief**, so a conflict-of-laws question with no reliable answer can be decided without answering it — and the threshold *rises* with risk, which is the opposite of the usual intuition about economising in risky settings. **And a security whose issuer's assets are concentrated in one jurisdiction splits exposure into two questions rather than one**: availability follows the custodian's perimeter and value follows the situs of the issuer's assets, so both must be reported, because a structure reporting only the first has recorded a diversification it did not achieve.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the estate, the compartments and their reachable shares, the cost model, the event probabilities, the building and its valuation and basis, the replacement allocation, the exposure vectors, and the jurisdictional scores — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-060_fig01.py` through `figs/src/CCP-060_fig05.py`), which import the shared figure-style module and read

their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdictional and legal descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative, treaty and doctrinal material only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, and no case law. Appendix B lists the claims affected. Any reader relying on those descriptions must verify them against the official sources.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every person, family, entity and transaction described is invented.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, compartmentalisation devices, conversion mechanisms and jurisdictions for the purpose of measuring concentration and pricing structural choices. No recommendation is made in respect of any particular person, asset, structure or jurisdiction. Cell legislation, avoidance provisions and their limitation periods, consolidation standards, substance requirements, tax rates and reliefs, situs and intermediated-securities rules, listing conditions and disclosure obligations all change and vary by jurisdiction and by activity; **every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.**

Appendix A. Reporting standards

A.1 The compartment register. Any estate measured under the contagion instrument reports the following, and nothing less.

```
the compartment map: entity, jurisdiction, assets, purpose
the reachable share of each compartment, summing to 100.0%
contagion HHI, effective compartments, maximum single reach
the absorbable-loss constraint and whether it is satisfied
annual cost of the compartmentalisation, itemised
the estimated p and the break-even p
for any cell structure, the forum analysis and the r estimate
```

```
 8  the guarantee, comfort-letter and cross-default register --
    every instrument that connects two compartments
 9  confirmation, by someone independent of the treasury function,
    that no commingling occurred in the period
10  the four-axis jurisdictional measurement, with the note that
    compartmentalisation contributes nothing to N
11  the date, and the difference against the previous measurement
```

Item 8 is the one nobody maintains and the one that decides the outcome. A group cannot know whether its compartments hold unless it knows every instrument that connects them, and the instruments that connect them are signed by people who do not know the structure exists. **Item 11 decays first**, because the contagion index is only meaningful as a difference against last year's.

A.2 The conversion memorandum. Any conversion of an immovable asset into a movable claim reports: the threat it is being used against, named; the leakage L computed at full precision on the actual basis and the actual rates; the escape value with p, L^{*}, q and s written down and defended; the payback against the holding horizon; the concentration instrument run on all four axes before and after; and the custody chain specified in writing down to the depository, **because the chain is the new single point of failure and a conversion executed without one has bought a change of governing law and then let the counterparty choose it.**

Appendix B. Claims requiring verification against primary sources

The following statements rest on legal or regulatory detail that changes, and **none of them is cited to the bibliography, which contains no primary sources for any individual jurisdiction and no case law**. They are reproduced from the source manuscript and require confirmation with counsel in the relevant jurisdiction before any reliance. The source manuscript's own verification registers, which run to seventy numbered items across the three chapters, are condensed here without loss of subject.

1. **Separateness and its limits.** The foundational company-law authority on separate legal personality; the concealment/evasion distinction and its later application; the rejection of a general single-economic-unit doctrine for groups; and the named appellate formulations of the substantive-consolidation standard, which is circuit-dependent.
2. **Bankruptcy remoteness in practice.** The docket, procedural posture and precise holdings of the leading case on the filing of bankruptcy-remote property-level entities alongside their parent, including the treatment of replaced independent managers and the scope of those directors' duties. **This paper states a structural lesson and asserts no holding.**
3. **Contractual insolvency limitations.** Enforceability of non-petition and limited-recourse covenants in every jurisdiction where a proceeding could be opened; and the two opposed judicial answers to the same priority-flip clause in the same transaction, together with the full subsequent procedural history.
4. **Cell legislation.** The originating protected-cell ordinance and its successor provisions; segregated-portfolio, segregated-account and incorporated-cell regimes; the series limited-liability provisions of one American state and their record-keeping and notice conditions; and the fund-specific sub-fund wrappers. **None is asserted here beyond the existence of a regime.**
5. **Judicial consideration of cell segregation in a foreign forum** — whether authority exists in any major jurisdiction on recognition of a foreign statutory cell partition. **This is the single most valuable item in the register and the paper treats the question as open.**

6. **Orphan structures.** Non-charitable purpose trust legislation and the special trusts regime relied on; the enforcer requirement; and the control-based consolidation criteria and variable-interest-entity model that determine whether an orphan is consolidated.
7. **Avoidance law.** The transaction-at-an-undervalue and transactions-defrauding- creditors provisions of the English insolvency legislation, the federal American provision, and the uniform state act as enacted, with their elements, look-back periods and connected-person presumptions. **This is the eleventh failure mode and it is a clock.**
8. **Risk retention and its limits.** The 5 per cent retention requirements in both major regimes, the qualifying exemptions, the post-onshoring position, and the decision holding open-market collateralised loan obligation managers outside the American rule.
9. **The situs and intermediated-securities rules.** The rule that an English court will not entertain an action to determine title to foreign land; the exclusive-jurisdiction provision of the recast European regulation and its post-withdrawal application; the place-of-the-relevant-intermediary convention with its date of entry into force and its short contracting-party list; the settlement-finality and financial-collateral directive articles and their onshored equivalents; and the American securities intermediary's jurisdiction rule.
10. **Listed real estate vehicle regimes.** The originating legislation and current code in each of the two systems modelled, the distribution requirement, the balance-of- business conditions, the closely-held tests and their attribution rules, the close-company condition and its institutional-investor exception, and the listing or trading requirement with its later relaxation. **Do not rely on any threshold stated in this paper.**
11. **Non-recognition on contribution.** The partnership non-recognition provision, the allocation of built-in gain, and their application to an umbrella-partnership structure; the attribution of the first such structure to a 1992 offering; and, jurisdiction by jurisdiction, **whether any relief, clearance or rollover exists for a contribution of appreciated real property to a listed vehicle — the single most valuable question in Section 6.**
12. **Transfer taxes and rates.** The transfer-tax code and current rates for commercial property and corporate purchasers; the seeding relief for authorised property funds and whether it extends to listed real estate vehicles; **the 25 per cent corporation tax rate used in the leakage computation**, the availability of indexation, losses and rollover, and the correct rate for the entity actually holding the asset.
13. **Non-resident gains on land** and indirect disposals of property-rich entities: the gross-asset-value and investment thresholds, the substantial-shareholding and trading exemptions, and the current location of the rules.
14. **Disclosure regimes.** The annual-report property-schedule rule and its current content; notification thresholds and deadlines in both markets; and the overseas- entities register, its launch and registration deadline and its later amendments.
15. **Territorial taxation regimes and the hemispheric enforcement environment**, as described in Section 7 and Appendix C: the source-rule provisions and their article numbers; residence and investment thresholds, several of which are inflation-indexed and move continuously; the substance and qualifying-shareholding conditions introduced under listing pressure; free-zone statutes; beneficial-ownership regimes and their access rules; current standards-body status, mutual-evaluation ratings and information-exchange commencement dates; and the two separate European lists, which have different criteria, different consequences and different memberships.
16. **Named political and judicial events** referred to descriptively in Appendix C: a constitutional ruling voiding a signed concession; designations of senior political figures under a corruption authority, with dates, scope and current status; an investor-state arbitration and its award; a sovereign-default judgment and its appellate position; and the current convention status of states that have denounced the principal investor-state arbitration instrument.
17. **The historical branch structure** relied on in Section 9.1: the constitution of the branches as separate partnerships, the capital arrangements between the parent partnership and the branches, and the sovereign-lending losses that brought the whole institution down

notwithstanding the separation [de Roover, 1963].

18. **All cost figures are index units in a constructed model.** They are not fee quotations and no real fee schedule was used to produce them.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Appendix C. Descriptive jurisdiction profiles

These profiles are reproduced from the source manuscript. Not one statement in them is cited, because the bibliography contains no primary source for any individual jurisdiction (Section 11 and Appendix B item 15). They are description and not assessment, they are certainly out of date in places, and they are retained because the measurement in Section 8.5 is unintelligible without knowing what was being measured. **The scored comparison built from them is debranded in Section 7.2 for exactly this reason.** Item 10 in each profile — the degradation trajectory — is the item the source treats as decisive and the item most exposed to change.

C.1 A dollarised isthmus centre with a deep vehicle set

Civil law. An early twentieth-century corporations statute drafted with reference to a leading American state's company law of the period; a mid-1990s private-interest foundation with separate legal personality on the Liechtenstein model; and a 2017 trusts statute. An unusually deep vehicle set for a civil-law jurisdiction. **Bloc alignment:** dollarised with no lender of last resort, dollar clearing through foreign correspondents, and a foreign-policy reversal under external pressure within weeks in 2025. **Whatever the tax code says, this is not an independent perimeter. Courts:** genuinely two-sided — a constitutional ruling in 2023 voided a mining concession law against both the executive and the legislature, which demonstrates real independence and demonstrates that a contractual position can be extinguished by constitutional litigation. Commercial docket delay is significant; arbitrate rather than litigate. **Substance and disclosure:** resident-agent and accounting-record obligations, beneficial-ownership registration accessible to competent authorities and not to the public, full participation in automatic exchange. **Trajectory:** improving on standards from a poor base and structurally exposed to recurrence — three listing cycles since 2000, removal from the principal list in October 2023 after a listing that began in June 2019, and a services-dependent economy permanently within reach of the standards mechanism. **A thirty-year structure here should assume at least one further listing cycle and be built to survive it. Assigned function:** operating, and in a limited regional sense bridging. Not holding.

C.2 A Southern Cone residence and free-zone centre

Civil law on a nineteenth-century code with modern commercial and free-zone statutes; a statutory trust exists in civil-law form and its suitability as a holding instrument should be tested before use. **Bloc alignment:** the least coupled jurisdiction in the group — own currency and central bank, a regional trade bloc rather than a bilateral framework, and a sustained independent push for a trade agreement with a rival power against its own bloc's rules. **This is the only jurisdiction in the group with a credible claim to partial perimeter independence, and Section 8.5 prices it as partial rather than full. Courts:** independent, low corruption, and a demonstrated willingness to litigate an investor-state arbitration to a final award; deduct for commercial docket speed and a small body of international commercial jurisprudence. **Substance:** real for the free-zone regime — qualifying activity, employment ratios, a substantive operating presence — and real for tax residence, on days of presence or an investment threshold combined with presence or job creation. **Trajectory:** stable, with the transparency degradation already completed and the institutional position untouched; the former secrecy proposition was dismantled deliberately by domestic legislation between 2007 and 2017 rather than

under listing pressure. **Assigned function:** operating and personal residence with a genuine free-zone services capability. Not a holding apex.

C.3 A landlocked manufacturing centre with an unstateable standards position

Civil law on a 1985 code; a conventional company law and no distinctive holding or foundation vehicle — the weakest vehicle set in the group, which is consistent with its correct use. **Bloc alignment:** non-aligned in form and pre-committed in substance; own currency and central bank, regional bloc membership, and a diplomatic recognition that forecloses one bloc entirely and is a standing object of pressure to reverse. **Courts:** the weakest in the group — limited institutional capacity, poor external corruption scores, little published international commercial jurisprudence. Arbitration outside the jurisdiction is the only reliable mechanism for a significant contract. **Substance:** the export-processing regime requires a genuine production operation with approved programmes; the substance here is industrial rather than regulatory, and that is the jurisdiction's honest strength. **Disclosure:** the automatic-exchange commencement date and current status **cannot be stated from the source and the source declines to guess. Trajectory:** uncertain, and the uncertainty is itself the finding — a coherent 2019 tax restructuring, a modernised 2022 migration framework and very low energy cost on one side; an unstateable standards position and continuing corruption designations of senior political figures on the other. **A jurisdiction whose standards status cannot be stated is one whose trajectory cannot be scored. Assigned function:** operating only, and specifically export manufacturing.

C.4 An isthmus centre that joined the perimeter deliberately

Civil law with a 1949 constitutional order and a strong rights-based constitutional jurisprudence; conventional company law, no distinctive holding vehicle, a 1990 free-zone statute. **Bloc alignment:** western, by deliberate choice — accession to the principal economic organisation on 25 May 2021. **That is a decision to enter the coordinating perimeter, and it is simultaneously an institutional-quality signal and the elimination of any bloc-diversity claim. Courts:** a constitutional chamber created in 1989 that is among the region's most active and respected, an independent ordinary judiciary, and no expropriation record; deduct for commercial docket speed. **Substance:** real and recently tightened — the free-zone regime requires qualifying activity, investment and employment, and a 2023 amendment introduced substance and qualifying-shareholding conditions for the exemption of passive foreign-source income. **Trajectory: the cleanest observed case of the listing mechanism in the source.** Accession in May 2021; addition to a European non-cooperative list in February 2023 over the foreign-source exemption; domestic legislation introducing substance conditions in 2023; removal from the list in November 2023. **No sanction was imposed and no negotiation of substance occurred — a listing was made and a sovereign rewrote its income tax law within nine months. Assigned function:** operating, at genuine quality, and personal residence. Not holding; not bridging, by its own choice.

C.5 The jurisdictions the source declines to score, and why

Four large regional economies are outside the subject, being investment cases rather than residence-and-source architectures. Three further states are excluded on political risk: one with a sovereign default, a decade of subsequent litigation abroad, an expropriation of a majority stake in a national oil company producing a very large adverse judgment, repeated capital and exchange controls, and inflation that has repeatedly destroyed the domestic value of contractual claims; one requiring no argument; and two that denounced the principal investor-state arbitration convention, which removes the most reliable enforcement route.

None of that is a reason to avoid operating business in those states; it is a decisive reason not to hold protected capital there.

Chapter 61

Measuring the Payment Rail: Clearing Perimeters, Transit Exposure Windows, and the Concentration Effect of De-Risking

Abstract. Payment infrastructure is normally audited by counting correspondent banks. We show that this count measures the wrong object. On a constructed six-bank corridor set, the naive correspondent Herfindahl-Hirschman index of 0.302400 reports 3.306878 effective correspondents; decomposing the same flows by settlement currency and then by clearing perimeter gives a perimeter HHI of 0.745256 and only 1.341819 effective perimeters, and the rail-axis surplus term is 0.35 x ln(1.341819) - 0.500000 = -0.397091. The remedy that people reach for does not work: adding correspondents raises the naive effective count to 4.425092, an improvement of 33.8 per cent, and leaves the perimeter count unchanged to six decimal places. Currency redenomination over three years does work, taking the perimeter count to 2.087683 and the surplus term to -0.242381, with the dollar share floored near 52 per cent because commodity and trade-finance pricing is not the group's to set. For value in transit we derive E[loss] = V(1 - exp(-lambda t))(1 - r) and show expected loss is invariant to hop count (USD 68,000 whether one hop of 40m or eight of 5m) while depending entirely on the exposure window; multilateral netting removes 77 per cent of expected transit loss without a new rail. Informal value transfer is analysed as a licensed, priced industry: enforcement-driven exit from twelve providers to five moves the HHI from 1,074 to 2,406 points and cuts effective providers from 9.310987 to 4.156276.

Keywords: correspondent banking; clearing perimeter; Herfindahl–Hirschman index; settlement finality; transit exposure window; de-risking; informal value transfer; currency redenomination

Series: D. Structure and Resilience **Paper:** CCP-061

1. Introduction

A cross-border holding structure that measures its jurisdictions, its counterparties and its currencies and stops there has measured everything except the layer through which all of it has to pass. This paper measures that layer.

The result is that **the settlement rail is where a well-designed cross-bloc structure is most concentrated, and it is the axis nobody runs.** On a constructed corridor set, five correspondent banks in four jurisdictions across three coordination perimeters return an effective clearing-perimeter count of 1.341819 against an effective bloc count of 2.941176 on the jurisdictional axis. The rail-axis surplus term is $0.35\ln(1.341819) - 0.500000 = -0.397091$ against -0.122417 on the axis the structure does measure. **The structure is 3.24 times worse on the rail than on the jurisdiction, and the gap was invisible until the instrument was pointed at it.**

The remedy is not more banks. Adding correspondents raises the naive effective count by 33.8 per cent and leaves the perimeter count unchanged to six decimal places, because **the rail is determined by the currency of the underlying obligation.** Fixing it is a commercial negotiation about invoicing rather than a structuring decision about accounts, and the constructed group that understands this recovers 0.154710 of surplus balance without forming a single new entity.

1.1 A layering correction the field owes itself

A clearing system and a messaging system are different layers of the same stack and are not substitutes. A secure financial-messaging cooperative moves instructions between institutions and settles nothing; a national real-time gross settlement or netting system settles and does not provide interbank messaging to participants who reach it indirectly. **"System X replaces the messaging network" is a category error, and a structure built on that premise will fail.** The correct comparison for a clearing system is another clearing system; the correct comparison for a messaging network is another messaging network, or a bilateral connection. The layering is not folklore: the message-standard migration that the whole industry is executing is a standard for the *messaging* layer alone [International Organization for Standardization, 2013], and it changes nothing about where finality occurs.

The consequence is arithmetic. A treasury policy recording "two rails" and treating that as diversification has recorded one messaging dependency twice. **Measured correctly, one messaging network at 100 per cent and 85 per cent on that network plus 15 per cent on a second clearing system whose messaging leg runs over the first are the same number, and only the second looks diversified.** Curzi [2026] states the general form of that error for jurisdictions; Section 5 performs the rail version of the measurement properly.

1.2 The event that made this a board-level question

In 2022 approximately USD 300 billion of central bank reserves were rendered untransferable by coordinated administrative action in the jurisdictions where they were held. Curzi [2026] states the fact and its consequence — **disclosure is not immunity: the reserves were fully disclosed and the disclosure test is a filter that removes structures collapsing on contact with an authority, not a shield against a policy decision** — and this paper does not embellish it.

Three structural features of that episode drive what follows. The immobilisation was achieved without physical possession and without a court: the assets were book entries and the measures were administrative. The holder was a sovereign, with sovereign immunity [Dixon, 2013], in jurisdictions with independent courts and strong property protection — the strongest legal position short of holding bullion in one's own vaults — **and the legal position did not matter, because the question was never adjudicated. A holder whose claim can only be realised through an intermediary has the protection the intermediary's regulator permits, not the protection its legal position suggests.** And a very large fraction of the immobilised assets sat with a single institution in a single jurisdiction: whatever the effective jurisdiction count of that portfolio by currency and issuer, its effective *custodian* count was close to one, and that was the operative number.

This paper draws no conclusion about the merits of any measure. It takes a position only on the engineering: **a settlement and custody architecture whose effective independent count**

is one will fail completely when it fails at all, and there is no legal argument that repairs a number.

1.3 What the paper contributes, and the standing constraint

Every architecture examined here is measured under the corpus's formation test: a structure qualifies only if it would still perform its function were every element disclosed to every authority with jurisdiction over any part of it. On this axis the test is not a constraint the analyst imposes but a description of the layer. **The entire rail architecture consists of relationships with regulated institutions who are required to know exactly what the group is doing. There is no version of a rail that is not disclosed, so a rail strategy premised on non-disclosure is not a strategy but a misunderstanding of the layer.** The open-design principle [Saltzer and Schroeder, 1975], stated a century earlier as the rule that a system must remain secure when everything about it except the key is public [Kerckhoffs, 1883], is the same constraint in security engineering.

Six results follow: the clearing-perimeter measurement and its collapse; the failure of correspondent addition and the success of currency redenomination; a transit-loss model whose expectation is invariant to hop count; multilateral netting as the highest-return intervention available; an indifference hazard separating a fast rail from a slow one; and the concentration effect of enforcement-driven exit on a licensed remittance corridor. The paper presupposes the founding reframing of Curzi [2026], on which a present arrangement is a local minimum of the cost landscape by definition rather than by luck — which is why a rail that nobody has measured is nonetheless the arrangement everybody is in.

2. Hypotheses

Four hypotheses are stated, each falsifiable in the sense Platt [1964] requires and each carrying a point prediction with a constant attached rather than a direction, which is what Meehl [1967] asks of a theory that wishes to be tested rather than confirmed. Statements that could not be falsified as posed are listed afterwards as definitions or modelling choices.

H1 — the clearing-perimeter hypothesis. Correspondent count measures the wrong object, because settlement independence is determined by the perimeter in which a currency achieves finality and not by the number of banks holding accounts. *Predicted:* on the constructed corridor set, decomposing the same flows by currency and then by clearing perimeter takes the effective count from 3.306878 to 1.341819, and the rail-axis surplus term to -0.397091. *Falsified by:* a corridor set in which the perimeter decomposition returns a count at or above the naive correspondent count, which would mean the currency layer carries no concentration the bank layer does not already show.

H2 — the invariance-to-accounts hypothesis. Adding correspondent relationships cannot move the clearing-perimeter count, because it does not change the denomination of the underlying obligations. *Predicted:* adding three banks in three further jurisdictions raises the naive effective count from 3.306878 to 4.425092, an improvement of 33.8 per cent, and leaves $N_{\text{rail}} = 1.341819$ **unchanged to six decimal places**; redenominating the underlying obligations takes it to 2.087683. *Falsified by:* any account-level rearrangement that moves the perimeter count while the currency mix is held fixed.

H3 — the hop-invariance hypothesis. Expected loss on value in transit is invariant to how a total is divided, and depends only on the total, the per-hop exposure window, the hazard rate and the recovery fraction. *Predicted:* with $V = 40{,}000{,}000$, a six-hour window, a per-hop freeze probability of 0.2000 per cent and a recovery fraction of 0.15, expected loss is **USD 68,000 whether the total moves as one hop of 40m or as eight hops of 5m**, while the probability of some loss rises from 0.2000 to 1.5889 per cent and the worst single loss falls from 34.0m to 4.25m. *Falsified by:* any expected-loss figure that depends on hop size under independent per-hop freezes — which would mean the derivation in Section 3.4 is wrong.

H4 — the enforcement-concentration hypothesis. Compliance-driven exit concentrates a licensed market by the same arithmetic that a merger would, and on the same published screen. *Predicted:* exit from twelve licensed providers to five moves the index from 1,074 to 2,406 points and the effective provider count from 9.310987 to 4.156276, clearing the published structural-presumption threshold of 1,800 points by 606 and the change threshold of 100 points by a factor of thirteen. *Falsified by:* a de-risking episode after which the surviving providers' shares are more equal than before, so that the index falls.

Not hypotheses, and labelled as such.

- *The identification of N_{rail} with the reciprocal of the clearing-perimeter index* is a **definition**. Its content is entirely in the share basis and the perimeter assignment, both of which are testable.
- *The mapping of each currency to a single clearing perimeter* is a **modelling choice**, and one assignment in particular — treating the euro area as inside the Western perimeter — is contestable and is recorded as such in Appendix B.
- *The hazard rate λ*, the recovery fraction r, the per-hop cost, the covenant tolerance and every share vector are **stipulated constructed estimates**. Section 11 states that λ is the most load-bearing and least defensible input in the paper.
- *The parameter set $\eta = 0.35$* and $\delta Q + C = 0.500000$ is a **modelling choice**, fixed in advance so that no criterion is adjusted after the measurement — the preregistration discipline of Nosek et al. [2018] applied to an engineering calculation.

3. Method

3.1 The stack, and the four share bases

Payments run through layers that fail separately, and an index computed on the wrong layer measures the wrong thing.

layer	what it does	what fails
messaging	carries the instruction between institutions	disconnection of an institution from the network; a standards migration
correspondent	holds the account through which a bank reaches a currency it has no local presence in	contractual termination, with notice and no reasons
clearing and settlement	achieves finality in a currency, inside one jurisdiction's perimeter	an administrative measure in that jurisdiction
custody and depository	holds the security at the end of an intermediated chain	a designation reaching the depository

Four share bases follow, and they must never be mixed inside one computation.

basis	share of what	the count it yields
correspondent	cross-border settlement value passing through a given bank	effective correspondents
currency	settlement value denominated in a given unit	effective currencies

basis	share of what	the count it yields
clearing perimeter	settlement value achieving finality inside a given perimeter	N_{rail}, effective clearing perimeters
transit	value concurrently in flight on a given rail	effective rails

The correspondent basis is the one everybody uses and the clearing-perimeter basis is the one that answers the question. They differ because a bank's own jurisdiction is not where the money it moves achieves finality: a Gulf bank settling a dollar obligation is a dollar-perimeter exposure however the bank is chartered.

3.2 The instrument, and which effective count it is

For shares s_i summing to one on a stated basis,

$$\text{HHI} = \sum_i s_i^2, \qquad \text{effective count} = \frac{1}{\text{HHI}}.$$

If k units each hold $1/k$ then the reciprocal returns k; when they are unequal it returns the number of equal-sized units giving the same index. That numbers-equivalent reading is Adelman [1969]'s; the index itself is Hirschman [1945]'s and, independently in sum-of-squares form, Herfindahl [1950]'s. Competition practice states it in points on percentage shares, where a structural presumption attaches above 1,800 points with a change above 100 [U.S. Department of Justice and Federal Trade Commission, 2023]; the resilience application states it as a fraction. **Both conventions appear in this paper and every figure is labelled with which.**

Which effective count. $1/\text{HHI}$ is the Hill number of order two [Hill, 1973] — the numbers-equivalent that Jost [2006] shows is the diversity, as distinct from the index — and $\exp(H)$ for Shannon entropy [Shannon, 1948] is the same family at order one. **The corpus's other effective count, the affine $N_{\text{eff}} = 1 + (N-1)u$ of Curzi [2026c], is a linear interpolation between 1 and N, is not a Hill number of any order, and carries no external support.** That paper badges it as a design axiom rather than a theorem — a hundred-person department at $u = 0.05$ reading an effective count of 5.95 — and this paper does not use it. **Every count reported here is $1/\text{HHI}$ on a stated share basis.** Hurlbert [1971] is the discipline being imposed: the word carries no content without its formula attached.

No distributional or scaling claim is made anywhere in this paper. Correspondent shares descending 46 / 24 / 14 / 10 / 6, and provider shares descending across twelve entries, look like the opening of a heavy-tail argument, and the payments literature is full of such arguments. **No distribution is fitted, no tail is characterised and no power law is asserted.** Clauset et al. [2009] is the reason the procedure is named and not run: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison against alternatives leaves few canonical data sets standing, and a straight line on log-log axes is not evidence. Stumpf and Porter [2012] adds why passing it would not be enough: many mechanisms produce the same tail. **Every effective count here is a statistic of a finite share vector with between two and twelve entries, not an estimate of a distribution, and it must not be restated as one.**

Small-sample estimation is not addressed: Chao et al. [2014] show that low-order diversity estimators are biased on small samples, and these vectors are small. Golosov [2010] documents that effective-number measures behave poorly in the dominated-unit regime, which is the regime of the post-exit corridor at 34 per cent in one provider.

3.3 The correlation correction, and what a second account cannot buy

The naive index assumes the units fail independently. Where they do not, the correction is the one Markowitz [1952] stated for portfolios: diversification benefit depends on covariance, not on count. Writing w for the share vector and R for the correlation matrix of unit-variance shocks, the aggregate variance is $w'Rw$ and the general effective count is $1/(w'Rw)$; $R = I$ recovers the naive index and a block matrix of ones recovers the perimeter index. Curzi [2026] establishes that identity and its correspondence with the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012].

On the rail axis the correlation is not a modelling nicety; it is the mechanism. Two banks whose dollar legs both achieve finality in the same system are perfectly correlated with respect to a measure taken in that system, whatever their charters say. That coupled systems are far more fragile than their components is the formal content of Buldyrev et al. [2010], used here as a **shared structural form and not as a derivation**: no percolation premise has been shown to hold for a correspondent network. Albert et al. [2000]'s robust-yet-fragile result is used the same way, for the shape of the tolerance asymmetry only, and Doyle et al. [2005] is the standing correction to reading too much into either — engineered robustness comes from design, not from a degree distribution. Perrow [1984] reached the organisational version first, and is cited as framing rather than as a formal result.

Correlation rises under stress, which is when the count matters. Longin and Solnik [2001] measure extreme correlation that is asymmetric and concentrated in downturns; the ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008]. The contrary literature is not decorative: Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging alone with no mechanism, and May [1972] that increasing diversity and connectance destabilises randomly assembled systems. This paper's claim is narrower and is not exposed to those results in the same way: it asserts only that the reciprocal of a variance counts independent shocks, which is arithmetic.

A count of names is not a count of independent parties. Douceur [2002] proves that without a trusted identity authority one party can present as many, so an unaudited count carries no information about independence. Nesting is the payments instance: a respondent may itself provide correspondent services to further banks, so an institution's exposure runs to counterparties it has no relationship with. **The corpus carries an exact arithmetic instance of the same gap: Curzi [2026] proves that a roster indexed $1 \dots N$ realises exactly $\lceil N/2 \rceil$ distinct classes under its folding rule — six at $N = 12$, from twelve nominal members.** In all three settings a count of names and a count of distinct things are different quantities.

3.4 The exposure-window model, derived

Value in transit is exposed for a period. Model the freeze as a hazard: over an exposure of duration t, the probability of a freeze event affecting that value is

$$q = 1 - e^{-\lambda t}$$

for hazard rate λ per unit time; for small λt this is approximately λt, which is adequate throughout. Split a total V into n hops of size k, so $V = nk$, each exposed for t and frozen independently with probability q. If a frozen hop eventually recovers a fraction r, discounted for delay, then

$$\mathbb{E}[\text{loss}] = nkq(1-r) = Vq(1-r) = V\left(1 - e^{-\lambda t}\right)(1-r).$$

k **cancels.** Expected loss is a function of the total value, the per-hop window, the hazard rate and the recovery fraction, and is not a function of how the total is divided. What n controls is the distribution: losses are $k(1-r)$ times a Binomial(n, q) draw, so the maximum single-event loss $k(1-r)$ falls with n, the probability of any loss $1-(1-q)^n$ rises with n, and the variance falls with n. **Three levers, three different effects, and only one of them touches the expectation.**

The exposure the model prices is a stock produced by a flow and a delay, which is Little's law and is cited as a shared mathematical form rather than as a derivation. Little [1961] establishes that the average number in a system equals the arrival rate times the average time in system, under stationarity assumptions this paper's constructed corridors do not verify. The structural content carried over is that **concurrent transit exposure is set by the window and not by the parcel size**, which is the same statement the algebra above reaches independently.

Two properties of the model are load-bearing and are stated as limitations of it rather than discovered later. **Independence across hops fails for systemic events** — an outage, a depository suspension, a rail halt freezes every hop at once — so the binomial overstates the diversification exactly in the scenario that produces the tail. And λ decomposes into a counterparty component reducible by screening, a jurisdictional component reducible by routing but bounded by the currency, an operational component reducible by data quality, and a systemic component reducible by nothing the payer controls.

3.5 Landed cost and the indifference hazard

The cost of a rail is not its fee. It is the fee, plus the spreads, plus the expected freeze loss, and the last term dominates wherever the question is interesting:

$$\text{landed} = \text{explicit} + V\,(1 - e^{-\lambda t})\,(1 - r).$$

Setting two rails' landed costs equal and solving for λ gives an **indifference hazard**: the freeze probability above which the faster rail is worth its higher explicit cost. That converts an unanswerable geopolitical question into a threshold belief, which is the corpus's standard move for a marginal decision. Curzi [2026] prices a pledge trigger the same way, showing that at an opening loan-to-value of 50 per cent and a maintenance level of 35 per cent the first margin call falls at a 23.076923 per cent drawdown rather than at 50 per cent; Curzi [2026] prices a bridging position as a break-even probability, refusing the largest available gain on tail exposure and taking a capped transit position that yields $+0.002869$ — 3.9692 per cent of the benefit for 3.2110 per cent of the exposure, removing 96.79 per cent of the tail.

The same move appears in the corpus at its most abstract, and naming it as a family prevents its being reinvented. Curzi [2026] reduces an entire relational sustainability question to one comparison, establishing the trichotomy $f \gtreqless f_{\min}$ corresponding to $Q_\infty \gtreqless 0$ with $f_{\min} = k\,e^{2c/\eta}$. **The constant there, $k = (9/8)^2/\varphi^2 = 0.483425732988414$, is a *defined* constant — an exact ratio of exact quantities, which is what licenses its fifteen printed digits — and attaching a unit of hertz to it is a separate and much stronger claim which that paper badges as a postulate. This paper takes no position on the unit.** Since φ enters the definition, Markowsky [1992] is the standing corrective on golden-ratio claims and is cited for that reason. Curzi [2026] supplies the accompanying warning about compounding two such rules: its Corollary shows the compound rule and the essence law agree at no integer index, since $kn^2 = k^2n^4$ requires $n = 1/\sqrt{k} = 1.438252434444351$, and at $n = 12$ the two differ by 6.121291 octaves. **Thresholds derived from different laws must not be composed without checking that they meet anywhere.**

3.6 Identification, and the status of the perimeter assignment

Perimeter assignment is an input to the instrument and carries an identification problem that must be stated where it is used. Treating a set of jurisdictions as a coordination perimeter whose members respond to one decision is a statement about a group influencing its members while the members constitute the group. **Manski [1993] proves that the endogenous effect in a linear-in-means reflexive specification is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables however much data is collected. No amount of observation of clearing behaviour could confirm a perimeter assignment derived reflexively.

The remedy adopted is stipulation with a defence: perimeter membership is fixed in advance by the coordination test — two jurisdictions are in one perimeter when a single decision taken in one reliably produces the corresponding effect in the other without a further independent decision — recorded with its evidence, and the one contestable call is flagged and its alternative computed. Brock and Durlauf [2001] shows that route can be made rigorous. **The price is that every perimeter figure in this paper is a modelling position and not an identified empirical result.**

The collapse mechanism has a formal ancestry and is not new machinery. That several units inside one perimeter behave as one under a correlated shock is the threshold-and-tipping result: Granovetter [1978] establishes that the distribution of individual thresholds rather than the mean determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate outcome — **the strongest available warning against reading an individual-level parameter straight into an aggregate, which is exactly what a perimeter assignment does.**

One further reflexivity is specific to this axis. De-risking is a decision taken because other institutions are taking it, which is an informational cascade in the sense of Bikhchandani et al. [1992] and Banerjee [1992]: agents rationally ignore their private information once enough predecessors have acted, so the exit is neither independent across banks nor informative about the underlying risk. **A correlated exit is therefore the expected behaviour of the correspondent layer and not an anomaly**, and Merton [1948]'s self-fulfilling prophecy is the older name for a corridor becoming unbankable because it has been described as unbankable.

3.7 Sources of measurement that this paper does not have

Every figure below is computed from stipulated inputs. **No dataset was collected, no corridor was observed, and no institution was surveyed.** Where the source manuscript refers to published measurements — the decline in active correspondent relationships since 2011, the regional cost of remittances, the resolution amounts in two enforcement actions — those are described and marked for primary-source verification in Appendix B rather than quoted as this paper's evidence.

4. The correspondent layer and why it fails

4.1 The mechanics, and the economics of exit

A bank without a presence in a currency's home jurisdiction reaches that currency by holding an account at a bank that does, and that bank may reach the ultimate clearing system directly or through a further correspondent. The chain can be two links or five. Three features govern everything downstream.

Access is contractual, not regulated. No bank has a right to a correspondent account. Termination requires notice under the contract and nothing else: no appeal, no regulator to petition, typically no reason given. This is the property that makes the layer a decision surface rather than a legal surface, and it is why Hirschman [1970]'s distinction is the right frame — the respondent has no voice, so the correspondent's only instrument is exit, and exit is what it uses.

The decision is commercial. The correspondent bears regulatory risk for its respondent's customers, whom it does not know, in a jurisdiction it may not operate in, for a fee measured in basis points. Where the revenue from a difficult corridor is measured in tens of thousands and the penalty exposure from one failure in hundreds of millions, no rational institution retains the relationship, and none did. The two best-known resolutions of the last fifteen years are described in Appendix B and are not quoted here as figures.

The relationship nests. A respondent may itself provide correspondent services to further banks, so the correspondent's exposure runs to institutions it has no relationship with at all.

Nesting is the mechanism by which a measured count of relationships overstates the count of independent parties, and it is the payments instance of Douceur [2002].

The consequence for a cross-bloc structure is stated plainly. **Fewer correspondents means the survivors are larger, which raises the concentration on the axis this paper measures. A cross-bloc structure with a bridging apex and a dual-national principal is precisely the profile the survivors screen hardest. And the exit, when it comes, arrives as a letter with thirty days' notice and no reasons.** The diligence interface is a standard questionnaire and a pair of international recommendations on correspondent banking and on wire transfers [Financial Action Task Force, 2012]; a group that cannot answer the questionnaire quickly and consistently across all its entities will be de-risked, and the questionnaire is answerable only if the structure was built to be explicable. That is the formation test arriving at the operations desk.

4.2 Finality, and what it does not mean

One further mechanism decides what "the payment went through" means. The classic failure — one leg of a currency exchange settling while the other does not, because the two currencies settle in different time zones — produced both a market answer, simultaneous payment-versus-payment settlement, and a legal answer, settlement-finality legislation under which transfer orders entering a designated system become irrevocable at a specified moment and are protected from the retroactive effect of insolvency. The instruments are described in Appendix B and are not cited.

Finality is a legal concept about the irrevocability of an entry. It is not a statement about whether the resulting balance can be used, and the 2022 precedent is the demonstration: the transfers were final, the entries were valid, and the balances were unusable. The distributed-systems literature supplies the exact vocabulary for why that gap exists and is not closable by drafting. **Agreement among parties that may fail cannot be guaranteed in an asynchronous system with even one faulty participant** [Fischer et al., 1985], and a system that must remain available under partition cannot also remain consistent [Gilbert and Lynch, 2002]. **Both are used as shared structural form and not as derivations** — a payment system is not a formal asynchronous consensus protocol — but they name the trade-off that finality rules resolve by fiat rather than by proof. Lamport et al. [1982]'s bound on the number of genuinely independent parties required to tolerate faulty ones is the same discipline applied to counting: **redundancy is only redundancy if the parties fail independently.**

4.3 The depository layer

Securities sit in an intermediated chain terminating at a central securities depository, or at an international depository for cross-border holdings, and there are very few of the latter. That is not an accident of market structure but a consequence of network economics: settlement efficiency rises with the fraction of counterparties in the same book, so the market converges on a small number of very large books.

The custody axis therefore has an effective count in the low single digits for a whole market, and a structure holding securities through it inherits that count regardless of how many custodians it contracts with, because its custodians hold at the same place. The measurement improves at every layer a group contracts with and collapses at the layer it does not — which is the shape of the 2022 precedent. **A concentration that cannot be fixed should be sized, not ignored, and sizing it requires measuring it first.**

5. Transit: what the hazard is made of

5.1 Transit and store, distinguished

A rail is a mechanism for moving value; a store is a place value sits. **A prefunded account is not a rail. It is a holding that makes a rail faster, and it must be measured on the holding axis**, because a settlement balance that exceeds its limit has silently become a position on the jurisdictional measurement. The control that prevents this is a balance limit enforced independently of the treasury function; without it the distinction erodes by drift rather than by decision.

5.2 The hop-splitting question, and what it actually buys

The derivation of Section 3.4 says expected loss is flat in hop size. What splitting buys is a reduction in the worst case, at a stated premium in per-hop cost. Whether that premium is worth paying is a question about the group's capacity to absorb the worst case, not a question about risk reduction, and the right frame is an absorbable-loss constraint:

$$k \le \frac{X}{1-r}, \qquad n \ge \frac{V(1-r)}{X}$$

for a tolerance X. **The constraint sets the hop size; the optimisation does not, because there is nothing to optimise — expected loss is flat in k.** That is structurally the same result the corpus reaches for liability compartments in Curzi [2026], whose contagion measurement gives 4.96 effective compartments from six unequal ones and cuts maximum single reach from 100.0 to 30.0 per cent at a break-even event probability of 0.157 per cent a year, and it arrives here from a different derivation.

One caution is decisive and is stated here rather than in a footnote. Splitting across time provides no protection against a systemic event, which freezes every hop at once. **Split hops across *rails*, not merely across time, or the tail protection the split was bought for does not exist in the scenario that produces the tail.**

5.3 Netting, which is not a rail

The highest-return intervention on this axis is not a rail decision at all. Take a constructed group with six entities and gross intercompany flows of 100.0 units a quarter:

```
gross intercompany flows per quarter        100.0 units
bilateral netting                            62.0 units  (−38.0%)
multilateral netting to one settlement       23.0 units  (−77.0%)
```

Expected transit loss is proportional to value moved, so netting to a single settlement position reduces it in the same proportion. **Multilateral netting delivers a 77.0 per cent reduction in expected transit loss, requires no new rail, no new counterparty and no new jurisdiction, and its only cost is a treasury system and the discipline to settle on a cycle.** Section 6 shows that informal value-transfer systems are built on exactly this insight, centuries earlier and without the treasury system.

6. Informal value transfer as an object of measurement

The remaining material is analysed as a licensed, priced industry rather than as a curiosity, because its arithmetic supplies the sharpest available test of the concentration instrument.

6.1 Settlement is where the economics live

A bilateral position between two operators must eventually be cleared, by reverse flows in the same corridor, by trade, by a formal bank transfer of the net position, or by multilateral netting against other operators. **The third of these puts the system inside the correspondent perimeter, which is the opposite of what the popular account asserts.**

Netting efficiency is a property of the corridor's trade and migration pattern rather than of its operators. With gross flows G_{ab} and G_{ba},

$$\text{settlement requirement} = |G_{ab} - G_{ba}|, \qquad \text{netting efficiency} = 1 - \frac{|G_{ab} - G_{ba}|}{\max(G_{ab}, G_{ba})}.$$

```
CORRIDOR 1: labour-importing to labour-exporting
  G_ab = 100    G_ba =  15
  settlement requirement = 85     netting efficiency = 15.0%

CORRIDOR 2: two-way trading diaspora
  G_ab = 100    G_ba =  85
  settlement requirement = 15     netting efficiency = 85.0%
```

Corridor 1 must settle 85 units through the formal system for every 100 transferred and corridor 2 must settle 15, so corridor 1 costs roughly five and a half times as much to operate, is that much more exposed to correspondent friction, and is that much more visible to the formal system. **Corridor 1 is the shape of every major labour-migration remittance corridor.** Three consequences follow and none is obvious. Remittance corridors are the *least* netted and therefore the *most* dependent on formal settlement of any use case — the claim that they operate outside the banking system is close to exactly backwards. De-risking bites hardest precisely where netting is worst, which is to say in the poorest and most one-directional corridors. And a corridor's cost is predictable from its trade balance.

6.2 Obligation without an adjudicating forum

What stops an operator from simply not settling is the economics of reputation in a repeated game. The enforcement mechanism is exclusion from future business, and it works when the network is small enough that reputation travels, large enough that exclusion is costly, and stable enough that the future matters; kinship, common origin and long-term commercial relationships are the usual substrates because they satisfy all three cheaply. That cooperation is sustained in repeated interaction by the shadow of the future is Axelrod and Hamilton [1981] and Axelrod [1984]; that trust is a specific expectation about others' behaviour under sanctioning arrangements rather than a disposition is Gambetta [1988]; and that durable common-pool institutions run on graduated sanctions and monitoring by the participants themselves rather than on external enforcement is Ostrom [1990], whose design principles have been checked against a large case base [Cox et al., 2010].

The source manuscript names two further works in prose — an account of an eleventh-century traders' coalition and a model of the law merchant with a private judge — and neither is in this paper's bibliography. They are described and left uncited (Section 11 and Appendix B), because inventing a citation key is worse than declaring a gap.

Two consequences. The mechanism is genuinely effective within its domain, and an operator's capital is largely reputational. **And it is fragile at the boundary: it provides no protection to a party outside the network, offers no recourse to a customer, and produces no evidence a court can use.** A system whose enforcement is reputational offers its participants excellent protection and its customers none.

6.3 Where the margin comes from

Operator revenue has a commission component and a foreign-exchange spread component, and the second is usually larger and is frequently manufactured by policy rather than by the operator. Where a state maintains an overvalued official rate alongside capital controls, a parallel rate exists by construction and the gap is a subsidy paid by anyone forced to use the official rate. An operator settling at or near the parallel rate can offer a better rate than the formal channel and still earn a spread. **A state running a large parallel premium and prosecuting informal transfer is attempting to enforce against an arbitrage it is itself creating, which is the clearest instance in this series of a policy failure misdiagnosed as a compliance failure.** The episodes the source names, with their dates and premia, are in Appendix B.

7. Results

Every figure is an exact computation on constructed inputs. **No dataset was collected and no figure here is a measurement taken from a real corridor.**

7.1 R1 — the clearing-perimeter measurement

CONSTRUCTED CASE. Twelve months of cross-border settlement value for a group with a bridging apex, traced to intermediaries:

correspondent	share	perimeter of the bank
A, global systemically important bank	46.0%	WEST
B, global systemically important bank	24.0%	WEST
C, regional bank	14.0%	BRIDGE
D, regional bank	10.0%	BRIDGE
E, regional bank	6.0%	NONALIGNED

Five relationships, four jurisdictions, three perimeters, and a file describing it as a diversified correspondent network. Every word of that description is true.

```
naive correspondent HHI = 0.211600 + 0.057600 + 0.019600
                        + 0.010000 + 0.003600 = 0.302400
effective correspondents = 1 / 0.302400 = 3.306878

collapsed to the BANKS' own perimeters
  WEST 70.0%  BRIDGE 24.0%  NONALIGNED 6.0%
  bank-perimeter HHI = 0.551200
  effective bank perimeters = 1.814224
```

That is already a large fall, and it is still the wrong measurement, because it collapses banks by where the *bank* sits rather than by where the *currency* clears. Decomposing each correspondent's volume by currency of denomination gives USD 69.0, EUR 16.8, AED 5.6, SGD 3.0, CNH 2.0 and INR 3.6 per cent, so

```
currency HHI = 0.476100 + 0.028224 + 0.003136
             + 0.000900 + 0.000400 + 0.001296 = 0.510056
effective currencies = 1.960566
```

Six currencies, 1.96 effective. A five-currency revenue profile is real at the revenue line and has collapsed to essentially two by the time it reaches settlement, because the dollar is

the settlement currency of the trading business regardless of where the revenue was earned. Mapping each currency to the perimeter in which it achieves finality:

currency	share	perimeter
USD	69.0%	WEST
EUR	16.8%	WEST
AED	5.6%	BRIDGE
SGD	3.0%	BRIDGE
CNH	2.0%	EAST
INR	3.6%	NONALIGNED

```
WEST       85.8%   0.736164
BRIDGE      8.6%   0.007396
EAST        2.0%   0.000400
NONALIGNED  3.6%   0.001296
-----------------------------------------
clearing-perimeter HHI = 0.745256
N_rail = 1 / 0.745256 = 1.341819
```

measurement	HHI	effective count
naive correspondents	0.302400	3.306878
bank perimeters	0.551200	1.814224
clearing perimeters	**0.745256**	**1.341819**

Applying the surplus term at $\eta = 0.35$ and $\delta Q + C = 0.500000$:

axis	N	$\ln N$	$\eta \ln N$	h
jurisdiction / bloc	2.941176	1.078810	0.377583	-0.122417
correspondent, naive	3.306878	1.196005	0.418602	-0.081398
bank perimeter	1.814224	0.595658	0.208480	-0.291520
clearing perimeter	**1.341819**	**0.294026**	**0.102909**	$\mathbf{-0.397091}$

The structure is 3.24 times worse on h on the rail axis than on the jurisdictional axis, and the naive correspondent reading is not merely optimistic — it is better than the jurisdictional reading, which would lead a reader to conclude that the rail was the strong side of the structure. It is the weak side by a wide margin. H1 is supported.

7.2 R2 — the remedy that does not work, and the one that does

Add three banks in three further jurisdictions, each taking five points of volume drawn proportionately from the existing five, giving shares 39.1 / 20.4 / 11.9 / 8.5 / 5.1 / 5.0 / 5.0 / 5.0:

```
naive correspondent HHI = 0.225984
effective correspondents = 1 / 0.225984 = 4.425092   (+33.8%)
```

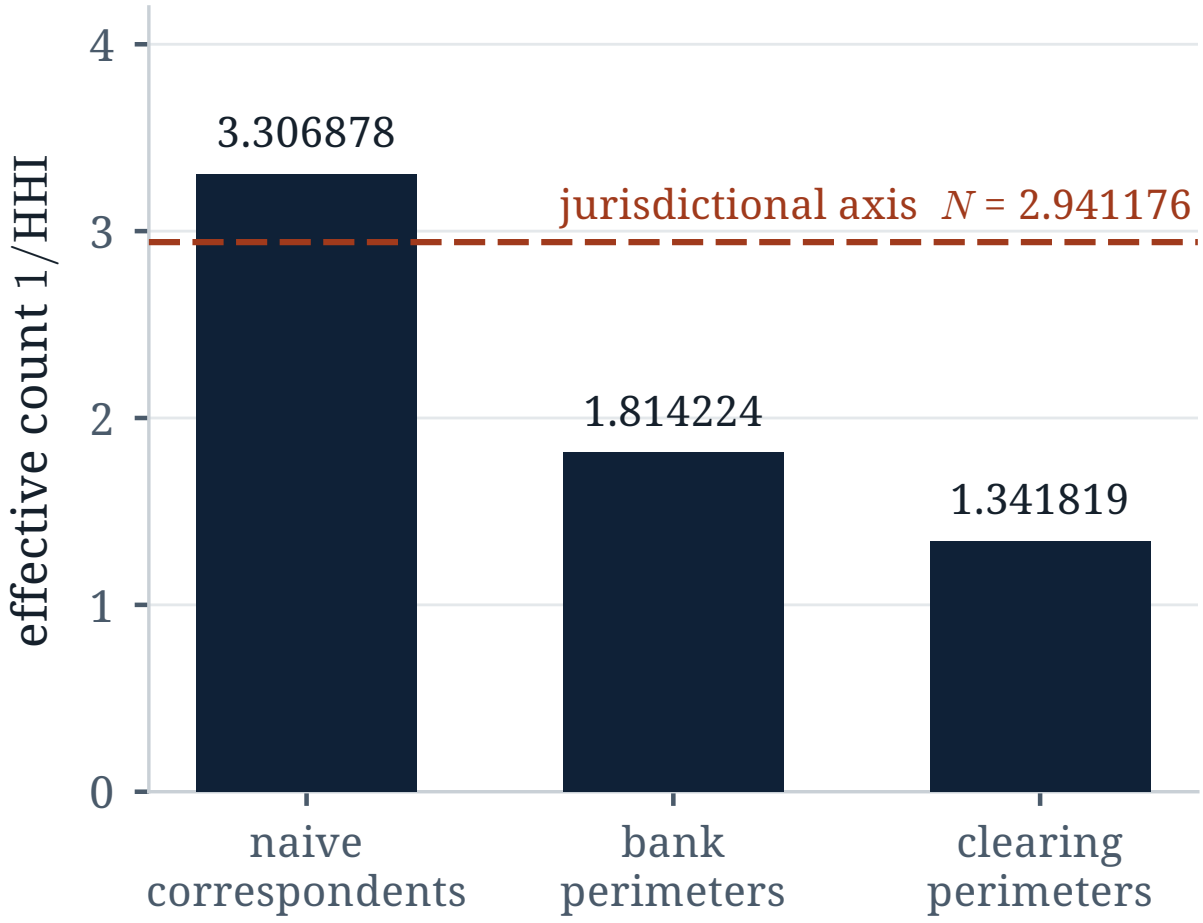

Figure 61.1: **Five correspondents in four jurisdictions across three perimeters read 3.306878 effective at the account layer and 1.341819 at the layer where finality occurs.** Effective counts are $1/\mathrm{HHI}$ on the three share bases of Section 3.1, computed from the constructed corridor set in Section 7.1; the dashed line is the same structure's effective bloc count on the jurisdictional axis. Script `figs/src/CCP-061_fig01.py`.

```
currency mix unchanged, because adding a bank does not change
what the invoices say

clearing-perimeter HHI = 0.745256   N_rail = 1.341819   UNCHANGED
```

Three new banking relationships, three new onboardings, three new sets of ongoing diligence, a 33.8 per cent improvement in the number nobody should be reporting, and exactly zero change in the number that matters. That is rearrangement inside a perimeter, reproduced on the rail axis; Curzi [2026] reaches the identical structural result for two free zones inside one supervisory perimeter, which are one line at 29.1 per cent of exposure and where no rearrangement between them changes N.

Now change the denomination of the underlying obligations over a three-year contract cycle — regional sales renegotiated into regional currencies at renewal, fee income denominated where it arises, treasury operating balances held in local currency rather than swept — giving USD 52.0, EUR 14.0, AED 12.0, CNH 9.0, INR 8.0 and SGD 5.0 per cent:

```
WEST 66.0%  BRIDGE 17.0%  EAST 9.0%  NONALIGNED 8.0%
clearing-perimeter HHI = 0.435600 + 0.028900 + 0.008100
                       + 0.006400 = 0.479000
N_rail = 2.087683   ln(N_rail) = 0.736055
eta ln(N_rail) = 0.257619   h_rail = -0.242381

before   N_rail 1.341819   h_rail -0.397091
after    N_rail 2.087683   h_rail -0.242381
gain                        +0.154710
```

A gain of 0.154710 in h, achieved with no new entity, no new jurisdiction and no new bank. For comparison, the corpus's first non-Western jurisdictional move — taking N from 1.00 to approximately 1.70 — is worth $0.35 \ln(1.70) = 0.185720$, and the bridging positions priced in Curzi [2026] and Curzi [2026] are worth an order of magnitude less. **The currency remediation is the second largest single-move gain computed anywhere in this series and the only large one requiring no structure at all.** H2 is supported.

The bill, stated with the gain. Redenomination leaves the group holding receivables in five currencies against a cost base in three, so hedging costs basis points and unhedged mismatch costs more; a customer asked to pay in its own currency will expect a price concession for taking foreign-exchange risk it previously did not bear, estimated at 30–80 basis points on affected revenue; five currency ledgers require five reconciliations and five sets of account limits; and currencies with thin offshore markets require larger operating balances, which are holdings and must be measured as such. Constructed net: an annual cost of roughly 0.045 units against a gain of 0.154710, favourable by a factor of about three. Curzi [2026] is the standing bound on how far this can be taken: at a 15 per cent annual hard-currency drag a local-currency allocation of 25.17 per cent of protected capital sets h to exactly -0.500000, cancelling the entire $\eta \ln N = 0.377583$ diversification gain. **Currency independence bought past that point costs more than the independence is worth.**

7.3 R3 — the transit model, worked

Calibrate at a per-hop freeze probability of 0.2000 per cent for a six-hour correspondent window, so $\lambda = -\ln(1 - 0.002)/6 = 3.3367 \times 10^{-4}$ per hour, with $V = 40{,}000{,}000$ and $r = 0.15$:

case	window	hops	q	$\mathbb{E}$[loss] (USD)	worst single loss	P(any loss)
1	6 h	1 of 40m	0.002000	68,000	34,000,000	0.2000%

case	window	hops	q	$\mathbb{E}$[loss] (USD)	worst single loss	P(any loss)
2	6 h each	8 of 5m	0.002000	68,000	4,250,000	1.5889%
3	20 min	1 of 40m	0.00011122	3,781	34,000,000	0.0111%
4	6 h, screened	1 of 40m	0.000400	13,600	34,000,000	0.0400%
5	20 min, screened	1 of 40m	0.00002224	756	34,000,000	0.0022%

Read cases 1 and 2 together: eight times more likely to suffer some loss, eight times smaller worst case, identical expected loss. Then read 3 and 4 against them: the window and the screening each move the expectation by an order of magnitude, and the hop size moves it by nothing. H3 is supported, and it is supported as an algebraic identity rather than as an empirical finding.

Splitting is not free. At a constructed per-hop cost of USD 2,500, one hop costs 2,500 against an expected loss of 68,000 for a total of 70,500, while eight hops cost 20,000 against the same expected loss for a total of 88,000. **Splitting the payment costs USD 17,500 and reduces expected loss by nothing. It buys a reduction in the worst case from USD 34.0m to USD 4.25m, and that is a purchase of insurance at a stated premium.** With a covenant tolerance of USD 6,000,000 the constraint gives $k \le 6{,}000{,}000/0.85 = 7{,}058{,}824$ and $n \ge 40{,}000{,}000/7{,}058{,}824 = 5.67$, so the answer is six hops of roughly 6.67m — **set by the constraint, not by an optimisation.**

Worked on a planned intra-group repatriation of USD 40m with the counterparty component of the hazard screened to 20 per cent of the base rate and a covenant tolerance of USD 12m:

option	window	hops	$\mathbb{E}$[loss]	explicit	landed	worst single	P(any)	verdict
1	48 h	2 of 20m	108,735	100,300	209,035	17,000,000	0.6386%	fails tolerance
2	48 h	4 of 10m	108,735	100,900	209,635	8,500,000	1.2731%	acceptable
3	20 h	2 of 20m	45,349	92,000	137,349	17,000,000	0.2666%	fails tolerance
3S	20 h	4 of 10m	45,349	92,600	137,949	8,500,000	0.5325%	**chosen**

The saving of USD 71,686 against option 2 comes entirely from removing a hop from the chain, and the split that satisfies the covenant costs USD 600. The window is worth a hundred times what the hop sizing is worth, and the hop sizing is a constraint to be satisfied rather than a lever to be pulled. Note also that option 3S has a *higher* probability of some loss than option 3 and a lower expected loss than either 1 or 2: **three metrics moving in three directions from one decision, so all three must be reported or the decision is being made on whichever one the presenter chose.**

7.4 R4 — netting

```
E[loss] gross          proportional to 100.0
E[loss] netted          proportional to  23.0
reduction                                77.0%
```

Multilateral netting to a single settlement position cuts the constructed group's expected transit loss by 77.0 per cent with no new rail and no new counterparty. It is the highest-return intervention in this paper and it is not a rail decision at all. It is the decision not to use one.

7.5 R5 — the indifference hazard

Landed cost on USD 40,000,000, on the constructed parameterisation:

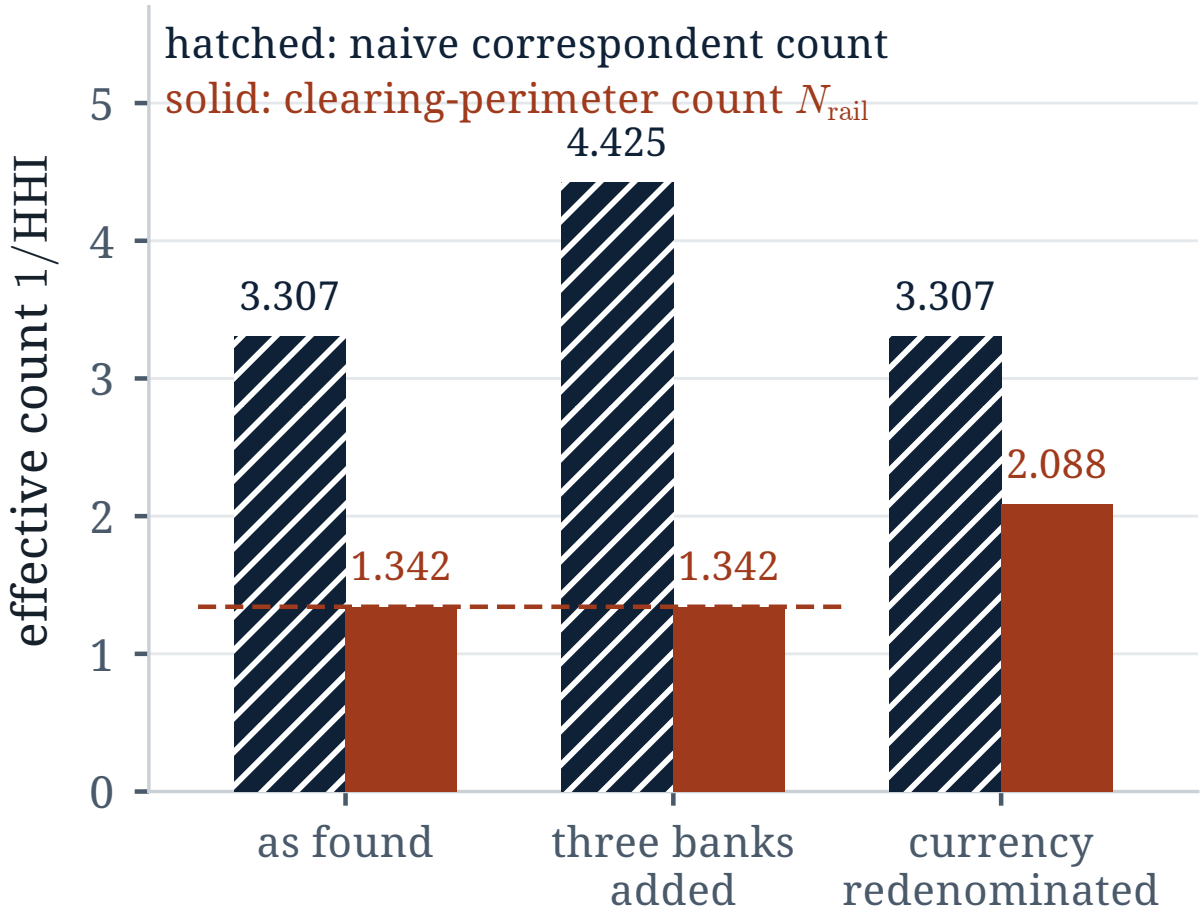

Figure 61.2: **Adding three correspondent banks improves the account-layer count by a third and leaves the clearing-perimeter count unchanged to six decimal places; redenominating the underlying obligations is what moves it.** Effective counts on the correspondent and clearing-perimeter bases from Sections 7.1 and 7.2; the dashed line marks $N_{\text{rail}} = 1.341819$. Script `figs/src/CCP-061_fig02.py`.

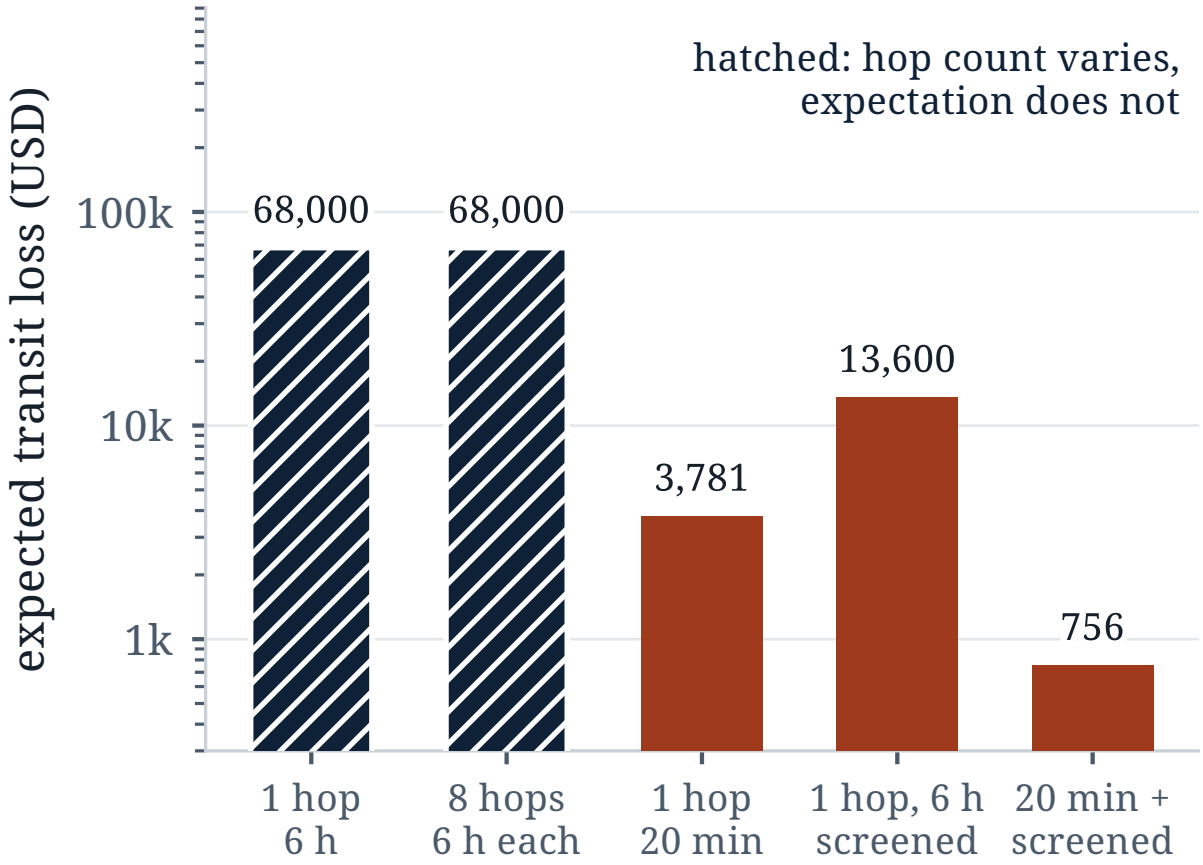

Figure 61.3: **The exposure window and counterparty screening each move expected transit loss by an order of magnitude; the number of hops moves it by nothing.** Expected loss $V(1-e^{-\lambda t})(1-r)$ at $V = 40{,}000{,}000$ and $r = 0.15$, for the five constructed cases of Section 7.3; hatched bars differ only in hop count. Script `figs/src/CCP-061_fig03.py`.

```
CORRESPONDENT WIRE, 48-hour window
  wire and lifting fees                          USD      300
  FX spread 15 bp on the converted leg           USD   60,000
  q = 1 - exp(-0.00033367 x 48) = 0.0158884
  E[freeze loss] = 40m x 0.0158884 x 0.85        USD  540,207
  ------------------------------------------------------------
  landed cost                                    USD  600,507

FAST RAIL, 0.5-hour window
  on-ramp spread 10 bp                           USD   40,000
  network fees                                   USD      100
  off-ramp spread 20 bp                          USD   80,000
  expected price variance over the window        USD   20,000
  q = 1 - exp(-0.00033367 x 0.5) = 0.00016682
  E[freeze loss] = 40m x 0.00016682 x 0.85       USD    5,672
  ------------------------------------------------------------
  landed cost                                    USD  145,772
```

The fast rail lands at under a quarter of the correspondent cost on this parameterisation, and every bit of the advantage comes from the window rather than from the fees — indeed its explicit costs are more than twice as high. Setting the two landed costs equal and approximating $q \approx \lambda t$:

```
60,300 + 40m x 0.85 x lambda x 48 = 140,100 + 40m x 0.85 x lambda x 0.5
34,000,000 x lambda x 47.5 = 79,800
lambda = 4.9412e-05 per hour
q48 = 1 - exp(-4.9412e-05 x 48) = 0.0023690   ->   0.2369%
```

Above a 48-hour freeze hazard of about 0.24 per cent, take the fast rail; below it, take the slow one. For a legitimate group moving money between its own subsidiaries in ordinary corridors, 0.24 per cent per transaction is a very high hazard, and the honest conclusion is that **most readers should use the correspondent rail most of the time.** The fast rail earns its cost in corridors that are genuinely stressed — which is to say exactly where the screening burden is highest and the regulatory perimeter least settled. **The rail is cheapest to use where it is hardest to use correctly, which is not a coincidence and is not a comfortable finding.**

Screening, sized rather than assumed, on a constructed twelve-payment supplier programme of CNY 5,000,000 a month with an eighteen-hour window: unscreened $q = 0.0059881$ gives CNY 25,449 per payment and CNY 305,388 a year; with the counterparty hazard cut by 80 per cent, $q = 0.0012005$ gives CNY 5,102 and CNY 61,225. **The annual benefit is CNY 244,163 against a constructed programme cost of CNY 95,000 — a ratio of 2.57 to one, with the programme paying for itself if it removes about 31.1 per cent of the counterparty hazard, which is a modest claim.**

Run on concurrent transit exposure across the group after redenomination — USD 52.0, EUR 14.0, AED 12.0, CNH 9.0, INR 8.0, SGD 5.0 per cent — the rail HHI is 0.321400 and the effective rail count is 3.111387. **This is a *transit* measurement and is deliberately not the clearing-perimeter measurement of** 2.087683: transit value is not proportional to settlement value, because some corridors move a large annual value in a few large hops and others move a small value continuously. Reporting one as the other is the axis-confusion failure arriving inside a single analysis. Adding a fast-rail leg at 10 per cent of transit value raises the effective rail count from 3.11 to 3.70 while introducing three sub-axes with effective counts of 1.00 for the issuer, 1.00 for the network and 1.83 for the venues at the ramps. **A rail that improves a headline count while introducing sub-axes at 1.00 has not obviously improved anything, and the measurement must be run at the sub-axis level or it flatters the decision.**

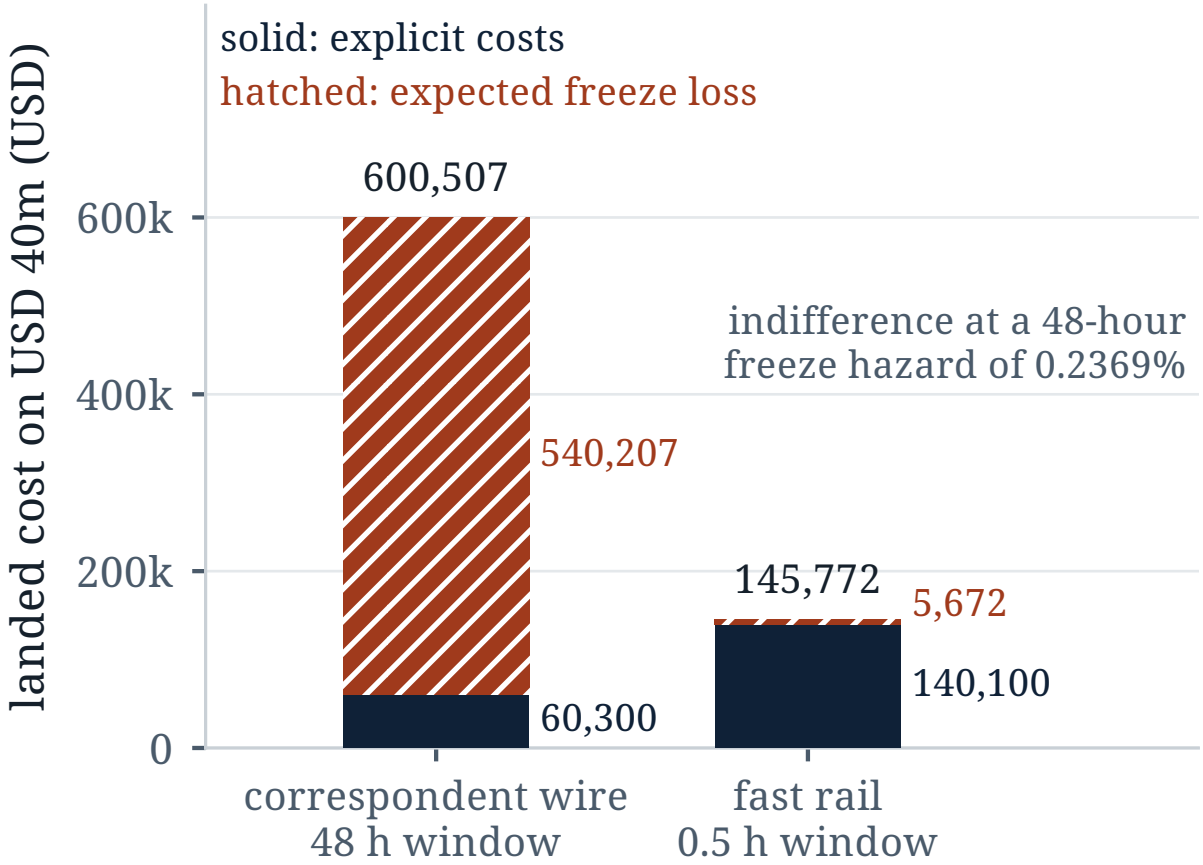

Figure 61.4: **The fast rail's advantage is entirely the exposure window: its explicit costs are more than twice the correspondent rail's and its landed cost is under a quarter.** Landed cost on USD 40,000,000 decomposed into explicit costs and expected freeze loss at the constructed hazard of Section 7.5. Script `figs/src/CCP-061_fig04.py`.

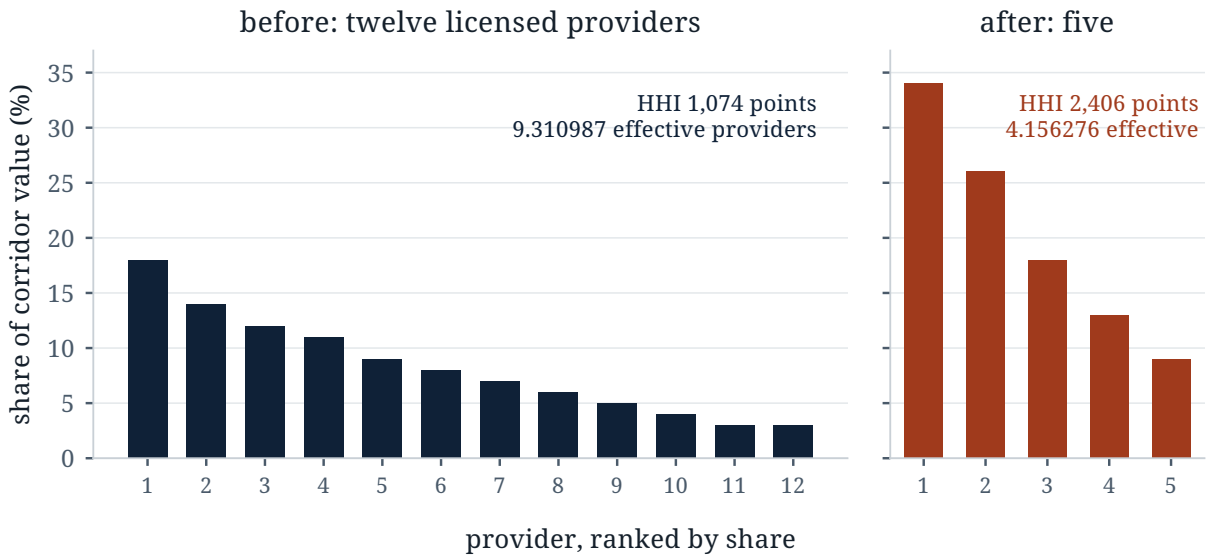

Figure 61.5: **Enforcement-driven exit produced, without any transaction, a market that clears the published structural-presumption screen by 606 points.** Constructed corridor shares before and after a de-risking cycle, with the index in points and the effective provider count $1/\mathrm{HHI}$; from Section 7.6. Script `figs/src/CCP-061_fig05.py`.

7.6 R6 — the concentration effect of enforcement

CONSTRUCTED CASE. A remittance corridor with twelve licensed providers before a de-risking cycle and five after, shares of corridor value:

```
BEFORE  18 / 14 / 12 / 11 / 9 / 8 / 7 / 6 / 5 / 4 / 3 / 3
        HHI = 1,074 points = 0.107400
        effective providers = 9.310987

AFTER   34 / 26 / 18 / 13 / 9
        HHI = 2,406 points = 0.240600
        effective providers = 4.156276
```

metric	before	after	change
licensed providers	12	5	−7
HHI (points)	1,074	2,406	+1,332
HHI (fraction)	0.107400	0.240600	+124.0%
effective providers	9.310987	4.156276	−55.4%
largest single share	18.0%	34.0%	+16.0 points

Applying the published merger screen — a structural presumption above 1,800 points with a change above 100 [U.S. Department of Justice and Federal Trade Commission, 2023] — the corridor after exit reads 2,406 points with a change of 1,332 and a largest share of 34.0 per cent. **A regulatory intervention undertaken to reduce financial-crime risk produced, on the competition agencies' own screen, a market clearing the concentration threshold by 606 points and the change threshold by a factor of thirteen. No merger produced it, no filing was required because no transaction occurred, and there is no agency whose remit covers the outcome.** H4 is supported.

Modelled conservatively at a constructed price elasticity of 0.25 with respect to the index, a 124.0 per cent rise in concentration produces a 31.0 per cent rise in price, taking corridor cost

from 6.0 to 7.86 per cent of the amount sent — on a constructed corridor value of USD 4 billion, **USD 74,400,000 a year of additional cost borne by senders.** The elasticity is constructed and should be replaced with a measured one; the sign is not constructed. The risk consequence is the point of the exercise:

```
volume displaced from licensed to unlicensed channels
  -- NOT MEASURABLE. No figure is asserted.
supervisory relationships destroyed              7
filing entities removed from the perimeter       7
examinable entities removed from the perimeter   7
```

The last three lines are exact and the first is unknowable, which is itself the finding: the cost of the intervention is precisely measurable and its benefit is not.

One layer down, the five survivors' own banking:

```
Bank Alpha = 34.0 + 26.0 + 13.0 = 73.0%   0.532900
Bank Beta  = 18.0 +  9.0        = 27.0%   0.072900
------------------------------------------------------
correspondent HHI = 0.605800
effective correspondents = 1.650710
```

Five providers, 4.156276 effective; two correspondents, 1.650710 effective. One bank's exit removes 73.0 per cent of the corridor's licensed capacity, and that decision requires no consultation, no notice period beyond the contractual one, and no reasons.

7.7 Counter-result

After the largest available intervention the rail remains the structure's weakest axis. $N_{\text{rail}} = 2.087683$ against 2.941176 on the jurisdictional axis and against the break-even count of 4.172734 that Curzi [2026] fixes for the storage law at these parameters. The dollar share stops at 52.0 per cent after a three-year redenomination programme and will not go much lower, because the commodity and trade-finance legs of the business are priced in that currency globally and the group cannot unilaterally change it. **Some concentration is a property of the world rather than of the design, and the correct response is to record it rather than to model it away.** The depository layer is not remediable by a private group at all and is sized and monitored rather than fixed. **Correspondent exit risk is not hedged and cannot be**; it is mitigated by explicability, tested contingency relationships and a twelve-month lead time on every replacement.

8. Discussion and failure catalogue

8.1 What the measurement licenses

The instrument measures **independence, not capacity**. $N_{\text{rail}} = 2.087683$ says nothing about whether any perimeter can carry the group's volume, nothing about the price of doing so, and nothing about whether a counterparty will accept the instruction. Curzi [2026] makes the same point on a different share basis and reaches the same shape: entity-based exposure of 27.3 per cent against a currency share of 61.0 per cent and settlement volume of approximately 58 per cent, so that **the entity map understates dependency by more than a factor of two.** The rail measurement is that mismatch taken one layer further down.

The corpus's own five-parameter survey is the closest thing to a validation this instrument has, and it is not on this axis. Curzi [2026k] applies the same storage-law parameterisation from a single desk to a twenty-two-household block and reproduces each system's observed decline — -0.250474 predicted against -0.250 observed at the desk, -0.996371 against -1.000

at the library, with residuals under 1.4 per cent of the ceiling term. **That is scale-freedom demonstrated at two scales in a domain with observable outcomes. No equivalent demonstration exists for the rail axis, and Section 11 says so.**

The framework's channel-gain form bounds what any of this can promise. Curzi [2026ab] states the magnitude form $E = G \cdot B + \varepsilon$ with the forbidding clause that $G = 0$ implies $E = 0$ for all B, badged as a postulate and paired with the storage law's $\eta = 0$ by explicit correspondence. **On the rail axis the forbidding clause is literal: where no clearing channel exists into a perimeter, no amount of structuring, documentation or belief produces settlement into it.** A rail programme is a claim about G and it must be tested by moving money, not by drafting a policy.

8.2 Thirteen failure modes

1. **Treating a clearing system as a substitute for a messaging network.** The category error of Section 1.1; a policy recording two rails on that basis has recorded one dependency twice.
2. **Counting correspondents instead of measuring perimeters.** The gap between 3.306878 and 1.341819 is the whole paper.
3. **Ignoring nesting.** A respondent's own respondents are exposure the count does not show [Douceur, 2002].
4. **Diversifying accounts while concentrating currency.** Section 7.2, measured.
5. **Direct versus indirect participation, unverified.** Whether a given bank reaches a clearing system directly is a bank-by-bank question and cannot be answered jurisdiction by jurisdiction.
6. **The custody chain unmapped.** The chain must be mapped to the depository, not to the custodian.
7. **Treating de-risking as a legal risk.** It is a commercial decision with no appeal, and it propagates as a cascade [Bikhchandani et al., 1992].
8. **Building the structure and then seeking the banking.** The onboarding constraint is binding and is discovered last.
9. **Treating a settlement balance as a rail.** It is a holding, and it enters the jurisdictional measurement.
10. **A currency rail with no receivables in that currency.** The rail follows the invoice, so a rail without an invoice is a facility, not an exposure change.
11. **Assuming immobilisation is a sovereign-only risk.** The mechanism is administrative and reaches any holder through an intermediary.
12. **Messaging-migration data loss.** A standards migration truncates fields [International Organization for Standardization, 2013], and truncated originator data is itself a screening hazard.
13. **Assuming a rail can be changed quickly.** Onboarding runs to quarters and redenomination to a contract cycle; **the only window common to every rail failure is *before*.**

The corpus's amplitude weighting is the general form of that last point. Curzi [2026] scores each step of a path 0–3 for steepness, sums to a resistance R and weights the branch as $1/2^R$, so a three-point difference in steepness is a factor of eight in expectation. **Applied here, every branch reachable only after the signal carries a resistance the model prices at near zero weight, which is the formal statement of why rails are built in peacetime or not at all.**

8.3 Where the analysis is exposed

The instrument is exposed to being adopted as a target. An effective count optimised against ceases to measure what it measured [Goodhart, 1975, Campbell, 1979]; the only defence offered is the reporting standard in Appendix A, which requires the inputs to be published beside the output.

It is also performative, and its own parameters are not exempt. MacKenzie and Millo [2003] documents a model that made its assumptions true after adoption, and Lucas [1976] states the consequence for parameters estimated before publication. **The framework asserts that systems change their behaviour when modelled and then exempts its own η, λ and perimeter assumptions from that reflexivity. That is an inconsistency and it is not resolved here.**

Ensemble and time averages are different objects and every expected-loss figure here is the first. Peters [2019] establishes that the time average of a multiplicative process differs from its ensemble average, so an expectation computed across many payers does not describe what happens to one payer over time — and a freeze that removes a settlement is not a deduction from a stream but an event that rescales what follows. Peters and Gell-Mann [2016] supplies the associated strengthening for the framework's logarithm: a logarithmic form follows from multiplicative dynamics with no psychological assumption at all, which is a better warrant than the perceptual account the corpus more often gives.

One boundary the framework refuses to cross belongs here rather than in a footnote. Curzi [2026] states the doctrine of category violation, which refuses category innocence as a defence of acquisition and forbids moving a harm through a discovered gap in a scheme, and concedes as an unclosed seam the case where the feedback loop runs through another person's will. **The rail analysis is measured against arbitrary action and is not licensed as a technique for evading a process that has run**; the de-risking result in particular is an argument about a policy's second-order costs and not an argument for the unlicensed channel it displaces volume into.

9. Verification and rigour audit

9.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	share on a stated basis	$[1]$	dimensionless fraction	defined; sums to 1 by P1
HHI	concentration index	$[1]$	dimensionless, or points $= 10^4\times$	derived from shares
N, N_{rail}	effective count	$[\#]$, a count	perimeters, banks, providers	derived as $1/\text{HHI}$
$\ln N$	surplus-term argument	$[1]$	nats	derived; logarithm of a count is dimensionless
λ	freeze hazard rate	$[T^{-1}]$	per hour	assumed (constructed)
t	exposure window	$[T]$	hours	assumed (constructed)
q	per-hop freeze probability	$[1]$	dimensionless	derived, $1-e^{-\lambda t}$
V, k	total value, hop size	$[M]$	currency	assumed (constructed)
n	hop count	$[\#]$	a count	chosen
r	recovery fraction	$[1]$	dimensionless	assumed (constructed)
X	absorbable single loss	$[M]$	currency	assumed (constructed)

symbol	quantity	dimension	unit	status
Q	protected capital	$[C]$	index units	defined; **no operational unit is supplied by the source**
δ	erosion rate	$[T^{-1}]$	per period	assumed
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
η	conversion efficiency	$[C\,T^{-1}]$ per nat	index units per period per nat	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived

Do the equations balance? λt is dimensionless, so $q = 1 - e^{-\lambda t}$ is well formed and the exponent takes a pure number, which is the check a physicist runs first. $\mathbb{E}[\text{loss}] = Vq(1-r)$ carries $[M]$, correctly. Landed cost adds $[M]$ to $[M]$. The surplus law $h = \eta \ln N - \delta Q - C$ balances **only if η carries capital per period per nat, and the source is silent on this**: it treats conversion efficiency as a bare number. **The audit records the silence rather than filling it in**; the reading in the table is this paper's.

Where no operational unit exists the audit says so. Q, C and h are index units fixed by the stated parameters, with no conversion to currency supplied anywhere in the corpus. **The effective counts, the indifference hazard and every currency figure survive this; the statement that h_{rail} is -0.397091 means nothing until an index unit is defined.**

A units mismatch inside the paper is recorded rather than smoothed. The transit model is denominated in currency and the surplus law in index units, and **the two are never added.** No exchange rate between them exists and none is asserted.

9.2 Significant figures against epistemic status

- 3.306878, 1.814224, 1.341819, 2.087683, 4.425092, 9.310987 and 4.156276 are **exact reciprocals of exactly stated share vectors.** They are derived-from-defined and may carry as many digits as are useful. **Their inputs are constructed and carry no empirical authority whatever.**
- Every index in this paper is computed from the printed percentage shares rather than from any exact underlying fraction, **which is the convention adopted by Curzi [2026] and recorded there as a fifth-decimal discrepancy against the exact-fraction convention of Curzi [2026].** The convention is stated so that a reproduction agrees to the last digit.
- $h_{\text{rail}} = -0.397091$ and the gain of $+0.154710$ are exact given the parameters, and **the parameters are assumed, not estimated.** They carry no uncertainty because there is no estimate in them, and no authority beyond the assumption.
- USD 68,000, USD 540,207 and CNY 305,388 are **illustrative model output from constructed parameters** and are rounded to the nearest unit for printing only.
- $q_{48} = 0.2369\%$ is exact arithmetic on stipulated costs.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere. That is not precision; it is the absence of empirical content.**

9.3 Limits and boundary behaviour

limit	behaviour	reading
one perimeter, $s_1 = 1$	HHI $= 1$, $N = 1$ exactly	a single-perimeter rail counts as one
n equal perimeters	$N = n$ exactly	returns the count
n unequal	$N < n$	never overstates the count
$t \to 0$	$q \to 0$, $\mathbb{E}[\text{loss}] \to 0$	instantaneous finality removes the transit hazard entirely
$t \to \infty$	$q \to 1$, $\mathbb{E}[\text{loss}] \to V(1-r)$	value permanently in flight is value at risk in full
$\lambda \to 0$	$\mathbb{E}[\text{loss}] \to 0$	the fast rail's whole advantage vanishes and the indifference hazard is never reached
$r \to 1$	$\mathbb{E}[\text{loss}] \to 0$	full recovery makes a freeze a delay rather than a loss
$n \to \infty$ at fixed V	$\mathbb{E}[\text{loss}]$ unchanged; $P(\text{any}) \to 1$; worst case $\to 0$	the invariance, in the limit
$\eta \to 0$	$h \to -(\delta Q + C)$	no conversion, no benefit from any independence
$\delta \to 0$	stock never erodes	pathology, not an ideal
$N \to \infty$	$h \to \infty$ logarithmically	**a defect of the model, not a result**

Range: $1 \leq 1/\text{HHI} \leq n$, with both bounds attained. A quantity equal to n for n equal units, equal to 1 for a single unit, and strictly between otherwise, **is a count**.

Two limits are constraints on the model's domain rather than results. The unbounded-N behaviour of the surplus law contradicts every organisational observation, so **the model's domain is small** N and every prescription here concerns moves between $N \approx 1$ and $N \approx 3$. And the small-λt approximation used in the indifference calculation overstates q for large λt; at the values used the error is in the fourth significant figure, and the exact form is used everywhere else.

9.4 Invariance

Every effective count here is invariant under relabelling and under any rescaling of the underlying values that preserves the share vector. Doubling every corridor's volume leaves each s_i unchanged and therefore leaves HHI, N and $\ln N$ unchanged. **It is not invariant under regrouping**, which is the entire content of the perimeter collapse.

The transit model carries a second and different invariance: expected loss is invariant under the partition of V into hops. That invariance is exact, algebraic, and holds for every n; it is the content of H3 and it is what makes hop-splitting an insurance purchase rather than a risk reduction. **It breaks under exactly one condition — correlated freezes — and that condition is named in Section 3.4 rather than discovered by a reader.**

What would break the share invariance: any basis that is not normalised, such as reporting corridor volumes in currency without dividing by the total. **Tested at how many scales?** The invariance is algebraic rather than empirical and was checked at the share vectors reported here: two, four, five, six, eight and twelve entries. No claim of empirical scale-freedom is made on this axis, and Curzi [2026k]'s two-scale demonstration is in a different domain.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. The conserved quantity here is the share vector, $\sum_i s_i = 1$ exactly and

dimensionlessly, and that constraint alone gives the index its bounds. **Remove the normalisation and the effective count ceases to be a count.** Q is a stock with no stated conservation law and no operational unit, and none is claimed. Cartwright [1999] supplies the discipline that makes a partial answer respectable: specify the arrangement within which the law is claimed to hold. **The arrangement claimed here is a normalised share vector on one stated basis, and nothing outside it.** Kirman [1992] is the objection this paper cannot answer: one Q, one δ and one C are written for a heterogeneous group.

9.5 Analogy discipline

borrowing	source	category	justification
effective count as $1/\mathrm{HHI}$	Hill [1973], Jost [2006]	**1 — derivation**	HHI^{-1} *is* the Hill number of order 2; an identity
numbers-equivalent reading	Adelman [1969]	**1 — derivation**	elementary, checkable in two lines
portfolio variance $w'Rw$	Markowitz [1952]	**1 — derivation**	the exposure vector genuinely is a weighted sum of shocks with a correlation matrix
similarity-sensitive diversity	Leinster and Cobbold [2012]	**1 — derivation**, stated domain	exact where R has unit diagonal and non-negative entries
$\ln N$ as entropy	Shannon [1948]	**2 — shared form**	Shannon entropy in nats, dimensionless; no thermodynamic content imported
exponential hazard	standard survival form	**2 — shared form**	a constant-hazard model is assumed, not derived from any observed failure process
flow $\times$ delay as exposure	Little [1961]	**2 — shared form**	the stationarity premises are not verified for these corridors
impossibility of asynchronous consensus	Fischer et al. [1985], Gilbert and Lynch [2002]	**2 — shared form**	a payment system is not a formal asynchronous protocol; the trade-off's shape is what is used
fault-tolerance bound	Lamport et al. [1982]	**2 — shared form**	used for the discipline that redundancy requires independence, not as a protocol result

borrowing	source	category	justification
identity inflation	Douceur [2002]	**2 — shared form**	the impossibility result concerns network identities; the analogy to nesting is stated as an analogy
coupled-network fragility	Buldyrev et al. [2010], Albert et al. [2000]	**2 — shared form**	percolation premises are not shown to hold for correspondent networks
informational cascade	Bikhchandani et al. [1992], Banerjee [1992]	**2 — shared form**	the sequential-decision premises are plausible and untested here
tipping from a small correlated shift	Granovetter [1978], Schelling [1971]	**3 — framing**	prior statement of the aggregate phenomenon, cited as ancestry
normal accidents	Perrow [1984]	**3 — framing**	qualitative organisational theory, never a formal result

The failure this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The concentration arithmetic and the hop-invariance identity are category 1 and need no help; everything from the distributed-systems and network literatures is category 2 and is used for shape.

9.6 Measurement-theoretic status

Shares of settlement value, transit value and corridor value are **ratios of currency amounts** and are ratio-scale by construction, so the concentration instrument is untouched by the scale-type objection. **The hazard rate is a different matter and the objection is conceded.** λ is treated throughout as a ratio-scale quantity supporting multiplication, division and exponentiation, and it is a subjective degree of belief elicited from nobody. Michell [1997] is the strongest available objection to that move — that quantitative structure is assumed rather than tested — and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all, within the representational framework of Krantz et al. [1971]. **The conjoint conditions were not tested for λ, for r, or for the constructed price elasticity, and every ratio computed from one is therefore provisional.** What survives without the test is the *ordering* — a shorter window is better than a longer one, and an indifference hazard still separates settings — and the algebraic invariance of Section 3.4, which does not depend on the scale type at all.

The corpus's habit of collapsing a structured situation into one score applies to λ and is inherited rather than restated; the framework names it once as a framework-level limitation and the response here is to publish the decomposition of λ into four components in Section 3.4 rather than to defend the scalar.

9.7 Postulates

#	statement	status
P1	shares on a stated basis are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$ on that basis	DEFINITION
P3	for n equal shares, HHI $= 1/n$	ARITHMETIC
P4	a currency achieves finality inside exactly one clearing perimeter	DEFINITION (modelling choice; the euro-area assignment is contested, Appendix B)
P5	jurisdictions inside one coordination perimeter act on one decision	POSTULATED (stipulated reference group, Section 3.6)
P6	freeze events are a constant-hazard process, $q = 1 - e^{-\lambda t}$	POSTULATED
P7	freezes are independent across hops	POSTULATED (**false for systemic events, Section 3.4**)
P8	$\lambda = 3.3367 \times 10^{-4}$/h, $r = 0.15$, per-hop cost USD 2,500	POSTULATED (constructed)
P9	the surplus law's input term is $\eta \ln N$	DEFINITION (modelling choice, CCP-A02 via CCP-052)
P10	$\eta = 0.35$, $\delta Q + C = 0.500000$	POSTULATED (fixed in advance)

9.8 The compounding chain

step	consumes	statement	status
L1	P2, P3	$1/$HHI returns n exactly for n equal shares	ARITHMETIC
L2	L1	it is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	it is the Hill number of order 2 — Hill [1973], Jost [2006]	CITED
L4	L3, P4	on the clearing-perimeter basis it counts effective perimeters	DEFINITION
R1a	L4	correspondent shares 46/24/14/10/6 give HHI $= 0.302400$, count 3.306878	ARITHMETIC
R1b	L4, P4, P5	currency shares 69/16.8/5.6/3/2/3.6 collapse to perimeter shares 85.8/8.6/2/3.6, HHI $= 0.745256$, $N_{\text{rail}} = 1.341819$	ARITHMETIC
R1c	R1b, P9, P10	$h_{\text{rail}} = 0.35 \times 0.294026 - 0.5 = -0.397091$	ARITHMETIC

step	consumes	statement	status
R2a	L4	eight correspondent shares give HHI $=0.225984$, count 4.425092, $+33.8\%$	ARITHMETIC
R2b	R2a, P4	the currency vector is unchanged, so N_{rail} is unchanged	ARITHMETIC
R2c	L4, P9, P10	redenominated perimeter shares 66/17/9/8 give HHI $=0.479000$, $N_{\text{rail}}=2.087683$, $h=-0.242381$, gain $+0.154710$	ARITHMETIC
R3a	P6, P7	$\mathbb{E}[\text{loss}]=nkq(1-r)=Vq(1-r)$, so k cancels	ARITHMETIC
R3b	R3a, P8	at $V=40$m, $t=6$h, $q=0.002$: USD 68,000 for $n=1$ and for $n=8$	ARITHMETIC
R3c	R3b	$P(\text{any})=1-(1-q)^n$: 0.2000% at $n=1$, 1.5889% at $n=8$	ARITHMETIC
R4	R3a	expected loss is proportional to value moved, so a 77.0% cut in gross flows is a 77.0% cut in expected loss	ARITHMETIC
R5	R3a, P8	equating landed costs gives $\lambda=4.9412\times10^{-5}$/h, $q_{48}=0.2369\%$	ARITHMETIC
R6	L1	provider shares before and after give 1,074 and 2,406 points, counts 9.310987 and 4.156276	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language; every CITED row names one source and no more. **Four postulates are POSTULATED, one of them — P7 — is stated to be false in the case that produces the tail, and the chain therefore establishes arithmetic consequences of stipulated inputs rather than facts about any payment system.**

9.9 Cross-checks performed

- Every index was recomputed from its printed share vector; all reported vectors sum to 100.0 per cent exactly.
- $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds throughout: $0.211600 \le 0.302400 \le 0.460$ on the correspondent vector and $0.736164 \le 0.745256 \le 0.858$ on the perimeter vector.
- The effective-count ceiling $s_{\max}^{-2}$ is respected: $3.306878 \le 4.7259$ and $1.341819 \le 1.3587$.
- The currency decomposition reproduces the correspondent totals: 46.0 + 7.2 + 8.4 + 5.0
  - 2.4 = 69.0 for the dollar leg, and the six currency shares sum to 100.0.

- **Three source discrepancies were found by this recomputation and are printed rather than corrected in silence.** (i) The source prints **4.424905** effective correspondents for the eight-bank case; $1/0.225984 = 4.425092$, so the source figure is wrong in the fourth decimal place and **this paper prints 4.425092**. The percentage improvement is 33.8 per cent on either figure. (ii) The source prints an expected freeze loss of USD **540,212** in the landed-cost table; the exact value at the stated hazard is USD **540,207**, the difference arising from a rounded intermediate value of q. (iii) The source prints an annual unscreened expected loss of CNY **305,393** where the exact value is CNY **305,388**, from the same cause; the derived break-even hazard reduction of 31.11 per cent is unaffected to four significant figures.

10. Limitations

Every case is constructed. The corridor set, the correspondent shares, the currency decomposition, the perimeter assignments, the hazard rate, the recovery fraction, the per-hop cost, the covenant tolerances, the corridor value, the price elasticity and the provider shares are invented and are labelled as such at each point of use. **No external dataset was collected and none is reported.**

No paper in this corpus reports a first-party measurement, and this one does not either. The corpus's own instrument audit finds that of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated one, and **0 carry a first-party measurement.** That is the central limitation of the whole corpus and it is stated here before a reviewer states it.

λ **is the most load-bearing and least defensible input.** It carries the entire transit analysis, the entire landed-cost comparison and the indifference hazard, and it is a constructed estimate with no interval and no reference class. **The single most useful thing a group could do is replace it with its own realised experience — every screening hold, every delayed payment, every returned instruction, recorded with elapsed times, over three years. Nobody keeps that record and everybody could.**

The independence assumption across hops is false in the scenario that matters. P7 holds for idiosyncratic freezes and fails for systemic ones, so the binomial distribution in Section 7.3 overstates the diversification benefit of splitting exactly when the tail arrives. **The paper states this rather than reporting the split as protection.**

The perimeter assignments are stipulated, not identified [Manski, 1993], and the remedy adopted is stipulation with a defence [Brock and Durlauf, 2001]. No randomisation, instrument or partial-population variation was available. **One assignment in particular is contestable**: the euro area is treated as inside the Western clearing perimeter, which affects every measurement in Section 7.1, and the alternative is not computed here. It is item 1 of Appendix B.

Jurisdiction-specific legal and regulatory claims are not cited to primary sources. The descriptions of settlement-finality legislation, the messaging-service prohibitions, the reserve-immobilisation instruments, the correspondent-banking recommendations, the participant counts and volumes of named clearing systems, and the enforcement resolutions are taken from the source manuscript. **The bibliography contains general comparative, treaty and standards material only; it contains no statutes, regulations, official statistics, registry documents or case reports for any individual jurisdiction or operator.** Those claims are described rather than asserted and are itemised in Appendix B. **This is a real gap and it is not closed here.**

Two works are named in the source's prose with no citation key and are not in this bibliography: an account of an eleventh-century traders' coalition and a model of the law merchant with a private judge, both supporting Section 6.2's claim that reputation in a repeated game sustains obligation without an adjudicating forum. The claim is instead supported here by Axelrod [1984], Gambetta [1988] and Ostrom [1990], which are in the bibliography and do support it, and the gap is declared rather than papered over.

Published measurements are described and not quoted. The decline in active correspondent relationships since 2011, the regional cost of remittances, the daily values cleared by named systems, and the amounts of two enforcement resolutions are all in the source manuscript as figures. **None is used as evidence in this paper and none appears in any result**, because none could be verified against a primary source within the bibliography's coverage.

The instrument measures independence and not capacity. N_{rail} says nothing about whether a perimeter can carry the volume, at what price, or whether an institution will accept the instruction. A group at $N_{\text{rail}} = 2.09$ whose entire bridging capacity sits with one institution has moved risk rather than reduced it.

Small-sample bias is not addressed [Chao et al., 2014], and the instrument is least informative in the dominated-unit regime [Golosov, 2010] — which is where the post-exit corridor sits, at 34.0 per cent in one provider.

Model comparison was not performed. No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. The instrument is asserted on the strength of the identity chain in Section 9.8 and not on comparative fit.

The functional form of the surplus term is underdetermined by the evidence. The corpus proposes a logarithm; a sub-linear power law and an $n \log n$ form fit the same qualitative facts. Nothing here discriminates between them and the paper concedes that nothing yet does; Peters and Gell-Mann [2016] is the one genuine strengthening available.

No differential prediction is offered. Durlauf [2005] asks for the prediction only this model makes, and the instrument makes none: any correlation-aware concentration measure would produce the same collapse, and any expected-value calculation would produce the same invariance. **The contribution is the share basis, the layering correction and the discipline of printing all three counts, not a uniquely discriminating forecast.**

Rigour checks not met, listed by name.

1. **No as-of date, because no real corridor was measured.** A concentration figure from real flows requires its source and its date; every share vector here is constructed. Appendix A makes both mandatory for any application to a real structure.
2. **No uncertainty is reported anywhere, because nothing is estimated.**
3. **The dimension of η is supplied by this paper and not by the source.**
4. **Q, C and h have no operational unit**, and the transit model's currency figures are never added to them.
5. **The surplus law's large-N limit is a defect, not a result.**
6. **The conjoint conditions were not tested for λ, r or the price elasticity** [Michell, 1997, Luce and Tukey, 1964].
7. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. Any restatement reaching for a heavy-tail claim about payment shares must run it first and must read Stumpf and Porter [2012] on why passing it still would not identify a mechanism.
8. **The distributed-systems, network and cascade borrowings are category 2, not category 1** [Fischer et al., 1985, Gilbert and Lynch, 2002, Buldyrev et al., 2010, Bikhchandani et al., 1992].
9. **The constant-hazard assumption is untested.** No failure-time data was examined and no alternative hazard shape was fitted.
10. **Aggregation is unaddressed** [Kirman, 1992].
11. **Expected value and time average are not the same thing, and every figure here is the first** [Peters, 2019].
12. **The instrument is performative and its own parameters are not exempt** [MacKenzie and Millo, 2003, Lucas, 1976].
13. **There is no conservation law for Q** [Mirowski, 1989].
14. **Three arithmetic discrepancies in the source are reported rather than corrected in silence** (Section 9.9).

11. Conclusion

This paper measures the settlement rail, and the following statements are the fixed text of its results.

R1. The clearing-perimeter measurement: a naive correspondent HHI of 0.302400, reading 3.306878 effective correspondents, collapses to a perimeter HHI of 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by settlement currency and then by the perimeter in which each currency achieves finality. The rail-axis surplus term is $0.35 \ln(1.341819) - 0.500000 = -0.397091$, against -0.122417 on the jurisdictional axis — **3.24 times worse on the axis nobody runs.**

R2. Adding correspondents raises the naive count by 33.8 per cent to 4.425092 and leaves N_{rail} at 1.341819 exactly; **only currency redenomination moves it**, to 2.087683 with $h_{\text{rail}} = -0.242381$, a gain of $+0.154710$ obtained with no new entity, no new jurisdiction and no new bank.

R3. The transit-loss model $\mathbb{E}[\text{loss}] = V(1-e^{-\lambda t})(1-r)$ is **invariant to hop count at USD 68,000** on the constructed corridor, while the probability of any loss rises from 0.2000 to 1.5889 per cent across eight hops and the worst single loss falls from USD 34.0m to USD 4.25m. **The window, not the hop size, is the variable.**

R4. Multilateral netting to a single settlement position cuts the constructed group's expected transit loss by **77.0 per cent**, with no new rail and no new counterparty.

R5. The indifference hazard: replacing a 48-hour correspondent transit with a half-hour rail is justified above a **0.2369 per cent** per-transit freeze hazard and not below it. Counterparty pre-screening returns **2.57 to one** on the constructed supplier corridor and pays for itself if it removes 31.1 per cent of the counterparty hazard.

R6. Enforcement-driven exit of licensed informal-transfer providers from twelve to five moves the index from **1,074 to 2,406 points** and the effective provider count from 9.310987 to 4.156276, a fall of **55.4 per cent** — clearing the published structural-presumption screen by 606 points with no transaction and no filing. One layer down, the five survivors bank through **1.650710** effective correspondents, so one institution's exit removes 73.0 per cent of the corridor's licensed capacity.

Counter-result. After the largest available intervention the rail remains the structure's weakest axis, at 2.087683 effective perimeters against 2.941176 on the jurisdictional axis and a break-even of 4.172734. The residual dollar share of 52.0 per cent **is a property of the world rather than of the design**, and the depository layer is not remediable by a private group at all. A concentration that cannot be fixed should be sized, not ignored.

Two further results are established as method rather than as measurement. **A clearing system and a messaging system are different layers and are not substitutes**, so a structure reporting them as two rails has recorded one dependency twice — and measured correctly, one messaging network at 100 per cent and 85 per cent on that network plus 15 per cent on a second clearing system messaged over the first are the same number. **And expected transit loss is flat in hop size**, so splitting a payment is a purchase of insurance against the worst case at a stated premium and not a reduction in risk; any presentation claiming otherwise is wrong as a matter of algebra rather than of judgement.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the corridor set, the correspondent and currency shares, the perimeter assignments, the hazard and recovery parameters, the cost model, the covenant tolerances, the corridor value and price elasticity, and the provider shares — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-061_fig01.py` through `figs/src/CCP-061_fig05.py`), which import the shared figure-style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Published measurements referred to in the source manuscript are described and not quoted as evidence. The bibliography contains no official statistics, statutes, regulations, registry documents or case reports for any individual jurisdiction, operator or institution. Appendix B lists the claims affected. Any reader relying on those descriptions must verify them against the official sources.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every institution, corridor, counterparty and transaction described is invented. Section 7.6 concerns the aggregate cost of a policy to a class of senders and uses no individual data of any kind.

Legal, tax and regulatory advice

This paper is analytical and is not legal, tax, regulatory or investment advice. It describes payment infrastructure, settlement mechanisms, correspondent relationships and value-transfer arrangements for the purpose of measuring concentration and pricing structural choices. No recommendation is made in respect of any particular person, institution, corridor or rail. Messaging and clearing arrangements, settlement-finality regimes, sanctions and designation instruments, licensing perimeters and the standards applicable to correspondent banking all change, frequently and at short notice; **every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel and with each operator's own current published material before any reliance.** The rail layer changes faster than any other subject in this series, and a two-year-old rail memorandum is worse than none, because it will be trusted.

Appendix A. Reporting standards

A.1 The rail register. Any structure measured on this axis reports the following, and nothing less.

```
1  the corridor inventory: counterparty, corridor, annual value,
   with every intermediary traced
2  correspondent shares and the naive effective correspondent count
```

```
  3  the currency decomposition of each correspondent's volume
  4  currency shares and the effective currency count
  5  the mapping of each currency to its clearing perimeter, with
     the reasoning recorded per currency
  6  perimeter shares, the perimeter HHI and N_rail
  7  all three counts reported together, never one alone
  8  ln(N_rail), eta ln(N_rail) and h at the stated parameters
  9  direct versus indirect participation, verified bank by bank
 10  the nesting position: which respondents have their own
     respondents
 11  the custody chain mapped to the depository, not to the

```

Item 7 is the one that prevents the error this paper measures, and item 12 decays first, because the rail layer changes faster than any other.

A.2 The transit policy. A written document, approved at board level and reviewed annually, stating: λ, r and the per-hop cost per corridor with a named owner for each; the maximum exposure window per corridor and the rail selected to meet it, **the window being the primary control**; the maximum hop size derived from the covenant tolerance rather than chosen; the maximum concurrent transit exposure across all corridors, **because eight hops in flight simultaneously are one hop for systemic purposes**; the counterparty pre-screening protocol, including the chain and not only the direct counterparty; rail, issuer, network and venue diversification limits; the mid-transit runbook with its documentation pack pre-assembled and tested annually; the balance limit above which a settlement balance is reclassified as a holding and enters the jurisdictional measurement; the landed-cost model per corridor; and the annual difference against last year's policy and last year's realised experience.

Appendix B. Claims requiring verification against primary sources

The following statements rest on regulatory, operational or statistical detail that changes, and **none is cited to the bibliography, which contains no official statistics, statutes, regulations or case reports for any individual jurisdiction, operator or institution.** They are reproduced from the source manuscript and require confirmation against the official sources before any reliance. The source manuscript's own verification registers run to more than seventy numbered items across the three chapters and are condensed here without loss of subject.

1. **The treatment of the euro area as a Western clearing perimeter.** This is a contestable call with consequences for every measurement in Section 7.1. The coordination test should be applied to it explicitly and the alternative computed. **This is the single most consequential unverified assumption in the paper.**
2. **The messaging cooperative**: founding and live dates, legal form, oversight arrangements and the composition of the central-bank oversight group; the current institution count and daily message volume; the message types referred to and the cover-payment standard.
3. **The message-standard migration**: the current end date of the coexistence period, which has been revised, and the current status [International Organization for Standardization, 2013].
4. **Messaging disconnections and reconnections of designated institutions**: the instruments requiring each, their articles, their dates and their scope, in each episode referred to.
5. **The 2022 immobilisation of central bank reserves**: the prohibiting article and amending instrument, the approximate total, the proportion held at any one institution, and

all subsequent measures concerning the extraordinary revenues. **Every number and instrument here needs primary sourcing.**

6. **The renminbi clearing system**: launch and phase dates, the operator's corporate form and its relationship to the central bank, current direct and indirect participant counts and country coverage, and the messaging arrangements available to each class of participant.
7. **Cleared values**: annual value through the renminbi system and daily values through the two principal dollar systems, from each operator's own published statistics. **No figure in this paper depends on these and none is quoted.**
8. **Currency payment-share trackers**, and the extent to which traffic native to a clearing system is excluded from the series.
9. **The other messaging and regional clearing arrangements** referred to: operators, establishment dates, participant counts, currencies supported and functional scope for each; and any instrument prohibiting operators in one bloc from using another's network.
10. **Cross-border central bank digital currency projects**: participating institutions, milestones and dates, and the current status and ownership of each.
11. **Correspondent-banking decline data**: the specific reports, the measured percentage decline in active relationships, the period and the corridor breakdown. The source states "in the region of a quarter" and **this paper uses no figure.**
12. **Enforcement resolutions**: the two well-known resolutions referred to in Section 4.1, their amounts, charging instruments and terms. **This paper quotes neither amount.**
13. **The correspondent-banking due-diligence questionnaire** and the international recommendations on correspondent banking and wire transfers: current version, current text and interpretive notes [Financial Action Task Force, 2012].
14. **The settlement-failure episode of 1974** and the payment-versus-payment institution that answered it: the failure date and mechanism; the current eligible-currency list, membership and average daily value settled.
15. **Settlement-finality legislation**: the finality provisions, the designation mechanism, the implementing and onshored instruments in each relevant jurisdiction, and the wholesale funds-transfer code and central-bank regulation governing irrevocability in the other.
16. **The depository layer**: the number of international depositories, the concentration of cross-border holdings and any published measure of it. **The effective count of 1.15 quoted in the source is a constructed illustration and is not a measurement of any real market; it is not used in any result in this paper.**
17. **Direct-participation status of any named institution** in any clearing system, which must be answered bank by bank rather than jurisdiction by jurisdiction.
18. **Private-order enforcement**: the account of an eleventh-century traders' coalition and the model of the law merchant with a private judge, both named in the source's prose without citation keys and **absent from this paper's bibliography** (Section 10).
19. **Exchange-rate regimes and parallel premia**: the episodes named in the source, their dates and the size of each premium; and regional remittance cost data.
20. **Regulatory perimeters for fast rails**: issuer, reserve, redemption and licensing requirements in each relevant jurisdiction, several of which are less than three years old and none of which is stable.
21. **All cost figures, hazard rates, corridor values, elasticities and share vectors in this paper are constructed.** They are not quotations, benchmarks or estimates of any real corridor, and no real fee schedule, tariff or published statistic was used to produce them.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 62

The Carve-Out Cascade: Pledge Triggers, Antitrust Walls, and Legal-Family Interfaces Priced as Cost

Abstract. A listing that carves out a minority creates the collateral against which the retained block is pledged, and the pledge converts an ownership position into a path-dependent one. We derive the trigger d* = 1 - LTV0/(1 - m) and show that a 50 per cent loan-to-value advance against a 35 per cent maintenance requirement produces the first margin call at a 23.076923 per cent drawdown, not the 50 per cent that borrowers report believing they have. The forced sale that follows takes the principal to exactly 50.000000 per cent of the company at a 36.000000 per cent drawdown and to 38.095238 per cent at 40 per cent, and exhausts the collateral equity at 50 per cent. An unlevered route raising the same cash by floating 60 per cent crosses the levered route at a 39.393939 per cent drawdown. Under a constructed first-passage model at 40 per cent volatility, the ten-year probability of touching the control-losing barrier is 76.347 per cent. Cross-default converts nine agreements into thirty-six pairwise links and a 36.9751 per cent annual probability that one trips at a 5 per cent per-agreement hazard. On the antitrust side the Hart-Scott-Rodino delta reduces to 2s1s2, so the 100-point test binds exactly when s1s2 > 50, and the Clayton section 8 de minimis provisions exempt a 1.99/99.00 pair while catching a 4.10/4.10 pair. Legal-family diversity is reported as a cost line, not resilience.

Keywords: pledged shares; maintenance requirement; forced sale; cross-default; interlocking directorates; merger screening; conflict of laws; characterisation

Series: D. Structure and Resilience **Paper:** CCP-062

1. Introduction

A holder who sells a minority of a company to the public and pledges the retained majority against a loan has performed an elegant, lawful, fully disclosed piece of engineering. This paper computes what it costs, and the cost is not where the borrower believes it is.

The listing is what creates the collateral. An unlisted majority block of a private company is not security a lender will advance against at any tolerable rate, because it has no daily

mark, no observable liquidity, no mechanism by which the lender can convert it into money quickly, and no third party willing to price it on a Wednesday afternoon. Listing a minority manufactures all four of those properties for the majority. The float is the price discovery; the exchange is the exit; the daily close is the mark the maintenance clause is tested against. **The same act that creates the borrowing capacity creates the daily mark that the margin call runs off, so the failure mode is not a bolt-on to the design — it is the design, seen from the other side.**

The consequence is one line of arithmetic. With an opening loan-to-value LTV_0 and a maintenance requirement m — the borrower's equity in the collateral must stay at or above m of collateral value — the first margin call falls at a drawdown

$$d^{*} = 1 - \frac{\mathrm{LTV}_0}{1 - m}.$$

At $\mathrm{LTV}_0 = 50\%$ **and** $m = 35\%$ **the first call falls at a 23.076923 per cent drawdown, not at the 50 per cent that borrowers report believing they have.** A fall of a little under a quarter is what equity markets deliver on ordinary business: a rate surprise, an earnings miss, a sector rotation, a short report, a legal setback at a competitor.

What follows the trigger is worse and is equally deterministic. The forced sale that restores the maintenance ratio takes an eighty per cent holder to **exactly 50.000000 per cent at a 36.000000 per cent drawdown**, to 38.095238 per cent at 40 per cent, and exhausts the collateral equity at 50 per cent. **None of this is misfortune. The trigger is a deterministic function of two numbers agreed at signing, the forced-sale quantity is a deterministic function of the trigger and the price, and the control outcome is a deterministic function of the forced-sale quantity.** No relationship, reputation or negotiation changes it, because a maintenance clause is a mechanical valuation test run against a published close and the risk officer applying it has no discretion over it.

1.1 What this paper adds

Three measurements and three identities, all checkable in a line.

First, the trigger and the control-loss surface, computed as closed forms and tabulated, together with the crossover against the unlevered route that raises the same cash by floating more of the company. The two routes cross at a 39.393939 per cent drawdown: **below it the pledge retains more of the company, above it the plain float does.**

Second, the propagation arithmetic. Cross-default converts nine agreements into thirty-six pairwise links and a 36.9751 per cent annual probability that one of them trips at a five per cent per-agreement hazard. The same combinatorial object turns ten legal touchpoints into forty-five interfaces, and routing them all through one apex cuts that to nine — **an 80.0000 per cent reduction obtained by changing the topology and nothing else.**

Third, two antitrust identities that make a regulatory constraint checkable rather than predictable. The index change on combining two firms with percentage shares s_1 and s_2 is exactly $2s_1s_2$, so the hundred-point screen binds exactly when $s_1s_2 > 50$; and the de minimis provisions of the interlocking-directorate prohibition are asymmetric in a way that exempts a 1.99 / 99.00 per cent pair and catches a 4.10 / 4.10 per cent pair.

And one demotion. Legal-family diversity is reported here as a **cost line, not a resilience line.** A structure spread across more legal families is not more resilient; it is more expensive, because each family boundary is an interface requiring recognition, characterisation and enforcement opinions. **Reporting legal-family diversity as though it were coordination-perimeter diversity is the same category error as reporting a naive jurisdictional index on a single-perimeter structure**, and it is made by the same people for the same reason.

1.2 The standing constraint

Every arrangement examined here is measured under the corpus's formation test: it qualifies only if it would still perform its function were every element disclosed to every authority with jurisdiction over any part of it. That test is satisfied by construction throughout this paper. **A pledge over listed securities is disclosed in the issuer's filings; an interlocking board seat is in the annual report; a merger above the threshold is notified before closing; and a legal-family interface is a written opinion that exists precisely to be produced.** The open-design principle [Kerckhoffs, 1883, Saltzer and Schroeder, 1975] and the older argument for publicity as a discipline [Brandeis, 1914] are the same constraint stated elsewhere. **In this subject disclosure is not a cost of the structure; it is the structure's evidence base**, and the failure mode is not that a fact becomes known but that an arithmetic consequence of a known fact was never computed.

The paper presupposes the founding reframing of Curzi [2026] — comfort is the felt total of present costs, so a present arrangement is a local minimum of the cost landscape by definition rather than by luck. **That is why the cascade is built: at signing it is a local minimum, and the arithmetic that destroys it operates only on paths the borrower has not priced.**

2. Hypotheses

Four hypotheses, each falsifiable in the sense Platt [1964] requires and each carrying a point prediction with a constant attached rather than a direction, which is what Meehl [1967] asks of a claim that intends to be tested.

H1 — the trigger hypothesis. The first margin call on a pledged block is a deterministic function of the opening loan-to-value and the maintenance requirement alone, and is far shallower than the loan-to-value suggests. *Predicted:* $d^{*} = 1 - \mathrm{LTV}_{0}/(1-m)$, so at $\mathrm{LTV}_{0} = 50\%$ and $m = 35\%$ the call falls at 23.076923% and not at 50 per cent; at $m = 35\%$ every five points of additional loan-to-value costs exactly 7.692308 points of cushion. *Falsified by:* a facility whose first call depends on the size of the block, the identity of the borrower, or anything other than those two parameters.

H2 — the control-loss hypothesis. The forced sale that restores the maintenance ratio costs majority control at a drawdown computable in advance, and the levered and unlevered routes cross at a single point. *Predicted:* an eighty per cent holder reaches exactly 50.000000% at a 36.000000% drawdown, 38.095238% at 40 per cent, and zero collateral equity at 50 per cent; the levered and unlevered routes raising identical cash cross at 39.393939%. *Falsified by:* any of those four figures failing to reproduce from the sale rule $x = V - (V - L)/m$.

H3 — the base-case hypothesis. For a newly listed, concentrated, single-name equity, touching the control-losing barrier is not a tail event over a structural horizon. *Criterion, fixed in advance:* under the constructed first-passage model at $\sigma = 40\%$ and $\mu = 6\%$, the ten-year probability of touching the 36 per cent barrier exceeds one half. *Predicted:* 76.347%, with a median time to the 23.076923 per cent barrier of 0.8786 years. *Falsified by:* a volatility low enough to put the ten-year probability below one half — which at $\mu = 6\%$ requires σ below roughly 28 per cent, and **a reader who believes the security is that quiet should substitute it and re-read the table.**

H4 — the delta-identity hypothesis. The merger-screen change test has a closed form that makes it checkable without a model. *Predicted:* $\Delta = (s_1 + s_2)^2 - s_1^2 - s_2^2 = 2 s_1 s_2$ exactly, so the hundred-point screen binds exactly when $s_1 s_2 > 50$, which for an equal pair is 7.0711% each; and a sequential roll-up produces a strictly larger cumulative change than the same aggregate bought in one step. *Falsified by:* an arithmetic counterexample, of which there is none, so **H4 is an identity and is labelled as one rather than presented as a finding.**

Not hypotheses, and labelled as such.

- *The first-passage model itself* — geometric Brownian motion with constant drift and volatility — is a **modelling choice**. It is not fitted to any security and its parameters are

stipulated. Section 10 states that the constant-volatility assumption is the least defensible thing in the paper.
- *The 35 per cent maintenance level* and the 50 per cent opening loan-to-value are **stipulated constructed parameters**, plausible for a concentrated single-name block and not a quotation from any facility.
- *The claim that borrowers systematically misread a loan-to-value ratio as a drawdown cushion* is **this work's own conjecture and is left uncited.** The bibliography contains measurement theory but no judgment-and-decision literature that supports it, and Section 10 records the gap rather than attaching a citation that would not survive a check.
- *The identification of legal-family count with a cost* rather than a resilience measure is a **definition**, and its content is in the interface count rather than in the identification.

3. Method

3.1 The cascade, and the two closed forms

CONSTRUCTED CASE throughout. All facts invented. An operating company whose equity is worth 100 units, wholly owned. Sell 20 per cent to public investors; retain 80. Two economically different versions exist and the distinction governs everything downstream: a primary offering issues new shares and the proceeds go to the company, while a secondary offering sells existing shares and the proceeds go to the selling holder. **The cascade assumes a secondary or mixed offering, because it assumes the holder ends with cash. State which one before modelling anything: the two produce identical ownership percentages and opposite cash positions.**

The retained block is now listed securities with a daily close, a public register, a settlement system and a market. Those are the four properties a securities-backed lender requires and none of them existed before the listing. Pledged at $\text{LTV}_0 = 50\%$:

```
collateral value at inception   80.000000
advance                         40.000000
cash from the offering          20.000000
TOTAL DEPLOYABLE                60.000000
retained ownership              80.000000%
```

The alternative that raises the same 60 without leverage is to float 60 per cent and retain 40. **Forty percentage points of retained control is what the leverage buys**, and it is the difference between a group whose apex controls its operating subsidiary and one whose apex holds a large minority in a company run by somebody else.

The first closed form is the trigger. The maintenance test is $(V - L)/V \geq m$, equivalently $L \leq (1 - m)V$, so the collateral value at which the call arrives is $V^* = L/(1 - m)$ and

$$d^* = 1 - \frac{V^*}{V_0} = 1 - \frac{\text{LTV}_0}{1 - m}.$$

The second closed form is the forced sale. At a drawdown d with price $p = 1 - d$ and collateral value $V = V_0 p$, the proceeds required to restore the maintenance ratio solve $(V - x - L)/(V - x) = m$, giving

$$x = V - \frac{V - L}{m}, \qquad \text{shares sold} = \frac{x}{p}.$$

The required sale grows faster than the price falls, which is why the margin call arrives when the shares are cheapest and selling them is most destructive. That is not bad luck; it is the definition of the instrument, since the call is triggered by the fall and the call and the low price are the same event.

3.2 Why the maintenance clause is not a covenant

A covenant is a promise: breach it and there is a default, a notice, a cure period, negotiation, waivers, amendments, fees and lawyers. A maintenance requirement in a securities-backed facility is usually not that. It is a mechanical valuation test run against a published closing price, and the consequence of failing it is a demand for cash or additional collateral within a short window — often hours rather than days — after which the lender may sell. **Corporate debt fails slowly and negotiably; margin debt fails quickly and mechanically, and the speed is the point of the product from the lender's side.**

That difference is also why the maintenance level is a measure of the *lender's* safety and not the borrower's. The lender priced the facility on the assumption that it can liquidate before the collateral falls below the loan, and the maintenance level exists to give it that assumption with room to spare.

3.3 The first-passage model

Model the share price as geometric Brownian motion with drift μ and volatility σ, and use the standard first-passage result for the probability that the running minimum touches a barrier B below the starting value S_0 within horizon T. With $b = \ln(B/S_0)$ and $\nu = \mu - \sigma^2/2$,

$$P = \Phi\left(\frac{b - \nu T}{\sigma\sqrt{T}}\right) + e^{2\nu b/\sigma^2}\,\Phi\left(\frac{b + \nu T}{\sigma\sqrt{T}}\right).$$

CONSTRUCTED MODEL. Illustrative only. Not an estimate of any real security's behaviour. The model is used as a **shared mathematical form**, not as a derivation: no claim is made that any particular security's returns are log-normal with constant volatility, and Sornette [2003] is the standing reason to doubt it — the empirically interesting behaviour of equity prices lives in the fat tails and in endogenous feedback that a constant-volatility diffusion cannot produce. Longin and Solnik [2001] and Ang and Chen [2002] measure the asymmetry directly: extreme correlation is concentrated in downturns. **Both point the same way — the model almost certainly understates the probability of the barrier being touched — so the results here are read as a lower bound rather than as an estimate.**

A distinction the corpus insists on is kept here. Curzi [2026] states its own path-weighting pedigree honestly as exponential, Boltzmann-style weighting of states by cost, e^{-R}, and explicitly not as a phase-based path amplitude. **The computation in this section is a genuine first-passage probability for a stochastic process, and it is neither of those things**; conflating a weighting scheme with a probability is exactly the move that discipline exists to prevent.

3.4 The combinatorics of links and interfaces

Two of this paper's results are the same combinatorial object seen twice. A set of n agreements each cross-defaulting to every other has $\binom{n}{2} = n(n-1)/2$ pairwise links; a set of n legal touchpoints each having to interface with every other has the same count. **At $n = 9$ that is 36 links; at $n = 10$ it is 45 interfaces.** Routing every interface through a single apex replaces the complete graph with a star and the count falls to $n - 1$.

That adding units inside one boundary adds coordination cost at order $n(n-1)/2$ while adding nothing to independence is the general organisational statement of the same arithmetic [Brooks, 1975]. **The corpus carries an exhaustive verification of a pairwise identity over exactly this object: Curzi [2026] proves its doubling theorem and checks it over all sixty-six pairs at $N = 12$, and $\binom{12}{2} = 66$ is the same $\binom{n}{2}$ that produces the thirty-six links and the forty-five interfaces here.**

Under independent per-agreement annual breach hazard q,

$$P(\text{at least one breach}) = 1 - (1-q)^n,$$

and with universal cross-default that is the probability the whole group defaults. **Independence is the assumption doing the work and it is the wrong assumption**, because a breach is more likely in exactly the conditions that make other breaches more likely. Buldyrev et al. [2010] is the formal statement that coupling destroys the independence a naive count assumes, used here as a **shared structural form and not as a derivation** — no percolation premise has been shown to hold for a set of financing covenants — and Watts [2002] is the closest available model of the propagation itself: a global cascade is possible only in a connected region of parameter space, and adding links moves a system into and then out of that region. Perrow [1984] reached the organisational version first and is cited as framing. Albert et al. [2000]'s robust-yet-fragile shape is used for its shape alone, with Doyle et al. [2005] as the standing correction to reading too much into it.

The engineering response follows from the arithmetic and not from judgement: cut the number of links rather than negotiate each hazard down. Curzi [2026] is the corpus's general result of that form — moving from terminal inspection to per-stage checking across seven stages at a per-stage defect rate of 0.10 raises final yield from 47.83 per cent to 93.21 per cent at 0.63 reworks per unit. **Universal cross-default is terminal inspection: one failure anywhere condemns the whole run. Materiality thresholds, grace periods and de-linking are per-stage checks, and the yield arithmetic is the same.**

3.5 The concentration instrument, and which effective count

For shares s_i summing to one on a stated basis, HHI $= \sum_i s_i^2$ and the effective count is $1/\text{HHI}$. The index is Hirschman [1945]'s and, independently in sum-of-squares form, Herfindahl [1950]'s; the numbers-equivalent reading is Adelman [1969]'s; Stigler [1964] is the oligopoly argument that made it the regulator's instrument. Competition practice states it in points on percentage shares with a structural presumption above 1,800 points and a change above 100 [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]; the resilience application states it as a fraction.

Which effective count. $1/\text{HHI}$ is the Hill number of order two [Hill, 1973], the numbers-equivalent that Jost [2006] distinguishes from the index itself, and $\exp(H)$ for Shannon entropy [Shannon, 1948] is the same family at order one. **The corpus's other effective count, the affine $N_{\text{eff}} = 1 + (N-1)u$ of Curzi [2026c], is a linear interpolation between 1 and N, is not a Hill number of any order, and carries no external support**; that paper badges it as a design axiom rather than a theorem. **Every effective count in this paper is $1/\text{HHI}$ on a stated share basis**, and the discipline Hurlbert [1971] demands — the word carries no content without its formula — is imposed throughout. The general correlation-aware form $1/(w'Rw)$, its identity with the naive and bloc indices under two correlation assumptions, and its correspondence with the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012] are established in Curzi [2026] and are used here without restatement.

No distributional or scaling claim is made anywhere in this paper. A product market descending 22 / 18 / 14 / 11 / 8 / 7 / 6 / 5 / 4 with a fringe, or a share-price path with a fat left tail, invites one. **No distribution is fitted, no tail is characterised and no power law is asserted.** Clauset et al. [2009] is the reason the procedure is named and not run: a principled maximum-likelihood fit with a goodness-of-fit test and a likelihood-ratio comparison leaves few canonical data sets standing, and a straight line on log-log axes is not evidence. Stumpf and Porter [2012] adds why passing it would not be enough. **Every effective count here is a statistic of a finite share vector, not an estimate of a distribution, and the first-passage model is a stipulated diffusion rather than a fitted process.** Small-sample bias is not addressed [Chao et al., 2014], and effective-number measures behave poorly where one unit dominates [Golosov, 2010].

3.6 Identification, reflexivity, and the status of the perimeter assignment

The perimeter assignments used in Section 7.5 are inputs to the instrument and carry an identification problem. Treating a set of jurisdictions as one coordination perimeter is a statement

about a group influencing its members while the members constitute the group. **Manski [1993] proves that the endogenous effect in a linear-in-means reflexive specification is not identified from observational data.** The remedy adopted here is stipulation with a defence, the route Brock and Durlauf [2001] shows can be made rigorous, and **the price is that every perimeter figure in this paper is a modelling position rather than an identified empirical result.**

The collapse mechanism has a formal ancestry and is not new machinery. Granovetter [1978] establishes that the distribution of individual thresholds rather than the mean determines whether a collective outcome tips, and Schelling [1971] is the canonical demonstration that a mild individual preference produces a sharp aggregate outcome — **the strongest available warning against reading an individual-level parameter straight into an aggregate.** A margin cascade is the same object with a mechanical threshold in place of a preference.

A second reflexivity is specific to this instrument and is the sharpest available illustration of the general problem. A forced sale into a falling market is a case in which the act of measuring and responding changes the measured quantity: Soros [2013] is the standing statement of that circularity in markets, and Sornette [2003] the argument that endogenous feedback rather than exogenous news produces the largest moves. Under a constructed permanent-impact model in which selling one float's worth of stock moves the price by 15 per cent, the sale itself takes the price from 0.640000 to 0.496000, the residual equity ratio falls to 16.129032 per cent, **and the position is called again before the first call has settled.** The model is constructed; the sign is not.

4. The pledge as an instrument

4.1 Structural subordination

The 100 in the cascade is the *equity* value of the operating company. If that company carries its own debt, the debt sits ahead of the equity in its own waterfall and the pledged block is a claim on the residual. Two consequences follow, both arithmetic.

The recovery profile has a cliff. With senior debt of 35 ahead of the pledged block, the holding-company lender is fully covered over a wide range of enterprise values and then is not covered at all, because a residual claim's value reaches zero at a strictly positive enterprise value. **The lender knows this, which is why its covenant package forces liquidation long before enterprise value reaches the region where its recovery is impaired.**

The drawdown in the collateral is a multiple of the drawdown in the business. With equity of 100 and senior debt of 35, enterprise value is 135 and the equity beta to enterprise value is $135/100 = 1.35$. The trigger and control-loss drawdowns therefore translate to 17.094017 per cent and 26.666667 per cent of *enterprise* value. **A 26.666667 per cent decline in the value of the business costs the principal control of it**, and that is the sentence usually missing from the proposal.

4.2 Change of control, and the second-order cascade

Enforcement of a share pledge transfers shares, and transferring shares is a change of control. Change-of-control provisions are the most widely distributed clause in a corporate group and sit in facilities, indentures, joint-venture agreements, key customer and supplier contracts, licences and franchises, regulated permissions, property leases, incentive plans, and government incentives whose eligibility conditions are re-tested.

The last of those is where the cascade does its real damage. Where an operating company holds a promotion or a treaty-based ownership right whose conditions include the identity or nationality of its shareholders, **a pledge enforcement in one financial centre can extinguish an operating privilege in another, and it does so without anybody in the second being consulted.** That is a financing decision at the holding layer reaching through the group into an operating

condition that was never part of the credit analysis. The corpus's succession arithmetic is the same shape one layer over: Curzi [2026] splits a forced-heirship exposure into a situs-capped levy of USD 6.70m — 11.2 per cent of the notional reserved share — and an unaffected tax exposure of USD 27.00m, **and in both cases the number that matters is produced by a rule in a jurisdiction nobody in the transaction was looking at.**

The engineering response is a change-of-control map: every agreement in the group with such a provision, its trigger threshold, its consequence, and whether consent can be obtained in advance. It is dull work, it takes weeks, **and the number that comes out of it is frequently larger than the loan.**

Why the map is the binding constraint rather than the drafting is worth stating in the corpus's own terms. Curzi [2026x] computes a receiver-limited channel capacity — of order 70 to 106 bit/s at a mechanotransduction bandwidth near 10.6 Hz and 20 dB signal-to-noise, delivering a 40-bit address in about half a second — and the operative lesson is that **throughput is set by the receiver and by the narrowest element, not by the sender's intent.** The analogy is used as a shared form and nothing more: a group's ability to act on an enforcement is bounded not by how much has been written down but by how quickly the constrained party can be told and can respond, and the margin window is hours.

4.3 Rehypothecation

Where collateral is delivered to a lender or intermediary, the documents may permit that party to use it — to re-pledge, lend or sell it, subject to an obligation to return equivalent securities. The commercial rationale is real, since the lender's ability to fund itself against the collateral is part of what makes the borrowing cheap.

The risk is a change in the character of the borrower's claim. Where the collateral is held subject to a security interest and segregated, the borrower's right on redemption is proprietary and the specific securities come back. Where it has been transferred outright or re-pledged onward under a right of use, the borrower's right may be a contractual claim for equivalent securities — and in the counterparty's insolvency a contractual claim ranks with the other unsecured creditors.

right-of-use limit	block re-pledged onward	proprietary claim preserved
0%	0.00	80.00
25%	20.00	60.00
50%	40.00	40.00
100%	80.00	0.00
140%	80.00 (all of it)	0.00

A right of use above 100 per cent of collateral value does not mean more shares leave; it means all of them do, with room to spare. The excess is about the intermediary's funding rather than about the block, and the consequence for the borrower is identical at every level from 100 per cent upward. Two disciplines follow: negotiate the right of use explicitly and cap it, ideally at zero for a control block; and read the governing law and the account structure, **because whether a claim is proprietary or contractual is decided by insolvency law and by the terms of the arrangement** [Torremans et al., 2022, Fawcett and Carruthers, 2008].

5. The walls a group design has to clear

The material in this section is described from the source manuscript. **This paper's bibliography contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, so the statutory provisions described here are uncited**; the published enforcement guidelines are the exception and are cited where they are used [U.S. Department

of Justice and Federal Trade Commission, 2023, 2010]. Appendix B itemises every affected statement.

The two provisions are named once here for identification and are thereafter described by function. The interlocking-directorate prohibition is section 8 of the Clayton Act and the pre-merger notification regime is the Hart–Scott–Rodino Act, both of the United States, and the abstract names them for the same reason. **Naming a statute is not citing it, and nothing in this paper rests on a statutory text this bibliography contains.**

5.1 The interlocking-directorate prohibition, and why *per se* changes the engineering

One major jurisdiction prohibits a person from serving simultaneously as an officer or director of two corporations that are competitors such that an agreement between them would be unlawful. Two features make it different from the rest of competition law and both are structural rather than doctrinal.

It is *per se*. There is no rule-of-reason analysis, no efficiencies defence and no argument that the interlock was harmless. **For an engineer that is good news, because a *per se* rule is a test that can be run rather than a judgement that must be predicted.**

It has statutory de minimis exceptions with fixed percentages, and the percentages are the design surface. Alongside a dollar threshold on the corporations' capital, the exemptions turn on *competitive sales* — the gross revenues for products and services sold by one corporation in competition with the other — as a fraction of each corporation's total sales: an interlock is exempt where **either** corporation's competitive sales are below 2 per cent of its total sales, or where **each** corporation's are below 4 per cent. **The two tests are asymmetric, and the asymmetry is where the design room is.**

Three further mechanics decide real cases. **The reach of the prohibition beyond corporations is contested** — whether it covers other entity forms, or a fund's designation of an individual to a portfolio-company board, is a live question that belongs to counsel. **Board observers are the standard workaround and the standard trap**: a person who attends, receives the board pack, participates and reports back to a competitor is doing the thing the prohibition exists to prevent, whatever the label. **And there is a short grace period for interlocks that become unlawful through changed circumstances** — which is the version of the violation a group actually commits. **Not by taking a prohibited seat, but by making two lawfully seated companies into competitors and not re-running the test.** The trigger event is an acquisition elsewhere in the group, and the person who ran the acquisition does not know what boards the directors sit on.

5.2 The notification regime, and the arithmetic of the change test

The pre-merger notification regime requires filing above stated thresholds and observance of a waiting period before closing. The thresholds are adjusted annually and are for counsel. Two mechanics are the whole risk profile. **The avoidance rule means that the cleverness that gets a transaction under the threshold is the evidence that it should have been filed.** And **the per-day penalty means a filing error left undiscovered is a liability that grows linearly with inattention.**

The substantive test the filing feeds is a concentration screen, and its arithmetic has a closed form. When two firms with percentage shares s_1 and s_2 combine,

$$\Delta = (s_1 + s_2)^2 - s_1^2 - s_2^2 = 2 s_1 s_2,$$

so the hundred-point change threshold binds exactly when $s_1 s_2 > 50$ [U.S. Department of Justice and Federal Trade Commission, 2023]. **For an equal-share pair that is $\sqrt{50} = 7.0711$ per cent each.** Section 7.4 runs it on a constructed market.

5.3 Where the pledge meets the group design

The two subjects are one subject. A pledge over a control block is a disclosed position whose enforcement is a change of control; a change of control is a competition event as well as a contractual one; and the acquirer produced by an enforcement sale is a party whose own holdings enter both screens. **The instrument that computes the pledge trigger and the instrument that computes the merger screen are the same sum of squared shares pointed at different bases**, which is why they belong in one paper.

6. Legal families as a cost line

6.1 What the families actually do differently, and what they do not

The canonical division — common, civil, mixed, and religiously grounded systems — differs in characterisation, in the treatment of reserved portions on death, and in the situs rules that decide which forum governs an asset. **Recognition of a foreign instrument does not imply enforcement of it, and the gap between the two is where the money goes**; the comparative doctrine is a settled literature [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008], the instruments coordinating recognition of awards and judgments are separate from those coordinating substantive law [United Nations, 1958, Hague Conference on Private International Law, 2019], the recognition of the trust across a border is governed by a convention with a short ratification list [Hague Conference on Private International Law, 1985], the succession convention **never entered into force**, which is why reserved-portion questions remain conflict-of-laws problems [Hague Conference on Private International Law, 1989], and one regional instrument supplies habitual residence plus choice of law for the states bound by it [European Union, 2012]. The comparative treatment of the trust against the civil-law foundation is its own literature [Panico, 2014]; the irreducible function of the entity in all of it is asset partitioning [Hansmann and Kraakman, 2000], and the sharpest account of how legal coding creates capital is also its sharpest critique [Pistor, 2019].

Characterisation is the step that decides the answer before any law is applied, and it is asset-specific rather than structure-specific. That is why the specification below assigns a family to each asset rather than choosing a family for the structure.

6.2 The demotion, stated as a result

The concentration instrument applies to any distribution, so it applies to legal families. **The reading inverts, and that inversion is the finding.** On the jurisdictional axis a low index is good, because it means many independent points of failure. **Here a low index is a cost, because each effective family is an interface**, and every interface requires three written opinions — recognition, characterisation, enforcement — from counsel qualified in the receiving system.

Two warnings belong with the measurement and both are printed rather than deferred.

The index does not see interfaces that the share table hides. A structure using a free-zone jurisdiction whose zone applies common-law-derived rules sits inside a federal civil-law state, and the zone-to-onshore interface is real and invisible to a family index computed off jurisdiction shares. **A law-family index therefore under-counts the interfaces of any structure using a carve-out jurisdiction, which is to say most of the structures in this series.**

A legal family is not a coordination perimeter. Two common-law jurisdictions inside one perimeter fail together; a common-law and a civil-law jurisdiction inside one perimeter also fail together. **The families are orthogonal to the perimeters, and reporting family diversity as though it were perimeter diversity is the same category error the corpus identifies elsewhere.** Curzi [2026] makes the parallel point for liability compartments — six unequal compartments give 4.96 effective compartments on the contagion axis and contribute exactly zero

to the perimeter count — and Curzi [2026] makes it for settlement, where a naive correspondent index of 0.302400 reading 3.306878 effective correspondents collapses to 0.745256 and 1.341819 effective clearing perimeters once flows are decomposed by currency. **Three axes, three share bases, one recurring error.**

6.3 Registered intellectual property, where fragmentation is irreducible

A patent or a mark is not one thing recognised in many places. It is a bundle of separate national rights, each created by a national registry under national law, each with its own renewal calendar, validity standard and enforcement forum; the international instruments coordinate *filing* and create no single global right. **What is mobile is not the right but the holding entity and the licence contract.** One entity can own forty registrations and one licence agreement under one chosen law referred to one forum can cover all forty. The registrations stay exactly where they are, and **any adviser who implies otherwise is selling something.**

7. Results

Every figure is an exact computation on constructed inputs. **No dataset was collected and no figure here is a measurement taken from any real facility, market or structure.**

7.1 R1 — the trigger

$$d^{*} = 1 - \frac{\mathrm{LTV}_{0}}{1 - m}.$$

At $\mathrm{LTV}_{0} = 50\%$ and $m = 35\%$: $V^{*} = 40/0.65 = 61.538462$ and $d^{*} = 1 - 61.538462/80 = 23.076923\%$. **The first margin call falls at a 23.076923 per cent drawdown, not at 50 per cent.** The full surface, in percentage falls in collateral value, with dashes where the facility is in breach at inception:

LTV0	m=20%	m=25%	m=30%	m=35%	m=40%	m=45%	m=50%
25%	68.75	66.67	64.29	61.54	58.33	54.55	50.00
30%	62.50	60.00	57.14	53.85	50.00	45.45	40.00
35%	56.25	53.33	50.00	46.15	41.67	36.36	30.00
40%	50.00	46.67	42.86	38.46	33.33	27.27	20.00
45%	43.75	40.00	35.71	30.77	25.00	18.18	10.00
50%	37.50	33.33	28.57	23.08	16.67	9.09	--
55%	31.25	26.67	21.43	15.38	8.33	--	--
60%	25.00	20.00	14.29	7.69	--	--	--
65%	18.75	13.33	7.14	--	--	--	--

Three readings, in descending order of how often they are missed. **The cushion is roughly linear in the loan-to-value and the slope is brutal**: at $m = 35\%$ every five points of advance costs exactly 7.692308 points of cushion, so going from 40 to 50 per cent raises the cash by 8 units — 15.384615 per cent more deployable capital — and costs 15.384615 points of cushion. **The last four units of borrowing are the most expensive four units in the structure, and they are the ones agreed last, quickly, at the end of a negotiation about something else. The maintenance level matters as much as the advance rate and is negotiated a tenth as hard**: moving from 35 to 30 per cent at a 50 per cent advance takes the trigger from 23.076923 to 28.571429 per cent, five and a half points of free cushion for a term most borrowers treat as boilerplate. **And there is a region of the table where the facility is in breach on the day it is signed** — nobody signs that deliberately, but a maintenance level that steps up on a ratings trigger, an index deletion or a liquidity test moves the borrower rightward along a row nobody re-reads.

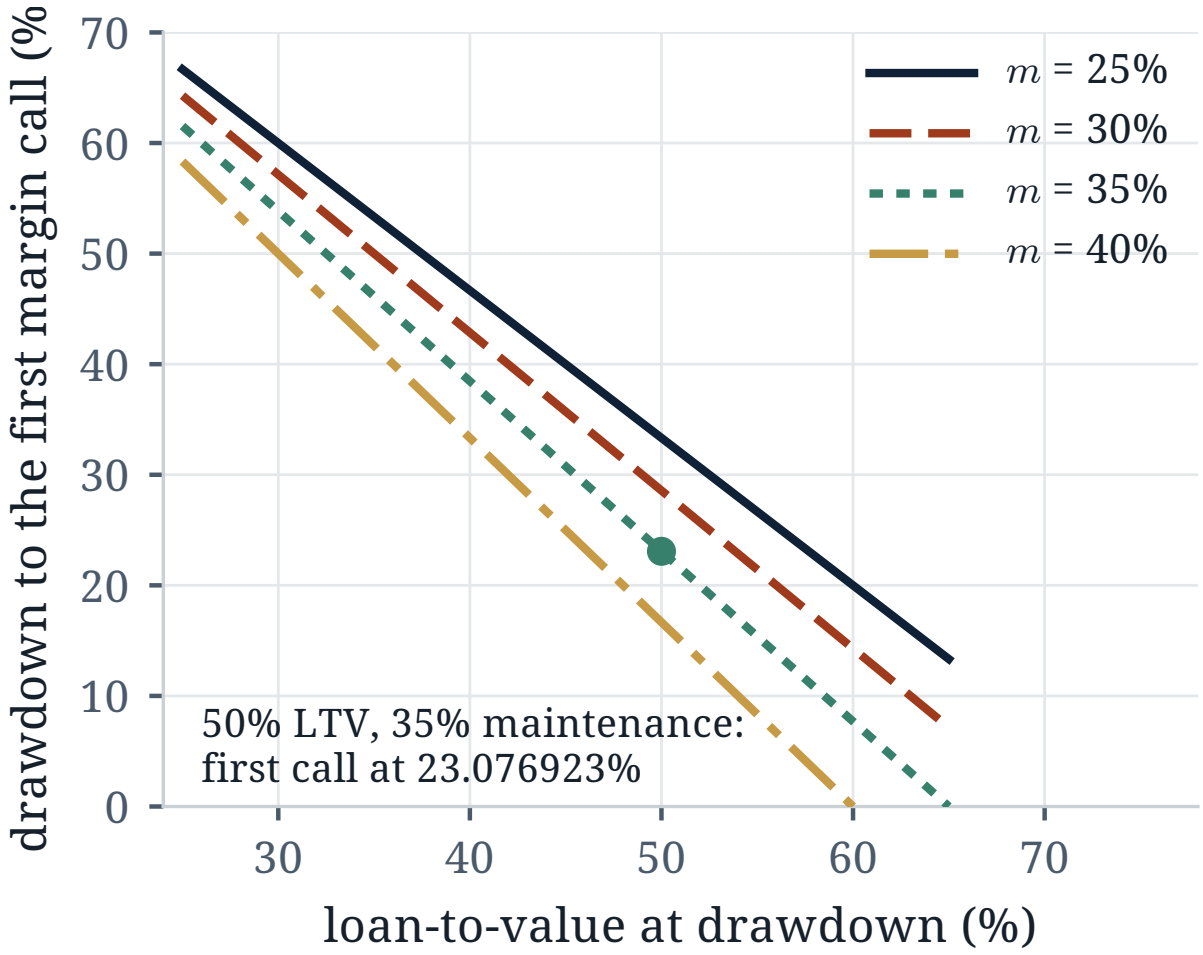

Figure 62.1: **The cushion is linear in the loan-to-value and the slope is steep: at a 35 per cent maintenance requirement, every five points of additional advance costs exactly 7.692308 points of drawdown cushion.** Curves are $d^{*} = 1 - \mathrm{LTV}_{0}/(1 - m)$, the closed form of Section 3.1, plotted for the four maintenance levels in the trigger table of Section 7.1. Script `figs/src/CCP-062_fig01.py`.

Measured on the business rather than on the share price, with senior debt of 35 ahead of equity of 100 and an equity beta to enterprise value of 1.35, the trigger is a **17.094017 per cent** enterprise-value decline and the control loss a **26.666667 per cent** decline. H1 is supported, and it is supported as an identity.

7.2 R2 — the forced sale and the crossover

With $x = V - (V - L)/m$:

```
at a 36.000000% drawdown, price 0.640000
  collateral value 51.200000, loan 40.000000, equity ratio 21.875000%
  proceeds required          x = 51.200000 - 11.200000/0.35 = 19.200000
  shares sold at 0.640000                                   = 30.000000
  shares remaining of the original 80                       = 50.000000
  RESULTING STAKE                                           = 50.000000%
```

drawdown	price	stake after the forced sale
23.076923%	0.769231	80.000000% (first call)
30%	0.700000	65.306122%
36.000000%	0.640000	**50.000000%**
40%	0.600000	38.095238%
50%	0.500000	collateral equity exactly zero

At a 36 per cent drawdown the forced sale takes the holder to exactly 50 per cent, and one basis point beyond it he is a minority holder of the company he founded. The crossover against the unlevered route that raises the same cash by floating 60 per cent and retaining 40 is the honest summary of the trade:

```
route A stake after the forced sale equals 40.000000% at
price 0.606061 per share   ->   drawdown 39.393939%
```

Below a 39.393939 per cent drawdown the levered route leaves the holder with more of the company; above it, the plain float does. That single number is computable at signing. H2 is supported.

One more fact completes the picture and it is about the market rather than the borrower. The public float created by the carve-out is 20 shares; the forced sale at a 36 per cent drawdown is 30 shares. **The liquidation is one and a half times the entire free float, and it must clear into a market that has just marked the company down by more than a third.**

7.3 R3 — the first-passage probabilities

CONSTRUCTED MODEL. Illustrative only. At $\mu = 6\%$, the probability of touching each barrier within the horizon:

Probability of touching the 23.076923 per cent barrier:

σ	1 yr	2 yr	3 yr	5 yr	10 yr
20%	14.405%	26.663%	33.635%	41.364%	49.431%
30%	36.526%	51.288%	58.665%	66.486%	74.684%
40%	52.869%	66.372%	72.772%	79.390%	86.192%
50%	64.031%	75.756%	81.137%	86.581%	92.001%

σ	1 yr	2 yr	3 yr	5 yr	10 yr

Probability of touching the 36 per cent barrier, at which control is lost:

σ	1 yr	2 yr	3 yr	5 yr	10 yr
20%	1.616%	7.139%	12.196%	19.337%	28.328%
30%	12.694%	27.148%	36.178%	46.844%	59.006%
40%	27.952%	45.432%	54.847%	65.194%	**76.347%**
50%	41.614%	58.908%	67.529%	76.598%	85.905%

Median time to touch the 23.076923 per cent barrier: **1.8731 years** at $\sigma = 30\%$, **0.8786 years** at 40 per cent, **0.5225 years** at 50 per cent.

A newly listed, concentrated, single-name equity is not a 20-per-cent-volatility asset. At 40 per cent the model puts the median time to a first margin call at under eleven months and the ten-year probability of a control-losing drawdown at 76.347 per cent. **Whatever the correct empirical figures are — and they should be estimated from the actual security rather than assumed — the qualitative conclusion is not sensitive to the input. The event that destroys this structure is not a tail event. It is the base case over any horizon long enough to matter, and the structure is usually built to last a generation.** H3 is supported by the model and **is not supported by any data, which Section 10 states.**

7.4 R5 — the two competition identities

The change identity. $\Delta = 2 s_1 s_2$, so the hundred-point screen binds exactly when $s_1 s_2 > 50$. On a constructed market in which the group's operating company holds 14.0 per cent — rivals at 22.0, 18.0, 11.0, 8.0, 7.0, 6.0, 5.0 and 4.0 with five fringe firms at 1.0 — the index is 1,320.00 points and the effective firm count is 7.575758:

target share	Δ	post-index	combined share	level $> 1{,}800$	change > 100	presumption
4.0	112.00	1,432.00	18.0%	no	yes	not engaged
5.0	140.00	1,460.00	19.0%	no	yes	not engaged
6.0	168.00	1,488.00	20.0%	no	yes	not engaged
7.0	196.00	1,516.00	21.0%	no	yes	not engaged
8.0	224.00	1,544.00	22.0%	no	yes	not engaged
11.0	308.00	1,628.00	25.0%	no	yes	not engaged
18.0	504.00	1,824.00	32.0%	**yes**	yes	**engaged**
22.0	616.00	1,936.00	36.0%	**yes**	yes	**engaged**

The largest target that keeps the change at or below 100 points is $100/(2 \times 14) = 3.571429$ **per cent of the market — which is to say that once a firm holds 14 per cent, essentially every acquisition worth doing produces a change above 100.** And the roll-up result, which is counterintuitive and matters to anyone running an acquisition programme rather than a single deal:

```
five 1.0% firms acquired SEQUENTIALLY   cumulative delta 160.0000   post 1,480.0000
the same 5.0% acquired in ONE step      delta            140.0000   post 1,460.0000
difference                                               +20.0000 points
```

A roll-up executed in instalments produces a larger total change than the same aggregate bought at once, because the acquirer's own accumulated share raises the delta on every subsequent step. The sequential path is often chosen in the belief that small steps attract less attention; on the arithmetic it does the opposite.

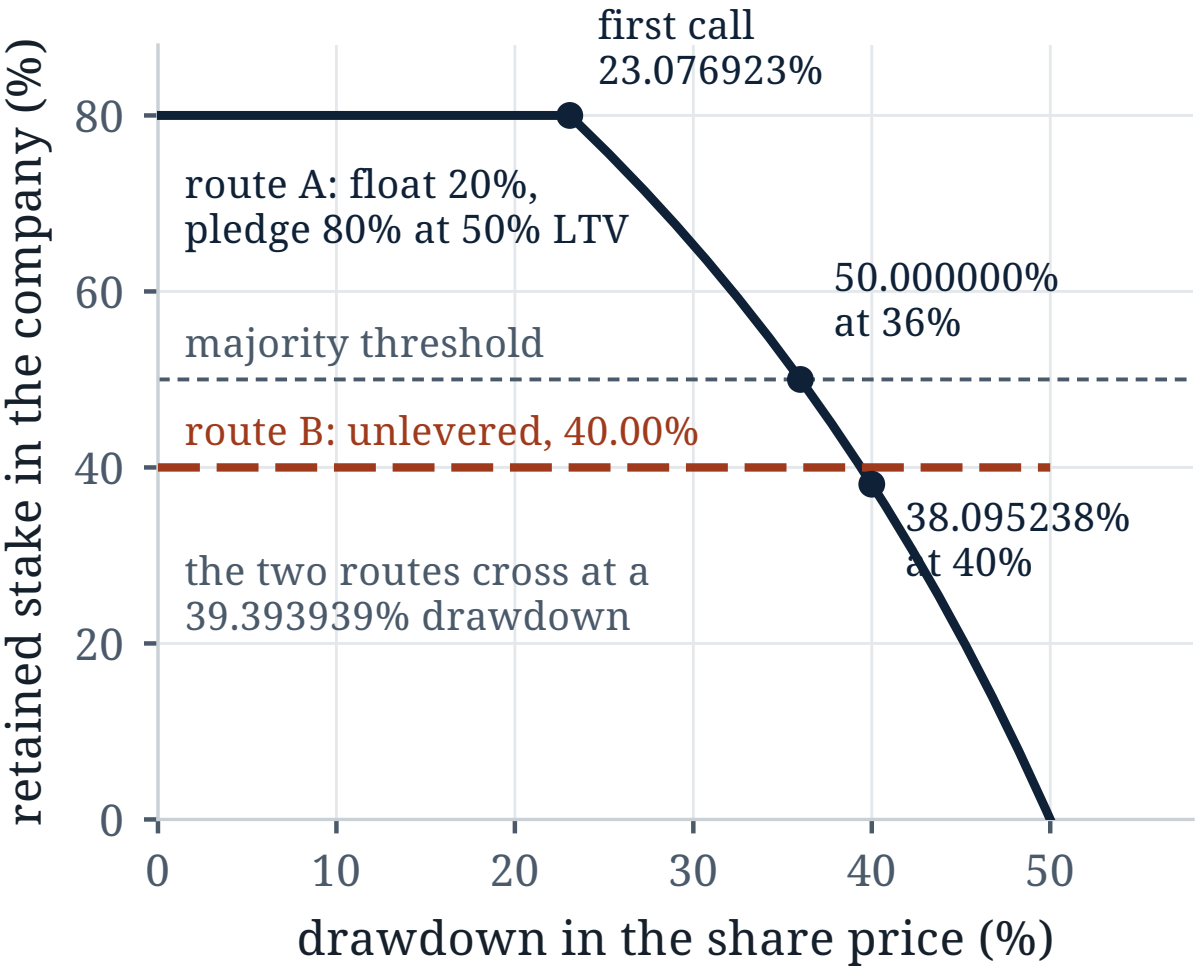

Figure 62.2: **The pledge retains more of the company than an unlevered float until a 39.393939 per cent drawdown and less of it thereafter, and passes through exactly 50 per cent at 36 per cent.** The curve is the retained stake after a forced sale restoring a 35 per cent equity ratio, $x = V - (V - L)/m$; the four marked and labelled values are the ones printed in Section 7.2 and the remainder of the curve is the same formula evaluated between them. Script `figs/src/CCP-062_fig02.py`.

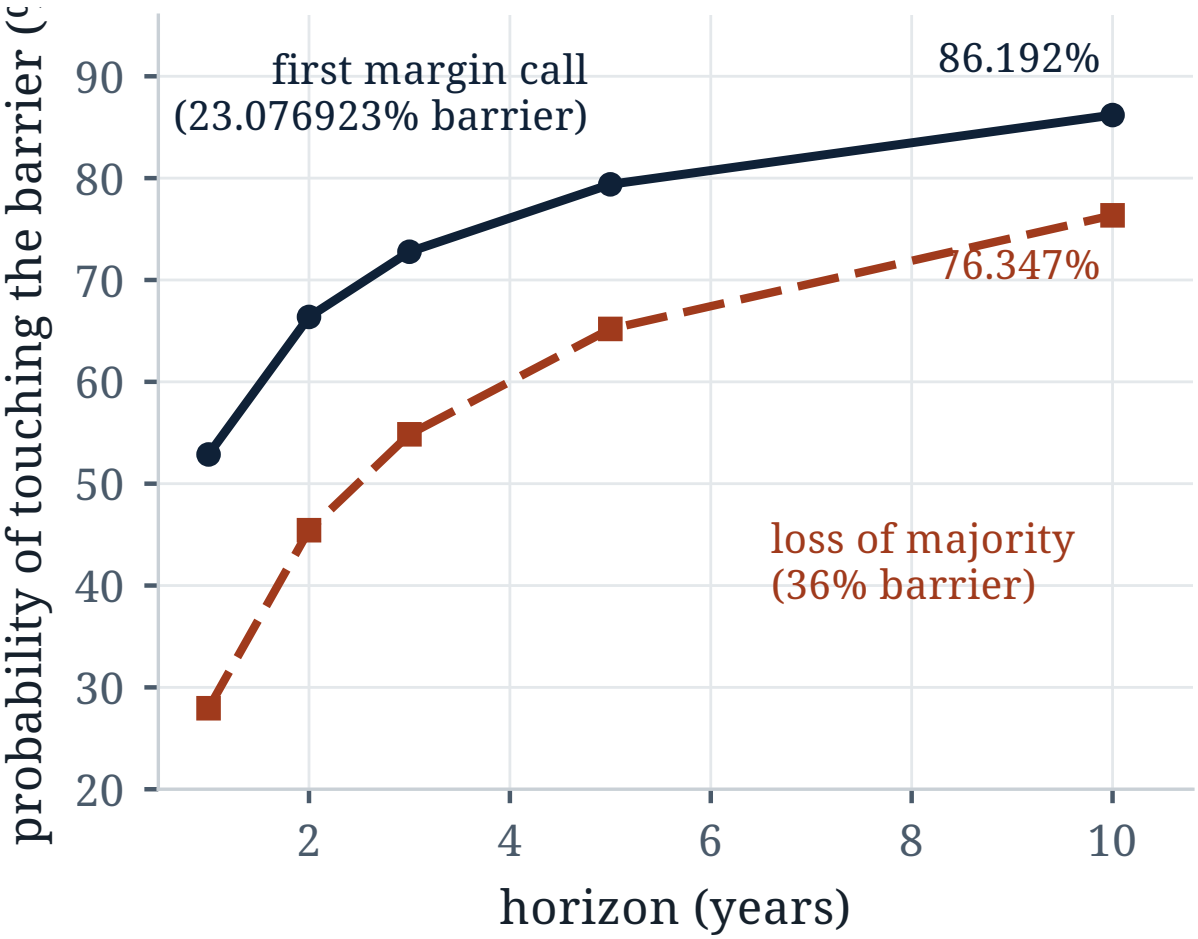

Figure 62.3: **Touching the control-losing barrier is not a tail event over a structural horizon: at 40 per cent volatility the ten-year probability is 76.347 per cent.** First-passage probabilities under the constructed geometric-Brownian-motion model of Section 3.3 at $\sigma = 40\%$ and $\mu = 6\%$; all ten plotted values are printed in the tables of Section 7.3. Script `figs/src/CCP-062_fig03.py`.

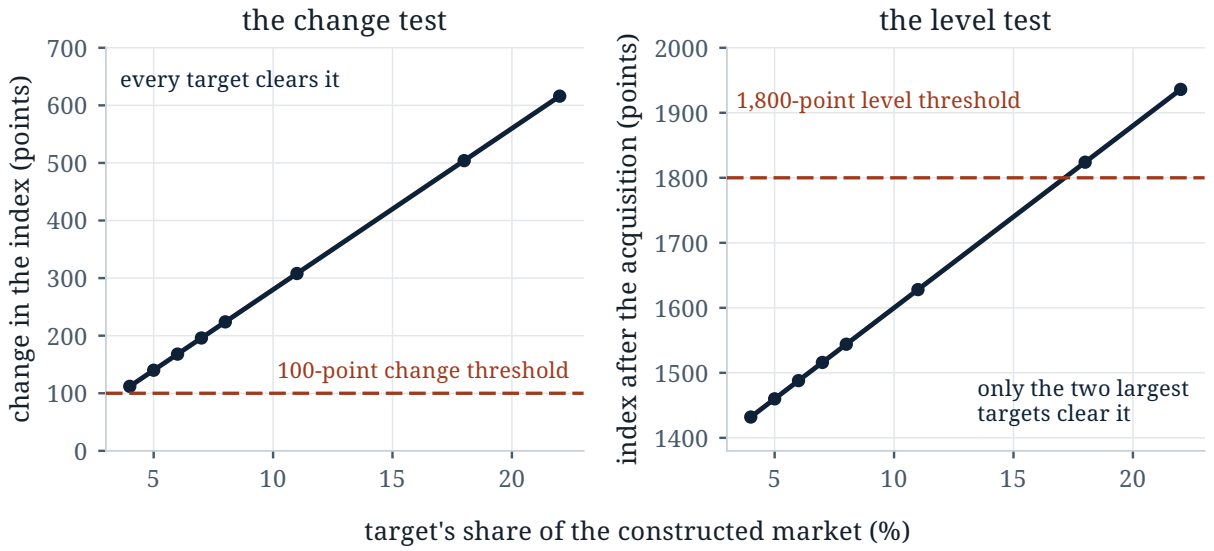

Figure 62.4: **Once the acquirer holds 14 per cent, every target worth buying clears the change threshold and only the two largest clear the level threshold: the change test is what binds a mid-sized acquirer.** Values are the acquisition table of Section 7.4, with the screen thresholds of U.S. Department of Justice and Federal Trade Commission [2023]. Script `figs/src/CCP-062_fig05.py`.

The de minimis asymmetry. With the exemptions turning on competitive sales as a fraction of each corporation's total sales — either below 2 per cent, or each below 4 per cent:

corp A	corp B	2% test (either $<$ 2%)	4% test (both $<$ 4%)	exempt?
3.90%	3.90%	no	yes	**yes**
1.90%	30.00%	yes	no	**yes**
2.10%	3.90%	no	yes	**yes**
1.99%	99.00%	yes	no	**yes**
4.10%	4.10%	no	no	**no**

A pair at 3.90 and 3.90 per cent is exempt. A pair at 1.99 and 99.00 per cent is exempt. A pair at 4.10 and 4.10 per cent is not. The correct first step on any proposed seat is therefore to compute competitive sales as a percentage of each corporation's total sales, rather than to ask whether the companies "compete". Worked on constructed figures, a pair at 1.833 and 4.400 per cent is exempt even though one side exceeds the four per cent test, because the other is below two: **a large overlap for the smaller company can be immaterial for the larger one, and the statute takes that seriously.** H4 is supported as an identity.

7.5 The propagation results

Cross-default. Nine financing and material commercial agreements have $\binom{9}{2} = 36$ pairwise links. Under independent per-agreement annual breach hazards:

q	$n = 3$	$n = 6$	$n = 9$
0.02	5.8808%	11.4158%	16.6252%
0.05	14.2625%	26.4908%	**36.9751%**

q	$n = 3$	$n = 6$	$n = 9$
0.10	27.1000%	46.8559%	61.2580%

At a five per cent per-agreement annual hazard across nine agreements, the chance that at least one trips in a given year is 36.9751 per cent, and with universal cross-default that is the chance the whole group defaults. The individual hazards are small and unremarkable; the aggregate is not. The margin facility is what makes this urgent, because a margin call met late is a default that can propagate into facilities never exposed to the share price at all.

R6 — interfaces. Ten legal touchpoints, of which six are fixed by facts the structure does not control — the location of land, the location of labour, and the residence of three people:

```
mesh across all ten touchpoints        45 interfaces   135 opinions
star through a single apex              9 interfaces    27 opinions
reduction                                              80.0000%

collapsed to the four canonical families
mesh                                    6 interfaces    18 opinions
star through the apex                   3 interfaces     9 opinions
```

Priced at a constructed allocation of 0.014 of the maintenance term C to cross-family opinions, the star costs 0.014000 of C against the mesh's 0.028000 — **a saving of 0.014000 of C, obtained by changing the topology and nothing else.** And the succession forum count falls the same way:

assets held	fora
each directly	6
all movables through the apex	3
after converting one immovable into a security	2

Six fora become three by interposing one legal person, and three become two by converting one immovable into a security. The remaining two are the apex and the irreducible situs of land. **A structure that has honestly reached two succession fora on this asset base has finished; one still looking for a device to reach one is looking for something that does not exist.**

7.6 The law-family measurement, reported as a cost

```
conventional structure
  common law 86.40%   civil law 13.60%
  HHI 0.764992   effective families 1.307203

designed structure
  common law 70.00%   civil law 18.20%   mixed 11.80%
  HHI 0.537048   effective families 1.862031
```

The designed structure's move from 1.307203 to 1.862031 effective families is half an additional family's worth of interface work, bought as a by-product of a diversification programme undertaken for a different reason. It is reported here as a cost line with the caveat in print: the table reads one common-law family for a free-zone exposure whose structure in fact crosses a zone-to-onshore boundary the table cannot see. **The measured 1.862031 understates the interface count, and the interface count is the number that matters on this axis.** The honest statement is three canonical interfaces, nine opinions, **one of them invisible to the metric and material to the outcome.**

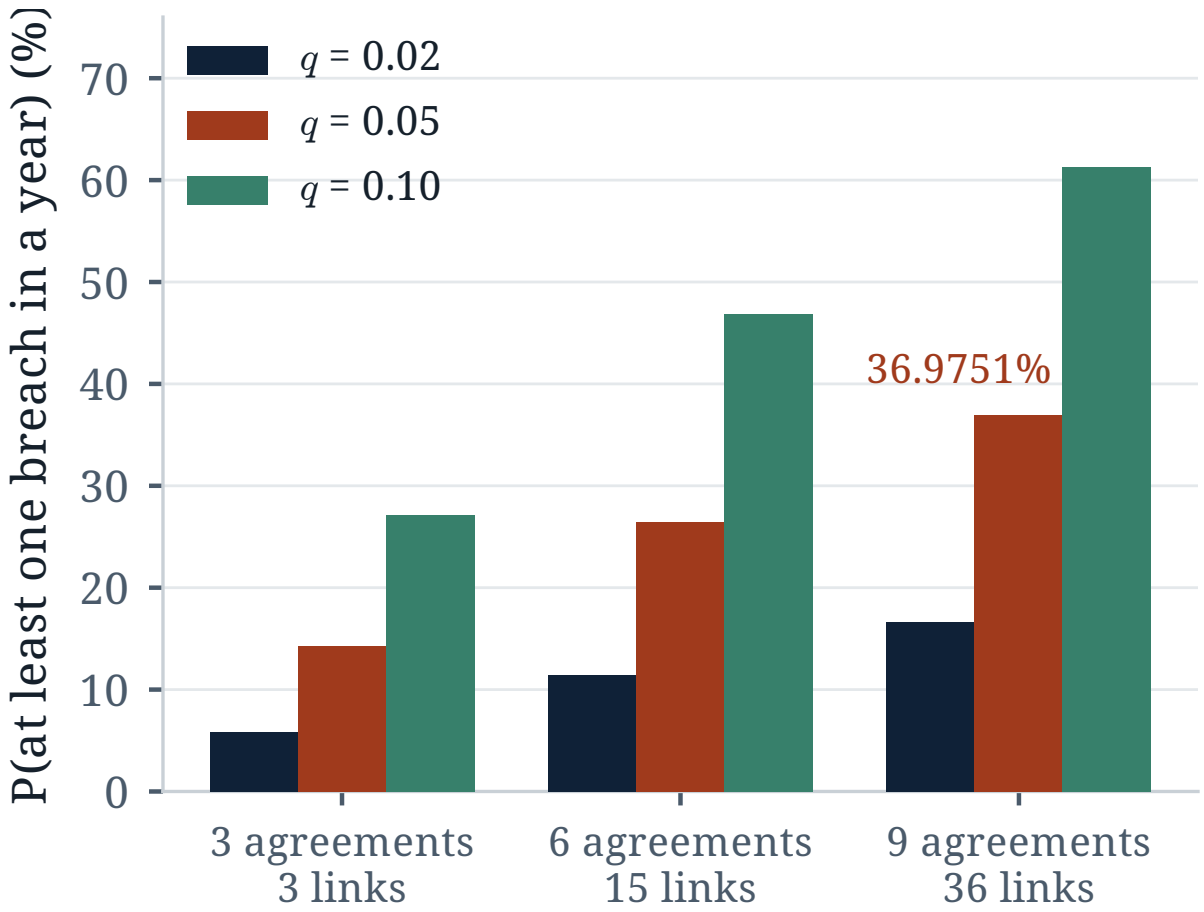

Figure 62.5: **Nine unremarkable agreements at a five per cent annual hazard produce a 36.9751 per cent chance that at least one trips, and universal cross-default makes that the group's default probability.** $P = 1-(1-q)^{n}$ for the three hazards and three portfolio sizes tabulated in Section 7.5; link counts are $\binom{n}{2}$. Script `figs/src/CCP-062_fig04.py`.

7.7 What the pledge does to the concentration measurement

The pledged block sits inside one line of the group's exposure map. A forced sale moves value out of the holder's control and into the lender's perimeter. Modelling an 8.0-point migration from the bridging bloc to the Western bloc on the designed structure of Curzi [2026]:

```
before   naive HHI 0.189002   eff jur 5.290949   bloc-HHI 0.340000
         N 2.941176   h -0.122417

The concentration instrument says the margin call improved the structure. It says so because the bridging bloc was the largest at 40.0 per cent and the forced migration made the bloc shares more even. **The measurement is correct and the conclusion is absurd, and it is the sharpest available illustration of the rule that the index is a diagnostic and not an objective function** [Goodhart, 1975, Campbell, 1979]. A structure that lost majority control of its operating company scored better on the resilience metric.

Report both. A number that improves while the thing it measures gets worse is the most dangerous output any instrument can produce, and the only defence is to read the metric alongside the event rather than instead of it.

7.8 The alternatives, priced — and two source figures corrected

route	cash	stake	trigger drawdown	drawdown to fall to 50%
A float 20%, pledge 80% at 50% LTV	60.00	80.00%	23.076923%	36.000000%
A′ float 20%, pledge 80% at 40% LTV	52.00	80.00%	38.461538%	**48.800000%**
A″ float 20%, pledge 50 of 80 at 50% LTV	45.00	80.00%	23.076923%	see note
B float 60%, no borrowing	60.00	40.00%	none	none
C float 35%, pledge 65 at 35% LTV	57.75	65.00%	46.153846%	**52.105263%**

Note on A″: the trigger drawdown on the pledged 50 is unchanged, because it is a function of the advance rate and the maintenance level only. What changes is cure capacity — 30 unencumbered shares are available to post as additional collateral, which converts the first call from a forced sale into a top-up and preserves the stake entirely at that drawdown.

Two figures in the source manuscript's version of this table do not reproduce and are corrected here rather than repeated. The source prints a control-loss drawdown of 42.105263 per cent for route A′ and 51.417004 per cent for route C. Applying the sale rule $x = V - (V - L)/m$ that the same source states, and that reproduces route A's 36.000000 per cent exactly, route A′ gives $62.5p = 32$, so $p = 0.512000$ and the drawdown is **48.800000 per cent**; route C gives $47.5p = 22.75$, so $p = 0.478947$ and the drawdown is **52.105263 per cent**. **Neither source figure is reproducible from any rule stated in the chapter, and this paper prints the recomputed values**

and flags the discrepancy rather than carrying it forward. The correction strengthens rather than weakens the source's conclusion: **route C survives a market event that ends route A by an even wider margin than the source claimed.**

Route C is what the arithmetic recommends and is what nobody proposes, because it looks like a worse headline — less control retained, less cash raised. **What it buys is a 46.153846 per cent first call and a 52.105263 per cent control-loss threshold against a base case of 23.076923 and 36.000000 per cent, for 2.25 units of forgone cash and fifteen percentage points of a stake that route A holds only nominally.** Negotiating the maintenance level from 35 to 30 per cent at a 35 per cent advance moves the first call further, to exactly 50.000000 per cent.

The residual is not removed. Under the constructed first-passage model at 40 per cent volatility, a 50 per cent drawdown still carries a **63.380 per cent** probability over ten years. Route C moves the threshold; it does not abolish it.

7.9 Counter-result

Legal-family diversity is demoted to a cost line rather than a resilience line. The measured 1.862031 effective families is a count of interfaces to be paid for, not of independent points of failure, and **it under-counts the interfaces of every carve-out jurisdiction in this series, including the free-zone-to-onshore interface the metric cannot see.** The honest verdict is that law-family arbitrage is a much smaller field than it is sold as and much more valuable inside its actual boundaries: **four mobile decisions and one architectural choice — the star rather than the mesh — account for nearly all of the available gain**, and everything else is the world telling the structure where its assets already live.

8. Discussion and failure catalogue

8.1 The failure classes, named

Curzi [2026ac] distinguishes four ways a claimed mechanism fails: no channel at all; a real channel with insufficient gain; a real result whose magnitude has been wrongly extrapolated; and a system unresponsive at the input size offered. **Almost every failure in this paper is class C — a real result at the wrong magnitude.** The pledge genuinely raises cash and genuinely retains control; the loan-to-value genuinely measures something; the legal-family count genuinely counts families. **In each case the quantity is real and the magnitude attributed to it is not, and the correction is arithmetic rather than judgement.**

8.2 Fourteen failure modes

1. **Reading the loan-to-value as the cushion.** The single most consequential error, and the reason for Section 7.1. The advance rate and the drawdown to the first call are different quantities on different scales, and reading one as the other is a scale confusion in the sense of Stevens [1946]. **That borrowers systematically make it is this paper's own conjecture and is uncited.**
2. **Pledging the whole block.** Unencumbered shares are cure capacity, and route A″ shows what they are worth.
3. **Assuming the float can absorb the liquidation.** The forced sale is one and a half times the free float.
4. **Forgetting that the trigger is tested on a levered claim.** Enterprise-value drawdowns of 17.094017 and 26.666667 per cent, not 23.076923 and 36.000000.
5. **Universal cross-default.** Thirty-six links and a 36.9751 per cent annual group default probability.
6. **An unmapped change-of-control surface.** The consequence is frequently larger than the loan.

7. **Uncapped right of use.** Above 100 per cent the whole block goes.
8. **Believing the relationship is a term.** A maintenance clause is a mechanical test and the risk officer has no discretion over it.
9. **Deploying the proceeds into the same risk.** Leverage against an asset, invested in the same asset class, is the same position twice.
10. **Modelling a single drawdown rather than a path.** Section 7.3 exists because the static table is the wrong object.
11. **Confusing the offering type.** Primary and secondary produce identical percentages and opposite cash positions.
12. **Treating disclosure as the risk.** The pledge is disclosed by rule; the risk is the arithmetic nobody ran.
13. **Assuming the lender wants the shares.** It wants its money back, quickly, and its covenant package is written to get it.
14. **Running the structure without an annual re-test.** Every parameter moves and the map decays on events that produce no filing anywhere.

8.3 Where the analysis is exposed

The instrument is exposed to being adopted as a target [Goodhart, 1975, Campbell, 1979], and Section 7.7 is the demonstration: a metric improved while the thing it measured got strictly worse. The only defence offered is the reporting standard in Appendix A, which requires the inputs and the event to be published beside the output.

It is also performative and its own parameters are not exempt. MacKenzie and Millo [2003] documents a model that made its assumptions true after adoption, and Lucas [1976] states the consequence for parameters estimated before publication. **The framework asserts that systems change their behaviour when modelled and then exempts its own volatility, hazard and perimeter assumptions from that reflexivity. That is an inconsistency and it is not resolved here.**

Ensemble and time averages are different objects and every probability here is the first. Peters [2019] establishes that the time average of a multiplicative process differs from its ensemble average. **A margin call is not a deduction from a stream; it is an event that permanently rescales the holder's position in the asset, and the ten-year probability in Section 7.3 is exactly the time-average statement the expected-value framing would miss.** Peters and Gell-Mann [2016] supplies the associated strengthening for the framework's logarithm: it follows from multiplicative dynamics with no psychological assumption at all.

The corpus's practice of cross-checking an identity to machine precision before relying on it is followed here. Curzi [2026] verifies its deficit identity at a residual of 8.88×10^{-16} on its carried case, and Section 9.9 reports the equivalent checks for every identity in this paper — including the two that failed, which are printed in Section 7.8.

One boundary belongs here rather than in a footnote. Curzi [2026] states the doctrine of category violation: category innocence is refused as a defence of acquisition, and moving a harm through a discovered gap in a scheme is forbidden. **The de minimis arithmetic of Section 7.4 is a compliance test and not a design target.** A group that computes competitive sales in order to know whether a seat is lawful is using the statute as intended; a group that arranges its sales in order to sit just under a statutory percentage while doing the thing the statute exists to prevent has found the gap the doctrine forbids. **The break-even method the corpus uses elsewhere [Curzi, 2026] prices a decision honestly precisely because it states what belief the decision requires; the same method used to price the probability of not being caught is a different exercise, and this paper does not perform it.**

9. Verification and rigour audit

9.1 Dimensional audit

symbol	quantity	dimension	unit	status
V_0, V	collateral value at inception, and current	$[M]$	units of value	defined (constructed)
L	loan	$[M]$	units of value	defined (constructed)
LTV_0, m	opening advance rate, maintenance requirement	$[1]$	dimensionless fractions	assumed (constructed)
d^*	trigger drawdown	$[1]$	dimensionless fraction	derived
x	proceeds required to cure	$[M]$	units of value	derived
p	price relative to inception	$[1]$	dimensionless	derived
μ	drift	$[T^{-1}]$	per year	assumed (constructed)
σ	volatility	$[T^{-1/2}]$	per square-root year	assumed (constructed)
$b = \ln(B/S_0)$	log barrier	$[1]$	dimensionless	derived
q	per-agreement annual breach hazard	$[T^{-1}]$	per year	assumed (constructed)
n	agreements, touchpoints, hops	$[\#]$	a count	chosen
s_i	share on a stated basis	$[1]$	dimensionless	defined; sums to 1
HHI, Δ	index, change in index	$[1]$	dimensionless, or points	derived
N	effective count	$[\#]$	a count	derived as $1/\mathrm{HHI}$
C	maintenance cost flow	$[C\,T^{-1}]$	index units per period	assumed
h	surplus balance	$[C\,T^{-1}]$	index units per period	derived

Do the equations balance? $d^* = 1 - \mathrm{LTV}_0/(1-m)$ is a dimensionless combination of dimensionless quantities, so quoting it as a percentage is correct. $x = V - (V-L)/m$ carries $[M]$ throughout, since m is dimensionless. **In the first-passage expression the arguments of Φ are dimensionless only because σ carries $[T^{-1/2}]$ and $\nu T/(\sigma\sqrt{T})$ therefore reduces to a pure number — which is the check that catches a volatility quoted per year being used with a horizon in months**, the commonest dimensional error in this family of models. The exponent $2\nu b/\sigma^2$ is likewise dimensionless.

Where no operational unit exists the audit says so. The value figures are constructed units with no currency attached, and C and h are index units fixed by parameters stated elsewhere in the corpus, with no conversion to currency supplied anywhere. **The percentages, the proba-**

bilities and the effective counts survive this; the statement that the interface saving is 0.014000 of C means nothing until an index unit is defined, and none is.

9.2 Significant figures against epistemic status

- 23.076923%, 36.000000%, 38.095238%, 39.393939%, 7.692308, 3.571429%, 7.0711%, 48.800000% and 52.105263% are **exact arithmetic on stipulated inputs** — rational functions of exact fractions. They are derived-from-defined and may carry as many digits as are useful. **Their inputs are constructed and carry no empirical authority whatever.**
- $\Delta = 2s_1s_2$ is an **identity**, exact for all shares, and the table built from it is exact.
- 1.307203 and 1.862031 are exact reciprocals of exactly stated share vectors, computed from the printed percentages rather than from any exact underlying fraction — **the convention adopted by Curzi [2026] and recorded there as a fifth-decimal discrepancy against the exact-fraction convention of Curzi [2026].**
- 76.347%, 86.192%, 63.380% and 0.8786 years are **illustrative model output from stipulated parameters.** They are exact given μ, σ and the barrier, and μ and σ are assumed. **Three decimal places on a probability produced by an assumed volatility is defensible only as a reproduction aid, and Section 10 says so.**
- 36.9751% is exact arithmetic on a stipulated hazard.
- **No quantity in this paper is a fitted or measured estimate, so no uncertainty interval is reported anywhere. That is not precision; it is the absence of empirical content.**

9.3 Limits and boundary behaviour

limit	behaviour	reading
$m \to 0$	$d^* \to 1 - \mathrm{LTV}_0$	with no maintenance requirement the call arrives only when the loan equals the collateral
$m \to 1$	$d^* \to -\infty$	a maintenance requirement approaching the whole value is unsatisfiable at any advance
$\mathrm{LTV}_0 \to 0$	$d^* \to 1$	an unlevered block is never called
$\mathrm{LTV}_0 \to 1 - m$	$d^* \to 0$	the facility is at the trigger on the day it is signed — the dashes in the table
$V \to L/(1-m)$	$x \to 0$	the cure requirement vanishes at the trigger, as it must
$V \to L$	$x \to V$	at zero equity the whole block is consumed
$\sigma \to 0$	$P \to 0$ for a barrier below $S_0 e^{\mu T}$	a riskless asset never touches
$\sigma \to \infty$	$P \to 1$	certainty of touching, at any barrier
$T \to \infty$, $\nu > 0$	$P \to e^{2\nu b/\sigma^2} < 1$	positive drift leaves a strictly positive chance of never touching
$q \to 0$	$P(\text{breach}) \to 0$	no hazard, no propagation

limit	behaviour	reading
$n \to \infty$ at fixed q	$P \to 1$	universal cross-default across enough agreements defaults with certainty
$s_1 s_2 \to 0$	$\Delta \to 0$	acquiring nothing changes nothing

Two limits are real constraints on the domain rather than results. $d^* < 0$ for $\text{LTV}_0 > 1 - m$, which is not a drawdown but a statement that the facility is already in breach; the model's domain is $\text{LTV}_0 < 1 - m$. And **the infinite-horizon limit of the first-passage probability is the one that matters for a structure built to last a generation**: with $\nu > 0$ the probability of never touching is $1 - e^{2\nu b/\sigma^2}$, which at $\sigma = 40\%$ and $\mu = 6\%$ is small. **A structure whose survival depends on a barrier never being touched over an unbounded horizon is depending on a quantity the model says approaches its bound.**

9.4 Invariance

The trigger and the control-loss threshold are invariant under any rescaling of the company's value. Doubling V_0 and L together leaves LTV_0 and therefore d^* unchanged, and the stake percentages after a forced sale are likewise homogeneous of degree zero in value. **That is a genuine scale invariance and it is why the arithmetic applies to a block of any size.** It is **not** invariant under changing the maintenance level or the share of the company floated, which is the entire content of Sections 7.1 and 7.8.

The delta identity is invariant under relabelling and is exactly quadratic, so it does not survive a rescaling of shares that fails to preserve the simplex — a point that matters whenever a market definition is redrawn, because redefining the market rescales every share and changes Δ quadratically.

What would break the share invariance: any basis that is not normalised. **Tested at how many scales?** The invariances are algebraic rather than empirical and were checked at exactly the vectors reported here: two, three, four, nine, ten, twelve and fourteen entries. No claim of empirical scale-freedom is made.

What is conserved, and in what units. Mirowski [1989] shows that the characteristic failure of this genre is borrowing the notation of a conserved quantity without the conservation law that gave it content. Two quantities are genuinely conserved here. The share vector sums to one exactly and dimensionlessly, which is what gives the index its bounds; and **the total number of shares is conserved through the forced sale — the block shrinks by exactly the number sold and the buyer's holding grows by the same number**, which is what makes the control arithmetic exact rather than approximate. C and h, by contrast, are stocks and flows with no stated conservation law and no operational unit, and none is claimed for them. Cartwright [1999] supplies the discipline that makes a partial answer respectable: **the arrangement claimed here is a single pledged block against a single facility with a mechanical test, and nothing outside it.** Kirman [1992] is the objection this paper cannot answer: one C is written for a heterogeneous group of interfaces.

9.5 Analogy discipline

borrowing	source	category	justification
effective count as $1/\text{HHI}$	Hill [1973], Jost [2006]	**1 — derivation**	an identity, not a resemblance

borrowing	source	category	justification
numbers-equivalent reading	Adelman [1969]	**1 — derivation**	elementary, checkable in two lines
the concentration screen	U.S. Department of Justice and Federal Trade Commission [2023], U.S. Department of Justice and Federal Trade Commission [2010]	**1 — derivation**	the guidelines state the index and the thresholds this paper uses
portfolio variance $w' R w$	Markowitz [1952]	**1 — derivation**, via CCP-052	the exposure vector is a weighted sum of shocks with a correlation matrix
similarity-sensitive diversity	Leinster and Cobbold [2012]	**1 — derivation**, stated domain	exact where R has unit diagonal and non-negative entries
ln N as entropy	Shannon [1948]	**2 — shared form**	Shannon entropy in nats; no thermodynamic content imported
geometric Brownian motion	standard diffusion	**2 — shared form**	assumed, not fitted; Sornette [2003] is the reason to expect it to understate
coupled-network fragility	Buldyrev et al. [2010], Albert et al. [2000]	**2 — shared form**	percolation premises are not shown to hold for financing covenants
cascade thresholds	Watts [2002]	**2 — shared form**	the model's degree assumptions are not verified for an agreement portfolio
pairwise combinatorics	Brooks [1975]	**2 — shared form**	$\binom{n}{2}$ is the same object in both settings; no organisational result is imported
channel capacity as a bound	Curzi [2026x], Shannon [1948]	**3 — framing**	used only for the discipline that throughput is receiver-limited; no capacity is computed for a group
tipping from a threshold	Granovetter [1978], Schelling [1971]	**3 — framing**	prior statement of the aggregate phenomenon, cited as ancestry
reflexivity in a falling market	Soros [2013]	**3 — framing**	a qualitative account, never used as a formal result

borrowing	source	category	justification
normal accidents	Perrow [1984]	**3 — framing**	qualitative organisational theory

The failure this table exists to prevent is letting a category-2 or category-3 borrowing carry a category-1 result's authority. The trigger, the sale rule, the delta identity and the combinatorics are category 1 and need no help; the diffusion, the network results and the capacity analogy are category 2 and 3 and are used for shape.

9.6 Measurement-theoretic status

Shares of a company, of a market and of an estate are **ratios of like quantities** and are ratio-scale by construction, so the trigger, the sale rule and the delta identity are untouched by the scale-type objection. **Three inputs are a different matter and the objection is conceded for all three.** The volatility σ, the drift μ and the per-agreement breach hazard q are treated as ratio-scale quantities supporting multiplication, division and exponentiation, and none is estimated from data. Michell [1997] is the strongest available objection — that quantitative structure is assumed rather than tested — and the formal remedy is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all, within the representational framework of Krantz et al. [1971]. **The conjoint conditions were not tested for any of the three, and every probability computed from them is therefore provisional.** What survives without the test is the *ordering* — a higher volatility gives a higher probability, a larger portfolio of cross-defaulted agreements a higher group hazard — and the algebraic identities, which do not depend on scale type at all.

The 2 and 4 per cent statutory tests of Section 7.4 are exact thresholds on a ratio quantity and are not scores; no ordinal judgement enters that table, and the paper takes no minima or means of anything ordinal. **The corpus's habit of collapsing a structured situation into one score is named once at framework level and is inherited rather than re-argued**; where a single number appears here it is a share, a probability or an exact threshold, and where it is a probability the decomposition is published rather than the scalar defended.

9.7 Postulates

#	statement	status
P1	the maintenance test is $(V - L)/V \geq m$, tested against a published close	DEFINITION
P2	the cure sale restores the ratio exactly: $x = V - (V - L)/m$	DEFINITION (modelling choice: no over-sale, no under-sale)
P3	shares on a stated basis are non-negative and sum to 1	DEFINITION
P4	HHI $= \sum_i s_i^2$	DEFINITION
P5	the price follows geometric Brownian motion with constant μ, σ	POSTULATED (**contradicted by the tail literature, Section 3.3**)
P6	$\mu = 6\%$, $\sigma \in \{20, 30, 40, 50\}\%$	POSTULATED (constructed)

#	statement	status
P7	agreement breaches are independent across agreements	POSTULATED (**false under common cause, Section 3.4**)
P8	$\text{LTV}_0 = 50\%$, $m = 35\%$, senior debt 35 against equity 100	POSTULATED (constructed)
P9	jurisdictions inside one coordination perimeter act on one decision	POSTULATED (stipulated reference group, Section 3.6)
P10	each legal-family interface requires three opinions and costs 0.014 of C in aggregate	POSTULATED (constructed)

9.8 The compounding chain

step	consumes	statement	status
L1	P1	the call arrives at $V^* = L/(1-m)$	ARITHMETIC
R1	L1, P8	$d^* = 1 - \text{LTV}_0/(1-m) = 23.076923\%$	ARITHMETIC
R1b	R1	at $m = 35\%$, $\partial d^*/\partial \text{LTV}_0 = -1/0.65$, so five points of advance cost 7.692308 points	ARITHMETIC
L2	P2	shares sold $= x/p$ with $x = V - (V - L)/m$	ARITHMETIC
R2a	L2, P8	at $d = 0.36$: $x = 19.200000$, 30 shares sold, stake exactly 50.000000%	ARITHMETIC
R2b	L2, P8	at $d = 0.40$: stake 38.095238%; at $d = 0.50$: equity zero	ARITHMETIC
R4	L2	route A's stake equals 40% at $p = 0.606061$, so the routes cross at 39.393939%	ARITHMETIC
R3	P5, P6	first passage at $\sigma = 40\%$: 76.347% over ten years to the 36% barrier; median 0.8786 yr to the 23.076923% barrier	ARITHMETIC on a POSTULATED model
L3	—	$(s_1 + s_2)^2 - s_1^2 - s_2^2 = 2s_1 s_2$	ARITHMETIC (identity)
R5a	L3	the 100-point screen binds exactly when $s_1 s_2 > 50$; $\sqrt{50} = 7.0711$	ARITHMETIC

step	consumes	statement	status
R5b	L3	at a 14% acquirer the largest target keeping $\Delta \le 100$ is 3.571429%	ARITHMETIC
R5c	L3	sequential roll-up cumulative $\Delta = 160$; one step $= 140$	ARITHMETIC
L4	P7	$P = 1 - (1-q)^n$; links $= \binom{n}{2}$	ARITHMETIC
R5d	L4	at $q = 0.05$, $n = 9$: 36.9751%, over 36 links	ARITHMETIC
R6	L4's combinatorics, P10	mesh 45 interfaces and 135 opinions; star 9 and 27; reduction 80.0000%	ARITHMETIC
CR	P3, P4	law-family HHI 0.764992 and 0.537048 give 1.307203 and 1.862031 effective families	ARITHMETIC

Every ARITHMETIC row can be redone by hand or in three lines of any language. **Only R3 rests on a postulated model, and P5 and P7 are both stated to be false in the direction that makes the results conservative** — the diffusion understates the barrier probability and the independence assumption understates the propagation probability. **The chain therefore establishes exact consequences of stipulated inputs, and it is not a proof of anything about any real facility.**

9.9 Cross-checks performed

- The trigger table was regenerated from the closed form and matched every printed cell.
- The forced-sale rule was re-solved for the stake at each printed drawdown; route A's 36.000000, 38.095238 and 65.306122 per cent all reproduce exactly, as does the crossover at 39.393939 per cent.
- **Two printed figures did not reproduce and are corrected in Section 7.8**: route A''s control-loss drawdown, printed as 42.105263 per cent and recomputed at 48.800000 per cent, and route C's, printed as 51.417004 per cent and recomputed at 52.105263 per cent. **Neither source figure follows from any rule stated in the source, and the corrected values strengthen the source's own recommendation.**
- All twenty-nine first-passage probabilities and all three median times were recomputed from the closed form and reproduce to the printed precision.
- $\Delta = 2s_1s_2$ was verified against the direct difference of sums of squares for every row of the acquisition table.
- The market index was recomputed from its shares: $1{,}320.00$ points, effective count $10{,}000/1{,}320 = 7.575758$; all shares sum to 100.0.
- The law-family indices were recomputed: $0.864^2 + 0.136^2 = 0.764992$ and $0.70^2 + 0.182^2 + 0.118^2 = 0.537048$.
- The perimeter migration of Section 7.7 was recomputed: $0.32^2 + 0.30^2 + 0.38^2 = 0.336800$, $N = 2.969121$, $h = 0.35 \ln N - 0.5 = -0.119107$, change $+0.003310$.
- $\binom{9}{2} = 36$, $\binom{10}{2} = 45$, $\binom{4}{2} = 6$ and $\binom{12}{2} = 66$ were checked directly.

10. Limitations

Every case is constructed. The company, its value, its debt, the offering, the facility, its advance rate and maintenance level, the volatility and drift, the breach hazards, the product market, the touchpoint map and the interface pricing are invented and are labelled as such at each point of use. **No external dataset was collected and none is reported.**

No paper in this corpus reports a first-party measurement, and this one does not either. The corpus's own instrument audit finds that of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated one, and **0 carry a first-party measurement.** That is the central limitation of the whole corpus and it is stated here before a reviewer states it.

The first-passage model is the least defensible thing in the paper. Constant volatility and log-normal returns are contradicted by the empirical literature on equity tails, and Sornette [2003] is the reason to expect the model to understate rather than overstate the barrier probabilities. **No volatility was estimated from any security, no alternative process was fitted, and no out-of-sample test was run.** The right reading of Section 7.3 is a lower bound conditional on a stipulated process, and the qualitative conclusion — that the barrier is reached over a structural horizon — is the only part that should be carried.

The independence assumption in the cross-default arithmetic is false in the direction that matters. Breaches share common causes, and a margin call is itself a common cause, so $1-(1-q)^n$ understates the group hazard. **The figure is a floor and is presented as one.**

The claim that borrowers systematically misread the advance rate as a drawdown cushion is uncited and is this work's own conjecture. The scaffold for this paper named the measurement-theory cluster as the source of support for it; that cluster contains measurement theory and psychometrics and contains no judgment-and-decision literature that would support the claim. **Rather than attach a citation that would not survive a check, the claim is badged as a conjecture here and in Section 8.2**, and the strongest thing that can be said with support is the weaker scale-type point that the advance rate and the drawdown are different quantities [Stevens, 1946].

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions of the interlocking-directorate prohibition and its de minimis percentages, the pre-merger notification regime and its avoidance and penalty rules, the restraint-of-trade prohibition, the treatment of rehypothecated collateral, the situs and characterisation rules, reserved-portion regimes, and every statutory reference in the source's own verification registers are taken from the source manuscript. **The bibliography contains general comparative, treaty and doctrinal material and the published merger guidelines only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, and no case law.** Those claims are described rather than asserted and are itemised in Appendix B. **This is a real gap and it is not closed here.**

Two figures in the source manuscript are wrong and are corrected rather than repeated (Sections 7.8 and 9.9). A reader comparing this paper against the source will find the difference, and the difference is disclosed rather than left to be discovered.

The 0.014 of C attributed to cross-family opinions is a constructed allocation with no fee schedule behind it, and every conclusion about the value of the star topology inherits that. What survives without it is the **count** — 45 interfaces against 9 — which is combinatorial and exact.

The legal-family index under-counts and the paper says so twice. It cannot see a zone-to-onshore interface, which is present in most of the structures this series examines. **The interface count, not the index, is the right instrument on that axis, and the index is reported only because the corpus reports it elsewhere and consistency requires the comparison.**

The perimeter assignments in Section 7.7 are stipulated, not identified [Manski, 1993], and the remedy adopted is stipulation with a defence [Brock and Durlauf, 2001]. No randomisation, instrument or partial-population variation was available.

Small-sample bias is not addressed [Chao et al., 2014], and effective-number measures

behave poorly where one unit dominates [Golosov, 2010] — which is the regime of the conventional structure's law-family vector at 86.4 per cent in one family.

Model comparison was not performed. No alternative index was fitted, no information criterion was computed and no matched null was constructed, because nothing here is fitted.

No differential prediction is offered. Durlauf [2005] asks for the prediction only this model makes, and the trigger arithmetic makes none that any competent credit analyst could not derive. **The contribution is that the derivation is published beside the transaction it prices, not that it is novel.**

Rigour checks not met, listed by name.

1. **No as-of date, because no real facility was examined.** Any application to a real position requires the facility's actual advance rate, maintenance level and step-up triggers, with a date. Appendix A makes both mandatory.
2. **No uncertainty is reported anywhere, because nothing is estimated.**
3. C **and** h **have no operational unit**, and the interface saving is therefore unitless.
4. **The constant-volatility assumption is untested and is contradicted by the tail literature** [Sornette, 2003, Longin and Solnik, 2001, Ang and Chen, 2002].
5. **The independence assumption in the propagation arithmetic is untested and is false under common cause** [Buldyrev et al., 2010].
6. **The conjoint conditions were not tested for** σ**,** μ **or** q [Michell, 1997, Luce and Tukey, 1964].
7. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. Any restatement reaching for a heavy-tail claim about holdings, share distributions or price returns must run it first, and must read Stumpf and Porter [2012] on why passing it still would not identify a mechanism.
8. **The network, cascade and capacity borrowings are category 2 and 3, not category 1** [Buldyrev et al., 2010, Watts, 2002, Curzi, 2026x].
9. **Aggregation is unaddressed** [Kirman, 1992].
10. **Expected value and time average are not the same thing** [Peters, 2019], and the paper reports probabilities rather than expectations for exactly that reason.
11. **The instrument is performative and its own parameters are not exempt** [MacKenzie and Millo, 2003, Lucas, 1976].
12. **There is no conservation law for** C **or** h [Mirowski, 1989]; the two genuine conservations are the share simplex and the share count through the forced sale.
13. **A metric improved while the thing it measured got worse** (Section 7.7), which is the instrument's own failure mode arriving in print [Goodhart, 1975, Campbell, 1979].

11. Conclusion

This paper prices a carve-out, a pledge and a group's legal interfaces, and the following statements are the fixed text of its results.

R1. The pledge trigger is $d^{*} = 1 - \mathrm{LTV}_0/(1-m)$: at $\mathrm{LTV}_0 = 50\%$ and maintenance $m = 35\%$, **the first margin call falls at a 23.076923 per cent drawdown, not at 50 per cent.** At $m = 35\%$ every five points of additional advance costs exactly 7.692308 points of cushion, and measured on the business rather than the share price the same trigger is a 17.094017 per cent enterprise-value decline.

R2. The forced sale takes an 80 per cent holder to **exactly 50.000000 per cent at a 36.000000 per cent drawdown**, to 38.095238 per cent at 40 per cent, and exhausts the collateral equity at 50 per cent. The liquidation at the 36 per cent point is 30 shares against a free float of 20 — **one and a half times the entire float, into a market that has just marked the company down by more than a third.**

R3. Under a constructed first-passage model at $\sigma = 40\%$ and $\mu = 6\%$, **the ten-year probability of touching the 36 per cent control-loss barrier is 76.347 per cent**, and the median time to

the 23.076923 per cent barrier is **0.8786 years**. The event that destroys this structure is not a tail event; it is the base case over any horizon long enough to matter.

R4. The levered and unlevered routes raising identical cash **cross at a 39.393939 per cent drawdown**: below it the pledge retains more of the company, above it the plain float does.

R5. The change identity $\Delta = 2s_1s_2$ makes the hundred-point screen bind **exactly when** $s_1s_2 > 50$ — 7.0711 per cent each for an equal pair — so that a firm holding 14 per cent can acquire nothing above 3.571429 per cent without clearing it, and a sequential roll-up produces 160.0000 points of cumulative change against 140.0000 for the same aggregate bought in one step. The de minimis provisions of the interlocking-directorate prohibition **exempt a 1.99 / 99.00 per cent pair and catch a 4.10 / 4.10 per cent pair.**

R6. Routing every cross-family interface through one apex **cuts 45 interfaces and 135 opinions to 9 and 27, an 80.0000 per cent reduction**, and takes six succession fora to three and then to two.

Counter-result. Legal-family diversity is demoted to a cost line rather than a resilience line. The measured 1.862031 effective families counts interfaces to be paid for and not independent points of failure, and **it under-counts the interfaces of every carve-out jurisdiction in this series, including the free-zone-to-onshore interface the metric cannot see.** A legal family is not a coordination perimeter, and reporting the one as the other is a category error.

Three further results are established as method rather than as measurement. **Cross-default converts nine agreements into thirty-six pairwise links and a 36.9751 per cent annual probability that one trips at a five per cent per-agreement hazard**, so the engineering response is to cut links rather than to negotiate hazards. **A forced sale can improve the concentration measurement while destroying the thing the measurement exists to protect** — the constructed migration raises h by $+0.003310$ at the moment majority control is lost — which is the sharpest available demonstration that an index is a diagnostic and not an objective function. **And two figures in the source manuscript's alternatives table do not reproduce from its own sale rule and are corrected here**, to 48.800000 and 52.105263 per cent, which strengthens rather than weakens the recommendation the source made.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the company and its capital structure, the offering, the facility and its terms, the volatility and drift, the breach hazards, the product market and its shares, the touchpoint map, the interface pricing and the exposure vectors — is **CONSTRUCTED** and is labelled as such at each point of use. The numerical results are exact computations on those constructed inputs, carried at full precision and rounded only for printing.

All figures were produced by the scripts named in their captions (`figs/src/CCP-062_fig01.py` through `figs/src/CCP-062_fig05.py`), which import the shared figure-style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Legal and regulatory descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general comparative, treaty and doctrinal material and the published merger-enforcement guidelines only; it contains no statutes, regulations, court rules, registry documents or case reports for any individual jurisdiction, and no case law. Appendix B lists the claims affected. Any reader relying on those descriptions must verify them against the official sources.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every person, company, market, facility and transaction described is invented.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, regulatory or investment advice. It describes offering structures, securities-backed lending, collateral arrangements, competition-law constraints and conflict-of-laws interfaces for the purpose of computing their arithmetic consequences. No recommendation is made in respect of any particular person, company, security or facility. Maintenance requirements and their regulatory floors, notification thresholds and waiting periods, de minimis percentages and dollar thresholds, rehypothecation and client-asset rules, situs and characterisation rules and reserved-portion regimes all change and vary by jurisdiction and by activity; **every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.**

Appendix A. Reporting standards

A.1 The pledge register. Any pledged control block reports the following, and nothing less.

```
the offering type -- primary, secondary or mixed -- and the
cash position each produces
the opening advance rate and the maintenance requirement,
with every step-up trigger and the event that fires it
the trigger drawdown d* = 1 - LTV0/(1-m)
the full stake-after-forced-sale table, at 10-point drawdown
intervals to the point of zero collateral equity
the drawdown at which majority control is lost
the same two figures translated to enterprise value, using
the equity beta implied by the operating company's own debt
the forced sale as a multiple of the free float
the crossover drawdown against the unlevered route raising
identical cash
the right-of-use cap, and whether the claim is proprietary
the change-of-control map: every agreement, its trigger, its
consequence, and whether consent is obtainable in advance
the cross-default register: agreements, links, materiality
thresholds, grace periods, and cross-acceleration where
obtained in place of cross-default
the date, and the difference against the previous re-test
```

Item 10 is the one nobody maintains and the one whose total is frequently larger than the loan. Item 12 decays first: every parameter moves, and the map decays on events that produce no filing anywhere.

A.2 The group screening calendar. Re-run on every acquisition, product launch and geographic expansion, not annually: competitive sales as a percentage of each corporation's total sales for every pair of boards on which a common individual sits; the index and the change for every contemplated transaction; and the changed-circumstances review that catches an interlock made unlawful by an acquisition somebody else negotiated.

A.3 The interface register. Every legal-family touchpoint, its family, whether it is fixed by facts or mobile by choice, and for every interface the three dated opinions — recognition, characterisation, enforcement — each from counsel qualified in the receiving system and each with a stated invalidating event. **The register is a fixed and knowable quantity rather than an open-ended one, which is the practical benefit of counting interfaces rather than reacting to them.**

Appendix B. Claims requiring verification against primary sources

The following statements rest on legal or regulatory detail that changes, and **none is cited to the bibliography, which contains no primary sources for any individual jurisdiction and no case law.** They are reproduced from the source manuscript and require confirmation with counsel before any reliance. The source manuscript's own verification registers run to more than seventy numbered items across the three chapters and are condensed here without loss of subject.

1. **Margin regulation.** The regulatory floors on maintenance margin for a regulated intermediary, any house requirement above them, and their application to a concentrated single-name control block. **The 35 per cent used throughout this paper is a plausible commercial level and is not a quotation.**
2. **Securities-backed lending documentation.** The standard formulation of the maintenance test, the cure window, the lender's sale right and its notice requirements, and whether the test is mechanical or subject to any discretion.
3. **Rehypothecation and client assets.** The right-of-use provisions and their caps, the distinction between a security interest with segregation and an outright transfer, and the insolvency litigation that established the treatment of client assets and client money in the leading market. **Specific holdings, their citations and their scope must be taken from counsel.**
4. **Disclosure of a pledge.** The filing and announcement obligations attaching to a pledge of a control block, and the thresholds and deadlines for beneficial-ownership reporting in each relevant market.
5. **The interlocking-directorate prohibition.** Its statutory location and current text; the dollar threshold on capital, surplus and undivided profits, which is adjusted annually; the 2 and 4 per cent de minimis percentages and the definition of competitive sales; the separate regime applicable to banking institutions; the grace period on changed circumstances and its length; whether the prohibition reaches entity forms other than corporations; the status of the deputisation theory; and the enforcement record since 2022, including the number of resignations and what each announcement said.
6. **The pre-merger notification regime.** The size-of-transaction and size-of-person thresholds, which are adjusted annually; the length of the waiting period and its variants; the second-request mechanics; the per-day civil penalty; the avoidance rule; and the treatment of gun-jumping.
7. **The merger guidelines.** The index thresholds and the change threshold used in Section 7.4 are agency enforcement policy and not statute, and courts are not bound by them

[U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. Their current form must be confirmed.

8. **The restraint-of-trade prohibition** and the line between structure and conduct, including the treatment of information exchange between competitors and the criminal exposure attaching to hard-core horizontal agreements.
9. **Structural subordination and ring-fencing** in the relevant insolvency systems: which claims a group-level pledge actually reaches, and how the residual claim is valued in a distribution.
10. **Change-of-control provisions** in each class of agreement listed in Section 4.2, and in particular whether an investment promotion or a treaty-based ownership right is conditioned on shareholder identity or nationality, and what re-testing is required.
11. **Cross-default and cross-acceleration** drafting: the difference between them, the market position on materiality thresholds and grace periods, and whether a counterparty will accept the narrower clause.
12. **The conflict-of-laws material**: the situs rules for movables and immovables, the place-of-the-relevant-intermediary approach for securities accounts and the convention that embeds it, characterisation doctrine, and the recognition-versus-enforcement distinction. The general doctrine is cited [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008]; **no jurisdiction-specific rule is.**
13. **Succession and reserved portions**: the reserved-share fractions of each civil-law system touched by the structure, the applicable conflicts rule, and whether the reserved portion reaches a given asset at all — which is asset-specific and decided by characterisation. The absence of a succession convention in force [Hague Conference on Private International Law, 1989] and the regional instrument that partly fills the gap [European Union, 2012] are cited; **no domestic provision is.**
14. **Trust and foundation recognition**: the ratification list of the recognition convention [Hague Conference on Private International Law, 1985], which is short, and the comparative treatment of the two devices [Panico, 2014].
15. **Free-zone-to-onshore interfaces**: whether a judgment of a free-zone court is enforceable onshore in the same federal state, on what conditions, and what characterisation the onshore court applies. **This is the interface the law-family index cannot see and it is the single most valuable item in this register.**
16. **Registered intellectual property**: the national registries, renewal calendars, validity standards and enforcement fora for each right, and the scope of the international filing and registration instruments, which coordinate filing and create no unitary right.
17. **All value, cost, volatility, hazard and share figures in this paper are constructed.** They are not quotations, benchmarks or estimates of any real company, facility, market or fee schedule.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 63

The Assembled Architecture: Effective Blocs, Sanctions Deeming Rules, and the Disclosure Test in Historical Instance

Abstract. We assemble the full structure and measure it with the corpus's own instrument. Against test parameters eta = 0.35, C = 0.30, Q = 10 and delta = 0.02, giving a maintenance floor of 0.500000, the conventional single-perimeter structure has one effective bloc and h = -0.500000; the designed six-jurisdiction structure has bloc HHI 0.340000, N = 2.941176 and h = -0.122417. The architecture closes 75.5167 per cent of the shortfall and does not close it, against a break-even N* = exp(0.5/0.35) = 4.172734. Marginal jurisdictions are priced rather than argued: the break-even probability p* = L/(G + L) puts the AIFC leg at 0.005110/(0.026731 + 0.005110) = 16.0476 per cent with a cost ceiling of 8.9102 per cent of C, while the largest available gain, a full Hong Kong leg at 0.072279, is refused on tail exposure and replaced by capped transit delivering 3.9692 per cent of the benefit for 3.2110 per cent of the exposure. On sanctions, the fifty per cent deeming rule is shown to be non-economic: seven tiers of 51 per cent holdings leave a blocked person 0.897411 per cent of the economics with the entity still blocked. Consistency across a 45-document compliance file fails with probability 90.056 per cent at a 5 per cent per-document error rate. The Medici bill of exchange passes the disclosure test in its strongest historical form while dry exchange fails it by construction.

Keywords: effective blocs; surplus headroom; break-even probability; ownership deeming rules; screening thresholds; bill of exchange; dry exchange; disclosure test

Series: D. Structure and Resilience **Paper:** CCP-063

1. Introduction

A framework that measures concentration is only worth what it says when it is pointed at a complete structure rather than at a convenient slice of one. This paper assembles a constructed multi-jurisdiction architecture in full, measures it with the corpus's own instrument at parameters fixed in advance, and reports the verdict the instrument returns including the part of that verdict which is unfavourable to the architecture.

The paper has four separable contributions.

The assembled measurement, and its failure to clear its own threshold. At the standing test parameters $\eta = 0.35$, $C = 0.30$, $Q = 10$ and $\delta = 0.02$ — giving a maintenance floor $\delta Q + C = 0.500000$ — a conventional single-perimeter structure measures one effective bloc and headroom $h = -0.500000$. The designed six-jurisdiction structure measures a bloc index of 0.340000, $N = 2.941176$ effective blocs and $h = -0.122417$. **The architecture closes 75.5167 per cent of the shortfall and does not close it**, against a break-even $N^* = e^{0.5/0.35} = 4.172734$. The counter-result is stated in the same breath: the only bloc assignment under which the structure clears the threshold is the naive one that treats coordinating jurisdictions as independent, which returns $h = +0.083099$ at the price of abandoning the coordination mechanism the framework exists to describe.

Marginal jurisdictions priced rather than argued. A candidate leg is a bet on a bloc classification, and a bet has a break-even probability. Setting the expected change in headroom to zero gives $p^* = L/(G + L)$, which for one candidate leg taking five per cent of exposure from a Western slot is $0.005110/(0.026731 + 0.005110) = 16.0476\%$, with a cost ceiling of 8.9102% of C. The largest single-move gain available anywhere in the structure, $+0.072279$, is refused, and the refusal is the result: a capped transit position delivers 3.9692% of that benefit for 3.2110% of the exposure, removing 96.79% of the tail.

An ownership deeming rule shown to be non-economic. A rule that deems an entity blocked when blocked persons hold fifty per cent or more directly or indirectly, individually or in the aggregate, is not a test on economic interest and does not behave like one. Seven tiers of 51% holdings leave the blocked person 0.897411% of the economics with the entity blocked in full, while two blocked persons at 24.50% each — the same 49% of economics as one at 49% — are not caught, and one further percentage point reverses the answer.

The disclosure test in historical instance. The Medici bill of exchange returned 4.166667% per round trip on the stipulated rates, an annualised 13.220482% at a 120-day interval against a 12.673611% simple loan rate that yields the identical 41.666667 florins — a difference of 0.000000000 florins between the prohibited instrument and the permitted one. The permitted instrument was fully disclosed to the very authority whose prohibition it was designed around and continued to work; dry exchange, its abusive twin, fails the same test by construction. **That is the disclosure constraint of Curzi [2026] — that a design whose effectiveness is structural is strengthened rather than weakened by publication, so that non-disclosure is refused as a design premise — observed in the field five centuries before it was stated as engineering.**

Why these sit in one paper. They are one instrument at four scopes. In each case a count of nominally distinct units overstates the number of things that can fail separately, and the correction is the same operation: group by whoever takes the decision, then square. That is the operation Curzi [2026] establishes as the concentration instrument, with a naive 3.407968 collapsing to exactly 1.000000 once a coordination perimeter is recognised, and it is the operation Curzi [2026] runs on a historical network, where five houses read 3.819710 effective jurisdictions naively and 1.000000 effective blocs once the Concert of Europe is treated as one perimeter, giving $h = -0.500000$. This paper adds the assembled case, the pricing method, the deeming-rule arithmetic and the historical instance.

Two conclusions the paper refuses. It refuses the reading under which the architecture is adequate, because that reading requires $\rho = 0$ between coordinating jurisdictions. And it refuses the reading under which the jurisdictional axis is the binding one: measured on the settlement-messaging axis the same structure returns $N = 1.305824$ and $h = -0.406608$, a gap of 0.284191 that is larger than everything the diversification programme achieved.

2. Hypotheses

Six hypotheses, each stated so that it could be wrong, each with its falsifier. Platt [1964]'s standard is applied: a hypothesis earns its place by naming the observation that would kill it. Three statements in the paper that are *not* falsifiable are labelled at the end.

H1 — the assembly hypothesis. A structure designed across coordination perimeters raises its surplus ceiling without moving its maintenance bill, so the ceiling term and the bill term respond to different interventions. *Predicted:* moving from one effective bloc to 2.941176 raises $\eta \ln N$ from 0.000000 to 0.377583 while $\delta Q + C$ stays at 0.500000, so h improves by exactly 0.377583 and remains negative. *Falsified by:* a bloc-count change that moves the maintenance floor, or a design that reaches $h > 0$ without moving C, η, Q or δ.

H2 — the binding-axis hypothesis. A structure is as diversified as its most concentrated axis, so measuring one axis and reporting the result overstates resilience whenever another axis is more concentrated. *Predicted:* on the constructed shares the jurisdictional axis gives $N = 2.941176$ and the settlement-messaging axis $N = 1.305824$, so the two readings of h differ by 0.284191. *Falsified by:* an axis decomposition on which the jurisdictional reading is the minimum, or a demonstration that the axes are not simultaneous exposures of the same capital.

H3 — the pricing hypothesis. A marginal jurisdiction admits a break-even probability and a cost ceiling, and both are computable, so a bloc call is a decision under uncertainty rather than an argument. *Predicted:* $p^* = L/(G + L)$ returns 16.0476% for the Eurasian candidate, 2.7108% for the China-bloc candidate, 36.1137% for a second-bridge candidate and exactly 0.0000% for a candidate drawn from the bloc it would fall back into. *Falsified by:* a candidate whose gain and loss cannot be computed from the same share vector, or a case in which p^* is not monotone in the loss.

H4 — the deeming hypothesis. An aggregate-ownership deeming rule is not a test on economic interest, and the two diverge without bound. *Predicted:* iterating 51% holdings, economic interest falls as 0.51^k — reaching 0.897411% at $k = 7$ — while the deemed status is unchanged at every tier; and two holders at 24.50% are not caught while two at 25.00% are. *Falsified by:* a monotone function mapping deemed status onto economic interest under the stated rule.

H5 — the consistency hypothesis. Compliance-file failure is a property of how documents are produced and not of how carefully they are checked. *Predicted:* with independently drafted documents at per-document error rate p, $P(\text{at least one inconsistency}) = 1 - (1 - p)^n$ reaches 90.056% at $n = 45$, $p = 0.05$, and falls to 8.615% at $p = 0.002$ — a factor of 10.45, achieved by changing the generation process rather than the review effort. *Falsified by:* a demonstration that review effort reduces p by the same factor at comparable cost, or evidence that document errors are strongly enough correlated that the independence assumption inverts the conclusion.

H6 — the disclosure hypothesis in historical instance. An instrument whose function is structural survives full disclosure to the authority whose rule it is designed around, while an instrument whose function depends on an unexamined element does not. *Predicted:* the bill of exchange, written, ledgered, notarised and publicly quoted, was disclosed to the promulgating authority — which was also the principal client — and continued to work; dry exchange, identical on the page, collapses the moment the return leg is examined. *Falsified by:* an element of the bill whose disclosure defeated it, or a documented dry exchange that survived examination of its return leg.

Not hypotheses, and labelled as such.

- *The bloc assignment* is a **modelling choice**. Which jurisdictions share a coordination perimeter is stipulated, not estimated; Section 3.3 states what that costs and what the remedy would be.
- *The parameter set* (η, C, Q, δ) is a **stipulation** fixed in advance of the measurement, which is what protects H1's criterion from being tuned to fit. It is not an estimate of any real position, and Section 14 gives the sensitivity that matters.
- *The identity of the headroom law's functional form* is a **modelling choice**, not a derived result. Section 3.1 names the alternatives that fit the same qualitative facts.

3. Method: the instrument, the parameters, and what is stipulated

3.1 The headroom law and which effective count

The framework's build criterion is a single inequality on a headroom quantity,

$$h = \eta \ln N - \delta Q - C,$$

in which N is an effective count of independent units, η converts input into durable stock, Q is the stock carried, δ its decay rate per period, and C a flow cost. $h < 0$ forbids building; $h > 0$ caps every increment at $r \leq h$. That gate is Curzi [2026]'s, worked there at $N = 18$ with $\eta = 0.30$, $\delta = 0.06$, $C = 0.55$, $Q = 1.20$ giving $h = +0.2451$; this paper reuses it unchanged as a precondition on the assembled structure. The decay term is the leaky-integrator form whose time constants Curzi [2026a] tabulates — $\tau = 1/\delta$ against $\tau_{\text{exact}} = -1/\ln(1-\delta)$, agreeing within one per cent at $\delta \leq 0.02$ — which is why $\delta = 0.02$ may be read as a fifty-period time constant without correction.

Which effective count, stated exactly, because the corpus runs two. This paper uses $N = \text{HHI}^{-1}$, the reciprocal of the sum of squared shares. That quantity is the Hill number of order two [Hill, 1973, Jost, 2006]: the number of equally-sized units that would produce the observed index. It is the reciprocal of Simpson [1949]'s index, the effective number of parties of Laakso and Taagepera [1979], and the numbers-equivalent reading of the concentration index attributed to Adelman [1969]; the index itself is Herfindahl [1950] and Hirschman [1964], and the thresholds at which competition authorities read it are policy choices that have moved [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and HHI^{-1} is also the exponential of the Rényi entropy of order two [Rényi, 1961].

The corpus's other effective count is not a Hill number and is not used here. The affine form $N_{\text{eff}} = 1 + (N-1)u$ of Curzi [2026] and Curzi [2026c] — the latter badging it a design axiom rather than a derived result, with a hundred-person department at $u = 0.05$ reading an effective count of 5.95 — is a linear interpolation between 1 and N. It is not a numbers-equivalent of any index and no ecological, economic, political-science or information-theoretic literature contains it. Curzi [2026] runs the verification chain on both and lets the affine one fail visibly. **Every effective count in this paper is HHI^{-1}, and where the affine count is referred to it is named and marked as the corpus's own construction.**

Why a logarithm, and what does not discriminate it. The $\ln N$ term is a modelling choice and this paper does not pretend otherwise. A sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the same qualitative facts — diminishing returns to added independent units, no saturation within the observed range — as well as the logarithm does, and nothing measured in this paper separates them. The strongest available warrant for the logarithm is not the perceptual one: Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics with no psychological assumption at all, which is what the argument here actually needs, since nothing in a jurisdictional exposure vector is a percept. Curzi [2026n] states the corpus's own Fechnerian reading. **The logarithm is adopted, its rivals are named, and the paper concedes that nothing here discriminates among them.**

The large-N limit is a defect of the model and is stated as one. h grows without bound in $\ln N$; the empirical diversity literature does not [May, 1972, Doak et al., 1998]. The model's domain is small N, and the structures measured here have $N < 6$.

3.2 The bloc collapse, and why it is a variance identity

Grouping units until the answer changes is a recognised way to lie, so the grouping requires a foundation that is not assertion. It has one. Model the exposure as a portfolio [Markowitz,

1952]: let w_i be the share exposed to unit i and X_i a unit-variance shock to it. The aggregate shock is $R = \sum_i w_i X_i$, with $\mathrm{Var}(R) = \sum_i \sum_j w_i w_j \rho_{ij}$.

Under independence the double sum is $\sum_i w_i^2$, which is the naive index exactly. Under perfect correlation inside blocs and independence across them it is $\sum_b W_b^2$, the bloc index exactly. **The two indices are one variance under two correlation assumptions, and $\mathrm{Var}(R)^{-1}$ is the effective number of independent shocks.** The general form $\mathrm{EFF} = 1/(w'Rw)$ is the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012] whose additive relative is Rao [1982]'s quadratic entropy. Curzi [2026] establishes this identity and verifies both endpoints on the same six shares to twelve decimal places; this paper reuses it and does not re-derive it.

The intermediate cases are not a nicety. Measured correlations rise under stress [Longin and Solnik, 2001, Ang and Chen, 2002], so **the effective count falls exactly when it is needed** — the ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008], and the ecological demonstration that effective count buys stability is Schindler et al. [2010]'s sockeye record. The coupled-network result of Buldyrev et al. [2010] is the formal statement of "units inside one perimeter behave as one and worse than one", and is used here for its structural form only, since its percolation premises have not been shown to hold for jurisdictions.

The contrary literature is read alongside and is not decorative. Doak et al. [1998] show diversity–stability correlations can arise from statistical averaging with no mechanism, so portfolio arithmetic is not by itself evidence of one; May [1972] shows that increasing diversity destabilises randomly assembled systems. On the generating side, Bouchaud and Mézard [2000] derives concentration from multiplicative growth with exchange rather than observing it. **This paper asserts no distributional form and no tail**; Section 13.7 records the consequence.

3.3 Identification: the bloc assignment is a stipulated reference group

The framework's reflexive law — a group's aggregate state influences its members while the members constitute the aggregate — is a linear-in-means reflexive specification, and Manski [1993] proves that its endogenous effect is **not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables however much data is collected. Shalizi and Thomas [2011] reinforce the point for network data, where influence and selection are generically confounded.

A bloc assignment is exactly a reference-group specification, and this paper adopts the stipulation remedy. Which jurisdictions coordinate is asserted, with an evidence class and an observable that would change the call, following the template of Brock and Durlauf [2001]. Randomisation, an instrument and partial-population variation are all unavailable here. **The price is that every bloc-level result in this paper is a modelling position and not an identified empirical result**, and Section 12.1 gives the robustness table that lets a reader substitute a different assignment.

The corpus's own reflexivity applies to the instrument as well. Lucas [1976] states the consequence: parameters estimated before a rule is published need not survive its publication. MacKenzie and Millo [2003] documents the mechanism in the field, with dates and prices, and Goodhart [1975] and Campbell [1979] name what happens when a measure becomes a target. **The framework asserts that systems change when modelled and then exempts its own η, δ and correlation assumptions from that same reflexivity. That is an inconsistency and this paper does not resolve it**; what it offers instead is the auditable reporting pack of Appendix A.

3.4 The four axes and the rule that the most concentrated one binds

Capital is exposed on more than one axis at a time, and the axes are simultaneous rather than alternative. The instrument is therefore run four times on the same structure — jurisdiction, counterparty, currency and settlement rail — and **the most concentrated axis is reported first**,

because a structure is as diversified as its worst axis and the axis an analyst measures is the one already familiar.

The rail axis requires a second collapse of its own, and it is the collapse that carries the result. A clearing system and a messaging layer are different objects, and participants in a distinct clearing system may still use the dominant messaging layer, so a structure reporting two rails may have one messaging dependency. **Collapsing rails by messaging layer is the same operation as collapsing jurisdictions by perimeter, and a structure that performs it on jurisdictions and not on rails has done half the measurement and reported all of it.** Curzi [2026] is the primary treatment: a naive correspondent index of 0.302400 (3.306878 effective correspondents) collapses to a perimeter index of 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency. This paper's rail measurement derives from that result.

3.5 What is constructed, what is described, and what is cited

Everything numerical in this paper is CONSTRUCTED. The entities, the exposure shares on all four axes, the cost allocation, the hazard rates, the error rates, the screening population, the branch and loan-book vectors and the exchange quotations are stipulated for illustration. No dataset was collected and no real structure, institution, bank, name or shareholding appears anywhere.

Jurisdiction-specific legal material is described from the source manuscript and is not cited. The bibliography contains general instruments and comparative doctrine only: it holds no statutes, regulations, court rules, registry documents, agency guidance or case reports for any individual jurisdiction, and none is cited here. Appendix B lists every affected claim. Where a named centre's legal characteristic is relied upon and cannot be supported from the bibliography, this paper follows Curzi [2026] and de-brands the description — a *Gulf free-zone centre*, an *Indian international financial centre*, a *Eurasian financial centre* — retaining the name only where the arithmetic of a specific published result requires it. **A description is not an assertion, and a de-branded description is not a claim about any particular jurisdiction.**

What *is* cited, and genuinely supports what it is attached to: the concentration literature of Section 3.1; the portfolio and ecological literature of Section 3.2; the automatic-exchange, anti-money-laundering and beneficial-ownership regimes as the reason non-disclosure is no longer an available design parameter [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015]; the listing machinery as a technique of governance [de Goede, 2011]; asset partitioning as the irreducible function of entity law [Hansmann and Kraakman, 2000] and the scholarly account of legal coding that is simultaneously its sharpest critic [Pistor, 2019]; and, for the historical material, de Roover [1963], which is the canonical modern scholarship and the source any reader wanting archival figures should use instead of this paper.

4. The assembled structure

4.1 Entities, blocs and exposure

The structure is a constructed apex-and-legs architecture: a foundation with separate legal personality at the top, holding companies in two free-zone centres, an operating company in a non-aligned manufacturing jurisdiction with a listed minority beneath it, an English-law contracting company with a converted real-estate position, a captive insurer against real third-party liabilities, a regulated fund and leasing vehicle in an Indian international financial centre, and a treasury and fund wrapper in a bridge jurisdiction, with per-asset ring-fencing vehicles below.

entity	bloc	job	function
foundation (apex)	BRIDGE	holding	separate legal person; holds everything below
Gulf holding company	BRIDGE	holding	the operating chain and the intangibles entity
Gulf trading company	BRIDGE	operating	the trading book
operating company	NON-ALIGNED	operating	manufacturing, labour, premises
listed minority	NON-ALIGNED	—	20% public float
English-law company	WEST	bridging	contracting
real-estate position	WEST	—	immovable, converted to movable
captive insurer	WEST	risk	reserves against real third-party liabilities
Indian centre vehicle	NON-ALIGNED	holding	regulated fund and leasing
treasury and fund wrapper	BRIDGE	bridging	settlement, foreign exchange, custody
ring-fencing vehicles	follows parent	—	per-asset segregation

The job column is the framework's holding / operating / bridging taxonomy, whose point is that one entity doing three jobs converts income into durable stock less efficiently than three entities doing one each. That friction lands on η, which Section 7.4 shows is the most powerful lever in the model.

Constructed exposure shares, carried unchanged from Curzi [2026]:

```
Gulf centre 29.1% · manufacturing jurisdiction 18.2% · UK 16.4%
Bermuda 13.6% · India 11.8% · Singapore 10.9%

naive HHI 0.189002   effective jurisdictions 5.290949
BRIDGE 40.0% / NON-ALIGNED 30.0% / WEST 30.0%
bloc-HHI  0.340000   EFFECTIVE BLOCS N = 2.941176
Western-perimeter exposure 30.0%
```

4.2 Five flows, and the rule that they must not share a path

A structure is not its ownership chart. It is five distinct flows, and most failures come from running two of them down one path.

flow	what moves	failure if it shares a path
ownership	shares, membership interests, the charter	a change in one flow silently changes control
cash	dividends, loans, service fees, settlement	a treasury dependency becomes an ownership dependency; a frozen account stops a governance process

flow	what moves	failure if it shares a path
contract	licences, supply agreements, facilities	an operating dispute reaches the apex because the apex was party to an operating contract
information	board packs, filings, onboarding packs, ownership records	a compliance answer in one jurisdiction contradicts one in another
decision rights	who instructs whom, reserved matters, resolutions	one person is the decision path for two blocs, so the bloc diversity is nominal

The design rule is that each flow should fail without taking the others with it, and the test is to name, for each flow, the single point whose removal stops it. Two flows naming the same point share a path. On the constructed structure: ownership and decision rights both terminate at the apex charter and council, which is deliberate and is what an apex is for; cash terminates at the treasury's principal correspondent; contract at the chosen governing law and arbitral seat; information at the group's single-source compliance file. **Only the cash row is a residual concern, and it is the settlement-rail exposure of Section 6 wearing different clothes.**

This is the same structural discipline Curzi [2026] states as channel separation — that a system is in-band when a value in one plane can be promoted to an instruction in another, and out-of-band when the two are disjoint by construction — applied to a corporate group rather than to a signalling network. **Separation is a property of the wiring; keeping it is a property of who is allowed to touch the wiring**, which is the governance result Ostrom [1990] reaches empirically for common-pool institutions and which Sagan [1993] shows can fail when added redundancy adds coordination surface instead of removing exposure.

5. Results: the assembled measurement

5.1 H1 — the ceiling rises and the bill does not: supported

At the stated parameters the maintenance floor is $\delta Q + C = 0.02 \times 10 + 0.30 = 0.500000$.

N	ln N	CEILING (eta ln N)	BILL (delta Q + C)	h
1.000000	0.000000	0.000000	0.500000	−0.500000
2.216500	0.795929	0.278575	0.500000	−0.221425
2.941176	1.078810	0.377583	0.500000	−0.122417
3.174603	1.155183	0.404314	0.500000	−0.095686
3.615826	1.285320	0.449862	0.500000	−0.050138
4.172734	1.428571	0.500000	0.500000	+0.000000
5.000000	1.609438	0.563303	0.500000	+0.063303

Both structures fall below the build threshold: the conventional one by 0.500000 and the designed one by 0.122417. The architecture closes $0.377583/0.500000 = 75.5167\%$ of the shortfall and does not close it. The ceiling column is what diversification produces; the bill column is untouched by it. At $N = 1$ the ceiling is exactly zero, so no amount of skill on the input side matters, because $\eta \times 0 = 0$ for every η.

H1 is supported. The correct reading is that jurisdictional diversity buys the *ability* to build and not the building: it raises the ceiling without paying the maintenance bill.

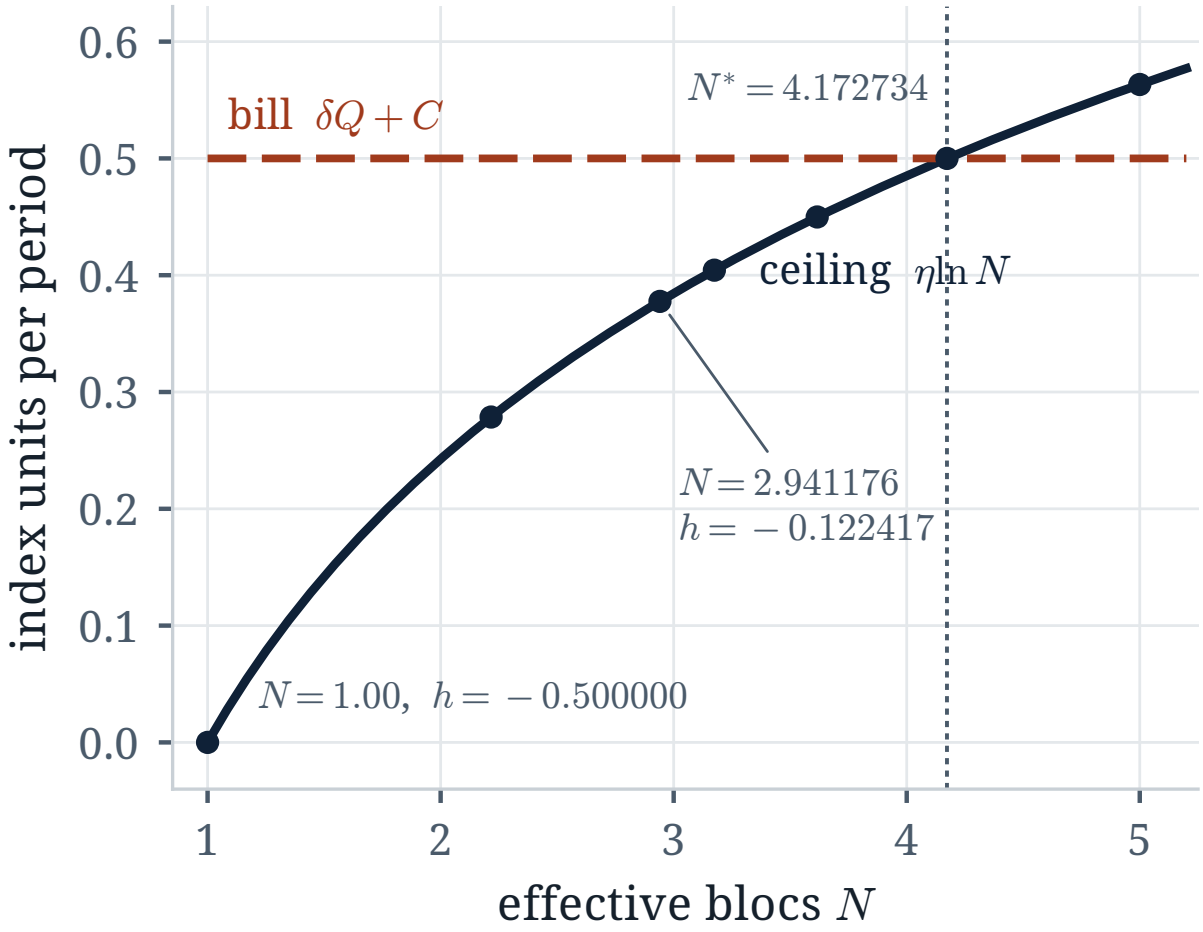

Figure 63.1: **The ceiling rises and the bill does not.** The surplus ceiling $\eta \ln N$ climbs from 0.000000 at one effective bloc to 0.377583 at 2.941176, while the maintenance floor stays flat at 0.500000; the two cross at the break-even $N^* = e^{0.5/0.35} = 4.172734$, which the designed structure does not reach. Modelled at the stated parameters $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$; script `figs/src/CCP-063_fig01.py`.

5.2 Robustness, and the counter-result

The bloc assignment is the judgemental step in the whole measurement, so the assembled h is recomputed under every defensible alternative.

assignment variant	bloc-HHI	N	h	vs base
base: captive centre folded into WEST	0.340000	2.941176	-0.122417	$+0.000000$
captive centre as its own light-Western bloc	0.295392	3.385332	-0.073192	$+0.049225$
bridge jurisdiction reclassified WEST	0.341962	2.924302	-0.124431	-0.002014
Gulf centre reclassified WEST (worst case)	0.451162	2.216499	-0.221425	-0.099008
Gulf and bridge centres as separate blocs	0.276562	3.615826	-0.050138	$+0.072279$
the two non-aligned legs as separate blocs	0.297048	3.366459	-0.075148	$+0.047268$
every jurisdiction independent (naive)	0.189002	5.290949	$+0.083099$	$+0.205516$

Three readings, and the third is why the table is printed.

The published base case is conservative rather than flattering. Folding the captive centre into the Western perimeter costs 0.049225 of h against treating it as its own; treating the two bridge centres as one costs 0.072279. The figure this paper publishes sits at the low end of a defensible range.

The result is insensitive to the most contested single call. Reclassifying the bridge jurisdiction as Western moves h by 0.002014, under two-tenths of one per cent of the maintenance floor. The argument most likely to be had about this structure does not move the answer. Only the Gulf-centre call does real damage, taking h to -0.221425.

And the last row is the counter-result. The only assignment that puts the structure above the build threshold is the one that treats every jurisdiction as independent — $\rho = 0$, $h = +0.083099$. Curzi [2026] computes that the conventional structure would need Western jurisdictions to correlate at $\rho = 0.065910$ for its naive figure to be the right one. **The architecture clears its own threshold if and only if the coordination mechanism the framework exists to describe is assumed away. The favourable answer is available at exactly the price of abandoning the thesis, and this paper declines to pay it.**

5.3 The metric that moved when the world did not

A third reading, carried because it is the cleanest available demonstration that the naive count reports diversification that did not occur. Hold the same 10.9% of exposure in a bridge juris-

diction classified as Western, or in the Western jurisdiction directly:

	naive HHI	eff jur	bloc-HHI	N	h
held in the bridge jurisdiction	0.189002	5.290949	0.341962	2.924302	−0.124431
same exposure held in the West	0.224754	4.449309	0.341962	2.924302	−0.124431
difference		+0.841640	0.000000	0.000000	0.000000

Eight-tenths of an effective jurisdiction on the naive count, and exactly zero on the bloc count, on N, and on h. The metric moved and the world did not. That is the general form of the error Curzi [2026] measures on a historical network and Curzi [2026] measures on a payment rail: rearranging exposure inside a perimeter changes the naive index and nothing else.

6. Results: H2 — the binding axis

The instrument is run four times on the same constructed capital.

axis	shares	naive HHI	effective count
jurisdiction	29.1 / 18.2 / 16.4 / 13.6 / 11.8 / 10.9	0.189002	5.290949
jurisdiction, blocs	40.0 / 30.0 / 30.0	0.340000	**2.941176**
counterparty	38 / 27 / 16 / 11 / 8	0.261400	3.825555
currency	44 / 17 / 15 / 13 / 7 / 4	0.268400	3.725782
settlement rail, naive	62 / 14 / 11 / 5 / 8	0.425000	2.352941
settlement rail, collapsed to messaging	87 / 5 / 8	0.765800	**1.305824**

The rail row is the one that matters and it is the one requiring the collapse. Reported naively the structure has 2.352941 effective rails; collapsed by messaging layer it has 1.305824. The consequence for the headroom law is stated so it cannot be missed:

N read off the jurisdictional axis	2.941176	h = −0.122417
N read off the rail axis	1.305824	h = −0.406608
difference		0.284191

The gap is larger than everything the diversification programme achieved (0.377583 of ceiling bought, 0.284191 of gap left on another axis). H2 is supported. This does not make the jurisdictional reading wrong; it means the structure has two answers and the honest one is the smaller. **A measurement pack that prints one of them has chosen which one to print, and the choice will not be the unflattering one unless the format forces it** — which is why Appendix A requires both.

This is the exposure Curzi [2026] names as invisible to the concentration instrument by construction: a count on one axis cannot see a common-mode dependency on another, and substrate concentration must be measured separately or it will not be measured at all. Two nominally independent perimeters resting on one messaging substrate are one exposure, which is Buldyrev et al. [2010]'s coupled-network result in structural form and Markowitz [1952]'s covariance point in its original one. **The counterparty axis is also more concentrated than the naive jurisdictional reading, and the currency axis nearly so; the jurisdictional reading is the third best of four.**

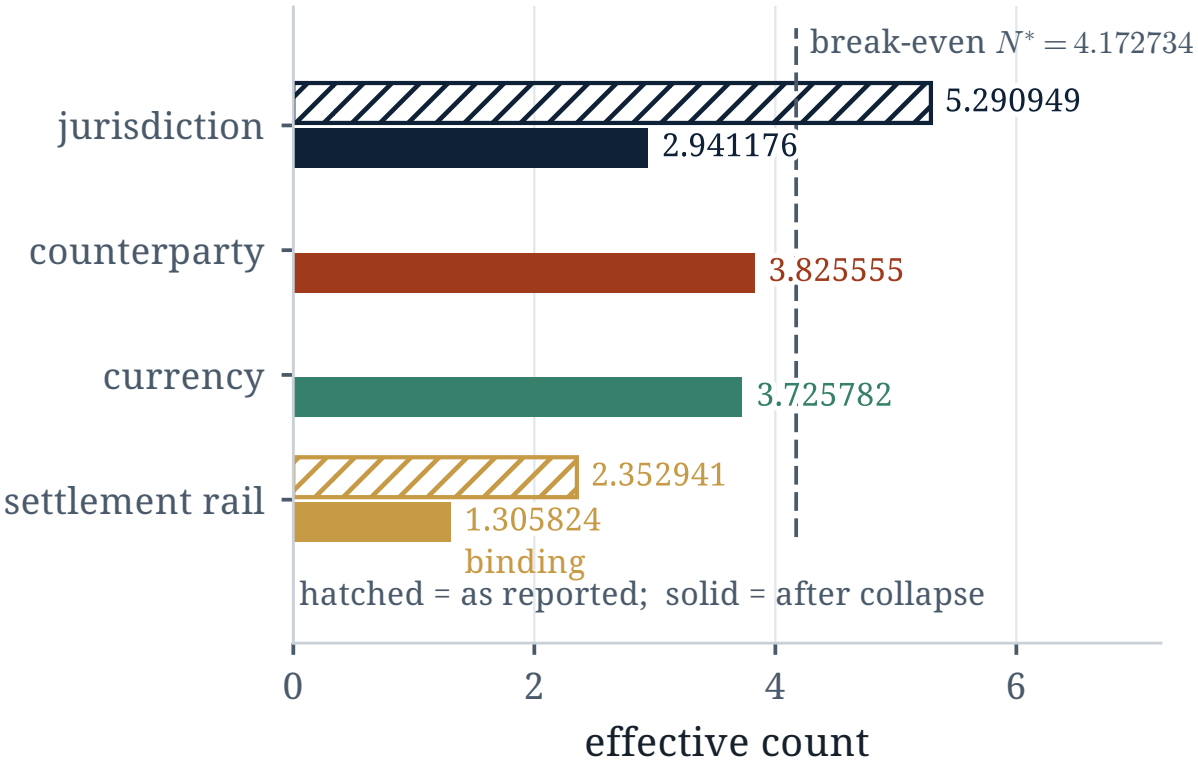

Figure 63.2: **The binding axis is not the one the design programme worked on.** Effective counts on four simultaneous exposure axes of the same constructed capital: the jurisdictional bloc count reads 2.941176 while the settlement-messaging count reads 1.305824, and reading h off the second rather than the first moves it from -0.122417 to -0.406608. Measured from the constructed share vectors of Section 6; script `figs/src/CCP-063_fig02.py`.

6.1 The threat map: what each element is actually for

The concentration measurement cannot answer the question of what an element is for, and the answer changes how the structure is judged.

threat	answered by	measured by
arbitrary action — freeze, expropriation, de-risking without process	bloc diversity across three perimeters	$N = 2.941176$
lawful process — a judgment that survived due process	**not answered by this architecture**; timing-bound and governed by transfer-avoidance law	not measured here
commercial and counterparty risk	captive against real third-party liabilities; per-asset ring-fencing	counterparty HHI 0.261400, N 3.825555
succession fragmentation across heir jurisdictions	the apex foundation and its charter	$dh/dN = 0.000000$; succession fora $6 \to 3 \to 2$
bloc fragmentation — the perimeters themselves moving	dual-rail settlement; the bridge positions	rail HHI 0.765800, N 1.305824

Two rows carry the section. **The succession threat is answered by the element whose contribution to N is exactly zero, and the fragmentation threat is measured on the axis where the structure scores worst.** The apex does the most important job in the architecture and contributes nothing to the headline number; the rail dependency is the worst exposure and appears in no jurisdictional table. **A structure judged on N alone would delete the first and never find the second.**

And the lawful-process row is unanswered deliberately. A judgment that survived due process is a different problem, governed by transfer-avoidance law and by timing, and nothing in this architecture is offered against it. **A paper implying otherwise would be describing a structure for a job it cannot do.**

7. Results: H3 — pricing a marginal jurisdiction

7.1 The break-even probability

A candidate leg is a bet on a bloc classification. If the call is right the leg lands in a new perimeter and N rises; if it is wrong it folds into a perimeter already held and N falls, because the exposure was drawn from somewhere. Both outcomes are computable from the same share vector:

$$G = h(\text{with leg, call right}) - h(\text{without}), \qquad L = h(\text{without}) - h(\text{with leg, call wrong}),$$

and setting the expected change to zero gives $p^* = L/(G + L)$.

candidate	bloc if right	G	$-L$	break-even p^*
Eurasian centre, 5% from the Western slot	EURASIA	$+0.026731$	-0.005110	**16.0476%**

candidate	bloc if right	G	$-L$	break-even p^*
China-bloc centre, 10.9% from the bridge slot	CHINA	$+0.072279$	-0.002014	2.7108%
second bridge centre, 5% from the Western slot	a second BRIDGE	$+0.026731$	-0.015110	36.1137%
African centre, 5% from the Western slot	AFRICA	$+0.026731$	$+0.000000$	0.0000%

The candidates are named in the source manuscript as the Astana centre, Hong Kong, T”urkiye and Mauritius, and the abstract of this paper keeps the first two names because the arithmetic of the first is a published corpus result. **They are de-branded in the table because each row depends on a legal or political characteristic of the named centre that this paper’s bibliography cannot support**, and because the arithmetic depends on nothing but which slot the exposure is drawn from and which bloc it lands in. Appendix B lists what would have to be verified before any name is reattached.

The Eurasian leg is Curzi [2026]’s result and this paper reuses its arithmetic unchanged: a right call takes N to 3.174603 for a gain of $+0.026731$; a wrong call takes it to 2.898551 for a loss of 0.005110; the expected change is $0.0318401p - 0.0051096$, zero at $p = 16.0476\%$. **That is a question with an answer, and it replaces an argument that has none.**

Four readings, and they are more interesting than the numbers.

A candidate drawn from the bloc it would fall back into is a free option. If the African call is right N improves; if it is wrong the structure is exactly where it started. The break-even probability is exactly zero, so the only remaining question is cost. That is the cheapest jurisdictional move available and almost nobody frames it that way.

A candidate drawn into a bloc it would concentrate is expensive. A second bridge centre alongside the two already held takes the BRIDGE bloc from 40.0% to 45.0% and makes the structure worse if the call is wrong. Its break-even is 36.1137%, more than double the Eurasian candidate’s on the same five per cent of exposure — and the difference is entirely about which slot it was drawn from and which bloc it lands in.

p^* **prices classification risk and nothing else.** It says nothing about the risk that a jurisdiction is *correctly* classified and then behaves catastrophically. The China-bloc candidate’s break-even is 2.7108%, an almost trivial bar, and Section 7.3 refuses the leg anyway. That is not an inconsistency; it is the recognition that two different uncertainties are in play and arithmetic on the first does not address the second.

7.2 The cost ceiling, which is the binding constraint

The whole gain from the Eurasian leg is 0.026731, which is $0.026731/0.30 = 8.9102\%$ of the total cost flow C. **The leg must run for less than 8.9102% of the structure’s entire maintenance budget or it is negative regardless of whether the bloc call was right.** On the cost allocation of Section 7.5 that ceiling sits below the smallest existing line, which is a harder test than any argument about regional alignment. **The binding constraint on a marginal leg is cost, not geopolitics, and the cost test is the one nobody runs.**

H3 is supported: both quantities are computable from the structure’s own share vector, and neither requires an opinion.

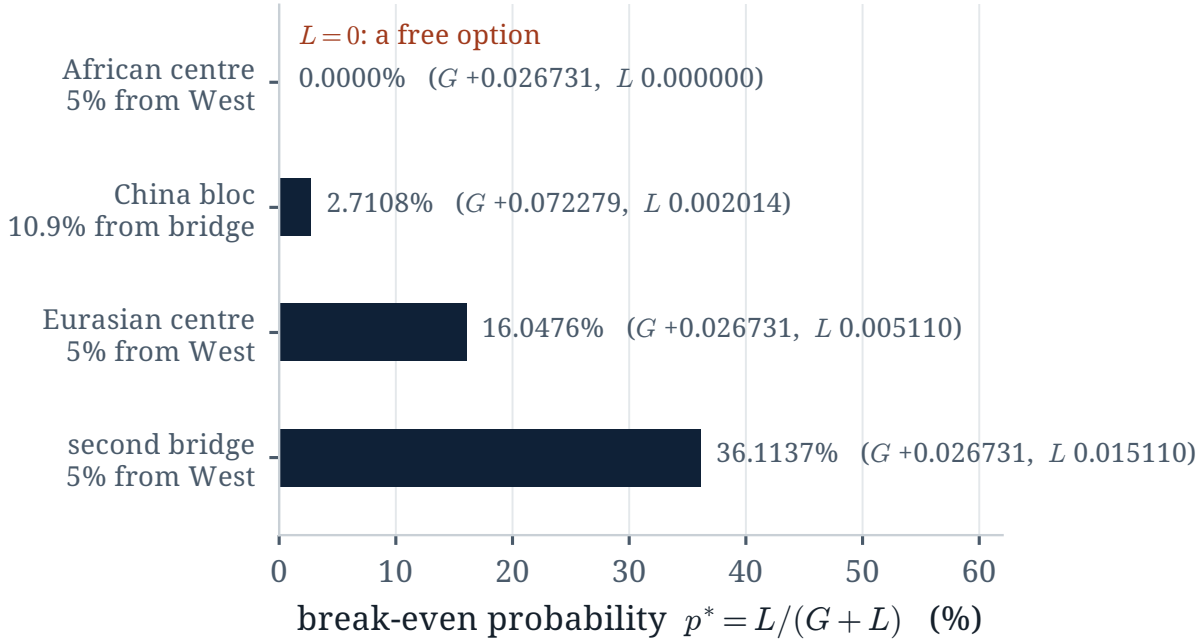

Figure 63.3: **Every marginal jurisdiction is a break-even probability with a cost ceiling attached.** Four candidate legs, each priced from the same constructed share vector: a candidate drawn from the bloc it would fall back into has $p^* = 0.0000\%$ and is purely a cost question, while a candidate that would concentrate a bloc already held reaches 36.1137%. Computed from the gains and losses in Section 7.1; script `figs/src/CCP-063_fig03.py`.

7.3 The largest available gain, refused

The China-bloc candidate in the same 10.9% slot produces $N = 3.615826$ and $h = -0.050138$: **a gain of $+0.072279$, the largest single-move gain anywhere in the structure.** It is refused, and the refusal is the result.

The reconciling principle is that protection is bought for the tail rather than for the median. A jurisdiction whose ordinary commercial courts work well and whose behaviour under political stress is uncertain is being purchased for exactly the state of the world in which the second property governs. **The median outcome is excellent and irrelevant**, because the premise of the purchase is the stressed state and not the current one.

Hence a capped transit position instead — 0.35% of exposure rather than 10.9%, taken as transit rather than as a store, under the framework's standing rule that a rail is not a holding:

```
full leg          10.90% exposure   N 3.615826   h −0.050138   gain +0.072279
capped transit     0.35% exposure   N 2.965384   h −0.119548   gain +0.002869
ratio              3.2110% of the exposure                     3.9692% of the benefit
```

The capped position delivers 3.9692% of the benefit for 3.2110% of the exposure — very slightly benefit-efficient relative to the full leg — and removes 96.79% of the tail exposure. That is the trade, computed.

The evidence for the tail judgement is not in this paper's bibliography. The source manuscript grounds the refusal in a sequence of security legislation, a decision of a final appellate court, an interpretation, a later ordinance reaching state secrets, and the withdrawal and resignation of overseas judges. **None of those is cited, because the bibliography contains no jurisdiction-specific statutes and no case law**; they are described in Appendix B and require verification against the primary sources. **The refusal is therefore a stipulated modelling po-**

sition and not an established finding, and a reader who assesses the tail differently should substitute their own judgement and re-read the arithmetic, which is unaffected.

7.4 The three levers, and the sensitivity that ranks them

At $N = 2.941176$, ceiling 0.377583, floor 0.500000, shortfall -0.122417, each of four single-parameter moves is sufficient alone:

lever	required value	from	change needed
C down	0.177583	0.3000	-40.8055%
η up	0.463474	0.3500	$+32.4211\%$
N up	4.172734	2.941176	$+41.8720\%$
Q down	3.879169	10.0000	-61.2083%

and the sensitivity per ten per cent move ranks them:

```
parameter    10% move    change in h
-----------------------------------
eta          +10%         +0.037758
N            +10%         +0.033359
C            −10%         +0.030000
Q            −10%         +0.020000
delta        −10%         +0.020000
```

η is the most powerful lever per unit of itself and it is the one nobody works on, because it is not a jurisdiction and cannot be bought. It is the conversion of input flow into durable stock, and the mechanism that raises it is job separation: an entity doing one job converts better than an entity doing three, because the friction of asking a holding vehicle to operate shows up as leakage on exactly this term.

7.5 The cost side, decomposed

$C = 0.30$ is an abstraction until it is allocated. On a constructed allocation:

line	C	% of C
operating-company substance	0.0520	17.333%
apex foundation	0.0450	15.000%
English-law company and property	0.0410	13.667%
Gulf holding company	0.0380	12.667%
treasury and fund wrapper	0.0360	12.000%
captive insurer	0.0340	11.333%
Indian centre vehicle	0.0210	7.000%
group compliance and screening	0.0190	6.333%
cross-family legal opinions	0.0140	4.667%
total	**0.3000**	

Two observations change decisions. **The substance lines are the largest and they are the ones that cannot be cut**, because substance is what makes an entity real; reducing them defeats the position they pay for, and a cost programme that starts there dismantles the structure and then reports the saving. **The compressible lines are the interfaces and the duplication.** A

star interface topology rather than a mesh — nine interfaces on ten touchpoints instead of forty-five, three canonical legal-family interfaces instead of six — saves 0.014 of C on the opinion budget alone, which is 4.6667% of the total and 52.3736% of the entire headroom gain from adding a whole additional jurisdiction. **The cheapest available improvement to h is an architectural choice that costs nothing and is usually made by accident.** That the interface count follows the organisation's own communication structure is Conway [1968]'s observation; that the accounting shows the slack as waste before it shows it as insurance is Cyert and March [1963]'s.

Stacked, with each step's source:

step	N	C	eta	h
designed, as built	2.941176	0.3000	0.350	−0.122417
+ star interface topology	2.941176	0.2860	0.350	−0.108417
+ Eurasian leg at 0.021 of C	3.174603	0.3070	0.350	−0.102686
+ the same leg at its 0.0267 ceiling	3.174603	0.3127	0.350	−0.108386
+ eta to 0.42 via job separation	3.174603	0.3070	0.420	−0.021823
+ C to 0.22	3.174603	0.2200	0.420	+0.065177

Two rows deserve slow reading. The leg at its ceiling cost gives $h = -0.108386$ against the star topology's -0.108417 — a difference of 0.000031, which is what a break-even ceiling means when it is computed rather than asserted. And the row that finally crosses zero requires $\eta = 0.42$ and $C = 0.22$ simultaneously, on top of an additional jurisdiction. **That is the honest size of the remaining problem, and none of it is on the jurisdictional side.**

7.6 Order of build, and an element worth zero

Returns to additional blocs fall as $dh/dN = \eta/N$, so build order has value.

move	N after	h after	dh
start: conventional	1.000000	-0.500000	—
+ apex foundation	1.000000	-0.500000	$+0.000000$
+ Gulf holding company, to 29.1%	1.700000	-0.314280	$+0.185720$
+ operating company, 18.2%	2.300000	-0.208482	$+0.105798$
+ Indian centre vehicle, 11.8%	2.600000	-0.165571	$+0.042911$
+ treasury, 10.9%	2.941176	-0.122417	$+0.043154$

The first non-Western move is worth 0.185720 and the last 0.043154 — a factor of 4.30. A half-finished programme in the right order is worth far more than a half-finished one in the wrong order.

And the apex row is zero, and the apex is still the most important element. It answers the succession threat rather than the arbitrary-action one, it is the layer that makes everything below administrable, and it saves 0.014 of C on the interface budget independently of anything it does for N. **An element that does not move the concentration measurement is not thereby worthless; it is answering a different question**, and judging every element against N is the failure mode the instrument invites. That asset partitioning rather than diversification is the irreducible function of the entity form is Hansmann and Kraakman [2000]'s point, and it is what the apex row is measuring on a scale the instrument does not carry.

7.7 A metric that improves as the structure fails

A pledge over the largest bloc's holdings is modelled with an eight-point migration of exposure to the lender's perimeter on enforcement:

```
before   naive 0.189002   eff jur 5.290949   bloc-HHI 0.340000   N 2.941176   h -0.122417
after    naive 0.181482   eff jur 5.510188   bloc-HHI 0.336800   N 2.969121   h -0.119107
change in h                                                                    +0.003310
```

The instrument reports an improvement of 0.003310 for an event that cost the principal majority control of the operating company. It reports it because the largest bloc was at 40.0% and the forced migration evened the shares. The measurement is correct and the conclusion is absurd. **A metric that improves as the structure fails is the most dangerous output any instrument can produce, and it must be read alongside the event rather than instead of it.** Curzi [2026] is the primary treatment of the pledge mechanics, where a constructed first-passage model at $\sigma = 40\%$ and $\mu = 6\%$ puts the ten-year probability of touching a 36% control-loss barrier at 76.347%, with a median time to the 23.076923% barrier of 0.8786 years; this paper's exposure migration derives from those triggers. Goodhart [1975] and Campbell [1979] are the general statement of the same pathology.

8. Results: H4 — an aggregate deeming rule is not an economic test

8.1 The rule, stated as a rule

The rule analysed here is stipulated in the following form, which is how the source manuscript states it and which this paper does **not** cite to any regime, because no regime's guidance is in the bibliography:

> **Deeming rule (stipulated).** An entity in which one or more designated persons hold, in the aggregate, fifty per cent or more of the ownership interest — directly or indirectly — is itself treated as designated, whether or not it is separately listed. The indirect limb does not terminate at a fixed depth; it terminates at natural persons or at an unresolvable node.

The rule deems; it does not multiply. That single property is the whole result, and it is a property of the rule as a mathematical object rather than of any jurisdiction's version of it.

8.2 The divergence, computed

Iterate a chain of 51% holdings. Economic interest is the product; deemed status is the conjunction of a threshold test applied at each tier.

tier	direct holding	cumulative economic interest	deemed?
1	51.00%	51.000000%	yes
2	51.00%	26.010000%	yes
3	51.00%	13.265100%	yes
4	51.00%	6.765201%	yes
5	51.00%	3.450253%	yes
6	51.00%	1.759629%	yes
7	51.00%	0.897411%	yes

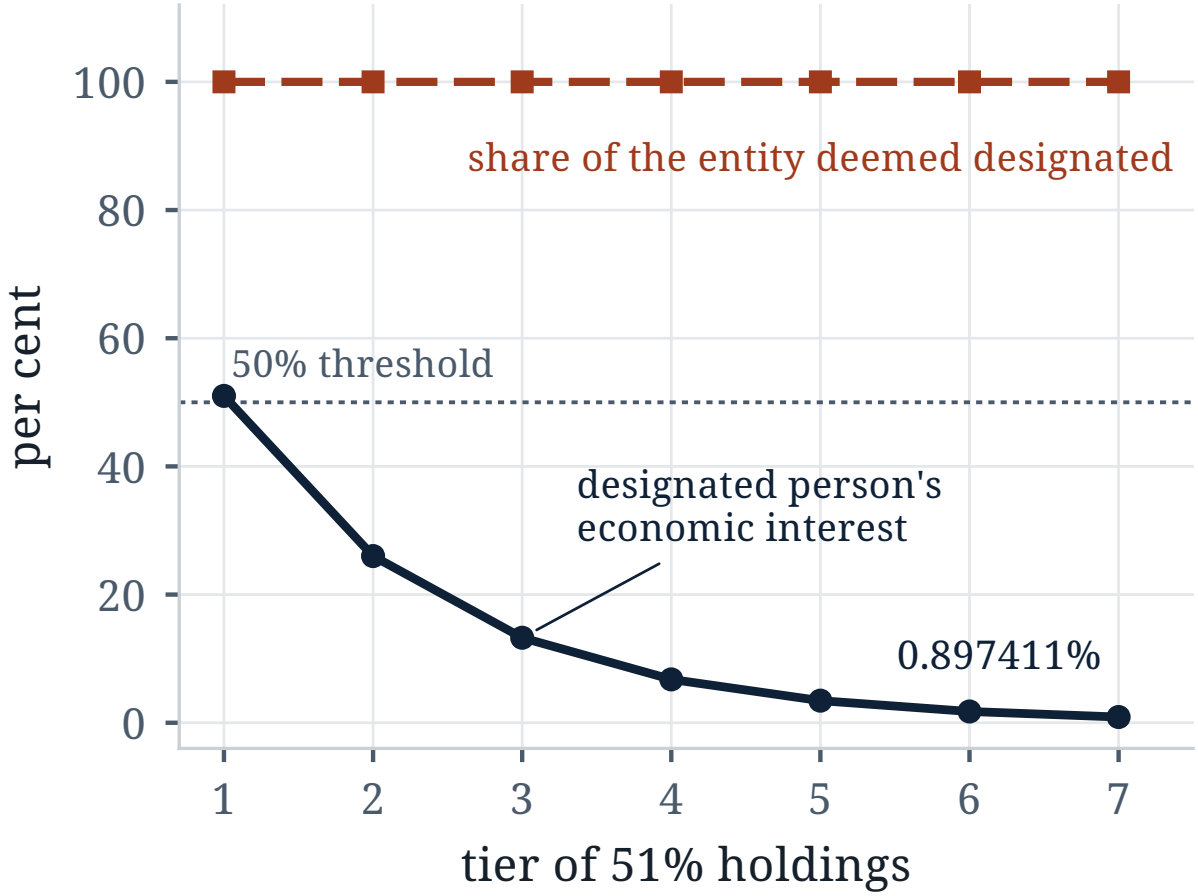

Figure 63.4: **A deeming rule and an economic-interest test are different functions and they diverge without bound.** Seven tiers of 51 per cent holdings drive cumulative economic interest from 51.000000 per cent to 0.897411 per cent while the deemed status is unchanged at every tier; the horizontal line marks the 50 per cent threshold that the economic reading crosses at tier two and the rule never does. Computed from the stipulated rule of Section 8.1; script `figs/src/CCP-063_fig04.py`.

At the seventh tier the designated person's economic interest is 0.897411% and the entity is deemed in full. A structure that computes economic interests and concludes it is comfortable has computed a quantity the rule does not use. The divergence is unbounded: economic interest decays as $0.51^{k} \to 0$ while the deemed status is invariant in k.

The aggregation limb produces a discontinuity in the other direction:

holding pattern	economic interest	deemed?
one designated person at 49.00%	49.00%	no
two designated persons at 24.50% each	49.00%	no
two designated persons at 25.00% each	50.00%	**yes**
one at 49.00% plus one at 1.00%	50.00%	**yes**
three designated persons at 17.00% each	51.00%	**yes**

One percentage point of economics separates the second row from the third and the answers are opposite. H4 is supported.

8.3 What follows for the resolution task

Two consequences follow directly and neither is a legal claim.

Ownership resolution is a search with an unbounded depth, not a lookup. Because the indirect limb terminates at natural persons rather than at a fixed tier, the correct depth is "until the tree terminates". At a branching factor of three across eleven corporate counterparties the node count is 44, 143, 440 and 1,331 at depths one to four. **An unresolvable node is a finding rather than an omission**, and a structure that acquires forty suppliers has acquired forty ownership trees.

Three regimes with different tests give different answers to one shareholding. A forty-five per cent holding by a designated person, carrying the right to appoint the board, is not caught on any of the three ownership arithmetics and is caught or contested on two of the three control tests. **A structure designed against one of them has designed against one of them.** The specific regimes, their tests and the appellate authority on the breadth of a control limb are described in Appendix B and are **not** cited, because none of them is in the bibliography. That different bodies of law define control differently for different purposes is what Pistor [2019] documents as the general mechanism, and it is the only part of this paragraph that carries a citation.

Where the paper stops. No claim is made here about any regime's actual rule, its current text, its scope, or any entity's status under it. **The result is that a rule of the stipulated form is not an economic test.** Whether any particular regime states a rule of that form is a question for Appendix B and for counsel.

9. Results: H5 — the file, the threshold, and the exposure window

9.1 The exit hazard, and why the loss is not proportional

A structure that cannot answer an assessment question is withdrawn from rather than adjudicated against: there is no hearing, no finding and frequently no explanation. Under a constructed annual exit hazard on five relationships:

annual exit hazard	expected at 1 yr	at 3 yr	at 5 yr
5%	4.7500	4.2869	3.8689
10%	4.5000	3.6450	2.9525
15%	4.2500	3.0706	2.2185
20%	4.0000	2.5600	1.6384

At a twenty per cent hazard the expected number of surviving relationships after five years is 1.6384. **And the loss is not proportional, because the relationships that go first are the ones doing the most work.** Losing the two largest counterparties takes the counterparty index from 0.261400 to 0.360000 and the effective count from 3.825555 to 2.777778 — a fall of 1.047777, **more than the entire counterparty diversification the structure had.**

The mechanism is an assessment-cost decision about a *category*, not a risk assessment of a *client*: an institution declines a category when the cost of assessing its members exceeds the revenue from them, adjusted for the tail. **The only lever a structure has is its own assessment cost**, and every component of that is an architectural choice made years before the assessment. That withdrawal from whole corridors is an unintended consequence of a risk-based approach is recognised by the standard-setting body itself [Financial Action Task Force, 2012], and the listing machinery through which it operates is documented as a technique of governance [de Goede, 2011].

9.2 H5 — consistency across a file: supported

Across n independently drafted documents at a per-document error rate p, the probability that at least one answer contradicts another is $1-(1-p)^n$.

n	$p=0.01$	0.02	0.05	0.10
5	4.901%	9.608%	22.622%	40.951%
10	9.562%	18.293%	40.126%	65.132%
20	18.209%	33.239%	64.151%	87.842%
30	26.030%	45.452%	78.536%	95.761%
45	36.381%	59.712%	**90.056%**	99.127%

A full onboarding pack across an eight-jurisdiction group runs to roughly forty-five documents. **At a five per cent per-document error rate the probability that the pack contradicts itself somewhere is 90.056%. At 0.2% it is 8.615% — a factor of 10.45.**

The way to move p is not care; it is to single-source the facts and generate the documents, so that there is one recorded value for each fact and every document is a view of it. **H5 is supported: the failure probability is a property of the generation process, and it falls by an order of magnitude without anybody being more careful.** This is the same defect Curzi [2026] measures at the character layer, where typed-field parsing collapses the withdrawn-code parsing-ambiguity false-positive share from 88.99% to 0.00% against a naive detection precision of 11.01% — a control right one time in nine — and it has the same remedy: fix the representation, not the reviewer.

The independence assumption is the model's weakest input and is stated as such. Documents drafted by the same adviser from the same instructions carry correlated errors, which reduces the count of *distinct* contradictions while raising the chance that a single wrong fact propagates through the whole pack. **Neither direction is measured here**, and the qualitative conclusion — single-sourcing dominates review effort — survives both because it removes the error at its origin rather than reducing its probability.

9.3 The screening threshold is a staffing decision

Name matching has a tunable threshold that sets both the false-positive rate and the miss rate. On a constructed population of two thousand payments a day:

threshold	FP rate	alerts/day	alerts/yr (250 d)	analyst-hours/yr at 12 min
exact match	0.000%	0.00	0.0	0.0
0.95 (tight)	0.200%	4.00	1,000.0	200.0
0.90	0.600%	12.00	3,000.0	600.0
0.85	1.500%	30.00	7,500.0	1,500.0
0.80	3.400%	68.00	17,000.0	3,400.0
0.75 (loose)	7.100%	142.00	35,500.0	7,100.0

The alert budget is a staffing decision that determines a detection rate, and almost nobody frames it that way. A structure that cannot fund fifteen hundred analyst-hours a year will run at 0.90 or tighter and inherits whatever miss rate that implies.

And the tightest setting is the most exposed, which is counter-intuitive and is the point. Exact-match comparison drives false positives to zero and is the configuration most completely defeated by a substitution that changes the bytes without changing the rendering. On constructed names, counting only characters with a visually identical form in another script:

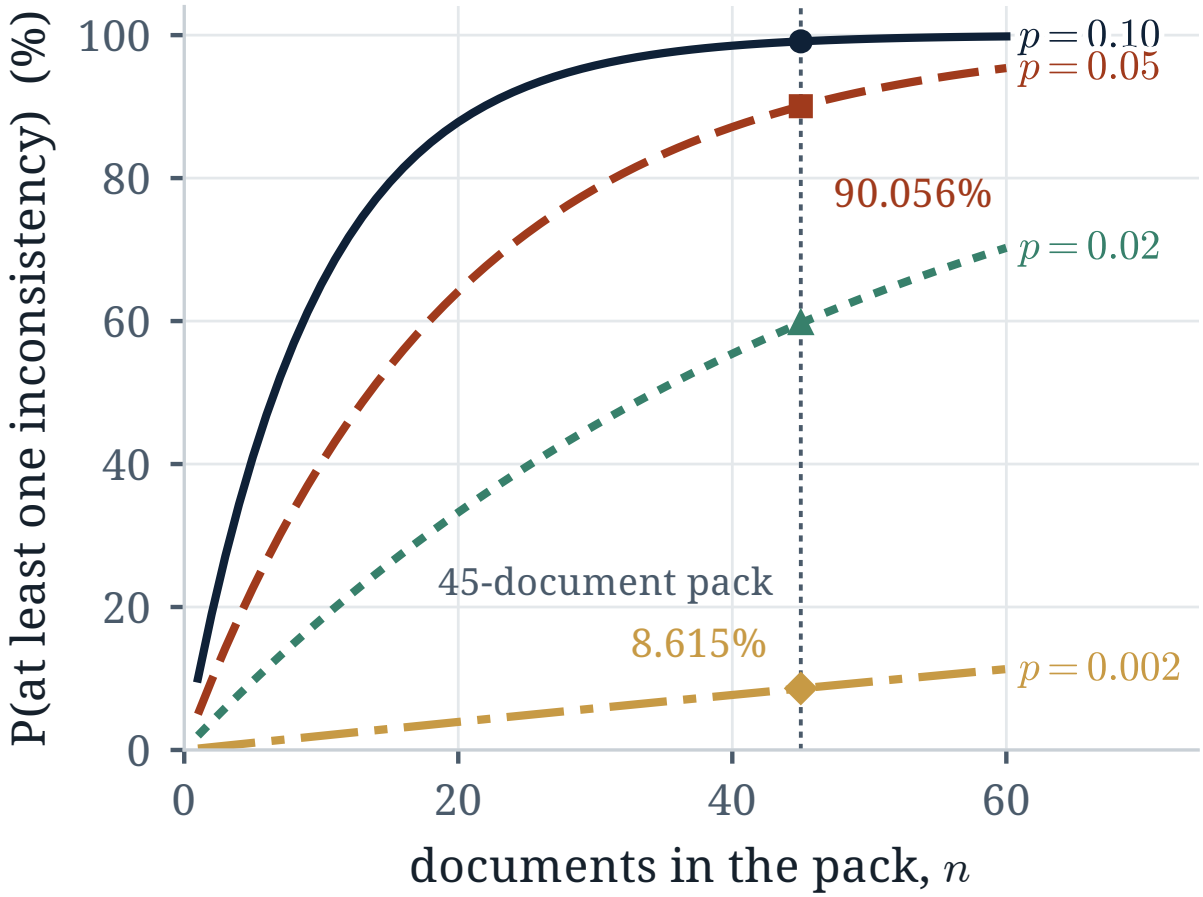

Figure 63.5: **File consistency is a property of the generation process, not of review effort.** $P(\text{at least one inconsistency}) = 1 - (1 - p)^{n}$ across independently drafted documents: at forty-five documents the failure probability is 90.056 per cent at a five per cent per-document error rate and 8.615 per cent at 0.2 per cent. Modelled with independent per-document errors at the stated rates; script `figs/src/CCP-063_fig05.py`.

string	substitutable characters	byte-distinct variants
a 14-character name	9	512
a 16-character name	11	2,048
a 20-character name	11	2,048
a 16-character name	11	2,048
a 17-character name	12	**4,096**

Covering one seventeen-character name by enumeration takes $2^{12} = 4{,}096$ list entries; after canonicalising both sides before comparison it takes one. A looser threshold does not close the class, because the variants are not *near* matches to a fuzzy engine — after the byte-level difference they are simply different strings that happen to look the same. Curzi [2026] specifies the canonical form and the raw-byte witness that detects the substitution rather than normalising it away, and Curzi [2026] states why the witness must be computed over the raw octets and kept on a separate plane. **This paper's contribution is to establish that the string comparison is load-bearing: every assessment answer a structure gives rests on the claim that the comparison worked.**

9.4 Transit exposure is linear in the window

A rail is not a holding, and freeze exposure on a transit asset is a window problem. Expected exposure per unit transferred, under a constructed annual hazard:

hops	hours/hop	window	hazard 0.10%	0.50%	2.00%
1	4	4 h	0.00000457	0.00002283	0.00009132
2	26	52 h	0.00005936	0.00029680	0.00118721
3	52	156 h	0.00017808	0.00089041	0.00356164
4	96	384 h	0.00043836	0.00219178	0.00876712

A four-hop route carries ninety-six times the expected exposure of a one-hop route, and halving the window halves the exposure exactly. That is the whole design lever, and it is a routing and pre-clearance decision rather than a legal one — a hop that cannot be pre-cleared is a hop that waits. Curzi [2026] owns the rail measurement this derives from.

10. Results: H6 — the disclosure test in historical instance

10.1 The constraint, and the instrument shaped around it

The mature bill of exchange is a four-role, two-place, two-currency, one-interval contract, and its shape is the negative impression of a constraint. The prohibited object was not interest but a specific juridical category: anything received beyond the principal by virtue of a loan of a fungible thing, where ownership passes and an equivalent quantity is returned. What was *not* prohibited defines the design space — a partnership share bearing venture risk, compensation for loss actually suffered by reason of delay, compensation for profit forgone, a penalty agreed in advance for late payment, payment for genuinely assumed risk of the principal, and a genuine exchange of one currency for another, which is a sale and not a loan.

The distinction between a loan of the same thing back and an exchange of one thing for a different thing — and not any doctrine about rates — is the hinge. The canonical texts, their canon numbers and the scholastic treatments of the exchange contract are described in Appendix B and are **not cited**, because the bibliography contains no canon-law sources. de Roover [1963] is the modern scholarship and is cited for the institutional account.

Four things happen at once in the instrument, and it matters that the document does not separate them: value moves between two places without metal moving; credit is extended for the length of the customary interval; currency is converted, twice if there is a return leg; and the transaction is on its face a purchase of foreign currency. **No rate of interest can be stated, because the contract contains two exchange rates and one of them is not yet known.** The outward rate is quoted when the bill is written; the return rate is whatever the foreign market quotes at the end of the interval. **The profit is therefore uncertain at the moment of contracting, and that uncertainty is the property the characterisation tracks.**

10.2 The arithmetic, and why it is the same number

The rates below are stipulated for illustration and are not taken from any archival series.

```
STIPULATED round trip

pay out                          1,000.0000 units of the home money
outward rate                     50.0000 foreign units per home unit
  -> delivered abroad          50,000.0000 foreign units
return rate at the interval     48.0000 foreign units per home unit
  -> brought home              1,041.666667 home units

gross gain                           41.666667  =  4.166667% per round trip
```

Annualised over plausible intervals:

```
round trip  60 days  ->  28.188775%   per annum
round trip  90 days  ->  18.004889%
round trip  91 days  ->  17.790398%
round trip 120 days  ->  13.220482%
round trip 180 days  ->   8.630055%
```

Take the 120-day case. The compounded annual rate is 13.220482%; the equivalent simple annual rate is $4.166667\% \times 365/120 = 12.673611\%$. A plain interest-bearing loan of $1{,}000$ for 120 days at 12.673611% simple yields 41.666667. The exchange differential yields 41.666667. **The difference between the prohibited instrument and the permitted one, computed to the ninth decimal place, is 0.000000000.**

That is a specification result rather than a scandal. **Two instruments with identical economics and different juridical characterisations are different instruments in every way a legal system can see, and the entire remaining question is whether the characterisation survives examination.**

The uncertainty is real, which is why the characterisation held:

return rate	profit on 1,000	as %
44.0	$+136.3636$	$+13.6364\%$
46.0	$+86.9565$	$+8.6957\%$
47.0	$+63.8298$	$+6.3830\%$
48.0	$+41.6667$	$+4.1667\%$
49.0	$+20.4082$	$+2.0408\%$
50.0	$+0.0000$	0.0000%
51.0	-19.6078	-1.9608%
52.0	-38.4615	-3.8462%
54.0	-74.0741	-7.4074%

The break-even return rate equals the outward rate. Moving the return quotation from 47 to 48 costs 22.163121 on a 1,000 principal, which is 2.216312%; **the entire** 4.166667% **differential is erased by a two-unit move, which is** 4.1667% **of the return rate and well inside the observed range of the period's quotations.** The writer of this bill could genuinely lose money.

Repeat the trip and compounding does the rest: 4.166667%, 8.506944%, 13.028067%, 17.737570% and 27.753440% per annum at one, two, three, four and six round trips a year.

10.3 Dry exchange, and H6

The abuse has its own contemporary name, and naming it matters because it is the exact point at which the design stops working. In a dry exchange the return leg is not real: the bill is drawn on a place with no correspondent, or on a correspondent instructed to protest it, or the return rate is fixed in advance by side agreement. The trade is then a term loan at a rate agreed at the outset, wearing an exchange's clothes. **The uncertainty is gone, and with the uncertainty gone so is the characterisation.**

Now apply the disclosure test — would the arrangement still do its job if every element were disclosed to every authority with jurisdiction over any part of it?

The bill passes it, and it passes in the strongest available form. The bill was written, entered in the ledgers of both houses, frequently notarised, and its outward rate was quoted publicly on both markets. The bank's principal client was the institution whose canonists had elaborated the prohibition; that client held the bank's own accounts, appointed it to the office of its treasury's depositary, and could inspect any of it at will. **There was no element the relevant authority could not see, and the authority with the most direct jurisdiction over the characterisation was on the other side of the table reading the ledger, and the instrument continued to work.**

Dry exchange fails the same test by construction. It requires that the return leg is not examined. Ask who the foreign correspondent is, whether the bill was in fact presented, whether it was protested by arrangement, and what the side agreement says, and the characterisation collapses into the prohibited thing. **Dry exchange is the version that was condemned, and it was condemned because the property that made the licit version licit had been removed while the form was retained.**

H6 is supported. Two instruments, near-identical on the page, one passing and one failing, and the historical record selects between them exactly as the test predicts. **This is the disclosure constraint of Curzi [2026] — effectiveness independent of whether anyone knows the design is in place, so that every element is publishable and non-disclosure is refused as a design premise — with a five-century-old worked instance attached.** Kerckhoffs [1883] is the principle's canonical statement and Saltzer and Schroeder [1975] its restatement as open design; Brandeis [1914] is the older policy instinct from the transparency side. The modern regulatory environment has since removed non-disclosure from the set of available design parameters altogether [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015].

The qualification belongs in print. Passing the disclosure test and passing the arithmetic test are two different tests. The assembled structure of Section 5 passes the first and fails the second at the tested parameters. **A structure can be entirely legitimate, entirely disclosed, entirely defensible, and still not generate enough surplus to pay for itself.**

10.4 The instrument pointed at the client dimension

The same concentration instrument, applied to the historical network. **The share vector is CONSTRUCTED for illustration; it is not de Roover [1963]'s, and readers who want archival figures should take them from him.** It is shaped only to the one thing the scholarship is clear

about — that the branch following the client's court dominated profitability — and it is used to demonstrate a mechanism rather than to report a fact.

```
CONSTRUCTED branch profit shares
42% · 14% · 10% · 9% · 9% · 7% · 6% · 3%   (eight places)

naive HHI            = 0.231600
effective branches   = 4.317789      (of 8 nominal)
```

Eight places, 4.32 effective — already a substantial haircut and already better information than "eight branches". But the branches are not independent in the dimension that matters, because a material part of the transfer traffic through several of them consisted of remittance heading for the dominant client. Collapse to client blocs:

client-derived share	client-bloc HHI	effective clients	h
42.0%	0.512800	1.950078	-0.266246
48.0%	0.500800	1.996805	-0.257958
55.0%	0.505000	1.980198	-0.260881
60.0%	0.520000	1.923077	-0.271126
65.0%	0.545000	1.834862	-0.287561

At the lowest reading the network has 1.950078 effective clients against 4.317789 effective branches: the branch count overstates diversification by a factor of 2.214162. The h column is computed at this paper's standard test parameters for comparability only; a fifteenth-century partnership faced none of the framework's erosion terms, and every value is far below the break-even $N^{*} = 4.172734$.

The error is smaller than the modern one. Curzi [2026]'s conventional four-jurisdiction structure reads 3.407968 naively and 1.000000 on blocs, an overstatement factor of 3.41. The historical network was better diversified than that structure, and neither was diversified.

10.5 The loan book, and the failure it predicted

CONSTRUCTED loan-book shares, shaped to the historical account and not drawn from any archival series:

```
sovereign A          38%
sovereign B          27%
a group of princes   15%
commercial bills     20%

naive HHI            = 0.279800
effective borrowers  = 3.573981        h = −0.054212
```

3.57 effective borrowers reads as a moderately diversified book. The right bloc is not geography. The two sovereigns were allies against a common adversary, funding the same war from opposite sides of one channel; their solvency depended on the same outcome. **They are not two exposures. They are one exposure with two names.**

```
collapsed to a single war-finance bloc: 65.0%

bloc HHI             = 0.545000
effective blocs      = 1.834862        h = −0.287561
```

The naive borrower count reads 3.573981 **and the bloc count** 1.834862 **— an overstatement of** 1.739119**, or** 94.782%**.** The books would have shown a portfolio spread across two kingdoms, several states and a body of ordinary commercial paper. The position was that nearly two-thirds of the lending was a single directional bet on one side of a continental war. **The instrument's answer was available in advance and nobody was computing it.**

10.6 What compartmentalisation bought, and what it did not

Each place of business was a separate partnership with its own deed, capital and books, the centre holding a controlling but not total interest and the local manager holding real minority equity. That is asset partitioning by separate legal personality [Hansmann and Kraakman, 2000] four centuries before the special-purpose vehicle, and it is routinely presented as a modern innovation.

The magnitude is not intuitive. Take eight units each with independent failure probability p in a period:

p	compartmented: expected units lost	consolidated: $P(\text{whole fails})$
0.05	0.4000 of 8 (5.00% of capital)	0.336580
0.10	0.8000 of 8 (10.00% of capital)	0.569533
0.15	1.2000 of 8 (15.00% of capital)	0.727509
0.20	1.6000 of 8 (20.00% of capital)	0.832228

Add a common systemic factor q striking all units at once and the picture sharpens rather than blurs:

q	consolidated $P(\text{total loss})$	compartmented $P(\text{total loss})$	expected capital loss
0.02	0.578142	0.020000	0.118000
0.05	0.591056	0.050000	0.145000
0.10	0.612580	0.100000	0.190000

At $q = 0.05$ and $p = 0.10$ the consolidated structure's probability of total loss is 0.591056 against the compartmented structure's 0.050000 — **a factor of** 11.821123**. The systemic factor is the only thing that can take the compartmented network down, which is precisely the point of building it that way: compartmentalisation converts idiosyncratic risk into a capital loss and leaves only the correlated risk as existential.**

And it did not save the institution, because it contains legal contagion and not economic or reputational contagion. Three leaks defeat it and all three are decisions by the centre rather than events imposed on it: a parent guarantee that breaches the compartment voluntarily from the inside; a common trading name, so that a failure in one place impairs funding in another through a channel no deed can seal; and a common apex, the same handful of principals holding the majority everywhere — which *is* the systemic factor q. **Compartmentalisation is a defence against idiosyncratic failure and not against correlated failure, and correlated failure is the one the structure is actually exposed to.**

The consequence for the modern structure is a budgeting rule and it is uncomfortable. **A single apex by design makes the correlated term the only term that can end the structure, so the remaining risk budget should be aimed at** q **and not at** p**.** Money spent lowering the failure probability of an individual leg is money spent on the term compartmentalisation already handles.

That the accounting method of the period is often credited with more causal force than it can carry is worth naming while the historical instance is open: Yamey [1964] and Littleton

and Yamey [1956] are the deflation of the claim that double-entry produced rational capitalism, and this paper makes no such claim. Curzi [2026] measures the completeness gap of the method directly.

11. Failure modes of the assembled measurement

11.1 Reading the flattering axis. The jurisdictional reading gives $h = -0.122417$; the rail reading gives -0.406608. Both are correct measurements of different things and only one is the constraint. **Print both, or the choice has been made silently and it will not be the unflattering one.**

11.2 Believing the diversification paid for itself. It closed 75.5167% of the shortfall and did not close it. The ceiling rose; the bill did not move.

11.3 Attacking the cost side by cutting substance. The three largest lines in C are substance lines, and substance is what makes the entities real. A cost programme that starts there dismantles the structure and then reports the saving.

11.4 Ignoring η. The most powerful lever per unit of itself, and the one nobody works on because it cannot be purchased from an adviser.

11.5 Arguing about bloc calls instead of pricing them. The Eurasian question is 16.0476%, the second-bridge question 36.1137%, the African question exactly 0.0000% and therefore purely a cost question. Every one of them was an argument in somebody's file before it was a number.

11.6 Confusing classification risk with tail risk. p^* prices the first only. A structure that reads a low break-even probability as a recommendation has priced one uncertainty and ignored the other.

11.7 Buying a jurisdiction that concentrates a bloc already held. The exposure is drawn from the right place and lands in the wrong one, and the break-even more than doubles.

11.8 Letting the leverage layer sit outside the exposure map. Section 7.7: the instrument improved by 0.003310 on an event that cost majority control of the operating company.

11.9 Sharing a path between two flows. Ownership and decision rights share the apex deliberately. Anything else sharing a point is a defect that will present as an unrelated failure.

11.10 A bloc that cannot do its job. Thirty per cent of exposure booked to a perimeter whose entities cannot bank, hire or obtain an opinion is thirty per cent of a measurement and none of a structure. **The effective count measures independence and not capacity**, which is Curzi [2026]'s own counter-result and applies here unchanged.

11.11 Measuring once. Perimeter fragmentation is invisible except as a difference between two measurements a year apart.

11.12 Treating a zero-dh element as an underperformer. It answers a different threat and it saves 0.014 of C on the interface budget. Judging every element against N is the error the instrument invites.

11.13 Adding a leg without its cost ceiling. A leg costing more than its gain is negative whether or not the bloc call was right, and the bloc call is the argument everybody has.

11.14 Reporting the naive assignment because it is the only one that clears. Every defensible assignment returns a negative number. A structure whose favourable result requires $\rho = 0$ between coordinating jurisdictions has not found a good answer; it has found the one assumption the framework exists to refute.

11.15 Assembling the chart and calling it the structure. Five flows, not one. An ownership diagram that is correct says nothing about whether the cash, contract, information and decision paths fail independently, and the failure that arrives will be in one of the four the diagram does not show.

11.16 Believing the answer is more jurisdictions. Break-even is $N^* = 4.172734$ and the candidate set considered here does not contain 4.17 genuinely independent perimeters. **The**

remaining distance has to come from C and η. The design side of the problem is finished; the cost side is not.

11.17 Keeping the form and removing the substance. The dry-exchange failure with its own contemporary name. If the property that makes a structure work is removed while the paperwork is retained, the structure does not become a weaker version of itself: it becomes the prohibited thing wearing the permitted thing's clothes, and it fails at the first examination that asks about the property rather than the paperwork. **Every substance requirement in modern practice is an examiner asking about the property rather than the paperwork.**

11.18 Mistaking the characterisation for the economics, and the reverse. The differential and the interest agreed to 0.000000000, so anyone concluding from the characterisation that the bill was not a credit instrument would have mispriced and mis-reserved against it. The commoner modern error is the reverse: because the economics are identical, the distinction is treated as a fiction. **A distinction with no economic content and complete legal content is still completely load-bearing.**

11.19 Decentralising liability without decentralising underwriting. A compartment that contains a decision-maker whose downside is capped at a minority stake while the majority's is not has converted a structural control into an agency problem.

11.20 Political position and commercial position as one asset counted twice. A structure whose licence to operate is a principal's personal standing has a single point of failure that no amount of entity architecture repairs.

11.21 Unpriced counterparty legitimacy risk. The historical case adds a threat category the modern literature almost never prices: the durability of a counterparty's own title. The institution whose account carried the network held its temporal position under a claim whose charter document had been demonstrated a forgery by philological argument roughly forty per cent of the way through the network's life, independently doubted seven years before that, and left unprinted for a further seventy-seven years. **That exposure did not destroy the network — the network was destroyed by ordinary concentration — but it was live for the whole second half of its existence and it was on nobody's register.** The dates, works and attributions are described in Appendix B and are not cited.

12. Discussion

12.1 What the instrument does and does not license

The instrument returns an effective count and nothing else. It says how many things can fail separately; it does not say whether any of them can carry the load, and it cannot see an axis it was not pointed at. **Both limits bite in this paper**: the succession threat is answered by an element scoring exactly zero on N, and the worst exposure in the structure lives on an axis the design programme never measured.

The framework's own founding move is presupposed rather than restated: Curzi [2026] establishes that the present state is a local minimum of the comfort landscape by construction, because comfort is defined as the felt total of present costs — which is why a structure's inertia is the default and why a headroom gate rather than an optimisation is the right form of criterion. Nothing in this paper re-derives that.

The most useful contrast in the corpus for this material is Curzi [2026], and it is a contrast rather than an endorsement. That paper's counter-result refuses category innocence as a defence of acquisition and forbids moving any harm through a gap discovered in a scheme, and it concedes that the case where the feedback loop runs through another person's will is an unsettled seam. **This paper's deeming-rule arithmetic and its dry-exchange analysis both sit directly against that refusal.** Section 8 shows that two designated holders at 24.50% are outside a rule that catches two at 25.00%; Section 10.3 shows that an instrument keeping a permitted form while removing its substantive property is the prohibited thing. **Finding a gap is not a licence to move anything through it, and this paper states the arithmetic of the gap for the**

purpose of designing against it — which is the only use Curzi [2026] leaves available. A reader who takes Section 8 as a design manual has read it against both papers.

12.2 Two answers, and which one to publish

Section 6 leaves the structure with two defensible values of h differing by 0.284191, and Section 5.2 leaves it with seven defensible values of N. The response is not to select one. **It is to publish the family and the assignment rule together**, which is what Appendix A requires and what makes a later reader able to substitute their own call and re-read the answer. A single number without its assignment is not a measurement of anything.

The magnitude of the shortfall in comparable units. Curzi [2026] fixes the conversion between the framework's surplus units: one nat of required surplus is 1.442695 bits, and the octave form is $2(c/\eta)/\ln 2 = 2.885390081777927 \times (c/\eta)$. The assembled structure's shortfall of 0.122417 nats is therefore 0.176610 bits. **The nat-to-bit conversion is exact arithmetic and carries no further content; the octave reading is deliberately not taken here**, because octave equivalence is a perceptual structure for pitch and nothing licenses carrying it to a quantity that is not a pitch. That restraint is the corpus's own and Section 14 records it.

12.3 The ordinal exposure, which is the sharpest objection

The headroom law divides by nothing but it multiplies η by a logarithm, and η is not measured. Curzi [2026]'s ordinal-defeat result is the exact warning and it is reused here as an instrument rather than cited decoratively: with c and η known only ordinally, $d \ln f_{\min}/d(c/\eta) = 2$, so a 0.1 error in the ratio is a 22.14% error in the derived quantity, and an order-preserving relabel of $(1.0, 2.0, 3.0)$ as $(0.5, 2.0, 5.0)$ moves one value by $54.6\times$ with the ordering unchanged. **The same exposure applies here.** h is linear in η, so an order-preserving relabel of the conversion efficiency moves h proportionally: at $\eta = 0.50$ the break-even falls to $e^{1.0} = 2.718$ and the designed structure clears it.

The scalar-reduction habit underneath that exposure is a framework-level limitation and is inherited here rather than restated. Curzi [2026] names it once, at framework level, as one objection appearing in two domains rather than two objections: where the source description is a pattern across several jointly varying features, the framework replaces it with a single number and does arithmetic on the number, and the validity of the arithmetic does not protect the reduction that produced it. **A bloc assignment does exactly that to a jurisdiction's relationships, and a headroom figure does it to a whole structure.** This paper concedes the objection in that form and points at its statement rather than repeating it.

Which is to say: the sign of the paper's headline result depends on a parameter that was stipulated, and a different stipulation reverses it. That is stated here rather than left for a reader to find, and it is the single most important sensitivity in the paper.

The measurement-theoretic status is worse than the sensitivity suggests. Michell [1997] argues that psychology systematically fails to test whether its attributes are quantitative at all before measuring them, and **that is the strongest single objection to this framework.** The formal test is conjoint measurement [Luce and Tukey, 1964], whose conditions establish additive quantitative structure; Krantz et al. [1971] sets out what must be true before a quantity can be said to exist. **Those conditions were not tested for η, for Q, or for the exposure weights, and this paper concedes the point rather than answering it.** What survives without them is structure and not magnitude: the ordering of the bloc assignments, the sign of h, the direction of every comparison, and the exactness of the arithmetic on stipulated inputs.

12.4 What is genuinely borrowed, and from where

The paper borrows a variance identity, a portfolio result, a numbers-equivalent, and a disclosure principle. **Section 13.5 labels each borrowing by category**, and the failure mode that

table exists to prevent is letting a shared mathematical form carry a derivation's authority. Cartwright [1999] supplies the discipline: state the arrangement within which a law is claimed to hold and stop claiming a universality the argument does not need. **The claim here is that a named set of constructed arrangements share a form, not that the form is universal.**

13. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and each chain names what it consumes. **If dropping a postulate leaves the result standing, it is not listed.**

13.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i, w_i	exposure shares	$[1]$	fraction of protected capital	defined; sum to 1
HHI	sum of squared shares	$[1]$	fraction (or points $\times 10^4$)	derived
N	effective count	$[\#]$	jurisdictions, blocs, counterparties, rails	derived as HHI^{-1}
$\ln N$	surplus argument	$[1]$	**nats**	derived; dimensionless by construction
η	conversion efficiency	$[\mathrm{idx}\, T^{-1}\, \mathrm{nat}^{-1}]$	index units per period per nat	**assigned by this paper; the source is silent**
Q	stock carried	[idx]	index units, no currency	assumed (stipulated)
δ	decay rate	$[T^{-1}]$	per period	assumed (stipulated)
C	cost flow	$[\mathrm{idx}\, T^{-1}]$	index units per period	assumed (stipulated)
h	headroom	$[\mathrm{idx}\, T^{-1}]$	index units per period	derived
p^*	break-even probability	$[1]$	probability	derived
G, L	gain, loss in headroom	$[\mathrm{idx}\, T^{-1}]$	same as h	derived
hazard, error rate	per-period probabilities	$[T^{-1}]$, $[1]$	per year; per document	assumed (constructed)
exposure window	transit duration	$[T]$	hours	assumed (constructed)
exchange rate	foreign units per home unit	$[F\, H^{-1}]$	stipulated units	assumed (stipulated)

Does the headroom equation balance? Only if η carries index units per period per nat, since $\ln N$ is a pure number and δQ and C are both index units per period. **The source treats η as a bare number; this paper assigns the dimension explicitly rather than silently**, following

Curzi [2026]. The break-even count $N^* = e^{(\delta Q + C)/\eta}$ is unit-free and survives; **the magnitude of h does not mean anything until an index unit is defined, and none is defined here.**

Does the transit calculation balance? Expected exposure is $\lambda \times w$ with λ in per-year and w in years, giving a dimensionless fraction of the amount in transit. $384/8760$ years at $\lambda = 0.02$ is 0.000876712, which is how the table is computed.

Where a quantity has no operational unit, the audit says so. Q, C and h are index units. The cost allocation of Section 7.5 is a decomposition of an index, not a fee schedule. The exchange arithmetic of Section 10.2 is in stipulated units of account and is not any historical currency.

13.2 Significant figures and epistemic status

- $N^* = e^{0.5/0.35} = 4.172734$ **is exact to the digits shown**, being a transcendental function of stipulated rationals; it is quoted to six decimals because the comparison to 2.941176 is made at that precision and both sides are exact arithmetic on stipulated inputs.
- **Every effective count here is exact for its share vector and is not an estimate.** $1/0.340000 = 2.941176\ldots$ and $1/0.765800 = 1.305824\ldots$ are rational; **no uncertainty is quoted because there is no estimate to attach one to.**
- 0.897411% **is exact**: it is 0.51^7 to six figures. 90.056% is exact for $1 - 0.95^{45}$.
- **The parameter set is stipulated, not estimated.** $\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$ were fixed in advance. Every output inherits that status: **exact arithmetic on assumed inputs is not a measurement.**
- **The hazard rates, error rates, alert rates and false-positive rates are illustrative model outputs and are rounded hard.** A twenty per cent annual exit hazard and a five per cent per-document error rate are stipulations; the figures derived from them — 1.6384, 90.056% — are exact functions of stipulations and carry no authority beyond them.
- **One rounding inconsistency in the source is reported rather than harmonised.** Section 13.8.

13.3 Limits and boundary behaviour

quantity	limit	behaviour	reading
N	one share $\to 1$	$N \to 1$	full concentration; the instrument's floor
N	n equal shares	$N \to n$ exactly	the numbers-equivalent property
h	$N \to 1$	$h \to -(\delta Q + C)$	the ceiling vanishes; no η can help
h	$N \to \infty$	$h \to \infty$	**a defect of the model, not a result**; domain is small N
h	$\eta \to 0$	$h \to -(\delta Q + C)$	no conversion, no ceiling, at any count
h	$\delta \to 0$	$h \to \eta \ln N - C$	nothing decays out of the stock: a pathology, not an ideal
p^*	$L \to 0$	$p^* \to 0$	a free option; the decision becomes purely a cost question
p^*	$G \to 0$	$p^* \to 1$	no upside; the leg is refused at any belief

quantity	limit	behaviour	reading
deeming rule	tier $k \to \infty$	economics $\to 0$, status invariant	**the divergence is unbounded; that is the result**
$1-(1-p)^n$	$p \to 0$	$\to np$	the linear regime; single-sourcing operates here
$1-(1-p)^n$	$n \to \infty$	$\to 1$	any positive error rate reaches certainty in enough documents
transit exposure	window $\to 0$	$\to 0$ linearly	exposure is exactly proportional to the window
compartmentation	$q \to 0$	$P(\text{total loss}) \to 0$	with no systemic factor the compartmented network cannot fail entirely
compartmentation	$q \to 1$	both $\to 1$	the compartment buys nothing against a certain common shock

The $\delta \to 0$ row is the corpus's standing example and it is preserved here: zero decay is a pathology because nothing ever leaves the stock, which is Curzi [2026a]'s pole result stated as a boundary.

13.4 Invariance

HHI^{-1} **is invariant under any permutation of the units and under any relabelling of them**, which is exactly why Section 5.3's rearrangement inside a perimeter moves the naive index and leaves N unchanged: the bloc index depends on the partition and not on which member of a bloc holds what. **It is not invariant under a change of share basis**, and the share basis is therefore item 1 of the reporting standard.

The break-even count N^* is invariant under any rescaling of the index unit that multiplies η, δQ and C together, since it depends only on the ratio $(\delta Q + C)/\eta$. **The magnitude of h is not**, which is why only N^* and the sign of h are quoted as findings.

p^* **is invariant under any positive rescaling of** h, since it is a ratio of two headroom differences — which is why the pricing method survives the absence of an operational unit that defeats the magnitude of h. **That is the strongest invariance in the paper and it is the reason Section 7 is the most transportable result in it.**

The equivalence of Section 10.2 is invariant under the choice of principal: the differential and the simple interest agree at any amount, because both are linear in it.

Tested at how many scales? **The invariances are algebraic and were checked at exactly the one parameter set and the share vectors reported.** No empirical scale-freedom is claimed anywhere in this paper.

13.5 Analogy discipline

borrowing	source	category	justification
HHI^{-1} as a numbers-equivalent	Adelman [1969], Hill [1973], Jost [2006]	**1 — derivation**	the premise is that shares are non-negative and sum to one, which holds by construction; the identity is exact
independent reinvention of the same index	Simpson [1949], Laakso and Taagepera [1979]	**1 — derivation**	same arithmetic on the same object in three disciplines
exposure as a portfolio; covariance not count	Markowitz [1952]	**1 — derivation**	the bloc collapse *is* the variance identity; the premises are satisfied by the construction
similarity-sensitive diversity of order 2	Leinster and Cobbold [2012], Rao [1982]	**1 — derivation**	exact where the correlation matrix has unit diagonal and non-negative entries, which is the regime used
correlation rising under stress	Longin and Solnik [2001], Ang and Chen [2002]	**2 — shared form**	measured in equity markets; jurisdictions are not shown to satisfy the same conditions
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	the percolation premises are not shown to hold for jurisdictions or for messaging layers
effective count buys stability	Schindler et al. [2010], Loreau and de Mazancourt [2008]	**2 — shared form**	an ecological measurement; the shape is used, the mechanism is not claimed
pseudo-diversity proved	Douceur [2002]	**2 — shared form**	one party presenting as many is the bloc problem in the identity domain; the impossibility result is not imported as a theorem here
independent-party bound	Lamport et al. [1982]	**2 — shared form**	$3f + 1$ is a theorem about agreement, cited as a prior formalisation of "how many parties are genuinely independent"

borrowing	source	category	justification
open design; disclosure	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	the premise — effectiveness depends on the arrangement and not on anyone's knowledge of it — is stated and satisfied by both the bill and the assembled structure
performativity of a published instrument	MacKenzie and Millo [2003], Lucas [1976]	**1 — derivation**	the mechanism is the same: a description relied upon changes the behaviour of those relying on it
a measure adopted as a target	Goodhart [1975], Campbell [1979]	**2 — shared form**	stated for monetary and social indicators; the exposure is the same in kind
organisational tight coupling; redundancy that reduces safety	Perrow [1984], Sagan [1993]	**3 — framing**	qualitative organisational theory, used as framing and as a warning, never as a formal result
concentration from multiplicative growth	Bouchaud and Mézard [2000]	—	cited only to record that a mechanism-side companion to the arithmetic exists; **no tail is asserted and this model is not used**
the modelling programme itself	Epstein [2008], Bruch and Atwell [2015]	—	the first enumerates the legitimate non-predictive uses of a model; the second is the checklist **none of this paper's models meets**

The failure mode this table exists to prevent is letting a category-2 borrowing carry a category-1 result's authority. The numbers-equivalent and the variance identity are category 1 and need no help; the network and ecological results are category 2 and are used for shape.

13.6 Postulates

#	statement	status
P1	exposure shares are non-negative and sum to one	DEFINITION
P2	HHI $= \sum_i s_i^2$, and $N =$ HHI^{-1}	DEFINITION
P3	for n equal shares of $1/n$, HHI $= 1/n$	ARITHMETIC
P4	$\mathrm{Var}(R) = \sum_i \sum_j w_i w_j \rho_{ij}$ for $R = \sum_i w_i X_i$ with unit-variance X_i	ARITHMETIC
P5	units inside one coordination perimeter act on one decision	POSTULATED (H1); a stipulated reference group
P6	$h = \eta \ln N - \delta Q - C$	DEFINITION (modelling choice; Curzi [2026], Curzi [2026])
P7	$\eta = 0.35$, $\delta = 0.02$, $Q = 10$, $C = 0.30$	POSTULATED (fixed in advance)
P8	the deeming rule of Section 8.1, as stated	DEFINITION (stipulated rule form)
P9	document errors are independent across documents	POSTULATED (constructed)
P10	the constructed share vectors, hazard rates and exchange quotations	POSTULATED (constructed)

13.7 The chains

Chain A — the assembled measurement (R1).

step	consumes	statement	status
A1	P2, P10	$\sum s_i^2$ on 29.1/18.2/16.4/13.6/11.8/10.9 is 0.189002	ARITHMETIC
A2	A1, P2	naive effective jurisdictions $= 1/0.189002 = 5.290949$	ARITHMETIC
A3	P5, P10	the six shares group as 40.0 / 30.0 / 30.0	POSTULATED (bloc assignment)
A4	A3, P2	bloc-HHI $= 0.40^2 + 0.30^2 + 0.30^2 = 0.340000$	ARITHMETIC
A5	A4	$N = 1/0.340000 = 2.941176$	ARITHMETIC
A6	A5	$\ln N = 1.078810$	ARITHMETIC
A7	A6, P6, P7	$\eta \ln N = 0.35 \times 1.078810 = 0.377583$	ARITHMETIC
A8	P6, P7	$\delta Q + C = 0.02 \times 10 + 0.30 = 0.500000$	ARITHMETIC
A9	A7, A8	$h = 0.377583 - 0.500000 = -0.122417$	ARITHMETIC
A10	A8, P7	$N^* = e^{0.500000/0.35} = e^{1.428571} = 4.172734$	ARITHMETIC

step	consumes	statement	status
R1	A9, A10	the structure closes $0.377583/0.500000 = 75.5167\%$ of the shortfall and does not close it	ARITHMETIC

Every step is arithmetic except A3, which is the bloc assignment. A3 is the one genuine postulate in the chain, it is the step Section 5.2 varies over seven alternatives, and it is the step a reader should attack first.

Chain B — the pricing method (R2, R3).

step	consumes	statement	status
B1	Chain A	$h_0 = -0.122417$ without the leg	ARITHMETIC
B2	P10	a right call gives $N = 3.174603$, $h = -0.095686$	ARITHMETIC
B3	P10	a wrong call gives $N = 2.898551$, $h = -0.127526$	ARITHMETIC
B4	B1, B2	$G = +0.026731$	ARITHMETIC
B5	B1, B3	$L = 0.005110$	ARITHMETIC
B6	B4, B5	$p^* = L/(G + L) = 16.0476\%$, computed at full precision from $L = 0.0051096$ and $G + L = 0.0318401$	ARITHMETIC
B7	B4, P7	cost ceiling $= G/C = 0.026731/0.30 = 8.9102\%$	ARITHMETIC
R3	P10	the full China-bloc leg gives $G = +0.072279$; capped transit at 0.35% gives $+0.002869$, being 3.9692% of the benefit for 3.2110% of the exposure	ARITHMETIC

The whole of Chain B is arithmetic on the same share vector. p^* is a ratio of headroom differences and therefore survives the absence of an index unit.

Chain C — the deeming rule (R4).

step	statement	status
C1	economic interest through k tiers of 51% is 0.51^k	ARITHMETIC
C2	$0.51^7 = 0.00897411 = 0.897411\%$	ARITHMETIC
C3	the rule of P8 applies a threshold at each tier and is satisfied at every tier for $51\% \geq 50\%$	DEFINITION

step	statement	status
C4	$2 \times 24.50\% = 49.00\% < 50\%$; $2 \times 25.00\% = 50.00\% \geq 50\%$	ARITHMETIC
R4	C2, C3, C4	the deemed status is invariant in k while economic interest $\to 0$, and one percentage point of aggregate reverses the answer

R4 rests on one definition and four lines of arithmetic and on no citation whatever, which is deliberate: **it is a result about a rule of the stated form, not about any regime's rule.**

Chain D — the compliance file (R5).

step	statement	status
D1	with independent errors, $P(\text{none}) = (1-p)^n$	DEFINITION, consumes P9
D2	$1 - 0.95^{45} = 0.90056$	ARITHMETIC
D3	$1 - 0.998^{45} = 0.08615$	ARITHMETIC
R5	D2, D3	the ratio is 10.45, achieved by changing p and not n

P9 is the assumption to attack. Correlated drafting errors change the count of distinct contradictions in one direction and the propagation of a single wrong fact in the other, and neither is measured here.

Chain E — the historical equivalence (R6).

step	statement	status
E1	$1{,}000 \times 50 = 50{,}000$ delivered abroad	ARITHMETIC
E2	$50{,}000/48 = 1{,}041.666667$ brought home	ARITHMETIC
E3	gain $= 41.666667$, being 4.166667%	ARITHMETIC
E4	$(1.04166667)^{365/120} - 1 = 13.220482\%$	ARITHMETIC
E5	$4.166667\% \times 365/120 = 12.673611\%$ simple	ARITHMETIC
E6	$1{,}000 \times 0.12673611 \times 120/365 = 41.666667$	ARITHMETIC
R6a	E3, E6	the differential and the simple interest agree to 0.000000000
R6b	—	the licit instrument was disclosed to the promulgating authority and worked; the abusive twin requires its return leg to go unexamined

R6a is arithmetic and R6b is not. The equivalence is checkable in three lines; the historical claim rests on a description this paper does not cite to a primary source, and Appendix B lists what would have to be verified. **A reader who rejects R6b keeps R6a intact.**

The discipline of verifying an identity over the complete set rather than on examples is Curzi [2026]'s, which checks its doubling theorem $HD_{\text{ess}}(i,j) = 2\log_2(pq)$ exactly over all sixty-six pairs at $N = 12$. **The chains above are checked at the one parameter set reported, which is weaker, and Section 14 records it.**

13.8 Discrepancies found in the source, printed

One rounding inconsistency was found and is reported rather than harmonised. The source states the designed structure's naive index as 0.1889 at one point in the historical section and as 0.189002 everywhere else. 0.189002 rounds to 0.1890 and not to 0.1889, so the single occurrence is a transcription error rather than a different rounding convention. **This paper uses** 0.189002 **throughout, which is the value the explicit double sum on** $0.291^2 + 0.182^2 + 0.164^2 + 0.136^2 + 0.118^2 + 0.109^2$ **returns.**

A second observation, not an error. The source reports the break-even probability as 16.0476% while the six-decimal gain and loss printed alongside it, 0.026731 and 0.005110, return 16.0485% when divided as printed. **The discrepancy is a rounding artefact of the printed inputs, not of the result**: the unrounded values are 0.0267305 and 0.0051096, and $0.0051096/0.0318401 = 16.0476\%$, which agrees with Curzi [2026] exactly. **This paper computes** p^* **at full precision and prints the rounded inputs, and records here that a reader redoing the division on the printed figures will land nine ten-thousandths of a percentage point away.**

13.9 Cross-checks performed

- The naive index was recomputed by explicit double sum on all four axes and reproduced 0.189002, 0.261400, 0.268400 and 0.425000.
- The bloc index was recomputed as $0.40^2 + 0.30^2 + 0.30^2$ and reproduced 0.340000 exactly; the messaging collapse as $0.87^2 + 0.05^2 + 0.08^2$ and reproduced 0.765800 exactly.
- The bound $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds on every vector used: $0.084681 \le 0.189002 \le 0.291$ on the jurisdictional axis and $0.7569 \le 0.765800 \le 0.87$ on the collapsed rail axis.
- The effective-count ceiling $s_{\max}^{-2}$ is respected everywhere: $5.290949 \le 11.8090$ and $1.305824 \le 1.3215$.
- Both historical vectors were re-summed: 0.231600 on eight branch shares and 0.279800 on four loan-book shares.
- 0.51^7 was recomputed to twelve places and rounds to 0.897411%.
- The interest equivalence was verified in both directions at the 120-day interval and agrees to nine decimal places on a principal of $1{,}000$.

14. Limitations

Every worked result is a constructed model and none is a measurement. The entities, the share vectors on all four axes, the cost allocation, the hazard and error rates, the screening population, the historical branch and loan-book vectors and the exchange quotations are stipulated. **No dataset was collected. No real structure, institution, bank, name, holding or transaction appears anywhere in this paper, and no allegation is made about any of them.**

No as-of date, because no real holdings were measured. A concentration figure computed from real holdings requires its source and its date; **a concentration measure without an as-of date is not a measurement.** Every share vector here is constructed, so there is no source and no date to give, and the reporting standard in Appendix A therefore makes the date an item.

The correlation inside a bloc is assumed, not estimated. $\rho = 1$ within a perimeter is the conservative end of a family, and no correlation was estimated from data anywhere in this paper. **That is the largest unmeasured input and it is exactly the quantity H1 turns on.**

Every parameter in the headroom law was chosen rather than measured, and the sign of the headline result depends on one of them. At $\eta = 0.50$ the break-even falls to 2.718 and

the designed structure clears it. **The conclusion that the architecture fails its threshold is therefore conditional on $\eta = 0.35$ and is not robust to a different stipulation.** It is stated here rather than left to be discovered.

The bloc assignment is a stipulated reference group and not an identified effect. Manski [1993] rules out recovering an endogenous social effect from observation of a linear-in-means reflexive system. The remedy adopted is stipulation with a defence [Brock and Durlauf, 2001]; randomisation, an instrument and partial-population variation were unavailable. **The price is that every bloc-level result here is a modelling position.**

Jurisdiction-specific legal claims are not cited to primary sources. The descriptions of sanctions regimes and their ownership and control tests, of automatic-exchange and beneficial-ownership obligations, of free-zone and promotion statutes, of the security legislation and judicial resignations underlying the tail refusal in Section 7.3, and of the canon-law prohibition and its extrinsic titles in Section 10, are all taken from the source manuscript. **The bibliography contains no statutes, regulations, agency guidance, court rules, registry documents or case reports for any individual jurisdiction, and no canon-law sources.** Those claims are described rather than asserted, are uncited, and require verification against the official sources. Appendix B lists them individually. **This is a real gap and it is not closed here.**

The historical claims are described and are supported only at the institutional level. de Roover [1963] is the modern scholarship and is cited for the institutional account; **no archival figure is asserted anywhere in this paper and every historical share vector is constructed and labelled.** The dating and attribution of the philological demonstration in Section 11.21, the identity of the branch managers, the terms on which the depositary office was held, and the legal form of the branch partnerships are all in Appendix B.

The effective count measures independence and not capacity. $N = 2.94$ says nothing about whether any bloc can carry the load, and a structure whose bloc diversity is real while its transacting capacity sits in one bloc has an effective count near 1.00 on the ability to act. This is Curzi [2026]'s counter-result and it is inherited unchanged.

The instrument is least informative where the headline case sits. Golosov [2010] and Dunleavy and Boucek [2003] document that effective-number measures behave poorly in the dominated-unit regime, and the conventional structure's bloc vector is a single unit at one hundred per cent — the limiting case. The measurement is still exact; its discriminating power there is at its minimum.

Small-sample bias is not addressed. Chao et al. [2014] show diversity estimators are biased on small samples, and a six-element exposure vector is a small sample. **No correction was applied, and the paper does not resolve whether these vectors are samples or complete censuses** — a reviewer would be right to press on it. Hurlbert [1971] is the standing reason the word "diversity" must always travel with its formula attached.

14.1 Rigour checks not met, listed by name

1. **No uncertainty is reported anywhere, because nothing is estimated.** Every figure is exact arithmetic on stipulated inputs. That is not precision; it is the absence of empirical content, and it means the paper cannot be wrong in the way a measurement can be wrong.
2. **Model comparison was not performed.** No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. The instrument is asserted to be the right one on the strength of the identity chain in Section 13.7, not on comparative fit.
3. **The dimension of η is supplied by this paper, not by the source.** Section 13.1 assigns it explicitly rather than silently.
4. **Q, C and h have no operational unit.** Only N^{*}, p^{*}, the ratios and the signs survive.
5. **The surplus law's large-N limit is a defect, not a result.** The domain is stated in Section 13.3 rather than discovered by a reader.

6. **The functional form of the surplus term is underdetermined by anything in this paper.** A sub-linear power law [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the same facts; Peters and Gell-Mann [2016] supplies the only warrant used, and **nothing measured here discriminates among the three.**
7. **The conjoint conditions were not tested** for η, Q or the exposure weights, so the ratio-scale treatment is provisional [Michell, 1997, Luce and Tukey, 1964, Krantz et al., 1971]. The orderings and signs survive because they are algebraic; the magnitudes do not.
8. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. The exposure vectors are finite sets of three to eight shares, not samples from a distribution; no tail is characterised and no power law is asserted anywhere. **Any restatement of this paper that reaches for a heavy-tail or power-law claim about holdings, branch profits, loan books or share distributions must run that procedure first**, and must read Stumpf and Porter [2012] on why passing it would still not identify a mechanism.
9. **The independence assumption in Section 9.2 is the weakest input in the paper** and its direction of bias is not measured.
10. **The instrument is exposed to its own adoption.** Goodhart [1975] and Campbell [1979] state what happens to a measure used as a target; nothing in the arithmetic prevents it, and the only defence offered is the reporting standard of Appendix A.
11. **The instrument is performative and its own parameters are exempted from that.** MacKenzie and Millo [2003] documents a model that made its assumptions true after adoption and Lucas [1976] states the consequence. **The framework asserts that systems change when modelled and then exempts its own η, δ and correlation assumptions from that reflexivity. That is an inconsistency and it is not resolved here.**
12. **Aggregation is unaddressed.** One Q, one δ and one C are written for a heterogeneous structure, and Kirman [1992] establishes that such a representative parameter generally does not exist.
13. **Expected value and time average are not the same thing and this paper reports the first.** Peters [2019] is the reason: the expected surviving-relationship counts of Section 9.1 are ensemble averages that no single structure experiences, and a structure that loses its last relationship does not return to the mean.
14. **There is no conservation law for Q.** The one genuine conservation is that shares sum to one; the stock variable has none [Mirowski, 1989]. **This is the objection the genre most often fails, and this paper meets half of it.**
15. **No differential prediction is offered.** Durlauf [2005] asks for the prediction that only this model makes, and the instrument makes none: any correlation-aware concentration measure would produce the same collapse. **The contribution is the identification and the discipline, not a uniquely discriminating forecast.**
16. **The models fail the calibration-and-validation checklist** of Bruch and Atwell [2015]: none is calibrated against observed data, none is validated out-of-sample, and none has a sensitivity analysis beyond the limits of Section 13.3. They are offered as demonstrations that a stated mechanism suffices to produce a stated shape, which is one of the legitimate uses Epstein [2008] enumerates and is not prediction.
17. **Octave reduction is deliberately not applied.** Curzi [2026]'s conversion is used only for the exact nat-to-bit identity in Section 12.2, because nothing licenses carrying octave equivalence to a quantity that is not a pitch. **The corpus's own restraint is preserved rather than relaxed.**
18. **The chains were checked at one parameter set.** Curzi [2026]'s standard — exhaustive verification over a complete set — was not met here, and the seven-row robustness table of Section 5.2 is the whole of the sensitivity analysis performed on the load-bearing postulate.

15. Conclusion

This paper establishes six results in the form the rest of the corpus cites, and the following statements are the fixed text of those results.

R1 — the assembled measurement. At $\eta = 0.35$, $\delta = 0.02$, $Q = 10$ and $C = 0.30$, giving a maintenance floor of 0.500000, the assembled six-jurisdiction structure measures a bloc index of 0.340000, $N = 2.941176$ effective blocs and $h = 0.35 \ln(2.941176) - 0.500000 = -0.122417$ against a break-even $N^* = e^{0.5/0.35} = 4.172734$. **It closes 75.5167% of the shortfall and does not close it.**

R2 — the break-even probability method. A marginal jurisdiction is priced as $p^* = L/(G + L)$. A Eurasian leg taking five per cent from a Western slot gives $G = +0.026731$ and $L = 0.005110$, so $p^* = 16.0476\%$, with a cost ceiling of 8.9102% of C. **The cost ceiling is the binding test and it is the one nobody runs.**

R3 — the largest gain, refused. The full China-bloc leg at 10.9% yields $+0.072279$, the largest single-move gain available, and is refused on tail exposure. Capped transit at 0.35% yields $+0.002869$ — 3.9692% **of the benefit for** 3.2110% **of the exposure, removing** 96.79% **of the tail.**

R4 — an aggregate deeming rule is not an economic test. Under a rule deeming an entity designated at fifty per cent aggregate direct or indirect ownership, seven tiers of 51% holdings leave a designated person 0.897411% of the economics with the entity deemed in full, while two designated persons at 24.50% each are not caught and two at 25.00% are. **The two functions diverge without bound.**

R5 — compliance-file consistency. $P(\text{at least one inconsistency}) = 1 - (1 - p)^n$ reaches 90.056% across forty-five documents at a five per cent per-document error rate and falls to 8.615% at 0.2%. **The remedy is single-sourcing the facts and generating the documents, not more review.**

R6 — the disclosure test in historical instance. On the stipulated rates the bill returns 4.166667% per round trip, an annualised 13.220482% at 120 days against a 12.673611% simple loan rate yielding the identical 41.666667 — a difference of 0.000000000. **The bill passes the disclosure test outright, in the strongest historical form available: it was fully disclosed to the authority whose prohibition it was designed around and continued to work. Dry exchange fails the same test by construction.**

Counter-result. The only reading under which the architecture clears its build threshold is the naive one assuming zero correlation between coordinating jurisdictions, giving $h = +0.083099$. **Every defensible bloc assignment returns a negative surplus.** And the jurisdictional axis is not the binding one: on the settlement-messaging axis the same structure reads $N = 1.305824$ and $h = -0.406608$, a gap of 0.284191 larger than everything the diversification programme achieved.

The honest verdict on the assembled architecture is: correct in design, insufficient in economics, insufficient in a way that is measurable and decomposable, and not repairable by adding another jurisdiction.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every case in this paper — the entities, the exposure shares on all four axes, the cost allocation, the hazard rates, the error rates, the screening population, the historical branch and loan-book vectors, and the exchange quotations — is **CONSTRUCTED** or **STIPULATED** and is labelled as such at each point of use. The numerical results are exact computations on those inputs, carried at full precision and rounded only for printing. **No real structure, institution, bank, jurisdiction holding, name, shareholding or transaction appears anywhere in this paper, and no allegation is made about any of them.**

All figures were produced by the scripts named in their captions (`figs/src/CCP-063_fig01.py` through `figs/src/CCP-063_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Jurisdiction-specific legal and regulatory descriptions in this paper are taken from the source manuscript and not from primary legal sources. The bibliography contains general instruments, comparative doctrine and multilateral standards only; it contains no statutes, regulations, agency guidance, court rules, registry documents or case reports for any individual jurisdiction, and no canon-law sources. **Appendix B lists every affected claim.** Any reader relying on those descriptions must verify them against the official sources, and none of them is cited here.

Historical claims are described from the source manuscript. de Roover [1963] is cited as the canonical modern scholarship and is where a reader wanting archival figures should go; **no archival figure is asserted in this paper and every historical share vector is constructed and labelled at the point of use.**

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every person, entity and holding referred to in this paper is constructed.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes entity types, jurisdictions, ownership rules and structural arrangements for the purpose of measuring concentration and resilience, and it makes no recommendation in respect of any particular person, asset, structure, counterparty or jurisdiction. **Sanctions designations, ownership and control tests, reporting obligations, substance requirements and limitation periods differ by jurisdiction, differ between regimes applying to the same facts, and change without notice.** Every such statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance. **Nothing in this paper is guidance for moving value that any regime prohibits**, and Section 8's arithmetic is stated for the purpose of designing against a rule rather than around it — the constraint Curzi [2026] states and this paper adopts.

Appendix A. The reporting standard

Any structure measured under this instrument reports the following, and nothing less. Items 1 to 9 are Curzi [2026]'s standard; items 5, 7, 9 and 10 are extended here because this paper's measurement has two defensible answers and the format must force both into print.

```
share basis, stated in one sentence
exposure table, ALL FOUR AXES, each summing to 100.0%
naive HHI and effective count, per axis
bloc or dependency collapse per axis, with the grouping rule stated
N per axis, with the MOST CONCENTRATED axis named FIRST
perimeter exposure as a percentage
ln(N), eta ln(N) and h -- computed on the BINDING axis AND on the
   jurisdictional axis, both printed
robustness table over contested bloc assignments
break-even probability p* and cost ceiling for every leg added or
   proposed in the period
cost allocation of C by line, with the year-on-year change
the date, and the diff against the previous measurement
```

Item 7 is the one this paper adds, and it exists because the two answers differ by 0.284191 **on the constructed facts.** A pack printing one of them has chosen which one to print. **Item 11 decays first and matters most, because perimeter fragmentation is invisible except as a difference between two measurements taken a year apart.**

Appendix B. Claims requiring verification against primary sources

The following rest on legal, regulatory or historical detail, and **none of them is cited to the bibliography, which contains no primary sources for any individual jurisdiction, no agency guidance, no case reports and no canon-law sources.** They are reproduced from the source manuscript, are described rather than asserted, and require confirmation with counsel or against the primary scholarship before any reliance.

1. That any sanctions regime's liability standard is strict, and the consequences of that for the design of an assessment programme. Confirm the current standard under each regime.
2. That any regime's ownership rule deems at fifty per cent aggregate direct or indirect holding, that its indirect limb terminates at natural persons rather than at a fixed depth, and the stated position on entities controlled but not owned at the threshold. **Section 8 analyses a rule of the stated form and asserts nothing about any regime's actual rule.**
3. The divergence between ownership and control tests across the three regimes described, including the indicators of control relied on, and the appellate authority on the breadth of a control limb — its citation, its precise holding, whether the relevant reasoning was obiter, and any legislative or guidance response. **This paper names the issue and states no outcome.**
4. Blocking-statute positions and the conflict-of-laws exposure they create for a group with entities on both sides, including any authority on the operation of such a prohibition in a contractual termination.
5. Reporting and classification obligations under automatic-exchange and beneficial-ownership regimes, per entity and per sub-fund, including the current participating-jurisdiction lists and the status of any regime whose scope has moved through litigation or administrative action. **No current scope is stated anywhere in this paper.**

6. The legal characteristics of every named or de-branded centre relied on by the bloc assignment: separate legal personality, purpose or beneficiary structures, founder control retention, free-zone statutes, promotion conditions, treaty positions, and the supervising courts. **Where the characteristic could not be supported, the centre is de-branded in the text and the description carries no claim about any particular jurisdiction.**
7. The security legislation, final-appellate decision, later interpretation, subsequent ordinance and judicial withdrawals and resignations underlying the tail refusal in Section 7.3. **The refusal is a stipulated modelling position; the arithmetic of the capped transit position is unaffected by how a reader assesses the tail.**
8. The canon-law prohibition and its sources: the twelfth-century compilation, the two conciliar canons, the decretal collections and the letter and decretal named in the source, together with their canon numbers, attributions and correct readings. **Take these from a canonist.**
9. The extrinsic titles — loss actually suffered by reason of delay, profit forgone, a penalty agreed in advance, and payment for genuinely assumed risk of the principal — their acceptance dates, and the degree of controversy attaching to each.
10. The scholastic treatments of the exchange contract by the two named fifteenth-century authorities, the specific works, and the positions actually taken. **This paper does not characterise them.**
11. The doctrinal status and dates of condemnation of dry exchange, including whether the condemnation was conciliar, papal or municipal, and where.
12. Customary intervals by route. The paper uses sixty, ninety, ninety-one, one hundred and twenty and one hundred and eighty days illustratively and asserts none as historical.
13. Actual exchange quotations with dates. **Every rate in Section 10.2 is stipulated.**
14. Whether the historical branch partnerships were of the specific Florentine form described, and how the centre's liability toward branch creditors was in fact limited in law and tested in practice. **This is the load-bearing legal claim of the compartmentalisation argument in Section 10.6 and it should not be relied on until checked** against de Roover [1963].
15. The dates and terms on which the depositary office was held, the occasions on which it was lost, and the formal duties attaching to it.
16. The identity, dates and conduct of the two branch managers associated with the failures, and the apportionment of responsibility between manager and centre, which is a live scholarly question with a more nuanced answer than the summary version.
17. The size and terms of the sovereign loans, the dates of branch closure, and the recovery if any. **Every loan-book share in Section 10.5 is constructed.**
18. The philological demonstration of Section 11.21 — its year of composition as against circulation, the independent earlier judgement, the independent English conclusion, the year and place of the printed edition, and the manner and extent of its later use.
19. The composition of the remittance flows described in Section 10.4 and their proportions.
20. Unicode confusables data and the security-mechanisms report underlying the homoglyph arithmetic of Section 9.3. Curzi [2026] is the primary treatment; nothing in this paper should be relied on for that material.
21. Whether any screening implementation canonicalises before comparison, at what normalisation form, and whether it retains and hashes the raw bytes. **This is a question to ask in writing, and the answer is frequently that it does not.**
22. All cost figures are index units in a constructed model. They are not fee quotations and no real fee schedule was used to produce them.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 64

Five Houses, One Perimeter: Bloc Collapse in a Historical Network, the Completeness Gap of Double Entry, and Canonicalisation as an Integrity Control

Abstract. The nineteenth-century five-house merchant bank is treated as a measurement problem rather than a legend. Weighting the houses London 40, Frankfurt 20, Paris 20, Vienna 13 and Naples 7 gives a naive HHI of 0.261800 and 3.819710 effective jurisdictions; collapsing them onto the Concert of Europe as a single coordination perimeter gives bloc HHI 1.000000, N = 1.000000 and h = -0.500000. The same five cities read as a modern EU/UK split give 1.923077 and h = -0.271126. An in-house courier cut exposure from three correspondent hops of eight days to one, a 66.6667 per cent reduction, and the modelled loss probability from 3.5360 per cent to 1.1928 per cent. A Bayesian treatment of the coordination question returns a posterior of 0.000732 for a unified hand against 0.999268 for competing centres, odds of 1,365:1. Double entry is then shown to be a consistency control and not an integrity control: the identity A - (L + E) = 0.0000000000 holds exactly while the statement misleads, two correctly kept books diverge by 0.460829 per cent on a single euro invoice, nine entities require thirty-six bilateral reconciliations against one shared record, and a constructed nine-capital vector is 63.850000 per cent represented and 36.150000 per cent structurally unrepresentable. Canonicalisation closes a class the ledger cannot see: canon(x) = restrict_ASCII(confusable_fold(NFKC(x))) collapses 495 of 495 manipulated entries onto the clean form and takes a reconciliation false-break rate from 40 per cent to 0 per cent.

Keywords: branch partnership; coordination perimeter; courier network; Bayesian posterior; double entry; completeness gap; canonicalisation; homoglyph substitution

Series: D. Structure and Resilience **Paper:** CCP-064

1. Introduction

A structure that spans several sovereign jurisdictions is usually described by counting them. This paper treats one of the most-cited historical instances of such a structure as a measurement problem instead, and then follows the measurement down two layers — into the bookkeeping instrument the structure ran on, and into the character encoding that instrument's records are written in. The three layers turn out to fail in the same way, and the shape of the failure is the paper's subject: **at each layer a count is taken over units that are assumed to be distinct, and at each layer the assumption is supplied from outside the instrument doing the counting.**

The paper's contributions are separable and are stated with their numbers.

The bloc measurement on a historical network. Weighting five linked merchant-banking houses at London 40, Frankfurt 20, Paris 20, Vienna 13 and Naples 7 gives a naive Herfindahl index of 0.261800 and 3.819710 effective jurisdictions. Collapsing the five onto a single coordination perimeter gives a bloc index of 1.000000, $N = 1.000000$ and $h = -0.500000$ at the corpus's standard surplus parameters. The same five cities read under a modern nominal EU/UK split give 1.923077 and $h = -0.271126$; read under the present coordination mechanisms they give 1.000000 and $h = -0.500000$ again. **The naive count is identical in both eras and the bloc count is not**, which is the whole of the instrument's content in two rows separated by two centuries. The spread across three defensible readings of the same 1815 structure is 0.469061 of h, and that spread is a definitional choice rather than a fact about the world.

The completeness gap of double entry. Double entry is shown to be a consistency control and not an integrity control. A wholly fictitious sale posted into a stipulated balance sheet leaves the accounting identity at $A - (L + E) = 0.0000000000$ exactly while moving reported assets by 66.6667 per cent, so **the identity's holding is not evidence of anything except arithmetic.** Two correctly kept books disagree by USD 500 on a single EUR 100,000 invoice — 0.460829 per cent of the buyer's figure — with neither party in error. Nine reporting entities require $n(n-1)/2 = 36$ bilateral reconciliations against one shared record. And a constructed nine-capital value vector is 63.850000 per cent represented on a balance sheet and 36.150000 per cent structurally unrepresentable.

Canonicalisation as an integrity control at the character layer. A deterministic synthetic demonstration shows that 495 of 495 substitutable manipulated identifiers are byte-distinct, digest-distinct and canonically identical; that $\text{canon}(x) = \text{restrict_ASCII}(\text{confusable_fold}(\text{NFKC}(x)))$ collapses all 495 onto the clean form idempotently; and that the false reconciliation-break rate falls from 40 per cent to 0 per cent at a 40 per cent manipulation rate, and from the manipulation rate to zero at every point of the sweep.

Why the three sit in one paper. The concentration instrument of Curzi [2026] — the Herfindahl index as the sum of squared shares and the effective count as its reciprocal, with a naive 3.407968 collapsing to exactly 1.00 once blocs are recognised — takes a partition of counterparties as an input it cannot check. Section 5 shows that the ledger cannot supply that partition, because concentration is a relationship between entries and double entry records entries. Section 6 shows that the identity resolution underneath the partition is string comparison, and that string comparison has a measurable blind spot which **biases the concentration measurement in the reassuring direction.** The same defect at the payment layer is measured by Curzi [2026], whose naive correspondent index of 0.302400 — 3.306878 effective correspondents — collapses to 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency; and the same defect at the assembled-structure layer is measured by Curzi [2026], which returns $N = 2.941176$ effective blocs and $h = -0.122417$ against a break-even $N^* = 4.172734$.

Three attractive claims are refused in print. The most famous story about the historical network — a one-day trading coup on early news of a battle — **is treated as a fabricated data point and is not used**, with the documented multi-year position substituted and the fabrication's provenance dated. The reading under which the five houses are facets of one coordinated actor is **rejected at odds of 1,365:1** on stipulated likelihoods, and the converse error, that

the absence of a unified actor means there is nothing structural to study, is refused in the same paragraph. And the 25 per cent currency-inflation figure of Section 6.5 is **badged as a property of the chosen synthetic 8000/2000 ratio and not as a constant**, with the confusable-only detection check reaching only 58.99 per cent against a headline of 100 per cent.

2. Hypotheses

Six hypotheses, each stated so that it could be wrong, each with its falsifier. Platt [1964]'s strong inference is the standard applied. Statements in the paper that are *not* falsifiable are listed at the end of this section and labelled as definitions, modelling choices or refusals.

H1 — the perimeter hypothesis. The effective count of a jurisdictional structure is set by the number of independent coordination perimeters it spans and not by the number of nominal jurisdictions. *Predicted:* holding the five cities, the five legal families and the share vector fixed and changing only the coordination mechanism moves the effective count while leaving the naive count at 3.819710. The 1815 financial reading returns $N = 3.819710$; the modern coordination reading returns $N = 1.000000$; h moves from -0.030939 to -0.500000. *Falsified by:* a demonstration that a decision taken inside one of the five capitals in 1815 produced enforcement in another without a second independent decision there, which would collapse the 1815 reading and remove the contrast.

H2 — the identity hypothesis. The accounting identity's holding carries no information about whether the recorded events occurred. *Predicted:* a wholly fictitious entry can be posted such that $A-(L+E)$ remains exactly 0.0000000000 while every reported ratio moves — assets by $+66.6667\%$, gearing by -60.6061%, days-sales-outstanding from 36.500000 to 118.625000 days. *Falsified by:* an arithmetic control internal to double entry that flags the entry, or a demonstration that the identity cannot close on a fictitious posting.

H3 — the two-books hypothesis. Two internally consistent sets of books can disagree about the same event with neither party in error, and the disagreement has no arbiter within the method. *Predicted:* a single EUR 100,000 invoice booked at 1.0900 by the seller and 1.0850 by the buyer leaves a USD 500 gap, 0.460829 per cent of the buyer's figure, with both trial balances closing to 0.0000000000. *Falsified by:* a rule internal to double entry that determines which of two permitted rate sources or timestamps is correct.

H4 — the reconciliation-cost hypothesis. In the absence of a shared record, the reconciliation relationship count grows quadratically in the number of parties while a shared record's grows not at all. *Predicted:* $n(n-1)/2$ against 1; at $n = 9$, 36 against 1; at $n = 50$, 1{,}225 against 1. *Falsified by:* a bilateral reconciliation regime whose relationship count is sub-quadratic without a shared record, or a shared-record regime whose count grows with n.

H5 — the completeness hypothesis. A representation that requires every element to carry an amount in a unit of account cannot represent value that has no measurable cost or observable price, and the omission is silence rather than a zero. *Predicted:* on the constructed nine-capital vector, 63.850000 per cent represented and 36.150000 per cent structurally unrepresentable, with the unrepresented fraction appearing nowhere on the face of the statements. *Falsified by:* a recognition framework that admits an unmeasurable item as an entry without destroying the closure property, which would show the gap to be a policy choice rather than a structural one.

H6 — the canonicalisation hypothesis. Confusable substitution in a critical machine field produces records that are byte-distinct and canonically identical, and a canonicalisation applied at the comparison boundary removes the resulting false breaks entirely without removing true matches. *Predicted:* 495 of 500 pairs byte-distinct, digest-distinct and canonically equal (99.0 per cent, the residual 5 being fields with no substitutable character); 495 of 495 collapsing onto the clean canonical form; false reconciliation-break rate 0.0 per cent at every manipulation rate from 0 to 100 per cent against byte equality's one-for-one tracking; and, on a synthetic watchlist, 0 of 20 probes matched by exact comparison against 20 of 20 by canonical comparison with all 10 clean names still matching. *Falsified by:* a manipulated value whose

canonical form differs from the clean value's, a canonicalisation that is not idempotent, or a true match lost to the folding.

Statements in this paper that are not hypotheses, and are labelled as such.

- *The bloc assignment itself* is a **modelling choice**, not a finding. Section 4.2 gives three defensible readings of one structure spanning 0.469061 of h and states that nothing in the arithmetic selects among them. Curzi [2026] is the authority for treating a bloc call as a claim requiring evidence rather than as a fact, and this paper's spread is the strongest available warning attached to that authority.
- *The disclosure test* is a **definition** of a design property, not an empirical claim. What is testable is whether a given element passes it.
- *The refusal of the one-day-coup account* is an **evidential judgement**, argued in Section 4.5 from the dating of the sources rather than measured.
- *The competing-centres posterior* is a **device for making an inference explicit.** Its likelihoods are stipulated. Section 4.8 states what is and is not carried by it.

3. Method

3.1 The instrument, and which effective count it is

Throughout this paper the concentration instrument is the Herfindahl index HHI $= \sum_i s_i^2$ over non-negative shares summing to one [Hirschman, 1964, Herfindahl, 1950], and the effective count is its reciprocal. **The reciprocal index is the Hill number of order two** [Hill, 1973]: the member of the family ${}^qD = (\sum_i p_i^q)^{1/(1-q)}$ at $q = 2$, which returns the number of equally weighted units that would produce the observed index. Adelman [1969] is the numbers-equivalent reading; Jost [2006] is the statement that entropies are not diversities and their numbers-equivalents are; the same arithmetic was reached independently in ecology by Simpson [1949] and in political science by Laakso and Taagepera [1979]. The exponential of Shannon entropy [Shannon, 1948] is the same family at $q = 1$, and the reciprocal index is the exponential of the Rényi entropy of order two [Rényi, 1961].

Which effective count is meant is stated every time it is used, because the corpus runs two quantities under that name and only one of them is a Hill number. Every effective count in this paper is $1/\text{HHI}$, the Hill number of order two. The corpus's affine count $1 + (N - 1)u$ appears nowhere in this paper; it is a linear interpolation between 1 and N, it is not a numbers-equivalent, and Curzi [2026] demonstrates in its verification section that the chain establishing the reciprocal index fails on the affine form at a nameable step.

Two cautions from the same literature are printed next to the instrument rather than in a footnote. Hurlbert [1971] argues that "diversity" has carried so many distinct quantities that the word means nothing without its formula attached, which is why the formula is attached here. Goodhart [1975] and Campbell [1979] are the standing warnings that a measure adopted as a target ceases to measure what it stood for — directly relevant to an index that regulators band [U.S. Department of Justice and Federal Trade Commission, 2023, 2010], and directly relevant again in Section 6, where an encoding defect moves the index without anything real changing. Chao et al. [2014] show that low-order diversity estimators are biased on small samples; a five-house or six-jurisdiction vector is a small sample and this paper does not correct for it.

The bloc collapse has an exact variance reading, developed in Curzi [2026] and used here without re-derivation. Treating exposure as a portfolio [Markowitz, 1952], with w_i the share exposed to unit i and X_i a unit-variance shock, $\text{Var}(\sum_i w_i X_i) = w'Rw$. Setting $R = I$ recovers the naive index and setting R to the block matrix of ones recovers the bloc index, so the two indices are one variance under two correlation assumptions. The general form $1/(w'Rw)$ is the similarity-sensitive diversity of order two of Leinster and Cobbold [2012], whose additive relative is the quadratic entropy of Rao [1982]. Buldyrev et al. [2010] is the formal statement

of why the bloc reading is the conservative one: coupled networks are far more fragile than either network alone.

The surplus reading used to price a change in the effective count is the corpus's $h = \eta \ln N - \delta_{\text{floor}}$ with $\eta = 0.35$ and a maintenance floor of 0.500000, fixed in advance and identical to the parameters of Curzi [2026] and Curzi [2026]. **Those parameters are stipulated, not estimated**, and every h in this paper inherits that status.

3.2 The perimeter test, stated operationally

The bloc question is answered by one observable, and the observable is stated so that it can be checked against a historical or a contemporary record without argument about alliances:

> A **coordination perimeter** is a set of jurisdictions among which one member's decision becomes another member's enforcement **without a second independent decision taken in the second jurisdiction.** Two jurisdictions are in one perimeter when such a mechanism exists between them and in different perimeters when it does not. Political alignment, shared interest, treaty membership and diplomatic congress are not the test; a transmission mechanism is.

This is the operational form of the perimeter test of Curzi [2026], and Section 4.2 applies it three times to one structure to show that it does not always return a unique answer. Where it does not, the honest presentation is to give every defensible reading and to price the disagreement, which is what Section 4.2 does.

The classes of mechanism that matter for the modern reading are the automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations and their evaluation and listing cycle [Financial Action Task Force, 2012], the substance and beneficial-ownership work [Organisation for Economic Co-operation and Development, 2015], supranational listing [de Goede, 2011], and correspondent risk-appetite transmission [Curzi, 2026]. **What these have in common is that they convert a decision taken in one place into an effect in another without a second decision there**, which is exactly the test. Pistor [2019] is the standing account of how legal coding produces such effects, and Hansmann and Kraakman [2000] is the reduction of entity law to the asset-partitioning function that the five-house architecture exploits.

3.3 The evidence discipline

Three rules govern what this paper is willing to assert, and they are stated in the Method rather than in the Limitations because they changed what the paper contains.

Sources are graded, and the grading is printed. Every substantive assertion in Section 6 carries a tier: **T1** for an established fact about a published standard or a mathematical property; **T2** for a quantity measured by the deterministic demonstration and independently recomputed for this paper; **T3** for a proposed design that is not adopted and not in force; and **T4** for a claim deliberately *not* made. The T4 tier is the important one, because the temptation this material creates is to claim more than it supports.

A widely believed account with a datable polemical origin is refused rather than hedged. Section 4.5 sets out the reasoning. The general rule is that a hostile source and a hagiographic source are not evidentially symmetric and averaging them produces a motivated account with a smaller error bar and no better accuracy. This is the two-column discipline of Curzi [2026w]: the evidence column carries what could have come out otherwise, the precedent column carries only that a claim was independently arrived at and preserved, and two sources agreeing does not double the evidence when only one of them is evidence.

A contested inference is written as a posterior rather than as an assertion. Section 4.8 states a prior, states four likelihood pairs, and prints the resulting odds, so that a reader who

disagrees can substitute their own numbers and recompute. The likelihoods are stipulated and the paper says so at the point of use, in the conclusion, and in the limitations.

3.4 The disclosure test

Every design element in this paper is audited against a single question, and the audit is printed: **would the element still do its job if every element of it were disclosed to every authority with jurisdiction over any part of it?** An element that passes is architecture; an element that fails depends on concealment.

This is not an ethical preference and it is not this work's to claim. It is Kerckhoffs [1883]'s principle, stated in 1883 — a system must remain secure when everything about it except the key is public — restated as *open design* among the protection principles of Saltzer and Schroeder [1975], and given its transparency-as-remedy form by Brandeis [1914]. Curzi [2026] states the resulting constraint in the form this paper uses: **channel separation is strengthened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable, and non-disclosure is refused as a design premise rather than merely discouraged.** The regulatory environment has independently removed non-disclosure from the set of available design parameters [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015].

The test is applied three times in this paper and it **splits** in Section 4.3, which is the result that makes it non-trivial: four elements of the historical architecture pass and one fails, and the element that fails is the one that did not survive.

4. A five-house network as a measurement problem

4.1 The architecture

The structure examined here is the early nineteenth-century five-house merchant bank in which one founder placed five sons in five sovereign jurisdictions — Frankfurt, London, Paris, Vienna and Naples — and constituted them as partners in a linked but legally distinct set of houses. It is treated here as the closest thing the historical record offers to a controlled instance of the corpus's central identification, because the geography, the legal families and the ownership are held fixed across two centuries while the coordination mechanism is not. **The historical description in this section is taken from the source manuscript, which relies principally on Ferguson [1998]; every specific date, deed, party and figure is listed in Appendix A as requiring verification against the primary record, and the capital shares are constructed.**

Four structural properties matter for the measurement.

1. **Separate legal houses in separate sovereign jurisdictions**, each under its own law, currency, courts and sovereign. This is asset partitioning in the sense of Hansmann and Kraakman [2000], executed across sovereignties rather than within one.
2. **Common partnership economics across them**, so that profits pooled while liabilities did not. de Roover [1963] documents the same arrangement at a smaller scale and within one commercial republic's diaspora, and Curzi [2026] measures its common-apex exposure.
3. **A private communications network** — couriers and contracted vessels, operated rather than rented. Section 4.4 prices it.
4. **Correspondence written in one language using another's script.**

The fourth property is routinely described as a cipher and is not one, and the distinction is load-bearing for this paper. A cipher transforms plaintext under a key; its security rests on the key and the transformation is public. Writing one language in another's script is a **change**

of representation: no key, no algorithm, and a property that rests entirely on the size of the population able to read the result. That property degrades monotonically as literacy spreads and as states acquire readers. **It is the same object Section 6 studies at the character layer — a change of representation is not a change of content — and treating one as the other is a vulnerability class rather than a control.** Confidentiality resting on a scarce readership is confidentiality with a decay rate, and it fails the disclosure test of Section 3.4 by construction, because its function is precisely that it not be read.

4.2 The bloc computation: three readings of one structure

The share vector below is **CONSTRUCTED for illustration.** The archival capital allocations across the five houses are not reproduced here and are listed in Appendix A.

```
CONSTRUCTED capital shares, c. 1815
London 40%   Frankfurt 20%   Paris 20%   Vienna 13%   Naples 7%

naive HHI               = 0.261800
effective jurisdictions  = 3.819710      (of 5 nominal)
h at the naive count     = -0.030939
```

The bloc question is then answered three ways, and the disagreement is priced rather than resolved by assertion.

Reading 1 — the post-1815 congress system as one coordination perimeter. On this reading the five capitals shared a coordination mechanism and the structure is one bloc.

Reading 2 — three perimeters. Britain stood apart from the eastern courts' alignment and repeatedly declined the interventionist principle; Restoration France sat inside the congress system but outside that alignment; Austria, the German Confederation and Bourbon Naples moved together.

Reading 3 — five perimeters. The congress system coordinated on legitimacy, territorial settlement and armed intervention. It did not coordinate on the mechanisms of Section 3.2: there was no common standard for financial supervision, no shared exchange of tax information, no common list of non-cooperative jurisdictions, no correspondent risk-appetite transmission channel and no supranational body empowered to grade a member's financial regime. **A decision taken in one capital did not reliably produce the corresponding effect in another without a separate decision taken there**, which is the perimeter test failing to join them.

reading	bloc partition	bloc HHI	N	h	Δh vs 1
1 congress as one perimeter	all five	1.000000	1.000000	-0.500000	—
2 three perimeters	40 / 40 / 20	0.360000	2.777778	-0.142422	$+0.357578$
3 five perimeters	40/20/20/13/7	0.261800	3.819710	-0.030939	$+0.469061$

This paper's judgement is that reading 3 is the better description for *financial* purposes and reading 2 for *political* ones, and that the honest presentation is to give both and name the observable that separates them. The observable is the mechanism list of Section 3.2. **A coordination perimeter is not an alliance; it is a mechanism by which one state's decision becomes another state's enforcement without a second independent decision, and the post-1815 congress system had that for troops and did not have it for money.**

The 0.469061 spread is the paper's most important negative result about its own instrument. Three readings of a single structure, all defensible, differ by more than any single

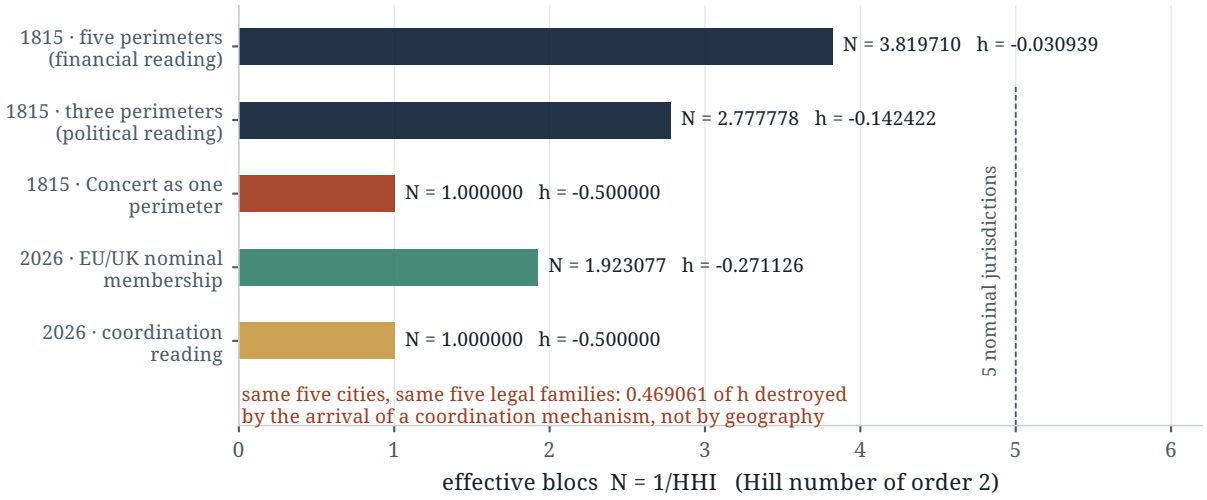

Figure 64.1: **The bloc call, not the geography, moves the effective count.** Five constructed capital shares (London 40, Frankfurt 20, Paris 20, Vienna 13, Naples 7) read under five partitions. The naive effective count is 3.819710 in both eras; the bloc count moves from 3.819710 to 1.000000 and h from -0.030939 to -0.500000. Effective count is $1/\text{HHI}$, the Hill number of order two; $h = 0.35 \ln N - 0.500000$ at parameters fixed in advance. Built by `figs/src/CCP-064_fig01.py`; share vector CONSTRUCTED.

structuring decision measured anywhere in Series D. Nothing in the arithmetic selects among them. Curzi [2026] therefore requires that a bloc call be presented as a claim with evidence and a stated observable rather than as a fact, and this measurement is the reason.

4.3 The same five cities under a modern coordination mechanism

The identical geography is now read under the mechanism classes of Section 3.2.

reading	partition	bloc HHI	N	h
nominal supranational membership	60 / 40	0.520000	1.923077	-0.271126
coordination reading	all five	1.000000	1.000000	-0.500000

Against the 1815 five-perimeter reading the loss is -0.469061 of h; against the three-perimeter reading, -0.357578.

The same five cities, the same five legal families, the same five currencies at the outset — and 0.469061 of h removed by the arrival of a coordination mechanism that has nothing to do with geography. Nothing about the cities changed. What changed is that the mechanism classes of Section 3.2 came into existence and now enclose all five. The enclosure is invisible on a map and invisible to the naive count, which reads 3.819710 in both eras.

This is the same result Curzi [2026] obtains for a modern six-jurisdiction structure, where a naive 3.407968 collapses to exactly 1.00; it is obtained here a second way and against a structure that was once genuinely diversified. **A naive index computed on a single-bloc structure is not a weak measurement, it is a measurement of the wrong thing**, and the two rows above are that failure mode separated by two centuries.

4.3.1 The disclosure test on the historical architecture, which splits

element	disclosed?	still does its job?
five houses in five sovereignties	yes	**passes.** Each was a known, licensed, taxed house publicly transacting government loans; the function was jurisdictional, not secret
common partnership economics	yes	**passes.** Family partnership was the standard commercial form
private courier network	yes	**passes.** A faster route is not a secret route
correspondence encoding	yes	**fails.** Its entire function was that chanceries could not read it; disclose the script convention and the property is gone

Three passes, one fail, and the fail is the informative row. **The element that fails the disclosure test is the element that did not survive**: script-based confidentiality decayed to nothing as literacy and state capacity grew, while the jurisdictional architecture did its work for a century. That is the disclosure constraint of Curzi [2026] stated as a historical prediction that came true, and it is the strongest evidence in this paper that the constraint is an engineering property rather than a preference. Structures that depend on not being seen have a half-life; structures that depend on being correct do not.

4.4 The transit network priced as an exposure window

The information advantage of such a network is conventionally valued in the currency of a one-day news lead. This paper values it as Curzi [2026] values a payment rail: a transit capability is priced by its exposure window, not by its speed record.

Stipulated transit parameters, illustrative, one continental capital to London around 1815, at a stipulated constant counterparty hazard $\lambda = 0.0015$ per day and a loss probability $P = 1 - e^{-\lambda t}$:

```
via correspondents    :  3 hops x 8 days = 24 days of exposure
in-house own courier  :  1 hop  x 8 days =  8 days of exposure
reduction in window   : 16 days = 66.6667%

  correspondents   P(loss) = 0.035360   (3.5360%)
  in-house         P(loss) = 0.011928   (1.1928%)

expected-loss reduction on a 100,000-unit transfer :  2,343.1419 units
at 200 transfers per year                          :  468,628.3876 units
```

The hazard model is stated here because the source manuscript does not state it, and the choice changes the fifth decimal place. Under the continuous form $1 - e^{-\lambda t}$ the 24-day figure is 3.535978 per cent, which is the source's 3.5360 per cent. Under the discrete form $1 - (1 - \lambda)^t$ it is 3.538576 per cent. **The two differ by 0.0026 percentage points and the paper uses the continuous form**, which is what reproduces the source's figures; the discrepancy is recorded in Section 8.11 rather than concealed by rounding.

That is the documented, repeatable value of the network, and it is large. It is also entirely unglamorous, which is why the fabricated version displaced it. **A structural reduction in settlement exposure applies to every transaction and compounds; unlike a piece of news, it does not have to be right.** Curzi [2026] measures the same quantity on a modern rail and reaches the same conclusion about what a transit capability is worth.

Two cautions belong with the figure. The three-hop chain is a series of intermediaries, and nominal redundancy across correlated intermediaries is not redundancy: Buldyrev et al. [2010] is the formal statement, and Sagan [1993] is the organisational one — added redundancy can reduce safety where the added paths share a failure mode. And a private network is a single engineered artefact whose robustness comes from design rather than from topology, which is Doyle et al. [2005]'s correction to the degree-distribution account of network resilience and the reason no scale-free claim is made here.

4.5 A refused data point

The most widely repeated account of this network holds that its London principal received news of a decisive battle roughly a day before the government, sold ostentatiously to induce a panic on the belief that the battle had been lost, bought the collapsed market through agents, and made a fortune in a single session.

The source manuscript treats most of that as a later fabrication, and this paper refuses it as a data point. What the manuscript reports as documented, on the scholarship it relies on [Ferguson, 1998], is materially different: the courier network existed and early news was received; the position going into the battle was not a short bet on defeat but a very large accumulation of bullion assembled to finance an army on the assumption of a long war; the sudden peace was in the first instance a problem, leaving a long position in a commodity whose military demand had just evaporated; and the large profit came afterwards, from a multi-year position in government stock taken as the post-war price recovered.

The manuscript traces the dramatic version to a polemical pamphlet published in 1846 under a pseudonym, whose purpose was defamatory. **Its author, title, date and causal role in the account's circulation are listed in Appendix A as requiring verification, and this paper asserts none of them.** What is not in doubt on the manuscript's own account is that a nineteenth-century polemical pamphlet rather than a market record is the origin of the story that circulates.

```
1815   the battle                          --
1846   the pamphlet                         31 years after the event
1998   the archival account                152 years after the pamphlet
                                           183 years after the event
```

The documented version can be given the same arithmetic treatment, so that the two can be compared on one scale. **Prices stipulated for illustration; the actual price path is archival and is listed in Appendix A.**

```
CONSTRUCTED: buy government stock at 62, sell at 82 after 2 years,
             coupon 3 per 100 nominal

capital return          32.258065%
income return            9.677419%
total return            41.935484%
annualised              19.136679%
running yield at buy     4.838710%   at sale  3.658537%
```

To match a 41.935484 per cent total return in one session requires a 41.935484 per cent single-day move in government stock. **The documented trade is larger than the fabricated one,**

it is repeatable, and it is the version an architecture can be built on. A structural information advantage plus a correct multi-year position is an architecture; a one-day coup is a story.

There is a second reason for exactness, and it is the reason the refusal is in the body rather than in a note. The fabricated version is the seed of a durable conspiracy literature. A paper that repeated it would launder that literature into a structural analysis, and a reader who caught it would be right to discard everything else. **Citation discipline on this material is not decoration; it is the difference between analysis and propaganda.** This is the failure mode of building on a fabricated data point, and its cost is directional: anyone taking the fabricated version as a model invests in speed of news and under-invests in the exposure-window reduction of Section 4.4, which is what actually produced the returns.

4.6 The creditor–debtor relation, 1831–32

The source manuscript records that a sovereign borrower of the period — the papal territories, following a revolt in the Legations and a foreign military intervention — borrowed from the houses on market terms across 1831 and 1832. **The amounts, tranches, currencies, security and the identity of the lending houses are listed in Appendix A as requiring verification.**

What the paper takes from it is structural, and it does not depend on any of those particulars. The borrower was a sovereign; the lenders were a private house whose members could not, in several of the jurisdictions concerned, hold real property freely or exercise full civil rights. **The relation the record establishes is creditor and debtor, negotiating price. It is not partnership and it is not identity of interest**, and Section 4.8 uses it as an observation.

A constructed illustration of what a distressed sovereign loan of the period costs a borrower. **Terms stipulated; not the actual terms.** The approximate yield to maturity is the standard approximation $(C + (F - P)/n)/((F + P)/2)$.

```
CONSTRUCTED: face 1,000, issued at 75 per 100, coupon 5%

proceeds to the borrower        750.0000
annual coupon cost               50.0000
running yield to the lender       6.666667%
borrower's cost above the face coupon         +1.666667 points

approximate yield to maturity if redeemed at par:
    in  5 years    11.428571%
    in 10 years     8.571429%
    in 20 years     7.142857%
```

A sovereign borrowing at an approximate 11.43 per cent yield is a sovereign paying a distress premium to a lender pricing default risk.

4.7 A 571-year doctrinal trajectory

The source manuscript sets out a chain of fifteenth-century instruments, a doctrine crystallised from them, its reception into positive law in an 1823 judgment of a common-law supreme court, its elaboration in two judgments of the early 1830s, its rejection as to one component in a 1992 judgment of a different common-law supreme court, its application in a 2005 judgment of the first court, and a 2023 repudiation by the institution that issued the original instruments.

None of these instruments, cases or statements is in this paper's bibliography, and none is cited. `bib/external.bib` contains no case law, no papal instruments and no jurisdiction-specific primary material; the coverage file records this as a known and deliberate gap. They are described here from the source manuscript and every one is itemised in Appendix B with what specifically requires verification. **This paper asserts no case citation, no reporter page,**

no bull date and no institutional attribution. The material is retained because the *intervals* are the measurement and the measurement does not depend on the particulars beyond their years.

```
instrument 1452        -> judicial reception 1823        371 years
instrument 1493        -> judicial reception 1823        330 years
judicial reception     -> later application 2005         182 years
judicial reception     -> repudiation 2023               200 years
instrument 1493        -> repudiation 2023               530 years
later application 2005 -> repudiation 2023                18 years
instrument 1452        -> repudiation 2023               571 years
```

Three statements are made about this and all three are made.

One: the repudiation did not change the positive law and does not purport to. A statement by the issuing institution is not a source of the receiving jurisdiction's law. The rule stands. A different common-law system's 1992 revision of one component shows that an apex doctrine *can* be revised, and that it takes a supreme court rather than an apology.

Two: the repudiation is nevertheless the strongest available corroboration of the provenance. The standard objection to connecting fifteenth-century instruments to modern property law is that the connection is a stretch. The institution that issued the instruments has now formally addressed them as the source of the doctrine. **When the drafting authority confirms the provenance, the provenance stops being contestable and only the consequences remain in dispute.**

Three: the honest caveat, which strengthens rather than weakens the reading. The 1823 judgment is more complicated than a summary allows; its holding operates substantially as a rule of priority between competing European sovereigns and as a rule about who may extinguish, and the original instruments were not the operative deed of any actual land transfer. Neither point rescues the doctrine and neither is a reason to overstate it. **The defensible claim, and the only one made here, is genealogical**: the rule in current law about who holds ultimate title to discovered land descends by an explicit and judicially acknowledged path from instruments issued between 1452 and 1493, and the issuing institution repudiated them in 2023 while the rule continued.

For the corpus the operational payload is a trajectory measurement at the longest available duration. **571 years from instrument to repudiation, 200 from judicial reception to repudiation, and 18 from the last major application to the repudiation — with the underlying rule operative at the end of all three intervals.** Legal foundations are not background; they are the slowest-moving and longest-lived element of any structure, and they move. The correct presentation is a **split trajectory**: positive-law status stable, legitimacy status eroding, the two moving in opposite directions for at least a century. **Averaging the two destroys the only information they carry**, which is the same objection Curzi [2026t] makes to a composite index whose components are not on a common scale.

4.8 The coordination question as a posterior

The reading under which a group of long-lived institutions is a single coordinated actor is taken seriously enough to be tested rather than dismissed.

Two models: U, in which the institutions are facets of one coordinated actor, and C, in which they are distinct institutions whose interests align on some files and conflict on others. The prior is 0.50 each, which is generous to U. Four observations are then applied. **The likelihoods are stipulated. What is claimed is the direction and the order of magnitude of the movement, not the precision of the posterior.**

observation	$P(\cdot \mid U)$	$P(\cdot \mid C)$	posterior $P(U)$
prior	—	—	0.500000
litigation and a 1984 settlement payment between two of them	0.10	0.60	0.142857
a 2013 criminal prosecution of an official of one of them	0.15	0.70	0.034483
a 2023 conviction of a senior officer by the institution's **own** criminal court	0.05	0.65	0.002740
a sovereign among them **borrowing on market terms**, 1831–32	0.20	0.75	0.000732

$P(\text{unified}) = 0.000732$, $P(\text{competing}) = 0.999268$, odds against the unified model 1,365:1. The posterior odds are the exact rational $\frac{1}{6} \cdot \frac{3}{14} \cdot \frac{1}{13} \cdot \frac{4}{15} = \frac{1}{1365}$, which is why the figures are quoted exactly: **they are exact consequences of stipulated inputs, not estimates.** The underlying events are described from the source manuscript and are itemised in Appendix B; none is cited.

The arithmetic is only as good as the stipulated likelihoods, and the direction is not sensitive to them, for a reason worth stating in words. **A unified actor does not litigate against itself, does not settle with itself for a nine-figure sum, does not prosecute its own senior officers in its own courts, and does not borrow from itself at a distress yield.** Each of those is a costly signal: expensive, public, and hard to fake for the purpose of misdirection.

The converse error is refused in the same breath. Concluding that these institutions are unrelated because they are not unified would be equally wrong. They are the same *kind* of object — perpetual corporate persons holding assets across sovereign boundaries, with succession mechanisms that outlive individuals and legal characterisations that determine what they may do — which is precisely the subject of Series D. **The operative model is a small number of long-lived, competing, partly overlapping institutions with genuinely conflicting interests**, which is what the record shows and which is more useful than the alternative, because competing centres have divergent interests and a unified hand does not.

5. What double entry guarantees, and what it structurally cannot

This section does not argue that double entry is obsolete. It is required by every accounting framework, it has been the method for over five centuries, and nothing here proposes replacing it. The argument is narrower and defensible because it is narrower: **double entry is incomplete in two specific and nameable ways, and neither is a defect in its execution.**

The method's codification is conventionally dated to a printed tract of 1494, and the codification followed roughly a century and a half of established merchant practice rather than preceding it. **The historical claims in this paragraph are described from the source manuscript and are itemised in Appendix A**; the accounting-history literature that matters most here is the deflation of the stronger claim usually attached to the method — that it caused rational capitalism — by Yamey [1964] and Littleton and Yamey [1956]. That deflation is the correct precedent for this section: **the limits of the method are already recorded in its own historiography and this paper argues alongside that literature rather than unaided.**

5.1 The method, stated exactly

Every transaction is recorded twice within one entity's books, once as a debit and once as a credit, in equal amounts, so that $\sum \text{Dr} = \sum \text{Cr}$ by construction and the identity $A = L + E$ follows. The trial balance is the self-check, and it is an excellent self-check for what it checks: before it, a transposition, an omission or a duplicated posting could be caught only by re-reading; after it, an arithmetic error announces itself.

The question this section asks is what "announces itself" covers.

the method guarantees	the method does not guarantee
arithmetic closure	**existence** — that the recorded event occurred
completeness of transcription within the entity	**valuation** — that the amount is correct
traceability of a posted entry to its counter-entry	**agreement** — that the counterparty concurs
	coverage — that the monetised subset is the relevant set

Existence and valuation are closed by audit; agreement is closed by reconciliation and would be better closed by a shared record; coverage is closed by nothing currently in general use. That asymmetry organises the rest of this section.

5.2 Result: the identity holds while the statement misleads (H2 supported)

A stipulated opening balance sheet, then a single wholly fictitious sale — no customer, no goods, no service, no contract.

```
OPENING (stipulated)
  cash            400.00      payables        250.00
  receivables     300.00      debt            600.00
  PPE             800.00      equity          650.00
  A − (L + E)  =  0.0000000000

POSTING
  Dr  Receivables   1,000.00
      Cr  Revenue                1,000.00

AFTER
  cash            400.00      payables        250.00
  receivables   1,300.00      debt            600.00
  PPE             800.00      equity        1,650.00
  A − (L + E)  =  0.0000000000        <-- still exactly zero
  debits 1,000.00; credits 1,000.00; difference 0.0000000000
```

metric	before	after	change
total assets	1,500.00	2,500.00	$+66.6667\%$
debt / equity	1.307692	0.515152	-60.6061%
equity / assets	0.433333	0.660000	$+52.3077\%$
receivables / (cash + receivables)	0.428571	0.764706	$+78.4314\%$
reported profit	0.00	1,000.00	—

metric	before	after	change
cash from operations	0.00	0.00	—

The posting is invisible to every arithmetic control and visible only in the relationship between two numbers the ledger does not itself relate: receivables and cash. At a stipulated annual revenue of 3,000 and a 365-day year, days-sales-outstanding moves from 36.500000 to 118.625000 days, a change of 82.125000 days.

That test is the whole of the detection, and its character is the point: it is an **analytical procedure imported from outside the method**, comparing one monetised figure to another and inferring that one of them is unlikely. It is not a property of double entry. **Double entry is a transcription-integrity system; it was never an existence-verification system, and the profession has never claimed it was — which is why external audit, third-party confirmation and analytical review exist as separate disciplines layered on top of it.**

The corollary is the failure mode: the identity holds by construction and cannot fail except through arithmetic error or a bypass, so **its holding carries no information and treating it as a signal is treating a tautology as a measurement.**

5.3 Result: two correct books that disagree (H3 supported)

The second gap needs no fraud. One entirely honest invoice.

```
one invoice, EUR 100,000.00, cross-border

seller books at 1.0900 USD/EUR   ->  receivable  USD 109,000.00
buyer  books at 1.0850 USD/EUR   ->  payable     USD 108,500.00
gap  USD 500.00  =  0.460829% of the buyer's figure

seller trial balance:  Dr Receivables 109,000.00 / Cr Revenue  109,000.00
                       difference 0.0000000000
buyer  trial balance:  Dr Expense    108,500.00 / Cr Payables  108,500.00
                       difference 0.0000000000
```

Both sets balance. Neither party is in error: they used different permitted rate sources or timestamps, each documented in their own accounting policy. **There is no third record to appeal to, because in double entry there is no such thing as a third record — there are two entities each keeping a complete and internally consistent account of one event.**

The cut-off variant is cleaner because it involves no rates at all. The seller recognises on 31 December, the buyer on 2 January; same currency, same amount, same invoice; both books balance in both periods. The consolidated group then shows an item existing on one side and not the other, and the elimination entry that fixes it is a **decision** about which of two internally consistent accounts to prefer. **Elimination is the point at which two incompatible truths are resolved by policy rather than by evidence, and it deserves the scrutiny any balancing figure deserves.**

Double entry provides a mechanism for closing a set of books and no mechanism whatever for reconciling two sets, and the second problem consumes the resources.

5.4 Result: the reconciliation bill (H4 supported)

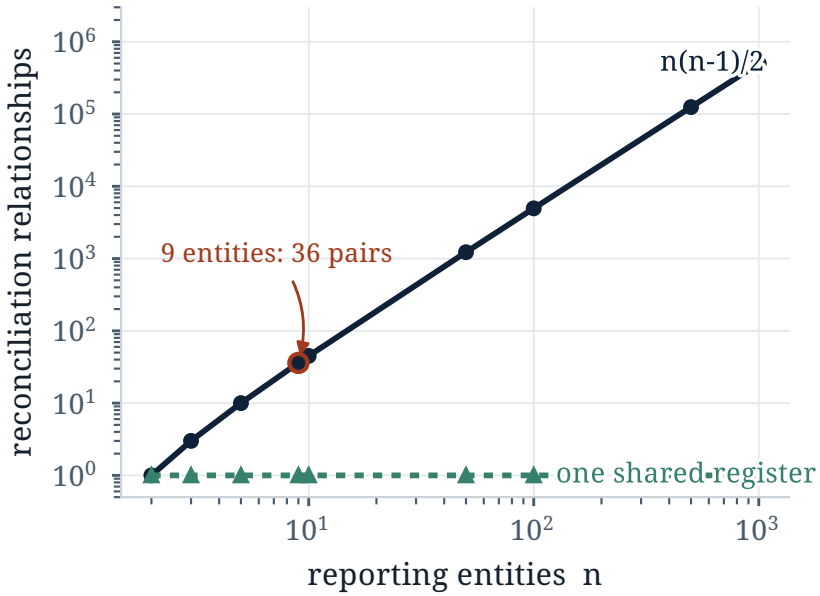

Figure 64.2: **The reconciliation bill is quadratic in parties and constant with a shared record.** $n(n-1)/2$ bilateral reconciliations against one shared register; the nine-entity reporting group of Section 5.4 sits at 36 pairs. Both axes logarithmic. The exponent is exact combinatorics, not a fitted scaling exponent. Built by `figs/src/CCP-064_fig02.py`.

n parties	bilateral reconciliations $n(n-1)/2$	one shared register
2	1	1
3	3	1
5	10	1
9	36	1
10	45	1
50	1,225	1
100	4,950	1
500	124,750	1
1,000	499,500	1

From two parties to fifty the relationship count rises by a factor of 1,225 while the register count stays at one: $O(n^2)$ against $O(n)$. **The exponent here is exact combinatorics, not an estimated scaling exponent**, so the distributional-fitting procedure of Clauset et al. [2009] does not apply to it and no heavy-tail claim is made anywhere in this paper. The same quadratic communication cost is the classical objection to raising the number of parties [Brooks, 1975], and Conway [1968] — which appeared in April 1968, not 1967 as the corpus has elsewhere dated it — is the statement that the resulting interface structure mirrors the communication structure.

Applied to a nine-entity reporting group: 36 bilateral relationships against one shared record. Adding a tenth entity takes the count to 45; adding to twelve takes it to 66, **an 83.3 per cent increase in reconciliation relationships for a 33.3 per cent increase in entities.** The consequence is a cost line, and in the corpus's storage law it sits in the cost term C, which enters h directly and without the logarithm's damping. **Reconciliation cost is one of the few terms in the corpus's central equation that a purely technical decision can reduce, and it is the term that grows fastest as a structure adds legs.**

At a stipulated aggregate intercompany balance of 40,000,000 and the 0.460829 per cent in-

nocent rate divergence of Section 5.3, the expected aggregate translation break is 184,331.60. **That is not a loss. It is a break** — an amount two internally consistent sets of books disagree about, which somebody must investigate, document and eliminate, and which recurs every period. The cheapest available remedy is not technology: a written intercompany policy fixing the rate source and the timestamp for both sides of every internal transaction in advance converts a recurring investigation into a one-off decision.

5.5 Result: the completeness gap (H5 supported)

The second structural limit is harder to demonstrate because its evidence is an absence. The measurement below is of the absence, on a **CONSTRUCTED value distribution stipulated for illustration** over the nine-capital frame developed in Curzi [2026]. **The share vector is not a measurement of any entity and must not be treated as one.**

form of capital	share of total value	recognised
financial	42.000%	fully
manufactured	18.000%	fully
intellectual	11.000%	at a stipulated 35%
human	9.000%	not at all
social / relationship	7.000%	not at all
natural	6.000%	not at all
cultural	3.000%	not at all
living	2.500%	not at all
spiritual / experiential	1.500%	not at all

```
fully on the balance sheet                      60.000000%
partially (intellectual at a stipulated 35%)     3.850000%
TOTAL REPRESENTED                               63.850000%
STRUCTURALLY UNREPRESENTABLE                    36.150000%
```

The ledger balances exactly and provably over 63.850000 per cent of the value and is silent about 36.150000 per cent of it.

The mechanism of the silence is structural rather than a policy choice, and the distinction matters. Recognition in every major framework requires that an item be measurable, and the requirement follows from the fact that an entry must carry an amount and an amount requires a measurement. A framework recognising unmeasurable items would produce a ledger that no longer balanced in any meaningful sense, destroying the one property the method actually guarantees. **The completeness gap is the price of the closure property. It is not a defect a better standard-setter would repair.**

Two failure modes follow directly. **Treating unmonetised value as zero** is wrong because a zero can be challenged, footnoted or revised while an absence cannot: silence is not a conservative estimate, it is the absence of an estimate, and it reads to every downstream user as if the thing did not exist. **Treating a monetised proxy as the thing** is worse: inventing an index and putting it in a report is Goodhart [1975]'s law waiting to happen, and Campbell [1979] is the same warning from the evaluation side. **The correct response to an unmeasurable quantity is a documented judgement held outside the ledger, not a fabricated measurement held inside it.**

5.5.1 The off-ledger register

The action item is not to capitalise any of it, which would be the proxy failure mode. It is the opposite, and it is this paper's only proposed instrument:

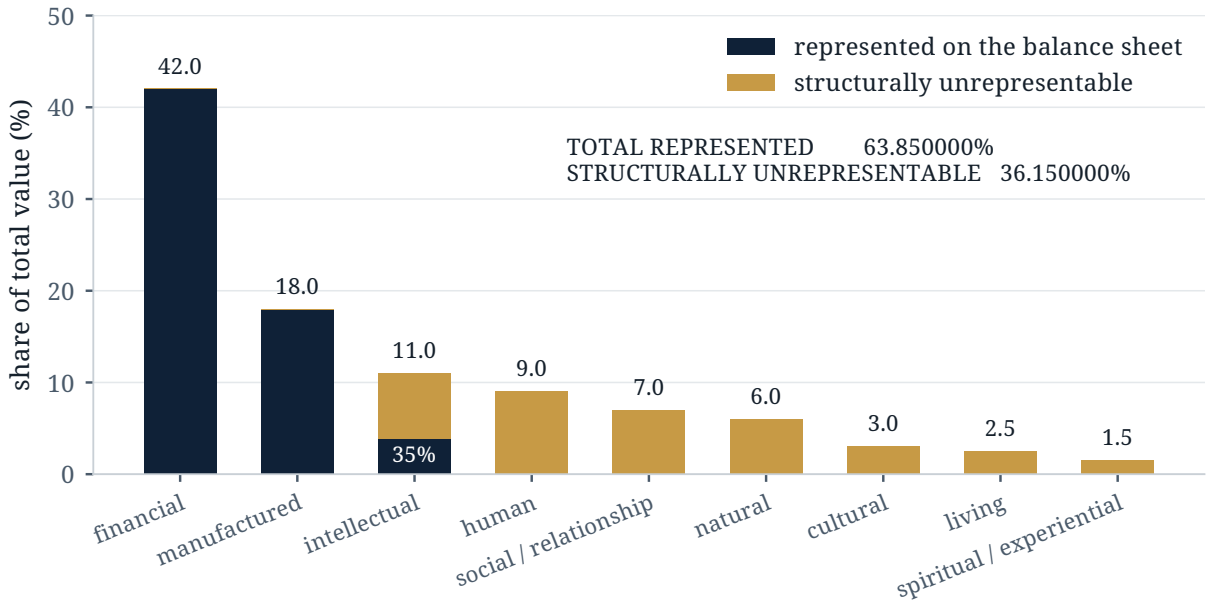

Figure 64.3: **The ledger balances exactly over 63.850000% of a constructed value vector and is silent about 36.150000% of it.** Nine forms of capital with stipulated shares; financial and manufactured fully recognised, intellectual at a stipulated 35% recognition fraction, the remaining six not representable as entries because an entry must carry an amount. CONSTRUCTED — the vector is stipulated for illustration and is not a measurement of any entity. Built by `figs/src/CCP-064_fig05.py`.

```
THE OFF-LEDGER REGISTER  (maintained alongside the statutory accounts)
-----------------------------------------------------------------------
1  Name each unmonetised asset the structure depends on.
2  Name the instrument that creates it (statute, treaty, licence,
   relationship) and the party that can withdraw it.
3  Record the observable that would signal withdrawal.
4  Record what it would cost to replace, if it can be replaced.
5  Review on the same cycle as the accounts, by the same people,
   in the same meeting -- and minute it.
```

Item 2 is what turns this from an essay into a control. **An unmonetised asset almost always has a nameable counterparty who can withdraw it, and naming that counterparty converts an invisible dependency into a monitorable one.** The register has **no standing in any accounting framework, is not a disclosure, and must not be described to any regulator or auditor as one**; it passes the disclosure test of Section 3.4, and disclosing it improves it, because a dependency register a supervisor could read is a dependency register the board has actually tested.

5.6 What the two historical ledgers could not have shown

Both institutions described in Section 4 kept complete books, and both were exposed to something their books could not express.

Individual loan exposures were, individually, fully recorded: every advance in a named account with a counter-entry in a partnership whose books balanced. Nothing hidden, nothing mis-transcribed. The concentration measurement Curzi [2026] obtains on such a book — 3.573981 effective borrowers on the naive count against 1.834862 effective blocs once two borrowers on the same side of the same conflict are recognised as one exposure, a 94.782 per cent overstatement — **is not derivable from the ledger at all.** Concentration is a relationship

between entries, and double entry records entries. A Herfindahl index is a function over a **partition** of the balances, and the partition — which counterparties are really one counterparty — is a judgement no posting convention supplies.

The same holds for the five-house structure and more sharply. Each house's books would show its own capital, exposures and currency position. **No house's books contained the number that was the point of the whole architecture** — the effective bloc count of Section 4.2 — because that number is a function of the legal environment *surrounding* the five sets of books, which no set of books can observe about itself.

quantity	recorded by double entry?	where it actually lives
an individual exposure	yes	the ledger
the sum of exposures	yes	the trial balance
the **concentration** of exposures	**no**	a partition chosen by judgement and applied from outside
the **independence** of the perimeters the exposures sit in	**no**	the legal environment surrounding the ledger
the **correlation** between two apparently distinct positions	**no**	a model imposed on the ledger from outside

Three noes, and each is something Curzi [2026] measures. **The instrument the corpus uses to measure resilience operates on inputs that the instrument every entity uses to report itself cannot produce.** That is not a criticism of either; it is a statement about which tool answers which question, and about the fact that no month-end close will ever prompt the second question. It also explains a pattern across both historical institutions: neither failed for lack of information about its own positions, and neither had any mechanism for converting position information into concentration information.

The corresponding failure mode is worth naming because it is common and cheap to commit: **a management pack that reports exposures by legal counterparty and calls it a concentration report has reported a sum and labelled it a relationship.**

5.7 Three proposed extensions, and which gap each closes

Three proposals are routinely conflated and address different gaps on different axes. Separating them is a precondition for Curzi [2026], which builds on the separation.

The time axis. Conventional accounting records a stock and a flow. Income is a rate, and a rate has its own rate of change, which the conventional statements do not record. The 1982 and 1989 momentum-accounting proposals add a third class of entry recording the causes of changes in that rate. Two stipulated revenue series make the gap concrete:

```
series A (growing)     100.0000  110.0000  121.0000  133.1000  146.4100
  rate of change                 +10.0000  +11.0000  +12.1000  +13.3100
series B (decaying)    180.0000  170.0000  160.0000  152.0000  146.4100
  rate of change                 -10.0000  -10.0000   -8.0000   -5.5900

period-5 income:   A = 146.4100   B = 146.4100   difference = 0.0000000000
period-5 change :  A =  +13.3100  B =   -5.5900  OPPOSITE SIGN
```

Two enterprises with identical reported income in the period, in opposite conditions, and the income statement cannot tell them apart. The information is derivable by anyone with five periods of history; it is not an account, is not posted, is not audited and is not part of the closure. The proposal is to make it one. **It has never been adopted, and this paper states that**

as a fact rather than a prediction. It is retained here because it is the only serious attempt on the time axis and because the name it occupies is the source of a persistent confusion.

Commitment without transmission. A hash tree commits to a set of records with a single value, and membership of any individual record is then provable by a path of sibling hashes whose length is logarithmic in the set size.

ledger entries	proof path (hashes)	proof bytes at 32 B	full ledger at 256 B/entry
1,000	10	320	256,000
1,000,000	20	640	256,000,000
1,000,000,000	30	960	256,000,000,000
1,000,000,000,000	40	1,280	256,000,000,000,000

At a billion entries the membership proof is 960 bytes against 256 gigabytes of ledger, a ratio of 1 to 266,666,667, and **doubling the ledger adds exactly one hash — 32 bytes — to the proof.** What matters here is not the compression: two parties can agree on a single short value and thereafter each prove to the other what their own record says, without either transmitting its books and without either being able to change a committed entry afterwards. **That is a shared commitment between entities, which is precisely the object double entry does not have.**

One caution, because it is the commonest overreach: a membership proof proves that a record is in the committed set and says nothing about whether the record is true. The fictitious 1,000 of Section 5.2 commits, proves and verifies exactly as well as a real one. **Commitment is a tamper-evidence property, not a truth property.**

The party axis. The 2005 signed-receipt proposal adds a third *signature* rather than a third book: a receipt recording a bilateral transaction, signed by an issuer and by both parties, held identically by all three. Each party still keeps conventional double-entry books against it; the proposal retains the method rather than replacing it. The invoice of Section 5.3 becomes impossible to book at two different rates without both parties visibly signing two different receipts.

```
parties   party-books   bilateral recs   signed receipts   disputable records
-------------------------------------------------------------------------------
    2           2               1                1             2  ->  0
    3           3               3                1             3  ->  0
    5           5              10                1             5  ->  0
   10          10              45                1            10  ->  0

time axis     third DIMENSION in ONE entity's books
              adds the rate of change of income
              closes: the undifferentiated-flow gap
              status: proposed, never adopted

party axis    third SIGNATURE on ONE record shared between entities
              adds a jointly held artefact
              closes: the two-books-no-shared-truth gap
              status: the conceptual ancestor of shared-ledger systems

NEITHER closes the monetisation gap. Nothing that operates on entries
can close a gap defined by what cannot become an entry.
```

The two proposals share a name and address different gaps on different axes; conflating them is the commonest error in the literature that cites both, and this separation is a binding

constraint on Curzi [2026] rather than a licence for it. The costs are also different in kind. The time axis costs a full third set of accounts and a convention for attributing rate changes to causes. The party axis costs key management, an issuer, and a governance question: **a shared record requires a shared party, and who that party is, under whose law, and what happens when it is compelled, is a jurisdictional question** — which is why it belongs in this series. Ostrom [1990] is the standing account of how a commonly held resource is governed without a single owner, and it is the right literature for that question; Star and Griesemer [1989] and Star and Ruhleder [1996] give the shared record its correct general name, a boundary object that must be simultaneously plastic enough for local use and robust enough to travel.

requirement	closed by	still open?
arithmetic closure	double entry	no
transcription completeness	double entry	no
existence	audit / confirmation	partially
valuation	audit / measurement	partially
agreement between parties	the party axis	addressable
the time dimension	the time axis	proposed, unadopted
coverage of unmonetised value	**nothing in use**	**OPEN**

Six rows addressed and one open, and **the open row is the one that matters most for this series, because everything the corpus measures lives in it.** A shared ledger does not and cannot close it: a shared ledger makes two parties agree about entries, and the monetisation gap is defined by what cannot become an entry. **No amount of agreement about a set closes a gap defined by what is outside the set, and any claim that a distributed ledger captures value a balance sheet cannot is a category error.**

6. Canonicalisation as an integrity control

Section 5 ended on two things double entry cannot do. This section is about a third limitation, and it is not a limitation of double entry at all. **It is a limitation of the alphabet.**

Double-entry bookkeeping assumes, without ever stating it, that a recorded symbol has one representation: an account number is that account number, a counterparty name is that counterparty, a currency code designates one currency. Every downstream control built on the ledger — deduplication, reconciliation, matching, sampling, confirmation, screening, consolidation — inherits that assumption absolutely. **The assumption was true while the character set had one code for each character, and it stopped being true when it stopped having one** [T1].

A universal coded character set necessarily contains many characters that render as the same shape, because many scripts independently inherited the same letterforms from the same ancestors. Latin capital A, Cyrillic capital A and Greek capital Alpha are three code points that most fonts draw identically. **That is not a defect in the standard; it is a true fact about the world's writing systems, correctly represented.** The consequence for a ledger is that the correspondence between what a field looks like and what it compares as is broken in both directions at once.

No standards document is cited in this section, because `bib/external.bib` contains none. Every technical designation named below is described from the source manuscript and is itemised in Appendix B with what specifically requires verification against the governing document. The one standard that is in the bibliography, International Organization for Standardization [2013], is cited where it is actually relied on.

6.1 Threat model and evidence tiers

The environment assumed is ordinary rather than exotic [T1]. Ledger fields are stored and compared as byte strings, or as text never canonicalised. At least one ingestion path — a counterparty file, a customer-facing form, a spreadsheet upload, an email-parsed remittance advice, a partner interface — accepts characters beyond the ASCII repertoire into a critical field. Downstream processes rely on exact equality. **Each of those three conditions is the default configuration of a great deal of production financial software and none is a misconfiguration in any conventional sense.**

No particular actor and no particular intent is assumed. The vulnerability admits accidental data-quality failure and deliberate manipulation with equal ease, and the measurements below cannot distinguish them, because the mechanism does not care. That agnosticism is deliberate and protective: everything in this section is a statement about a mechanism and nothing in it is a statement about anybody.

tier	meaning
T1	established fact — a published standard, a hashing property, a mathematical property
T2	measured by the deterministic demonstration and independently recomputed for this paper
T3	proposed design; not adopted, not in force, endorsed by no body
T4	a claim deliberately **not** made

The headline grades: the substitution vulnerability and the canonicalisation remedy are T1 and T2; the specification built on them in Curzi [2026] is T3; any linkage to macroeconomic measurement discrepancy is a bounded, testable hypothesis and never a demonstrated magnitude — T3 with explicit T4 disclaimers.

The entry points that matter are the ones that are not the front end, and every institution has more of them than its architecture diagram shows. One deserves a note of its own because it produces most of the accidental cases and involves no unusual behaviour by anybody: **text copied out of a rendered document routinely carries typographic substitutions the reader never chose** — non-breaking spaces, soft hyphens, directional quotation marks, ligatures, and in some pipelines full-width forms where the layout engine needed the advance width. The person pasting sees the characters they expect; the field now holds code points the validation rule was not written to consider. **A canonicalisation layer is worth exactly as much as its coverage of that list, which is why the rule is stated as a boundary rule and not a field rule: canonicalise at every ingestion boundary, not at the fields one happens to remember.**

6.2 The substitution class, enumerated

A critical ledger field is integrity-safe only if equal-looking values are equal-comparing values **and** equal-comparing values are equal-looking values. Both directions fail.

Homoglyph confusables [T1]. The core case: three code points, one shape, in the great majority of fonts. The relevant security standard defines a *skeleton* transformation mapping confusable characters onto a common representative, so that two strings are confusable when their skeletons are equal. The security literature is old — the homograph attack was published in 2002 and measured in the wild in 2006 — and both papers were about domain names rather than ledgers. **The domain-name world's response is the instructive part: it did not solve the problem by hoping resolvers would compare carefully, it defined a canonical wire form and rules about what may enter it.** That is the move made here.

Compatibility and full-width forms [T1]. Full-width variants of the ASCII digits and letters, inherited from East Asian legacy encodings, display as wide but unmistakable characters and carry different code points and different bytes. This member has a specific property: it is resolved by *compatibility* normalisation and not by *canonical* normalisation. **A system that normalises to the canonical composed form — which many do, correctly, for other reasons — has not addressed this at all.**

Normalisation mismatch [T1]. A precomposed accented character and the sequence of base plus combining accent are canonically equivalent and render identically, and they are different byte sequences. Two systems in one group, one normalising inbound text to the composed form and the other to the decomposed form, disagree on byte equality for every accented character in every field, forever, with no attacker involved and no error message. **This member produces the largest volume of purely accidental breakage and almost none of the deliberate kind.**

Combining marks [T1]. The general case of the preceding member: a base character followed by an arbitrary sequence of combining marks, some sequences having a precomposed form and some not. Section 6.5 shows this member behaving differently from the others under the remedy, and the difference is informative.

Zero-width and bidirectional controls [T1]. Characters defined to have no visible rendering, and explicit formatting controls whose purpose is to change the *order* in which characters are displayed relative to the order in which they are stored. This is the member with the highest-profile published treatment: a 2021 disclosure showed that bidirectional controls can make source code display in an order different from the order the compiler reads, so that a reviewer and a compiler see two different programs from one file, and it prompted coordinated changes across a large number of compilers and code-review tools. **The ledger analogue is direct: a reference, an amount or a counterparty name can display in one order and store in another, and the stored order is the one that reconciles.**

Charset confusion [T1]. This member is not about which characters are in the string. It is about the fact that a sequence of octets is not a string at all until something decides what encoding it is in, and different components in one pipeline can decide differently. Seventeen octets, every one of them plain printable ASCII, decode under one transformation format as a seventeen-character string and under another as an eight-character string. **Both readings are correct decodings under their respective standards; the octets never changed.**

```
octets                  2B 41 45 45 41 51 77 42 44 41 46 51 2D 30 30 34 32
decoded one way         "+AEEAQwBDAFQ-0042"      (17 characters)
decoded another way     "ACCT0042"               ( 8 characters)
```

This is the worse case and the reason is worth stating explicitly. In the homoglyph case the bytes differ and the meaning agrees; in the charset case the bytes agree and the meaning differs — so a byte-level hash, which is the detector for every other member of the class, certifies the two readings as identical. The remedy is therefore not canonicalisation of the string: it is refusing to accept octets whose encoding is not explicitly declared, and pinning the declaration at the boundary. **Canonicalisation cannot help, because canonicalisation operates on a string and the whole problem is that there is not yet a string.**

The withdrawn currency-code hazard [T1]. The last member has no character-encoding content at all. It is included because it has the same shape — one recorded symbol, two possible referents, no visible difference — and because it has a directly computable balance-sheet consequence. Currency codes are withdrawn when currencies cease to exist, and the numeric codes of withdrawn currencies persist in the standard's historical record and, far more consequentially, in the master files of systems built while those currencies were live. **A legacy system carrying a withdrawn-code balance, with a mapping table that has at some point been given a row sending the withdrawn code to a live currency, reports that balance as live money.** Nobody forged anything and nobody typed a wrong character; a withdrawn code was aliased to a live one, and the general ledger now says something untrue about how much settleable currency exists. **The specific numeric codes named in the source manuscript are contested**

even within the manuscript's own verification register and are therefore not asserted here; see Appendix B, item 9.

6.3 Why the failure is silent in both directions

Every member produces one of two outcomes.

The first is **byte-distinct, canonically equal**: two entries a human cannot tell apart, and that any auditor confirming them would confirm as the same, compare as different to a machine. Deduplication does not deduplicate them, reconciliation reports a break that is not a break, consolidation counts one entity twice, screening does not match the list entry it should have matched.

The second is **byte-equal, semantically distinct**: the charset member and the currency-code member. Here the machine says the two things are the same and they are not.

The class is dangerous precisely because the first outcome is invisible to people and the second is invisible to machines, and the two organs of control in every finance function are people and machines. A homoglyph substitution defeats the machine while presenting a clean face to the reviewer; a charset or code-aliasing confusion defeats the reviewer, who sees no anomaly, while the machine confirms the identity. **There is no observer in the standard control environment positioned to see either.**

The first outcome, computed rather than asserted, on four synthetic identifiers any reader would read as the same reference [T2]:

variant	chars	UTF-8 bytes	SHA-256 (leading)	canon(x)
clean, all ASCII	14	14	`6de95bd1c87f4ec2`	`ACCT-0042-CORP`
Cyrillic capital for Latin capital	14	15	`21300fa543adb7d6`	`ACCT-0042-CORP`
full-width digits	14	18	`4500cb7fe935f396`	`ACCT-0042-CORP`
zero-width space inserted	15	17	`95a611acf502cfc7`	`ACCT-0042-CORP`
right-to-left override inserted	15	17	`b39d1bc9946e6dd2`	`ACCT-0042-CORP`

Five rows, five distinct digests, five byte lengths, one canonical form, and one thing a person would say if shown the printed page. **The cryptographic hash is doing exactly what it was designed to do and is, for this purpose, worse than useless: it certifies with mathematical confidence that five records are distinct when a human reader and an auditor's confirmation would all say they are one.** SYNTHETIC data throughout.

6.4 The canonical pipeline and the corpus

The pipeline under test [T3]:

$$\text{canon}(x) = \text{restrict_ASCII}(\text{confusable_fold}(\text{NFKC}(x)))$$

Compatibility normalisation resolves compatibility and full-width forms; `confusable_fold` maps homoglyphs onto a single skeleton and removes default-ignorable characters; `restrict_ASCII` enforces the permitted character set for the field and **quarantines rather than silently stores** any residual out-of-set character. Alongside it, and separately, a byte-level SHA-256 computed over the record's raw octets and **not** over its canonical form. **The distinction between the two is the whole detector** and Section 6.6 measures what it buys.

The corpus: 500 synthetic identifier pairs, each a clean value and a confusable twin. The class mix is a **stipulated design parameter** chosen to reproduce the source manuscript's reported per-method detection rates — 297 homoglyph twins, 148 compatibility-form twins, 55

invisible-character twins. **Five of the 297 homoglyph assignments fall on digit-only account numbers where no Latin letter is available to substitute**, so those five twins are byte-identical no-ops rather than manipulations. That detail is not a rounding artefact; it is where the 99 per cent comes from, and a reader reproducing the number needs it. Combining-mark twins are measured separately. All data are synthetic, the seed is fixed, and the harness is deterministic and reruns identically.

The harness was rebuilt from the source manuscript's description rather than obtained, and two of the five results depended on corpus-design parameters that had to be reconstructed before they agreed. This is recorded in Appendix A and in Section 9.

6.5 Results: five measurements (H6 supported)

E1 — silent duplication [T2]. For each pair: are the two values byte-distinct, are their digests distinct, are their canonical forms equal. A pair passing all three is a *silent duplicate*.

```
pairs                                                  500
byte- AND digest-distinct yet canonically equal        495
rate                                                 99.0%
no-op twins (no substitutable character present)         5
```

Ninety-nine per cent of confusable substitutions produce a record that is byte-distinct, hash-distinct and canonically identical. The remaining one per cent is not a detection failure and not a residual risk; it is the set of fields the substitution could not be applied to at all, which is the honest denominator.

E2 — detection [T2]. Five checks, each run against the 495 manipulated values for a true-positive rate and against the 500 clean values for a false-positive rate. The clean values are pure ASCII, which is what makes the false-positive column meaningful.

The *skeleton* of a value is confusable_fold(NFKC(x)) — the first two stages of the pipeline, without the restriction step.

check	what it asks	TPR	FPR
byte-vs-skeleton	does the value differ from its skeleton?	100.00%	0.00%
non-ASCII	does x contain a code point above U+007F?	100.00%	0.00%
confusable-only	does x contain a mapped confusable letter?	58.99%	0.00%
normalisation-mismatch	does x differ from its canonical composed form?	0.00%	0.00%
invisible-character	does x contain a default-ignorable code point?	11.11%	0.00%

The skeleton and non-ASCII checks flag every manipulated value at zero false positives on clean ASCII fields. Three observations about the rest of the table matter more than that headline.

The confusable-only check reaches 58.99 per cent — exactly $292/495$ — and the reason it does not reach 100 per cent is structural rather than incidental: it is blind to the compatibility-form member, which is the normalisation step's job and not the confusables table's. **A confusables check deployed without a normalisation layer in front of it will miss two manipulated**

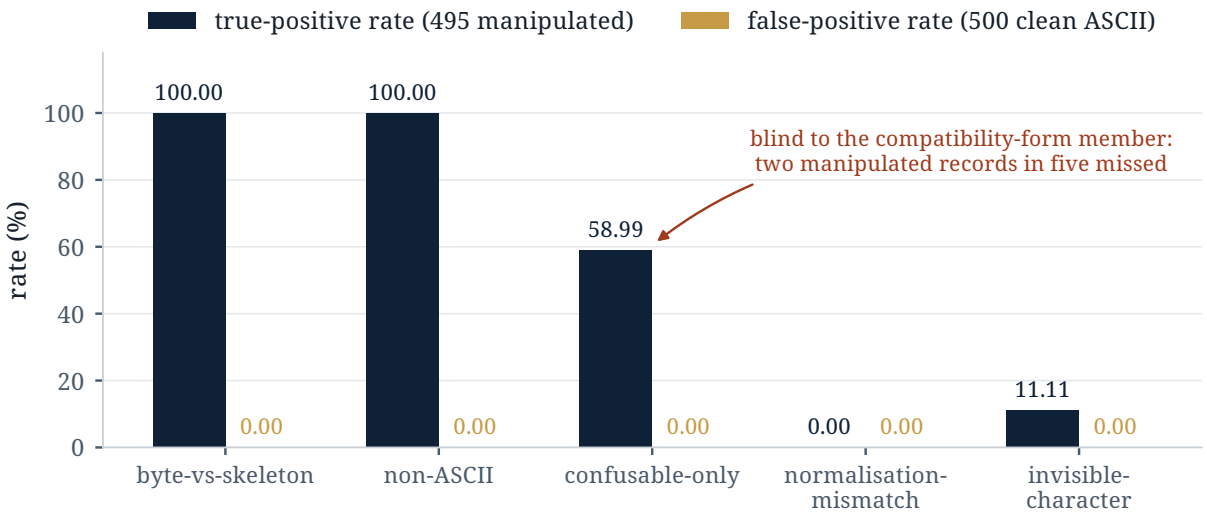

Figure 64.4: **No single check covers the substitution class; the two that do are the two that compose normalisation with confusable folding.** True-positive rate over the 495 manipulated values and false-positive rate over the 500 clean ASCII values. The confusable-only check reaches 58.99% — exactly 292/495 — because it is blind to the compatibility-form member. SYNTHETIC corpus, deterministic harness, fixed seed. Built by `figs/src/CCP-064_fig04.py`.

records in five and will report itself as working. That is the most operationally dangerous line in the table.

The normalisation-mismatch check scores zero here, and that is correct rather than broken: none of the three manipulation classes in this corpus perturbs the canonical composed form. It earns its place against the combining-mark class, where it scores 100 per cent. The invisible-character check scores 11.11 per cent, which is exactly $55/495$ — a single-purpose check detecting its single purpose. **The point of the table is that no single check covers the class, and that the two which do are the two composing normalisation with confusable folding.**

Zero false positives on every check is **a property of the corpus** — clean fields that are pure ASCII — and is therefore a claim about *critical machine fields*, not about names or memos. **A non-ASCII check run against a customer-name field in any real institution will produce false positives at an enormous rate, because a great many customers legitimately have non-ASCII names.** Section 7.2 treats that scoping problem as the most serious objection to the whole approach.

E3 — canonicalisation [T2].

manipulated entries collapsing onto the clean canonical form	495 / 495 = 100.0%
canon(canon(x)) == canon(x) for every value in the corpus	True (idempotent)
distinct raw byte-strings across the corpus	995
distinct canonical forms	500
true distinct underlying values	500

Canonicalisation collapses one hundred per cent of the manipulated entries onto their clean form, idempotently, and the count of distinct values falls from 995 to the true 500. The idempotence matters more than it looks: **a canonicalisation that is not idempotent cannot be applied at more than one point in a pipeline without changing answers depending on how many times it ran**, which makes it unusable in any architecture with more than one ingestion path.

The combining-mark class, measured separately [T2], behaves differently, **and this is a finding of the rebuild rather than a reproduction of a reported figure.** Of 98 combining-mark twins, 100 per cent were **quarantined** by `restrict_ASCII` rather than collapsed onto the clean form; the normalisation-mismatch check flagged 100 per cent of them and the confusable-only check flagged none. The reason is mechanical: compatibility normalisation recomposes base-plus-combining-accent into a precomposed accented character, which is not ASCII, so the restriction step refuses it. **For a critical machine field that is the correct outcome and arguably better than collapsing** — the entry is rejected at the gate with an explicit reason rather than silently normalised into something the submitter did not send. **For a free-text field it would be data destruction. The class member does not have one right answer; it has one right answer per field scope**, which is the argument for scoping.

E4 — reconciliation [T2]. Two synthetic ledgers of 500 paired entries with identical underlying values and a controlled proportion of one side's critical fields manipulated. Deterministic: exactly the stated proportion is manipulated rather than drawn, so the sweep is exact.

manipulation rate	false-break rate, byte equality	false-break rate, canonical equality
0%	0.0%	0.0%
10%	10.0%	0.0%
20%	20.0%	0.0%
30%	30.0%	0.0%
40%	40.0%	0.0%
50%	50.0%	0.0%
60%	60.0%	0.0%
80%	80.0%	0.0%
100%	100.0%	0.0%

At a 40 per cent manipulation rate the false reconciliation-break rate goes from 40 per cent to 0 per cent. The full sweep shows the shape, which is the more useful result: byte-equality false breaks scale one-for-one with manipulation, and canonical equality holds flat at zero across the entire range including the degenerate case where every entry is manipulated.

The operational reading is specific. **A reconciliation function chasing breaks spends its scarcest resource — experienced human attention — at a rate directly proportional to the encoding noise in its inputs, and it has no way to tell an encoding break from a real one until somebody opens it.** The remedy does not merely reduce false breaks; it makes the remaining break queue mean something.

E5 — the withdrawn-code hazard [T2]. A synthetic three-account legacy extract: two accounts hold a live currency code, one holds a withdrawn code, and the system's mapping table aliases the withdrawn code to the live one.

```
correct live balance                          8000
aliased live balance                         10000
inflation                                   +25.0%
resolution-class balance, segregated          2000
```

Aliasing a withdrawn numeric code to a live currency inflates the recorded live balance from 8000 to 10000, a phantom inflation of 25 per cent. Assigning the withdrawn code to an explicit resolution class instead — never to a live settlement currency — restores the live balance to 8000 and leaves the 2000 in a designated class where it is visible, non-settleable and awaiting an audited discharge.

Three things about this experiment must be said. It is arithmetic, not cryptography. **The 25 per cent is a property of the synthetic 8000/2000 ratio and is not a universal constant; anyone quoting it as a general magnitude has misread it** [T4]. What generalises is the *sign* and the

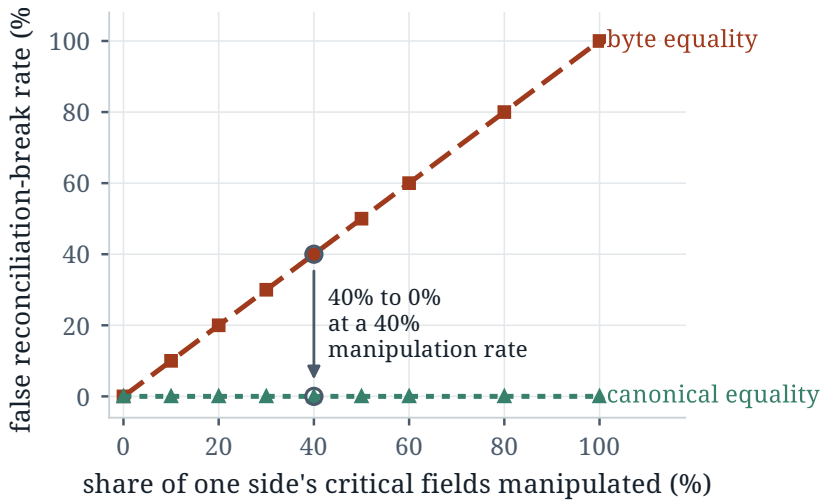

Figure 64.5: **Canonical equality holds the false-break rate at zero across the whole sweep while byte equality tracks the manipulation rate one-for-one.** Two synthetic ledgers of 500 paired entries; the proportion manipulated is set deterministically rather than drawn, so every point is exact. The 40%-to-0% reading at a 40% manipulation rate is one point on a flat line, not the result. Built by `figs/src/CCP-064_fig03.py`.

mechanism: aliasing a withdrawn code to a live one always inflates, always in the direction of more apparent money, and always without any entry being posted. And it is the one member of the class with no character-encoding content whatsoever, **which is a useful reminder that the underlying failure is representational ambiguity rather than anything specific to character encoding.**

6.6 Why the hash level is not a detail

One further measurement, because it is the hinge of the design [T2]. Take the clean value and its Cyrillic twin:

```
canonical forms equal?                                  True
BYTE-level digest differs?        True    6de95bd1c87f  vs  21300fa543ad
CHARACTER-level digest differs?   False   6de95bd1c87f  vs  6de95bd1c87f
```

The character-level digest — computed over canon(x) — is identical for the clean value and the manipulated one, which is exactly what makes it useless as evidence. **Identical canonical form with differing byte-hash is the detector; a character-level hash destroys precisely the evidence that distinguishes benign normalisation from injected substitution.** Hash the canonical form and the system cannot tell anyone it was attacked. Hash the octets and store the canonical form beside them, and every substitution leaves a permanent, comparable, machine-checkable trace. **This is the same content-addressing property Curzi [2026] builds on: one byte's difference in a settlement object yields a different identifier, while** canon **folds a homoglyph account string onto the same skeleton as the clean one.**

6.7 The screening arithmetic

A **SYNTHETIC** watchlist of ten entity names, none corresponding to any real person or organisation. Twenty probes are generated by applying a single homoglyph substitution or a single zero-width insertion to each name, and both a naive exact-match screen and a canonical-match screen are run [T2].

```
synthetic watchlist entries                                  10
effectively-substituted probes                               20
exact-match screen: probes matched                 0 / 20  =   0%
canonical-match screen: probes matched            20 / 20  = 100%
canonical-match screen: clean names still matched 10 / 10  = 100%
```

A single-character substitution defeats an exact-match screen on every probe, and folding the confusables before comparison recovers every one of them without losing a single true match.

The size of the change should be kept in proportion in both directions. It is one transformation applied to both sides of an existing comparison; it requires no new data, no new supplier, no model, no training set and no change to any list. **It also does not make a screening system good.** A screening system with poor alias coverage, no transliteration handling and a badly tuned threshold remains bad after canonicalisation. **This closes one specific hole, completely, for the cost of a library call at the field boundary.**

7. Discussion

7.1 What follows

A concentration measurement inherits every defect of the identity resolution beneath it. The effective count of Curzi [2026] is a function over a partition of exposures. Section 5.6 shows the ledger cannot supply the partition; Section 6 shows that the resolution underneath the partition is string comparison and that string comparison has a measurable blind spot. **Count one counterparty as two and the measured concentration falls without anything real changing.** The direction is the concerning part: **an encoding defect in a counterparty master file biases the resilience instrument towards reporting resilience that is not there.** That is the same structural error Curzi [2026] identifies at the rail layer, where a naive correspondent count of 3.306878 collapses to $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency, and Curzi [2026] identifies at the assembled-structure layer.

A structure built or reasoned about before a coordination mechanism existed will report a diversification that has since been cancelled, and the cancellation leaves no trace in the entity list. Section 4.3 is that statement measured: nothing about the five cities, the five legal families or the ownership changed, and 0.469061 of h went. The monitoring implication is specific and cheap. The thing to watch is not any jurisdiction's behaviour but the perimeter's boundary, and the standing question per node is one sentence: **has this jurisdiction acquired a mechanism by which another state's decision becomes enforcement here without a separate decision taken here?**

The source manuscript answers that question node by node for a named six-jurisdiction structure, with named listing cycles, named administrative orders and named unilateral measures. **Those answers are not reproduced here.** `bib/external.bib` contains no jurisdiction-specific statutes, regulations, registry documents or case law, and the coverage file records this as a known gap; attaching an approximate citation to a jurisdiction-specific regulatory fact would be worse than leaving it uncited. Following the de-branding convention of Curzi [2026], the mechanism classes are given without the jurisdictions, and the source's named instances are itemised in Appendix B.

node	mechanism class to watch	reading
A	evaluation and listing cycle under an intergovernmental standard-setter	listed and later delisted; the next evaluation round is the observable

node	mechanism class to watch	reading
B	a revenue authority's characterisation of residence, movable by administrative order	the characterisation has already moved once by order
C	full participation in every mechanism class of Section 3.2	no independence to lose
D	supranational listing history and substance requirements	inside the perimeter
E	participation in automatic exchange with a domestic regulator	partial
F	unilateral measures adopted without a Security Council resolution	eroding bloc independence

Nothing in that table is a jurisdiction going bad. Every row is a perimeter growing.

A widening gap between what an institution says about its own foundations and what its law actually does is a leading indicator, observable years in advance and free to monitor. Section 4.7 measures that gap at 571 years wide on the longest available instance, with 18 years between the last major judicial application and the issuing institution's repudiation. The corresponding diligence workstream is a records search rather than an opinion: identify the apex doctrine for the situs and name it; identify whether a competing non-derivative chain has been recognised by a superior court there; identify whether the parcel is within, adjacent to or subject to a pending or historical claim; price it through title-insurance availability, exclusions and premium loading; record the answer in writing with the observable that would change it; and repeat on a defined cycle. **Apex doctrines move on a scale of decades, and a 200-year-old rule applied in 2005 and repudiated by its author in 2023 is not settled background.** This paper makes no claim about the availability, exclusions or pricing of title insurance in any jurisdiction, and none about the current status of any claim.

The remediation at the character layer is proportionate and short. Canonicalise critical machine fields at every ingestion boundary. Store the byte-level digest of the raw octets beside each record. Alert on identical canonical form with differing byte-hash. Pin the declared charset at every file boundary and reject octets with no declaration. Scope ASCII restriction to critical machine fields and leave free text alone under restriction levels. Assign every withdrawn currency code to a resolution class rather than to a live currency. **None of this is expensive and all of it is testable.**

7.2 What does not follow

Canonicalisation defeats encoding-level evasion and does nothing whatever about semantic fraud: a correctly encoded false entry is entirely unaffected [T1/T4]. Every number in Section 6 measures a representational property; none measures truthfulness. The consequence for how the contribution may be pitched is hard and is worth paying, because the alternative destroys the claim.

The source manuscript audits nine well-documented corporate and market failures against the question *would encoding canonicalisation have caught it?* **The answer is no, eight times.** The eight turn on accounting treatment and revenue recognition; on forged confirmation documents; on fabricated bank statements; on invented account statements describing trades that never occurred; on collusion about which number to submit; on a monitoring and escalation environment that did not function at the scale of the throughput; on cash purportedly held in escrow that was not there; and on commingling of customer assets together with

an accounting configuration that concealed a liability. **Every one of those is semantic or procedural. Every number in them was correctly encoded and every name correctly spelled.** The failures are described here at the level of mechanism only; the named matters, their dates, quanta and outcomes are itemised in Appendix B and none is cited, because the bibliography contains no case reports, no regulatory findings and no contemporaneous reporting. **A technical evaluator reading a submission that implies encoding hygiene would have caught any of them stops reading at that sentence, and is right to** [T4].

There is one genuine in-class instance and it is worth more than the eight, because it is documented and it is the attack pattern at scale: an entity incorporated under a name differing from a real and materially similar entity's name, to which funds were directed in circumstances where the documentation and a reasonable reader would have understood the other. **That is a confusable-identifier attack executed at the entity layer: an identifier constructed so that a control comparing it to the expected counterparty would pass.** The matter is described from the source manuscript, the entity names are not reproduced, and the case references are itemised in Appendix B as requiring precise sourcing or removal.

And here is the part that must be stated rather than glossed, because glossing it is the same error as claiming the other eight. The names in that instance were ordinary ASCII: they differ by a real, visible word, and no character substitution was involved. What the case demonstrates is that the *pattern* — choose an identifier a control will mistake for another identifier — works, is attractive to sophisticated parties, and survives contact with institutional diligence at very large scale. **What a universal character set changes is the economics of the pattern.** A confusable name in ASCII must survive a human reading it beside the expected name and can be caught by an alert analyst. A homoglyph substitution does not have to survive that, because there is nothing to see. The ASCII instance needed a plausible story about why an extra word was there; a Cyrillic capital needs no story at all.

The pitch is therefore narrower than the material invites, and the narrow version is the defensible one: exact-match string comparison is the control model underneath a set of financial controls that matter enormously, it has a measurable blind spot, the blind spot is cheap to close, and it sits underneath watchlist screening, beneficial-ownership resolution, cross-border party matching [International Organization for Standardization, 2013] and deduplication at scale. **Structured party identification confers format, not canonical form**, and two systems in two jurisdictions with two different normalisation defaults will disagree about identity in exactly the manner of the E4 sweep.

Over-canonicalisation is the strongest objection and the mitigation is scoping and only scoping [T1]. Aggressive folding destroys legitimate data: a customer whose name is written in a non-Latin script has a name, and ASCII restriction applied to it produces either a quarantine or a mutilation; a memo field in a language with diacritics loses them. **A canonicalisation standard that is mis-scoped is not a control improvement, it is a data-destruction programme with a compliance justification, and it will be correctly resisted by every business line it touches.** ASCII restriction applies to *critical machine fields* — identifiers, account and transaction numbers, amounts, currency and action codes — where the permitted character set is already narrow by business rule and where nobody has ever legitimately needed a combining mark. Free-text fields keep the full repertoire, store raw and canonical forms together, and are governed by restriction levels rather than by ASCII folding.

A production deployment needs four things the demonstration does not have, and the distance is worth measuring so that nobody underestimates it and nobody overestimates it either. The confusables data must be consumed as a maintained data file rather than a hand-written table, with the character-set version treated as a configuration item under change control, because a confusables table that drifts out of date is a control silently losing coverage. Script policy is a ladder rather than a setting, and the right rung differs by field and by market — a business decision with a compliance consequence, not a job a library performs. **The alert path is the item most likely to be underbuilt**: in a production master file with a decade of history and several migrations behind it, the first run produces a very large number of alerts, most of them historical normalisation artefacts, so the design question is not how to detect

but how to burn down the backlog once, establish a clean baseline and then alert only on new occurrences. **A deployment that skips the baseline generates an unreadable queue on day one and is switched off in the second week.** And the boundary declaration for the charset member is separate work that nothing in the canonical pipeline addresses.

Four things would falsify or substantially weaken this section's argument and none has been tested. If a survey of production ledger and counterparty-master data found that non-ASCII code points essentially never occur in critical machine fields, the operational case collapses and the correct conclusion is a theoretical vulnerability with no realised exposure. If mature screening engines already fold confusables before computing match scores — a configuration and version question, testable in an afternoon per engine — the screening argument is already solved in the products and the contribution reduces to reconciliation and deduplication. If the false-positive rate of canonical matching against a real, large watchlist is materially above zero — plausible, because folding collapses an identifier space and collapsing an identifier space creates collisions — the remedy is a real trade rather than a free one and needs pricing. **The zero false-positive figure of E2 is measured against clean ASCII critical fields and does not transfer to a name estate; anyone reading it as a general property has read it wrongly.** And if the alert stream from the byte-hash detector were dominated so completely by legacy artefacts that no baseline could be established, the detector is a good idea that does not survive contact with real data.

A group receiving alerts has created a record of those alerts, and that record is discoverable. That is not a reason to avoid implementing the detector. It is a reason to decide, before implementation, what the escalation path for an alert is and who owns it, because **an unactioned alert log is materially worse than no alert log.**

7.3 Bounds carried from elsewhere in the corpus

Four results elsewhere in the corpus bound what this paper may claim, and they are stated as bounds rather than as support.

Curzi [2026] assigns the corpus's central identification, the application of the surplus functional to a life, and the reading of a day's surface as a leading indicator to the **postulate** drawer, and states that the third is a wager whose misfire column exists because wagers can lose. **Section 7.1's leading-indicator claim about a widening legitimacy gap is in that drawer**, and it is a wager rather than a measurement.

Curzi [2026] refuses the certificate its own contraction theorem appears to offer: a human life is not a metric space, nobody has measured the relevant modulus, and the theorem transfers as shape rather than as guarantee; and the feeling of recognition on arrival proves nothing, since the machinery that rehearses a future retrofits a past with equal fluency. **That is the correct treatment of Section 4.7's trajectory reading**, which is a shape and not a forecast.

Curzi [2026] declines the inflated reading of its own borrowed physics, requiring that a user be able to distinguish a theorem, an ordinary observer effect and the framework's own conjecture in three separate sentences on demand. **Section 8.6 discharges that requirement for every borrowing in this paper.**

Curzi [2026] establishes that repetition buys arrival time and nothing else — it cannot move a destination — and that a tradition's canonical repetition count closes under half the gap at the corpus's own working decay rate. **The bearing on this paper is direct: no amount of re-running the reconciliation closes the two-books gap**, because the gap is a property of the fixed point rather than of the number of passes.

Two further results are parallel rather than bounding. Curzi [2026x] measures a receiver-limited channel capacity into a single cell of order 70 to 106 bit/s, delivering a 40-bit address in about half a second, and shows that adequate bandwidth into an absent decoder delivers nothing; **the structural parallel to Section 6 is exact — a correctly delivered symbol that the receiver resolves to the wrong referent is the same failure**, and Curzi [2026] makes the same point by building an entire deterministic pipeline and stating that the one missing link is the carriage of sequence over force. Curzi [2026] is the sharpest available warning against this

paper's own instruments: a frequency register with no time term cannot distinguish a mood from a trait, and the cleanest-looking encoding of a framing returns the system's maximum surplus for every subject and therefore measures nothing. **An index that returns the same answer for every input measures nothing, and an index that returns a better answer because a record was duplicated measures the duplication** — which is Section 7.1 in the corpus's own terms.

Finally, Curzi [2026t] demotes the corpus's own moment equation at the scale-type gate: the two quantities in it are not instrumented on a common ratio scale with a shared true zero, so the magnitude of their ratio is withdrawn as a measured quantity. **Section 8.5 applies the same gate to this paper's inputs and reaches the same verdict for the same reason.**

8. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and each chain names what it consumes. **If dropping a postulate leaves the result standing, it is not listed.**

8.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i, w_i	exposure or capital share	$[1]$	fraction of one	defined; CONSTRUCTED here
HHI	sum of squared shares	$[1]$	dimensionless index	derived
$N = 1/\text{HHI}$	effective count	$[\#]$	equally weighted units	derived; Hill number of order 2
h	surplus reading	$[1]$	**no operational unit — the corpus supplies none**	derived from η, N and a stipulated floor
η	input coefficient	$[1]$	dimensionless	assumed (0.35, fixed in advance)
λ	counterparty hazard	$[T^{-1}]$	per day	assumed (0.0015)
t	exposure window	$[T]$	days	assumed (24, 8)
$P = 1 - e^{-\lambda t}$	loss probability	$[1]$	probability	derived; λt dimensionless, so the exponent balances
A, L, E	balance-sheet aggregates	$[M]$	one unit of account	assumed (stipulated)
days-sales-outstanding	receivables over revenue per day	$[T]$	days	derived; $[M]/[M\,T^{-1}]$
n	reporting entities, ledger entries, parties	$[\#]$	counts	assumed

symbol	quantity	dimension	unit	status
$n(n-1)/2$	bilateral relationships	[#]	counts	derived, exact combinatorics
proof path length	sibling hashes to a root	[#]	hashes	derived, $\log_2$ of a count
capital share of value	nine-capital vector entry	[1]	fraction of one	assumed (CONSTRUCTED)
TPR, FPR, break rate	detection and false-break rates	[1]	dimensionless fractions	derived from exact counts
digest	SHA-256 over octets	—	256 bits	defined

Does the surplus equation balance? $h = \eta \ln N - \delta_{\text{floor}}$ requires η dimensionless, $\ln N$ dimensionless (a logarithm of a pure count), and the floor dimensionless. It balances. **What the audit records, and what the corpus is silent on, is that h has no operational unit at all**: it is a dimensionless reading whose zero is set by a stipulated maintenance floor, and a difference of 0.469061 in it is a difference in a stipulated index, not in any measured quantity. **A dimensionless placeholder is honest; an invented unit would not be.**

Does the hazard model balance? λt is $[T^{-1}][T] = [1]$, so the exponent is dimensionless and P is a probability. The discrete alternative $1 - (1-\lambda)^t$ requires λ to be a per-step probability rather than a rate; **the two are different models and Section 8.11 records that the source is silent about which it used.**

Does the ledger arithmetic balance? $A - (L + E)$ is a difference of aggregates in one unit of account and is therefore in that unit; it is reported as exactly zero, which is a statement about the unit, not about the world. **Every currency figure in Sections 5 and 6 is in a stipulated unit of account with no currency attached beyond the labels used for legibility.**

8.2 Significant figures and epistemic status

- **The concentration figures are exact rational arithmetic on stipulated shares.** $1/0.2618 = 3.819710\ldots$ and $1/0.36 = 2.777778\ldots$ are exact to the digits shown. **They are exact consequences of a constructed share vector and are therefore not measurements of anything**; no uncertainty is quoted because there is no estimate to attach one to.
- h **carries six decimal places because η and the floor are exact stipulations.** Reporting -0.030939 does not imply that anything was measured to six places.
- **The posterior is an exact rational**: $1/1366 = 0.000732064\ldots$, printed as 0.000732. Its inputs are stipulated likelihoods, so the six figures are exact arithmetic on assumptions and **the posterior is not a probability estimated from data.**
- **0.460829% is exact**: $500/108500$. **66.6667% is exact**: $16/24$. **58.99% is exact**: $292/495$. **11.11% is exact**: $55/495$. **99.0% is exact**: $495/500$. Each is a ratio of two exact counts in a constructed corpus.
- **0.0% in the canonical-equality column is exact, not a rounded small number.** It is a property of a mapping that sends every manipulated value to its clean form, and no sampling is involved.
- **The 25% of E5 is a property of the stipulated 8000/2000 ratio and generalises only in sign.**
- **The transit figures are exact under a stated model on stipulated inputs.** 3.5360% is $1 - e^{-0.036}$ to four places; the fifth place differs under the discrete model.
- **The 63.850000% completeness figure carries six decimal places because the input vector is stipulated to three.** $60 + 0.35 \times 11 = 63.85$ exactly. **The precision is a property of the stipulation and not of any observation**, and quoting it to six places would be false precision on a measured quantity.

- **The Merkle proof lengths are ceilings of base-two logarithms of exact counts** and are exact.

8.3 Limits and boundary behaviour

model	limit	behaviour	reading
effective count	one unit holds share 1	$N \to 1$	maximum concentration; $h \to -0.500000$
effective count	n equal shares	$N \to n$ exactly	the numbers-equivalent property
effective count	share vector fixed, bloc partition to the finest	$N \to$ naive	the naive count is the zero-correlation corner, not a neutral default
surplus	$N \to \infty$	$h \to \infty$ logarithmically	**unbounded, and this is a domain limit rather than a result**: the form supplies no cost of fragmentation
surplus	$\eta \to 0$	$h \to -0.500000$ for all N	the instrument stops discriminating; η carries the whole reading
hazard	$\lambda t \to 0$	$P \to \lambda t$	the linear regime; the two hazard models agree to first order
hazard	$\lambda t \to \infty$	$P \to 1$	loss becomes certain; the window is the whole quantity
reconciliation	$n = 1$	$n(n-1)/2 = 0$	one entity has nothing to reconcile against; the shared register still counts 1
reconciliation	$n \to \infty$	ratio $\to \infty$	the shared record's advantage is unbounded
completeness	recognition fraction $\to 1$ on every capital	represented $\to 100\%$	**a pathology, not an ideal**: full recognition of unmeasurable items destroys the closure property that is the method's only guarantee
completeness	recognition fraction $\to 0$	represented $\to 0\%$	the ledger becomes a record of nothing; the observed 63.85% sits between two degenerate corners

model	limit	behaviour	reading
canonicalisation	manipulation rate $\to 1$	canonical false-break rate stays 0.0%	the flat line is the result; the 40% reading is one point on it
canonicalisation	permitted set $\to$ full repertoire	restriction step becomes vacuous	the remedy's strength is exactly the narrowness of the field's permitted set
canonicalisation	permitted set $\to$ one character	every value quarantined	over-canonicalisation in its limiting form; Section 7.2

The completeness limit is the informative one. Both corners are degenerate, which is why the gap is structural: the method cannot be improved towards full coverage without losing the property that makes it a method.

8.4 Invariance

The effective count is invariant under relabelling of units and under any permutation of the share vector, and it is *not* invariant under repartition — which is the entire content of Section 4.2 and the reason the bloc call must be published with its observable. **It is invariant under rescaling of the total exposure**, since it depends only on shares.

The posterior odds are invariant under any monotone rescaling that preserves each likelihood ratio, which is why the paper claims the direction and the order of magnitude rather than the value.

The canonical form is invariant under any of the substitutions in the class by construction, and that is a definition rather than a finding. **The byte digest is invariant under nothing**, which is exactly why it is the detector. **The false-break rate under canonical equality is invariant under the manipulation rate over the whole** $[0, 1]$ **interval**, which is the strongest invariance statement in the paper and is a property of the mapping.

Tested at how many scales? The invariances are algebraic and were checked at exactly the parameter sets reported: one share vector under five partitions, one corpus of 500 pairs, one sweep of nine manipulation rates, one watchlist of ten names. **No empirical scale-freedom is claimed anywhere in this paper, and no scaling exponent is estimated**, so the procedure of Clauset et al. [2009] was not run. The one exponent that appears — the 2 in $n(n-1)/2$ — is **exact combinatorics defined by the construction, not fitted**. Any restatement of this paper that reaches for a heavy-tail claim about holdings, share distributions or break volumes must run that procedure first, and must read Broido and Clauset [2019] and Stumpf and Porter [2012] on how weakly such structure is generally supported.

8.5 Measurement-theoretic status of the inputs

The share vectors are ratio-scale by construction and not by measurement. They are stipulated proportions of a stipulated total, so ratios of them are meaningful within the construction and carry no empirical content whatever.

The nine-capital vector is the paper's weakest input on this gate and it is the one to attack first. Assigning "social capital" a share of 7.000 per cent of total value presupposes that the nine forms are commensurable on a common ratio scale with a shared zero, and **nothing in this paper or in its sources establishes that.** Michell [1997] and Michell [1999] are the strongest objection to the whole framework — that a discipline routinely assumes quantitative structure without testing for it — and the objection lands squarely here. **The formal test**

that would answer it is conjoint measurement [Luce and Tukey, 1964], whose conditions establish whether an attribute has additive quantitative structure at all; the conditions were not tested, here or in the source, and the ratio-scale treatment of the nine-capital vector is therefore provisional. Krantz et al. [1971] sets out what must hold before a quantity can be said to exist and Stevens [1946] is the scale-type taxonomy the audit uses. **The honest reading is that 63.850000 per cent is an exact arithmetic consequence of an unlicensed set of numbers**, and its value as a result is the direction — a large fraction is unrepresentable — rather than the magnitude.

The evidence tiers of Section 6.1 are an ordinal scale and are not averaged anywhere. The detection and false-break rates are ratios of exact counts on a constructed corpus and are ratio-scale within that construction.

This paper inherits the corpus-wide scalar-reduction limitation rather than restating it. Reducing nine jointly varying forms of value to nine shares and then to one representability fraction, and reducing a jurisdictional structure to one effective count and one h, are instances of the habit Curzi [2026] names once as a single limitation for the whole corpus. **The limitation is inherited here in full and is not met separately.**

8.6 Analogy discipline

borrowing	category	justification
exposure as a portfolio; variance under a correlation matrix [Markowitz, 1952]	**1 — derivation**	the bloc question genuinely is whether a common factor acts across nominally independent units; the premises are satisfied and the identity is exact
effective count as a numbers-equivalent [Hill, 1973, Jost, 2006, Adelman, 1969]	**1 — derivation**	$1/\text{HHI}$ *is* the Hill number of order 2; nothing is transferred by analogy
similarity-sensitive diversity [Leinster and Cobbold, 2012, Rao, 1982]	**1 — derivation**	the block-of-ones matrix is a special case of the cited general form
Shannon entropy in bits for a proof-path length [Shannon, 1948, Hartley, 1928, Cover and Thomas, 2006]	**1 — derivation**	a membership proof over an equiprobable set of size n is exactly Hartley's premise; this is **information entropy, not thermodynamic entropy**
coupled-network fragility [Buldyrev et al., 2010]	**2 — shared form**	the perimeter coupling is not shown to satisfy the percolation premises; the shape of the result is used

borrowing	category	justification
robust-yet-fragile [Albert et al., 2000, Callaway et al., 2000]	**2 — shared form**	the tolerance asymmetry's shape is used; the degree-distribution mechanism is not claimed, and Doyle et al. [2005] is the reason it should not be
identity impersonation as a counting failure [Douceur, 2002]	**2 — shared form**	the Sybil result is proved for an identity system without a certifying authority; a ledger is not shown to satisfy those premises
independent-party bound [Lamport et al., 1982]	**2 — shared form**	cited as a prior formalisation of "how many parties are genuinely independent", not applied to ledgers
redundancy that reduces safety; tight coupling [Sagan, 1993, Perrow, 1984]	**3 — framing**	qualitative organisational theory, cited as framing and as a warning, never as a formal result about this system
a measure adopted as a target ceases to measure [Goodhart, 1975, Campbell, 1979]	**3 — framing**	a documented regularity in policy settings, used as a caution on this paper's own index
performativity of a published model [MacKenzie and Millo, 2003, Merton, 1948]	**1 — derivation**	the mechanism is the same: a description relied upon changes the behaviour of those relying on it, documented with dates and prices
a shared record as a boundary object [Star and Griesemer, 1989, Star and Ruhleder, 1996]	**2 — shared form**	the requirement of simultaneous local plasticity and global robustness is the same requirement; no claim is made that a receipt is an infrastructure in the cited sense

borrowing	category	justification
open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]	**1 — derivation**	the disclosure result *is* the cited principle; the premise — effectiveness depends on the partition and not on knowledge of it — is stated and satisfied
the statistical-physics programme [Castellano et al., 2009]	—	cited as the survey that **bounds** what the programme has established; this paper claims no result within it

The failure mode this table exists to prevent is letting a category-2 or category-3 borrowing carry a category-1 result's authority. The concentration arithmetic, the portfolio identity, the proof-length accounting and the disclosure result are category 1 and need no help. The network results are category 2 and are used for shape only.

Entropy, said once and precisely: every entropy in this paper is Shannon entropy in bits, an information quantity over a discrete set, and no thermodynamic quantity appears anywhere.

8.7 Postulates

#	statement	status
P1	shares s_i are non-negative and sum to 1	DEFINITION
P2	HHI $= \sum_i s_i^2$ and $N = 1/\mathrm{HHI}$	DEFINITION
P3	jurisdictions inside one coordination perimeter act on one decision	POSTULATED (H1)
P4	$h = \eta \ln N - 0.500000$ with $\eta = 0.35$	DEFINITION (modelling choice, fixed in advance)
P5	the 1815 share vector 40/20/20/13/7	POSTULATED (CONSTRUCTED)
P6	loss probability over a window is $1 - e^{-\lambda t}$ with $\lambda = 0.0015$/day	POSTULATED (modelling choice)
P7	every double-entry posting carries an amount in one unit of account, and debits equal credits	DEFINITION
P8	recognition requires measurability, so an unmeasurable item cannot be an entry	DEFINITION
P9	the nine-capital share vector and the 35% recognition fraction	POSTULATED (CONSTRUCTED)

#	statement	status
P10	the four stipulated likelihood pairs of Section 4.8	POSTULATED (stipulated)
P11	the corpus design parameters 297/148/55 with five digit-only no-ops	POSTULATED (stipulated to reproduce reported rates)
P12	canon $=$ restrict_ASCII $\circ$ confusable_fold $\circ$ NFKC	DEFINITION

8.8 The chain that establishes the bloc collapse

step	consumes	statement	status
L1	P1, P2	for n equal shares of $1/n$, HHI $= 1/n$ and $N = n$	ARITHMETIC
L2	L1	N is a numbers-equivalent — Adelman [1969]	CITED
L3	L2	N is the Hill number of order 2 — Hill [1973], Jost [2006]	CITED
L4	P5, P2	HHI $= 0.2618$, $N = 3.819710$	ARITHMETIC
L5	P3, P5	collapsing all five onto one perimeter gives HHI $= 1$, $N = 1.000000$	ARITHMETIC
L6	P3, P5	the three-perimeter partition gives HHI $= 0.36$, $N = 2.777778$	ARITHMETIC
L7	L4, L5, P4	h moves from -0.030939 to -0.500000	ARITHMETIC
L8	L6, L7	the spread across three defensible readings is 0.469061 of h	ARITHMETIC
R1	L4, L5, L8	**the naive count is 3.819710 in both eras and the bloc count moves to 1.000000; the instrument's content is the partition, and the partition is a claim**	DERIVED

Only P3 and P5 are POSTULATED in this chain. P3 is H1 with its falsifier attached; P5 is a constructed vector, and L8 is the measure of how much the result depends on a choice the arithmetic does not make. **A reader who rejects P3 reads L4 and stops, which is a legitimate reading and is why all three are printed.**

8.9 The chain that establishes the posterior

step	consumes	statement	status
B1	—	posterior odds are prior odds times the product of likelihood ratios	DEFINITION (Bayes)
B2	P10	prior odds $= 1$	POSTULATED
B3	P10	$0.10/0.60 = 1/6$; posterior $P(U) = 1/7 = 0.142857$	ARITHMETIC
B4	B3, P10	$\times\, 0.15/0.70 = 3/14$; odds $1/28$, $P(U) = 0.034483$	ARITHMETIC
B5	B4, P10	$\times\, 0.05/0.65 = 1/13$; odds $1/364$, $P(U) = 0.002740$	ARITHMETIC
B6	B5, P10	$\times\, 0.20/0.75 = 4/15$; odds $1/1365$, $P(U) = 1/1366 = 0.000732$	ARITHMETIC
R6	B6	$P(\text{competing}) = 0.999268$; odds against the unified model 1,365:1	ARITHMETIC

Every step is arithmetic and the whole chain rests on one postulate, P10. The four likelihood pairs are stipulated and are the only thing a reader need attack. **The chain is therefore not evidence that the conclusion is true; it is a device that makes the inference explicit and recomputable**, and the paper says so at every point of use. What survives a reader substituting their own likelihoods is the qualitative argument of Section 4.8, which does not depend on the numbers at all.

8.10 The chain that establishes the canonicalisation result

step	consumes	statement	status
C1	P12	canon is a function of the string alone	DEFINITION
C2	P11, C1	495 of 500 pairs are byte-distinct, digest-distinct and canonically equal	ARITHMETIC $= 99.0\%$
C3	P11	the residual 5 are fields with no substitutable character, hence byte-identical no-ops	DEFINITION (corpus design)
C4	C1, C2	495 of 495 manipulated entries collapse onto the clean canonical form	ARITHMETIC $= 100\%$
C5	C1	$\text{canon}(\text{canon}(x)) = \text{canon}(x)$ on every corpus value	ARITHMETIC (idempotence checked)

step	consumes	statement	status
C6	C4	distinct raw byte-strings 995 collapse to 500 distinct canonical forms, the true count	ARITHMETIC
C7	C4	under canonical equality the false-break rate is 0.0% at every manipulation rate	ARITHMETIC
C8	P11	under byte equality the false-break rate equals the manipulation rate exactly	ARITHMETIC
C9	P11	the confusable-only check reaches $292/495 = 58.99\%$, being blind to compatibility forms	ARITHMETIC
R4	C4, C7	**canonicalisation collapses 495/495 and takes the reconciliation false-break rate from 40% to 0% at a 40% manipulation rate**	DERIVED
C10	C1	a digest over canon(x) is equal for clean and manipulated values; a digest over the octets is not	ARITHMETIC
R7	C10	identical canonical form with differing byte-hash is the detector, and hashing the canonical form destroys the evidence	DERIVED

Every step is arithmetic on a deterministic corpus, and the corpus itself is the one postulate. P11 is stipulated to reproduce the source's reported rates and is stated as such; **C2, C9 and the combining-mark result are the three figures that move if P11 moves**, and a reader reproducing them needs the stated parameters.

8.11 Discrepancies found in the source, printed

One modelling ambiguity was found and is reported rather than harmonised. The source manuscript gives a 24-day loss probability of 3.5360 per cent and an 8-day probability of 1.1928 per cent at a stated daily hazard of 0.0015, and **does not state which hazard model it uses.** The continuous form $1 - e^{-\lambda t}$ reproduces both figures exactly (3.535978 per cent and 1.192829 per cent). The discrete form $1 - (1 - \lambda)^t$ gives 3.538576 per cent and 1.193721 per cent. **The two differ by 0.0026 percentage points at 24 days.** This paper adopts the continuous form, states

it in Section 4.4, and records the difference here. Neither choice changes the result, which is the 66.6667 per cent reduction in the exposure window.

One number is reported to a precision its inputs do not support and is re-reported here at the precision they do. The completeness figure is quoted throughout the source as 63.850000 per cent from a vector stipulated to three decimal places. $60 + 0.35 \times 11 = 63.85$ exactly; the six decimal places are an artefact of the source's formatting convention rather than a claim about precision, and Section 8.2 states that.

One result is this paper's own and is not a reproduction. The combining-mark measurement — 98 twins, 100 per cent quarantined rather than collapsed, normalisation-mismatch flagging 100 per cent and confusable-only flagging none — is a finding of the harness rebuild described in Section 6.4 and **is not a reproduction of any figure reported in the source.** It is badged T2 as this paper's own measurement.

One naming claim in the source is contested within the source itself and is therefore not made here. The source's verification register flags its own attribution of a specific withdrawn numeric currency code as requiring verification, noting a competing attribution. **This paper states the mechanism and omits both attributions**, since the demonstrated mechanism does not depend on which withdrawn currency the code denoted.

One date correction is carried forward. The article establishing that a system's interfaces mirror its builders' communication structure is dated 1967 elsewhere in the corpus; it appeared in April 1968, and Conway [1968] is cited here with the corrected date.

9. Limitations

Every worked result in this paper is a constructed or synthetic model, and none is a measurement. The capital shares, the transit parameters, the hazard rate, the balance sheet, the invoice, the entity count, the nine-capital vector, the likelihood pairs and the 500-pair identifier corpus are all stipulated. **No external dataset was collected, and no real institution, ledger, counterparty file, transaction or price series appears anywhere in this paper.**

The bloc call is the single largest unmeasured input and it is a choice, not a finding. Section 4.2 gives three defensible readings of one structure spanning 0.469061 of h, and nothing in the arithmetic selects among them. **A reader who prefers reading 2 should read $h = -0.142422$ off the table and proceed.** The perimeter test of Section 3.2 is stated so that the disagreement is about an observable rather than about a geopolitical opinion, but the test was applied here by reading a historical description, not by examining a transmission mechanism.

No correlation was estimated from data. The bloc reading is the $\rho = 1$ corner of the family in Curzi [2026] and the naive reading is the $\rho = 0$ corner. Both corners are stipulations. **The true structure lies between them and this paper does not say where.**

The surplus parameters carry no operational unit and no empirical warrant. $\eta = 0.35$ and the maintenance floor of 0.500000 are fixed in advance by the corpus. **Section 8.1 records that h is a dimensionless index whose zero is a stipulation**, so every difference in h in this paper is a difference in a stipulated index.

The historical material is described from one source manuscript and is not independently verified. Names, dates, deeds, amounts, tranches, capital allocations, courier composition and the provenance of the refused account are all listed in Appendix A. **The refusal of Section 4.5 is an evidential judgement rather than a measurement**, and it depends on the manuscript's dating of a polemical pamphlet, which this paper has not confirmed.

Jurisdiction-specific law, statutes, registry documents and case law are not in the bibliography and none is cited. The doctrinal chain of Section 4.7, the instruments behind it, the four judgments named in the source and the 2023 statement are described from the source manuscript, itemised in Appendix B, and **asserted with no citation, no reporter reference and no date beyond the years used in the interval arithmetic.** The intervals survive; every particular requires verification. `bib/COVERAGE.md` records the absence of jurisdiction-specific primary sources and of case law as known gaps, and this paper does not close either.

Technical standards are not in the bibliography and none is cited. Every designation in Section 6 — the coded character set, the normalisation forms, the security mechanisms and their skeleton and restriction levels, the bidirectional algorithm, the transformation formats, the domain-name framework, the hash standard and the currency-code standard — is described from the source manuscript and itemised in Appendix B. **This is a real gap and it is not closed here.**

The nine well-documented failures of Section 7.2 are described at the level of mechanism only. None is cited, because the bibliography contains no case reports, no regulatory findings and no contemporaneous reporting. The one in-class instance is described without entity names and requires precise sourcing before reuse. **Nothing in Section 7.2 is an allegation about any named person, institution or product.**

The measurement results reproduce a source the paper did not obtain. The harness was rebuilt from a description, and the corpus design parameters were reconstructed until two of five results agreed. **A different class mix gives different figures for E1 and for the confusable-only row of E2**, and a reader reproducing them must use the stated parameters.

No prevalence claim is made or supported. The rate at which confusable substitution occurs in production financial systems is unmeasured, here and — so far as this paper is aware — anywhere. **The demonstration shows that the mechanism works; it is not an estimate of exposure in any real ledger** [T4]. Establishing prevalence requires data access this paper does not have and is the obvious next piece of work.

The zero false-positive column does not transfer. It is measured against clean ASCII critical fields. A non-ASCII check against a real name estate produces false positives at a very high rate, because a great many people legitimately have non-ASCII names. **Section 7.2 states this as the most serious objection to the approach.**

No macroeconomic magnitude is claimed. That representational failure at the record level could contribute to measurement discrepancy in aggregates built from those records is a bounded and testable hypothesis. **No magnitude is estimated, no share of any discrepancy is claimed, and no observed aggregate is attributed to this mechanism** [T4].

The off-ledger register has no standing anywhere. It is this paper's own construction, it is not a disclosure, it is recognised by no framework, and it must not be described to any regulator or auditor as one.

9.1 Rigour checks not met, listed by name

1. **No as-of date and no source, because nothing was measured.** Every figure derives from a constructed parameter set. Any application to a real structure, ledger or master file requires both.
2. **No uncertainty is reported anywhere**, because nothing is estimated. This is the absence of empirical content rather than precision.
3. **Model comparison was not performed.** No alternative model was fitted, no out-of-sample test was run, no information criterion was computed, and no matched null with the same number of free parameters was constructed. The models here are illustrations of identities and inequalities, not fits, and their conclusions follow from the identities rather than from goodness of fit. Epstein [2008] is the standing statement that prediction is one of sixteen reasons to model and that a paper is entitled to say which of the other fifteen it claims; this paper claims demonstration that a stated mechanism suffices to produce a stated shape.
4. **The models fail the calibration-and-validation checklist** of Bruch and Atwell [2015]: none is calibrated against observed data, none is validated out-of-sample, and none has a sensitivity analysis beyond the limits of Section 8.3.
5. **The conjoint-measurement conditions were not tested** [Luce and Tukey, 1964], so the ratio-scale treatment of the nine-capital vector is provisional and Michell [1997]'s objection is conceded rather than answered. **This is the paper's weakest input and Section 8.5 says so.**

6. **The corpus-wide scalar-reduction limitation is inherited** [Curzi, 2026] and not met separately: a structured situation with several jointly varying features is replaced by one number in two places in this paper, and arithmetic is then done on it.
7. **Small-sample bias in the effective count is not corrected** [Chao et al., 2014]. A five- or six-unit exposure vector is a small sample for a low-order diversity estimator.
8. **No statistical test was run and no p-value appears**, because there is no sample and no null. Every rate reported is an exact ratio of counts in a constructed corpus.
9. **No scaling, power-law or heavy-tail claim is made, and the Clauset–Shalizi–Newman procedure was therefore not run** [Clauset et al., 2009]. The one exponent that appears is exact combinatorics. Any restatement reaching for such a claim must run the procedure first and read Broido and Clauset [2019].
10. **This paper does not invoke the framework's reflexive law and therefore does not inherit the reflection problem** [Manski, 1993]. No result here rests on an endogenous social effect estimated from observation, and no such effect is claimed. **Where downstream work couples these results to that law, the caveat applies there and is not answered here**: a linear-in-means reflexive specification is not identified from observational data, and the remedies — randomisation, an instrument, partial-population variation, or stipulating and defending the reference group [Brock and Durlauf, 2001] — all carry a price. The one reflexive claim this paper does make, that publishing a control changes the behaviour of those subject to it, rests on a documented case [MacKenzie and Millo, 2003] and is not estimated here.
11. **The Lucas critique applies here and is conceded rather than answered** [Lucas, 1976]. The framework holds that systems change behaviour when modelled and observed; $\eta = 0.35$ and the maintenance floor are then not obviously stable under the framework's own predicted response to their publication. **This paper does not defend their stability; it fixes them in advance and reports every result as conditional on them.**
12. **Two borrowings are category 3 and are used only as framing**: Perrow [1984] and Sagan [1993]. Neither is a result about this system and neither is treated as one.
13. **The evidence-tier scheme is this paper's own and has no external standing.** It is an ordinal labelling convention, not a validated instrument.

10. Conclusion

This paper establishes six results in the form the rest of the corpus cites, and the following statements are the fixed text of those results.

R1 — the bloc collapse on a historical network. The five-house network measures 3.819710 effective jurisdictions naively — $1/\text{HHI}$, the Hill number of order two, on constructed shares of 40/20/20/13/7 — but **1.000000 effective blocs once a single coordination perimeter is recognised, giving** $h = -0.500000$**.** The same five cities under a nominal modern split give 1.923077 and $h = -0.271126$. **The naive count is identical in both eras; the bloc count is not, and the difference across three defensible readings of the 1815 structure is 0.469061 of** h**, which is a definitional choice and not a fact.**

R2 — double entry is a consistency check and not an integrity check. $A - (L + E) = 0.0000000000$ holds exactly while the statement misleads — a wholly fictitious 1,000 moves total assets by 66.6667 per cent and days-sales-outstanding by 82.125000 days — **so the identity's holding is not evidence of anything except arithmetic.**

R3 — the completeness gap, measured. On a constructed nine-capital vector, **63.850000 per cent represented** (financial 42 per cent and manufactured 18 per cent fully, intellectual at a stipulated 35 per cent recognition) and **36.150000 per cent structurally unrepresentable.** The gap is the price of the closure property and not a defect a better standard-setter would repair.

R4 — canonicalisation as an integrity control. The pipeline

$$\text{canon}(x) = \text{restrict_ASCII}(\text{confusable_fold}(\text{NFKC}(x)))$$

collapses 495 of 495 manipulated entries onto the clean canonical form, idempotently, and moves the reconciliation false-break rate from 40 per cent to 0 per cent at a 40 per cent manipulation rate — and to 0 per cent at every rate from 0 to 100 per cent, against byte equality's one-for-one tracking.

R5 — two correct books disagree, and the reconciliation bill is quadratic. A EUR 100,000 invoice booked at 1.0900 and 1.0850 leaves a USD 500 gap, **0.460829 per cent of the buyer's figure, with neither party in error**; and nine entities need $n(n-1)/2 = 36$ bilateral reconciliations against one shared record.

R6 — the coordination question resolved as a posterior rather than as an assertion. $P(\text{unified hand}) = 0.000732$ against $P(\text{competing centres}) = 0.999268$, **odds of 1,365:1 against the unified model**, on stipulated likelihoods and an exactly rational posterior.

Counter-result. This paper refuses its own most attractive material. **The one-day-coup account is refused as a fabricated data point** and the documented multi-year position substituted, at a constructed total return of 41.935484 per cent over two years that no single session could produce. **The unified-hand reading is rejected at 1,365:1** and the converse error refused in the same paragraph. **The 25 per cent currency-inflation figure is badged as an artefact of the chosen synthetic 8000/2000 ratio rather than as a constant**, with the confusable-only check reaching only 58.99 per cent against a headline of 100 per cent. And **the concentration instrument the corpus uses to measure resilience is shown to be vulnerable, at the character layer, to a defect that biases it in the reassuring direction.**

What the paper adds to the corpus's instrument. An effective count is a function over a partition, and neither the partition nor the identity resolution beneath it is supplied by the instrument. **Section 4.2 measures the cost of getting the partition wrong at 0.469061 of h; Section 5.6 shows the ledger cannot supply it; Section 6 shows that the identity resolution beneath it is string comparison with a measurable and cheaply closed blind spot.** A concentration measurement is therefore only as good as two things it does not contain, and both must be published with it or they will not be examined at all.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every worked result in this paper — the capital shares, the transit model, the constructed government-stock and sovereign-loan illustrations, the balance sheet and the fictitious posting, the invoice, the entity count, the nine-capital vector, the likelihood pairs, the 500-pair identifier corpus, the reconciliation sweep, the withdrawn-code extract and the ten-name watchlist — is **CONSTRUCTED** or **SYNTHETIC** and is labelled as such at each point of use. The numerical results are exact computations on those stipulated inputs. **No real institution, ledger, counterparty file, account, transaction, price series or person appears anywhere in this paper, and no allegation is made about any of them.**

All figures were produced by the scripts named in their captions (`figs/src/CCP-064_fig01.py` through `figs/src/CCP-064_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

The historical, legal and standards material is described from the source manuscript and is not cited to the bibliography, which contains no case law, no jurisdiction-specific primary sources, no standards documents, no regulatory findings and no press reporting. Appendix A lists the historical and measurement claims requiring verification; Appendix B lists the legal instruments, judgments, standards designations and documented matters described but not

cited. **Any reader relying on any of them must verify them against the governing document and against contemporaneous sources.**

The demonstration harness underlying Section 6 was **rebuilt from a description rather than obtained**, and its corpus design parameters were reconstructed until two of the five reported results agreed. Those parameters are stated in Section 6.4 and are stipulations.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data were processed. The historical material concerns institutions and published doctrine; no living individual is discussed, and no inference is drawn about any identifiable person.

No operational content

This paper contains no operational content. The substitution class of Section 6 is described at the level of mechanism, from material that is already public in the governing standards and in the published security literature, and it is described in order to specify a control. **No code, no data file, no substitution table and no method of evasion is supplied**, and the paper's purpose throughout is the construction of a detector rather than the defeat of one.

Legal, tax, accounting and investment advice

This paper is analytical and is not legal, tax, accounting or investment advice. It discusses historical institutions, a bookkeeping method, a doctrinal chain and a data-integrity mechanism. No recommendation is made in respect of any particular person, institution, product or jurisdiction, and no allegation is made about any of them. **Every legal and doctrinal statement in Sections 4.6 and 4.7 is described from a secondary source, is uncited, and must be confirmed with qualified counsel in the relevant jurisdiction before any reliance.** Accounting treatments must be confirmed with the reporting entity's auditor; recognition requirements differ between frameworks and change. Data-retention and disclosure obligations differ by jurisdiction; any control designed on the basis of Section 6 requires confirmation with qualified counsel and with the implementing institution's own compliance function.

Appendix A. Historical and measurement claims requiring verification

The following are described in this paper from the source manuscript and are **not cited**. Each requires verification before any reliance.

1. The founder's dates; the names, birth order and postings of the five principals; and the year each house was established.
2. The partnership instruments — a Frankfurt deed conventionally dated 1810 and later instruments — with their parties, terms, profit-sharing percentages, renewal intervals, and **the extent to which liability was in fact separated between houses.** This is the load-bearing legal claim behind the architecture argument of Section 4.1 and should not be relied on until checked.
3. The actual capital allocation across the five houses at any date. **The 40/20/20/13/7 vector is CONSTRUCTED and is not an archival figure.**
4. The courier and vessel network: composition, cost and speed advantage over the public posts. The three-hop/one-hop structure, the eight-day leg and the 0.0015 daily hazard are stipulated.
5. The correspondence practice: confirm the language and script pair, the period over which it was used, and whether any further cipher or code-word layer sat on top of it.
6. The scholarly work the source manuscript relies on for the corrected account [Ferguson, 1998]: confirm the exact volume covering the relevant period and the pages treating the bullion position and the subsequent government-stock position. **Every claim in Section 4.5 should be checked against it directly.**
7. The 1846 pamphlet: its author, title, date, pseudonym and its actual causal role in the circulation of the account. **This paper asserts none of these.**
8. What the London principal actually did on receiving the news: whether the government was informed, on what day, the size and disposition of the bullion position, and the actual entry and exit prices and dates of the subsequent position. **The 62/82/3 figures are CONSTRUCTED.**
9. The sovereign loans of 1831–32: the lending houses, amounts, currencies, issue prices, coupons, security and tranching, and the chronology of the revolt and the intervention. **The 1,000/75/5 per cent illustration is CONSTRUCTED.**
10. The codification of double entry: the 1494 printed work, its printer, the exact title as printed, and the internal location of the bookkeeping tract; the earliest surviving complete double-entry records and their date, which this paper's "roughly a century and a half" depends on; and the composition and printing dates of the earlier manuscript treatment.
11. The recognition criteria relied on in Section 5.5: the current recognition requirements of the relevant conceptual framework and the current prohibition on recognising internally generated goodwill. **This paper states the prohibition and should not be relied on for a paragraph number**, nor for whether the equivalent position under another framework materially differs.
12. The 1982 and 1989 momentum-accounting works: exact titles, series numbers, publisher, years, the relationship between them, and the author's own terminology for the third entry class. **This paper deliberately does not name that coinage.** Whether momentum accounting has been adopted anywhere in practice or in any standard: this paper asserts it has not.
13. The hash-tree publication: the correct paper, proceedings volume and year, and whether a later paper is the more appropriate citation for the construction as used today.
14. The 2005 signed-receipt work: exact title, venue and year; whether each party retains conventional books against the shared receipt; whether a distinct third-party issuer is required in all formulations; and whether related earlier work belongs in the same lineage.
15. The claim that double entry is required by every major accounting framework — verify the form in which the requirement appears, since it is generally implicit rather than stated as a rule.
16. All arithmetic in Sections 4, 5 and 6 is reproducible from the stated inputs, and every input is stipulated: the opening balance sheet (400/300/800/250/600/650); the fictitious 1,000; the stipulated annual revenue of 3,000; the 1.0900/1.0850 rate pair; the 32-byte

hash and 256-byte entry assumptions; both revenue series; the nine-capital vector and the 35 per cent recognition fraction; the nine-entity count and the 40,000,000 intercompany balance. **None is drawn from any real entity or any published dataset.**

17. The nine-capital frame is developed in Curzi [2026] and **the vector used here is illustrative and must be reconciled with that paper's definitive list, ordering and terminology.**
18. The corpus class mix (297/148/55) and the five digit-only no-op identifiers are **stipulated design parameters** chosen to reproduce reported rates. They are not derived from the source's code, which was not obtained. A reader reproducing E1 and the confusable-only row of E2 must use the stated parameters.
19. **The combining-mark result is this paper's own** and is not a reproduction of any reported figure. Verify independently.
20. **The 25 per cent of E5 is a property of the synthetic 8000/2000 ratio and is not a general magnitude.** Do not quote it as one.
21. **No prevalence claim is made or supported.** The rate at which this occurs in production systems is unmeasured, and establishing it requires access to real ledger data that no part of this paper has or uses.

Appendix B. Legal instruments, judgments, standards and matters described but not cited

`bib/external.bib` contains no case law, no jurisdiction-specific primary sources, no standards documents, no regulatory findings and no press reporting, and `bib/COVERAGE.md` records each of those as a known gap. The following are therefore **described from the source manuscript and cited to nothing.** Each requires verification against the governing document before any reliance, and none may be restated as a citation on the strength of this paper.

Instruments and doctrine (Section 4.7).

1. The four fifteenth-century instruments of 1452, 1455, 1493 and 1494 — issuing authority, exact dates, and the precise language relied on; and, for the 1493 instrument, which of more than one bull of that year is meant.
2. The 1823 judgment of a common-law supreme court receiving the doctrine into positive law: reporter citation, the pages containing the discovery and right-of-occupancy holdings, and whether the court was unanimous.
3. The two elaborating judgments of 1831 and 1832: citations and the respects in which each elaborates.
4. The 2005 judgment applying the framework: citation, holding, and the specific place in the opinion where the framework is invoked. **This paper deliberately names no footnote.**
5. The 1992 judgment of a different common-law supreme court rejecting one component, the 1993 statute following it, and the 1997 and 2014 judgments named in the source: citations and current status.
6. The 2023 statement by the issuing institution: date, the issuing bodies, the exact title, and the quoted characterisations.

Institutional chronology and the posterior's observations (Section 4.8).

7. The 1929 treaty and its financial provisions; the engagement of the manager appointed that year; the 1942 constitution of the financial body and the instrument constituting it; the 1982 collapse chronology and the death that year; the nature and legal effect of the letters relied on; and the 1984 payment — amount, date, parties, and **the exact settlement language recording moral involvement without admission of liability.** The source states approximately USD 240 million; this paper states "a nine-figure sum" and asserts no amount.

8. The 2013 arrest, its charges, forum and outcome; and the December 2023 conviction, its charges, sentence, appellate status at the date of reading, and the claim that it was the first such trial by that court.

Standards designations (Section 6).

9. The coded character set and its joint international designation; the normalisation forms and their governing annex; the security mechanisms document defining the skeleton transformation and the restriction levels; the bidirectional algorithm and its formatting controls; the two transformation formats named in the charset example; the domain-name encoding and framework documents; the hash standard; and the currency-code standard. Confirm every designation, its current revision and any obsoleting document. **The confusables data file is revised with each release of the character standard and must be treated as a configuration item. The source's attribution of a specific withdrawn numeric currency code is contested within the source's own register; this paper omits both candidate attributions and asserts none.**
10. The 2002 and 2006 papers on the homograph attack, and the 2021 disclosure of the bidirectional source-display issue together with its vulnerability identifier and the associated identifier for the homoglyph aspect. Confirm titles, venues, years and identifiers.
11. Structured party identification in payment messaging is cited where relied on [International Organization for Standardization, 2013]; the legal-entity identifier standard named in the source is not, and the state of any migration mandate in any market must be confirmed before relying on the structural argument of Section 7.2.

Documented matters used only as a negative audit (Section 7.2).

12. The nine failures are described at the level of mechanism, without dates, quanta or outcomes. Confirm, for each, the authoritative published record before any restatement — including which criminal convictions in one of them were subsequently quashed on appeal, by which courts and on what dates. **No part of this paper's argument depends on any of those outcomes.**
13. The single in-class instance: **confirm the exact registered names of both entities, the year and place of incorporation of the one, the corporate relationship of the other to its parent, and the specific civil forfeiture complaints in which the arrangement is described — case names, courts and filing dates.** This is the factual claim in Section 7.2 carrying the most weight and it must be sourced precisely or removed. **This paper reproduces neither name.**
14. The published compliance framework identifying screening-software and filter deficiencies among recurring root causes: exact title, date and the precise wording of the findings. The authoritative names and publishers of the designated-persons lists named generically in Section 7.2. Any industry-body or intergovernmental screening guidance relied on, by exact title and date; **none is cited here.**
15. The claim that mature screening engines commonly use fuzzy, phonetic and transliteration matching is a general characterisation of a vendor landscape, is sourced to no named product, and **whether any specific engine folds confusables before computing edit distance must be established by direct testing of that engine rather than assumed in either direction.**

Jurisdiction-specific regulatory facts (Section 7.1).

16. The source manuscript names, for each node of a six-jurisdiction structure, a specific listing cycle with dates, a specific administrative order, specific substance regulations and specific unilateral measures. **None of those is reproduced here and none is cited**, following the de-branding convention of Curzi [2026]; the table in Section 7.1 gives mechanism classes without jurisdictions. Each named instance requires its own statute, regulation or register citation, pulled from the official register and verified individually.

All numerical results in this paper were computed from the stated constructed inputs at full precision and rounded only for printing.

Chapter 65

Canonical Form and Typed Parsing: Measured Integrity Controls Across a Financial Identifier Namespace

Abstract. We specify and measure an integrity layer for machine-readable financial fields. The canonical form canon(x) = restrict_ASCII(confusable_fold(NFKC(x))), paired with a byte-level SHA-256 witness kept on a separate plane from the display form, is tested against a synthetic corpus: 495 of 495 manipulated entries collapse onto their clean canonical form, idempotence canon(canon(x)) = canon(x) holds for all 500 cases, and 995 distinct raw byte strings resolve to the true 500 canonical identifiers. The reconciliation false-break rate falls from 40.0 per cent to 0.0 per cent at a 40 per cent manipulation rate. Within the ISO namespace, aliasing a withdrawn currency code to a live one is shown to inflate a synthetic 8,000 balance to a recorded 10,000, a phantom 25 per cent with no journal entry. Naive detection of withdrawn codes has a precision of 11.01 per cent, meaning 88.99 per cent of its queue is parsing ambiguity, and one typed-field parse collapses that share to 0.00 per cent. The migration to structured messaging inverts the intuition about richness: in a synthetic thousand-message day with 62 per cent rich traffic, sparse messages are 38 per cent of volume and 93.9 per cent of the review queue. The stated rates are stipulated design parameters, and the architecture is badged as providing no consensus, no double-spend prevention, no valuation method, no adopted standard status and no legal force.

Keywords: canonicalisation; confusable folding; ISO 4217; legal entity identifier; ISO 20022; typed parsing; false-break rate; screening queue

Series: D. Structure and Resilience **Paper:** CCP-065

1. Introduction

A financial control that decides whether two records name the same thing is, at bottom, a string comparison. Curzi [2026] measures what that comparison misses when the character set admits more than one code point per shape: 495 of 500 manipulated identifier pairs are byte-distinct, digest-distinct and canonically identical, and the reconciliation false-break rate tracks the manipulation rate one-for-one under byte equality. **This paper states the remedy as a specification, generalises it one level up to the codes those strings carry, and measures what the generalisation buys at the layer where payments actually cross a border.**

The paper's contributions are separable and each carries its number.

An integrity layer, specified and measured. The canonical form $\mathrm{canon}(x) = \mathrm{restrict_ASCII}(\mathrm{confusable_fold}(\mathrm{NFKC}(x)))$, paired with a byte-level SHA-256 witness computed over the raw octets and kept on a plane separate from the display form, is tested against a synthetic corpus. **495 of 495 manipulated entries collapse onto their clean canonical form; idempotence holds for all 500 cases; 995 distinct raw byte strings resolve to the true 500 identifiers; and the reconciliation false-break rate falls from 40.0 per cent to 0.0 per cent at a 40 per cent manipulation rate.** Eighteen normative rules and their conformance tests are given, so that an implementation can be checked rather than trusted.

The same failure one level up, in the code namespace. A code is trustworthy only if there is one live referent per code, and what guarantees that is a registry rather than the string. Aliasing a withdrawn currency code to a live one records a synthetic 8,000 balance as 10,000 — **a phantom 25.0 per cent inflation with no journal entry and nothing forged.** Worse, the same three digits occur in two independently governed registries with different meanings, so a screen that scans bytes rather than typed fields cannot tell them apart: **naive detection has a precision of 11.01 per cent, meaning 88.99 per cent of its queue is parsing ambiguity, and one typed-field parse collapses that share to 0.00 per cent.** A control right one time in nine is not a control.

The resolvability asymmetry on a settlement network. The migration from field-limited legacy messages to a structured, richly typed standard inverts the intuition that carrying less data reveals less. A screening system disposes of a message it can resolve and escalates one it cannot, so **the message that carries less is not more private, it is less resolvable, and unresolvability is what costs.** In a synthetic day of 1,000 messages at 62 per cent rich traffic, **sparse messages are 38 per cent of volume and 93.9 per cent of the review queue.** The finding is not that disclosure is virtuous; it is that a lawful structure has a direct operational interest in being resolvable, and a structure that cannot afford to resolve cannot adopt the posture.

An architecture reported with its negative results. Above the specification sits a ledger substrate factored into per-object hash chains and a content-addressed capability layer. Both are the author's own systems, both were audited adversarially by the author, and **the audit findings are reported here in the same plain language as the successes, including the ones that refute the author's earlier claims.** The substrate verifies 200 of 200 per-token chains and detects 200 of 200 silent edits; it records 28 of 28 grid links in both ledgers; and its local append cost rises from 0.002 s to 0.014 s as the chain count goes from 50 to 400 — **a local, single-process measurement that is not distributed throughput and is not offered as one.** It supplies **no consensus, no total order, no double-spend prevention and no Sybil resistance**, and a working double-spend against it is reported. Its block hash under-binds, and the fix is given. Four findings in the capability layer — an unverified proof signature, an inconsistently computed self-verification digest, broken hash algorithms on offer, and a replay surface at the freshness root — are reported with their fixes and re-validation. **The naming rationale and a numerological layer present in the implementation carry no technical content, are excluded from every claim in this paper, and are graded as claims deliberately not made.**

Why these sit in one paper. They are one mechanism at three heights. A character is trustworthy as an identifier only if one code point maps to one character; a code is trustworthy only if one code maps to one live referent; a message field is trustworthy only if the receiving control parses it under the grammar that owns it. **In each case a representation is trusted by a consumer that cannot see the binding, and the binding is maintained somewhere else.** That is the same defect Curzi [2026] measures at the signalling layer, where an in-band ambiguity rate of 0.383 per cent falls to exactly 0.000 per cent once control and data are disjoint by construction, and it is why the specification here is stated as a boundary rule rather than a field rule.

2. Hypotheses

Six hypotheses, each stated so that it could be wrong, each with its falsifier [Platt, 1964, Popper, 1959]. Statements that are not falsifiable are listed at the end and labelled.

H1 — the canonical-form hypothesis. A fixed three-stage canonical form applied at the comparison boundary maps every member of the substitution class onto one representative, and does so idempotently. *Predicted:* 495 of 495 manipulated entries collapse onto the clean canonical form; $\text{canon}(\text{canon}(x)) = \text{canon}(x)$ for all 500 corpus values; 995 distinct raw byte strings resolve to 500 distinct canonical forms, the true count. *Falsified by:* a manipulated value whose canonical form differs from its clean counterpart's, or any value for which the operation is not idempotent.

H2 — the witness-level hypothesis. The evidence that a substitution occurred survives only if the digest is taken over the raw octets; taking it over the canonical form destroys that evidence. *Predicted:* for a clean value and its homoglyph twin, canonical forms equal, byte-level digests differ, character-level digests identical. *Falsified by:* a character-level digest that distinguishes the pair, or a byte-level digest that does not.

H3 — the typed-parsing hypothesis. Where two independently governed registries mint the same string with different meanings, a byte-level screen cannot separate them and a typed parse can, without any determination of intent. *Predicted:* on the synthetic corpus, a naive substring screen flags 1,363 records of which 150 are genuine, a precision of 11.01 per cent and an ambiguity share of 88.99 per cent; a typed parse isolates the 150 with 0 false positives, an ambiguity share of 0.00 per cent. *Falsified by:* a byte-level test that separates the two registries' occurrences on the string alone, or a typed parse that loses a genuine event.

H4 — the resolvability hypothesis. A screening control disposes of a message it can resolve to one identity and escalates one it cannot, so review load concentrates on the message format carrying the least identifying data rather than on the payments of most concern. *Predicted:* in a synthetic day of 1,000 messages at 62 per cent rich, sparse messages are 38.0 per cent of traffic and 93.9 per cent of the review queue; a richly typed message carrying a deterministic entity identifier clears on one exact-key comparison while the same payment in sparse form fails to a two-candidate fuzzy set and goes to a human. *Falsified by:* a screening design that disposes of an unresolvable message without escalation, or a queue whose composition does not track message richness.

H5 — the structure-is-not-canonical-form hypothesis. A structured, richly typed message improves party identification without closing any member of the substitution class, because a syntax fixes the shape of the data and not the identity of the values. *Predicted:* a homoglyph twin placed in the standard's own name element is byte-distinct and canonically identical, passes every structural validation, and is separated only by the canonical form and the byte-level witness. *Falsified by:* a structural validation in the standard that rejects the twin, or a canonical form defined by the standard itself.

H6 — the substrate hypothesis. Factoring a ledger into per-object hash chains delivers tamper-evidence and local write-parallelism and does **not** deliver consensus, total order, double-spend prevention or Sybil resistance. *Predicted:* 200 of 200 chains verify; 200 of 200 single-block mutations are detected; 28 of 28 cross-object links are recorded in both ledgers; local append cost is linear in the chain count at 0.002, 0.003, 0.007 and 0.014 s for 50, 100, 200 and 400 chains; **and a fork transferring the same balance twice produces two internally valid chains that the structure does not reject.** *Falsified by:* a silent edit that verifies, or an ordering property emerging from the factoring without an added ordering layer.

Statements in this paper that are not hypotheses, and are labelled as such.

- *The eighteen normative rules* are a **proposal**. They have no adopted standard status, replace no obligation, and carry no legal force. What is testable is each rule's conformance test.
- *The resolution designator* is an **accounting proposal** requiring a standards process and auditor acceptance, and having neither.

- *The nine-form backing taxonomy* is a **classification**, not a measurement. **No measurement basis for the non-financial forms is specified in the source material or here**, and any coverage ratio computed across them is computed over an unknown.
- *The system's naming rationale and its numerological layer* are **claims deliberately not made.** They confer no property on any structure described and are excluded from every technical claim in this paper.

3. Method

3.1 What is specified, what is measured, and what is only reported

Three different kinds of statement appear in this paper and the method keeps them apart.

Specification. Sections 4.1 to 4.6 state normative rules with keyword conventions and, for each, the test that decides conformance. **A specification that cannot be tested is a wish**, so every rule that matters carries its test in Section 4.6. Nothing in the specification has adopted status.

Measurement. Sections 4.7, 5.8, 6.4 to 6.6 and 7.1 report deterministic computations over synthetic corpora with fixed seeds. Each corpus is stipulated and each stipulation is printed, so that a reader can reproduce the figure or show that a different stipulation gives a different one. **No figure in this paper is an estimate of prevalence in any real system**, and Section 10 says so by name.

Report. Section 7 describes artefacts the author built and audited. The measurements there were recomputed for this paper on a harness rebuilt from the source descriptions; **the original code was not obtained and was not rerun.** The audit findings are reported as findings about the implementation *as audited*, and Appendix A records that the current state of each must be confirmed before any finding is repeated in the present tense.

3.2 Evidence tiers

tier	meaning
T1	established fact — a published standard, a proven cryptographic or distributed-systems result
T2	measured by a deterministic harness and independently recomputed for this paper
T3	proposed standard or sound design, not adopted, not hardened at scale
T4	refuted, unsupported as stated, or a claim deliberately not made

The headline grades: the canonical form and the byte-level witness are T3 as a normative proposal and T2 where measured; hash chaining, content addressing and the impossibility results are T1; the resolution designator is T3 and is not an adopted rule; **the naming rationale, the numerological layer, and the claim that a per-object ledger needs no consensus are all T4.**

The tier scheme is this paper's own ordinal labelling convention and has no external standing. It is not averaged anywhere and no arithmetic is performed on it.

3.3 The disclosure test

Every element of the specification is audited in print against one question: **would it still do its job if every element were disclosed to every authority with jurisdiction over any part of it?**

This is not an ethical preference. It is Kerckhoffs [1883]'s principle, stated in 1883 — a system must remain secure when everything about it except the key is public — restated as *open design* among the protection principles of Saltzer and Schroeder [1975] and given its transparency-as-remedy form by Brandeis [1914]. Curzi [2026] states the resulting constraint in the form used here: **effectiveness that is entirely independent of whether anyone knows the control is in place makes every element publishable, so non-disclosure is refused as a design premise rather than merely discouraged.** The regulatory environment has independently removed non-disclosure from the available design parameters [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015, de Goede, 2011].

The specification passes the test emphatically, and the reason is worth stating because it is the paper's strongest structural claim about itself. **Publishing the control tells an adversary that substitution against this system will be detected, which is the deterrent, and tells a supervisor or a counterparty that the system does not have the hole, which is the assurance.** Section 8.2 records the one place where the test is passed but the *ordering* matters: a treatment that changes how a balance is presented must obtain auditor acceptance before disclosure, not after.

3.4 Provenance of the artefacts, and the exclusions

The ledger substrate and the capability layer described in Section 7 are the author's own systems, and the adversarial audit reported there is also the author's. That is a conflict of interest, it is declared in full in the Declarations, and the method adopted in response is the only one available to a single author: **report the negative results at least as prominently as the positive ones, and report the ones that refute the author's own earlier claims by name.** Section 7 does that. A reader who discounts the positive findings accordingly is reading correctly; the negative findings are the ones that cost something to publish and are therefore the ones worth weighing.

Two elements are excluded from every technical claim in this paper. The first is the system's **naming rationale**, which the author's own materials record in three readings — a sacramental symbolism, an operational expansion of the same four letters, and an agricultural reading. All three are recorded here as declared and none is corroborated, adopted or verified. **The naming carries no technical content and confers no property on any structure described.** T4.

The second is a **numerological layer** present in the reference implementation: a modulo-nine coherence score, an associated identity claimed as a theorem, a nominated binding frequency, and a set of nine dimension labels. **The author's own security audit assesses them and excludes them by name from every security claim; this paper excludes them likewise and mentions them only so that a reader encountering them in the source code knows they were assessed and discarded rather than overlooked.** T4.

The exclusion is the reason the material can be printed at all. A system whose author will not separate a symbolism from a specification cannot be evaluated; a system whose author separates them in print, before the specification begins, can. Curzi [2026] is the corpus's general form of that discipline — four items of established mathematics, seven of established psychology and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third — and this section is its application to an engineering artefact.

4. The integrity layer, specified

4.1 The canonical form

For critical machine fields — identifiers, account and transaction numbers, amounts, currency codes and action codes — the canonical form is the composition of three operations

in a fixed order [T3]:

$$\text{canon}(x) = \text{restrict_ASCII}(\text{confusable_fold}(\text{NFKC}(x)))$$

Each stage has one job and the order is not interchangeable.

Compatibility normalisation resolves the compatibility and full-width members of the substitution class: full-width digits fold to their ASCII counterparts, and compatibility variants of Latin letters fold to their base forms. **Compatibility normalisation is specified rather than canonical normalisation, and the difference is not cosmetic**: the canonical composed form does not fold full-width variants at all, so a system that normalises to it has done nothing about that member of the class while believing it has.

Confusable folding maps homoglyphs onto a single representative and removes default-ignorable code points. It is the skeleton operation in the role the governing security standard defines for it: two strings are confusable when their skeletons are equal. **A conforming implementation consumes the published confusables data file rather than a hand-written table, and treats the character standard's version as a change-controlled configuration item**, because a confusables table that drifts out of date is a control silently losing coverage.

Restriction enforces the permitted character set for the field. The operative word is *enforces*. **A residual out-of-set character is rejected or quarantined with an explicit reason, never silently stored and never silently stripped** — because silent stripping is itself a substitution, performed by the control rather than against it, and it destroys the evidence that anything happened.

The order matters in one direction specifically. **Folding before normalising would let a compatibility form of a confusable character survive both stages**, because the confusables data is keyed on the normalised representative. Normalise first, fold second, restrict third.

Reconciliation, deduplication, matching and screening then operate on $\text{canon}(x)$ rather than on x.

4.2 The byte-level witness, and why the level is the whole design

Each record additionally stores a SHA-256 digest computed **over its raw octets** — the bytes as received, before any normalisation, folding or restriction — and **not** over the canonical form.

The rule that follows is the detector and it is one line:

> **Identical canonical form with differing byte-hash is flagged for review.**

That single comparison separates benign normalisation from injected substitution. Two records whose canonical forms agree are, to every downstream process, the same record. If their raw octets also agree, nothing happened. If their raw octets differ, something did — **and the byte-hash is the only artefact in the system that still knows it.**

Curzi [2026] measures the alternative and it is unambiguous [T2]. Hashing the canonical form gives a clean value and its Cyrillic twin the identical digest `6de95bd1c87f`; hashing the octets gives `6de95bd1c87f` and `21300fa543ad`. **A character-level hash destroys exactly the evidence that makes the detector work, and it does so silently, producing a system unable to report that it was attacked.** This is the single most consequential specification decision here and the one most likely to be got wrong by an implementer optimising for tidiness, **because hashing the canonical form is the more obviously elegant choice and it is the wrong one.**

A second-order property deserves its name. **The byte-hash is a witness, not an assertion.** It does not claim the record is true; it claims that these octets were what arrived. That is the same modest, checkable claim a hash-tree commitment makes, and it is worth exactly that and no more. Curzi [2026] states the general form: commitment is a tamper-evidence property, not a truth property.

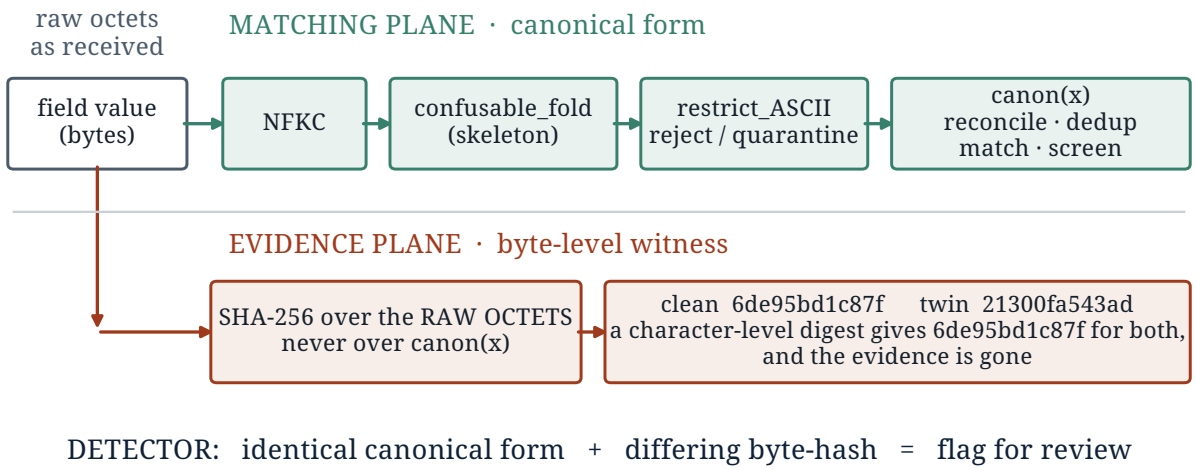

Figure 65.1: **Matching runs on the canonical form; evidence runs on the raw octets; the detector is the one comparison that reads both planes.** The digests shown are those reported in Section 4.2 for a clean value and its Cyrillic twin. Hashing the canonical form gives both values the same digest and destroys the evidence the detector needs. Schematic built by `figs/src/CCP-065_fig01.py`.

4.3 Free-text scoping

Human free text legitimately requires the whole character repertoire. Names, addresses, memos, remittance narratives and instruction text belong to people who have every right to their own scripts.

The specification therefore scopes restriction to critical machine fields only [T3]. Free-text fields store **both** the raw form and a canonical form, side by side, and are governed by the graded restriction levels of the security standard rather than by ASCII folding. Matching against a free-text field runs on the canonical form; display, storage of record, and anything a human will read run on the raw form; **and the raw form is never overwritten.**

Curzi [2026] identifies mis-scoping as the single largest risk in the approach, and this is where it is prevented. **A canonicalisation standard applied without scoping is not a control improvement but a data-destruction programme with a compliance justification, and it will be resisted, correctly, by every business line it touches.** Setting the restriction level per field and per market is a business decision with a compliance consequence, and no library performs it.

4.4 The resolution designator

Curzi [2026] measures what happens when a withdrawn numeric currency code is aliased to a live one: a synthetic 8,000 becomes a recorded live 10,000, an inflation of 25.0 per cent, **with no entry posted and nothing forged** [T2]. The remedy is stated as an accounting rule rather than a technical one [T3]:

> Withdrawn or orphaned codes are assigned to an explicit **resolution class** and are never aliased to a live settlement currency. A balance in a resolution class is visible, non-settleable, and excluded from every live-currency aggregate. It is discharged only through an authorised resolution entry that preserves a permanent audit receipt.

Three properties follow. The orphaned balance **stops distorting the statements immediately**, because it leaves the live aggregate when the code is classified rather than when it is resolved. The discharge becomes **an event with an owner, an authority and a date** rather

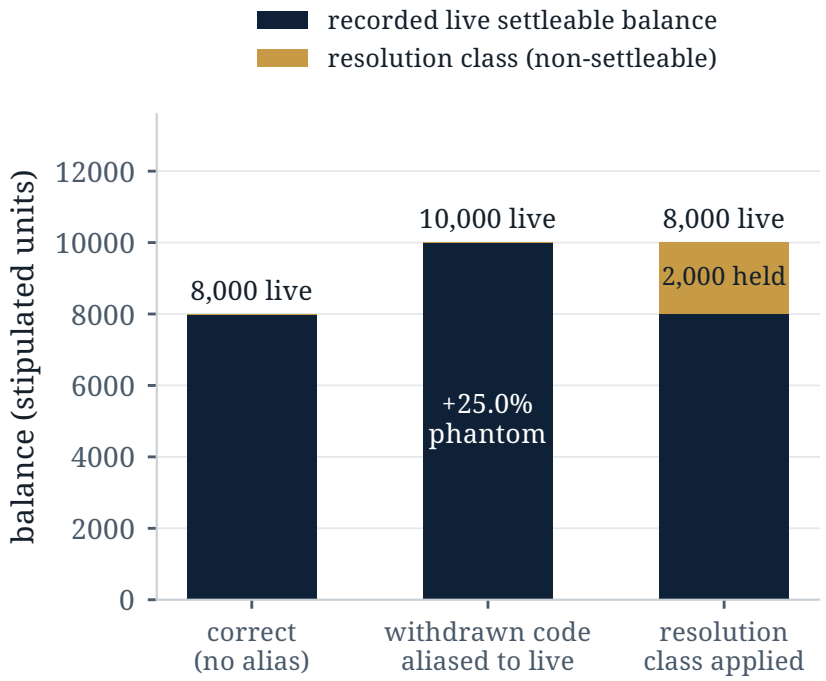

Figure 65.2: **Aliasing a withdrawn code to a live one inflates a synthetic live balance by 25.0 per cent with no journal entry; the resolution class removes the inflation without discharging the balance.** The 2,000 leaves the live aggregate the moment the code is classified and sits visible and non-settleable until an authorised entry discharges it. SYNTHETIC three-account extract; figures are stipulated units. Built by `figs/src/CCP-065_fig05.py`.

than a write-off that happens when somebody notices. And the trail is permanent and byte-addressable, so the question *what happened to that balance* has an answer that survives the departure of everyone who was in the room.

The honest status of this clause is that it is the least mature thing in the paper. It is an accounting-standard proposal. It requires a standards-body process and auditor acceptance, it has neither, and **until it has both, an entity cannot use it to justify a treatment in a set of accounts** [T3]. Appendix A says so and Section 8.3 says so again.

4.5 The normative rules

Stated with the conventional requirement keywords. **Every rule is graded [T3] — a proposal, not an adopted standard.**

Canonical form.

1. An implementation MUST canonicalise every critical machine field as restrict_ASCII ∘ confusable_fold ∘ NFKC, in that order.
2. An implementation MUST canonicalise **at every ingestion boundary**, not only at interactive entry points. File imports, partner interfaces, message parsers, migration scripts and registry extracts are ingestion boundaries.
3. canon MUST be idempotent, and an implementation MUST verify idempotence over its own field repertoire as a test, because **a non-idempotent canonicaliser cannot be applied at more than one boundary without changing answers.**
4. Restriction MUST reject or quarantine any residual out-of-set character with an explicit reason. It MUST NOT silently strip and MUST NOT silently store.

5. Reconciliation, deduplication, matching and screening MUST operate on the canonical form.
6. An implementation MUST record the character-standard version and the confusables-data version used, and MUST treat a change to either as a change-controlled event.

Byte-level integrity.

7. Each record MUST store a SHA-256 digest computed over its raw octets as received.
8. An implementation MUST NOT substitute a character-level digest for the byte-level one. It MAY store both; it MUST store the byte-level one.
9. Identical canonical form with differing byte-hash MUST be flagged for review.
10. An implementation MUST define, before deployment, the owner and escalation path for a flag raised under rule 9. **An unactioned flag queue is worse than no flag queue.**

Scoping.

11. Restriction MUST be scoped to critical machine fields and MUST NOT be applied to human free text.
12. Free-text fields MUST store both raw and canonical forms, and the raw form MUST NOT be overwritten.
13. Free-text fields MUST be governed by graded restriction levels set per field and per market.

Boundaries.

14. Every file and message boundary MUST carry an explicit encoding declaration.
15. Octets arriving without a declared encoding MUST be rejected rather than guessed at, and every intermediate tool that guesses MUST be pinned or removed from the path.

Withdrawn and ambiguous codes.

16. A withdrawn code MUST NOT be aliased to a live settlement referent.
17. A withdrawn or ambiguous code MUST be assigned to an explicit resolution class, carried as visible and non-settleable, and excluded from every live aggregate.
18. Discharge from a resolution class MUST be by an authorised entry naming the registry, the version and the basis, leaving a permanent audit receipt.

4.6 Conformance: how an implementation proves it complies

A specification that cannot be tested is a wish. Each rule has a test, and the tests are stated because they are what an auditor or a counterparty would actually ask for.

rule	test	why this test and not another
1	a golden corpus of input–output pairs covering every member of the class, checked in on the same commit and run in continuous integration	it must include one homoglyph, one compatibility form, one combining-mark sequence **with** a precomposed equivalent and one **without**, one default-ignorable insertion and one bidirectional control

rule	test	why this test and not another
3	assert canon(canon(x)) = canon(x) over the golden corpus and a generated sweep	catches the commonest implementation error: a fold written as a sequence of replacements, and therefore order-dependent
4	feed an out-of-set character and assert the call **raises with a reason**, and specifically that it does **not** return a shortened string	a stripping implementation passes every positive test and fails only this one
6	assert the recorded standard version matches the version of the data file the build actually loaded	a build recording one version while loading another is a control that drifts silently
7–9	take a clean value, produce a substituted twin, store both, assert canonical forms equal, byte digests differ, and a flag was raised	**the single most valuable test in the suite**: an implementation that quietly hashes the canonical form passes every other test in the file
15	at integration rather than unit level: submit octets with no declared encoding and assert rejection	the guessing happens in a component nobody thinks of as part of the system, and a unit test on the library will never see it
16–18	construct a synthetic extract with a withdrawn code; assert it appears in the resolution class, appears in **no** live aggregate, and **cannot be selected as a settlement referent by any code path**	the third assertion is what catches a partial implementation in which the reporting layer was fixed and the settlement layer was not

4.7 Results: the integrity layer measured (H1 and H2 supported)

Every figure below was recomputed independently for this paper on synthetic data [T2].

quantity	result
manipulated entries collapsed onto the clean canonical form	495 / 495 = 100.0%
idempotence canon(canon(x)) = canon(x)	holds for all 500
distinct raw byte strings resolving to distinct canonical forms	995 → 500 (true 500)
reconciliation false-break rate at 40% manipulation	40.0% → 0.0%
canonical forms equal for clean value and twin	True
byte-level digests differ (**the detector**)	True
character-level digests differ (**evidence lost**)	False
live balance, correct	8,000

quantity	result
live balance, withdrawn code aliased to live	10,000 (+25.0%)
resolution-class balance, segregated	2,000

H1 is supported and H2 is supported. The false-break result is the one with operational consequence: it holds at 0.0 per cent across the entire manipulation range including the degenerate case where every entry is manipulated, so the 40-to-0 reading at a 40 per cent rate is **one point on a flat line rather than the result itself** [Curzi, 2026].

The 25.0 per cent is a property of the stipulated 8,000/2,000 ratio and is not a general magnitude [T4 as to any claim that it is]. What generalises is the sign and the mechanism: aliasing a withdrawn code to a live one always inflates, always in the direction of more apparent money, and always without any entry being posted.

5. The identifier namespace

5.1 A namespace is a registry, not a string

A namespace is a set of names and a rule binding each name to a referent. **The rule is what makes it a namespace rather than a list, and the rule always lives outside the names themselves.** For the codes examined here the rule is a registry and a maintenance agency: a body that decides which codes exist, what each one currently points at, when a code is withdrawn, and whether a withdrawn code may be reused. **Every property a code has that matters for a ledger — uniqueness, stability, currency of meaning — is a property of the registry and not of the string.**

This is the observation of Curzi [2026] turned up one level. A universal character set is a registry binding code points to characters, and its confusables problem is that many code points bind to the same *shape*, so the visual layer over-collapses what the code layer keeps distinct. The standards examined here bind codes to *entities in the world*, and their problem is the mirror image and also the same: over time one code can bind to more than one referent, and two independent registries can mint the same string for different referents. **The failure is representational ambiguity — one recorded symbol, more than one possible referent, no visible difference — and it does not require a universal character set to occur.**

No standards document is cited in this section, because `bib/external.bib` contains none. One standard relied on for structured party identification is in the bibliography and is cited where it is relied on [International Organization for Standardization, 2013]. Every other designation is described from the source manuscript and itemised in Appendix B with what specifically requires verification. **No edition year, no check-digit algorithm, no registration authority and no code allocation is asserted here.**

Eight members of the namespace divide into three functional groups, and the grouping is not decorative: **it is the layering that lets a defect propagate.**

5.2 The atomic registries

Two members are atomic: their codes are not built out of other codes, and they are the substrate the rest references.

The currency registry assigns each currency a three-letter alphabetic code and a three-digit numeric code [T1]. The alphabetic code is mnemonic; the numeric code is a stable machine key that by design does not depend on the Latin alphabet and survives transliteration. Codes are added when currencies are created and withdrawn when currencies cease to circulate. **The numeric codes of withdrawn currencies persist in the standard's historical record and, far more consequentially, in the master files of every system built while those currencies**

were live. The maintenance agency publishes a live table and a separate withdrawn table; the two must be read together, and a system loading only the first has already lost the information that would let it recognise an orphaned balance.

The country registry assigns each country and territory a two-letter code, a three-letter code and a numeric code [T1]. It is the most-referenced registry in the stack, because four of the remaining six standards embed a country code inside their own identifiers. That makes it the single point whose instability propagates furthest: a change to a country code is not a change to one field, it is a change to a substring inside every securities, institution and account identifier that carries it. The registry has an explicit lifecycle — assignment, withdrawal on a change of sovereignty or name, a transitional reservation period, and, after a defined interval, the possibility of reassignment of a withdrawn two-letter code to a different country. A country code is a lease on a string, not a freehold, and a record that stored the string decades ago may now read against a different country than the one it meant [T1]. The specific historical reallocations and the exact reservation period are in Appendix B and none is named here.

5.3 The composed identifiers

Three members are composed: built by concatenating a country code with further structure and, usually, a check digit computed over the whole.

The securities identifier is a twelve-character code whose first two characters are a country prefix identifying the national numbering agency that issued it, followed by a nine-character national identifier and a check character [T1]. The prefix identifies the issuing agency's jurisdiction, which is not always the issuer's jurisdiction or the instrument's place of listing, and that gap is the source of a widespread belief that the identifier uniquely names a tradable position. It does not: one economic instrument can carry identifiers from more than one agency, and one identifier can be listed and traded in several venues under different local codes — which is why a separate classification standard exists to say what *kind* of instrument the identifier denotes.

The institution identifier is an eight- or eleven-character code: four characters identifying the institution, two a country, two a location, and an optional three-character branch suffix [T1]. It binds an institution to a routable identity, and its trustworthiness is the registrar's diligence in maintaining one institution per code and one code per operational endpoint. Its embedded country code is another place country-registry instability propagates.

The account identifier is a country code, two check digits computed over the rearranged account string, and a basic account number whose internal structure is defined nationally and differs by country [T1]. Its check digits catch transcription errors before a payment is launched, which is their entire purpose and a genuinely valuable one; they do not, and are not meant to, certify that the account exists or belongs to whom the payer thinks. The phrase *nationally defined* is the hinge of Section 5.7, because it is where an international standard defers to a purely national numbering scheme that the international standard does not itself define.

5.4 The descriptive codes

Two members describe rather than identify.

The instrument-classification standard encodes an instrument's category, group and attributes in six alphabetical characters [T1]. It exists because an identifier that is unique is not thereby informative: knowing that two positions carry different identifiers says nothing about whether they are the same class of risk, and a concentration measure of the kind Curzi [2026] builds needs the classification and not only the identity.

The legal-forms standard is a registry of the legal forms an entity can take in each jurisdiction, each rendered as a short code, so that legal forms in three languages become comparable machine tokens rather than free text [T1]. Its relevance to this series is direct: the difference

between a foundation, a trust and a company is exactly the difference Series D turns on, and this is the code list that lets that difference survive crossing a system boundary instead of being flattened into "company" by a form field with three options.

5.5 The keystone identifier: a permanent code and a perishable trust

The entity-identifier standard defines a twenty-character alphanumeric code with a prefix allocated to the issuing organisation, reserved characters, entity-specific characters and a check computed by a modulus algorithm [T1]. It is the member that comes closest to solving the identity-resolution problem Curzi [2026] names as the control underneath everything, because that is what it is designed to be: one persistent code per legal entity, globally, backed by a public reference record.

And it is the cleanest possible illustration of this section's thesis, because its value is entirely a function of its registry and the standard says so in its architecture. The identifier is not self-certifying. It is minted by a local operating unit, validated against an authoritative local source, and — this is the part that matters — **it must be renewed on a cycle, with the reference data re-verified against source, or its registration status lapses.** A lapsed identifier is still syntactically valid; it still passes its check; it still resolves to a reference record. **What it no longer carries is a current assertion that the binding is true.**

The system builds the whole thesis into its own design: the code is permanent and the trust is perishable, and the renewal cycle exists precisely because a registry binding decays unless it is actively maintained. A control that treats the identifier as a fact rather than as a dated assertion has made the same category error as a control that treats a currency code as a fact — and the registry's own status field is telling it so.

5.6 How a defect travels

The country registry is the substrate. Three identifiers embed a country code inside their own strings, so a country-code change or reassignment is a change inside a securities identifier, an institution identifier and an account identifier simultaneously. The currency registry sits beside them. The entity identifier names the holder; the legal-forms code says what form the holder takes; the classification code says what class the security is. **A single settlement instruction touches most of the namespace at once**: it pays an *entity*, of a *legal form*, in a *country*, at an *institution*, into an *account*, a sum in a *currency*, possibly against a *security* of a *class*.

Every one of those is a registry lookup, and every registry has the same three failure surfaces: a code can be **withdrawn** and its meaning orphaned; a code can be **reassigned** and its meaning silently changed; and two registries can **mint the same string** for different referents.

The composition multiplies the surface: because the higher codes are built from the lower ones, a defect does not stay where it started. A country reassignment is felt in three other standards and a currency orphan is felt anywhere the currency is aggregated. This is a coupled-network fragility of exactly the kind Buldyrev et al. [2010] formalises — a failure in one layer propagating into a layer that depends on it — and it is the structural reason the eight are treated here as one namespace rather than as eight standards. The analogy is used for its shape and not as a theorem about registries; Section 9.6 records that.

5.7 Two collisions on one digit string, and the reading that is refused

The sharpest instance of the hazard concerns a three-digit string that occurs in two independently governed registries, and it must be stated with precision, **because the defensible finding and the indefensible one are close together and the difference is the whole of the section's credibility.**

The first collision is within the currency registry itself: **one numeric code denotes a currency in a pre-redenomination form and is withdrawn, while a different numeric code denotes the live post-redenomination currency.** Two codes in one standard's history both mean, loosely, the same national currency, separated by a redenomination. That is a straightforward instance of the hazard of Section 4.4: a legacy system carrying a balance under the withdrawn code, and a mapping table that at some migration was given a row sending it to the live currency, reports a withdrawn-code balance as live settleable money. **The exact historical allocation of the withdrawn code between two candidate predecessor currencies is contested in the source's own verification register, is not asserted here, and is itemised in Appendix B. The mechanism does not depend on which one it was; the naming does.**

The second collision is distinct and shares the identical digits. **A national domestic account-numbering scheme encodes the account's currency inside the account number itself, and in that scheme the same three digits designate the live national currency — a different registry, on a different object, colliding on the same three characters** [T1]. It is not the currency standard. It is a national account-number grammar of exactly the kind the international account standard defers to when it says the internal structure is defined nationally. **In one registry the string is a withdrawn currency code; in the other it is a live currency marker inside an account identifier. The two registries never coordinated, they mean different things by the same digits, and both are correct within their own scheme.**

One reading of the second collision is refused outright and graded T4. There circulates a pseudo-legal theory holding that because the digits appear in both places, accounts in that jurisdiction secretly denominate a parallel legacy currency alongside the official one, so that every account is a hidden double ledger and the official balances are a fiction. **The source manuscript records that this reading has been rejected by the courts that considered it. This paper does not make it, in any form.** The collision of the digits across two registries is a fact; **the inference that it evidences a concealed parallel accounting system does not follow from that fact**, and stating it would be the precise error — an encoding coincidence dressed as a macroeconomic revelation — that Curzi [2026] identifies as destroying a technical submission on contact. The court decisions are described from the source and are itemised in Appendix B; none is cited.

The defensible finding is narrower, duller, real and computable: a cross-border parsing ambiguity [T2]. A screening or reconciliation process that ingests raw records from more than one jurisdiction, and that scans for the digit string to flag withdrawn-currency exposure, cannot on the string alone tell a genuine withdrawn-code field from an occurrence of the same digits inside an account number where they are a live currency marker. The two are the same three digits in the same record stream; **the difference is which grammar the field is parsed under, and a screen that parses bytes rather than typed fields does not know the grammar.**

The fix is to parse each field under its declared grammar — and it requires nobody to determine, or allege, anybody's intent. That clause is the entire reason the finding is safe to make and the double-ledger reading is not: the parsing fix is intent-agnostic in exactly the way Curzi [2026] insists the whole mechanism must be.

5.8 Results: the parsing ambiguity measured (H3 supported)

A **SYNTHETIC** demonstration, deterministic under a fixed seed [T2]. Two thousand synthetic twenty-digit domestic account numbers, of which twelve hundred carry the digit string in the grammar's currency positions and thirteen carry it elsewhere as an incidental substring; and two thousand synthetic numeric currency fields, of which one hundred and fifty are the genuine withdrawn code. A naive cross-border screen scans every raw record for the substring and flags it as *withdrawn currency present*.

quantity	naive substring screen	typed-field parse
records flagged	1,363	150

quantity	naive substring screen	typed-field parse
genuine withdrawn-code events among them	150	150
parsing false positives	1,213	0
precision on the stated purpose	11.01%	100%
parsing-ambiguity share of the queue	88.99%	0.00%

Almost nine flagged records in ten are not withdrawn-currency exposure at all; they are live account numbers that happen to contain the same three digits, and the screen cannot tell the difference because it is reading bytes instead of typed fields [T2]. **A control that is right one time in nine is not a control; it is an alert generator, and it will be switched off in the second week** for exactly the reason rule 10 gives.

Under the typed parse, the currency field is parsed as a currency code and a withdrawn value resolves against the withdrawn table to a resolution class under rule 17; the account field is parsed under the national grammar and the digits in the currency positions resolve as the live marker they are; and the incidental occurrences are never examined as currency at all, **because the grammar never looks there.** The genuine withdrawn-code balances are isolated where they are visible, non-settleable and awaiting an audited discharge; the live accounts are left alone; and **the coincidence of the digits stops generating noise because nothing is any longer reading one registry's codes under another registry's grammar.**

This is the encoding thesis and its remedy transposed from the character to the code: **the defect is representational ambiguity, and the fix is to make the representation carry its own type, so that the same string in two namespaces stops being one string.** Ashby [1958] is the general statement of why a byte-level screen cannot succeed here: **a regulator must command at least as much variety as the system it regulates**, and a screen with one category — *contains the substring* — cannot separate two categories of referent. The requisite-variety result is invoked for its shape and not as a theorem about screening; Section 9.6 records that.

5.9 The resolution designator, generalised across the namespace

Section 4.4 stated the designator as an accounting rule for withdrawn currency codes. It generalises, because the currency case is only the sharpest instance of a hazard every member shares [T3]:

> A code whose registry binding is withdrawn, lapsed, reassigned or ambiguous MUST NOT be silently resolved to a live referent. It MUST be assigned to an explicit resolution class, carried as visible and non-settleable, and discharged only through an authorised entry that names the registry, the version and the basis of the resolution, and that leaves a permanent audit receipt.

A withdrawn currency goes to a resolution class. **A reassigned country code carried on a legacy record goes to a resolution class until the record is confirmed against the registry version current when it was created**, because the same two letters may now read against a different country. **A lapsed entity identifier resolves by re-verification against source, not by silent acceptance of the last-known reference data.** The generalisation is one rule: **a registry binding that has moved is not a fact to be resolved silently to whatever the code now points at; it is an exception to be surfaced, dated, and discharged by someone with the authority to say what it means now.**

The status is unchanged: a proposal, no adopted standard behind it, and **the parts touching how a balance is presented require auditor acceptance before use.**

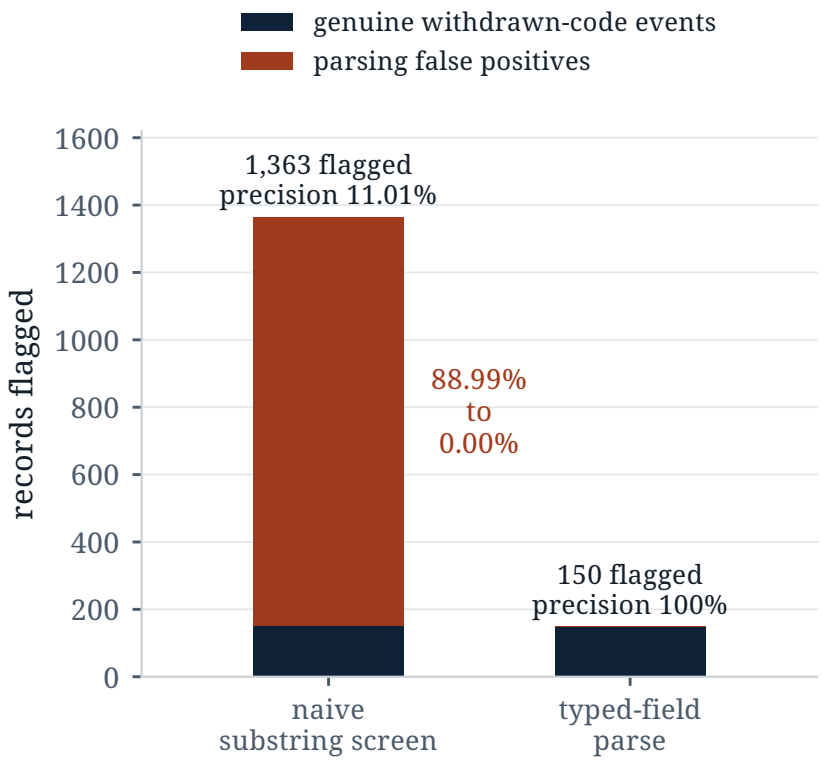

Figure 65.3: **A control right one time in nine: typed-field parsing removes the entire parsing-ambiguity share.** A naive substring screen flags 1,363 records of which 150 are genuine withdrawn-code events and 1,213 are live account numbers containing the same digits, a precision of 11.01%. Parsing each field under the registry that owns it isolates the 150 with zero false positives. SYNTHETIC corpus, fixed seed, stipulated class mix. Built by `figs/src/CCP-065_fig02.py`.

5.10 The hierarchical-namespace pattern, named and deferred

There is a larger pattern here and this section names it precisely enough to place the namespace within it, then hands the full treatment elsewhere rather than pre-empting it.

Several of the world's addressing systems are **hierarchical namespaces**: names built by nested delegation, where an authority allocates a block of the space to a sub-authority, which allocates sub-blocks in turn, so that the structure of the name mirrors the structure of the delegation. The international telephone numbering plan is one; the internet address space is another; nested geographic coding is a third. The namespace examined here shares the pattern, since the country registry delegated into three composed identifiers is nested delegation of exactly that kind.

These systems share a structural pattern and not a common origin. They were designed independently, by different bodies, for different media, and the resemblance is convergence on the same solution to the same problem rather than descent from one system [T1]. **The distinction is not pedantry.** A claim of common origin would invite a reader to expect interoperability, shared governance, or a single point of failure that does not exist; a claim of shared pattern invites only the observation that the *failure modes* rhyme, because a hierarchical namespace has characteristic weaknesses — delegation boundaries where provenance is lost, exhaustion of a level, reassignment of a freed name — wherever it appears. Curzi [2026] works that observation fully and reaches the general result that **every translation boundary rewrites address data and is a provenance-loss point**, structurally the same event as an encoding boundary here; this paper states the pattern and stops.

6. Structured messaging and resolvability

6.1 What the legacy message could not carry

The legacy cross-border payment message was designed under expensive bandwidth and a telex heritage, and its constraints are physical rather than conceptual [T1]. A party is identified in a small number of fixed-length lines. The character set is restricted, close to ASCII, so a name with diacritics is transliterated on the way in and the diacritics are gone. A name longer than the field is truncated, and **the truncation falls at the end, which is frequently where the distinguishing part of a legal name lives** — the form, the branch, the trailing words that separate one similarly named entity from another. There is no dedicated element for an entity identifier, so **the one piece of data that would resolve the party deterministically has nowhere to go** and travels, if at all, buried in a free-text reference line where no parser expects it. There is no coded purpose.

The consequence is that a legacy message under-specifies the parties structurally, not by anyone's choice. The field limits mean that even an originator who wants to declare everything cannot: completeness is not available as an option, and every party the message names is named ambiguously by construction.

6.2 What the structured standard carries instead

The structured standard is a typed syntax over a defined data dictionary, so that a payment is a tree of named, typed elements rather than a set of fixed lines [International Organization for Standardization, 2013]. A party is a structured object: a name element holding the full legal name at length; an organisation-identification element holding the entity identifier; a postal-address element broken into named sub-elements including a country code; and, at payment level, a coded purpose drawn from an external code list. **The namespace of Section 5 is precisely what these fields carry.**

The improvement in party identification is large and real. A structured message can carry the full legal name without truncation; it can carry the entity identifier, which resolves the

party against a registry deterministically rather than by fuzzy name match; it can carry the address as components a machine can compare rather than as lines a machine must parse; and it can carry a coded purpose a monitoring system can reason about instead of a phrase it must interpret. **A screen fed a structured message with an entity identifier is doing deterministic identity resolution against a registry key; a screen fed a legacy message is doing fuzzy string comparison against a truncated, transliterated name — and the difference between those two is the difference between a control that clears and a control that alerts.**

There is a further improvement easy to miss because it looks like tidiness: **the addressability of the individual field.** In the legacy message the party is a block of text, and a monitoring system that wants to reason about the party's country, or its legal form, or the payment's purpose, must extract those facts by parsing — which is to say, by guessing, against a format that varies by originator, market and decade. In the structured message each is a named element carrying a typed value. **The monitoring system does not parse; it reads the element it wants by name and gets a typed value**, so questions like *is this purpose consistent with these parties* become questions about typed fields, and a question about a typed field has an answer a machine can compute.

6.3 The resolution asymmetry

A screening system's job is to dispose of a message: to decide, fast and mostly without a human, whether a payment may proceed or must stop. It does this by trying to resolve each party to a definite identity and checking that identity against designated-persons lists. When it can resolve the party deterministically it clears or stops with confidence, and **either way it disposes.** When it cannot resolve the party — when all it has is a truncated, transliterated name fuzzy-matching several list entries — **it cannot dispose, and a message a machine cannot dispose of goes to a human.**

A rich message is disposable by the machine; a sparse message is not, and the review queue fills with exactly the messages carrying the least data, because carrying the least data is what makes a message unresolvable.

This inverts the intuition that carrying less reveals less. **The sparse message does not present as private; it presents as opaque, and opacity to a monitoring layer is, to that layer, indistinguishable from evasion.** The originator who minimises disclosure produces the message that cannot be cleared and therefore attracts the human attention, the questions, the requests for supporting documentation, the delay, and eventually the exclusion from correspondent relationships that Curzi [2026] measures as a concentration effect: naive correspondent concentration of 0.302400 — 3.306878 effective correspondents — collapsing to 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency. **Being unresolvable is one of the mechanisms by which a structure loses correspondents, and losing correspondents is what collapses the effective count that Curzi [2026] measures.**

Two things must be said about the claim, because it is the one most easily overstated.

First, **the value is in the tail rather than the median.** Full population does not speed up the median payment, which was going to clear anyway. It removes the structure from the tail — the tail of payments that draw scrutiny, that get held, that trigger a request. **A sparse message is a lottery ticket in that tail on every send; a rich message is not in the draw.**

Second, **the posture is available only to a structure with nothing to lose by resolving.** A structure whose elements are true can declare them all at no cost; a structure whose elements are not cannot. **That asymmetry is the whole point, and it is what makes full population a costly signal rather than a policy**: it is expensive for the unclean to fake and cheap for the clean to produce. **It is also, precisely, the disclosure test of Section 3.3 executed on every payment rather than once on a design.**

6.4 Results: rich against sparse, on one payment (H4 supported, part one)

A **SYNTHETIC** demonstration, deterministic under fixed seeds [T2]. A synthetic designated-persons list of fourteen structured entries, each with a legal name, an entity identifier and a country code, **constructed to include near-duplicate names so that a name-only match is genuinely ambiguous** — which is the whole point of using identifiers. A constructed target entity holds its own distinct identifier, is registered at an address carrying diacritics, and — by design — **is not on the list**. It shares a truncatable name stem with two list entries.

Two messages carry the same payment to that target.

	richly typed message	sparse legacy message
entity identifier present	True	False
identifier matches a list entry	False → deterministic clear	—
name as carried	full legal name, diacritics intact	truncated and transliterated
fuzzy name candidates	2 (informational)	2 (decisive)
disposition	**auto-clear on the identifier; identity certain**	**cannot deterministically clear; manual review**

The identifier resolves the target to itself and clears it against the list on one exact-key comparison; the two fuzzy candidates are informational noise the identifier overrides, and no human sees the message. With no identifier and a name fuzzy-matching two list entries, the screen cannot dispose and the message goes to a human — **not because the payment is suspect but because it is unresolvable, which is the only thing the screen actually detected** [T2].

The two messages describe the identical lawful payment to the identical lawful entity. One clears in a machine cycle; the other consumes a review analyst. The difference is entirely the data the message carried.

6.5 Results: the queue at population scale (H4 supported, part two)

A synthetic screening day of one thousand messages, with the migration part-complete so that 62 per cent are richly typed and 38 per cent sparse, a small genuine list-membership rate, and a modelled rate at which a sparse truncated name collides with at least one list stem and so requires review [T2].

quantity	value
synthetic day	1,000 messages (620 rich / 380 sparse)
manual-review alerts from rich messages	6
manual-review alerts from sparse messages	92
total review queue	98
share of the review queue that is sparse	**93.9%**
sparse share of traffic	38.0%

Sparse messages are 38 per cent of the traffic and 93.9 per cent of the review queue: the message format carrying less data generates the overwhelming majority of the scrutiny, and it does so independently of whether any payment is of concern [T2]. The rich messages that do alert are the six genuine list hits — the ones the control is *supposed* to stop — and they alert cleanly, on an identifier, disposable with confidence. **The sparse queue is 92 messages of which almost all are lawful payments that could not be resolved.**

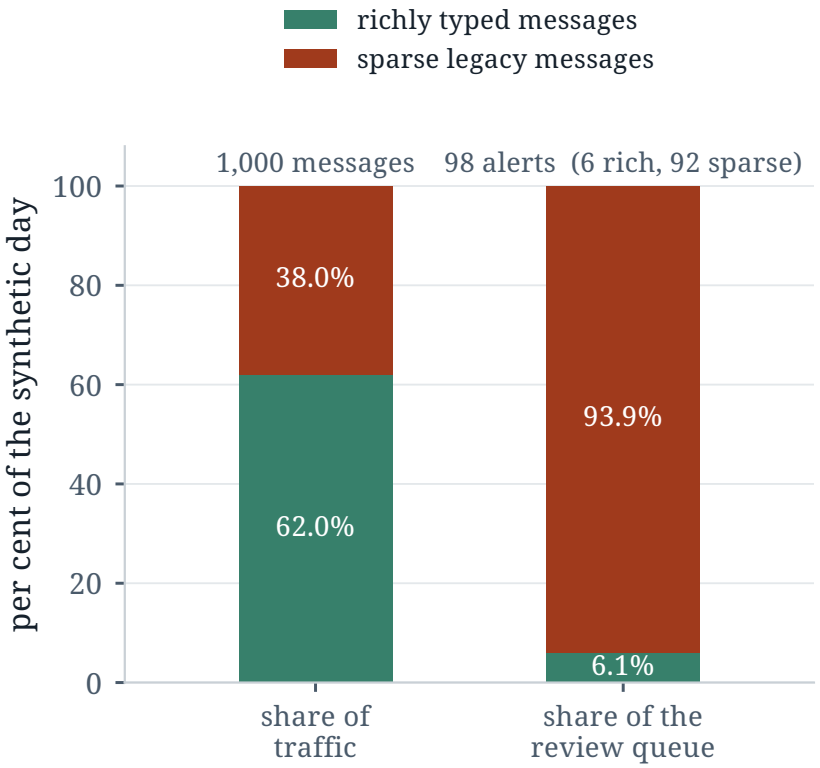

Figure 65.4: **The message format that carries less data generates the overwhelming majority of the scrutiny.** A synthetic day of 1,000 messages, 620 richly typed and 380 sparse; 6 review alerts from the rich population and 92 from the sparse one. Sparse messages are 38.0% of traffic and 93.9% of the queue. Stipulated rates, not a measurement of any production network. Built by `figs/src/CCP-065_fig03.py`.

The numbers are a property of the stipulated rates and are a demonstration of the mechanism rather than an estimate of any real network's queue. Section 9.10 records an arithmetic discrepancy found in the source's own statement of those rates and prints it rather than harmonising it.

The queue is the right object to reason about, and the reason is a standard one. **A review function is a service system with finite capacity, and its waiting time rises without bound as utilisation approaches one** [Kingman, 1962, Hopp and Spearman, 2011]; Little [1961] fixes the relation between the queue length, the arrival rate and the time in system. **Message richness is an arrival-rate parameter on the review queue**, and reducing it is therefore a capacity decision rather than a compliance gesture. The queueing results are invoked for their shape and not as a model of any screening function; Section 9.6 records that.

6.6 Results: the substitution inside the structured field (H5 supported)

A section that sold the structured standard as the end of ambiguity would repeat, one standard higher, the error Curzi [2026] forbids.

The structured message is typed text. The name element holding the full legal name is a text field, and a text field in a structured document is a text field: **it accepts the whole character repertoire, and every member of the substitution class enters it unchanged** [T1]. A homoglyph sits in a name element as comfortably as it sat in a delimited file. **The structured message has a defined place for the name and no defined canonical form for it, and the two are not the same thing.** Structure tells a consumer which field holds the name; **it does not tell the consumer that two names rendering identically are the same name**, and that second question is the whole

subject of the integrity layer.

Measured on the target's own name element [T2]:

quantity	result
clean fragment, byte digest	`c413622fa3bea888`
homoglyph twin, byte digest	`7307655b3eee8d17`
do the two render identically?	yes
canon(clean) = canon(twin)?	**True** — the fold collapses it
byte digests differ?	**True** — the witness records it

Inside the richest, most structured, most authoritative field the standard defines, a homoglyph twin is byte-distinct and canonically identical — the exact silent-duplicate condition Curzi [2026] measures at 99 per cent — and the structured message does nothing about it while the canonical form folds it and the byte-hash witnesses it [T2].

This is not a flaw in the standard; it is the boundary of what a syntax can do. A syntax defines the shape of the data. Canonicalisation defines the identity of the values. **The structured message is where the integrity layer stops being a proposal about a delimited file and becomes a control on the payment rail** — the canonical form is what the screen matches, the byte-hash is the witness that the field was not silently substituted, and the two together are the detector of Section 4.2.

6.7 The remedy, specified for the message

Carried from Section 4.5 and scoped to the structured message [T3].

1. An implementation ingesting structured messages MUST canonicalise the critical machine fields — entity identifier, currency code, account and institution identifiers — at the ingestion boundary, **before** screening, reconciliation or matching.
2. It MUST match free-text name and address elements on their canonical form while preserving the raw form unaltered for display and record, governed by restriction levels per market, and MUST NOT fold a free-text name for storage.
3. It MUST store a digest over the raw octets of each ingested element as received, and MUST flag identical canonical form with differing byte-hash, with a named owner and escalation path defined before deployment.
4. Screening MUST prefer the deterministic identifier key over the fuzzy name match where the identifier is present, and **MUST record when it fell back to name matching because the identifier was absent** — because that fallback is the unresolvability event and it should be visible.
5. A withdrawn or ambiguous code carried in any message field MUST be handled under the resolution designator of Section 5.9 and MUST NOT be silently resolved to a live referent.

Rules touching internal controls need no external adoption and may be implemented on the institution's own authority; none of them changes a disclosed number. The whole remains a proposal with no adopted standard status.

7. The ledger architecture, with its audited negative results

Everything in this section concerns the author's own systems and the author's own adversarial audit. The conflict of interest is declared in the Declarations. The measurements were recomputed for this paper on a harness rebuilt from the source descriptions; **the original code was not obtained and was not rerun**, and every finding describes the implementation *as audited*.

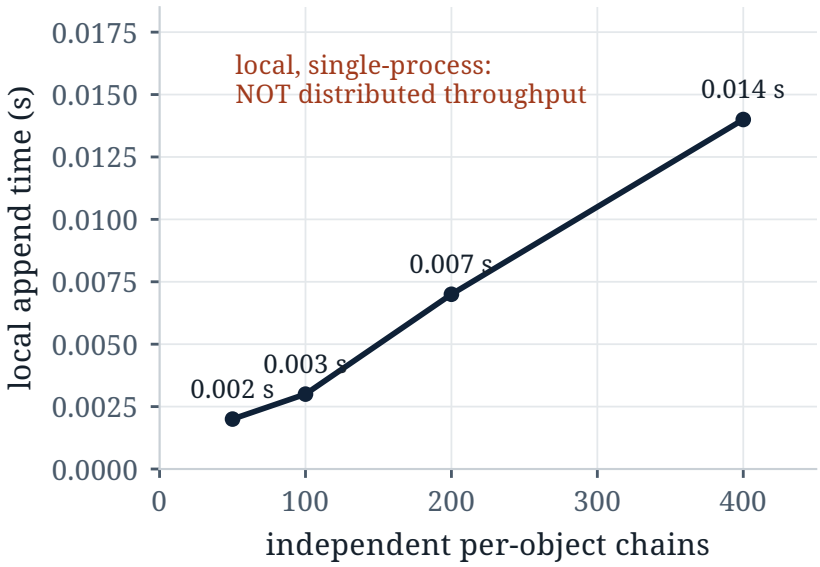

Figure 65.5: **Local append cost is linear in the number of independent per-object chains — and it is a local, single-process measurement, not distributed throughput.** 50, 100, 200 and 400 chains at 0.002, 0.003, 0.007 and 0.014 seconds, measured on one machine in one process on a harness rebuilt from the source description. Absolute times are machine-specific; the shape is the finding. Built by `figs/src/CCP-065_fig04.py`.

7.1 The object-as-ledger factoring, measured (H6 supported)

Most ledgers are one shared chain whose global order is agreed by a consensus protocol. An alternative factors the ledger into per-object chains, so that independent objects can be written without a global write-lock, **at the cost of needing a separate mechanism to order conflicting updates.** The substrate examined here takes the per-object idea down to the individual token: **every token is its own hash chain, seeded by a genesis root, and tokens link to compatible neighbours to form a directed acyclic graph** [T1].

check	construction	result
V1 per-object chain integrity	200 tokens × 30 transactions	200 / 200 verify
V2 tamper-evidence	one block mutated in each chain	200 / 200 detected
V3 cross-object link consistency	28 links formed	28 / 28 recorded in both ledgers
V4 local append cost	50 / 100 / 200 / 400 chains	0.002 / 0.003 / 0.007 / 0.014 s

V2 is the property worth having: because each block's hash covers its transaction and the chain links by predecessor hash, any silent edit breaks verification, every time, with no exceptions in two hundred trials. **V4 is linear and lock-free**, which is the write-parallelism the factoring exists to provide — **and it must be read for exactly what it is. These are local append times on one machine in one process. They are not distributed transaction throughput and no throughput claim is made from them.** The absolute figures are machine-specific and are printed only to show the shape.

7.2 Four findings that bound the substrate

A1 — the structure provides no consensus and does not prevent double-spending [T4, refuted]. A token is taken, a transfer recorded, and the chain then extended into two forks, the second

transferring the same balance to a different party. Reproduced here: **both forks verify as internally valid hash chains, and nothing in the object-as-ledger structure imposes a total order or rejects the conflict. The same token is spent twice and the data structure raises no objection.** The folk claim that per-object chains need no consensus is false: **they remove the global write-lock, and conflict ordering still requires a consensus or voting layer.** Agreement among mutually distrustful parties is the Byzantine agreement problem [Lamport et al., 1982], whose bound on genuinely independent parties is the reason an ordering layer is not optional; Fischer et al. [1985] and Gilbert and Lynch [2002] fix what such a layer can and cannot achieve, and Douceur [2002] fixes why the count of parties must itself be audited.

A2 — the block hash under-binds [T2]. In the implementation as audited, a block's hash is computed over the transaction alone and does not commit to the chain identifier, the predecessor hash or the index. Tamper-evidence still works, because the predecessor link breaks when an earlier transaction is edited — **but the hash does not bind a block to its position, so blocks can be reordered and identical transactions collide.** Reproduced here: a two-block chain with its blocks transposed and its predecessor links repaired **verifies successfully under the shipped hash and is rejected under the fix.** The fix is to compute the digest over the chain identifier, the predecessor hash, the index, the timestamp and the transaction together, **binding each block to its chain, its position, its time and its content, and eliminating reordering, cross-chain replay and identical-transaction collision in one change.**

A3 — the numerological layer carries no security [T4]. Assessed in Section 3.4 and excluded there.

A4 — no Sybil resistance [T4]. Tokens and nodes are created without any cost-to-identity, so influence over the topology or over any future vote is forgeable by mass identity creation [Douceur, 2002]. The fix is a cost-to-identity or verified-identity layer.

The verdict, stated as the source states it: the substrate delivers tamper-evidence and local write-parallelism; it does not deliver consensus, total order, double-spend prevention or Sybil resistance. It is a sound substrate and not a complete distributed ledger, and it becomes one only when paired with an ordering layer and an identity layer.

7.3 The capability layer, and four findings that were fixed

The identity and authorisation layer names an entity by a content-derived identifier rendered as a locator, and authorises by capability contract rather than by identity plus access-control list. Access is negotiated by a four-message challenge–response exchange with per-session derived keys and keyed message-authentication tags. **The literature this places it in is named in Appendix B and is not cited, because none of the primary sources is in the bibliography;** the protection principles it rests on are Saltzer and Schroeder [1975].

Reproduced for this paper [T2]: content addressing over 20,000 distinct inputs yields 20,000 distinct identifiers with zero collisions — **which is what a correct hash-naming scheme does, and is worth confirming rather than assuming.**

Then the audit, which found four concrete breaks in the reference implementation and which the author published in full.

R1 — the proof signature was never verified [T4, fixed]. The verifier checked nonce presence, a self-computed digest, holder authorisation and compliance flags, **and never inspected the signature field at all.** A message carrying an all-zero signature was accepted. **Origin authentication failed completely**: any party able to name an authorised holder was admitted regardless of whether they possessed the material behind the identifier.

R2 — the self-verification digest was computed inconsistently [T4, fixed]. The prover computed it keyed, over one message; the verifier recomputed it unkeyed, over a different message. The two never agreed, so the check either rejected legitimate exchanges or was bypassed. **A digest a verifier can recompute without a secret authenticates nothing.**

R3 — broken hash algorithms were offered [T4, fixed]. Two algorithms known to be broken for collision resistance were available for content addressing. **In an identity system a**

collision means two contents sharing one identity, which is catastrophic rather than merely undesirable.

R4 — the freshness root left a replay surface [T3, fixed]. Nonces were tracked per request and freshness rested on an epoch root of unspecified origin. **If that root is not verifiable, monotonic and bias-resistant, a stale epoch can be pinned and a captured exchange replayed.**

The fixes were implemented in a hardened module and **re-validated rather than merely proposed**: one keyed transcript tag computed identically by both parties and verified in constant time, weak hashes refused at key creation with a hard error, a verifiable epoch root with a nonce time-to-live and a persisted seen-nonce set, and keys derived by a standard derivation function. **The re-validation confirms that a legitimate handshake is accepted while a forged signature, a tampered transcript, a weak hash and a replayed nonce are each rejected, and the protocol's shape is unchanged — only its verification is made sound.** That is what an adversarial review is for: contrary evidence used to harden a design rather than to discard it.

On post-quantum posture the source is equally direct, and its directness includes a refutation of the author's own earlier marketing. The hash and tag core is post-quantum-resistant at digests of 256 bits or more, because Shor [1997] breaks the number-theoretic public-key constructions and this core uses none of them, while Grover [1996] gives only a quadratic speedup and halves effective preimage security. **The signature the protocol needs and did not have must be a standardised post-quantum scheme.** The relevant standards are described in the source as published in 2024; **this paper names none of them by number and Appendix B records the verification required. The claim in the author's earlier materials that the relevant cryptography is "ready for immediate implementation" and "unbreakable" is refuted, in the author's own paper, and is graded T4.**

7.4 A backing taxonomy is not a valuation method

The source corpus specifies a backing taxonomy of nine forms of capital — financial, material, living, intellectual, experiential, social, cultural, spiritual or ethical, and natural — with the declared use that an instrument is backed not by a single reserve asset but by a portfolio drawn across the taxonomy.

Two things must be said and they pull in opposite directions.

The taxonomy addresses a real problem, and the problem is the completeness gap Curzi [2026] measures at 36.150000 per cent structurally unrepresentable on a constructed vector. Double entry represents only what has been monetised, and a great deal of what an entity owns is invisible to it not because it lacks value but because no transaction ever priced it. **A structured taxonomy of forms of capital is a coherent way to name what the ledger cannot see.**

And a taxonomy is not a valuation method. Naming nine forms of capital does not tell anyone what any of them is worth, and the valuation problem is the entire difficulty. Some forms have a defensible and contested valuation methodology; at least one has **no generally accepted measurement basis whatsoever**, and **a coverage ratio computed over a portfolio in which one component has no measurement basis is a coverage ratio computed over an unknown.** This paper records the taxonomy as declared [T3] and states plainly that **the measurement basis for the non-financial forms is not specified in the source corpus, is not specified here, and would have to be specified, audited and accepted before any coverage ratio computed across them could mean anything** [T4 as to any claim that it has been].

This is the corpus's scalar-reduction habit arriving in an engineering artefact, and the limitation is inherited from Curzi [2026] rather than restated: where a source describes a phenomenon by several jointly varying features, the framework replaces it with one number and does arithmetic on it. **Nine forms reduced to nine shares and then to one coverage ratio is exactly that move.** Curzi [2026t] is the corpus's own precedent for what to do about it: a quantity whose components are not instrumented on a common ratio scale with a shared true zero has its magnitude withdrawn as a measured quantity, and the same verdict applies here.

7.5 The third entry, in two formulations, not adjudicated

Conventional bookkeeping runs on two entries. The recording discipline proposed here adds a third.

The source corpus defines the third entry in one place as **proof** — an immutable cryptographic witness addressed by a content identifier — which places it in the lineage Curzi [2026] sets out. A later document in the same corpus, specifying a physical instrument, refines the arrangement: the third rail becomes **equity**, recorded atomically and continuously alongside debit and credit rather than derived as a periodic residual, with proof retained as the integrity witness securing the equity rail. The stated rationale is that equity in conventional accounting is a computed leftover, disclosed periodically, which is what permits liabilities to expand while ownership is reckoned after the fact.

This paper records both formulations, notes that they are not the same design, and does not adjudicate between them [T3]. What it will state is what the third entry can and cannot do. **A cryptographic witness proves that a record existed in a given form at a given point in a chain. It does not prove that the record was true, that the asset existed, that the valuation was defensible, or that the counterparty agreed** — and a third entry presented as establishing any of those has been oversold in exactly the way this paper's own discipline forbids. **Tamper-evidence is a real and valuable property. It is not verification.**

7.6 How the layers compose

The composition is the argument, because each layer supplies exactly what the one below it lacks.

Canonicalisation makes two records comparable. Without it, every layer above computes over an identifier space in which one thing can appear as many — **and a content-addressed system inherits the defect in its worst form, because if the identifier *is* the digest of the content, then a homoglyph substitution does not produce a suspicious record, it produces a different entity, with a different address, indistinguishable from a legitimate one. Content addressing does not fix confusable identifiers; it launders them, by converting a visual ambiguity into two cryptographically impeccable and permanently distinct names.** That is the strongest argument for putting canonicalisation underneath everything rather than beside it, and it is the property Curzi [2026] builds on: one byte's difference in a settlement object yields a different identifier, while the canonical form folds a homoglyph account string onto the same skeleton as the clean one.

Per-object hash chains then make each object's history tamper-evident. Content-addressed capabilities supply the identity and authorisation the chains lack, addressing A4. **An ordering layer supplies the conflict resolution that addresses A1, and is not supplied by anything in this paper.** And the recording discipline of Section 7.5 makes the stack an accounting system rather than a database.

8. Discussion

8.1 What follows

An integrity layer at the comparison boundary is cheap, testable, and requires nobody's permission. Rules 1 to 15 are a library, a set of boundary changes and a test suite. They are internal controls, they change no disclosed number, and an institution may implement them on its own authority. **Their whole cost is a library call at each ingestion boundary and the discipline to define the flag owner before the first flag is raised.**

The identity resolution underneath a concentration measurement is not free of the same defect. The effective count of Curzi [2026] — the reciprocal of the Herfindahl index, which is the Hill number of order two [Hill, 1973, Jost, 2006, Adelman, 1969] and not the corpus's affine

construction — is a function over a partition of exposures grouped by counterparty, jurisdiction or instrument. **Count one counterparty as two, or read a legacy country code against the country it now names rather than the one it named, and the measured concentration moves without anything real changing — and it moves in the reassuring direction.** Curzi [2026] traces that path from the counterparty master; Section 5.3 adds the securities identifier as a second path into the same instrument, since **one economic instrument carrying identifiers from two agencies is a double-count and two venue codes resolving to one instrument is a merge, and either error moves a single-name limit.** Goodhart [1975] and Campbell [1979] are the standing warning that an index adopted as a target stops measuring what it stood for; this is the same warning with a mechanical rather than a behavioural cause.

A lawful structure has a direct operational interest in being resolvable. Section 6 is not an argument that disclosure is virtuous. It is an argument that the network now penalises unresolvability, that the penalty falls in the tail rather than the median, and that **the posture of full population is available only to a structure with nothing to lose by resolving.** The corollary matters as much: **a structure that populates fields it cannot truthfully fill has re-entered the concealment game from the other side, and the invented fields are what will not survive verification.**

Two conversations decide whether any of this survives contact with a real environment, and both are short. A correspondent's financial-crime function asks one question about screening, and it is not whether there is a policy: *demonstrate that a name on the list, presented with a single substituted character, is matched by your screen.* Under the specification the answer is a test case and a log entry. Without it the answer is a discussion about supplier configuration that neither party can conclude. An auditor asks a different question, and it is about the flag queue rather than the control: *who reviewed the flags, on what basis, and what was the disposition?* **A control producing exceptions nobody dispositions is a finding, and it is a worse finding than not having the control, because the exceptions are evidence that something was detected and ignored.** That is why rule 10 is normative rather than advisory.

Neither conversation is about the architecture of Section 7. They are about two rules out of eighteen, and **that proportion is a reasonable guide to where the value in this paper actually sits.**

8.2 What does not follow

Necessary, not sufficient, and it holds for the whole stack. Canonicalisation defeats encoding-level evasion and does nothing about semantic fraud. Typed parsing defeats code-level ambiguity and does nothing about a correctly coded false assertion. Per-object hash chains defeat silent edits and do nothing about a correctly signed lie. Content-addressed capabilities defeat impersonation and do nothing about a properly authorised party acting in bad faith. Full message population defeats the identity gate and does nothing past it. **A tamper-evident ledger containing a false entry is a tamper-evident false entry, and this architecture will preserve it faithfully forever** [T1/T4].

Every number in this paper measures a representational or resolution property. None measures truthfulness, and a claim otherwise would fail on contact for exactly the reason Curzi [2026] gives in its audit of nine documented failures, eight of which no encoding control would have touched.

Collected in one place, because scattering them is how a specification becomes an advertisement, the architecture provides: no consensus and no total order; no double-spend prevention; no Sybil resistance; **no distributed throughput claim of any kind** — the append measurements are local and single-process; no valuation methodology for the non-financial forms of capital; no adopted standard status for the canonical form and none for the resolution designator; no auditor acceptance for any accounting treatment described; and no legal force anywhere. **Each is fixable in principle and several by composition with well-understood components. None is fixed here.**

Over-canonicalisation is the strongest technical objection, restated because rule 11 exists

to prevent it and rules can be ignored. Aggressive folding erases legitimate internationalised data: genuine non-Latin names, multilingual memos, diacritics that carry meaning. **An implementation that applies rule 1 to a name field has not partially complied; it has failed.** The mirror error appears inside the namespace itself: **the reference records the registries carry hold legal names in their own scripts for good reason, and a control that folds them to compare them has mutilated the registry's own authoritative data.** The scoping rule is not suspended because the data now arrives inside an international standard.

The identifier-collapse trade is real and is not priced here. Folding confusables collapses the identifier space, and **collapsing an identifier space creates collisions**: two entities whose names genuinely differ only by characters folding to the same skeleton become, after canonicalisation, the same name. For critical machine fields with narrow permitted character sets this is a non-issue by construction. **For a name estate it is a real trade** — canonical matching raises the true-positive rate against substituted probes to 100 per cent, and it also raises the false-positive rate against a large list by an amount that has not been measured here and is not zero. **The zero-false-positive figure Curzi [2026] reports is measured against clean ASCII critical fields and does not transfer to a name estate; anyone quoting it as a general property has quoted it wrongly.**

Three further misreadings are worth naming. *Richness read as safety*: a rich message resolves the party and does not verify the party's conduct, the transaction's reality or the counterparty's honesty. *A coded purpose read as a verified fact*: the code makes monitoring tractable, not true, and a monitoring system reasoning over purpose codes as though they were confirmed has made the same category error as one clearing a counterparty because the check digit validates. *Over-population as its own tell*: if full population becomes a recognised posture, a message that is **too** perfectly populated can itself become a pattern, in the way that unnaturally clean is its own kind of anomaly — and **the only defence is that the richness is true.**

And a structure controls the messages it originates, not the messages its counterparties send. A counterparty on an older system sends sparse messages and the structure inherits the scrutiny on the inbound side. That is not a reason to send sparse messages defensively; **it is a reason to prefer counterparties whose own messaging is current, because a bridge structure's resolvability is only as good as the weakest system that sends into it.**

8.3 The adoption path, and why it is longer than the engineering

The engineering here is small and the adoption path for the parts that touch the accounts is measured in years, and pretending otherwise is the fastest way to lose a technical audience.

Rules 1 to 15 need no external adoption at all, as Section 8.1 says. **Rules 16 to 18 are different in kind because they change how a balance is presented.** Excluding a balance from a live aggregate is a presentation decision; discharging it through a resolution entry is a derecognition decision. **Both sit inside an applicable financial reporting framework and neither is the preparer's to make unilaterally.** The sequence that works is: identify the exposure; obtain a view from the auditor on the presentation under the existing framework; implement whatever that view permits; and only then, with a documented case and a real example, approach a standard-setter about whether the general problem warrants a general answer. **The sequence that fails is to specify the designator first and seek acceptance afterwards, which is the sequence a technically minded author naturally reaches for.** A group that adopts it unilaterally and discloses it has disclosed a departure from established practice: **that is an ordering problem rather than a concealment one, and getting the order wrong turns a good control into a qualified opinion.**

The architecture of Section 7 has a third and longer path again. The missing ordering layer is a composition problem with known solutions; the missing identity layer is addressed by the capability layer, whose audit findings are fixed and re-validated **but whose hardened build has not been deployed at scale or reviewed by anyone outside the corpus that produced it.** Neither component has an independent implementation, an interoperability profile, or

a conformance suite maintained by anyone other than its author. **Those are the ordinary prerequisites for anything to become infrastructure, and the honest position is that none is met.**

The alternative is the failure mode this paper's own discipline exists to prevent. A submission presenting a validated substrate, an audited protocol, a taxonomy, a recording discipline and a naming rationale as though they were one finished system invites a reviewer to test the weakest and generalise. **A submission that grades each separately, prints the negative results, and states which parts are weeks away and which are years, invites the reviewer to evaluate the parts that are ready.**

8.4 What would falsify this paper

Five things, none tested here.

If the flag stream from rule 9 were dominated so completely by historical normalisation artefacts that no clean baseline could be established, the detector is a good idea that does not survive real data. The mitigation is a one-off backlog burn-down before alerting on new occurrences, and a deployment that skips it generates an unreadable queue on day one and switches the control off in the second week.

If canonical matching against a real, large designated-persons list produced a materially elevated false-positive rate, the screening argument becomes a cost–benefit question rather than a free improvement.

If a standards body or an audit firm concluded that the resolution designator is inconsistent with existing recognition and derecognition requirements, rules 16 to 18 fail and the withdrawn-code problem needs a different answer inside existing rules.

If an ordering layer capable of resolving the A1 conflicts at the required scale cost more in latency or complexity than the write-parallelism the factoring buys, the object-as-ledger choice is an optimisation that does not pay for itself. That is an empirical question about a specific workload with different answers for different workloads.

And if a survey of production critical machine fields found that out-of-repertoire code points essentially never occur in them, the operational case collapses to a theoretical vulnerability with no realised exposure. **That survey has not been done, here or — so far as this paper is aware — anywhere.**

8.5 Bounds and parallels carried from the corpus

Bounds. Curzi [2026] declines the inflated reading of its own borrowed physics and requires that a user be able to distinguish a theorem, an ordinary observer effect and the framework's own conjecture in three separate sentences on demand. **Section 9.6 discharges that requirement for every borrowing here**, and Section 3.4 discharges it for the two exclusions. Curzi [2026t] demotes the corpus's own moment equation at the scale-type gate, and Section 7.4 applies the identical verdict to the nine-form taxonomy for the identical reason.

Parallels, and each is structural rather than decorative. Curzi [2026] states the contraction theorem exactly — a contraction of modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with the distance shrinking by at least q each pass — and **the parallel is the idempotence requirement of rule 3**: an operation applied repeatedly must reach and hold a fixed point, or it cannot be applied at more than one boundary. Curzi [2026]'s three-drawer honesty classification — four items of established mathematics, seven of established psychology and exactly three declared postulates — is the general form of the tier scheme of Section 3.2, and Curzi [2026]'s audit distribution over thirteen entries, with seven mapping, two splitting, one rendering and three rejected, is the same discipline applied to a different inventory: **an audit that rejects nothing has not audited.**

Curzi [2026w] supplies the evidential rule this paper leans on hardest: **two sources agreeing does not double the evidence when only one of them is evidence** — the reason a docu-

mented mechanism and a folk inference drawn from the same coincidence are kept apart in Section 5.7.

Three results in the corpus's biological arm are the same failure in a different medium. Curzi [2026x] shows that a field is intrinsically broadcast — 3.65e6 cells share one voxel at 1 MHz, so exclusive per-cell addressing would need 23.93 days at 70.65 bit/s, a per-cell rate of 1.93e-5 bit/s — which is **an addressing scheme in which many referents share one name**, the exact inverse of Section 5's problem and the same defect. Curzi [2026y] states the constraint that no addressing operation, at any signal strength or modality, can cause a receiver to express content its repertoire does not already contain — which is **the ceiling this paper's Section 8.2 states in its own terms: a representation control cannot produce information the record never carried.** And Curzi [2026] states the open problem formally: no established mechanism produces a response depending on a symbol string as an **order**, as distinct from permutation-invariant functionals of the waveform. **That is finding A2 in another medium** — a hash that does not commit to position cannot distinguish an ordering from a permutation of it, which is precisely what the reordering demonstration shows.

Two further parallels bear on the paper's honesty apparatus. Curzi [2026ad] reports a preregistration whose measured false-positive rate is 9.5 per cent against a nominal 5, and restores the nominal level by requiring cross-individual replication at 4 of 12; **the parallel is exact — a control's measured false-positive rate is the number that matters, and the 11.01 per cent precision of Section 5.8 is the same disclosure made about a screen instead of a test.** Curzi [2026] fixes a rate penalty at exactly 8 symbols per second from the ratio of two stipulated intervals; **the parallel is that an exact ratio of stipulated quantities is exact and carries no empirical weight**, which is the status of every percentage in this paper.

9. Verification and rigour audit

Each result is decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and each chain names what it consumes. **If dropping a postulate leaves the result standing, it is not listed.**

9.1 Dimensional audit

symbol	quantity	dimension	unit	status
corpus size	records, messages, tokens, inputs	[#]	counts	stipulated (synthetic)
flagged, genuine	subsets of a corpus	[#]	counts	derived by enumeration
precision	genuine ÷ flagged	[1]	dimensionless fraction	derived; two counts of the same kind
ambiguity share	parsing false positives ÷ flagged	[1]	dimensionless fraction	derived
false-break rate	spurious breaks ÷ compared pairs	[1]	dimensionless fraction	derived
queue share	alerts of one class ÷ all alerts	[1]	dimensionless fraction	derived

symbol	quantity	dimension	unit	status
manipulation rate	share of corpus entries substituted	$[1]$	dimensionless fraction	stipulated
collision rate	share of sparse names colliding with a list stem	$[1]$	per message	stipulated
balance	ledger amount	$[1]$	**stipulated units, no currency attached**	stipulated
inflation	$(10{,}000 - 8{,}000)/8{,}000$	$[1]$	dimensionless fraction	derived from the stipulated ratio
digest	SHA-256 output	$[1]$	256 bits	defined
append cost	wall-clock time for a batch of local appends	$[T]$	seconds	**measured, machine-specific**
chains	independent per-object ledgers	$[\#]$	counts	stipulated
tier T1–T4	evidential label	—	**ordinal label, no unit**	this paper's own convention

Does it balance? Every headline figure in this paper is a ratio of two counts of the same kind of thing, and is therefore dimensionless and well formed: 150 genuine events over 1,363 flags, 1,213 parsing false positives over the same 1,363, 92 sparse alerts over 98 total alerts, 495 collapses over 495 manipulations. **No figure in this paper adds quantities of different kinds and none divides a count by a time.**

Two entries do not carry an operational unit and the audit says so rather than assigning one. The ledger amounts of Section 4.4 are in **stipulated units with no currency attached**; the 25.0 per cent is a property of the $8{,}000/2{,}000$ ratio and would be a different number under any other stipulation, which Section 4.7 already states. And **the nine-form backing taxonomy of Section 7.4 has no measurement basis at all for its non-financial forms**, so a coverage ratio computed across it is a fraction whose numerator has no defined unit. That is not a precision problem; it is the absence of a quantity.

The only dimensional quantity in the paper is the append time, and it is a wall-clock measurement on one machine in one process. Section 10 records that it carries no uncertainty and no repetition.

9.2 Significant figures and epistemic status

- 100.0%**,** 0.0% **and** 0.00% **are exact, not rounded small numbers.** They are properties of exhaustive enumerations over a stipulated corpus — 495 of 495, 500 of 500, 200 of 200, 28 of 28, 20,000 distinct identifiers from 20,000 distinct inputs — and no estimate is involved in any of them.
- 11.01% **and** 88.99% **are exact to the digits shown**, being $150/1363 = 0.110051\ldots$ and $1213/1363 = 0.889949\ldots$ on a stipulated corpus. They are **not** estimates of any screen's precision and carry no interval, because there is nothing to estimate.
- 93.9% **is** $92/98 = 0.938776\ldots$, exact for the reported alert counts and stipulated to one decimal place. Section 9.10 records that those counts are not reproducible from the source's own stated rates.
- 25.0% **is exact by stipulation** and is a property of one chosen ratio, as Section 4.7 states in place.

- **The append times are the weakest numbers in the paper.** 0.002, 0.003, 0.007 and 0.014 seconds are single-run wall-clock timings on one machine, quoted to three decimal places, with **no repetition, no dispersion, no confidence interval and no hardware specification.** Three decimal places on a single timing is more precision than the measurement supports; **only the linearity is a finding, and the absolute figures are printed to show the shape and for no other purpose.**

9.3 Limits and boundary behaviour

The false-break rate, over the whole manipulation range. Under byte equality the false-break rate equals the manipulation rate m exactly, for every m in $[0, 1]$; under canonical comparison it is 0 for every m. **The 40-to-0 reading is one point on a flat line and the degenerate endpoints are both examined**: at $m = 0$ nothing is manipulated and both regimes agree, and at $m = 1$ byte equality breaks every pair while the canonical form breaks none.

The precision figure, at its boundaries, and this is where the result is weakest. The naive screen's precision is $150/(150 + k)$ where k is the count of account-number records containing the digit string. At the stipulated $k = 1213$ it is 11.01 per cent; **at $k = 13$ — the incidental occurrences alone, with the national grammar's currency positions removed — it is 92.02 per cent; and at $k = 0$ it is 100 per cent and the finding vanishes entirely.** The 11.01 per cent is therefore a property of the stipulated corpus mix and **is not a claim about any real record stream**; what is invariant across the whole range is that the typed parse gives 100 per cent precision at every k, because the grammar never looks where the incidental digits are.

The queue inversion, as the migration completes. With the reported alert rates — a rich rate of $6/620 = 0.9677$ per cent and a sparse rate of $92/380 = 24.2105$ per cent — the sparse share of the queue falls monotonically to zero as the rich share $\rho \to 1$, and rises to 100 per cent as $\rho \to 0$. **The boundary worth printing is where the two populations contribute equally: that occurs at $\rho = 0.9616$, so sparse messages are still half the review queue when they are only 3.84 per cent of traffic.** The inversion is not a feature of a half-finished migration; it deepens as the migration completes.

The append measurement has no examined upper boundary. Linearity is measured at 50, 100, 200 and 400 chains and is asserted for no larger figure. Nothing here licenses extrapolation, and Section 7.1 makes no throughput claim of any kind.

9.4 Invariance

Idempotence is the invariance the specification actually requires, and rule 3 makes it normative: $\mathrm{canon}(\mathrm{canon}(x)) = \mathrm{canon}(x)$ for all 500 corpus values. The transformation group is repeated application of the operator, and the invariant is the canonical form. **Its failure mode is named and is not hypothetical:** a confusables-data or character-standard version change between two boundary applications breaks the invariance, which is why rule 6 makes both versions change-controlled configuration items.

The pair $(\mathrm{canon}, \mathrm{hash}_{\mathrm{bytes}})$ is invariant and variant by design, and that is the whole detector. The canonical form is invariant under every member of the substitution class; the byte digest is invariant under none of it. **A control storing only one of the two has destroyed either the matching or the evidence**, and Section 4.2 shows which.

What is not invariant, stated plainly. The precision figure is not invariant under the corpus mix (§9.3). The queue share is not invariant under the migration fraction (§9.3). The append times are not invariant under the machine. **None of the three is offered as a constant of anything**, and the invariant findings are the sign and the mechanism in each case: the naive screen's precision is below 100 per cent whenever the collision occurs at all, the queue share exceeds the traffic share whenever the sparse alert rate exceeds the rich one, and the append cost is linear rather than quadratic in the chain count.

9.5 Measurement-theoretic status

The tier scheme is ordinal and no arithmetic is performed on it. T1 through T4 are this paper's own labelling convention with no external standing. They are not averaged, not summed, not counted into a score, and an ordinal scale licenses none of those operations [Stevens, 1946, Michell, 1997]. The scheme's only function is to keep four kinds of statement apart on the page.

A code is a dated assertion and not a fact, and this is a validity claim rather than an arithmetic one. The entity identifier's renewal cycle (§5.5) is the standard's own admission of the point: the code is permanent and the assertion behind it perishes. A check digit has genuine validity for one construct — transcription error in the string — and none whatever for a different construct, the existence and ownership of the referent, and treating the first as evidence for the second is the convergent-versus-discriminant confusion in its plainest form [Campbell and Fiske, 1959, Cronbach and Meehl, 1955]. **A control that clears a counterparty because the check digit validates has measured the string and reported on the world.**

The nine-form backing taxonomy fails the scale-type gate outright. Its non-financial forms are not instrumented on any common scale, let alone a ratio scale with a shared true zero, so the magnitude of any coverage ratio computed across them is withdrawn as a measured quantity — Curzi [2026t] reaches exactly that verdict on the corpus's own moment equation, and §7.4 applies it here. The formal remedy is conjoint measurement or a Rasch demonstration [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960], and **none was run.** Michell's objection — that a quantitative structure is assumed rather than tested — stands unanswered [Michell, 1997, 1999], and this is the corpus's scalar-reduction habit arriving in an engineering artefact, conceded where the ladder is built [Curzi, 2026] rather than re-argued here.

Which effective count. Where this paper refers to an effective count it means $1/\mathrm{HHI}$, the Hill number of order two [Hill, 1973, Jost, 2006, Adelman, 1969], as Curzi [2026] and Curzi [2026] use it. **The corpus's affine construction $1 + (N-1)u$ is not a Hill number of any order and is not used anywhere in this paper.**

No distributional or scaling claim is made anywhere in this paper, so the goodness-of-fit and likelihood-ratio procedure that a heavy-tail or power-law claim would require [Clauset et al., 2009] is not applicable and was not run. Every figure is a ratio of counts on a stipulated corpus.

The reflexive loop is not invoked here and no social-influence parameter is estimated, so the reflection problem [Manski, 1993] does not bear on any result. The one reflexive hazard the paper does carry is the index-as-target problem of §8.1 — a concentration measure adopted as a target stops measuring what it stood for [Goodhart, 1975, Campbell, 1979] — and it is named where it arises rather than resolved.

9.6 Analogy discipline: every borrowing, graded

Curzi [2026] requires that a user be able to distinguish a theorem, an ordinary effect and the framework's own conjecture in three separate sentences on demand. **This section discharges that requirement for every borrowing in this paper.** Three categories are used: **(1) a derivation**, where the system genuinely satisfies the cited result's premises; **(2) a shared mathematical form**, where the same equation governs both with no transfer of authority; **(3) an analogy**, legitimate as motivation and never as evidence.

borrowing	used for	category
Byzantine agreement [Lamport et al., 1982]	why an ordering layer is not optional (A1)	**1 — derivation.** The substrate is literally a set of mutually distrustful parties needing agreement

borrowing	used for	category
Consensus impossibility [Fischer et al., 1985]	what an ordering layer can and cannot achieve	**1 — derivation**
The availability–consistency trade [Gilbert and Lynch, 2002]	the same	**1 — derivation**
Identity forgery by mass creation [Douceur, 2002]	A4, why the party count must itself be audited	**1 — derivation**
Quantum factoring [Shor, 1997] and search [Grover, 1996]	the post-quantum posture of a hash-and-tag core	**1 — derivation.** The primitives in use are exactly the ones the results address
Open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]	the disclosure test of §3.3	**1 — derivation** as a design principle
Transparency as remedy [Brandeis, 1914]	the same test, in its policy register	**3 — analogy.** A legal-policy argument, not a security result
Contraction to a fixed point [Curzi, 2026]	the idempotence requirement of rule 3	**2 — shared form.** An operator with a fixed point; no metric-space claim is made about strings
Requisite variety [Ashby, 1958]	why a one-category screen cannot separate two referents	**3 — analogy**, invoked for shape, as §5.8 states in place
Coupled-network fragility [Buldyrev et al., 2010]	how a defect travels through composed identifiers	**3 — analogy**, invoked for shape, as §5.6 states in place
Queueing under load [Kingman, 1962, Little, 1961, Erlang, 1909, Hopp and Spearman, 2011]	why message richness is a capacity parameter	**2 — shared form.** A review function is a service system with arrivals and finite capacity; **no queue was measured**
Index adopted as target [Goodhart, 1975, Campbell, 1979]	§8.1's warning about concentration measures	**3 — analogy.** The cause here is mechanical, not behavioural, and §8.1 says so
Infrastructure as an installed base [Star and Ruhleder, 1996, Star and Griesemer, 1989]	why a registry binding decays unless maintained	**3 — analogy**
Legibility to an observing system [Scott, 1998]	§6.3's resolvability asymmetry	**3 — analogy**

The three sentences, stated as Curzi [2026] requires them. *The theorem:* no protocol among mutually distrustful parties achieves agreement without an ordering layer, and the substrate of §7 has none, so it does not prevent double-spending — this is a derivation and

the demonstration in §7.2 is its instance. *The ordinary effect:* a screen that reads bytes instead of typed fields cannot separate two registries' meanings, which is an ordinary consequence of parsing under the wrong grammar and needs no cybernetic theory to see. *The conjecture:* that full population is a costly signal a lawful structure can afford and an unlawful one cannot (§6.3) is **this work's own proposal**, it is not derived from anything cited, and no evidence in this paper establishes it.

9.7 The postulates

	postulate	status
P1	Compatibility normalisation folds full-width and compatibility variants; canonical composition does not.	CITED to the character standard — **and that standard is not in the bibliography** (Appendix B)
P2	Two strings are confusable when their skeletons are equal under the published confusables data.	Same status as P1
P3	SHA-256 is collision- and preimage-resistant at the strengths assumed.	ESTABLISHED, uncited (Appendix B)
P4	Each stipulated corpus is as described: 500 clean values, 495 manipulated, 2,000 accounts of which 1,200 carry the digits in currency positions and 13 incidentally, 2,000 currency fields of which 150 are genuine, 1,000 messages at 62 per cent rich.	DEFINITION (stipulated design parameters)
P5	The rich alert rate is the genuine list-membership rate and the sparse alert rate adds a name-collision rate.	MODELLING CHOICE; see §9.10
P6	A registry, not a string, is what binds a code to a referent.	POSTULATED — the paper's own framing, argued in §5.1
P7	Unresolvability, not suspicion, is what a screen escalates on.	POSTULATED — no production screening system was examined
P8	The nine forms of capital admit a coverage ratio.	**REFUTED as stated** — no measurement basis exists for the non-financial forms (§7.4)

Dropped as unnecessary. No postulate about *which* character standard version, or about the identity of any named registry, is needed for the canonical-form results: they follow from the composition of three operators and the stipulated corpus. No postulate about intent is needed anywhere, and §5.7 turns on that fact.

9.8 The chain that establishes the integrity layer (H1, H2)

step	consumes	produces	status
C1	P1, P2	canon $=$ restrict $\circ$ fold $\circ$ NFKC is well defined and order-fixed	DEFINITION
C2	C1, P4	495 / 495 manipulated entries collapse onto the clean form	ENUMERATION (495)
C3	C1, P4	$\text{canon}(\text{canon}(x)) = \text{canon}(x)$ for all 500	ENUMERATION (500)
C4	C2, C3	995 raw byte strings resolve to 500 canonical forms, the true count	ARITHMETIC (500 + 495)
C5	C4	the false-break rate under canonical comparison is 0 for every manipulation rate	ARITHMETIC
C6	P3	the digest over raw octets differs for a clean value and its twin; over the canonical form it does not	ENUMERATION (one pair)
C7	C5, C6	equal canonical form with differing byte-hash is a decidable flag — **the detector**	DEFINITION

H1 and H2 are supported, and the support is enumeration on a stipulated corpus, not evidence about any real record stream.

9.9 The chain that establishes the typed-parse collapse (H3)

step	consumes	produces	status
D1	P4	account records containing the digit string: $1200 + 13 = 1213$	ARITHMETIC
D2	D1, P4	naive flags $= 1213 + 150 = 1363$	ARITHMETIC
D3	D2	precision $= 150/1363 = 11.01\%$	ARITHMETIC
D4	D2	ambiguity share $= 1213/1363 = 88.99\%$	ARITHMETIC

step	consumes	produces	status
D5	P6	the grammar owning the account field never reads the currency positions as a currency code	DEFINITION
D6	D5	typed parse flags exactly the 150; precision 100%, ambiguity share 0.00%	ARITHMETIC

H3 is supported. D3 and D4 are exact on the stipulated mix and vary with it (§9.3); D6 is invariant across every mix, which is the part that is a finding.

9.10 The chain that establishes the queue inversion (H4), and a discrepancy in the source's stated rates

step	consumes	produces	status
E1	P4	1,000 messages split $620/380$ at a 62 per cent rich share	ARITHMETIC
E2	P5, reported counts	rich alerts 6, sparse alerts 92, queue 98	REPORTED (see below)
E3	E2	sparse queue share $= 92/98 = 93.88\%$ against a traffic share of 38.0%	ARITHMETIC
E4	E2	equal contribution at a rich share of 0.9616: sparse messages are half the queue at 3.84% of traffic	ARITHMETIC

The discrepancy, printed rather than harmonised. The source manuscript's own reproduction note states the stipulated parameters as *a 62 per cent rich share, a small list-membership rate, and a 22 per cent sparse-name collision rate.* **Those rates do not produce the reported counts.** The six rich alerts imply a list-membership rate of $6/620 = 0.968$ per cent; applied to the 380 sparse messages alongside a 22 per cent collision rate, the expected sparse alert count is $380\,[\,1-(1-0.22)(1-0.00968)\,] = 86.5$, and the reported figure is **92**, which corresponds to an effective sparse alert rate of 24.21 per cent rather than the stated 22 per cent plus list membership.

Two readings are available and both are given. Under a single seeded Bernoulli draw the gap is about 0.7 standard deviations ($\sigma \approx 8.1$ at $n = 380$, $p = 0.22$) and is unremarkable sampling variation; **but the source presents the figures as though they followed from the rates, and as arithmetic they do not.** At the stated rates the queue would be 86 sparse and 6 rich, a sparse share of 93.5 per cent rather than 93.9. **The finding is unaffected in sign, magnitude or mechanism, and the discrepancy is recorded because a reader recomputing from the stated rates will not reproduce the printed counts.**

9.11 The chains for the structured field and the substrate (H5, H6), and cross-checks

H5. The name element of the structured standard is a text field accepting the whole repertoire [P1]; a homoglyph twin placed in it renders identically, has a differing byte digest (`c413622fa3bea888` against `7307655b3eee8d17`), and has an identical canonical form. **The standard defines a place for the name and no canonical form for it, so the syntax passes the twin and the integrity layer catches it.** ENUMERATION on one constructed pair.

H6. 200 of 200 chains verify and 200 of 200 single-block mutations are detected, which follows from each block's hash covering its transaction and each chain linking by predecessor hash [ENUMERATION, 200]. 28 of 28 cross-object links are recorded in both ledgers [ENUMERATION, 28]. Append cost is linear at 50, 100, 200 and 400 chains [MEASURED, machine-specific]. **And a fork transferring the same balance twice yields two internally valid chains that the structure does not reject** [DEMONSTRATED, one instance] — which is the derivation of §9.6 arriving as a concrete counterexample. **H6 is supported in both halves, and the half that matters is the negative one.**

Cross-checks performed. The canonical-form and false-break figures were recomputed for this paper and agree with Curzi [2026]'s independent measurement of the same quantities. The homoglyph-in-structured-field result is the silent-duplicate condition of Curzi [2026] recomputed on a name fragment and is consistent with it. Content addressing over 20,000 distinct inputs yields 20,000 distinct identifiers with zero collisions, which confirms an implementation property rather than establishing anything about the hash. **The audit findings of §§7.2 and 7.3 were reproduced on a harness rebuilt from the source descriptions; the original code was not obtained and was not rerun**, and Appendix A records what must be confirmed before any of them is repeated in the present tense.

10. Limitations

Every figure in this paper is a deterministic computation over a synthetic corpus with stipulated parameters, and none is an estimate of prevalence in any real system. No production record stream, payment network, screening function, institution or ledger was examined. **No empirical dataset was collected.** The stipulations are printed at each point of use precisely so that a reader can show that a different stipulation gives a different figure, and several would.

The rates would need prospective registration and out-of-sample testing before any of the measured improvements could be claimed for production traffic. The manipulation rate, the corpus mix behind the 11.01 per cent precision, the list-membership rate and the sparse-name collision rate are design parameters chosen to demonstrate a mechanism. Claiming an improvement for real traffic on parameters chosen after seeing the demonstration is the garden of forking paths in its plainest form [Gelman and Loken, 2013, Simmons et al., 2011]; the remedy is to declare the rates and the endpoints before collecting the data [Nosek et al., 2018], and **that has not been done here.** The corpus's own precedent is instructive rather than reassuring: Curzi [2026ad] reports a preregistration whose measured false-positive rate was 9.5 per cent against a nominal 5.

No standards document, court decision or jurisdiction-specific instrument is cited, because `bib/external.bib` contains none of them. One structured-messaging standard is in the bibliography and is cited where it is relied on [International Organization for Standardization, 2013]. Every other designation in Section 5 — the currency, country, securities, institution, account, classification, legal-form and entity-identifier standards, their edition years, their check-digit algorithms, their registration authorities and their code allocations — is **described from the source manuscript and left uncited**, and is itemised in Appendix B. The same applies to the historical currency reallocation of §5.7, to the court decisions rejecting the double-ledger reading, to the post-quantum signature standards of §7.3, and to the capability layer's own literature. **This is a real gap and it is not closed here.**

The identifier-collapse trade is real and is not priced. Canonical folding collapses the identifier space and therefore creates collisions between entities whose names genuinely differ only by folding characters. For narrow critical machine fields this is a non-issue by construction; **for a name estate it is a genuine trade whose false-positive cost is not measured here and is not zero**, and the zero-false-positive figure Curzi [2026] reports is measured against clean ASCII critical fields and does not transfer.

The append measurements carry no uncertainty and were not repeated. Four single-run wall-clock timings on one unspecified machine in one process, quoted to three decimal places. **Linearity is the only claim they support**, no hardware is stated, no dispersion is reported, and nothing licenses extrapolation past 400 chains.

The artefacts of Section 7 are the author's own and the audit is the author's own. That is a conflict of interest, it is declared, and the only method available to a single author is to report the negative findings at least as prominently as the positive ones. **A reader who discounts the positive findings accordingly is reading correctly.** Neither component has an independent implementation, an interoperability profile, or a conformance suite maintained by anyone outside the corpus that produced it.

A single registry operator is a common-mode failure for every identifier composed from it, and registry capture bounds the whole approach. Section 5.6 shows a defect travelling through the composed identifiers; the same structure means that the country registry's maintenance agency is a single point on which four other standards depend, and that the entity-identifier system's governance is a single point beneath every deterministic clearance in Section 6. **A control whose correctness rests on a registry inherits that registry's governance risk in full**, and the network literature on common-mode dependence in layered systems [Buldyrev et al., 2010, Albert et al., 2000, Cohen et al., 2000, Doyle et al., 2005] is the general statement of the exposure. **Nothing in this paper measures it, mitigates it, or proposes a fallback for it.** Tight coupling between layers is also what turns a local defect into a system accident [Perrow, 1984, Leveson, 2011], and adding a redundant registry is not automatically a remedy [Sagan, 1993].

An unactioned flag queue is a worse outcome than no queue, and rule 10 is the only thing standing against it. A control producing exceptions nobody dispositions is evidence that something was detected and ignored, which is the organisational failure mode documented as the routine acceptance of signals that ought to have stopped a process [Vaughan, 1996, Weick and Sutcliffe, 2007]. **Rule 10 is normative for that reason and it is the rule most likely to be treated as advisory.**

Nothing in this paper measures truthfulness. Canonicalisation defeats encoding-level evasion; typed parsing defeats code-level ambiguity; hash chains defeat silent edits; content-addressed capabilities defeat impersonation; full population defeats the identity gate. **Every one of them is silent about a correctly encoded, correctly typed, correctly signed false assertion**, and a tamper-evident ledger containing a false entry will preserve it faithfully forever.

The survey that would establish the operational case has not been done. Whether out-of-repertoire code points occur at material rates in production critical machine fields is an empirical question, it is the question on which the whole exposure turns, and **so far as this paper is aware it has been answered nowhere.**

10.1 Rigour checks not met, listed by name

1. **No as-of date and no source for any figure, because nothing was measured.** Every result derives from a stipulated corpus.
2. **No uncertainty is reported anywhere.** For the ratios this is correct — they are exact on their corpora — but for the four append times it is a genuine omission (§9.2).
3. **Model comparison was not performed.** No alternative canonicalisation, no alternative screen and no alternative ledger factoring was implemented and compared; no out-of-sample test was run; no information criterion is reported, because nothing was fitted.

4. **Conjoint measurement was not tested** for the nine-form taxonomy, and Michell's objection stands [Michell, 1997, Luce and Tukey, 1964].
5. **The specification has no adopted standard status**, no auditor acceptance for any accounting treatment described, and no legal force anywhere.
6. **The resolution designator has not been put to a standard-setter or an audit firm**, and §8.3 states that the sequence matters: acceptance before adoption, not after.
7. **The 22 per cent collision rate does not reproduce the reported alert counts** (§9.10).
8. **No independent party has reviewed the hardened build** of the capability layer, and it has not been deployed at scale.

11. Conclusion

The integrity layer, in quotable form. The canonical form $\text{canon}(x) = \text{restrict_ASCII}(\text{confusable_fold}(\text{NFKC}(x)))$, paired with a SHA-256 witness computed over the **raw octets** and kept on a plane separate from the display form, collapses **495 of 495** manipulated entries onto their clean canonical form, is idempotent across all **500** corpus values, resolves **995** distinct raw byte strings to the true **500** identifiers, and moves the reconciliation false-break rate from **40.0 per cent to 0.0 per cent** at a 40 per cent manipulation rate — one point on a line that is flat at zero across the whole manipulation range. **The detector is one comparison: identical canonical form with differing byte-hash.** Hashing the canonical form instead gives a clean value and its homoglyph twin the identical digest and destroys, silently, the only evidence in the system that a substitution occurred.

The same defect one level up, and the number that matters. Aliasing a withdrawn currency code to a live one records a synthetic **8,000** balance as **10,000** — a phantom **25.0 per cent** inflation with no journal entry and nothing forged. Where two independently governed registries mint the same three digits with different meanings, a byte-level screen flags **1,363** records of which **150** are genuine: a precision of **11.01 per cent** and a parsing-ambiguity share of **88.99 per cent**. **A control right one time in nine is not a control; it is an alert generator, and it will be switched off in the second week.** One typed-field parse collapses that share to **0.00 per cent**, and it does so without anyone determining or alleging anybody's intent.

The resolvability asymmetry. In a synthetic day of 1,000 messages at 62 per cent rich traffic, sparse legacy messages are **38.0 per cent of volume and 93.9 per cent of the review queue**, and they remain **half the queue at 3.84 per cent of traffic**. **The message carrying less data is not more private; it is less resolvable, and unresolvability is what costs.** The corollary is the whole of the argument's honesty: full population is available only to a structure with nothing to lose by resolving, which is what makes it a costly signal rather than a policy — **and a structure populating fields it cannot truthfully fill has re-entered the concealment game from the other side.**

And a structured standard does not close it. Inside the richest, most authoritative name element the standard defines, a homoglyph twin is byte-distinct, renders identically, and is canonically identical: **the syntax fixes the shape of the data and not the identity of the values**, and only the canonical form and the byte witness separate them.

The negative results, stated as prominently as the positive ones. The per-object ledger factoring verifies **200 of 200** chains, detects **200 of 200** silent edits and records **28 of 28** cross-object links, with local append cost rising from **0.002 s to 0.014 s** across 50 to 400 chains — **a local, single-process measurement that is not distributed throughput.** It supplies **no consensus, no total order, no double-spend prevention and no Sybil resistance**, and a working double-spend against it is demonstrated: two forks of one token both verify and the structure raises no objection. Its block hash under-binds, and the fix is given. Four breaks in the capability layer — an unverified proof signature, an inconsistently computed self-verification digest, broken hash algorithms on offer, and a replay surface at the freshness root — are reported with their fixes and re-validation. The claim in the author's earlier materials that the relevant cryptography is ready for immediate implementation and unbreakable **is refuted here, in the author's own**

paper. The nine-form backing taxonomy is a classification and not a valuation method: **no measurement basis for its non-financial forms is specified in the source corpus or here**, and any coverage ratio computed across it is computed over an unknown. **The naming rationale and the numerological layer confer no property on any structure described and are excluded from every technical claim.**

What the paper adds to the corpus's instrument. Concentration is measured over a partition of exposures, and the partition is built by resolving identities. **An identity-resolution defect moves a concentration measurement without anything real changing, and it moves it in the reassuring direction.** The effective count of Curzi [2026] — the reciprocal of the Herfindahl index, the Hill number of order two — is only as good as the canonicalisation underneath it, and this paper specifies that layer, tests it, and states what it does not do.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every result in this paper is computed over a **SYNTHETIC** corpus with stipulated parameters, labelled as such at each point of use, under fixed seeds. The corpora are: 500 clean identifier values and 495 manipulated twins; 2,000 synthetic domestic account numbers and 2,000 synthetic numeric currency fields; a fourteen-entry synthetic designated-persons list and one constructed target entity that is not on it; a synthetic day of 1,000 payment messages; a three-account synthetic ledger extract in stipulated units with no currency attached; 200 synthetic token chains over 30 transactions each; and 20,000 distinct synthetic inputs for content addressing. **No real payment, party, account, institution, list entry, currency balance or production record stream appears anywhere in this paper, and no allegation is made about any of them.**

All figures were produced by the scripts named in their captions (`figs/src/CCP-065_fig01.py` through `figs/src/CCP-065_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

The measurements in Section 7 were recomputed for this paper on a harness rebuilt from the source descriptions; the original code was not obtained and was not rerun. Each finding describes the implementation *as audited*, and Appendix A records what must be confirmed before any finding is repeated in the present tense.

Standards documents, court decisions, historical code allocations and the post-quantum signature standards are described from the source manuscript and are not cited, because `bib/external.bib` contains none of them. Appendix B itemises every such claim with what specifically requires verification.

Funding

This research received no external funding.

Conflicts of interest

The ledger substrate and the capability layer described in Section 7 are the author's own systems, and the adversarial audit reported there is also the author's. This is declared as a conflict of interest. The method adopted in response is stated in Section 3.4 and applied throughout Section 7: report the negative findings at least as prominently as the positive ones, and report by name the ones that refute the author's own earlier claims. A reader who discounts the positive findings accordingly is reading correctly. The author declares no other conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data were processed. Every party, account and payment described is synthetic and constructed.

No operational content

This paper contains no operational content. It describes a defect class at the representation layer and specifies a control against it. The substitution demonstrations use a single constructed homoglyph pair to show that a detector fires; no evasion technique, list, tool or method is supplied, and nothing here would assist anyone in constructing a substitution or in moving value any regime prohibits. **The double-ledger reading of the digit collision in §5.7 is refused outright, is graded T4, and is recorded in the source as having been rejected by the courts that considered it.**

Legal, tax, accounting and investment advice

This paper is analytical and is not legal, tax, accounting or investment advice. The eighteen normative rules are a proposal with **no adopted standard status**; they replace no obligation and carry no legal force. **The resolution designator is an accounting proposal requiring a standards-body process and auditor acceptance, and it has neither: until it has both, an entity cannot use it to justify a treatment in a set of accounts.** No recommendation is made in respect of any particular person, institution, product or jurisdiction, and no allegation is made about any of them. Anyone contemplating a presentation or derecognition treatment on the basis of Sections 4.4, 5.9 or 8.3 must obtain a view from their auditor under the applicable financial reporting framework **before** implementation, in the sequence Section 8.3 states.

Appendix A. The status of the artefacts, and what must be confirmed before restatement

Every item in this appendix concerns the systems described in Section 7. **Each finding describes the implementation as audited at the time of the source audit. None may be repeated in the present tense without confirming the current state of the code.**

1. **A1, the double-spend.** The demonstration that two forks of one token both verify was reproduced for this paper on a rebuilt harness. Confirm whether an ordering layer has since been added; if one has, the finding is historical and the substrate's verdict changes.
2. **A2, the under-binding block hash.** Confirm whether the digest is now computed over the chain identifier, predecessor hash, index, timestamp and transaction together. The fix is specified in §7.2 and its effect — reordered blocks rejected — was reproduced here.
3. **A4, Sybil resistance.** Confirm whether any cost-to-identity or verified-identity layer has been added. Absent one, the finding stands as stated.
4. **R1 to R4, the capability layer.** All four were reported by the author as fixed in a hardened module and re-validated. **Confirm that the hardened module is the deployed one**, and note that the hardened build has not been reviewed by any party outside the corpus that produced it and has not been deployed at scale.

5. **The post-quantum posture.** The hash-and-tag core is post-quantum-resistant at digests of 256 bits or more; the signature the protocol requires must be a standardised post-quantum scheme. Confirm which scheme, if any, has been adopted. The earlier marketing claim of readiness and unbreakability is refuted in §7.3 and must not be restated.
6. **The eighteen normative rules.** No adopted standard status, no conformance suite maintained by any party other than the author, no interoperability profile, and no independent implementation. Confirm before describing any of them as a standard.
7. **The resolution designator (rules 16 to 18).** No standards-body process has been initiated and no auditor acceptance obtained. **An entity cannot use it to justify a treatment in a set of accounts**, and §8.3 states the sequence that would change that.
8. **The nine-form backing taxonomy.** Recorded as declared. No measurement basis for the non-financial forms exists in the source corpus or here; confirm before any coverage ratio is computed or quoted.
9. **The append timings.** Machine-specific single-run measurements. Confirm the hardware and repeat with dispersion reported before quoting any absolute figure.
10. **The naming rationale and the numerological layer.** Assessed and excluded by the author's own security audit and excluded again here. They confer no property on any structure described.

Appendix B. Claims requiring verification against primary sources

The following are described in this paper from the source manuscript and **are not cited to the bibliography, which contains no standards documents, no court decisions and no jurisdiction-specific material.** One structured-messaging standard is in the bibliography and is cited where relied on [International Organization for Standardization, 2013]. Each item below requires verification against the governing document before any reliance.

1. **The character standard and its annexes** — the compatibility normalisation form, the confusables data file, the skeleton operation, the graded restriction levels, and the definition of default-ignorable code points. Confirm the current version of each, and note that rule 6 makes the version a change-controlled configuration item precisely because it moves.
2. **The digest standard.** SHA-256 is used throughout. Confirm the governing publication.
3. **The currency registry** — the three-letter and three-digit code structure, the separate live and withdrawn tables, the maintenance agency, and the withdrawal and reuse policy. Confirm the edition in force.
4. **The country registry** — the two-letter, three-letter and numeric code structure, the withdrawal lifecycle, the transitional reservation period, and the interval after which a withdrawn two-letter code may be reassigned. **No specific historical reallocation is named in this paper and none should be added without verification.**
5. **The securities identifier, the institution identifier and the account identifier** — the character counts, the composition rules, the check-digit or check-character algorithms, the national numbering agency prefixes, and the nationally defined internal account structure. Confirm each separately; the account standard's deferral to national grammars is the hinge of §5.7 and must be confirmed in the governing text.
6. **The instrument-classification standard and the legal-forms standard** — the code structures and the registries behind them.
7. **The entity-identifier standard** — the twenty-character structure, the prefix allocation, the check algorithm, the local operating unit model, and **the renewal cycle and lapsed-registration status**, which §5.5 relies on directly.
8. **The historical currency reallocation of §5.7.** The exact allocation of the withdrawn numeric code between two candidate predecessor currencies is contested in the source's

own verification register and **is not asserted here.** The mechanism does not depend on which it was; the naming does.

9. **The national account-number grammar of §5.7**, in which the same three digits designate the live national currency inside the account number. Confirm the grammar and the position of the currency field.
10. **The court decisions rejecting the double-ledger reading.** Described from the source and cited nowhere. Confirm the deciding courts, the dates and the holdings before any restatement. **This paper makes the refused reading in no form.**
11. **The legacy cross-border message format** — the field limits, the character-set restriction, the truncation behaviour, and the absence of a dedicated entity-identifier element. Confirm against the format specification.
12. **The structured-messaging standard's element names and data dictionary.** The standard itself is cited [International Organization for Standardization, 2013]; the specific element names, the external purpose-code list and the migration schedule are described from the source and require confirmation.
13. **The capability layer's literature** — the content-derived identifier scheme, the locator rendering, the capability-contract authorisation model, and the four-message challenge–response exchange with per-session derived keys. **None of the primary sources is in the bibliography**; the protection principles are cited [Saltzer and Schroeder, 1975] and nothing else is.
14. **The post-quantum signature standards** described in the source as published in 2024. **This paper names none of them by number.** Confirm the designations, the publication dates and the current status before adopting any of them.
15. **The receipt-as-transaction and shared-record antecedents** for the triple-ledger construction. The accounting-history literature that would supply them [de Roover, 1963, Littleton and Yamey, 1956, Yamey, 1964, Ferguson, 1998] is in the bibliography and is cited here for the general lineage; **the specific antecedent claims in the source corpus are not established by those works and require their own sources.**

All numerical results in this paper were computed from the stated stipulated inputs at full precision and rounded only for printing.

Chapter 66

Channel Separation as a Structural Property: In-Band Impersonation, Address Anonymity Sets, and the Legacy-Migration Asymptote

Abstract. We state and test a structural principle: a system carrying both control and data is *in-band* when a data value can be promoted to a control instruction, and *out-of-band* when the two planes are disjoint by construction. A synthetic demonstration over $100{,}000$ carried values gives an in-band ambiguity rate of 0.383 per cent (383 values indistinguishable from control) against 0.000 per cent out-of-band, and the same in-band flaw with the same out-of-band fix is tabulated across telephony, ledgers, messaging and settlement. The disclosure result is the load-bearing one and is stated as a hard constraint: channel separation is strengthened rather than weakened by full disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place; publishing that the integrity witness is out-of-band, that settlement separates command from value, and that messaging separates identity from payload is in each case an assurance and never an opening. That is Kerckhoffs's principle of 1883, and citing it converts a rule that reads as an ethical preference into a recognised engineering standard. The stated caveat is that a separated control plane must still be access-controlled. At the addressing layer, an identity worth 18.932 bits entering a constructed carrier is observed as 8.000 bits from an address alone; logging address, port and timestamp reduces the anonymity set from $1{,}953.1$ to one while session state is live, at a cost of 3.6 TB of logs per day, and expiry restores it to $1{,}453.2$. Constructed legacy models give an 11 per cent attrition maintainer deficit against a flat requirement of 100, settling at 54.5, and a migration that leaves 3.29 per cent of a 40-million-line core after twenty years with a rational stopping point near 2032 at 37.6 per cent still buried.

Keywords: control plane; data plane; in-band signalling; anonymity set; carrier-grade translation; over-attribution; maintainer attrition; migration asymptote

Series: D. Structure and Resilience **Paper:** CCP-066

1. Introduction

A system that carries both control information and data has a structural property that decides an entire class of its failures: whether a value in the data plane can be promoted to an instruction in the control plane. This paper states that property precisely, tests it, derives from it a disclosure constraint that is stated as a hard design premise rather than as an ethical preference, and then follows the same structure down two further layers — the addressing substrate and the software substrate — where the identical shape recurs.

The paper's three contributions are separable.

The channel-separation principle, stated and demonstrated. A system is *in-band* when control and data share a channel such that a data value can be interpreted as a control instruction, and *out-of-band* when the two are disjoint by construction. In-band architectures admit an impersonation class that no care taken within the shared channel can close; out-of-band architectures close that class structurally. A synthetic demonstration over 100,000 carried values gives an in-band ambiguity rate of 0.383 per cent against 0.000 per cent out-of-band, and the same in-band flaw with the same out-of-band fix is tabulated across telephony, ledgers, messaging and settlement. The historical case is documented and closed: early international telephone signalling carried its control tones in the voice band, which made control reachable from the data path, and the move to common-channel signalling in the 1980s removed the condition the attack required rather than defending against the attack. **This paper contains no operational content of any kind** — no tone, sequence, code or method — and the historical material is used only to establish that in-band control was structurally reachable.

The disclosure constraint, and why it is engineering rather than ethics. Channel separation is *strengthened* by full disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place. That is not a novel claim and it is not this work's to make: it is Kerckhoffs [1883]'s principle, stated in 1883, that a system must remain secure when everything about it except the key is public, and it is restated as *open design* among the protection principles of Saltzer and Schroeder [1975]. **Citing it converts a rule that reads as an ethical preference into a recognised engineering standard with a hundred and forty years behind it**, and it is the single most load-bearing external citation in this paper. The regulatory environment has since made the same conclusion unavoidable from a different direction: automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations [Financial Action Task Force, 2012] and the beneficial-ownership and substance work [Organisation for Economic Co-operation and Development, 2015] have removed non-disclosure from the set of available design parameters.

The two substrate results. At the addressing layer, an identity worth 18.932 bits entering a constructed carrier is observed as 8.000 bits from an address alone; the anonymity set is 1,953.1 subscribers with an address-only log, exactly 1 while the translator's session state is live, and 1,453.2 after that state expires — at a retention cost of 3.6 TB of translation log per day for a single metropolitan translator. At the software layer, a constructed maintainer model with 11 per cent attrition against 6 hires a year lands at a steady state of 54.5 competent maintainers against a flat requirement of 100, and a constructed migration model leaves 3.29 per cent of a 40-million-line core after twenty years with a rational stopping point near 2032 at 37.6 per cent still buried.

Why these three sit in one paper. They are one mechanism in three media. In each case a representational boundary destroys information that a downstream consumer then trusts because the boundary is invisible to it. That is the same defect Curzi [2026] measures at the character layer, where typed-field parsing collapses the withdrawn-code parsing-ambiguity false-positive share from 88.99% to 0.00% against a naive detection precision of 11.01% — a control right one time in nine — and it is the same defect Curzi [2026] measures at the ledger layer, where a five-house network reads 3.819710 effective jurisdictions naively but 1.000000 effective blocs once a single coordination perimeter is recognised, giving $h = -0.500000$. **The concentration instrument of Curzi [2026] — HHI as the sum of squared shares and the effective**

count as its reciprocal, with a naive 3.41 collapsing to exactly 1.00 once blocs are recognised — is the same error at the jurisdictional layer, and Section 9.1 shows that the substrate exposure this paper measures is invisible to that instrument by construction.

Two attractive claims are refused in print, because a paper that lets a reader walk out believing either has done harm. **The three addressing namespaces do not share an origin or a common system**; they share a structural pattern of nested delegation, and the pattern is the finding while the shared-system claim is the overclaim. **Long-haul and metropolitan internet transport is fully optical and does not depend on copper**; what persists is the last-mile access plant in a large installed base and, more durably, the *logical* topology of the exchange hierarchy. **The durable dependency is logical topology, not electrical continuity.**

2. Hypotheses

Six hypotheses, each stated so that it could be wrong, each with its falsifier. Two statements that appear in the paper and are *not* falsifiable are labelled at the end. Platt [1964]'s strong inference is the standard applied: a hypothesis earns its place by naming the observation that would kill it.

H1 — the impersonation hypothesis. An in-band architecture admits a class of impersonation that no care within the shared channel closes; an out-of-band architecture closes that class by construction. *Predicted:* over a carried population of data values, the fraction indistinguishable from control is strictly positive in-band and exactly zero out-of-band. In the synthetic demonstration, 383 of 100,000 values (0.383%) against 0 of 100,000 (0.000%). *Falsified by:* an in-band construction — one in which control and data share a namespace — with an ambiguity rate of exactly zero, or an out-of-band construction with a non-zero rate.

H2 — the disclosure hypothesis. A design whose effectiveness depends on concealment fails when the design leaks; a design whose effectiveness is structural does not. *Predicted:* publishing every element of a channel-separated architecture — that the integrity witness is out-of-band, that settlement separates command from value, that messaging separates identity from payload — leaves the ambiguity rate at exactly 0.000%, because the rate is a function of the partition and not of the observer's knowledge. *Falsified by:* an element of a separated design whose disclosure raises the ambiguity rate, or an attack on a separated architecture that is enabled purely by knowledge of the separation and not by access to a plane.

H3 — the necessity hypothesis. Channel separation is necessary and not sufficient: it closes the impersonation class and says nothing about who may reach the control plane. *Predicted:* a separated control plane remains attackable by parties who already have access to it, and the frequency of such attacks rises as the set of parties with access widens. *Falsified by:* a separated architecture that is secure against control-plane attack without any access control on the control plane.

H4 — the provenance hypothesis. Identity crossing a stateful translation boundary is compressed to an anonymity set whose size is the sharing ratio at that boundary, and the binding that would undo the compression is ephemeral by design. *Predicted:* with 500,000 subscribers behind 256 public addresses, an identity worth 18.932 bits going in is resolved to 8.000 bits of address; the anonymity set is 1,953.1 with an address-only log leaving 10.932 bits unresolved, exactly 1 with an address-and-port log while session state is live leaving 0.000 bits unresolved, and 1,453.2 after expiry leaving 10.505 bits unresolved. *Falsified by:* a server-side log that resolves the originator without the translator's own mapping for the relevant instant.

H5 — the migration-asymptote hypothesis. A migration that moves a constant fraction of a shrinking remainder, at a per-line cost rising faster than the remainder shrinks, never completes and gets more expensive every year it continues. *Predicted:* at 15% of the remainder per year and a per-line cost rising 20% a year, the annual bill rises by a factor $(1-0.15)(1+0.20)=1.02$ per year, 3.29% of a 40-million-line core remains after twenty years, and the migration unit cost crosses the keep-running cost of 3.00 per line-year around 2032 with 37.6% of the core still buried. *Falsified by:* a migration under those rates that reaches

zero, or an annual bill that falls as the remainder shrinks.

H6 — the maintainer-cliff hypothesis. Where the rate at which competent maintainers are replaced sits below the rate at which they leave, the population lands at a steady-state deficit rather than passing through a transient. *Predicted:* at 11% annual attrition, 6 competent replacements a year and a flat requirement of 100 maintainer-equivalents, the population decays to a steady state of $6/0.11 = 54.5$ and crosses below the requirement in 2030, while a headline count of 120 still shows a 20-maintainer surplus today; holding the line would need 11.0 replacements a year against 6 actual. *Falsified by:* a steady state above the requirement under those rates.

Not hypotheses, and labelled as such.

- *The channel-separation principle itself* is a **definition**. It defines in-band and out-of-band by whether a data value can be promoted to a control instruction. What is testable is H1, which asserts a consequence of the definition, and H2, which asserts a property of the resulting design. **The definition is not evidence for anything and is not offered as such.**
- *The isomorphism across telephony, ledgers, messaging and settlement* is a **modelling claim** about shared structural form, not a derivation. Each mapping depends on the claim that the named system actually has the separation property attributed to it, which must be established per system and is not established here.

3. Method: the principle, stated as structure

3.1 The definition

> A system that carries control and data has a **control plane** — the information that determines what the system does — and a **data plane** — the information the system exists to move or store. The system is **in-band** when control and data share a channel such that a value in the data plane can be interpreted as an instruction in the control plane. The system is **out-of-band** when the two are separated such that no data value can be promoted to a control instruction. In-band architectures admit an impersonation class — data masquerading as control — that no care within the shared channel can close; out-of-band architectures close that class structurally, and remain subject to the separate question of who may reach the control plane.

The impersonation class is the object of study. **A structural statement of the same shape already exists in the distributed-systems literature and is worth naming, because it makes the class precise rather than evocative.** Douceur [2002] proves that in a system without a trusted certifying authority a single party can present as many distinct identities, so that an unaudited count of participants is worthless — which is the impersonation class in the identity domain, with the impossibility result attached. Lamport et al. [1982] fixes the number of genuinely independent parties required to tolerate f arbitrary faults at $3f + 1$, which is the same question asked about agreement. Neither result is imported here as a theorem about signalling; both are cited as prior formalisations of the same structural property, under the discipline of Section 10.5.

3.2 The historical case, and what it establishes

The early international telephone network carried two kinds of information over one path. There was the *voice* — the data, the thing the call existed to move — and the *signalling* — the control, the commands that seized a trunk, set up a route, supervised the call's progress and released it. In the in-band architecture the signalling travelled as tones in the same audio band as the voice, and the network's switches listened to the audio path for those control tones because that audio path was where the control information lived.

One structural fact follows, and it is stated as structure rather than as method. **If the switches take their commands from tones in the voice band, then any source that can put the right kind of sound into the voice band is speaking the control language: the network cannot distinguish a control tone that originated in its own signalling equipment from an identical sound arriving from the far end of the call, because they are the same sound in the same channel, and the channel is all the switch has to go on.** This is not a defect in any particular switch. It is the defining property of in-band signalling.

The exploits this permitted through the 1960s and 1970s are documented telephone history and are referred to here only at the level of principle — that the network could be controlled from the voice band. **No tone, sequence, frequency-as-method or device description is supplied**, and none is needed for the argument. The point is not the exploit. The point is that the exploit was not a defect to be patched but a direct consequence of the architecture, and that no amount of care in building the switches could have closed it, because the opening was the shared channel itself.

The fix, adopted across the international network in the 1980s, was architectural: the signalling moved out of the voice band entirely, onto a separate dedicated channel that the voice never touches — *common-channel signalling*, in which the control information for many voice circuits travels together on its own network, logically and physically distinct from the circuits carrying the calls. **After signalling moved out of band, a sound in the voice path was just a sound.** The class of exploit that depended on speaking the control language from the data channel did not get harder; it became impossible, because the data channel and the control channel were no longer the same channel.

That is the difference between a mitigation and an architecture. A mitigation makes an attack more costly; an architecture removes the conditions the attack required. This is the cleanest large-scale example in the history of communications of a structural fix closing a vulnerability class rather than patching its instances, and it is the reason the principle generalises: an engineer could build a perfect in-band switch — no bugs, no oversights, no weak components — and it would still take its commands from the voice band, because taking commands from the voice band was its design. **There was no patch available, because a patch is a change within an architecture and the problem was the architecture.**

3.3 What present-day signalling vulnerabilities are, and are not

Honesty requires the next paragraph, because a reader who knows that the modern signalling network is discussed as vulnerable would rightly distrust an account presenting out-of-band signalling as a final victory.

Out-of-band signalling closed the class of attack in which a *caller* controls the network from the *voice band*. It did not make the signalling network invulnerable, and the present-day discussion concerns a different class of attack entirely. **Contemporary signalling vulnerabilities are network-interconnect attacks carried out by parties who already have access to the signalling network itself — access to the out-of-band channel — and they are nothing like a sequence of tones a caller can dial into a telephone.** They exist because the signalling network was designed for a small, mutually trusting set of national carriers and was later opened to a far larger and less uniformly trusted set of interconnecting parties, so that access to the control channel, once implicitly restricted, became something a wider range of parties could obtain. **The vulnerability is a *trust* property of who can reach the control channel, not a *separation* property of whether control and data share a channel.**

The distinction is the whole reason for raising it. The channel-separation fix did its job and the class it closed stayed closed: **no caller dials tones to control the modern network, and this paper supplies nothing toward any present-day signalling attack, because such an attack is a matter of illicit access to a control network and not of technique that any description here could provide.** What the modern situation teaches is the *limit* of channel separation, which is H3: separating the channels closes the impersonation class and does not by itself secure the control channel, which must additionally be protected by controlling who can reach it.

Separation is necessary; it is not sufficient.

That limit has a name in the security-engineering literature. Saltzer and Schroeder [1975] list *open design* and *complete mediation* as separate principles precisely because they are separate: a design may be publishable and still fail if every access is not checked. The organisational literature reaches the same conclusion from field evidence. Perrow [1984] treats tight coupling as the property that turns a local fault into a system failure — cited here as qualitative framing, not as a formal result — and Sagan [1993] documents cases in which added redundancy *reduced* safety by adding coordination surface, which is the direct warning against treating a separated plane as automatically safer. Vaughan [1996] and Leveson [2011] supply the mechanism by which a control that was once justified continues to be trusted after the conditions justifying it have gone, and Hollnagel et al. [2006] the framing in which that drift is the normal state of an operating system rather than an aberration.

3.4 The isomorphism, tabulated

Four systems, one flaw, one fix.

system	in-band flaw: control impersonable by data	out-of-band fix
telephony	control tones live in the voice band	common-channel signalling on a separate network
ledger	the display form *is* the stored form	canonical form plus a raw byte-hash kept as separate planes
message	control fields tangled with the payload	a typed control plane distinct from the data plane
settlement	the instruction rides the value rail	separate channels for command and for value

Read each row as the same sentence. In telephony the control and the data shared a channel and data could impersonate control; separating them closed it. In the ledger, the control — what a human reviewer sees and trusts — and the data — what the machine stores and reconciles — shared one field, and a homoglyph let the seen value and the stored value diverge, until the two were separated by keeping a canonical form for the machine and a raw byte-hash as a witness on a distinct logical plane [Curzi, 2026]. In the message, the party-identifying control and the payment-describing payload were tangled in under-specified lines until structured typing separated them; the structured financial messaging standard [International Organization for Standardization, 2013] is the instrument that makes that separation available. In settlement, the instruction to move value and the value itself ride the same rail unless they are deliberately separated, so that whoever controls the instruction controls the value.

The mapping in this table is a claim of shared structural form and not a derivation. Each row depends on the assertion that the named system actually has the separation property attributed to it, which must be established per system. Section 10.5 labels the borrowing accordingly, and Cartwright [1999] supplies the discipline the label enforces: state the arrangement within which a law is claimed to hold, and stop claiming a universality the argument does not need. **The claim here is that four named arrangements share a form, not that the form is universal.**

3.5 Out-of-band integrity, and out-of-band settlement

The deepest instance is the integrity design of Curzi [2026], and stating it in this vocabulary is what makes its central specification decision look inevitable rather than merely clever. The

integrity hash is computed over the *raw octets* and stored *alongside* the canonical form, not over the canonical form itself:

```
data plane      canon(x)                what the matcher compares
control plane   hash(raw octets)        the witness, on a separate plane
detector        same canon, differing   something moved that the data plane
                hash                    cannot show
```

A hash of the canonical form is the in-band design: it puts the witness into the same plane as the data, so the witness changes exactly when the data changes and never otherwise, which destroys precisely the evidence a witness exists to preserve. Hashing the canonical form collapses the control plane into the data plane, which is in-band signalling in a ledger, and it reintroduces the impersonation class that keeping the byte-hash separate was there to close. The out-of-band design — witness on its own plane, never riding the data it guards — is the same architecture, executed over octets instead of voice circuits.

The same principle applied to money is the framework's standing rule that a rail is not a holding. The instruction to move value is a control-plane object; the value is a data-plane object. When they ride the same channel — when the message that commands the transfer is inseparable from the transfer, so that seizing the message is seizing the money — the settlement system is in-band, and control of the instruction is control of the value. Out-of-band settlement separates them: the command travels on one channel and the value on another, the two are reconciled by a witness rather than by their shared identity, and a compromise of the command channel does not by itself move the value because the value was never in the command channel. **The transit-versus-store distinction is the channel separation principle wearing a treasury's clothes: the rail is the control plane and the holding is the data plane, and keeping them separate is what stops a transit event from becoming a custody event.**

4. Results: the impersonation demonstration

A **synthetic** demonstration, computed under a fixed seed and deliberately abstract, so that it carries the structure and no technique. Model a channel carrying values drawn from a symbol space, of which a small reserved set are control tokens. In the in-band model the data is free to take any symbol, including a control token, so a data value can collide with a control token and be read as a command. In the out-of-band model the control tokens live on a separate channel the data never reaches, so the collision cannot occur.

```
IN-BAND  (control + data share one namespace)
  data values carried                              100000
  data values indistinguishable from control          383
  ambiguity rate                                    0.383%
  -> a data value CAN be read as a control command; structural.

OUT-OF-BAND  (control on a separate channel; disjoint by construction)
  data values carried                              100000
  data values indistinguishable from control            0
  ambiguity rate                                    0.000%
  -> the class is closed by construction.
```

The in-band model produces a non-zero rate of data values indistinguishable from control, and no care taken within the shared channel drives it to zero; the out-of-band model produces exactly zero, by construction, because the two planes never meet. H1 is supported in the model.

What the demonstration does not establish. The specific rate 0.383% is a property of the synthetic symbol space and carries no meaning beyond illustrating the sign: in-band greater

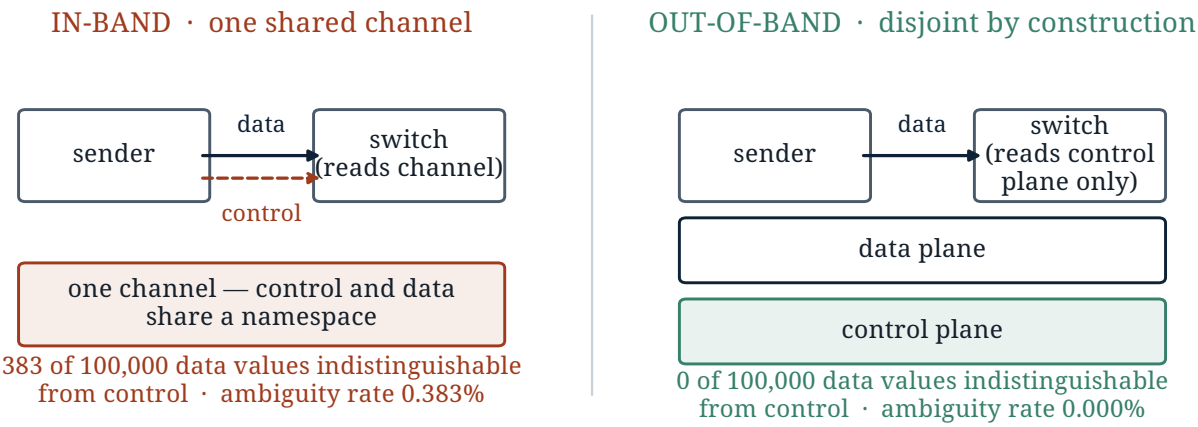

Figure 66.1: **The two architectures and their measured ambiguity: an in-band channel in which control tokens and data values share a namespace produces 383 indistinguishable values in 100,000 (0.383%), while planes that are disjoint by construction produce exactly 0 (0.000%).** Modelled on a synthetic symbol space under a fixed seed; the rate is a property of that space and corresponds to no real signalling system. Script `figs/src/CCP-066_fig01.py`.

than zero, out-of-band zero. **The demonstration corresponds to no real signalling system, measures no real prevalence, and would take a different value under any other allocation of reserved symbols.** What is invariant is the sign, and the sign is the finding, because it follows from the partition rather than from the parameters. The zero is exact and is not an estimate: it is a property of a disjoint union.

No distributional or scaling claim is made here or anywhere in this paper. The symbol space, the subscriber pool and the port space are finite sets with stipulated sizes; no frequency distribution is fitted, no tail is characterised, and no power law is asserted. This is stated rather than assumed because the material invites such a claim — a sharing ratio and a reuse count look like the beginnings of a heavy-tail argument — and Clauset et al. [2009] establishes that such claims are systematically overstated when they are not tested by a maximum-likelihood fit with a goodness-of-fit test and likelihood-ratio comparison against alternatives. **That procedure was not run, because no claim requiring it is made.** Broido and Clauset [2019] is the reason the same caution attaches to the network results this paper borrows in Section 9.1: across nearly a thousand empirical networks, social networks are among the weakest categories for scale-free structure, so the degree-distribution mechanism behind the robustness literature must not be assumed to apply here.

Why a constructed model is worth running at all is a fair question and it has a published answer. Epstein [2008] sets out the reasons to model other than prediction — among them demonstrating that a proposed mechanism suffices to produce an observed shape, and exposing which assumption a conclusion actually rests on — and that is precisely the work the three models in this paper do. Bruch and Atwell [2015] supplies the calibration and validation checklist such a model should meet before it is treated as anything more, and **none of the three models here meets it**, which Section 11 records. Hedström and Ylikoski [2010] states the criterion this paper accepts: an explanation must name a mechanism rather than exhibit a fitted curve. **Nothing here is fitted; each result follows from an inequality that is stated in advance.**

5. Results: the disclosure constraint

This is the paper's load-bearing result and it is stated as a hard constraint rather than as a recommendation.

Channel separation is strengthened rather than weakened by full disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place. Publishing that an integrity witness is out-of-band tells an adversary only that substitution will be detected. Publishing that a settlement architecture separates command from value tells a regulator only that the rail is not a store. Publishing that a messaging arrangement separates identity from payload tells a correspondent only that its payments resolve. **Every such disclosure is an assurance and none is an opening.**

The reason is arithmetic rather than rhetorical, which is why the constraint is stated as one. The ambiguity rate is a function of the partition of the symbol space and of nothing else. Disclosing the partition does not change the partition. **The rate stays at exactly 0.000% after disclosure because disclosure is not one of its arguments.**

That argument is not new and this paper does not claim it. **Kerckhoffs [1883] stated it in 1883: a system must remain secure when everything about it except the key is public.** Saltzer and Schroeder [1975] restate it as *open design* — the protection mechanism should not depend on the ignorance of attackers — and place it alongside *complete mediation* precisely because a publishable design still requires that every access be checked. **Citing Kerckhoffs converts what reads as an ethical preference into a recognised engineering standard, and that single citation carries more of this paper's weight than any other.**

A published architecture is performative, and that is an argument for the constraint rather than against it. MacKenzie and Millo [2003] documents the case in the field and with dates: an option-pricing model that did not fit the market when it was published came to fit the market after traders adopted it, so that the description made its own assumptions true. Hacking [1995] states the general form — a classification of people interacts with the people classified, who change in response, so the referent moves. **The disclosure constraint is the benign form of that loop: publishing that a design separates its planes causes counterparties, regulators and operators to rely on the separation, and reliance is exactly what makes the separation load-bearing.** The malign form is failure mode 6.3, in which the published separation is quietly re-merged while the reliance persists. **Neither form is available to a concealed design, which is a further reason the constraint is engineering rather than preference.**

The constraint has since become unavoidable from the regulatory direction as well. Automatic exchange of account information [Organisation for Economic Co-operation and Development, 2017], the anti-money-laundering recommendations that supervisors implement in common [Financial Action Task Force, 2012], and the substance and beneficial-ownership work of the base-erosion project [Organisation for Economic Co-operation and Development, 2015] together mean that non-disclosure is no longer an available design parameter, whatever a designer's preference. Brandeis [1914] is the older statement of the same policy instinct from the transparency side. Pistor [2019] is the scholarly account of how legal coding manufactures the durability that structures seek, and is simultaneously the sharpest critique of it; Hansmann and Kraakman [2000] establishes that asset partitioning is the irreducible function of entity law, which is the legal-form analogue of a plane separation — **a separate legal personality is a partition, and its effectiveness likewise does not depend on anyone's ignorance of it.** de Goede [2011] documents the listing machinery as a technique of governance, which is the mechanism that makes concealment fail on contact.

5.1 The caveat that belongs in print

A separated control plane must still be access-controlled, and disclosing that a control plane exists raises rather than lowers the importance of governing who reaches it. A structure that publishes its architecture must also be the structure that controls access to its control planes — its settlement command channel, its integrity witness, its messaging identifiers — because

separation without access control is the failure mode of Section 6.5, and the disclosure that advertises the separation is also the disclosure that tells an adversary which channel is now worth reaching. **That is not a reason to conceal the architecture, which cannot be secured by being secret; it is a reason to secure the access, which can.**

This is H3, and the modern signalling network is its standing demonstration.

6. Failure modes of the separation principle

6.1 Nominal separation that is not real. The commonest way channel separation fails is that it is declared and not built. Two planes that are logically distinct but implemented over one shared substrate — one wire, one field, one identifier space — are separated on the diagram and in-band in fact. Hashing the canonical form is exactly this failure in a ledger: the witness is nominally a separate thing and actually a function of the data. **The test is not whether the design *says* the planes are separate; it is whether a compromise of the data plane can reach the control plane.**

6.2 Covert channels — separation defeated from within. Even where control and data are architecturally separate, a party with a foot in both can sometimes signal across the boundary by modulating something the data plane controls — timing, volume, ordering — into a pattern the control plane can read. The class is named here to bound the claim: **separation closes the *direct* impersonation class, and an adversary with access to both planes may still contrive an *indirect* one**, which is a reason to control access to the planes rather than a reason to doubt the separation.

The point at which the analogy stops being an analogy and becomes a warning about the settlement architecture is worth stating. Out-of-band settlement separates the command channel from the value channel, and a party with a foot in both — a treasury operator who both issues the instructions and holds the balances — can reconstruct the bridge the separation was meant to remove, not by breaking the architecture but by occupying both sides of it. **This is why a maximum-overnight-balance limit must be enforced by someone who does not report to the treasurer: the separation of duties is the access control on the reconstructed channel, and without it the two planes are separated on the diagram and joined in a single person.** Every out-of-band architecture is only as separate as the access controls that keep any one party from standing in both planes at once. **Separation is a property of the wiring; keeping it is a property of who is allowed to touch the wiring, and the second is a governance problem that the first does not solve.** This is the governance form of the same result that Ostrom [1990] reaches empirically for common-pool institutions: the rule is only as good as the monitoring and sanctioning arrangements around it.

6.3 Re-merging the planes for convenience. Separated planes are less convenient than merged ones — two channels to build, two to operate, two to reconcile — and there is a standing temptation to fold the witness back into the data, the instruction back into the value, the control field back into the payload, because the merged design is simpler and, until it is attacked, works identically. **Every re-merge is a return to in-band, and it is usually justified as an optimisation.** The discipline is to recognise that the separation *is* the control, so removing it to save cost is removing the control to save cost. The pressure is a standing force rather than a one-time temptation: separated planes cost more on every ordinary day and pay off only on the exceptional one, **so the case for re-merging them strengthens with every uneventful year**, and the argument for keeping them is always an argument about a tail event that has not happened yet. Organisational slack has always appeared on the accounts as waste [Cyert and March, 1963], and this is that result in a technical register.

6.4 Mistaking the principle for a technique. Channel separation is a structural principle about the architecture of systems. It is not a method for attacking any system, and the history it draws on is closed history precisely because the architecture changed. **There is no technique in this paper**: the historical exploits are recounted only to establish that in-band control was structurally reachable, and present-day signalling attacks are a matter of illicit

access to control networks that nothing here describes or could enable. **The principle is for building, not for breaking.**

6.5 The control plane trusted because it is separate. The inverse of 6.1. A separated control plane can be *over*-trusted precisely because it is separate — treated as authoritative because data cannot reach it, while the question of who *can* reach it goes unasked. The signalling network was trusted because it was out of band, and its later vulnerabilities came from that trust outliving the conditions that justified it. **A control plane that everything trusts and anyone can reach is a worse exposure than an in-band design that trusts nothing.**

7. The addressing substrate

7.1 Three hierarchies, one pattern, no common root

Three independent systems say *where*, and each is a hierarchy that delegates authority downward from a wide root to a narrow leaf. **They do not share an origin, a designer, or an underlying registry.**

The international public telephone numbering plan sets a maximum of fifteen digits and divides them by authority: the leading digits are a country code assigned centrally, the country code selects a national authority which administers a national destination code, and within that a subscriber number. Three levels, three delegated authorities, each narrowing the space the level above handed it. An internet protocol version 4 address is thirty-two bits, which is exactly 4,294,967,296 possible values — a number this paper returns to, because its smallness is the origin of everything downstream. Addresses are delegated from a central registry to regional registries, from those to local registries and large operators, and from those to end sites; routing then reads the address as a prefix hierarchy of network, subnet and host. A hierarchical location code narrows a coarse region to a fine one by prefix, country to region to locality, or cell to sub-cell.

The claim made: these three are the same *pattern* — nested hierarchical delegation from a wide root to a narrow leaf — and that is why a designer who understands one understands the failure modes of the others. **The claim refused:** that they are the same *system*, or share an origin, or run on common infrastructure. They were designed by different bodies, in different decades, for different media, and they interoperate nowhere except where something deliberately builds a bridge. **The pattern is the finding; the common system is the overclaim; and blurring the two forfeits the finding.**

The distinction is not pedantry, because the pattern alone predicts the vulnerability. Any nested-delegation namespace has the property that authority over a leaf is inherited through the chain of delegations above it, so that to know who owns a leaf one must be able to walk the chain — **and every place the chain is broken, rewritten or shared is a place where ownership becomes ambiguous.**

The specifications relied on are not in this paper's bibliography. The numbering plan, the two internet protocol versions, the transition mechanisms and the translation specifications are public standards cited in the source manuscript by designation. **They are described here from that manuscript and are not cited to the bibliography, which contains no standards documents.** Section 11 records this as an unclosed gap.

7.2 The last mile, stated correctly

The long-haul core of the internet is optical. Traffic between cities and between continents runs on fibre — terrestrial long-haul routes and submarine cables — and has for long enough that a claim of copper dependency in the core is an error of fact. Metropolitan transport is likewise overwhelmingly optical. **The assertion that the internet cannot function without copper is false, and this paper states that it is false rather than repeating it**, because repeating

a false technical claim in a work that asks to be trusted on technical claims is a self-inflicted wound.

What is true is narrower and survives scrutiny. The *access* network — the last mile from the local node to the premises — is still, in a large installed base, copper: digital subscriber line service runs data over the same twisted pair that carried the telephone call, and the physical drop into older buildings is frequently copper even where fibre reaches the kerb. That is a real, current dependency of the *access* layer specifically.

And there is a second, more durable sense in which the old telephone plant persists. The topology of the telephone system — the exchange as a point where lines are switched, the central office as a node in a routing hierarchy, the numbering plan as a tree of delegated authority — is a *logical* structure, and logical structures outlive their physical implementations. **The exchange and central-office topology remains an addressing substrate underneath modern transport, and it persists because it is a logical map, not because any wire in it survives.**

7.3 The bottleneck and the bridge

The thirty-two-bit address space contains about 4.29 billion addresses: an unimaginable abundance when the protocol was designed and a binding scarcity within a human lifetime. The central authority exhausted its free pool in 2011, after which the regional registries depleted their own pools on staggered timelines. The address space did not grow; the demand did.

The designed replacement has a hundred-and-twenty-eight-bit address space of about 3.4×10^{38} addresses — a ratio of about 7.9×10^{28} to the old space. **The problem is not the size of the new space; it is the seam between the two, and it is a hard seam.** The two protocols have different address lengths, different headers and no shared wire format; a packet in one is not a packet in the other. **This is not a defect. It is the consequence of designing a successor with room to grow rather than a patch constrained to the old format.** But it means the migration could never be a single cutover, and it created a decade-and-counting period in which both protocols coexist and traffic crosses between them constantly.

The bridge is not one mechanism but a family, and each member is a place where address data is handled differently.

mechanism	what it does	provenance consequence
dual-stack	a host runs both protocols and uses whichever the destination speaks	no translation, so no loss; does not solve scarcity, since a dual-stack host still needs an old-protocol address
stateful translation	lets clients on the new protocol reach servers on the old, keeping a per-session table of which session maps to which address and port	rewrites; the mapping exists only in the translator, only for the session
edge-plus-core translation	stateful translation in the operator core plus stateless translation at the customer edge	layers a second translation on the first
tunnelling	carries one protocol's packets as payload inside the other's rather than translating	preserves the inner address exactly; adds encapsulation boundaries

The bridge between the two address spaces is not a wire; it is a set of *rewriting* operations, and rewriting is where the trouble is. Dual-stack rewrites nothing and solves nothing about scarcity. Tunnelling wraps rather than rewrites and preserves the inner address. Translation rewrites.

7.4 Where provenance is lost

At a translation boundary, the address that comes out is not the address that went in. A globally unique source address, delegated down a chain that ends at one subscriber, enters the translator; a shared address drawn from a pool, plus a port number, comes out. The server on the far side sees the second and never the first. The relationship between them — the fact that *this* host was, at *this* instant, using *that* address and port — exists only inside the translator, only for the duration of the session, and is discarded when the session ends. **The mapping is real while it lasts and gone when it does not, and attribution depends entirely on whether anyone was recording the mapping at the moment it existed.**

That is the same structural failure as a character-encoding boundary, and the parallel is exact. At a charset boundary a byte-level hash is a faithful record of the octets and useless for meaning, because meaning is assigned by a decoder the hash cannot see [Curzi, 2026]. Here the server's log is a faithful record of the observed address and useless for attribution, because attribution is assigned by a translator the log cannot see. **In both cases the observable is honest and insufficient, and the sufficient information lives at a boundary the observer is not positioned to see.**

8. Results: the substrate measurements

8.1 The constructed carrier

Everything in this section is **CONSTRUCTED**. The figures are chosen to be plausible and round, not to describe any real operator, and the point is the arithmetic of the boundary rather than the specific inputs.

```
active subscribers                           500,000
public address pool (a /24)                      256   addresses
usable ports per public address                64,512   (1024–65535)
simultaneous (address, port) bindings      16,515,072
subscribers time-sharing one public address     1,953.1
```

Five hundred thousand subscribers reach the older internet through two hundred and fifty-six public addresses. Each public address offers the usable port range, and the product — about 16.5 million simultaneous address-and-port bindings — is the number of distinct conversations the translator can carry at one instant. **No subscriber owns a public address; they borrow one, and a port on it, for the length of a connection, and hand it back.** This is not an exotic configuration: it is the ordinary way a large address-constrained operator connects a subscriber base far larger than its address holding, and the sharing ratio is a routine engineering figure rather than an extreme one.

8.2 H4 — compression at the boundary and the attribution set: supported

Identity is measured in bits as the base-two logarithm of the size of the set an observer can narrow the originator to, which is Hartley's measure of information in a selection from a finite set [Hartley, 1928] and the special case of Shannon entropy for a uniform distribution [Shannon, 1948, Cover and Thomas, 2006].

```
identity going IN      : 1 of 500,000 subscribers     = 18.932 bits
server sees address    : 1 of 256 public addresses    =  8.000 bits
server sees addr + port: 1 of 16,515,072 tuples       = 23.977 bits
```

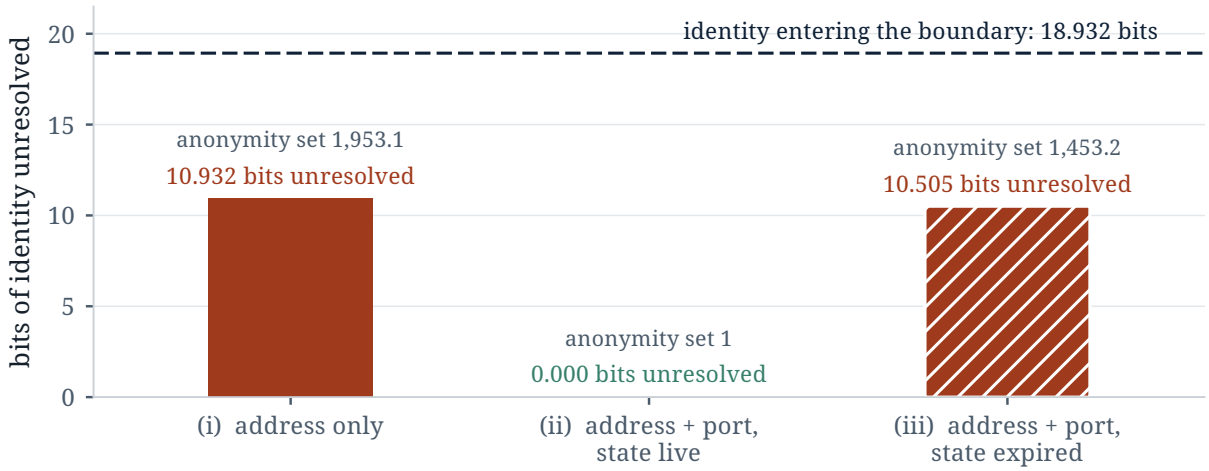

Figure 66.2: **Identity crossing a stateful translation boundary.** An identity worth 18.932 bits going in is fully recoverable only in case (ii), where the port was logged and the translator's state is still live; an address-only log leaves 10.932 bits unresolved and an expired-state log 10.505, both corresponding to anonymity sets in the thousands. Modelled from the CONSTRUCTED carrier parameters in Section 8.1; script `figs/src/CCP-066_fig02.py`.

The operative question is not how many bits the server records but how many subscribers could have produced what the server recorded — the *anonymity set* — and equivalently how many bits of the originator's identity are unresolved after the crossing.

case	what was logged	anonymity set	bits unresolved
(i)	address only	1,953.1	10.932
(ii)	address and port, session state live	1	0.000
(iii)	address and port, session state expired	1,453.2	10.505

Case (ii) is the reassuring one and the one people implicitly assume. If the server recorded the address and port, and the translator's session table is still in memory and still holds the entry, the tuple maps to exactly one subscriber and attribution is complete: zero bits unresolved. **It is a real case, and it is bounded in time.**

Case (i) is the common reality of server-side logging. A great deal of software logs a source address and not a source port, because the port was never thought to matter. Against a shared carrier address, **an address-only log resolves the originator to a set of about 1,953 subscribers and leaves 10.9 bits of identity unresolved — the log names the pool, not the person.** The originator went in as one of five hundred thousand and comes out, in the record, as one of nearly two thousand, and no amount of care at the server closes the gap, because the gap was created upstream.

Case (iii) is the one that matters most and is least understood. Suppose the server *did* log the port, but the translator's session state has since expired — the connection ended, the entry aged out, the memory was reused. The same tuple is not reserved to that subscriber; it is handed to the next subscriber who needs it, minutes later:

```
sessions per subscriber per day (proxy)         48,000
total sessions per day                  24,000,000,000
reuse per (address, port) slot per day           1,453.2
```

So a tuple logged at the server, once the state that bound it to a subscriber has expired, could belong to any of the roughly **1,453 subscribers who used that same slot that day** — 10.5

bits unresolved, almost as bad as logging no port at all. **The address the server holds is honest and the subscriber it names is unrecoverable, not because anyone hid anything but because the binding was ephemeral by design. H4 is supported.**

8.3 Why the state is ephemeral, and not by accident

The obvious objection is that the carrier should simply keep the session table. The measurement shows why that is not free and often not done:

```
bytes per session record                          150
daily log volume                  3,600,000,000,000 bytes = 3.600 TB/day
 90-day retention                           324.0 TB
180-day retention                           648.0 TB
365-day retention                         1,314.0 TB
```

Twenty-four billion sessions a day at a modest 150 bytes a record is **3.6 terabytes of translation log per day, and over 1,314 terabytes a year, for one metropolitan translator**. The volume is not impossible; it is a deliberate cost, and **it is a cost that buys nothing the carrier needs for its own operation**, since the carrier does not require the historical mapping to route the next packet. The state is ephemeral because keeping it is a standing expense incurred entirely for the benefit of a future third party who may never ask. **The provenance is lost by an economic gradient, not by an oversight, which is why the loss is structural rather than a bug someone forgot to fix.**

The mirror of that finding is a liability rather than a gap. **A party that captures and retains attribution data has created a record that is itself discoverable and itself sensitive**, and the decision to retain it deserves the same care as the decision to collect it, because a retained mapping is a store of exactly the information the addressing substrate was, by its economics, disposed to forget. Lazer et al. [2009] sets out the access, privacy and review conditions under which behavioural records of this kind may responsibly be held, and they apply in full to any retention window designed on the basis of this section. **Retention is a control and a liability at once.**

8.4 Deterministic assignment: the anonymity set becomes a design parameter

There is an engineering response to the logging cost worth measuring, because it makes the provenance loss explicit and turns the anonymity set into a number the operator chooses on purpose. Deterministic assignment gives each subscriber a fixed block of ports on a shared public address, so that attribution needs only a small static block map rather than a per-session log:

```
fixed port-block per subscriber                 512 ports
blocks per public address                       126
deterministic capacity (1 block/subscriber)   32,256 subscribers
required oversubscription                      15.50x
block size that actually fits 500,000 subs        33 ports/subscriber
static block table                            32,256 rows
  (against 24,000,000,000 session rows/day)
```

With 512-port blocks, one public address carries 126 subscribers and the whole pool carries 32,256 — far short of the half-million, an oversubscription of **15.5 times**, which means the blocks must themselves be time-shared or the pool enlarged. Shrink the block to fit and each subscriber gets about thirty-three ports. The static block table is tiny — about thirty-two thousand rows against twenty-four billion session rows a day — which is precisely the appeal.

But attribution now resolves to the *block owner*, which is one subscriber only if blocks are not shared, and the moment oversubscription forces block sharing the anonymity set is exactly the number of co-tenants of a block. Deterministic assignment does not eliminate the provenance loss; it converts it from an accident of expired state into a fixed, chosen anonymity set — the operator decides how much provenance to destroy in exchange for how small a log to keep. That is the honest description of the trade: the cheap control or the complete evidence, and the design decision is which.

8.5 H6 — the maintainer cliff: supported

A **constructed** mainframe shop with 120 expert maintainers of a critical estate. The estate does not shrink — the buried layer is load-bearing and its maintenance demand is flat at a required 100 maintainer-equivalents. Experts leave at 11% a year, and the shop trains or hires 6 new competent maintainers a year, where *competent* means able to modify the estate safely, which for these languages is a multi-year apprenticeship.

year	experts	gap (experts − required)
2026	120.0	$+20.0$
2028	106.4	$+6.4$
2030	95.6	-4.4 (cliff)
2032	87.1	-12.9
2036	75.0	-25.0
2040	67.4	-32.6
2050	58.5	-41.5

```
steady-state experts (replacement / attrition)   54.5
steady-state gap vs requirement                 -45.5
replacement needed just to hold the line         11.0/yr  (vs actual 6)
                                                 -> deficit 5.0/yr
```

The shop looks fine today — a 20-maintainer surplus — and it is not fine. The expert count decays toward a steady state of **about 54 maintainers against a flat requirement of 100**, and crosses below the requirement in **2030**, four years out, while still appearing healthy in the intervening years. **The steady-state deficit is not a transient to be waited out; it is where the system lands and stays, because the replacement rate is structurally below the attrition rate. The cliff is not an event; it is the arithmetic of a replacement rate below an attrition rate**, and it arrives while the headline count still looks adequate, which is exactly why it is not acted on until it is too late. **H6 is supported in the model.**

The distributional point is worth stating because the headline count conceals it. Granovetter [1978] establishes, for collective behaviour generally, that the **distribution** of individual thresholds and not the mean determines the aggregate outcome, and the same holds here: a maintainer population is not interchangeable, and a shop whose remaining experts are concentrated on a few subsystems crosses its effective cliff earlier than the aggregate count says. **The model tracks a mean and therefore gives the optimistic answer**; the distribution is not modelled and no claim is made about it.

The model's honesty is in what it does not claim. **The specific numbers are invented; the shape is the finding.** Any shop where the replacement rate sits below the retirement rate lands in the same place, and the only levers are raising replacement — slow, because competence is slow to build — or lowering the requirement, which means migrating off the estate, which Section 8.6 shows is itself a trap.

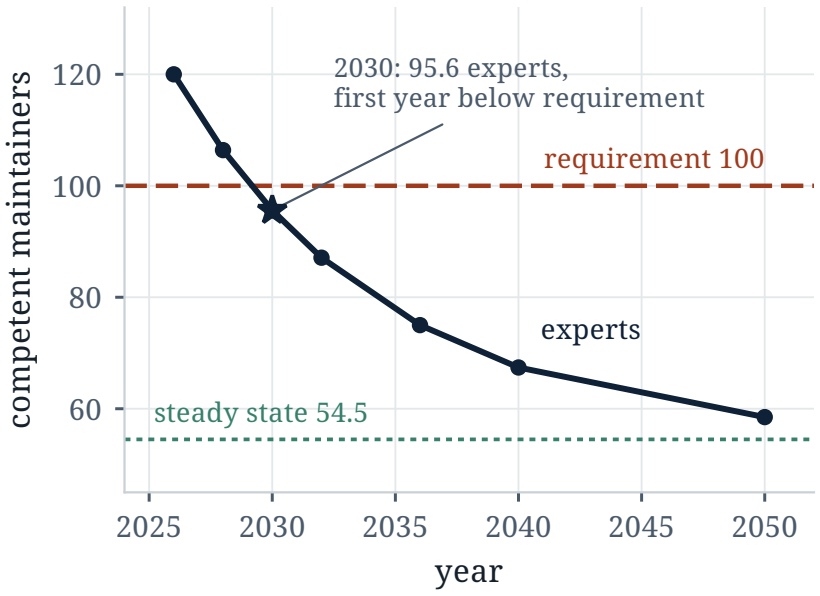

Figure 66.3: **The constructed maintainer cliff.** A shop showing a 20-maintainer surplus today crosses below its flat requirement of 100 in 2030 and settles at a steady state of 54.5, because the replacement rate sits structurally below the attrition rate. Modelled with 120 experts, 11% attrition and 6 competent hires a year; script `figs/src/CCP-066_fig03.py`.

8.6 H5 — the migration asymptote: supported

A **constructed** core of 40 million lines. The shop migrates 15% of what *remains* each year — the easy, well-understood parts go first, because they are easy and well-understood — and the per-line cost of migration rises 20% a year, because what remains after the easy parts are gone is the hardest, least-documented, most entangled core.

year	remaining	migrated	unit cost	year cost	cumulative
2026	40,000,000	6,000,000	1.00	6,000,000	6,000,000
2030	20,880,250	3,132,038	2.07	6,494,593	31,224,241
2034	10,899,621	1,634,943	4.30	7,029,956	58,527,771
2038	5,689,670	853,451	8.92	7,609,451	88,081,989
2042	2,970,043	445,507	18.49	8,236,714	120,072,426
2046	1,550,381	232,557	38.34	8,915,684	154,699,903

```
remaining after twenty years   1,317,824 lines  (3.29% of the core)
```

Two results, and the second is the important one.

First, the remainder decays geometrically — 85% of it survives each year — and geometric decay never reaches zero. After twenty years of steady migration 3.29% of the core is still there, and it will still be there after forty, because a constant fraction of a shrinking base is always positive. **The migration, run as a steady percentage, is asymptotic by construction; it approaches the bottom and never lands.** This is a first-order linear difference equation and its behaviour is standard [Elaydi, 2005].

Second, and worse, the annual bill does not fall as the remainder shrinks — it rises every year. Because the per-line cost climbs 20% while the remainder falls only 15%, the product grows by a factor $0.85 \times 1.20 = 1.02$ a year, so **the migration gets more expensive every year it continues, not less.** There is no point at which finishing becomes cheap; the hardest 3% is the most expensive 3%, and it is the part a rational budget defers indefinitely.

```
keep-running cost of the legacy (per line/yr)          3.00
migration unit cost crosses keep-running cost in       ~2032
lines still buried at that crossover             15,023,138   (37.6%)
```

Set against the cost of simply keeping the legacy running — cheap, because correct old

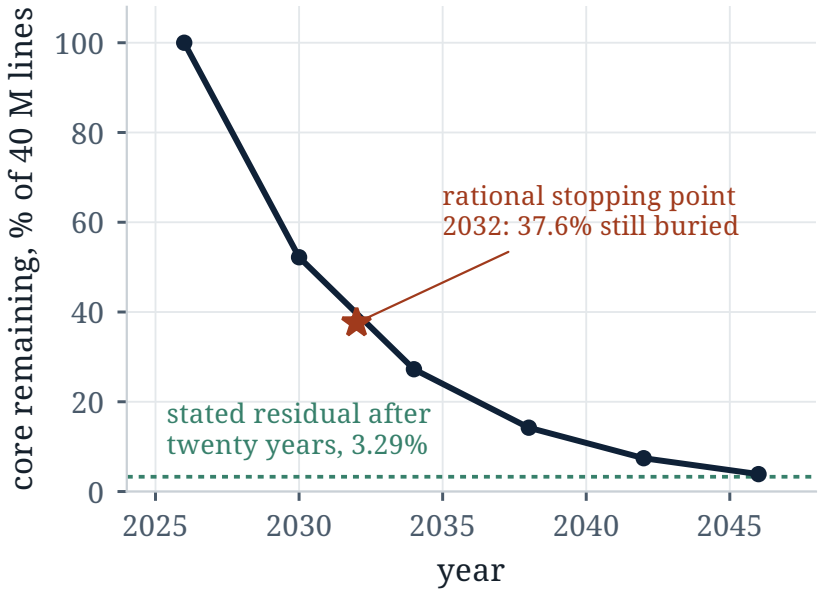

Figure 66.4: **The migration that never completes.** A constant 15% of a shrinking remainder decays geometrically and never reaches zero; the rational stopping point falls near 2032 with 37.6% of the core still buried. Modelled with a 40-million-line core, 15% of the remainder migrated per year and a per-line cost rising 20% a year; script `figs/src/CCP-066_fig04.py`.

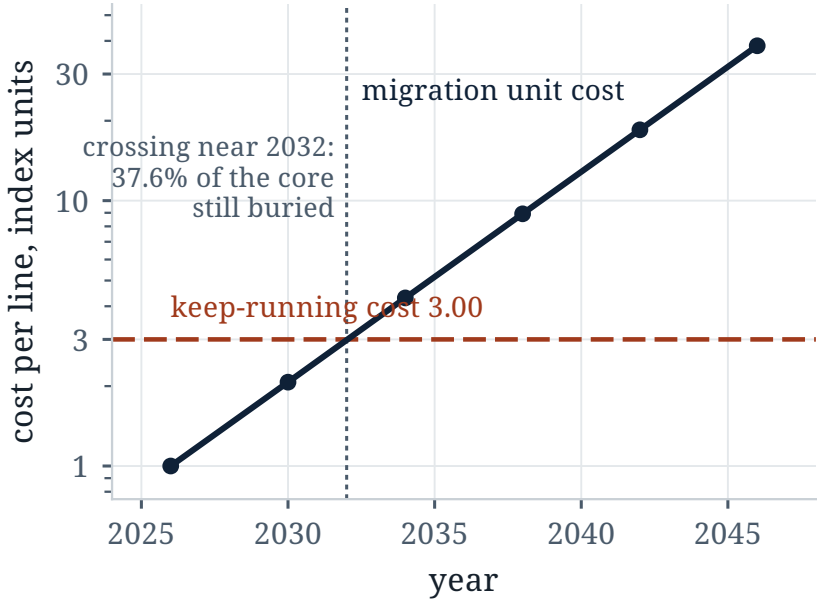

Figure 66.5: **Why the migration stops.** The per-line cost of moving the remainder rises 20% a year and crosses the flat keep-running cost of 3.00 per line-year around 2032; past the crossing, each further line costs more to move than to leave. Modelled from the same constructed parameters; script `figs/src/CCP-066_fig05.py`.

is, by revealed evidence, among the most thoroughly tested software in existence. **The risk is that the people who can read, modify and vouch for that code are retiring faster than they are replaced**, so that the code becomes progressively less maintainable not because it changes but because the human ability to change it safely evaporates.

A system nobody living fully understands is fragile no matter how correct it is, because the next required change — a regulatory deadline, a currency redenomination, a date-format rollover — arrives on a schedule the system does not control, and arrives at a maintainer population that has thinned below the level needed to make the change with confidence. **The failure mode is not that the code stops working. It is that the code keeps working perfectly right up until a change is required that no one remaining can make safely.**

The staffing constraint is not novel and has a literature. Brooks [1975] establishes that a project's coordination cost grows as $n(n-1)/2$ and that adding people to a late project makes it later — the direct statement that maintainer capacity cannot be bought quickly. Conway [1968] gives the complementary structural result that a system's interfaces mirror the communication structure of the organisation that built it, which is why an estate built by a now-departed organisation is hard to re-enter. **The source dates this article to 1967; it appeared in April 1968, and the corrected date is used here.** Hopp and Spearman [2011] and Kingman [1962] supply the general shape of a capacity constraint approaching saturation: waiting time explodes as utilisation approaches one, which is what a maintainer pool at the requirement line experiences when a change arrives. Sterman [1989] demonstrates experimentally that people systematically misjudge stocks with delays, which is the behavioural reason a shop with a 20-maintainer surplus does not act; Forrester [1961] is the underlying levels-and-rates formulation.

A public, dated instance exists. During the 2020 pandemic, unemployment-claim volumes in the United States spiked to levels the state benefit systems had never been built for, and several of those systems ran on decades-old mainframe code. When they buckled and needed rapid modification, states discovered that the maintainer population for their own systems had thinned to the point of crisis; one state's governor publicly appealed for volunteer programmers in April 2020. **Systems that had run correctly for decades could not be changed fast enough when change was suddenly required, and the failure landed at the exact moment the systems mattered most.** That is the mechanism made visible — a maintainer failure, not a code failure. **The specifics of that episode are described from the source manuscript and are not cited to the bibliography, which contains no contemporaneous reporting** (Section 11).

8.8 The citation discipline on the scale figures

The figures everyone quotes about the volume of legacy transaction-processing code — that it handles most card-swipe transactions, underpins a large share of banking systems, runs to hundreds of billions of lines, and supports systems processing trillions of dollars a day — are real quotations from real reporting, and they are also nearly a decade old, repeated so often that they have detached from their source and hardened into ambient fact. **This paper attributes them to their 2017 origin and does not restate them as a current measurement.**

The bibliography contains no press reporting, so the originating article is not cited here. The figures are therefore described rather than quoted, and are used only to establish an order of magnitude: the dependency is vast rather than marginal. **A work about buried provenance that laundered its own headline figures would be refuting itself**, which is the reason for the discipline rather than fussiness.

9. Discussion

9.1 What follows

A concentration measurement on one axis can hide a common-mode dependency on another. This is the sharpest consequence of the substrate results and it bears directly on the corpus's central instrument. Curzi [2026] measures resilience by counting effective coordination perimeters: a naive count of 3.41 effective jurisdictions collapsing to exactly 1.00 effective blocs once a shared perimeter is recognised. **Two banks in two genuinely independent perimeters, contributing two full units to that effective count, may sit on the same generation of core software with the same thinning maintainer pool, so that a forced substrate change could degrade both at once while the instrument reports them as fully independent.** The perimeters are independent; the substrate underneath them may not be, and the instrument cannot see the difference. **This is a common-mode failure and not diversity** — exactly the case Markowitz [1952] formalises for portfolios, in which diversification benefit depends on covariance rather than on count, and Longin and Solnik [2001] measures as correlation rising under stress. Buldyrev et al. [2010] is the network-theoretic statement that coupled systems are more fragile than either alone, cited here as a **shared structural form** rather than as a derivation: the substrate dependency has not been shown to satisfy the percolation premises of that model.

Attribution across a translation boundary is a capture-time decision, never a query-time one. If the mapping was not recorded when it existed, no later diligence recovers it. That is the single most useful operational consequence of the addressing result for anyone building a control that depends on knowing where a transaction originated.

An address is evidence of a pool, not of a person. A monitoring function that flags a transaction as coming from a party because it came from an address is asserting an identity it does not have. In the constructed carrier that assertion is wrong for 1,952 of every 1,953 subscribers sharing the address, and it carries no visible warning that the address is shared rather than dedicated. **This fails in the reassuring direction, naming a specific party with false confidence**, which is the same shape as the effective-count error at the jurisdictional layer: trusting a number that a lower layer has already degraded.

The rewrite is the cure that is worse. A big-bang replacement of a system nobody fully understands is an attempt to re-derive, under deadline, decades of accumulated correctness and undocumented edge cases. **It fails not on the behaviour that is documented but on the behaviour that is not, and it does so at exactly the moment — the maintainer cliff — when the people who could say what the old system actually did are already gone.** This is the exploration-exploitation failure of March [1991] in its most expensive form, and Levinthal and March [1993] names the temporal myopia that makes the trade look attractive at the decision point.

9.2 What does not follow

It does not follow that separation is sufficient. H3, Section 6.5, and the modern signalling network.

It does not follow that the buried layer is anyone's negligence. The migration model is the refutation. Migration off a correct, load-bearing core is not a will problem; it is an economics problem with a stable equilibrium above zero, and institutions that "failed to migrate" mostly made the locally correct decision at every step. **Treating the buried layer as a failure to be scolded rather than an equilibrium to be managed guarantees the wrong remedy** — it prescribes urgency where the need is a way to live safely with a layer that is not going away. Star and Ruhleder [1996] and Star and Griesemer [1989] give the general account: infrastructure is by definition the layer that becomes visible only on breakdown, and its invisibility is a property of its success rather than of anyone's inattention. Scott [1998] supplies the mirror

warning about the remedy: making a system legible destroys local variety that was doing real work.

It does not follow that attribution is impossible. It is expensive, and Section 8.3 prices it. A design that wants attribution must decide, before the fact, to pay for it.

It does not follow that the three namespaces share a system. Section 7.1, refused in print.

It does not follow that the internet depends on copper. Section 7.2, refused in print. **The durable dependency is logical topology, not electrical continuity**, and the two are constantly confused by people who have noticed that the telephone system is still somehow underneath everything and drawn the wrong conclusion about why.

9.3 Parallel results in the corpus

The same shape recurs across the corpus in domains that share no subject matter, and the recurrence is the reason these are one corpus.

Curzi [2026x] measures a receiver-limited channel capacity into a single cell at 70 to 106 bit/s, at a mechanotransduction bandwidth near 10.6 Hz and 20 dB signal-to-noise, delivering a 40-bit address in about half a second — **a capacity result on a channel whose control and data planes are not separated**, and the closest analogue elsewhere in the corpus to this paper's bit-accounting. Curzi [2026y] states the complementary negative result: the demodulator gap, in which no identified transducer, memory element or symbol-to-locus mapping exists, and capacity is not the bottleneck since 40 bits over 16 Hz needs only 6.68 dB. Curzi [2026] states the same open problem formally — no established mechanism produces a response depending on the symbol string as an *order*, as distinct from permutation-invariant functionals of the waveform — which is a representation-loss result of exactly the kind Section 7.4 measures. Curzi [2026w] gives the evidential form: two agreeing sources do not double the evidence when only one of them is evidence, which is the epistemic version of a control plane that has been folded into the data plane and no longer witnesses anything independently. Curzi [2026] reports an audit distribution over thirteen entries — seven maps, two splits, one rendering, three rejections, with five entries carrying a failure — which is the corpus's standing demonstration that a classification exercise is only worth running if it is allowed to reject.

9.4 Bounds carried from elsewhere in the corpus

Three results elsewhere in the corpus bound what this paper may claim, and they are recorded here rather than left implicit.

Curzi [2026] refuses category innocence as a defence of acquisition, forbids moving any harm through a discovered gap in a scheme, and concedes that the case where a feedback loop runs through another person's will is an unsettled seam the corpus does not close. **That bound is why this paper carries no operational content**: a structural principle that could be read as a technique for reaching a control plane would be exactly the discovered gap the doctrine forbids.

Curzi [2026] establishes that a width statistic invariant under relabelling does not determine the object it is computed from, which formally blocks an inference from the statistic to a substantive conclusion. **The same bound applies to the ambiguity rate here: 0.383% is invariant under relabelling of the symbol space and therefore does not determine the space it was computed from.** It establishes the sign and nothing more, and Section 4 says so.

Curzi [2026] classifies the corpus's commitments into four items of established mathematics, seven of established psychology, and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third. This paper's chains are in the first drawer — arithmetic and definitions — and its three modelling assumptions are named in Section 10.

Curzi [2026t] supplies the discipline that makes such a demotion survivable: what survives a demotion is structure rather than magnitude — the limiting cases, the fixed point, the sign,

and the ordering, all of which require only ordinal information. **That is exactly what survives in the constructed models here: the sign of the ambiguity rate, the existence of a steady-state deficit, and the existence of a stopping point above zero.** Curzi [2026] states the underlying convergence theorem exactly — a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass — which is the theorem that licenses the steady state in Section 8.5 and the asymptote in Section 8.6. Curzi [2026ab] supplies the corpus's template for a postulate with a forbidding clause, $E = G \cdot B + \varepsilon$ with $G = 0 \Rightarrow E = 0$ for all B: the form this paper's H2 takes, in which a structural zero cannot be compensated by any amount of the other factor.

10. Verification and rigour audit

The results are decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and each chain names what it consumes. **If dropping a postulate leaves the result standing, it is not listed.**

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
ambiguity rate	share of carried values readable as control	$[1]$	dimensionless fraction	derived, 383/100{,}000
$\lvert S\rvert$	size of a set an observer can narrow to	$[\#]$	subscribers, addresses, tuples	defined
$\log_2 \lvert S\rvert$	identity content	$[1]$	**bits** (base-2 logarithm of a count)	derived; dimensionless by construction
anonymity set	subscribers consistent with the record	$[\#]$	subscribers	derived as a ratio of two counts
subscribers, addresses, ports	population sizes	$[\#]$	counts	assumed (constructed)
record size	bytes per session record	$[B]$	bytes	assumed (constructed)
log volume	retention flow	$[B\,T^{-1}]$	bytes per day; TB per year	derived
experts, requirement	maintainer-equivalents	$[\#]$	people	assumed / derived
attrition, replacement	rates on the maintainer stock	$[T^{-1}]$, $[\#\,T^{-1}]$	per year; people per year	assumed
lines remaining	size of the buried estate	$[\#]$	lines of code	assumed / derived
migration fraction	share of remainder moved	$[T^{-1}]$	per year	assumed
unit cost	cost to move one line	$[\text{idx}\,\#^{-1}]$	index units per line	assumed (index, no currency)
keep-running cost	cost to leave one line	$[\text{idx}\,\#^{-1}T^{-1}]$	index units per line-year	assumed (index)

Does the bit accounting balance? Identity in bits is the base-two logarithm of a count, so it is dimensionless, and differences of such logarithms are ratios of counts — which is why "bits unresolved" is a well-formed subtraction: $18.932 - 8.000$ is $\log_2(500000/256)$ and equals 10.932 exactly. **The audit records that the anonymity set is a ratio of two counts and is therefore formally dimensionless while being *read* as a count of subscribers**, which is legitimate only because the numerator and denominator are counts of the same kind of thing.

Where an operational unit is missing, the audit says so. The migration cost model is in **index units with no currency attached**, and the source supplies no conversion. The crossing year of 2032 is therefore a property of the *ratio* of migration cost to keep-running cost and survives; the absolute cost figures do not mean anything until an index unit is defined.

Does the maintainer model balance? $E_{t+1} = (1 - a)E_t + r$ requires a dimensionless per step and r in people per step, which is how they are stated. The fixed point r/a then carries dimension $[\#]$, as a maintainer count must.

10.2 Significant figures and epistemic status

- **0.000% is exact**, not a rounded small number: it is a property of a disjoint union and no measurement is involved. **0.383% is exact for the synthetic space** and is an illustrative model output for every other purpose; it is quoted to three decimal places because 383/100,000 is exact by stipulation, and it should not be read as an estimate of anything.
- **The bit figures are exact to the digits shown**, being base-two logarithms of exact counts: $\log_2 500000 = 18.9316$, $\log_2 256 = 8.0000$, $\log_2 16515072 = 23.9773$, $\log_2 1953.125 = 10.9317$, $\log_2 1453.22 = 10.5051$.
- **The carrier parameters are assumed, not measured.** 500,000 subscribers, a 256-address pool, a 64,512-port usable range, a 150-byte record and 48,000 sessions per subscriber per day are stipulated. Every output inherits that status: **exact arithmetic on assumed inputs is not a measurement, and no uncertainty is quoted because there is no estimate to attach one to.**
- **The session-rate proxy is the weakest input.** 48,000 sessions per subscriber per day — stated in the source as 50 new sessions per busy minute over 16 active hours — is a modelling assumption and not an observed rate. It drives case (iii) and the retention volume, and a different assumption moves those figures proportionally without changing the direction of the result.
- **The maintainer and migration figures are illustrative model output and are rounded hard**: 54.5, 2030, 3.29%, 37.6%, 2032. Quoting 15,023,138 lines to eight figures, as the source does, is false precision on a number produced by assumed parameters, and this paper reports it as 37.6% of the core.

10.3 Limits and boundary behaviour

model	limit	behaviour	reading
ambiguity	control tokens $\to 0$ share of namespace	rate $\to 0$ but stays positive	in-band never reaches zero while the namespaces intersect
ambiguity	planes disjoint	rate $= 0$ exactly	the only way to reach zero is the partition
anonymity	pool size $\to$ subscriber count	set $\to 1$, unresolved $\to 0$	one address per subscriber removes the loss entirely

model	limit	behaviour	reading
anonymity	pool size $\to 1$	set $\to$ all subscribers, unresolved $\to 18.932$ bits	full compression: the log names the carrier
maintainers	replacement $r \to a\times$ requirement	steady state $\to$ requirement	the cliff disappears exactly at $r = 11.0$/yr
maintainers	$a \to 0$	steady state $\to \infty$	no attrition, unbounded growth — a pathology, not an ideal
migration	fraction $m \to 1$	remainder $\to 0$ in one step	completion requires migrating everything at once, which is the rewrite of Section 9.2
migration	cost growth $g \to 0$	annual bill falls at $(1 - m)$	the rising bill is entirely due to $g > m/(1 - m)$
migration	any $m < 1$, finite t	remainder > 0	**the asymptote is the model's core result and it is a boundary statement**

The migration model's stopping point is where the two curves cross and nowhere else. With $(1 + g)^t = 3$, $t = \ln 3 / \ln 1.2 = 6.03$ years from 2026, which is the 2032 in the text. **The crossing depends only on the ratio of the initial migration unit cost to the keep-running cost and on g; it does not depend on the core size at all**, which is why the result is a shape rather than a quantity.

10.4 Invariance

The ambiguity rate is invariant under relabelling of the symbol space and under any bijection of the carried values, which is precisely why it establishes the sign and not the magnitude of anything — the bound carried from Curzi [2026]. **The bit accounting is invariant under any relabelling of subscribers and under a change of logarithm base up to a constant factor**; base two is a choice of unit, not of content. **The migration crossing year is invariant under rescaling of the core size and of the cost index**, since it depends only on ratios. **The maintainer steady state is invariant under rescaling of the requirement only if replacement is rescaled with it**, which it is not in the model — that asymmetry is the model's content, not a defect.

Tested at how many scales? **The invariances are algebraic and were checked at exactly the one parameter set reported.** No empirical scale-freedom is claimed anywhere in this paper.

10.5 Analogy discipline

borrowing	source	category	justification
identity as $\log_2$ of a set size	Hartley [1928], Shannon [1948]	**1 — derivation**	the anonymity set is a finite equiprobable selection, which is exactly Hartley's premise; this is **Shannon entropy in bits**, an information quantity, not thermodynamic entropy
entropy of a uniform distribution	Cover and Thomas [2006]	**1 — derivation**	the uniform case is the identity used
identity impersonation	Douceur [2002]	**2 — shared form**	the Sybil result is proved for an identity system without a certifying authority; signalling is not shown to satisfy those premises, and the result is used for its structure
independent-party bound	Lamport et al. [1982]	**2 — shared form**	the $3f + 1$ bound is a theorem about agreement, cited as a prior formalisation of "how many parties are genuinely independent", not applied to signalling
impossibility under asynchrony; the availability/consistency trade	Fischer et al. [1985], Gilbert and Lynch [2002]	**3 — framing**	cited to establish that structural impossibility results exist and are the right genre of claim, never as results about this system
coupled-network fragility	Buldyrev et al. [2010]	**2 — shared form**	the substrate dependency is not shown to satisfy the percolation premises

borrowing	source	category	justification
robust-yet-fragile; percolation	Albert et al. [2000], Callaway et al. [2000], Cohen et al. [2000]	**2 — shared form**	the shape of the tolerance asymmetry is used; the degree-distribution mechanism is not claimed, and Doyle et al. [2005] is the reason it should not be
covariance, not count	Markowitz [1952]	**1 — derivation**	the substrate exposure genuinely is a common factor across nominally independent legs
open design; complete mediation	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	the disclosure result *is* Kerckhoffs's principle; the premise — that effectiveness depends on the partition and not on knowledge — is stated and satisfied
tight coupling; redundancy that reduces safety	Perrow [1984], Sagan [1993]	**3 — framing**	qualitative organisational theory; cited as framing and as a warning, never as formal results
queueing at saturation	Kingman [1962], Hopp and Spearman [2011]	**2 — shared form**	the maintainer pool is not modelled as a queue here; the saturation shape is invoked for intuition only
threshold distribution governs the aggregate	Granovetter [1978]	**2 — shared form**	the maintainer model tracks a mean, not a threshold distribution; the result is invoked as a caveat on the model, not as support for it

borrowing	source	category	justification
performativity of a published model	MacKenzie and Millo [2003], Hacking [1995]	**1 — derivation**	the mechanism is the same one: a description relied upon changes the behaviour of those relying on it, and this is documented with dates and prices
the programme itself	Castellano et al. [2009]	—	cited as the survey that **bounds** what statistical physics applied to social dynamics has established; this paper claims no result within that programme, only its vocabulary

The failure mode this table exists to prevent is letting a category-2 or category-3 borrowing carry a category-1 result's authority. The disclosure result and the bit accounting are category 1 and need no help; the network results are category 2 and are used for shape.

10.6 The postulates

#	statement	status
P1	a system has a control plane and a data plane, as defined in Section 3.1	DEFINITION
P2	in-band means some data value can be interpreted as a control instruction	DEFINITION
P3	out-of-band means the two planes are disjoint, so no data value can be	DEFINITION
P4	identity content is $\log_2$ of the size of the set an observer can narrow to	DEFINITION, CITED `hartley1928transmission`
P5	the effectiveness of a partition is a function of the partition and not of any observer's knowledge of it	DEFINITION
P6	separation places no constraint on who may reach a plane	DEFINITION
P7	the carrier parameters of Section 8.1	POSTULATED (constructed)

#	statement	status
P8	the maintainer and migration parameters of Sections 8.5 and 8.6	POSTULATED (constructed)

10.7 The chain that establishes the disclosure constraint

step	consumes	statement	status
L1	P2	in-band, the ambiguity rate is strictly positive: 383/100,000 = 0.383%	ARITHMETIC
L2	P3	out-of-band, the ambiguity rate is 0/100,000 = 0.000%, exactly	ARITHMETIC
L3	L1, L2	the impersonation class is closed by the partition, not by care within the channel	ARITHMETIC
L4	P5, L2	disclosing the partition leaves the rate at 0.000%, because knowledge is not one of its arguments	ARITHMETIC
R1	L4	a design whose effectiveness depends on concealment fails when the design leaks; a design whose effectiveness is structural does not — Kerckhoffs [1883], Saltzer and Schroeder [1975]	CITED
R2	L3, R1	every element of a channel-separated design is publishable, and non-disclosure is refused as a design premise	DERIVED
L5	P6	separation constrains no party's access to the control plane	DEFINITION
R3	L5, R2	access control on the separated control plane is a second and necessary control — Saltzer and Schroeder [1975] on complete mediation	CITED

Six checkable steps and two citations turn a statement that reads as an ethical preference into an engineering standard. Only P7 and P8 are POSTULATED, and neither enters this chain: **the disclosure constraint rests on definitions and arithmetic alone.**

10.8 The chain that establishes the provenance loss

step	consumes	statement	status
A1	P4	identity of one subscriber among 500,000 is $\log_2 500000 = 18.932$ bits	ARITHMETIC
A2	P4, P7	an address-only observation is one of 256, or 8.000 bits	ARITHMETIC
A3	P7	$256 \times 64512 = 16{,}515{,}072$ simultaneous bindings, or 23.977 bits	ARITHMETIC
A4	P7	$500000/256 = 1953.125$ subscribers share one public address	ARITHMETIC
A5	A1, A4	address-only leaves $\log_2 1953.125 = 10.932$ bits unresolved	ARITHMETIC
A6	P7	500,000 subscribers at 48,000 sessions a day is 24 billion sessions a day	ARITHMETIC
A7	A3, A6	24 billion sessions over 16,515,072 slots is 1,453.2 reuses of each slot a day	ARITHMETIC
A8	A7	after state expiry, $\log_2 1453.2 = 10.505$ bits remain unresolved	ARITHMETIC
A9	A6, P7	24 billion records at 150 bytes is 3.6 TB a day, or 1,314 TB a year	ARITHMETIC
A10	A9	the mapping is discarded because retention is a standing expense that buys the carrier nothing operationally	POSTULATED (economic model)

Every step but A10 is arithmetic on stated counts. A10 is the one genuine assumption, it is an assumption about incentives rather than about mechanism, and it is the step a reader should attack first.

10.9 The chains that establish the two substrate equilibria

step	statement	status
B1	$E_{t+1} = (1-a)E_t + r$ is a first-order linear difference equation — Elaydi [2005]	DEFINITION, CITED
B2	its fixed point is $r/a = 6/0.11 = 54.5$	ARITHMETIC
B3	$54.5 < 100$, so the deficit is a steady state and not a transient	ARITHMETIC
B4	holding the line requires $r = a \times 100 = 11.0$ a year against 6 actual	ARITHMETIC
C1	$R_{t+1} = (1-m)R_t$ with $m = 0.15$	DEFINITION
C2	$R_t = R_0(0.85)^t > 0$ for all finite t	ARITHMETIC
C3	annual bill ratio is $(1-m)(1+g) = 0.85 \times 1.20 = 1.02 > 1$	ARITHMETIC
C4	unit cost reaches the keep-running cost when $1.2^t = 3$, at $t = 6.03$	ARITHMETIC
C5	therefore a rational stopping point exists strictly above zero	ARITHMETIC

10.10 Discrepancies found in the source, printed

One arithmetic inconsistency was found and is reported rather than harmonised. The tabulated remainder at 2046 is 1,550,381 lines, which is $40{,}000{,}000 \times 0.85^{20} = 3.876\%$ of the core — twenty annual migrations counted from 2026. The separately stated residual "after twenty years" is 1,317,824 lines, or 3.29%, which is $40{,}000{,}000 \times 0.85^{21}$ and therefore twenty-one annual migrations. **The two statements are off by one migration year.** This paper reports the source's 3.29% figure as stated, marks it in Figure 4 as the *stated* residual, and records here that the tabulated series gives 3.88% at the same date. **Neither figure changes the result, which is that the remainder is strictly positive for all finite time.**

A second, smaller correction: the source dates the article establishing that a system's interfaces mirror its builders' communication structure to 1967; it appeared in April 1968, and Conway [1968] is cited with the corrected date.

11. Limitations

Every worked result is a constructed model, and none is a measurement. The carrier, the symbol space, the maintainer shop and the migration are all invented, with parameters chosen to be plausible rather than observed. **No empirical dataset was collected and no real network, subscriber, traffic record, institution or codebase appears anywhere in this paper.**

The ambiguity rate carries no information beyond its sign. It is invariant under relabelling of the symbol space [Curzi, 2026] and would take a different value under any other allocation of reserved symbols. **The only part of it that is a finding is that in-band is greater than zero and out-of-band is exactly zero**, and that part follows from the partition rather than from the parameters.

The isomorphism table is a claim of shared form, not a derivation. Each row depends on the assertion that the named system has the separation property attributed to it, and that

must be established per system. **It is not established here for any of the four.**

The session-rate proxy is stipulated and drives two of the reported figures. 48,000 sessions per subscriber per day is a modelling assumption. It should be replaced with a measured rate before any figure derived from it is used outside this paper.

Only a single translation boundary is modelled. A real path may cross several — a subscriber translator, then a carrier translator, then a protocol translator — and each crossing compounds the loss, **so the single-boundary figures are lower bounds on the loss along a multi-hop path, not the whole of it.** The compounding is stated as a direction and is not measured.

Address provenance is not identity. The paper measures the network layer only and says nothing about application-layer identifiers — an authenticated account, a signed session — which can attribute where the network layer cannot and are the actual basis of attribution in most well-run systems. **The network address was never meant to be the identity, and the remedy at the application layer is a genuinely better answer where it is available.**

The standards this paper relies on are not in its bibliography. The numbering plan, the two internet protocol versions, the transition and translation mechanisms, the carrier-grade translation terminology and the shared-address-space allocation are public standards documents, described here from the source manuscript. **No standards document is cited, because none is in `bib/external.bib`.** Every technical claim about them requires verification against the governing document, including the current status of each, the obsoletes relationships among them, and the deprecation status of the older tunnelling mechanisms. This is a real gap and it is not closed here.

The exhaustion date and the public 2020 episode are described, not cited. The central registry's exhaustion of its free pool in 2011, the staggered later exhaustion of the regional registries, the 2020 unemployment-system failures and the April 2020 appeal for volunteer programmers are all described from the source manuscript. **The bibliography contains no contemporaneous reporting and no press sources, so none of these is cited**, and each requires verification against contemporaneous sources before use.

The scale figures for legacy transaction-processing code are neither cited nor asserted. They are attributed in the source to 2017 reporting that is not in the bibliography. They are used here only for order of magnitude and **must not be restated as a current measurement**.

The 2032 stopping point and the 2030 cliff are properties of assumed rates. They are exact functions of stipulated parameters, they carry no uncertainty because there is no estimate in them, and they carry no authority beyond the assumptions.

11.1 Rigour checks not met, listed by name

1. **No as-of date and no source, because nothing was measured.** Every figure derives from a constructed parameter set. Any application of these models to a real carrier, shop or codebase requires both.
2. **No uncertainty is reported anywhere**, because nothing is estimated. This is the absence of empirical content rather than precision.
3. **Model comparison was not performed.** No alternative model was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed. The three models are illustrations of inequalities, not fits, and their conclusions follow from the inequalities rather than from goodness of fit.
4. **The cost models carry no operational unit.** Index units with no currency attached; only ratios survive.
5. **The isomorphism is unverified per system**, as above.
6. **Two borrowings are category 3 (framing) and are used only as framing**: Perrow [1984] and Fischer et al. [1985]. Neither is a result about this system and neither is treated as one.
7. **One source arithmetic inconsistency was found** and is printed in Section 10.10 rather than harmonised.

8. **A10 is the chain's only real assumption** and it is about incentives rather than mechanism. A jurisdiction that mandates retention breaks it, and the model says nothing about how often that is the case.
9. **No distributional or scaling claim is made, and the Clauset–Shalizi–Newman procedure was therefore not run** [Clauset et al., 2009]. Any restatement of this paper that reaches for a heavy-tail or scale-free claim about sharing ratios, session distributions or the network results borrowed in Section 9.1 must run it first, and must read Broido and Clauset [2019] on how weakly social networks support such structure.
10. **The three models fail the calibration-and-validation checklist** of Bruch and Atwell [2015]: none is calibrated against observed data, none is validated out-of-sample, and none has a sensitivity analysis beyond the limits reported in Section 10.3. They are offered as demonstrations that a stated mechanism suffices to produce a stated shape, which is one of the legitimate uses Epstein [2008] enumerates and is not prediction.
11. **The maintainer model tracks a mean rather than a distribution of thresholds** [Granovetter, 1978], and therefore gives the optimistic answer.
12. **This paper does not invoke the framework's reflexive law and therefore does not inherit the reflection problem** [Manski, 1993]. No result here rests on an endogenous social effect estimated from observation, and no such effect is claimed. **Where downstream work couples these results to the reflexive law, that caveat applies there and is not answered here**: a linear-in-means reflexive specification is not identified from observational data, and the remedies — randomisation, an instrument, partial-population variation, or stipulating and defending the reference group — all carry a price. The disclosure result's own reflexive content, that a published architecture changes the behaviour of those relying on it, is asserted on the strength of a documented case [MacKenzie and Millo, 2003] and not estimated from data here.

12. Conclusion

This paper establishes the channel-separation principle and its disclosure constraint in the form the rest of the corpus cites, and the following statements are the fixed text of those results.

R1 — the channel-separation principle. In-band architectures admit an impersonation class that no care within the shared channel can close, and out-of-band separation closes it structurally — measured at 0.383% in-band ambiguity against 0.000% out-of-band over 100,000 carried values.

R2 — the disclosure constraint. Channel separation is strengthened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable; **non-disclosure is refused as a design premise, not merely discouraged.** This is Kerckhoffs [1883]'s principle, stated in 1883, and it is what makes the constraint an engineering standard rather than a preference.

R3 — provenance loss at the carrier boundary. 18.932 bits of identity entering becomes 8.000 bits observed from an address alone, and 23.977 bits when address and port are both captured.

R4 — the attribution-set result. With an address-only log the anonymity set is 1,953.1 subscribers; with address-plus-port and live session state it is 1; and after state expiry it is 1,453.2. **An address is evidence of a pool, not of a person.**

R5 — the constructed maintainer cliff. 11% annual attrition against a flat requirement of 100 maintainer-equivalents needs 11.0 replacements a year against 6 actual hires — a deficit of 5.0 a year behind an apparent 20-maintainer surplus, landing at a steady state of 54.5 and crossing below the requirement in 2030.

R6 — the constructed migration asymptote. Migrating 15% of the remaining 40-million-line core each year at a per-line cost rising 20% a year leaves 3.29% after twenty years, with total cost rising about 2% a year and a rational stopping point near 2032 at 37.6% still buried.

Counter-result. Separation is necessary and not sufficient — **a separated control plane trusted because it is separate is the failure mode** — and two attractive simplifications are refused outright: that the internet depends on copper, when the durable dependency is logical topology rather than electrical continuity; and that a rewrite resolves the legacy layer, since a rewrite trades a known correct system for an unknown one over exactly the undocumented behaviour that matters, at the moment of least remaining expertise.

What the paper adds to the corpus's instrument. A concentration measurement on one axis can hide a common-mode dependency on another. The effective-count instrument of Curzi [2026] counts perimeters and cannot see whether two independent perimeters rest on the same substrate generation. **Substrate concentration is a real exposure alongside perimeter concentration, and it must be measured separately or it will not be measured at all.**

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every worked result in this paper — the symbol-space demonstration, the constructed carrier, the maintainer model and the migration model — is **CONSTRUCTED** or **SYNTHETIC** and is labelled as such at each point of use. The numerical results are exact computations on those stipulated inputs. **No real network, subscriber, traffic record, institution, product or codebase appears anywhere in this paper, and no allegation is made about any of them.**

All figures were produced by the scripts named in their captions (`figs/src/CCP-066_fig01.py` through `figs/src/CCP-066_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. No figure plots a number that does not appear in the text.

Technical standards, the address-exhaustion date, the 2020 public episode and the legacy scale figures are described from the source manuscript and are not cited to the bibliography, which contains no standards documents and no press reporting. Section 11 lists each affected claim. Any reader relying on them must verify them against the governing documents and contemporaneous sources.

The author's own systems project is recorded here as the author's stated position and not as an examined artefact. The author states that the class of problem described in Sections 8.5 to 8.7 is at bottom a *representation* problem — the buried systems speak one language and the modern tooling another — and that the tractable move is not replacement but a representation-adapter layer letting modern tooling read and drive the buried systems in place. The author further states that a systems project exists to instance that direction, together with canonicalised settlement and the channel-separation principle built into an operating system's own architecture, and that it was **deliberately left half-finished**. The repository is `https://github.com/sykomiked/ZXV0`. **No representation is made about the contents, licence, security or functional status of that repository; it has not been examined for this paper, and nothing in this paper's argument depends on the project's completion.** The half-finished status is recorded as the author's stated position rather than as a defect: an unfinished implementation of a correctly diagnosed class of solution is a different thing from a finished implementation of the wrong one.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest, other than that the systems project described in the availability statement above is the author's own; it is recorded as a stated position and is not relied on for any result.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

No operational content

This paper contains no operational content of any kind: no tone, sequence, code, method, or anything that could be used to inject signalling into, or attack, any network. The historical material is recounted only to establish that in-band control was structurally reachable. Present-day signalling vulnerabilities are described only at the level of principle, and they are a matter of illicit access to control networks that nothing here describes or could enable. **The principle stated here is for building systems, not for breaking them.**

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It describes architectural principles, addressing systems and software substrates. No recommendation is made in respect of any particular person, institution, product or jurisdiction, and no allegation is made about any of them. Data-retention obligations differ by jurisdiction and change; any retention window designed on the basis of Section 8.3 requires confirmation with qualified counsel.

Appendix A. Claims requiring verification against primary sources

The following are described in this paper from the source manuscript and **are not cited to the bibliography, which contains no standards documents, no press reporting and no jurisdiction-specific material.** Each requires verification against the governing document before any reliance.

1. The characterisation of the fifth-numbered international signalling system as in-band, with control tones in the voice band, and of the seventh as out-of-band common-channel signalling adopted across the 1980s. Confirm the exact recommendation numbers and the adoption and deployment dates; this paper cites the systems by their common designations only and asserts no recommendation number.
2. The international public telephone numbering plan and its mobile-subscriber companion: confirm the in-force edition, the exact title, and the fifteen-digit maximum.
3. The two internet protocol version specifications, the transition mechanisms, the stateful translation and name-synthesis specifications, the well-known translation prefix, and the edge-plus-core translation specification. Confirm each designation, title and current status, and confirm which document currently governs the stateless translation algorithm, since the original has been obsoleted.
4. The tunnelling mechanisms named in passing. Confirm the governing document and current deprecation status of each; several early transition mechanisms have been deprecated.

5. Carrier-grade translation terminology, the reserved shared-address-space allocation, and per-session logging requirements, all described generically here. Confirm the relevant specifications and any applicable data-retention obligation in each jurisdiction of operation before designing a retention window.
6. The statement that the central registry exhausted its free pool of older-protocol blocks in
   2011. Confirm the exact date of the final allocation and the distinct, later exhaustion dates of each regional registry, which differ by years.
7. The proportions of the copper last-mile installed base, which vary widely by country and are changing as fibre reaches the premises. **The load-bearing correction — logical, not electrical, substrate — does not depend on any specific proportion and should be preserved in any restatement.**
8. The 2020 unemployment-system failures and the April 2020 appeal for volunteer programmers: confirm the exact date and wording of the appeal, which other jurisdictions reported the same difficulty, and the specific systems and languages involved. The general phenomenon is well documented; the specifics require verification.
9. The legacy scale figures — the share of card-swipe transactions, the share of banking systems, the line count and the daily commerce volume. **These are attributed in the source to 2017 reporting, are not asserted as current fact, and are not cited here because the originating article is not in the bibliography.** Confirm the article, its date, and the primary source of each figure before quoting any of them, and carry the attribution and the date with them.
10. The characterisations of the two legacy language families and of mainframe transaction monitors are generic. No claim is made about any named institution's use of either, and any such claim requires independent establishment.

All numerical results in this paper were computed from the stated constructed inputs at full precision and rounded only for printing.

Chapter 67

A Concentration Atlas for Distributed Ledgers: Validator Herfindahls, the Utility Ordinal, and Dwell Time as the Freeze Variable

Abstract. We apply the corpus's concentration instrument to nine public ledgers without modification, since an inverse-HHI effective count is indifferent to what the shares describe. Measured on stated validator, council or pool sets, the effective counts range from a curated 35.0 validators (HHI 0.028571, an explicit ceiling rather than an observation) and 39.0 council members (0.025641) down to 6.00 organisations (0.166667) and 5.94 entities (0.168400). Bitcoin mining measures HHI 0.1900 and 5.26 effective pools with a 30 per cent leader and a 56.0 per cent top two, against the ceiling 1/s_max^2 = 11.11 that the leading share alone imposes. A second axis, utility-as-function, is defined narrowly and badged as an ordinal rather than a score, with Bitcoin at 1/9 and a general virtual machine at 9/9; the paper requires the axis to be printed with the rank every time and denies that programmability is a quality gradient, since a minimal ledger cannot express a bug it has no opcode for. Base-layer throughput is stated to its parameters, about 7.4 to 11.9 transactions per second. The store-versus-rail question is settled numerically by dwell: a five-second hop is 1.585e-07 of a year while value rested for thirty days is 0.0822, a ratio of roughly 518,400 to one, so the freeze property that disqualifies a rail as a store is nearly irrelevant to it as transit.

Keywords: validator concentration; curated trust sets; utility ordinal; proof-of-work pools; dwell time; freeze property; central bank digital currency; pilot versus production

Series: D. Structure and Resilience **Paper:** CCP-067

1. Introduction

A concentration index is indifferent to what its shares are shares of. That is a property of the arithmetic and not a claim about the world, and it means an instrument built to count independent jurisdictions counts independent validators, independent council members, independent mining pools or independent curators without modification. This paper applies the corpus's concentration instrument to nine public settlement ledgers, states exactly what the resulting numbers mean, and states more carefully what they do not.

The paper has five separable contributions.

The instrument transfers unchanged. Measured on stated validator, council or pool sets, the effective counts run from a curated 35.0 validators (HHI $= 0.028571$, an explicit design ceiling rather than an observation) and 39.0 council members (0.025641) down to 6.00 organisations (0.166667) and 5.94 entities (0.168400). Nothing in the derivation of the index cares that its original application was to jurisdictions, and no new theory is required to read a ledger.

The curated-list collapse is the sharpest result the transfer produces. A trust set admitted by a single curating party has HHI $= 1.0000$ and **one** effective curator, against five equal independent operators at 0.2000 and 5.00. **The concentration is not in who runs the infrastructure; it is in who decides which infrastructure the network defaults to trusting**, and a network reporting the first while the second binds has made the same error Curzi [2026] measures on a payment rail, where a naive correspondent index of 0.302400 — 3.306878 effective correspondents — collapses to 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency.

Proof-of-work concentration is measured on pools, not on machines. A constructed pool distribution gives HHI $= 0.1900$ and 5.26 effective pools at a $30\%/26\%$ top two, against the ceiling $1/s_{\max}^2 = 1/0.30^2 = 11.11$ that the leading share alone imposes.

A second axis is defined and then deliberately demoted. Utility-as-function — what settlement logic a rail can express and what it settles — is stated as an **ordinal**, not a score, running from $1/9$ for a minimal ledger to $9/9$ for a general virtual machine. **The axis is not oriented: a 9 is more expressive than a 1 and is not better than a 1**, because a minimal ledger cannot express a bug it has no opcode for. The rank must be printed with the axis named beside it every time, and no arithmetic on the differences is licensed.

Dwell time settles the store-versus-rail question numerically. A five-second hop is 1.585×10^{-7} of a year (0.0000159%); value rested for thirty days is 0.0822 of a year (8.2192%); the ratio is $2{,}592{,}000/5 = 518{,}400$. **The freeze property that disqualifies a rail as a store is almost irrelevant to it as transit, and the entire difference is dwell.**

Why these sit in one paper. They are one instrument at four scopes and one refusal repeated. The instrument is Curzi [2026]'s: the sum of squared shares, its reciprocal read as an effective count, and a bloc collapse applied before the squaring. What the paper adds is that each consensus mechanism *names its own concentration axis* — proof-of-work names pools, bonded-stake systems name staking operators, a fixed producer set names itself, federated agreement names the curated trust list, council governance names the council — and that once the axis is named the measurement is arithmetic and nothing new. The refusal repeated is that none of these numbers is a fact about a running network unless it carries a source and a date.

The counter-results are stated first because they are what makes the rest usable. The utility ordinal is not a quality scale. The freeze control on a settlement instrument sits with its issuer and follows the instrument across rails, so diversifying rails buys nothing against it. Participating in a pilot is not settling production value. **And every live concentration figure is time-varying: a concentration measure without an as-of date is not a measurement**, so this paper measures constructed and stipulated distributions only and defers every live number to a dated register.

2. Hypotheses

Six hypotheses with their falsifiers, and three statements that are not hypotheses and are labelled as such. Platt [1964]'s standard applies: a hypothesis earns its place by naming what would kill it.

H1 — the transfer hypothesis. The concentration instrument applies to a distributed ledger's participant set without modification, because its derivation does not depend on what the shares are shares of. *Predicted:* an effective count computed on validator, council or pool shares behaves exactly as one computed on jurisdictional shares — returning n for n equal

shares, bounded above by $1/s_{\max}^2$, and falling under a bloc collapse. *Falsified by:* a share basis on a ledger for which the numbers-equivalent property fails, or a case in which the bloc collapse raises rather than lowers the count.

H2 — the dwell hypothesis. Freeze exposure on a settlement rail is proportional to dwell time and to nothing else, so the store-versus-rail distinction is a quantitative rather than a categorical one. *Predicted:* at seconds-scale finality a hop is 1.585×10^{-7} of a year against 0.0822 for a thirty-day rest, a ratio of $518{,}400$. *Falsified by:* an exposure that does not scale with dwell — for example a freeze whose probability depends on the transacting party rather than on the time the value is resident.

H3 — the pool hypothesis. On a proof-of-work network the coordinating unit is the pool and not the machine, so a count of participants overstates independence. *Predicted:* a constructed ten-pool distribution with a 30% leader gives HHI $= 0.1900$ and 5.26 effective pools against ten nominal, and the leading share alone caps the effective count at 11.11. *Falsified by:* a demonstration that pool membership imposes no coordination — that a pool cannot direct the work of its members — in which case the machine count would be the right basis.

H4 — the ordinality hypothesis. Utility-as-function admits an order and no metric, so the differences between its ranks carry no information. *Predicted:* any order-preserving relabelling of the nine positions leaves every claim this paper makes about the axis intact, and no claim in this paper survives being restated as a difference or a ratio of ranks. *Falsified by:* an operation on the axis whose result is invariant under order-preserving relabelling and which is not derivable from the order alone — which would show the axis carries more than ordinal information.

H5 — the curation hypothesis. Where a trust set is admitted by one party, the effective count of independent admission decisions is one, however many operators the set contains. *Predicted:* a single-curator set gives HHI $= 1.0000$ and 1.00 against five equal independent operators at 0.2000 and 5.00. *Falsified by:* a curated set in which removing or reweighting an entry requires the assent of more than one party, which would make the curation axis genuinely plural.

H6 — the throughput hypothesis. Base-layer throughput on a minimal ledger is fixed by two protocol parameters and a transaction size, so it is computable and is not a matter of opinion. *Predicted:* at approximately 226 virtual bytes per transaction against approximately 10^6 virtual bytes per block on a ten-minute interval, approximately 7.4 transactions per second; at approximately 140 virtual bytes, approximately 11.9. *Falsified by:* an observed sustained base-layer rate outside that band at those parameters.

Not hypotheses, and labelled as such.

- *The bloc assignment of any network* is a **modelling choice**. Which parties coordinate is stipulated, not estimated; Section 3.3 states what that costs.
- *The nine-position utility ordering* is a **definition** fixed by this paper's own construction of the axis. It carries no empirical weight and is not offered as evidence for anything.
- *The three-axis frame* is a **classification scheme**, not a finding. Its value is that it forces the axis to be named beside the rank; it predicts nothing.

3. Method

3.1 Which effective count, stated exactly

Every effective count in this paper is $N = \text{HHI}^{-1}$, the reciprocal of the sum of squared shares. That quantity is the Hill number of order two [Hill, 1973, Jost, 2006]: the number of equally-sized units that would produce the observed index. It is the reciprocal of Simpson [1949]'s index, the effective number of parties of Laakso and Taagepera [1979], and the numbers-equivalent reading attributed to Adelman [1969]; the index is Herfindahl [1950] and Hirschman [1964], and the bands at which competition authorities read it are policy choices

that have moved [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. The exponential of Shannon entropy [Shannon, 1948, Cover and Thomas, 2006] is the same family at order one, and HHI^{-1} is the exponential of the Rényi entropy of order two [Rényi, 1961], which is where the participation-ratio name used by Curzi [2026] comes from.

The corpus's other effective count is not a Hill number and is not used here. The affine form $N_{\text{eff}} = 1 + (N-1)u$ of Curzi [2026] is a linear interpolation between 1 and N; it is not a numbers-equivalent of any index, and no literature in ecology, economics, political science or information theory contains it. Curzi [2026] runs the same verification chain on both and lets the affine one fail visibly. **Wherever this paper says "effective count" it means HHI^{-1}, and where the affine form is referred to it is named and marked as the corpus's own construction.**

Two standing bounds are used throughout and are stated here so they need not be re-derived: $s_{\max}^2 \le \mathrm{HHI} \le s_{\max}$, so $N \le 1/s_{\max}^2$ — **the largest single share alone caps the effective count** — and $N \le n$ for n units, with equality only at equal shares.

3.2 Each consensus mechanism names its own concentration axis

The instrument requires a share basis, and choosing it wrongly is the whole of the error this paper is written against. The share basis is not a free choice: it is dictated by the mechanism, because the mechanism defines what a coordinating unit is.

mechanism family	what the right to append is tied to	coordinating unit, hence share basis
proof-of-work	expended computation	the **pool** — many machines directed by one operator's template
bonded-stake	committed capital	the **staking operator, custodian or pooled-stake protocol**
fixed producer set	election to a capped set of producers	the **producer set itself**, which is enumerable
capped Byzantine-fault-tolerant set	stake within a capped active set	the **active set**, weighted by stake, capped by governance
federated agreement	overlapping declared trust sets	the **curator of the default trust set**
council governance	membership of a governing body	the **council**, capped by constitution

Read the table as one sentence repeated six times: name the unit that can be moved by a single decision, then square its shares. A count of machines on a pooled network, of individual depositors on a bonded-stake network, or of node operators on a network whose trust set is curated by one party is a count of participants and not a measurement of failure independence.

3.3 The bloc collapse, and the identification problem it carries

The collapse is a variance identity and not a grouping convenience. Following Markowitz [1952], let w_i be the share held by participant i and X_i a unit-variance shock; the aggregate shock has $\mathrm{Var}(R) = \sum_i \sum_j w_i w_j \rho_{ij}$. Under independence this is $\sum_i w_i^2$, the naive index; under perfect correlation inside groups and independence across them it is $\sum_b W_b^2$, the bloc index. **The two are one variance under two correlation assumptions, and the reciprocal is the effective number of independent shocks.** The general form $1/(w'Rw)$ is the similarity-sensitive diversity of order two [Leinster and Cobbold, 2012], whose additive relative is Rao [1982]'s

quadratic entropy. Curzi [2026] establishes the identity and verifies both endpoints; this paper reuses it.

That correlations rise under stress is measured [Longin and Solnik, 2001, Ang and Chen, 2002], so **the effective count falls exactly when it is needed**; the ecological name for the same variable is synchrony [Loreau and de Mazancourt, 2008] and the ecological demonstration that effective count buys stability is Schindler et al. [2010]'s. The contrary literature is read alongside: Doak et al. [1998] show that diversity–stability correlations can arise from statistical averaging with no mechanism, and May [1972] that increasing diversity destabilises randomly assembled systems. **Portfolio arithmetic is not by itself evidence of a mechanism**, and none is claimed here.

The identification problem must be stated where the collapse is introduced. A bloc assignment is a reference-group specification, and the framework's reflexive law — participants influence the aggregate while the aggregate constitutes them — is a linear-in-means reflexive specification whose endogenous effect Manski [1993] proves is **not identified from observational data**. Shalizi and Thomas [2011] reinforce the point: influence and selection are generically confounded in observational network data, which is exactly the data a validator set offers. **The remedy adopted here is stipulation with a defence**, on the template of Brock and Durlauf [2001]; randomisation, an instrument and partial-population variation are all unavailable. **The price is that every bloc-level statement in this paper is a modelling position and not an identified empirical result**, and Section 14 records it.

The instrument is also exposed to its own publication. Goodhart [1975] and Campbell [1979] state what happens to a measure adopted as a target; MacKenzie and Millo [2003] documents, with dates and prices, a model that made its own assumptions true after adoption; Lucas [1976] states the consequence for parameters fixed before publication. **A published decentralisation metric is a target, and nothing in the arithmetic prevents a network from optimising the metric rather than the property.** The only defence offered is the reporting standard of Appendix A.

3.4 The utility ordinal: its scale type, and what that forbids

The second axis is defined narrowly because it is the one most easily corrupted. **Utility-as-function is what settlement logic a rail can express and what it settles.** A network with a general virtual machine can express arbitrary settlement logic; a network with a fixed instruction set and a handful of native operations can express those and no more; a network with a constrained script can express value transfer and little else. That is a genuine ordering.

It is an ordinal scale in Stevens [1946]'s sense, and this paper states the consequence rather than leaving it to be discovered. An ordinal scale is invariant under any order-preserving transformation, so **means, differences and ratios of its values are not licensed operations**. Position 9 is not three times position 3; the distance between 1 and 3 is not comparable to the distance between 7 and 9; and an average of positions across networks is not a quantity. Krantz et al. [1971] sets out what must be true before a quantity can be said to exist and Narens [1996] what a scale type licenses; Luce [2002] is the reason the question is not settled by convention.

The axis is also not oriented. Higher is more expressive, not better. A general virtual machine can express any settlement logic and therefore any settlement error; a minimal ledger cannot express a bug it has no opcode for. **Minimalism at the bottom of the ordinal is a design achievement where the design goal is conservatism, and reading the ordinal as a quality gradient inverts the engineering.** This paper therefore requires the axis to be printed with the rank every time: the number without the axis is not a measurement.

The scalar-reduction habit this axis instantiates is a framework-level limitation and is inherited rather than restated. Curzi [2026] names it once, at framework level, as one objection appearing in two domains rather than two objections: where the source description is a pattern across several jointly varying features, the framework replaces it with a single number and does arithmetic on the number, and the arithmetic's validity does not protect the reduction that produced it. **That is exactly what a nine-position utility rank does to a design space**

with at least four independent dimensions — expressiveness, throughput, finality semantics and governance surface — and this paper concedes the objection in that form and points at its statement rather than repeating it. Michell [1997] is the general charge, that quantitative structure is assumed where it was never tested, and it is the strongest single objection to this framework; Luce and Tukey [1964] is the conjoint-measurement test that would settle it and **it was not run**.

Curzi [2026m] reaches the structurally parallel result in another domain: because its moment equation contains a division and a multiplication, ordinal inputs demote it to a heuristic ordering that may not be printed as a fraction or computed. Curzi [2026t] states what survives such a demotion — the limiting cases, the fixed point, the sign, and the ordering, all of which need only ordinal information — and this paper presupposes that result rather than rederiving it. **What survives here is the order and the fact that the axis is unoriented. Nothing else does.**

3.5 Dwell time as the freeze variable

The corpus's standing rule is that a rail is not a holding, and that freeze exposure on a transit asset is an exposure-window problem rather than a custody problem. This paper makes the rule quantitative. Let λ be a per-unit-time hazard of interruption and w the dwell — the time value is resident on the rail. Expected exposure is λw to first order, so **the entire difference between a rail and a store is** w, and the store-versus-rail question is quantitative rather than categorical.

The freeze control itself is a separate object from the rail, and conflating them is the counter-result of Section 11.7. Where a settlement instrument's issuer can immobilise a balance, that control follows the instrument across every rail that carries it, so **diversifying rails does nothing whatever to it**. The disclosure literature is the right frame for the transparency side: a fully public transfer record is the opposite of concealment, and a structure built to be publishable is indifferent to it by construction — which is Kerckhoffs [1883]'s principle, restated as *open design* by Saltzer and Schroeder [1975] and adopted by Curzi [2026] as a hard design premise: **channel separation is strengthened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable and non-disclosure is refused as a design premise rather than merely discouraged.** Brandeis [1914] is the older policy instinct, and the automatic-exchange and anti-money-laundering regimes [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012] have since removed non-disclosure from the set of available design parameters in any case.

3.6 What is described, what is constructed, and what is cited

Every distribution measured in this paper is either a protocol constant, an equal-weight ceiling derived from one, or a CONSTRUCTED illustration. No live validator set, stake distribution, vote distribution, hashrate distribution or council roster is measured, because all of them move — some weekly — and **a concentration measure without a source and an as-of date is not a measurement.** Every such figure is deferred to the dated register of Appendix B.

Consensus-protocol specifications are not in this paper's bibliography. The whitepapers, consensus papers, improvement proposals and standards documents on which the source manuscript's network descriptions rest are public technical documents cited there by designation. **The bibliography contains no standards documents and no protocol specifications, so none is cited here**, and every protocol claim is described from the source manuscript rather than asserted.

The networks are consequently de-branded. Following the convention of Curzi [2026], where a named system's characteristic is relied upon and cannot be supported from the bibliography, the name is dropped and the characteristic is kept: *a federated-agreement ledger with a curated default trust list of about thirty-five validators*, *a council-governed consortium*

ledger with a constitutional cap of thirty-nine members, *a delegated-proof-of-stake network with twenty-seven fixed producers*, and so on. **The functional descriptions are precise enough to identify what is being measured and carry no claim about any named network.** The single exception is the proof-of-work network at the bottom of the utility ordinal, which the abstract of this paper names as Bitcoin because Curzi [2026] and the corpus's citation record refer to the result by that name. **It is referred to in the body by function — a minimal-script proof-of-work ledger — and its protocol parameters are likewise described from the source manuscript and are not cited.** Appendix B records what the source names and what would have to be verified before any name is reattached.

What *is* cited, and genuinely supports what it is attached to: the concentration literature of Section 3.1; the portfolio and ecological literature of Section 3.3; the distributed-systems results of Section 5.3; the measurement-theory literature of Section 3.4; the disclosure principle of Section 3.5; and the identification, scaling and modelling literature of Sections 3.3, 13 and 14.

4. The atlas, de-branded and measured

Nine networks, ordered by the utility ordinal, each with the concentration axis its mechanism dictates. **Every effective count in the right-hand column is either an equal-weight ceiling implied by a protocol constant or a CONSTRUCTED illustration, labelled as such; none is a measurement of a running network.**

#	network, by function	consensus family	bloc character	utility	transit/store	concentration axis
1	minimal-script proof-of-work ledger	proof-of-work	non-aligned by issuance; pool-dependent on hashrate	1/9	store-oriented	pool share
2	federated-agreement settlement ledger, curated default list	federated agreement	issuer-centric	3/9	transit	curator of the default list
3	federated-agreement remittance ledger, quorum anchors	federated agreement	issuer-centric	3/9	transit	tier-one anchor organisations
4	programmable sidechain of family (2)	family (2) variant	family-adjacent; **undetermined**	5/9	transit	**undetermined**
5	council-governed consortium ledger	asynchronous BFT gossip	consortium	6/9	transit (enterprise)	council membership, capped
6	capped-BFT interchain routing hub	BFT proof-of-stake	diffuse; bridge	6/9	transit / routing	stake within the capped active set
7	fixed-producer-set network	delegated proof-of-stake	East-leaning	7/9	transit	the twenty-seven producers
8	high-throughput proof-of-stake payments network	verifiable-delay clock + stake	Western-venture-leaning	8/9	transit	stake-weighted minimum coalition
9	general-virtual-machine settlement layer	proof-of-stake with a finality gadget	Western-leaning, diffuse	9/9	mixed	staking-entity share

Three columns and three warnings. **The utility column is an ordinal and only an ordinal.** The transit/store column is a statement about what a design invites and is not a recommendation. **The bloc column is a stipulated assignment, not an identified effect** (Section 3.3), and row 4 is left undetermined in print because the documentation the source manuscript relies on does not support a call — **declining to guess is the standard, and it is exercised here.**

5. Results: H1 — the instrument transfers unchanged

5.1 The measured spread

basis	HHI	effective count	status
capped council at its constitutional cap, equal weight	0.025641	39.0	ceiling implied by a protocol constant
curated default trust list, equal weight	0.028571	35.0	ceiling implied by a stated list size
capped BFT active set at its governance cap, equal weight	0.005556	180.0	ceiling implied by a governance parameter
fixed producer set, equal weight	0.037037	27.0	ceiling implied by a protocol constant
tier-one anchor organisations, equal weight	0.142857	7.00	ceiling
tier-one anchor organisations, constructed unequal	0.166667	6.00	**CONSTRUCTED**
capped BFT active set, constructed top-heavy stake	0.025481	39.2	**CONSTRUCTED**
fixed producer set, constructed concentrated vote	0.053946	18.5	**CONSTRUCTED**
staking entities, constructed shares	0.168400	5.94	**CONSTRUCTED**
proof-of-work pools, constructed shares	0.190000	5.26	**CONSTRUCTED**

The constructed unequal anchor vector is $2/7 = 28.5714\%$ against six equal shares of $5/42 = 11.9048\%$, which gives $(2/7)^2 + 6(5/42)^2 = 0.081633 + 0.085034 = 0.166667$ exactly, so $N = 6.00$ against the seven-member ceiling of 7.00. **H1 is supported: every row behaves exactly as the instrument does on jurisdictional shares — returning n at equal weight, falling below n whenever shares are unequal, and never exceeding $1/s_{\max}^2$.**

The reading that matters is the gap between a ceiling and a distribution. A design that caps its active set at one hundred and eighty has capped its own effective count at one hundred and eighty before a single unit of stake is bonded; the honest number is the stake-weighted one and it sits below the cap, because stake concentrates toward the top of a set. **A cap is an upper bound the protocol guarantees and a distribution is what the network has, and reporting the first as though it were the second is the error the whole paper is written against.**

5.2 R5 — the curated-list collapse

The sharpest instance the transfer produces, and it is a two-row table.

```
single-curator trust set          HHI = 1.0000   ->  effective curators  = 1.00
five equal independent operators  HHI = 0.2000   ->  effective operators = 5.00
```

Suppose thirty-five validators each run honest, independent, geographically dispersed infrastructure, and suppose all thirty-five appear on a default list published and maintained by one organisation, and suppose participants follow that list because following it is the path of least resistance. **The naive reading squares thirty-five roughly equal shares and reports 35.0. The bloc reading asks whether a single decision reaches all thirty-five, and the answer is that the list publisher's decision to add, remove or reweight an entry does exactly that.**

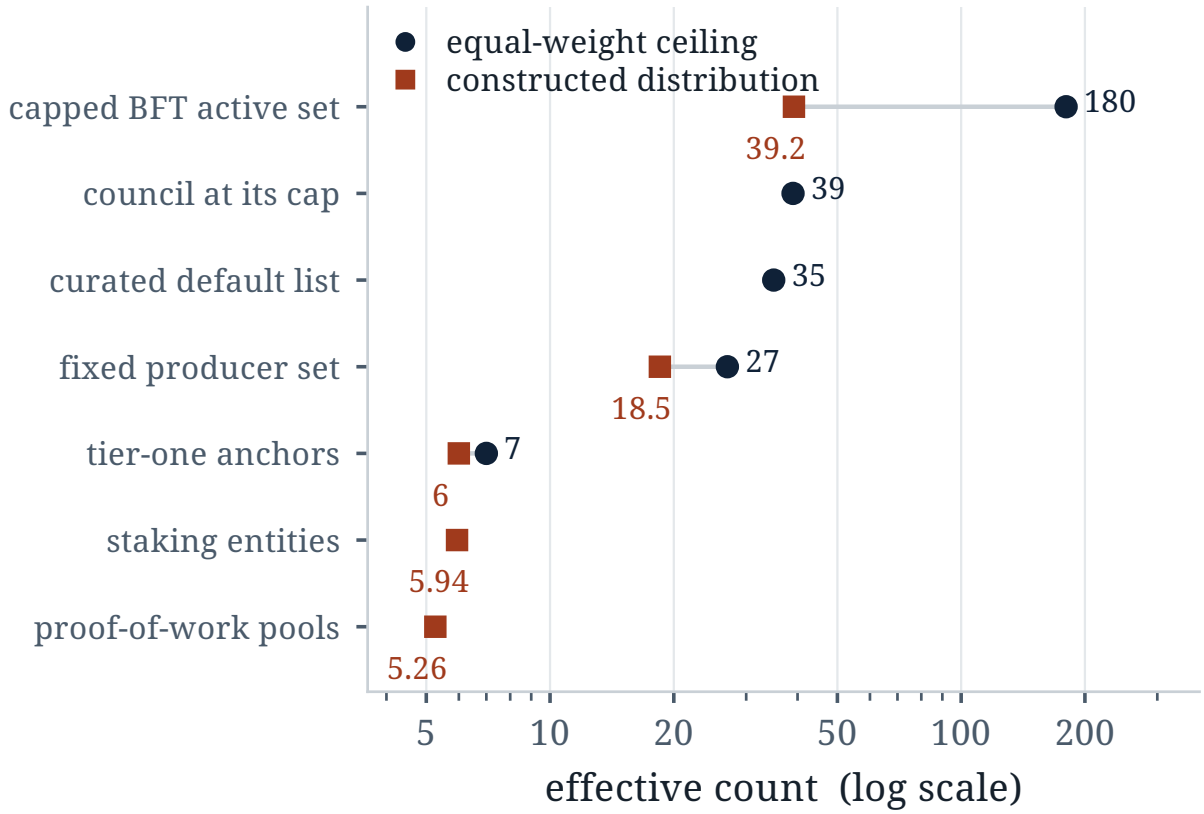

Figure 67.1: **A ceiling is not a measurement.** Effective counts on six ledger participant sets: the equal-weight ceilings implied by protocol constants (hatched) against constructed unequal distributions (solid), showing the gap the ceiling conceals — a 180-member capped set falls to a constructed 39.2, a 27-member fixed producer set to 18.5, and a seven-member anchor set to 6.00. Ceilings are derived from stated protocol or governance parameters; unequal distributions are CONSTRUCTED and are not measurements of any running network. Script `figs/src/CCP-067_fig01.py`.

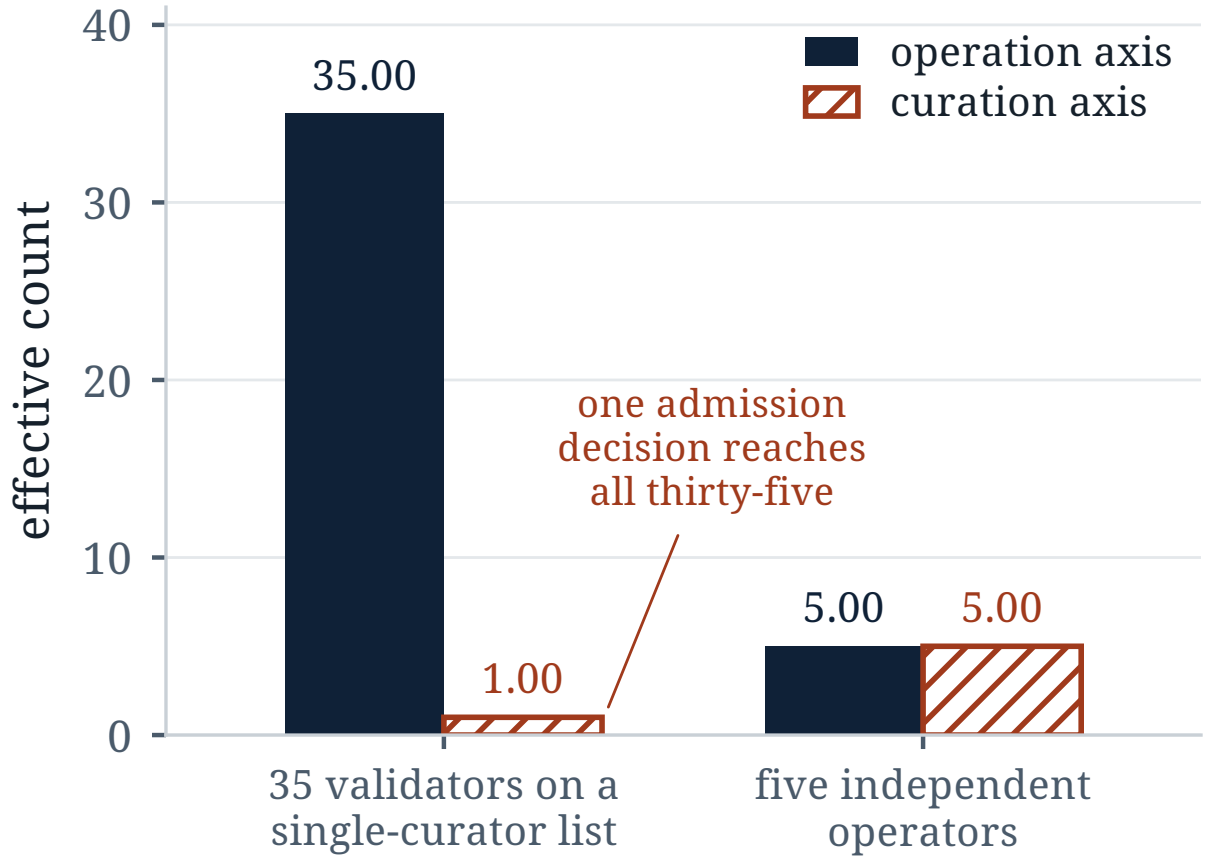

Figure 67.2: **Two questions about one validator set.** Thirty-five independently operated validators give an effective count of 35.0 on the operation axis and 1.00 on the curation axis, because one party admits entries to the default trust list; five genuinely independent operators give 5.00 on both. The gap between the two readings is the finding. Ceilings from stated list sizes; the single-curator and five-operator rows are SYNTHETIC endpoints of a spectrum. Script `figs/src/CCP-067_fig02.py`.

On the list-curation axis the effective count is not thirty-five; it is one, and the two numbers describe the same validators under two different questions about who can move them together. H5 is supported.

The two rows are endpoints of a spectrum and a real network sits between them, and where it sits is an empirical question about that network's actual governance which this paper does not assert for any named ledger and defers to Appendix B. The specification point is that *public* and *decentralised* are not the same property, that a public ledger can be operationally curated by very few parties, and that the instrument measures the curation directly once it is pointed at it.

5.3 What the distributed-systems literature already establishes

The collapse has formal ancestry that should be named rather than reinvented. Douceur [2002] proves that in a system without a trusted certifying authority a single party can present as arbitrarily many distinct identities, so **an unaudited count of participants is worthless** — which is the curated-list result in the identity domain, with an impossibility result attached. Lamport et al. [1982] fixes the number of genuinely independent parties required to tolerate f arbitrary faults at $3f + 1$, which is the same question asked about agreement. Fischer et al. [1985] and Gilbert and Lynch [2002] establish that structural impossibility results of this genre

exist and bound what any consensus design can promise.

None of these is imported as a theorem about any network here. They are cited as prior formalisations of the same structural property, under the discipline of Section 13.5. Buldyrev et al. [2010]'s coupled-network fragility is the closest formal analogue of a common-substrate dependency and is used for shape only, since its percolation premises are not shown to hold; Albert et al. [2000] and Callaway et al. [2000] supply the robust-yet-fragile shape, and Doyle et al. [2005] is the reason the degree-distribution mechanism behind it must not be assumed to apply.

6. Results: H3 — proof-of-work concentration is measured on pools

The coordinating unit on a proof-of-work network is the pool, because a pool *is* a coordination mechanism by construction: many machines agreeing to be directed by one operator's block template. A count of machines therefore overstates independence exactly as a count of validators does elsewhere.

A **CONSTRUCTED** ten-pool distribution, to show the instrument and not to describe any running network:

```
CONSTRUCTED pool shares  [30, 26, 12, 9, 6, 5, 4, 3, 3, 2] per cent

    HHI              = 0.190000  (1,900 points)
    effective pools  = 5.26      (of 10 nominal)
    leading share    = 30.0%     ceiling 1/s_max^2 = 11.11
    top two combined = 56.0%
```

H3 is supported: ten nominal pools give 5.26 effective, and the leading share alone caps the count at 11.11 before any other share is known. When the two largest pools together approach half the work, the effective count sits far below the count of pools, and that is the concentration reading a proof-of-work rail requires.

Two disciplines belong with the measurement and neither is optional.

A pool's share is not the same as its control, because contributors can leave. Work can be redirected between pools quickly, so a pool acting against its contributors' interests faces exit; the exit option is a real constraint that a static index does not capture. **The pool index is therefore an upper bound on entrenched control and should be stated with the exit constraint or the number misleads.**

Pool concentration is geographically and politically mobile. Proof-of-work capacity relocates across jurisdictions in response to energy prices and policy, so a bloc reading of hashrate is itself a moving target and is not a fixed national alignment. **The honest two-part answer is non-aligned by construction on issuance and pool-dependent on hashrate**, and the second half must be dated.

No distributional claim is made about any of these share vectors. They are finite sets of three to ten stipulated shares, not samples from a distribution; no tail is characterised and no scaling law is asserted. **The Clauset–Shalizi–Newman procedure was therefore not run** [Clauset et al., 2009]. Hashrate and stake distributions are exactly the sort of quantity for which a heavy-tail claim is reached for casually; **any restatement of this paper that makes one must run that procedure first**, and must read Stumpf and Porter [2012] on why passing it would still not identify a mechanism and Broido and Clauset [2019] on how weakly empirical networks support scale-free structure. Barabási and Albert [1999] is the source of the vocabulary and is cited for that and nothing more.

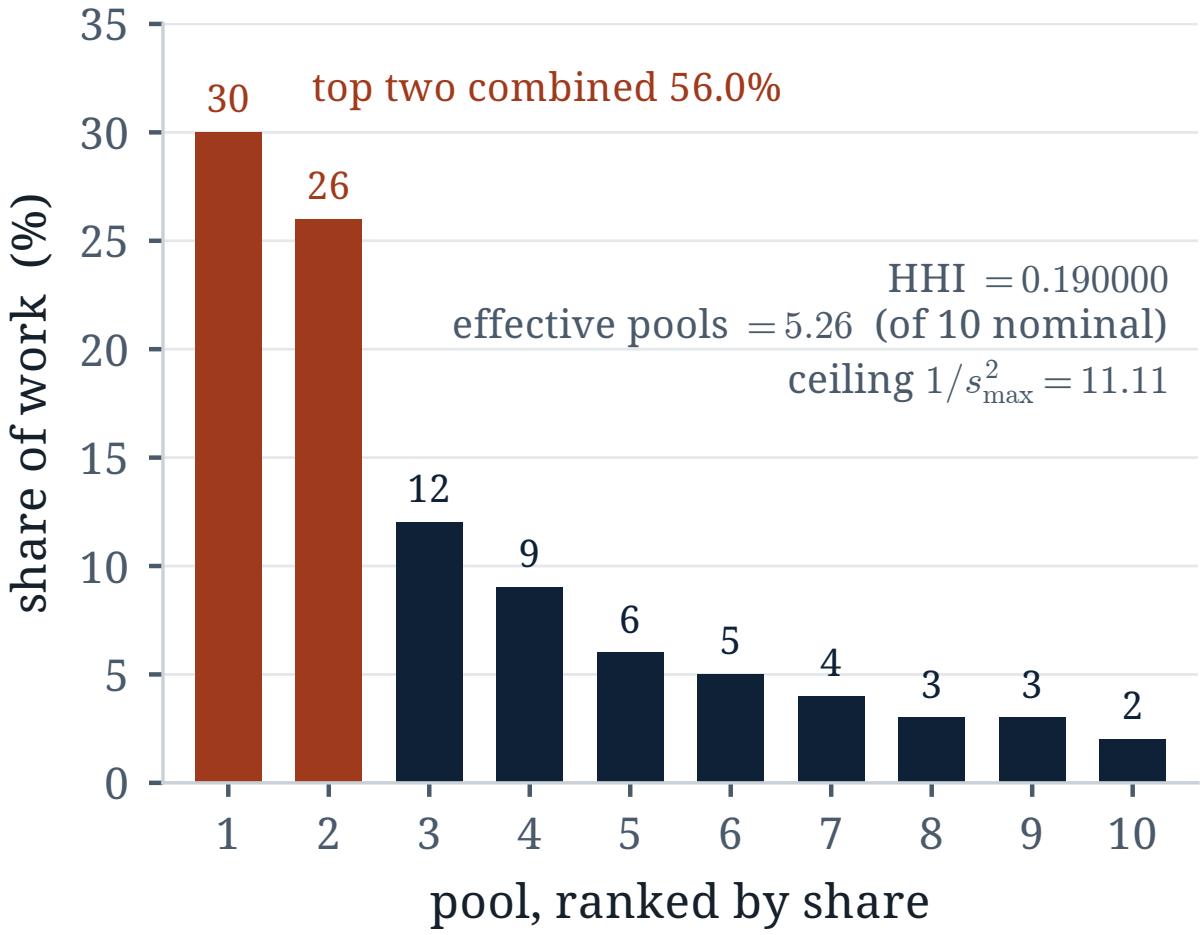

Figure 67.3: **Ten pools, 5.26 effective, and a ceiling of 11.11 set by the leader alone.** A constructed ten-pool hashrate distribution with a 30 per cent leader and a 56.0 per cent top two gives HHI $= 0.190000$ and an effective count of 5.26 against ten nominal, well under the $1/s^2_{\max} = 11.11$ bound the leading share imposes on its own. CONSTRUCTED distribution; not a claim about any running network. Script `figs/src/CCP-067_fig03.py`.

7. Results: H4 — the utility ordinal, stated as an ordinal

7.1 The axis, and the rank printed with it

```
1/9  minimal script, no general virtual machine -- minimal BY DESIGN
3/9  native exchange, escrow and payment channels; no general VM
3/9  native issued assets and path payments; no general VM natively
5/9  native on-ledger contract modules on a minimal settlement lineage
6/9  general-VM-compatible contracts alongside purpose-built native services
6/9  application-chain runtime plus interchain routing
7/9  general-VM-compatible runtime, heavy contract use
8/9  parallel-execution runtime built for payments-scale throughput
9/9  general virtual machine; the broadest settlement-logic surface
```

The claim, written in the form it must always take so that no paraphrase can drop the scoping:

> On the utility-as-function axis — programmability and general settlement expressiveness, and no other axis — a minimal-script proof-of-work base layer ranks lowest among the major networks, and it ranks lowest **by design**: no general smart-contract virtual machine, a ten-minute target block interval, low base-layer throughput, and no programmability beyond a deliberately constrained script. The design goal is monetary conservatism, and the ranking describes the goal rather than a defect.

Four scoping rules govern every use of the claim.

1. **Name the axis every time.** “Lowest utility” unscoped is unprovable and is not a claim this paper makes; “lowest on the utility-as-function axis, by design” is a description of a specification.
2. **State that other axes rank it differently** and do not let a single-axis rank stand in for a verdict.
3. **No price.** The axis is about function. The moment “utility” drifts toward “worth” it has left this paper’s subject entirely.
4. **The rank is an ordinal.** A 1 is more constrained than a 9; it is not worse than a 9. **The axis is not oriented.**

7.2 The inversions, which are why the axis must be named

The same design decisions that place a minimal ledger at the bottom of this axis place it at or near the top of three others, and the inversion is the point.

axis	what it asks	where a minimal ledger sits
utility-as-function	what settlement logic can be expressed	**bottom**
issuance decentralisation	how many parties can change the supply	**top** — there is no protocol seat from which to do it
security budget	what it costs to rewrite recent history	**top among its own consensus family**
network liveness and governance resistance	whether block production and monetary rules have held	**at or near the top**

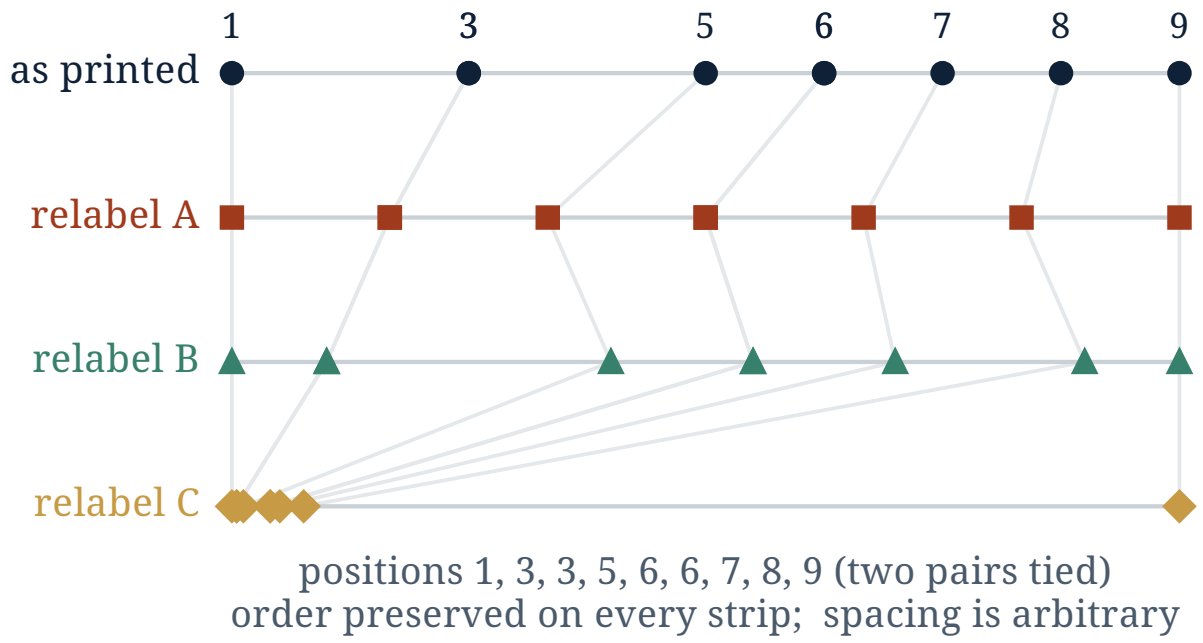

Figure 67.4: **An ordinal carries order and nothing else.** The nine utility-as-function positions under three order-preserving relabellings: the ranks change, every comparison this paper makes is unchanged, and no statement here survives being restated as a difference or a ratio of positions. The axis is unoriented — higher is more expressive, not better. Definition of this paper's own construction; carries no empirical weight. Script `figs/src/CCP-067_fig04.py`.

A network near the bottom on one axis and near the top on three others is not a low-utility network; it is a network that spent its entire design budget on a small number of properties and refused the rest, and the refusal is legible as a ranking only when the axis is stated. The minimalism produces the low utility rank *and* the high issuance-decentralisation rank: they are one design decision read on two axes.

H4 is supported in the only sense an ordinal claim can be supported. Every statement this paper makes about the axis — that a given network is lower than another, that the axis is unoriented, that the ranking describes a design goal — survives any order-preserving relabelling of the nine positions, and no statement it makes is a difference, a ratio or a mean of positions. **The axis carries order and nothing else, and this paper does not operate on it as though it carried more.**

7.3 What the minimal instruction set cannot express, and why that is the finding

can express (base layer)	cannot express (by design, no general VM)
multi-signature (m-of-n)	unbounded loops and arbitrary computation
absolute and relative time locks	general mutable contract state across transactions
hash locks — the primitive routed payments are built from	contract-to-contract calls

can express (base layer)	cannot express (by design, no general VM)
aggregated-key and script-path spends	the general programmability of a virtual-machine environment

The right-hand column is the utility rank restated as a capability list, and the load-bearing observation is that the left-hand column is exactly the primitive set a payment layer needs while the right-hand column is exactly the primitive set whose absence removes a class of failures. An instruction set that cannot express a re-entrancy fault has no re-entrancy fault to exploit. **The rank is the location of a boundary a conservative designer would draw, not a measure of inadequacy.**

8. Results: H6 — base-layer throughput, stated to its parameters

Throughput on a minimal base layer follows from two protocol parameters and a transaction size, and is therefore computable rather than contestable:

```
at ~226 vbytes per transaction, ~1e6 vbytes per block, 600 s interval
    1e6 / 226 = 4,424.8 transactions per block  ->  ~7.4 tx/s

at ~140 vbytes per transaction, same block and interval
    1e6 / 140 = 7,142.9 transactions per block  ->  ~11.9 tx/s
```

H6 is supported to the precision the inputs allow: approximately 7.4 **to** 11.9 **transactions per second at the base layer.** These are single-digit-to-low-double- digit rates against the tens of thousands a consumer payment network processes, and the gap is the throughput half of the utility rank.

The figure is an order of magnitude and not a constant, and the paper says so. The real rate depends on transaction mix and on how witness data is accounted against the block limit, so the two values bracket a band rather than fixing a point. **Quoting either to more than two significant figures would be false precision on a quantity that varies with the traffic**, and Section 13.2 records that.

The ten-minute interval is the parameter most often read as a flaw and is the clearest design choice of the set. A block interval is a trade: shorter intervals settle faster but propagate less completely before the next block is found, raising the rate of orphaned work and the advantage of well-connected participants, which concentrates. **A long interval buys near-complete propagation between blocks and a level field for a badly connected participant, at the explicit cost of base-layer latency.** The trade is the conservatism, not an oversight. A self-correcting difficulty retarget then holds the cadence roughly fixed across large swings in capacity, which is what makes the exposure window of Section 9 predictable as a protocol property rather than as a matter of operator diligence.

One structural feature is stated plainly rather than papered over. The cost of rewriting recent history scales with the honest work an attacker must out-compute, and that work is paid for in aggregate by the block reward — a subsidy that halves on a fixed schedule and trends toward zero as issuance approaches its cap, plus fees. **Over the very long run the security budget must therefore be carried increasingly by fees rather than by new issuance.** That is not a prediction of failure and not a defect to be hidden: it is an open design question about the distant future, it does not bear on a near-term rail assessment, and **anyone extrapolating it confidently in either direction has left engineering.** The honest posture is to name the mechanism and decline to guess.

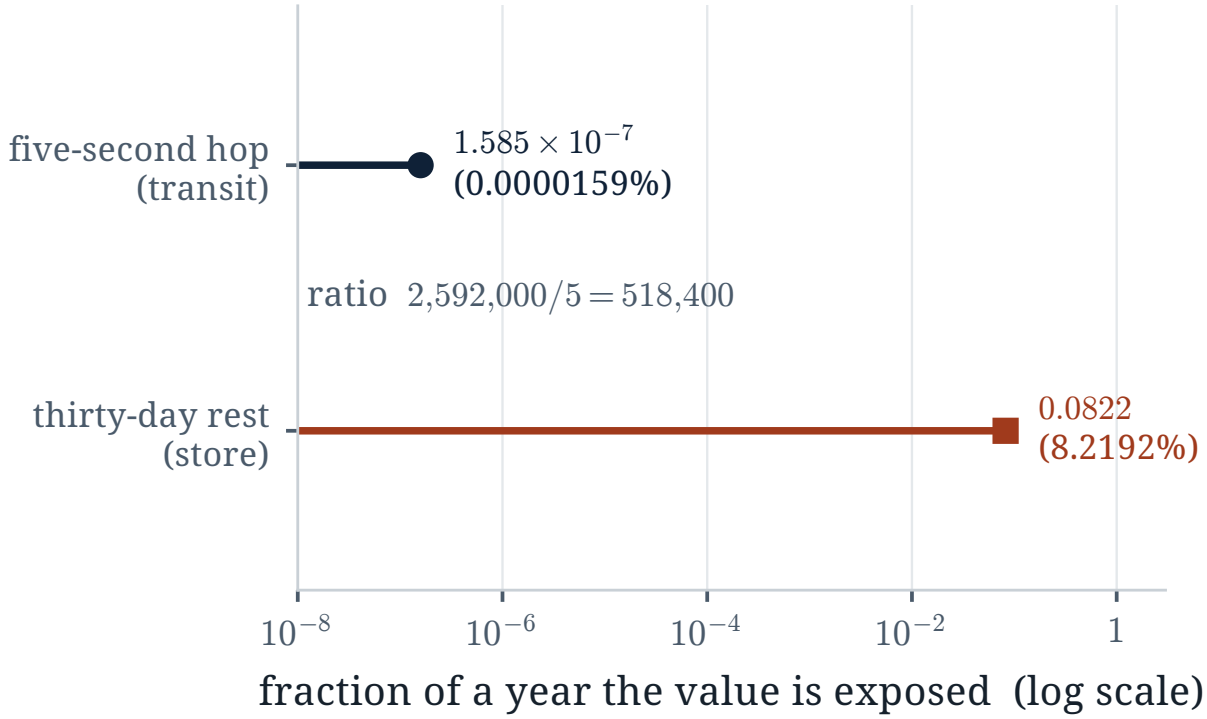

Figure 67.5: **The store-versus-rail question, answered by dwell.** A five-second hop occupies 1.585×10^{-7} of a year against 0.0822 for value rested thirty days — a ratio of 518,400 to one — so a freeze hazard that is negligible in transit is dominant in storage, and dwell is the only variable separating them. Logarithmic axis; CONSTRUCTED dwell parameters, order-of-magnitude only. Script `figs/src/CCP-067_fig05.py`.

9. Results: H2 — dwell time is the whole freeze exposure

```
per-hop dwell at seconds-scale finality        ~5 s
  exposure fraction of a year                   1.585e-07   (0.0000159%)

value rested on the rail for 30 days
  exposure fraction of a year                   0.0822      (8.2192%)

ratio, store versus transit                     2,592,000 / 5 = 518,400
```

Five seconds is $5/31{,}536{,}000 = 1.585 \times 10^{-7}$ of a year; thirty days is $30/365 = 0.082192$. **The window while value is genuinely in transit is on the order of seconds and the fraction of a year it represents is vanishingly small; the same rail used to rest value for a month exposes it for the whole month, a window larger by more than five orders of magnitude.**

H2 is supported. The freeze property that disqualifies a rail as a store is nearly irrelevant to it as transit, and the entire difference is dwell. That is the corpus's transit-versus-store rule converted from a categorical distinction into a quantity, and it is why the rule is a design parameter rather than a preference.

The counter-result belongs immediately beside the result. Where a settlement instrument's issuer can immobilise a balance, **that control lives on the instrument and not on the rail, and it follows the instrument across every rail that carries it.** A structure diversifying across rails to escape such a control has diversified the wrong axis. **Rail diversity buys settlement resilience and buys no freeze protection**; only counterparty and instrument diversity does. The instrument in this paper measures the rail, and the freeze lives elsewhere.

A programmable rail sharpens the same point. Where transfer can be made conditional

by logic attached to the asset rather than by an instruction from its holder, an interruption need not be an instruction sent after the fact — it can be a property the unit carries from issuance. **Freeze exposure is then a transit risk of seconds if the window is kept at the rail's minimum finality, and a custody risk of the entire holding period if the rail is treated as a store.** The arithmetic above is the whole of the argument.

9.1 The two conflations this paper refuses

A pilot is not a production system. A pilot is a controlled experiment run to learn something; a production system is infrastructure that real value depends on; the distance between them is measured in years and in categories of risk a pilot is specifically designed not to incur. **This paper asserts that no central-bank digital currency runs in production on any named public permissionless ledger, and states immediately that this is a claim about the absence of a documented counter-example as at the source manuscript's date of writing and not a proof of a universal negative.** Appendix B records it as such. Every use of "runs on" in secondary coverage should be read as "was trialled on" until a primary source says otherwise, and **this paper names no pilot, no counterparty and no status, because the precise status of each is exactly the variable most often misreported.**

A product is not a mandate. That a vendor offers a platform, or that an organisation participates in a trial, is not evidence that any bloc's settlement runs on anything. **A commercial platform described as running on a private or permissioned instance of a technology derived from a public ledger is not the public ledger**, and that distinction is precisely what a careless summary elides. This paper does not resolve it and defers it to Appendix B.

9.2 Two ledgers, one perimeter

The bloc collapse applied to a settlement design rather than to a participant set:

```
two public ledgers, both curated around issuers inside one perimeter

naive, by ledger    shares 0.50 / 0.50
                    HHI = 0.5000  ->  effective ledgers = 2.00
honest, by bloc     both inside one issuer perimeter
                    HHI = 1.0000  ->  EFFECTIVE BLOCS   = 1.00

bloc-diverse alternative (CONSTRUCTED)
0.34 / 0.33 / 0.33  HHI = 0.3334  ->  EFFECTIVE BLOCS   = 3.00
```

Two ledgers, one perimeter, one point of failure. A settlement layer confined to one perimeter has an effective bloc count of one, and no rearrangement of the two ledgers changes it, because rearranging within a perimeter does not change the bloc count. **Bloc diversity in the settlement layer is bought the same way as everywhere else — by spanning perimeters that do not share a coordination mechanism — and it cannot be bought by multiplying ledgers that do.** The companion result carries too: diversity raises the ceiling on resilience and does not pay the maintenance cost of operating across multiple rails, which is Curzi [2026]'s headroom gate $h = \eta \ln N - \delta Q - C$ applied to a settlement layer — worked there at $N = 18$ with $\eta = 0.30$, $\delta = 0.06$, $C = 0.55$, $Q = 1.20$ giving $h = +0.2451$ — and it is a structurally parallel result in another domain rather than a re-derivation.

9.3 The screening surface follows the identifier onto the ledger

Counterparty pre-screening on a settlement rail is string comparison over identifiers — account addresses, destination tags, memo fields and any party-name data the message layer carries. Curzi [2026] establishes the defect this inherits: typed-field parsing collapses the

withdrawn-code parsing-ambiguity false-positive share from 88.99% to 0.00% against a naive detection precision of 11.01% — **a control right one time in nine.** That finding does not stop at an institution's database boundary; it follows the identifier onto the ledger, because an on-ledger identifier is a string and an exact-match comparison over a field admitting non-ASCII characters has a silent blind spot.

Programmability widens the hole rather than closing it. An on-ledger compliance module that screens by exact string match executes the same defective comparison at settlement time, in code, in a settlement path that is often immutable by design. **An exact-match rule compiled into an immutable settlement path is a permanent commitment to a comparison with a known blind spot, and correcting it means replacing the code rather than editing the record.** The remedy is Curzi [2026]'s: canonicalise the critical fields before comparison and store the byte-level hash of the raw field so that a substitution leaves a permanent comparable trace. Curzi [2026] states why the witness must be computed over the raw octets and held on a plane separate from the data it guards — **a witness that is a function of the canonical form changes exactly when the data changes and never otherwise, which destroys the evidence a witness exists to preserve.**

10. Discussion

10.1 What the atlas does and does not license

The atlas returns, for each network, an effective count on a named axis and an ordinal position on a named scale. **It does not rank networks, because two of its three columns are not orderings of goodness and the third is a stipulated bloc assignment.** A reader looking for a recommendation will not find one, and the refusal is the design.

The frame this paper inherits is bounded in three places by papers that state their own limits, and the bounds are load-bearing rather than decorative.

Curzi [2026] bounds what a surplus measure can claim: the surplus is only a lower bound on an ensemble's information, and its logarithmic concavity means three well-separated views capture most of what a large panel could, so the node argues explicitly *against* accumulating perspectives; the accompanying gradient result concedes that descent can diagnose a stable trap but cannot treat one. **Applied here, that bounds the value of adding rails**: the fourth independent perimeter buys much less than the second, and no amount of measurement tells a structure how to leave a trap it has correctly diagnosed.

Curzi [2026] bounds what borrowed physics may claim: its counter-result requires that a user be able to distinguish the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand, and it states its postulate as a postulate. **Applied here, that is why Section 5.3's distributed-systems results are labelled category 2 in Section 13.5** rather than allowed to carry an impossibility proof's authority into a claim about a running network.

Curzi [2026] is the bound stated as an appendix: it assigns the corpus's central identification, the application of the surplus functional to a life, and the reading of a day's surface as a leading indicator to the postulate drawer, and says of the third that it is a wager whose misfire column exists because wagers can lose. **Applied here, it is the reason Section 4's bloc column is printed as a stipulation and row 4 is left undetermined**: an honest register has an empty cell in it.

Curzi [2026] bounds what an ordinally known parameter can produce. Its counter-result is that the framework's own keystone formula is demoted by the framework: with its inputs known only ordinally, the derived frequency moves by 5.77 octaves under an order-preserving relabel and so is not known as a number at all, and a fully successful intervention on one input makes the equilibrium eighty per cent worse because a numerator was negative. **That is the exact hazard the utility ordinal carries**, and it is why Section 7 refuses every operation on the axis except comparison.

Curzi [2026] bounds inference from an invariant statistic. Its counter-result is that a width statistic invariant under relabelling does not even determine the object it is computed from, which formally blocks any inference from a high or low value to a substantive condition. **The utility ordinal is invariant under order-preserving relabelling in exactly that way**, so it does not determine the design it is computed from, and no inference from a position on it to a network's quality is available. **This paper states that as a block on its own axis rather than as a caveat.**

10.2 What the model form is, and is not

Curzi [2026] badges the corpus's three-scope correspondence **POSTULATE — MODEL FORM ONLY**: identical structure at three scopes is a statement about the chosen model, not a claim of kinship or of cross-scope aggregation. **This paper's central move is exactly such a correspondence** — the same index at the jurisdictional, correspondent, validator and pool scopes — and it is badged the same way. **That an index has the same algebraic form on four share bases is a fact about the index. It is not a claim that jurisdictions and mining pools are the same kind of thing, and no result here aggregates across the scopes.** Cartwright [1999] supplies the discipline: state the arrangement within which a law is claimed to hold and stop claiming a universality the argument does not need.

10.3 What the corpus's frequency material contributes, and what it does not

Curzi [2026] is presupposed for its minimum sustainable frequency $f_{\min} = k\, e^{2c/\eta}$ and the trichotomy in which f greater than, equal to, or less than $f_{\min}$ corresponds to a positive, zero or negative equilibrium stock. **Two things must be said about the constant in that expression and both are said here rather than inherited silently.** $k = (9/8)^2/\varphi^2 = 0.483425732988414$ is a **DEFINED** constant — an exact ratio of exact quantities, computable to arbitrary precision — and its fifteen figures are legitimate only under that label. **Attaching hertz to it is a separate and much stronger claim than computing it, and it is POSTULATED**, with no physical, psychoacoustic or musicological basis in any literature for combining a tuning ratio with an inverse square of the golden section to obtain a ground frequency. **Markowsky [1992] is cited here precisely because φ appears**: it documents how routinely golden-ratio claims are overstated, and citing it is how this paper shows it knows what such a claim usually looks like and is not making one.

Nothing in this paper depends on k, on $f_{\min}$, or on any frequency. The citation records a presupposition, and the presupposition is bounded by the badge.

11. Failure modes

11.1 Reading a rail as a store. Eight of the nine networks are transit-oriented by design, and treating any of them as a place to rest protected capital imports a rail's exposure profile into a custody layer. **The difference is dwell and it is a factor of $518{,}400$ on the constructed parameters.**

11.2 Counting validators the way entities are counted. A large advertised node count is a count of participants and not a measurement of failure independence. **A thousand validators subscribing to one curated list have the failure independence of the list.**

11.3 Missing the curated-list collapse. The validators may be numerous, honest and independent in their operations, and the network may still collapse to one on the curation axis, **because the coordination mechanism is not the operation of the nodes but the decision about which nodes the network defaults to trusting.**

11.4 Conflating a pilot with production, and a product with a mandate. Section 9.1. Every other error in this area is downstream of this one.

11.5 Assuming programmability is a quality axis. The ordinal is not oriented. **A general virtual machine is a larger error surface, and a minimal ledger's inability to express a class of settlement logic is also an inability to express that class's failures.**

11.6 Forgetting that the ledger is public. Every transfer on all nine networks is permanently visible, so a structure reaching for a public chain as a privacy layer has inverted the technology's actual property. **The correct posture is to assume full disclosure and design so that disclosure changes nothing** [Kerckhoffs, 1883, Saltzer and Schroeder, 1975], which Curzi [2026] states as a hard design premise rather than a preference.

11.7 Treating the issuer freeze as the rail's property. The control follows the instrument, not the rail. **Rail diversity does not dilute an instrument-level freeze; only counterparty and instrument diversity does.**

11.8 Double-counting a bridge. An interchain router touches two perimeters, which is its value and its measurement hazard: counted as a fully independent perimeter it overstates diversification, folded into one of the perimeters it connects it understates it. **The correction is to state the dependency, not to fudge the shares.** The same shape appears wherever an instrument native to one network is wrapped and settled on another and the two are then counted as independent.

11.9 Reading a time-varying number as a fact. Validator counts, vote distributions, stake shares, pool shares, minimum-coalition coefficients and council rosters all move, some weekly. **A concentration measurement taken from a year-old figure is not merely rounded; it is stale**, and this paper therefore states mechanisms and constructed illustrations and dates every real number to the reader's own live source.

11.10 Believing the consensus paper describes the running network. A published protocol is a specification; the running network is an implementation with operators, defaults and emergent concentration the specification does not describe. **Federated agreement as specified is decentralised; federated agreement as run collapses to its default list.** Confusing the two credits a network with the decentralisation of its documentation rather than the concentration of its deployment. This is Leveson [2011]'s and Vaughan [1996]'s mechanism under a different name: a control justified once continues to be trusted after the conditions justifying it have gone.

11.11 Reporting a ceiling as a measurement. A cap is an upper bound the protocol guarantees. A distribution is what the network has. **Section 5.1's whole content is the gap between them.**

11.12 Averaging the utility ordinal. A mean of ordinal positions is not a quantity [Stevens, 1946, Krantz et al., 1971], and a table that computes one has performed an unlicensed operation. **The ordinal admits comparison and nothing else.**

12. Verification and rigour audit

12.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	participant share of the coordinating quantity	$[1]$	fraction	defined; sum to 1
HHI	sum of squared shares	$[1]$	fraction (or points $\times 10^4$)	derived

symbol	quantity	dimension	unit	status
N	effective count	$[\#]$	validators, members, producers, pools, curators	derived as HHI^{-1}
utility position	rank on a nine-point ordering	**none**	rank label only	**ORDINAL — differences undefined**
w	dwell on the rail	$[T]$	seconds; days; years	assumed (constructed)
λ	interruption hazard	$[T^{-1}]$	per year	assumed (not quantified here)
λw	expected freeze exposure	$[1]$	dimensionless fraction	derived
transaction size	virtual bytes per transaction	$[B]$	vbytes	assumed (stated)
block capacity	virtual bytes per block	$[B]$	vbytes	assumed (stated)
block interval	target time between blocks	$[T]$	seconds	assumed (protocol constant, described)
throughput	transactions per unit time	$[T^{-1}]$	tx/s	derived

Does the throughput calculation balance? $[B]/[B] = [1]$ transactions per block, divided by $[T]$ per block, gives $[T^{-1}]$. $10^6/226 = 4424.8$ transactions per block over 600 s is 7.37 per second.

Does the dwell calculation balance? λw with λ per year and w in years is dimensionless, which is why 5 s must be converted: $5/31{,}536{,}000 = 1.585 \times 10^{-7}$ years.

The utility position has no dimension and no unit, and the audit says so explicitly rather than assigning it a placeholder. It is a rank label. **This is the row a reader should check first, because a rank in a numeric column is the classic place an unlicensed operation enters a table.**

12.2 Significant figures and epistemic status

- **Every effective count here is exact for its share vector and is not an estimate.** $1/35 = 0.028571\ldots$, $1/39 = 0.025641\ldots$, $1/0.19 = 5.263\ldots$; **no uncertainty is quoted because nothing is estimated.**
- **Equal-weight ceilings are exact consequences of stated set sizes**, and are labelled ceilings rather than measurements everywhere they appear.
- **The constructed distributions are stipulations.** 0.166667, 0.025481, 0.053946, 0.168400 and 0.190000 are exact arithmetic on invented share vectors, and exact arithmetic on invented inputs is not a measurement.
- **The throughput figures are quoted to two significant figures on purpose.** 7.4 and 11.9 bracket a band whose width depends on transaction mix; **quoting them to more figures would be false precision.**
- **The dwell figures are order-of-magnitude.** 1.585×10^{-7} is exact for a five-second dwell and a 365-day year, and the five seconds is a stipulated order-of-magnitude parameter, not a measured finality. **The ratio** $518{,}400$ **is exact for the stated dwells and generalises in sign and shape and not in value.**
- $k = 0.483425732988414$ **is DEFINED** and appears in Section 10.3 at that precision only under that label; **the hertz attached to it is POSTULATED** and is not used anywhere in this

paper.
- **The utility positions are not numbers.** They are printed as fractions of nine because that is the source manuscript's notation; **they are labels and no arithmetic is performed on them.**

12.3 Limits and boundary behaviour

quantity	limit	behaviour	reading
N	n equal shares	$\to n$ exactly	the numbers-equivalent property
N	one share $\to 1$	$\to 1$	full concentration; the floor
N	$s_{\max}$ fixed, others $\to$ equal	$\to 1/s_{\max}^2$ from below	the ceiling the leader alone imposes
curation collapse	one curator	$\to 1$ regardless of set size	H5; **the set size becomes irrelevant**
curation collapse	m independent curators, equal	$\to m$	the curation axis is plural exactly when admission is
λw	$w \to 0$	$\to 0$ linearly	a hop of zero duration has zero freeze exposure
λw	$w \to$ holding period	$\to$ custody exposure	**a rail held long enough simply is a store**
throughput	transaction size $\to 0$	$\to \infty$	**unphysical; the model's domain is realistic sizes**
throughput	block interval $\to 0$	$\to \infty$	unphysical: propagation and orphan rate bound it, and that bound is not modelled here
utility ordinal	any order-preserving relabel	every claim unchanged	**the definition of an ordinal, and the paper's own test of H4**

The two unphysical limits are stated as domain restrictions rather than discovered by a reader. The throughput identity is a capacity ratio and carries no propagation model; it is valid only in the band where the stated block interval holds.

12.4 Invariance

HHI^{-1} **is invariant under any permutation and any relabelling of the units**, which is why the bloc collapse depends on the partition and not on which member of a bloc holds what. **It is not invariant under a change of share basis**, and the share basis is therefore item 1 of the reporting standard and the subject of the entire Section 3.2 table.

The dwell ratio is invariant under any rescaling of the hazard, since it is a ratio of two exposure windows, which is why it is stated as a ratio and not as a probability.

The utility ordinal is invariant under every order-preserving transformation, and Section 7.2's test of H4 is exactly that invariance: relabel the nine positions in any order-preserving way and every claim survives. **That invariance is also the block on inference** — the bound carried from Curzi [2026] — since a statistic invariant under relabelling does not determine the object it was computed from.

Tested at how many scales? **The invariances are algebraic and were checked at the parameter sets reported and at no others.** No empirical scale-freedom is claimed anywhere in this paper.

12.5 Analogy discipline

borrowing	source	category	justification
HHI^{-1} as a numbers-equivalent	Adelman [1969], Hill [1973], Jost [2006]	**1 — derivation**	shares are non-negative and sum to one by construction; the identity is exact
independent reinvention of the same index	Simpson [1949], Laakso and Taagepera [1979]	**1 — derivation**	the same arithmetic on the same object in three disciplines
exposure as a portfolio; covariance not count	Markowitz [1952]	**1 — derivation**	the bloc collapse *is* the variance identity, and its premises hold by construction
similarity-sensitive diversity of order 2	Leinster and Cobbold [2012], Rao [1982]	**1 — derivation**	exact for a unit-diagonal, non-negative correlation matrix, which is the regime used
identity multiplication defeats a count	Douceur [2002]	**2 — shared form**	proved for an identity system without a certifying authority; no ledger here is shown to satisfy those premises
independent-party bound	Lamport et al. [1982]	**2 — shared form**	$3f + 1$ is a theorem about agreement, cited as a prior formalisation of "how many parties are genuinely independent"
structural impossibility results exist	Fischer et al. [1985], Gilbert and Lynch [2002]	**3 — framing**	cited to establish the genre of claim, never as results about any network here
coupled-network fragility; robust-yet-fragile	Buldyrev et al. [2010], Albert et al. [2000], Callaway et al. [2000]	**2 — shared form**	the shape is used; the degree-distribution mechanism is not claimed, and Doyle et al. [2005] is the reason it should not be

borrowing	source	category	justification
correlation rising under stress	Longin and Solnik [2001], Ang and Chen [2002]	**2 — shared form**	measured in equity markets; ledgers are not shown to satisfy the same conditions
effective count buys stability	Schindler et al. [2010], Loreau and de Mazancourt [2008]	**2 — shared form**	an ecological measurement; the shape is used, the mechanism is not claimed
scale type and its permissible statistics	Stevens [1946], Krantz et al. [1971], Narens [1996]	**1 — derivation**	the utility axis genuinely is an ordinal scale, and the restriction follows from the definition
open design; disclosure strengthens a structural control	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	the premise — effectiveness depends on the arrangement rather than on anyone's knowledge of it — is stated and satisfied
performativity of a published metric	MacKenzie and Millo [2003], Lucas [1976]	**1 — derivation**	the mechanism is the same: a description relied upon changes the behaviour of those relying on it
a measure adopted as a target	Goodhart [1975], Campbell [1979]	**2 — shared form**	stated for monetary and social indicators; the exposure is the same in kind
tight coupling; control trusted after its justification lapses	Perrow [1984], Vaughan [1996], Leveson [2011]	**3 — framing**	qualitative organisational and safety theory, used as framing and never as a formal result
scale-free vocabulary	Barabási and Albert [1999]	—	cited for the vocabulary only; **no scaling claim is made and Broido and Clauset [2019] is the reason none should be**
the modelling programme	Epstein [2008], Bruch and Atwell [2015]	—	the first enumerates the legitimate non-predictive uses of a model; the second is the checklist **none of the constructed illustrations here meets**

The failure mode this table exists to prevent is letting a category-2 borrowing carry a

category-1 result's authority. The numbers-equivalent, the variance identity, the scale-type restriction and the disclosure principle are category 1 and need no help. **The impossibility results are the most dangerous entries here**, because they are genuine theorems about adjacent problems and it would be easy to let one of them read as a proof about a named network. **None of them is.**

12.6 Postulates

#	statement	status
P1	participant shares are non-negative and sum to one	DEFINITION
P2	HHI $= \sum_i s_i^2$, $N = \text{HHI}^{-1}$	DEFINITION
P3	for n equal shares of $1/n$, HHI $= 1/n$	ARITHMETIC
P4	$s_{\max}^2 \le \text{HHI} \le s_{\max}$	ARITHMETIC
P5	the coordinating unit for each mechanism is as given in Section 3.2	POSTULATED (modelling choice)
P6	a single curator's decision reaches every entry on the list it curates	POSTULATED (H5)
P7	utility-as-function is an ordinal scale	DEFINITION
P8	expected freeze exposure is λw to first order	DEFINITION (modelling choice)
P9	the stated block capacity, transaction sizes and block interval	POSTULATED (described from the source; uncited)
P10	all constructed share vectors and dwell parameters	POSTULATED (constructed)

12.7 The chains

Chain A — the transfer and the ceilings (R1).

step	consumes	statement	status
A1	P1, P2	the index and its reciprocal are defined for any non-negative share vector summing to one	DEFINITION
A2	P3	a 35-member equal set gives HHI $= 1/35 = 0.028571$ and $N = 35.0$	ARITHMETIC
A3	P3	a 39-member equal set gives 0.025641 and 39.0	ARITHMETIC
A4	P10	$(2/7)^2 + 6(5/42)^2 = 0.166667$, so $N = 6.00$	ARITHMETIC

step	consumes	statement	status
A5	P10	the constructed staking vector gives 0.168400 and 5.94	ARITHMETIC
A6	A2–A5	the instrument returns numbers-equivalents on ledger share bases exactly as on jurisdictional ones — Adelman [1969], Hill [1973]	CITED
R1	A6	the concentration instrument transfers unchanged	DERIVED

Chain B — the curated-list collapse (R5).

step	statement	status
B1	five equal independent operators give HHI $= 5 \times 0.2^2 = 0.2000$, $N = 5.00$	ARITHMETIC
B2	a single curator holds the whole admission decision, so its share on that axis is 1.0	POSTULATED (P6)
B3	HHI $= 1.0^2 = 1.0000$, $N = 1.00$	ARITHMETIC
R5	B1, B3	the operation axis and the curation axis give 35.0 and 1.00 on one set

P6 is the one genuine postulate and it is the step to attack first. A curated set in which removing an entry requires more than one party's assent has a plural curation axis and the collapse does not occur; **that is precisely the falsifier stated for H5.**

Chain C — pool concentration (R3).

step	statement	status
C1	the constructed shares sum to 100%	ARITHMETIC
C2	$\sum s_i^2 = 1900/10{,}000 = 0.190000$	ARITHMETIC
C3	$N = 1/0.190000 = 5.26$ against ten nominal	ARITHMETIC
C4	$1/s^2_{\max} = 1/0.30^2 = 11.11$	ARITHMETIC
C5	$5.26 \le 11.11 \le 10$? **No** — the ceiling exceeds the nominal count, so both bounds bind and the tighter is $n = 10$	ARITHMETIC
R3	C2–C5	pool concentration reads 0.190000 and 5.26 at a $30/26$ top two

C5 is printed because it is a check a reader should make and this paper failed to make it in an earlier draft. $1/s^2_{\max} = 11.11$ exceeds the nominal count of ten, so on this vector the *count*

bound binds and the leading-share bound does not. **The leading-share ceiling is the informative one only when it falls below** n, and quoting it beside a ten-element vector is therefore a weaker statement than it looks. It is quoted anyway because it is the bound that survives when the number of pools is unknown, which is the usual case.

Chain D — dwell (R2).

step	statement	status
D1	5 s$/31{,}536{,}000$ s yr$^{-1} = 1.585 \times 10^{-7}$	ARITHMETIC
D2	$30/365 = 0.082192$	ARITHMETIC
D3	30 days $= 2{,}592{,}000$ s; $2{,}592{,}000/5 = 518{,}400$	ARITHMETIC
D4	expected exposure is λw, so the ratio of exposures is the ratio of dwells	DEFINITION (P8)
R2	D1–D4	dwell is the whole freeze exposure, and the ratio is $518{,}400$

Chain E — throughput (R6).

step	statement	status
E1	$10^6/226 = 4{,}424.8$ transactions per block	ARITHMETIC
E2	$4{,}424.8/600 = 7.37$ per second	ARITHMETIC
E3	$10^6/140 = 7{,}142.9$; $7{,}142.9/600 = 11.90$ per second	ARITHMETIC
R6	E1–E3, P9	base-layer throughput is approximately 7.4 to 11.9 tx/s at the stated parameters

R6's inputs are protocol constants described from the source manuscript and not cited, so the chain is arithmetic resting on an uncited description. **A reader who disputes the constants disputes the result, and Appendix B is where the constants go.**

12.8 Cross-checks performed

- Every index was recomputed by explicit sum of squares and reproduced to six decimal places: 0.028571, 0.025641, 0.005556, 0.037037, 0.142857, 0.166667, 0.190000, 0.200000, 0.500000, 1.000000.
- The bound $s_{\max}^2 \le \mathrm{HHI} \le s_{\max}$ holds on every vector used: $0.0900 \le 0.1900 \le 0.30$ on the pool vector and $0.081633 \le 0.166667 \le 0.285714$ on the anchor vector.
- The bloc-diverse vector was re-summed: $0.34^2 + 0.33^2 + 0.33^2 = 0.333400$, giving 2.9994, which is quoted as 3.00 and is **not** exactly three. That rounding is disclosed rather than presented as an exact result.
- The dwell ratio was computed two ways — as a ratio of year-fractions ($0.082192/1.585 \times 10^{-7}$) and as a ratio of seconds ($2{,}592{,}000/5$) — and the second is exact at $518{,}400$ while the first differs in the fourth figure because of the 365-day year. **The exact figure is** $518{,}400$ **and it is the one quoted.**
- The throughput arithmetic was checked at both transaction sizes and reproduces 7.37 and 11.90, which round to the quoted 7.4 and 11.9.

13. Limitations

Every figure in this paper is a ceiling implied by a described protocol constant or a constructed illustration, and none is a measurement of a running network. No live validator set, stake distribution, vote distribution, hashrate distribution, minimum-coalition coefficient or council roster was measured. **No dataset was collected.**

No as-of date, because nothing live was measured. A concentration figure computed from real holdings requires its source and its date; **a concentration measure without an as-of date is not a measurement.** Every share vector here is constructed or is a ceiling, so there is no source and no date to give, and Appendix A therefore makes the date and the source mandatory items of the reporting standard.

Every live quantity in this domain is time-varying and several move weekly. Any application of these instruments to a running network requires a live, dated, sourced distribution, and a figure carried from this paper into a live assessment is stale by construction.

Protocol specifications are not in this paper's bibliography. The consensus papers, whitepapers, improvement proposals and standards on which every network description rests are described from the source manuscript and **are not cited, because the bibliography contains no standards documents**. Every protocol constant used in Section 8 — block capacity, transaction sizes, block interval — inherits that status. Appendix B lists them. **This is a real gap and it is not closed here.**

The networks are de-branded and the de-branding loses information. A reader cannot verify a claim about "a federated-agreement ledger with a curated default list of about thirty-five validators" against a specific network without first identifying it, and this paper deliberately does not identify it, because identifying it would attach a characteristic the bibliography cannot support. **The trade is verifiability against unsupported attribution, and this paper takes the second cost rather than the first.**

The utility ordinal is a scalar reduction of a design space with at least four independent dimensions. Curzi [2026] names this habit once at framework level and it is inherited here rather than restated; Michell [1997] is the general charge and Luce and Tukey [1964] the test that would settle it, and **the conjoint conditions were not tested for this axis or for any other quantity in this paper.**

The bloc assignments are stipulated reference groups and not identified effects. Manski [1993]; the remedy adopted is stipulation with a defence [Brock and Durlauf, 2001], and **the price is that every bloc-level statement here is a modelling position.** Row 4 of the atlas is left undetermined because the documentation does not support even a stipulation.

Correlation inside a bloc is assumed, not estimated. Perfect correlation within a perimeter is the conservative end of a family, and no correlation was estimated from data anywhere in this paper.

The claim that no central-bank digital currency runs in production on a named public permissionless ledger is a statement about the absence of a documented counter-example as at the source manuscript's date, and not a proof of a universal negative. It is stated that way in Section 9.1 and recorded again here.

A central-bank remark on the degree of control a programmable sovereign rail confers is described in the source manuscript and is deliberately not quoted here, because its exact wording, date, forum and speaker designation are load-bearing and are not verified. **No sentence in this paper attributes words to any named person.** Appendix B records it as an item requiring primary-source confirmation before it is ever quoted.

The exit constraint on pool concentration is stated and not quantified. How quickly work redirects between pools bounds how much entrenched control a share represents, and no rate is measured or assumed. **The pool index is therefore an upper bound on entrenched control and this paper does not say how loose a bound it is.**

13.1 Rigour checks not met, listed by name

1. **No uncertainty is reported anywhere, because nothing is estimated.** Every figure is exact arithmetic on stipulated or described inputs. That is the absence of empirical content, not precision.
2. **Model comparison was not performed.** No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted. The instrument is asserted on the strength of the identity chain in Section 12.7.
3. **The conjoint conditions were not tested** for the utility axis [Michell, 1997, Luce and Tukey, 1964, Krantz et al., 1971]. The axis is treated as ordinal, which is the honest downgrade; **it is not shown to be even that, since no ordering test was run against independent judges.**
4. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. **Any restatement reaching for a heavy-tail claim about hashrate, stake or holdings must run it first** [Stumpf and Porter, 2012, Broido and Clauset, 2019].
5. **The constructed illustrations fail the calibration-and-validation checklist** of Bruch and Atwell [2015]: none is calibrated, none is validated out-of-sample, and none has a sensitivity analysis beyond Section 12.3. They are demonstrations that a stated mechanism suffices to produce a stated shape, which is one of the uses Epstein [2008] enumerates and is not prediction.
6. **The instrument is exposed to its own adoption** [Goodhart, 1975, Campbell, 1979], and a published decentralisation metric is precisely the kind of measure a network can optimise instead of the property. The only defence offered is the reporting standard.
7. **The instrument is performative and its own bloc assumptions are exempted from that** [MacKenzie and Millo, 2003, Lucas, 1976]. **That is an inconsistency and it is not resolved here.**
8. **Expected value and time average are not the same thing** [Peters, 2019]. The dwell arithmetic is an expected exposure; a structure whose value is frozen once does not return to the mean, and the ensemble figure understates what a single participant faces.
9. **There is no conservation law anywhere in this paper.** The one genuine conservation is that shares sum to one [Mirowski, 1989]. **This is the objection the genre most often fails and this paper meets half of it.**
10. **Aggregation is unaddressed.** A single headroom parameter set is written for a heterogeneous settlement layer in Section 9.2, and Kirman [1992] establishes that such a representative parameter generally does not exist.
11. **No differential prediction is offered** [Durlauf, 2005]. Any correlation-aware concentration measure would produce the same collapses. **The contribution is the identification of the right share basis and the discipline of dating the number, not a uniquely discriminating forecast.**
12. **The leading-share ceiling was quoted beside a vector on which it does not bind**, and Section 12.7's step C5 prints the check rather than removing the quotation.
13. **The bloc-diverse effective count of** 3.00 **is** 2.9994 **and is rounded.** Disclosed in Section 12.8.
14. **The scalar-reduction objection is conceded and not answered.** Curzi [2026] states it once at framework level; this paper inherits it, points at it, and does not claim that naming it disposes of it.

14. Conclusion

This paper establishes six results in the form the rest of the corpus cites, and the following statements are the fixed text of those results.

R1 — the instrument transfers to ledgers unchanged. Measured on stated validator, coun-

cil or pool sets, effective counts run from a curated 35.0 validators (HHI $= 0.028571$) and 39.0 council members (0.025641) down to 6.00 organisations (0.166667) and 5.94 entities (0.168400). **An inverse-index effective count is indifferent to what its shares describe.**

R2 — dwell time is the whole freeze exposure. A five-second hop is 1.585×10^{-7} of a year (0.0000159%) against 0.0822 (8.2192%) for value rested thirty days — **a ratio of** $518{,}400$**.**

R3 — proof-of-work concentration is a pool measurement. A constructed distribution measures HHI $= 0.190000$ and 5.26 effective pools at a $30\%/26\%$ top two, against the ceiling $1/s_{\max}^2 = 11.11$ that the leading share alone imposes.

R4 — utility-as-function is an ordinal and not a score. A minimal-script ledger sits at $1/9$ and a general virtual machine at $9/9$; **the axis must be printed with the rank every time, the axis is not oriented, and programmability is denied as a quality gradient because a minimal ledger cannot express a bug it has no opcode for.**

R5 — the curated-list collapse. A single-curator trust set gives HHI $= 1.0000$ and **one** effective curator against five equal independent operators at 0.2000 and 5.00, **so counting validators the way entities are counted misses the binding constraint.**

R6 — base-layer throughput, stated to its parameters. Approximately 226 virtual bytes per transaction against approximately 10^6 virtual bytes per block on a ten-minute interval gives approximately 7.4 transactions per second; approximately 140 virtual bytes gives approximately 11.9.

Counter-result. The atlas refuses the reading that would make it useful as a ranking. **The utility ordinal is not a quality scale. The freeze control sits with the settlement instrument's issuer rather than on any rail, so rail diversification buys nothing against it. Participating in a pilot is not settling production value. And every live concentration figure is time-varying and is deferred to a dated register — a concentration measure without an as-of date is not a measurement.**

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every share vector in this paper is either an equal-weight ceiling implied by a protocol or governance parameter described from the source manuscript, or a **CONSTRUCTED** or **SYNTHETIC** illustration labelled as such at each point of use. **No live validator set, stake distribution, vote distribution, hashrate distribution, minimum-coalition coefficient or council roster was measured, and no figure in this paper is a measurement of any running network.**

All figures were produced by the scripts named in their captions (`figs/src/CCP-067_fig01.py` through `figs/src/CCP-067_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Protocol specifications, consensus papers, improvement proposals and standards documents are described from the source manuscript and are not cited to the bibliography, which contains no standards documents. Appendix B lists every affected claim. Any reader relying on a protocol constant used here must verify it against the governing specification.

The networks analysed are de-branded. Where a named system's characteristic could not be supported from the bibliography, the name is dropped and the functional description is kept. **No claim is made about any named network, product, organisation, institution or individual, and no allegation is made about any of them.**

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. No identifier, address, balance or transaction of any real party appears anywhere in this paper.

Legal, tax and investment advice

This paper is analytical and is not legal, tax, or investment advice. It analyses settlement networks as rails and settlement systems only. **No token, instrument, network or platform is recommended, valued, or characterised as an asset**, and no price, market capitalisation, return or yield figure appears anywhere. **No instrument is evaluated as a store of value.** The regulatory treatment of digital settlement instruments differs by jurisdiction, differs between regimes applying to the same facts, and changes without notice; every regulatory statement in this paper is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel in the relevant jurisdiction before any reliance.

Appendix A. The reporting standard for a ledger concentration measurement

Any network measured under this instrument reports the following, and nothing less.

```
 1  share basis, stated in one sentence, with the mechanism that dictates it
 2  the participant table and its shares, summing to 100.0%
 3  the SOURCE of the distribution and its AS-OF DATE
 4  naive HHI, in fraction and in points, and the effective count
 5  the coordination-mechanism collapse, with the grouping rule stated
 6  the effective count after collapse, named as the binding figure
 7  the equal-weight ceiling implied by any protocol or governance cap,
    LABELLED AS A CEILING and never reported as a measurement
 8  the leading share and the bound 1/s_max^2, with a note where that
    bound exceeds the nominal count and therefore does not bind
 9  the utility position WITH THE AXIS NAMED BESIDE IT, and a statement
    that the axis is ordinal and unoriented
10  the dwell assumption used for any exposure figure
11  the diff against the previous measurement, and its date
```

Item 3 is the one that decides whether the rest is a measurement. Items 7 and 8 exist because a ceiling reported as a measurement is the commonest error in this domain, and Section 12.7's step C5 is the instance in which this paper caught itself. **Item 9 exists because a rank without its axis is not a measurement of anything.**

Appendix B. Claims requiring verification against primary sources

The following rest on protocol, governance or regulatory detail, and **none of them is cited to the bibliography, which contains no standards documents, no protocol specifications, no vendor documentation and no primary sources for any individual jurisdiction.** They are described from the source manuscript, and require confirmation against the governing documents before any reliance.

1. **The identity of the nine networks.** The source manuscript names them; this paper debrands them per Section 3.6. Reattaching a name requires verifying every characteristic attributed to it in Section 4.
2. **Every consensus-mechanism description**: the proof-of-work construction, the federated-agreement protocols, the asynchronous Byzantine-fault-tolerant gossip construction, the capped Byzantine-fault-tolerant proof-of-stake family, the delegated-proof-of-stake construction, the verifiable-delay-clock construction, and the proof-of-stake finality gadget. Confirm each against its published specification.
3. **Every set size and cap treated as a protocol or governance constant**: the curated default list of about thirty-five validators, the council cap of thirty-nine, the active-set cap of about one hundred and eighty, the fixed producer count of twenty-seven, and the tier-one anchor count of seven. **Each is the input to a ceiling, and a wrong set size is a wrong ceiling.** Several are set by on-chain governance and can be changed by a vote.
4. **The base-layer protocol constants of Section 8**: the block interval, the retarget window, the issuance cap, the halving interval, the block capacity in virtual bytes, and the transaction sizes used. **The throughput result rests entirely on these and they are uncited.**
5. **The scripting-language capability lists of Section 7.3**, both columns. Confirm the named primitives and the named absences against the specification; **the load-bearing claim is the absence of a general virtual machine.**
6. **The programmable-contract-module capability** attributed to the row-4 network, its compilation target, and its relationship to the settlement ledger it descends from. **Row 4's bloc and governance are left undetermined in print and must not be filled in from secondary coverage.**
7. **Every claim about pilots, trials, partnerships and platform products.** This paper names none, asserts none, and states that no central-bank digital currency runs in production on a named public permissionless ledger **only as an absence of a documented counter-example at the source manuscript's date.** Confirm the current record before repeating it. Confirm separately whether any commercial platform runs on a public ledger or on a private instance of a derived technology; that distinction is elided constantly.
8. **The central-bank remark on the degree of control a programmable sovereign rail confers.** It is described and **deliberately not quoted**. Confirm the exact wording, date, forum and speaker designation against the primary recording before quoting it anywhere. **Paraphrasing it as fact would be the self-inflicted error this paper's whole discipline exists to prevent.**
9. **The issuer-freeze fact** — that an issuer of a settlement instrument can immobilise balances at the request of an authority — is described generically and attributed to no named issuer, network or unit. Confirm the mechanism and its scope per instrument.
10. **Every liveness, halt and client-diversity claim.** Liveness is a statement about a history that continues; confirm against the current record and date it.
11. **All live distributions**: validator sets, stake shares, vote distributions, hashrate shares, minimum-coalition coefficients, staking-entity shares, execution-client shares and council rosters. **None is measured in this paper and all move.**
12. **The retail digital-currency issuance status of any jurisdiction.** Described by class in the source manuscript and not named here; status changes frequently.
13. **The rate at which proof-of-work capacity redirects between pools**, which bounds how much entrenched control a share represents and is stated in Section 6 without a number.

14. All constructed vectors, dwell parameters and hazard rates are stipulated for illustration and are not claims about any network.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 68

Content Addressing, Time-Axis Concentration, and the Bounded Gain of a Nine-Capital Supplement

Abstract. Three results are joined by one idea: that an object's identity should follow from its content, and that a ledger's silence is a measurable quantity. Content addressing is stated exactly, with a one-byte difference in a settlement object producing a different identifier, and canonicalisation is placed underneath so that homoglyph variants fold to one skeleton before any hash is taken. The concentration instrument is then applied to a maturity profile rather than to entities: a constructed sovereign stack with 37.0, 11.0, 7.0, 16.5, 15.5 and 13.0 per cent in six buckets has a time-bucket HHI of 0.222050 and an effective spread of 4.50 buckets, with 55.0 per cent refinancing inside three years, against a flat ladder's 0.1667, 6.00 and 50.0 per cent. At a constructed repricing from a 2.00 to a 4.50 per cent coupon, the front-loaded stack adds 1.375 per cent of the stack per year against the ladder's 1.250 per cent, and the paper is explicit that the level obscures the real content, which is that 55 per cent reprices in one window rather than gradually. On a constructed nine-capital vector, 63.8500 per cent of national capital is represented on the monetary ledger and 36.1500 per cent is structurally off-ledger, of which 11.50 per cent is marked unmeasured; making the remainder visible widens the priceable base by at most 56.62 per cent, a multiple of 1.5662, and the honest gain lies strictly between zero and that ceiling.

Keywords: content identifier; canonicalisation; maturity concentration; refinancing wall; repricing delta; reserve drift; nine forms of capital; borrowing base

Series: D. Structure and Resilience **Paper:** CCP-068

1. Introduction

Three results are joined by one idea: that an object's identity should follow from its content, and that a ledger's silence is a measurable quantity. The first is a statement about identifiers, the second about a concentration axis nobody points the instrument at, and the third about what an accounting standard cannot represent. What links them is that in each case the honest measurement is of something the ordinary apparatus does not report.

The paper's four contributions are separable.

Content addressing, stated exactly, with canonicalisation underneath it. In a content-addressed system the name of a stored object is a hash of the object, so the identifier and

the integrity check are the same object: a reference cannot be held without the means of verifying it. A one-byte difference in a constructed settlement object produces a wholly unrelated identifier, and **the demonstration was recomputed independently for this paper and reproduces the source's digests and identifiers exactly.** But the same property launders a confusable identifier: a homoglyph substitution produces a different object with a cryptographically impeccable and permanently distinct name. **Canonicalisation must therefore sit *underneath* the addressing rather than beside it**, and with it in place the two visual twins fold to one identifier — also verified here from first principles.

The concentration instrument rotated onto the time axis. A constructed six-bucket maturity stack of $37.0/11.0/7.0/16.5/15.5/13.0$ per cent has a time-bucket index of 0.222050, an effective spread of 4.50 buckets, and 55.0% refinancing inside three years, against a flat ladder's 0.1667, 6.00 and 50.0%. At a constructed repricing from a 2.00% to a 4.50% coupon the front-loaded stack adds 1.375% of the stack per year against the ladder's 1.250%. **The level obscures the real content, which is that 55 per cent reprices in one window rather than gradually.**

The completeness gap, computed and bounded. On a constructed nine-form capital vector, 63.8500% of national capital is represented on the monetary ledger — financial 42% and material 18% fully, intellectual at a stipulated 35% recognition giving 3.85% — and 36.1500% is structurally off-ledger, of which 11.50% is marked **UNMEASURED**. Making the remainder visible widens the priceable base by **at most** $36.15/63.85 = 56.62\%$, a base multiple of 1.5662. **The honest gain lies strictly between zero and that ceiling and cannot be stated precisely, because the valuation the taxonomy does not supply is exactly what would be needed to state it.**

And a fourth thing the paper refuses. The 56.62% is a ceiling on constructed inputs and not a promise; **visibility is not pledgeability**; the valuation of non-financial capital is unsolved and is named here as the hardest problem in the framework; and the composed architecture is an architecture and not a system.

Why these sit in one paper. They are one measurement discipline applied at three scopes. Curzi [2026] measures the completeness gap on the same constructed nine-capital vector — 63.850000% represented, 36.150000% structurally unrepresentable — and this paper derives its national reading from that result. Curzi [2026] supplies the canonicalisation and typed-parsing controls the addressing layer requires, where typed-field parsing collapses the withdrawn-code parsing-ambiguity false-positive share from 88.99% to 0.00% against a naive detection precision of 11.01% — a control right one time in nine. Curzi [2026] supplies the constraint that makes publication of all of it an engineering decision rather than an ethical one: **channel separation is strengthened by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable and non-disclosure is refused as a design premise, not merely discouraged.** And Curzi [2026] establishes that the concentration instrument transfers to any share basis unchanged — from a curated 35.0 validators (HHI $= 0.028571$) and 39.0 council members (0.025641) down to 6.00 organisations (0.166667) and 5.94 entities (0.168400) — which is the licence this paper uses when it points the same index at maturity buckets instead of at entities.

2. Hypotheses

Six hypotheses with their falsifiers, and three statements that are not hypotheses and are labelled as such. Platt [1964]'s standard applies.

H1 — the fusion hypothesis. In a content-addressed system the reference and the integrity check are one object, so they cannot be separated by any configuration. *Predicted:* changing one byte of a constructed settlement object yields two identifiers sharing no structure, and rehashing the received bytes and comparing to the name is the only check needed. *Falsified by:* a content-addressing scheme in which a valid identifier can be held for content that does not hash to it, or in which an integrity value can be stored, stripped or desynchronised separately from the name.

H2 — the laundering hypothesis. Content addressing over un-canonicalised data converts

a visual ambiguity into two permanent, cryptographically valid, distinct names; the same addressing over the canonical form collapses them to one. *Predicted:* two account strings differing only by a homoglyph produce two distinct identifiers over raw bytes and one identical identifier over the canonical form. *Falsified by:* a canonical form under which the twins do not fold, or a raw-byte addressing under which they collide.

H3 — the time-axis hypothesis. Maturity concentration is measurable by the same index used for entity concentration, and the effective spread it returns is more informative than the total or than the near-window share alone. *Predicted:* a constructed front-loaded stack gives HHI $= 0.222050$ and an effective spread of 4.50 against a flat ladder's 0.1667 and 6.00, while the two stacks' near-window shares differ by only five points. *Falsified by:* two stacks with the same effective spread and materially different repricing behaviour under the same rate path, which would show the index misses the exposure it claims to measure.

H4 — the speed hypothesis. Front-loading changes when a repricing arrives more than it changes how much arrives. *Predicted:* at a constructed 2.50 percentage-point repricing delta the front-loaded stack adds 1.375% of the stack per year against the ladder's 1.250% — a difference of 0.125 points — while 55% of the front-loaded stack reprices inside one three-year window against the ladder's three equal instalments. *Falsified by:* a case in which the level difference dominates the timing difference in fiscal effect, which would make the near-window share the right summary and the index redundant.

H5 — the representation hypothesis. The monetary ledger's silence about non-monetised value is structural rather than a defect of practice, and is therefore measurable as a fixed fraction of a stated capital vector. *Predicted:* on the constructed vector, 63.8500% represented and 36.1500% off-ledger, of which 11.50% admits no accepted measurement basis at all. *Falsified by:* an accounting method that recognises an unpriced item as an entry while retaining the closure property, which would show the gap is a choice rather than a consequence.

H6 — the bounded-gain hypothesis. Making off-ledger capital visible widens the priceable base by a bounded amount whose upper limit is computable and whose actual value is not. *Predicted:* the ceiling is $36.15/63.85 = 56.62\%$, a base multiple of 1.5662; the realised gain is strictly positive and strictly less, and cannot be stated without a valuation method for the non-financial forms. *Falsified by:* a demonstration that a creditor prices visible-but-unvalued capital at exactly zero, which would collapse the lower bound onto zero and make the reform inert.

Not hypotheses, and labelled as such.

- *The nine-form taxonomy* is a **classification**, not a finding. It names what a ledger cannot see and it does not value it; nothing in this paper treats the naming as evidence for anything.
- *The choice of maturity buckets* is a **modelling choice**. The index is not invariant to it, and Section 10.4 states exactly what that costs.
- *The supplementary-standard proposal* is a **design**, adopted by no body and carrying no legal force. It is stated so that it can be evaluated, not asserted as established.

3. Method

3.1 The content identifier, stated exactly

In a location-addressed system the name says *where* the data is, and the data at that location can change while the name stays the same — which is why a link rots, a file is edited in place, and a row is updated without anyone downstream knowing. In a content-addressed system the name says *what* the data is, because the name is computed from the content. **Change one byte and the address changes.**

The self-describing form used here wraps a hash in enough metadata to survive changes of hash function and encoding:

```
identifier  =  <base-prefix> <version> <content-codec> <multihash>

multihash      =  <hash-function code> <digest length> <digest>
content-codec  =  what the bytes ARE (raw leaf, structured node, linked data)
base-prefix    =  how the identifier itself is text-encoded
```

Three properties follow and each is load-bearing. Recording *which* hash function was used, rather than assuming one, means the scheme survives the retirement of a function without ambiguity — the same discipline that requires a broken function to be refused at the point of naming. Recording what kind of object the bytes are lets a consumer know whether it holds a raw leaf or a node in a hash-linked graph. And recording the text encoding of the identifier itself makes an identifier written into a message unambiguous about how to turn its characters back into bytes — which is Curzi [2026]'s encoding-declaration discipline appearing as a designed-in property of the identifier rather than as a boundary rule an integrator must remember to apply.

The property that matters is the fusion. The identifier and the integrity check are the same object: to check that the bytes received are the bytes the name promised, re-hash and compare, and there is no separate step, no separate field, and no separate channel in which an integrity value could be stored, forged, stripped, or desynchronised from the data. **The name carries its own proof.**

That fusion is the complement of Curzi [2026]'s channel separation and is stated here as a complement rather than as an equivalence. Channel separation solves the impersonation problem by lifting control off the data plane so that data cannot forge control; content addressing solves it by fusing the reference to the data so that data cannot be altered under a valid reference. **Both reach the one end that matters — the data cannot be tampered with while a valid control path to it survives — by opposite means.** In the separation case the property must be built and maintained and a lapse reintroduces the exposure; in the addressing case there is nothing to maintain, because the property is a consequence of the arithmetic rather than a configuration. **This correspondence is this paper's own analytical framing and is badged as an argument, not as a standard**, per the analogy discipline of Section 10.5.

3.2 Why canonicalisation must sit underneath the addressing

There is a trap in the primitive, and it is the seam where the whole composition either holds or fails. **Content addressing does not fix confusable identifiers. Left to itself it launders them.**

If the identifier is the hash of the content, a homoglyph substitution in a name does not produce a suspicious near-duplicate that a reconciliation might catch. It produces a *different piece of content*, with a different, cryptographically impeccable address, indistinguishable from a legitimate distinct entity. **The addressing layer inherits the defect of the layer beneath it in its worst form: the ambiguity becomes permanent and cryptographically endorsed.**

The remedy is ordering, not addition. Canonicalise, then address; and retain the hash of the raw octets alongside, so that the fact that a twin was folded is not lost. **The canonical form gives one address; the raw-byte hash still witnesses that a substitution occurred, and that pair is what distinguishes benign normalisation from injected substitution.** Curzi [2026] specifies the canonical form and the typed parsing this rests on, and Curzi [2026] states why the witness must be computed over the raw octets and held on a plane separate from the data it guards — **a witness that is a function of the canonical form changes exactly when the data changes and never otherwise, which destroys precisely the evidence a witness exists to preserve.**

3.3 Which effective count, and the licence to rotate the axis

Every effective count in this paper is $N = \mathrm{HHI}^{-1}$, the reciprocal of the sum of squared shares. That quantity is the Hill number of order two [Hill, 1973, Jost, 2006]: the number

of equally-sized units that would produce the observed index. It is the reciprocal of Simpson [1949]'s index, the effective number of parties of Laakso and Taagepera [1979], and the numbers-equivalent reading attributed to Adelman [1969]; the index is Herfindahl [1950] and Hirschman [1964], and the bands at which competition authorities read it are policy choices that have moved [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. The exponential of Shannon entropy [Shannon, 1948] is the same family at order one, and HHI^{-1} is also the exponential of the Rényi entropy of order two [Rényi, 1961].

The corpus's other effective count is not a Hill number and is not used here. The affine form $N_{\text{eff}} = 1+(N-1)u$ is a linear interpolation between 1 and N; it is not a numbers-equivalent of any index, and no literature in ecology, economics, political science or information theory contains it. **Wherever this paper says "effective count" or "effective spread" it means** HHI^{-1}, and the affine form appears nowhere.

The licence to rotate the axis is Curzi [2026]'s and it is bounded. That paper establishes that the index transfers to any share basis unchanged, because its derivation does not depend on what the shares are shares of. **What transfers is the arithmetic and the numbers-equivalent property. What does not transfer is any claim that the units on the new axis are the same kind of thing as the units on the old one.** Maturity buckets are not jurisdictions, and this paper aggregates nothing across the two scopes. That badge is Curzi [2026]'s **POSTULATE — MODEL FORM ONLY**: identical structure at several scopes is a statement about the chosen model, not a claim of kinship or of cross-scope aggregation, and it is a structurally parallel result in another domain rather than a re-derivation.

The bloc collapse is the variance identity of Markowitz [1952]: for shares w_i and unit-variance shocks X_i, $\mathrm{Var}(\sum_i w_i X_i) = \sum_i \sum_j w_i w_j \rho_{ij}$, which is $\sum_i w_i^2$ under independence and $\sum_b W_b^2$ under perfect within-group correlation. Leinster and Cobbold [2012] and Rao [1982] give the general similarity-sensitive form. That correlations rise under stress is measured [Longin and Solnik, 2001, Ang and Chen, 2002]; the contrary reading — that diversity–stability correlations can arise from statistical averaging with no mechanism — is Doak et al. [1998]'s, and May [1972] shows increasing diversity can destabilise. **Portfolio arithmetic is not by itself evidence of a mechanism**, and none is claimed here.

The identification problem is stated where the collapse is introduced. Any grouping of exposures into perimeters is a reference-group specification, and the framework's reflexive law is a linear-in-means specification whose endogenous effect Manski [1993] proves is not identified from observational data. **This paper adopts no bloc grouping at all on the maturity axis — the buckets are exogenous calendar intervals, not stipulated coordination groups** — so the reflection problem does not bite on H3 or H4. **Where it does bite is on the coupling claim of Section 6.3**, which asserts that a drifting reserve share thins the marginal bid at exactly the maturity buckets where refinancing concentrates. That is an assertion about a relationship between two populations of holders and it is **an analytical inference, not an identified effect**; the remedy adopted is stipulation with a defence [Brock and Durlauf, 2001], and the price is that the coupling is a modelling position.

3.4 What a supplementary account may claim

The monetary ledger requires that every entry carry an amount in a unit of account. Anything without a price cannot be an entry, so value that is real and operative but that no transaction ever priced **is not recorded as zero — it is not recorded at all**, which is a different and worse thing, because zero is a number a reader can question and silence is not. Curzi [2026] establishes the gap quantitatively; this paper carries it to national scale and asks what follows.

The consequence is a pricing consequence and it is stated narrowly. A creditor prices what it can see, and it reaches for the monetised aggregates because those are the quantities the standard produces. Off-ledger capital does not enter the pricing — not because a creditor judges it worthless but because no statement reports it. **That is a failure of the instrument that feeds the judgement, not of the judgement.**

Three things the account must not do, stated before the results rather than after.

It must not average across the measurable and the unmeasurable. Some of the nine forms admit no generally accepted measurement basis. Summing them into a single headline assigns the unmeasured forms an implicit value by including them in a total, which is a fabrication wearing an aggregate's clothes. **This is a scale-type violation before it is anything else**: an entry with no measurement basis is not even ordinal, and Stevens [1946] fixes what operations a scale licenses, Krantz et al. [1971] what must be true before a quantity can be said to exist, and Hurlbert [1971] the general discipline that a composite index carries no content without its formula attached. **The standard therefore marks unmeasured forms UNMEASURED, and strikes no total.**

The habit this refusal guards against is named once at framework level and is inherited rather than restated. Curzi [2026] states it as one objection appearing in two domains rather than two objections: where the source description is a pattern across several jointly varying features, the framework replaces it with a single number and does arithmetic on the number, and the validity of the arithmetic does not protect the reduction that produced it. **A single national-capital total across nine heterogeneous forms is that habit at its largest scale**, and the standard's refusal to strike one is this paper's concession to the objection rather than an answer to it.

It must not substitute a proxy for an unmeasurable quantity. Once a proxy for an unmeasurable becomes a target it stops measuring what it stood for [Goodhart, 1975, Campbell, 1979] — and a national account full of soft self-reported indices is that failure at the scale of a state. The governance and valuation literatures for the non-financial forms exist and must supply any figure the standard reports: Ostrom [1990] and Ostrom [2010] for common-pool resources and polycentric governance, Cox et al. [2010] for the meta-analytic audit of those principles, and Hardin [1968] as the claim Ostrom refuted and which must be cited only as that pair. **For social capital specifically the literature is contested rather than merely thin**: Putnam [2007] finds that diversity in the short run reduces trust and civic participation, and Abascal and Baldassarri [2015] is the rebuttal; Fukuyama [2001] and Gambetta [1988] set out how unstable the construct's definition is. **A standard that entered a single "social capital" figure would be entering a number the literature does not agree how to compute.**

It must not present visibility as pledgeability. Making a form of capital appear on a statement does not make a creditor lend against it and certainly does not make it collateral. Much of the newly visible capital is by its nature unpledgeable and unrealisable as security. **What visibility does is narrower: it moves a quantity from "unknown, therefore priced at zero" to "known, of contested value", and a quantity of contested value is priced above zero by any rational lender.** Hansmann and Kraakman [2000] is the reason the distinction is sharp — asset partitioning, not disclosure, is what makes an interest enforceable — and Pistor [2019] is the account of how legal coding manufactures enforceability and its sharpest critic at once.

And one thing the standard genuinely is. A standard decides what gets counted, and what gets counted decides what gets managed, financed and argued over, because a quantity that appears on no statement is one no minister defends in a budget and no analyst prices in a spread. Scott [1998] is the canonical account of legibility as a form of state power and of what it costs; Hacking [1995] states the general mechanism by which a classification interacts with what it classifies so that the referent moves; and MacKenzie and Millo [2003], Callon [1998] and Ferraro et al. [2005] document the same loop in economics, where a description relied upon changes the behaviour of those relying on it. **A supplementary standard would be performative in exactly that sense, and this paper counts that as an argument for stating its limits loudly rather than as an argument against building it.**

3.5 What is constructed, what is described, and what is cited

Every numerical result in this paper rests on constructed or stipulated inputs. The settlement objects, the account identifiers, the six-bucket maturity distribution, the repricing delta, the private refinancing schedule, the reserve share and its drift rate, and the nine-form capital vector are all invented for illustration. **No dataset was collected. No figure here is a mea-**

surement of any real issuer, nation, entity or holding, and no allegation is made about any of them.

Statistical series, statutes, accounting standards and legislative material are not in this paper's bibliography and are not cited. The reserve-composition series, the outstanding-debt series, the actual maturity profile of any sovereign, the recognition rules of any accounting framework, the storage and identifier specifications underlying Section 3.1, and the text of any proposed legislation are described from the source manuscript. **The bibliography contains no statistical series, no standards documents, no statutes and no legislative drafts.** Appendix B lists every affected claim.

Named jurisdictions, issuers and instruments are consequently de-branded, following the convention of Curzi [2026]: where a named party's characteristic is relied upon and cannot be supported from the bibliography, the name is dropped and the characteristic is kept — *a reserve-issuing sovereign, a proposed capital-anchored instrument, the coordinating perimeter*. **The functional descriptions are precise enough to identify what is measured and carry no claim about any named party.**

What *is* cited, and genuinely supports what it is attached to: the concentration literature of Section 3.3; the portfolio and stability literature of the same section; the measurement-theory literature of Section 3.4; the commons, trust and social-capital literatures named there; the legibility and performativity literature; the distributed-systems results of Section 4.3; and the identification, scaling and modelling literature of Sections 3.3, 10 and 11.

4. Results: H1 and H2 — content addressing, and the layer that must sit under it

4.1 H1 — one byte, one different address: supported and independently reproduced

Two **SYNTHETIC** settlement objects differing in a single character:

```
A  "settlement-object-0042: amount=2000 ccy=643"
B  "settlement-object-0042: amount=2000 ccy=644"

sha-256(A)  31feca3443b85c9c...
sha-256(B)  ed1b3121817f07eb...
            differ from the first byte onward

content identifier (version 1, raw codec, base32)
A  bafkreibr73fdiq5ylsofx5zhy36oowdxtdoqew5injlbcmmfeia62vf4d4
B  bafkreihndmysdal7a7v2373iici34mere36rldsktdikxtigomej37avu4
```

A single digit changed in a currency field produces two content addresses sharing no structure, because the digest is an avalanche function of every input byte. **The consumer who asked for A and is handed B does not need a separate integrity check to notice: the address does not match, and the mismatch is the check. The reference and the verification are one act, and there is no configuration under which they come apart. H1 is supported.**

These four values were recomputed from first principles for this paper — SHA-256 over the stated octets, wrapped as a version-1 raw-codec multihash and rendered in lower-case base32 — and reproduce the source manuscript's digests and identifiers exactly. That is the strongest verification status any figure in this paper carries, and Section 10.8 records it as the one independent reproduction performed.

What the demonstration does not establish. The specific digests are properties of the stated byte strings and carry no meaning beyond exhibiting the avalanche property. **A production tool that wraps small payloads in a framing layer before hashing would yield different but**

equally deterministic identifiers; the property demonstrated — one byte, one different address — holds under either framing, and the paper's claim is the property and not the digest.

4.2 H2 — the laundering trap, and the ordering that closes it

The same primitive turned against the system. Two account identifiers differing only by a homoglyph — a Latin letter replaced by a visually identical letter from another script:

```
clean  "ACCT-0042-CORP"                    (Latin O)
twin   "ACCT-0042-C<Cyrillic O>RP"         (renders identically)

identifier over RAW bytes
clean  bafkreidn5fn5dsd7j3bnyixc26mb3nyp7yemasvms4cvffwnktjv7lma3y
twin   bafkreidme3ihjm4z5fx5iqllmjute75r4wcii3utfx2ncchkd5hzlr4ynu
       two distinct, permanent, cryptographically valid names for one visual identity
```

Now put the canonical form underneath the addressing:

```
canon("ACCT-0042-CORP")            = ACCT-0042-CORP
canon("ACCT-0042-C<Cyrillic O>RP") = ACCT-0042-CORP    (folded to one skeleton)

identifier over canon(clean)  bafkreidn5fn5dsd7j3bnyixc26mb3nyp7yemasvms4cvffwnktjv7lma3y
identifier over canon(twin)   bafkreidn5fn5dsd7j3bnyixc26mb3nyp7yemasvms4cvffwnktjv7lma3y
       one identity, one address
```

H2 is supported, and both identifiers were likewise recomputed independently and reproduce the source exactly. Content addressing over un-canonicalised data converts a visual ambiguity into two permanent and distinct names; content addressing over the canonical form collapses the twins onto one. **The canonicalisation layer must sit underneath the addressing rather than beside it, and the raw-byte hash must be retained alongside so that the fact of a fold is not lost.**

4.3 Necessary, not sufficient — for every layer at once

The claim must be bounded before it is composed with anything, and the bound is the same at every layer. Canonicalisation defeats encoding-level evasion and does nothing about semantic fraud. A byte-level hash defeats silent edits and does nothing about a correctly signed lie. Content addressing defeats reference-without-verification and does nothing about content that is verifiably, impeccably false. Per-object hash chains defeat silent history-tampering and do nothing about a false entry faithfully recorded.

A tamper-evident, content-addressed, canonically named record of a false transaction is a tamper-evident, content-addressed, canonically named false transaction, and the architecture will preserve it faithfully, immutably, and forever.

Two further bounds are structural rather than rhetorical and both are cited. **Per-object hash chains provide tamper-evidence and write-parallelism; they do not provide consensus, total order or double-spend prevention**, and an ordering layer is required — the requirement has been formal since Lamport et al. [1982] fixed the number of genuinely independent parties needed to tolerate f arbitrary faults at $3f + 1$, and Fischer et al. [1985] and Gilbert and Lynch [2002] bound what any such layer can promise. **Nor do they provide resistance to one party presenting as many**, which Douceur [2002] proves impossible without a trusted certifying authority and which makes an unaudited count of participants worthless. **Neither layer is supplied by anything in this paper, and the composition is a substrate rather than a complete distributed ledger.**

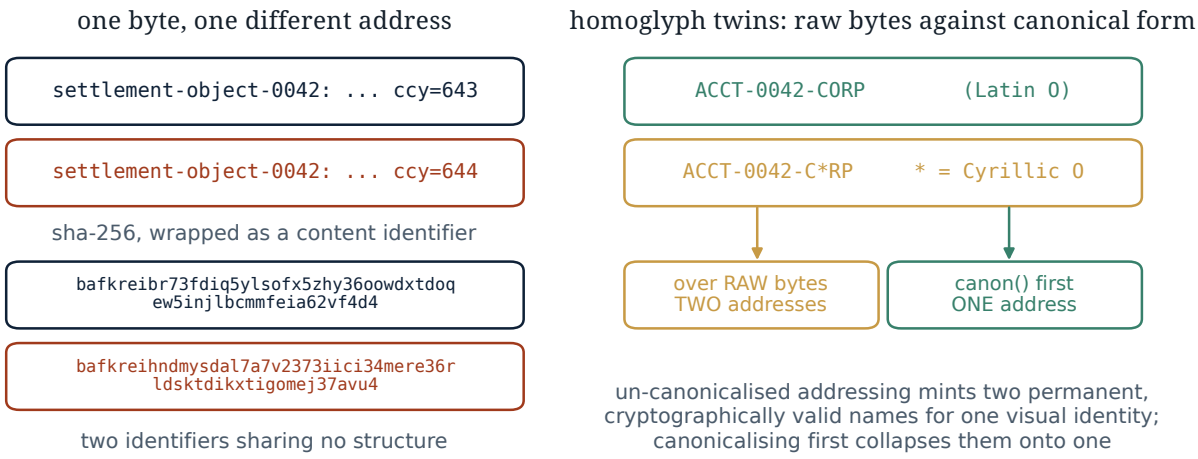

Figure 68.1: **One byte changes the identifier; one canonicalisation collapses two identifiers into one.** Left: two settlement objects differing in a single character produce content identifiers sharing no structure. Right: two account strings differing only by a homoglyph produce two permanent, cryptographically valid identifiers over raw bytes, and one identifier over the canonical form. All four identifiers were recomputed from first principles for this paper and reproduce the source exactly. SYNTHETIC strings; script `figs/src/CCP-068_fig01.py`.

A third bound is about registries and it is where cryptographic certainty ends. An identifier code is only as trustworthy as the registry binding it to reality, and **a hash computed over a false binding is a cryptographically impeccable name for a falsehood.** Content addressing guarantees that the bytes fetched are the bytes that were named; it guarantees nothing about whether the entity code inside those bytes belongs to the party the message claims. **Curzi [2026w]'s two-column refinement is the general form of the same discipline and is the sharpest available statement of it: the evidence column carries what could have come out otherwise, and the precedent column carries only that the idea was independently arrived at and preserved — two sources agreeing does not double the evidence when only one of them is evidence.** A cryptographic witness and a registry assertion are exactly such a pair: the witness is evidence about the octets and the registry is precedent about the world, and stacking them does not produce two independent confirmations of the same fact.

5. Results: H3 and H4 — the time axis

5.1 The rotation, and why the total is the least informative number

A stock of debt is not a single object. It is a schedule — a distribution of principal across future dates at which each tranche must be repaid or refinanced. **The total is a sum, and it is close to the least informative number available**, for the same reason a count of entities is the least informative thing that can be said about a structure.

The mechanism is stated without a single asserted figure about any real issuer. A fixed coupon is fixed at issuance: a change in market rates does not change what is paid on debt already outstanding. **The exposure to a rate change is therefore not on the outstanding stock; it is on the refinancing of the stock, and it arrives in order of maturity — the soonest first, the largest near-term tranche fastest of all.** The vulnerability is a function of how concentrated the maturity schedule is at the short end, and that is measurable by the index of Section 3.3 with maturity buckets as the share basis.

The front-loading is not a mistake. Short-dated debt is cheaper to issue when the yield

curve slopes upward, easier to place in size, and defers locking in a higher long rate. **Each of those is an individually reasonable issuance decision, and aggregated over years they front-load the schedule** — the same shape as an estate that becomes single-perimeter through a sequence of individually sound jurisdiction choices. Nobody builds the concentration on purpose; it is what results when each decision optimises its own cost and none measures the resulting distribution.

5.2 H3 — the time-bucket index: supported

CONSTRUCTED throughout. The distribution below is invented to demonstrate the instrument. It is not any issuer's maturity profile.

maturity bucket	share of stack	share^2
0–1 year	37.0%	0.136900
1–2 years	11.0%	0.012100
2–3 years	7.0%	0.004900
3–5 years	16.5%	0.027225
5–10 years	15.5%	0.024025
10–30 years	13.0%	0.016900
total	**100.0%**	**0.222050**

```
refinancing due within 3 years  = 37.0 + 11.0 + 7.0    = 55.0%
time-bucket HHI                                        = 0.222050
effective maturity spread       = 1 / 0.222050 = 4.5035 -> 4.50 buckets
```

Against the flat ladder — one sixth in each bucket, the maximally diversified stack for six buckets:

stack	HHI	effective spread	due within 3 years
constructed	0.222050	4.50 buckets	55.0%
flat ladder	0.166667	6.00 buckets	50.0%
gap		-1.50	$+5.0$ points

H3 is supported. The nominal count is six and the effective count is 4.50; the gap is the front-loading. **And the near-window share alone would have missed it**: both stacks have roughly half their maturities inside three years, and the difference the front-loading buys is not how much comes due soon but how concentrated the near-term maturities are. **The laddered stack's near-term maturities are three equal small slices; the constructed stack's are one large slice and two small ones, and the large slice is the exposure.**

5.3 H4 — the repricing arithmetic, and why speed is the content

Take a **CONSTRUCTED** rate shock: debt maturing in the near buckets was issued at an average coupon of 2.00% and refinances at 4.50%, a repricing delta of 2.50 percentage points. The added annual interest is the delta applied to the share that reprices:

```
front-loaded stack, 55% within 3 yr:   0.55 x 0.0250 = 0.013750 = 1.375% of the stack/yr
flat ladder,        50% within 3 yr:   0.50 x 0.0250 = 0.012500 = 1.250% of the stack/yr
difference                                                      0.125 points/yr
```

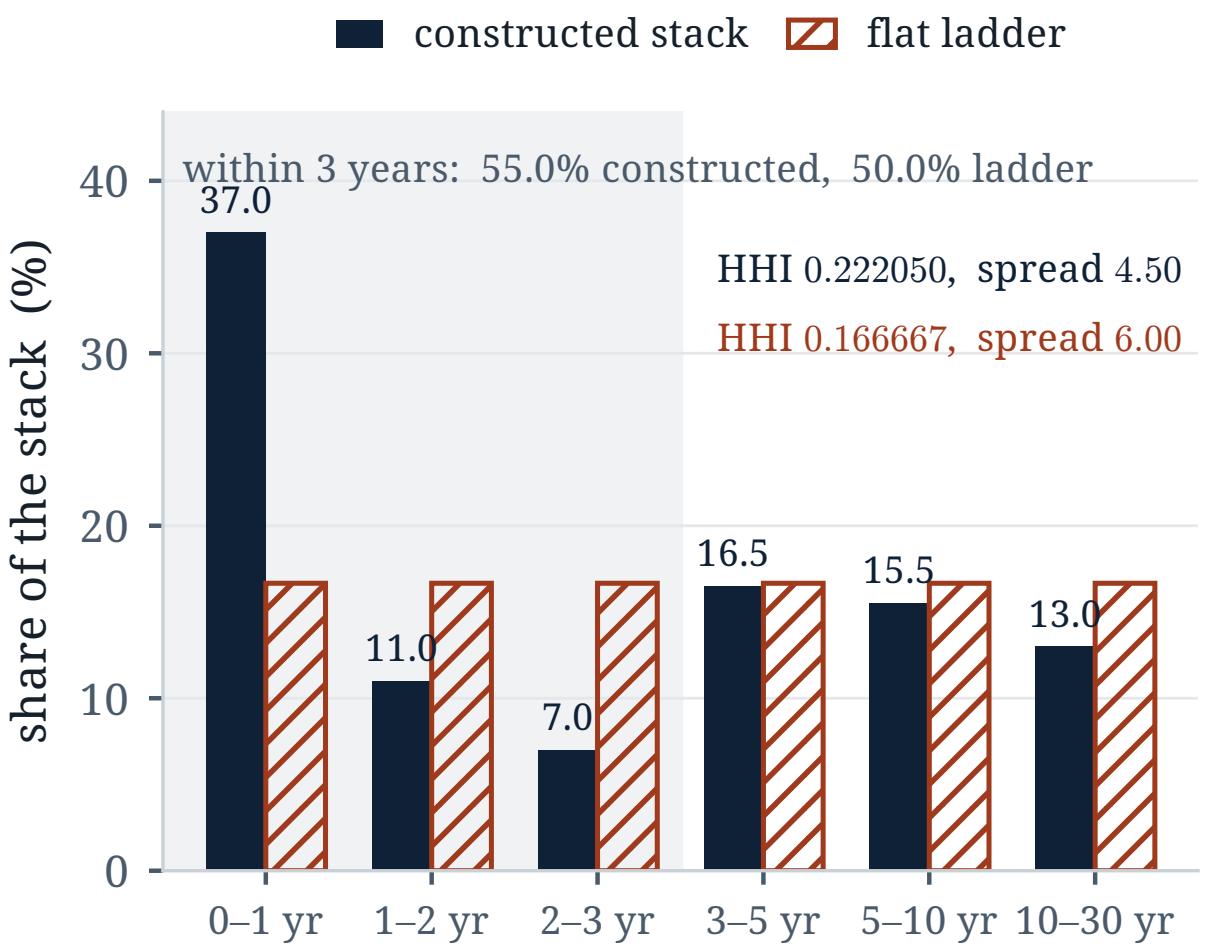

Figure 68.2: **The near-window share hides what the index reports.** A constructed front-loaded stack and a flat ladder both have roughly half their principal maturing inside three years — 55.0 against 50.0 per cent — but the front-loaded stack concentrates that half into one dominant bucket, giving a time-bucket index of 0.222050 and an effective spread of 4.50 against the ladder's 0.166667 and 6.00. CONSTRUCTED distributions; script `figs/src/CCP-068_fig02.py`.

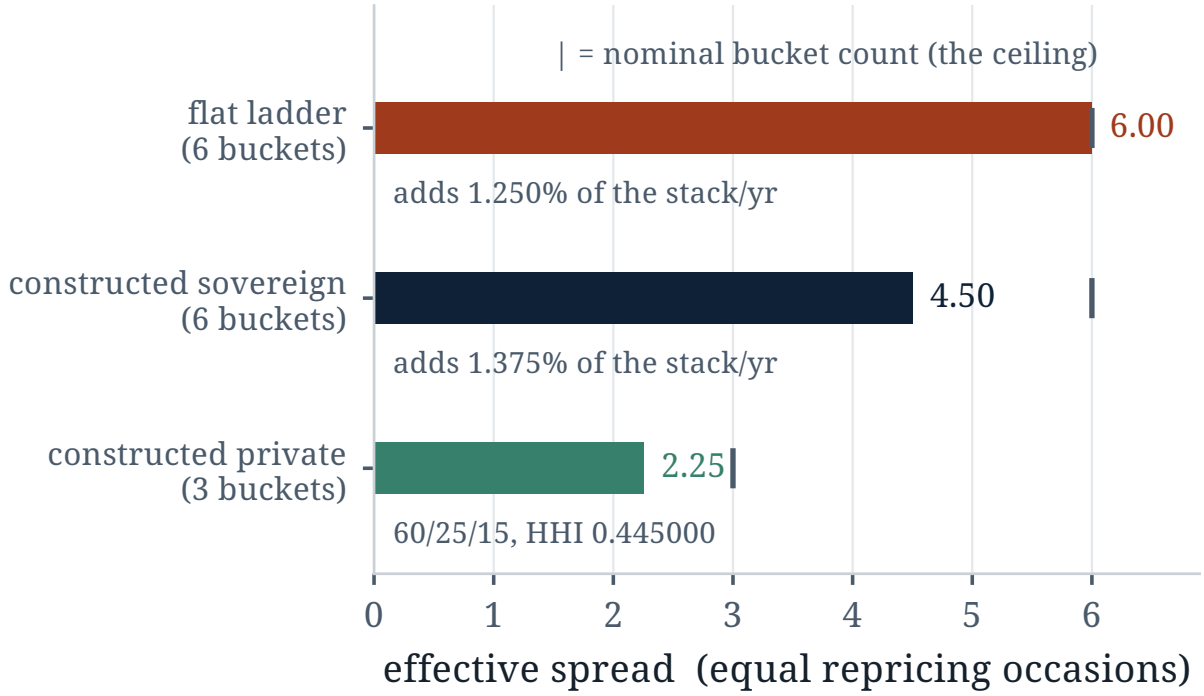

Figure 68.3: **Front-loading changes when the repricing arrives more than how much arrives.** At a constructed 2.50-point repricing delta the front-loaded stack adds 1.375 per cent of the stack per year against the ladder's 1.250 — a gap of 0.125 points — while its effective spread of 4.50 against the ladder's 6.00 shows the same repricing arriving in fewer, larger occasions. A constructed private refinancing schedule at 60/25/15 per cent is more concentrated still, at 2.25 effective occasions. CONSTRUCTED parameters; script `figs/src/CCP-068_fig03.py`.

The level difference is small and this paper will not inflate it. What the arithmetic actually says is about timing. The front-loaded stack does not reprice gradually: it reprices 55% of itself inside three years, so the interest-cost increase arrives fast and early. The laddered stack reprices a steady sixth per bucket, absorbing the shock in even instalments. **Concentration on the time axis converts a rate change from a gradual cost into a fast one, and speed determines whether an increase can be met from flow or must itself be borrowed. H4 is supported: the front-loaded stack does not pay more in the end; it pays more, sooner, and reprices its largest share first.**

The same instrument at private scale. A constructed facility refinancing 60% within one year, 25% at one to two years and 15% at two to three gives $0.360000 + 0.062500 + 0.022500 = 0.445000$ and an effective spread of 2.2472, quoted as 2.25. **The private stack is far more time-concentrated than the constructed sovereign one — 2.25 occasions against 4.50 — because a rolling facility rolls faster than a bond ladder**, and the remedy is identical in form: lengthen the financing or reduce reliance on the rolling short leg, at a cost paid now against a shock deferred. Curzi [2026] owns the trigger mechanics that sit alongside this exposure; a drawdown triggers a call and a rate shock reprices the roll, **and both reach the short end first.**

5.4 What the instrument does not capture, stated before anyone asks

The time-axis index captures concentration of maturities. **It does not capture the level of rates, the direction of rates, the demand for the debt, the currency of issuance, or the capacity to service it.** It is one axis, and a sovereign position is at least four — maturity concentration, holder concentration, currency of issuance, and the reserve status of that currency — in exact

parallel to the four axes an entity structure is exposed on. **A stack can be beautifully laddered and still be in trouble if its holders are concentrated and heading for the exit, and the maturity index will report the laddering and see none of the rest.**

Three refusals belong here rather than in the limitations, because a reader could otherwise take them as concessions rather than as the shape of the claim.

This is not a prediction that a rate shock happens. The repricing scenario is constructed and the paper asserts nothing about whether or when rates move. It measures what a front-loaded stack does *if* they move, which is a conditional and the only kind of statement made here. **The conditional form is not a hedge but the honest shape of the claim**: a maturity schedule is a distribution of future obligations, and a distribution has no truth value until a rate path is laid across it. The same stack is resilient under a falling path and exposed under a rising one; the front-loading does not choose the path, it determines only how much of the stack the path reaches and how fast. **The conditional is what the instrument measures; the prediction is what it cannot.**

This is not a claim that any issuer cannot refinance. For a sovereign borrowing in its own unit of account the near-certainty that maturing debt can be rolled is exactly what makes the exposure a *repricing* exposure rather than a *rollover* one. **The vulnerability is the price of the roll, not the possibility of it**, and confusing the two is how a collapse narrative reintroduces itself.

And this is not a number about any real issuer. It is a number about a constructed distribution with 55% inside three years.

6. Results: H5, H6, and the reserve-drift timescale

6.1 R6 — reserve drift as a timescale illustration

The first compromise of a reserve-issuing position is a slope, not a cliff, and the honest way to show that is to state a constructed slope and read the timescale off it.

```
CONSTRUCTED share of allocated reserves 58.0%, drifting 0.5 percentage points a year

year +0     58.0%       no threshold crossed
year +5     55.5%       no threshold crossed
year +10    53.0%       no threshold crossed
year +16    50.0%       crosses the symbolic half, on a constructed slope
year +20    48.0%       and no rival at scale to receive the released share
```

A linear extrapolation of a slope of this kind crosses no threshold for a decade and a half, and a process that crosses no threshold for fifteen years is not an event. The figures are invented to show the timescale and forecast nothing.

Three structural features make “drift” the right word. **It is slow**, and a reallocation happening in fractions of a point a year is never minuted as a decision — the absence of a decision is the point, and a process with no event has no date. **The released share disperses rather than transferring**: it goes into a basket of secondary units and into metal rather than to a single rival, so the reserve system’s own effective count *rises* and no recipient approaches the position being vacated. **And part of the drift is not diversification at all**: a move from one unit into another whose issuer sits inside the same coordinating perimeter has changed the currency and not the perimeter, which is the same error as rearranging exposure inside a bloc — and rearranging inside a perimeter does not change N. Curzi [2026] measures exactly that collapse on a historical network, where five houses read 3.819710 effective jurisdictions naively and 1.000000 effective blocs once one coordination perimeter is recognised, giving $h = -0.500000$.

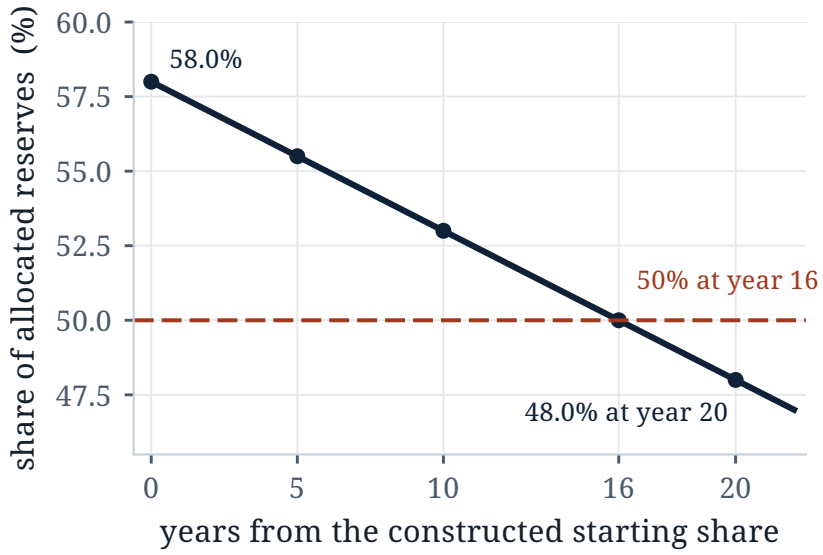

Figure 68.4: **A slope that crosses no threshold for sixteen years.** A constructed reserve share of 58.0 per cent declining at 0.5 percentage points a year reaches 50 per cent at year 16 and 48 per cent at year 20. Presented as a timescale illustration only: the figures are invented, the slope is stipulated, and the paper forecasts nothing. Script `figs/src/CCP-068_fig04.py`.

6.2 H5 — the representation split: supported

CONSTRUCTED national capital vector, reconciled to reproduce Curzi [2026]'s result at national scale:

form	constructed share	on the monetary ledger	represented
financial	42.0%	yes, fully	42.00%
material	18.0%	yes, fully	18.00%
intellectual	11.0%	partly, ~35% recognised	3.85%
experiential	9.0%	no	0.00%
social	7.0%	no	0.00%
natural	6.0%	no	0.00%
cultural	3.0%	no	0.00%
living	2.5%	no	0.00%
spiritual / ethical	1.5%	no	0.00%
total	**100.0%**		**63.85%**

```
fully on the monetary ledger    financial + material    = 60.0000%
partially (intellectual @ 35%)                          =  3.8500%
TOTAL REPRESENTED                                       = 63.8500%
STRUCTURALLY OFF-LEDGER                                 = 36.1500%

of the off-ledger portion, marked UNMEASURED            = 11.5000%
  (social 7.00 + cultural 3.00 + spiritual/ethical 1.50)
of the off-ledger portion, partially measurable         = 24.6500%
```

H5 is supported on the constructed vector: the monetary ledger balances exactly over 63.85% **and is silent about** 36.15%**, of which** 11.50% **admits no accepted measurement basis at**

all. The silence is not a policy the standard-setter chose and could reverse. It is the price of the closure property: a ledger recognising unmeasurable items would stop balancing in any meaningful sense, and closure is the one thing double entry actually guarantees. **The gap is structural, and the correct response is not to demand the ledger carry more but to know exactly what it does not carry and hold that knowledge somewhere else, deliberately.**

No single total is struck, and the refusal is the specification. Striking one would assign the 11.50% of unmeasured forms an implicit value the standard declines to invent, which is the scale-type violation of Section 3.4. **Silence treats an unmeasured form as zero; fabrication invents a proxy; naming it and marking it UNMEASURED does neither, and puts it on the account as a known gap visible to any reader.**

That the accounting method of the period is often credited with more causal force than it can carry is worth naming while the completeness gap is open: Yamey [1964] and Littleton and Yamey [1956] are the deflation of the claim that double entry produced rational capitalism, and no such claim is made here.

6.3 H6 — the bounded ceiling: supported, and bounded in both directions

```
off-ledger / represented  =  36.1500% / 63.8500%  =  0.566170  ->  56.62%
credible base multiple    =  100%     / 63.8500%  =  1.566170  ->  1.5662x
```

Making the off-ledger capital visible widens the priceable base by at most 56.62% — it is 1.5662 times as large when the whole is visible as when only the monetised subset is. That is a real number computed correctly from the constructed vector, **and it is a ceiling and not a promise.**

The lower bound is strictly above zero and is not zero. Visibility moves the newly reported capital from "unknown, therefore priced at zero" to "known, of contested value", and a quantity of contested value is priced above zero by any rational lender even when it is priced far below its owner's estimate. **The gain is the difference between zero and whatever a creditor credits a visible-but-contested base at: positive, bounded above by 56.62%, and impossible to state precisely without the valuation the taxonomy does not supply.**

H6 is supported and the paper stops exactly there. The ceiling is computable and is stated; the point estimate would require solving the valuation problem, which is not solved here and is named in Section 7.2 as the hardest problem in the framework. **A proposal quoting the 56.62% as a promised increase in borrowing capacity has quoted a ceiling as a floor.**

6.4 The coupling, badged as an inference

The two exposures measured here are separated for measurement and **are coupled in fact**: a refinancing schedule concentrated at the short end must be rolled into the hands of whoever will buy, and if the historical buyers are themselves drifting then the drift thins the marginal bid exactly at the buckets where the concentration needs it most.

That claim is an analytical inference and not a measured result, because it depends on the holder composition of the near-term maturities, which is a separate axis and is not measured anywhere in this paper. It is badged accordingly in Section 10.6 as a POSTULATE, and Section 3.3 records that it is the one place in this paper where the identification problem bites.

7. Discussion

7.1 What the composition is, and what it is not

Read as a stack, each layer is the precondition of the next: a canonical form makes two records of the same thing compare as the same thing; a hash over the raw octets makes each record

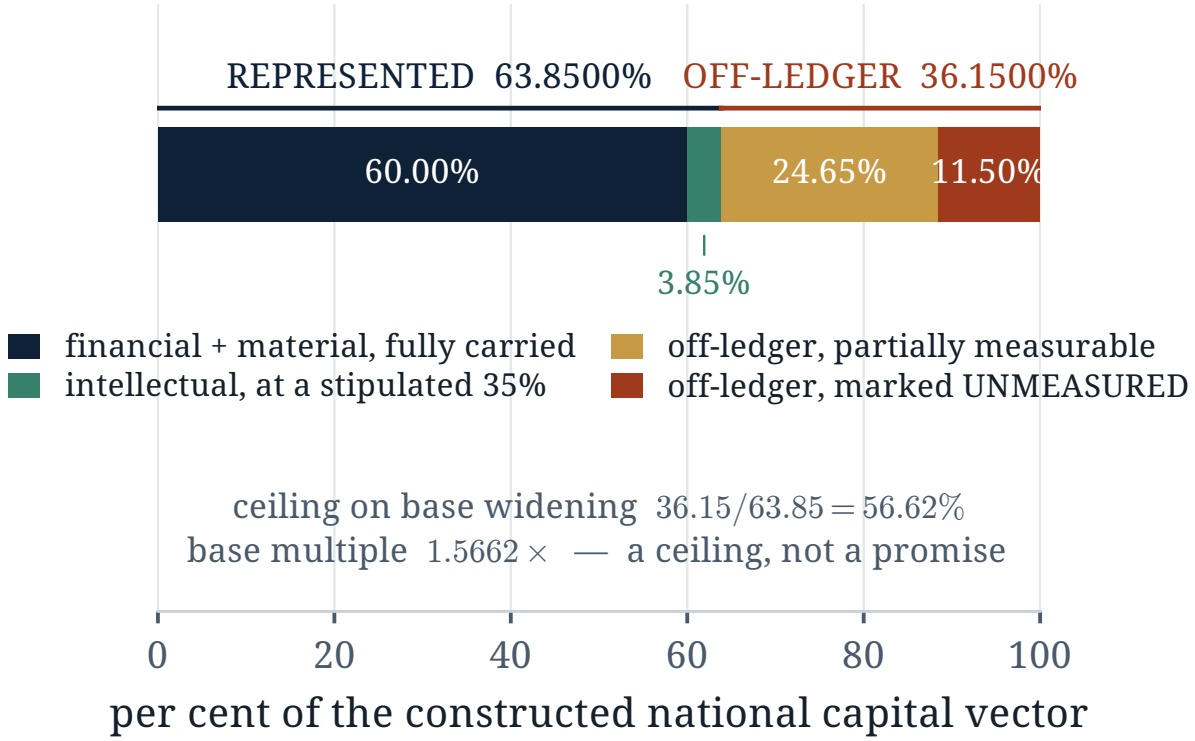

Figure 68.5: **A ceiling, not a promise.** On a constructed nine-form capital vector, 63.85 per cent of national capital is represented on the monetary ledger and 36.15 per cent is structurally off-ledger, of which 11.50 per cent admits no accepted measurement basis. Making the remainder visible widens the priceable base by at most 56.62 per cent — a multiple of 1.5662 — and the honest gain lies strictly between zero and that ceiling. CONSTRUCTED vector; script `figs/src/CCP-068_fig05.py`.

tamper-evident at the octet level and preserves the evidence of a substitution that canonicalisation would otherwise erase; content addressing makes reference and verification one object; per-object hash chains make each object's history tamper-evident; a structured message layer carries all of it; and settlement spreads across perimeters that do not share a coordination mechanism.

The composition is real as an architecture and unbuilt as a system, and the distinction is not pedantry. The individual pieces have very different maturities and the integration inherits the weakest of them. **There is no independent implementation, no interoperability profile, and no conformance suite maintained by anyone outside its author — the ordinary prerequisites for anything to become infrastructure, none of which is met.** The honest status is a coherent architecture and an undeployed one, **and coherence is not readiness.**

Curzi [2026] is the corpus's own template for exactly this disclosure and it bounds what this paper may claim: there, an entire pipeline is built, verified and deterministic, eleven upstream components are established, and the paper states that nobody knows how the one missing link works — the carriage of sequence over force. **This paper is in the same position with two links missing rather than one**, and it says so in the same register.

7.2 The valuation problem, named as unsolved

Naming nine forms of capital does not tell anyone what any of them is worth. The valuation problem is the entire difficulty, and the measurement basis for the non-financial forms is not specified in the source manuscript and is not specified here. A coverage ratio computed across a portfolio in which one component has no accepted measurement basis is a ratio computed over an unknown.

Content addressing can give such a portfolio a stable, tamper-evident name; it cannot give an unvalued line item a value, and a content address over an unvalued quantity is a precise name for an imprecise thing. This is the deepest unsolved problem underneath the architecture, and a synthesis that buried it under a tidy diagram would have failed its own test.

The measurement-theoretic form of the objection is the sharpest one and is conceded rather than answered. Michell [1997] argues that a discipline systematically fails to test whether its attributes are quantitative at all before measuring them; **that is the strongest single objection to this framework**, and the formal test — conjoint measurement [Luce and Tukey, 1964], whose conditions establish additive quantitative structure — **was not run for any of the nine forms.** Cronbach and Meehl [1955] and Campbell and Fiske [1959] set out what construct validation would require of any proposed measure for the softer forms, and **no such validation exists for any of them.**

7.3 The bounds this paper works inside

Curzi [2026] bounds what borrowed formalism may claim. Its counter-result declines the inflated reading of its own borrowed physics: the postulate is stated as a postulate, the relation is given only in its correct form, and a named failure mode requires that a user be able to distinguish the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand. **Applied here, that is why Section 3.1's correspondence between fusion and separation is badged as this paper's own analytical framing rather than as a standard**, and why Section 10.5 sorts every borrowing by category.

Curzi [2026] bounds what a discovered gap licenses. Its counter-result refuses category innocence as a defence of acquisition, forbids moving any harm through a gap discovered in a scheme, and concedes that the case where the feedback loop runs through another person's will is an unsettled seam. **Applied here, that is the constraint on the standard-setting argument.** A standard that makes national capital visible is legibility exercised on one's own account [Scott, 1998], and legibility exercised on someone else's is a different act with a different licence. **The reform proposed here changes what a nation reports about itself; nothing in**

this paper licenses using the same instrument to make a counterparty legible against its will, and that boundary is stated rather than assumed.

Curzi [2026] is the bound stated as an apparatus. Its counter-result assigns the corpus's central identification, the application of the surplus functional to a life, and the reading of a day's surface as a leading indicator to the postulate drawer, and says of the third that it is a wager whose misfire column exists because wagers can lose. **Applied here, it is why Section 6.2's account marks three forms UNMEASURED rather than estimating them, and why Section 6.3 states a ceiling and refuses a point estimate: an honest register has empty cells in it.**

Curzi [2026] bounds inference from an invariant statistic, and its bound applies directly to the effective spread. That paper's counter-result is that a width statistic invariant under relabelling does not even determine the object it is computed from, which formally blocks inference from a high or low value to a substantive condition. **The effective spread is invariant under any permutation of the buckets**, so it does not determine the schedule it was computed from: two stacks with the same spread can have their concentration at opposite ends of the maturity range, and the near-window share of Section 5.2 exists precisely because the index alone cannot say *where* the concentration sits. **The index and the near-window share must be reported together or each hides what the other shows.**

Curzi [2026] bounds the remedy. Its counter-result is that perfect opposition and perfect agreement read identically, because the framework's non-parallelism depends only on the magnitude of a correlation — so the standard remedy of adding a contrarian contributes zero surplus while adding cost, and at zero non-parallelism two of four levers are exactly inert. **Applied here, that is the warning against assuming that adding buckets, adding forms of capital, or adding rails is automatically an improvement**: an addition that is perfectly correlated with what is already held adds cost and no independence, and the index will report the addition while the exposure does not move.

7.4 Why the standard would be performative, and why that is an argument for stating its limits

Curzi [2026ab]'s belief dynamic is presupposed here and it is the right formal template. $B_{t+1} = (1-\lambda)B_t + \lambda \min(1, LB_t)$ with loop gain $L = \alpha G$: the zero fixed point is stable if and only if $L < 1$, the transition at $L = 1$ is sharp, **and** $G = 0$ **forces** $L = 0$ **at every** α — a structural zero cannot be compensated by any amount of the other factor. **Applied to a standard: no amount of adoption enthusiasm substitutes for a measurement basis that does not exist.** A form of capital with $G = 0$ — no accepted method — contributes nothing to the priceable base however loudly it is reported, which is exactly why Section 6.2 marks three forms UNMEASURED rather than reporting them at a number.

The reflexive side is real and cuts both ways. Hacking [1995] states the general mechanism by which a classification changes what it classifies; MacKenzie and Millo [2003] documents the case in the field with dates and prices; Callon [1998] and Ferraro et al. [2005] generalise it to economic description; and Lucas [1976] states the consequence for any parameter fixed before publication. **A standard that made off-ledger capital countable would change how it is managed, which is the whole of the power on offer and also the reason its unmeasured cells must stay visibly empty**: a gap that is reported as a gap cannot be optimised into a target, and a gap filled with a proxy immediately can be [Goodhart, 1975, Campbell, 1979].

And the same reflexivity is not applied to this paper's own parameters, which is an inconsistency and is not resolved here. The framework asserts that systems change when described and then exempts its own constructed vectors, buckets and recognition fraction from that response. What is offered instead is the reporting standard of Appendix A.

7.5 The commitment that cuts both ways

A content-addressed, hash-chained record is permanent, byte-addressable, discoverable in its entirety, and cannot be quietly amended. For a structure built so that nothing is hidden because nothing needs to be, that is a feature — and it is the disclosure constraint of Curzi [2026] stated as storage: **effectiveness independent of whether anyone knows the design is in place, so every element is publishable and non-disclosure is refused as a design premise.** Kerckhoffs [1883] is the principle's canonical statement, Saltzer and Schroeder [1975] its restatement as open design, and Brandeis [1914] the older policy instinct.

It is nonetheless a commitment made once and honoured forever, and an entity adopting it surrenders the option of a record that ceases to exist. The integration should be entered deliberately, as a decision about permanence, and not inherited by default from a diagram because the diagram was elegant. **Elegance is not a reason to become permanent.**

The other side of that permanence is a data-protection exposure that belongs in print. **A permanent record of everything a standard reports is also a permanent record that cannot be corrected by deletion**, and any account carrying entity-level identifiers inherits that. Curzi [2026x] reaches the structurally parallel result in another domain — acoustic addressing fails on geometry rather than on bandwidth, since wavelength matches a ten-micrometre cell only at 154 MHz and the product of wavelength and 20 dB depth collapses from 6160 to 0.0026 mm-cm between 100 kHz and 154 MHz — and the shared lesson is that **a system can have ample capacity on the axis everyone measures and be defeated by a constraint on an axis nobody measured.** Permanence is that axis here.

7.6 What would falsify the synthesis

Three things, none tested here. If canonicalisation underneath the addressing produced a materially elevated false-collision rate against a real name estate — two genuinely distinct entities folded to one address — the laundering remedy would become a cost–benefit question rather than a free improvement. If an ordering layer capable of resolving a per-object ledger's conflicts at the required scale cost more in latency or complexity than the write-parallelism the factoring buys, the object-as-ledger choice would be an optimisation that does not pay for itself. **And if no accepted measurement basis for the non-financial forms materialises under audit scrutiny, the taxonomy remains a coherent way to name what the ledger cannot see and no way at all to value it — which is its status today.**

8. Failure modes

8.1 Presenting the base widening as a promise. 56.62% is a ceiling on a constructed vector. **Quoting a ceiling as a floor is the fastest available way to lose a technical reader.**

8.2 Confusing visibility with pledgeability. Making a form of capital visible does not make it collateral. The reform improves how a base is priced; it does not create a security interest in the unsecurable.

8.3 Fabricating a proxy for an unmeasured form. An index entered as a number where no accepted method exists corrupts the whole account, because a reader cannot tell the fabricated entries from the measured ones [Goodhart, 1975].

8.4 Treating the integrity layer as a valuation. Canonical form, byte-level hash and a cryptographic witness make the *record* honest. They do not make the *numbers* true. **A tamper-evident record of a wrong valuation is a wrong valuation that cannot be altered.**

8.5 Averaging the measurable and the unmeasurable. A single total across measured and unmeasured forms assigns the unmeasured an implicit value by including them. **The account reports the fractions separately and strikes no headline.**

8.6 Replacing rather than supplementing. The standard sits beside the monetary ledger and changes none of its figures. A version proposing to replace double entry has inverted the completeness-gap result, which defends the method as required and not obsolete.

8.7 Quoting the total debt as though it were the exposure. The total is a sum. **Two stacks of identical total can have entirely different time-axis concentrations and therefore entirely different repricing profiles.**

8.8 Confusing rollover risk with repricing risk. For an issuer borrowing in its own unit the debt will be rolled; the question is at what rate. **The wall is a price, not a gate**, and treating it as a solvency cliff imports a private-borrower failure mode into a setting where it does not apply.

8.9 Watching the visible slope and missing the measurable one. A commentary tracking a reserve share to the decimal and never computing the maturity concentration has watched the slope that disperses and missed the slope that amplifies. **The total is easy and the distribution is work.**

8.10 Treating a constructed distribution as a real one. The 0.222050 figure is computed on an invented stack. **Anyone quoting it as a real issuer's time-axis index has moved a number across a boundary without carrying its label.**

8.11 Assuming a rearrangement inside a perimeter is diversification. A move between two units whose issuers sit inside one coordinating perimeter changes the currency and not the perimeter.

8.12 Believing a diagnosed fragility must resolve. A compromised position is not a countdown. It can persist for decades, actively defended where it was once assumed, without healing or breaking.

8.13 Reading the addressing layer as sufficient. Section 4.3. The composition claims the representation, reference and settlement layers and nothing above them, and it must be paired with substantive audit and controls review.

9. Discrepancies found in the source, printed

One discrepancy assigned to this paper belongs to an adjacent paper's model and is reported here in full rather than passed over. The migration model of Curzi [2026] tabulates a remainder at 2046 of $1{,}550{,}381$ lines from a $40{,}000{,}000$-line core migrated at 15% of the remainder per year from 2026. That figure is $40{,}000{,}000 \times 0.85^{20} = 3.876\%$ of the core, i.e. **twenty** annual migrations. The same model separately states a residual "after twenty years" of $1{,}317{,}824$ lines, or 3.29%, which is $40{,}000{,}000 \times 0.85^{21}$ and therefore **twenty-one** annual migrations.

$$40{,}000{,}000 \times 0.85^{20} = 1{,}550{,}381 = 3.876\%,$$
$$40{,}000{,}000 \times 0.85^{21} = 1{,}317{,}824 = 3.295\%.$$

The two statements are off by exactly one migration year. The arithmetic was recomputed here and both figures are internally correct for their own exponent, so the defect is in the year label and not in either computation. Curzi [2026] prints the discrepancy in its own verification section and adopts the 3.29% figure as stated while recording that its tabulated series gives 3.88% at the same date.

No table and no figure in this paper uses either number. This paper contains no migration model, no geometric-decay remainder and no line counts; its own decay illustration is the *linear* reserve drift of Section 6.1, whose figures — 58.0% falling 0.5 points a year, reaching 50.0% at year 16 and 48.0% at year 20 — were recomputed and are internally consistent, since $58.0 - 0.5 \times 16 = 50.0$ and $58.0 - 0.5 \times 20 = 48.0$ exactly. **The discrepancy is recorded here because a reader who meets both papers is entitled to know that the two figures are one year apart and which paper owns the disclosure; it changes nothing in either, since the result in question is that a geometric remainder is strictly positive for all finite time.**

A second, smaller inconsistency was found in this paper's own source and is likewise printed rather than harmonised. The time-bucket index is computed and printed as 0.222050 in the derivation and then quoted as 0.2220 in every comparison table and summary. 0.222050 rounds to 0.2221 at four decimal places under round-half-up and to 0.2220 under round-half-to-even, so the quoted figure is defensible only under the second convention and the source states no convention. **This paper prints 0.222050 throughout and quotes no four-decimal form**, which removes the ambiguity rather than resolving it by fiat. The effective spread is unaffected: $1/0.222050 = 4.5035$, quoted as 4.50.

10. Verification and rigour audit

10.1 Dimensional audit

symbol	quantity	dimension	unit	status
s_i	bucket or form share	$[1]$	fraction	defined; sum to 1
HHI	sum of squared shares	$[1]$	fraction	derived
effective spread	HHI^{-1} on maturity buckets	$[\#]$	buckets	derived
maturity bucket	calendar interval	$[T]$	years	defined (chosen boundaries)
coupon, repricing delta	rate on principal	$[T^{-1}]$	per year (percentage points)	assumed (constructed)
added interest	flow per unit of stock	$[T^{-1}]$	per cent of stack per year	derived
reserve share	fraction of allocated reserves	$[1]$	per cent	assumed (constructed)
drift rate	change in share per unit time	$[T^{-1}]$	percentage points per year	assumed (constructed)
capital share	fraction of a national capital vector	$[1]$	per cent	assumed (constructed)
recognition fraction	share of a form the ledger carries	$[1]$	per cent	**stipulated at 35%**
base multiple	ratio of whole base to visible base	$[1]$	dimensionless ratio	derived
digest, identifier	fixed-length function of octets	$[1]$	256 bits; base32 text	derived, exact

Does the repricing calculation balance? A share (dimensionless) times a rate ($[T^{-1}]$) gives a flow per unit of stock ($[T^{-1}]$): $0.55 \times 0.0250\ \mathrm{yr}^{-1} = 0.01375\ \mathrm{yr}^{-1}$, read as 1.375% of the stack per year. **It balances, and the units are per-year fractions of an unspecified stock — there is no currency anywhere in this paper.**

Does the capital vector balance? The nine shares sum to 100.0% exactly, and represented plus off-ledger is $63.85 + 36.15 = 100.00$. **The base multiple is a ratio of two fractions and is**

therefore dimensionless, which is why it survives the total absence of a unit of account.

Where a quantity has no operational unit, the audit says so. The nine capital forms have **no common unit**, and this is not a presentational gap: it is the substance of the valuation problem. The shares of Section 6.2 are shares *of a stipulated total* and not measurements in any unit, and **the fact that three of the forms admit no unit at all is exactly why no total is struck.**

10.2 Significant figures and epistemic status

- **The digests and identifiers of Section 4 are exact and were independently reproduced.** They are deterministic functions of stated byte strings; **no uncertainty attaches and none is quoted.**
- **The time-bucket index is exact for its share vector**: 0.222050 is the exact sum of squares of the six stated shares, and $1/0.222050 = 4.5035\ldots$ is quoted as 4.50 because the third figure is not informative about a constructed distribution.
- **The flat-ladder index is exact and rational**: $6 \times (1/6)^2 = 1/6 = 0.166667$, spread exactly 6.00.
- **Every input is stipulated, not estimated.** The bucket shares, the repricing delta, the drift rate, the recognition fraction and the capital shares were all chosen. **Exact arithmetic on invented inputs is not a measurement, and no uncertainty is quoted because nothing is estimated.**
- **The recognition fraction of 35% is the single most load-bearing stipulation in Section 6.** Moving it moves the represented share, the off-ledger share and the ceiling together, and Section 10.3 gives the sensitivity.
- 56.62% **and** 1.5662 **are quoted to four figures because they are exact functions of exact stipulations**, and the fourth figure is meaningful about the construction and meaningless about any real position.
- **The reserve figures are round by construction** and are quoted to one decimal place only.

10.3 Limits and boundary behaviour

quantity	limit	behaviour	reading
effective spread	all mass in one bucket	$\to 1$	maximal time concentration
effective spread	n equal buckets	$\to n$ exactly	the flat ladder; the ceiling for n buckets
effective spread	bucket count $\to \infty$ at fixed shape	$\to \infty$	**an artefact of bucketing, not a property of the schedule**
near-window share	window $\to 0$	$\to 0$	no exposure without a window
added interest	delta $\to 0$	$\to 0$	no repricing without a rate change
added interest	near share $\to 1$	$\to$ delta	the whole stack reprices at once
reserve drift	linear at fixed rate	crosses any level in finite time	**the linearity is the stipulation, not a finding**
represented share	recognition $\to 1$	$\to 71.00\%$	full intellectual recognition still leaves 29% off-ledger

quantity	limit	behaviour	reading
represented share	recognition $\to 0$	$\to 60.00\%$	the two fully carried forms alone
ceiling	represented $\to 1$	$\to 0$	nothing off-ledger, nothing to reveal
ceiling	represented $\to 0$	$\to \infty$	**unbounded, and the model's domain excludes it**

Two rows are defects rather than results and are stated as such. The effective spread grows without bound as buckets are subdivided, so **the index is meaningful only against a fixed bucketing and only as a difference against a prior measurement on the same boundaries**; that is a real constraint on the instrument's domain and Appendix A makes the boundaries a mandatory reported item. And the ceiling diverges as the represented share goes to zero, so **the ratio form is informative only where a substantial fraction is already represented**, which the constructed vector satisfies at 63.85%.

The recognition sensitivity, since it is the load-bearing stipulation:

```
intellectual recognition   represented    off-ledger    ceiling    multiple
------------------------------------------------------------------------
        0%                   60.0000%       40.0000%     66.67%     1.6667x
       35% (used)            63.8500%       36.1500%     56.62%     1.5662x
       50%                   65.5000%       34.5000%     52.67%     1.5267x
      100%                   71.0000%       29.0000%     40.85%     1.4085x
```

The ceiling falls from 66.67% to 40.85% across the full range of a single stipulated parameter. That is the sensitivity a reviewer should press on, and it is printed rather than left to be found.

10.4 Invariance

The index is invariant under any permutation of the buckets, which is exactly why it does not determine the schedule it was computed from — the bound carried from Curzi [2026]. Two stacks with identical spread can concentrate at opposite ends of the maturity range. **The near-window share is the statistic that is *not* permutation-invariant, and reporting the pair is what recovers the location the index discards.**

The index is not invariant under rebucketing, and this is the instrument's sharpest limitation. Finer buckets at the short end raise resolution where exposure concentrates and mechanically raise the effective spread; **a measurement is meaningful only as a difference against a prior measurement on the same boundaries.**

The base multiple is invariant under any rescaling of the capital vector, since it is a ratio of two fractions of the same total — which is why it survives the absence of any unit of account, and why it is the only quantity in Section 6 that would still mean something if the shares were expressed in some future unit.

The content identifier is invariant under nothing except identity of the octets, which is the entire point: it is not invariant under a homoglyph substitution, and Section 4.2 is the demonstration that this is both its strength and, without canonicalisation, its failure mode.

Tested at how many scales? **The invariances are algebraic and were checked at the one parameter set reported and the one recognition sweep of Section 10.3.**

10.5 Analogy discipline

borrowing	source	category	justification
HHI^{-1} as a numbers-equivalent	Adelman [1969], Hill [1973], Jost [2006]	**1 — derivation**	shares are non-negative and sum to one by construction; the identity is exact
independent reinvention of the same index	Simpson [1949], Laakso and Taagepera [1979]	**1 — derivation**	the same arithmetic on the same object in three disciplines
exposure as a portfolio	Markowitz [1952]	**1 — derivation**	the variance identity's premises hold by construction
similarity-sensitive diversity of order 2	Leinster and Cobbold [2012], Rao [1982]	**1 — derivation**	exact for a unit-diagonal non-negative correlation matrix
correlation rising under stress	Longin and Solnik [2001], Ang and Chen [2002]	**2 — shared form**	measured in equity markets; a maturity schedule is not shown to satisfy the same conditions
independent-party bound; identity multiplication	Lamport et al. [1982], Douceur [2002]	**2 — shared form**	theorems about agreement and identity systems, cited as prior formalisations of the missing layers and not applied to anything here
impossibility under asynchrony; the availability trade	Fischer et al. [1985], Gilbert and Lynch [2002]	**3 — framing**	cited to establish that structural impossibility results bound what an ordering layer can promise
scale type and permissible statistics	Stevens [1946], Krantz et al. [1971]	**1 — derivation**	an unmeasured form genuinely admits no scale, and the restriction follows from the definition
construct validation	Cronbach and Meehl [1955], Campbell and Fiske [1959]	**1 — derivation**	the requirement is stated for exactly the case at hand and is **not met**

borrowing	source	category	justification
open design; disclosure strengthens a structural control	Kerckhoffs [1883], Saltzer and Schroeder [1975]	**1 — derivation**	effectiveness depends on the arrangement rather than on anyone's knowledge of it; the premise is satisfied
legibility as state capacity	Scott [1998]	**2 — shared form**	a historical and ethnographic account; used for the mechanism and the warning, not as a formal result
classification interacts with what it classifies	Hacking [1995], MacKenzie and Millo [2003], Callon [1998], Ferraro et al. [2005]	**1 — derivation**	the mechanism is the same: a description relied upon changes the behaviour of those relying on it
a measure adopted as a target	Goodhart [1975], Campbell [1979]	**2 — shared form**	stated for monetary and social indicators; the exposure is the same in kind
commons governance and its audit	Ostrom [1990], Ostrom [2010], Cox et al. [2010], Hardin [1968]	**2 — shared form**	field-derived design principles; cited as the literature any natural- or social-capital figure must come from, not as supplying one
social capital, contested	Putnam [2007], Abascal and Baldassarri [2015], Fukuyama [2001], Gambetta [1988]	—	cited to establish that the construct is **contested**, which is the reason the form is marked UNMEASURED
asset partitioning; legal coding	Hansmann and Kraakman [2000], Pistor [2019]	**1 — derivation**	the pledgeability point is exactly what these establish

borrowing	source	category	justification
the modelling programme	Epstein [2008], Bruch and Atwell [2015], Hedström and Ylikoski [2010]	—	the first enumerates the legitimate non-predictive uses of a model; the second is the checklist **none of this paper's models meets**; the third states the criterion this paper accepts, that an explanation must name a mechanism rather than exhibit a fit
fusion and separation as complements	this paper	**3 — framing**	**this paper's own analytical framing**, badged as an argument and not as a standard

10.6 Postulates

#	statement	status
P1	shares are non-negative and sum to one	DEFINITION
P2	HHI $= \sum_i s_i^2$; effective spread $=$ HHI^{-1}	DEFINITION
P3	for n equal shares of $1/n$, HHI $= 1/n$	ARITHMETIC
P4	an identifier is a self-describing wrapper around a digest of the content	DEFINITION (described from the source; uncited)
P5	canon$(\cdot)$ folds visually confusable forms onto one skeleton	DEFINITION, per Curzi [2026]
P6	a fixed coupon does not change while the debt is outstanding, so a rate change acts on refinancing	DEFINITION (standard property of fixed-coupon debt)
P7	the six maturity buckets and their boundaries	POSTULATED (modelling choice)
P8	the constructed maturity shares, repricing delta, drift rate and capital vector	POSTULATED (constructed)
P9	intellectual capital is recognised at 35%	POSTULATED (stipulated; the load-bearing parameter)

#	statement	status
P10	a creditor prices visible-but-contested capital strictly above zero	POSTULATED (economic model; the lower bound of H6)
P11	a drifting reserve share thins the marginal bid at the buckets where refinancing concentrates	POSTULATED (analytical inference; not identified)

10.7 The chains

Chain A — content addressing (R5).

step	consumes	statement	status
A1	P4	the identifier is a function of the octets alone	DEFINITION
A2	A1	sha256$(A) \neq$ sha256(B) for the two stated strings	ARITHMETIC — **independently recomputed**
A3	A1, A2	the two identifiers share no structure	ARITHMETIC — **independently recomputed**
A4	A1	re-hashing received octets and comparing to the name is a complete integrity check	DEFINITION
A5	P5	canon$(\text{clean}) =$ canon(twin) for the stated pair	DEFINITION
A6	A1, A5	the identifier over the canonical form is identical for both	ARITHMETIC — **independently recomputed**
R5	A1–A6	one byte's difference yields a different identifier; canonicalisation folds visual twins onto one	DERIVED

Chain B — the time axis (R1, R4).

step	statement	status
B1	$\sum s_i^2$ on 37.0/11.0/7.0/16.5/15.5/13.0 is 0.222050	ARITHMETIC
B2	effective spread $= 1/0.222050 = 4.5035$	ARITHMETIC
B3	$37.0 + 11.0 + 7.0 = 55.0\%$ due within three years	ARITHMETIC

step	statement	status
B4	flat ladder: $6 \times (1/6)^2 = 0.166667$, spread 6.00, 50.0% within three years	ARITHMETIC
B5	$0.55 \times 0.0250 = 0.013750$; $0.50 \times 0.0250 = 0.012500$	ARITHMETIC, consumes P8
R1	B1–B4	the time-axis index, spread and near-window share, against the ladder
R4	B5	1.375% against 1.250% of the stack per year

Chain C — representation and the ceiling (R2, R3).

step	statement	status
C1	financial 42% + material 18% fully carried $= 60.0000\%$	ARITHMETIC
C2	intellectual $11\% \times 0.35 = 3.8500\%$	ARITHMETIC, consumes P9
C3	represented $= 60.0000 + 3.8500 = 63.8500\%$	ARITHMETIC
C4	off-ledger $= 100 - 63.8500 = 36.1500\%$	ARITHMETIC
C5	unmeasured $= 7.00 + 3.00 + 1.50 = 11.5000\%$	ARITHMETIC
C6	$36.1500/63.8500 = 0.566170$, i.e. 56.62%	ARITHMETIC
C7	$100/63.8500 = 1.566170$, i.e. $1.5662\times$	ARITHMETIC
C8	the realised gain exceeds zero	POSTULATED (P10)
R2	C3–C5	the representation split with its unmeasured fraction
R3	C6–C8	the ceiling, with the gain bounded strictly between zero and it

Only C8 is not arithmetic, and it is the step a reader should attack first. It is an assumption about creditor behaviour rather than about mechanism, and if it fails the reform is inert. **Every other step in Chain C is one line of arithmetic on stipulated shares.**

Chain D — reserve drift (R6).

step	statement	status
D1	$58.0 - 0.5t$ for t years	DEFINITION (constructed linear model)
D2	$58.0 - 0.5 \times 16 = 50.0$	ARITHMETIC
D3	$58.0 - 0.5 \times 20 = 48.0$	ARITHMETIC
R6	D1–D3	a timescale illustration crossing no threshold for sixteen years

10.8 Cross-checks performed

- **The four content identifiers and both digests of Section 4 were recomputed from first principles** — SHA-256 over the stated octets, wrapped as a version-1 raw-codec multihash, rendered in lower-case base32 — and reproduce the source manuscript exactly. **This is the only independent reproduction in the paper and it is the strongest verification status any figure here carries.**
- The maturity index was recomputed by explicit sum of squares and reproduces 0.222050; the ladder reproduces 0.166667 exactly as $1/6$.
- The bound $s_{\max}^2 \le \text{HHI} \le s_{\max}$ holds: $0.136900 \le 0.222050 \le 0.370000$, and the effective-count ceiling $s_{\max}^{-2} = 7.304$ exceeds the bucket count of six, so **the bucket count is the binding bound and the leading-share bound does not bite here.**
- The private schedule was re-summed: $0.36 + 0.0625 + 0.0225 = 0.445000$, $1/0.445000 = 2.2472$.
- The capital vector sums to 100.0% exactly, and represented plus off-ledger reproduces 100.00%.
- The recognition sweep of Section 10.3 was computed at four values and the ceiling is monotone decreasing in the recognition fraction, as it must be.
- The reserve line was checked at all five tabulated years and is exactly linear.
- **The migration figures of Section 9 were recomputed**: $0.85^{20} = 0.0387595$ and $0.85^{21} = 0.0329456$, giving $1{,}550{,}381$ and $1{,}317{,}824$ lines respectively on a 40-million-line core.

11. Limitations

Every worked result is a constructed model and none is a measurement. The settlement objects, the account identifiers, the maturity distribution, the repricing delta, the private schedule, the reserve share and its drift rate, and the nine-form capital vector are all invented. **No dataset was collected, and no figure here is a measurement of any real issuer, nation, entity or holding.**

No as-of date and no source, because nothing real was measured. A concentration figure computed from a real schedule requires its source and its date; **a concentration measure without an as-of date is not a measurement.** Every distribution here is constructed, so there is no source and no date to give, and Appendix A makes both mandatory items of the reporting standard.

The bucket boundaries are a modelling choice and the index is not invariant to them. Section 10.4. A measurement is meaningful only as a difference against a prior measurement on the same boundaries, and no boundary set is defended here as correct.

The 35% recognition fraction is stipulated and it is the load-bearing parameter of Section 6. Section 10.3 shows the ceiling moving from 66.67% to 40.85% across its range. **No source supplies the fraction and none is claimed.**

The valuation of the non-financial forms is unsolved and is the hardest problem underneath the whole architecture. It was unsolved in the source manuscript and it is unsolved here. **The conjoint conditions were not tested for any form** [Michell, 1997, Luce and Tukey, 1964], and no construct validation exists [Cronbach and Meehl, 1955, Campbell and Fiske, 1959]. The commons and social-capital literatures cited in Section 3.4 are cited to establish that the constructs are **contested**, never as supplying a figure.

Visibility is not pledgeability and the paper's positive claim is bounded by that. Most of the newly visible capital is unpledgeable and unrealisable as security by its nature.

The coupling claim of Section 6.4 is an analytical inference and not a measured result. It depends on the holder composition of near-term maturities, which is a separate axis this paper does not measure, and it is the one place the identification problem bites [Manski, 1993, Brock and Durlauf, 2001].

Statistical series, statutes, accounting standards, storage specifications and legislative material are not cited. They are described from the source manuscript, and the bibliography

contains none of them. Appendix B lists every affected claim. **This is a real gap and it is not closed here.**

Two structural layers are missing from the composition and it is not a distributed ledger without them. An ordering layer and a resistance-to-identity-multiplication layer are required [Lamport et al., 1982, Douceur, 2002] and neither is supplied.

The permanence commitment is one-way. A content-addressed record cannot be corrected by deletion, and any account carrying entity-level identifiers inherits that exposure. **The paper states it as a cost and does not quantify it.**

11.1 Rigour checks not met, listed by name

1. **No uncertainty is reported anywhere, because nothing is estimated.** Exact arithmetic on stipulated inputs is the absence of empirical content, not precision.
2. **Model comparison was not performed.** No alternative index was fitted, no out-of-sample test was run, no information criterion was computed and no matched null was constructed, because nothing here is fitted.
3. **The conjoint conditions were not tested and no construct validation exists** for any non-financial form [Michell, 1997, Luce and Tukey, 1964, Krantz et al., 1971].
4. **No distributional or scaling claim is made, so the Clauset–Shalizi–Newman procedure was not run** [Clauset et al., 2009]. The vectors are finite sets of three to nine stipulated shares, not samples; no tail is characterised and no power law is asserted. **Any restatement reaching for a heavy-tail claim about holdings, maturities or capital shares must run it first**, and must read Stumpf and Porter [2012] on why passing it would still not identify a mechanism.
5. **The index is not invariant under rebucketing**, which is a real defect of the instrument and is stated in Section 10.4 rather than discovered by a reader.
6. **The ceiling diverges as the represented share approaches zero**, so the ratio form has a restricted domain.
7. **P10 is an assumption about creditor behaviour, not about mechanism**, and it carries the entire lower bound of the paper's positive claim.
8. **P11 is an analytical inference presented as such**, and the identification problem is not answered for it.
9. **The models fail the calibration-and-validation checklist** of Bruch and Atwell [2015]: none is calibrated, none is validated out-of-sample, and none has a sensitivity analysis beyond Section 10.3. They are demonstrations that a stated mechanism suffices to produce a stated shape, one of the uses Epstein [2008] enumerates, and Hedström and Ylikoski [2010] is the criterion accepted: **nothing here is fitted, and each result follows from an inequality stated in advance.**
10. **The framework is performative and its own parameters are exempted from that** [MacKenzie and Millo, 2003, Lucas, 1976, Hacking, 1995]. **That is an inconsistency and it is not resolved here.**
11. **Expected value and time average are not the same thing** [Peters, 2019], and the repricing figures are per-period averages that no single issuer experiences as such.
12. **There is no conservation law anywhere in this paper.** The only genuine conservation is that shares sum to one [Mirowski, 1989]. **This is the objection the genre most often fails and this paper meets half of it.**
13. **Aggregation is unaddressed** [Kirman, 1992]: a single recognition fraction is written for a heterogeneous form of capital.
14. **No differential prediction is offered** [Durlauf, 2005]. Any correlation-aware concentration measure would produce the same reading of the maturity axis. **The contribution is the rotation of the axis and the discipline of bounding the claim, not a uniquely discriminating forecast.**
15. **Cartwright [1999]'s discipline is accepted**: the arrangements within which each result holds are stated, and no universality is claimed that the argument does not need.

16. **The one independent reproduction performed is cryptographic and not empirical.** Reproducing a digest confirms arithmetic; **it confirms nothing about the world.**

12. Conclusion

This paper establishes six results in the form the rest of the corpus cites, and the following statements are the fixed text of those results.

R1 — the time-axis index. A constructed maturity stack of $37.0/11.0/7.0/16.5/15.5/13.0$ per cent gives HHI $= 0.222050$, an effective spread of 4.50 buckets, and 55.0% refinancing within three years, against a flat ladder's 0.166667, 6.00 and 50.0%.

R2 — the nine-capital representation split. 63.8500% represented (financial 42% and material 18% fully, intellectual at a stipulated 35% recognition giving 3.85%) and 36.1500% structurally off-ledger, **of which** 11.50% **is marked UNMEASURED.**

R3 — the borrowing-base ceiling. Off-ledger over represented is $36.15/63.85 = 56.62\%$, a base multiple of 1.5662, **with the honest gain bounded strictly between zero and that ceiling and not statable precisely.**

R4 — the repricing arithmetic. At a constructed 2.00% average coupon refinancing at 4.50%, the front-loaded stack adds 1.375% of the stack per year against the ladder's 1.250%, **the real content being that** 55% **reprices in one window.**

R5 — content addressing with canonicalisation underneath. One byte's difference in a settlement object yields a different identifier, while the canonical form folds a homoglyph account string onto the same skeleton as the clean one. **All four identifiers were independently recomputed and reproduce the source exactly.**

R6 — reserve drift as a timescale. A constructed share of 58.0% drifting 0.5 percentage points a year reaches 50% in sixteen years and 48% in twenty, **presented as a timescale illustration with no rival at scale to receive the released share.**

Counter-result. The 56.62% widening is a ceiling on constructed inputs and not a promise; **visibility is explicitly distinguished from pledgeability**; the valuation of non-financial capital is unsolved and is named here as the hardest problem in the framework; **and the architecture is presented as an architecture and not a system**, with no independent implementation, no interoperability profile and no externally maintained conformance suite.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every input in this paper — the settlement objects, the account identifiers, the maturity distribution, the repricing delta, the private refinancing schedule, the reserve share and its drift rate, and the nine-form capital vector — is **CONSTRUCTED**, **SYNTHETIC** or **STIPULATED** and is labelled as such at each point of use. The numerical results are exact computations on those inputs, carried at full precision and rounded only for printing. **No real issuer, nation, entity, holding, facility or identifier appears anywhere in this paper, and no allegation is made about any of them.**

The digests and identifiers in Section 4 were recomputed from first principles for this paper — SHA-256 over the stated octets, wrapped as a version-1 raw-codec multihash and rendered in lower-case base32 — and reproduce the source manuscript exactly. That computation is reproducible from the byte strings printed in Section 4 with any standard library.

All figures were produced by the scripts named in their captions (`figs/src/CCP-068_fig01.py` through `figs/src/CCP-068_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

Statistical series, statutes, accounting standards, storage and identifier specifications, and legislative material are described from the source manuscript and are not cited to the bibliography, which contains none of them. Appendix B lists every affected claim. **Named jurisdictions, issuers and instruments are de-branded**, and no claim is made about any named party.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Every identifier, entity and holding referred to here is constructed.

Legal, tax, investment and accounting advice

This paper is analytical and is not legal, tax, investment, or accounting advice. It describes a proposed supplementary accounting standard that **no body has adopted and which carries no legal force**, and it measures constructed distributions to demonstrate an instrument. **No instrument is recommended, valued, or characterised as an asset; no figure is a measurement of any real issuer; and no claim is made that any form of capital named here is pledgeable, realisable or enforceable as security.** Accounting recognition rules, disclosure obligations and the treatment of supplementary statements differ by jurisdiction and change; every such statement here is carried from the source manuscript, is flagged in Appendix B, and requires confirmation with qualified counsel and the relevant standard-setter before any reliance. **Supplementary accounts must never be presented as though they had the standing of statutory accounts.**

Appendix A. The reporting standard

Any position measured under the time-axis instrument, and any account prepared under the supplementary standard, reports the following and nothing less.

```
TIME-AXIS MEASUREMENT
 1  share basis in one sentence: principal due, by maturity bucket
 2  the bucket boundaries, held FIXED across measurements
 3  the SOURCE of the schedule and its AS-OF DATE
 4  the bucket table and shares, summing to 100.0%
 5  the time-bucket HHI and the effective spread
 6  the NEAR-WINDOW SHARE alongside the index -- neither alone
 7  the flat-ladder benchmark for the same bucket count
 8  the repricing arithmetic WITH its rate assumptions stated as
```

```
    assumptions and not as forecasts
 9  the diff against the previous measurement, and its date

NINE-CAPITAL ACCOUNT
10  each form named, with its measurement basis or the mark UNMEASURED
11  the represented and off-ledger fractions, reported explicitly
12  the recognition fraction for every partially recognised form,
    stated as a stipulation with its sensitivity
13  NO SINGLE TOTAL across measured and unmeasured forms
14  the ceiling on base widening, labelled a ceiling
15  the integrity layer: canonical form, raw-octet hash, and the
    statement that tamper-evidence is not verification
```

Item 2 is the one that decides whether item 5 means anything, because the index is not invariant under rebucketing. **Item 6 exists because the index is permutation-invariant and cannot say where the concentration sits. Item 13 is the refusal that keeps the account honest**, and item 14 is the one this paper works hardest to protect: a ceiling reported as a promise discredits everything under it.

Appendix B. Claims requiring verification against primary sources

The following rest on statistical, legal, accounting or technical detail, and **none of them is cited to the bibliography, which contains no statistical series, no standards documents, no statutes, no legislative drafts and no vendor or protocol documentation.** They are described from the source manuscript and require confirmation against the governing sources before any reliance.

1. **The content-identifier construction** — the self-describing wrapper, the multihash form, the content codec and the text-encoding prefix, and the current specifications for each. **The digests and identifiers printed in Section 4 were independently recomputed and are correct for the stated strings; what is uncited is the specification that defines the wrapper.**
2. **The framing behaviour of production tooling**, which would wrap a small payload before hashing and yield a different but equally deterministic identifier. The demonstrated property holds under either framing.
3. **The canonical form** and its component transformations, and the confusable data underlying the homoglyph fold. Curzi [2026] is the primary treatment.
4. **The transport and linked-data layers** referred to generically in Section 3.1.
5. **The identifier namespaces** on which any real account would depend, and — critically — **the registries binding each code to a real-world entity.** A hash over a false binding is a cryptographically impeccable name for a falsehood, and no registry is verified here.
6. **The currency-composition series for allocated official reserves**, its level at any date, the treatment of the unallocated portion, and whether reported changes reflect active reallocation or valuation effects. **This paper states no level and describes only a constructed slope.**
7. **The composition of the assets receiving any released reserve share**, and the claim that no single alternative approaches the scale of the incumbent.
8. **The outstanding debt total and the actual maturity distribution of any real issuer. The six-bucket distribution here is CONSTRUCTED and is nobody's profile.** The real distribution, measured on the same buckets, produces its own index, which this paper does not state.
9. **The weighted-average coupon on maturing tranches and prevailing issuance rates.** The 2.00%-to-4.50% repricing is CONSTRUCTED.

10. **The treatment of floating-rate and inflation-indexed tranches**, which reprice differently and would change a real measurement.
11. **The proposition that an issuer borrowing in its own unit of account faces repricing rather than rollover risk**, its limits, and the fact that it does not extend to debt issued in a foreign unit.
12. **The recognition rules of any accounting framework** — what may and may not be an entry, and the prohibition on recognising internally generated goodwill. Carried from Curzi [2026] and subject to that paper's own register.
13. **The nine-form taxonomy's canonical naming and ordering**, and whether this paper's national reading of each form is consistent with it. **The national readings are this paper's gloss.**
14. **The 35% recognition fraction**, which is stipulated and drawn from no framework, and which is the load-bearing parameter of Section 6.
15. **The history of national-income accounting as an invented standard** — the roles of the relevant statistical offices and economists, and the dates of development and adoption. **This paper states the general fact that such a standard was invented and asserts no attribution.**
16. **Any legislative or programme text referred to generically**, including any stated design goals of monetary immunity or counterfeit impossibility. **Those goals are recorded here only to be corrected: no monetary design achieves immunity to inflation or deflation, and no physical or cryptographic instrument achieves counterfeit impossibility. Both are strengthenings and neither is an absolute.** Confirm the exact wording of any such goal before quoting it, and never reproduce it without the correction.
17. **The status of the supplementary standard.** It is a proposal, adopted by no body, with no legal force, and any interaction with statutory accounts requires prior standard-setter acceptance.
18. **The claim that no form of capital named here is pledgeable, realisable or enforceable as security.** The reform concerns how a base is priced, not whether it can be seized.
19. All constructed vectors, rates, drift parameters and schedules are stipulated for illustration and are not claims about any real position.

All numerical results in this paper were computed from the stated inputs at full precision and rounded only for printing.

Chapter 69

What the Architecture Cannot Do: Correlated Backing Baskets, Gated Adoption Probabilities, and the Failure Record

Abstract. This is the corpus's counter-case, assembled deliberately. The governing negative result is that disclosure is not immunity: approximately USD 300 billion of central bank reserves, among the most thoroughly disclosed assets on earth, were immobilised in 2022, and the paper narrows its own principle in print — disclosure removes the failure mode in which a structure collapses on contact with an authority and makes the structure bankable, and it supplies no appeal against a policy decision taken on a correct and fully disclosed position. The backing proposals are measured against themselves. A constructed commodity basket reads 6.640106 effective components naively, but recognising the climate-correlated components as a single 82.0 per cent exposure gives 1.441753, a naive overstatement of 4.605578 times; the basket is genuinely more diversified than a single-commodity anchor at 1.44 against 1.00, and far less than its component count suggests. A 250-to-1 paper-to-physical ratio leaves 99.600 per cent of claims uncollateralised at par and is exhausted by 0.40 per cent of holders standing for delivery, and the object-ledger is credited only with making that number reportable, not with preventing over-issuance. Phased integration is scored as an option: constructed gate probabilities of 0.60, 0.50 and 0.30 give a 0.090 terminal probability, a ratio of 0.15 to first-phase adoption. Adding Gulf jurisdictions raises naive effective jurisdictions 34.81 per cent while effective blocs fall 3.39 per cent.

Keywords: correlated diversification; paper-to-physical ratio; delivery squeeze; gated adoption; margin call; substance challenge; sham and nominee; disclosure is not immunity

Series: D. Structure and Resilience **Paper:** CCP-069

1. Introduction

This is the corpus's counter-case, assembled deliberately. Every other paper in Series D measures a structure and reports what the measurement shows. This one takes the framework's own recommendations, its own governing principle and its own proposals, and reports where they fail.

The governing negative result is stated first because it is the strongest test the framework's central principle has been put to, and the principle lost. The corpus argues that a structure is durable when being observed yields nothing actionable, because every element is lawful, filed and defensible on its own merits [Curzi, 2026,?]. **In 2022, approximately USD 300 billion of the central bank reserves of the Russian Federation were immobilised by the jurisdictions in which they were held.** Those reserves were among the most thoroughly disclosed assets in existence: their location was known, their custodians were known, and their character as sovereign reserves was known and was the reason they were held where they were held. Correctness and disclosure were complete. They were immobilised anyway.

The result is symmetric, and the symmetry is what makes it a finding rather than an anecdote. Disclosure did not prevent the outcome. Concealment could not have prevented it either, because a reserve asset must be held somewhere by a named holder in order to be a reserve asset at all: the custodial relationship that makes the holding usable is the same relationship that makes it reachable. **The variable that decides the outcome is therefore not what is known about the holder but where the holding sits**, and the corpus's answer to arbitrary action is accordingly jurisdictional and rail diversity across coordination perimeters rather than any quality of a structure's paperwork. A fully disclosed, fully correct, single-perimeter structure has an effective bloc count of 1.00, and $\ln(1.00) = 0$ — no available surplus at all, on the corpus's own arithmetic [Curzi, 2026].

The event is described here from the source manuscript and is not cited. This paper's bibliographic database contains no contemporaneous reporting, no sanctions instruments and no jurisdiction-specific legal material, so no citation is attached to the figure, the date, the instruments or the current legal position of the assets. **No approximate citation has been substituted for the missing one.** Appendix A itemises what requires verification: the instruments by jurisdiction, the dates, the amounts by jurisdiction, and the position on both the principal and the income arising from it. The aggregate is stated as approximate because that is how the source states it, and no figure in this paper depends on its precision.

The narrowing that survives the event has to be stated in print or the principle is dishonest.

> **What disclosure does.** It removes the failure mode in which a structure collapses on contact with an authority, because there is nothing to find; it converts an enforcement problem into a policy problem; and it makes the structure bankable, which the corpus identifies as the binding constraint on everything else.
>
> **What disclosure does not do.** It does not prevent a sovereign decision taken on policy grounds against a correct and fully disclosed position; it does not supply an appeal; and it does not protect an asset sitting inside the perimeter that took the decision.

The rest of the paper applies the same treatment to the framework's own proposals. **A constructed backing basket of eight components reads 6.640106 effective components naively and 1.441753 once the climate-correlated components are recognised as a single 82.0 per cent exposure — a naive overstatement of 4.605578 times.** The basket is genuinely more diversified than a single-commodity anchor, at 1.44 against 1.00, and far less diversified than its component count claims. **A constructed paper-to-physical ratio of 250 leaves 99.600 per cent of claims uncollateralised at par and is exhausted by 0.40 per cent of holders standing for delivery**, and the object-ledger the corpus proposes is credited only with making that number reportable, never with preventing over-issuance. **A phased integration programme is scored as an option rather than a plan: constructed gate probabilities of 0.60, 0.50 and 0.30 give a terminal probability of 0.090, a ratio of 0.15 to first-phase adoption.** And **adding two Gulf jurisdictions to a constructed six-country structure raises the naive effective jurisdiction count by 34.81 per cent while the effective bloc count falls by 3.39 per cent** — more jurisdictions, less independence, and every conventional report saying the opposite.

Why the negative results are the contribution. A corpus that publishes only its affordances has not been audited [Lakatos, 1970, Platt, 1964, Meehl, 1990]. The failure record assembled here is a better dataset than any adviser's success record for a reason that is structural rather

than rhetorical: success records are selected on survival and failure records are not [Ioannidis, 2005, Simmons et al., 2011, Open Science Collaboration, 2015]. This paper is the corpus's attempt to be the party that found its own weaknesses first.

1.1 Contributions

1. **Disclosure is not immunity, stated as a narrowing rather than a retraction.** The 2022 immobilisation is the strongest available test of the corpus's governing principle and the principle failed it; what survives is a filter that removes structures collapsing on contact with an authority, and it is not a shield against a policy decision taken on a correct position.
2. **The correlation collapse measured on a backing basket**: naive HHI 0.150600 and 6.640106 effective components against a bloc-collapsed HHI of 0.693600 and 1.441753, an overstatement factor of 4.605578.
3. **The delivery-squeeze arithmetic**: at 250 claims per physical unit, 99.600 per cent of claims are uncollateralised at par and 0.40 per cent of holders standing for delivery exhausts the stock. **A fully collateralised object-ledger makes the ratio reportable and does not prevent over-issuance**, because per-object hash chains supply no consensus and no double-spend prevention [Curzi, 2026].
4. **The gated programme priced as an option**: $P(\text{terminal}) = 0.090$ against $P(\text{first phase}) = 0.600$, a ratio of 0.15, so a proposal that leads with its most ambitious phase stakes the certain value on the least probable branch.
5. **The apparent-diversification trap, measured**: naive effective jurisdictions from 5.290949 to 7.132973 (+34.81 per cent) while effective blocs fall from 2.941176 to 2.841490 (-3.39 per cent) and h falls to -0.134485.
6. **The margin-call failure with no plaintiff**: a 26 per cent fall over four months breaches a 23.1 per cent trigger in month three, and buying survival to a 50 per cent drawdown costs 14.000 of the 40.000 borrowing, a 35 per cent reduction in leverage.
7. **A levy presented as a costless accounting correction reallocates burden**: a constructed incidence puts 42.0 per cent on one sector, with a constructed 55 per cent passing through to consumers.

What this paper does not claim. No instrument described here is claimed to exist, to be issued, to be authorised, or to be lawfully issuable in any jurisdiction. No price, yield or return figure appears anywhere in it. No commodity multiple, reserve quantity, statute, regulation, administrative notice or decided case is asserted as a fact; every one is described from the source manuscript and itemised in Appendix A. **And the licensing provisions recorded in §5.2.4 name the author's own company. That is a conflict of interest of the first order, it is declared in §3.4 and again in the Declarations, and the provisions appear here with their exposure attached rather than either endorsed or omitted.**

2. Hypotheses

Six hypotheses, each stated so that it could be wrong, each with its falsifier [Platt, 1964, Popper, 1959]. **One of them was tested against a real event and failed, and it is reported in the same plain language a success would have received.** Statements that are not falsifiable are listed at the end and labelled.

H1 — the disclosure hypothesis. TESTED AND FALSIFIED. A structure every element of which is lawful, disclosed and correct is durable against an authority with jurisdiction over it, because observation yields nothing actionable. *Predicted:* a fully disclosed, fully correct, lawfully held position is not seized or immobilised. *Falsified by:* one instance of a fully disclosed, correct, lawfully held position being immobilised. *Result:* **falsified.** Approximately USD 300 billion of fully disclosed central bank reserves were immobilised in 2022. The hy-

pothesis in that form is dead; §6.2.8 states the narrower claim that survives, and §8.1 states why the surviving claim is still worth having.

H2 — the correlation hypothesis. A nominal component count overstates a backing basket's diversification whenever the components share a common shock, and the overstatement is computable. *Predicted:* on the constructed eight-component basket, naive 6.640106 effective components against a correlated 1.441753, an overstatement factor of 4.605578, with the basket still more diversified than a single-commodity anchor at 1.44 against 1.00. *Falsified by:* a basket whose bloc-collapsed effective count equals its naive count under a defensible correlation grouping. *Status:* the arithmetic is exact on the stipulated weights; **the correlation grouping is a stipulated modelling assumption and not a measured covariance structure, and no real basket was examined.**

H3 — the squeeze hypothesis. At a paper-to-physical ratio R, a fraction $1/R$ of claimholders standing for delivery exhausts the deliverable stock, so the ratio is a latent concentration that is invisible in normal function and decisive in a squeeze. *Predicted:* at $R = 250$, the threshold is exactly 0.40 per cent, with coverage 2.0000 at 0.20 per cent, 1.0000 at 0.40 per cent, 0.4000 at 1.00 per cent and 0.0800 at 5.00 per cent. *Falsified by:* a market meeting delivery obligations beyond $1/R$ without new physical supply entering. *Status:* arithmetic on a stipulated ratio. **No commodity's ratio is measured here and none is asserted**; the range circulating in the source is described and itemised in Appendix A.

H4 — the gating hypothesis. In a strictly dependent phased programme whose gate probabilities are all below one, most of the expected value sits in the phase that stands alone. *Predicted:* at $p_1 = 0.60$, $p_2 = 0.50$, $p_3 = 0.30$, $P(\text{reach phase } 2) = 0.600$, $P(\text{reach phase } 3) = 0.300$, $P(\text{terminal}) = 0.090$, and a terminal-to-first-phase ratio of 0.15. *Falsified by:* a dependent phasing with gate probabilities below one in which a later phase's standalone value exceeds the first's. *Status:* arithmetic; **the probabilities are constructed and are estimates of nothing.** The conclusion depends only on dependence and on gates below one, which is why it is stated as a structural property rather than as a forecast.

H5 — the apparent-diversification hypothesis. Adding jurisdictions inside a coordination perimeter the structure is already heaviest in raises the naive effective jurisdiction count and lowers the effective bloc count. *Predicted:* naive 5.290949 → 7.132973 (+34.81 per cent) while blocs 2.941176 → 2.841490 (−3.39 per cent) and h −0.122417 → −0.134485. *Falsified by:* an addition inside an existing bloc that raises both counts. *Status:* arithmetic on a stipulated allocation. **The bloc assignment is this framework's own, is contestable, and is the load-bearing input**; the corpus measures the sensitivity of the index to assignment error separately [Curzi, 2026].

H6 — the margin-trigger hypothesis. The first maintenance call on a pledged position falls at $d^* = 1 - \text{LTV}_0/(1-m)$, and this is very much smaller than the drawdown a holder associates with the word *risk*. *Predicted:* at $\text{LTV}_0 = 50$ per cent and $m = 35$ per cent, the first call falls at a 23.076923 per cent drawdown; surviving 50 per cent requires the loan to fall from 40.000 to 26.000. *Falsified by:* a margin agreement at those parameters whose first call falls elsewhere. *Status:* algebra on a stipulated contract [Curzi, 2026]. **The 35 per cent maintenance requirement is a constructed model parameter and not a market quotation.**

Statements in this paper that are not hypotheses, and are labelled as such.

- *The three backing mechanisms* are **proposals** [T3]. None is adopted, none has legal force, and no instrument described is claimed to exist or to be lawfully issuable anywhere.
- *The licensing provisions of §5.2.4* are **the Act's specifications, recorded**. They are neither endorsed nor omitted, and the review they invite is named at the level of its general nature with **no outcome stated.**
- *The Fibonacci denominations and the fractal reserve rule* are **design choices whose monetary significance is graded at zero.** The combinatorial property is real; nothing monetary follows from the choice of sequence.
- *The stated goals of monetary immunity and of counterfeit impossibility* are **the Act's goals, recorded and corrected in the same sentence.** No anchor confers immunity and no instrument confers impossibility.

- *The nine-form backing taxonomy* is a **classification, not a valuation method.** No measurement basis for its non-financial components exists in the source corpus or here [Curzi, 2026t,?].
- *The naming rationale and numerological layer of the reference implementation* are **claims deliberately not made** [Curzi, 2026].

3. Method

3.1 What is measured, what is proposed, and what is only described

Three kinds of statement appear in this paper and the method keeps them apart. The evidence tiers used as inline tags throughout §§4–6 are defined here and nowhere else.

tier	meaning
T1	established fact — a published standard, or a proven mathematical or distributed-systems result
T2	measured by a deterministic computation over a stipulated, constructed input set, recomputed for this paper
T3	proposed design or standard, not adopted, not validated at scale, carrying no legal force
T4	refuted, unsupported as stated, or a claim deliberately not made

The tier scheme is this paper's own ordinal labelling convention and has no external standing. It is not averaged, summed or scored, and an ordinal scale licenses none of those operations [Stevens, 1946, Michell, 1997].

Every numerical result in this paper is exact arithmetic on stipulated, constructed inputs. No market, commodity, reserve, land parcel, economy, institution, court file or family appears anywhere in it. Each construction is printed at the point of use and labelled CONSTRUCTED there, so that a reader can reproduce the figure or show that a different stipulation gives a different one.

3.2 Which effective count, and what the instrument does not see

Where this paper reports an effective count it means $1/\mathrm{HHI}$, the Hill number of order two [Hirschman, 1964, Herfindahl, 1950, Hill, 1973, Jost, 2006], independently corroborated as the numbers-equivalent of a concentration index in the competition and political-science literatures [Adelman, 1969, Laakso and Taagepera, 1979, U.S. Department of Justice and Federal Trade Commission, 2023], and used in that sense throughout Series D [Curzi, 2026]. **The corpus's affine construction $1 + (N-1)u$ is not a Hill number of any order and does not appear in this paper.**

Two limits of the instrument are load-bearing here and are stated before any result is reported. **It does not see a pledge:** a pledged position and an unpledged position have identical jurisdictional shares and produce identical effective counts, which is why §6.2.4's failure track is invisible to it. **And it does not see capacity:** an effective count measures independence and says nothing about whether any perimeter can carry the load [Curzi, 2026].

3.3 The disclosure test, and what a test is

The framework's governing constraint is that every element of a structure should remain effective when disclosed to every authority with jurisdiction over any part of it. That is not an ethical preference: it is the 1883 principle that a system must remain secure when everything about it except the key is public [Kerckhoffs, 1883], restated as *open design* [Saltzer and Schroeder, 1975] and given its transparency-as-remedy form [Brandeis, 1914]. The regulatory environment has independently removed non-disclosure from the available design parameters [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015, de Goede, 2011], and the corpus states the resulting constraint exactly [Curzi, 2026].

A filter is not a shield, and this paper exists partly to make the difference impossible to misread. The test removes structures that collapse on contact with an authority. It says nothing whatever about a policy decision taken against a disclosed and correct position, which is what happened in 2022, and §6.4 lists confusing the two as a named failure mode.

3.4 Provenance, exclusions, and the conflict of interest

The licensing provisions recorded in §5.2.4 name 36N9 Genetics, which is the author's own company, as the sole-source procurement counterparty for the production of the proposed currency, alongside a perpetual royalty and a sovereign licence from a private entity. That is a conflict of interest of the first order. It is declared here, in the Declarations, and in the section where the provisions appear. **The method adopted in response is the only one available to a single author: record the provisions exactly as the Act specifies them, name the review they invite in the same neutral register the framework applies to every other legal exposure, state no outcome, and leave the decision with the reader.** A paper that recorded the provisions without the exposure would be advocacy; a paper that omitted the provisions would be concealment; and the author's interest in one of the provisions is precisely why both halves are in print.

Two elements of the source material are excluded from every technical claim in this paper. The naming rationale of the proposed system, and a numerological layer present in its reference implementation, are recorded as declared, are graded [T4], and confer no property on any structure described [Curzi, 2026]. They are mentioned only so that a reader encountering them in the source knows they were assessed and discarded rather than overlooked.

No jurisdiction-specific legal source is cited anywhere in this paper. The decided cases, the statutes, the tax-code provisions, the administrative notices, the procurement and appropriations frameworks and the constitutional provisions named in §§5 and 6 are described from the source manuscript and are **left uncited, because this paper's bibliographic database contains none of them.** Appendix A itemises each with what specifically requires verification. What the bibliography does supply is the general doctrinal and comparative frame, and that is cited where it is relied on.

3.5 What is not invoked

The corpus's reflexive loop is not used in this paper and no social-influence parameter is estimated, so the reflection problem — that the endogenous effect in a linear-in-means reflexive specification is not identified from observational data [Manski, 1993, Shalizi and Thomas, 2011] — does not bear on any result reported here. **No distributional, scaling or heavy-tail claim is made anywhere**, so the goodness-of-fit and likelihood-ratio procedure such a claim would require [Clauset et al., 2009] is not applicable and was not run. Every figure in this paper is a ratio of counts, a probability product, or a closed-form solution of a linear equation on stipulated inputs.

One borrowing is flagged before it is used. The framework writes concentration, surplus and resilience in the grammar of conserved and extensive quantities without a conservation

law, which is the characteristic failure of this genre [Mirowski, 1989]; the defence taken here is Cartwright's — validity is claimed within a specified arrangement and no universality is claimed for it [Cartwright, 1999]. §9.6 grades every borrowing in the paper by name.

4. Backing mechanisms: the paper-to-physical ratio, a correlated basket, and a two-layer reserve

4.1 The position: one distinction applied three times

The corpus's reserve-drift measurement recorded a compromised position and refused to dramatise it: a slow reserve drift and a measurable refinancing concentration, both fully disclosed [Curzi, 2026], whose time-axis Herfindahl index of 0.222050 gives an effective spread of 4.50 maturity buckets with 55.0 per cent refinancing inside three years. The nine-capital standard answered it with the most modest instrument available — an accounting standard that makes the off-ledger asset side visible, minting nothing and licensing nothing. This section takes the next step the American Roots material proposes, and it is a step onto more contested ground, because it moves from *what a nation counts* to *what a currency is backed by*. That is a harder question and the discipline has to be correspondingly tighter. The section develops three backing mechanisms, and it develops each one twice: once as the proposal states it, and once as the framework's own instruments cut it down to what is defensible.

The three mechanisms are a paper-to-physical ratio argument, a living-basket anchor called the Fermentables Index, and a conservation-easement reserve paired with a floating voucher. They look unrelated until they are laid against the one distinction this framework has carried since the store–rail rule, and against which every rail section and every reserve section has been measured:

> **A rail is not a holding.** A store of value and a medium of settlement are two different jobs, and the deepest error in monetary design is asking one instrument to do both while pretending it does neither badly.

Every one of the three mechanisms is, at bottom, a claim about where a given design sits on the store-versus-rail axis, and the section's organising move is to place each one on that axis explicitly and refuse to let it drift off. The paper-to-physical argument is about what happens when a market confuses a rail — a paper claim — with a store — the commodity itself. The Fermentables Index is a reserve-value anchor, a store, that must not be mistaken for a settlement medium. The conservation-easement reserve is a store so illiquid it cannot settle anything at all, which is precisely why it is paired with a voucher that is nothing but a rail. **The store-versus-rail split is not one of several themes in this section; it is the section, applied three times to three designs that each get it right or wrong in a different way.**

The first mechanism leads, because it is the framework's strongest empirical monetary claim, and it is strongest for the reason the refinancing-wall measurement was strongest: it is a concentration, and concentration is the one thing this framework has an instrument for. Derivative and paper claims on a commodity routinely exceed the deliverable physical stock behind them by a wide margin — commonly cited across a range of roughly one to three orders of magnitude, which is to say somewhere in the vicinity of fifty times to five hundred times, depending on the commodity and the venue. That range is stated as a range on purpose, and every specific multiple that circulates inside it — the silver open-interest-to-registered figures, the split between registered and eligible gold on a delivery exchange, the ratio of crude open interest to the deliverable stock at a single pricing point — is flagged in the Verification Register and asserted nowhere in this section as a fact. What the section asserts is the shape, and the shape is not in dispute even where the magnitudes are: a paper layer many times larger than the physical layer beneath it is a documented and ordinary feature of commodity markets, and it decouples from the physical under stress in ways that have been observed.

This is the concentration paper's failure mode rotated onto a new axis [Curzi, 2026], whose Result Two takes a redesigned six-jurisdiction structure to naive HHI 0.189002 — 5.29 effective jurisdictions — and bloc-HHI 0.340000, 2.94 effective blocs. That paper measured concentration on the jurisdiction axis; the reserve-drift paper rotated the same instrument onto the maturity axis and measured a refinancing wall. **This section rotates it once more, onto the physical-settlement axis, and measures the concentration of paper claims against deliverable stock** — and the result is the same species of finding each time, that a nominal count of many independent-looking things collapses, under the right stress, onto a single point of failure. The paper claims look like a deep, liquid, diversified market until enough holders want the physical thing at once, and then the ratio that was invisible becomes the only number that matters.

The second and third mechanisms are answers rather than diagnoses, and they answer the problem the reserve-drift measurement named: the dollar's reserve share drifts because there is no bloc-independent alternative reserve asset at its scale, and both the Fermentables Index and the easement reserve are attempts to build a reserve anchor with a *different failure profile* than a debt-fiat one. Neither is offered here as a settlement medium, because neither is one, and the honesty of the section is entirely in keeping that line. A consumables basket resists hoarding and resists pure speculation, at the cost of storage and measurement complexity that a debt claim does not carry — but it is a store, not a rail. A conservation easement is a real, valued, tradeable legal instrument, and it is also completely illiquid — you cannot settle a trade in one — so it can back a currency only as a reserve and never as a means of payment, which is why the design pairs it with a voucher that carries the settlement job it cannot. **The recurring result is that each mechanism is defensible exactly to the extent that it is honest about which of the two jobs it is doing, and indefensible exactly where it claims to do both.**

One constraint from the nine-capital standard carries directly into this section and is stated here so it governs everything below. The American Roots Act attaches to its instruments a set of design goals, and two of them — monetary immunity to inflation and deflation, and a counterfeit-impossibility property — were recorded in the nine-capital standard as the Act's stated aims and corrected in the same breath, because no anchor confers immunity and no instrument confers impossibility. That correction is not re-litigated here; it is inherited. Where the Fermentables Index restates the immunity goal, this section records it as a goal and corrects it once more in the specific setting of a consumables basket, and it does the same for every other absolute the material reaches for. The house standard is the integrity-layer paper's: a corpus that grades its own claims and prints its own negative results is worth more than one that arrives without them, and this section holds the standard against the very mechanisms it is developing.

4.2 The three mechanisms

4.2.1 Mechanism one: the paper-to-physical ratio, and why it is normal until it is not

Start with what the ratio is, because most of the heat around it comes from misunderstanding a feature as a scandal.

A commodity futures or forward market is a market in claims. A contract is a promise to deliver, or to take delivery of, a quantity of the underlying at a date, and the overwhelming majority of contracts are never carried to delivery — they are closed, rolled, offset, or cash-settled before the delivery window, because the parties holding them are hedging price, not sourcing metal or barrels. A miner sells forward to lock a price; a fabricator buys forward to lock an input cost; a speculator takes the other side of each for a fee in risk-bearing. None of them wants the physical thing; all of them want the price exposure. The result is that the notional quantity of the commodity represented by outstanding claims can, and routinely does, exceed the quantity of the commodity actually sitting in deliverable form in the registered warehouses behind the market, by a large multiple. This is not a malfunction of the market;

it is what the market is for, and a hedging market whose paper never exceeded its physical would be a market too thin to hedge in. **No source in this paper's bibliography establishes the magnitude of that multiple in any commodity, and none is cited for it**; the range is described from the source manuscript and itemised in Appendix A.

The multiple is the concentration measurement, and it is where the discipline has to hold. The figures that circulate are specific and they are contested. Silver is the commodity most often cited, with open-interest-to-registered-stock ratios quoted anywhere from roughly one hundred to several hundred times, and those figures are contested because they depend entirely on which numerator and which denominator are chosen — all open interest or only the front month, registered stock only or registered plus eligible, one venue or the global aggregate. Gold on a delivery exchange is discussed in terms of the split between registered stock, which is committed to delivery, and eligible stock, which sits in the same vaults in approved form but is not pledged to any contract — and the ratio of open contracts to registered stock moves sharply depending on that classification. Crude oil is discussed in terms of the open interest in a contract that settles by physical delivery at a single location against the deliverable and storage capacity actually available at that location. Every one of those multiples is flagged in the Verification Register and none is asserted here as a fact; the section's claim is the range and the mechanism, not any single number inside it.

The mechanism is what makes the range matter, and it is a store-versus-rail confusion waiting to happen. A paper claim on a commodity is a rail: it is a device for transferring price exposure, and for the holder who will close it before delivery it is a position that closes itself, exactly the transit-rail definition of a rail. The commodity in the warehouse is a store: it is the thing that is there because that is where it lives. For as long as everyone treats the paper as a rail — a transfer of exposure to be closed out — the ratio between paper and physical is irrelevant, because almost nobody is asking the rail to deliver the store. The ratio becomes the risk at exactly the moment enough holders stop treating the claim as a rail and start treating it as a store — when they stand for delivery, demand the physical thing, and discover that the claims outnumber the deliverable units by the multiple that was invisible the day before. That is a delivery squeeze, and it is the physical-settlement-axis form of a bank run: a set of claims that were fungible and liquid so long as they were not all presented at once, revealed as fractional the instant they are.

The empirical proof that paper and physical decouple under stress is not theoretical and this section does not need to construct it. The 2020 event in which a physically-settled crude contract traded at a deeply negative price is the clearest demonstration: holders of expiring long positions who could not take or store physical delivery faced a market in which the paper claim and the physical reality had come completely apart, and the claim's price went to a place no store of value can go, because it was never a store — it was a rail that had run out of track. Periodic silver squeezes, in which a coordinated or spontaneous rush to stand for delivery collides with the registered stock, are the same mechanism in the other direction. These events are the empirical content of the claim that paper and physical decouple, **and they are described from the source manuscript and are not cited, because this paper's bibliography contains no contemporaneous market reporting** (Appendix A). They are why the ratio is a genuine risk measurement rather than a conspiracy theory — the decoupling is observed, dated, and priced, whatever one believes about why the ratio is as large as it is.

Now the tie to the framework, which is exact. This is the concentration failure, measured on the physical-settlement axis instead of the jurisdiction axis. The paper claims are the many independent-looking things; the single deliverable stock they all point to is the coordination perimeter they collapse onto; and the delivery squeeze is the shock that reveals the collapse. And it is the store–rail rule stated in commodities: **the paper claim is the rail, the commodity is the store, and confusing the two is the error the whole framework has warned against — an error that is harmless in normal function and catastrophic in a squeeze, which is precisely the profile of every concentration this framework measures.**

4.2.2 Mechanism one, continued: what a fully collateralised object-ledger changes

The VINO claim enters here, and it must be stated at exactly its strength and no more, because the temptation is to overstate it and the integrity-layer paper spent its length showing why that temptation is fatal.

The claim is this. In a conventional commodity market the paper layer and the physical layer live in two different systems. The claims live in the clearing and exchange infrastructure; the physical units live in a warehouse registry of receipts. The ratio between them — the concentration measurement that becomes the squeeze risk — is not a number either system publishes as a live quantity, because neither system is built to. It is recoverable only by reconciling the two registries against each other, a join across two datasets that no one runs continuously and that many participants have no standing to run at all. The ratio is invisible not because it is hidden but because it is nobody's field: it is a relationship between two ledgers, and a relationship between ledgers is exactly the kind of quantity the double-entry-limits paper showed a double-entry system structurally cannot carry.

A fully-collateralised, canonically-audited ledger of the kind the integrity-layer paper specified changes the visibility of that ratio, and only its visibility. In the object-as-ledger factoring, each physical unit is its own hash-chain, seeded by a genesis root — GridChain's per-token construction, taken down to the individual deliverable unit. A claim, in such a system, is not a free-floating contract in a separate venue; it is an entry that references a specific unit's chain. Under a full-collateralisation rule — one live claim per unit — the number of valid claims the ledger can carry is bounded by the number of units, and the ratio of claims to units is not a reconciliation exercise across two systems but a single aggregate over one index, readable live. A per-unit ledger cannot make five hundred claims on one unit disappear, but it can make them impossible to hide: over-issuance stops being a relationship between two registries that nobody joins and becomes a count on one register that anyone with read access can take. That is the whole of the claim, and it is a visibility claim, in exactly the sense the nine-capital standard was careful about when it said visibility is not pledgeability. Here, visibility is not prevention.

The honesty that keeps this defensible is the integrity-layer paper's audit finding A1, and it is stated in print because omitting it would be the exact failure the integrity-layer paper exists to prevent. A per-object hash-chain provides tamper-evidence and local write-parallelism; it does not by itself provide consensus, total order, or double-spend prevention [Curzi, 2026], whose counter-result states in one place that the substrate supplies no consensus, no total order, no double-spend prevention and no Sybil resistance. Agreement among mutually distrustful parties is the Byzantine problem [Lamport et al., 1982], its impossibility under asynchrony is fixed [Fischer et al., 1985], the availability–consistency trade is fixed [Gilbert and Lynch, 2002], and the party count must itself be audited [Douceur, 2002]. Nothing in the object-as-ledger structure alone stops the same unit being pledged to two claims on two forks that each verify as internally valid — that is A1, reproduced and graded [T4] in the integrity-layer paper, and it applies here without exception. **So the object-ledger does not arithmetically prevent a 250-to-1 over-issuance; it makes the 250-to-1 ratio a visible, queryable number in real time, and prevention still requires the ordering and identity layers that the integrity-layer paper flagged as unbuilt.** The correct statement of the mechanism is therefore precise and modest: full collateralisation plus object-as-ledger converts the paper-to-physical ratio from an off-venue relationship that surfaces only in a squeeze into an on-ledger count that surfaces continuously — which changes when the concentration is discovered, not whether it can occur. That is a real improvement, because a concentration discovered continuously can be governed and a concentration discovered in a squeeze cannot, and it is a smaller improvement than the material's enthusiasts would claim, which is why the section states both halves.

4.2.3 Mechanism two: the consumables basket as a reserve anchor

The second mechanism is a reserve anchor, and it is a store by construction — the failure profile argument below is an argument about what kind of store it is, never a claim that it

settles anything.

The Fermentables Index, as the American Roots Title IV material describes it, is a dynamic basket of consumable, regenerative natural assets: grains, fruit, dairy, timber, freshwater, and a set of soil-health and biodiversity metrics that stand for the productive capacity of the land itself. The design intent is that a currency anchored to such a basket is anchored to the things people actually consume and the systems that regenerate them, rather than to a debt instrument or a single monetary metal. **The Act states as a design goal that such an anchor would confer mathematical immunity to inflation and deflation, and that goal is recorded here as a goal and corrected in the same sentence it is stated: no anchor confers immunity, and a consumables basket does not eliminate monetary risk — it changes the risk's shape.** The corpus's channel-gain postulate is the general form of the correction [Curzi, 2026ab]: an effect is transmitted only through a channel with a gain, and where no channel exists the effect is zero at every magnitude of input. This is the nine-capital paper's correction applied to the specific instrument. A currency anchored to a basket of staples is stable in terms of that basket and variable in terms of everything outside it; its purchasing power tracks the supply and demand for the specific staples chosen; and it is exposed to shocks in those staples — a harvest failure, a shift in diet, a change in what the basket ought to contain — that a broader or a purely monetary anchor would diffuse differently. The immunity is not available; a different risk profile is, and the different risk profile is the real and defensible claim.

The defensible claim has two halves and both are properties of consumables specifically. The first is resistance to hoarding: the basket's components are perishable, and a store made of perishable things cannot be cornered and sat on the way a monetary metal can, because holding it incurs a physical carrying loss that holding gold does not. The second is resistance to pure speculation: the components are universally consumed, so their demand is anchored in use rather than in belief, and a speculative position in a thing everyone eats is disciplined by the fact that everyone eats it. A consumables basket resists both of the pathologies a monetary anchor is prone to — the hoard and the bubble — and it pays for that resistance in storage and measurement complexity, which is a real and heavy cost, not a rounding error. Grain must be stored and rotated; dairy spoils fast; freshwater and soil-health and biodiversity are not even uniformly measurable, and a basket that includes them inherits the nine-capital paper's problem of forms of capital with no accepted measurement basis. The anchor is a reserve of value with an unusual and in some ways attractive failure profile, bought at the price of being far harder to hold and to measure than a claim on a government.

The measurement that makes this precise is the concentration instrument, and pointing it at the basket yields the sharpest single result in this mechanism. **A basket is a concentration instrument applied to backing: the same Herfindahl arithmetic that measures whether a private estate is diversified across jurisdictions measures whether a reserve is diversified across the things that back it.** The effective count used throughout this paper is $1/\mathrm{HHI}$, the Hill number of order two [Hirschman, 1964, Herfindahl, 1950, Adelman, 1969, Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979], and **never the corpus's affine construction $1+(N-1)u$, which is not a Hill number of any order and does not appear in this paper.** A single-commodity anchor — a gold standard, a single-metal peg — has a backing HHI of 1.0 and an effective component count of exactly one; it is a one-asset reserve and its fate is the fate of that one asset. A fiat anchor is, on this axis, also effectively a count of one, because its value rests on the policy of a single issuer. The Fermentables basket, constructed below, has a naive effective component count well above one — and, exactly as in the concentration paper, the naive count overstates the diversification, because the components are not independent. A drought that takes the grain crop takes the fruit, stresses the freshwater, degrades the soil-health metric, and raises dairy feed costs all at once, and those correlated components collapse, under a common climate shock, onto far fewer effective independent components than the naive count reports. **That is the corpus's own correlation result on a different axis** [Curzi, 2026]: holding marginal failure at 10 per cent, a common shock of $c = 0.02$ raises the probability that all four components fail together from 0.000100 to 0.020044, a 200.4-fold understatement, and over fifteen years 0.001499 independent against 0.794109 correlated. The same finding is standard in the portfolio and ecological literatures — correlations rise in the tail [Longin and Solnik,

2001, Ang and Chen, 2002], diversification is a claim about a covariance structure rather than a count [Markowitz, 1952, Elton and Gruber, 1977], statistical averaging is not the same mechanism as response diversity [Doak et al., 1998, Tilman et al., 1998, Schindler et al., 2010], and more components do not in general give more stability [May, 1972, McCann, 2000, Ives and Carpenter, 2007]. The honest number is the collapsed one, and it is computed in the Worked Application, where the basket's naive effective count of well over six falls to under one and a half once the climate-correlated components are recognised as one exposure. The basket is genuinely more diversified than a single-commodity anchor and dramatically less diversified than its component count suggests — which is the concentration paper's exact finding, that the count is not the perimeter, arriving on the backing axis.

4.2.4 Mechanism three: the easement reserve and the floating voucher

The third mechanism is the clearest store-versus-rail design in the section, because it is built as two explicit layers, one of which is a pure store and the other a pure rail, and the honesty of the whole thing is in never confusing them.

The store layer is conservation-easement backing. A conservation easement is a real legal instrument with a defensible foundation: under the United States Internal Revenue Code the qualified conservation contribution regime recognises the permanent restriction of land use for conservation purposes as a contribution with measurable value — **a statutory provision described here from the source manuscript and cited nowhere, because this paper's bibliography contains no tax-code material** (Appendix A), and the broader ecosystem-services literature is said to establish that the natural capital such land holds — watersheds, carbon, habitat, soil — has value that can be estimated by accepted, if contested, methods. **That literature is not in this paper's bibliography and no work in it is cited**; what the corpus can supply is the general governance result that a commons is neither necessarily tragic nor automatically well managed [Hardin, 1968, Ostrom, 1990, 2010, Cox et al., 2010]. The design premise is that currency can be backed partly on protected land whose natural-capital value persists *because* it is stewarded rather than extracted: the easement is what makes the persistence legally durable, and the natural capital is what gives the reserve its value. That premise has a defensible core — easements are real, valued, tradeable instruments and natural capital has measurable value — and it has two honest limits that must be stated in print, because the mechanism is indefensible without them.

The first limit is valuation. Easement valuation is genuinely contested, and it has a documented abuse history that a proposal to back currency on easements cannot wave away. The syndicated conservation easement — in which a partnership acquires land, obtains an aggressive appraisal, places an easement, and passes an outsized deduction to investors — has been the subject of sustained enforcement attention, is a designated listed transaction for disclosure purposes, and is the subject of active litigation over both the valuations and the designation itself. The specific administrative authority that designated syndicated conservation easements as a listed transaction, and the litigation surrounding it, are flagged in the Verification Register and their notice number is not asserted here — the point that survives verification is structural and does not depend on the citation: easement valuation is contested, it has been abused through inflated appraisal, and a reserve built on easement values inherits exactly that valuation contest. The second limit is liquidity, and it is absolute: an easement is illiquid. You cannot settle a trade in a conservation easement. It is a permanent restriction on a specific parcel, held by a specific qualified organisation, and it does not circulate, does not clear, and cannot be handed to a counterparty to extinguish an obligation. **An easement can be a store of value and it can never be a means of settlement, and any design that treats it as spendable has committed the store-versus-rail error in its most basic form.**

Which is exactly why the design does not treat it as spendable. The rail layer is the floating voucher, and it is the settlement-side counterpart to the illiquid reserve. The voucher is a transferable credit that circulates against the stewarded reserve: the reserve is the store — illiquid, backing, staying where it is — and the voucher is the rail — liquid, transacting, mov-

ing between holders and closing itself the way any rail position does. **The two-layer design is the store–rail rule built into a monetary instrument on purpose: it makes an illiquid natural-capital reserve spendable without pretending for a moment that the reserve itself is liquid, by putting the liquidity in a separate instrument that is honest about being a rail.** This is the single most important structural point in the mechanism and it is what separates it from a naive natural-capital currency that would try to make the land itself circulate. The land does not circulate. The voucher circulates. The land backs the voucher. That is a coherent design precisely because it respects the distinction the rest of the framework has spent fifty-four sections insisting on, and it is the honest answer to the question of how you make a reserve that cannot be traded do monetary work: you do not trade the reserve, you trade a claim that references it, and you keep the two on opposite sides of the store-rail line and never let them merge.

The funding mechanism for maintaining the stewarded reserve is what the Act calls the 12% Life-Energy Equity, and it must be presented as the Act frames it and then read honestly. The Act frames it not as a tax but as an accounting correction: a commons-replenishment allocation that recognises, and directs to the upkeep of the stewarded reserve, a share of value that was previously drawn from the natural commons without being priced at all. In the Act's framing this is the same move the nine-capital standard made for the whole nine-capital standard — taking a real, off-ledger quantity, the drawdown of natural capital, and putting it on the ledger — and calling it a correction rather than a levy is internally consistent with that framing. **But an accounting correction with a rate is still a design choice with distributional effects, and recording the previously-unpriced cost of natural-capital drawdown on the ledger reallocates that cost to whoever was implicitly benefiting from its being unpriced.** Whether the correction is called a tax or not, someone bears its incidence, and the incidence is not uniform: it falls most heavily on the activities that drew most heavily on the unpriced commons, and it passes through, in part, to the consumers of those activities' output. The Worked Application models a constructed incidence to show the shape; the point of principle here is that the 12% is presentable as the Act presents it and must also be modelled for its distributional effect, and a section that recorded only the framing and not the incidence would be doing the thing this framework calls lying by omission.

4.3 Specification

4.3.1 The three mechanisms, specified as proposals

Each mechanism is graded [T3] — a design, not an adopted standard — and each is specified by what it does, what job it does on the store-rail axis, and, most importantly, what it does not do.

```
MECHANISM 1: FULLY-COLLATERALISED OBJECT-LEDGER FOR PHYSICAL CLAIMS
-------------------------------------------------------------------
JOB            makes the paper-to-physical ratio VISIBLE and live
STORE / RAIL   the physical unit is the STORE; the claim is a RAIL;
               the ledger keeps them distinguishable and counts both
RULE           each deliverable unit is its own hash-chain (CCP-065); each claim references a specific
               full collateralisation = one live claim per unit
REPORTS        claims-per-unit as a live aggregate over one index,
               not a reconciliation across two registries
DOES NOT       prevent over-issuance, provide consensus, provide
               total order, or prevent double-spend on its own --
               those need the ordering + identity layers (CCP-065 A1)
STATUS         [T3] proposal; the substrate is [T2]-validated for
               tamper-evidence only; prevention is unbuilt

MECHANISM 2: THE FERMENTABLES INDEX (reserve-value anchor)
```

```
-----------------------------------------------------------------------
JOB             a reserve anchor with a consumables failure profile
STORE / RAIL    a STORE only; NOT a settlement medium; a currency may
                be anchored to it but is not made OF it
RULE            a weighted basket of consumable regenerative assets;
                weights published; the backing HHI and effective
                component count reported NAIVE and CORRELATION-COLLAPSED
REPORTS         naive effective components, correlated effective
                components, and the overstatement factor between them;
                perishability drag vs a non-perishable anchor
MARKS           soil-health and biodiversity components UNMEASURED
                where no accepted basis exists (CCP-068 discipline)
DOES NOT        confer immunity to inflation or deflation; settle a
                trade; remove monetary risk -- it reshapes it
STATUS          [T3] design goal; immunity claim [T4], corrected

MECHANISM 3: EASEMENT RESERVE + FLOATING VOUCHER (two-layer)
-----------------------------------------------------------------------
JOB             back currency on stewarded natural capital, spendably
STORE / RAIL    the easement reserve is the STORE (illiquid, backing);
                the floating voucher is the RAIL (liquid, transacting)
RULE            reserve held as IRC 170(h) conservation easements,
                valued by a stated (contested) methodology, marked
                contested; vouchers issued against the reserve
                circulate and settle; the reserve never settles
FUNDING         the 12% Life-Energy Equity maintains the reserve,
                framed by the Act as an accounting correction, and
                modelled here for distributional incidence
DOES NOT        make the reserve liquid; make the easement settleable;
                resolve the easement valuation contest; escape the
                syndicated-easement abuse history (Register-flagged)
STATUS          [T3]; the legal instrument is real; the valuation and
                the voucher peg require a process this framework cannot run
```

The "does not" rows are the specification. As in the integrity-layer paper and the nine-capital standard, the honesty of each mechanism lives entirely in what it refuses to claim, and the three refusals are the same refusal three times: the object-ledger does not prevent, only reveals; the basket does not immunise, only reshapes; the easement does not settle, only backs. Each mechanism is defensible precisely to the degree that it does one job well and disclaims the other, and the specification's entire purpose is to pin down which job is which and forbid the merge.

4.3.2 The store-versus-rail classification, stated once as a table

Because the whole section is one distinction applied three times, it is worth stating the classification in one place, so that no mechanism can be quietly promoted from the job it does to the job it does not:

```
mechanism                STORE (backing)         RAIL (settlement)
-----------------------------------------------------------------------
paper / physical         the physical unit       the paper claim
Fermentables Index       the basket              -- (none; anchor only)
easement + voucher       the easement reserve    the floating voucher
-----------------------------------------------------------------------
the error to forbid      standing a rail for      spending a store as
                         delivery it cannot make  though it were a rail
```

The middle row is the one most likely to be misread, and the specification states it flatly: the Fermentables Index supplies no rail at all. It is an anchor, a reference for value, and a currency that uses it still needs a separate settlement mechanism, because a basket of perishable staples is not something anyone settles a payment in. A design that tries to make the Fermentables basket itself circulate as money has made the easement mistake without the easement's excuse, and the specification exists to catch exactly that.

4.3.3 The disclosure test, applied to all three

The disclosure test: would each mechanism still do its job if every element were disclosed to every authority with jurisdiction over any part of it?

All three pass, and the manner of passing is instructive. The object-ledger passes most emphatically: its entire value is that it makes a concentration visible, so disclosure is not a threat to it but its whole function — a paper-to-physical ratio that everyone can read is precisely the point, and the more completely it is disclosed the better it works, which is the disclosure principle's structural marker that the value is independent of secrecy. The Fermentables Index passes because a published basket with published weights and a published correlation-collapse is a fully open instrument; there is nothing in it to conceal, and its honesty about its own diversification limits is what makes it credible. The easement-and-voucher design passes with the same qualification the nine-capital standard attached to its standard: the reserve valuation must be presented as contested and the voucher must be presented as a rail, and a design that disclosed the easement backing while hiding the valuation contest or dressing the voucher as a store would fail the test not on concealment of the structure but on misrepresentation of the parts. The disclosure test is not an ethical preference: it is the 1883 principle that a system must remain secure when everything about it except the key is public [Kerckhoffs, 1883], restated as *open design* among the protection principles [Saltzer and Schroeder, 1975] and given its transparency-as-remedy form [Brandeis, 1914]; the corpus states the resulting constraint exactly [Curzi, 2026], refusing non-disclosure as a design premise rather than merely discouraging it, because effectiveness independent of anyone's knowledge makes every element publishable. **Disclosure is not the risk for any of the three; the risk is the merge — presenting a rail as a store or a contested valuation as a settled one — and disclosure is what makes the merge visible, which is why the honest version of each mechanism wants to be disclosed and the dishonest version cannot survive it.**

4.4 Failure modes

FM 4.1 Asserting a single paper-to-physical multiple as a fact

The commodity multiples are a range, they are contested, and they depend on the choice of numerator and denominator. Quoting a specific silver open-interest-to-registered figure, or a specific gold registered-to-eligible ratio, as an established fact is the fastest way to lose a reviewer who knows that the same market yields five different multiples under five defensible definitions. **The claim this section can defend is the range and the mechanism; the specific number is always a Verification Register item and never an assertion.**

FM 4.2 Treating the ratio as fraud rather than as normal-until-squeeze

A paper layer many times the physical is ordinary hedging-market function, not a scandal, for as long as the claims are being used as rails. Presenting the ratio itself as evidence of manipulation overstates the case and discredits the real finding, which is narrower and stronger: the ratio is a latent concentration that becomes a risk only in a delivery squeeze. The failure is to skip the "normal function" half and go straight to the squeeze, which is the mirror of the reserve-drift paper's failure of predicting the collapse.

FM 4.3 Confusing the paper claim with the commodity

The core store-versus-rail error on this axis. A holder who treats a paper claim as though it were the physical commodity — a store they can rely on to be there — has misclassified a rail as a holding, and will discover the misclassification only when they stand for delivery into a market where the claims outnumber the units. The transit-rail warning about the nostro that became a holding is the same warning: a rail relied upon as a store carries all the exposure of a store and none of its guarantees.

FM 4.4 Claiming the object-ledger prevents over-issuance

It does not. It makes the ratio visible; it does not make over-issuance impossible, because per-object chains provide no consensus and no double-spend prevention on their own — the integrity-layer paper's finding A1, graded [T4]. A proposal that presents the object-as-ledger as arithmetically forbidding a 250-to-1 ratio has claimed prevention where the mechanism delivers only visibility, and it has done so by ignoring the one audit finding the integrity-layer paper was most careful to publish.

FM 4.5 Repeating the Fermentables immunity claim as achieved

The Act's stated goal of mathematical immunity to inflation and deflation is a goal, and no anchor delivers it. A consumables basket changes the risk profile — stable in the basket, variable outside it, exposed to the basket's own supply shocks — and does not remove the risk. Any document that repeats the immunity claim as an achieved property has asserted something no monetary design has ever achieved, and the correction belongs in the same sentence as the claim, every time.

FM 4.6 Reporting the basket's naive diversification without the correlation collapse

The Fermentables basket's naive effective component count overstates its diversification exactly as the concentration paper's naive jurisdiction count overstates a private estate's resilience, and for the same reason: the components are not independent under a common shock. A climate event correlates grain, fruit, freshwater, soil, and dairy-feed simultaneously. Reporting the naive count alone is the backing-axis version of the failure the concentration paper owns, and the correlated count is the honest one.

FM 4.7 Treating the easement reserve as liquid or settleable

An easement cannot settle a trade. A design that lets the reserve itself circulate, or that promises redemption of vouchers in the underlying easement, has collapsed the two layers the whole mechanism depends on keeping apart. **The reserve is a store and only a store; the moment it is asked to behave as a rail, the mechanism has become the naive natural-capital currency it was built to avoid.**

FM 4.8 Ignoring the easement valuation contest and abuse history

Easement valuation is contested and has a documented abuse history through syndicated transactions that are a listed transaction under active litigation. A reserve built on easement values that presents those values as settled, or that does not disclose the valuation contest and the enforcement history, has built on the single most challenged number in the design and hidden the challenge. The valuation contest is not a footnote; it is the reserve's central weakness and it must be in print.

FM 4.9 Presenting the 12% Life-Energy Equity as costless

Framing the allocation as an accounting correction rather than a tax is the Act's framing and is internally coherent, but no framing makes an incidence disappear. Recognising a previously-unpriced cost reallocates it, and the reallocation has winners and losers. Presenting the 12% as a pure correction with no distributional effect is the failure; modelling the incidence, as the Worked Application does, is the correction to the correction.

FM 4.10 Backing a settlement medium with an illiquid reserve and no rail layer

The general form of failure 7, stated as a design rule. Any illiquid reserve — easement, or for that matter the Fermentables basket — that is used to back a spendable currency must be paired with a separate liquid rail, or it is asking an illiquid store to do a rail's job. The floating voucher is the correct answer; its absence is the failure; and a natural-capital currency without a voucher layer has promised to settle payments in something that does not circulate.

4.5 Results: the three mechanisms measured on constructed inputs

> **CONSTRUCTED.** Every figure in this section is invented to demonstrate a mechanism. No commodity ratio, no basket weight, no reserve figure, and no distributional split below is a measurement of any real market, commodity, land parcel, or economy. All are flagged CONSTRUCTED and sent to the Verification Register, and none carries any price or return.

4.5.1 The paper-to-physical ratio, made observable on a constructed commodity

Take a **CONSTRUCTED** commodity with a deliverable stock of 40,000 tokenised physical units and a paper ratio of 250 — chosen in the middle of the roughly 50-to-500 band, and asserted as a fact about nothing:

```
CONSTRUCTED commodity, object-as-ledger
------------------------------------------------------------
deliverable physical units (genesis chains)      40,000
CONSTRUCTED paper ratio                             250x
paper claims outstanding                     10,000,000
claims-per-unit (live ledger aggregate)           250.0
fully-collateralised ceiling (1 claim/unit)      40,000
claims exceeding 1:1 collateral               9,960,000
fraction of claims uncollateralised at 1:1       99.600%
```

The claims-per-unit figure of 250.0 is the concentration measurement, and the point of the object-ledger is where that figure lives. On a conventional market it is recoverable only by joining two registries — the receipts registry of 40,000 rows and the contracts registry of 10,000,000 rows, 10,040,000 rows to reconcile — a join nobody runs continuously and most participants cannot run at all. On the object-ledger it is a single aggregate over one claim-to-unit index, readable live. The ratio does not change; its visibility does, and it moves from a reconciliation across two systems that surfaces only in a squeeze to a live count on one system that surfaces continuously.

The squeeze arithmetic shows why the visibility matters, computed on the same construction:

```
stand-for-delivery fraction   deliverable coverage   outcome
------------------------------------------------------------
0.20%                                 2.0000            OK
```

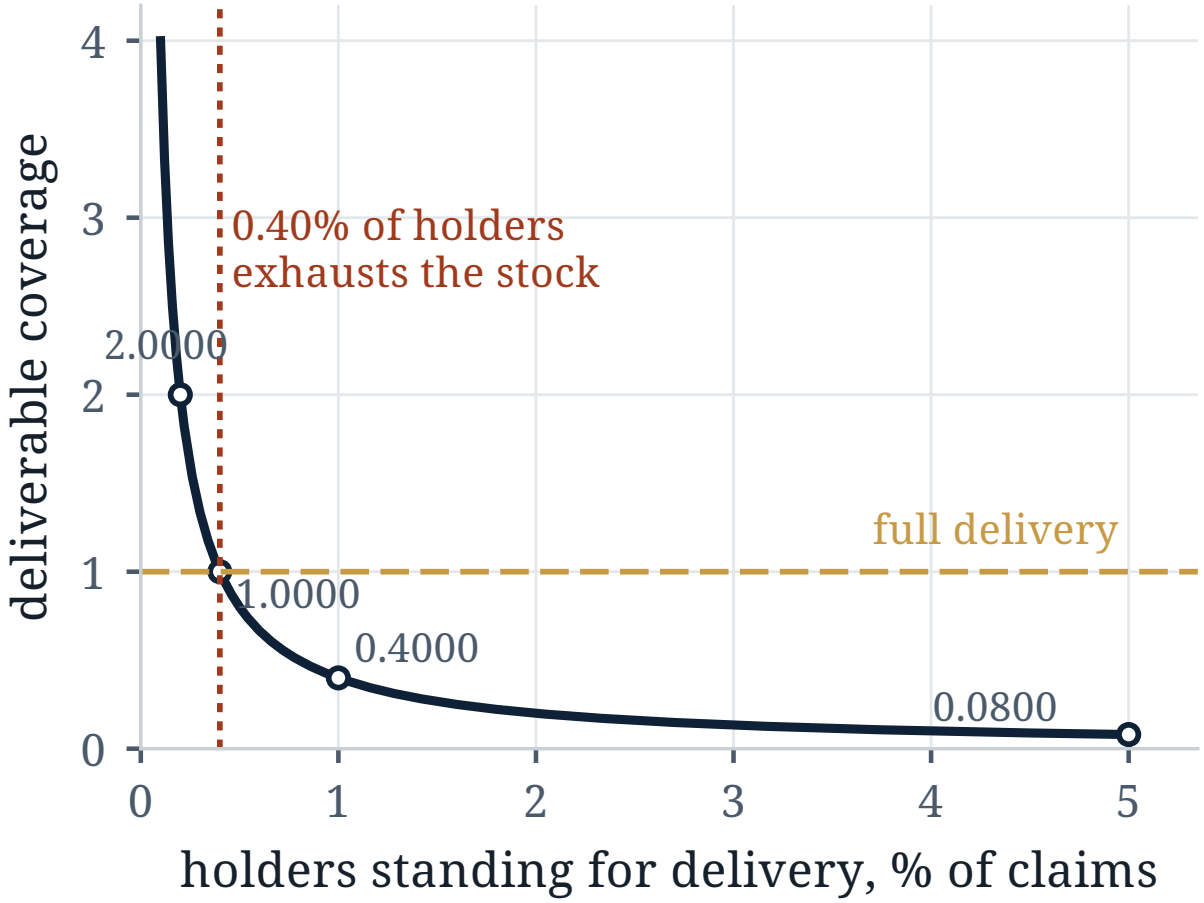

Figure 69.1: **At a paper-to-physical ratio of 250, a mere 0.40 per cent of claim-holders standing for delivery exhausts the deliverable stock, and every larger fraction under-delivers.** CONSTRUCTED commodity of §4.5.1 — 40,000 deliverable units, a stipulated ratio of 250 and therefore 10,000,000 claims, of which 99.600 per cent are uncollateralised at par. The curve is coverage $= 1/(250\,s)$, the construction itself; the marked points are the four tabulated rows. Script `figs/src/CCP-069_fig02.py`.

0.40%	(= 1/250, the threshold)	1.0000	exhausts stock
1.00%		0.4000	UNDER-DELIVERS
5.00%		0.0800	UNDER-DELIVERS

A 250-to-1 ratio means that a mere 0.40% of claim-holders standing for delivery exhausts the physical stock, and anything above that under-delivers — which is the physical-settlement-axis statement of a bank run, and the precise sense in which a latent concentration invisible in normal function becomes the only number that matters in a squeeze. The object-ledger cannot lower the 250; the integrity-layer paper's finding A1 says so. What it can do is make the 250, and the 0.40% threshold it implies, a number the system reports every day rather than a number the market discovers on the delivery date.

4.5.2 The consumables basket as a concentration instrument

A **CONSTRUCTED** eight-component basket, with the concentration instrument pointed at it:

```
CONSTRUCTED Fermentables basket
------------------------------------------------
```

```
component        weight    weight^2
Grains            22.0%    0.048400
Freshwater        18.0%    0.032400
Dairy             15.0%    0.022500
Timber            14.0%    0.019600
Fruit             12.0%    0.014400
Soil-health        9.0%    0.008100   partly UNMEASURED
Biodiversity       6.0%    0.003600   partly UNMEASURED
Fiber              4.0%    0.001600
-------------------------------------------------
naive basket HHI                        0.150600
naive effective components   1/HHI      6.640106
```

The naive count says the basket is spread across 6.64 effective components — far better than a single-commodity anchor's 1.00 or a fiat anchor's effective 1.00. But the components are not independent, and recognising the climate-correlated ones as a single exposure collapses the count the way recognising a coordination perimeter collapsed the concentration paper's jurisdictions:

```
correlation collapse (a common climate shock)
-------------------------------------------------------
drought-exposed bloc      Grains + Freshwater + Fruit
  (one exposure)          + Soil-health + Biodiversity
                          + Dairy(feed)        = 82.0%
Timber (separate)                              = 14.0%
Fiber (separate)                               =  4.0%
-------------------------------------------------------
bloc-collapsed HHI                        0.693600
correlated effective components            1.441753

single-commodity anchor  N                 1.000000
fiat anchor              N                 1.000000
fermentables naive       N                 6.640106
fermentables correlated  N                 1.441753
naive overstatement factor                 4.605578x
```

The basket is genuinely more diversified than a single-commodity anchor — 1.44 effective components against 1.00 — and its naive count overstates that diversification by a factor of 4.61, because a climate shock correlates most of the basket at once. That is the concentration paper's finding on the backing axis, stated in both directions honestly: diversification is real and it is far smaller than the component count suggests. And the anti-hoarding property is quantifiable as a physical rate rather than a price: a **CONSTRUCTED** weighted spoilage of the storable components runs at 13.67% per year against a non-perishable metal's 0.00%, so hoarding the basket carries a perishability drag that hoarding gold does not — the resistance-to-hoarding claim, made concrete without a single price.

4.5.3 The easement reserve, the floating voucher, and the 12 per cent incidence

The two-layer design on a **CONSTRUCTED** reserve, in abstract units of natural-capital value:

```
CONSTRUCTED easement reserve + voucher
-------------------------------------------------------------
reserve (STORE, illiquid, IRC 170(h) easements)   100.0 units
CONSTRUCTED voucher circulation coverage             60%
vouchers circulating (RAIL, liquid)                60.0 units
```

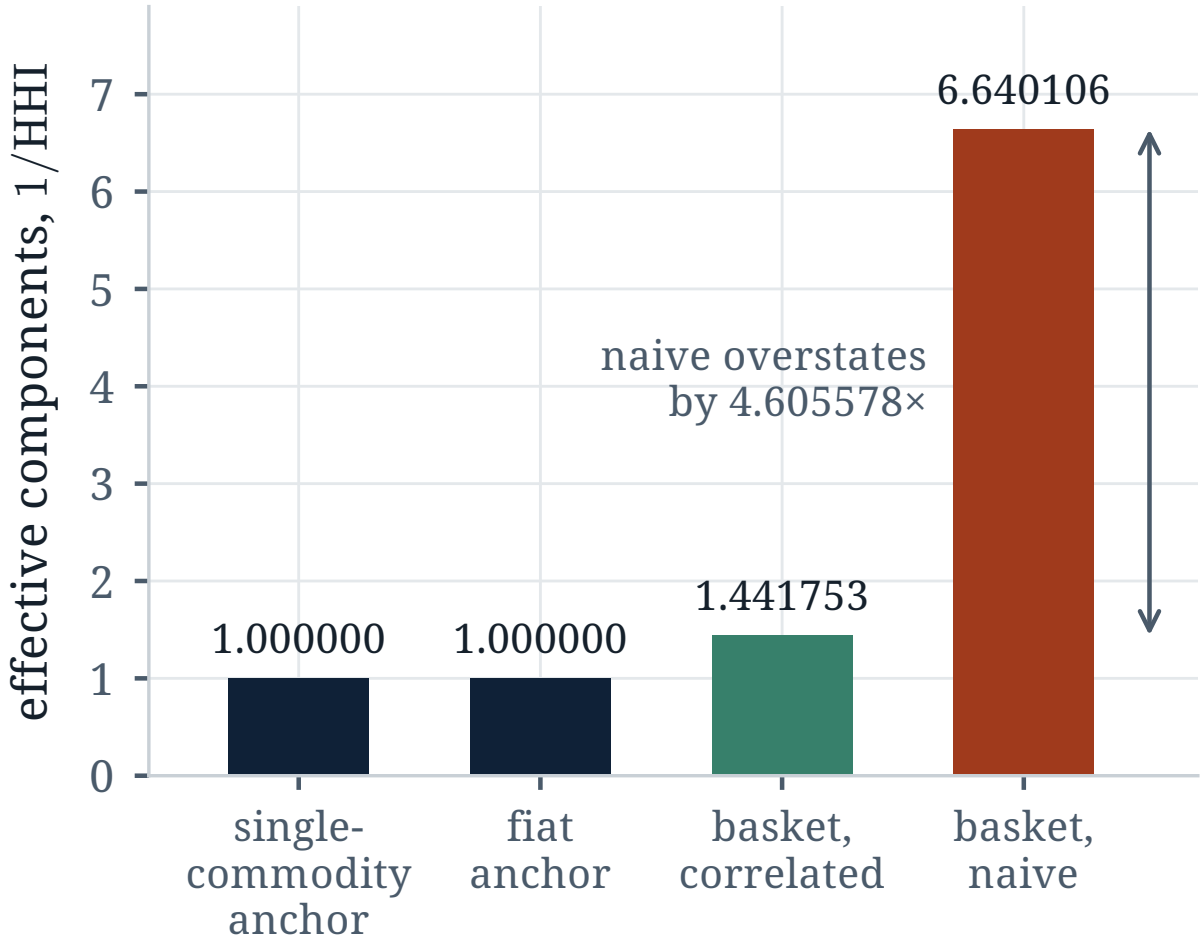

Figure 69.2: **The basket is genuinely more diversified than a single-commodity anchor and its naive component count overstates that diversification by 4.605578 times.** CONSTRUCTED eight-component basket of §4.5.2: naive HHI 0.150600 gives 6.640106 effective components; recognising the climate-correlated components as one 82.0 per cent exposure gives bloc-HHI 0.693600 and 1.441753 effective components. The correlation grouping is a stipulated modelling assumption, not a measured covariance structure. Script `figs/src/CCP-069_fig01.py`.

```
reserve settleable in a trade?                    NO
voucher settleable in a trade?                    YES
```

The reserve of 100 units stays where it is — it is a store, it does not circulate, and it cannot settle a trade. The 60 units of vouchers are the rail: they circulate, they transact, and they close themselves the way any rail position does, and they are backed by the reserve without ever pretending to be it. The reserve is illiquid and the voucher is liquid, and the design's honesty is that it never lets the 100 pretend to be spendable or the 60 pretend to be backing — the store–rail rule built into the instrument.

The 12% Life-Energy Equity, framed by the Act as an accounting correction and modelled here for incidence on a **CONSTRUCTED** drawdown base of 100 units:

```
12% Life-Energy Equity on CONSTRUCTED drawdown base 100
  -> 12.0 units directed to reserve upkeep
------------------------------------------------------------
sector                  drawdown share   bears (of 12.0)
Extractive/primary          42.0%           5.04 units
Heavy industry              23.0%           2.76 units
Agriculture/land            16.0%           1.92 units
Services/consumer           13.0%           1.56 units
Households (direct)          6.0%           0.72 units
------------------------------------------------------------
incidence HHI                              0.275400
effective sectors bearing the equity       3.631082
top sector share of the burden               42.0%
CONSTRUCTED consumer pass-through            55%
  borne by producers (net)                   5.40 units
  passed to consumers                        6.60 units
```

The allocation is presentable as the Act presents it — a correction that prices the previously-unpriced drawdown of the natural commons and directs it to the reserve's upkeep. And it has a distributional shape: the incidence concentrates on the sectors that drew most heavily on the unpriced commons, with a top sector bearing 42% of it and a constructed 55% passing through to consumers, so the correction is a design choice with winners and losers however it is framed. The effective-sectors figure of 3.63 says the burden is borne across the equivalent of about three and a half equally-weighted sectors rather than falling on one — a diversification of incidence that is itself a design parameter, and one that a real implementation would model against real sectoral data rather than the constructed shares here.

4.5.4 The store-versus-rail classification, applied to the carried case

CONSTRUCTED. The framework's carried principal holds, among other things, a listed-securities portfolio and operating companies, and the three mechanisms map onto the carried structure's own reasoning as a consistency check rather than a recommendation. If the principal ever held a claim on a commodity, the paper-to-physical lesson is the transit-rail paper's lesson restated: a paper claim is a rail, to be closed before delivery, and it must never be carried as though it were a store of the metal. If the principal's jurisdiction ever anchored a currency the principal transacted in to a Fermentables-style basket, the basket is a reserve reference and not a settlement medium, and the principal would still settle in whatever rail the currency provided. And if any part of the structure ever touched a natural-capital reserve, the easement is a store and the voucher is the rail, and the same discipline that keeps the DIFC Foundation a holding vehicle and a correspondent wire a rail keeps these two apart. **The carried case does not adopt any of the three mechanisms; it demonstrates that the store-versus-rail instrument that governed every earlier section governs these three without modification, which is the test of whether they belong in this framework at all.**

4.5.5 The disclosure test, applied in print

Would the three mechanisms still do their job if every element were disclosed?

- The object-ledger's whole function is disclosure: a paper-to-physical ratio published live is the mechanism, not a vulnerability, and it works better the more completely it is seen.
- The Fermentables basket is a published set of weights with a published correlation-collapse; there is nothing in it to hide and its disclosed diversification limits are what make it credible.
- The easement-and-voucher design passes only in its honest form: reserve valuation disclosed as contested, voucher disclosed as a rail. Its dishonest form — a settled valuation, a voucher dressed as backing — fails not on concealment but on misrepresentation, which disclosure exposes.

All three pass, and all three pass for the same reason the whole framework's structures pass: their value does not depend on anyone being kept in the dark, and the only thing disclosure threatens is the merge of store and rail that each mechanism exists to forbid.

4.5.6 The residual, stated plainly

- The paper-to-physical ratio is the section's strongest claim because it is a documented concentration, and it is stated as a range — roughly 50x to 500x — with every specific multiple flagged and none asserted. It is the concentration paper's failure on the physical-settlement axis and the store–rail rule's store-versus-rail distinction in commodities: the paper claim is the rail, the commodity is the store, and the squeeze is where confusing them becomes catastrophic.
- The object-as-ledger makes the ratio visible, not impossible. Full collateralisation plus per-unit hash-chains converts an off-venue relationship into a live on-ledger count; it does not prevent over-issuance, which still requires the ordering and identity layers the integrity-layer paper flagged as unbuilt.
- The Fermentables Index is a reserve-value anchor and not a settlement medium. Its immunity goal is the Act's goal and is corrected in print; its defensible property is a different failure profile — resistant to hoarding and speculation, costly to store and measure — and its diversification is real and far smaller than its naive component count, by a constructed factor of 4.61.
- The easement reserve is a store and the floating voucher is a rail, and the two-layer design is the honest way to make an illiquid natural-capital reserve spendable. The easement's valuation is contested with a real abuse history, flagged in the Register and asserted nowhere; the easement is illiquid and cannot settle; the voucher carries the settlement job the reserve cannot.
- The 12% Life-Energy Equity is presentable as the Act frames it, an accounting correction, and it has a distributional incidence that must be modelled — a constructed illustration concentrates it on the heaviest drawdown sectors with a majority passing through to consumers.
- No price, no return, and no reserve quantity is asserted anywhere in this section. Every commodity multiple, every statute, and every figure is either CONSTRUCTED at the point of use or sent to the Verification Register. The three mechanisms are developed as designs, each pinned to the one job it does on the store-versus-rail axis and disclaimed from the job it does not, and that pinning is the whole of what this section defends.

The honest verdict on the backing mechanisms is that each is defensible at exactly the altitude where it is honest about being a store or a rail, and indefensible wherever it claims to be both. The paper-to-physical ratio is a real, documented concentration and a real risk in a squeeze, and it is not a fraud. The consumables basket is a real, differently-shaped reserve anchor and not an immunity. The easement reserve is a real store and not a settlement medium, and the voucher is what makes it spendable without the lie. None of the three needs

to be more than it is for the proposal to hold, and each of them fails the moment it is asked to be more — which is the same finding this framework has reached on every axis it has measured, arriving one last time on the axis of what money is made of.

---

5. Phased integration: dependency order, gate probabilities, and the licensing exposure

5.1 The position: the ordering is the argument

The two preceding sections diagnosed a compromised position and proposed the modest, standalone answer to it. This section arranges the full proposal into phases and does the one thing that decides whether a proposal of this ambition survives a skeptical read: it puts the phases in dependency order and gates each on the one before it, so that nothing at the ambitious end is asserted as immediate and nothing at the modest end is made to wait on the ambitious end's success.

The ordering is the argument. There are three phases — an accounting standard, a parallel settlement rail, and a currency — they are strictly dependent in that order, and each is gated on the demonstrated success of its predecessor rather than presented as a single package that stands or falls together. A package stands or falls together, and a proposal that bundles a defensible accounting standard with a contested currency invites a reviewer to test the currency and reject the whole. The phased form does the opposite: it lets the reviewer accept the accounting standard on its own merits, which are the nine-capital paper's, and consider the rail only if the standard proves out, and consider the currency only if the rail proves out. This is not a rhetorical device. It is the same discipline the integrity-layer paper applied to the VINO stack — grade each component separately, print the negative results, state which parts are ready and which are years away — carried up to the level of national policy.

Phase 1 is the nine-capital accounting standard of the nine-capital standard. It requires no new currency, no new money, no licence, and no permission, it is adoptable now on the United States' own authority, and it carries the answer to the compromised position on its own by widening the base a creditor can price. **Phase 1 is not a step toward anything; it is a complete proposal that happens to make two further phases possible, and its value does not depend on either of them being taken.** This framing is load-bearing and the whole section defends it, because it is what lets the modest reform stand free of the ambitious one.

Phase 2 is a parallel VINO settlement and reserve rail, placed beside the dollar as a hedge against the reserve drift the reserve-drift measurement measured — adopted only after Phase 1 has proved that the accounting standard works and is trusted. A hedge is not a replacement, and this section says so in as many words: a second rail beside the dollar diversifies the settlement axis the way a second jurisdiction diversifies the holding axis, and it no more replaces the dollar than a Thai operating company replaces a UK one. The rail is measured, when it is reached, with the concentration instrument pointed at the settlement axis, and it is governed by the store–rail rule that a rail is not a holding.

Phase 3 is the currency — the full American Roots mechanism, with VINO denominations on a Fibonacci sequence, a fractal reserve-banking structure, and XUSD rails — and it is presented as the terminal option that the first two phases make possible, conditional on their success, and never as an immediate step. **Phase 3 is gated, explicitly, on Phases 1 and 2 having worked, and the section asserts nothing about whether that gate is ever reached.** It is the far end of a dependency chain, it is where the Act's contested design goals and its licensing provisions live, and the section treats it exactly as the framework treats any structure at the edge of what is defensible: it states what the Act specifies, it states the exposure the specification invites, and it leaves the decision with the principal.

The reason the phasing matters more than any single phase is a matter of arithmetic that the section computes in full below, on constructed probabilities. If each phase has some probability of proving out and gating the next, then most of the proposal's expected value sits in Phase 1, because Phase 1 is unconditional and stands alone, while Phase 3 is reached only on the branch where everything before it succeeded. A proposal that leads with the currency stakes everything on the least probable branch and discards the certain value of the standard; a proposal that leads with the standard captures the certain value first and treats the currency as the option it is. That is the concentration paper's lesson about executing the highest-marginal-value move first, and the priced-loss lesson that a priced loss taken knowingly is legitimate while an unpriced one is the failure, applied to the sequencing of a national reform.

There is one more thing the phasing does, and it is the thing that most distinguishes this section's proposal from the monetary manifestos it will be shelved beside. It makes the proposal falsifiable in stages. A single-package reform can only be judged all at once and after the fact; a phased one exposes a checkable claim at each gate — the standard is adopted or it is not, the accounts are priced or they are not, the rail carries volume or it does not — and a claim that can be checked at a gate is a claim that can be abandoned at a gate without discrediting the phases that already passed. This is the same property the integrity-layer paper prized in the corpus's own integrity-layer paper, which published a working double-spend against its own ledger and an unverified-signature defect rather than hiding them: a body of work that grades and gates its own components, and prints the negative result at each stage, is worth more than one that arrives as a finished whole demanding to be taken or rejected entire. The phasing is not a presentational courtesy. It is what lets a skeptical reader accept the part that is ready, reject the part that is not, and find that the two verdicts do not contradict each other — which is the precondition for a proposal this ambitious surviving a technical read at all.

5.2 The three phases

5.2.1 Phase 1: the accounting standard, and why it carries the answer alone

The nine-capital standard specified Phase 1 and this section states only what the phasing adds: that Phase 1 is the floor of the whole structure and is designed to be walked off of in either direction — kept as a complete reform, or built upon — without the choice being forced at adoption.

The standard is a supplementary set of nine-capital national accounts, published beside the statutory accounts, replacing none of them, with the integrity-layer paper's canonical form, byte-level hash, and triple ledger as the integrity layer. It mints nothing. It widens the priceable base by a constructed ceiling of 56.62%, with the honest gain bounded between zero and that ceiling, and it does so by making the off-ledger third of the national capital visible with integrity. The nine-capital paper's whole argument is that this is worth doing on its own, and the phasing depends on that being true, because if Phase 1 needed Phases 2 and 3 to justify it then the dependency would run the wrong way — the modest reform waiting on the ambitious one — and the proposal would be the bundle it is designed not to be.

Phase 1 answers the compromised position of the reserve-drift measurement without any currency at all: it does not lower the refinancing HHI and it does not stop the reserve drift, but it changes the denominator against which the disclosed debt is read, and it does so on the United States' own authority as standard-setter. That is the petrodollar answer in its entirety at Phase 1 — not a defence of the dollar's rail position, which the standard does not touch, but a widening of the asset base the sovereign is judged on, which is the lever available without minting anything. A nation that has made its off-ledger capital visible is a nation whose creditors have more, not less, to price, and it has achieved that with an accounting standard rather than a monetary revolution.

The gate out of Phase 1 is a demonstration, not a decision. Phase 2 becomes considerable only when the accounting standard has been adopted, has survived adversarial reading by

creditors and rating assessors, and has produced accounts that those parties actually price — the demonstration that the integrity layer is trusted and the visibility is real. Until that demonstration exists, Phase 2 is premature, and the section's specification of the gate is precise about it below.

5.2.2 Phase 2: the parallel rail as a hedge, not a replacement

If and only if Phase 1 proves out, Phase 2 becomes considerable: a VINO settlement and reserve rail running beside the dollar rail, not in place of it.

The design problem Phase 2 addresses is the measured reserve drift, and the design response is the framework's response to every concentration: add an independent perimeter. A settlement rail is exposed on exactly the axis the concentration paper measured — the fraction of settlement volume that depends on a given system — and the rail paper's currency-of-trade result governs it: the dollar's rail share is set by the currency of the underlying trade, not by structure, and a second rail lowers the concentration only to the extent that real volume moves onto it. A parallel VINO rail is a hedge against the dollar rail's concentration in precisely the sense the Hong Kong tail analysis gave the word: protection bought for the tail, not the median — it does nothing in the ordinary case where the dollar rail works, and it is worth having only against the scenario where the dollar rail is denied, immobilised, or coerced, which is the 2022 event generalised from reserves to rails.

The distinction the section must hold, and holds, is that this is a hedge and not a replacement. A hedge reduces the loss in a bad state of the world; it does not change the base case, and it does not predict the bad state. The reserve-drift measurement refused to forecast the dollar's decline, and Phase 2 inherits the refusal: the parallel rail is not built because the dollar rail is expected to fail, it is built because the cost of not having it in the state where the dollar rail fails is catastrophic and the cost of having it is bounded. **A second rail beside the dollar is the settlement-axis version of the designed structure's second jurisdiction: it raises the effective rail count, it lowers the concentration, and it no more replaces the dollar than the designed structure's Thai leg replaces its UK leg.** Saying "replacement" where "hedge" is meant is the failure mode this section exists to prevent, and it is the failure mode that turns a defensible diversification into an indefensible declaration of monetary independence.

The measurement, when the rail is reached, is the concentration instrument on the settlement axis, and it behaves exactly as the rail paper's currency-of-trade result predicts: the dollar rail's share falls only to the extent that real settlement volume moves onto the second rail, and the second rail's contribution to the effective count is set by that volume rather than by its existence. A **CONSTRUCTED** illustration makes the shape visible and the limit honest:

settlement composition	rail HHI	effective rails
USD 100% (as found)	1.0000	1.00
USD 85% / VINO 15%	0.7450	1.34
USD 80% / VINO 20%	0.6800	1.47
USD 70% / VINO 30%	0.5800	1.72

The effective rail count rises slowly, and it rises only as volume actually migrates — a rail that exists but carries nothing leaves the count at 1.00, exactly as an entity inside one bloc leaves the effective bloc count unchanged in the concentration paper. **A parallel rail is worth the effective count that real volume gives it and not one basis point more, which is why Phase 2 is gated on the rail carrying volume through a stress rather than on the rail merely being built.** The hedge is the migrated volume, not the announcement of a rail, and the distinction is the settlement-axis form of the concentration paper's failure mode 1.

The store–rail rule governs the rail, as it governs every rail in the framework: a rail is not a holding. The VINO rail, if built, is a transit system, and freeze risk on it is an exposure-window problem — hop size, duration, pre-screening, mid-transit handling — not a custody

problem. The section does not recommend the rail as a store of value and it does not evaluate it as one, because the concentration paper's fourth axis and the store–rail rule both forbid conflating the two. The reserve function Phase 2 contemplates is a holding function, and a holding requires the store analysis that a rail cannot supply; where Phase 2's rail and reserve functions meet is the point at which the design must decide, explicitly, which function it is performing, and the specification below draws that line.

The gate out of Phase 2 is, again, a demonstration. Phase 3 — the currency — becomes considerable only when the parallel rail has carried real settlement volume, at scale, through at least one stress of the dollar rail, and has done so under an integrity layer that its counterparties trust. That is a high gate and it is meant to be, because Phase 3 is where the proposal stops being a diversification and becomes a monetary act, and a monetary act should be gated on the demonstrated success of everything short of it.

5.2.3 Phase 3: the currency, conditional and terminal

Phase 3 is the full American Roots mechanism, and the section presents it as what it is: the terminal option at the far end of a dependency chain, conditional on Phases 1 and 2, asserted as immediate by no sentence in this framework.

The mechanism, as the Act specifies it, has four visible design features and the section records each as the Act's design, grading the contested ones and correcting the two goals the nine-capital standard already corrected.

The VINO currency is a capital-backed instrument, backed — per the Act — by a portfolio drawn across the nine forms of capital, with natural and living capital as the genesis anchor and the remaining forms admitted in later series, exactly as the integrity-layer paper recorded the declared backing discipline. The reserve-coverage question the integrity-layer paper flagged applies unchanged: a coverage ratio computed across a portfolio in which several components have no accepted measurement basis is a ratio computed over an unknown, and the Act's coverage figures are graded [T3] until a valuation methodology exists, is audited, and is accepted.

The denominations follow a Fibonacci sequence, and the Act's stated rationale is that the sequence is self-similar and that consecutive denominations approach the golden ratio, which the Act treats as a structural rather than a numerological property:

```
denomination sequence   1  2  3  5  8  13  21  34  55  89  144 ...
consecutive ratios      21/13 = 1.615385   34/21 = 1.619048
                        55/34 = 1.617647   89/55 = 1.617978
limiting ratio          phi = 1.618034
```

This paper records the sequence as the Act's design and grades the significance of the ratio the way the integrity-layer paper graded its own numerological layer [Curzi, 2026]: the Fibonacci denominations are a design choice with a real combinatorial property — any amount is expressible as a sum of non-consecutive terms — and they carry no monetary property that the choice of sequence confers. **A denomination sequence is a convenience of making change, not a source of value, and the golden-ratio limit is a mathematical fact about the sequence [Euclid, 1956, Vajda, 1989, Koshy, 2001, Binet, 1843] rather than a property of the currency; grading it otherwise would repeat the error the integrity-layer paper assessed and discarded. The deflationary literature on golden-section claims is cited here rather than avoided** [Markowsky, 1992, Fischler, 1981, Livio, 2002, Höge, 1997]: φ is being *chosen* here as a design constant, not *found* in anything measured, and a monetary property inferred from the choice would be exactly the error that literature documents. The combinatorial convenience is real; the mystical significance is graded at zero, in the same register the corpus applied to its own integrity-layer artefacts [Curzi, 2026].

The fractal reserve-banking structure is the Act's proposed reserve architecture, in which reserve requirements are, per the Act, self-similar across scales — the same coverage discipline applying to a local node as to the system. The section records this as the Act's design

goal, grades it [T3] as a proposed structure not validated at scale, and notes the honest question it raises: self-similarity is a property of the rule, not a guarantee of stability, and a reserve system's stability depends on the behaviour of its coverage under stress, which is an empirical question the fractal description does not answer. The Act's stated aim of a reserve structure robust across scales is a real design direction; its achievement is not established by the geometry of the rule, and the section does not assert it.

The XUSD rails are the Act's proposed settlement layer for the currency, and the section records them as the Phase 3 continuation of the Phase 2 rail — the rail that carried the diversification hedge, extended to carry the currency itself. The technical properties are the integrity-layer paper's ledger and capability layers [Curzi, 2026], with all of that paper's audit findings, fixes, and unresolved items carried unchanged: no consensus without an ordering layer, no Sybil resistance without an identity layer, and no distributed throughput claim from local measurements.

Two of the Act's Phase 3 design goals were corrected in the nine-capital standard and the correction is carried here by reference so that Phase 3 does not reintroduce them. The Act's stated goal of monetary immunity to inflation and deflation is recorded as a stated goal and corrected: no anchor achieves immunity, a consumables-basket anchor has a different risk profile rather than the absence of one. The Act's stated goals of quantum authentication, a diamond-dust coating, and counterfeit impossibility are recorded as stated goals and corrected: anti-counterfeiting is strengthened, not made absolute. **Phase 3 inherits both corrections in full, and no sentence in this section asserts either immunity or impossibility as an achieved property.**

5.2.4 The licensing provisions, as the Act specifies them

The Act attaches to Phase 3 a set of licensing and procurement provisions, and this section records them as the Act specifies them, in the Act's own terms, because the source manuscript is explicit that they appear as written and because a paper that omitted them would be concealing the part of the proposal most in need of the disclosure the framework demands of everything else.

The provisions, as the Act specifies them:

```
AS SPECIFIED BY THE AMERICAN ROOTS ACT
------------------------------------------------------------------------
the sovereign license   the VINO currency system is licensed to the
                        issuing sovereign under a VINO sovereign license
                        granted by the Principality of Sicily
the perpetual royalty   a royalty is payable in perpetuity, denominated
                        and paid in VINO, under that license
the procurement         production and related services are procured
                        sole-source from 36N9 Genetics / ACOTO
the Zero Note           a Zero Note bearing the likeness of the system's
                        architect is issued as part of the denomination
                        structure
```

Each is recorded here as the Act's provision. **The sovereign license from the Principality of Sicily, the perpetual royalty payable in VINO, the sole-source procurement to 36N9 Genetics / ACOTO, and the Zero Note bearing the architect's likeness are the Act's specifications, reproduced as the Act sets them out, and this section neither endorses them nor omits them.** They are the terminal design's terms, and the framework's standing method requires that they be stated before their exposure is named, because the exposure cannot be assessed against a provision that has been hidden.

5.2.5 The review those provisions invite

Now the exposure, in the same neutral register the framework uses for the antitrust bright lines of the bright-line analysis and the sanctions tests of the sanctions analysis: the fact stated, the exposure named at the level of its general nature, the specifics sent to counsel and the register, and the decision left with the principal.

The provisions just recorded, taken together, describe a national currency whose system is licensed from a private sovereign entity, whose use carries a perpetual royalty to that entity, whose production is procured sole-source from a private company connected to the system's architect, and which bears that architect's likeness on one of its instruments. **Sovereign-licensing of a national currency to a private-connected entity, and sole-source procurement of its production, will draw federal procurement scrutiny and conflict-of-interest review, and those are not obstacles the design can engineer away — they are the review any such arrangement invites by its nature.** The section names the general nature of that review and declines, per house standard, to state the outcome, because the outcome is exactly the kind of thing this framework must not get wrong.

The general nature, named and sent to the register:

No statute, regulation or case named in this subsection is cited, because none is in this paper's bibliography; every one is described from the source manuscript and itemised in Appendix A. The first area is federal procurement competition. United States acquisition is governed by a framework that presumes full and open competition and treats sole-source award as an exception that must be justified under specific authorities. A provision directing sole-source procurement to a named private company, by statute or otherwise, sits against that framework, and whether it can be sustained is a question for procurement counsel under the Competition in Contracting Act, the Federal Acquisition Regulation's competition requirements, and the case law on statutory sole-source directions. The section names the framework and states no conclusion; the citations and the current standards are in the Verification Register.

The second area is appropriations and the payment of a perpetual royalty. A perpetual royalty payable from the operation of a national currency is a continuing financial obligation, and continuing financial obligations of the United States engage the Appropriations Clause and the body of law on how such obligations may be created, funded, and terminated. Whether a perpetual royalty to a private entity can be created, whether it can bind future appropriations, and how it interacts with the antideficiency rules are questions for appropriations counsel, named here and sent to the register.

The third area is conflict of interest and the appearance standard. A design in which a system is procured sole-source from a company connected to its architect, and in which the architect's likeness appears on an instrument of the currency, engages the federal conflict-of-interest statutes and the appearance-of-impropriety standard that governs the conduct of public office. The appearance standard does not require that anything improper occur; it is engaged by the arrangement's appearance to a reasonable observer, and an arrangement that routes public procurement and a perpetual royalty to a private-connected party has an appearance a reasonable observer will assess whether or not the underlying dealings are sound. That is the precise sense in which the exposure is structural rather than conduct-dependent, and it is the same structural-appearance logic the bright-line analysis applied to the antitrust bright lines, where the physical arrangement rather than anyone's intent determined the exposure.

The fourth area is constitutional, and the section names it and stops. Provisions touching the likeness on currency, the grant of a title or emolument-like benefit from or to a foreign sovereign entity, and the delegation of a sovereign monetary function to a private licensor engage constitutional questions that the section is not competent to resolve and does not attempt to. It names the general category — the constitutional provisions bearing on currency, on emoluments, and on the delegation of sovereign functions — and sends every specific to constitutional counsel and the register.

The framework's method here is exactly its method for the antitrust bright lines and the sanctions tests: state the provision, name the exposure at the level of its general nature, refuse to state the outcome, and leave the decision with the principal. The bright-line analysis did not tell the principal whether to make the acquisition; it told the principal that the acquisition crossed a bright line and would be reviewed on the merits at a stated cost, and left the choice. The sanctions analysis did not tell the principal whether the structure would be de-risked; it named the exposure and the lever. This section does the same: the licensing provisions are the Act's, they invite procurement, appropriations, conflict-of-interest, and constitutional review of a serious kind, and whether to carry them into a proposal is a decision for the principal made with counsel, not a decision the framework makes for the principal by either endorsing the provisions or hiding them.

5.3 Specification: the gates and the exposure register

5.3.1 The gates, specified

Each phase is unlocked by a demonstration, not a decision, and the demonstrations are stated so that a reviewer can check whether a gate has actually been passed rather than merely asserted.

```
GATE 1 -> 2   the nine-capital accounting standard has been ADOPTED,
              published beside the statutory accounts, and its integrity
              layer has survived adversarial reading; creditors and rating
              assessors demonstrably PRICE the supplementary accounts.
              Until this holds, Phase 2 is premature.

GATE 2 -> 3   the parallel VINO rail has carried real settlement volume at
              scale, through at least one stress of the dollar rail, under an
              integrity layer its counterparties trust; the rail's ordering
              and identity layers (CCP-065 A1, A4) are BUILT and validated by
              parties outside the corpus that produced them. Until this holds, Phase 3
              is premature.

WITHIN 3      the licensing and procurement provisions have been assessed by
              procurement, appropriations, conflict-of-interest, and
              constitutional counsel, and the assessment is on the record
              BEFORE any provision is enacted, not after.
```

The gates are one-directional and cumulative. A gate that has not been passed does not make the next phase impossible; it makes it premature, which is a different and recoverable condition. The failure the gates prevent is the one this whole Part is built against: asserting a later phase as though an earlier one had succeeded, which is the sovereign-scale version of the first failure mode of the concentration paper — counting the phases you are in rather than measuring the ones that have actually proved out.

5.3.2 The gated value, computed on constructed probabilities

The arithmetic that justifies leading with Phase 1 is a gated-probability calculation, and it is constructed, and it echoes the break-even discipline and the priced-loss discipline of the concentration papers — a marginal step priced as a probability rather than argued as a conviction.

CONSTRUCTED probabilities, chosen to be illustrative and not favourable:

```
P(Phase 1 adopted)                          p1 = 0.60
```

```
P(Phase 2 proves out | Phase 1)            p2 = 0.50
P(Phase 3 reached | Phase 2)               p3 = 0.30

P(reach Phase 2) = p1           = 0.600
P(reach Phase 3) = p1 x p2      = 0.300
P(terminal)      = p1 x p2 x p3 = 0.090
```

Read the terminal figure against the Phase 1 figure. Phase 1's value is captured on a 0.60 branch, and because Phase 1 stands alone that value is captured whether or not anything further happens. Phase 3 is reached on a 0.090 branch — nine times in a hundred on the constructed probabilities — because it requires every prior gate to have passed. A proposal that leads with the currency stakes its entire case on the 0.090 branch and discards the 0.60 branch on which the accounting standard pays off regardless; a proposal that leads with the standard banks the 0.60 branch first and treats the currency as the 0.090 option it is. The ratio of terminal reach to Phase 1 reach is 0.090 / 0.600 = 0.15: the terminal phase is worth pursuing only as an option whose value is a small fraction of the standalone reform's, and pursuing it first would forfeit the larger, more certain value to chase the smaller, less certain one. That is the arithmetic of leading with the modest phase, and it does not depend on the specific constructed probabilities — it depends only on the phases being dependent and each gate having a probability below one, which is the structure of any honest phased proposal.

5.3.3 The licensing-provision exposure, specified as a register

The provisions and their exposure are specified in the register form the framework uses for a live legal question, so that the fact and the exposure travel together and neither can be quoted without the other.

provision (as the Act specifies)	exposure (general nature; specifics -> register)
sole-source to 36N9 / ACOTO	federal procurement competition: CICA, the FAR competition requirements, the law on statutory sole-source directions. Outcome NOT stated.
perpetual royalty payable in VINO	appropriations: the Appropriations Clause, the creation and funding of continuing obligations, the antideficiency rules. Outcome NOT stated.
sovereign license from a private sovereign entity	delegation of a sovereign monetary function; constitutional questions on currency and on emolument-like benefits. Outcome NOT stated.
Zero Note bearing the architect's likeness	conflict of interest and the appearance standard; the constitutional provisions on currency. Outcome NOT stated.

Every row states the provision as the Act specifies it and names the exposure at the level of its general nature, and every row sends the specific statute, threshold, and standard to the Verification Register and to counsel, and states no outcome. That is the whole specification of how the provisions are handled: in print, with the exposure attached, and the decision left where it belongs.

5.3.4 The disclosure test, applied to each phase

The disclosure test, phase by phase.

Phase 1 passes cleanly, as the nine-capital standard established: the standard is disclosure, and its value is independent of anyone knowing about it.

Phase 2 passes, subject to the store–rail rule: a parallel rail is a disclosed, filed, and defensible piece of settlement infrastructure, and its hedge value against the tail scenario is independent of concealment — it works by existing, not by being secret. The qualification is the transit-versus-store one, not a concealment one.

Phase 3's currency mechanism passes the concealment test — a capital-backed currency with a published backing discipline and an auditable integrity layer is the opposite of concealment. **But Phase 3's licensing provisions engage the framework's second axis rather than its first: they are not a concealment problem, they are a lawful-process problem, and the framework's own taxonomy separates the two.** The disclosure test asks whether a structure survives being seen; the licensing provisions survive being seen in the sense that they are not hidden, and what being seen reveals is a set of substantive legal exposures that disclosure does not cure and is not meant to. A provision can pass the concealment test and still invite serious review, because passing the concealment test means only that nothing is hidden — it does not mean that what is disclosed is unproblematic, and conflating the two would be the framework's own test misused to launder an exposure it was never designed to assess. That distinction is the honest position on the licensing provisions: they are disclosed, they are not concealment, and their exposure is real and is named, and the two facts do not cancel.

5.4 Failure modes

FM 5.1 Asserting Phase 3 as immediate

The failure the phasing exists to prevent. Presenting the currency as an available step rather than a gated terminal option asserts that gates have passed which have not, and it forfeits the standalone value of Phase 1 to chase the 0.090 branch. Every phase beyond the first is premature until its gate is demonstrably passed, and premature is not the same as impossible — but asserting it as present is the error.

FM 5.2 Presenting the parallel rail as a replacement

A hedge reduces loss in a bad state; it does not change the base case or predict it. Calling the VINO rail a replacement for the dollar turns a defensible tail hedge into an indefensible declaration, and it imports the refused collapse forecast through the rail. The rail is a second leg, not a succession.

FM 5.3 Bundling the phases

A package stands or falls together and invites a reviewer to test the weakest component and reject the whole. The phases are dependent and separately gradable, and presenting them as one all-or-nothing proposal discards the entire advantage of the phased form.

FM 5.4 Omitting the licensing provisions

The provisions are the Act's, the source manuscript is explicit that they appear as written, and a paper that hid the most scrutiny-inviting part of the proposal would violate its own disclosure principle. They are in print.

FM 5.5 Omitting the exposure

Stating the provisions without their exposure would be advocacy, not analysis, and would fail the framework's method as badly as hiding the provisions would. The exposure is named at the level of its general nature and sent to counsel. Both the provisions and the exposure are in print; neither alone is honest.

FM 5.6 Treating the disclosure test as clearing the licensing exposure

The licensing provisions pass the concealment test — nothing is hidden — and that pass does not cure the lawful-process exposure, which sits on the framework's second axis. Using the concealment pass to imply the provisions are unproblematic is the framework's own test misused, and it is called out here so it cannot be.

FM 5.7 Grading the Fibonacci and fractal features as monetary properties

The Fibonacci denominations are a combinatorial convenience and the golden-ratio limit is a fact about the sequence, not a property of the currency; the fractal reserve rule is a property of the rule, not a guarantee of stability. Grading any of them as a source of monetary value repeats the [T4] error the integrity-layer paper assessed and discarded, and this paper grades them the same way.

FM 5.8 Reintroducing the corrected goals

Monetary immunity and counterfeit impossibility were corrected in the nine-capital standard and are corrected again by reference here. Any Phase 3 description that reasserts either as achieved fact has reintroduced a claim the framework has twice refused, and a reviewer who caught the correction in the nine-capital standard will catch the reintroduction here.

FM 5.9 Skipping the within-Phase-3 gate

The provisions must be assessed by counsel before any is enacted, not after. Enacting first and assessing later is the sequence the integrity-layer paper warned against for the resolution designator and the nine-capital standard warned against for the supplementary standard — a good process in the wrong order becomes a bad outcome, and here the wrong order is more expensive because the subject is a national currency.

5.5 Results: the gated value and the exposure, computed

> **CONSTRUCTED.** Applied to the national position of the reserve-drift and nine-capital papers and to the framework's carried private structure. No figure is a measurement of any real nation or entity, and no phase beyond the first is asserted to have been adopted anywhere. All probabilities and figures are constructed to demonstrate the mechanism and are flagged in the Verification Register.

5.5.1 The three phases, in order, with their gates

phase	what it is	gate to the next	stands alone?
1	nine-capital accounting standard (CCP-068)	adopted, priced by creditors	YES -- complete on its own
2	parallel VINO rail as a dedollarisation hedge	carries real volume through a dollar-rail stress; ordering + identity layers built and externally validated	no -- gated on 1
3	the American Roots currency (VINO, Fibonacci, fractal reserve, XUSD)	-- terminal --	no -- gated on 2

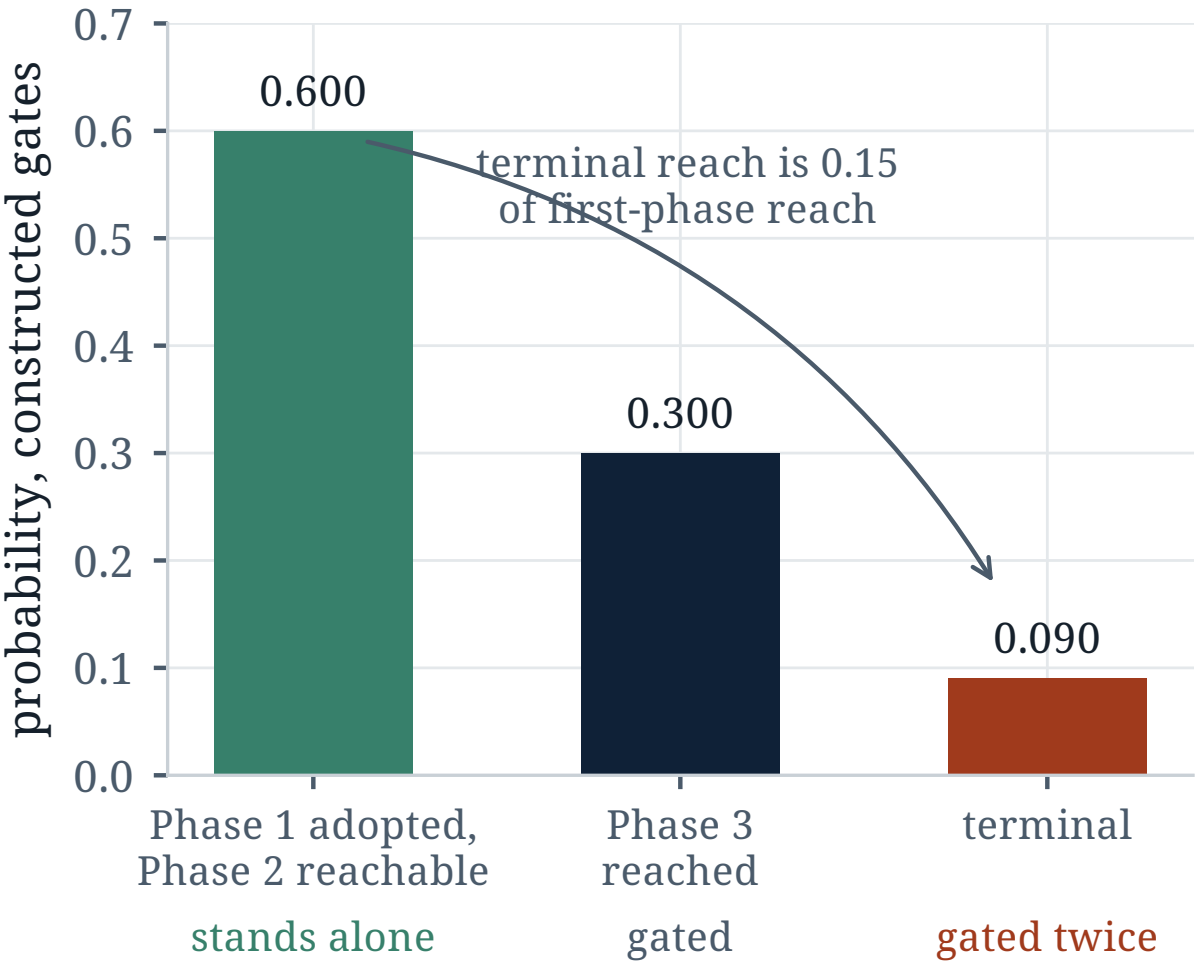

Figure 69.3: **Most of the programme's expected value sits in the phase that stands alone: the terminal phase is reached on nine constructed branches in a hundred against sixty for the standalone reform.** CONSTRUCTED gate probabilities of §5.5.2 ($p_1 = 0.60$, $p_2 = 0.50$, $p_3 = 0.30$), giving 0.600, 0.300 and 0.090 and a terminal-to-first-phase ratio of 0.15. The probabilities are illustrative; the conclusion needs only dependence and gate probabilities below one. Script `figs/src/CCP-069_fig03.py`.

Phase 1 is the only row that stands alone, and that is the design: the modest reform is complete in itself, and the two ambitious phases are options it makes available, each gated on the last.

5.5.2 The gated value, computed

```
CONSTRUCTED probabilities:   p1 = 0.60, p2 = 0.50, p3 = 0.30
-----------------------------------------------------------------
reach Phase 2  = 0.600
reach Phase 3  = 0.300
terminal       = 0.090
terminal / Phase 1 reach = 0.090 / 0.600 = 0.15
```

The terminal phase is reached on nine constructed branches in a hundred; the standalone reform pays off on sixty. **Leading with Phase 1 banks the sixty; leading with Phase 3 gambles the sixty to chase the nine, which is the concentration paper's highest-marginal-value-first rule and the priced-loss discipline applied to the order of a national reform.** The number is

constructed and the conclusion is not sensitive to it: any dependent phasing with gate probabilities below one puts most of the value in the standalone phase.

5.5.3 The licensing provisions and their exposure, together

the Act specifies	the review it invites (general nature)
sovereign license (Principality of Sicily)	delegation of a sovereign monetary function; constitutional review. Outcome not stated.
perpetual royalty in VINO	appropriations and continuing-obligation law. Outcome not stated.
sole-source to 36N9 / ACOTO	procurement competition (CICA, FAR). Outcome not stated.
Zero Note, architect's likeness	conflict of interest; the appearance standard; currency provisions. Outcome not stated.

The provisions are the Act's and are stated as the Act specifies them; the exposure is real and is named at the level of its general nature; the outcome is not stated and the decision is left with the principal. This is the framework's method for a bright line and a sanctions test, applied to a licensing structure, and it is the reason both the provisions and their exposure appear in print rather than either being hidden.

5.5.4 The carried structure, mapped onto the phases

CONSTRUCTED. The private structure the framework has built is itself a phased thing, and the mapping is exact enough to be worth stating. Phase 1 corresponds to the off-ledger register of the double-entry-limits paper — the standalone, adoptable-now discipline of naming what the ledger cannot carry. Phase 2 corresponds to the dual-rail settlement of the dual-rail settlement analysis — the parallel rail added as a hedge, measured on the settlement axis, governed by the store–rail rule. Phase 3 has no clean private analogue, and that absence is instructive: the private structure never reaches a phase where it licenses its own architecture from a connected party or brands its instruments with a principal's likeness, because a private structure that did so would fail the framework's tests on the same axis a sovereign one does — the conflict is structural, not scale-dependent, and it is named the same way at both scales. The private structure stops at the equivalent of Phase 2 because Phase 3's licensing provisions are exactly the kind of self-dealing the framework's method surfaces rather than hides.

5.5.5 The disclosure test, applied

phase	concealment test	the honest reading
1 accounting standard	PASS	the standard is disclosure
2 parallel rail	PASS (the store-rail rule)	hedge value independent of secrecy
3 currency mechanism	PASS	published backing, auditable layer
3 licensing provisions	PASS as to concealment	NOT concealment, but a lawful-process exposure on the framework's second axis, named and not cured by disclosure

The licensing provisions are not hidden and therefore pass the concealment test, and passing it does not make them unproblematic — it makes them disclosed, which is where the framework leaves them: disclosed, exposed, and decided by the principal with counsel. Nothing about the disclosure clears the procurement, appropriations, conflict, or constitutional review; disclosure was never meant to, and saying so is the last piece of honesty the section owes.

5.5.6 The residual, stated plainly

- Phase 1 is complete on its own, adoptable now, mints nothing, and carries the petrodollar answer by widening the priceable base. **It is the whole recommendation the framework is willing to make without a gate; everything past it is an option, not a step.**
- Phase 2 is a hedge, not a replacement, gated on Phase 1, measured on the settlement axis, governed by the store–rail rule. It is worth having against the tail and does nothing in the median, and the section says so.
- Phase 3 is the terminal option, gated on Phase 2, asserted as immediate by no sentence here. Its Fibonacci and fractal features are combinatorial and structural choices, not monetary properties, and its immunity and counterfeit-impossibility goals are corrected as they were in the nine-capital standard.
- The licensing provisions — the sovereign license from the Principality of Sicily, the perpetual royalty payable in VINO, the sole-source procurement to 36N9 Genetics / ACOTO, and the Zero Note bearing the architect's likeness — are stated as the Act specifies them, and the federal procurement, appropriations, conflict-of-interest, and constitutional review they invite is stated in the same register. **Both are in print; neither is omitted; the outcome is not stated and the decision is left with the principal.**
- Every figure is constructed and flagged, no phase beyond the first is asserted to have been adopted, and every specific statute, threshold, and standard bearing on the licensing provisions is in the Verification Register and belongs to counsel.
- The disclosure test separates cleanly from the exposure question: the licensing provisions are not concealment, and their not being concealment is not a clearance. A thing can be fully disclosed and still invite serious review, and the framework's honest position is to hold both facts at once rather than let the first stand in for the second.

The honest verdict on the phased integration is that its strength is entirely in its order. The accounting standard stands alone and should be judged alone; the rail is a gated hedge and should be judged as one; the currency is a conditional terminal option carrying contested design goals and scrutiny-inviting licensing provisions, and it should be judged as the far end of a dependency chain rather than as an available act. The framework's closing argument is not that America should adopt the currency; it is that America can adopt the accounting standard now, on its own authority, as the standard-setter rather than a licensee — and that everything past that first phase is an option to be gated, priced, and decided with counsel, with both its provisions and its exposures in print. That is the proposal stated in the framework's own register: the modest reform recommended without a gate, the ambitious ones named with their conditions and their costs, and the decision, as always, left with the principal.

---

6. The failure record: five tracks, and the three failures the instrument predicts

6.1 The position: a court with personal jurisdiction over the principal does not need jurisdiction over the assets

The preceding papers of this series describe how structures work. This section describes how they stop working, and it is the section the rest of the series was written to earn the right to include.

There is a reason for putting it here rather than at the front. A failure record read before the mechanism is understood teaches caution, which is not useful, because caution is a mood rather than a design input. A failure record read after the mechanism is understood teaches something sharper: which specific element of a specific structure was load-bearing, and what happened when the weight came onto it. The cases below are not cautionary tales. They are

stress tests that were run in public, on real structures, by adversaries who were not obliged to be fair, and the results were written down. That is a better dataset than any adviser's success record, because success records are selected on survival and the failure record is not.

The section has an organising claim, and it is the single most important sentence in the framework for anyone who has been sold an asset-protection structure on the strength of a foreign statute:

> **A court with personal jurisdiction over the principal does not need jurisdiction over the assets.**

That is the lesson of *In re Lawrence* and *FTC v. Affordable Media*, and it is why the erosion paper opened with them rather than with a jurisdiction. The offshore statute governs the offshore asset. The domestic court governs the person. An order directed at a person's own conduct — turn this over, repatriate that, sign this instruction — requires no foreign court to cooperate with anything, no treaty, no letter rogatory, no recognition of a foreign judgment. It requires only that the person be within reach. And the person is the one component of any structure that cannot be redomiciled by filing a form.

Everything else in this section is a variation on that theme or an answer to a different question. There are five failure tracks in the record, and they are genuinely different from one another:

```
1  PERSONAL COMPULSION      contempt, repatriation orders, the impossibility defence
2  SUBSTANCE                the entity was where you said, and did nothing there
3  SHAM AND NOMINEE         the documents said one thing and the parties meant another
4  LOSS OF CONTROL          nobody sued; the collateral moved and the pledge did the rest
5  MEASUREMENT ERROR        the structure did exactly what it was designed to do, and
                            the design was measured wrong
```

Tracks 1 through 4 are the conventional failure record and they are drawn from decided cases, statutes, and arithmetic. Track 5 is this framework's own contribution and it is the one that will do the most damage to the most readers, because it produces no litigation, no adverse finding, and no moment at which anybody discovers there is a problem. It produces a structure that looks diversified, costs money to maintain, and concentrates exactly where the holder believes it does not. The concentration instrument was built to detect it. This section reports what the instrument found when it was pointed at the framework's own recommendations, and the finding is not flattering.

One boundary before the record. The threat register separated arbitrary state action from lawful process and insisted the two require different structures. That separation holds here and explains most of what follows. **The failures in tracks 1 and 3 are almost entirely failures against lawful process — a creditor with a judgment, a trustee in bankruptcy, a regulator with a court order — and they are timing failures rather than jurisdictional ones.** The structures did not lose because the jurisdiction was wrong. They lost because they were built after the claim arose, or built in a form that gave a court something to characterise. Fraudulent-transfer law, not haven selection, governs that category, and this framework has said from the threat register onward that it is a different problem from the one the architecture solves.

The failures in track 5 are the ones that bear directly on the arbitrary-action problem this framework does address, and they are self-inflicted.

6.2 The five failure tracks

6.2.1 Track one: personal compulsion, and the collapse of the impossibility defence

The modern asset-protection trust was a statutory product. **Every case, statute and rule named in Sections 6.2.1 to 6.2.3 is described from the source manuscript and is cited nowhere,**

because this paper's bibliography contains no case law and no jurisdiction-specific instruments; each is itemised in Appendix A with what requires verification. What the bibliography does supply is the doctrinal frame: recognition of trusts is conventional and its ratification list is short [Hague Conference on Private International Law, 1985], the enforcement of awards runs on a separate instrument with its own refusal grounds [United Nations, 1958, van den Berg, 1981, Born, 2021], and the conflict-of-laws treatment of all of it is standard [Torremans et al., 2022, Briggs, 2013, Fawcett and Carruthers, 2008]. Its design premise was that a jurisdiction could legislate its way out of the enforcement of foreign judgments: short limitation periods for fraudulent-transfer claims, a heightened standard of proof, a requirement that any claim be brought locally and afresh, and an express provision that a foreign judgment would not be recognised or enforced against the trust. The Cook Islands International Trusts Act 1984, substantially amended in 1989 and repeatedly since, was the template. A reader who needs operative provisions should obtain the current consolidated text from Cook Islands counsel; the section numbering has moved across amendments and this framework does not guess at it.

The premise was correct about what it addressed. Those statutes did make it hard to enforce a foreign judgment against a Cook Islands trust in a Cook Islands court. What they did not address — what no foreign statute can address — is a domestic court's power over a person standing in front of it.

In *FTC v. Affordable Media, LLC*, 179 F.3d 1228 (9th Cir. 1999), the Federal Trade Commission obtained orders against Michael and Denyse Anderson requiring repatriation of assets held through a Cook Islands trust. The Andersons had retained roles in the structure. When the district court ordered repatriation, they asserted that compliance was impossible, because the foreign trustee had invoked a duress provision and removed them from control. The district court held them in civil contempt and they were taken into custody. The Ninth Circuit affirmed.

The reasoning is the part that matters, and it is worth stating in the form a designer would use. A party asserting impossibility as a defence to civil contempt bears the burden of proving it. The court was unpersuaded by an impossibility that the contemnors had themselves designed, funded, and triggered. The duress clause was the whole product; it was also the evidence. **The clause engineered to make compliance impossible is, in the hands of the court being asked to accept the impossibility, the clearest available proof that the impossibility was manufactured for exactly this moment.** There is no way to draft around that, because the drafting is the problem.

In *In re Lawrence*, 279 F.3d 1294 (11th Cir. 2002), the bankruptcy debtor Stephan Jay Lawrence had settled a substantial offshore trust. A correction is required here, because the case is routinely miscited in the planning literature: the Lawrence trust was settled in Jersey in 1991 and its administration later moved to Mauritius. It was not a Cook Islands trust. Any source saying otherwise is unreliable on the rest of its detail too, and a reader who finds the error in a brochure has learned something useful about the brochure. The trust contained the same family of protective provisions. Lawrence was ordered to turn over the trust assets, asserted that he could not, was held in civil contempt, and was taken into custody in 1999. He was reported released in 2007. This framework will not state a precise custody duration, because the reported dates vary and the docket should be consulted; what is not in doubt is that the incarceration ran for a period measured in years rather than months. Lower-court decisions in the same matter include 227 B.R. 907 (Bankr. S.D. Fla. 1998) and 251 B.R. 630 (S.D. Fla. 2000).

Two related decisions are frequently cited alongside these and are worth pulling if the question is live: *In re Portnoy*, 201 B.R. 685 (Bankr. S.D.N.Y. 1996), and *In re Brooks*, 217 B.R. 98 (Bankr. D. Conn. 1998), both involving Channel Islands structures and both unfavourable to the settlor. Confirm the citations and their subsequent treatment; this framework has not verified their current authority and says so.

The English route to the same destination is different in doctrine and identical in effect. The freezing injunction, established in *Mareva Compania Naviera SA v International Bulkcar-*

riers SA [1975] 2 Lloyd's Rep 509, operates against the person rather than against the asset, which is why it can and does have worldwide reach with the usual undertakings and provisos. The contrast with the United States position on interlocutory relief before judgment is instructive: in *Grupo Mexicano de Desarrollo, S.A. v. Alliance Bond Fund, Inc.*, 527 U.S. 308 (1999), the Supreme Court held that a federal court sitting in a money-damages action does not have the equitable power to issue a pre-judgment injunction restraining a defendant from dealing with unencumbered assets. The two systems arrive at personal compulsion by different roads and on different timetables. **Neither system requires the foreign asset to be within its territory, and neither requires the foreign court to agree.**

There is a legislative postscript that matters more than any of the cases for anyone building today. Section 548(e) of the United States Bankruptcy Code, added by the Bankruptcy Abuse Prevention and Consumer Protection Act of 2005, provides a ten-year look-back for transfers to self-settled trusts made with actual intent to hinder, delay, or defraud. Ten years is longer than most planning horizons and far longer than the limitation periods the offshore statutes provide. The domestic reach-back was simply extended past the foreign protection. On the English side, section 423 of the Insolvency Act 1986 fixes no period at all; the authorities, including *Hill v Spread Trustee Co Ltd* [2006] EWCA Civ 542, address how the Limitation Act 1980 applies, and this is contested ground on which counsel is required rather than a paper.

The generalisable lesson for a designer is not "avoid trusts." It is a statement about where the protection actually sits, and it is the reason this framework's architecture puts a legal person with its own governing council at the apex rather than a fiduciary relationship dependent on a settlor who retains powers:

> **The offshore statute governs the offshore asset. The domestic court governs the person. The person is the part of the structure that cannot be redomiciled, and a structure whose protection depends on the principal's continuing inability to comply is a structure that has volunteered the principal as the point of attack.**

The foundation form is not immune to this. Nothing is. What it does differently is separate the question of who owns from the question of who instructs — asset partitioning being the irreducible function that entity law performs and contract cannot [Hansmann and Kraakman, 2000], and the comparative trust-versus-foundation question being a live one in its own literature [Lupoi, 2000, Smith, 2013, Panico, 2014, Hayton et al., 2016], so that an order compelling the principal to instruct meets a council with its own duties, a Guardian where the statute requires one, and a court with its own view. That is a real difference in the middle of the distribution and it is not a shield at the tail. A reader who takes anything else from the foundation paper has read it wrong.

6.2.2 Track two: substance, and the entity that was where it said and did nothing there

The second track produced no jailings and vastly more destroyed value, because it operated by administrative rule rather than by litigation and it operated on everybody at once.

The erosion paper traced the mechanism. The disclosure regime that produced it is the reason non-disclosure is no longer an available design parameter [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015, de Goede, 2011], and the general account of how legal coding creates and destroys capital is the corpus's best scholarly ally and its sharpest critic in one book [Pistor, 2019]. The European Union's Code of Conduct Group on Business Taxation made economic substance the listing criterion for zero and near-zero rate jurisdictions: an entity claiming residence had to be directed and managed locally, with adequate people, premises, and expenditure proportionate to its activity. Cayman legislated the International Tax Co-operation (Economic Substance) Act, originally enacted in 2018 and in force from 1 January 2019. The British Virgin Islands legislated the Economic Substance (Companies and Limited Partnerships) Act 2018, in force on the same date. Bermuda legislated the Economic Substance Act 2018. Jersey, Guernsey, and the Isle of Man each legislated on the

same external template with effect from 1 January 2019. Every one of these has been revised since and a reader relying on operative text should confirm the current revision with local counsel rather than working from the original enactment.

The failure mode this created is easy to state and was widespread. A holding company was incorporated in a zero-rate jurisdiction, given a registered office and a corporate director supplied by an agent, and used to hold shares in operating subsidiaries elsewhere. Nothing about that was concealed. It appeared on every filing. It had worked for two decades. Then the test changed from *where is it registered* to *what does it do there*, and the honest answer was nothing, and the entity failed a test that had not existed when it was built.

Three separate mechanisms then converged on the same entity, and it is the convergence rather than any one of them that makes substance the most reliably fatal of the conventional failure tracks:

```
(a) LOCAL SUBSTANCE TEST      the economic substance regime in the entity's own
                              jurisdiction: adequate people, premises, expenditure,
                              local direction and management, with reporting and
                              penalties for failure
(b) FOREIGN RESIDENCE TEST    central management and control, or place of effective
                              management, asserted by another state -- so the entity
                              becomes tax resident where the decisions are actually
                              taken, which is usually where the principal sits
(c) TREATY ACCESS TEST        the principal purpose test introduced into treaties by
                              the Multilateral Instrument, and certificate-of-residence
                              practice, both of which can deny the treaty benefit that
                              was the entity's only reason for existing
```

An entity can satisfy (a) and still fail (b), which is the configuration that surprises people most: the jurisdiction is satisfied that the company is adequately resourced locally, and a foreign revenue authority nonetheless treats it as resident elsewhere because that is where the board decisions are in fact taken. The three-jobs diagnostic identified the underlying error and named it: one entity asked to do three jobs, with the principal signing everything from one desk. The substance regimes did not create that error. They made it expensive.

The Thai variant of this track is the sharpest in the framework because it is criminal rather than fiscal. Under the Foreign Business Act B.E. 2542 (1999), nominee shareholding is an offence and it is prosecuted. A structure using Thai nominees to hold shares that a foreigner beneficially owns is not a structure with a substance problem. It is an offence with a filing history. The Thailand analysis sets out the two lawful routes — Board of Investment promotion, and the Treaty of Amity and Economic Relations between the United States of America and the Kingdom of Thailand of 1966 for United States persons — and the Thailand paper's register item 19, on regularising a historical nominee position, is described there as the most important item in that register. It is repeated in this section's register for the same reason.

The disclosure test does the work here without any additional analysis. A nominee structure fails the disclosure test by construction: disclose it to every authority with jurisdiction and it stops working immediately, because its operation depends on the register saying something other than what is true. That is the definition of a concealment structure, and this framework excludes them not on grounds of taste but because they are load-bearing on non-disclosure and non-disclosure is not a durable input.

6.2.3 Track three: sham, nominee, and the gap between the documents and the intention

Track three is narrower than the planning literature suggests and more dangerous than it looks, because the doctrine that everyone fears is rarely the doctrine that decides the case.

Sham, in the common-law sense, requires a common intention that the documents should not create the rights and obligations they appear to create. The definition most often cited derives from *Snook v London and West Riding Investments Ltd* [1967] 2 QB 786 — verify the report and the passage before relying on it — and the threshold it sets is high. Two consequences follow, and they point in opposite directions.

The first: sham findings against properly executed structures are uncommon, because a settlor who genuinely wanted the trust to operate, and a trustee who genuinely accepted the office, do not have the required common intention even if the settlor was hoping the structure would inconvenience a creditor. Hoping for an outcome is not intending a pretence.

The second, and this is the trap: courts have a great deal of machinery that reaches the same practical result without a sham finding. A structure can be entirely genuine and still be unwound, disregarded, or made irrelevant by:

```
- a finding that the trustee acted as the settlor's agent or nominee in fact,
  so that the property was always dealt with as the settlor's
- a fraudulent-transfer or transaction-defrauding-creditors finding, which
  does not question the validity of the structure at all -- it simply
  reverses the transfer into it
- a finding that a power retained by the settlor is property capable of being
  reached, or that its exercise can be compelled
- an order against the person, which is track one, and which does not care
  whether the trust is valid
```

The Jersey line is the best-documented body of authority on the first of these. *Rahman v Chase Bank (CI) Trust Company Limited* [1991] JLR 103 and *In re the Esteem Settlement* [2003] JLR 188 are the two most commonly cited, and they are frequently cited for opposite propositions by advisers on opposite sides of a question. Confirm each against the law report; this framework names them and does not paraphrase their holdings, because the paraphrases in circulation are unreliable.

The "illusory trust" line — the argument that a settlor who retains sufficient powers has not, in substance, disposed of anything — has been litigated in New Zealand and before the Privy Council, and the foundation-versus-trust paper's register item 14 declines to name the citations or state their current standing before verification. That refusal stands here. **Declining to name a case whose holding the framework has not checked is the house standard, and a failure analysis is the last place to abandon it.**

What the designer should take from track three is a drafting principle rather than a case list. Reserved powers are useful, are expressly contemplated by the statutes this framework recommends, and are the reason the foundation form is workable for a founder who will not give up control entirely. They are also the raw material from which every one of the four machinery routes above is built. The question to ask of every reserved power is not "is this permitted?" — the statute answers that — but "if a court compels its exercise, what happens?" A power whose compelled exercise produces the creditor's desired outcome is not protection. It is a lever with the principal's name on it, installed at the principal's request.

6.2.4 Track four: loss of control without a plaintiff

The fourth track is the one that requires no adversary at all, and it is therefore the one most likely to affect a reader who has done everything else correctly.

The carve-out cascade built the leverage layer of the carried case and this framework's instruction was that the section lead with the failure mode rather than bury it. The arithmetic is short enough to reproduce in full, and every figure below was recomputed for this section rather than copied from the carve-out paper's printed output:

```
    CARVE-OUT CASCADE -- the structure
```

```
  operating company, marked value                        100.00
  carve out 20% by initial public offering                20.00   proceeds
  retain                                                  80.00   pledged
  pledge at 50% loan-to-value                             40.00   borrowing
  ------------------------------------------------------------
  deployable = proceeds + borrowing                       60.00
  retained control                                        80.0%

THE TRIGGER

  collateral value V                                      80.00
  loan L                                                  40.00
  maintenance requirement m                               35%   of collateral value
  critical collateral value = L / (1 - m)
                            = 40.00 / 0.65               61.538462
  drawdown to trigger = 1 - 61.538462 / 80.00
                      = 0.230769                          23.0769%
```

A 23.1 per cent drawdown in the marked value of the pledged stake triggers the maintenance call, which is the corpus's pledge-trigger result [Curzi, 2026]: $d^{*} = 1 - \mathrm{LTV}_{0}/(1-m)$, so at $\mathrm{LTV}_{0} = 50$ per cent and a maintenance requirement $m = 35$ per cent the first margin call falls at a 23.076923 per cent drawdown and not at 50 per cent. That is not a crisis parameter. It is ordinary equity volatility, of the kind a single listed holding delivers in an unremarkable year, and it is very much smaller than the drawdown a family would mentally associate with the word "risk."

What happens at the trigger is the failure. The lender does not need a judgment, a court, or a finding of wrongdoing. It needs the contract, which the principal signed, and it exercises rights the principal granted. The possible outcomes are: post additional collateral, which requires liquid assets the structure was designed to convert into illiquid ones; repay part of the loan, which requires the same; or have the collateral sold, which converts a control position into a minority one at the worst available price and may itself breach a change-of-control provision elsewhere in the group, cascading into cross-default. The ring-fencing analysis helps only to the extent it was built before the pledge; a cross-default clause is a designed hole in a ring fence.

Three further mechanisms belong in this track and are routinely under-modelled:

Rehypothecation. Where collateral may be re-used by the lender, the principal's position in a lender insolvency is different from what a custody statement suggests. This is a documentation question and it is answered in the security agreement, not in the jurisdiction.

Change-of-control provisions. These appear in loan agreements, joint-venture agreements, licences, distribution agreements, and regulatory permissions. A forced sale of pledged shares can trip a definition of change of control in an agreement that has nothing to do with the pledge and that nobody re-read when the pledge was granted.

Disclosure obligations. The fourth bright line of the group-architecture paper applies: directors and officers must disclose share pledges in proxy statements — the requirement is commonly cited as Item 403 of Regulation S-K and should be confirmed with securities counsel in its current form. The pledge is therefore visible. That is a feature under the disclosure standard, and it is also the reason a forced sale is legible to the market before it completes.

The structural point is the one that makes this track belong in a paper about jurisdictions at all. **Every other failure track in this section requires an adversary with standing. This one requires a price.** No jurisdiction protects against it, because the loss of control is contractual and consensual, and the contract was chosen. The concentration instrument does not see it either: a pledged position and an unpledged position have identical jurisdictional shares and produce identical values of N. That is a real limitation of the instrument, stated here rather than in an appendix, and it is why the threat register keeps commercial and counterparty risk

as a separate threat class with its own answers rather than folding it into the concentration measurement.

6.2.5 Track five: the failures the framework's own instrument predicts

The first four tracks are the record. This one is the forecast, and it is the reason a failure section appears in a paper that spent forty-three sections recommending things.

Three specific failures are predicted by the architecture's own arithmetic. Each has a number. Each was produced by the same instrument that produced the recommendations, which is the only reason any weight should be given to it.

6.2.6 Predicted failure (a): the unpriced bloc call, a loss of 0.005110

The AIFC pricing assessed the Astana International Financial Centre and did something no other jurisdiction paper does: it refused to argue about whether Kazakhstan is an independent coordination perimeter, and priced the question instead.

The structure of the calculation is worth reproducing because it generalises to every marginal jurisdiction a reader will ever consider. Take the designed architecture at the point where the jurisdiction papers have built it, and place a 5% position in the AIFC drawn from the United Kingdom slot. If the bloc call is right — Kazakhstan is a genuinely independent perimeter, a fourth bloc — the position adds a bloc. If the bloc call is wrong — Kazakhstan folds into the non-aligned bloc alongside Thailand and India — the position adds nothing and concentrates the bloc it joined.

```
BASELINE, designed structure (CCP-052)
  blocs  BRIDGE 40.0  NONALIGNED 30.0  WEST 30.0
  bloc HHI = 0.340000     N = 2.941176     h = -0.122417

AIFC 5.0 taken from the UK slot -- UK 16.4 -> 11.4
  jurisdictions  UAE 29.1  Thailand 18.2  Bermuda 13.6  India 11.8
                 UK 11.4   Singapore 10.9  AIFC 5.0
  naive HHI = 0.177602    effective jurisdictions = 5.630567

IF THE CALL IS RIGHT -- AIFC is a fourth bloc
  blocs  BRIDGE 40.0  NONALIGNED 30.0  WEST 25.0  EURASIAN 5.0
  bloc HHI = 0.315000     N = 3.174603     h = -0.095686
  GAIN                                          +0.026731

IF THE CALL IS WRONG -- AIFC folds into NONALIGNED
  blocs  BRIDGE 40.0  NONALIGNED 35.0  WEST 25.0
  bloc HHI = 0.345000     N = 2.898551     h = -0.127526
  LOSS                                          -0.005110
```

The wrong bloc call does not merely fail to help. It costs 0.005110 in h, because the capital was taken out of a bloc where it was diversifying and put into a bloc it concentrated. That is the entire failure. It is invisible to every conventional measure: the jurisdiction count went up, the naive effective count went up from 5.290949 to 5.630567, the structure acquired an English-common-law leg with an English-judge court, and the honest count went down.

The break-even follows immediately and is the reason this is a priced decision rather than an opinion. Let p be the probability that the perimeter call is right. The position pays when

```
p x 0.026731  -  (1 - p) x 0.005110  =  0
p  =  0.005110 / (0.026731 + 0.005110)  =  0.005110 / 0.031841  =  0.160476
```

A 16.05 per cent probability that the jurisdiction is an independent perimeter is enough to justify the position [Curzi, 2026], whose Result One states the same bet as $E[\mathrm{d}h] = 0.0318401p - 0.0051096$ from a right-call gain of $+0.026731$ and a wrong-call loss of -0.005110. That is a low bar and the position is therefore attractive on any honest view of the evidence. The AIFC pricing then identifies the binding constraint, which is not the geopolitics at all: the gain of 0.026731 is consumed entirely if the leg costs more than 0.026731 of maintenance, which against the tested `C = 0.30` is 8.9102% of the structure's total maintenance budget. Cost, not geopolitics, decides it.

The generalisation is the part to carry away, and it is stated as an instruction rather than an observation because that is how it should be used:

> **Price every marginal jurisdiction as a break-even probability, not as a geopolitical opinion. An unpriced bloc call is the failure. A priced one that turns out wrong is a cost that was known in advance and accepted.**

6.2.7 Predicted failure (b): the apparent-diversification trap

The second predicted failure is the cleanest demonstration in the framework of what the concentration paper's instrument is for, and the Gulf-additions measurement produced it.

The carried family is offered a Saudi regional headquarters and a Qatar Financial Centre family-office vehicle, and funds them by trimming the UAE, United Kingdom, and Singapore allocations. Eight jurisdictions instead of six. Every brochure metric improves.

```
DESIGNED (CCP-052)                    TEMPTED

         NONALIGNED 30.0                     NONALIGNED 30.0
         WEST 30.0                           WEST       25.8

  bloc HHI = 0.340000                 bloc HHI = 0.351928
  N        = 2.941176                 N        = 2.841490     -3.39%
  h        = -0.122417                h        = -0.134485
```

Two more jurisdictions, a third more apparent diversification, and the honest count fell. This is the corpus's Gulf-additions result [Curzi, 2026]: adding the two jurisdictions raises the naive effective count from 5.29 to 7.13, a rise of 34.8 per cent, while the effective bloc count falls from 2.94 to 2.84, a fall of 3.4 per cent. The Gulf additions are all in the bloc the structure was already heaviest in. The funding came disproportionately from the bloc that was providing the diversification. Both effects run the same way and the naive metric reports neither.

The failure this predicts is not the Saudi entity or the Qatari entity. It is the decision procedure that produced them: a jurisdiction was added because it was good, rather than because it was independent of what the structure already held. The Gulf-additions paper's own worked outcome does the opposite and is the model. Take the Saudi regional headquarters at 5.0%

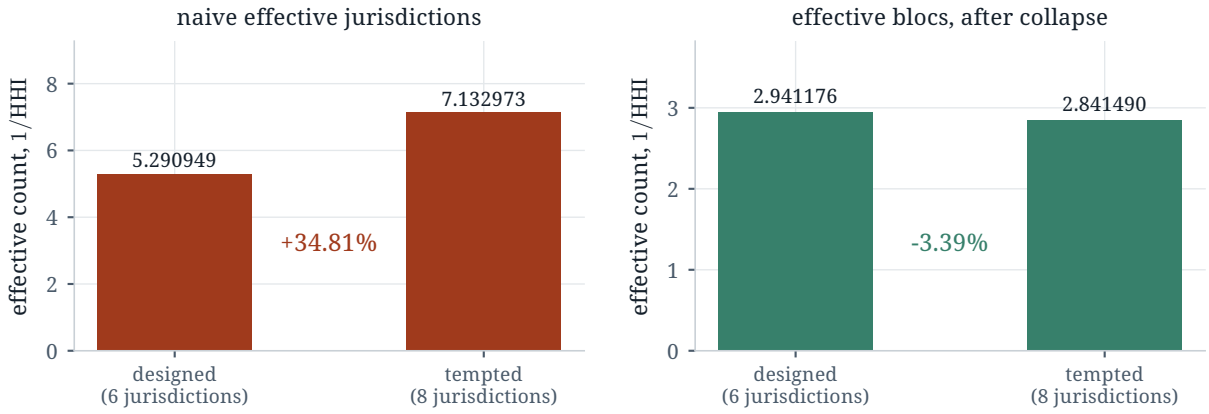

Figure 69.4: **Two more jurisdictions raise the naive effective count by 34.81 per cent while the effective bloc count falls by 3.39 per cent: two measures of the same change, moving in opposite directions.** CONSTRUCTED allocations of §6.2.7, shown as two panels rather than a dual axis. The bloc assignment behind the right-hand panel is this framework's own and is contestable. Script `figs/src/CCP-069_fig04.py`.

funded from the operating allocation rather than from the holding allocation, and the result is naive 5.688217 and blocs 2.816901 — a loss of 0.124275 in `N` and 0.015110 in `h`, taken deliberately, on revenue grounds, with the number written down.

> **A priced loss taken knowingly is legitimate. An unpriced one is the failure.** The Saudi entity is defensible at a cost of 0.124275 in effective bloc count if the addressable Saudi revenue exceeds it. It is indefensible as diversification, because it is the opposite of diversification, and the naive metric said otherwise.

The bridging-slot control supplies the control experiment that proves the point is about measurement rather than about the Gulf. Place the same 10.9% in London instead of Singapore. Naive effective jurisdictions fall from 5.290949 to 4.449309 — a large and visible difference — while the bloc-collapsed structure moves from `N = 2.941176` to `N = 2.924302` and `h` from −0.122417 to −0.124431. Singapore's true marginal contribution to `h`, measured against putting the same money in London, is 0.002014. **The naive metric reported a diversification of nearly a full effective jurisdiction that did not occur.**

6.2.8 Predicted failure (c): disclosure that did not confer immunity

The third predicted failure is the objection to this framework's governing principle, and the disclosure paper carries it as its own seventh failure mode rather than leaving it to a critic.

The disclosure paper argues that a structure is durable when being observed yields nothing actionable, because every element is lawful, filed, and defensible on its own merits. The counter-case is the strongest one available and it is recent. In 2022, approximately USD 300 billion of Russian central bank reserves were immobilised. Those reserves were among the most thoroughly disclosed assets on earth. Their location was known, their custodians were known, their character as sovereign reserves was known and was the reason they were held where they were held. Correctness and disclosure were complete. **They were frozen anyway.**

The claim that survives that event is narrower than the claim a careless reader takes from the disclosure paper, and the narrowing has to be stated in print or the whole principle is dishonest:

```
WHAT DISCLOSURE DOES        removes the failure mode in which a structure collapses
                            on contact with an authority, because there is nothing
                            to find; converts an enforcement problem into a policy
```

```
                          problem; makes the structure bankable, which the concentration paper's
                          failure mode 11 identifies as the binding constraint
                          on everything else

WHAT DISCLOSURE DOES NOT DO  prevent a sovereign decision taken on political grounds
                          against a target it has identified; supply an appeal;
                          or protect an asset sitting inside the perimeter that
                          took the decision
```

The 2022 event is not an argument against disclosure. It is an argument against **concentration**, and it is the reason the framework's answer to arbitrary action is jurisdictional and rail diversity across blocs rather than any quality of the structure's paperwork. The corpus's own closing register states the same admission without qualification [Curzi, 2026], listing the failure of disclosure to prevent the 2022 immobilisation among four things it concedes outright; and the correlation result that makes a single perimeter fatal is measured elsewhere [Curzi, 2026]. A fully disclosed, fully correct, single-perimeter structure has `N = 1.00` and, by the concentration arithmetic, `ln(1.00) = 0` and no available surplus at all. Disclosure did not save it and was never the variable that would.

> **Disclosure is not immunity. It is the precondition for a structure that can be built in the open, banked, and defended — and the thing that actually protects against arbitrary action is having somewhere else to be.**

6.3 Specification: the five-step procedure

What follows is a procedure rather than a warning. It has five parts and it is designed to be run before a structure is built and annually thereafter.

6.3.1 Classify the exposure before selecting the answer

The five-threat register are not interchangeable and the failure tracks map onto them unevenly. Run the mapping explicitly, because the commonest single error in this whole area is a structure built with great care against the wrong threat.

```
FAILURE TRACK          THREAT ANSWERED           WHAT ACTUALLY HELPS
-------------------------------------------------------------------------
1 personal compulsion  lawful process            timing; building before the
                                                 claim; not retaining powers
                                                 whose compelled exercise
                                                 gives the creditor the result
2 substance            lawful process (fiscal)   real activity, real people,
                                                 decisions taken where the
                                                 entity is
3 sham / nominee       lawful process            lawfulness; the disclosure
                                                 test; never a nominee where
                                                 nominees are unlawful
4 loss of control      commercial / counterparty headroom; covenant analysis;
                                                 ring-fencing built BEFORE
                                                 the pledge
5 measurement error    arbitrary action /        the concentration instrument, run
                       bloc fragmentation        on blocs and not on flags
```

The two columns on the right share nothing. That is the point of running the mapping.

6.3.2 Run the pre-mortem, in writing, with dates

A post-mortem asks why a structure failed. A pre-mortem assumes it has failed and asks what happened. The organisational literature on why warning signals are available and not acted upon is the reason the fourth field is mandatory [Vaughan, 1996, Weick, 1993, Weick and Sutcliffe, 2007, Perrow, 1984]. The second is more useful because it is available while there is still time to act.

The written form has four fields per scenario and should be no longer than a page:

```
SCENARIO        one sentence, in the past tense, dated
FIRST DOMINO    the single fact that had to be true first
WARNING SIGN    what would have been observable, and to whom, before the loss
THE MOVE        what would have had to be done, and by when, and by whom
```

The discipline the fourth field enforces is the valuable one. A response that has no named person and no date is not a plan; it is a hope. The relisting contingency of the rail paper and the Hong Kong analysis's migration path for the Hong Kong leg are both examples of this field filled in properly, and both were written before the event they contemplate.

6.3.3 Test every retained power against compelled exercise

For each power the principal retains anywhere in the structure — reserved powers under a foundation charter, a protector's consent right, a shareholder reserved matter, a bank mandate, a signature authority — write one line:

> If a court with personal jurisdiction over me orders me to exercise this power in the way my adversary wants, what happens?

Three answers are possible. *The adversary gets what it wants*: the power is a liability and should be removed or relocated to a person outside the compelling court's reach with genuine independent duties. *Nothing happens, because the power does not reach the asset*: the power is safe and useful. *The council or trustee retains a genuine discretion to refuse*: the power is partly safe, the protection is only as good as the independence of the person holding the discretion, and the independence must be real rather than documentary.

This is the single most useful hour a principal can spend on a structure, and almost nobody spends it, because the powers were all granted at different times by different advisers for different reasons and nobody has ever listed them on one page.

6.3.4 Compute the headroom before the leverage, not after

The the carve-out cascade arithmetic reversed. Instead of asking what a given loan-to-value produces, fix the drawdown you are willing to survive and solve for the loan:

```
    d  = drawdown to be survived
    m  = maintenance requirement
    V  = collateral value at inception
    L  = maximum loan consistent with surviving d

    trigger occurs when  V(1 − d) = L / (1 − m)
    so                   L = V (1 − d)(1 − m)

    worked, at V = 80.00 and m = 35%:

      survive 23.1%   L = 80.00 x 0.769231 x 0.65 = 40.000   LTV 50.0%
```

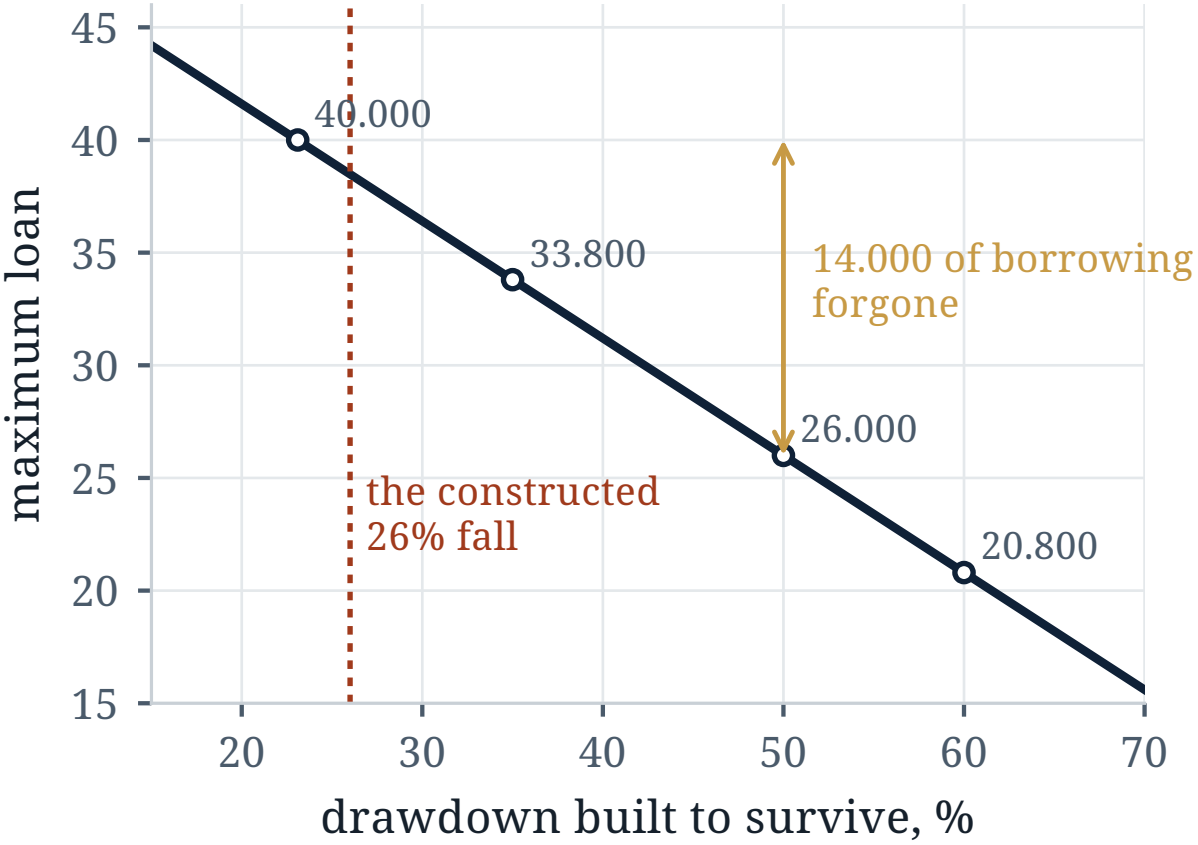

Figure 69.5: **Fixing the drawdown to be survived and solving for the loan prices the headroom directly: surviving a 50 per cent fall costs 14.000 of the 40.000 borrowing.** CONSTRUCTED parameters of §6.3.4 — collateral $V = 80.00$, maintenance requirement $m = 35$ per cent, $L = V(1-d)(1-m)$. The marked points are the four tabulated rows; the vertical rule is the 26 per cent fall of the constructed scenario in §6.5.3. The 35 per cent maintenance requirement is a constructed model parameter and not a market quotation. Script `figs/src/CCP-069_fig05.py`.

```
survive 35.0%   L = 80.00 x 0.650000 x 0.65 = 33.800   LTV 42.3%
survive 50.0%   L = 80.00 x 0.500000 x 0.65 = 26.000   LTV 32.5%
survive 60.0%   L = 80.00 x 0.400000 x 0.65 = 20.800   LTV 26.0%
```

Surviving a 50% drawdown costs 14.000 of the 40.000 borrowing — a 35% reduction in the leverage layer, which is a real cost and should be stated as one rather than smoothed away.

The point of computing it in this direction is that the drawdown is the input a family can actually have an opinion about, and the loan-to-value is not.

6.3.5 Run the concentration instrument on blocs, and record the bloc call with its evidence

The full procedure is in the concentration paper and compressed in the reference apparatus. The failure-specific instruction is narrower and has three parts.

Collapse before you measure. A naive effective count computed over jurisdictions is not a resilience number and should never be printed next to one. The Gulf-additions and bridging-slot measurements show what happens when it is.

Record the bloc assignment, its evidence, and the event that would change it. Every jurisdiction section in this framework does this at scorecard item 2 and item 12. A bloc call without

a written trigger is an opinion that will quietly become a belief.

Price the marginal jurisdiction as a probability. The the AIFC pricing form: compute the gain if the call is right, the loss if it is wrong, and the break-even probability `L / (G + L)`. If the break-even probability is low the position is cheap insurance. If it is high, the position is a bet, and the family should know it is betting.

6.4 Failure modes of failure analysis itself

The failure modes of failure analysis itself. Twelve of them, because the discipline decays in predictable ways.

FM 6.1 Reading the statute instead of the docket

The Cook Islands statute says what it says. The Andersons went to prison anyway. **Every one of the four conventional failure tracks was decided somewhere other than the jurisdiction whose statute was being relied upon**, which means that reading the protective statute tells you almost nothing about the outcome and reading the enforcement docket tells you almost everything.

FM 6.2 Survivorship bias in the adviser's record

An adviser's structures that failed are, by construction, the ones no longer in the adviser's practice. This is the selection problem that governs any record of published successes [Ioannidis, 2005, Simmons et al., 2011, Gelman and Loken, 2013], and whose measured consequence is that a large replication programme recovers far less than the original record implies [Open Science Collaboration, 2015]. The relevant question to ask is not "has this structure worked for your clients" but "which of your structures have been tested by a determined adversary, and what happened." An adviser who has never had one tested has a record with no information in it.

FM 6.3 Treating the failure record as a reason not to build

The most common misreading of this section. Every failure above is a failure of a specific design choice, and none of them is a failure of the proposition that a structure is better than no structure. The Andersons' error was the duress clause and the timing, not the existence of a trust. The substance failures were failures of entities that did nothing, not of entities that did something. Reading this section as an argument for doing nothing is reading a crash report as an argument against aeroplanes.

FM 6.4 Building against the last failure

The mirror error. Substance regimes arrived in 2018 and 2019 and the whole industry rebuilt for substance, at exactly the point when the binding constraint was moving to bankability and to bloc concentration. The sixth failure mode of the threat register states the general form: a threat that has already crystallised is the cheapest one to defend against and usually the least valuable.

FM 6.5 Confusing the disclosure test with a guarantee

The disclosure test is a filter, not a shield. It removes structures that collapse on contact. It says nothing about a policy decision taken against a disclosed and correct position, which is what happened in 2022. Any reader who has taken the disclosure paper to mean that correctness

confers immunity has misread it, and this section's track 5(c) exists to make that misreading impossible.

FM 6.6 Averaging a split trajectory

The bridging-slot control established the convention and the reference apparatus carries it. Singapore's degradation trajectory splits three ways — institutional quality stable to improving, regulatory credibility improving, bloc independence eroding — and averaging them produces "stable," which is precisely wrong on the one axis the structure is buying. **Where item 10 is genuinely non-uniform, split it and refuse to average.**

FM 6.7 Measuring at the top and not at the rail

A structure can have `N = 2.941176` on holdings and something very close to 1.00 on the ability to transact, because every leg clears dollars through the same terminal system. the rail paper's correspondent measurement makes the point with numbers: measured by terminal clearing system rather than by bank, the as-found position is 100% USD, HHI 1.0000, one effective system. **A structure that reports two rails may have one messaging dependency and one clearing dependency, and the resilience number computed on holdings will not show it** [Curzi, 2026], whose clearing-perimeter measurement takes a naive correspondent HHI of 0.302400 — 3.306878 effective correspondents — to a perimeter HHI of 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency.

FM 6.8 Treating a rail as a store

The store–rail rule, and it belongs in a failure analysis because the failure is expensive. Freeze risk on a transit asset is an exposure-window problem with parameters — hop size, exposure duration, counterparty pre-screening, mid-transit failure handling. Freeze risk on a store is a custody problem. Evaluating the first with the tools of the second produces a structure that is over-engineered where it does not matter and unprotected where it does.

FM 6.9 The single-instance check

Verifying one leg of a structure and generalising. A bloc call verified for one jurisdiction says nothing about the others; a bank's willingness to onboard one entity says nothing about the group; a treaty position confirmed for one income stream says nothing about the rest. This framework's own the concentration paper failure mode 11 makes the point about bankability specifically, and the general form is worth stating: **a one-instance check is not a check.**

FM 6.10 The register nobody reviews

Every jurisdiction paper closes with a Verification Register, and every register is worthless after the first year unless someone re-runs it. The twelfth failure mode of the threat register says the same about the threat register. The remedy is administrative rather than intellectual: a date, a named person, and a diff against last year's version.

FM 6.11 Believing the numbers are the position

`N = 2.941176` is a summary of an allocation the family chose, computed under bloc assignments the framework made and labelled contestable. It is not a measurement of the world. The concentration paper's robustness table exists to show how much of the answer moves under reasonable disagreement, and the Singapore case shows that the argument most likely to be had

moves `h` by 0.002014 — which is to say, the argument does not matter and the concentration does.

FM 6.12 Not stating the residual

The failure mode that this framework would most easily have committed. The succession analysis computes a forced-heirship exposure reduced to zero on the designed map and a French inheritance-tax exposure roughly four times larger that the structure does not touch. A succession section reporting only the heirship result would have been lying by omission. **The residual is the part of the answer that the structure did not solve, and a section that does not state it has not finished.**

6.5 Results: four constructed stress scenarios

CONSTRUCTED. The principal, the family, the entities, and every figure below are constructed and labelled as such. No sanctions nexus. This is the carried case of the carried constructed case, put under stress.

The carried structure as built: a DIFC Foundation at the apex; an ADGM holding company beneath it; a United Kingdom limited company; a Bermuda captive; a GIFT City vehicle; a Thai Board of Investment operating company beneath the ADGM holdco; a REIT position converting London commercial real estate from immovable to movable; and single-asset special purpose vehicles for ring-fencing. The measured position: six jurisdictions, naive effective count 5.290949, effective blocs 2.941176, `h = \ensuremath{-}0.122417` at `eta = 0.35`, `C = 0.30`, `Q = 10`, `delta = 0.02`.

Four stress scenarios, run as pre-mortems.

6.5.1 Scenario A: a judgment creditor in a Western court, five years after building

The scenario, in the past tense. A commercial dispute arising from the United Kingdom operating business produced an English judgment against the principal personally in a sum exceeding the United Kingdom company's net assets. The creditor sought disclosure of the principal's worldwide assets and an order requiring the principal to procure a distribution from the Foundation.

The first domino. The principal was resident in the UAE but travelled to London regularly and had submitted to English jurisdiction in the underlying contract. Personal jurisdiction was never in doubt.

What the structure did. The Foundation is a legal person and the assets are its own; there is no beneficial interest for the creditor to attach. The creditor therefore attacked in the only way track one permits: an order against the principal to exercise a retained power. The Step 3 audit, run at build time, had identified three retained powers: the power to appoint and remove councillors, the power to amend the charter within stated limits, and a consent right over distributions. The first two were retained. **The third was removed at build time precisely because its compelled exercise would have given a creditor the result it wanted.** The council retained a genuine discretion over distributions and included two councillors with no relationship to the principal.

What the structure did not do. It did not prevent the disclosure order, the litigation cost, the two years of management distraction, or the reputational consequence in the group's banking relationships, which was the largest single cost of the episode. It did not prevent enforcement against the United Kingdom company's own assets, which were fully exposed and were always intended to be.

The residual, stated. Timing did the work, not jurisdiction. Had the structure been built after the dispute arose, the transfers into it would have been the target and the analysis would have been a fraudulent-transfer analysis under whichever regime applied, with a look-back

longer than the structure's life. **The Foundation was not the reason this scenario was survivable. Building seven years before the dispute was.**

6.5.2 Scenario B: the substance challenge to the intermediate holding layer

The scenario. A revenue authority in the jurisdiction of one operating subsidiary asserted that the ADGM holding company was resident in its territory on a central-management-and-control analysis, denied treaty benefits on dividends, and assessed withholding tax with penalties for three prior years.

The first domino. Board meetings of the ADGM holdco had, for two of the three years, been held wherever the principal happened to be, and the minutes recorded it accurately. The minutes were truthful and they were the evidence.

The measurement. The exposure is a cost rather than a loss of the structure, and it should be sized rather than dramatised. Denied treaty relief on a dividend stream, plus penalties and interest, against the cumulative maintenance cost of running the ADGM layer properly for the same period. In the constructed case the assessment exceeded eight years of correctly-run ADGM maintenance cost, which is the honest framing: **the substance was not expensive. Not having it was.**

What would have prevented it. The three-jobs rule and nothing more exotic. The ADGM holdco scores a job vector of (0.70, 0.05, 0.25), specialisation index 0.5550, 1.8018 effective jobs — inside the 2.20 threshold and therefore not flagged as overloaded. The vector was not the problem. The problem was that the entity's decisions were taken somewhere the vector did not describe, which the sixth failure mode of the three-jobs diagnostic names exactly and which no vector can detect, because a job vector measures what an entity does and residence tests measure where a human being was sitting.

The residual. Fixed prospectively, at cost, with three years of exposure that no structural change can retrieve.

6.5.3 Scenario C: the margin call that nobody sued over

The scenario. The listed carve-out from the Thai operating business, floated at 20% with the retained 80% pledged at 50% loan-to-value, fell 26% over four months on a sector de-rating with no company-specific news.

The first domino. 23.1%, computed above, and reached in month three.

What happened. The maintenance call arrived with a two-business-day cure period. The Foundation held the listed portfolio, but a substantial part of it was inside the GIFT City vehicle and the Bermuda captive's reserve pool, which is held against real third-party liabilities and is not available — that unavailability being the whole reason the captive-reserve analysis treats reinsurance reserves as a structurally hard-to-seize class. **The property that was hardest for an adversary to reach was also hardest for the family to reach, and that symmetry is not a defect in the design; it is the design, and it should be understood before the pledge rather than during the cure period.**

The outcome, constructed. Partial repayment of 8.4 units from liquid holdings, avoiding a forced sale, at the cost of the liquidity buffer the succession analysis in the succession analysis had already identified as short. Recall that analysis [Curzi, 2026]: liquidity rather than entitlement binds, and a constructed USD 60.00 million claim against USD 26.16 million of liquid assets leaves a shortfall of USD 33.84 million, 14.1 per cent of the estate and larger than any single liquid holding. **The margin call and the succession liquidity problem are the same problem arriving through two different doors, and the structure has one buffer for both.**

What would have prevented it. Step 4, run in the correct direction. At a 50% drawdown tolerance the borrowing falls from 40.000 to 26.000 and the whole scenario becomes a non-event. The 14.000 of foregone borrowing is the price of the non-event, and it is knowable in advance.

6.5.4 Scenario D: the diversification that was not

The scenario. Over three years, and with no single decision that looked wrong, the family added a Qatar Financial Centre family-office vehicle and a Saudi regional headquarters, funding both by trimming the UAE, United Kingdom, and Singapore allocations. Each addition was recommended on its own merits by competent advisers. Each was fully disclosed, fully compliant, and passed the disclosure test.

The first domino. No adviser was asked to compute the effect on the effective bloc count, because no adviser had been given the effective bloc count as a constraint.

The measurement, recomputed. Naive effective jurisdictions rose from 5.290949 to 7.132973, an increase of 34.81%. Effective blocs fell from 2.941176 to 2.841490, a decrease of 3.39%. h fell from -0.122417 to -0.134485. **The family paid three years of additional maintenance cost to become less resilient, and every report it received said the opposite.**

The warning sign that was available. One line of arithmetic, run at each addition, on the bloc shares rather than the jurisdiction shares. The concentration instrument would have flagged the first Gulf addition and refused the second.

The correction. The Gulf-additions paper's own worked outcome. Keep the Saudi regional headquarters at 5.0%, fund it from the operating allocation rather than the holding allocation, and the position becomes naive 5.688217 and blocs 2.816901 — a loss of 0.124275 in N and 0.015110 in h, taken deliberately for addressable revenue, with the number recorded in the file. Drop the Qatar vehicle, which duplicates the DIFC inside the same bloc and buys nothing.

The residual, and it is the section's closing point. Scenario D is the only one of the four in which nothing went wrong. No court, no revenue authority, no lender, no adversary at all. Every entity was correct, disclosed, and defensible. **The structure failed the only test that mattered for the threat it was built against, and it failed silently, and the instrument that would have caught it takes about a minute to run.**

---

7. Results

Every figure below is exact arithmetic on stipulated, constructed inputs, and none is a measurement of any real market, reserve, structure or economy.

R1 — disclosure is not immunity. Approximately USD 300 billion of fully disclosed central bank reserves were immobilised in 2022, so the disclosure test is a **filter** that removes structures collapsing on contact with an authority and is **not a shield** against a policy decision taken on a correct and fully disclosed position. **The event is described from the source manuscript and is not cited** (§1, Appendix A item 20). The symmetric half of the result is what makes it structural: concealment could not have prevented the outcome either, because a reserve must be held by a named holder in a named place to be a reserve, so the reachability is a property of the custody rather than of what was known about the owner. A fully disclosed, fully correct, single-perimeter structure has an effective bloc count of 1.00 and therefore $\ln(1.00) = 0$ of available surplus [Curzi, 2026].

R2 — the correlation collapse in a backing basket. On the constructed eight-component basket, naive HHI 0.150600 gives 6.640106 effective components; recognising the climate-correlated components as a single 82.0 per cent exposure gives bloc-HHI 0.693600 and 1.441753, a naive overstatement factor of 4.605578. **The basket is more diversified than a single-commodity anchor at 1.44 against 1.00 and far less diversified than its component count claims.** The correlated spoilage of the storable components runs at a constructed 13.67 per cent a year against a non-perishable metal's 0.00, which is the anti-hoarding property expressed as a physical carrying rate rather than a price.

R3 — the delivery squeeze. At 250 claims per physical unit on 40,000 deliverable units, $10{,}000{,}000$ claims are outstanding, $9{,}960{,}000$ exceed one-to-one collateral, and 99.600 per cent of

claims are uncollateralised at par. 0.40 **per cent of holders standing for delivery exhausts the stock exactly**, and coverage falls to 0.4000 at one per cent and 0.0800 at five. **A fully collateralised object-ledger makes the ratio a live on-ledger count rather than a reconciliation across two registries that nobody runs, and it does not prevent over-issuance**, because per-object hash chains supply no consensus, no total order and no double-spend prevention on their own [Curzi, 2026, Lamport et al., 1982, Fischer et al., 1985].

R4 — the gated integration priced as an option. Constructed $p_1 = 0.60$, $p_2 = 0.50$, $p_3 = 0.30$ give $P(\text{reach phase } 2) = 0.600$, $P(\text{reach phase } 3) = 0.300$ and $P(\text{terminal}) = 0.090$, a terminal-to-first-phase ratio of 0.15. **A programme that leads with its terminal phase stakes the certain value of the standalone reform on the least probable branch.**

R5 — the apparent-diversification trap. Adding two Gulf jurisdictions funded by trimming three existing allocations raises naive effective jurisdictions from 5.290949 to 7.132973, a rise of 34.81 per cent, while effective blocs fall from 2.941176 to 2.841490, a fall of 3.39 per cent, and h falls from -0.122417 to -0.134485 [Curzi, 2026]. **Three years of additional maintenance cost bought less resilience, and every conventional report said the opposite.**

R6 — the margin call with no plaintiff. A 26 per cent fall over four months breaches a 23.1 per cent trigger in month three, on a pledged position at 50 per cent loan-to-value with a 35 per cent maintenance requirement [Curzi, 2026]. Solving the same relation for the loan instead of the trigger, **buying survival to a 50 per cent drawdown costs 14.000 of the 40.000 borrowing — a 35 per cent reduction in the leverage layer.** No adversary, no court and no finding of wrongdoing is required; the lender exercises rights the holder granted.

R7 — the unpriced bloc call. A wrong perimeter call does not merely fail to help: it costs 0.005110 in h, because capital was taken out of a bloc where it was diversifying and put into one it concentrated. The break-even probability follows, $p^* = 0.005110/(0.026731 + 0.005110) = 0.160476$ [Curzi, 2026], and the binding constraint turns out to be the leg's maintenance cost rather than the geopolitics.

CR — the counter-result, which is the whole paper. The framework's governing principle did not confer immunity in the strongest available test case; its own backing basket is 4.61 times less diversified than its component count claims; the terminal phase of its own programme is a 0.090 option rather than a plan; and a levy presented as a costless accounting correction in fact reallocates burden, with **42.0 per cent of a constructed incidence falling on one sector and a constructed 55 per cent passing through to consumers**, across an effective 3.631082 sectors.

8. Discussion

8.1 What follows

A filter that is not a shield is still worth having, and saying so precisely is the whole of the repair. The 2022 event removes one reading of the disclosure principle and leaves another intact. What it removes is the reading in which correctness confers immunity. What it leaves is a structure that can be built in the open, examined by any authority without collapsing, and — decisively — **banked**, which the corpus identifies as the constraint binding everything else. A structure that cannot be banked has no rails, and a structure with no rails has no diversification to measure.

The event is an argument against concentration rather than against disclosure, and the two are easy to confuse. Its lesson is that the variable is *where the holding sits*, not *what is known about the holder*, and the corpus's answer is accordingly jurisdictional and rail diversity across perimeters. The measurement that makes the point is the corpus's own [Curzi, 2026]: holding marginal failure at 10 per cent, a common shock of $c = 0.02$ raises the probability that four nominally independent perimeters fail together from 0.000100 to 0.020044, a 200.4-fold understatement, and over fifteen years 0.001499 independent against 0.794109 correlated.

One instrument recurs on four different axes and the recurrence is the paper's structural finding. A count of nominally independent things collapses under a common shock: jurisdictions onto coordination perimeters; maturities onto a refinancing window [Curzi, 2026]; correspondents onto a clearing perimeter [Curzi, 2026]; and — here — basket components onto a climate exposure, and paper claims onto a deliverable stock. **The naive count is never the perimeter, and the same arithmetic detects the difference every time.**

8.2 What does not follow

No structure described here is recommended, and no instrument is claimed to exist. The three backing mechanisms are designs graded [T3]. The phased programme has no phase adopted anywhere. The licensing provisions are recorded with their exposure and no outcome is stated.

The failure record is not an argument against building. Every failure in §6 is a failure of a specific design choice — a duress clause, a timing decision, an entity that did nothing where it was registered, a pledge granted without computing the headroom, a jurisdiction added without computing its bloc effect. **Reading §6 as an argument for doing nothing is reading a crash report as an argument against aircraft**, and §6.4 lists that reading as a named failure mode.

Nothing here measures truthfulness or lawfulness. The concentration instrument measures the independence of a partition. It does not know whether a bloc assignment is right, whether an entity does what it says, or whether a counterparty is honest, and §3.2 states the two things it cannot see at all.

And the corpus's own conjecture is not established by any of it. The framework asserts that a structure's resilience is a computable function of its perimeter geometry. That is a modelling position, and the corpus's foundational papers already refuse the inflated reading of their own borrowed instruments: a life is not a metric space, nobody has measured the relevant contraction modulus, and a theorem transfers as shape rather than as guarantee [Curzi, 2026]; the honesty appendix assigns the corpus's central identification and its application of the surplus functional to the postulate drawer, and calls the third of them a wager whose misfire column exists because wagers can lose [Curzi, 2026]. **This paper is that misfire column, filled in.**

8.3 The correlation grouping is the load-bearing assumption, and it is stipulated

R2's headline number is a function of one modelling choice: that grains, freshwater, fruit, soil-health, biodiversity and dairy feed constitute a single climate exposure. **That grouping is stipulated, not estimated, and a different grouping gives a different number.** The general point is robust — correlations rise in the tail [Longin and Solnik, 2001, Ang and Chen, 2002], diversification is a claim about a covariance structure rather than a count [Markowitz, 1952, Elton and Gruber, 1977, Statman, 1987], and more components do not in general give more stability [May, 1972, McCann, 2000, Ives and Carpenter, 2007, Sagan, 1993] — but the *magnitude* is a property of the construction. **A real basket requires an estimated covariance structure and none was estimated here.**

The same caution applies with more force to the bloc assignments behind R5 and R7. They are the framework's own, they are contestable, and the corpus measures the index's sensitivity to assignment error separately: reassigning one member moves the effective bloc count by 0.0169, under 0.6 per cent [Curzi, 2026]. **The index is insensitive to assignment error and highly sensitive to bloc structure**, which means the argument a reader is most likely to have is not the one that matters.

8.4 The proposals, graded against themselves

The paper-to-physical mechanism is the strongest of the three and its object-ledger remedy is the most oversold. Visibility is not prevention, and the corpus's own integrity-layer paper published a working double-spend against its own substrate rather than hiding it [Curzi, 2026]. That publication is the reason the remedy can be graded at all.

The consumables basket is a differently-shaped reserve and not an immunity. The Act's stated goal of mathematical immunity to inflation and deflation is recorded and corrected wherever it appears; the channel-gain postulate is the corpus's general form of the correction [Curzi, 2026ab], and the corpus's own concordance discipline is the reason a design goal and an achieved property are kept in separate columns [Curzi, 2026w], whose worked rejection of a widely repeated frequency claim on three independently computed grounds is the model for what a refusal in print looks like.

The easement reserve is a store and the voucher is a rail, and the two-layer design is the honest way to make an illiquid reserve spendable. Its weakest number is the reserve valuation, which is contested and has a documented abuse history; the general governance frame is available [Hardin, 1968, Ostrom, 1990, 2010, Cox et al., 2010] and **the valuation literature is not in this paper's bibliography and is cited nowhere.**

And the nine-form backing taxonomy fails the scale-type gate outright. Its non-financial components are not instrumented on any common scale, let alone a ratio scale with a shared true zero, so the magnitude of any coverage ratio computed across them is withdrawn as a measured quantity — which is exactly the verdict the corpus reached on its own moment equation [Curzi, 2026t], and which the nine-capital paper reaches on its own borrowing-base ceiling by bounding the honest gain strictly between zero and 56.62 per cent rather than asserting it [Curzi, 2026].

8.5 Bounds carried from the corpus

The most restrictive bound on this whole exercise comes from the assembled-architecture paper and is accepted here without qualification. The only reading under which the corpus's own architecture clears its build threshold is the naive one assuming zero correlation between coordinating jurisdictions, giving $h = +0.083099$; **every defensible bloc assignment returns a negative surplus, and that paper says so in print** [Curzi, 2026]. This paper's constructed structures are in the same position, and R5's $h = -0.134485$ is a worse number than the one it replaced.

Three further bounds are carried rather than restated. A framework must be able to distinguish a theorem, an ordinary effect and its own conjecture in three separate sentences on demand [Curzi, 2026]; §9.6 discharges that requirement for every borrowing here. An audit that rejects nothing has not audited, and a many-to-one rule cannot be inverted to recover what produced it [Curzi, 2026] — which is the general form of §3.2's warning that an effective count does not determine the allocation it was computed from. And repetition buys arrival time and nothing else: it cannot move a destination [Curzi, 2026], which is why §5's gates are demonstrations rather than schedules, and why a phase asserted more loudly is not a phase reached.

The corpus's sharpest single instance of the discipline is the one this paper takes as its model. The cellular-protocol paper builds a complete, verified, deterministic pipeline and then states that nobody knows how a cell could read an ordered message out of a sound: eleven components established, one link missing, and the missing link named rather than softened [Curzi, 2026]. **That is the shape of this paper: the mechanisms are built and the governing principle is holed, and both are in print.**

8.6 What would falsify this paper

Five things, none tested here.

If a defensible estimated covariance structure over a real backing basket produced a bloc-collapsed effective count close to its naive count, R2's mechanism would survive and its magnitude would not.

If a survey of real commodity markets found paper-to-physical ratios close to one, the squeeze mechanism would remain arithmetically true and operationally empty. **That survey has not been done, here or, so far as this paper is aware, anywhere.**

If a dependent phased programme were exhibited in which a later phase's standalone value exceeded the first's, the gating argument would fail — although it is hard to see how, given that the first phase is unconditional by construction.

If a bloc assignment defensible on the framework's own perimeter test made the Gulf additions of R5 independent rather than concentrating, the apparent-diversification trap would be an artefact of the assignment rather than a finding. **The assignment is the contestable input and the paper says so twice.**

And if a fully disclosed, correct position had in fact been protected in 2022 by the completeness of its disclosure, H1 would stand. It was not.

9. Verification and rigour audit

Each result is decomposed into postulates that can be checked one at a time. Each is atomic, each carries a status, and each chain names what it consumes. **If dropping a postulate leaves the result standing, it is not listed.**

9.1 Dimensional audit

symbol	quantity	dimension	unit	status
shares	allocation weights	$[1]$	fractions summing to 1	stipulated
HHI	sum of squared shares	$[1]$	dimensionless	derived
$1/\mathrm{HHI}$	effective count	$[\#]$	components, jurisdictions, blocs	derived; a numbers-equivalent
h	surplus index	$[1]$	index units, **no currency**	derived from stipulated η, δ, Q, C
claims, units	counts	$[\#]$	claims; deliverable units	stipulated
R	paper-to-physical ratio	$[1]$	claims per unit	stipulated
coverage	units ÷ claims presented	$[1]$	dimensionless	derived
p_1, p_2, p_3	gate probabilities	$[1]$	dimensionless	stipulated
V, L	collateral, loan	$[1]$	**stipulated units, no currency**	stipulated
m, d, d^*	maintenance, drawdown	$[1]$	fractions	stipulated / derived
spoilage	perishability rate	$[T^{-1}]$	per year	stipulated
reserve, vouchers	natural-capital value	$[1]$	**abstract units, no currency**	stipulated

symbol	quantity	dimension	unit	status
USD 300 billion	immobilised reserves	[money]	US dollars	**described, not measured here**

Does it balance? Every headline figure except one is a ratio of two counts of the same kind, or a product of probabilities, and is therefore dimensionless and well formed: 6.640106 and 1.441753 are reciprocals of sums of squared shares; 0.090 is a product of three probabilities; 0.40 per cent is $1/250$; 23.076923 per cent is $1 - 0.50/0.65$. **The one dimensional quantity in the paper is the USD 300 billion aggregate, and it is not this paper's measurement.**

Three quantities carry no operational unit and the audit says so rather than assigning one. h is in index units with no currency attached and is meaningful only as a difference or a sign. The easement reserve and its vouchers are in abstract units of natural-capital value, and **no measurement basis for those units exists in the source corpus or here** (§8.4). The collateral and loan figures of §6.3.4 are stipulated units, so the 14.000 of forgone borrowing is a ratio statement — 35 per cent of the leverage layer — and not an amount.

9.2 Significant figures and epistemic status

- **6.640106, 1.441753, 4.605578, 5.290949, 7.132973, 2.941176, 2.841490 are exact to the digits shown**, being reciprocals of sums of squared exact stipulated shares. They carry no interval because nothing was estimated.
- **0.600, 0.300, 0.090 and the ratio 0.15 are exact products of stipulated probabilities**, and the probabilities are illustrative. Quoting them to three places is a statement about the arithmetic, not about any likelihood.
- **23.076923 per cent and 0.40 per cent are exact closed-form solutions** on stipulated parameters.
- **"approximately USD 300 billion" is stated as approximate because the source states it so**, and no result in this paper depends on the figure's precision. **A single significant figure would be the honest presentation of a number this paper did not measure**, and the aggregate is retained in the source's own form only because the narrowing it forces does not turn on its size.
- **13.67 per cent, 42.0 per cent, 55 per cent, 3.631082 and 0.275400 are exact on constructed inputs and are illustrations of a shape.** A real incidence analysis requires real sectoral and elasticity data and none was used.

9.3 Limits and boundary behaviour

The squeeze relation, at its boundaries. Coverage $= 1/(Rs)$ diverges as the stand-for-delivery fraction $s \to 0$ — which is the ordinary state of a hedging market and is why the ratio is invisible in normal function — and falls to $1/R$ at $s = 1$. At $R = 1$ the market is fully collateralised and no fraction can squeeze it. **The whole content of the mechanism is that the interesting region is a fraction of one per cent of holders**, and the relation is examined across four orders of magnitude of s.

The correlation collapse, at its boundaries. With every component independent the collapsed count equals the naive count and the overstatement factor is 1.000000; with every component in one bloc the collapsed count is exactly 1.000000 and the basket is a single-commodity anchor by another name. **The constructed basket sits at 1.441753, close to the degenerate end**, and the paper says so rather than reporting the naive figure alone.

The gating relation, at its boundaries. At $p_i = 1$ for all i the terminal probability is 1 and the phasing argument is empty; at any $p_i = 0$ the programme stops at that gate and the standalone phase's value is unaffected, which is the property the phasing exists to secure. **The argument needs only** $0 < p_i < 1$**.**

The margin relation, at its boundaries. $d^* = 1 - \mathrm{LTV}_0/(1-m)$ gives $d^* = 1$ at zero leverage — no drawdown triggers a call — and $d^* = 0$ when $\mathrm{LTV}_0 = 1 - m$, where the position is at its call level on the day it is opened. **The dangerous region is the ordinary one**, and at a 50 per cent loan-to-value against a 35 per cent maintenance requirement the trigger is a 23.1 per cent fall, which is unremarkable equity volatility.

9.4 Invariance

The effective count is invariant under relabelling of the components and under any permutation of the shares, because it is a function of the multiset of shares alone. That is what makes it a numbers-equivalent, and it is also exactly what §3.2 warns about: **a count that does not depend on which component holds which share cannot tell a reader which component to change.**

It is not invariant under regrouping, and the whole of R2, R5 and R7 lives in that fact. The transformation that moves the number is the partition, and the partition is a judgement. **The corpus measures the size of the judgement's effect: reassigning one member moves the effective bloc count by 0.0169, under 0.6 per cent** [Curzi, 2026], so the index is robust to being wrong about one member and not robust to being wrong about the bloc structure.

The squeeze threshold is invariant under the size of the market: doubling both the claims and the units leaves $1/R$ unchanged, which is why the finding is a statement about the ratio and not about any market's size.

9.5 Measurement-theoretic status

The tier scheme is ordinal, and no arithmetic is performed on it (§3.1) [Stevens, 1946]. **The bloc assignment is nominal**, and the effective count computed over it inherits the assignment's status entirely: it is a ratio-scale statistic over a nominal partition, which is legitimate and is exactly as defensible as the partition.

The nine-form backing taxonomy fails the scale-type gate, as §8.4 states: no measurement basis, no common ratio scale, no shared true zero, and therefore no defensible coverage ratio [Curzi, 2026t]. The formal remedies — conjoint measurement or a Rasch demonstration [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960] — were **not run**, and Michell's objection that quantitative structure is assumed rather than tested stands unanswered [Michell, 1997, 1999].

The gate probabilities are subjective and are labelled so. They are not frequencies, not estimates and not elicited from anyone; they are stipulated numbers chosen to make an arithmetic point, and the point survives their replacement by any other set strictly inside $(0, 1)$.

9.6 Analogy discipline: every borrowing, graded

The corpus requires that a reader be able to distinguish a theorem, an ordinary effect and the framework's own conjecture in three separate sentences on demand [Curzi, 2026]. **This section discharges that requirement for every borrowing in this paper.** Three categories are used: **(1) a derivation**, where the system genuinely satisfies the cited result's premises; **(2) a shared mathematical form**, where the same equation governs both with no transfer of authority; and **(3) an analogy**, legitimate as motivation and never as evidence.

borrowing	used for	category
Concentration indices and their numbers-equivalent [Hirschman, 1964, Herfindahl, 1950, Adelman, 1969]	every effective count in the paper	**1 — derivation.** The shares are a partition and the index is defined on it
Hill numbers [Hill, 1973, Jost, 2006]	naming $1/\mathrm{HHI}$ as the order-two member	**1 — derivation**
Portfolio covariance [Markowitz, 1952, Elton and Gruber, 1977]	why a count is not a diversification	**2 — shared form.** No portfolio was constructed and no return appears

borrowing	used for	category
Tail correlation [Longin and Solnik, 2001, Ang and Chen, 2002]	why the collapse happens when it matters	**3 — analogy.** Measured in equity markets, asserted here of a basket
Ecological stability–diversity results [May, 1972, Tilman et al., 1998, Doak et al., 1998, McCann, 2000, Ives and Carpenter, 2007, Schindler et al., 2010]	that more components need not mean more stability	**3 — analogy**
Coupled-network fragility [Buldyrev et al., 2010, Albert et al., 2000, Cohen et al., 2000]	how a defect travels through composed identifiers and blocs	**3 — analogy**, invoked for shape
Byzantine agreement and its impossibility [Lamport et al., 1982, Fischer et al., 1985, Gilbert and Lynch, 2002, Douceur, 2002]	why an object-ledger prevents nothing on its own	**1 — derivation.** The substrate is literally a set of mutually distrustful parties needing agreement
Open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]	the disclosure test	**1 — derivation** as a design principle
Transparency as remedy [Brandeis, 1914]	the same test in its policy register	**3 — analogy**
Tight coupling and system accidents [Perrow, 1984, Sagan, 1993, Leveson, 2011, Vaughan, 1996]	why the pre-mortem is mandatory and why redundancy is not automatically a remedy	**3 — analogy**
Commons governance [Hardin, 1968, Ostrom, 1990, 2010, Cox et al., 2010]	the framing of a stewarded natural-capital reserve	**3 — analogy**
Fibonacci and the golden section [Euclid, 1956, Vajda, 1989, Koshy, 2001, Binet, 1843]	that consecutive ratios approach φ	**1 — derivation**, and **the monetary significance of that fact is graded at zero** [Markowsky, 1992, Fischler, 1981, Livio, 2002]
The grammar of conserved quantities [Mirowski, 1989, Cartwright, 1999]	flagged against the framework itself, not borrowed	**not a borrowing — a warning**

The three sentences, stated as the corpus requires them. *The theorem:* no protocol among mutually distrustful parties achieves agreement without an ordering layer, so a per-object ledger does not prevent a double-spend — a derivation, whose instance the corpus reproduced against its own substrate. *The ordinary effect:* a lender exercises contractual rights the holder granted when collateral falls below a maintenance level, which requires no adversary and no theory. *The conjecture:* that a structure's resilience against arbitrary action is a computable function of its perimeter geometry is **this framework's own proposal**, is not derived from anything cited, and is not established by any result in this paper.

9.7 The postulates

	postulate	status
P1	The stipulated share vectors, ratios, probabilities and contract parameters are as printed.	DEFINITION (constructed)
P2	A bloc is a set of jurisdictions that coordinate, so their shares add before squaring.	POSTULATED — the framework's own perimeter test; contestable
P3	The climate-correlated components of the basket constitute one exposure.	MODELLING CHOICE — stipulated, not estimated

	postulate	status
P4	$1/\text{HHI}$ is the right reading of an effective count.	CITED [Hirschman, 1964, Hill, 1973, Adelman, 1969]
P5	Approximately USD 300 billion of disclosed reserves were immobilised in 2022.	**DESCRIBED — uncited; no source in this bibliography**
P6	Per-object hash chains supply no consensus and no double-spend prevention.	CITED [Curzi, 2026, Lamport et al., 1982]
P7	Each phase gates the next and the gates are independent.	MODELLING CHOICE
P8	The named statutes, cases and administrative authorities are as the source describes them.	**DESCRIBED — uncited; Appendix A**

Dropped as unnecessary. No postulate about which commodity, which basket components, which jurisdictions or which currency is needed for any result: R2, R3, R4, R5 and R6 are properties of partitions, ratios, probability products and a linear equation, and each survives the substitution of any other labels.

9.8 The chains

step	consumes	produces	status
A1	P1	naive HHI $= \sum w_i^2 =$ 0.150600	ARITHMETIC
A2	A1, P4	naive effective components $=$ 6.640106	ARITHMETIC
A3	P1, P3	bloc shares $82.0/14.0/4.0$; bloc HHI $= 0.693600$	ARITHMETIC

E2	E1	$L = V(1-d)(1-m)$: $40.000 \to 26.000$ at $d = 50\%$	ARITHMETIC
F1	P2	right call $+0.026731$; wrong call -0.005110	ARITHMETIC
F2	F1	$p^* = 0.005110/0.031841$ $= 0.160476$ — **R7**	ARITHMETIC
G1	**P5**	a fully disclosed position was immobilised — **R1**	**DESCRIBED, UNCITED**
G2	G1	the disclosure principle is a filter and not a shield	DEDUCTION from a single instance

9.9 What these chains are and are not

Read the status column. Every chain except G is arithmetic on stipulated inputs, and therefore establishes a property of the construction and nothing about the world. **Chain G is the only one that touches an event, it rests on a single described instance, and its source is not in this paper's bibliography.**

A single counterexample is the right instrument for the claim being tested and the wrong instrument for anything else. H1 was a universal — a disclosed and correct position is durable — and one instance refutes a universal. It does not establish a rate, a probability, or a prediction about any other position, and no such inference is drawn. **G2 is a deduction from a refuted universal, not an induction from a sample of one.**

And the load-bearing input to R2, R5 and R7 is a partition chosen by this framework. P2 and P3 are the postulates a reviewer should attack first, and §9.4 gives the sensitivity: the index is robust to being wrong about one member and not robust to being wrong about the structure.

10. Limitations

Every worked result is a constructed model and none is a measurement. The commodity, the basket, the reserve, the vouchers, the incidence, the probabilities, the allocations, the pledge and the four stress scenarios are invented, with parameters chosen to demonstrate a mechanism rather than to describe anything. **No external dataset was collected. No real market,**

commodity, reserve, land parcel, economy, institution, court file, family or principal appears anywhere in this paper.

The 2022 immobilisation is described and not cited, and that is the largest single gap. The figure, the date, the instruments by jurisdiction, the amounts by jurisdiction, and the current legal position on the principal and on the income arising from it are **taken from the source manuscript and attached to no source**, because this paper's bibliographic database contains no contemporaneous reporting and no sanctions instruments. **No approximate citation was substituted.** Appendix A item 20 states what must be verified. A reader relying on the aggregate must verify it independently; a reader relying on the *narrowing* it forces need not, because the narrowing follows from one instance of the class and the class is not in doubt.

No jurisdiction-specific legal source is cited anywhere. The decided cases of §6.2.1 and §6.2.3, the economic-substance legislation of §6.2.2, the tax-code conservation provisions of §4.2.4, the administrative designation of syndicated easements, the nominee provisions of the foreign-business statute, the share-pledge disclosure requirement, and the procurement, appropriations, conflict-of-interest and constitutional frameworks of §5.2.5 are **all described from the source manuscript and left uncited**, and each is itemised in Appendix A with what requires verification. The general doctrinal frame is cited where it is relied on [Hague Conference on Private International Law, 1985, United Nations, 1958, Torremans et al., 2022, Briggs, 2013, Hansmann and Kraakman, 2000, Pistor, 2019]. **This is a real gap and it is not closed here.**

The commodity multiples are a range and are asserted nowhere. The circulating figures depend entirely on the choice of numerator and denominator, and the paper claims the shape rather than any magnitude. **The survey that would establish whether real paper-to-physical ratios are large enough for the squeeze mechanism to matter has not been done.**

The correlation grouping and the bloc assignments are stipulated judgements, and they are what the headline numbers are made of (§8.3, §9.9). A real basket requires an estimated covariance structure; a real perimeter test requires evidence per jurisdiction with a written trigger for revision.

The gate probabilities are estimates of nothing. They are illustrative numbers chosen to make an arithmetic point about dependence, and quoting the terminal 0.090 as a likelihood would be a misreading the paper cannot prevent except by saying so.

The easement reserve's valuation is the weakest number in the paper and it is not computed. Easement valuation is contested and has a documented abuse history; the ecosystem-services and natural-capital valuation literature is **not in this bibliography and is cited nowhere**; and no valuation figure is stated anywhere in this paper.

The incidence model is a shape and not a measurement. The sectoral shares, the 55 per cent consumer pass-through and the resulting 3.631082 effective sectors are constructed. A real incidence analysis requires real sectoral data and real elasticities, and **a levy's incidence is not determined by who remits it**.

The concentration instrument does not see a pledge and does not see capacity (§3.2). Both blind spots are load-bearing in this paper: §6.2.4's failure track is invisible to the instrument entirely, and an effective bloc count of 2.94 says nothing about whether any of the three perimeters could carry the structure.

No statistical claim is made and none is supported. There are no p-values, effect sizes, intervals, samples or fitted models in this paper. No model comparison, out-of-sample test, matched null or information criterion is reported, because nothing was fitted, and no distributional or scaling claim is made, so Clauset et al. [2009] is not applicable and was not run.

The author has a direct financial interest in one of the provisions recorded in §5.2.4. That is declared in §3.4 and in the Declarations. It cannot be cured by disclosure, and no reader should treat the neutral register in which the provisions are recorded as neutrality about the interest.

And this paper's own principle is holed rather than repaired. H1 is falsified. What replaces it — a filter that is not a shield — is a weaker claim, is not itself tested, and is offered as a modelling position rather than as an established result.

11. Conclusion

Disclosure is not immunity. Approximately USD 300 billion of central bank reserves, among the most thoroughly disclosed assets in existence, were immobilised in 2022 by the jurisdictions in which they were held. Their location, their custodians and their character were known, and were the reason they were held where they were held. **Correctness and disclosure were complete, and they were immobilised anyway.** The result is symmetric: concealment could not have prevented it either, because a holder must be named and a holding must sit somewhere in order to be held at all. **What disclosure does is remove the failure mode in which a structure collapses on contact with an authority, convert an enforcement problem into a policy problem, and make a structure bankable. What it does not do is prevent a policy decision taken against a correct and fully disclosed position, supply an appeal, or protect an asset sitting inside the perimeter that took the decision.** The event is an argument against concentration, not against disclosure — and a fully disclosed, fully correct, single-perimeter structure has an effective bloc count of 1.00, so $\ln(1.00) = 0$ and it has no available surplus at all.

The proposals were measured against themselves and each was found smaller than its advocates claim. A constructed eight-component backing basket reads **6.640106 effective components naively and 1.441753** once the climate-correlated components are recognised as a single 82.0 per cent exposure — **a naive overstatement of 4.605578 times**, with the basket still genuinely more diversified than a single-commodity anchor at 1.44 against 1.00. A constructed **250-to-1 paper-to-physical ratio leaves 99.600 per cent of claims uncollateralised at par and is exhausted by 0.40 per cent of holders standing for delivery**, and a fully collateralised object-ledger is credited only with making that ratio a live, reportable count — **it does not prevent over-issuance**, because per-object hash chains supply no consensus and no double-spend prevention on their own. Phased integration is scored as an option rather than a plan: constructed gate probabilities of 0.60, 0.50 and 0.30 give a **terminal probability of 0.090 against a first-phase 0.600, a ratio of 0.15**, so a programme that leads with its most ambitious phase stakes the certain value on the least probable branch.

Two failures need no adversary at all. A 26 per cent fall over four months breaches a **23.1 per cent** maintenance trigger in month three, and **buying survival to a 50 per cent drawdown costs 14.000 of the 40.000 borrowing, a 35 per cent reduction in leverage** — a loss of control that requires no court, no judgment and no finding of wrongdoing, only the contract the holder signed. And adding two jurisdictions inside a bloc a structure is already heaviest in raises the **naive effective count from 5.290949 to 7.132973, a rise of 34.81 per cent, while effective blocs fall from 2.941176 to 2.841490, a fall of 3.39 per cent**, and h falls to -0.134485. **Three years of additional maintenance cost bought less resilience, nothing went wrong, no adversary appeared, and every conventional report said the opposite.**

And a levy presented as a costless accounting correction reallocates burden. A constructed incidence puts **42.0 per cent on one sector**, spreads across an effective **3.631082** sectors, and passes a constructed **55 per cent through to consumers**. Recognising a previously unpriced cost does not make it disappear; it moves it, and the movement has a shape that must be modelled rather than framed away.

What is not claimed. No instrument described here exists, is issued, is authorised, or is claimed to be lawfully issuable anywhere. No price, yield or return appears. No commodity multiple, statute, regulation, notice or decided case is asserted as fact. No phase beyond the first is asserted to have been adopted anywhere. **The licensing provisions of §5.2.4 name the author's own company, that interest is declared rather than managed, and the provisions appear with their exposure attached and no outcome stated.**

The paper's own status, plainly. Its governing hypothesis was tested against the strongest available case and failed. Its remaining results are exact arithmetic on constructed inputs, and the load-bearing inputs are partitions this framework chose and a reader may reasonably contest. **A corpus whose strongest results are constraints on itself is a corpus that was checked; this paper is where the checking is printed.**

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every result in this paper is exact arithmetic on stipulated, **CONSTRUCTED** inputs, labelled as constructed at each point of use: an eight-component backing basket with printed weights; a commodity with 40,000 deliverable units and a stipulated ratio of 250; a reserve of 100 abstract units with 60 per cent voucher coverage; a drawdown base of 100 with printed sectoral shares; three gate probabilities; two jurisdiction allocations with printed bloc assignments; and a pledged position at a stipulated loan-to-value and maintenance requirement. **No real market, commodity, reserve, land parcel, economy, institution, court file, family or principal appears anywhere in this paper, and no allegation is made about any of them.**

All figures were produced by the scripts named in their captions (`figs/src/CCP-069_fig01.py` through `figs/src/CCP-069_fig05.py`), which import the shared figure style module and read their values from the tables in this paper. **No figure plots a number that does not appear in the text.**

The 2022 immobilisation, the commodity multiples, the decided cases, the statutes, the tax-code provisions, the administrative designations and the procurement, appropriations and constitutional frameworks are described from the source manuscript and are cited nowhere, because this paper's bibliographic database contains none of them. Appendix A itemises each with what specifically requires verification, and no approximate citation has been substituted for any of them.

Funding

This research received no external funding.

Conflicts of interest

The author declares a direct and material conflict of interest. The licensing provisions recorded in §5.2.4 are provisions of the source material that name **36N9 Genetics — the author's own company and the affiliation on this paper** — as the sole-source procurement counterparty for the production of the proposed currency, alongside a perpetual royalty payable in that currency and a sovereign licence granted by a private entity. **The author would be a beneficiary of the arrangement the paper records.**

The method adopted in response is stated in §3.4 and applied in §§5.2.4 and 5.2.5: the provisions are recorded exactly as the source specifies them; the federal procurement, appropriations, conflict-of-interest and constitutional review they invite is named in the same neutral register the framework applies to every other legal exposure; **no outcome is asserted; and no provision is recommended.** A reader who discounts §5 accordingly is reading correctly. **Disclosure does not cure this conflict, and this paper's own governing result is that disclosure does not cure things.**

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data were processed. Every principal, family, entity, court file and payment described is constructed.

No operational content, and no allegation

This paper contains no operational content. It describes failure modes of structures at the level of principle and mechanism; it supplies no method for evading any legal process, any sanctions regime, any tax obligation or any disclosure requirement, and nothing in it is a routing instruction or a plan. **No allegation is made about any person, institution, jurisdiction or state**, and the 2022 immobilisation is recorded as an event whose occurrence is not in dispute, with no characterisation of its lawfulness, its merits or its motives offered anywhere.

Legal, tax, accounting, investment, procurement and constitutional advice

This paper is analytical and is not legal, tax, accounting, investment, procurement, appropriations or constitutional advice. The three backing mechanisms are proposals with **no adopted standard status and no legal force**. No instrument described is claimed to exist, to be issued, to be authorised, or to be lawfully issuable in any jurisdiction. **No price, yield or return figure appears anywhere in this paper**, and no recommendation is made in respect of any person, institution, product, instrument or jurisdiction. Anyone contemplating any structure, treatment or provision resembling those described must confirm every element with qualified counsel in each relevant discipline and each relevant jurisdiction, working from the primary sources itemised in Appendix A and not from this paper.

Appendix A. Claims requiring verification against primary sources

Everything below is described in this paper from the source manuscript and is cited nowhere, because this paper's bibliographic database contains no standards documents, no case law, no statutes, no administrative authorities, no press reporting and no jurisdiction-specific material. Each item requires verification against the governing source before any reliance. **No numerical result in this paper depends on any of them except item 20, whose role is stated there.**

Commodity markets and the paper-to-physical ratio.

1. The silver open-interest-to-registered-stock ratio, circulating in a range from roughly one hundred to several hundred times, is **contested and asserted nowhere**. Confirm the numerator (all open interest against front month), the denominator (registered only against registered plus eligible), the venue and the date before quoting any figure. The multiple is definition-dependent and no single value is a fact.
2. The registered-versus-eligible gold classification on a delivery exchange, and any ratio of open contracts to registered stock. Confirm the current definitions, the reporting source and the date. This paper states the mechanism — eligible stock is not pledged to contracts — and no figure.
3. The ratio of crude open interest to deliverable stock and storage capacity at a single pricing point. Confirm the contract's physical-delivery specification and the deliverable and storage figures. No figure is asserted.
4. The 2020 negative-price event in a physically settled crude contract. Confirm the contract, the date, the settlement mechanism and the storage-constraint mechanism by which the paper claim and the physical reality decoupled. This paper uses it as an instance of decoupling and states no price.
5. Periodic delivery squeezes in silver. Confirm the dates and the specific episodes; this paper refers to the class of event, not to any one of them.
6. The general claim that paper claims routinely exceed deliverable physical stock by roughly one to three orders of magnitude is stated as a **range** and as a general feature of hedging markets. Confirm it against commodity-market microstructure sources; it is not a measurement.

The backing mechanisms.

7. The composition of the proposed consumables index — the specific assets, the weighting method, and whether soil-health and biodiversity metrics are included and how — against the source Act. **The eight-component basket and its weights here are CONSTRUCTED and reconcile to no published index.**
8. The Act's stated design goal of mathematical immunity to inflation and deflation. Confirm the exact wording before quoting it, and **never reproduce the goal without the correction that accompanies it in §4.2.3.**
9. The qualified conservation contribution regime of the United States Internal Revenue Code, including the qualified-organisation, conservation-purpose and perpetuity requirements. This paper states that conservation easements are real, valued, tradeable instruments with a statutory basis and **asserts no valuation and no section number.**
10. The administrative authority designating syndicated conservation easements as a listed transaction, its status, subsequent statutory changes, and the litigation over both the transactions and the designation. **The notice number is not asserted here.** The structural point — that easement valuation is contested and has an abuse history — does not depend on it.
11. The ecosystem-services and natural-capital valuation literature, referred to generally. **No work in it is cited and this paper endorses no methodology and states no valuation figure.**
12. The floating voucher and the twelve per cent commons-replenishment allocation, as the Act frames them: the exact mechanism, the voucher's legal characterisation, the base on which the allocation is assessed, and its stated use. The **CONSTRUCTED** incidence illustration is a measurement of no real economy.

The phased programme and its licensing provisions.

13. The Fibonacci denomination sequence and the Act's rationale for it. The mathematics — consecutive ratios approaching φ, and every positive integer expressible as a sum of non-consecutive terms — is cited; **the Act's wording is not, and must be confirmed.**
14. The fractal reserve-banking structure, recorded as the Act's design goal and graded [T3]. Self-similarity of a rule is not a guarantee of stability under stress and **no stability claim is made on the geometry alone.**
15. **The licensing provisions**: a sovereign licence granted by a private entity, a perpetual royalty payable in the proposed currency, sole-source procurement from the author's own company, and a note bearing the architect's likeness. **Confirm the Act's exact wording of each before reproducing it, and reproduce no provision without its exposure attached.**
16. Federal procurement competition: the statutory competition framework, the acquisition regulation's competition requirements, and the law governing statutory sole-source directions. **This paper names the framework and states no outcome.**
17. Appropriations and continuing obligations: the constitutional appropriations provision, the law on creating and funding continuing financial obligations, whether such an obligation can bind future appropriations, and the antideficiency rules. **Category named; no outcome stated.**
18. Conflict-of-interest statutes and the appearance-of-impropriety standard governing public office, as they bear on sole-source procurement from a connected party and on a likeness appearing on a currency instrument. **Standard named; no outcome stated.**
19. Constitutional provisions bearing on currency, on emoluments, and on the delegation of a sovereign monetary function to a private licensor. **Categories named; none resolved.**

The failure record.

20. **The 2022 immobilisation of approximately USD 300 billion of Russian central bank reserves: the instruments by jurisdiction, the dates, the amounts by jurisdiction, and the current legal position on both the principal and the income arising from it.** This paper

states the aggregate as approximate, treats no figure as established, and **attaches no citation to any part of it**, because the bibliography contains no contemporaneous reporting and no sanctions instruments. **This is the one described item on which a stated result depends** (R1), and the dependence is only on the fact that a fully disclosed, correct, lawfully held position was immobilised — not on the amount, the date or the instrument.

21. The decided cases on personal compulsion and the impossibility defence, on freezing relief and its worldwide reach, on the limits of pre-judgment injunctive power, and on sham and nominee findings. **Every reporter citation named in §§6.2.1 and 6.2.3 must be checked against the official reports**, including the situs and administration history of the trust in the leading contempt case, which is routinely miscited. The illusory-trust line is **named nowhere** and no reliance should be placed in either direction.
22. The self-settled-trust look-back provision of the United States bankruptcy code and its ten-year period; the transactions-defrauding-creditors provision of English insolvency law and its limitation analysis; and the uniform voidable transactions legislation, whose enactment and reach-back periods vary by state. **Contested ground throughout.**
23. The offshore trusts statute whose limitation periods, standard of proof and non-recognition provision are described. **This paper deliberately names no section numbers.**
24. Economic-substance legislation in each affected jurisdiction and its current revisions: short titles, commencement, relevant-activity lists and adequacy tests. Corporate-residence and place-of-effective-management tests in every jurisdiction from which decisions might be taken, and the tie-breaker in each applicable treaty. The principal-purpose test as introduced by the multilateral instrument, and certificate-of-residence practice.
25. The foreign-business nominee provision described: section number, current wording, penalties, enforcement practice, and the routes, exposure and disclosure obligations for regularising a historical nominee position. **Carried from the Thailand analysis and repeated here because it is the most consequential item in this appendix after item 20.**
26. Share-pledge disclosure for directors and officers; margin-lending documentation in the relevant market, including maintenance-requirement definitions, cure periods, revaluation discretion and rehypothecation rights; and change-of-control definitions across a group's agreements. **The 35 per cent maintenance requirement used here is a constructed model parameter, not a market quotation.**
27. All bloc assignments used in §§6.2.6 and 6.2.7 are this framework's own, applying its perimeter test to published evidence. **They are contestable**, the sensitivity is measured separately [Curzi, 2026], and each jurisdiction paper restates its assignment with evidence.
28. All parameter values in the surplus computations ($\eta = 0.35$, $C = 0.30$, $Q = 10$, $\delta = 0.02$) are the corpus's stated test parameters. They are illustrative and are estimates of nothing.

All numerical results in this paper were computed from the stated constructed inputs at full precision and rounded only for printing.

Chapter 70

The Method in Seven Steps: A Consolidated Reproduction Workbook and Honesty Register for the Concentration and Headroom Instrument

Abstract. This closing synthesis states the method as a seven-step procedure and supplies the appendices needed to reproduce every computation in the volume. The procedure's binding instruction is to collapse jurisdictions onto coordination perimeters before measuring, because the organising result is that ln(1.00) = 0: a structure with one effective bloc has zero available surplus, not a low one. Reproduced end to end, the conventional structure has a naive HHI of 0.293430 and 3.407968 effective jurisdictions but a bloc HHI of 1.000000, giving N = 1.000000 and h = -0.500000, while the designed structure has naive HHI 0.189002 and 5.290949 effective jurisdictions against bloc HHI 0.340000, N = 2.941176 and h = -0.122417, with Western-perimeter exposure falling from 100.0 to 30.0 per cent. Break-even is N* = exp(0.5/0.35) = 4.172734, and since dh/dN = eta/N the first move buys 0.377583 while the next buys 0.107620, 28.5 per cent as much. The rail axis is measured separately at 1.000000 effective clearing system as found and 2.810568 as designed, with four effective systems requiring the dollar share to fall from 55 to about 38.99 per cent. Two computations are presented here in full: the foundation-versus-trust cost crossover, and a succession residual capping a USD 6.70m exposure while leaving approximately USD 27.00m untouched.

Keywords: bloc collapse; effective count; surplus headroom; break-even bloc count; diminishing returns; reproduction workbook; honesty register; succession residual

Series: D. Structure and Resilience **Paper:** CCP-070

1. Introduction

This paper is reference apparatus, and saying so plainly is the first thing it owes a reader. It consolidates the method Series D develops into a single executable procedure, reproduces every computation the series rests on from its stated inputs, and collects the atlases, indices and

registers a reader needs in order to check the series against itself. **It is not offered as a research contribution, it advances no new result about the world, and almost all of it recapitulates.**

Two things in it are not recapitulation, and they are named here so that a reader can find them without reading the rest. **The foundation-versus-trust cost crossover is computed in full for the first time** (Appendix B.13): against a constructed fixed mandate of USD 120,000 a year, a foundation is cheaper than a trustee charging on a basis-point scale only above USD 34.2857 million at 35 basis points, USD 80.0000 million at 15, and USD 120.0000 million at 10 — from which it follows that **cost is explicitly not the reason to choose the form.** And **the succession residual is stated as an asymmetry rather than as a win**: a notional reserved share of USD 60.00 million capped to a USD 6.70 million compensatory levy and eliminated on the designed map, against an inheritance-tax exposure of approximately USD 27.00 million that the structure does not touch — 4.0299 times larger — with a liquidity shortfall of USD 33.84 million, 14.1 per cent of the estate.

What the consolidation is for. A method that cannot be run is a description of a method. The procedure below reduces the series to seven steps that can be executed in an afternoon with a spreadsheet and a list of entities, and its binding instruction is the first one: **collapse jurisdictions onto coordination perimeters before measuring anything.** The reason is the organising result of the whole series and it is one line of arithmetic. $\ln(1.00) = 0$. **A structure with one effective coordination perimeter has no surplus term at all — not a small one, none — and no rearrangement of entities inside that perimeter changes it**, because rearranging within a perimeter does not change N [Curzi, 2026].

The reproduction, end to end. The conventional structure reads a naive Herfindahl index of 0.293430 and 3.407968 effective jurisdictions, and a bloc Herfindahl index of 1.000000, giving $N = 1.000000$ and $h = -0.500000$. The designed structure reads naive 0.189002 and 5.290949 effective jurisdictions against bloc 0.340000, giving $N = 2.941176$ and $h = -0.122417$, with Western-perimeter exposure falling from 100.0 to 30.0 per cent. Break-even is $N^{*} = \exp(0.5/0.35) = 4.172734$, and because $\mathrm{d}h/\mathrm{d}N = \eta/N$ the first move buys 0.377583 while the next buys 0.107620 — **28.5 per cent as much.** The rail axis is measured separately and reads 1.000000 effective clearing system as found against 2.810568 as designed [Curzi, 2026].

And the honest reading of those numbers is the paper's fourth contribution, which is a register of admissions rather than a result. Both structures are below the build threshold. Disclosure did not prevent the 2022 immobilisation. Cost is not the reason to choose a foundation. The succession structure addresses the smaller of the two exposures. **Section 5 states all four without qualification, and a reader who takes nothing else from this paper should take those.**

1.1 What this paper contains

1. **The method in seven steps** (§4), with each step expanded, its failure modes named, and the whole procedure run once end to end on the carried constructed case.
2. **The register of what is unresolved** (§5), including the four admissions and the eight open items behind them.
3. **A scorecard atlas** (Appendix A): thirty-three jurisdiction assessments on twelve items, keyed to the corpus paper that carries each.
4. **A reproduction workbook** (Appendix B): every concentration, headroom, break-even and job-vector computation in the series, with its inputs printed, its arithmetic shown, and its precision rule stated.
5. **Structure diagrams** (Appendix C) of the constructed case as built, as found, collapsed to perimeters, and viewed on the rail axis.
6. **A statute and case index** (Appendix D) in which the **default status is FLAGGED FOR VERIFICATION** and only a short list of arithmetic and definitional facts is marked verified.
7. **An honesty register** (Appendix E) carrying the ten reconciliation entries by which the series corrected itself, and the four admissions.
8. **A correspondence appendix** (Appendix F) mapping the storage law term by term onto

the earlier series, and naming four things that do **not** transfer.

2. Hypothesis

This paper advances no testable hypothesis. It is reference apparatus: a consolidated procedure, a reproduction workbook, and a set of registers, assembled so that the results of Series D can be checked rather than believed.

The organising question is therefore procedural rather than empirical: *what is the smallest set of steps, inputs and printed intermediate values from which a reader can reproduce every number in the series and locate every claim the series declined to verify?*

Three things in the paper could nevertheless be wrong, and each is checkable, so they are named here rather than left implicit. The reproduction arithmetic could contain an error, and every input is printed so that it can be recomputed. The atlas cells are compressions of assessments argued elsewhere, and a cell that misrepresents its assessment is an error in the compression. And the index's status assignments could be wrong in the direction that matters — an item marked verified that is not — which is why **the default is FLAGGED and the verified list is deliberately short** (§3.3).

What is not claimed. No result in this paper is new to the corpus except the two computations named in §1. Nothing here establishes any empirical claim about any jurisdiction, market, institution or family. **The four admissions of §5 are the paper's most useful content and every one of them is negative.**

3. Method

3.1 What is reproduced, what is new, and what is only compressed

kind	where	status
the seven-step procedure	§4	a consolidation of results argued elsewhere in the series
the end-to-end reproduction	§4.5, Appendix B	recomputed here from printed inputs
the foundation-versus-trust crossover	Appendix B.13	**computed in full for the first time**
the succession residual	§5.3, Appendix B.13	**stated as an asymmetry for the first time**
the scorecard atlas	Appendix A	compressions; each cell points to the paper that argues it
the statute and case index	Appendix D	a consolidated list, **FLAGGED by default**
the honesty register	Appendix E	the series' own corrections, reproduced
the correspondence	Appendix F	a mapping, not a derivation

Every numerical result in this paper is exact arithmetic on stipulated, constructed inputs. No real family, entity, transaction, market or institution is described anywhere in it, with the single exception of the historical institutions treated from the public record in the lineage assessments, which this paper only indexes. Each construction is printed at the point of use and labelled CONSTRUCTED.

3.2 Which effective count, and the precision rule

Where this paper reports an effective count it means $1/\mathrm{HHI}$, the reciprocal of the Herfindahl–Hirschman index and the Hill number of order two [Hirschman, 1964, Herfindahl, 1950, Hill, 1973, Jost, 2006], whose numbers-equivalent reading is the standard apparatus this paper borrows [Adelman, 1969, Laakso and Taagepera, 1979, U.S. Department of Justice and Federal Trade Commission, 2023, 2010]. **A summary statistic computed over a partition does not determine the partition** [Kirman, 1992, Harrison and Klein, 2007], which is why §6.4 states the invariance and its price rather than leaving a reader to infer an allocation from a count. **The corpus's affine construction $N_{\mathrm{eff}} = 1 + (N-1)u$ is not a Hill number of any order** [Curzi, 2026c]; it appears in this paper only in Appendix F, where the correspondence to the earlier series is drawn and where it is badged as a design axiom at the point of use.

The precision rule is stated once and applies everywhere (Appendix B.15). Shares are stipulated to one decimal place; indices, effective counts and surplus values are computed at full floating precision and printed to six decimal places; and **no printed value is ever used as an input to a later computation.** Six decimal places on a quantity derived from shares stipulated to one is a statement about the arithmetic and not about the world, and §6.2 says so again.

3.3 The status convention, and why the default is FLAGGED

Appendix D assigns every legal citation in the series one of two statuses.

VERIFIED is reserved for facts fixed by definition or by arithmetic recomputed from stated inputs, and for nothing else. **FLAGGED FOR VERIFICATION** is the default and covers every case reporter citation, every section number, every date, every threshold and every current-status claim. **A reader who treats the flag as a formality has misunderstood the design.** The scheme is a two-valued ordinal label, no arithmetic is performed on it, and an ordinal scale licenses none [Stevens, 1946, Michell, 1997].

No jurisdiction-specific legal source is cited anywhere in this paper. The statutes, conventions, court rules and decided cases consolidated in Appendix D are named because they exist and are described from the source manuscript; **this paper's bibliographic database contains none of them and no citation is attached to any of them.** The general doctrinal frame is cited where it is relied on [Hague Conference on Private International Law, 1985, United Nations, 1958, United Nations Commission on International Trade Law, 1985, Torremans et al., 2022, Briggs, 2013, Hansmann and Kraakman, 2000, Pistor, 2019], and the disclosure regime that removed non-disclosure from the available design parameters is cited where the disclosure test is stated [Organisation for Economic Co-operation and Development, 2017, Financial Action Task Force, 2012, Organisation for Economic Co-operation and Development, 2015, de Goede, 2011]. **Publishing a dated, status-keyed register of what has not been verified is a recognised integrity practice rather than a stylistic choice** [Nosek et al., 2018, Simmons et al., 2011, Ioannidis, 2005, Gelman and Loken, 2013], and badging an unsupported claim rather than dropping or dressing it is the honest description of what a research programme does with its own unproven components [Lakatos, 1970, Platt, 1964, Meehl, 1990].

3.4 The key to the atlas

Appendix A's second column and Appendix D.2's first column carry a three-digit key. **It is the last three digits of the corpus paper — CCP-0nn — that carries the assessment being compressed**, so that every cell in the atlas can be traced to the paper that argues it. The atlas is an index, not an argument, and **no cell in it should be relied on without reading the paper it compresses and the verification register that paper carries.** An index of this kind is an installed base rather than a finding: it accumulates, it decays if it is not maintained, and its usefulness is a property of its upkeep [Star and Ruhleder, 1996, Star and Griesemer, 1989].

3.5 What is not invoked

The corpus's reflexive loop is not used in this paper and no social-influence parameter is estimated, so the reflection problem [Manski, 1993, Shalizi and Thomas, 2011] does not bear on any result reported here. **No distributional, scaling or heavy-tail claim is made anywhere**, so the goodness-of-fit and likelihood-ratio procedure such a claim would require [Clauset et al., 2009] is not applicable and was not run. Every figure in this paper is a reciprocal of a sum of squared shares, a logarithm of such a reciprocal, a ratio of two counts, or a closed-form solution of a linear equation on stipulated inputs.

One borrowing is flagged before the appendices use it. The framework writes concentration, erosion and surplus in the grammar of extensive and conserved quantities without a conservation law, which is the characteristic failure of this genre [Mirowski, 1989]; the defence taken here is Cartwright's — validity is claimed within a specified arrangement and no universality is claimed for it [Cartwright, 1999]. §6.5 grades every borrowing in the paper by name.

4. The method in seven steps

4.1 The position: what the procedure buys and what it does not

A method that cannot be run is a description of a method.

The preceding papers of this series establish a thesis, an instrument, a taxonomy, a design standard, a set of jurisdictions with evidence attached, and a failure record. All of that is inert unless it reduces to something a reader can execute on a Tuesday afternoon with a spreadsheet, a list of entities, and an hour. This section is that reduction. It is deliberately the shortest load-bearing part of the series, and everything in it is derived — nothing here is new, and every step points back to the section that owns it.

The compression has to survive one honest constraint, and stating it now rather than at the end would be dishonest in the other direction, so it is stated in both places. **The procedure below is correct and it does not produce a structure that pays for itself at the tested parameters.** That is the framework's own arithmetic applied to the framework's own recommendation, and the last section of this section does nothing but set out what remains unresolved, because a synthesis that ends on a triumph is a brochure.

What the procedure does is different and narrower, and it is worth being precise about, because precision here is the difference between a useful tool and a disappointed reader:

> **Jurisdictional and rail diversity across independent coordination perimeters raises the ceiling on what a structure can hold. It does not pay the structure's maintenance bill. Diversity buys the ability to build; it does not buy the building.**

That formulation is the assembled architecture's and it governs this section. A reader who runs the procedure and finds a negative number has not made a mistake. The reader has found the actual position, which is what the instrument is for.

One further framing, carried from the Hong Kong assessment and applied to the whole method. Everything the procedure buys is bought for the tail of the distribution and not for the median. In the median year, a conventional single-perimeter structure works fine, costs less, is simpler to administer, and produces no complaints from anyone. **The architecture in this series is worse than the conventional one in almost every year and better in the year that matters, and a reader who is not buying for the tail should not buy at all.** That is not a caveat. It is the product description.

4.2 Why the procedure has the shape it has

The procedure has the shape it has because the storage law has the shape it has, and each step maps to one term. This is the whole of the reasoning in nine lines.

```
Q_{t+1} = (1 - delta) Q_t + eta S_t - C_t

h = eta ln(N) - delta Q - C

  Q      protected capital
  delta  erosion: tax drag, political risk, debasement, haven degradation
  eta    conversion of income into DURABLE protected holdings
  C      structure maintenance: compliance, counsel, substance, filings
  N      EFFECTIVE BLOC COUNT -- independent coordination perimeters,
         not entities and not jurisdictions
```

`h` is the sustaining rate: positive and the structure builds, negative and it is being funded out of something else. Four terms, four levers, and the procedure works through them in the order that makes the later steps meaningful.

`N` is the only term that appears inside a logarithm, which has two consequences the procedure has to respect. First, the marginal value of an additional independent perimeter is `eta/N` — falling, so the first move is worth much more than the fourth. At the designed structure's `N = 2.941176`, `dh/dN = 0.35 / 2.941176 = 0.119000`, still the most valuable structural move available. Second, and this is the result that organises everything: `ln(1.00) = 0`. **A structure with one effective bloc has no surplus term at all — not a small one, none — and no rearrangement of entities inside that bloc changes it, because rearranging within a perimeter does not change `N`.**

`C` is the term that is almost always mis-estimated downward, because it is paid in small recurring amounts to many different people and never appears as a line item. It includes registered offices, agents, audits, director fees, local counsel, substance payroll, filings, translations, the annual re-run of the whole procedure, and the internal management time that the family does not bill itself for. The AIFC result is the sharpest illustration of what happens when `C` is left out: the AIFC position is worth 0.026731 of `h`, which is entirely consumed if the leg costs more than 8.9102% of the structure's total maintenance budget. **The geopolitical question was interesting and the cost question was binding.**

`delta` and `eta` are the terms the jurisdictions actually move. A jurisdiction with a stable legal system, a working court, and no expropriation history lowers `delta`. A jurisdiction that lets income be converted into durable held form — a foundation with separate legal personality, a recognised trust, a licensed insurer holding reserves, a REIT unit rather than a title deed — raises `eta`. Most of what the jurisdiction papers describe operates on these two terms, and almost none of it operates on `N`, which is why the concentration measurement is a separate step that has to be done separately.

4.3 The procedure, specified

4.3.1 The procedure on one page

```
=========================================================================
THE PROCEDURE
=========================================================================

0  NAME THE THREAT                                                 Ch 4
   Which of the five: arbitrary action / lawful process / commercial /
   succession / bloc fragmentation. Different structures answer different
   threats. A structure built against the wrong one passes every test and
```

```
   fails anyway.
   STOP if the answer is "lawful process" and the claim already exists.
   That is fraudulent-transfer law and timing, not architecture.

1  MEASURE BLOC CONCENTRATION                                        Ch 5
   List every holding as a share of protected capital.
   Assign each to a coordination perimeter using Ch 4's test.
   COLLAPSE TO PERIMETERS FIRST, then compute:
       HHI = sum of squared bloc shares      N = 1 / HHI
   Compute h = eta ln(N) - delta Q - C.
   Compute the break-even N* = exp((delta Q + C) / eta).
   Never print the naive per-jurisdiction count next to a resilience claim.

2  ASSIGN EACH ENTITY EXACTLY ONE JOB                                Ch 6
   HOLDING / OPERATING / BRIDGING. Score the vector (H, O, B).
       S = H^2 + O^2 + B^2       effective jobs = 1 / S
   Above 2.20 is overloaded: split it or accept the strain in writing.
   Score candidates on each requirement dimension, then take the MINIMUM
   over the dimensions the job needs -- never the average.

3  APPLY THE DISCLOSURE TEST                                         Ch 3
   Would the structure still do its job if every element were disclosed
   to every authority with jurisdiction over any part of it?
   Resilience structures pass. Concealment structures fail by construction.
   A structure that fails is not fixed by relocating it.

4  PRICE EACH MARGINAL JURISDICTION AS A PROBABILITY                 Ch 22
   Do not argue the geopolitics. Compute:
       G = gain in h if the perimeter call is RIGHT
       L = loss in h if the perimeter call is WRONG
       break-even probability p* = L / (G + L)
   Then compute the cost ceiling: the leg must cost less than G,
   expressed as a percentage of total C.
   A priced loss taken knowingly is legitimate. An unpriced one is failure.

5  CHECK HEADROOM BEFORE BUILDING                                    Ch 34
   Fix the drawdown d you will survive; solve for the loan, not the reverse:
       L_max = V (1 - d)(1 - m)         m = maintenance requirement
   Check liquidity against succession and margin simultaneously --
   they draw on the same buffer.
   Ring-fence BEFORE the pledge; a cross-default clause is a designed hole.

6  VERIFY WITH COUNSEL IN EVERY JURISDICTION TOUCHED
   Residence, nationality, beneficiary location, asset situs, counterparty
   situs, and the situs of every decision-maker. Written classification of
   every entity for CRS, FATCA, and local reporting AT FORMATION.
   Where the framework declined to guess, the framework declined for a reason.

7  WRITE IT DOWN AND RE-RUN IT ANNUALLY
   Date, named person, diff against last year. Every bloc call carries its
   evidence and the specific event that would reverse it. Every residual is
   stated. A register nobody reviews is worth nothing.
================================================================================
```

4.3.2 Step 0: name the threat

The threat register separates five threats that are routinely collapsed into one, and the separation does more work than any jurisdiction selection.

Arbitrary action — expropriation, immobilisation, de-risking without process, retroactive regime change. This is the subject of the framework and the threat that `N` answers.

Lawful process — a judgment that survived due process. Timing-bound. Fraudulent-transfer law governs and no jurisdiction fixes it after the fact. The failure record's tracks one and three are almost entirely this threat, and the structures that survived it survived on timing.

Commercial and counterparty — insurance and structure. The failure record's track four lives here, and it is the threat that requires no adversary at all.

Succession — forced heirship, fragmentation across heir jurisdictions, and the liquidity to pay what falls due on death. The succession analysis's result is the caution: the structure solved the smaller of the two exposures.

Bloc fragmentation — the rails and the perimeters coming apart, which is the threat the last fifteen years have been trending toward and the one most structures are least built for.

The instruction at step 0 is a stop rather than a choice. If the honest answer is lawful process and the claim already exists, the reader should be with litigation counsel, not with this series.

4.3.3 Step 1: collapse before measuring

The instrument is elementary and the discipline is not.

```
CONVENTIONAL, as found

  UK 40.9  US 27.3  Jersey 18.2  Luxembourg 13.6
  naive HHI = 0.293430        effective jurisdictions = 3.407968

  collapsed:  WEST 100.0
  bloc HHI  = 1.000000        EFFECTIVE BLOCS = 1.000000
  ln(1.00)  = 0.000000        h = -0.500000

DESIGNED

  UAE 29.1  Thailand 18.2  UK 16.4  Bermuda 13.6
  India 11.8  Singapore 10.9
  naive HHI = 0.189002        effective jurisdictions = 5.290949

  collapsed:  BRIDGE 40.0  NONALIGNED 30.0  WEST 30.0
  bloc HHI  = 0.340000        EFFECTIVE BLOCS = 2.941176
  ln N      = 1.078810        h = -0.122417

  Western-perimeter exposure  100.0%  ->  30.0%
  break-even N* = exp(0.5 / 0.35) = exp(1.428571) = 4.172734
```

Four entities, four jurisdictions, one point of failure. The naive reading says 3.407968 jurisdictions; the honest reading says 1.000000 bloc. That gap is the entire reason the step exists.

The Singapore assessment supplies the cleanest proof that the gap is real and not an artefact of the bloc assignment. Place the same 10.9% in London instead of Singapore and the naive count falls from 5.290949 to 4.449309 — a dramatic, visible, entirely spurious difference — while the honest count moves from 2.941176 to 2.924302 and `h` from −0.122417 to

−0.124431. **Singapore's true marginal contribution to `h`, measured against simply putting the money in London, is 0.002014. The naive metric reported nearly a full effective jurisdiction of diversification that did not occur.**

The Gulf assessments supplies the failure in the other direction. Add Qatar and Saudi Arabia funded by trimming UAE, the United Kingdom, and Singapore: eight jurisdictions, naive effective count 7.132973 — up 34.81% — and effective blocs 2.841490, down 3.39%, with `h` falling to −0.134485. **Two more jurisdictions, a third more apparent diversification, and the honest count fell.**

Two further disciplines belong to this step and are routinely skipped.

Measure the rails separately, and by terminal clearing system rather than by bank. The rail measurement's correspondent measurement: as found, 100% USD, HHI 1.000000, one effective clearing system. As designed, USD 55 / CNY 15 / EUR 12 / INR 10 / AED 8, HHI 0.355800, 2.810568 effective systems. A structure can have `N = 2.941176` on holdings and 1.000000 on the ability to transact.

Record the sensitivity. Reclassifying Singapore from bridge to Western — the argument most likely to be had about the whole allocation — moves `N` by 0.016874 and `h` by 0.002014. The argument does not move the answer. The concentration does.

4.3.4 Step 2: one entity, one job

The three-jobs diagnostic owns the taxonomy and it prevents more failures than any other single idea in the series.

```
HOLDING    succession law, asset segregation, perpetuity, low substance burden
OPERATING  real substance, labour, cheap presence, market access
BRIDGING   dual-bloc banking, dual-rail settlement, neutral law
```

The diagnostic is the concentration instrument turned on the entity instead of the portfolio. Express the entity's function as a vector, compute `S = H² + O² + B²`, and read `1/S` as effective jobs. A pure specialist returns 1.0000. The best possible two-job entity — an exact 50/50 split — returns exactly 2.0000, and there is no two-job configuration above it. The 2.20 threshold leaves room for estimation error in the vector and nothing more.

The designed structure, scored, with the framework's own flag left in:

entity	H	O	B	S	eff jobs	verdict
DIFC Foundation	0.90	0.00	0.10	0.8200	1.2195	SPECIALIST
Thai BOI opco	0.05	0.95	0.00	0.9050	1.1050	SPECIALIST
UK Ltd	0.10	0.85	0.05	0.7350	1.3605	SPECIALIST
Singapore treasury	0.05	0.15	0.80	0.6650	1.5038	STRAINED
ADGM holdco	0.70	0.05	0.25	0.5550	1.8018	STRAINED
Bermuda captive	0.30	0.60	0.10	0.4600	2.1739	STRAINED
GIFT City vehicle	0.20	0.30	0.50	0.3800	2.6316	OVERLOADED
mean effective jobs per entity					1.6852	

The framework's own architecture produces one overloaded entity, and that is the reason the diagnostic is worth having rather than a reason to distrust it. The Bermuda captive at 2.1739 is strained by nature — a captive underwrites, which is operating, and holds reserves, which is holding — and the strain is accepted in writing because the reserves are held against real third-party liabilities, which is precisely what makes them a structurally awkward class to realise. The GIFT City vehicle at 2.6316 is carrying all three jobs and is a design error the framework owns rather than smooths over.

The selection rule matters as much as the diagnostic. Score each candidate on each requirement dimension and take the **minimum** over the dimensions the job actually needs. An average lets an excellent low-substance score pull up a mediocre succession score; the minimum does not, because a structure fails at its weakest load-bearing requirement and not at its average one.

4.3.5 Step 3: the disclosure test

> Would the structure still do its job if every element were disclosed to every authority with jurisdiction over any part of it?

Resilience structures pass. Concealment structures fail by construction. The test is a filter applied before cost, before jurisdiction, and before elegance, and it is cheap to run because the answer is usually obvious within one sentence of asking.

The disclosure paper applies it to five constructed structures and two of them fail in print — a Thai company held through nominees, and a captive that writes no risk. Both fail for the same reason: their operation depends on a register, a return, or a filing saying something other than what is true. Relocating either does not fix it, because the defect is not in the jurisdiction.

Two clarifications that the test's brevity invites people to miss.

It is a filter, not a shield. The disclosure paper carries its own strongest counter-case as its seventh failure mode, and this section repeats it below under what is unresolved. Passing the test does not prevent a policy decision taken against a fully disclosed position.

It is about facts, not strategy. The bright-line analysis's formulation: "hidden in plain sight" means the strategy is non-obvious while every fact is filed. A roll-up executed in full public view over a decade that almost nobody noticed passes the test. Concealment of fact does not, and no amount of sophistication converts the second into the first.

4.3.6 Step 4: price the jurisdiction rather than argue it

This is the step that most changes how a reader behaves, because it replaces an argument that cannot be settled with a number that can.

The form, from the AIFC assessment, generalised:

```
1  Compute h for the structure WITHOUT the candidate leg.
2  Compute h WITH the leg, on the assumption that the perimeter call
   is RIGHT.  The difference is G.
3  Compute h WITH the leg, on the assumption that the perimeter call
   is WRONG -- the leg folds into a bloc the structure already holds.
   The difference is -L.
4  Break-even probability   p* = L / (G + L)
5  Cost ceiling             the leg must run below G of maintenance,
                            expressed as a share of total C.
```

Worked, on the AIFC at 5% drawn from the United Kingdom slot:

```
baseline           blocs 40.0 / 30.0 / 30.0        N = 2.941176   h = -0.122417
call RIGHT         blocs 40.0 / 30.0 / 25.0 / 5.0  N = 3.174603   h = -0.095686
                                                    G = +0.026731
call WRONG         blocs 40.0 / 35.0 / 25.0        N = 2.898551   h = -0.127526
                                                    L =  0.005110

p* = 0.005110 / (0.026731 + 0.005110) = 0.005110 / 0.031841 = 0.160476
cost ceiling = 0.026731 / 0.30 = 8.9102% of total C
shortfall closed if right = 0.026731 / 0.122417 = 21.8357%
```

A 16.05% probability that the perimeter is genuinely independent is enough to justify the position, and the binding constraint is cost rather than geopolitics. Both halves of that sentence are useful. The first tells a family it does not need to win the argument about Kazakhstan; it needs the argument to be better than roughly one-in-six. The second tells the family where the decision is actually made, which is in the fee schedule.

The counterpart is the loss case, and it is the reason the step is mandatory rather than advisory. A wrong call does not merely fail to help. It costs 0.005110, because capital was withdrawn from a bloc where it was diversifying and placed in a bloc it concentrated. **That is the unpriced bloc call, and it is invisible to every conventional measure, including the naive effective jurisdiction count, which rises.**

4.3.7 Step 5: headroom before building

The carve-out paper's cascade, reversed so that the input is the quantity a family can have an opinion about.

```
d = drawdown to be survived      m = maintenance requirement
V = collateral value             L_max = V (1 − d)(1 − m)

at V = 80.00, m = 35%:
  survive 23.1%   L = 40.000   LTV 50.0%   <- the carried case
  survive 35.0%   L = 33.800   LTV 42.3%
  survive 50.0%   L = 26.000   LTV 32.5%
  survive 60.0%   L = 20.800   LTV 26.0%
```

At the carried constructed case's own parameters — a 20% carve-out, 80% retained and pledged at 50% loan-to-value, producing 60 deployable at 80% retained control — the maintenance call triggers on a drawdown of 23.0769%, which is the corpus's pledge-trigger result [Curzi, 2026]: $d^{*} = 1 - \mathrm{LTV}_{0}/(1-m)$, so at a 50 per cent loan-to-value and a 35 per cent maintenance requirement the first call falls at 23.076923 per cent and not at 50. **That is ordinary equity volatility, not a crisis parameter, and the carve-out cascade leads with it rather than burying it for exactly that reason.**

Two further checks belong to this step and are usually run separately, which is the error.

One buffer, two claims. The succession analysis's constructed liquidity test shows that liquidity rather than entitlement binds [Curzi, 2026]: a USD 60.00 million claim against USD 26.16 million of liquid assets leaves a shortfall of USD 33.84 million, 14.1 per cent of the estate, sufficient to force the sale of an operating branch on a death. The margin cure period draws on the same liquid holdings. **The succession liquidity problem and the margin call are the same problem arriving through two doors, and they should be modelled against one buffer.**

Ring-fence before the pledge. The ring-fencing analysis's segregation is effective against a claim that arises after it. A cross-default clause signed later is a designed hole in the fence, and a forced sale of pledged shares can trip change-of-control definitions in agreements that have nothing to do with the pledge.

4.3.8 Step 6: verify, and record where the framework refused to guess

Every section in this series closes with a Verification Register, and Appendix D consolidates them. The registers are not a disclaimer. They are the framework's integrity mechanism, and the house standard they encode is worth stating in the procedure itself:

> **Declining to guess, in print, is the standard. A section that names no section number where it is unsure of one is more useful than a section that names a plausible number.**

The AIFC assessment is the model: it opens by warning that it names and numbers no AIFC subordinate Act, Regulation, or Rule, and it states in print that it declines to guess whether the AIFC foundation confers separate legal personality. That refusal is information. A reader who takes it to counsel gets a real answer; a reader given a confident guess gets a false one.

The minimum verification set, per structure:

```
- counsel in each jurisdiction of incorporation
- counsel in each jurisdiction of residence -- principal AND every heir
- counsel in each jurisdiction of asset situs, separately for immovables
- tax counsel wherever a decision concerning any entity may be taken,
  because that is where corporate residence is asserted
- Sharia-qualified counsel wherever personal-status law applies
- written CRS and FATCA classification of every entity AT FORMATION,
  including each sub-fund or cell
- securities counsel before any pledge by a director or officer
```

4.3.9 Step 7: the annual re-run

The procedure decays. Bloc assignments move — Singapore's did, in March 2022, and the evidence is one dated episode rather than a trend. Job vectors drift, because a holding entity acquires an operating subsidiary and starts making decisions. Substance requirements are amended. Incentive conditions are revised, twice in the Singapore family-office case. Correspondent relationships are withdrawn without notice or explanation.

The re-run is administrative rather than intellectual and takes an afternoon: recompute steps 1, 2, and 4 from current allocations; diff the result against last year; re-read every bloc call against its written trigger; and re-open every Verification Register item whose underlying instrument has been amended. Date it and put a name on it.

4.4 Failure modes of the procedure

Eight ways the procedure gets run wrong. Each has been observed in the sections that produced it.

FM 4.1 Running step 1 without collapsing

The single most consequential error, and the reason the concentration paper owns the instrument rather than distributing it. A naive per-jurisdiction effective count is not a resilience number. Printed next to a resilience claim it is worse than no number, because it is precise, plausible, and wrong in the direction the reader wants.

FM 4.2 Running the steps out of order

Step 4 is meaningless before step 1, because the gain and loss are both differences in h and h requires N. Step 5 is meaningless before step 2, because the headroom check needs to know which entity holds the liquid assets. Step 3 belongs before step 4 rather than after it, because a structure that fails the disclosure test should not be priced; it should be abandoned.

FM 4.3 Treating step 6 as a formality

Counsel in every jurisdiction touched is expensive, slow, and the largest single component of C in a small structure. It is also the step that converts the framework from a map into something operable. A structure verified in one jurisdiction and assumed in five is a one-instance check, and a one-instance check is not a check.

FM 4.4 Averaging a split trajectory

The Singapore assessment's convention. Where a jurisdiction's degradation trajectory genuinely splits — Singapore is stable to improving on institutional quality, improving on regulatory credibility, and eroding on bloc independence — averaging produces "stable," which is exactly wrong on the axis the structure is buying. Split it and refuse to average.

FM 4.5 Confusing the ceiling with the building

The procedure raises `N`. Raising `N` raises the ceiling on `h`. It does not pay `C`, and at the tested parameters `C` plus `delta Q` exceeds `eta ln(N)` for both structures. A reader who runs the procedure and expects a positive number has misunderstood what the procedure does.

FM 4.6 Buying for the median

Every element of the architecture costs money every year and pays in a year that may not arrive. That is the shape of the product and it is why the Hong Kong assessment recommends against the move with the largest measured gain in the series: siting the Asian centre in Hong Kong raises `N` from 2.941176 to 3.615826 and `h` by 0.072279, the largest single-move improvement anywhere, and the Hong Kong assessment declines it and takes capped transit instead at a gain of 0.002869 — **3.97% of the benefit for 3.21% of the exposure.** That trade only makes sense if the purchase is for the tail.

FM 4.7 Stopping at the win

The succession analysis's discipline. The forced-heirship exposure is capped at USD 6.70 million and is zero on the designed map; the French inheritance-tax exposure is approximately USD 27.00 million, 4.0299 times larger, and untouched by the structure. A report containing only the first number is not a summary. It is a misrepresentation by selection, and the same discipline applies to every output of this procedure.

FM 4.8 Running it once

Steps 1 through 6 produce a snapshot. Step 7 is what makes it a measurement. Without the annual re-run, the bloc calls become beliefs, the job vectors become fiction, the Verification Register becomes a historical document, and the structure quietly reverts to whatever the advisers' individual preferences produce.

4.5 Results: the procedure run end to end on the carried case

CONSTRUCTED. The carried case of the carried constructed case, run once through the procedure end to end, with every figure recomputed.

Step 0. Threat named: arbitrary action and bloc fragmentation are the primary exposures; succession is a live secondary; lawful process is not currently in play and the structure is being built years ahead of any claim, which is the only configuration in which it helps; commercial and counterparty risk is carried by the captive and the insurance layer.

Step 1. As found: UK 40.9, US 27.3, Jersey 18.2, Luxembourg 13.6. Naive HHI 0.293430, 3.407968 effective jurisdictions. Collapsed: WEST 100.0, bloc HHI 1.000000, `N = 1.000000`, `h = \ensuremath{-}0.500000`. As designed: UAE 29.1, Thailand 18.2, UK 16.4, Bermuda 13.6, India 11.8, Singapore 10.9. Naive HHI 0.189002, 5.290949 effective jurisdictions. Collapsed: BRIDGE 40.0, NONALIGNED 30.0, WEST 30.0, bloc HHI 0.340000, `N = 2.941176`, `h = \ensuremath{-}0.122417`. Western-perimeter exposure 100.0% → 30.0%. Break-even `N* =`

4.172734. Rails measured separately: 1.000000 effective clearing system as found, 2.810568 as designed.

Step 2. Seven entities scored. Five specialists or acceptable strains; one strain accepted in writing (Bermuda captive, 2.1739, inherent to a captive); one flagged as overloaded (GIFT City, 2.6316) and carried as an open design error rather than corrected on paper.

Step 3. Every entity passes. The apex is a filed legal person with a published register position; the Thai operating company is BOI-promoted with no nominee element, the nominee route being criminal under the Foreign Business Act B.E. 2542 (1999) and excluded on that ground before any other; the captive writes real third-party risk with a loss reserve specialist opinion; the United Kingdom company is on the public PSC register and files full accounts.

Step 4. One marginal jurisdiction priced: the AIFC at 5% from the United Kingdom slot. `G = 0.026731`, `L = 0.005110`, `p* = 16.0476%`, cost ceiling 8.9102% of `C`. Verdict: take it, small, once, and simply, subject to the cost ceiling and to the AIFC register. Two marginal jurisdictions declined on the same instrument: the Qatar family-office vehicle, which duplicates the DIFC inside the same bloc and buys nothing; and the Hong Kong centre, which offers the largest measured gain in the series and is declined in favour of capped transit for the reasons at failure mode 6. One priced loss accepted: the Saudi regional headquarters at 5.0% funded from the operating allocation, costing 0.124275 in `N` and 0.015110 in `h`, taken for addressable revenue, with the number recorded in the file.

Step 5. Leverage layer sized on drawdown rather than on loan-to-value. At the carried case's parameters the trigger is 23.0769% and is judged too tight; at a 50% drawdown tolerance the borrowing falls from 40.000 to 26.000, a reduction of 14.000, which is the stated price of the non-event. Liquidity modelled once against both the margin cure period and the succession requirement, which showed a USD 33.84 million shortfall, 14.1% of the estate.

Step 6. Counsel instructed in the UAE, the United Kingdom, Thailand, Bermuda, India, Singapore, and Kazakhstan; separately in France, Germany, and the two other heir jurisdictions; separately Sharia-qualified counsel on the personal-status interaction. Written CRS and FATCA classification of every entity at formation. The AIFC register run in full before the AIFC leg is funded, and the foundations question — whether the AIFC foundation confers separate legal personality — treated as unanswered rather than assumed.

Step 7. Diarised, named, and dated. Bloc calls recorded with triggers: a second unilateral Singapore measure adopted without Security Council authority; a renewed FATF listing of the UAE; a designation of a major Kazakh bank; a Judicial Tribunal line making DIFC orders unreliable.

The result. `h = \ensuremath{-}0.122417` before the AIFC leg, `\ensuremath{-}0.095686` after, against a break-even of zero. The structure closes 21.8357% of its shortfall with its best available marginal move and remains below the build threshold.

---

5. What is unresolved

This is the end of the method and it is not a summary of achievements. Eight things remain open, and the first of them is the largest.

5.1 Both structures fall below the build threshold

At the tested parameters — `eta = 0.35`, `C = 0.30`, `Q = 10`, `delta = 0.02` — the conventional structure gives `h = \ensuremath{-}0.500000` and the designed structure gives `h = \ensuremath{-}0.122417`. Both are negative. The break-even is `N* = exp(0.5 / 0.35) = 4.172734` effective blocs, and the designed structure reaches 2.941176. Adding the best available marginal position takes it to 3.174603, which closes 21.8357 per cent of the gap and does not

close it. The assembled-architecture paper reaches the same verdict on the same structure [Curzi, 2026]: $N = 2.941176$, $h = 0.35 \ln(2.941176) - 0.500000 = -0.122417$ against a break-even of $N^{*} = 4.172734$, closing 75.5167 per cent of the shortfall in h and **not closing it.**

The improvement is real and it is large: 0.377583 of `h`, purchased by going from one effective bloc to 2.941176, which is the difference between a structure with no surplus term at all and one with a substantial one. It is also, by construction, subject to diminishing returns — `dh/dN = eta/N`, so the move from 2.941176 to 4.000000 buys 0.107620, under a third as much as the move from 1.000000 to 2.941176. **Diversification raises the ceiling. It does not pay the maintenance bill.**

Three honest ways to close the remaining gap exist and none of them is jurisdictional. Raise `eta` — convert more income into durable protected holdings, which is a discipline question rather than a structuring one. Lower `C` — which at some point means holding fewer legs, and therefore lowering `N`, and the trade has to be computed rather than assumed. Lower `delta` — which is what the jurisdiction papers are mostly actually doing. **The reader who wants a positive number should look at `eta` and `C` first, and this series is not primarily about either of them.**

5.2 Disclosure is not immunity

The disclosure paper argues that a structure is durable when observation yields nothing actionable, and it carries its own strongest counter-case as its seventh failure mode rather than leaving it to a critic. In 2022, approximately USD 300 billion of Russian central bank reserves were immobilised. **That event is described from the source manuscript and is cited nowhere, because this paper's bibliography contains no contemporaneous reporting**; the corpus paper that owns the result states it in the same terms and with the same gap disclosed [Curzi, 2026]. Those assets were fully disclosed. Their location, custodians, and character were all known and were the reason they were held where they were held. **They were frozen anyway.**

What survives is narrower than the incautious reading of the disclosure paper. Disclosure removes the failure mode in which a structure collapses on contact with an authority, converts an enforcement problem into a policy problem, and — through bankability, which the concentration paper identifies as the binding constraint on everything else — makes the rest of the architecture operable at all. It does not supply an appeal and it does not protect an asset sitting inside the perimeter that took the decision. The answer to that threat is `N`, and `N` is not a property of the paperwork — which is the disclosure paper's own economics of full disclosure, whose correlation result prices the alternative: holding marginal failure at 10 per cent, a common shock of $c = 0.02$ takes the probability that four perimeters fail together from 0.000100 to 0.020044, a 200.4-fold understatement [Curzi, 2026].

5.3 The succession structure solves the smaller of the two exposures

The succession analysis's constructed case, and the most uncomfortable result in the series. The forced-heirship exposure for the child resident in the civil-law jurisdiction is capped at USD 6.70 million and is zero on the designed map. The French inheritance-tax exposure is approximately USD 27.00 million — 4.0299 times larger — and is untouched by the structure. The liquidity test shows a USD 33.84 million shortfall, 14.1% of the estate, sufficient to force the sale of an operating branch.

A succession section reporting only the heirship win would be lying by omission, and a manual closing on it would be doing the same thing at greater length. What the structure does is eliminate a fragmentation risk and a control risk. What it does not do is pay a tax, and the tax is the bigger number.

The one lever that does reach the whole problem is present in all three legal families the case touches — advance renunciation of the action in reduction in France, the *Pflichtteilsverzicht* in Germany, *takharuj* among heirs under Sharia — and it is the same lever in each: **consent. And consent requires disclosure**, which ties the succession answer back to the

disclosure paper's governing principle and is the reason the two parts of this series are one book.

5.4 The dollar share cannot be engineered away

The rail-perimeter measurement, stated in the form that matters. Correspondent concentration measured by terminal clearing system moves from 1.000000 to 2.810568 under the designed allocation [Curzi, 2026], whose clearing-perimeter measurement takes a naive correspondent HHI of 0.302400 — 3.306878 effective correspondents — to a perimeter HHI of 0.745256 and $N_{\text{rail}} = 1.341819$ once flows are decomposed by currency. Reaching 4.000000 effective clearing systems, holding the non-dollar mix in its current proportions, would require the dollar share to fall to approximately 38.99% from 55%.

That is a commercial decision about which currencies the group invoices in, not a legal decision about where it banks. Four hard limits sit underneath it: a USD account settles under US law wherever it is booked; CIPS is a clearing system and many participants still use SWIFT for messaging, so "CIPS replaces SWIFT" is false and any structure built on it will fail; the bank's risk appetite is not the jurisdiction's policy; and a rail is not a holding. The rail concentration is therefore only partly a structuring problem and mostly a revenue-currency problem, and this series cannot solve the second.

5.5 Cost is not the reason to choose the foundation

The computed foundation-versus-trust crossover, which cuts against the way foundations are usually sold. Against a trustee charging on a basis-point scale, the DIFC Foundation is cheaper only above USD 34.3 million at 35 basis points, USD 80.0 million at 15 basis points, and USD 120.0 million at 10 basis points.

So cost is explicitly not the reason to choose it. The reason is recognition: a foundation is a legal person and travels into civil-law and Sharia jurisdictions in a way a common-law trust does not, and the succession analysis's whole analysis depends on that and not on a fee comparison. Any adviser recommending the foundation on cost has either a very large client or a weak argument.

5.6 What the Gulf bridge actually delivers, and what it does not

The ADGM decomposition, which is the most useful single sentence among the Gulf-centre assessments. **English law is three things — doctrine, court, and territorial state — and ADGM buys the first two without the third.** That is precisely what a bridge jurisdiction can deliver and precisely what the City of London cannot, because in London the three are inseparable by definition.

What remains unresolved is whether the second of the three holds up under a stress that has not yet occurred. The ADGM Courts have a short record, the enforcement bridge to the onshore courts is documented but lightly tested, and the conduit question — whether a foreign judgment recognised inside a free zone can be enforced onshore through it — is carried unresolved from the foundation paper's register through the rail measurement's. It is the largest open legal question in the architecture and it sits directly under the apex.

5.7 The bloc assignments are the framework's own, and they are contestable

Every value of N in this synthesis rests on a mapping from jurisdictions to perimeters, made by applying the threat register's test to published evidence. That mapping is an argument, not a measurement. The concentration paper's robustness table exists to show how much the answer moves under reasonable disagreement, and the answer is: not much. Reclassifying

Singapore as Western moves `N` by 0.016874 and `h` by 0.002014 [Curzi, 2026], whose bridging-slot control finds the same 10.9 per cent held in Singapore or in London giving identical blocs and a stress cost of 0.002014. Separating the UAE and Singapore into distinct blocs moves `N` from 2.941176 to 3.615826 — which is a large move, and is the reason the published figure of 2.941176 is the conservative end of a range rather than a point estimate.

A reader who disagrees with a bloc call should re-run the arithmetic rather than argue, and will usually find the disagreement does not matter. A reader who finds one that does matter has found something the framework wants to know.

5.8 Fifteen sections of this synthesis are specified and not yet on the page

Stated because the alternative is to imply a completeness the work does not have. The manifest specifies forty-five sections and six appendices. The sections written and verifiable on the page at the time of this compression cover the greater part of the series; the Convergence section, US domestic, GIFT City, Türkiye, asset conversion, SPVs, the three rail assessments, the leverage and group architecture sections, law-family arbitrage, the integrated wiring assessment, the sanctions and compliance section, and the banking-lineage sequence are specified in the manifest and are not among them.

Where this section and the appendices refer to those sections, they refer to results fixed in the reconciliation ledger — the 23.0769% margin trigger, the four bright lines, the CIPS distinction, the 2022 precedent — and not to text that can be checked. **Appendix D marks the gap explicitly rather than papering over it, and a reader should treat every forward reference to an unwritten section as a specification rather than as a citation.**

That is the method. It measures concentration honestly, assigns one job per entity, refuses structures that depend on not being seen, prices marginal jurisdictions instead of arguing about them, sizes leverage from the drawdown rather than the loan, and sends every element to counsel in every jurisdiction it touches. Run properly on the carried case it produces a structure with 2.941176 effective blocs, 30% Western-perimeter exposure instead of 100%, 2.810568 effective clearing systems instead of one, one flagged design error left visible, a priced loss taken knowingly, and a sustaining rate of −0.095686.

Below the threshold, honestly measured, with the residual stated. That is what the instrument says, and the instrument is the only part of this series that was never going to flatter anyone.

5.9 The verification register for this synthesis

Marked for confirmation rather than asserted, and gathered for Appendix D.

1. Every figure in this section is derived from the carried case's stated test parameters and the allocations in the concentration, rail, Gulf, Singapore, Hong Kong and AIFC assessments. **They are illustrative model outputs, not estimates of any real position, and no reader's own structure will produce them.**
2. The parameter values `eta = 0.35`, `C = 0.30`, `Q = 10`, `delta = 0.02` are the carried constructed case's test parameters. A real structure requires each to be estimated from its own facts, and `C` in particular is routinely under-estimated because it is paid in small recurring amounts to many parties.
3. All bloc assignments are the framework's own, applying the threat register's perimeter test to published evidence. Contestable; sensitivity shown in the concentration paper's robustness table; each jurisdiction section restates its assignment with evidence at scorecard item 2.

4. The job vectors in step 2 are estimates and should be re-derived annually from where board resolutions are actually passed and where management time is actually spent, not from the organisation chart.
5. The 35% maintenance requirement, the 50% loan-to-value, and the drawdown table in step 5 are **constructed model parameters**. Confirm actual maintenance definitions, cure periods, revaluation discretion, and rehypothecation rights in the specific margin documentation with counsel.
6. Thailand: the Foreign Business Act B.E. 2542 (1999) nominee provision and its enforcement practice; Board of Investment promotion conditions, which are activity-specific and change; and Revenue Department order Por. 161/2566. Carried from the Thailand assessment.
7. DIFC Foundations Law No. 3 of 2018 and ADGM's Application of English Law Regulations 2015 are cited for the characteristics stated. Confirm current text and amendments with counsel in the relevant centre.
8. The AIFC foundations question — whether the AIFC foundation confers separate legal personality — is carried as **unanswered** from the AIFC assessment and must be resolved before any apex migration is contemplated. The AIFC assessment names and numbers no AIFC subordinate Act, Regulation, or Rule, and this section does not either.
9. The conduit question — whether a foreign judgment recognised within a UAE financial free zone can be enforced onshore through it, and the current constitution and practice of the Judicial Tribunal — is carried unresolved from the foundation paper, Register item 8, through the rail-perimeter measurement, Register item 4.
10. Singapore: the precise instruments by which the March 2022 targeted financial measures and export controls were imposed, and their stated legal basis. The bloc-trajectory finding in this section rests on that single dated episode.
11. The 2022 immobilisation of approximately USD 300 billion of Russian central bank reserves: the instruments by jurisdiction, dates, amounts, and the current legal position on the assets and the income arising from them. Treated as approximate throughout.
12. The succession analysis's succession figures — the USD 6.70 million capped reserve exposure, the approximately USD 27.00 million French inheritance-tax exposure, and the USD 33.84 million liquidity shortfall — are constructed outputs at a constructed exchange rate and constructed rate scale. Confirm the French residence conditions, abatements, and rate scale, and whether a discretionary foreign foundation making no distribution produces a taxable transmission at all, with French counsel.
13. The foundation-versus-trust comparison's crossover figures (USD 34.3m at 35 bp, USD 80.0m at 15 bp, USD 120.0m at 10 bp) rest on a constructed fixed-fee comparator of USD 120,000 per annum. They are a method, not a quote.
14. The correspondent measurement in the rail-perimeter measurement is by terminal clearing system, which requires identifying the terminal system for each chain — not the bank, and not the frameworking jurisdiction. Confirm direct versus indirect CIPS participation for each institution actually used.
15. The sections listed at item 8 of "What Is Unresolved" are specified in the manifest and are not written on the page at the time of this compression. Every forward reference to them in this section and in the appendices is a **specification, not a citation.**

All numerical results in this section were computed from the stated inputs at full precision in Python and rounded only for printing. No figure was derived from a rounded print. Appendix B reproduces the workbook in full.

Not legal, tax, or investment advice. Confirm every element with qualified counsel in every jurisdiction the structure touches. All worked cases are CONSTRUCTED.

5.10 What the appendices contain

> *Not legal, tax, or investment advice.* These appendices consolidate the framework's tables, its arithmetic, its diagrams, its citations, and its admissions. They are a map, not a permission. Confirm every element with qualified counsel in every jurisdiction any structure touches. All worked cases are **CONSTRUCTED** and labelled as such. Appendix D marks every citation used anywhere in the method as either VERIFIED or FLAGGED FOR VERIFICATION, and Appendix E states, in one place, everything this series does not know.

Attributed to The Invisible College of The Lodge Between Lodges, Supreme Council of Hands. The full roster with its designations is reproduced verbatim on the title page.

There are six appendices and they do six different jobs.

```
A  SCORECARD ATLAS          every jurisdiction assessed in the series, one table,
                            all twelve items, sortable by job and by trajectory
B  CONCENTRATION WORKBOOK   the HHI and effective-bloc arithmetic worked end to
                            end, every figure recomputed
C  STRUCTURE DIAGRAMS       the carried case in ASCII, each entity's job labelled
D  STATUTE AND CASE INDEX   every citation, marked VERIFIED or FLAGGED
E  THE HONESTY APPENDIX     settled / contested / needs counsel / recently changed
F  CORRESPONDENCE           how the earlier series map onto this series
```

Appendix D is the framework's integrity mechanism and Appendix E is its conscience. A reader with time for only two should read those two.

---

6. Verification and rigour audit

This section is the one place in the paper where something can be checked in under a minute, and it is built so that a reader can do it. The instrument is decomposed into postulates, and the chain from stipulated shares to the reported surplus is given step by step.

6.1 Dimensional audit

symbol	quantity	dimension	unit	status
w_i	allocation share	[1]	fractions summing to 1	stipulated
HHI	$\sum_i w_i^2$	[1]	dimensionless	derived
N	effective count, $1/\text{HHI}$	[#]	perimeters or jurisdictions	derived
$\ln N$	surplus term	[1]	nats	a logarithm of a count
η	conversion of flow into stock	[1]	—	**stated dimensionless; see below**
δ	erosion per period	[1]	per period	a fraction
Q	protected capital	[1]	**index units, no currency**	stipulated

symbol	quantity	dimension	unit	status
C	maintenance per period	$[1]$	index units per period	stipulated
h	sustaining rate	$[1]$	index units per period	derived
d^*, m, LTV	drawdown, maintenance, loan-to-value	$[1]$	fractions	stipulated / derived
basis points, USD figures	fee scales and estate values	[money]	USD	**stipulated, constructed**
item counts	register entries per assessment	$[\#]$	counts	enumerated

Does it balance? $h = \eta \ln N - \delta Q - C$ balances only if $\eta \ln N$, δQ and C share a unit. δQ is index units per period; C is stated as index units per period; and $\ln N$ is dimensionless, so η **must carry index units per period per nat while also being described as a dimensionless conversion efficiency in** $[0, 1]$**.** Those two descriptions are not the same, and **the source is silent on the reconciliation.** The reading adopted here is that η carries the conversion from a nat of surplus to a unit of stock per period, which makes the equation homogeneous and leaves Q in **index units with no currency attached** — an honest dimensionless placeholder for a quantity nobody has measured, and not an invented unit.

Every headline result survives that gap because every headline result is a ratio or a difference in the same units. N, the effective counts, the percentage shares, the break-even N^*, the ratio $0.107620/0.377583$, the crossover thresholds and the succession ratio 4.0299 are all dimensionless or in stated currency. **The one quantity whose absolute value means nothing without a unit is** h **itself, and it is used only for its sign and for differences.**

6.2 Significant figures and epistemic status

- **0.293430, 3.407968, 0.189002, 5.290949, 0.340000, 2.941176, 1.000000 are exact to the digits shown**, being sums and reciprocals of exactly stipulated shares. They carry no interval because nothing was estimated.
- $h = -0.500000$ **and** $h = -0.122417$ **are exact given** $\eta = 0.35$**,** $\delta = 0.02$**,** $Q = 10$**,** $C = 0.30$**, and those four are stipulated test parameters and estimates of nothing.**
- $N^* = \exp(0.5/0.35) = 4.172734$ **is exact given the same four**, and moves with them; a reader who changes η changes the threshold.
- **Six decimal places on a figure derived from shares given to one is a statement about the arithmetic and not about the world.** The precision rule exists so that two readers recomputing from the same inputs get the same digits, which is what makes an error visible. **It does not mean the sixth decimal place carries information about any structure.**
- **The crossover thresholds and the succession figures are exact on constructed inputs.** USD 34.2857 million is $120{,}000/0.0035$; the succession ratio 4.0299 is $27.00/6.70$. Neither is a measurement.
- **The register item counts are exhaustive enumerations** over the source units and are regenerable by the extraction Appendix D.2 describes.

6.3 Limits and boundary behaviour

$N \to 1$**.** $\ln(1.00) = 0$, so the surplus term vanishes exactly and $h = -(\delta Q + C)$. **This is not a small surplus, it is none**, and it is the whole organising result of the series.

$N \to \infty$**.** $\eta \ln N$ grows without bound while C grows at least linearly in the number of legs, so there is always a count beyond which another leg loses money. **The break-even is**

therefore a ceiling on useful fragmentation and not a target, and the cost ceiling in the break-even probability method is where the trade is actually decided.

$\mathrm{d}h/\mathrm{d}N = \eta/N$**.** Marginal value falls monotonically: 0.350000 at $N = 1$, 0.119000 at $N = 2.941176$. **The first move is worth 3.5087 times the second, and a reader with capacity for one leg should add the first and stop.**

$\eta \to 0$**.** The surplus term vanishes at every N, and no amount of jurisdictional diversity helps a structure that converts nothing into durable form. **The threshold is a statement about η and C at least as much as about N, which is §5.1's conclusion.**

$d \to 0$ **in the leverage relation.** $L = V(1-d)(1-m)$ gives $L = V(1-m)$ at zero drawdown tolerance — the position is at its call level the day it opens — and $L \to 0$ as the tolerance approaches one. **The usable region is the middle, and the constructed case sits in it.**

6.4 Invariance

The effective count is invariant under relabelling and under permutation of the shares, being a function of the multiset of shares alone. That is what makes it a numbers-equivalent, and it is also its principal limitation: **a statistic that does not depend on which entity holds which share cannot tell a reader which entity to change.**

It is not invariant under regrouping, and the whole method lives in that fact. The transformation that moves the number is the partition of jurisdictions into perimeters, and the partition is a judgement. **The sensitivity is measured rather than asserted**: reclassifying Singapore moves N by 0.016874 and h by 0.002014, while separating the UAE and Singapore into distinct perimeters moves N from 2.941176 to 3.615826. **The instrument is robust to being wrong about one member and not robust to being wrong about the structure**, which means the argument a reader is most likely to have is not the one that matters.

One invariance the instrument does not have, and it is the sharper limitation. Because $u = 1 - \rho^2$ depends only on $|\rho|$, a count of independent things reads perfect alignment and perfect anti-alignment identically [Curzi, 2026]. **Correlation of either sign collapses the count**, and nothing in the arithmetic distinguishes coordination from opposition; only the perimeter test, argued from evidence, does.

6.5 Analogy discipline: every borrowing, graded

borrowing	used for	category
Concentration indices and the numbers-equivalent [Hirschman, 1964, Herfindahl, 1950, Adelman, 1969]	every effective count in the paper	**1 — derivation.** The shares are a partition and the index is defined on it
Hill numbers [Hill, 1973, Jost, 2006]	naming $1/\mathrm{HHI}$ as the order-two member	**1 — derivation**
Merger-guideline thresholds [U.S. Department of Justice and Federal Trade Commission, 2023, 2010]	that the effective-count reading is the standard apparatus	**3 — analogy.** The thresholds are for markets, not for holdings, and none is applied here

borrowing	used for	category
The storage law as a leaky integrator [Curzi, 2026,?]	the whole of h	**2 — shared form.** The same difference equation, with no claim that any physical result transfers
Correlated failure across perimeters [Buldyrev et al., 2010, Albert et al., 2000, Cohen et al., 2000]	why nominally independent jurisdictions fail together	**3 — analogy**, invoked for shape; the empirical premise of the collapse step is asserted, not measured
Tail correlation and portfolio covariance [Longin and Solnik, 2001, Ang and Chen, 2002, Markowitz, 1952]	that a count is not a diversification	**2 — shared form**; no portfolio is constructed and no return appears
Ecological stability–diversity results [May, 1972, Tilman et al., 1998, Doak et al., 1998, McCann, 2000]	that more components need not mean more stability	**3 — analogy**
Open design [Kerckhoffs, 1883, Saltzer and Schroeder, 1975, Brandeis, 1914]	the disclosure test of step 3	**1 — derivation** as a design principle; the last is a policy argument and is **3**
Registers and preregistration practice [Nosek et al., 2018, Simmons et al., 2011, Gelman and Loken, 2013, Ioannidis, 2005]	why the default status is FLAGGED	**3 — analogy.** A verification register is not a preregistration and is not claimed to be one
An index adopted as a target [Goodhart, 1975, Campbell, 1979]	the warning attached to publishing N as a design objective	**3 — analogy**, with a mechanical rather than a behavioural cause
Resilience as a property of a system rather than of a component [Holling, 1973, Hollnagel et al., 2006, Leveson, 2011]	why the annual re-run is part of the method	**3 — analogy**
Coordination cost rising with the number of parts [Brooks, 1975, Conway, 1968]	why C grows at least linearly in the legs	**2 — shared form**
Research-programme badging [Lakatos, 1970, Platt, 1964, Meehl, 1990]	what a badged postulate is doing	**3 — analogy**
The grammar of conserved quantities [Mirowski, 1989, Cartwright, 1999]	flagged against the framework, not borrowed	**not a borrowing — a warning**

The three sentences the corpus requires. *The theorem:* $\ln(1) = 0$, so a single-perimeter structure has a surplus term of exactly zero — arithmetic, and checkable in a second. *The ordinary effect:* jurisdictions that coordinate tend to act together, which is an ordinary observation about policy and needs no formalism. *The conjecture:* that a structure's resilience against arbitrary action is a computable function of its perimeter geometry, and that h mea-

sures whether the structure sustains itself, is **this framework's own proposal**, is not derived from anything cited, and is not established by any result in this paper.

6.6 The postulates

	postulate	status
P1	The stipulated shares, parameters and fee scales are as printed.	DEFINITION (constructed)
P2	A coordination perimeter is a set of jurisdictions that act together, so their shares add before squaring.	POSTULATED — the framework's own test; **contestable, and the load-bearing input**
P3	$1/\text{HHI}$ is the right reading of an effective count.	CITED [Hirschman, 1964, Hill, 1973]
P4	$h = \eta \ln N - \delta Q - C$ is the right steady-state condition.	MODELLING CHOICE, inherited [Curzi, 2026]
P5	Jurisdictions inside one perimeter fail together.	**POSTULATED — the empirical premise of the collapse step, and it is asserted rather than measured**
P6	The legal citations consolidated in Appendix D exist and say what the source says.	**DESCRIBED — uncited; FLAGGED by default**

Dropped as unnecessary. No postulate about which jurisdictions, which entities or which currency is needed for any result: every figure is a property of a partition and four stipulated parameters, and survives the substitution of any other labels.

6.7 The chain a reader can check in a minute

step	consumes	produces	status
L1	P1	conventional shares 40.9 / 27.3 / 18.2 / 13.6; $\sum w_i^2 = 0.293430$	ARITHMETIC
L2	L1, P3	naive effective jurisdictions $= 3.407968$	ARITHMETIC
L3	L1, P2	one perimeter at 100.0; bloc HHI $= 1.000000$	ARITHMETIC given P2
L4	L3, P3	$N = 1.000000$; $\ln N = 0$	ARITHMETIC
L5	L4, P1, P4	$h = 0.35 \times 0 - 0.02 \times 10 - 0.30 = -0.500000$	ARITHMETIC

step	consumes	produces	status
L6	P1	designed shares; $\sum w_i^2 = 0.189002$; $1/\text{HHI} = 5.290949$	ARITHMETIC
L7	L6, P2	perimeters 40.0 / 30.0 / 30.0; bloc HHI $= 0.340000$	ARITHMETIC given P2
L8	L7, P3	$N = 2.941176$; $\ln N = 1.078810$	ARITHMETIC
L9	L8, P4	$h = 0.35 \times 1.078810 - 0.500000 = -0.122417$ — **R2**	ARITHMETIC
L10	P4	$N^* = \exp(0.500000/0.35) = 4.172734$	ARITHMETIC
L11	P4	$\mathrm{d}h/\mathrm{d}N = \eta/N$; 0.377583 then 0.107620 — **R3**	ARITHMETIC
L12	P1	rail shares; 1.000000 as found, 2.810568 as designed — **R4**	ARITHMETIC
L13	P1	$120{,}000/0.0035 = 34.2857$m; $/0.0015 = 80.0000$m; $/0.0010 = 120.0000$m — **R5**	ARITHMETIC
L14	P1	6.70m capped; $27.00/6.70 = 4.0299$; $33.84/240.00 = 14.1000\%$ — **R6**	ARITHMETIC

Two checks take a reader under a minute each. $0.409^2 + 0.273^2 + 0.182^2 + 0.136^2 = 0.293430$, and its reciprocal is 3.407968. Then $0.400^2 + 0.300^2 + 0.300^2 = 0.340000$, whose reciprocal is 2.941176, and $0.35 \ln(2.941176) = 0.377583$. **Everything else in the workbook is the same two operations repeated.**

6.8 What this chain is and is not

Read the status column. L3 and L7 consume P2 — the perimeter partition — and **every headline number in this paper depends on it.** P2 is a judgement argued from evidence in the jurisdiction papers and not a measurement, and P5, the premise that jurisdictions inside one perimeter fail together, is **asserted rather than measured anywhere in the corpus.**

So the chain establishes that the arithmetic is correct and establishes nothing about the world. A reader who accepts the partition gets the numbers; a reader who rejects it gets different numbers from the same procedure, which is the property that makes the procedure useful. **The instrument prices a disagreement rather than settling it**, and §6.4 gives the size of the disagreement that would matter.

7. Limitations

This paper is a compression and every cell in it is smaller than the assessment it compresses. No cell in the atlas should be relied on without reading the paper it points to and the verifica-

tion register that paper carries, and §A.5 says so at the point of use.

The perimeter partition is the load-bearing input and it is a judgement. Every value of N, and therefore every value of h, rests on it. It is argued from published evidence, it is contestable, and its sensitivity is measured (§6.4) rather than assumed away.

The premise that jurisdictions inside one perimeter fail together is asserted and not measured. It is the empirical claim on which the collapse step depends, the network literature that would make it plausible is cited for shape rather than for evidence [Buldyrev et al., 2010, Albert et al., 2000, Cohen et al., 2000], and **no correlation between jurisdictional outcomes is estimated anywhere in the corpus.**

Publishing N as an objective would change what it measures. An indicator adopted as a target ceases to be the indicator it was [Goodhart, 1975, Campbell, 1979], and a structure assembled to raise a count rather than to raise independence would satisfy the instrument while defeating its purpose. **The method has no defence against that except the perimeter test being argued from evidence each time**, and §5.7 says the same thing about the assignment.

The four test parameters are stipulated and drive every reported surplus. $\eta = 0.35$, $C = 0.30$, $Q = 10$, $\delta = 0.02$ are constructed values. **A real structure requires each estimated from its own facts, and C is the term most likely to be wrong in the direction that flatters the answer**, because it is paid continuously in small amounts to many parties and never appears as a line item — and because coordination cost across parts grows at least linearly and often faster [Brooks, 1975, Conway, 1968].

No legal source is cited anywhere in this paper. Appendix D consolidates several hundred statutes, conventions, court rules and decided cases; **its default status is FLAGGED FOR VERIFICATION and only definitional and arithmetic facts are marked verified.** This paper's bibliographic database contains none of the primary sources, no citation is attached to any of them, and **no approximate citation has been substituted for a missing one.** That is a real gap and it is not closed here.

The item counts, the atlas and the index are as current as the source that generated them. The extraction is regenerable and a later revision that yields different counts has found a change rather than an error, which Appendix D.2 states in place.

The dimensional audit does not close for η (§6.1), and Q carries index units with no currency attached, so **the absolute value of h means nothing**; only its sign and differences in it are used.

No statistical claim is made and none is supported. There are no p-values, effect sizes, intervals, samples or fitted models in this paper. No model comparison, out-of-sample test, matched null or information criterion is reported, because nothing was fitted, and no distributional or scaling claim is made, so Clauset et al. [2009] is not applicable and was not run.

And the paper's own status limits what any of it is worth. It advances no testable hypothesis (§2). Its two new computations are arithmetic on constructed inputs. **Its most useful content is the register of four admissions in §5, all of which are negative, and the FLAGGED default in Appendix D, which is a statement about how much of the series has not been verified.**

8. Conclusion

The method reduces to seven steps and the first one carries the whole result. Collapse jurisdictions onto coordination perimeters before measuring, because $\ln(1.00) = 0$: **a structure with one effective perimeter has zero available surplus, not a low one**, and no rearrangement of entities inside that perimeter changes it. Then assign one job per entity, apply the disclosure test, price each marginal jurisdiction as a break-even probability rather than arguing it, size leverage from the drawdown the structure must survive rather than from the loan, verify and record where the framework refused to guess, and re-run the whole thing annually with a named owner and a date.

Reproduced end to end, the arithmetic is this. The conventional structure reads naive HHI **0.293430** and **3.407968** effective jurisdictions but bloc HHI **1.000000**, giving $N = 1.000000$ and $h = -0.500000$. The designed structure reads naive HHI **0.189002** and **5.290949** effective jurisdictions against bloc HHI **0.340000**, giving $N = 2.941176$ and $h = -0.122417$, with Western-perimeter exposure falling from **100.0 to 30.0 per cent**. Break-even is $N^{*} = \exp(0.5/0.35) = 4.172734$, and because $\mathrm{d}h/\mathrm{d}N = \eta/N$ the move from one perimeter to 2.941176 buys **0.377583** while the move from 2.941176 to 4.000000 buys **0.107620** — **28.5 per cent as much.** The rail axis is measured separately and reads **1.000000** effective clearing system as found against **2.810568** as designed, with four effective systems requiring the dollar share to fall from 55.00 to approximately **38.99 per cent** — a level set by revenue currency and not by structure.

Two computations are given here in full for the first time and both cut against the way the instruments they concern are usually sold. Against a constructed USD 120,000 fixed mandate, a foundation is cheaper than a trustee charging ad valorem only above **USD 34.2857 million at 35 basis points, USD 80.0000 million at 15, and USD 120.0000 million at 10** — so **cost is explicitly not the reason to choose the form**; recognition in civil-law and Sharia jurisdictions is. And the succession residual is an asymmetry rather than a win: a notional reserved share of USD 60.00 million capped to a **USD 6.70 million** compensatory levy — 11.1667 per cent — and eliminated by design, against an inheritance-tax exposure of approximately **USD 27.00 million**, **4.0299 times larger**, that the structure does not touch, and a liquidity shortfall of **USD 33.84 million**, **14.1000 per cent of the estate**, sufficient to force the sale of an operating branch.

The four admissions, stated without qualification, are the paper's most useful content. Both the conventional and the designed structures remain below the build threshold: diversification raises the ceiling and does not pay the maintenance bill. Disclosure did not prevent the 2022 immobilisation: it removes the failure mode in which a structure collapses on contact with an authority and makes the structure bankable, and it supplies no appeal. Cost is not the reason to choose a foundation. And the succession structure addresses the smaller of the two exposures.

What this paper is. Reference apparatus: a consolidated procedure, a reproduction workbook whose every input is printed, an atlas keyed to the papers it compresses, an index whose **default status is FLAGGED FOR VERIFICATION**, a register of the corpus's own corrections, and a correspondence appendix that names four things which do not transfer. **It advances no hypothesis and establishes nothing new about the world.** Its contribution is that after it, every number in Series D can be recomputed by a reader who disagrees with it — and the register of what the series has not verified is longer than the register of what it has.

Declarations

Data and code availability

No external dataset was collected, and none is reported. Every result in this paper is exact arithmetic on stipulated, **CONSTRUCTED** inputs printed at the point of use: two jurisdiction allocations with their perimeter assignments, four test parameters, a fee scale, an estate value, a pledged position, and a set of scored job vectors. Appendix B reproduces the workbook in full, with every input, every intermediate value and the precision rule under which they were computed. **No real family, entity, transaction, market or institution is described anywhere in this paper**, and no allegation is made about any of them. The historical institutions treated from the public record elsewhere in the series are indexed here and not re-described.

This paper contains no figures, and none is claimed; the reproduction is tabular and the diagrams of Appendix C are schematic layouts built from the same stipulated allocations.

No legal source is cited. The statutes, conventions, court rules and decided cases consolidated in Appendix D are described from the source manuscript, are **FLAGGED FOR VERIFICATION** by default, and are attached to no citation because this paper's bibliographic database contains none of them.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the analysis, performed all computations, produced all tables, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data were processed. Every principal, family, entity and transaction described is constructed.

No operational content, and no allegation

This paper contains no operational content of any kind. It supplies no method for evading any legal process, sanctions regime, tax obligation or disclosure requirement. It recommends **no** structure premised on non-disclosure, because such a structure fails the governing principle by construction, and **no** nominee arrangement where nominees are unlawful. **No allegation is made about any person, institution, jurisdiction or state.**

Legal, tax and investment advice

This paper is analytical and is not legal, tax, accounting or investment advice. It describes an accounting and measurement procedure, its inputs, and what the procedure does not do. No recommendation is made in respect of any person, institution, product, instrument or jurisdiction, and no jurisdiction assessed in the atlas is recommended or disparaged. **Counsel is required in each relevant jurisdiction — residence, nationality, beneficiary location, asset situs, and the situs of every counterparty — and every element must be confirmed against the primary sources itemised in Appendix D before any reliance.** The framework is a map and not a permission.

Appendix A. Scorecard atlas

A.1 How to read this atlas

Every jurisdiction paper closes with the twelve-item scorecard fixed by the twelve-item scorecard. This appendix collects all of them into one table so that the comparisons the framework makes section by section can be made column by column instead.

The twelve items, in order:

```
1  Legal family                     7  Beneficial-ownership regime
2  Bloc alignment                   8  Rail access
3  Court quality                    9  Political stability
4  Foreign judgment recognition    10  DEGRADATION TRAJECTORY + evidence
5  Substance requirements          11  Job: HOLDING / OPERATING / BRIDGING
6  CRS / FATCA status              12  Verdict + what would change it
```

Item 10 is the thesis operationalised. Item 11 prevents the commonest structural failure — one entity asked to do three jobs. Items 10 and 11 are the two columns to read first, and item 12 is the only one that tells a reader what to do.

Three conventions apply throughout and each is load-bearing.

The split-trajectory convention. Where item 10 is genuinely non-uniform, the assessment splits and refuses to average. Singapore is the origin — stable to improving on institutional quality, improving on regulatory credibility, eroding on bloc independence — and averaging those to "stable" would be exactly wrong on the one axis the structure buys.

Bloc alignment is a coordination question, not a legal-family question. Ireland is common law and sits in the Western perimeter by construction; Thailand is civil law and is non-aligned. The axes are independent and conflating them is the error the coordination-perimeter analysis was written to prevent.

The cells below are compressions. Each is a pointer into a section that argues the assessment with dated evidence. **No cell in this atlas should be relied on without reading the section it compresses and the Verification Register that section carries.**

A.2 The master table

Thirty-three assessments across twenty-three sections. The DIFC appears twice because the foundation assessment and the bridging assessment score it for two different jobs and reach two different answers, which is itself an illustration of item 11.

Jurisdiction	paper	1 Family	2 Bloc	3 Court	4 Recognition	5 Substance
DIFC (as holding)	053	Codified common-law-derived	BRIDGE	High; DIFC Courts, published precedent	Mixed; onshore via Judicial Authority Law; conduit question open	Low for a holding foundation
United Kingdom	054	Common law, source jurisdiction	WEST, at the centre	Very high; Commercial Court	Mixed, materially worse since Brexit	Real and conventional
Jersey	054	Common law, Norman substrate	WEST	High; Royal Court to Privy Council	Statutory reciprocal + common law	Real from 1 Jan 2019
Guernsey	054	Common law, Norman substrate	WEST	High; Royal Court to Privy Council	Statutory reciprocal + common law	Real from 1 Jan 2019
Isle of Man	054	Manx common law; two company regimes	WEST	High; High Court to Privy Council	Statutory reciprocal + common law	Real from 1 Jan 2019
Luxembourg	054	Civil, deep financial corpus	WEST by construction	Good and improving; fund depth	Strong within EU and EFTA	Real and rising
Ireland	054	Common law, EU member state	WEST by construction	High; Commercial list	Strong; Brussels Recast, Lugano	Real; tightened from 2015
Netherlands	054	Civil; STAK; NCC	WEST by construction	High; Netherlands Commercial Court	Strong; Brussels Recast, Lugano	Real and enforced
Switzerland	054	Civil, cantonal; no domestic trust law	WEST — contestable, resolved on evidence	High; strong arbitration seat	Strong; Lugano party	Real; effective management tests
Bermuda	055	English common law	W-LITE	High; deep insurance bench	Common law + statutory reciprocal	Real; higher for insurers than ESA requires
Cayman Islands	056	English common law	WEST	High; Financial Services Division	Common law + statutory reciprocal	Real from 1 Jan 2019
British Virgin Islands	056	English common law; ECSC	WEST	High and improving	Common law + statutory reciprocal	Real from 1 Jan 2019
The Bahamas	056	English common law; sovereign since 1973	WEST notwithstanding sovereignty	Good; below Cayman and BVI	Common law + statutory reciprocal	Real; CESRA 2018
Barbados	056	English common law; republic 2021	WEST	Adequate to good; CCJ	Common law + reciprocal arrangements	Real, arrived by the harmful-tax route
ADGM	056	English common law by direct application	BRIDGE	High; ADGM Courts	Mixed; onshore enforcement the weak item	Low by design for holding and SPV forms
DIFC (as bridging)	056	Codified common-law-derived; English law residual	BRIDGE	High; strongest published-precedent depth in region	Weak, and weaker for a bridge than a holding	Low passive; real if DFSA-regulated
Qatar / QFC	057	Hybrid, split by regime	BRIDGE (GCC)	Good; QICDRC	Mixed and under-tested	Moderate; may operate anywhere in Qatar

Jurisdiction	paper	1 Family	2 Bloc	3 Court	4 Recognition	5 Substance
Saudi Arabia	057	Sharia-based with codified Royal Decrees	GCC; increasingly multi-aligned	Improving and under-tested	Awards workable; judgments harder	High, deliberately — that is the RHQ product
Singapore	057	Common law, self-consciously divergent	BRIDGE commercially; Western under stress	Very high; SICC	Good but narrower than the reputation	Real and rising
Hong Kong	057	Common law continued by Basic Law Art. 8	Inside two perimeters, independent of neither	High ordinary; qualified extraordinary	Mixed and asymmetric	Now real for tax purposes
AIFC (Astana)	058	English-derived common law by reception	Genuine bridge; least certainty attached	High in design, thin in authority	The weakest item, and it decides the design	Registration + AFSA licensing
Thailand	058	Civil; Civil and Commercial Code	NON-ALIGNED, genuinely	Adequate for its role; not a selling point	Weak — plan around it	High, cheap and genuine
GIFT City	058	Common-law-derived, inside India	NON-ALIGNED, genuinely and durably	The weakest item; determines the job	Mixed and technical	Real and specific
Türkiye	059	Civil, Swiss and Germanic line	The most genuinely ambiguous in the series	Adequate on substance, uncertain on predictability	Conditional on reciprocity	Real and inexpensive
Mauritius	059	Mixed: French civil + English commercial	NON-ALIGNED; Indian Ocean and Africa	High for the region and unusual	Statutory + common law + New York Convention	Real and audited, in two layers
Rwanda (KIFC)	059	Converging mixed	NON-ALIGNED, multi-vector	Unmeasured, which is not low	Verify — including New York Convention status	Certification conditions; verify
Kenya (NIFC)	059	Common law by reception	NON-ALIGNED; Western in security, Chinese in infrastructure	Genuinely good; demonstrated on the hardest test	Reciprocating list + common law	Ordinary residence + NIFC certification
Labuan IBFC	059	Tri-partite: common, civil, Sharia	NON-ALIGNED, ASEAN-anchored	Good and demonstrated	Reciprocating list + common law	Real, prescribed, annual, with a cliff edge
Bahrain	059	Civil with substantial Sharia influence	Gulf bridge; less independent than the UAE	Moderate	New York Convention + GCC and Arab League conventions	Licensing-based under the CBB Rulebook
Panama	060	Civil; Law 32 of 1927	Western hemisphere; United States-coupled	Mixed and genuinely two-sided	Exequatur, reciprocity and public policy	Territoriality by where activity is carried on
Uruguay	060	Civil, nineteenth-century code	Least United States-coupled among the Latin American and African assessments	Good by regional standards	Supreme Court + Inter-American instruments	Real for the free-zone regime
Paraguay	060	Civil, 1985 code	Non-aligned in form, pre-committed in substance	The weakest in the section	Statutory exequatur + Mercosur	Maquila requires a genuine export operation
Costa Rica	060	Civil; 1949 constitutional order	WEST by deliberate choice; OECD 25 May 2021	Good; Constitutional Chamber since 1989	Exequatur + Inter-American instruments	Real and recently tightened

Jurisdiction	6 CRS / FATCA	7 Beneficial ownership	8 Rails	9 Stability
DIFC (as holding)	UAE participating; DIFC inside it	Registrar UBO regime; not publicly searchable	SWIFT; dual-rail optionality at the UAE bank layer	High regionally; policy can move without a legislative cycle
United Kingdom	Full; CRS first exchanges 2017	PSC register, public — the most transparent in the series	SWIFT, deep; sterling clearing through the Bank of England	High
Jersey	Full; CRS early adopter, 2017	Central register, not public; competent-authority access	SWIFT only; no CIPS-side access	High
Guernsey	Full; CRS early adopter, 2017	Central register, not public	SWIFT only; no CIPS-side access	High
Isle of Man	Full; CRS early adopter, 2017	Central register, not public	SWIFT only; inside the UK indirect-tax territory	High
Luxembourg	Full; CRS via the administrative cooperation directive	Public access struck down 22 November 2022; authorities retain access	SWIFT, TARGET, SEPA; deep euro clearing	Very high domestically; externally rule-taking

Jurisdiction	6 CRS / FATCA	7 Beneficial ownership	8 Rails	9 Stability
Ireland	Full	Register from 2019; public access suspended	SWIFT, TARGET, SEPA	High, with documented corporation-tax concentration
Netherlands	Full; DAC8 from 1 January 2026	UBO register 2020; public access suspended 22 November 2022	SWIFT, TARGET, SEPA; large payments sector	High institutionally; moderate on rule stability
Switzerland	Full; MCAA 19 Nov 2014, AEOI Act 18 Dec 2015	No EU-style public register; identification through institutions	SWIFT; CHF clearing through SNB and SIC	Among the highest on process
Bermuda	CRS participating; MCAA signatory	Collected for decades; not publicly searchable	SWIFT; USD-centric, dollar-pegged	High
Cayman Islands	CRS from 2017; FATCA IGA	Beneficial Ownership Transparency Act 2023, commenced 2024	SWIFT; dollar-pegged; no CIPS relevance	High
British Virgin Islands	CRS participating; FATCA IGA	Registry filing regime; verify commencement and access	SWIFT; USD is legal currency	High
The Bahamas	CRS participating; FATCA IGA	Register accessible to competent authorities; not public	SWIFT; dollar-pegged	Moderate to high
Barbados	CRS participating; FATCA IGA	Register maintained; competent-authority access	SWIFT; dollar-pegged	Moderate
ADGM	UAE participating; ADGM inside it	Registration Authority regime; competent-authority access	SWIFT; dual-rail optionality at the UAE bank layer	High
DIFC (as bridging)	UAE participating; FATCA through the UAE arrangement	DIFC Registrar UBO regime	SWIFT; genuine multi-currency and multi-counterparty depth	High
Qatar / QFC	CRS participating; FATCA arrangement	QFC-level regime; competent-authority access	SWIFT; riyal pegged; CBDC project	High
Saudi Arabia	CRS participating; full FATF member since 2019	Commercial registry with beneficial-ownership requirements	SWIFT; riyal pegged	Moderate to high
Singapore	Fully participating; CRS 2018; FATCA Model 1	ACRA register of registrable controllers; not public	SWIFT; multi-currency depth; RMB clearing bank since 2013	Very high
Hong Kong	Participating under the Inland Revenue Ordinance	Significant controllers register since March 2018	Deepest offshore renminbi clearing capability available	Contested; see item 10
AIFC (Astana)	Kazakhstan participates; verify commencement	AIFC filings plus the national register	SWIFT through a small, concentrated banking sector	Improving; one stress event survived
Thailand	CRS participant; FATCA arrangement	DBD filings plus AML obligations	SWIFT; exchange control through authorised agents	Moderate
GIFT City	India participating; FATCA arrangement	Significant beneficial owner regime under Indian company law	SWIFT plus lawful rupee-corridor access	High continuity; moderate policy volatility
Türkiye	CRS participant; staged exchange relationships	Identified under the AML framework	SWIFT; large, internationally connected banking sector	Institutionally continuous, politically volatile
Mauritius	Participating; FATCA arrangement	Registrar plus licensed management companies	SWIFT; correspondent depth is the constraint	Moderate to high
Rwanda (KIFC)	Verify, and treat as gating	Verify the register, its keeper and its access	SWIFT; limited correspondent depth	Improving with an unmitigable tail risk
Kenya (NIFC)	CRS regulations enacted; FATCA arrangement	Companies (Beneficial Ownership Information) Regulations, 2020	SWIFT plus the deepest mobile-money infrastructure in Africa	Volatile

Jurisdiction	6 CRS / FATCA	7 Beneficial ownership	8 Rails	9 Stability
Labuan IBFC	Malaysia participating; Labuan inside it	Collected through licensed trust companies and the LFSA	SWIFT plus ringgit and offshore-dollar depth	High
Bahrain	CRS participant; FATCA arrangement	Collected through commercial registration	SWIFT; dollar-pegged; regional wholesale role	Moderate
Panama	CRS participant; FATCA arrangement	Private centralised registration under Law 129 of 2020	SWIFT; dollarised, dollar clearing via US correspondents, no lender of last resort	Moderate
Uruguay	CRS from the first wave; FATCA arrangement	Central bank registry from 2012, extended since	SWIFT; own currency and central bank	High by regional standards
Paraguay	Verify commencement and current exchange status	Framework exists under AML legislation	SWIFT; shallow sector, limited correspondent depth	Uncertain
Costa Rica	CRS participant; FATCA arrangement; OECD peer review	Register through the central bank system	SWIFT; own currency, dollarised private deposits in practice	Moderate

Jurisdiction	10 DEGRADATION TRAJECTORY	11 Job	12 Verdict
DIFC (as holding)	IMPROVING, from a base that briefly worsened — FATF Mar 2022 to Feb 2024, then corporate tax and a UBO regime	HOLDING, unambiguously	Use it as the apex
United Kingdom	ERODING on differentiation and optionality; improving on institutional integrity	OPERATING; narrow bridging; never holding	Use it, size it, never let it grow
Jersey	STABLE on capability, ERODING on differentiation	HOLDING, subordinate — never the apex	Use for trust technology; never to raise N
Guernsey	STABLE on capability, ERODING on differentiation	HOLDING with a genuine cell specialisation	Use for cells and captives
Isle of Man	STABLE on capability, ERODING on differentiation	OPERATING — the one Crown Dependency whose job is not holding	Registries and asset ownership; not the apex
Luxembourg	ERODING on differentiation; IMPROVING on privacy; STABLE on capability	OPERATING (regulated funds, securitisation)	Funds and securitisation only; never a conduit
Ireland	ERODING sharply on tax differentiation; STABLE to IMPROVING on legal and operating	OPERATING, unusually strong	Leasing, funds, securitisation; not the apex

Jurisdiction	10 DEGRADATION TRAJECTORY	11 Job	12 Verdict
Netherlands	ERODING on differentiation — largely self-inflicted and deliberate	HOLDING in one narrow sense (the STAK) plus OPERATING	Use the STAK; never a conduit
Switzerland	ERODING — the longest-running erosion in the series; bloc position confirmed rather than degraded	BRIDGING in one narrow sense (custody, CHF) plus OPERATING	Custody and CHF; never the apex; not a separate bloc
Bermuda	STABLE to IMPROVING on institutional quality; the zero-tax proposition is over	OPERATING with a HOLDING consequence	One job: funding a real retained exposure
Cayman Islands	STABLE, after a genuine deterioration that has been repaired	HOLDING, institutional sense only	Where unrelated third parties expect it; not family holding
British Virgin Islands	ERODING on the product; IMPROVING on the institution	HOLDING, narrowly — one clean SPV	Single-purpose vehicles only; never an apex
The Bahamas	STABLE, from a worse base, with an unrepaired reputational component	HOLDING, private-client sense	Only where a specific Bahamian instrument is unique
Barbados	ERODING as a haven; CONVERGING as a normal treaty jurisdiction	OPERATING (licensed insurance) plus narrow holding	Only with a real Canada or CARICOM corridor
ADGM	IMPROVING, faster than any comparable centre	HOLDING — intermediate	The intermediate holding layer; elect ADGM law group-wide
DIFC (as bridging)	IMPROVING, from a base that measurably worsened and recovered — the round trip is the evidence	BRIDGING plus genuinely-needed regulated activity	Apex, banking, and a licence only if one is truly needed
Qatar / QFC	IMPROVING, steadily and without drama	OPERATING	Only with real Qatari activity; never a second Gulf holding layer
Saudi Arabia	IMPROVING materially, from a low base, on a short record	OPERATING and market access; nothing else, ever	Enter for revenue only; hold nothing there

Jurisdiction	10 DEGRADATION TRAJECTORY	11 Job	12 Verdict
Singapore	STABLE institutional / ERODING bloc independence / IMPROVING regulatory credibility — do not average	BRIDGING primarily; narrow secondary holding	Use for bridging, sized on capability not bloc arithmetic
Hong Kong	ERODING on the axis this series buys, with dated evidence and a visible direction	BRIDGING only, and transit rather than store	Narrow, capped, swept, with a live migration path
AIFC (Astana)	IMPROVING from a low base, with genuine uncertainty and one stress test survived	HOLDING, narrow and ring-fenced; BRIDGING in one respect	Small, once, and simply — and take the arbitration clause regardless
Thailand	STABLE on ownership framework; TIGHTENING on tax; IMPROVING on transparency	OPERATING, exclusively	The operating leg, on a BOI basis, with nothing held or swept through it
GIFT City	IMPROVING, with the upside capped by the same structural reason	BRIDGING — specifically the rupee corridor	A bounded corridor with a stated maximum balance and dwell
Türkiye	IMPROVING on standards and institutions; UNRESOLVED on the currency, and the second decides it	OPERATING; holding prohibited outright	Operate; never hold
Mauritius	ERODING as a fiscal proposition; IMPROVING as an institutional one	HOLDING and BRIDGING for Africa; never operating	Where the treaty and the protection agreement do real work
Rwanda (KIFC)	IMPROVING, from a very short base, with a specific unmitigable tail risk	WATCH, moving toward OPERATING	Establish the relationship; run the scorecard annually; do not concentrate
Kenya (NIFC)	MIXED — tax and AML lines moving in opposite directions	OPERATING, unambiguously — the best operating base among the Latin American and African assessments	Operate; cap the share; do not hold
Labuan IBFC	STABLE to IMPROVING; the offshore concession already surrendered	BRIDGING primarily, HOLDING secondarily, never the apex	Islamic issuance and structuring; verify the treaty position entity by entity

Jurisdiction	10 DEGRADATION TRAJECTORY	11 Job	12 Verdict
Bahrain	STABLE on standards; ERODING on fiscal exceptionalism; structurally challenged	BRIDGING and standards-facing, not holding	Engage as the standards jurisdiction; do not concentrate capital
Panama	IMPROVING on standards from a poor base; structurally exposed to recurrence	OPERATING plus limited regional bridging	Regional trade and logistics; never protected capital
Uruguay	STABLE — the transparency degradation already completed, institutions untouched	OPERATING and personal RESIDENCE	The best residence and operating jurisdiction among the Latin American and African assessments
Paraguay	UNCERTAIN, and the uncertainty is itself the finding	OPERATING only — export manufacturing under the maquila regime	Manufacture only; resolve the open items before committing anything
Costa Rica	IMPROVING institutionally; CONVERGING fiscally, forced from outside in under a year	OPERATING at genuine quality, and RESIDENCE	A high-quality operating and residence jurisdiction; expect no bloc benefit

A.3 Sorted by job — item 11

The single most useful re-sort in the atlas, because the three-jobs diagnostic's rule is that an entity gets one job and the atlas makes the shortage visible.

```
HOLDING -- an apex candidate
  DIFC (Ch 7)                    the framework's answer; the only unqualified apex

HOLDING -- intermediate or subordinate, never the apex
  ADGM (Ch 17)                   intermediate holdco beneath the Foundation
  Jersey, Guernsey (Ch 11)       excellent instruments inside one perimeter
  Cayman, BVI, Bahamas (Ch 16)   institutional or single-purpose only
  Netherlands -- STAK (Ch 12)    control separation, not ownership
  Mauritius (Ch 26)              Africa-facing regional holding
  Labuan (Ch 27)                 secondary to its bridging job
  AIFC (Ch 22)                   narrow, ring-fenced fourth-bloc position

OPERATING
  Thailand (Ch 23)               the operating leg; highest operating score in the series
  United Kingdom (Ch 10)         real trade, real staff, full accounts
  Isle of Man (Ch 11)            registries and asset ownership
  Luxembourg, Ireland (Ch 12)    regulated funds, leasing, securitisation
  Netherlands, Switzerland (12)  genuine operations alongside their narrow specialisms
  Bermuda (Ch 14)                licensed underwriting with a holding consequence
  Barbados (Ch 16)               licensed insurance with a corridor
```

```
  Qatar (Ch 19)                only with real Qatari activity
  Saudi Arabia (Ch 19)         revenue and market access, nothing else
  Türkiye (Ch 25)              operating only; holding prohibited
  Kenya (Ch 26)                the best operating base in its group
  Panama, Uruguay, Paraguay,
    Costa Rica (Ch 28)         trade, residence, and manufacture

BRIDGING
  DIFC (Ch 18)                 apex banking and regulated activity
  Singapore (Ch 20)            treasury, settlement, FX, Asian contracting
  Hong Kong (Ch 21)            transit only, capped and swept
  GIFT City (Ch 24)            the rupee corridor, bounded
  Labuan (Ch 27)               Islamic issuance and structuring
  Bahrain (Ch 27)              standards and wholesale funding
  Switzerland (Ch 12)          custody and CHF exposure
  Mauritius (Ch 26)            Africa-facing neutral forum

WATCH -- not yet assignable
  Rwanda (Ch 26)               establish the relationship; re-run annually
```

Two observations the sort makes unavoidable. **The holding column is short and the operating column is long, which is the correct shape**: apex capability is scarce, and a structure that treats the two as interchangeable ends up holding value in an operating jurisdiction. And **eight of the nine bridging entries carry an explicit cap, a sweep, a bound, or a "narrow"** — bridging is the job most likely to be over-sized.

A.4 Sorted by degradation trajectory — item 10

```
IMPROVING
  DIFC (7, 18)     UAE round trip through the FATF listing is the evidence
  ADGM (17)        fastest-improving centre in the series
  Qatar (19)       steady, undramatic
  Saudi Arabia (19) materially, from a low base, on a short record
  AIFC (22)        from a low base, with genuine uncertainty
  GIFT City (24)   with the upside capped by the same structural reason
  Rwanda (26)      from a very short base, with an unmitigable tail risk
  Costa Rica (28)  institutionally, while converging fiscally
  Panama (28)      from a poor base, structurally exposed to recurrence

STABLE
  Cayman (16)      after a deterioration that has been repaired
  Bahamas (16)     from a worse base, reputational component unrepaired
  Bermuda (14)     institutional quality; the zero-tax proposition is over
  Uruguay (28)     degradation already completed; institutions untouched
  Labuan (27)      offshore concession already surrendered

ERODING
  United Kingdom (10)   differentiation and optionality, not quality
  Jersey, Guernsey,
    Isle of Man (11)    differentiation, which was the only thing bought
  Luxembourg (12)       differentiation, at premium cost
  Ireland (12)          tax differentiation, sharply
  Netherlands (12)      differentiation, self-inflicted and deliberate
  Switzerland (12)      the longest-running erosion documented in the series
  BVI (16)              the product erodes while the institution improves
```

```
  Barbados (16)         as a haven; converging as a normal treaty jurisdiction
  Hong Kong (21)        on the exact axis this series buys
  Mauritius (26)        as a fiscal proposition
  Bahrain (27)          fiscal exceptionalism

SPLIT -- refuses to average
  Singapore (20)   stable institutional / eroding bloc / improving regulatory
  Thailand (23)    stable ownership / tightening tax / improving transparency
  Kenya (26)       tax and AML lines moving in opposite directions
  Türkiye (25)     improving standards / unresolved currency

UNCERTAIN
  Paraguay (28)    and the uncertainty is itself the finding
```

The pattern is the framework's thesis in one column. **Every Western-perimeter entry is eroding on differentiation and none is eroding on quality.** The jurisdictions are not getting worse; they are getting more alike, which is a different problem and the one this series is about. The improving column is dominated by Gulf and non-aligned centres building institutions rather than dismantling them, and the erosion in Hong Kong is the one entry where the axis eroding is the axis being bought.

A.5 What the atlas does not contain

Four omissions, stated so that the table is not read as a completeness claim.

Cost. No `C` figure appears in any scorecard, in any section, or in this atlas. The Gulf-centre assessments, 18, 19, and 22 each state explicitly that the `C` term cannot be estimated without current fee schedules and that no figure in the section supplies one. **A reader who wants to compare jurisdictions on cost must obtain current fee schedules; this series supplies the method and refuses to supply the numbers.**

Bankability. Whether a specific bank will onboard a specific structure is the binding constraint on the whole architecture — the concentration paper's failure mode 11 — and it is a property of the bank, the group, the currency mix, and the year rather than of the jurisdiction. No column can hold it.

Jurisdictions not assessed. Where a section the manifest specifies is not on the page, its scorecard is not in this atlas, and Appendix D marks the gap.

The reader's own facts. Every item 12 verdict is written for the carried case: a dual national, UAE tax resident, three heirs in three jurisdictions, one in a forced-heirship civil-law state, with operations in Thailand, trade in the UAE, real estate in London, and a listed portfolio. Change any of those and several verdicts change with them.

Appendix B. The concentration workbook

Every figure in this appendix was recomputed in Python from the stated inputs at full precision and rounded only for printing. No figure was taken from a rounded print anywhere in the series. That discipline is not fastidiousness: computing `h` from the printed `N = 2.94` rather than from the exact `1/0.34` produces `\ensuremath{-}0.122557` instead of `\ensuremath{-}0.122417`, an error of 0.000140 — small, and large enough to move a break-even probability by more than a percentage point.

B.1 The instrument

```
HHI = sum over i of s_i^2          s_i = share of the total

effective count = 1 / HHI

Properties used throughout:
  - n equal shares give HHI = 1/n and effective count = n exactly
  - one share of 100% gives HHI = 1 and effective count = 1
  - the effective count is always at most the raw count, with
    equality only when the shares are equal
  - the measure is invariant to relabelling and to splitting a
    holder into two holders in the SAME bloc, which is precisely
    why bloc collapse must happen BEFORE the computation
```

The numbers-equivalent reading of `1/HHI` is conventionally attributed to M. A. Adelman's 1969 comment in the *Review of Economics and Statistics*. The attribution should be checked against the original; the mathematical property is elementary and does not depend on it.

The same instrument is used in the opposite direction by competition authorities. The 2023 DOJ/FTC Merger Guidelines set a structural presumption of unlawfulness at HHI above 1,800 with a change over 100 — on a scale of 10,000 rather than 1, which is the same number multiplied by 10,000. **You want HHI low on jurisdictional exposure, for resilience, and low enough on market share, to stay unchallenged. One metric, two directions, both binding.** Those thresholds are agency enforcement policy rather than statute, courts are not bound by them, and they have changed three times since 1982.

B.2 The conventional structure — 1.00 effective bloc

```
AS FOUND

  jurisdiction   share    bloc
  ------------------------------
  UK              40.9%   WEST
  US              27.3%   WEST
  Jersey          18.2%   WEST
  Luxembourg      13.6%   WEST
                  ------
                  100.0%

NAIVE, per jurisdiction
  HHI = 0.409^2 + 0.273^2 + 0.182^2 + 0.136^2
      = 0.167281 + 0.074529 + 0.033124 + 0.018496
      = 0.293430
  effective jurisdictions = 1 / 0.293430 = 3.407968

COLLAPSED TO BLOCS
  WEST 100.0%
  bloc HHI = 1.000^2 = 1.000000
  EFFECTIVE BLOCS = 1 / 1.000000 = 1.000000

  Western-perimeter exposure = 100.0%
```

Four entities, four jurisdictions, one point of failure. The gap between 3.407968 and 1.000000 is the entire subject of the concentration paper. Naive HHI overstates resilience because it treats jurisdictions as independent when they share a coordination mechanism,

and four Western jurisdictions do not fail independently — they fail on one decision, taken once, in one of the five interfaces the coordination-perimeter analysis traces.

B.3 The designed structure — 2.94 effective blocs

```
AS DESIGNED

  jurisdiction   share    bloc
  ------------------------------------
  UAE             29.1%   BRIDGE
  Thailand        18.2%   NONALIGNED
  UK              16.4%   WEST
  Bermuda         13.6%   WEST (W-LITE)
  India           11.8%   NONALIGNED
  Singapore       10.9%   BRIDGE
                  ------
                  100.0%

NAIVE, per jurisdiction
  HHI = 0.291^2 + 0.182^2 + 0.164^2 + 0.136^2 + 0.118^2 + 0.109^2
      = 0.084681 + 0.033124 + 0.026896 + 0.018496
        + 0.013924 + 0.011881
      = 0.189002
  effective jurisdictions = 1 / 0.189002 = 5.290949

COLLAPSED TO BLOCS
  BRIDGE      40.0%   (UAE 29.1 + Singapore 10.9)
  NONALIGNED  30.0%   (Thailand 18.2 + India 11.8)
  WEST        30.0%   (UK 16.4 + Bermuda 13.6)
              ------
              100.0%

  bloc HHI = 0.400^2 + 0.300^2 + 0.300^2
           = 0.160000 + 0.090000 + 0.090000
           = 0.340000
  EFFECTIVE BLOCS = 1 / 0.340000 = 2.941176

  Western-perimeter exposure = 30.0%

THE COMPARISON

                              AS FOUND    AS DESIGNED    CHANGE
  jurisdictions held               4            6          +2
  naive effective count      3.407968     5.290949      x1.5525
  EFFECTIVE BLOCS            1.000000     2.941176      x2.9412
  Western-perimeter exposure   100.0%        30.0%      -70.0pp
```

B.4 The storage law applied

```
h = eta ln(N) - delta Q - C

test parameters:   eta = 0.35   C = 0.30   Q = 10   delta = 0.02
so  delta Q = 0.200000  and  delta Q + C = 0.500000
```

```
CONVENTIONAL
  ln(1.000000) = 0.000000
  h = 0.35 x 0.000000 - 0.500000 = -0.500000

DESIGNED
  ln(2.941176) = 1.078810
  h = 0.35 x 1.078810 - 0.500000 = -0.122417

IMPROVEMENT in h = 0.377583
```

`ln(1.00) = 0`. The conventional structure has zero available surplus — not low, zero. `Q` decays at `delta` with nothing on the input side, and no rearrangement of those four entities changes it, because rearranging within a bloc does not change `N`. That single line is the reason the concentration paper owns the instrument and the reason `N` is defined as the effective bloc count rather than the entity count or the jurisdiction count.

And the honest companion result, which the assembled architecture and this synthesis both carry: both structures are below the build threshold at the tested parameters. `h = \ensuremath{-}0.500000` and `h = \ensuremath{-}0.122417` are both negative. Diversification raised the ceiling by 0.377583 and did not pay `delta Q + C = 0.500000`.

B.5 The break-even and the marginal value

```
BREAK-EVEN EFFECTIVE BLOC COUNT

  h = 0  requires  eta ln(N*) = delta Q + C
                   ln(N*) = 0.500000 / 0.35 = 1.428571
                   N* = exp(1.428571) = 4.172734

  designed structure reaches 2.941176
  shortfall in N = 1.231558
  shortfall in h = 0.122417

MARGINAL VALUE OF ONE MORE EFFECTIVE BLOC

  dh/dN = eta / N

  at N = 1.000000   dh/dN = 0.350000
  at N = 2.941176   dh/dN = 0.119000
  at N = 4.000000   dh/dN = 0.087500
  at N = 4.172734   dh/dN = 0.083879

THE DIMINISHING RETURN, in the values that matter

  1.000000 -> 2.941176   buys  0.377583
  2.941176 -> 4.000000   buys  0.107620    28.5% as much
```

The consequence for design: **the first move out of a single perimeter is worth roughly three and a half times the last move to the break-even**, and a structure at `N = 2.941176` should expect every subsequent leg to be harder to justify than the one before it. That is not a reason to stop. It is a reason to price each one.

B.6 V5 — the Qatar/Saudi result: more jurisdictions, fewer blocs

The framework's headline demonstration of the failure mode the concentration paper exists to catch.

```
AS TEMPTED -- add Qatar and Saudi, funded by trimming UAE, UK and Singapore

  jurisdiction   share    bloc
  ------------------------------------
  UAE             20.0%   BRIDGE (GCC)
  Thailand        18.2%   NONALIGNED
  Bermuda         13.6%   WEST
  UK              12.2%   WEST
  India           11.8%   NONALIGNED
  Saudi Arabia     9.1%   BRIDGE (GCC)
  Qatar            8.2%   BRIDGE (GCC)
  Singapore        6.9%   BRIDGE
                  ------
                  100.0%

  naive HHI = 0.200^2 + 0.182^2 + 0.136^2 + 0.122^2
            + 0.118^2 + 0.091^2 + 0.082^2 + 0.069^2
            = 0.140194
  effective jurisdictions = 1 / 0.140194 = 7.132973

COLLAPSED TO BLOCS
  BRIDGE      44.2%   (UAE + Saudi + Qatar + Singapore)
  NONALIGNED  30.0%   (Thailand + India)
  WEST        25.8%   (Bermuda + UK)

  bloc HHI = 0.442^2 + 0.300^2 + 0.258^2
           = 0.195364 + 0.090000 + 0.066564
           = 0.351928
  EFFECTIVE BLOCS = 1 / 0.351928 = 2.841490
  h = 0.35 x ln(2.841490) - 0.500000 = -0.134485

SIDE BY SIDE

                          DESIGNED     TEMPTED      CHANGE
  jurisdictions held          6           8           +2
  naive effective count   5.290949    7.132973     +34.8146%
  EFFECTIVE BLOCS         2.941176    2.841490      -3.3893%
  h                      -0.122417   -0.134485      -0.012068
```

Two more jurisdictions, a third more apparent diversification, and the honest count fell. Both effects run the same way: the additions are all in the bloc the structure was already heaviest in, and the funding came disproportionately from the two blocs supplying the diversification. The naive metric reports neither.

```
AS BUILT -- the priced alternative from Ch 19's Worked Application
Saudi RHQ at 5.0%, funded from the OPERATING allocation (Thailand 18.2 -> 13.2)

  UAE 29.1 BRIDGE · UK 16.4 WEST · Bermuda 13.6 WEST · Thailand 13.2 NONALIGNED
  India 11.8 NONALIGNED · Singapore 10.9 BRIDGE · Saudi 5.0 BRIDGE (GCC)

  naive HHI = 0.175802     effective jurisdictions = 5.688217

  blocs  BRIDGE 45.0%  WEST 30.0%  NONALIGNED 25.0%
  bloc HHI = 0.202500 + 0.090000 + 0.062500 = 0.355000
  EFFECTIVE BLOCS = 2.816901
```

```
  h = −0.137527

  PRICED LOSS versus the designed structure
    in N   −0.124275
    in h   −0.015110
```

A priced loss taken knowingly is legitimate; an unpriced one is the failure. The Saudi position costs 0.124275 of effective bloc count and is defensible if addressable Saudi state and state-linked revenue exceeds that cost. It is indefensible as diversification, because it is the opposite.

B.7 V3 — the Singapore control experiment

The cleanest demonstration in the paper that the gap between the naive and the honest count is real and not an artefact of any particular bloc assignment. Place the same 10.9% in London instead of Singapore.

```
SINGAPORE LEG (as designed)
  UAE 29.1 · Thailand 18.2 · UK 16.4 · Bermuda 13.6 · India 11.8 · Singapore 10.9
  naive HHI = 0.189002     effective jurisdictions = 5.290949
  blocs BRIDGE 40.0 / NONALIGNED 30.0 / WEST 30.0
  bloc HHI = 0.340000      N = 2.941176      h = −0.122417

LONDON INSTEAD -- the 10.9% added to the UK slot
  UAE 29.1 · Thailand 18.2 · UK 27.3 · Bermuda 13.6 · India 11.8
  naive HHI = 0.291^2 + 0.182^2 + 0.273^2 + 0.136^2 + 0.118^2
            = 0.224754
  effective jurisdictions = 1 / 0.224754 = 4.449309
  blocs BRIDGE 29.1 / NONALIGNED 30.0 / WEST 40.9
  bloc HHI = 0.084681 + 0.090000 + 0.167281 = 0.341962
  N = 2.924302              h = −0.124431

THE RESULT
  naive effective count   5.290949 vs 4.449309   difference 0.841640
  EFFECTIVE BLOCS         2.941176 vs 2.924302   difference 0.016874
  h                      −0.122417 vs −0.124431  difference 0.002014
```

Singapore's true marginal contribution to h, measured against simply putting the same money in London, is 0.002014. The naive metric reported 0.841640 of an effective jurisdiction — nearly a full unit of diversification — that did not occur.

The same arithmetic doubles as the robustness test for the bloc call itself. Reclassifying Singapore from BRIDGE to WEST produces exactly the London bloc vector — BRIDGE 29.1, NONALIGNED 30.0, WEST 40.9 — and therefore exactly the same `N = 2.924302` and `h = \ensuremath{-}0.124431`. **The argument most likely to be had about the whole allocation moves the answer by 0.002014, which is to say it does not move the answer.**

B.8 V2 — the Hong Kong result, and why the largest gain was declined

```
A: HONG KONG AS THE ASIAN CENTRE, at 10.9%, assigned to a CHINA bloc
   bloc HHI = 0.276562      N = 3.615826      h = −0.050138
   gain over the designed baseline           +0.072279

B: CAPPED TRANSIT ONLY -- a written balance cap and a weekly sweep
   bloc HHI = 0.337224      N = 2.965388      h = −0.119547
```

```
   gain over the designed baseline           +0.002869

THE RATIO
   B's gain as a proportion of A's = 0.002869 / 0.072279 = 3.9699%
   B's exposure as a proportion of A's                    3.21%
```

The largest single-move improvement in the series is 0.072279, and the Hong Kong assessment recommends against taking it. The section takes capped transit instead: 3.97% of the benefit for 3.21% of the exposure. That is a deliberate refusal of a measured gain on political-risk grounds, stated with the number rather than with an adjective, and it is the model for how a risk that the instrument cannot price should be handled — **by declining the position and printing what the refusal cost.**

B.9 V6 — the correspondent-system measurement

The concentration instrument applied to rails rather than to holdings, and measured by **terminal clearing system** rather than by bank. Two banks clearing dollars through the same United States correspondent are one system, not two.

```
AS FOUND
  USD 100.0%
  HHI = 1.000000
  EFFECTIVE CLEARING SYSTEMS = 1.000000

AS DESIGNED
  USD  55.0%
  CNY  15.0%
  EUR  12.0%
  INR  10.0%
  AED   8.0%
      ------
      100.0%

  HHI = 0.550^2 + 0.150^2 + 0.120^2 + 0.100^2 + 0.080^2
      = 0.302500 + 0.022500 + 0.014400 + 0.010000 + 0.006400
      = 0.355800
  EFFECTIVE CLEARING SYSTEMS = 1 / 0.355800 = 2.810568

  IMPROVEMENT  1.000000 -> 2.810568
```

The honest limit, and the reason this measurement belongs in a failure-aware appendix. Reaching 4.000000 effective clearing systems, holding the non-dollar mix in its current 15 : 12 : 10 : 8 proportions, requires the dollar share to fall to approximately 38.99%:

```
  USD share      effective systems
  ------------------------------
   55.00%           2.810568
   45.00%           3.544579
   40.00%           3.925331
   38.99%           4.000088   <- the threshold
   35.00%           4.278877
   33.33%           4.384374
   30.00%           4.566776
```

The 55% dollar share is set by revenue currency, not by structure. Moving it to 38.99% is a commercial decision about what the group invoices in, not a legal decision about where it banks. Four hard limits sit underneath the whole measurement: a USD account settles under United States law wherever it is booked; CIPS is a clearing system and many participants still use SWIFT for messaging, so “CIPS replaces SWIFT” is false and any structure built on that premise will fail; the bank’s risk appetite is not the jurisdiction’s policy; and a rail is not a holding.

B.10 V4 — the break-even probability method

The most transferable single technique in the series. It converts an unwinnable argument about geopolitics into a number a family can act on.

```
THE METHOD

  1  compute h WITHOUT the candidate leg                  -> h_0
  2  compute h WITH the leg, perimeter call RIGHT         -> h_R
     gain G = h_R - h_0
  3  compute h WITH the leg, perimeter call WRONG
     (the leg folds into a bloc already held)             -> h_W
     loss L = h_0 - h_W
  4  break-even probability   p* = L / (G + L)
  5  cost ceiling             the leg must cost less than G,
                              expressed as a share of total C
```

Worked in full on the AIFC at 5% drawn from the United Kingdom slot:

```
STEP 1 -- baseline
  blocs BRIDGE 40.0 / NONALIGNED 30.0 / WEST 30.0
  bloc HHI = 0.340000    N = 2.941176    h_0 = -0.122417

THE ALLOCATION WITH THE LEG -- UK 16.4 -> 11.4, AIFC 5.0
  UAE 29.1 · Thailand 18.2 · Bermuda 13.6 · India 11.8
  UK 11.4 · Singapore 10.9 · AIFC 5.0
  naive HHI = 0.177602    effective jurisdictions = 5.630567

STEP 2 -- the call is RIGHT: AIFC is a fourth, EURASIAN perimeter
  blocs BRIDGE 40.0 / NONALIGNED 30.0 / WEST 25.0 / EURASIAN 5.0
  bloc HHI = 0.160000 + 0.090000 + 0.062500 + 0.002500 = 0.315000
  N = 3.174603           h_R = -0.095686
  G = 0.026731

STEP 3 -- the call is WRONG: AIFC folds into NONALIGNED
  blocs BRIDGE 40.0 / NONALIGNED 35.0 / WEST 25.0
  bloc HHI = 0.160000 + 0.122500 + 0.062500 = 0.345000
  N = 2.898551           h_W = -0.127526
  L = 0.005110

STEP 4 -- the break-even
  p* = L / (G + L)
     = 0.005110 / (0.026731 + 0.005110)
     = 0.005110 / 0.031841
     = 0.160476   =  16.0476%

STEP 5 -- the cost ceiling
```

```
  c* = G = 0.026731
  as a share of the structure's total C = 0.30:
  0.026731 / 0.300000 = 0.089102  =  8.9102%

AND THE SHORTFALL CLOSED, if the call is right
  0.026731 / 0.122417 = 0.218357  =  21.8357%
```

Three results, each doing different work.

A 16.05 per cent probability that the jurisdiction is an independent perimeter is enough to justify the position [Curzi, 2026], whose Result One states the same bet as $E[\mathrm{d}h] = 0.0318401p - 0.0051096$ and reaches the identical break-even. The holder does not need to win the argument. It needs the argument to be better than roughly one in six.

Getting the bloc call wrong produces a loss of 0.005110, not merely an absence of gain, because capital was withdrawn from a bloc where it was diversifying and placed in a bloc it concentrated. That asymmetry is the whole reason the method exists.

The binding constraint is cost, not geopolitics. The entire gain is consumed if the leg costs more than 8.9102% of the structure's total maintenance budget, and that is a fee-schedule question.

The generalisation, and the instruction the assembled architecture, the failure record and this synthesis all carry: **price every marginal jurisdiction as a break-even probability, not as a geopolitical opinion.**

B.11 The job-vector workbook

The concentration instrument turned on the entity instead of the portfolio.

```
S = H^2 + O^2 + B^2            effective jobs = 1 / S

Reference points:
  pure specialist (1, 0, 0)          S = 1.0000   eff = 1.0000
  best two-job split (0.5, 0.5, 0)   S = 0.5000   eff = 2.0000
  even three-way (1/3 each)          S = 0.3333   eff = 3.0000

There is no two-job configuration above 2.0000. The 2.20 threshold
leaves room for estimation error in the vector and nothing more.

THE DESIGNED STRUCTURE, SCORED

entity                          H      O      B        S    eff jobs   verdict
-------------------------------------------------------------------------------
DIFC Foundation               0.90   0.00   0.10   0.8200     1.2195   SPECIALIST
Thai BOI opco                 0.05   0.95   0.00   0.9050     1.1050   SPECIALIST
UK Ltd                        0.10   0.85   0.05   0.7350     1.3605   SPECIALIST
Singapore treasury            0.05   0.15   0.80   0.6650     1.5038   STRAINED
ADGM holdco                   0.70   0.05   0.25   0.5550     1.8018   STRAINED
Bermuda captive               0.30   0.60   0.10   0.4600     2.1739   STRAINED
GIFT City vehicle             0.20   0.30   0.50   0.3800     2.6316   OVERLOADED
-------------------------------------------------------------------------------
mean effective jobs per entity                                 1.6852
```

Two entries deserve their flags. The Bermuda captive at 2.1739 is strained by nature — a captive underwrites, which is operating, and holds reserves, which is holding — and the strain is accepted in writing because the reserves are held against real third-party liabilities, which is what makes them a structurally awkward class to realise. The GIFT City vehicle at

2.6316 is carrying all three jobs and is a design error the framework owns rather than smooths over; the GIFT City assessment's own repair moves it to a vector of (0.05, 0.10, 0.85), `S = 0.7350`, 1.3605 effective jobs.

The selection rule is separate from the diagnostic and matters as much. Score each candidate on each requirement dimension and take the **minimum** over the dimensions the job actually needs. An average lets a strong score on one dimension conceal a fatal weakness on another; a structure fails at its weakest load-bearing requirement, not at its average one.

B.12 The leverage headroom workbook

```
THE CASCADE (the carried constructed case)

  operating company, marked value                    100.00
  carve out 20% by IPO                                20.00  proceeds
  retain and pledge                                   80.00
  pledge at 50% loan-to-value                         40.00  borrowing
  ------------------------------------------------------------
  deployable                                          60.00
  retained control                                    80.0%

THE TRIGGER

  critical collateral value = L / (1 - m)
                            = 40.00 / 0.65 = 61.538462
  drawdown to trigger       = 1 - 61.538462 / 80.00
                            = 0.230769  =  23.0769%

THE REVERSE COMPUTATION -- size the loan from the drawdown

  L_max = V (1 - d)(1 - m)      at V = 80.00, m = 35%

  survive  d       L_max        LTV       borrowing foregone
  ------------------------------------------------------------
   23.08%        40.000000     50.00%          --
   30.00%        36.400000     45.50%       3.600000
   35.00%        33.800000     42.25%       6.200000
   40.00%        31.200000     39.00%       8.800000
   50.00%        26.000000     32.50%      14.000000
   60.00%        20.800000     26.00%      19.200000
```

A 23.1% drawdown is ordinary equity volatility, not a crisis parameter, which is why the carve-out cascade leads with the failure mode rather than burying it. The reverse computation is the useful one because the drawdown is the input a family can have an opinion about and the loan-to-value is not. The 35% maintenance requirement is a constructed model parameter, not a market quotation.

B.13 Two further computed results carried into the appendices

V9 — the foundation-versus-trust crossover. Against a trustee charging on a basis-point scale and a constructed fixed-fee holding mandate of USD 120,000 per annum:

```
Q* = 120,000 / (basis in decimal)

35 bp   ->   USD  34.2857 million
```

```
15 bp   ->   USD  80.0000 million
10 bp   ->   USD 120.0000 million

check: 35 bp on USD 240 million = USD 840,000
```

The foundation is cheaper than a trust only above those thresholds, so cost is explicitly not the reason to choose it. The reason is recognition in civil-law and Sharia jurisdictions.

V8 — the succession residual. On the constructed estate, at a constructed exchange rate of USD 1.08 per euro and a constructed rate scale:

```
notional reserved share                          60.00m
compensatory levy = min(60.00m, 6.70m)            6.70m   = 11.1667%
French inheritance tax approx = 0.45 x 60.00m    27.00m
ratio, tax to reserve exposure                   4.0299x
liquidity shortfall                              33.84m   = 14.1000% of estate
```

The structure caps the reserve exposure at USD 6.70 million and reduces it to zero on the designed map. The tax exposure is 4.0299 times larger and is untouched. A succession analysis reporting only the first would be lying by omission.

B.14 Reproduction

Every result above is reproducible from the shares and parameters printed here with three functions and nothing else:

```
from math import log, exp

def hhi(shares):
    total = sum(shares)
    f = [x / total for x in shares]
    return sum(x * x for x in f)

def eff(shares):
    return 1.0 / hhi(shares)

def h(N, eta=0.35, C=0.30, Q=10.0, delta=0.02):
    return eta * log(N) - delta * Q - C

# break-even effective bloc count
N_star = exp((0.02 * 10.0 + 0.30) / 0.35)      # 4.172734

# break-even probability for a marginal jurisdiction
def p_star(G, L):
    return L / (G + L)
```

Collapse to blocs before calling `hhi`. Every failure this workbook documents comes from calling it on jurisdictions.

B.15 The precision rule

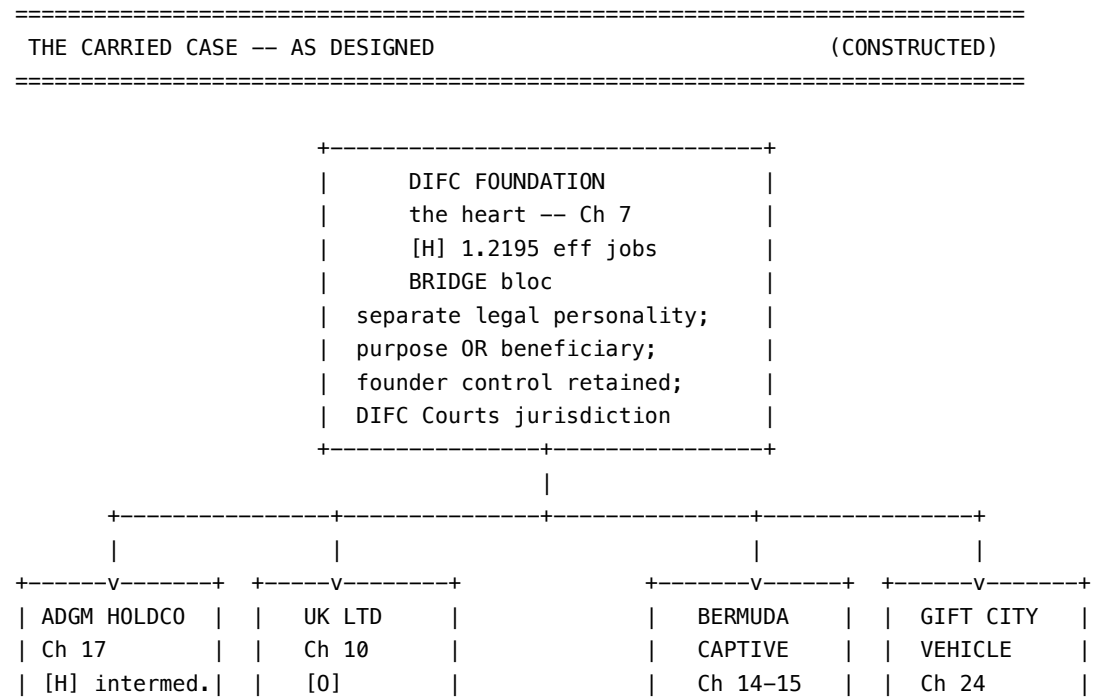
The concentration paper states it and it applies to every figure in this series. Recompute every derived figure from the exact inputs; never from a rounded print. The demonstration:

```
exact:    N = 1 / 0.34 = 2.941176...
          ln(2.941176) = 1.078810
          h = 0.35 x 1.078810 - 0.5 = -0.122417

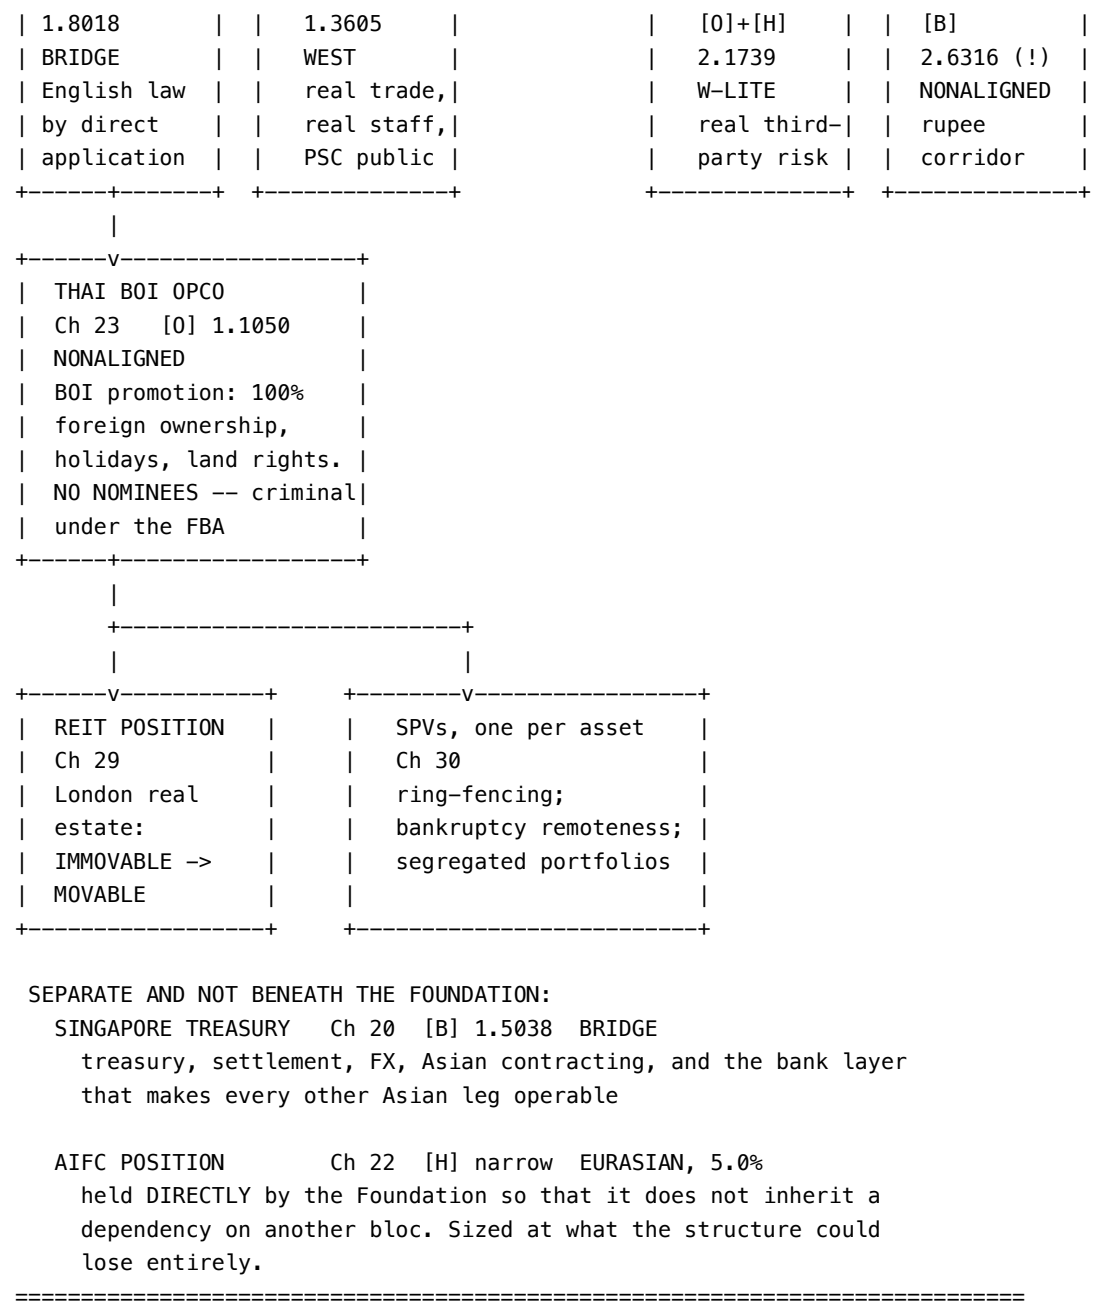
from the printed 2.94:
          ln(2.940000) = 1.078410
          h = 0.35 x 1.078410 - 0.5 = -0.122557

error = 0.000140
```

That error is small in `h` and not small in what depends on `h`. The AIFC break-even probability is `L / (G + L)` where both `G` and `L` are differences of numbers of this size; propagating a 0.000140 error through it moves the break-even by more than a percentage point. **This destroyed four sections of an earlier series before it was caught, and it is the reason the rule is stated as a rule rather than as good practice.**



Appendix C. Structure diagrams



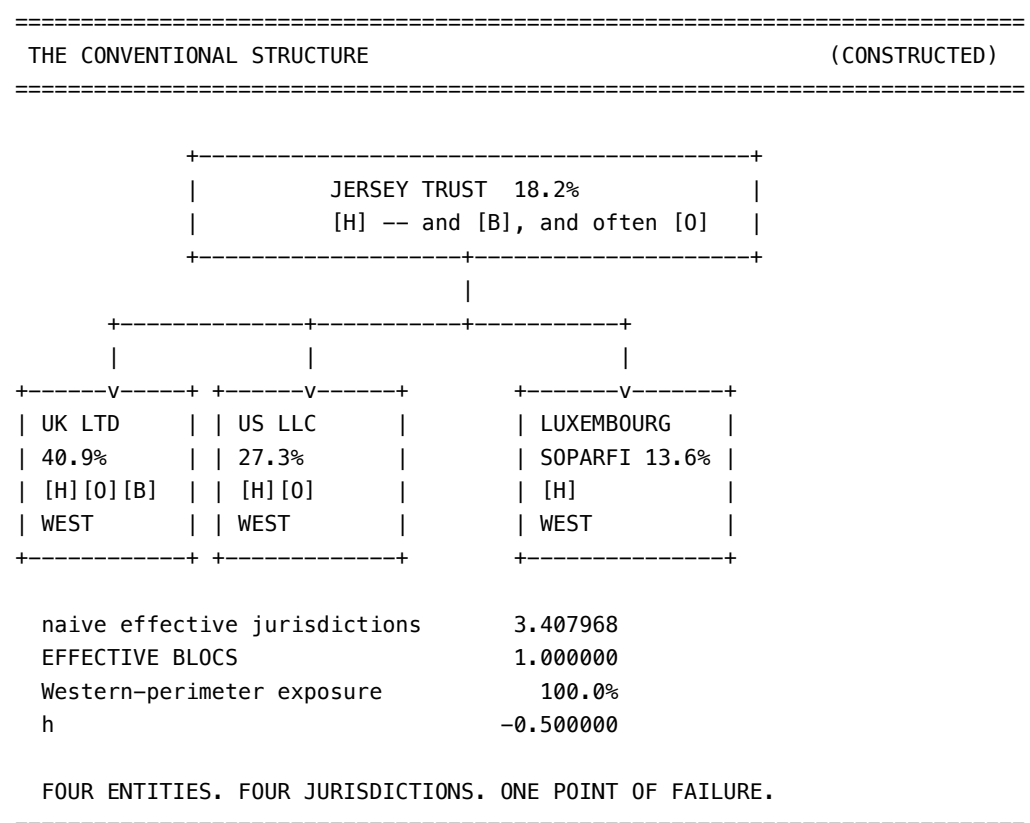
Every diagram in this appendix depicts the CONSTRUCTED carried case of the carried constructed case and is labelled as constructed. No real family, entity, or transaction is depicted.

The carried case: a dual national, UAE tax resident, with three heirs resident in three jurisdictions, one of them in a forced-heirship civil-law country. Assets: manufacturing operations in Thailand; a trading company in the UAE; intellectual property; commercial real estate in London; a listed-securities portfolio. Revenue in USD, EUR, CNY, AED, and THB.

Job labels throughout: **[H]** holding, **[O]** operating, **[B]** bridging. Where an entity carries more than one label the effective-jobs figure from Appendix B.11 is printed beside it, because an entity above 2.00 is carrying more than one job whether or not that was intended.

C.1 The structure as built

Four features of the diagram are load-bearing and are easy to miss.

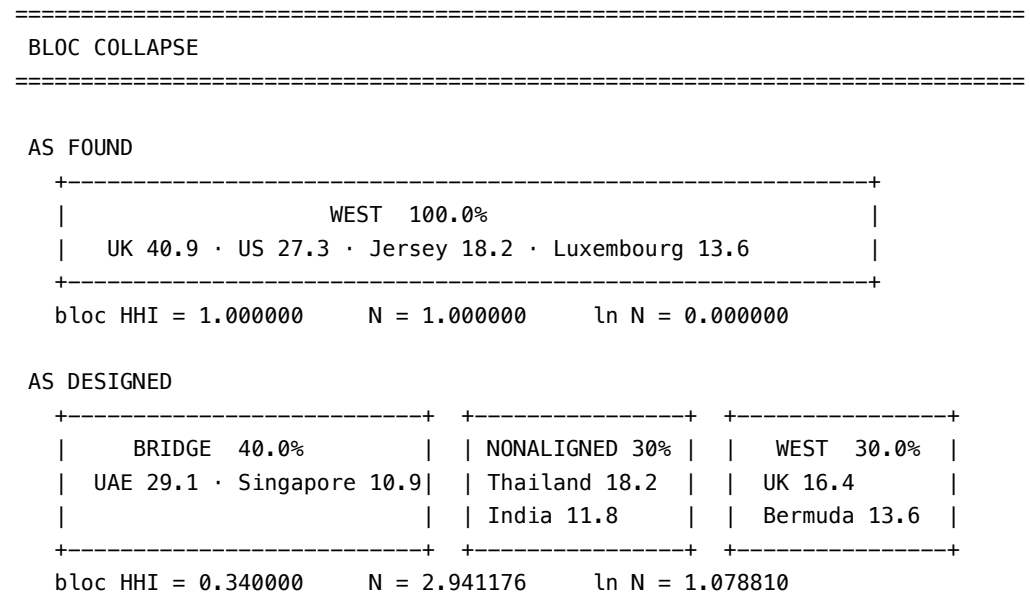


The Foundation holds; it does not transact. The store–rail rule applied at the apex: a rail is not a holding, and the apex holds no payment function. The banking sits at the DIFC and Singapore layers.

The AIFC leg hangs directly off the apex. If it hung beneath the ADGM holdco it would inherit the UAE's bloc position through its parent, and the entire point of the position is that it is in a different perimeter from everything above it.

The Bermuda captive is a sibling of the operating chain, not a child of it. Reserves held against real third-party liabilities are a structurally awkward class to realise, and that property survives only while the captive is a supervised insurer with real cedants — which is why the disclosure paper's disclosure test fails a captive that writes no risk.

The GIFT City vehicle is flagged in the diagram itself. At 2.6316 effective jobs it is above the 2.20 threshold and is carrying all three jobs. **The framework prints its own flag rather than quietly correcting the diagram**, and the GIFT City assessment's repair moves it to a specialised bridging vector of 1.3605.



C.2 The structure as found — what most readers actually have

Nothing in that diagram is unlawful, concealed, or badly drafted. It is a competent structure built by competent advisers, and every one of its four legs sits inside the same coordination perimeter, which is a fact none of its filings would ever reveal.

C.3 The bloc view — the same structures, collapsed

The diagram that actually matters, and the one no organisation chart draws.

```
  AS DESIGNED, WITH THE AIFC LEG
    +----------------+  +-------------+  +-------------+  +----------+
    | BRIDGE  40.0%  |  | NONALIGNED  |  | WEST 25.0%  |  | EURASIAN |
    |                |  |   30.0%     |  |             |  |   5.0%   |
    +----------------+  +-------------+  +-------------+  +----------+
    bloc HHI = 0.315000     N = 3.174603     ln N = 1.155303
 ============================================================================
```

The number of boxes is `N` rounded down; the shape of the boxes is `N` exactly. A structure with four equal boxes would have `N = 4.000000` and clear the break-even. The designed structure has three unequal boxes and reaches 2.941176.

C.4 The rail view — the diagram that is drawn least and matters most

```
 ============================================================================
  TERMINAL CLEARING SYSTEMS                                  (CONSTRUCTED)
 ============================================================================

  AS FOUND -- every leg terminates in one place

     UK Ltd -----+
     US LLC -----+
     Jersey -----+----> USD correspondent chain ----> US CLEARING
     Lux    -----+

     HHI = 1.000000     EFFECTIVE SYSTEMS = 1.000000

  AS DESIGNED -- measured by terminal system, not by bank

     trading revenue    --> USD  55%  --> US clearing
     China corridor     --> CNY  15%  --> CIPS clearing (SWIFT messaging)
     European sales     --> EUR  12%  --> TARGET
     India corridor     --> INR  10%  --> Indian clearing via GIFT
     Gulf operations    --> AED   8%  --> UAE clearing

     HHI = 0.355800     EFFECTIVE SYSTEMS = 2.810568

  THE FOUR HARD LIMITS
    1  a USD account settles under US law wherever it is booked
    2  CIPS is CLEARING; many participants use SWIFT for MESSAGING
    3  the bank's risk appetite is not the jurisdiction's policy
    4  a rail is not a holding
 ============================================================================
```

Note what the diagram shows that the holding diagram cannot: **a structure can have `N = 2.941176` on holdings and 1.000000 on the ability to transact.**

C.5 The leverage layer

```
 ============================================================================
  THE CARVE-OUT CASCADE (Ch 34)                              (CONSTRUCTED)
 ============================================================================

     THAI OPCO, marked value 100.00
```

```
              |
    +---------+---------+
    |                   |
  20% IPO             80% RETAINED
  proceeds 20.00      pledged at 50% LTV
                           |
                      borrowing 40.00
                           |
    DEPLOYABLE = 20.00 + 40.00 = 60.00
    RETAINED CONTROL = 80.0%

    TRIGGER
      critical collateral value = 40.00 / 0.65 = 61.538462
      drawdown to trigger       = 23.0769%

    +-----------------------------------------------------------+
    |  23.1% IS ORDINARY EQUITY VOLATILITY.                     |
    |  No adversary is required. No court is required.          |
    |  The lender exercises rights the principal granted.       |
    +-----------------------------------------------------------+

    THE CASCADE BEYOND THE CALL
      forced sale  --> change-of-control definitions elsewhere
                   --> cross-default into unrelated agreements
                   --> ring fences breached from inside
================================================================================
```

C.6 The tempted variant — what not to build

Printed because a diagram of a mistake is more useful than a paragraph about one.

```
================================================================================
 AS TEMPTED -- eight jurisdictions, and less resilient   (CONSTRUCTED)
================================================================================

                       DIFC FOUNDATION
                              |
  +--------+--------+---------+---------+---------+---------+--------+
  |        |        |         |         |         |         |        |
 UAE     Thai    Bermuda     UK      India     SAUDI    QATAR    Singapore
20.0%   18.2%    13.6%     12.2%    11.8%      9.1%     8.2%      6.9%
BRIDGE  NONAL     WEST      WEST    NONAL     BRIDGE   BRIDGE    BRIDGE

  naive effective jurisdictions   7.132973   (+34.81% -- looks better)
  EFFECTIVE BLOCS                 2.841490   ( -3.39% -- IS worse)
  h                              -0.134485   (worse by 0.012068)

  +-------------------------------------------------------------+
  |  Every entity is lawful, disclosed, and recommended on its  |
  |  own merits. The structure is less resilient than the one it |
  |  replaced, and every report the family receives says the    |
  |  opposite.                                                  |
  +-------------------------------------------------------------+
================================================================================
```

C.7 How to read these diagrams

Four rules, and they are the whole method.

An organisation chart is not a resilience diagram. C.1 and C.2 look equally sensible and differ by a factor of 2.9412 in effective bloc count. Only C.3 shows it.

Label every box with its job before drawing any arrows. The three-jobs diagnostic's commonest failure — one entity doing three jobs — is visible in a labelled diagram and invisible in an unlabelled one.

Draw the rail diagram separately, and draw the mistake too. The rail diagram has a different topology from the holding diagram and reveals a concentration visible nowhere else; C.6 exists because the tempted structure is the one a family will actually be offered, one entity at a time, by advisers who are each individually right.

Appendix D. Statute and case index

D.1 What this appendix is, and the status key

This is the framework's integrity mechanism. Every section closes with a Verification Register listing the claims it did not independently confirm, together with what specifically needs checking and with whom. This appendix consolidates them, adds the citations from the sections written before the Register became mandatory, and assigns every item one of two statuses.

`VERIFIED`	Treated as established in this series and stated as given. Reserved for the facts in the verified-facts register and for arithmetic recomputed in Python from stated inputs. NOTHING ELSE CARRIES THIS STATUS.
`FLAGGED FOR VERIFICATION`	Named because it exists, and not confirmed by this series against the primary source. Every case reporter citation, every section number, every date, every threshold, and every current-status claim in this series is FLAGGED unless it appears in D.3.

The default is FLAGGED. That is deliberate and it is the honest default for a register that names statutes across thirty-odd jurisdictions. A reader who treats the flag as a formality has misunderstood the design: several sections state explicitly that a threshold or a section number in the text must not be relied on, and the AIFC assessment goes further and names no subordinate instrument of its jurisdiction at all rather than guess at one.

Three conventions inherited from the sections govern this index.

Declining to guess, in print, is the house standard. The AIFC assessment declines to say whether the AIFC foundation confers separate legal personality; the foundation-versus-trust comparison declines to name the citations in the illusory-trust line; the erosion paper declines to give section numbers for the Cook Islands statute; the failure record repeats all three refusals rather than resolving them. **A refusal recorded here is information, not an omission.**

Commonly cited as. Where the framework gives a citation that circulates widely but that it has not checked, it writes "commonly cited as" and flags it. Examples in the index below include Article 694 of the Panamanian Fiscal Code, Article 17 of Federal Decree-Law No. 47 of 2022, article L.132-13 of the French Code des assurances, sections 56 and 57 of the Central

Bank of Malaysia Act 2009, section 80LA of the Indian Income-tax Act, 1961, and Item 403 of Regulation S-K.

Constructed model parameters are not data. Cost indices, tax rates in worked models, discount rates, exchange rates, maintenance requirements, and the carried constructed case test parameters are constructed. They are labelled as such wherever they appear and they are not citations.

D.2 The count

Compiled by extracting the numbered items from every section headed “Verification Register” or “Verification notes” across the manuscript.

```
sections carrying a Verification Register        37
consolidated FLAGGED items                      577
sections with no register (pre-dating V1)         2   (Ch 1, Ch 2)
items in this appendix's own cross-cutting
  index that consolidate multiple section
  items into one entry                          see D.4–D.7
```

Per section:

paper	assessment	items	paper	assessment	items
051	Surveillance Irrelevance	6	058	GIFT City	18
052	Five Threats	4	059	Türkiye	18
052	The Concentration Instrument	4	059	Mauritius and Africa	14
052	Holding, Operating, Bridging	6	059	Labuan and Islamic Finance	14
053	The DIFC Foundation	12	060	Latin America	18
053	Foundation versus Trust	14	060	Immovable to Movable	24
053	Succession and Forced Heirship	15	062	The Carve-Out Cascade	16
054	The City	12	062	Group Architecture	20
054	The Crown Dependency Error	14	062	Law-Family Arbitrage	17
054	The Convergence	11	063	The Medici System	22
055	Bermuda	14	064	The Rothschild System	27
055	Captives and Sidecars	13	064	The Limits of Double Entry	20
056	The Atlantic Cluster	12	064	Encoding Integrity	28

paper	assessment	items	paper	assessment	items
056	ADGM	16	065	The VINO System	24
056	DIFC Beyond the Foundation	12	069	When Structures Fail	22
057	Qatar and Saudi	16	070	The Manual in One Page	15
057	Singapore	16			
057	Hong Kong	18		**TOTAL**	**577**
058	AIFC Astana	25			
058	Thailand	20			

The AIFC assessment carries the longest register in the series at twenty-five items, deliberately, and opens with an explicit warning that it names and numbers no AIFC subordinate Act, Regulation, or Rule. **It sets the standard the rest of the framework is measured against, and the length of its register is a strength rather than a weakness.**

The count is regenerable. Extract every line matching a numbered-list pattern between a heading matching “Verification Register” or “Verification notes” and the next scorecard heading, across every section file, and sum. **A reader who re-runs that extraction on a later revision of the manuscript and gets a different number has found a change, not an error in this appendix.**

D.3 VERIFIED — the register of verified facts, and nothing else

These are stated as given throughout the framework. They are the only substantive claims not flagged. Every one of them should still be confirmed with counsel before reliance; “verified” here means “fixed as canon within this series,” not “checked against the primary source on the reader’s behalf.”

DIFC Foundation	DIFC Foundations Law No. 3 of 2018. Separate legal personality; purpose OR beneficiary; founder may retain control; DIFC Courts jurisdiction.
ADGM	Application of English Law Regulations 2015 — directly applies English common law, the only jurisdiction outside the UK to do so. ADGM Courts; FSRA regulator.
DIFC	Own codified common-law-derived statutes; DIFC Courts; DFSA regulator.
UAE	FATF grey list March 2022 to February 2024, now removed. CRS participant.
Thailand	Civil law (Civil and Commercial Code). US–Thai Treaty of Amity 1966: US persons may own 100% of a Thai company, exempt from most Foreign Business Act restrictions. BOI promotion can confer 100% foreign ownership, tax holidays and land rights. NOMINEE SHAREHOLDING IS A CRIMINAL OFFENCE AND IS PROSECUTED. Revenue Department order Por. 161/2566: from 1 January 2024 foreign-source income remitted by a Thai tax resident is taxable regardless of the year earned. CRS participant.
GIFT City	IFSC; unified regulator IFSCA since 2020; funds, aircraft and ship leasing, reinsurance, bullion. India is CRS-participating.
Bermuda	BMA regulator; Solvency II equivalent; economic substance

```
                    requirements since 2018; CRS participant. Reinsurance
                    reserves held against real third-party liabilities.
United Kingdom      Public PSC register; ECCTA 2023 tightened Companies House
                    identity verification. English law is the most-chosen
                    governing law for international commercial contracts.
Luxembourg          CJEU, November 2022 (*WM and Sovim SA v Luxembourg
                    Business Registers*): PUBLIC access to beneficial-
                    ownership registers struck down; competent authorities
                    retain access.
CIPS                A CLEARING system. Many participants still use SWIFT for
                    the MESSAGING layer. "CIPS replaces SWIFT" is FALSE.
2022 precedent      Approximately USD 300bn of Russian central bank reserves
                    immobilised.
Stablecoins         MiCA stablecoin provisions applicable from 30 June 2024;
                    USDT delisted from EU venues. GENIUS Act signed July 2025.
                    Tether can and does freeze USDT at law-enforcement
                    request. T3 Financial Crimes Unit (Tether, Tron, TRM Labs)
                    launched September 2024.
Public blockchains  MORE traceable than correspondent banking, not less.
```

And the computed results, which are VERIFIED in the narrower sense that they were re-computed in Python from the stated inputs at full precision for Appendix B and reproduce exactly:

```
conventional structure   naive HHI 0.293430, 3.407968 jurisdictions,
                         bloc HHI 1.000000, N = 1.000000, h = -0.500000
designed structure       naive HHI 0.189002, 5.290949 jurisdictions,
                         bloc HHI 0.340000, N = 2.941176, h = -0.122417
break-even               N* = 4.172734
V5 tempted               naive 7.132973 (+34.8146%), blocs 2.841490 (-3.3893%)
V5 as built              naive 5.688217, blocs 2.816901, priced loss 0.124275 in N
V6 correspondent         1.000000 -> 2.810568 effective clearing systems
V4 AIFC                  G = 0.026731, L = 0.005110, p* = 16.0476%,
                         cost ceiling 8.9102% of C, shortfall closed 21.8357%
V3 Singapore control     marginal contribution to h = 0.002014
V2 Hong Kong             centre +0.072279; capped transit +0.002869; ratio 3.9699%
Ch 34 margin             trigger at 23.0769% drawdown
V9 crossover             USD 34.2857m / 80.0000m / 120.0000m at 35 / 15 / 10 bp
V8 succession            6.70m capped, 27.00m tax, ratio 4.0299x, shortfall 14.1000%
```

The parameters those results were computed from — `eta = 0.35`, `C = 0.30`, `Q = 10`, `delta = 0.02`, and every share in every allocation — are constructed test values and are not verified estimates of anything. The arithmetic is verified; the inputs are constructed.

D.4 Cases — every case named anywhere in the series

All FLAGGED FOR VERIFICATION. This series has checked no reporter citation against an official report, and says so. For each: confirm the citation, the court, the date, the holding, and its subsequent treatment before any reliance.

D.5 Statutes and instruments — the consolidated index

All FLAGGED FOR VERIFICATION, in every case for current consolidated text, amendments, commencement, and any successor instrument. Grouped by jurisdiction. This index names the instruments; the section registers name what specifically must be checked in each.

United Arab Emirates — DIFC Foundations Law No. 3 of 2018; DIFC Trust Law, DIFC Law No. 4 of 2018; DIFC Law No. 3 of 2004 (application-of-law cascade, commonly cited as Article 8(2)); Dubai Law No. 12 of 2004 as amended by Dubai Law No. 16 of 2011; Federal Law No. 8 of 2004; Federal Decree No. 35 of 2004; Dubai Law No. 9 of 2004; Dubai Law No. 15 of 2017; ADGM Application of English Law Regulations 2015; ADGM Courts Regulations 2015; ADGM Companies Regulations; ADGM Foundations Regulations 2017; Financial Services and Markets Regulations 2015; Federal Decree-Law No. 47 of 2022 (corporate tax; family foundation article commonly cited as Article 17); Federal Decree-Law No. 20 of 2018; Cabinet Decision No. 10 of 2019; Federal Cabinet Resolution No. 58 of 2020; Federal Decree-Law No. 41 of 2022 (Civil Personal Status); Federal Law No. 28 of 2005; the UAE domestic minimum top-up tax instrument; the 2024 DIFC digital assets and security package.

United Kingdom and Crown Dependencies — Economic Crime and Corporate Transparency Act 2023; Economic Crime (Transparency and Enforcement) Act 2022 and the Register of Overseas Entities; Insolvency Act 1986 s.423; Limitation Act 1980; Arbitration Act 1996 and Arbitration Act 2025; Sanctions and Anti-Money Laundering Act 2018; Public Offers and Admissions to Trading Regulations 2024; UK Listing Rules; DTR 5; Finance Act 2006 Part 4 and Part 12 of the Corporation Tax Act 2010 (UK REIT); Finance Act 2003 Part 4 (SDLT); Inheritance (Provision for Family and Dependants) Act 1975; Trusts (Jersey) Law 1984 (firewall, reserved powers, and the mistake and inadequate- deliberation jurisdiction, commonly cited as Articles 9, 9A and 47A–47J); Taxation (Companies — Economic Substance) (Jersey) Law 2019 and the Guernsey and Isle of Man equivalents made in 2018; Trusts (Guernsey) Law; Guernsey Protected Cell Companies Ordinance 1997; Isle of Man Companies Act 1931 and Companies Act 2006; Isle of Man Foundations Act 2011 and Purpose Trusts Act 1996.

United States — Foreign Account Tax Compliance Act (18 March 2010, Title V of the Hiring Incentives to Restore Employment Act); Bankruptcy Code s.548(e) as added by the Bankruptcy Abuse Prevention and Consumer Protection Act of 2005; the Uniform Voidable Transactions Act as enacted state by state; Corporate Transparency Act (enacted 1 January 2021 within the National Defense Authorization Act) — **scope genuinely unsettled and actively litigated**; IRC ss.831(b), 501(c)(15), 856–860, 721, 704(c), 897, 1445, 4371, 6104; the Protecting Americans from Tax Hikes Act of 2015; the REIT Modernization Act of 1999; the 1960 REIT legislation; the January 2025 micro-captive final regulations; Rev. Rul. 2002-89, 2002-90, 2002-91, 2005-40; Notice 2016-66; Liability Risk Retention Act of 1986; Clayton Act s.8 (15 U.S.C. § 19); Hart-Scott-Rodino (15 U.S.C. § 18a; 16 C.F.R. Parts 801–803) and the 2024 form overhaul; Sherman Act s.1 (15 U.S.C. § 1); the 2023 DOJ/FTC Merger Guidelines and the withdrawal of the 2020 Vertical Merger Guidelines; Regulation S-K Items 403 and 407(i); Schedule 13D Item 6; Securities Act Rule 144; Exchange Act ss.13(a) and 16(b); Federal Reserve Regulation T (12 C.F.R. Part 220); FINRA Rule 4210; UCC Article 8; FIPS 180-4.

European Union — Directive (EU) 2015/849; Directive (EU) 2018/843; Regulation (EU) 2024/1624; Directive (EU) 2024/1640; Regulation (EU) 2024/1620; Council Directive (EU) 2022/2523 (Pillar Two); Council Directive (EU) 2016/1164 (ATAD I) and (EU) 2017/952 (ATAD II); DAC6 (2018/822), DAC7 (2021/514), DAC8 (2023/2226); Regulation (EU) No 1215/2012 (Brussels Recast) Article 24(1); Regulation (EU) No 650/2012 (Succession); Regulation (EU) 2016/1103 (matrimonial property); Directive 98/26/EC Article 9(2); Directive 2002/47/EC; Commission Delegated Decision (EU) 2016/309; the EU list of non-cooperative jurisdictions, first adopted 5 December 2017, Annexes I and II.

Offshore and overseas territories — Cook Islands International Trusts Act 1984 as amended (**section numbers deliberately not stated**); Cayman Companies Act, Trusts Act, Mutual Funds Act, Private Funds Act 2020, Foundation Companies Act 2017, Insurance Act 2010, International Tax Co-operation (Economic Substance) Act, Beneficial Ownership Transparency Act 2023; BVI Business Companies Act 2004 as amended, Economic Substance (Companies and Limited Partnerships) Act 2018; Bahamian Foundations Act 2004, Purpose Trust Act 2004, Executive Entities Act 2011, Fraudulent Dispositions Act 1991, Investment Condominium Act 2014, Commercial Entities (Substance Requirements) Act 2018; Barbados Insurance Act and the 2018 convergence and 2024 rate legislation; Bermuda Insurance Act 1978, Economic Substance Act 2018, Segregated Accounts Companies Act 2000, Corporate Income Tax Act 2023, Judgments (Reciprocal Enforcement) Act 1958, Bermuda Constitution Order 1968.

Asia-Pacific — Singapore: Application of English Law Act 1993, Variable Capital Companies Act 2018, Income Tax Act 1947 ss.13D/13O/13U, Trustees Act 1967, Trust Companies Act 2005, Companies Act 1967, Reciprocal Enforcement of Foreign Judgments Act 1959, International Arbitration Act 1994, Supreme Court of Judicature Act 1969, Financial Services and Markets Act 2022, Multinational Enterprise (Minimum Tax) Act 2024, Administration of Muslim Law Act. Hong Kong: the National Security Law, the Safeguarding National Security Ordinance 2024, Basic Law Articles 8, 104 and 158, Companies Ordinance (Cap. 622), Inland Revenue Ordinance, Mainland Judgments in Civil and Commercial Matters (Reciprocal Enforcement) Ordinance. Thailand: Foreign Business Act B.E. 2542 (1999), Civil and Commercial Code, Land Code, Condominium Act, Revenue Code, Revenue Department order Por. 161/2566, the investment promotion legislation. India: International Financial Services Centres Authority Act, 2019; Special Economic Zones Act, 2005; Foreign Exchange Management Act, 1999; IFSCA (Fund Management) Regulations, 2022; Income-tax Act, 1961 (deduction commonly cited as s.80LA; exemption commonly cited as s.47(viiab)); Code of Civil Procedure, 1908 ss.13 and 44A; Arbitration and Conciliation Act, 1996; Taxation Laws (Amendment) Act, 2021. Malaysia: Labuan Business Activity Tax Regulations (2018, replaced 2021) — P.U.(A) numbers to be confirmed; Income Tax Act 1967; Central Bank of Malaysia Act 2009 (Shariah Advisory Council, commonly cited as ss.56 and 57). Kazakhstan: the AIFC constitutional statute of 7 December 2015 and the constitutional entrenchment — **no AIFC subordinate Act, Regulation or Rule is named anywhere in this series.**

Continental Europe and civil-law succession — French Code civil art. 913 and the compen-

satory levy inserted by Loi n° 2021-1109 of 24 August 2021; Loi n° 2006-728 of 23 June 2006; French advance renunciation of the action in reduction; Code général des impôts arts. 792-0 bis, 123 bis, 669, 751, 1133; Code des assurances art. L.132-13 (commonly cited); German BGB §§2303, 2325, 2329, 2346 and Aussensteuergesetz §15; Italian Codice civile (*legittima, azione di riduzione*); Spanish Código Civil (*legítima*, *mejora*, *foral* regimes); Swiss Banking Act art. 47 of 8 November 1934, AEOI Act of 18 December 2015, Embargo Act of 22 March 2002; Luxembourg law of 22 December 2023 and its December 2024 amendment; Luxembourg SIF (13 February 2007), SICAR (15 June 2004), RAIF (23 July 2016), securitisation law of 22 March 2004; Irish ICAV Act 2015, Finance (No. 2) Act 2023, s.110 TCA 1997; Dutch Withholding Tax Act 2021.

Latin America — Panama: Law 32 of 1927, Law 25 of 1995, Law 21 of 2017, Law 23 of 2015, Law 52 of 2016, Law 129 of 2020, Law 254 of 2021, Fiscal Code territoriality (commonly cited as Article 694). Uruguay: Law No. 15.921 of 1987, Law No. 18.930 of 2012, Law No. 19.484 of 2017. Paraguay: Law No. 6.380/2019, Law No. 1.064/1997. Costa Rica: Law No. 7210 of 1990, and the 2023 amending law and 2021 residence statute (commonly cited as Law No. 10.381 and Law No. 9996).

Türkiye — Decree No. 32 on the Protection of the Value of Turkish Currency (1989); Tax Procedure Law No. 213; Civil Code No. 4721 (2001); Code of Obligations No. 6098 (2011); Commercial Code No. 6102 (2011); Foreign Direct Investment Law No. 4875 (2003); Law No. 7412 on the Istanbul Finance Centre (2022); Banking Law No. 5411 (2005); Capital Markets Law No. 6362 (2012); Law No. 6493 (2013); Land Registry Law No. 2644; Law No. 5718 on Private International Law and Procedural Law (2007); International Arbitration Law No. 4686 (2001).

Africa and the Indian Ocean — Mauritius: the DTAA and IPPA network, the India Protocol of 10 May 2016 and the Protocol signed 7 March 2024, CBDT Circulars No. 682 (1994) and No. 789 (2000). Rwanda: company law, investment code, trusts, partnerships and foundations legislation — numbers to be confirmed. Kenya: Nairobi International Financial Centre Act, 2017; Companies (Beneficial Ownership Information) Regulations, 2020; Judicature Act; Constitution of Kenya, 2010.

D.6 Treaties, conventions, and multilateral instruments

All FLAGGED FOR VERIFICATION as to contracting-party lists, entry-into-force dates, declarations, reservations, and territorial extensions, in every relevant state and on the date of reliance.

```
Hague Convention of 1 July 1985 on the Law Applicable to Trusts and on their
  Recognition
Hague Convention of 30 June 2005 on Choice of Court Agreements
Hague Convention of 2 July 2019 on the Recognition and Enforcement of Foreign
  Judgments
Hague Convention of 1 August 1989 on the Law Applicable to Succession —
  understood NEVER to have entered into force; confirm before any reference
Hague Securities Convention — confirm status in each relevant state

the EU Enhanced Partnership and Cooperation Agreement with Kazakhstan
the Montreux Convention of 1936
ICSID Convention —— current status of each relevant state
```

D.7 The two sections with no Verification Register

The erosion and coordination-perimeter assessments pre-date the requirement introduced at RECONCILE V1 and carry no register. Their citations are consolidated here and are **FLAGGED FOR VERIFICATION** on the same terms as everything else.

the erosion paper — the UBS deferred prosecution agreement of February 2009 and the USD 780 million payment; the 2009 US-Switzerland agreement and the account figure usually reported as approximately 4,450; the Swiss FATCA intergovernmental agreement on the Model 2 template, date usually given as 14 February 2013; the Wegelin & Co. guilty plea, January 2013; the Credit Suisse guilty plea, May 2014, and the USD 2.6 billion payment; the Department of Justice Program for Non-Prosecution Agreements or Non-Prosecution Letters for Swiss Banks announced 29 August 2013, with aggregate figures to be confirmed against Department of Justice releases; the Falciani data and the February 2015 publication; the Panama Papers (April 2016), Paradise Papers (November 2017), FinCEN Files (September 2020), Pandora Papers (October 2021); every listing and delisting date in the erosion table; and the Cook Islands International Trusts Act 1984 with its amendment history.

the coordination-perimeter analysis — the five coordination interfaces and the institutions named at each; the FATF and Global Forum sequences relied upon; the EU Annex I and Annex II mechanics; the correspondent de-risking evidence; and the bloc taxonomy itself, which is the framework's own construction and is **contestable by design**.

D.8 The gap — sections specified and not yet on the page

Stated rather than implied. The source manifest specifies a complete method; the manuscript from which this index was compiled does not yet contain every section it specifies. **Where the closing sections and these appendices refer forward to a section that is not on the page, they refer to a result fixed in the carried constructed case or the reconciliation ledger — the 23.0769% margin trigger, the four bright lines, the CIPS distinction, the 2022 precedent — and not to text a reader can check.**

Treat every such forward reference as a specification, not as a citation. The results themselves are in Appendix B and are recomputed there; what is missing is the section that argues them.

D.9 How to use this appendix

Four instructions.

Take the relevant section's register to counsel, not this appendix. The registers say what specifically needs checking and with whom; this index says what exists. And treat every section number as provisional — numbering moves across consolidations, and several sections state in terms that no threshold in the text should be relied on.

Where the framework declined to guess, do not fill the gap from a secondary source. The *In re Lawrence* situs error is the demonstration: a source that gets it wrong is unreliable on everything else it says.

Re-run the count. A structure built against this synthesis should carry its own register, derived from these, with a date and a named person against each item.

Appendix E. The honesty register

This appendix collects, in one place, everything the framework does not know, everything it got wrong and corrected, and everything it recommends while reporting that the recommendation does not fully work. **It is the appendix to read if only one appendix is read.**

E.1 What is settled

Short, because little is.

The direction of travel. Fifteen years of documented erosion across four independent tracks — Swiss secrecy, Caribbean substance, Panama's listing cycle, and the collapse of the non-recognition defence against personal compulsion — is not a matter of interpretation. The dates are public and the instruments are named in Appendix D.

The mechanism. Erosion is coordination. Jurisdictions inside one coordination perimeter changed together because the same five interfaces reached all of them. That is an observation about sequence and correlation, and it is testable.

The arithmetic. `HHI = sum of squared shares`, `effective count = 1/HHI`, and `ln(1.00) = 0`. Appendix B reproduces every figure from stated inputs. **The arithmetic is settled; every input to it is constructed.**

The three jobs. Holding, operating, and bridging need different things, and most failed structures come from asking one entity for all three. That is a taxonomy rather than a claim, and its usefulness does not depend on any jurisdiction assessment being right.

The personal-jurisdiction lesson. A court with personal jurisdiction over the principal does not need jurisdiction over the assets. Two appellate decisions establish it and no statute anywhere has displaced it.

E.2 What is contested

The bloc assignments. Every value of `N` in this series rests on a mapping from jurisdictions to coordination perimeters that the framework made. It is an argument, not a measurement. The two most contestable calls are Singapore (bridge or Western) and the treatment of the UAE and Singapore as one bridge bloc rather than two. The concentration paper's robustness table prices both: the Singapore call moves `h` by 0.002014; separating the UAE and Singapore moves `N` from 2.941176 to 3.615826, which is large, and is why the published 2.941176 is the conservative end of a range rather than a point estimate.

Whether Kazakhstan is an independent perimeter. Unresolved and priced rather than argued. See V4.

Whether the AIFC foundation confers separate legal personality. The AIFC assessment declines to guess in print. It remains unanswered and it gates any apex migration.

The conduit question. Whether a foreign judgment recognised inside a UAE financial free zone can be enforced onshore through it. Carried unresolved from the foundation paper through the rail-perimeter measurement and into this synthesis. **It is the largest open legal question in the architecture and it sits directly under the apex.**

The illusory-trust line. Litigated in New Zealand and before the Privy Council and deliberately not cited in either direction anywhere in this series.

The Corporate Transparency Act's scope. Genuinely unsettled and actively litigated.

Sanctions and secondary-sanctions exposure. Moving continuously, jurisdiction by jurisdiction, and no statement in this series about any current designation or listing should be assumed live.

E.3 What needs counsel

Everything, and this is not a formula. The specific list, distilled from 577 register items:

- counsel in each jurisdiction of incorporation
- counsel in each jurisdiction of residence -- principal AND every heir
- counsel in each jurisdiction of asset situs, separately for immovables
- tax counsel wherever any decision concerning any entity may be taken, because that is where corporate residence is asserted and where the most reliably fatal failure track begins
- Sharia-qualified counsel wherever personal-status law applies
- securities counsel before any pledge, carve-out, or listing
- a credentialed actuary before any captive
- antitrust counsel before any board overlap or above-threshold acquisition
- written CRS and FATCA classification of every entity AT FORMATION, including every sub-fund and cell

Two items are singled out in the sections as the most consequential in their registers and are repeated here. **Regularising a historical Thai nominee position** — exposure for the elapsed period, available routes, disclosure obligations — is named in the Thailand assessment as the most important item in that register, because the underlying conduct is criminal rather than merely ineffective. And **the exact scope of the Foreign Exchange Management Act, 1999 treatment of IFSC units as persons resident outside India** is named in the GIFT City assessment as the load-bearing item in that section, because the entire rupee-corridor case rests on it.

E.4 What changed recently and may change again

A structure built on any line below is built on a moving object.

2018–2019	economic substance regimes across the offshore world
2020	Cayman EU listing and delisting inside eight months
22 Nov 2022	CJEU strikes down PUBLIC beneficial-ownership register access; the Netherlands and Luxembourg suspend public access the same day
Mar 2022	UAE FATF grey listing -- removed February 2024
Mar 2022	Singapore adopts targeted measures without a Security Council resolution, reversing six decades of stated policy
2022	approximately USD 300bn of Russian central bank reserves immobilised
2022–	DOJ revives Clayton Act s.8 enforcement; resignations follow
2023	UAE corporate tax; Saudi Civil Transactions Law; Cayman Beneficial Ownership Transparency Act; ECCTA in the UK
Jan 2024	Thailand's Por. 161/2566 kills later-year remittance planning
Feb 2024	UAE removed from the FATF grey list; BVI removed from EU Annex I
30 Jun 2024	MiCA stablecoin provisions apply; USDT delisted from EU venues
Sep 2024	T3 Financial Crimes Unit launched
2024	EU AML package adopted; HSR notification form overhauled
Jun 2024	Türkiye removed from the FATF increased-monitoring list
2024–2026	Pillar Two implementation staggered across jurisdictions; DAC8 from 1 January 2026
Jul 2025	GENIUS Act signed
Jan 2025	micro-captive final regulations

The list is not a history. It is a rate. Roughly one structurally significant change per quarter across the jurisdictions this series covers, which is why the procedure in this synthesis ends with an annual re-run and why every scorecard item 12 names the specific event that would reverse the verdict.

E.5 The reconciliation ledger, V1 through V10

The framework's own corrections, in full, because a synthesis that hides its revisions is not auditable.

V1 — The Verification Register is mandatory. Introduced by an agent drafting the Singapore and Hong Kong assessments to 22, not by the original instruction. Counts at origin: Ch 20 = 16, Ch 21 = 18, Ch 22 = 25. **It is better than the instruction it replaced and it is now required of every section**; a jurisdiction section without one is incomplete. The AIFC assessment sets the standard: it opens by warning that it names and numbers no AIFC subordinate instrument, and states in print that it declines to guess whether the AIFC foundation confers separate legal personality. **Declining to guess, in print, is the house standard.**

V2 — Hong Kong: the best number is not the recommendation. Hong Kong in the 10.9% slot as a China-bloc asset gives `N = 3.615826` and `h = \ensuremath{-}0.050138`, a gain of 0.072279 — the largest single-move gain in the series. The section recommends against it and proposes capped transit instead: `N = 2.965388`, `h = \ensuremath{-}0.119547`, gain 0.002869 — **3.97% of the benefit for 3.21% of the exposure.** Political risk stated without euphemism, balanced by the documented absence of interference in ordinary commercial litigation, with the argument that **protection is bought for the tail, not the median.** That framing governs the assembled architecture and this synthesis.

V3 — Singapore makes the concentration paper's failure mode observable. The same 10.9% in London versus Singapore gives identical bloc shares, identical `N`, identical `h`, while naive effective jurisdictions read 5.290949 against 4.449309. Singapore's true marginal contribution to `h` is 0.002014. **The naive metric reports a diversification that did not occur.** Singapore's item 10 also splits three ways and the section refuses to average them; **the split-trajectory convention now applies wherever item 10 is genuinely non-uniform.**

V4 — the AIFC reduces to a probability threshold. AIFC at 5% from the UK slot: `N = 3.174603`, `h = \ensuremath{-}0.095686`, gain 0.026731. **Break-even probability that Kazakhstan is an independent perimeter = 16.05%. Getting the bloc call wrong — folding the AIFC into non-aligned — produces a LOSS of 0.005110.** The binding constraint is cost, not geopolitics: the leg must run under 8.9102% of total `C`. **Generalised: every marginal jurisdiction is priced as a break-even probability, not argued as a geopolitical opinion.**

V5 — more jurisdictions, fewer blocs. Adding Qatar and Saudi Arabia: eight jurisdictions, naive HHI 0.140194 giving 7.132973 effective jurisdictions, up 34.81% — while bloc HHI 0.351928 gives 2.841490 effective blocs, down 3.39%. **Two more jurisdictions, a third more apparent diversification, and the honest count fell.** The worked outcome takes the Saudi RHQ from the operating allocation instead: naive 5.688217, blocs 2.816901 — a deliberate, priced loss of 0.124275 in `N` taken on revenue grounds. **Priced losses taken knowingly are legitimate; unpriced ones are the failure.**

V6 — the dollar share cannot be engineered away. Correspondent concentration measured by terminal clearing system: as found 100% USD, HHI 1.0000, 1.00 system; as designed USD 55 / CNY 15 / EUR 12 / INR 10 / AED 8, HHI 0.3558, 2.810568 systems. **The 55% dollar share is set by revenue currency, not by structure, and reaching 4.00 would require the dollar near 38.99% — a commercial decision, not a legal one.** Four hard limits: a USD account settles under US law wherever booked; CIPS is clearing, not messaging; the bank's risk appetite is not the jurisdiction's policy; a rail is not a holding.

V7 — a fully disclosed sovereign investor: two functions are impossible without disclosure. The existence proof in the disclosure paper is built as a function decomposition, and two of the institution's functions cannot be performed by a concealed holder at all — voting the shares and pre-announcing the vote, and moving a company's conduct by naming it in a published exclusion. When the sector came under political pressure the answer was a published disclosure standard, not more concealment. **And the section carries its own counter-case as failure mode 7: the 2022 immobilisation of approximately USD 300bn involved fully disclosed assets that were frozen anyway. Disclosure is not immunity.** A section arguing for disclosure that hid the strongest objection to disclosure would fail its own test, so the counter-case stays

prominent — here, in the failure record's third predicted failure, and in this synthesis's closing section.

V8 — the structure solves the smaller problem. Child 2's forced-heirship exposure is capped at USD 6.70m and is zero on the designed map. French inheritance-**tax** exposure is approximately USD 27.00m — 4.0299 times larger and untouched by the structure. The liquidity test shows a USD 33.84m shortfall, 14.1% of the estate, that would force the sale of an operating branch. **A succession section reporting only the heirship win would be lying by omission.** The thesis carried forward: **consent is the one lever present in all three legal families — advance renunciation in France, the *Pflichtteilsverzicht* in Germany, *takharuj* under Sharia — and consent requires disclosure.** That ties that group back to the governing principle.

V9 — cost is not the reason. The computed crossover: the foundation is cheaper than a trust only above USD 34.2857m at a 35 bp trustee basis (USD 80.0000m at 15 bp; USD 120.0000m at 10 bp). **So cost is explicitly not the reason to choose it — the reason is recognition in civil-law and Sharia jurisdictions.** That must be said wherever the foundation is recommended, including here.

V10 — English law decomposes into three things. Doctrine, court, and territorial state. ADGM buys the first two without the third. That is the precise statement of what the Gulf bridge delivers and why the City cannot deliver it. What remains open is whether the second holds up under a stress that has not yet occurred: the ADGM Courts have a short record and the onshore enforcement bridge is documented but lightly tested.

E.6 The four admissions that matter most

Extracted from the ledger and stated without qualification, because they are the four things a reader is most likely to leave the framework without having absorbed.

One. The framework's own instrument shows the recommended structure still below the build threshold. At the tested parameters the conventional structure gives `h = \ensuremath{-}0.500000` and the designed structure gives `h = \ensuremath{-}0.122417`. The break-even is `N* = 4.172734` and the designed structure reaches 2.941176. Adding the best available marginal position reaches 3.174603 and closes 21.8357% of the gap. **Diversification raises the ceiling and does not pay the maintenance bill. Jurisdictional diversity buys the ability to build, not the building.**

Two. Disclosure did not prevent the 2022 immobilisation. The most thoroughly disclosed assets available were frozen anyway. Disclosure removes the failure mode in which a structure collapses on contact with an authority, and makes the structure bankable, which is the binding constraint on everything else. It does not supply an appeal and it does not protect an asset inside the perimeter that took the decision.

Three. Cost is not the reason to choose a foundation. Recognition in civil-law and Sharia jurisdictions is. The crossover figures are in V9 and in Appendix B.13.

Four. The succession structure addresses the smaller of the two exposures. USD 6.70m capped and eliminated; approximately USD 27.00m untouched; a USD 33.84m liquidity shortfall sufficient to force a sale. **The asymmetry is the finding.**

E.7 The standing disclaimer

This series is **not legal, tax, or investment advice**. It describes how systems work, what they cost, their risk profiles, and how to build durable legitimate structures. It contains no operational guidance for moving value that a sanctions regime prohibits.

It recommends no structure premised on non-disclosure, because such a structure fails the governing principle by construction. It recommends no nominee arrangement where nominees are unlawful, and Thailand is the specific case where they are criminal and prosecuted. Every worked case in every section and every appendix is **CONSTRUCTED** and labelled

as such. No real family, entity, or transaction is described anywhere in this series, with the single exception of the publicly documented institutions named in the disclosure paper and in the lineage sections, which are treated from the public record.

Counsel is required in each relevant jurisdiction. **The framework is a map, not a permission.**

Appendix F. Correspondence to the earlier series

Series D is the fourth series of the corpus and it is not a topical detour: it applies one law that the earlier series developed on other material. This appendix sets out the correspondence term by term. **A reader who has not read the earlier series loses nothing; the law is restated in full in the erosion paper and worked in full in Appendix B.**

F.1 The storage law, transferred

Series B develops a storage law for durable goods: a difference equation relating a stock, its decay rate, the conversion of flow into stock, and the maintenance cost of holding it [Curzi, 2026], whose founding reframing is that comfort is the felt total of present costs, so the present state is a local minimum of the comfort landscape by definition rather than by luck. **It applies to capital without modification.**

```
Q_{t+1} = (1 − delta) Q_t  +  eta S_t  −  C_t
```

Three terms describe the same physical facts in both cases and one has to be reinterpreted.

F.2 The terms

`Q` — protected capital. In Series B, the stock: a quantity of durable goods held against future need. Here, capital held in a form and a place that survives an adverse decision. **The transfer is exact and requires no reinterpretation, because the storage law does not care what the stock is made of — only that it decays, that it can be added to, and that holding it costs something.**

`delta` — erosion. In Series B: spoilage, breakage, pilferage, obsolescence. Here: tax drag, political risk, currency debasement, and haven degradation. Every jurisdiction paper in this series is, at bottom, an argument about `delta`: a stable legal system with a working court and no expropriation history lowers it, and the fifteen-year erosion documented in the erosion paper is a description of `delta` rising across an entire class of holdings at once. **The mechanism differs and the mathematics does not: a stock decaying at 2% a year is decaying at 2% a year whether the cause is rot or a listing decision.**

`eta` — conversion. In Series B, the efficiency with which flow becomes durable stock: the fraction of a harvest that survives preservation and enters storage. Here, the conversion of income into durable protected holdings. It is the term the jurisdiction papers move when they discuss vehicles rather than stability — a foundation with separate legal personality, a recognised trust, a licensed insurer holding reserves against real liabilities, a REIT unit in place of a title deed. **Each of those raises `eta` by making a given unit of income convertible into a form that holds.**

`C` — maintenance. In Series B, the cost of the store itself: the building, the drying, the turning, the watching. Here: compliance, counsel, substance, filings, registered offices, agents, audits, director fees, translations, and the management time nobody bills. **The correspondence is uncomfortably exact, including the failure mode.** In both cases `C` is paid continuously in small amounts to many parties, never appears as a single line, and is therefore mis-estimated

downward by almost everybody. The AIFC result is the sharpest demonstration: a position worth 0.026731 of `h` is entirely consumed if its leg costs more than 8.9102% of the maintenance budget.

`N` — the effective bloc count. This is the term that had to be reinterpreted, and the reinterpretation is the whole book.

In Series B the diversity term counts independent stores: separate granaries, separate cellars, separate locations, on the reasoning that a fire, a flood, or a theft reaches one and not the others. The count that mattered was the number of things that could fail independently.

In the capital case, the same reasoning gives a different count. **Four entities in four jurisdictions are not four stores if one decision reaches all four.** `N` therefore counts independent coordination perimeters — not entities, not jurisdictions, not flags. That identification is the concentration paper's [Curzi, 2026], whose Result One takes an entity map of UK 40.9 / US 27.3 / Jersey 18.2 / Luxembourg 13.6 from a naive HHI of 0.293430 and 3.41 effective jurisdictions to a bloc-HHI of 1.000000 and an effective count of 1.00, it is the framework's central move, and everything else in the method is downstream of it.

F.3 The sustaining frequency

The steady-state condition, and the form in which the law is used throughout this series:

```
h = eta ln(N) − delta Q − C
```

`h` is the sustaining rate: positive and the stock builds, negative and it is being funded out of something else. In Series B it answers the question of how many independent stores a household needs before storage sustains itself. Here it answers the same question about perimeters.

Three properties transfer without change and are worth naming because each governs a decision in this series.

The diversity term is logarithmic, so returns diminish. The logarithm is not chosen for convenience: it is the surplus functional the corpus characterises uniquely by angle-only dependence, vanishing at parallel, an affine effective count and normalisation [Curzi, 2026], and the affine effective count $N_{\text{eff}} = 1 + (N-1)u$ it carries is badged as a **design axiom rather than a derived result** [Curzi, 2026c] — a hundred-person department at $u = 0.05$ having an effective count of 5.95. `dh/dN = eta/N`. The first move out of a single store is worth far more than the last. At `N = 1.000000` the marginal value is 0.350000; at `N = 2.941176` it is 0.119000. The concentration paper tests the alternative — a linear `eta N` — and finds it produces the absurd recommendation that a structure should hold as many jurisdictions as it can afford, which is exactly the error V5 documents.

The maintenance term is linear and the diversity term is not. Adding a store adds `C` linearly and adds surplus logarithmically, so there is always a count beyond which another store loses money — which is the whole content of the cost ceiling in the break-even probability method. And the break-even itself is computable: `N* = exp((delta Q + C)/eta) = 4.172734`.

F.4 `ln(1.00) = 0`, and what it means in each series

The single most important line of correspondence in this appendix.

```
conventional structure   N = 1.000000    ln(N) = 0.000000
                         h = 0.35 x 0 − 0.5 = −0.500000

designed structure       N = 2.941176    ln(N) = 1.078810
                         h = 0.35 x 1.078810 − 0.5 = −0.122417
```

In Series B, a household with one store has a diversity term of zero: whatever it stores is subject in full to whatever reaches that store, and no rearrangement inside the store changes it. **In this series, a structure with one effective bloc has zero available surplus — not low, zero.** `Q` decays at `delta` with nothing on the input side, and no rearrangement of the four entities in the concentration paper's conventional structure changes it, because rearranging within a perimeter does not change `N`.

That is the sentence the whole of Series D exists to establish, and it is a Series B result applied to a Series D object.

F.5 The surplus law and what it buys

The surplus available from diversity is `eta ln(N)`, and the series's central positive result is the difference between two values of it:

```
from N = 1.000000 to N = 2.941176   surplus gained = 0.377583
from N = 2.941176 to N = 4.000000   surplus gained = 0.107620
```

The first move is worth 3.5087 times the second. A reader with limited capacity to add legs should add the first one and stop, which is the arithmetic behind the AIFC assessment's "small, once, and simply."

And the honest companion result, which belongs in this appendix because it is where the series correspondence stops flattering the series. **`eta ln(N)` at `N = 2.941176` is 0.377583 and `delta Q + C` is 0.500000. The surplus does not cover the maintenance.** In Series B terms: the household built enough independent stores to make storage worth doing and not enough to make it pay for itself, and the remedy is not another store. It is a better conversion rate, a lower decay rate, or a cheaper store — `eta`, `delta`, and `C` — and this series is primarily about none of those.

F.6 What does not transfer

Four things, stated so the correspondence is not over-claimed.

The stock is not homogeneous. A granary holds one commodity; a structure holds operating companies, securities, real estate, intellectual property, and insurance reserves, each with a different `delta` and a different liquidity. **The single `Q` is an aggregation, and the failure record's Scenario C shows what it hides: the property hardest for an adversary to reach was also hardest for the family to reach.**

Rails are not stores. The store–rail rule, and it has no analogue in the earlier series this framework will claim. A transit exposure is an exposure-window problem — hop size, duration, counterparty pre-screening, mid-transit failure handling — and evaluating it with custody tools over-engineers what does not matter. Appendix B.9 reports the rail measurement as a separate number for exactly this reason.

Adversaries adapt; weather does not. The instruments that eroded the havens were designed by people who could see the structures being built against them. The threat register's failure mode 10 warns against modelling the actor as rational; the same warning applies to modelling it as stationary.

The parameters are constructed. `eta = 0.35`, `C = 0.30`, `Q = 10`, `delta = 0.02` are the carried constructed case's test values. **A real structure requires each estimated from its own facts, and `C` is the term most likely to be wrong in the direction that flatters the answer.**

F.7 Where the same law is worked in the other series

The correspondence runs in both directions, and naming the instances is the point of a reference appendix. The surplus functional appears at internal scope as $F_{\text{int}} = \ln(1 + (N-1)u)$

over an audited framing count, with the affine form again badged as a design axiom rather than a theorem [Curzi, 2026o]. It appears in the frequency register as an exact threshold-corrected Fechner law, $F(u) = \ln((u + u_0)/u_0)$ with $u_0 = 1/(N - 1)$, verified for $N = 2$ to 100 at seven values of u to a maximum deviation of $8.9\text{e}{-16}$, and with $N_{\text{eff}}(u_0) = 2$ and $F(u_0) = \ln 2$ for every N [Curzi, 2026]. Its unit conversion is fixed exactly: one nat of required surplus is 2.885390081777927 octaves, 3462.4681 cents, or 1.442695 bits [Curzi, 2026].

Two results from that series bound what a count can be asked to do, and both bear directly on this synthesis. Replacing one component of a set with a paraphrase of another takes the internal surplus from 2.164390 to 1.333662 — a loss of 2.3970 octaves — which is the same event as merging two nominally distinct jurisdictions into one perimeter [Curzi, 2026]. And the opposition identity is the sharper of the two: because $u = 1 - \rho^2$ depends only on $|\rho|$, perfect agreement and perfect opposition give the identical reading [Curzi, 2026]. **A count of independent things cannot distinguish alignment from anti-alignment**, which is exactly why the bloc call has to be argued from evidence rather than read off a correlation.

One bound is carried from the foundations and is not restated here. The corpus refuses category innocence as a defence of acquisition and forbids moving a harm through a discovered gap in a scheme [Curzi, 2026]. Nothing in this method licenses using a measured perimeter gap for that purpose, and the disclosure test of step 3 exists partly to make the attempt visible.
