A unified research bundle of seventy working papers.

Abstract of the Corpus

Stable arrangements persist even when they are poor ones. This corpus treats that persistence as a measurement problem, applying the apparatus of physics — potentials, first-order filters, fixed points, effective counts — to psychological and social systems across seventy working papers (1,836,200 words) in four series.

Series A — Foundations (6 papers) fixes the definitions: comfort as the felt total of present costs, so the present state is a local minimum of a comfort landscape by construction; the reflexive loop $T(x) = W(x, M(x))$, whose fixed points are self-fulfilling prophecies; and Banach's contraction condition, the one theorem the framework owns. **Series B — Engineering the Surplus** (33) builds the core: a storage law read as a leaky integrator, $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, with fixed point $Q* = (\eta S - C)/\delta$; the headroom gauge $h = \eta lnN - \delta Q - C$; and an interaction surplus $F(u) = ln(1+(N-1)u)$ on non-parallelism $u = 1 - (x \cdot y)^2$, shown to be exactly a Fechner law with threshold $u_0 = 1/(N-1)$. **Series C — Frequency, Essence, and Mind** (11) derives a threshold $f_min = k \cdot e^{2c/\eta}$ over an essence law $f(n) = k \cdot n^2$, $k = (9/8)^2/\varphi^2 = 0.483425732988414$. **Series D — Structure and Resilience** (20) carries $HHI = \Sigma(share^2)$ with effective count $1/HHI$ into jurisdictional structure: a four-jurisdiction holding arrangement measures 3.41 effective jurisdictions naively, 1.00 once shares collapse onto coordination blocs.

The physics is used under a badging convention naming what is derived, what modelled and what postulated. The identification of quantum with anticipatory uncertainty is badged a postulate and priced against itself — decoherence in 1.98e-17 s against a 1 ms neural event — and the one storage law written at three scopes is badged model form only. Negative results are reported with the rest. Nothing rests on fieldwork: of 27 audited parameter-by-scope cells, 19 have an estimator, one a validated value, none a first-party measurement. The preregistered fit of the storage law failed its own second falsification rule, returning a 2.8 per cent held-out advantage over a matched AR(1) against a declared 10 per cent margin. The falsification suite is anti-conservative against itself: iid permutation false-rejects at 0.108 against a nominal 0.05. The corpus's own scale-type protocol demotes its moment equation $M = (D/P) \cdot E$ to an ordinal heuristic, and a 316-entry bibliography names ten central claims with no supporting literature — among them $N_eff = 1 + (N-1)u$, which is not a Hill number, and Series C's constant and square form.

Executive Summary

What this corpus is

Seventy working papers, 1,836,200 words, developing one framework and testing it. The organising question is why stable arrangements persist when they are poor ones, and the method is to treat that persistence as a measurement problem rather than a moral one. The apparatus is borrowed from physics — potentials, first-order filters, fixed points, effective counts — and applied to psychological and social systems.

How to read it

The four series are ordered by dependency, not by importance. **Series A** fixes definitions. **Series B** builds the storage law and the surplus functional and does most of the measurement work. **Series C** extends the apparatus to frequency and mind, and is the most exposed part of the corpus. **Series D** applies the concentration instrument to jurisdictional structure, and contains its best-grounded results.

Each paper stands alone: it carries its own abstract, hypotheses, method, results, verification, limitations and references. The papers also cite each other densely — 980 internal citations, every paper citing at least thirteen others and cited by at least eight, with any paper reachable from any other in at most three steps. A reader may therefore enter anywhere.

The badging convention

Every use of a physical result is labelled where it is made, as one of three things: a **derivation**, where the system genuinely satisfies the physical premises; a **shared mathematical form**, where the same equation governs both cases with no claim that the physics transfers; or a **postulate**, asserted by this work and carrying no external warrant. Most of the corpus is the second kind, which is respectable. The convention exists so that no claim of the second or third kind can borrow the authority of the first.

Each paper's *Verification* section decomposes its results into atomic postulates, each checkable on its own by arithmetic, by definition, or by a single citation, and then shows the compounding chain that produces the result. Every step carries its status. A chain resting mostly on definitions and postulates is identified as such in the section that presents it.

What the corpus does not establish

These are stated here, at the front, rather than left to be discovered.

- **No first-party measurement.** Of twenty-seven audited parameter-by-scope cells, nineteen have an estimator, one has a validated value, and none is a first-party measurement. Nothing here rests on fieldwork conducted for this work.
- **The preregistered fit failed its own rule.** The confirmatory test of the storage law returned a 2.8 per cent held-out advantage over a matched AR(1) against a declared margin of 10 per cent. The rule was set in advance and it was not met.
- **The falsification suite is anti-conservative against itself.** An independent-permutation control false-rejects at 0.108 against a nominal 0.05.
- **The corpus demotes its own moment equation.** Its scale-type protocol reduces $M = (D/P)$ $cdot E$ to an ordinal heuristic.
- **Two different effective counts travel under one name.** $1/$ $mathrm HHI$ and $exp(H)$ are Hill numbers of order two and one and are well grounded. $1+(N-1)u$ is a linear interpolation, is *not* a Hill number, and has no supporting literature.
- **Series C rests on postulates.** The essence law, its constant, and the extension of octave equivalence beyond pitch have no supporting literature. They are badged as postulates wherever they appear.
- **Quantitative structure is assumed, not tested.** The framework treats psychological quantities as having landscape structure. The conjoint-measurement conditions that would license that treatment were not tested.

The corpus's claim to credibility is not that it has no weaknesses. It is that it is the party that found them, and printed them.

Abstract of the Corpus ii

Executive Summary iii

I Foundations 1

1 Comfort as a Local Minimum: The Founding Definitions of the Creature Comforts Framework and the Ground-State Node 2

2 The Ledger, the Gradient, and the Arithmetic of Difference: Carrying Cost, Desire Lines, and the Surplus Functional f(u) = ln(1 + (N-1)u) 30

3 Weighting Futures by Resistance: The Comfort-Weighted Amplitude, Cue Placement, and the Resolution-Disturbance Trade-Off 60

4 The Spoken Word and the Returned Difference: Performative Commitment, Echo Reading, and the Doctrine of Category Violation 89

5 Convergence and Its Dark Twin: The Contraction Mapping, the Audit of Arrival, and the Consent Law of Closure 119

6 The Reference Apparatus of the Foundations Volume: The Closing Procedure, the Protocol Index, and an Audit of the Three-Class Honesty Ledger 143

II Engineering the Surplus 196

7 The Storage Law as a Leaky Integrator: Decay, Poles, and Why Zero Loss Destroys Arrival 197

8 Conversion, Coordination Cost, and Headroom: Why Eta Is the First Lever and Why the Optimum Group Is Smaller Than the Crossover 260

9 The Effective Count and the Logarithmic Ceiling: Auditing Roster Size Against Non-Parallelism 323

10 Crossing Versus Divergence: Decomposing Non-Parallelism, the Decay of u, and the Room as a Circuit Element 405

11 Passive Geometry and the Reverberant Tail: Crenellation, Parabolic Focus, and the Acoustic Exclusion of Quiet Participants 491

12 Thresholds, Substrate, and the Table With No Head: Three Built-Environment Levers Priced Against the Storage Law 553

13 Turn-Taking, Complex Contagion, and the Critical Boundary-Cost Multiplier: Three Channels into the Surplus Law 611

14 Order Without a Centre: Stigmergic Media, Independence Protocols, and the Institutional Maintenance Term 648

15 Surveying and Preregistering the Storage Law: A Measurement Protocol, and a Confirmatory Fit That Failed Its Own Baseline Test 720

16 A Gated Intervention Procedure and a Thirty-Two-Entry Failure Catalog for the Storage Law 775

17 Five Worked Systems and the Essence Bridge: Testing Scale-Freedom in the Storage Law and Identifying the Effective Count as a Pitch Index 848

18 Conversion Keys and Modal Design: Deriving a Room, a Cadence and a Pitch Lattice from an Essence Set Without Subliminal Signal 928

19 The Moment Equation and the Calibration Ratio: A Fixed Point at Contact, a Self-Imposed Demotion to Ordinal Scale, and the Price of Stored Error 1002

20 The Perceptual Lens: Fechner's Law as the Register of the Surplus Functional, with a Postulate Method and Its Held-Out Tests 1069

21 The Internal Surplus and the Self as Storage: Auditing One Observer's Framings, and the Stored-Error Track That Feels Identical From Inside 1131

22 The Launch Budget and the Desire Line: A Rectified Surplus Fund Against a Barrier, and Why Momentum Does Not Cross a Wide Shallow Ridge 1188

23 The Return Difference, the Contraction, and a Formulary That Demotes Five of Its Own Nine Entries 1246

24 The Dyad and the Group Moment: Opposition Is Parallel, Calibration Costs All the Headroom, and Distortion Does Not Average 1344

25 Trust, Reciprocity and Obligation as Quantities: Where Trust Enters the Storage Law, and Nine Ways the Internal/External Correspondence Breaks 1416

26 The Formula Validation Protocol, Scale Type, and Specific Objectivity: Demoting the Corpus's Own Moment Equation and Pricing Its Restoration 1491

27 The Falsification Suite Measured Against Itself: An Anti-Conservative Shuffle, a 52.7 Per Cent Demand-Characteristic Pass Rate, and a Programme With a 35.8

Per Cent Survival Probability 1565

28 Star Polygons, Cadence, and the Ledger: gcd(N,k) as Parallelism, Division of a Fixed Budget as a Theorem, and What an Eleven-Operation Audit Does Not Prove 1650

29 The Two Columns and the Concordance Register: Why Agreeing Traditions Stop Adding Evidence After the Second, and a Register That Rejects One Bridge in Five 1728

30 The Cell as Receiver, the Channel and Its Capacity, and Addressing Without Editing: Adequate Bandwidth Into an Absent Decoder 1805

31 Addressing the Non-Coding Genome: The Latency Constraint, the Missing Demodulator, and an Exact Sonification Pipeline 1863

32 Conjugate Uncertainty at Three Levels: The Kennard Bound, the Gabor Limit, and a Badged Information-Budget Analogue for Forecasts 1920

33 Quantum Formalism Without Licence: Born-Rule Statistics, Decoherence Timescales in Warm Tissue, and the Casimir Force at Biological Scale 1987

34 Belief Creates Reality If the Belief Is Grounded in Truth: A Conditional Postulate, Its Channel-Gain Form, and the Placebo Case 2043

35 Where Belief Fails: Four Failure Classes, a Priced Bank Run, and the Grounding Protocol That Kills Most Claims 2099

36 Narrative as Regulatory Input: A Fully Disclosed Sonification Chain, a Zero-Resultant Corpus, and a Preregistration That Prices Its Own Nulls 2173

37 Protocols at Two Scopes and a Finite Failure Catalogue: Headroom Gating, the Participation-Ratio Effective Count, and Thirty Manifestation Faults 2240

38 One Model Form at Three Scopes: The Instrument Audit, Five Breaks in the Correspondence, and a 156-Entry Status Register 2312

39 Four Structural Results and an Honesty Register: The Closing Synthesis and Reference Apparatus of Engineering the Surplus 2372

III Frequency, Essence, and Mind 2462

40 The Sustaining Frequency: f_min = k e^(2c/eta) as an Equivalence Between the Storage Fixed Point and the Essence Bridge 2463

41 The Minimum Sustainable Frequency: A Pitch Criterion for Relational Sustainability and the Count-Based Essence Index That Feeds It 2505

42 Octave Folding and the Odd-Part Class Rule: The Frequency of a Mood, of a Trait, and the Self as a Chord 2586

43 Consonance, Collision, and the Divided Self: A Firewall Between Harmonic Dissonance and Psychological Distress 2626

44 Three Routes to the Relationship Frequency: The Unison Result and the Elasticity-Reserve Split Between Levers 2697

45 Two Octaves per Doubling Against a Quadratic Cost: Roster Ceilings, the Parallel Wall, and When Tuning Must Halt 2735

46 Auditing a Traditional Operation Set Against a Parameter Model: Seven Maps, Two Splits, Three Rejections, and the Many-to-One Compound Rule 2806

47 Refinement as Contraction: Why Repetition Cannot Move a Fixed Point, and an Evidential Audit of the Tradition It Comes From 2875

48 A Disclosed Sonification Protocol for Sequence-Encoded Content, and the Missing Transducer That Makes It a Research Design and Not a Technique 2950

49 Destiny as a Fixed Point: Conservation of Drive Under Cost Transfer, the Completeness of the Lever Set, and the Corpus's Register of Demotions 3015

50 Reference Apparatus for the Frequency Framework: Constants, Lattice Tables, Measurement Protocols, and a Four-Drawer Classification of Evidential Status 3080

IV Structure and Resilience 3131

51 Correlated Jurisdictions: Coordination Perimeters, Erosion, and the Economics of Full Disclosure 3132

52 The Concentration Instrument: Bloc Collapse and the Effective Count of Jurisdictions 3181

53 The Apex Vehicle: Foundation Against Trust, and the Arithmetic of Forced Heirship 3228

54 Institutional Quality Without Independence: London, the Crown Dependencies, and the European Convergence 3278

55 Entity Maps Understate Dependency: The Dollar Axis, the Insurance Reserve, and a Scored Captive Rubric 3316

56 Substance Repricing and the Clearing-System Count: The Atlantic Cluster, ADGM, and the Limits of a Second Enclave 3359

57 Diversification That Does Not Pay: Gulf Additions, an Indifferent Bridging Slot, and a Capped Transit Position 3400

58 Pricing an Uncertain Bloc Call: AIFC Option Value, Thailand's Share of the Gain, and the GIFT City Corridor 3438

59 Currency Drag, Cost Ceilings, and Funding-Source Independence 3474

60 Compartments, Conversions, and the Confidence a Cell Wall Requires 3509

61 Measuring the Payment Rail: Clearing Perimeters, Transit Exposure Windows, and the Concentration Effect of De-Risking 3553

62 The Carve-Out Cascade: Pledge Triggers, Antitrust Walls, and Legal-Family Interfaces Priced as Cost 3589

63 The Assembled Architecture: Effective Blocs, Sanctions Deeming Rules, and the Disclosure Test in Historical Instance 3624

64 Five Houses, One Perimeter: Bloc Collapse in a Historical Network, the Completeness Gap of Double Entry, and Canonicalisation as an Integrity Control 3669

65 Canonical Form and Typed Parsing: Measured Integrity Controls Across a Financial Identifier Namespace 3719

66 Channel Separation as a Structural Property: In-Band Impersonation, Address Anonymity Sets, and the Legacy-Migration Asymptote 3762

67 A Concentration Atlas for Distributed Ledgers: Validator Herfindahls, the Utility Ordinal, and Dwell Time as the Freeze Variable 3797

68 Content Addressing, Time-Axis Concentration, and the Bounded Gain of a Nine-Capital Supplement 3829

69 What the Architecture Cannot Do: Correlated Backing Baskets, Gated Adoption Probabilities, and the Failure Record 3863

70 The Method in Seven Steps: A Consolidated Reproduction Workbook and Honesty Register for the Concentration and Headroom Instrument 3931

Foundations

Chapter 1

Comfort as a Local Minimum: The Founding Definitions of the Creature Comforts Framework and the Ground-State Node

Abstract. This opening instalment of the Foundations series states the framework's premises and fixes the definitions the later series cite. Comfort is redefined as the felt total of current costs rather than as pleasure, and a life's trajectory is modelled as a path through a comfort landscape governed by the same shape of law as stationary action. The physics is stated exactly: the action is stationary, not necessarily minimal, written $\delta S = 0$, and the variational form licenses no teleology. Change is modelled as gradient descent, $x_{n+1} = x_n - \eta \nabla f(x_n)$, with its known behaviours of local trapping and of oscillation under too large a step. Reflexivity is written as $T(x) = W(x, M(x))$, and the self-fulfilling prophecy is identified as a fixed point of that map; the Banach condition $d(T(x), T(y)) \leq k\, d(x, y)$ with $0 \leq k < 1$ is stated as the one theorem the framework owns outright, together with the two premises, completeness and a uniform modulus, that it does not establish. The central claim, that the present moment is always a local minimum, is presented as a mechanism rather than a verdict, and departure is priced at the height of the nearest ridge rather than the depth of the current basin. The framework's single postulate, that the uncertainty of quantum measurement and the uncertainty of a foreseen future are the same kind, is stated and explicitly badged as a postulate; $\sigma_x \sigma_p \geq \hbar/2$ is given in the Kennard–Robertson form, as a fact about state preparation rather than about measurement disturbance. Three disanalogies between a person and a physical minimiser are conceded on the record, four hypotheses are stated in falsifiable form, and none of the four is tested here.

Keywords: stationary action; comfort landscape; gradient descent; reflexive loop; fixed point; self-fulfilling prophecy; postulate badging; local minimum

Series: A. Foundations **Paper:** CCP-A01

1.0.1 1. Introduction

1.1 The question

A person's circumstances are usually explained in one of two registers. Either they are the product of choice, in which case a poor position is a failure of will; or they are the product of

circumstance, in which case a poor position is a failure of luck. Both readings are common, both are consequential, and neither is a mechanism. A mechanism would have to say what quantity is being optimised, what the optimisation does at its resting points, and what it would cost to leave one.

This paper asks whether a person's stable position can be modelled as a local minimum of a scalar cost surface, and whether that model licenses a practical intervention. It is the opening instalment of the Foundations series of *Psychological and Sociological Physics: The Creature Comforts Corpus*, and it fixes the definitions on which the remaining sixty-nine papers draw. Thirty-seven of them cite the results established here. Because those results are load-bearing elsewhere, this paper states them in a form intended to be quoted rather than paraphrased, and reports its own weaknesses at the same precision as its claims.

1.2 What this paper contributes

Seven results are established or fixed here, labelled R1 through R7 and restated verbatim in the Conclusion.

R1 redefines comfort as the felt total of present costs rather than as pleasure, with the consequence that the present state is a local minimum of the comfort landscape by construction rather than by luck. **R2** writes the reflexive loop as $T(x) = W(x, M(x))$ and identifies the self-fulfilling prophecy as a fixed point of that composition of seeing and responding, while recording that the specification is not identified from observational data and is therefore a modelling position rather than a measured effect. **R3** states the principle of stationary action as $\delta S = 0$, with the correction that the honest form is stationarity and not minimality, and with the further statement that the variational form licenses no teleology. **R4** states the Banach condition $d(T(x), T(y)) \leq k\, d(x, y)$ with $0 \leq k < 1$, from which existence, uniqueness and geometric convergence from any starting point follow. **R5** states the framework's single postulate — that the uncertainty of quantum measurement and the uncertainty of a foreseen future are the same kind of uncertainty — and badges it as a postulate in the same sentence, giving $\sigma_x \sigma_p \geq \hbar/2$ only in its correct state-preparation reading. **R6** concedes three disanalogies between a person and a physical minimiser: noise, plasticity of the landscape, and response to imagined costs, the last of which physics has no analogue for. **R7** prices departure at the height of the nearest ridge rather than the depth of the current basin, which distinguishes conditions that want engineering from conditions that want acceptance.

A counter-result is stated with equal weight: the identification of a life with a minimising physical system is a postulate and not established physics; three disanalogies break the analogy; and locating oneself at a local minimum is an exoneration rather than an endorsement, because *local* was never a compliment.

1.3 Register, sources, and what is not reproduced here

The source manuscript is written in two registers, a narrative one and an analytic one, deliberately braided. This paper reports the analytic register. The narrative material is not reproduced: it is a fictional exposition and carries no analytical claim that the treatise does not also carry. Where the source's ceremonial vocabulary names a construct — *the ground state, the still water, the seal* — the construct is renamed to what it is, and the ceremonial name is reported once, as an object of study, because the framework's use of a redundant second encoding is itself one of its methodological claims and is examined in Section 8. The framework's narrative register has a respectable precedent in the operations literature, where the same choice was made for the same stated reason [Goldratt and Cox, 1984].

The source also contained an audience statement naming a particular professional community. That framing has been removed and is not reproduced. It was inessential to every claim the paper makes, and its removal changes no result.

1.0.2 2. Hypothesis

The framework advances a small number of claims that could be wrong, a larger number of definitions that could not, and exactly one postulate. Keeping the three apart is the framework's own stated discipline and this section enforces it; Figure 1 is that discipline's ledger, and the single postulate is the only entry in it that this work owns. A hypothesis that nothing could falsify is restated below as a definition or a postulate, and labelled as such [Popper, 1959].

H1 — the ground-state hypothesis. For a person under stable constraints, the occupied state is a local minimum of a scalar cost surface defined over immediately reachable alternatives: every small departure presents, to the whole weighing system rather than to deliberate reason, as a net cost. *Predicted:* if the cost of each adjacent alternative could be elicited, no adjacent alternative would carry a lower total than the occupied state, and this would hold irrespective of the occupant's reported satisfaction with the occupied state. *Falsified by:* a person stably occupying a state while a reachable adjacent state carries a lower elicited total cost, and no barrier separating them. *Status:* testable in principle; not tested here. The elicitation instrument does not exist, for reasons set out in Section 10.2.

H2 — the ridge hypothesis. Persistence in a state is governed by the height of the cheapest barrier out of it, not by the depth of the state itself. *Predicted:* two occupants of basins differing several-fold in depth but sharing a barrier height will show comparable persistence; two occupants of equally deep basins with different barrier heights will not. *Falsified by:* persistence tracking depth and not barrier height across matched cases. *Status:* testable; not tested here. Figure 3 is an illustration of the prediction, not a measurement of it.

H3 — the gradient hypothesis (the framework's practical claim). A concretely seen alternative of lower cost re-grades the surface, and relaxation toward it proceeds without an additional effort term. *Predicted:* an intervention that makes a lower-cost alternative concretely visible produces movement toward it; an intervention that applies pressure toward the same alternative without making it visible does not, and at sufficient pressure produces movement away. *Falsified by:* movement proportional to applied pressure and independent of the concreteness of the seen alternative. *Status:* testable; not tested here, and the second limb — movement away under pressure — has no supporting entry in this corpus's external bibliography. It is reported as an uncited empirical claim in Section 10.3.

H4 — the step-size hypothesis. Change attempted in corrections larger than the discrepancy that prompted them oscillates or diverges rather than settling. *Predicted:* the sign pattern of successive corrections alternates before amplitude grows, so alternation is an early warning available before failure. *Falsified by:* monotone convergence under corrections systematically larger than the observed discrepancy. *Status:* mathematically true of the modelled recursion (Figure 2); the transfer to human correction is a shared mathematical form, not a derivation, and is treated as such in Section 9.

D1 — comfort (definition, not hypothesis). Comfort is the felt total of present costs: effort owed, dangers watched, dreads carried, identities maintained, options held open. Pleasure is one term in that total and not the total. This is a stipulation. It cannot be falsified; it can only be judged useful or useless, and its measurement-theoretic status is audited in Section 9.2.

D2 — the reflexive loop (definition). $T(x) = W(x, M(x))$, where M is the occupant's model of the situation and W is the world's response to an action taken on that model. A self-fulfilling prophecy is a fixed point of T. This is a definition and a naming, not a claim; the sociological phenomenon it names was described and named long before [Merton, 1948].

P1 — the Postulate (postulate, not hypothesis, and not promoted to one). Observer participation in the reflexive loop of prediction is structurally the same phenomenon as observer participation in quantum measurement. Nothing in physics licenses this. It is offered as a correspondence of structure, adopted as working doctrine, and defended only by its fruits. It is stated in full and audited in Section 6, where the reasons it is not an H-numbered hypothesis are given.

1.0.3 3. The comfort landscape

3.1 Comfort is the felt total of costs, not pleasure

The ordinary picture of a comfort zone is a fence: the zone is a place, the occupant is inside it, the good things are outside, and growth is the act of leaving. The framework replaces the fence with a floor. The comfort zone is not a place a person is in; it is the place a person is. It travels with the occupant, because the occupant — like any system that settles — has already come to rest in the least costly arrangement available under current constraints, continuously and without deliberation.

That reframing only works once the sentiment is drained from the word. Under D1, comfort is the running total of what everything currently charges. Pleasure is one small bright line in that accounting; the accounting runs day and night whether or not anything is pleasant, and it is the accounting that steers. A person in a grey job, a stale room, or an aching accommodation of self to circumstance is not outside their comfort zone. They are at the bottom of it, and the greyness is what this particular bottom feels like. *Comfortable* and *uncomfortable* are therefore not synonyms for *happy* and *unhappy*, and the framework concerns only the first pair.

This is the founding reframing, R1. It is a definition and it does the work a good definition does: it makes a previously moralised description into an addressable one.

3.2 Stationary action, stated exactly

The framework borrows its governing image from classical mechanics, and the borrowing must be stated precisely because it is stated imprecisely almost everywhere else.

Of all the trajectories a system might trace between two configurations, the trajectory actually taken is the one for which the accumulated quantity called the action is *stationary* — unchanged to first order under small variations of the path. In symbols, $\delta S = 0$. The physical statement is stationarity, not minimality. For many ordinary systems the stationary path is in fact a minimum, which is why the principle is usually introduced as least action and why the intuition of a system taking the cheapest route is a serviceable working intuition; but the honest form is stationarity, and this paper uses the honest form. Light entering water bends at the angle that makes its travel time stationary; a chain hung from two points finds the catenary; a soap film spanning a bent wire solves a minimisation problem overnight. None of these systems knows anything, and that is the point: least-cost paths are not chosen by minds, they are what settling is.

Two further statements belong with this one and are R3's remaining content. First, the variational form licenses no teleology. That a system's realised path makes the action stationary is a statement about the structure of the equations of motion, not a statement that the system is aiming at anything, and any reading in which a trajectory is drawn toward a goal is an importation the mathematics does not carry. Second, the framework's application of this shape to a life is an application of *shape*. The source says so on the page at every occurrence, and this paper preserves that discipline; the analogy-category audit is in Section 9.1.

3.3 Local minima and gradient descent

Below the physics there is only calculus, and the calculus is checkable with kitchen equipment. A marble in a tipped bowl comes to rest where every direction it might roll is uphill. The mathematician calls such a point a local minimum, and both words carry a limit. *Local:* the bowl may sit on a table and the table in a house on a hill; the marble rests where it rests not because nowhere is lower but because every path away begins with an ascent. *Minimum of what:* of the potential surface as it stands, not of the surface the marble might prefer.

Once comfort is pictured as a surface — high ground costly, low ground cheap — one of the best-understood procedures in applied mathematics is imported whole. From wherever

claim	established in
Stationary action $\delta S = 0$	physics
Minima and gradients	calculus
Contraction mapping theorem	mathematics
Judgment and habit findings	psychology
Measurement uncertainty ≡ foresight uncertainty	this work

4 established · 1 badged POSTULATE

Figure 1.1: The framework's own inventory of formal claims: four are established outside this work, and exactly one — the correspondence between measurement uncertainty and the uncertainty of a foreseen future — is badged as this work's postulate. The counts are the source's, which states "the complete inventory of the book's formal claims ... There are five". Schematic; no measured quantity.

you are, step in the direction that most steeply reduces the cost, and repeat:

$$x_{n+1} = x_n - \eta \nabla f(x_n)$$

where f is the cost surface, ∇f its local slope, and η the step size. Every well-characterised behaviour of this procedure describes a way that human change succeeds or fails.

It settles into whatever local minimum it happens to be near, not the deepest on the map — which is why a person can be stuck in a life that is merely locally comfortable while a far better minimum sits one ridge over, invisible from where they stand. It moves without any effort term, purely by slope — which is why the framework's central practical claim (H3) is that *seeing* a nearer, deeper comfort is itself the intervention: the lower ground has to be made visible, and relaxation does the rest. And if the step size is wrong — too large, too forced — the procedure overshoots and oscillates instead of settling (H4, Figure 2). The oscillation regimes of a first-order recursion are standard [Elaydi, 2005, Kelley and Peterson, 2001]; the basin structure that makes the local/global distinction consequential is equally standard [Strogatz, 2015]; and the gain-and-stability vocabulary in which the failure is usually diagnosed is the control engineer's [Åström and Murray, 2008].

3.4 The present state is a local minimum, by construction

What survives the caveats is the ground-state result, R1 in its operational form: **the present moment is always a local minimum of the occupant's comfort landscape.** Wherever a person now sits — this chair, this job, this city, this silence toward a sibling, this hour of reading instead of any of the ten thousand other things — they sit there because, under the constraints and prices as their system has weighed them, every small departure has presented as a net cost. Not to deliberate reason; deliberate reason is a late committee that reviews decisions mostly after they ship. To the whole weighing.

The argument is symmetrical and short: had any adjacent arrangement been reliably cheaper *as the system prices it*, the person would already be there. The evidence is the ordinary evidence of habits never decided on and identities never chosen. The settling never stops.

The result reads as an accusation only if it is misread by exactly half. It is a mechanism, and a mechanism cannot accuse. What it can do is exonerate — of the specific charge that

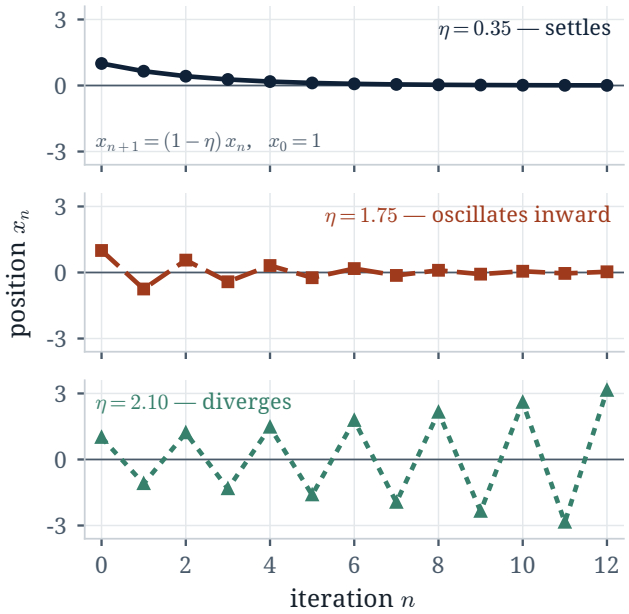

Figure 1.2: Step size, not intention, decides whether descent settles. Modelled, not measured: cost surface $f(x) = x^2/2$, so the descent recursion reduces exactly to $x_{n+1} = (1-\eta)x_n$, with $x_0 = 1$ and $\eta \in \{0.35, 1.75, 2.10\}$. Below $\eta = 2$ the recursion converges; at $\eta > 2$ it diverges while remaining perfectly well intentioned. Script: `figs/src/CCP-A01_fig02.py`.

one's circumstances are a failure of will. If effort was never the engine, its shortage was never the fault. But the exoneration is not a blessing. A local minimum can be shallow, grey, and very far from the lowest place the surface holds. The framework does not teach that where a person is, is good. It teaches that where they are is *ground* — real, load-bearing, arrived at lawfully — and that no intervention can be launched from anywhere else, for the same reason that no navigator can plot a course from a position they refuse to occupy.

Two boundary readings are refused explicitly, because both are available and both are wrong. The result is not a doctrine of desert: to say that a position is a lawful minimum of a surface says nothing whatever about who graded the surface. Some surfaces are carved by their occupants; many are carved by birth, by policy, and by other people's decisions arriving like weather, and a creature settling lawfully into terrain it never chose is not thereby endorsing the terrain. The mechanism describes; it does not justify. Nor is the result contentment teaching: the traditions that counsel wanting what one has aim to *deepen* the occupied minimum, whereas this result aims only to *locate* it, and is indifferent to the verdict that follows.

3.5 Departure is priced at the ridge (R7)

The question every grey position eventually raises — *if I dislike it here, why do I stay?* — has a mechanical answer that does not require a defect of character.

Departure is priced at the rim, not at the destination. What holds an occupant is rarely the depth of the minimum but the height of the nearest ridge, and ridges are made of very ordinary material: a pension vesting in four years, a lease, an ageing parent in the next town, the specific dread of being a beginner again at forty, an identity that would have to be buried with honours. A shallow minimum ringed by high ridges holds exactly as firmly as a deep one, and feels entirely different from inside. That difference — held versus home — is worth locating precisely, because the two call for different work. The deep minimum wants acceptance. The shallow one ringed with ridges wants engineering, and engineering, unlike exhortation, begins with an accurate map of the terrain as found.

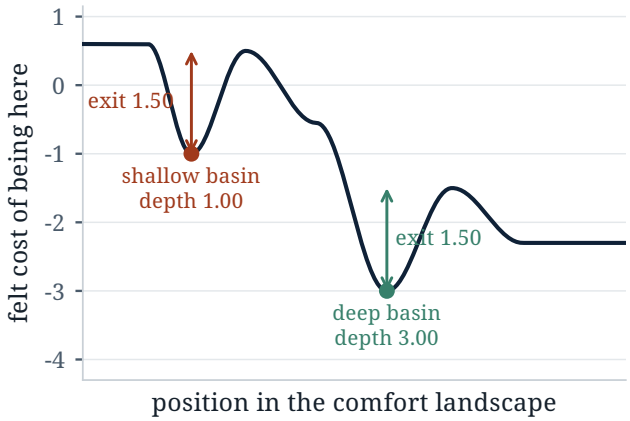

Figure 1.3: Persistence is set by barrier height, not by basin depth. Modelled, not measured: a one-dimensional surface laid out through explicit control points and smoothed by raised-cosine interpolation so that two basins differ threefold in depth (1.00 against 3.00 cost units) while sharing an identical cheapest exit of 1.50 units. Both barrier figures are computed from the plotted curve. Script: `figs/src/CCP-A01_fig03.py`.

The same geometry supplies the framework's diagnosis of professional over-specialisation. A silo is a local minimum: deep because years of training and reward have carved it, narrow because it admits one vocabulary and one set of tools, and walled by comfort rather than by ignorance. The specialist could learn the neighbouring domain; what the specialist cannot easily do is want to, in the moment, against the gradient, because every direction out is uphill and gradient descent does not go uphill. This is why exhortation fails, and it is the mechanism by which organisational learning destroys the variance that produced its own advantage [March, 1991]. The prescription that follows is not force but terrain: the connecting pattern is to be made the cheaper place to stand, so that migration happens by the same gradient that produced the trap. The limit of that prescription is real and is stated in Section 8.3.

3.6 Noise, and the one place it helps

The first of the three conceded disanalogies (R6) has a use before it has a cost. A person is noisy: they jitter, err, and are jostled, and the jostling sometimes throws them over ridges no gradient would carry them across.

Metallurgy names the corresponding technique. A metal cooled quickly freezes into whatever strained arrangement it happened to occupy; cooled slowly, with heat enough to keep the atoms jostling, it finds its way over small ridges into deeper minima and comes out stronger. Search procedures borrowed the trick whole: add noise, then quiet it gradually, and the search escapes shallow traps it would otherwise die in. The framework's claim is that disrupted seasons of a life — the move, the loss, the enforced interval — function as that heat: positions held for decades come loose, ridges that were walls become steps, and the settling that follows can reach hollows the settled years could not.

This paragraph carries no citation, deliberately. Simulated annealing is standard, but it has no entry in this corpus's external bibliography (Section 10.3), and the transfer from an annealing schedule to a disrupted life is in any case a shared mathematical form at best. It is reported here as the framework states it, and flagged.

1.0.4 4. The reflexive loop (R2)

A person is not a ball on a fixed surface, because a person carries a model of the world, acts on the model, and thereby changes the world, which changes what the next model should be.

Write M for the occupant's model — their read of the situation — and W for the world's response to an action taken on the basis of that model. Then the next state of the system is

$$T(x) \;=\; W(x,\, M(x))$$

The model reads state x and prescribes an action; the world processes the state together with that action and returns the next state. T is the composition of seeing and responding (Figure 4). This is D2, and it is a definition.

The structure is not exotic. It is the everyday structure of markets, reputations, deterrence, morale, and every situation in which what people believe will happen helps decide what happens. The self-fulfilling prophecy is exactly a fixed point of such a loop: a belief that, once acted upon, brings about the conditions that make it true [Merton, 1948]. Its companion — purposive action producing the consequence nobody modelled — is the same machinery read from the other end [Merton, 1936]. The general programme of treating one mathematics of feedback as governing both machines and organisms is older still [Wiener, 1948]. The move of modelling a human operator inside a control loop as a transfer function is older than every claim in this section.

Two exposures attach to the loop and are recorded here rather than in Limitations, because they qualify the definition itself. First, a loop whose state variable is also its own published indicator degrades: a measure that becomes a target ceases to be a good measure, and any instrument built on this framework is exposed to that [Campbell, 1979]. Second, the loop's W term includes the observer's own presence: expectancy effects on the observed are real as a design threat even where their magnitude is disputed [Jussim and Harber, 2005].

A third exposure is decisive, and it is stated here, at the point of introduction, rather than deferred to a footnote. Written as an aggregate relation — a group's state influencing its members while the members constitute the group — $T(x) = W(x, M(x))$ is a reflexive, linear-in-means specification, and the endogenous effect in such a specification is **not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is collected [Manski, 1993]. No quantity of fit, held out or otherwise, recovers the parameter. The network route is foreclosed by a companion result: influence and selection are generically confounded in observational network data, so resemblance between interacting parties is not evidence that the interaction produced it [Shalizi and Thomas, 2011]. **R2 is therefore a modelling position, not an identified empirical result.** This paper adopts no identification remedy; Section 9.4 names the remedies that exist, prices each, and says why none is claimed here.

1.0.5 5. The contraction condition (R4)

This is the one theorem the framework owns outright, and it is stated with its premises visible because the premises are where the transfer succeeds or fails.

Take a complete metric space (X, d): a set of states with a notion of distance, in which every sequence that bunches up ever more tightly converges to a state that is actually in the space. Take a map $T : X \to X$. Call T a **contraction** if there is a constant k with $0 \le k < 1$ such that for every pair of points $x, y \in X$

$$d(T(x),\, T(y)) \;\le\; k\, d(x, y)$$

Then Banach [1922] guarantees three things, as proven fact rather than as tendency. First, T has a fixed point: a state x^* with $T(x^*) = x^*$. Second, that fixed point is unique. Third, it is

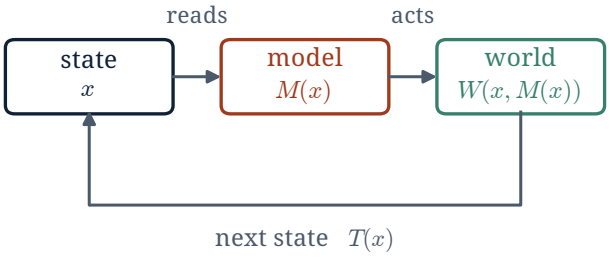

Figure 1.4: The reflexive loop and the two conditions that close it. Schematic; no plotted quantity. The composition $T(x) = W(x, M(x))$ is the paper's definition D2; the fixed-point equation and the contraction condition are stated beneath it as the two separate things they are — one an equation a state may satisfy, the other a property the map may have. Script: `figs/src/CCP-A01_fig04.py`.

reached from anywhere: starting the iteration at any point whatever and applying T repeatedly, the sequence converges to x^*, and it converges geometrically, the remaining distance shrinking by at least the factor k each pass.

Uniqueness is worth seeing done, because it takes one line and it is the part operators disbelieve. Suppose x^* and y^* are both fixed. Then $d(x^*, y^*) = d(T(x^*), T(y^*)) \le k\, d(x^*, y^*)$, so $(1 - k)\, d(x^*, y^*) \le 0$; since $k < 1$ this forces $d(x^*, y^*) = 0$, and the two points were one point.

Read in the framework's terms: if the reflexive loop of a life can be made into a contraction — if each pass through *see, act, the world answers, see again* reliably shrinks the distance between where the occupant is and a particular foreseen state — then that foreseen state is not a hope. It is a fixed point; it is unique; and it will be reached, from wherever the occupant happens to start, by iteration. That is the object the framework teaches the construction of, primarily upon oneself. The instrument in its exact form, together with the a posteriori bound that makes it self-reading, is the subject of the companion paper: the statement that a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass [Curzi, 2026].

What is a theorem here, and what is not. The theorem is a theorem. The claim that a human life *can be arranged* to satisfy its premises is the framework's, and the premises are exactly where the difficulty lives. Two of them are load-bearing and neither has been demonstrated for this application:

- *Completeness.* The state space must contain the limits of its own Cauchy sequences. Nothing establishes that a space of life-states does.
- *Contraction with a uniform modulus.* There must exist a single $k < 1$ bounding the shrinkage for **every** pair of states, not merely for the pairs an operator happens to visit. Nobody has measured such a k for any human loop.

Where the modulus is one or greater the guarantee does not weaken, it inverts: unit gain gives an isometry, which orbits without arriving, and gain above one gives an amplifier, in which corrections sized to delayed feedback arrive as new errors. That is the same failure the step-size hypothesis H4 describes, and it is why this paper treats the contraction as a *condition to be checked*, not a property to be assumed. The corpus applies the same condition to its storage law, where the decay rate plays the role of $1 - k$: the map $Q_{t+1} = (1 - \delta)Q_t + \eta S_t - C_t$ is Lipschitz with modulus $1 - \delta$, so $\delta > 0$ is precisely what makes it a contraction, and $\delta = 0$ is shown to be a pathology rather than an ideal — no contraction, no unique fixed point, and an

error-persistence column of all ones, so that no mistake ever decays out of the stock [Curzi, 2026a]. The corresponding fixed-point elasticities are measured elsewhere in the corpus: η at $+1.594$, δ at -1.000, u at $+0.770$ and C at -0.594, so that a ten per cent efficiency gain is worth 2.7 times a ten per cent cost cut [Curzi, 2026q]. The contraction constant $1-\delta$ and the exact error law $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ are verified to a maximum residual of 2.0624×10^{-15} over a hundred passes [Curzi, 2026].

1.0.6 6. The Postulate, stated and badged (R5)

6.1 The uncertainty relation, stated honestly

For a quantum state, the product of the standard deviations of two conjugate observables — position and momentum being the canonical pair — is bounded below:

$$\sigma_x \, \sigma_p \;\geq\; \frac{\hbar}{2}$$

This is the Kennard–Robertson form [Kennard, 1927], and the point the popular accounts get wrong must be got right here and in every later occurrence. **It is not, at its core, a statement that a clumsy measurement disturbs a delicate system.** There is a related and real measurement-disturbance effect, and it is a different statement. This one is about the *state itself*: position and momentum are Fourier conjugates, and no state — measured or unmeasured, observed or alone in the dark — can be sharply defined in both at once, for the same reason that no signal can be simultaneously a sharp spike in time and a single pure frequency. The spread is intrinsic. It is a property of what a quantum state is, not of what an instrument does to it.

The sloppy version — *the observer disturbs the observed* — is exactly the version a careless argument would lean on. This paper states the strict version, uses only the strict version, and does not build on the sloppy one.

6.2 The Postulate

There is a second kind of uncertainty, wholly outside physics, in the reflexive loop of Section 4: a future that is affected by being foreseen is, for that reason, genuinely uncertain in a way that has nothing to do with ignorance and cannot be removed by better information. Measuring the position of a particle sharpens position at the expense of momentum. Foreseeing a future, and acting on the foresight, alters the future foreseen. In both, the act of observation participates in the thing observed.

The Postulate (P1), badged in the sentence that states it: it is postulated — not derived, not demonstrated, and not licensed by physics — that these two uncertainties are the same kind of uncertainty; that observer participation in the reflexive loop of prediction is structurally the same phenomenon as observer participation in quantum measurement.

The status of that claim is stated exactly. It is **not** a theorem. It is **not** established physics. It is **not** a claim that the mind is a quantum system, that neurons compute with wavefunctions, or that consciousness collapses anything; the framework makes none of those claims and would be wrong if it did. It is a proposed correspondence of structure between two reflexive phenomena arising in wholly different substrates. It may be accepted, held at arm's length as a suggestive analogy, or rejected outright, and the practical framework stands either way — because everything the framework actually asks a practitioner to do is licensed by the reframing of Section 3, the gradient descent of Section 3.3, the loop of Section 4, and the theorem of Section 5, none of which need the Postulate at all.

6.3 Why the Postulate is not an H-numbered hypothesis

It is not listed with H1–H4 because no observation distinguishes the world in which it holds from the world in which it does not. A structural correspondence between two mathematical descriptions is a fact about the descriptions, and asserting that the underlying phenomena are therefore of one kind adds nothing an experiment could detect. Under a strict falsifiability criterion the Postulate is not a scientific claim at all [Popper, 1959]. The framework's own account of what it is doing is better rendered in the vocabulary of research programmes: the Postulate is a hard-core commitment that is protected rather than tested, and its warrant is the productivity of the belt of testable claims around it [Lakatos, 1970].

The hazard the badge exists to prevent is well documented. A physics result cited outside the conditions of its own derivation transfers only its authority and none of its content — a habit whose clearest example is the traversable-wormhole literature, which is routinely invoked as support for shortcuts between distant states when its own conclusion is that such a shortcut requires exotic matter violating the averaged null energy condition [Morris and Thorne, 1988]. That is precisely the failure the badge is designed to make impossible here.

1.0.7 7. The three conceded disanalogies (R6)

The framework's honesty condition requires that the ways in which a person is not a marble be listed rather than left to a reviewer. Three are conceded on the record.

7.1 Noise. A person jitters, errs, and is jostled, and the jostling sometimes carries them over ridges no gradient would cross. A marble in a still bowl does not. The use of this disanalogy is Section 3.6; its cost is that no trajectory prediction from the model can be deterministic, and that the model therefore predicts distributions at best, and in its present state does not predict those either.

7.2 Plasticity. A person's surface re-grades itself as they learn, which no bowl's does. This is not a small correction. It means the objective function is non-stationary, that a minimum located today may not be a minimum next season, and that adaptation moves the reference level against which cost is felt. The empirical form of that plasticity is well known: subjective states decay toward a set point after large changes of circumstance [Brickman et al., 1978], though the strong reading of that finding has been substantially revised — set points move, adaptation is incomplete, and individuals differ [Diener et al., 2006]. The framework's practical claim depends on the revised reading and would be defeated by the strong one, and that dependency is stated here rather than discovered later.

7.3 Foresight. A person responds to costs that do not exist yet — costs they have merely imagined — and this is the one term for which physics has no analogue at all. A creature that responds to imagined costs is a creature whose surface can be re-graded by an act of imagination. This is not a flaw in the analogy; it is the entire remainder of the framework, and it is what makes H3 a claim rather than a restatement.

1.0.8 8. The framework's own apparatus

8.1 The twelve constructs

The framework is organised as twelve numbered constructs in four groups of three. The table is reproduced because it is the framework's index and because later papers address constructs by number. The right-hand column records the correspondence to an earlier ten-part scheme from which the framework descends; two constructs have no ancestor there, and the table says so rather than inventing one.

No.	Construct	Function (operational)	Function (ceremonial register)	Earlier scheme	Group
00	STILLPOINT	The occupant is always at a local minimum: the present state is the comfort zone by definition, not by luck	The ground state; the water at rest	— (first assumed node)	I
01	LEDGER	Honest inventory of current comforts and their actual costs	The test of the stone	KIN.0 VALIDATE	I
02	GRADIENT	Comfort differentials; least-action paths; desire lines	Water does not negotiate	— (second assumed node)	I
03	HORIZON	Nonlinear extrapolative reasoning; branch-tracing; surplus of non-parallel sightlines	The many windows of the one tower	KIN.1 TRANSMED	II
04	WAVE	The future as a comfort-weighted amplitude; reading amplitudes	The sea before the wind chooses	KIN.3 MYTHOS	II
05	LURE	Placing the idea of greater comfort where the self will encounter it; cues, triggers, named days	The baited horizon	KIN.4 FORGE	II
06	UNCERTAINTY	The Postulate: observation participates; trade-offs of knowing	The veil that measures the measurer	KIN.6 CHECK	III
07	COLLAPSE	Commitment as measurement; the spoken prediction	The word that closes the sea	KIN.2 KERNEL	III
08	ECHO	The world answers; reflexive loops; first return signal	The voice that comes back changed	KIN.8 MULTIPLAY	III
09	RECURSE	Iteration; drift correction; the spiral, not the circle	The stair that climbs itself	KIN.5 RECURSE	IV
10	FIXEDPOINT	The self-fulfilling prediction as the fixed point of a contracting loop	The room that was always furnished	KIN.7 ETHIC	IV
11	SEAL	Closing the working; consent; when not to run the procedure at all	The seal; the vow	KIN.9 SEAL	IV

Group I establishes position and asks for no change; that restraint is calibration, not gentleness. Group II trains the seeing. Group III is the act, and it opens with the Postulate stated as a postulate, so that the act is not performed by anyone who has been permitted to mistake the Postulate for a theorem. Group IV is the finishing: iteration, arrival, and closure. The ethics are stated last not because they matter least but because a constraint stated before capability is a mood, and stated after capability is a commitment.

The two constructs without an ancestor are the framework's first teaching in miniature. The earlier scheme began at validation because it assumed that the ground an operator stood on and the slope that ground made under their feet were simply there: conditions, not workings. The framework's finding is that both are running processes, and so the count became twelve.

8.2 The redundant second encoding, examined

The framework states each item three times: as mechanism, as mathematics, and as rite. The third statement adds no information. The framework's stated reason is that a claim held in one form is held in one way, and that the second encoding survives conditions the first does not. This paper reports that as the framework's claim and does not endorse it, because no entry in this corpus's external bibliography establishes it (Section 10.3). What can be said is narrower and is worth saying: the practice of pairing every prescription with a named failure mode has a well-developed precedent in design method, and the practice of delivering a procedural argument in narrative form has a precedent in operations [Goldratt and Cox, 1984]. Neither precedent establishes a transfer advantage. Both establish that the choice is not eccentric.

The ceremonial register is analysed here, not performed. Where the source sets a mnemonic in Latin — *quies fundamentum, non carcer*, rest is the foundation and not the cage; *aqua in fundo quiescit*, the water rests at the bottom — these are recorded as the framework's own tags for its results, and the second is the ceremonial name for R1.

One substantive distinction survives translation and is not ornamental. The framework distinguishes *resignation* from *accuracy*. Resignation is a verdict about the future rendered from the present. Accuracy declines to be wrong about the present and renders no verdict about the future. The two are confused by nearly everyone at first, and the operational difference is testable in principle: when circumstances change, the resigned are surprised, having filed the old level as permanent, and the accurate simply re-level, having filed nothing.

8.3 The reflexive loop at institutional scale

The framework applies D2 above the level of the individual, and the application is worth stating because it is where the loop does visible work and where its limits are sharpest.

Four positions are advanced. First, self-sovereignty is not the absence of accountability but its internalisation: the sovereign keeps their own books, and the honesty must be greater precisely because no external party is auditing. Second, sovereignty does not abolish organisations but re-situates them — their function shifts from governing subjects to coordinating nodes, which is a more demanding job, not a lesser one; the empirical literature on durable common-pool governance describes exactly such coordination and supplies design principles derived from cases rather than postulated [Ostrom, 1990]. Third — the point on which the doctrine turns — sovereignty becomes a threat by one path, suppression: a power fears that autonomy is dangerous, acts on the fear, the action produces resistance, the world returns a threat that is now real, and the power reads the returned threat as confirmation. That is $T(x) = W(x, M(x))$ written at institutional scale, and it is the plain self-fulfilling prophecy of Section 4 doing real explanatory work [Merton, 1948]. Fourth, the mature posture is therefore integration rather than secession, and integration means the deliberate maintenance of a complementary, non-parallel pair whose difference is preserved rather than dissolved.

The fourth position rests on an arithmetic the framework uses throughout: several non-parallel viewpoints yield more together than any one alone, and the surplus is a function of their *difference*, vanishing when the viewpoints are identical, and growing only logarithmically thereafter. The framework states the diminishing returns rather than overselling the effect, and this paper states the literature on both sides, because the evidence is genuinely two-sided.

The functional form is underdetermined, and this paper says so rather than asserting one. The framework's surplus is logarithmic in the count. Two established alternatives fit the same qualitative facts equally well: social impact grows as a power of the number of sources with an exponent below one, established with psychological data [Latané, 1981], and network value has been argued to grow as $n \log n$ rather than as any of the usual candidates [Briscoe et al., 2006]. All three are decelerating functions of the count and nothing in this paper discriminates between them. **A paper asserting the logarithmic form owes a discriminating test, and this**

one does not have one.

What can be said in the logarithm's favour is a warrant that does not depend on the perceptual story at all: the growth rate of a multiplicative process is logarithmic, so a logarithmic form can be a dynamical consequence rather than a psychological assumption [Peters and Gell-Mann, 2016]. Where this corpus justifies a logarithm on Fechnerian grounds [Fechner, 1966], that warrant is the weaker of the two, because it requires the perceptual claim to be true. Where the quantity in question is generated multiplicatively, the dynamical warrant is available and should be preferred. This paper does not establish that the comfort surplus is generated multiplicatively; it records which argument would be needed.

Supporting: novel information arrives across weak, dissimilar ties [Granovetter, 1973]; the formal result that groups of diverse problem solvers can outperform groups of high-ability solvers exists and is much cited [Hong and Page, 2004]. Against: that result has been argued to be either trivially true or dependent on conditions amounting to the conclusion [Thompson, 2014], and the exchange that followed is the honest context — a defence [Kuehn, 2017]. Three incompatible constructs are called diversity — separation, variety and disparity — so any measure of difference must declare which it is, and the framework's has not [Harrison and Klein, 2007]. And the strongest structural warning is that difference does not add monotonically: creative success rises and then *falls* with cohesion, an inverted U [Uzzi and Spiro, 2005]; in the largest natural setting studied, short-run diversity reduced trust and civic participation, a finding its author did not want [Putnam, 2007], though the effect largely disappears under better controls [Abascal and Baldassarri, 2015]; contact across difference produces value only under stated conditions [Allport, 1954]; the same conclusion holds in randomly assembled ecological systems, where increasing diversity and connectance *destabilises* [May, 1972]; and in engineered systems redundancy can reduce safety outright [Sagan, 1993]. Two further results bound the prescription sharply: adding independent-looking components inside one coupling perimeter increases interactive complexity and can make catastrophic failure a system property rather than an operator error [Perrow, 1984]; and a count of participants that has not been audited for independence is worthless, because one party can present as many [Douceur, 2002].

The framework's own concentration instrument makes the last point in numbers. Four jurisdictions holding 40.9, 27.3, 18.2 and 13.6 per cent give a naive Herfindahl index of 0.293430 and 3.41 effective jurisdictions; collapsing them into the single bloc they actually form gives a bloc index of 1.000000 and an effective count of 1.00 [Curzi, 2026]. Stated as a procedural rule: $\ln(1.00) = 0$, so a structure with one effective bloc has zero available surplus rather than a low one, and the first step of the method is to collapse before measuring [Curzi, 2026]. That reading of $1/\mathrm{HHI}$ as a numbers-equivalent is the standard one [Hill, 1973]. It applies to $1/\mathrm{HHI}$; it does not apply to the framework's own affine effective count, for reasons recorded in Section 10.4.

The parallel exposure in identification is measured in the corpus: with an address-only log the attribution set is 1,953.1 subscribers; with address plus port and live session state it is 1; and after state expiry it is 1,453.2 — so an address is evidence of a pool, not of a person [Curzi, 2026]. The general principle behind such disclosure constraints is an engineering standard rather than an ethical preference: a system must remain secure when everything about it except the key is public [Kerckhoffs, 1883].

1.0.9 9. Method: what kind of borrowing each borrowing is

9.1 Analogy discipline

Every physics borrowing in this paper is labelled at first use as one of three things: a derivation, in which the physical result is used because the system genuinely satisfies its premises; a shared mathematical form, in which the same equation governs both with no claim that the underlying physics applies; or an analogy, a suggestive correspondence with no formal warrant, legitimate as motivation and never as evidence. The labels for this paper are collected

here so that a reader can check them against the text.

Borrowing	Category	Warrant, and what is not claimed
Stationary action, $\delta S = 0$ (Sec. 3.2)	3 — analogy	The action functional of a life is not defined and no Lagrangian is exhibited. The borrowing supplies an image of a resting trajectory. The variational form licenses no teleology, and no physical result is transferred.
Local minima and gradients (Sec. 3.3)	2 — shared form	The mathematics of a stationary point of a scalar field is the same mathematics wherever the field comes from. No claim that the field is a potential energy.
Gradient descent (Sec. 3.3)	2 — shared form	The recursion and its convergence and oscillation regimes hold for any differentiable cost and any step size; the transfer claim is that human change has this recursion's shape, not its physics [Elaydi, 2005, Strogatz, 2015].
Annealing and noise (Sec. 3.6)	2 — shared form, uncited	Escape from shallow minima under decreasing noise is a property of the search procedure. No entry in this corpus's bibliography supports it, and none is claimed.
The reflexive loop (Sec. 4)	1 — derivation, within its own definition	$T = W \circ (\mathrm{id}, M)$ is a definition; nothing is imported. The sociological identification is cited, not derived [Merton, 1948].
Banach's theorem (Sec. 5)	1 — derivation, **conditional**	Genuine derivation *if and only if* the space is complete and the map contracts with a uniform modulus. Neither premise is established for a human loop, so the claim is stated as conditional and the condition is printed [Banach, 1922].
$\sigma_x \sigma_p \geq \hbar/2$ (Sec. 6.1)	quoted exactly, then 3 — analogy	Quoted in its state-preparation reading [Kennard, 1927]. Its extension to a foreseen future is P1, a postulate, and is badged at every occurrence.

Borrowing	Category	Warrant, and what is not claimed
“Thermodynamics of attention” (Sec. 9.3)	3 — analogy, and a poor one	The source’s phrase. There is no energy, no temperature, and no conserved quantity. Reported and marked; not used.

The corpus’s title claims physics, and the claim attracts a specific literature of objection which is better cited than ignored. The historical form of the objection is that economics imported the formal apparatus of nineteenth-century physics without its empirical discipline [Mirowski, 1989]; the general form is that laws hold in patches rather than universally, so importing a law’s form is not importing its scope [Cartwright, 1999]; and the version from inside physics is that a system’s behaviour at one scale is not derivable from the laws governing its parts, which is the strongest available warning against reading a shared equation as a shared mechanism [Anderson, 1972]. The programme this corpus belongs to has been criticised sharply from within for modelling without contact with data [Sobkowicz, 2009]. This paper’s position is the one the table above encodes: category 2 is respectable and is where most of the framework sits, and the failure mode to guard against is a category-2 or category-3 use borrowing the certainty of category 1.

9.2 Scale type, and the objection that bites hardest

The dimensional audit belongs with the verification chain and is given as Section 13.4; what follows here is the part of the audit that constrains the argument rather than the notation.

The model treats comfort as having landscape structure — gradients, minima, ridge heights, differences of depth. That presupposes at minimum an interval scale, and nothing in the source establishes one. This is the framework’s sharpest exposure, and the objection has a name and an author: psychology, on this account, systematically assumes that its attributes are quantitative without ever testing whether they are [Michell, 1997]. **This is the strongest single objection to the framework and it is not answered here.** The formal test for whether an attribute has additive quantitative structure at all is conjoint measurement [Luce and Tukey, 1964], whose conditions — single, double and triple cancellation — are exactly what would have to be checked. **They were not tested.** The standard against which any such claim is judged is set out in the measurement-foundations literature [Krantz et al., 1971], and a route that does not require respondents to use numbers at all is available and unused [Rasch, 1960].

The honest position, adopted here: **comfort is treated as quantitative by stipulation, not by demonstration.** Everything in Sections 3 and 5 that uses differences, ratios of depths, or a metric d is therefore provisional at the level of its arithmetic, however sound its logic. The construct-validation programme that would be required is specified and not run [Cronbach and Meehl, 1955], and the self-report instruments the framework would need are exposed to well-documented distortions: people cannot reliably report the causes of their own behaviour [Nisbett and Wilson, 1977], and a question that names a component of well-being induces a focusing illusion in the answer [Kahneman et al., 2006]. A further formal obstacle applies to any similarity-based reading of difference: psychological similarity is asymmetric and violates the triangle inequality, so it is not a metric [Tversky, 1977], which bears directly on the assumption in Section 5 that d exists at all.

9.3 Limits and boundary behaviour

Each relation stated above, at the boundaries of its parameters.

- $\eta \to 0$. The descent recursion becomes the identity: no movement, and the occupant remains at the initial state for ever. The model's prediction at this limit is that a correctly seen alternative with no step at all produces nothing, which is correct and uninteresting.
- $\eta \to 2/L$ **from below, for a surface of curvature** L. Convergence becomes arbitrarily slow with alternating sign; at $\eta = 2/L$ the recursion is an isometry and orbits; above it, divergence. For the modelled quadratic of Figure 2, $L = 1$, so the boundary is exactly $\eta = 2$. This is the mathematical content of H4 and the model's only sharp prediction.
- $k \to 1^{-}$. The contraction bound survives but the convergence rate goes to zero and the a posteriori bound $q/(1-q)$ diverges: arrival is guaranteed and unbounded in time. The theorem does not fail; it stops being useful, which is a distinction worth keeping.
- $k = 1$. No guarantee at all. An isometry has no fixed point in general and no theorem.
- $k > 1$. Divergence; the loop manufactures error. The corpus's storage-law instance of the same boundary is $\delta \to 0$, where the map ceases to contract and the error-persistence column becomes all ones [Curzi, 2026a].
- **Barrier height** $\to 0$ **(Sec. 3.5).** The basin ceases to be a basin and the occupant is not in a minimum at all; H2 is vacuous in this limit and the model has nothing to say.
- **Barrier height** $\to \infty$. Persistence is total and departure is impossible by gradient. The model then predicts that only the noise term of Section 3.6 can move the occupant, which is a real prediction and one the framework's own protocol does not test.

9.4 Identification, and the framework turned on itself

This subsection belongs to Method because it decides what kind of thing R2 can be. It is the paper's most consequential methodological statement and it goes against the framework.

The reflection problem. The reflexive loop of Section 4, written at the level of a group, is a linear-in-means specification in which the mean behaviour of a reference group enters each member's behaviour while being constituted by it. In that specification the endogenous social effect is not identified from observational data: it is not separable from contextual effects — the exogenous characteristics of the reference group — nor from correlated unobservables that make members of a group alike for reasons that have nothing to do with influence [Manski, 1993]. This is a theorem about what the data can support, not a complaint about sample size, and no amount of held-out performance changes it. The same conclusion arrives from the network side: homophily and contagion are generically confounded in observational network data, so a resemblance between interacting parties cannot be attributed to the interaction [Shalizi and Thomas, 2011]. **The remedies, and what each costs.** Four are available and none is free.

Remedy	What it buys	What it costs
Randomisation of exposure	Identification of the endogenous effect directly	An experiment; infeasible for most of what this framework describes, though social-convention tipping has been demonstrated experimentally [Centola et al., 2018]
An instrument for group composition	Identification without an experiment	A defensible exclusion restriction, which the framework does not have
Partial-population variation	Identification from differential treatment within groups	A designed intervention reaching part of a population
Stipulating the reference group and defending the stipulation	Identification conditional on the stipulation	The stipulation itself must be argued and can be wrong [Brock and Durlauf, 2001]

The fourth is the realistic route for this framework, and it is the one the corpus should take. The template is a discrete-choice model with social interactions, derived from a standard random-utility foundation, which states explicitly the conditions under which its interaction parameter is econometrically identified [Brock and Durlauf, 2001]. An interaction parameter that is merely *definable* is not the same object as one that is *estimable*, and this corpus has so far produced only the first.

This paper adopts no remedy. R2 is stated as a modelling position. It is a definition with a mechanism attached, not an identified empirical result, and every downstream paper citing R2 inherits that status. An unidentified parameter presented as measured would be a defect; a modelling position presented as one is not.

One existence proof, which the framework has otherwise lacked. That reflexivity of this shape *occurs* is not in doubt, and the best documented instance is a market. When the Black–Scholes option-pricing model was published its prices did not fit the market; after traders adopted it, the market came to fit the model, with dates and price data recording the convergence [MacKenzie and Millo, 2003]. That is a reflexive fixed point observed in the field, and it establishes that the mechanism is real without establishing that any particular loop is one. The more general point that classifications of people alter the people classified has been argued directly [Hacking, 1995]. That literature supplies existence, not identification, and the distinction is exactly the one this subsection is drawn to keep.

The framework turned on itself: the Lucas critique. The framework asserts that a system changes its behaviour when it is modelled and observed. Applied consistently, that assertion falls on the framework's own parameters. Parameters estimated in a population that does not know the model cannot be assumed to survive in a population that has read it, because the decision rules the parameters summarise are themselves responses to the environment the model describes [Lucas, 1976]. This is not an outside objection; it is the framework's own thesis pointed at itself, and a framework that exempts its own coefficients from its own central claim is not self-consistent.

The paper's answer, stated so that it can be held against it: **the framework's parameters are not claimed to be stable under its own dissemination, and no result in this paper depends on their being so.** Three consequences follow and are accepted. First, any future estimate of η, δ or an interaction parameter must record the reading status of the population it was estimated in, as a covariate and not as a footnote. Second, the framework's own predictions about a reader constitute a regime change for that reader, so a before-and-after design on a single person is confounded by construction. Third, the framework's practical claim (H3) is *strengthened* rather than weakened by this, because H3 says exactly that a concretely seen alternative re-grades the surface: a person who has read the framework has a different surface, and the framework predicts that. What the framework may not do — and this paper does not — is claim a stable numerical coefficient while asserting that being modelled changes behaviour. Those two claims are not compatible and the second is retained.

1.0.10 10. Procedure and case material

10.1 The location procedure

The framework's first procedure locates the occupied minimum and asks for no change. It is reproduced here in operational form because later papers refer to its outputs.

Seven consecutive days, one hour each, at a fixed place and a fixed hour chosen once and not renegotiated. Materials are deliberately minimal — a notebook, a pencil, weather-adequate clothing, no clock in view. The hour proceeds as follows. **(1)** A spoken bearing, once: *I am where my life has set me down*; it is a bearing, not a vow, and is said even when it feels false. **(2)** For roughly the first fifteen minutes, an inventory of present comfort in the present tense, in sentences beginning *Right now I am…*, ordered body first, then immediate surroundings, then situation. Ten lines is the floor; no entry is too small, and smallness is the point. **(3)** A fantasy audit: when attention departs for a better elsewhere — which is

instrument, not failure — the elsewhere is recorded in one line and beneath it, invariably, the present position of the body: *the body sat in a chair, warm, fed.* The repetition is the finding. **(4)** A pricing glance: after each recorded elsewhere, one word only for what going there would cost. No elaboration and no solving. **(5)** The remainder of the hour is spent without steering; restlessness is expected to crest between minutes thirty-five and fifty. **(6)** A spoken close: *this is the floor; the floor holds.* **(7)** On the seventh day, all seven days are read aloud straight through and every comfort appearing three times or more is underlined. The list of underlines is the procedure's product: the load-bearing comforts as distinct from the decorative ones, which no occupant knows in advance.

Three standing rulings from the source are worth recording because they are falsifiable operational claims and not preferences. First, the hour does not divide: the restlessness that crests in the third quarter is the material, and a divided hour never reaches it. Second, an operator away from the fixed seat sits the hour anyway and marks the page *displaced*, because the contrast between fixed and displaced pages separates comforts that travel with the body from comforts that were property of the chair. Third, the procedure is re-run after any sharp re-grading of circumstance — a move, a loss, an arrival — because an occupant who assumes their old coordinates after a large event is navigating terrain that is no longer there.

10.2 Five characteristic failures

The framework catalogues five ways the location procedure fails. They are reproduced in full, since a procedure supplied without its failure catalogue is an advertisement.

F1. Status-quo rationalisation (ceremonial: *the pond that calls itself the sea*). Having learned that the present is a lawful local minimum, the occupant promotes it to the global minimum: *I am here by law, therefore here is best, therefore nothing need be done.* This borrows the framework's own mathematics for the swindle. The correction is in the definitions: *local* was never a compliment.

F2. Confusing affect with position (*the storm painted on the wall*). The occupant sits at a genuine minimum amid genuine anguish and concludes the model is false: *I am not comfortable, I am miserable, therefore this is not my comfort zone.* But the model never claimed the floor was pleasant; it claimed the floor was cheap as the system prices things, and familiar dread can cost less at the margin than unfamiliar hope. The test: name what would have to be done in the next hour to change the source of the anguish, and observe the gradient rise.

F3. Reactive self-report (*the statue at the shore*). The occupant sits the hour as an exhibit, and the pages return a portrait instead of a position. The mark of it is that the pages read well; genuine pages are repetitive and faintly humiliating. This failure mode is the framework's own restatement of a general and severe exposure of self-report instruments [Nisbett and Wilson, 1977].

F4. Anhedonic flatness mistaken for stillness (*the frozen bowl*). There is a state in which nothing costs because nothing registers, and the procedure cannot locate anything, because location presupposes a working instrument of felt cost. The framework's ruling is stated without ceremony and is retained here: this is a manual of attention and not a treatment; if the underlined comforts on the seventh day number zero, the appropriate course is to seek help first.

F5. Fantasy substitution (*the feast eaten in the doorway*). The imagined elsewhere, run nightly in ever richer detail, discharges the drive it names. The source states that this has been measured. **No entry in this corpus's external bibliography supports it**, and the claim is therefore reported here as the framework's, uncited (Section 10.3). The procedural defence — the invariant second line returning the dreamer to the platform — is independent of whether the mechanism is as described.

Four of the five share one root: they convert a survey into a story — of arrival, of exile, of virtue, of appetite — and a story is exactly what the location procedure asks the occupant briefly to do without. The fifth is not a failure of the occupant at all and is listed only so that it is looked for.

10.3 Case material

The source records one worked case in enough detail to report. An operator designated Renata, a night-shift nurse in her ninth year on a respiratory ward, ran the location procedure in late winter, sitting the hour at her kitchen table from 08:40 to 09:40 each morning directly after shift.

Her first day's page opened *comfortable nowhere*, and then recorded eleven inventory lines, among them: *right now I am off my feet; right now nothing is beeping; right now nobody's family is asking me for numbers I don't have.* Her fantasy audit returned one recurring elsewhere — a walk-in clinic in a coastal town visited once at nineteen. Beneath it, day after day, the second line accumulated: *the body sat in a warm kitchen, fed, in wool socks.* Her pricing glances read, in order across the week: *pension, pension, seniority, Marco, pension* — five recorded glances resolving to three distinct named barriers, one of which is a person (Figure 5).

On the fifth day she recorded the finding the source regards as the procedure's signature, arriving unprompted: *the clinic dream shows up at minute forty. Every day. Minute forty is when the radiator gets going and my feet finally stop hurting. I only dream of leaving once I'm warm. On the ward I never think about the clinic at all.* That observation is the framework's departure-lounge claim in the occupant's own words: escape imagining is a surplus expenditure, performed with resources left over after the present is paid for, and therefore manufactured almost exclusively at local minima. The framework's name for that claim — "the thermodynamics of attention" — is an analogy and a poor one, and is marked as such in Section 9.1; the observation underneath it is a timing regularity that the procedure can record and that a larger sample could test.

Her seventh-day reading produced four underlined recurring comforts: silence of machines, weight off feet, heat, and — annotated *did not expect this one* — being unreachable. She did not resign that week; nothing in the procedure asked her to. What changed, she reported, was the direction of an old accusation: she had spent years telling herself she lacked the courage to leave nursing, and the pages showed something structurally different — an occupant at a real minimum, whose every small departure carried a real price with a real name, one of the names being a person. Her own summary was: *I thought I was stuck. I'm not stuck. I'm placed. Placed I can work with.*

Two further details are kept because they instruct. On her second day she nearly abandoned the procedure, for the common stated reason *this is making me feel worse*; the framework's ruling is that the second-day trough is expected and is evidence of function, because an accurate survey of a hard position hurts to precisely the degree that inaccuracy had been doing the comforting. And her underline list did nothing for three weeks by rule, after which it became the opening stock of the cost inventory, where three of her four load-bearing comforts carried costs she had never priced and one discomfort carried nine years of unrecognised payment.

What this case is and is not. It is a single, self-reported, unblinded, retrospective case with no control condition and no independent measurement. It is offered as an illustration of what the procedure returns, not as evidence that the procedure works. Its status is exactly that of any single reported psychological observation, which current replication estimates should be read against [Open Science Collaboration, 2015].

1.0.11 11. Results

11.1 Definitions fixed. D1 (comfort as the felt total of present costs) and D2 (the reflexive loop $T(x) = W(x, M(x))$) are stated in the form the remaining papers cite. Neither is a finding; both are stipulations, and Section 9.2 records that D1 lacks an operational unit and an established scale type.

11.2 Results established by derivation. R3 and R4 are established. $\delta S = 0$ is stated in its correct stationary form with the explicit rider that the variational form licenses no teleology.

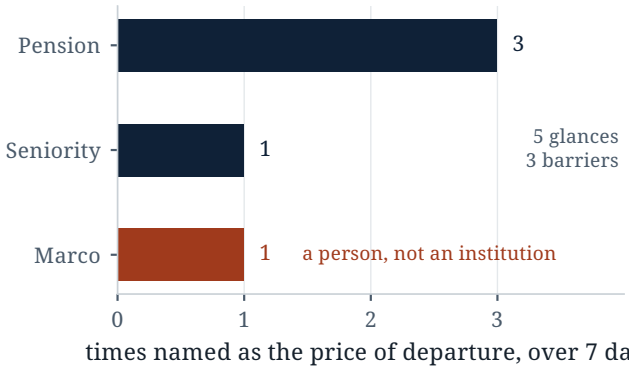

Figure 1.5: In one worked case, seven days of pricing glances resolve five recorded barriers to three names, and one of the three is a person rather than an institution. Measured from the case record as reported in the source, which lists the week's glances in order as "Pension. Pension. Seniority. Marco. Pension."; the same week's seventh-day reading returned four underlined recurring comforts. Script: `figs/src/CCP-A01_fig05.py`.

The Banach condition and its three consequences — existence, uniqueness, geometric convergence from any start — are established, and the uniqueness argument is given in full in Section 5. **This establishment is conditional and the condition is not met by anything demonstrated in this paper:** completeness of the state space and a uniform contraction modulus are premises, not findings, and no k has been measured for any human loop.

11.3 Results established by construction. R1 and R7 follow from D1 by argument rather than by measurement, and R6 is a concession rather than a result. R1 is established in the weak sense that matters: given D1, the occupied state is a local minimum by construction, and the argument is the symmetry argument of Section 3.4. R7 — departure priced at the ridge — follows from the same geometry and is illustrated, not measured, in Figure 3.

11.4 Hypotheses tested. None. H1, H2 and H3 are stated in falsifiable form and are not tested in this paper. No dataset was collected; no instrument capable of eliciting the required quantities exists, for the measurement-theoretic reasons in Section 9.2. H4 is true of the modelled recursion and untested in its human application. This is a negative result and is reported in the same plain language a positive one would receive: **the framework's four testable hypotheses stand untested, and the paper that states them supplies no evidence for any of them.**

11.5 The Postulate. P1 is stated, badged, and left unpromoted. Section 6.3 gives the reason it cannot be numbered among the hypotheses. Its practical consequence is nil: every procedure in Section 10 runs without it.

11.6 Case material. One case is reported. It illustrates the procedure's output and establishes nothing about the procedure's effect.

1.0.12 12. Discussion

12.1 What follows

If comfort is the felt total of present costs, three consequences follow immediately and are the framework's genuine yield.

The first is diagnostic. A position that will not yield to exhortation is not thereby evidence of a defect in the occupant, and treating it as such misroutes the intervention. What the model asks for instead is a barrier survey: name the ridges, price them, and observe which of them are made of material that could be renegotiated. Renata's week produced exactly such a survey, and its most consequential finding — that one of the three barriers was a person — is the

kind of finding a motivational account cannot produce, because a motivational account does not have a place to put it.

The second is prescriptive and is where the framework's practical claim lives. If movement is by gradient, then the intervention is on visibility rather than on effort. That is H3, and its corollary is that pressure is contraindicated: pressure adds a term that the loop of Section 4 returns with a sign the intervener did not intend.

The third is structural. Because T is a composition, a loop can be diagnosed by its gain rather than by its content, and the diagnosis carries across scales. The same gain analysis that says a personal correction was too large says that an institutional response to autonomy was too large, and predicts, in both cases, that the returned difference will be read as vindication.

12.2 What does not follow

That a position is lawful does not make it good, deserved, or fairly graded. That a loop has a fixed point does not mean it has been shown to contract. That the mathematics of two domains coincides does not mean the domains do; that is precisely what P1 asserts and precisely why P1 is a postulate. And nothing in this paper licenses the operation of any of its procedures on another person: the framework's own constraint — no future spoken over another's path without their word — is argued at length in the companion paper and is not a courtesy but a stability condition [Curzi, 2026].

Two further non-implications are worth stating because the corpus's later results tempt them. The framework's affine effective count is used across the corpus, including in the essence bridge that feeds a count into a pitch criterion, where the minimum sustainable frequency is $f_{\min} = k\, e^{2c/\eta}$ with $k = 0.483425732988414$ Hz and the trichotomy $f \gtrless f_{\min}$ corresponds to $Q_\infty \gtrless 0$ [Curzi, 2026], and where the deficit identity $D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)\,Q_\infty$ makes the octave deficit and the steady-state gauge the same number [Curzi, 2026]. Two cautions attach. First, k is a *defined* constant, exact by construction, and its fifteen significant figures are defensible only on that basis; attaching hertz to it is a separate and much stronger claim than computing it, and this paper does not endorse that attachment. Second, the general hazard of reading a chosen ratio as a discovered natural constant is well documented and the documentation should be read before any such reading is offered [Markowsky, 1992].

12.3 Relation to the corpus

The definitions fixed here are consumed downstream in a specific and checkable way. The storage law's leaky-integrator form and its pathology at zero decay [Curzi, 2026a] instantiate the contraction condition of Section 5 in a system with an explicit state variable. The preregistered measurement protocol for that law reports a confirmatory fit that failed its own second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, notwithstanding a 40.3 per cent advantage over persistence, 97.7 per cent over direct input, and $p = 0.0005$ against a shuffle control [Curzi, 2026i]; that is the corpus's own strongest evidence that its instruments can fail, and it is cited here rather than in a footnote. The same five-parameter survey applied from one desk to a twenty-two household block reproduced each system's observed decline — predicted -0.250474 against observed -0.250 at the desk, -0.996371 against -1.000 at the library, residuals under 1.4 per cent of the ceiling term [Curzi, 2026k]. The moment equation's fixed point $D = P$, $r = 1$, $M = E$, with unit elasticity of exactly ± 1 in all three terms and the ceiling $0 \le M \le \ln N$ making the $P \to 0$ divergence finite [Curzi, 2026m], is the same fixed-point structure applied to a calibration ratio. And the corpus's conditional postulate on belief — $E = G \cdot B + \varepsilon$ with the forbidding clause $G = 0 \Rightarrow E = 0$ for all B, badged as a postulate and paired by explicit correspondence with the storage law's $\eta = 0$ [Curzi, 2026ab] — is the template this paper's P1 follows: a strong claim, stated with the clause that forbids its abuse, and badged.

1.0.13 13. Verification

This section is not a summary. It decomposes the paper's results into pieces small enough that a reader can check each one without checking any other, and states for each piece which of four things it is: `ARITHMETIC` (redo the calculation), `DEFINITION` (fixed earlier in this paper), `CITED` (one named external source), or `POSTULATED` (asserted here, with no external support). The razor is applied: any postulate that could be dropped with the results still following has been dropped.

13.1 Postulates

Each is atomic and each is checkable on its own.

- **P1 (DEFINITION).** Comfort is the felt total of present costs. *Check:* it is D1; nothing else is required.
- **P2 (DEFINITION).** The occupant's state is a point in a set X on which a real-valued cost f is defined. *Check:* stipulated in Section 3.1. **Note: this is the paper's largest unearned assumption and Section 9.2 says so.**
- **P3 (DEFINITION).** A local minimum of f at x means $f(x) \leq f(y)$ for all y in some neighbourhood of x. *Check:* standard definition; no source needed.
- **P4 (POSTULATED).** A person's occupied state is the cheapest immediately reachable state as their own system prices it. *Check:* not checkable from outside the framework; this is the substantive content of H1 and it is asserted, not demonstrated.
- **P5 (DEFINITION).** M maps a state to a model; W maps a state and a model to a next state; $T = W(\cdot, M(\cdot))$. *Check:* D2. **Note: as a definition this is free; as an empirical specification it is not identified from observation [Manski, 1993], so nothing downstream may treat its parameters as estimable without adopting one of the remedies in Section 9.4.**
- **P6 (DEFINITION).** A fixed point of T is an x^* with $T(x^*) = x^*$.
- **P7 (CITED: `banach1922operations`).** On a complete metric space, a map satisfying $d(T(x), T(y)) \leq k\, d(x, y)$ with $0 \leq k < 1$ has exactly one fixed point, reached from any start, with error shrinking by at least k per pass.
- **P8 (POSTULATED).** A space of life-states is complete, and a human reflexive loop admits a uniform contraction modulus $k < 1$. *Check:* **not checkable, and not checked. This is the premise on which the entire transfer of P7 rests.**
- **P9 (CITED: `kennard1927quantenmechanik`).** $\sigma_x \sigma_p \geq \hbar/2$ is a property of the quantum state, not of measurement disturbance.
- **P10 (POSTULATED).** The uncertainty of P9 and the uncertainty of a foreseen future are the same kind of uncertainty. *Check:* not checkable; this is the framework's Postulate and is badged wherever it appears.

Postulates dropped as unnecessary: the annealing analogy (Section 3.6) was tested for load and carries none — every result below survives its removal — and the narrative-transfer claim (Section 8.2) likewise. Both are reported in the text and neither is used.

13.2 The compounding chain

Each line consumes only the outputs named on its left.

```
P1 + P2          -> L1   a scalar cost is defined over states     DEFINITION
L1 + P3          -> L2   local minima of that cost are defined    DEFINITION
L2 + P4          -> R1   the occupied state IS a local minimum    POSTULATED (via P4)
R1 + P3          -> L3   every small departure carries a cost     ARITHMETIC
L3               -> R7   persistence is set by barrier height,
                         not by basin depth                       ARITHMETIC
L1               -> L4   descent x_{n+1} = x_n - eta grad f       DEFINITION
```

```
L4              -> H4   |1 - eta L| >= 1 gives non-convergence    ARITHMETIC
P5 + P6         -> R2   a self-fulfilling prophecy is a fixed
                        point of T                               DEFINITION
                        (as an empirical specification: NOT
                        IDENTIFIED, see 9.4)                     POSTULATED
P7              -> R4   the Banach condition and its three
                        consequences                             CITED
R2 + R4 + P8    -> C1   a well-built prediction is reached from
                        anywhere                                 POSTULATED (via P8)
P9              -> L5   the uncertainty relation, stated right   CITED
L5 + P10        -> R5   the Postulate, badged                    POSTULATED
(concessions)   -> R6   noise, plasticity, foresight             DEFINITION
```

What this chain shows, stated plainly. Of the seven results, exactly two — R3 and R4 — rest on `CITED` or `ARITHMETIC` steps alone. R1 passes through P4 and is therefore `POSTULATED` at its load-bearing step. C1, the framework's most attractive conclusion, passes through P8, which is not checkable and was not checked. R5 is `POSTULATED` by construction and says so.

A chain whose steps are mostly `DEFINITION` and `POSTULATED` is not a proof, and this one is mostly `DEFINITION` and `POSTULATED`. What it is instead is a specification of exactly which two premises would have to be established for the framework's central conclusion to follow: P4 (that occupancy tracks cheapest reachability) and P8 (completeness plus a uniform modulus). Those two are the whole bill. That is a smaller and more addressable bill than the framework's rhetoric suggests, and stating it is this section's only purpose.

13.3 The checks a reader should run first

1. **Redo the uniqueness argument** in Section 5. It is three lines and needs no source.
2. **Redo Figure 2's recursion** by hand for $\eta = 2.10$: $x_n = (-1.1)^n$, so $|x_{12}| = 1.1^{12} \approx 3.14$. The figure should agree.
3. **Check the dimensional table** in Section 9.2 for an invented unit. There is none, because comfort has no operational unit and the table says so.
4. **Check every occurrence of** $\sigma_x \sigma_p \geq \hbar/2$ for the state-preparation reading. There are two, in Sections 6.1 and 9.1, and both carry it.
5. **Check that the analogy table in Section 9.1 assigns category 1 to exactly two entries**, and that both carry an explicit statement of the premise that is not established.
6. **Check that R2 is never described as measured**, in this paper or in any paper citing it. It is a modelling position; Section 9.4 says so and the Conclusion repeats it.

13.4 Dimensional audit

Every symbol used above, with its dimension, its unit, and its epistemic status. The audit is short because the framework is honest about how few of its quantities have units at all.

Symbol	Meaning	Dimension	Unit	Status
x	state of the occupant	none assigned	none	defined; an index into a state set, not a measured coordinate
$f(x)$	felt total of present costs (comfort)	none assigned	**no operational unit exists**	defined (D1); not measured anywhere in this paper

Symbol	Meaning	Dimension	Unit	Status
∇f	local slope of the cost surface	$[f]$ per $[x]$	none	derived from f; inherits f's lack of a unit
η	step size	$[x]^2/[f]$ for the ratio to close	none	modelling parameter, chosen, not measured
n	iteration index	dimensionless	passes	defined
$d(\cdot,\cdot)$	distance between states	$[x]$	none	assumed to exist; not constructed
k, q	contraction modulus	dimensionless	—	defined; **never measured for a human loop**
T, M, W	maps on states	—	—	defined (D2)
δS	variation of the action	energy $\times$ time	J·s	quoted from physics; not a quantity of this framework
$\sigma_x, \sigma_p, \hbar$	quantum standard deviations, reduced Planck constant	m, kg·m·s^{-1}, J·s	SI	quoted from physics; not quantities of this framework

Does the central relation balance? The descent recursion $x_{n+1} = x_n - \eta \nabla f(x_n)$ balances only if η carries dimensions $[x]^2/[f]$. Since neither $[x]$ nor $[f]$ has been given an operational unit, the balance is formal: it is satisfied by construction and constrains nothing. **The source is silent on the dimensions of comfort, and this paper does not supply them.** A dimensionless placeholder is the honest entry; an invented unit would not be.

A quantity with no operational unit is entered as having none. No unit was invented for comfort, and none should be inferred from the fact that the recursion balances.

1.0.14 14. Limitations

The framework's credibility rests on this section being longer and more specific than a reviewer expects. Each item names what would falsify the claim or what the paper cannot support.

14.1 Comfort's scale type is stipulated, not demonstrated. This is the paper's principal exposure and it is stated first. Everything with landscape structure — depth, gradient, ridge height, the metric d — presupposes at least interval structure, and none was established. The strongest objection to the framework is that psychology routinely assumes quantitative structure without testing for it [Michell, 1997]; the formal test that would settle the matter exists [Luce and Tukey, 1964, Krantz et al., 1971] and was not applied. **Falsified by:** a conjoint-measurement study on any operationalisation of comfort that fails double cancellation. The framework would then have to be restated on an ordinal basis, which would remove Figure 3's arithmetic and Section 5's metric entirely.

14.2 No hypothesis was tested and no data were collected. H1–H4 are stated in falsifiable form and left standing. Section 11.4 reports this as a result. The framework's own preregistration discipline is the correct remedy and was not exercised here [Nosek et al., 2018], and the analytic flexibility available in any later confirmatory attempt should be constrained in advance [Simmons et al., 2011, Gelman and Loken, 2013].

14.3 Claims with no supporting literature in this corpus's bibliography. These are listed individually because a reviewer will find them, and finding them first is the point.

- *Pressure on a person's choices produces counter-movement.* The framework calls this reactance and treats it as one of the best-replicated findings in its literature. `bib/external.bib` **contains no entry for it.** The claim is retained in the text because it is load-bearing for H3's second limb, and it is retained **uncited**. Nothing in this bibliography supports it and no citation was attached to make it look supported.
- *Losses weigh roughly twice what equal gains weigh; people overvalue what they already hold; paid costs recruit fresh ones; cues placed in the path of a behaviour govern it more reliably than resolutions about it.* These are the source's fourth class of formal claim. **The bibliography contains no entry for loss aversion, for the endowment effect, for sunk-cost escalation, or for cue-based habit formation.** The class is stated in the paper and is uncited throughout.
- *A goal vividly enjoyed in imagination is partially discharged, spending the drive that would have moved the feet* (failure mode F5). **No entry.** Reported as the framework's claim.
- *A pattern learned as a narrative transfers across domains where a pattern learned as a checklist does not.* This is the framework's justification for its own form. **No entry.** Reported and not endorsed (Section 8.2).
- *Simulated annealing, and its transfer to disrupted seasons of a life.* **No entry.** Reported and flagged in Section 3.6 and in the analogy table.
- *The uncertainty of a foreseen future is the same kind as the uncertainty of a quantum state.* No entry, and none is possible; this is P1 and is badged accordingly.

14.4 The contraction premises are unverified. Section 5 states them; Section 13.1 lists them as P8; and the honest consequence is that the framework's most attractive conclusion — arrival guaranteed, from anywhere, at a rate — is available only conditionally. No k has been measured for any human loop by anyone, including the authors of this corpus.

14.5 Parameters chosen rather than measured. η in Figure 2 and every control point in Figure 3 were chosen to make a stated prediction visible. They are not estimates. The step-size boundary $\eta = 2$ is exact only for the quadratic actually plotted, whose curvature is 1 by construction; for any other surface the boundary is $2/L$ and L is unknown for comfort surfaces. The barrier heights in Figure 3 are computed from the plotted curve, but the curve itself is stipulated.

14.6 Illustrative rather than empirical results. Figures 1, 2, 3 and 4 illustrate; only Figure 5 reports numbers from a record, and that record is a single self-reported case (Section 10.3). Nothing in this paper constitutes evidence that the location procedure changes anything.

14.7 The self-report instruments the framework needs are exposed. People cannot reliably report the causes of their own behaviour [Nisbett and Wilson, 1977], and any question naming a component of well-being induces a focusing illusion [Kahneman et al., 2006]. The framework's own failure mode F3 anticipates this at the level of a single operator's pages; the instrument-level problem is not thereby solved.

14.8 The instrument corrupts what it measures. A quantitative indicator adopted for social decision-making distorts the process it monitors [Campbell, 1979]. The framework's own effective counts are exactly such indicators, and this exposure is structural rather than incidental.

14.9 The surplus-from-difference claim is stated monotonically and the evidence is not. Section 8.3 gives both sides. A monotone claim cannot survive Uzzi and Spiro [2005], Putnam [2007], May [1972] and Sagan [1993] unqualified, and this paper does not assert one; the framework elsewhere does, and that is a defect in the framework rather than in the literature.

14.10 A scope note on the framework's own effective count. The corpus runs two different effective counts. The reading of $1/\mathrm{HHI}$ as a numbers-equivalent is exact and fully grounded [Hill, 1973]. The framework's own affine count is **not** a Hill number of any order and has no precedent in ecology, economics, political science or information theory. It is this corpus's

own construction. Where this paper cites the Hill-number literature it does so only for $1/\text{HHI}$, and no reader should transfer that grounding to the affine count.

14.11 The reflexive loop is not identified, and this is the framework's most serious methodological problem. As an aggregate specification, $T(x) = W(x, M(x))$ places the endogenous social effect beyond identification from observational data [Manski, 1993], and the network route is closed by the generic confounding of influence with selection [Shalizi and Thomas, 2011]. This paper adopts no remedy and therefore states R2 as a modelling position (Section 9.4). **Falsified by, or rather resolved by:** a partial-population or randomised design, or a defended stipulation of the reference group in the manner of Brock and Durlauf [2001]. Until one of those is run, every corpus claim of the form "the interaction produced the shared state" is unsupported, and this includes claims the corpus currently makes.

14.12 The framework's own parameters are not exempt from its own thesis. The framework asserts that being modelled and observed changes behaviour, which by the Lucas critique means its own coefficients cannot be assumed stable across populations that have or have not read it [Lucas, 1976]. Section 9.4 states the paper's answer — that no stability is claimed and no result here depends on it — and the cost is real: no cross-population comparison of a framework parameter is currently interpretable, and no single-person before-and-after design is clean.

14.13 The logarithmic form is underdetermined. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the same qualitative facts as the corpus's logarithm. **Nothing in this paper discriminates between them.** The strongest available warrant for a logarithm is dynamical rather than psychophysical [Peters and Gell-Mann, 2016], and it applies only where the underlying process is multiplicative, which has not been established for comfort.

14.14 Legibility risk. The framework's central operation is to make an implicit surface explicit. The historical record on schemes that improve a situation by making it legible is not encouraging: legibility can destroy the local variety that made the system work [Scott, 1998]. This applies to the framework's own instrument and is not merely a caution about other people's.

1.0.15 15. Conclusion

The framework's seven results are stated below in the exact form in which the rest of the corpus cites them. Downstream papers should quote this text rather than paraphrase it.

R1. Comfort is the felt total of present costs, not pleasure; therefore the present state is a local minimum of the comfort landscape by definition rather than by luck.

R2. The reflexive loop is $T(x) = W(x, M(x))$, and a self-fulfilling prophecy is a fixed point of that composition of seeing and responding. **R2 is a modelling position, not an identified empirical result:** as an aggregate specification the endogenous effect is not identified from observational data, and no remedy is adopted here [Manski, 1993]. Papers citing R2 inherit that status and must not present the loop's parameters as measured.

R3. The principle of stationary action is $\delta S = 0$; the honest form is stationarity, not minimality, and the variational form licenses no teleology.

R4. If T satisfies $d(T(x), T(y)) \leq k\, d(x, y)$ with $0 \leq k < 1$ on a complete metric space, then T has exactly one fixed point, it is reached from any starting point, and convergence is geometric with ratio at most k.

R5. The Postulate: the uncertainty of quantum measurement and the uncertainty of a foreseen future are the same kind of uncertainty. This is a postulate and is badged as one wherever it appears. $\sigma_x \sigma_p \geq \hbar/2$ holds only in its state-preparation reading and says nothing about measurement disturbance.

R6. Three disanalogies between a person and a physical minimiser are conceded: noise, plasticity of the landscape, and response to imagined costs. The third, foresight, is the term for which physics has no analogue.

R7. Departure is priced at the height of the nearest ridge, not at the depth of the current basin; a shallow basin ringed by high ridges holds as firmly as a deep one, and the two conditions call for different work — engineering in the first case, acceptance in the second.

Counter-result. The identification of a life with a minimising physical system is a postulate rather than established physics; three disanalogies break the analogy; and locating oneself at a local minimum is an exoneration and not an endorsement, since *local* was never a compliment.

What is established, then, is a set of definitions with a clear consequence, one theorem with two unmet premises, and one badged postulate that no result requires. What is not established is every hypothesis the framework advances. The framework's contribution at this stage is that it says which two premises would settle the matter — that occupancy tracks cheapest reachability, and that the loop contracts with a uniform modulus on a complete space — and that it declines to claim either.

1.0.16 16. Declarations

Data and code availability. No external dataset was collected for this paper and none exists. The case material in Section 10.3 is reported from the source manuscript's own record and is not a dataset. All figures are generated by the scripts named in their captions (`figs/src/CCP-A01_fig01.py` through `figs/src/CCP-A01_fig05.py`), which import the shared style module `lib/figstyle.py`; every number plotted is either computed within the script or quoted from the source text identified in the script's docstring.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures, and the text.

Ethics. No human-subjects research was conducted for this paper. No personal data were collected or processed. The case material in Section 10.3 is drawn from the source manuscript, is presented under a pseudonym as it appears there, and is illustrative rather than evidential; it was not gathered under a research protocol and is not offered as one. Nothing in this paper is clinical advice, and Section 10.2's fourth failure mode records the framework's own instruction that a person in an anhedonic state should seek appropriate help before applying any procedure described here.

Use of the ceremonial register. The source manuscript is in part an initiatory document. This paper analyses that register as an object of study and does not reproduce it. Sections 8.1 and 8.2 report the framework's ceremonial names and Latin mnemonics as data about the framework, not as instructions to a reader.

Chapter 2

The Ledger, the Gradient, and the Arithmetic of Difference: Carrying Cost, Desire Lines, and the Surplus Functional f(u) = ln(1 + (N-1)u)

Abstract. This instalment develops three expository nodes and states the surplus functional the engineering series later builds on. Holdings are priced in four carrying-cost currencies - coin, hours, attention, and foreclosure - and discomforts are assayed for four yield currencies, including contrast, on the argument that felt comfort is a difference detector and so decays toward zero over weeks while the carrying cost bills at full rate indefinitely - an asymmetry offered as the mechanism that assembles a depleted life without any single bad decision. The gradient node states force as the negative gradient of a potential, argues that the variational and local formulations are one equation written twice, and treats worn paths as the theory's observable: a desire line is the integral of many small descents, and its reproduction after the recording medium is erased is offered as evidence that the pattern lies in the force field. The horizon node states the surplus of N non-parallel sightlines as f(u) = ln(1 + (N-1)u), uniquely determined by four requirements - angle-only dependence, zero surplus at parallelism, an effective count affine in u, and normalisation - with N_eff = 1 + (N-1)u read as an effective number of views. Two limits are stated rather than hidden: the functional is a lower bound on the ensemble's information, not the information, and its concavity means most of the available gain arrives with the first few genuinely divergent views.

Keywords: carrying cost; hedonic adaptation; desire lines; surplus functional; effective count; non-parallelism; lower bound; local minimum

Series: A. Foundations **Paper:** CCP-A02

2.0.1 1. Introduction

1.1 The question

Three questions sit underneath most of what this corpus later computes, and none of them is usually asked in the same place. What does a held arrangement actually cost its holder, once the invisible currencies are counted? What is the observable of a comfort gradient — the

thing a sceptic could go and measure? And how much does a second, third or fortieth point of view add to a first?

This paper answers all three, because in the source framework they are one node's work each and the answers interlock. The costing answer is a four-currency ledger plus one asymmetry law. The observable is the worn path. The arithmetic answer is a single functional,

$$f(u) \;=\; \ln\!\big(1+(N-1)u\big)$$

which the remaining sixty-nine papers of the corpus use more than any other formula it contains. Thirty-six of them cite the results established here. Because those results are load-bearing elsewhere, this paper states them in a form intended to be quoted rather than paraphrased, and it prints the two limits of the functional at the same volume as the functional itself: it is a *lower bound* and not the information, and its concavity is an argument against collecting viewpoints rather than for it.

The paper also reports, at the same precision it reports its results, three things that go against the framework. The functional's form is underdetermined by the existing evidence. Its effective count is not a Hill number and has no external precedent. And the source's own summary claim — that three well-cut views capture the greater part of what a gallery could — is true only as a comparison of angles, not of counts, and the break-even is computed here for the first time.

1.2 What this paper contributes

Seven results are established or fixed here, labelled R1 through R7 and restated verbatim in the Conclusion.

R1 states the surplus functional $f(u) = \ln(1 + (N-1)u)$, uniquely characterised by four requirements — dependence on angles alone, zero surplus at parallelism, an effective count affine in u, and normalisation — with $N_{\text{eff}} = 1 + (N-1)u$ read as an effective number of views. **R2** records that the functional is deployed as a *lower bound* on the ensemble's information and not as the information itself: it logs the floor and not the ceiling. **R3** states the binding clause of R1: a second opinion drawn from a source that shares training, incentives and premises with the first is worth $\ln 1 = 0$ of surplus. **R4** states the four-currency carrying cost — coin, hours, attention, foreclosure — against the law that felt comfort decays over weeks while carrying cost does not decay at all. **R5** identifies the worn path as the theory's observable: a desire line is the integral of many small descents, and its reproduction after the recording medium has been erased is the evidence that the pattern lies in the force field rather than in the record. **R6** states that the variational form of a mechanical law is equivalent to the local differential law, so that the principle licenses no teleology — the path obeys its ground instant by instant. **R7** states the honest limit of descent: a gradient finds the nearest low place and not the best one, so the analysis can diagnose a stable trap and cannot treat one.

A counter-result is stated with equal weight. The surplus is bounded twice over: it is only a lower bound on the ensemble's information, and its logarithmic concavity means that a few well-separated views capture most of what a large panel could, so the framework argues explicitly *against* accumulating perspectives. The gradient material then concedes that descent can diagnose a stable trap but cannot treat one, and the ledger material concedes that the pricing biases on which it leans have no supporting entry anywhere in this corpus's bibliography.

1.3 Register, sources, and what is not reproduced here

The source manuscript is written in two registers, a narrative one and an analytic one, deliberately braided. This paper reports the analytic register. The narrative material is a fictional exposition and carries no analytical claim the treatise does not also carry; it is not reproduced. Where the source's ceremonial vocabulary names a construct — *the test of the stone*, *water does not negotiate*, *the many windows of the one tower* — the construct is renamed to what it

is, and the ceremonial name is reported once, as an object of study, because the framework's use of a redundant second encoding is one of its own methodological claims. The framework's choice of a narrative vehicle for a procedural argument has a respectable precedent in the operations literature, where the same choice was made for the same stated reason [Goldratt and Cox, 1984].

The material below corresponds to three of the source's twelve constructs — the inventory, the gradient, and the horizon — and is presented as one argument because the third consumes the first two: the arithmetic of difference is what tells an analyst how many honest viewpoints a survey of their own ground is worth.

A note on chunk boundaries. The source volume was re-split after a de-framing correction, and the file assigned to this paper begins partway through the inventory material and ends partway through the horizon material. Section 3 therefore reports the inventory node's doctrine, procedure and failure catalogue but not its opening narrative; Section 5 reports the horizon node's arithmetic and its procedure but not its closing failure catalogue, which falls in the file assigned to the next paper in this series. Nothing analytical is lost at either seam, and both seams are marked here rather than papered over.

2.0.2 2. Hypothesis

The material below divides into claims that could be wrong, definitions that could not, and one modelling choice presented as an axiom. Keeping the three apart is the framework's own stated discipline and this section enforces it. A hypothesis that nothing could falsify is restated as a definition or a postulate and labelled as such [Popper, 1959].

H1 — the carrying-cost hypothesis. Every held arrangement charges its holder in four currencies — coin, hours, attention, and foreclosure — and the last two are systematically omitted from unaided estimates of what a holding costs. *Predicted:* an itemisation performed in a fixed four-currency order returns a strictly larger set of costs than an open-ended request for the same holding's costs, and the increment is concentrated in the third and fourth currencies. *Falsified by:* matched itemisations in which the fixed-order protocol returns no more attention or foreclosure entries than the open-ended one. *Status:* testable in principle; **not tested here**, and no instrument for eliciting an attention charge exists (Section 6.2).

H2 — the decay-asymmetry hypothesis (the ledger's central claim). The felt return on a held comfort decays toward zero on a scale of weeks while its carrying cost does not decay at all, so that a life can accumulate a large and rising cost against a falling felt return without any single bad decision. *Predicted:* for a holding acquired at a known date, reported felt return declines monotonically with time held, while an itemised cost, re-elicited, does not. *Falsified by:* itemised costs declining at the same rate as felt return, or felt return not declining. *Status:* testable; **not tested here**. Figure 3 is an illustration of the prediction under two chosen time constants, not a measurement of either.

H3 — the desire-line hypothesis. Repeated movement through a setting is a better survey of that setting's comfort gradients than any statement of intention about it, and the survey is recoverable after the recording medium is erased. *Predicted:* after a complete erasure of the physical record of use — snowfall, resurfacing, a move — the same routes reappear within a few cycles, in the same places, without any transfer of information through the erased medium. *Falsified by:* routes failing to reappear after erasure, or reappearing only where the erased record was in fact preserved. *Status:* observed repeatedly in the built-environment literature and treated there as a design method [Whyte, 1980, Gehl, 1971]; the transfer to a personal day is the framework's, and is **not tested here**.

H4 — the surplus hypothesis. The value added by N viewpoints over one viewpoint depends on the angles between them and not on their number, and is $\ln(1+(N-1)u)$. *Predicted:* two panels of equal size but different measured non-parallelism differ in aggregate performance as the ratio of their $\ln N_{\text{eff}}$ values, and a panel at $u = 0$ performs exactly as a single member does. *Falsified by:* a panel at measured $u = 0$ outperforming a single member, or by a power-law or $n \log n$ form fitting held-out data better at equal parameter count. *Status:* **not**

tested here, and currently underdetermined. Two established rival forms fit the same qualitative facts (Section 5.6). The uniqueness argument establishes that the form follows from the four requirements; it does not establish that the four requirements are the ones the evidence supports.

H5 — the concavity hypothesis. Because f is concave in N_{eff}, most of the available gain arrives with the first few genuinely divergent views, so adding views past a small number is dominated by raising the angles between the views already held. *Predicted:* at fixed cost, a protocol that raises measured u outperforms one that raises N, above a small N. *Falsified by:* performance continuing to track N at fixed u past the point where $\ln N_{\text{eff}}$ has flattened. *Status:* mathematically true of the functional (Figure 2); the transfer to any practice is untested.

D1 — non-parallelism (definition). $u \in [0, 1]$ is a measure of the non-parallelism of a set of viewpoints, with $u = 0$ meaning every viewpoint faces the same way and $u = 1$ meaning each contributes a direction of view the others lack entirely. The corpus's operationalisations are $u = 1 - (x \cdot y)^2$ on unit direction vectors [Curzi, 2026c] and $u = 1 - \rho^2$ from the decorrelation of errors [Curzi, 2026o]. Both are stipulations. Neither is derived.

D2 — the effective count (definition, and a modelling choice inside it). $N_{\text{eff}} = 1 + (N - 1)u$. The *affine* form is a design axiom of this corpus and not a theorem; the corpus badges it as such in the papers that use it [Curzi, 2026c,o], and this paper badges it here. It is **not** a Hill number of any order, and Section 5.2 states what follows from that.

D3 — carrying cost (definition). The carrying cost of a holding is the standing charge of keeping it, itemised in coin, hours, attention and foreclosure, and is distinct from its acquisition price. This is a stipulation. Its measurement-theoretic status is audited in Section 6.2.

P1 — the relaxation postulate. That a life relaxes through its comfort landscape as a physical system relaxes through its states is postulated wherever the gradient material is applied to a person. The source states this postulate in its own text — "the Lodge does not claim you are water; the Lodge claims the mathematics is the same shape" — and this paper preserves the badge at every occurrence. Nothing in physics licenses it.

2.0.3 3. The carrying-cost ledger

3.1 Four carrying-cost currencies

The framework's first analytical move is to replace a holding's *purchase price* with its *carrying cost*, and to insist that the carrying cost be itemised in a fixed order across four currencies. The term is borrowed from warehousing, where the fact that storage is never free is not a discovery but the trade's first principle, and where the standing cost of held stock is an ordinary line item [Hopp and Spearman, 2011]. Written as a system of levels and rates, a held arrangement is a stock with a continuous outflow, and the outflow is what this section prices.

The four currencies, in the order the framework fixes:

1. **Coin.** The monetary charge. The framework calls it the least interesting currency on the ground that the world already itemises it, and the ledger's contribution is not here.
2. **Hours.** Not the hours a holding fills, which were chosen, but the hours it *appoints*: maintenance, tending, and the arrangement of a life around a feeding schedule.
3. **Attention.** The background awareness a held thing charges while untouched. The framework's claim is that this charge compounds invisibly and is the dominant term for people who report exhaustion without a corresponding workload: not too much work, but too many open accounts, each billing a quiet standing awareness, none itemised anywhere. That a person's simultaneous holdings are bounded by a capacity rather than by effort is old and well established [Miller, 1956], and the general statement — that any regulator has a finite channel and must have at least as much variety as what it regulates — is Ashby's [Ashby, 1956]. Neither result establishes that a *held comfort* draws on that capacity while untouched; that is the framework's claim and it is uncited (Section 10.3).

4. **Foreclosure.** What a holding forbids. Every held position closes others by being held: the lease that forecloses the leaving, the reputation that forecloses the beginner's mistakes, the standing arrangement that forecloses — so long as it stands, and precisely because it stands — a decision. The framework's note on foreclosure is that it never sends an invoice, because what it takes never existed to be missed, and its procedural rule is that foreclosure is written *last*, after the first three currencies have been attempted.

The procedural rule attached to the four is that a holding is priced in all four before "nothing" may be written in any of them, and that a dash is earned by a second look and never by a first.

3.2 Four yield currencies, and the contrast term

The framework's second move is symmetrical and is the one that keeps the instrument from becoming an indictment: a discomfort is *assayed* rather than discarded, in four yield currencies — information, training, position, and contrast.

Three of the four are unremarkable. *Information*: a standing ache may be an accurate report on a situation everyone else has agreed to describe pleasantly. *Training*: a hard hour may be the one hour in which the body outranks the head. *Position*: a hard duty may hold open a door that comfort would let swing shut.

The fourth is the framework's own and is worth stating carefully, because it is the term on which the ledger's decay law later depends. **Contrast**: a comfort is a difference before it is a state. The warmth is manufactured at the threshold, by the cold that preceded it; a life engineered to contain no thresholds does not become a life of continuous warmth but a life in which warmth has nothing to be measured against and leaves the instrument's range. The framework's operational consequence is that some fraction of a person's discomfort is not billing them but *calibrating* them, keeping a difference detector supplied with differences.

The contrast term has real support and the support should be named exactly, because it is narrower than the framework's use of it. That perception is organised around a moving reference level rather than an absolute one is Helson's adaptation-level result [Helson, 1948]; that sensation tracks a ratio to a just-noticeable increment rather than an absolute magnitude is Weber's, integrated into a logarithm by Fechner [Weber, 1834, Fechner, 1966]; and that subjective states return toward a set point after large changes in circumstance is the hedonic-adaptation finding [Brickman et al., 1978], in the substantially revised form that allows set points to move and individuals to differ [Diener et al., 2006]. What none of these establishes is the framework's stronger claim that *deliberately retained* discomfort raises the felt value of a comfort. That is an intervention claim and it is untested; it is stated here as the framework's and badged.

3.3 The decay asymmetry (R4)

The two columns are joined by one law, and it is the ledger's whole yield:

> **Comforts fade from feeling long before they fade from billing.**

The mechanism the framework offers is the difference detector of Section 3.2: felt experience registers changes and lets constants sink below notice, so the pleasure of a held comfort decays toward zero on a schedule of weeks, while its carrying cost does not decay at all. The shelf bills at full rate indefinitely, in coin, hours, attention and foreclosure, felt or not.

Run that asymmetry across a decade of accumulation and the framework's conclusion follows without any bad decision being required: a stock of comforts that no longer comfort, each billing its original rent, the total rising as the felt total falls. This is R4, and it is the framework's account of how a depleted arrangement assembles itself out of individually defensible acquisitions.

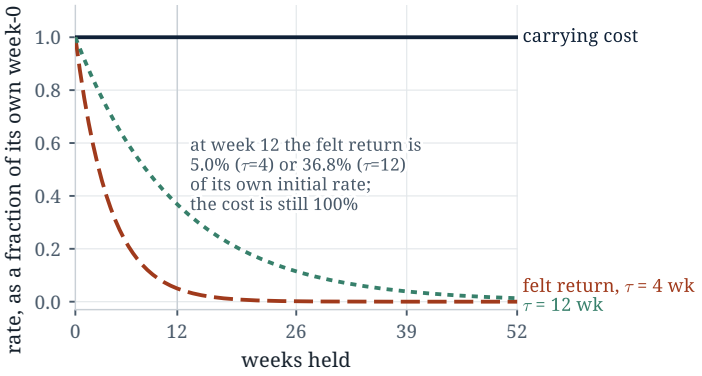

Figure 2.1: **Felt return falls; the carrying cost does not.** Modelled, not measured: the source states only that felt comfort "decays toward zero on a schedule of weeks" while carrying cost "does not decay at all", and supplies no time constant, so two are chosen here — $\tau = 4$ and $\tau = 12$ weeks — to show that the conclusion does not depend on the choice. Both series are expressed as a fraction of their own week-zero rate, so the chart carries one measure and not two. Script: `figs/src/CCP-A02_fig03.py`.

Two things must be said about the law's status. First, **the framework supplies no time constant.** It says "weeks" and nothing more. Figure 3 therefore models the asymmetry at two chosen constants rather than one, so that a reader can see that the qualitative conclusion is insensitive to the choice and that no measured rate is being smuggled in. Second, **no felt audit can catch the asymmetry**, because the felt auditor is the same difference detector that lost the goods. This is the framework's argument for a written instrument, and it is the same argument the self-report literature makes from the other side: people report the causes of their own states with a confidence unrelated to accuracy [Nisbett and Wilson, 1977], those reports are shaped by how the question was asked [Schwarz, 1999], and directing attention at a named component of well-being distorts the judgement of it [Kahneman et al., 2006].

The corpus's own storage law is the same asymmetry written as a difference equation, and it supplies the decay term the ledger lacks. The measured instance most relevant here is that doing nothing to a stock of order costs 63 per cent of it over twenty-four months, while a forced integration that raises realised non-parallelism from $u = 0.1155$ to $u = 0.3465$ — lifting surplus by 121 per cent while raising cost by 279 per cent — costs 78 per cent of it over twelve [Curzi, 2026g]. That is the ledger's law measured on a stock rather than on a feeling, and it is the corpus's own evidence that the cure can bill faster than the disease.

3.4 The pricing bias, and what this bibliography cannot support

The framework's clinical claim is that the felt price and the written price are computed by different machinery, and that only the written price can be audited. It supports the claim by naming three well-known asymmetries: that a loss weighs roughly twice a gain of the same size; that an object is overvalued by the mere fact of being held; and that a cost already paid recruits further costs in its defence. It then draws one consequence with real analytical content — that the held arrangement's costs bill in the invisible currencies while any alternative quotes its price in the visible ones at the door, so the current arrangement always *looks* cheaper than it is and every exit always looks dearer.

This corpus's external bibliography contains no entry for loss aversion, for the endowment effect, or for sunk-cost escalation. The claims are load-bearing for the framework's argument and are retained in the text; they are retained **uncited**, and they are listed individually in Section 10.3. No citation has been attached to make them appear supported. What *can* be supported from this bibliography is narrower and is stated instead: that self-reports of one's own causes are unreliable [Nisbett and Wilson, 1977], that they are question-dependent [Schwarz,

1999], and that a quantity adopted as a target for one's own management ceases to be a good measure of what it was adopted to track [Campbell, 1979, Goodhart, 1975] — an exposure that applies to the ledger itself and not only to the arrangements it prices.

The asymmetric-visibility consequence, by contrast, does not require the three uncited findings at all. It follows from R4 alone: a cost that has fallen below felt notice is not thereby cheaper, and an alternative's costs are quoted at the moment of maximum visibility. That derivation is given in the verification chain (Section 9.2) precisely so that a reader can see which parts of the argument survive the removal of the uncited material. All of it does.

3.5 The inventory procedure and its five failure modes

The framework's inventory procedure is reproduced in operational form because later papers refer to its outputs. Seven evenings of twenty minutes; a card for each holding, one to a card, in the plainness of a bin label rather than the abstraction of a title; the four cost currencies written on the back in fixed order with foreclosure last; a separate class of cards for discomforts, each assayed in the four yield currencies with **unpriced** written where nothing surfaces and no yield invented; one card audited per evening against three questions — what does it buy, what does it forbid, who would the holder be in a year if it kept its job; the whole read aloud; the cards filed in any order except importance, since ordering by importance is valuation smuggled into an inventory; and the box dated, because prices move with the season.

Two procedural rulings are falsifiable operational claims rather than preferences and are recorded as such. First, **validation precedes valuation**: the procedure forbids acting on a card during the inventory, on the ground that a hand that counts while wanting counts wrong. Second, **the resisting card**: the framework predicts that at least one card in any honest run will not accept its reverse, holds that the resistance locates an unresolved holding rather than a failure of the instrument, and requires that such a card be stood upright and left unwritten rather than forced or retired.

The framework catalogues five ways the inventory fails. They are reproduced in full, since a procedure supplied without its failure catalogue is an advertisement.

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-F1	The price paid twice	Sunk-cost fallacy: past spending entered as present value	**none** (Section 10.3)
CC-F2	The stone that weighs more in the hand	Endowment effect: possession inflates felt value, so the stock is overpriced and the shelf underpriced	**none** (Section 10.3)
CC-F3	The ledger written for the auditor	Inward-turned impression management; the inventory as self-presentation	Nisbett and Wilson [1977] and Schwarz [1999] bear on it but do not state it
CC-F4	The scourge in the counting-house	The audit collapsing into rumination; counting moves, scourging loops	**none**

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-F5	The drawer nailed shut	Experiential avoidance: the resisting card promoted to a forbidden one, so that every adjacent card must be mispriced to keep it plausible	**none**

The source's labels for these five are renamed here with the prefix `CC-` to keep them clear of this paper's own results R1–R7.

The framework's own closing note on the catalogue is worth keeping because it is a structural observation rather than an exhortation: none of the five failures is a failure of *finding too much*. Each is a way of writing fewer true lines while appearing to write more. The framework's stated countermeasure is plainness, spoken aloud, one item at a time, dated — which is a documentary control and is the same class of instrument the corpus uses to audit its own procedures [Curzi, 2026u].

2.0.4 4. The gradient

4.1 The tilt, not the level

The gradient material opens with a correction that everything after it rests on: a person does not experience comfort as a level but as a difference.

The physical statement is exact and is quoted exactly. For a conservative field, the force is the negative gradient of the potential,

$$\mathbf{F} = -\nabla U$$

the minus sign carrying only the direction of the push. Nothing in such a field responds to *where it is*; everything responds to how the ground falls away from where it is. The framework's claim is that a person's minute-to-minute experience has this grammar: what is felt is the differential between this posture and that one, this room and the next.

The claim is a **shared mathematical form** and not a derivation, and it is labelled as such in Section 6.1. What licenses the shape is the psychophysical result that perception is organised around a moving reference level [Helson, 1948] and that a just-noticeable difference is a ratio to the current level rather than an absolute increment [Weber, 1834]. What is *not* licensed is any inference from the physics: there is no potential energy here, no conserved quantity, and no unit.

4.2 Stationary action and its local twin (R6)

For a body moving between two fixed configurations, the action S is computed along each candidate path as the integral of the Lagrangian, and the path actually taken is the one for which the action is *stationary*:

$$\delta S = 0, \qquad S = \int L\, dt, \qquad L = T - V$$

Three statements belong with this and constitute R6's content.

First, $\delta S = 0$ is a **stationarity condition and not a superlative**. The name "least action" is a historical courtesy; the mathematics requires only that small variations of the path produce

no first-order change. A stationary path may be a minimum, and may equally be a saddle. The founding paper of this series states the same correction and this paper preserves it.

Second, **the principle licenses no teleology, and the reason is a proof rather than a caution.** The variational statement is exactly equivalent to a local differential law: the Euler–Lagrange equations, which are Newton's laws in different notation. The global-sounding statement ("of all paths, the stationary one") and the local statement ("at each instant, respond to the slope you are on") are the same equation written twice. The path does not know its destination; the path obeys its ground instant by instant, and the obedience adds up to what looks, afterwards, like design. **This corpus's external bibliography contains no classical-mechanics text, so the Euler–Lagrange equivalence is stated here without a citation** and is listed in Section 10.3. It is standard, it is checkable in any graduate mechanics course, and no entry in this file supports it.

Third — and this is the consequence the framework actually uses — **a trajectory alone cannot distinguish a chosen path from an obeyed one.** A trajectory satisfying $\delta S = 0$ is simultaneously a story of local necessity and a story of global election, and no measurement performed on the path separates them, because they are not two claims. This is a statement about the equations and it is exact. Its extension to a person's day is P1.

The source also gives one paragraph to the path-integral account, in which every path contributes with a phase turning with its action and nearly all cancel, leaving the neighbourhood of the stationary path as the survivor. **This corpus's bibliography contains no entry for that formalism either**; the paragraph is reported as the source states it, badged, and used for nothing. Every result in this section survives its deletion, which is why the verification chain does not consume it.

4.3 Desire lines as the observable (R5)

A theory of comfort differentials would remain unfalsifiable if the gradient left no tracks. The framework's claim is that it leaves tracks, and that the tracks are the node's data.

A **desire line** is the worn path that appears beside a designed one — the corner the pavement refused to cut, the diagonal across a lawn worn to the width of one person. Formally, and this is R5's first limb, a desire line is not a decision but the *integral of many small descents*: each crossing a single creature answering the local tilt between where it stands and where its errand is, none of which felt like a choice and all of which were recorded. It is gradient descent drawn on the ground by the optimiser, in the medium of grass.

That observed movement through a built setting is a more reliable survey of the setting's actual use than its designed intention is not the framework's discovery. It is the working method of a whole tradition of urban observation: the systematic filming and counting of how people actually occupy public space [Whyte, 1980], the same programme carried out as a design discipline [Gehl, 1971], the argument that a plan's legibility is not the same thing as its use and the observation that a plan drawn at a drafting table and a plan walked into existence are different objects. The framework's contribution is not the observation but the extension: **a person's day is a yard**, and the routes, the reached-for objects, and the answered letters are the same class of data.

> **The designed path is a theory. The worn path is the data.**

R5's second limb is the framework's answer to the obvious objection — that a worn path proves only the ground's habit and not the walker's gradient. The answer is an erasure test. A snowfall wipes the record to zero: no channel, no groove, no residue of the previous traffic. Within a few days the same paths reappear, in the same places, with the same bends, drawn by feet that consulted no memory but their own errands. **When a pattern survives the erasure of its medium, the pattern was not in the medium.** It was in the field of forces that drew it, and it will be drawn again in any medium offered.

The argument is sound as stated and its limits should be stated with it. It establishes that the pattern is not stored in the surface; it does not establish that the pattern is stored in a

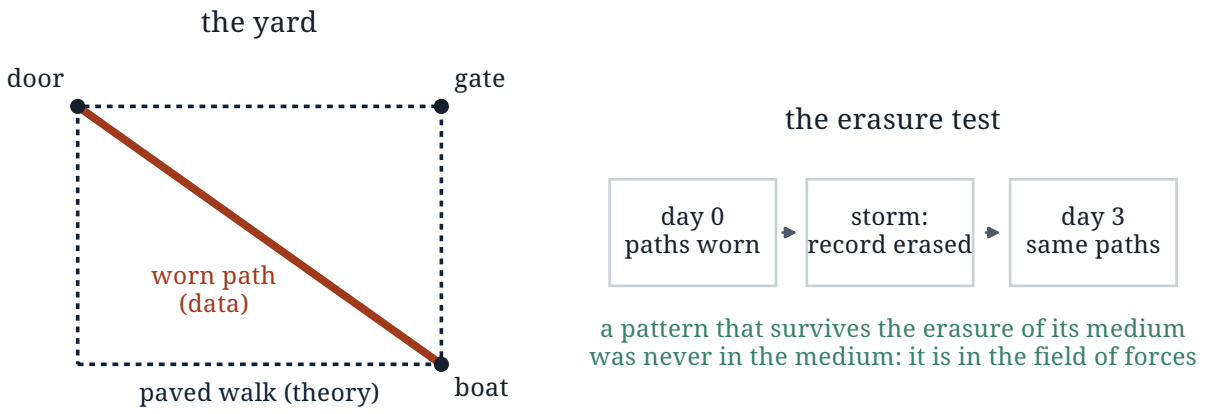

Figure 2.2: **The worn path is the survey; the erasure test is what makes it evidence.** Schematic; no plotted quantity. The left panel redraws the source's own monospace diagram of a yard, which sets a dotted designed walk around the edge and a solid worn path across the diagonal. The right panel states the source's erasure argument: a pattern reproduced after its recording medium is destroyed was never held in the medium. Script: `figs/src/CCP-A02_fig04.py`.

comfort gradient rather than in any other stable feature of the walkers or the terrain. An erasure test discriminates *record* from *generator*; it does not identify the generator. That distinction is the same one Section 6.3 draws about the framework's social claims, and it is drawn here so that R5 is not read as more than it is.

4.4 The office of the ground: four grading tools

The framework's practical prescription follows from R5 and R6 together, and it is stated as an inversion of the usual advice: effort applied at the moment of maximum tilt is the wrong instrument, and the right instrument is applied earlier, to the terrain, in a calm hour. Four tools are named.

1. **Distance.** Every reach is priced in steps. Bring the wanted thing one room nearer; send the unwanted thing one room further. The framework notes that the effective distances are surprisingly small — a drawer against a countertop, a pocket against a bag.
2. **The default.** Whatever happens when nothing is decided is the strongest current in a day, because nothing is what will most dependably be done. A default is a decision made once, in a good hour, that then stands over an unbounded number of bad ones.
3. **Friction, in both directions.** Add a step to the path that should be less worn; remove a step from the path that should deepen. The framework's ruling is that friction added without a channel opened beside it is a fence, and that fences fail — which is its third failure mode below.
4. **The first step.** A path's traffic is set less by its length than by the tilt of its first two feet. The prescription is to arrange for beginning to be smaller than not beginning.

One discipline binds the four: each is applied *once, in the calm, to the ground*, and never repeatedly, in the heat, to the self. The framework's stated test for any proposed change is a worst-day test — would this still work on a day when the person is tired, late, and out of virtue? — and its ruling is that an intervention requiring virtue is refused as a category.

None of this has a supporting entry in this corpus's bibliography. There is no entry for choice architecture, for default effects, for cue-based habit formation, or for implementation intentions. The four tools are reported as the framework's and are uncited; they are listed in Section 10.3. The framework's own case for them is R5: if behaviour is the integral of local

descents, then the leverage is on the local tilts, and that argument is internal and does not require the missing literature.

The framework also names five ways the grading procedure fails. Renamed with the CC– prefix to keep them clear of this paper's results: **CC-G1**, the survey falsified toward the surveyor's better self; **CC-G2**, the operator who accepts the map and rejects the method, attacking the steepest divergence with resolve at the hour of maximum tilt and then booking the failure to character; **CC-G3**, the fence the feet ignore — restriction without re-grading, where the water rises against the barrier, finds the gap beside it, and cuts a worse channel with resentment in it; **CC-G4**, the operator who begins choosing paths *because* they are steep, mistaking cost for worth; and **CC-G5**, the survey that becomes the residence, in which maps of maps accumulate and no object is ever moved.

CC-G3's mechanism is named by the source as reactance — that pressure on a perceived freedom produces counter-movement. **This corpus's external bibliography contains no entry for reactance.** The claim is retained because it is load-bearing for the framework's distinction between grading and fencing, and it is retained uncited, exactly as the other papers of this series retain it. What can be supported is the weaker and sufficient statement that added control and added redundancy can reduce rather than increase the safety of a coupled system [Sagan, 1993, Perrow, 1984].

4.5 The honest limit of descent (R7)

The gradient material ends by confessing its own failure condition, and the confession is R7.

Gradients are local. That is their power — they require no map, no foresight and no committee — and it is exactly their weakness: **descent finds the nearest low place, not the best one.** A system relaxes to the bottom of its own basin and stops, in perfect obedience, with a deeper basin one ridge away that it will never visit, because every direction out is uphill. The basin structure that makes the local/global distinction consequential is standard [Strogatz, 2015].

The shape of the trap is worth marking precisely, because it is what makes the condition hard to see from inside. The stranded system is *not* uncomfortable. It is at the bottom of everything it can register: every local differential points back, every small departure genuinely costs more than it returns, and so every honest instrument on the valley floor reports that nothing is wrong. Nothing *is* wrong, except the one thing no instrument on the valley floor can measure — the existence of a better valley.

R7's consequence is a limitation on the framework's own method and is stated as one: **the gradient analysis can diagnose a stable trap and cannot treat one.** Descent cannot climb out; applied effort against the gradient is the failure mode CC-G2. The only exit the framework offers that does not fight the gradient is a change in what can be seen, which re-grades the surface and lets the same descent that produced the trap carry the system out of it. That claim is stated in falsifiable form in the founding paper of this series and is untested there; nothing in this paper tests it either.

The same geometry is the corpus's account of professional over-specialisation, and the organisational literature reached the result independently: an organisation that learns fast homogenises and destroys the variance that produced its own advantage [March, 1991]. The prescription that follows is terrain rather than exhortation, and its own limit is that making a working system legible to a plan can destroy the local variety the system was running on [Scott, 1998].

2.0.5 5. The arithmetic of difference

5.1 The four requirements and the functional (R1)

The framework poses the question formally: when several viewpoints are taken on one thing, how much more do the many see than the one? Let there be N viewpoints and let $u \in [0, 1]$

measure their non-parallelism (D1), with $u = 0$ meaning all viewpoints parallel and $u = 1$ meaning each contributes a direction the others lack.

The framework states four requirements:

- **S1 (angles only).** The surplus depends only on the angles between viewpoints, and not on any viewpoint's size, weight or prestige.
- **S2 (zero at parallel).** Perfectly parallel viewpoints yield zero surplus.
- **S3 (affine effective count).** The many-viewpoint case decomposes as an effective count that grows evenly — that is, affinely — with u.
- **S4 (normalisation).** The scale is normalised, so that nothing is smuggled in through the units.

Under S1–S4 the surplus of N viewpoints over one is

$$f(u) \;=\; \ln\!\big(1 + (N-1)u\big)$$

This is R1. Read term by term: the inner expression is a count, $N_{\text{eff}} = 1 + (N-1)u$, the **effective number of viewpoints**. At $u = 0$ it equals 1 — ten parallel viewpoints are one viewpoint. At $u = 1$ it equals N. Between, it interpolates linearly. The surplus is the *logarithm of that affine effective count*: a headcount audited for redundancy, and then logged.

Two statements about the status of R1 are required and are made here rather than left to a reader.

S3 is a design axiom, not a derived property. The corpus badges it as such where it uses it: the affine effective count with $u = 1 - (x \cdot y)^2$ and surplus $S = \ln N_{\text{eff}}$ is explicitly recorded as a design axiom rather than a derived result [Curzi, 2026c], and the same badge is carried in the internal form $F_{\text{int}} = \ln(1 + (N-1)u)$ with $u = 1 - \rho^2$ from error decorrelation, where the affine form is badged as design axiom S3 rather than as a theorem [Curzi, 2026o]. **A uniqueness theorem conditional on a chosen axiom establishes that the form follows from the axiom, and nothing more.** That is the whole logical content of R1, and the corpus's own reference apparatus records it in exactly those terms: the surplus form is filed as *proved conditionally on a chosen design axiom* [Curzi, 2026].

Uniqueness-under-axioms is an established genre and this result must be positioned inside it, not presented as novel. The genre begins with the axiomatic characterisation of entropy [Shannon, 1948] and continues through the later axiomatisations of the same quantity [Aczél et al., 1974]. The framework's S1–S4 argument is a member of that genre and inherits both its strength (the form is forced once the axioms are granted) and its weakness (the axioms are the claim).

5.2 The effective count is affine, and it is not a Hill number

This subsection states a correction that applies corpus-wide and that a reviewer familiar with the diversity literature will otherwise supply.

The corpus runs **two different effective counts**, and only one of them has external grounding.

- $1/\text{HHI}$, the reciprocal of the sum of squared shares, is the Hill number of order 2, and $\exp(H)$ is the Hill number of order 1. Both are exact, well-grounded numbers-equivalents [Hill, 1973, Jost, 2006], and reinvented independently in competition economics and in political science. The corpus's concentration instrument uses exactly this reading: four holders at 40.9, 27.3, 18.2 and 13.6 per cent give a naive index of 0.293430 and 3.41 effective holders, while collapsing them into the single bloc they actually form gives an index of 1.000000 and an effective count of 1.00 [Curzi, 2026]. Both of those numbers are reproduced exactly in Section 9.2.

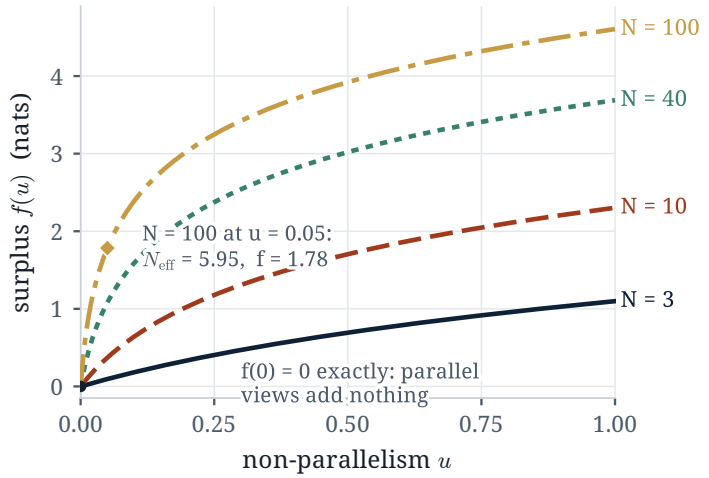

Figure 2.3: **The surplus is the logarithm of an audited headcount, and it is exactly zero when the viewpoints are parallel.** Computed from the source's own formula $f(u) = \ln(1 + (N-1)u)$ with $N_{\text{eff}} = 1 + (N-1)u$. The annotated point is the corpus's own worked instance: a hundred-member group at $u = 0.05$ has an effective count of 5.95 and a surplus of 1.78 nats [Curzi, 2026c]. Script: `figs/src/CCP-A02_fig01.py`.

- $N_{\text{eff}} = 1 + (N-1)u$ is a **linear interpolation between 1 and** N. It is not a Hill number of any order. No literature in ecology, economics, political science or information theory contains it. It is this corpus's own construction.

The distinction matters because the two are used under one name across the corpus, and a reviewer who reaches for the Hill-number literature as support will find it does not apply. The repair is cheap and is made here: **where this paper cites the Hill-number literature it does so only for** $1/\text{HHI}$ **and** $\exp(H)$**, and no reader should transfer that grounding to the affine count.**

One formalism does exist that makes a diversity index depend on the dissimilarity *between* types rather than only on their frequencies [Rao, 1982], and it is the closest external relative of what the framework is attempting. It does not reduce to the affine form, and the corpus has not shown that its u is a case of it. Stating the relationship as *unestablished* is the honest position and is adopted here.

A related warning is that "diversity" names at least three incompatible constructs — separation, variety, and disparity — so any measure of difference must declare which it is [Harrison and Klein, 2007]. The corpus's u has not declared. On the two operationalisations the corpus does supply, $u = 1-(x \cdot y)^2$ [Curzi, 2026c] and $u = 1-\rho^2$ [Curzi, 2026o], it is a *separation* measure on a squared alignment, which has a consequence the corpus states plainly: a pair in perfect opposition and a pair in perfect agreement both read $u = 0$, $N_{\text{eff}} = 1$ and surplus zero, because the extremality condition is stated on the squared alignment [Curzi, 2026r]. That is a real and counter-intuitive property and it is worth naming: **on this measure, disagreement is not difference.**

5.3 Zero at parallelism (R3)

S2 is the binding clause of the whole construction, and it is R3.

Perfectly parallel viewpoints yield $\ln(1) = 0$. Not "little": zero. A second opinion sought from a source whose training, incentives and premises replicate the first opinion's is worth exactly nothing in surplus. Agreement between aligned instruments is not evidence; it is echo.

This is the clause the corpus's downstream instruments actually run on. Stated as a procedural rule: $\ln(1.00) = 0$, so a structure with one effective bloc has zero available surplus rather

than a low one, and the first step of the method is to collapse before measuring [Curzi, 2026]. The concentration instrument's worked case is the same statement in numbers: four nominally separate holders whose independence does not survive an audit collapse to an effective count of 1.00 [Curzi, 2026].

The external literature supports the clause from several directions and is worth citing in full, because R3 is the framework's strongest claim and also its most easily overstated one. The formal statement that a group of diverse problem solvers can outperform a group of high-ability solvers exists and is much cited [Hong and Page, 2004], though it has been argued to be either trivially true or dependent on conditions amounting to the conclusion [Thompson, 2014]. The mechanisms that *destroy* u without reducing N are equally well established: informational cascades, in which later members rationally copy earlier ones and stop contributing information [Bikhchandani et al., 1992], which lowers u without lowering N and is therefore the exact failure R3 names.

The sharpest external statement of R3, however, is fifty years older than the corpus and comes from finance: **diversification benefit depends on covariance, not on count** [Markowitz, 1952]. N uncorrelated holdings and N perfectly correlated holdings have the same N and entirely different behaviour. That is R3 with the mathematics attached, published in 1952, and this paper states so rather than presenting R3 as new. The corollary is worse and is also established: correlations rise under stress, so the effective count falls exactly when it is needed [Longin and Solnik, 2001]. An audited count is not a permanent property of a structure.

One further requirement follows from R3 and is engineering rather than philosophy: a count that has not been audited for independence is worthless, because one party can present as many [Douceur, 2002]. An unaudited N is not a count; it is a claim about a count.

5.4 Concavity, and what a few views actually buy

The logarithm buys most with its first coin. Going from one viewpoint to a second, genuinely non-parallel, yields the largest single gain the set will ever see; the tenth adds a sliver and the fortieth adds almost nothing. The framework draws the practical conclusion explicitly, and the conclusion runs *against* the reflex the result is usually used to justify: the craft is not the hoarding of perspectives but the cutting of a few at genuinely divergent angles.

The framework states this as: "three honest windows, set wide, capture the greater part of what a gallery could." **That claim is not true as a comparison of counts and this paper says so.** At full non-parallelism, three viewpoints give $\ln 3 = 1.0986$ nats and forty give $\ln 40 = 3.6889$ nats, so three capture 29.8 per cent of forty and not "the greater part". The claim is true as a comparison of *angles*, which is what the framework's own arithmetic is about: three fully non-parallel viewpoints exceed forty viewpoints at any u below

$$u^{*} \;=\; \frac{2}{39} \;=\; 0.051282\ldots$$

since $1 + 39u^{*} = 3$ exactly. Forty near-duplicates at $u = 0.05$ give $N_{\text{eff}} = 2.95$ and a surplus of 1.0818 nats, which is less than three well-separated viewpoints give. **That is the defensible version of the framework's claim, and the framework does not state it in that form.** It is stated in that form here, with its break-even, and the correction is recorded in Section 7.6 rather than applied silently.

The marginal arithmetic is worth printing because it prices the framework's advice. At $u = 1$ the k-th viewpoint adds $\ln k - \ln(k-1)$: the second adds 0.6931 nats, which is 63.1 per cent of what three viewpoints reach in total; the tenth adds 0.1054; the fortieth adds 0.0253. A protocol that uses three viewpoints rather than thirty is therefore not a compromise forced by time. It is what the functional recommends.

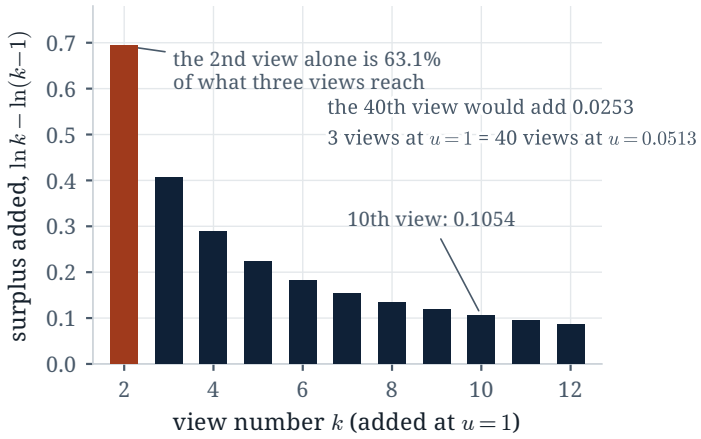

Figure 2.4: **Concavity is the argument against collecting viewpoints.** Arithmetic on the source's own formula: at full non-parallelism the k-th viewpoint adds $\ln k - \ln(k-1)$, so the second alone is 63.1 per cent of what three reach and the fortieth adds 0.0253 nats. The two annotations state the break-even the source does not compute: three fully non-parallel viewpoints equal forty viewpoints at $u = 0.0513$. Script: `figs/src/CCP-A02_fig02.py`.

5.5 A lower bound, not the information (R2)

The framework attaches one limit to R1 and treats it as doctrine rather than as a disclaimer, and this paper reports it at the same weight.

The surplus functional is a lower bound on the ensemble's information, not the information. The true information carried by N viewpoints can exceed what the formula certifies, because the formula prices only what follows from the angles alone — the bare geometry of how the viewpoints differ — and is silent about what any particular viewpoint contributes on any particular occasion. The framework's own phrase for the position is that it logs the floor and not the ceiling, and its argument for preferring that direction of error is that a floor can be built on.

This is R2, and it constrains every downstream use. A quantity reported as a bound may be used to establish that a structure has *at least* a given surplus; it may not be used to establish that a structure has *only* that surplus, nor may it be subtracted from a measured quantity as though the two were commensurable. The distinction is standard in information theory, where a bound and an attained value are different objects [Shannon, 1948, Cover and Thomas, 2006], and the corpus states the restriction in its own terms [Curzi, 2026].

Two corpus results turn on R2 being read as a bound. The corpus's headroom instrument reports realised surplus as a *percentage of the ceiling* $\ln N$ rather than as an absolute quantity, and the collective case it works reaches 57.37 per cent of that ceiling at $u = 0.25$, rising to 74.65 per cent at $u = 0.45$ [Curzi, 2026]; both percentages are reproduced exactly in Section 9.2 and neither would be interpretable if f were being read as the ensemble's information. And the corpus's structural instruments report an effective count of independence explicitly *without* claiming it measures capacity: the effective count says nothing about whether any bloc can carry the load [Curzi, 2026].

5.6 The form is underdetermined, and this paper concedes it

R1's uniqueness is conditional on S1–S4. The prior question — whether S1–S4 are the requirements the evidence supports — is open, and this paper does not close it.

Two established rival forms fit the same qualitative facts. Social impact grows as a *power* of the number of sources with an exponent below one, a result established with psychological

data in 1981 and given a dynamic cellular-automaton form in *Psychological Review* in 1990 [Latané, 1981]. Network value has been argued, from communications economics, to grow as $n \log n$ [Briscoe et al., 2006]. All three — power, $n \log n$, and $\ln(1 + (N-1)u)$ — are decelerating in the count, all three reproduce the qualitative facts the framework appeals to, and **nothing in this paper discriminates between them.** The general form of the difficulty is that many mechanisms produce indistinguishable curves, so a fitted shape is weak evidence for a generative mechanism [Stumpf and Porter, 2012]. What a reviewer will ask for is the *differential* prediction — the observation this model makes that a neighbouring model does not [Durlauf, 2005]. **This paper does not have one.**

Two things can honestly be said in the logarithm's favour.

The first is a warrant that does not require the perceptual story at all: the growth rate of a multiplicative process is logarithmic, so a logarithmic form can be a dynamical consequence rather than a psychological assumption [Peters and Gell-Mann, 2016]. Where this corpus justifies a logarithm on Fechnerian grounds [Fechner, 1966], that warrant is the weaker of the two, because it requires the perceptual claim to be true. **This paper does not establish that the comfort surplus is generated multiplicatively**; it records only which argument would be needed.

The second is negative and is therefore worth more. **No scaling or power-law claim is made anywhere in this paper.** The exponent question does not arise, because the functional's shape is *defined by the model rather than estimated from data*. Where any paper in this corpus does make a distributional or heavy-tail claim, the principled maximum-likelihood, Kolmogorov–Smirnov and likelihood-ratio procedure is binding and must be run and reported [Clauset et al., 2009]; this paper states that it makes no such claim, so that the absence of the procedure here is a scope statement and not an omission.

5.7 Convergence, invariants, and the breaking window

The single trace shows what one branch holds. A set of traces shows what holds across branches, and the audit that extracts it is R3 run in reverse.

Lay the terminal states of several non-parallel traces side by side and look for features that appear in all of them. A feature shared by *parallel* traces means nothing: the traces were bound to agree, and their agreement is one vote counted many times — which is R3. A feature shared by traces built on assumptions that contradict one another cannot be explained by the assumptions, because the assumptions disagree about everything else. The framework calls such a survivor a **horizon-fact** and is careful about what it is a fact about: not about the future, but about the composition — the system that all the traces were obliged to run on.

The framework then states its own strongest objection to the procedure, and states it as a mandatory step rather than a caveat. **Convergence can also mean the viewpoints secretly share an angle.** All of them were cut by one person, with that person's practised blindnesses, and an invariant may be nothing more than a habit that reached every trace. The required check is to attempt, in earnest, one further honest trace that lands *without* the invariant — the assumption a stranger would choose. If it can be built, the invariant is struck. If it genuinely cannot, the invariant is promoted, carrying the warrant *tested against the best available attempt to break it*. That is a severe-test discipline in the strong sense: a design that discriminates between named alternatives rather than accumulating agreement with one and it is the same standard the preregistration literature imposes on a prediction [Nosek et al., 2018].

The framework's own worked case is reported here because it shows what the procedure returns and because it contains a refusal, which is the part usually omitted. Three traces of one person's next three years, built on contradictory assumptions — continuation, a single named intervention, and the branch the person had been declining to look at — landed in three settings that agreed on nothing: not the premises, not the finances, not the job title. One concrete feature stood in all three. The mandatory fourth trace, built on an assumption chosen to break that feature, could not be landed without it, so the feature was promoted.

Figure 2.5: **Three traces built on contradictory assumptions agreed on exactly one feature, and the mandatory breaking trace could not be landed without it.** Measured from the source's own case record, which states that the three landed futures agree on neither the premises, nor the finances, nor the job title, and names the single surviving feature. Each row is a concrete feature the record names; each column a trace the record reports. Script: `figs/src/CCP-A02_fig05.py`.

This is a single self-reported case and it establishes nothing about the procedure's validity. It is offered as an illustration of the procedure's output. The base rate against which any single reported psychological observation should be read is not encouraging [Open Science Collaboration, 2015].

2.0.6 6. Method: what kind of borrowing, what scale, and what is identified

6.1 Analogy discipline

Every physics borrowing in this paper is labelled at first use as one of three things: a **derivation**, in which the physical result is used because the system genuinely satisfies its premises; a **shared mathematical form**, in which the same equation governs both with no claim that the underlying physics applies; or an **analogy**, a suggestive correspondence with no formal warrant, legitimate as motivation and never as evidence. The labels are collected here so that a reader can check them against the text.

Borrowing	Category	Warrant, and what is not claimed
$\mathbf{F} = -\nabla U$ (Sec. 4.1)	2 — shared form	The statement is exact for a conservative field. No claim that a comfort landscape is a potential, that anything is conserved, or that any unit transfers.
Stationary action $\delta S = 0$ (Sec. 4.2)	3 — analogy	No action functional of a life is defined and no Lagrangian is exhibited. The borrowing supplies the image of a resting trajectory. The variational form licenses no teleology.

Borrowing	Category	Warrant, and what is not claimed
The Euler–Lagrange equivalence (Sec. 4.2)	1 — derivation, **within mechanics only**	A genuine theorem of classical mechanics, used only to establish that the global statement carries no teleology. **Uncited: this bibliography holds no mechanics text.**
The path-integral account (Sec. 4.2)	quoted, then unused	Reported as the source states it. **Uncited.** No result consumes it; the chain in Section 9.2 does not contain it.
Gradient descent and local minima (Sec. 4.5)	2 — shared form	The convergence and trapping behaviour hold for any differentiable cost. The transfer claim is that behaviour has this recursion's shape, not its physics [Strogatz, 2015].
Carrying cost as a stock outflow (Sec. 3.1)	2 — shared form	Levels and rates are the same mathematics wherever the level comes from [Hopp and Spearman, 2011]. No claim that comfort is inventory.
The logarithm in $f(u)$ (Sec. 5.1)	2 — shared form, contested	An information-theoretic form used on a quantity that has not been shown to be an information measure. The alternative warrants are named in Section 5.6.
"Effective count" (Sec. 5.2)	**1 for $1/\mathrm{HHI}$, 3 for the affine count**	Hill numbers are exact numbers-equivalents; the affine count is this corpus's own construction with no precedent, and the two are kept apart throughout.

The corpus's title claims physics, and the claim attracts a specific literature of objection which is better cited than ignored. The historical form is that economics imported the formal apparatus of nineteenth-century energetics without the conservation law that gave energy its content [Mirowski, 1989], which is precisely the hazard for a framework whose central object is a stock that accumulates, leaks and is spent: **this paper claims nothing is conserved, and states that no invariance has been exhibited beyond the one in Section 9.5.** The general form of the objection is that laws hold in shielded local arrangements rather than universally, so importing a law's form is not importing its scope; and the field this corpus's title claims membership of has been surveyed and bounded, with the vocabulary the corpus uses given definitions it can be held to [Castellano et al., 2009]. The criterion the discipline named in the corpus's title will actually apply is that an explanation must name a mechanism rather than exhibit a fitted curve, and the standing answer to the charge that such work forecasts nothing is to say which of the other purposes of modelling it is claiming. This paper claims explanation of structure and not prediction.

Where a result carries a constant of this corpus's own construction — the minimum sustainable frequency $f_{\min} = k\,e^{2c/\eta}$ with $k = 0.483425732988414$ Hz [Curzi, 2026] — two cautions apply and are recorded once here rather than at each mention. That constant is **defined**, exact by construction as $(9/8)^2/\varphi^2$, and its fifteen significant figures are defensible only on that basis; **attaching hertz to it is a separate and much stronger claim than computing it**, and this paper endorses neither the attachment nor any reading of it as a discovered natural constant. The general hazard of reading a chosen golden-section ratio as a fact about the world is documented and should be read before any such reading is offered [Markowsky, 1992].

6.2 Scale type, and the objection that bites hardest

Everything in Section 3 that adds, subtracts or compares carrying costs presupposes at least an interval scale, and everything in Section 5 that reads a *ratio* of surpluses presupposes a ratio scale. Nothing in the source establishes either.

This is the framework's sharpest exposure and the objection has a name and an author: psychology systematically assumes that its attributes are quantitative without ever testing whether they are [Michell, 1997]. **This is the strongest single objection to the framework and it is not answered here.** The formal test for whether an attribute has additive quantitative structure is conjoint measurement [Luce and Tukey, 1964], whose single, double and triple cancellation conditions are exactly what would have to be checked, against the standard set out in the measurement-foundations literature [Krantz et al., 1971]. **They were not tested.** A route that does not require respondents to use numbers at all is available and unused [Rasch, 1960]. The classification of scales that fixes which operations each licenses is Stevens's [Stevens, 1946], and the century-long dispute over whether the psychophysical function is logarithmic or a power law is itself evidence of how hard the underlying question is [Stevens, 1957].

The honest position, adopted here: carrying cost and comfort are treated as quantitative by stipulation, not by demonstration. The corpus applies the same demotion to itself elsewhere and the demotion is the correct instinct: because the moment equation contains a division and a multiplication, ordinal data for either of its inputs demote it to a heuristic ordering that may not be printed as a fraction or computed [Curzi, 2026m]. **That demotion rule applies to this paper's own material and is applied.** Specifically:

- $f(u)$ and N_{eff} are licensed at ratio scale **only where u is computed from a quantity with its own ratio structure** — a squared inner product of unit vectors [Curzi, 2026c] or a squared correlation [Curzi, 2026o]. Both of those are dimensionless numbers on $[0, 1]$ with a true zero, so the arithmetic of Section 5 is licensed *by them* and not by this framework.
- Where u is instead elicited as a judgement of how different two viewpoints are, it is at best ordinal, and $\ln(1 + (N-1)u)$ may then be used only as a monotone ordering. It may not be printed as a number of nats.
- Carrying cost in *coin* and in *hours* has a natural unit and licenses arithmetic. Carrying cost in *attention* and *foreclosure* has none, and the ledger's four-way total is therefore **not a sum of commensurable quantities.** The source prints the four currencies as a single ledger entry; this paper records that they do not add.

A further formal obstacle applies to any similarity-based reading of u: psychological similarity is asymmetric and violates the triangle inequality, so it is not a metric [Tversky, 1977]. Where u is intended as one minus a similarity, that result bears directly on whether u is even well defined.

6.3 Identification: the reflection problem, and the framework turned on itself

Section 5's arithmetic is used across this corpus on *groups*: departments, panels, blocs. The moment it is used that way it becomes a claim about social interaction, and a claim about

social interaction invites the question of whether its parameter could be recovered from observation. It could not, and this is stated here in Method rather than in a footnote, because it fixes what R1 and R3 can be.

The corpus's central formal object is the reflexive loop $T(x) = W(x, M(x))$, fixed in the founding paper of this series. Written as an aggregate relation — a group's state influencing its members while the members constitute the group — **that is a linear-in-means reflexive specification, and the endogenous social effect in such a specification is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is collected [Manski, 1993]. The network route is closed by the same family of result, since influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011].

The consequence for this paper is specific. A group's non-parallelism u is *definable* — D1 gives two constructions — and, from observational data on a group, it is not *estimable* as a causal quantity: any association between a measured u and a measured outcome is not separable from the reasons people with different views end up in the same group. The available remedies are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation, the last having an explicit template in a discrete-choice model that states the conditions under which its interaction parameter is econometrically identified [Brock and Durlauf, 2001]. **This paper adopts none of them.** R1 and R3 are therefore **modelling positions rather than identified empirical results**, and every downstream paper citing them inherits that status. An interaction parameter that is merely definable is not the same object as one that is estimable, and this corpus has so far produced only the first.

That reflexivity of this shape *occurs* is separately documented and the documentation matters because it is the existence proof the framework otherwise lacks: when the Black–Scholes option-pricing model was published its prices did not fit the market, and after traders adopted it the market came to fit the model, with dates and price data recording the convergence [MacKenzie and Millo, 2003]. The more general statement — that classifications of people alter the people classified, so the referent moves — has been argued directly [Hacking, 1995]. That literature supplies existence, not identification, and the distinction is the one this subsection exists to keep.

The framework turned on itself. The corpus asserts that systems change their behaviour when modelled and observed. Applied consistently, that assertion falls on the corpus's own parameters: a u, a decay rate or a cost coefficient estimated in a population that has not read the framework cannot be assumed to survive in one that has, because the decision rules those parameters summarise are themselves responses to the environment the model describes [Lucas, 1976]. This is not an outside objection; it is the corpus's own thesis pointed at itself. The position taken here, stated so that it can be held against the paper: **no stability of this framework's parameters under its own dissemination is claimed, and no result in this paper depends on any.** A further and independent aggregation problem applies wherever a single u is written for a group whose members differ, and this paper does not address it.

2.0.7 7. Results

7.1 Definitions fixed. D1 (non-parallelism), D2 (the affine effective count) and D3 (carrying cost) are stated in the form the remaining papers cite. None is a finding. D2 in particular carries a modelling choice — the affine form — inside what reads as a definition, and Section 5.1 badges it.

7.2 Results established by derivation, conditional on the axioms. R1 is established *given* S1–S4, and the conditionality is the result's whole content: the functional follows from the requirements, and the requirements are a choice. R2 (lower bound) and R3 (zero at parallelism) follow from R1 by inspection. R6 (the variational form is equivalent to the local law, and licenses no teleology) is a theorem of classical mechanics, established, and **uncited in this bibliography**. R7 (descent finds the nearest low place) is standard.

7.3 Results established by construction. R4 (the four-currency carrying cost against the decay asymmetry) and R5 (the worn path as observable, authenticated by the erasure test) are specifications and arguments rather than measurements. R5's erasure argument is valid for what it claims — that the pattern is not stored in the medium — and does not identify the generator, which Section 4.3 states.

7.4 Hypotheses tested. None. H1 through H5 are stated in falsifiable form and none is tested here. No dataset was collected and no instrument capable of eliciting an attention charge or a foreclosure charge exists, for the measurement-theoretic reasons in Section 6.2. This is a negative result and is reported in the same plain language a positive one would receive: **the five hypotheses this paper states stand untested, and the paper that states them supplies no evidence for any of them.**

7.5 Reproduction of the corpus's own arithmetic. Five numerical claims that this paper's internal citations carry were recomputed. Four reproduce and one does not.

- The concentration instrument's naive index over shares 40.9, 27.3, 18.2 and 13.6 per cent is $0.409^2 + 0.273^2 + 0.182^2 + 0.136^2 = 0.293430$ exactly, and its reciprocal is 3.40797, printed as 3.41 [Curzi, 2026]. **Reproduced.**
- The option-value ceiling $p = (c + 0.0051096)/0.0318401$ reaches $p = 1$ at $c = 0.0318401 - 0.0051096 = 0.0267305$, and $0.0267305/0.30 = 0.089102$, printed as 8.9 per cent of the maintenance budget [Curzi, 2026]. **Reproduced.**
- The headroom instrument's realised-surplus percentages are reproduced exactly at $N = 18$: $\ln(1 + 17 \times 0.25)/\ln 18 = 1.6582281/2.8903718 = 0.573708$, printed as 57.37 per cent, and $\ln(1 + 17 \times 0.45)/\ln 18 = 2.1575593/2.8903718 = 0.746464$, printed as 74.65 per cent [Curzi, 2026]. **Reproduced**, and the reproduction also fixes $N = 18$, which the cited summary does not state.
- The same source's equilibrium at $u = 0.25$, $(0.30 \times 1.6582 - 0.55)/0.06 = -0.8755$, reproduces to -0.875526 when the unrounded surplus 1.6582281 is used, confirming that the printed four-decimal figure is correct and that the *displayed* 1.6582 is a rounding of the input rather than the input itself. **Reproduced, with that clarification.**
- **Not reproduced:** the companion figure for the same case at $u = 0.45$. Under the parameters as quoted, $(0.30 \times 2.1575593 - 0.55)/0.06 = +1.6211$, not the $+3.2878$ the summary states. Recovering $+3.2878$ requires a surplus of 2.490893, that is $u = 0.6513$ at $N = 18$, so either a parameter other than u also moves in that scenario or the figure is in error. **This paper does not resolve which**, and cites only the reproduced parts of that result. The discrepancy is printed here rather than smoothed over.

7.6 A correction to the source. The source's summary claim that three well-cut viewpoints "capture the greater part of what a gallery could" is false as a comparison of counts — three capture 29.8 per cent of forty at $u = 1$ — and true as a comparison of angles, with break-even at $u^* = 2/39 = 0.051282$ (Section 5.4). The corrected form is what this paper states and what downstream papers should quote.

2.0.8 8. Discussion

8.1 What follows

Three consequences follow from R1–R3 taken together, and they are the framework's genuine yield in this instalment.

The first is a rule for adding a viewpoint: the question is never whether the new viewpoint is *good* but what angle it holds that no viewpoint already present holds. R3 makes that a matter of arithmetic rather than of judgement, and it converts a familiar piece of advice into a check that can fail.

The second is a rule against accumulation. Concavity means that beyond a small number of genuinely divergent viewpoints, the marginal purchase is negligible, and effort is better spent raising the angles between the viewpoints already held. The corpus's own measurement

makes the same point from the cost side: raising realised non-parallelism by a factor of three raised surplus by 121 per cent and cost by 279 per cent, which made the position worse rather than better [Curzi, 2026g]. **Raising u is not free, and the framework's monotone reading of its own functional obscures that.**

The third is diagnostic and belongs to Section 4. If behaviour is the integral of local descents, then a position that will not yield to exhortation is not evidence of a defect in the person occupying it, and the intervention that follows is on the terrain rather than on the will. What R7 adds is the limit: where the trap is stable, the analysis can locate it and cannot open it.

8.2 What does not follow

That a functional is unique under four requirements does not make the requirements right. That an effective count is called a count does not make it a Hill number. That a worn path is data does not make the gradient the only generator that could have drawn it. That the corpus's arithmetic reproduces does not make the quantities it operates on ratio-scaled.

Two further non-implications are worth stating because the corpus's later results tempt them. First, **the surplus law is monotone increasing in u and the evidence is not.** Supporting: novel information arrives across weak, dissimilar ties [Granovetter, 1973]. Opposing, and unavoidable: creative success rises and then *falls* with cohesion, an inverted U rather than a monotone gain [Uzzi and Spiro, 2005]; in the largest natural setting studied, short-run diversity reduced trust and civic participation, a finding its author did not want [Putnam, 2007], though the effect largely disappears under better controls [Abascal and Baldassarri, 2015]; in randomly assembled ecological systems increasing diversity and connectance *destabilises* [May, 1972]; and a diversity–stability correlation can arise from statistical averaging with no mechanism at all [Doak et al., 1998]. **A monotone claim cannot survive that list unqualified, and this paper does not assert one.**

Second, the ledger is itself an indicator, and an indicator adopted as a target degrades [Campbell, 1979, Goodhart, 1975]. Nothing in the framework protects its own instrument from that, and the exposure is structural rather than incidental.

8.3 Relation to the corpus

The functional fixed here is consumed downstream in a specific and checkable way. The engineering series applies it to rosters and reports the affine effective count with $u = 1 - (x \cdot y)^2$, badged as a design axiom and worked at a hundred members and $u = 0.05$ to an effective count of 5.95 [Curzi, 2026c]. The same form is applied inside a single observer, with $u = 1 - \rho^2$ from error decorrelation and the affine form badged as design axiom S3 [Curzi, 2026o]. The dyadic case supplies R3's sharpest instance: opposition and agreement both read $u = 0$ [Curzi, 2026r]. The headroom instrument feeds f into an equilibrium and reports realised surplus as a fraction of $\ln N$ [Curzi, 2026]. The concentration instrument supplies the *other* effective count, exactly grounded, and the bloc collapse that makes the difference between the two visible [Curzi, 2026]. The consolidated method restates R3 as its first procedural step: collapse before measuring, because $\ln(1.00) = 0$ [Curzi, 2026]. And the option-pricing case shows what the arithmetic looks like when a marginal viewpoint is priced against its own cost ceiling [Curzi, 2026].

Three results elsewhere in the corpus bound what this paper may claim. The corpus's own falsification suite measured its shuffled-input control and found it **anti-conservative**: against a nominal 0.05 across 500 null trials, independent permutation rejected at 0.108, circular shift at 0.120 and block permutation at 0.060 [Curzi, 2026u]. That is the corpus's strongest evidence that its own controls can mislead, and it is the correct prior for any future test of H1–H5. The corpus's demotion of its moment equation on scale-type grounds is the rule this paper applies to its own four-currency total [Curzi, 2026m]. And the corpus's damage integral — in which eight periods of the wrong lever order cost twelve periods of permanent lag, a minimum stock

of -2.373029 from $+1.000000$ and 111.133601 stock-periods of cumulative gap [Curzi, 2026] — is the quantified form of R7's warning that a correctly diagnosed trap can still be treated in the wrong order.

Two further results are cited for the structure they share rather than the domain they occupy. The consonance–redundancy identity, in which the minimum essential harmonic distance of 2.0000 is attained by exactly the six collision pairs $\{1{:}2,\ 2{:}4,\ 3{:}6,\ 4{:}8,\ 5{:}10,\ 6{:}12\}$ and by nothing else [Curzi, 2026], is R3 in a different alphabet: exact coincidence yields exactly the degenerate value, and near-coincidence does not. And the pitch criterion $f_{\min} = k\,e^{2c/\eta}$ [Curzi, 2026] is the corpus's clearest instance of a defined constant carrying a unit it was not derived with, which is why the cautions of Section 6.1 are attached to it here.

2.0.9 9. Verification

This section is not a summary. It decomposes the paper's results into steps small enough that a reader can check each one without checking any other, and labels each `ARITHMETIC` (a reader can redo it), `DEFINITION` (true by this paper's own construction), `CITED` (a named external source supports it) or `POSTULATED` (asserted here, no external support). The razor is applied: any postulate whose removal leaves the results standing has been removed.

9.1 Postulates

- **P1 (DEFINITION).** $u \in [0, 1]$ measures non-parallelism, with $u = 0$ meaning parallel and $u = 1$ meaning fully non-parallel. *Check:* D1.
- **P2 (DEFINITION, and a modelling choice).** $N_{\text{eff}} = 1 + (N - 1)u$: the effective count is **affine** in u. *Check:* D2. **Note: this is the paper's largest unearned assumption. It is a design axiom, it is not a Hill number, and no external literature contains it (Section 5.2).**
- **P3 (DEFINITION).** The surplus depends only on the angles between viewpoints (S1), is zero at parallel (S2), and is normalised (S4).
- **P4 (ARITHMETIC).** Given P2 and P3, $f(u) = \ln N_{\text{eff}}$ is the unique admissible form. *Check:* the uniqueness argument, which is a member of the established uniqueness-under-axioms genre [Aczél et al., 1974].
- **P5 (ARITHMETIC).** $\ln 1 = 0$. *Check:* redo it.
- **P6 (ARITHMETIC).** ln is strictly concave, so $\ln k - \ln(k-1)$ is strictly decreasing in k. *Check:* redo it.
- **P7 (CITED: `cover2006elements`).** A bound on an information quantity and the quantity itself are different objects, and a bound may not be substituted for a measurement.
- **P8 (POSTULATED).** The felt return on a held comfort decays toward zero over weeks while its carrying cost does not decay. *Check:* **not checkable from outside the framework and not checked. This is the substantive content of H2 and it is asserted.** Its perceptual half has partial support [Helson, 1948, Brickman et al., 1978]; its cost half has none.
- **P9 (POSTULATED).** A repeated route through a setting is generated by a comfort differential rather than by any other stable feature of the walker or the terrain. *Check:* **not checked.** The erasure test rules out the recording medium and nothing else (Section 4.3).
- **P10 (CITED: `strogatz2015nonlinear`).** Gradient descent converges to a local, not a global, minimum of the surface it is run on.
- **P11 (POSTULATED).** A person's day relaxes through a comfort landscape as a physical system relaxes through its states. *Check:* not checkable; this is the framework's relaxation postulate and is badged wherever it appears.

Postulates dropped as unnecessary: the path-integral account of Section 4.2 was tested for load and carries none — every result below survives its removal — and so did the three uncited pricing biases of Section 3.4, whose conclusion is re-derived from P8 alone. Both are reported in the text and neither is used.

9.2 The compounding chain

Each line consumes only the outputs named on its left.

P1 + P2	-> L1	N_eff = 1 + (N−1)u is defined	DEFINITION
L1 + P3 + P4	-> R1	f(u) = ln(1 + (N−1)u)	DEFINITION (via P2)
R1 + P5	-> R3	f(u) = 0 exactly at u = 0	ARITHMETIC
R1 + P6	-> H5	the k−th view adds ln k − ln(k−1), which is decreasing in k	ARITHMETIC
R1 + P7	-> R2	f is a LOWER BOUND, not the information	CITED
P8	-> R4	felt return decays, carrying cost does not; the gap widens	POSTULATED
R4	-> L2	a held arrangement's costs are underquoted relative to an alternative's	ARITHMETIC
P9	-> R5	the worn path is the observable	POSTULATED
(mechanics)	-> R6	stationarity is equivalent to the local law; no teleology	CITED (no entry in this file)
P10	-> R7	descent reaches the nearest low place, not the best	CITED
R7 + P11	-> C1	a person can be stably trapped at a locally optimal arrangement	POSTULATED (via P11)

What this chain shows, stated plainly. Of the seven results, exactly three — R3, R2 and R7 — rest on ARITHMETIC or CITED steps alone once R1 is granted. R1 itself passes through P2, the affine axiom, and is therefore DEFINITION at its load-bearing step: **R1 is not a discovery about viewpoints; it is what follows from choosing an affine effective count.** R4 and R5 are POSTULATED. R6 is a genuine theorem that this bibliography cannot cite. C1 — the conclusion the framework is built toward — passes through P11, which is not checkable and was not checked.

A chain whose steps are mostly DEFINITION and POSTULATED is not a proof, and this one is mostly DEFINITION and POSTULATED. What it is instead is a specification of exactly which three premises would have to be established for the framework's conclusions to follow: P2 (that the effective count is affine rather than some other interpolation), P8 (the decay asymmetry), and P9 (that a worn path is generated by a comfort differential). That is the whole bill, and it is smaller and more addressable than the framework's rhetoric suggests.

9.3 The checks a reader should run first

1. **Redo** $\ln 1 = 0$ and confirm that R3 is arithmetic and not rhetoric. It is the clause the corpus's concentration instruments actually run on.
2. **Redo the concentration arithmetic.** $0.409^2 + 0.273^2 + 0.182^2 + 0.136^2 = 0.293430$, and $1/0.293430 = 3.40797$. The corpus prints 0.293430 and 3.41 [Curzi, 2026]. It agrees.
3. **Redo the affine count.** $1 + 99 \times 0.05 = 5.95$, and $\ln 5.95 = 1.783391$. The corpus prints 5.95 [Curzi, 2026c]. Figure 1 marks the point.
4. **Redo the break-even of Section 5.4.** $1 + 39u = 3$ gives $u = 2/39 = 0.051282$, and $\ln(1 + 39 \times 0.05) = \ln 2.95 = 1.081805 < \ln 3 = 1.098612$. Figure 2 states both.
5. **Redo the headroom percentages.** $\ln(1 + 17 \times 0.25)/\ln 18 = 0.573708$ and $\ln(1 + 17 \times 0.45)/\ln 18 = 0.746464$, printed as 57.37 and 74.65 per cent [Curzi, 2026]. They agree; the accompanying equilibrium at $u = 0.45$ does not (Section 7.5).
6. **Check that** $k = 0.483425732988414$ **is labelled defined at every occurrence**, and that no sentence in this paper attaches hertz to it on this paper's own authority. There is one occurrence, in Section 6.1, and it carries both cautions.

7. **Check that R1 and R3 are never described as measured**, in this paper or in any paper citing them. They are modelling positions; Section 6.3 says so and the Conclusion repeats it.

9.4 Dimensional audit

Every symbol used above, with its dimension, its unit, and its epistemic status. The audit is short because few of these quantities have units at all, and the table says so rather than inventing any.

Symbol	Meaning	Dimension	Unit	Status
N	number of viewpoints	dimensionless	count	defined; an integer
u	non-parallelism	dimensionless	none	defined on $[0, 1]$; two operationalisations exist, both stipulated
N_{eff}	effective count	dimensionless	count	**defined, affine, not a Hill number**; not measured anywhere
$f(u)$	surplus	dimensionless	nats	derived from N_{eff}; a bound, not a measurement
$\ln N$	surplus ceiling	dimensionless	nats	derived; $f \leq \ln N$ with equality at $u = 1$
coin cost	monetary carrying cost	currency	currency units	measurable in principle; has a natural unit
hours cost	appointed time	time	hours	measurable in principle; has a natural unit
attention cost	standing awareness charge	none assigned	**no operational unit exists**	defined (D3); **not measurable by any instrument the framework supplies**
foreclosure cost	options closed by holding	none assigned	**no operational unit exists**	defined (D3); not measurable
U	potential (quoted)	energy	J	quoted from physics; not a quantity of this framework
F	force (quoted)	energy per length	N	quoted from physics; not a quantity of this framework
S, L	action, Lagrangian (quoted)	energy $\times$ time; energy	J·s; J	quoted from physics; not quantities of this framework

Symbol	Meaning	Dimension	Unit	Status
τ	felt-return time constant (Fig. 3)	time	weeks	**chosen, not measured; the source supplies none**
k	reference constant (quoted)	see note	quoted as Hz	**defined exactly as $(9/8)^2/\varphi^2$; the hertz is a separate claim**

Does the central relation balance? $f(u) = \ln(1 + (N-1)u)$ balances only if the argument of the logarithm is dimensionless, and it is: N is a count and u is a dimensionless number on $[0, 1]$, so N_{eff} is a pure number and f is in nats. **That is the one equation in this paper whose dimensions are unambiguous**, and it is unambiguous because both of its inputs were defined to be dimensionless rather than measured.

Does the ledger balance? No, and the source is silent on why. The four-currency carrying cost is presented as one accounting of a holding, but coin has a currency unit, hours has a time unit, and attention and foreclosure have none. A sum across the four is not a sum of commensurable quantities and cannot be formed. The framework does not in fact form one — it writes four lines and never adds them — but it also never says that they cannot be added, and any downstream reader who totals them is doing something the dimensions forbid. **This paper says it.**

A quantity with no operational unit is entered as having none. No unit was invented for attention or for foreclosure, and none should be inferred from the fact that the surplus functional balances.

9.5 Limits, boundary behaviour, and the one invariance

Each relation above, at the boundaries of its parameters.

- $u \to 0$**.** $N_{\text{eff}} \to 1$ and $f \to 0$ for every N. This is R3 and it is exact, not asymptotic: at $u = 0$ the surplus is zero and not small. A group of any size at $u = 0$ is one member.
- $u \to 1$**.** $N_{\text{eff}} \to N$ and $f \to \ln N$, the ceiling. The corpus's headroom instruments report realised surplus against exactly this ceiling [Curzi, 2026].
- $N = 1$**.** $N_{\text{eff}} = 1$ for every u, and $f = 0$. The functional is well behaved and says the obvious thing: a single viewpoint has no surplus over itself regardless of what u is set to. Note that u is undefined at $N = 1$, since there is no angle to measure; the formula's insensitivity to it at $N = 1$ is what makes that harmless.
- $N \to \infty$ **at fixed** $u > 0$**.** $f \to \infty$ logarithmically and without bound. **This is a constraint on the model's domain and is stated as one.** Nothing in the framework bounds the surplus of an arbitrarily large panel, and the empirical literature says the curve turns over rather than continuing to rise [Uzzi and Spiro, 2005]. The domain should be restricted to the range over which a cost term is also modelled; the corpus does this in its engineering papers by pairing f with an explicit cost [Curzi, 2026g,?] and does not do it here.
- $N \to \infty$ **at fixed** N_{eff}**.** Requires $u \to 0$ as $1/N$: an unbounded panel of near-duplicates. The functional handles this correctly and it is the regime the corpus's bloc collapse is designed to detect [Curzi, 2026,?].
- **Carrying cost** $\to 0$ **in all four currencies.** The framework's ruling is that this never occurs and that a written zero is a failure of the second look. **That is not a boundary condition; it is an unfalsifiable rule**, and it is restated in Section 10.4 as such.
- **Felt return with no decay.** R4 becomes vacuous, and the framework's account of an accumulated depletion has no mechanism. H2 is therefore the hypothesis whose failure would remove the ledger's entire analytical content, which is why it is stated first among the falsifiable ones.

- **Barrier height $\to 0$ around a local minimum (Section 4.5).** The basin ceases to be a basin and R7 is vacuous. **Barrier height $\to \infty$.** The trap is total and descent cannot leave it; the framework's only remaining exit is a change in what can be seen, which is untested.

On invariance. The framework claims no scale-freedom and this paper claims none for it. The one invariance exhibited is that f is unchanged under any relabelling of the viewpoints and under any transformation preserving the pairwise angles; it is a consequence of S1 rather than a finding, and it has been checked at no scale because nothing here is measured. **No conserved quantity is exhibited anywhere in this paper**, which is the specific answer this corpus owes to the charge that it has borrowed the grammar of a conserved quantity without the conservation law [Mirowski, 1989].

2.0.10 10. Limitations

Each item names what would falsify the claim, or what the paper cannot support.

10.1 The affine effective count is this corpus's own construction and has no external precedent. This is the paper's principal exposure and it is stated first. $1 + (N-1)u$ is a linear interpolation between 1 and N. It is not a Hill number of any order, and no literature in ecology, economics, political science or information theory contains it (Section 5.2). Where this paper cites the Hill-number literature it does so only for $1/\text{HHI}$ and $\exp(H)$ [Hill, 1973, Jost, 2006]. **Falsified by:** a demonstration that some other interpolation — geometric, or a Hill number of some order — fits an outcome better at equal parameter count. Nothing here rules one out.

10.2 The functional's form is underdetermined. A power law with exponent below one [Latané, 1981] and an $n \log n$ form [Briscoe et al., 2006] fit the same qualitative facts. **Nothing in this paper discriminates between them**, and the paper has no differential prediction of the kind a reviewer will ask for [Durlauf, 2005]. The strongest available warrant for a logarithm is dynamical rather than psychophysical [Peters and Gell-Mann, 2016], and it applies only where the underlying process is multiplicative, which has not been established for any quantity in this paper.

10.3 Claims with no supporting literature in this corpus's bibliography. Listed individually, because a reviewer will find them and finding them first is the point.

- *Losses weigh roughly twice equal gains; a held object is overvalued by the holding; a paid cost recruits fresh costs in its defence.* Load-bearing for Section 3.4 and for failure modes CC-F1 and CC-F2. **`bib/external.bib` contains no entry for loss aversion, for the endowment effect, or for sunk-cost escalation.** Retained **uncited**; the conclusion that depends on them is re-derived from R4 alone (Section 9.2).
- *Pressure on a perceived freedom produces counter-movement (reactance).* Load-bearing for failure mode CC-G3 — the fence the feet ignore. **No entry.** Retained uncited, as it is in the other papers of this series.
- *Cues placed in the path of a behaviour govern it more reliably than resolutions about it; if-then plans tied to concrete cues outperform bare intentions; defaults govern outcomes.* The entire warrant for the four grading tools of Section 4.4. **No entry for choice architecture, default effects, implementation intentions or habit formation.** Reported as the framework's and uncited.
- *A held comfort draws on attentional capacity while untouched.* The attention currency of Section 3.1. Miller [1956] and Ashby [1956] establish that capacity is bounded; **neither establishes that an unattended holding consumes it.** The stronger claim is uncited.
- *The Euler–Lagrange equivalence of the variational and local formulations.* R6. **This bibliography contains no classical-mechanics text.** The result is standard and is stated here without a citation rather than with a wrong one.
- *The path-integral account of stationarity.* **No entry.** Reported once, used for nothing, and excluded from the verification chain.
- *That deliberately retained discomfort raises the felt value of a comfort* (the contrast yield, Section 3.2). The adaptation literature supports a moving reference level [Hel-

son, 1948, Brickman et al., 1978]; **it does not support the intervention claim**, which is uncited.

10.4 One of the framework's own rules is unfalsifiable and is marked. The inventory's ruling that a written "nothing" in a cost currency indicates a failure of the second look rather than an absence of cost cannot be wrong: any counter-example is absorbed as insufficient looking. It is retained here because it is a *procedural* instruction rather than an empirical claim, and it is relabelled as one. As an empirical claim — that every holding charges in every currency — it is not stated and should not be.

10.5 Parameters chosen rather than measured. The two time constants in Figure 3 ($\tau = 4$ and $\tau = 12$ weeks) were chosen; the source supplies none, and the pair is plotted precisely so that no single choice is mistaken for an estimate. The values $N \in \{3, 10, 40, 100\}$ in Figure 1 were chosen to span the framework's own worked range. Figures 1, 2 and 3 contain no measured quantity of any kind. Figure 4 is a schematic. Only Figure 5 reports features from a record, and that record is a single self-reported case.

10.6 Scale type is stipulated, not demonstrated, and the four-currency total does not add. Section 6.2 gives the full statement. The strongest objection to the framework is that psychology assumes quantitative structure without testing for it [Michell, 1997]; the test exists [Luce and Tukey, 1964, Krantz et al., 1971] and **was not applied**. Two of the four carrying-cost currencies have no operational unit, so the ledger's four lines are not summable (Section 9.4). **Falsified by:** a conjoint-measurement study on any operationalisation of carrying cost that fails double cancellation, which would remove the arithmetic of Section 3 entirely.

10.7 u has not declared which construct of difference it is. Three incompatible constructs are called diversity — separation, variety, disparity — and any measure must say which [Harrison and Klein, 2007]. On the corpus's own operationalisations u is a separation measure on a squared alignment, with the consequence that perfect opposition and perfect agreement are indistinguishable [Curzi, 2026r]. That is a real limitation on what R1 can be used to say about a group that disagrees.

10.8 The surplus is stated monotonically and the evidence is two-sided. Section 8.2 gives both sides. A monotone claim cannot survive Uzzi and Spiro [2005], Putnam [2007], May [1972] and Doak et al. [1998] unqualified.

10.9 Nothing here is identified. As an aggregate specification, any claim that a group's u produces its output is not identified from observational data [Manski, 1993], and the network route is closed by the generic confounding of influence with selection [Shalizi and Thomas, 2011]. This paper adopts no remedy and therefore states R1 and R3 as **modelling positions rather than identified empirical results** (Section 6.3). **Resolved by:** a randomised or partial-population design, or a defended stipulation of the reference group in the manner of Brock and Durlauf [2001].

10.10 The framework's own parameters are not exempt from its own thesis. By the Lucas critique, a u estimated in a population that has not read the framework cannot be assumed stable in one that has [Lucas, 1976]. No stability is claimed and no result here depends on any; the cost is that no cross-population comparison of u is currently interpretable.

10.11 The erasure test identifies a negative, not a positive. R5's argument establishes that a reproduced pattern is not stored in its recording medium. It does not establish that the generator is a comfort gradient rather than a schedule, an obligation, or a physical constraint. **This is the difference between ruling out one explanation and establishing another**, and the framework's presentation does not mark it.

10.12 One cited corpus figure could not be reproduced. Section 7.5 records that the equilibrium quoted for the headroom instrument's collective case at $u = 0.45$ does not follow from the parameters as quoted. The disagreement is printed rather than harmonised, and no claim in this paper depends on the figure.

10.13 The instrument corrupts what it measures. A quantitative indicator adopted for one's own decision-making distorts the process it monitors [Campbell, 1979, Goodhart, 1975]. The ledger and the effective count are both such indicators, and the exposure is structural.

10.14 No hypothesis was tested and no data were collected. H1–H5 stand. The discipline that would make a later confirmatory attempt credible is specified and not exercised [Nosek et al., 2018], and the analytic flexibility available in any such attempt should be constrained in advance. The corpus's own control measured anti-conservative at 0.108 against a nominal 0.05 [Curzi, 2026u], which is the prior any such test should be read against.

2.0.11 11. Conclusion

The seven results are stated below in the exact form in which the rest of the corpus cites them. Downstream papers should quote this text rather than paraphrase it.

R1. The surplus of N viewpoints over one is $f(u) = \ln(1+(N-1)u)$, uniquely determined by four requirements — dependence on the angles alone, zero surplus at parallelism, an effective count affine in u, and normalisation — with $N_{\text{eff}} = 1 + (N-1)u$ read as an effective number of viewpoints. **The uniqueness is conditional on the affine axiom, which is a design choice and not a theorem, and N_{eff} is not a Hill number of any order.** R1 is a modelling position, not an identified empirical result [Manski, 1993].

R2. The functional is a **lower bound on the ensemble's information, not the information itself**: it logs the floor and not the ceiling. It may be used to establish that a structure has at least a given surplus; it may not be substituted for a measurement of what the structure actually carries.

R3. Zero at parallelism is the binding clause. A second opinion drawn from a source that shares training, incentives and premises with the first is worth $\ln 1 = 0$ of surplus. Agreement between aligned instruments is echo and not evidence. The same result, with the mathematics attached, is that diversification benefit depends on covariance and not on count [Markowitz, 1952].

R4. Carrying cost is itemised in four currencies — coin, hours, attention, foreclosure — against the law that felt comfort decays toward zero over weeks while carrying cost does not decay at all, so that a depleted arrangement can assemble itself without any single bad decision. **Two of the four currencies have no operational unit and the four do not sum.**

R5. The worn path is the theory's observable: a desire line is the integral of many small descents, and its reproduction after the erasure of the recording medium is evidence that the pattern lies in the field of forces rather than in the record. **The erasure test rules out the medium; it does not identify the generator.**

R6. The variational form of a mechanical law is equivalent to the local differential law, so the principle licenses no teleology: the path obeys its ground instant by instant, and no measurement on a trajectory distinguishes a chosen path from an obeyed one.

R7. The honest limit of descent: a gradient finds the nearest low place and not the best one, so the analysis can diagnose a stable trap and cannot treat one. Only a change in what can be seen resolves it, and that claim is untested.

Counter-result. The surplus is bounded twice over — it is only a lower bound on the ensemble's information, and its logarithmic concavity means a few well-separated viewpoints capture most of what a large panel could, so the framework argues explicitly against accumulating perspectives. **The source's own statement of that second bound is corrected here:** three fully non-parallel viewpoints capture 29.8 per cent of what forty capture at $u = 1$, and exceed forty viewpoints only below $u^* = 2/39 = 0.051282$. The gradient material then concedes that descent can diagnose a stable trap but cannot treat one, and the ledger material concedes that the three pricing asymmetries it leans on have no supporting entry anywhere in this corpus's bibliography.

What is established, then, is one functional that follows exactly from four stated requirements, two limits on that functional that the framework prints as loudly as the functional itself, one observable with a valid negative authentication, and one theorem of mechanics this bibliography cannot cite. What is not established is any of the five hypotheses, the affine axiom that R1 depends on, or the decay asymmetry the ledger is built around. The paper's

contribution at this stage is that it names the three premises whose settlement would decide the matter — that the effective count is affine, that felt return decays while cost does not, and that a worn path is generated by a comfort differential — and that it declines to claim any of them.

2.0.12 12. Declarations

Data and code availability. No external dataset was collected for this paper and none exists. The worked case reported in Section 5.7 is drawn from the source manuscript's own record and is not a dataset. All figures are generated by the scripts named in their captions (`figs/src/CCP-A02_fig01.py` through `figs/src/CCP-A02_fig05.py`), which import the shared style module `lib/figstyle.py`; every number plotted is either computed within the script from a formula stated in this paper or quoted from the source text identified in the script's docstring. Three of the five scripts contain assertions that fail if the numbers they plot cease to agree with the source claims they are drawn from.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures, and the text.

Ethics. No human-subjects research was conducted for this paper. No personal data were collected or processed. The worked case in Section 5.7 is drawn from the source manuscript, is presented under the pseudonym it carries there, and is illustrative rather than evidential; it was not gathered under a research protocol and is not offered as one. Nothing in this paper is clinical advice.

Use of the ceremonial register. The source manuscript is in part an initiatory document. This paper analyses that register as an object of study and does not reproduce it; ceremonial names are reported only where they identify a construct this paper renames.

Chapter 3

Weighting Futures by Resistance: The Comfort-Weighted Amplitude, Cue Placement, and the Resolution-Disturbance Trade-Off

Abstract. This instalment sets out a scoring procedure for candidate futures, an account of environmental cue placement, and the trade-off law governing how finely a foreseen outcome should be specified. Branches traced forward are scored step by step for steepness on a four-point scale; the accumulated resistance R weights the branch as 1 / 2^R, so two branches differing by three points of honest steepness differ by a factor of eight. The pedigree is stated plainly as exponential, Boltzmann-style discounting of states by cost, and explicitly not as a phase-based path amplitude. A robustness test follows: break one middle step and halve the weight again if the branch cannot reroute, on the argument that plans are systematically imagined as their own best case. Futures adjacent to present arrangements are held to consolidate first, by default rather than by choice, and three classes of settled future are distinguished. The cue-placement node is fenced by a licence clause before any technique is given: arrangement of one's own path, or of the path of someone who has asked, is legitimate, and arrangement of another's path is refused. The framework holds that the refusal is self-enforcing, counter-movement rising with the detected push; that mechanism has no supporting entry in this corpus's bibliography and is reported uncited, and the ethical argument is shown to stand without it. Three placement laws follow, with friction priced in seconds. Finally the resolution-disturbance law: a finely fixed outcome buys precision by cluttering the path and inviting optimisation of the indicators rather than the outcome, while an infinitely coarse one exerts no gradient at all. The framework's single postulate is restated and badged, and the scoring rule's arithmetic is demoted to an ordering on scale-type grounds.

Keywords: resistance weighting; exponential discounting; planning fallacy; implementation intention; cue placement; reactance; resolution trade-off; default consolidation

Series: A. Foundations **Paper:** CCP-A03

3.0.1 1. Introduction

1.1 The question

A framework that treats a life as a landscape of costs owes three further things before it can be operated. It must say how a candidate future is *scored*, since a landscape without a scoring rule ranks nothing. It must say what may legitimately be done to a person's environment once the scoring is in hand, since a scoring rule that licenses arrangement licenses arrangement of other people too. And it must say how finely a foreseen outcome should be specified, since the act of specifying is itself an act performed on the path.

This paper supplies all three and prices each. The scoring rule assigns each step of a candidate branch an integer resistance from 0 to 3, sums it to a branch total R, and weights the branch as 2^{-R}. The environmental rule is fenced by a licence clause before any technique is given: arrangement of one's own path, or of the path of a person who has asked, is legitimate; arrangement of another's path is not, and the framework's claim is that it fails mechanically as well as ethically. The specification rule is a trade-off: a finely fixed outcome buys precision by cluttering the path and by inviting the optimisation of indicators rather than of outcomes, while an infinitely coarse one exerts no gradient at all.

Thirty corpus papers cite the results established here. Because those results are load-bearing elsewhere, this paper states them in a form intended to be quoted rather than paraphrased.

It also reports four things that go against the framework, at the same precision it reports its results. The scoring rule sums an ordinal judgement and then exponentiates it, which the corpus's own scale-type discipline forbids. The framework's exponential weight is one of a family of forms and nothing here discriminates it from the others. Five of the seven empirical mechanisms the framework leans on have no supporting entry anywhere in this corpus's bibliography. And the source's own worked example prints a weight ratio of "roughly a thousand" for two branches whose stated resistances differ by twenty points, where the framework's own rule gives $2^{20} = 1{,}048{,}576$ — a discrepancy of three orders of magnitude, printed here rather than corrected in silence.

1.2 What this paper contributes

Seven results are established or fixed here, labelled R1 through R7 and restated verbatim in the Conclusion.

R1 states the comfort-weighted amplitude: score each step of a branch 0 to 3 for steepness, sum to a resistance R, and weight the branch as 2^{-R}, so that a three-point difference in steepness is a factor of eight in expectation. **R2** states the pedigree honestly as exponential, Boltzmann-style weighting of states by cost, e^{-R} up to a change of base, and explicitly **not** as a phase-based path amplitude. **R3** states the neighbour test: break one middle step of a branch and halve its weight again if it cannot reroute, penalising plans that require every step to succeed. **R4** states the freezing law: futures adjacent to present arrangements consolidate first, by adjacency and default rather than by choice, with chosen, geographic and unsettled-underneath cases distinguished. **R5** states the licence clause that precedes all cue technique: arrangement is legitimate only on one's own path or on the path of a person who asked, because detected steering is claimed to produce counter-movement proportional to the discovered push. **R6** states three placement laws — site the cue on an already-walked path, represent the first step and never the summit, and re-site the cue once it has stopped being noticed — with friction priced in seconds of added or removed effort. **R7** states the resolution–disturbance law: fine specification buys precision at the cost of path disturbance, indicator-optimisation and the foreclosure of unlisted routes, while infinite coarseness exerts no gradient at all.

A counter-result is stated with equal weight. The uncertainty material declines the inflated reading of its own borrowed physics: the framework's postulate is stated as a postulate rather

than as a consequence, the physical relation is given only in its correct state-preparation form, and a named failure mode requires that a practitioner be able to distinguish the theorem, the ordinary observer effect and the framework's own conjecture in three separate sentences on demand.

1.3 Register, sources, and the chunk boundaries

The source manuscript is written in two registers, a narrative one and an analytic one, deliberately braided. This paper reports the analytic register. The narrative material is a fictional exposition and carries no analytical claim the treatise does not also carry; it is not reproduced. Where the source's ceremonial vocabulary names a construct — *the count of the undecided water*, *the veil that measures the measurer*, *the trapline* — the construct is renamed to what it is, and the ceremonial name is reported once, as an object of study.

The source volume was re-split after a de-framing correction, and the boundaries of the file assigned to this paper do not coincide with the source's own divisions. Two consequences are marked here rather than papered over. **At the opening**, the file begins with the failure catalogue and closing material of the preceding construct — the horizon procedure, whose arithmetic is stated in the preceding instalment of this series — and that catalogue is reported in Section 3, because it is substantive and because leaving it out would lose a failure mode the corpus elsewhere relies on. **At the close**, the file ends immediately after the uncertainty construct's ceremonial statement, so the procedure and failure catalogue belonging to that construct fall in the file assigned to the next paper in this series and are not reported here. Section 7 therefore states the trade-off law and its riders without its operating protocol, and says so at the point where the protocol would have appeared.

3.0.2 2. Hypothesis

The material below divides into claims that could be wrong, definitions that could not, and one postulate that the source itself labels as such. A hypothesis that nothing could falsify is restated as a definition or a postulate and labelled as such [Popper, 1959].

H1 — the resistance-weighting hypothesis. The relative likelihood that a person completes one candidate course of action rather than another is governed by the accumulated steepness of the individual steps, and falls by half for each point of accumulated steepness. *Predicted:* across a set of dated, scored branches, completion rates fall geometrically in R with a halving constant near one point, and do not track the attractiveness of the endpoint. *Falsified by:* completion tracking endpoint attractiveness at equal R, or falling in R at a rate materially different from one halving per point. *Status:* testable in principle; **not tested here.** The halving constant is a stipulation and no one has estimated it (Section 12.5).

H2 — the robustness hypothesis. A branch that cannot survive the failure of one middle step is materially less likely to complete than a branch of equal R that can reroute. *Predicted:* among branches matched on R, those that survive a simulated single-step failure complete more often. *Falsified by:* completion independent of single-step robustness at matched R. *Status:* testable; **not tested here.** The specific penalty — one further halving — is a stipulation, not an estimate.

H3 — the adjacency hypothesis (the freezing law). Futures requiring the smallest change from present arrangements consolidate first, by default rather than by choice, so that most of a person's medium-term future is settled before it is considered. *Predicted:* the fraction of a person's future commitments that were never explicitly chosen rises with the passage of time under stable circumstances. *Falsified by:* commitments arising at rates independent of their distance from present arrangements. *Status:* **not tested here**, and the mechanism the source names for it — default effects and habit consolidation — has no supporting entry in this corpus's bibliography (Section 12.3).

H4 — the placement hypothesis. A physical cue sited on an already-walked path, at reaching height, representing only the first step, raises the completion rate of the step it represents,

and the effect decays as the cue becomes familiar and is restored by re-siting it. *Predicted:* completion rises after placement, decays over weeks, and recovers on re-siting without any change to the cue itself. *Falsified by:* no decay, or no recovery on re-siting. *Status:* testable and cheap to test; **not tested here.** The framework's supporting literature — implementation intentions, cue-driven habit, friction measured in seconds — has **no entry** in this corpus's bibliography, and the claim is therefore reported uncited (Section 12.3).

H5 — the resolution–disturbance hypothesis (the paper's sharpest claim, and its weakest support). For a future coupled to its own foreseeing, the fineness with which the outcome is specified and the disturbance imposed on the path cannot both be made small: their product is bounded below. *Predicted:* across matched undertakings, those specified more finely show more measured effort spent on checking and on indicator maintenance, and a lower rate of arrival by routes not listed in advance. *Falsified by:* finely specified undertakings showing no more checking and no fewer unlisted routes than coarsely specified ones. *Status:* **not tested, and not currently testable as stated**, because neither the resolution of a specification nor the disturbance of a path has been operationalised, and because the source states plainly that the bound's constant has never been measured by anyone.

D1 — resistance (definition). The resistance of a step is an integer in $\{0, 1, 2, 3\}$: 0 for a step that would be taken while unwell, 1 for one that ordinary resolve suffices for, 2 for one that requires a good day, 3 for one that requires a better self than usually answers. The resistance of a branch is the sum over its steps. This is a stipulated rating scale. Its measurement-theoretic status is audited in Section 8.2 and it does not survive that audit intact.

D2 — the licence clause (definition, and a constraint). Cue placement is performed only on the practitioner's own path, or on the path of a person who has asked. This is a stipulated constraint on the method's domain, not an empirical claim, and it is stated before any technique in the source and before any technique here.

P1 — the Postulate. The uncertainty of a future that is affected by its own foreseeing is postulated to be the same *kind* of uncertainty as that of a quantum state: not merely an ignorance in the observer but a participation of the observing in the observed, with the trade-off structure carrying over in *shape*. Nothing in physics licenses this. The source states it as a postulate and this paper preserves the badge at every occurrence.

3.0.3 3. Material carried across the opening boundary

The file assigned to this paper opens with the failure catalogue of the preceding construct. It is reported here because it is substantive, because one of its five entries is the sharpest statement in the whole volume of a result the corpus relies on elsewhere, and because a procedure supplied without its failure catalogue is an advertisement. The source's labels are renamed with a `CC-` prefix to keep them clear of this paper's own results.

CC-W1. The smeared pane. *Named mechanism: anchoring and scenario contamination.* The analyst switches assumptions mid-trace, importing a rescue from one branch into another, and produces a composite assembled from parts that cannot coexist, each purchased under an assumption the others deny. The source's warning is that the product reads as *richer* than an honest trace, which is precisely what makes it dangerous.

CC-W2. One assumption repeated. *Named mechanism: pseudo-diversity; the illusion of independent confirmation.* Three assumptions are cut from one premise — three costumes on one position — and their agreement is read as convergence. **The source prices this exactly, and the pricing is the reason this entry is reproduced:** non-parallelism $u = 0$, effective count $N_{\text{eff}} = 1$, surplus $\ln 1 = 0$. Three parallel viewpoints are one viewpoint. The collision test — the requirement that each new assumption contradict an existing one somewhere in its consequences — exists for this fault alone.

CC-W3. Vividness mistaken for probability. One branch is rendered in detail and the others in outline, and the branches are then weighed by brightness of rendering rather than by honesty of steps. The remedy the source prescribes is procedural evenhandedness: the same number of steps and the same number of sensory particulars for every branch.

CC-W4. The unbuilt branch. The refused branch is never traced at all, and the audit proceeds over a set curated to be survivable. The cost is not a missing future but a corrupted convergence: an invariant certified across only the bearable branches is an invariant of the analyst's tolerance rather than of their situation.

CC-W5. The straight line drawn on a curved surface. *Named mechanism: linear extrapolation past the regime in which the trend holds.* The present's visible motion is extended in a straight line and the drawing is called a trace. No step consulted the step before it.

Two of these five have an external literature this corpus can cite and three do not. CC-W2's arithmetic is the corpus's own and is fixed in the preceding instalment of this series. CC-W5 is the standard warning against fitting a trend outside the regime that produced it, and the general form of the warning — that a curve's shape is weak evidence for the mechanism that produced it — is established [Stumpf and Porter, 2012]. CC-W1, CC-W3 and CC-W4 name mechanisms (anchoring, availability, motivated reasoning) for which **this corpus's external bibliography contains no entry**, and they are reported uncited.

3.0.4 4. The comfort-weighted amplitude

4.1 What is borrowed, and what is not

The source opens this material with an unusually careful statement of what it is borrowing, and the care is worth preserving because the borrowing is where a framework of this kind usually fails.

The physical account it quotes is the quantum-mechanical one: the state of a system is a wavefunction assigning to each configuration an *amplitude*, a complex number with a size and a phase; the probability of finding the system in a configuration is the square of the amplitude's size; amplitudes can cancel, so two nonzero routes to the same outcome can sum to zero, which is interference and is measured routinely; between measurements the state evolves smoothly and deterministically; and what happens at measurement remains an open question on which the mathematics does not adjudicate. The source states the last point explicitly and takes no side, which is the correct posture and is preserved here. **This corpus's external bibliography contains no entry for the Born rule and none for the postulates of quantum mechanics as such**; the one entry bearing on the measurement question is the decoherence programme's founding statement [Zeh, 1970], and the remainder of the physical account in this subsection is therefore reported as the source states it and is **uncited** (Section 12.3).

What the framework then borrows is stated by the source as three things and no more, and this paper endorses the enumeration:

1. **Weighted coexistence until resolution.** A future, before commitment, is handled as many coexisting branches each carrying a weight, rather than as one hidden fact. This is not a physical claim; it is how any forecaster holds a future.
2. **Weights attach to paths, not endpoints.** What a route contributes is set by the whole of the route and not by the attractiveness of its destination.
3. **The outcome that occurs is the one its own small variations agree with.** In the physical account the classical path survives because neighbouring routes have nearly the same action and reinforce, while elsewhere they cancel. The framework's transfer is that the future that arrives is the one that still arrives when the plan goes slightly wrong.

The source explicitly refuses the fourth borrowing that would be available and attractive — that the future is *literally* a superposition — and states the refusal in its own text. That refusal is R2's content and is treated in Section 4.3.

4.2 The scoring rule and the weight (R1)

The procedure is stated operationally because later papers refer to its outputs.

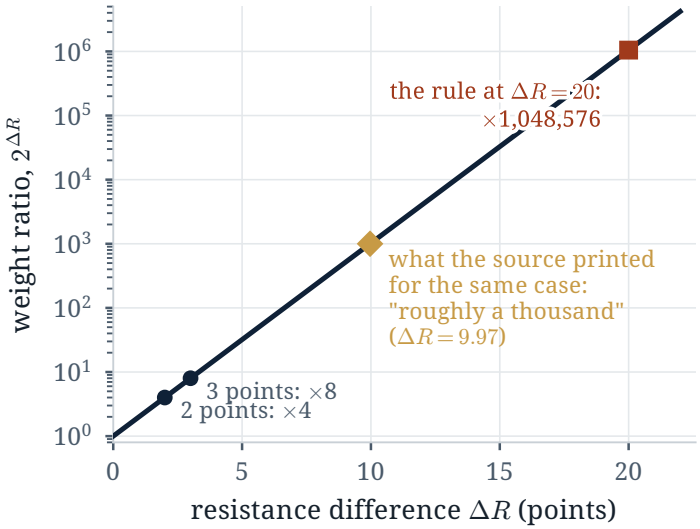

Figure 3.1: **The rule, and a printed error in it.** Arithmetic on the source's own statement that a branch's weight "falls by half for every point of resistance it carries above the easiest branch's total". The two annotated small cases are the source's own. The two markers at the right are the same worked case read two ways: the source records branch resistances of 29 and 9, so its own rule gives a weight ratio of $2^{20} = 1{,}048{,}576$, while the text prints the ratio as "roughly a thousand", which corresponds to $\Delta R = 9.97$. Script: `figs/src/CCP-A03_fig01.py`.

Take the candidate branches. Walk each forward in steps — twelve is the protocol's number, months or moves as the branch divides. At each step ask one question and only one: *how steep is this single step for the person who actually shows up on a tired morning?* Score it on the four-point scale of D1. Sum the scores along the branch: that is R, the branch's resistance. Take the smallest R among the branches as the reference and subtract it from each, so that the easiest branch sits at $\Delta R = 0$. Then

$$w(\Delta R) \;=\; 2^{-\Delta R}$$

so that a branch three points steeper than the easiest carries one eighth the weight. This is R1. The source's own instances are two: a three-point difference is a factor of eight, and the two-point difference between an exercise machine at home and one across town is a factor of four — which the source offers as the mechanism behind the annual emptying of gymnasiums.

Two features of the rule are worth stating plainly because they are what make it a rule rather than a sentiment. It is **path-summed**: the endpoint contributes nothing, and the protocol requires the endpoint to be physically covered during the scoring. And it is **anchored at the minimum**, so it produces relative weights only. It cannot be read as a probability of any branch in isolation, and Section 8.2 states why it cannot be read as a probability at all.

4.3 The pedigree, stated honestly (R2)

R2 is a disclaimer that the source states as doctrine, and it is the most creditable sentence in this material.

The weight 2^{-R} is **exponential discounting of states by their cost**. Its nearest relative is the Boltzmann–Gibbs weighting of a state by $e^{-\beta E}$, which is exactly the distribution that maximises entropy subject to a mean-cost constraint [Jaynes, 1957, 2003]. Written that way, $2^{-R} = e^{-R \ln 2}$, so the framework's halving-per-point is the exponential form with $\beta = \ln 2$ in units of resistance points. **It is not Feynman's phase.** A path amplitude carries a phase and

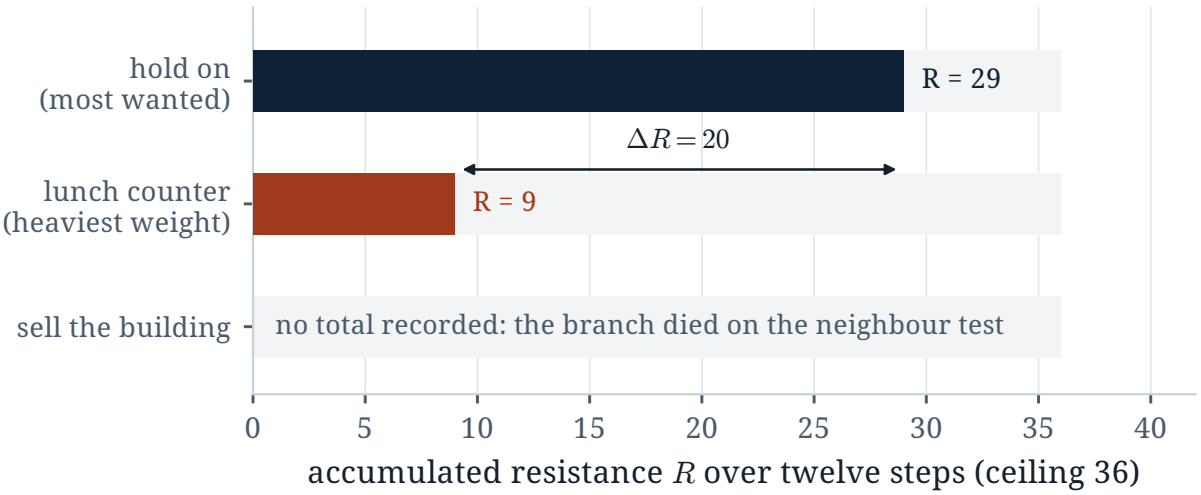

Figure 3.2: **The worked case's resistance budgets, against the ceiling its own scale fixes.** Measured from the source record, which prints "R totals 29" for the continuation branch and "R totals 9" for the intervention branch and gives no total for the third, which the record states died at the neighbour test. The ceiling of 36 is twelve steps at the scale's maximum of 3. Script: `figs/src/CCP-A03_fig02.py`.

can cancel; an exponential weight is positive and cannot. The source says this in its own text — "we use the physicist's insight about paths and neighbours; we use the statistician's actual numbers" — and this paper preserves the distinction at every occurrence.

The distinction is not pedantic, and its cost is exact. **Every claim the framework makes about cancellation is therefore unsupported by its own arithmetic.** Section 4.5 reports the framework's treatment of ambivalence, which it describes in the language of two routes arriving out of phase and unmaking each other; under 2^{-R} nothing cancels, because all the weights are positive. The framework's cancellation talk is a picture and not a computation, and this paper marks it as one wherever it appears.

One further honesty belongs with R2. The exponential is **one member of a family**. A one-parameter generalisation of the entropy that generates it produces a family of weightings of which the exponential is the special case [Tsallis, 1988], and nothing in the source or in this paper discriminates the exponential from the alternatives on any evidence. The halving constant, in particular, is a round number chosen for arithmetic convenience.

4.4 The neighbour test (R3)

The robustness step is the framework's transfer of the stationary-phase idea, and it is the part of the borrowing that does real work.

For each branch, choose one step in its middle third and declare it failed. Ask whether the branch reroutes or dies. If it dies, halve its weight again and mark it *fragile*. The rationale the source gives is that a branch requiring every step to go right is a branch with no agreement among its neighbours, and such branches do not survive contact.

The framework attaches an external warrant — that plans are systematically imagined as their own best case, so robustness rather than optimality predicts completion. **This corpus's external bibliography contains no entry for the planning fallacy**, and the claim is retained **uncited** (Section 12.3). What can be supported is narrower and is stated instead: that the predictability of individual life outcomes is low even under ideal data conditions, so any single planned trajectory should be held loosely [Hofman et al., 2017, Salganik et al., 2020].

R3's own penalty — one further halving — is a stipulation. Nothing establishes that fragility costs a factor of two rather than a factor of ten or nothing at all, and Section 12.5

says so.

4.5 Cancellation and the ambivalent branch

The framework's treatment of ambivalence deserves reporting because it contains a genuine operational instruction and an unsupported mechanism, and the two can be separated cleanly.

The instruction: where a branch's computed weight is high and the practitioner is nonetheless not moving toward it, the framework directs that both accounts of that future be written on the same card, side by side and named — the account in which arriving is a homecoming and the account in which arriving is a defeat — so that the conflict becomes visible arithmetic instead of invisible weather.

The mechanism: that the two accounts *cancel*, arriving at the same outcome out of phase. **Under the framework's own weighting they cannot**, for the reason given in Section 4.3: 2^{-R} is positive and superposes additively. The source also names an approach–avoidance mechanism from the clinical literature, for which **this corpus's bibliography contains no entry**. Both are reported and neither is used; the instruction survives their removal, since writing two accounts of one future on one card is defensible as a bookkeeping rule regardless of what mechanism, if any, underlies the conflict.

4.6 Reading without preferring: three procedural rules

The framework attaches three rules to the scoring, and all three are recognisable as standard research hygiene rather than as novel doctrine, which is a point in their favour and is stated as such.

The outside view. Score a branch against the recorded fates of everyone else who has attempted it before adjusting for particulars. The framework's phrasing — that the inside of a plan is a showroom, lit and priced to move — is vivid and its content is the base-rate discipline. The relevant external result is that individual life outcomes are barely predictable even from fifteen years of high-quality longitudinal data by a hundred and sixty teams, so an individual's confident inside view carries very little information [Salganik et al., 2020, Hofman et al., 2017].

The standing scorer. Write the weights down, date them, and check afterwards whether the stated proportions occurred at the stated rates. The framework asserts that people who keep score improve and people who do not, do not. **No entry in this bibliography establishes that**, and it is reported uncited. What is established, and what the rule amounts to, is that a prediction registered in advance constrains what can later be claimed to have been predicted [Nosek et al., 2018], that the space of analytic and interpretive choices is otherwise wide enough to support almost any conclusion [Simmons et al., 2011, Gelman and Loken, 2013], and that a directional prediction is nearly costless whereas a point prediction with a constant in it is not [Meehl, 1967, 1990].

The moved observer. Re-score the branches from more than one standpoint — tired and rested, in the character of a harsh critic and of a friendly one — and mark the steps on which the readings disagree by two or more as contested rather than resolving them. The framework's argument is that the branch which appears attractive does so partly because of where the observer is standing, and that a branch attractive from every standpoint the observer can occupy has something in it beyond the observer's geometry. This is a sensitivity analysis given a memorable name, and the framework says so.

4.7 The failure catalogue of the weighing

Five failure modes are named, renamed here with the `CC–` prefix.

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-A1	The flattering wind	Optimism bias; scoring the wanted branch as the intended self	**none**
CC-A2	The drowned pilot	Catastrophising; one vivid disaster taken as the base rate	**none**
CC-A3	Walking on young ice	Premature closure; consolidation by adjacency mistaken for choice	**none**
CC-A4	The single sample	Extrapolation from $N = 1$; re-weighting on one observation	Salganik et al. [2020] bears on it; the source's own remedy is a minimum of three independent observations
CC-A5	The connoisseur of the undecided	Analysis paralysis; deferral dressed as diligence	**none**; the source's own mark for it is "a beautiful ledger and an unchanged life"

Four of the five carry no citable support in this corpus. They are retained because a failure catalogue is the most useful part of a procedure, and they are retained uncited.

3.0.5 5. The freezing law (R4)

The framework's account of how a future settles is stated as a physical analogy and then, correctly, as a claim about defaults.

Shallow water freezes before deep water: it holds less stored heat and sits out of the stirring. The framework's transfer is that **futures adjacent to present arrangements consolidate first, and consolidate whether or not they are chosen**, by adjacency, by default, and by the thinness of the change they require. Its practical consequence is the one worth quoting: by the time most people ask what their life will be, much of the answer has already settled along the margin, and they are standing on it as they ask.

The transfer is a **shared mathematical form at best and an analogy at worst**, and it is labelled in Section 8.1 as an analogy, because nothing in the thermodynamics of a lake constrains anything about a calendar and no premise of the physical result is shown to be satisfied. What survives the removal of the analogy is a claim about defaults, and it is the claim the framework actually uses.

The operational content is a three-way classification of settled futures, and this is R4's citable form:

- **Frozen by choice** — consolidated in some earlier period by deliberate arrangement. The framework treats these as the practitioner's built assets.
- **Frozen by geography** — consolidated by adjacency and default, never chosen, frequently useful, and to be walked on knowingly rather than gratefully.
- **Reed-marked** — settled in appearance, with something unresolved still running underneath. The framework's instruction is to mark these rather than to test them with weight.

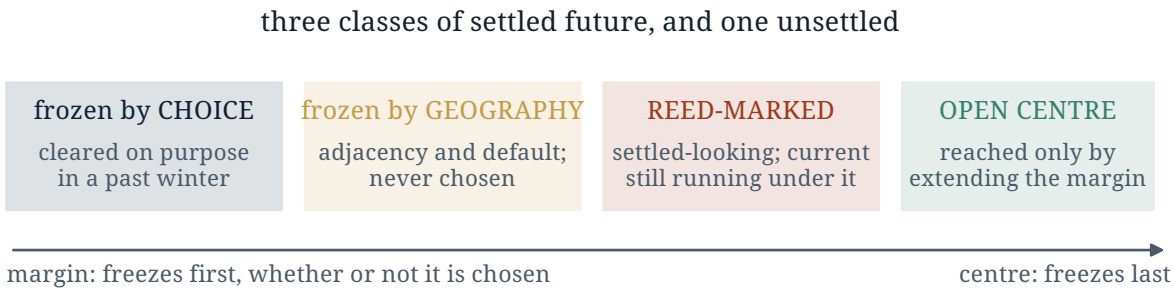

Figure 3.3: **Three classes of settled future, and one unsettled.** Schematic; no plotted quantity. The classification and the margin-to-centre ordering are the source's own: futures adjacent to present arrangements consolidate first, whether or not they are chosen, and the open region is reached by extending the margin rather than by preferring the centre. Script: `figs/src/CCP-A03_fig04.py`.

And one unsettled class: the open region far from every present arrangement, which the framework holds is reached not by preferring it but by extending the margin toward it one placed step at a time — which is what Section 6 is about.

The mechanism the framework names for the freezing — default effects and the consolidation of habit — has no supporting entry in this corpus's bibliography and is reported uncited (Section 12.3). H3 is therefore stated as a hypothesis with a named falsifier and no supporting literature, which is an honest position and a weak one.

3.0.6 6. Cue placement

6.1 The licence clause (R5)

The source states its constraint before its technique, and this paper preserves the order, because the order is part of the claim.

> **Arrangement of one's own path, or of the path of a person who has asked, is the method. Arrangement of another person's path is not.**

The framework gives two reasons and they have very different standing, so they are separated here.

The first is ethical and needs no literature: a technique that works below the awareness of its target, in a channel where the target cannot defend themselves without becoming someone who distrusts every encouragement, is coercion whatever its intent. The framework states this as law rather than as counsel, and the corpus states it as law elsewhere.

The second is mechanical: that a person who discovers they were steered recoils from the direction of the steering with a force proportional to the discovered push. **This corpus's external bibliography contains no entry for reactance.** The claim is retained because it is load-bearing for the framework's argument that the constraint is self-enforcing, and it is retained **uncited**, exactly as the other papers of this series retain it. What can be supported is narrower and is stated instead: that expectations held about a person alter what that person produces, though the effect is smaller and less accumulative than the popular account holds [Rosenthal and Jacobson, 1968, Rosenthal and Fode, 1963, Jussim and Harber, 2005]; and that a theory adopted as a description of people can make itself true by changing how they are treated [Ferraro et al., 2005].

R5 is therefore **a stipulated constraint with an ethical argument and an uncited mechanical one.** The stipulation stands without the mechanism; the framework's stronger claim, that the prohibition enforces itself, does not.

6.2 Three placement laws (R6)

The technique itself is three laws, and each is stated with the friction it prices.

First: site the cue on a path already walked. A cue is an interception of an existing route rather than an invitation to a new one. The framework's named failure is placement where the practitioner *ought* to pass rather than where they do, and its prescribed remedy is one day of self-observation — an application of the worn-path observable fixed in the preceding instalment of this series — followed by placement at the strongest observed station, at reaching height and in the line of the resting eye.

Second: represent the first step and never the summit. The cue must be exactly the size of the next action. The framework's argument is the gradient argument: a system moves when the next step is downhill and is incapable of taking any step but the next one, so a cue depicting the whole undertaking adds the whole undertaking's weight to the next step. Its named failure is a cue that produces a flinch, which it holds trains avoidance with perfect efficiency.

Third: re-site the cue when it stops being noticed. A cue wins attention by contrast and singularity and then loses it as the eye files the familiar as background. The framework's ruling is that this is a perceptual event rather than a moral one, and that the response is to move the cue rather than to reproach oneself. It fixes a standing inspection interval for exactly this reason.

A fourth law is stated as the third's shadow: friction added to a path is as much a part of the method as friction removed from one, with the framework's preference for removal on the ground that a life engineered mainly by self-obstruction becomes adversarial to itself.

The framework prices friction in seconds — some twenty seconds of added or removed effort, it claims, decides behaviour at rates no stated resolution matches. **This corpus's bibliography contains no entry for that finding, none for implementation intentions, and none for cue-driven habit**, which together are the entire external warrant the framework claims for this section. All three are reported uncited and listed in Section 12.3. **The scaffold for this paper names an organisational-dynamics cluster as the source of that support; the cluster does not in fact contain it, and this paper records the gap rather than attaching the nearest plausible key.**

What survives without the missing literature is the framework's internal argument, which is R6's defensible core: *if* behaviour follows local gradients, then a cue that lowers the resistance of a step by one point is worth a doubling of the branch's weight under R1, and that is an arithmetic consequence of R1 rather than an empirical claim.

6.3 The named day and the neutral instrument

Two devices are given at more length, and both are stated by the source in a form that distinguishes them from superstition; the distinction is the interesting part and is preserved.

The named day. One day of the week is designated for a standing question and a written page. The framework's account of why it works has three parts and one addition, and it is careful to claim nothing beyond them. First, the calendar becomes a self-synchronising trigger, so the appointment re-arrives without effort. Second, it creates a place to file relevant material that would otherwise be discarded, so observations accumulate rather than dying on the day they occur. Third — and this is the part the framework insists on stating plainly — it deliberately harnesses the frequency illusion: an attention loaded with a standing question finds material relevant to it that was always present and unfound. The framework's own statement is that the events were there and the gathering is new. Its stated boundary is that a practitioner must be able to say, in plain words, why an ordinary day works; and that the inability to say so is the border between the method and augury.

That boundary is the strongest single sentence in this material and it is preserved verbatim in substance. Its cost is that **the frequency illusion, the fresh-start effect of temporal landmarks, and the claim that scheduled attention accumulates relevance all have no entry**

in this corpus's bibliography and are reported uncited. The one part of the account that can be supported is the resource argument: attention is a bounded channel and a scheduled appointment is a way of allocating it [Miller, 1956, Ashby, 1956].

The neutral instrument. A deliberately meaning-free object is placed on a daily path so that whatever is projected onto it is projected somewhere the practitioner can read it. The framework's claim is not that projection can be started or stopped but that it can be *given a designated instrument*, and that an instrument taking no side returns the practitioner's own state with unusual purity. It is careful to say what such an instrument reads: not the world, but the reader. **No entry in this bibliography supports the projective-instrument claim**, and it is reported uncited. What *is* supported, and what applies to the device with some force, is that any quantity a person adopts as an indicator of their own progress and then acts on ceases to be a good indicator of it [Campbell, 1979, Goodhart, 1975].

6.4 What a cue buys, in the weighting

The join between Sections 4 and 6 is arithmetic and is worth stating exactly, because it is the only quantitative claim in this material that does not require any missing literature.

Under R1 a branch's weight is 2^{-R}. A cue that re-prices one step from "requires a good day" to "already in motion" removes two points of resistance from that step and therefore multiplies the whole branch's weight by $2^2 = 4$. One point removed doubles it; two well-placed cues that each remove one point quadruple it. The source states exactly this, and it is correct **as arithmetic on R1**. It is not evidence that cues remove resistance points, which is H4 and is untested.

The ordering law follows and is stated as a rule: **weigh first, then place.** Placing cues on an unweighted branch amplifies whatever is nearest rather than whatever is best, with all the efficiency the section claims; weighing without placing produces the failure mode CC-A5, a complete ledger and an unchanged situation.

6.5 The failure catalogue of placement

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-L1	The cue on the unwalked path	Cue absent at the point of decision	**none**; the source's mark is a cue the practitioner cannot recall seeing
CC-L2	The summit painted on the jar	Oversized cue conditioning avoidance	**none**
CC-L3	The cue gone to furniture	Habituation; inattention to the familiar	**none**; remedy is re-siting, not reproach
CC-L4	Placement on another's path	Covert influence and the recoil it purchases	**none** (reactance; Section 12.3). The ethical argument of Section 6.1 stands without it

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-L5	Everything named	Apophenia; the frequency illusion unharnessed until the record fills with signs and stops containing findings	**none**; the source's remedy is scarcity — one named day, one instrument

CC-L5 is worth marking as the framework auditing its own device: the named day works, on the framework's own account, because it is *scarce*, and the mode of failure is the practitioner's success at the technique.

3.0.7 7. The resolution–disturbance trade-off

7.1 The uncertainty relation, stated correctly

The source states the physical result at length and states it correctly, and the correctness is load-bearing for what follows, so it is preserved exactly.

For a quantum state, the product of the standard deviations of two conjugate observables is bounded below:

$$\sigma_x \, \sigma_p \;\geq\; \frac{\hbar}{2}$$

This is the Kennard–Robertson form [Kennard, 1927], and the point the popular accounts get wrong is got right by the source. **It is not, at its core, a statement that a clumsy measurement disturbs a delicate system.** It is a statement about which states can exist: position and momentum are Fourier conjugates, and no state — measured or unmeasured — can be sharply defined in both, for the same reason that no signal can be both an instant and a pure frequency. The source makes the acoustic version explicit — a drum tap is sharp in time and therefore has no pitch; a bowed note has a pitch and therefore occupies duration — and that is exactly the correct pedagogy, because the acoustic trade-off is the same theorem in a domain where nobody is tempted to invoke an observer.

The corpus proves the point in that domain rather than asserting it. The time–frequency bound $\Delta t \, \Delta f \;\geq\; 1/(4\pi) \;=\; 0.079577471545948$ follows from the same variational argument as $\sigma_x \sigma_p \geq \hbar/2$ with the substitution $p = \hbar k$ deleted; Gaussian windows saturate it and a Hann window costs 2.6 per cent [Curzi, 2026z]. The value is reproduced exactly in Section 11.3. The underlying signal-theoretic result — that a signal cannot be arbitrarily localised in time and in frequency at once — is Gabor's [Gabor, 1946].

The source also records, correctly, that Heisenberg first explained the principle with a disturbance parable and that the parable was retired from the theorem's proof within the year. **That historical statement has no supporting entry in this bibliography** and is reported as the source's.

7.2 The observer effect, kept in a separate drawer

The source's second move is to insist that the uncertainty relation and the observer effect are different objects, and to keep them in separate drawers throughout. This paper preserves the separation and regards it as the material's chief methodological virtue.

- **The uncertainty relation is about what can exist.** No state is sharp in both members of a conjugate pair, watched or unwatched. It would hold in a universe with no observers in it.

- **The observer effect is about what asking costs.** To measure a system one must interact with it, and the interaction enters the system's history. A pressure gauge bleeds pressure; a thermometer drinks heat. This is ordinary and classical and long predates quantum theory.

The source names the welding of these two into a single slogan — "observation changes reality" — as the specific failure it is guarding against, and requires that a practitioner be able to state the theorem, the observer effect and the framework's own conjecture in three separate sentences on demand. That requirement is the counter-result of this paper and is restated in the Conclusion.

7.3 The mirror catalogue, audited

The source then leaves physics and lists five phenomena of observer participation in human systems, calling all five "real, replicated, and mundane". They are reported here with an audit of what this corpus can actually cite for each, because the source's blanket description is not accurate for all five.

1. **Measurement reactivity** — a counted behaviour changes because it is counted. **No entry.**
2. **The mere-measurement effect** — asking a person whether they intend to do something shifts whether they do it. **No entry.**
3. **The warm gaze** — observed people perform differently for their observers. The source itself attaches a caution to the founding factory study, and the caution is correct: the systematic review of that literature finds the effect poorly characterised and frequently overstated [McCambridge et al., 2014]. **Cited, and the citation bounds rather than supports the source's use.**
4. **The expectant eye** — an observer who expects a result tends to find it, by small steerings below awareness. Supported [Rosenthal and Fode, 1963, Rosenthal and Jacobson, 1968], and bounded by the finding that such effects are real but small, do not typically accumulate, and often dissipate, with most expectations turning out to be accurate rather than causal [Jussim and Harber, 2005]. **Cited with its bound.**
5. **The measure that becomes a target** — an indicator adopted for consequential decisions is gamed and the process it tracked is corrupted. Fully supported [Campbell, 1979, Goodhart, 1975].

Two of the five cannot be cited from this corpus's bibliography at all, and two more are cited by entries that bound the claim rather than establish it. The source's characterisation of the catalogue as uniformly established is therefore not sustained, and this paper says so. What survives is the fifth item, which is fully supported, and the fourth, which is supported in a reduced form — and the fifth is the one the framework actually needs, since the trade-off law of Section 7.5 turns on indicator corruption rather than on reactivity.

7.4 The Postulate, stated and badged

The source states its central conjecture in full and labels it a postulate in the sentence that states it. This paper preserves the badge.

> **The Postulate.** The uncertainty of a foreseen future — a future that is affected by its own foreseeing — is proposed to be the same *kind* of uncertainty as the physicist's: not merely an ignorance in the observer but a participation of the observing in the observed; and the trade-off mathematics that governs the one is proposed to govern the other in *shape*.

The source's own accounting of what is established and what is postulated is structured as three walls and a fourth, and the accounting is accurate on its own terms and is reproduced:

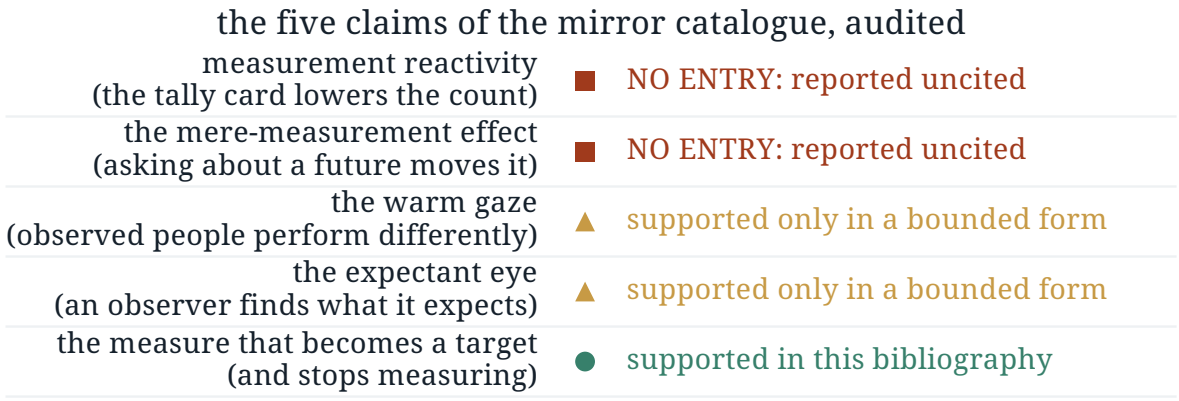

Figure 3.4: **The five claims of the mirror catalogue, audited against this corpus's own bibliography.** The source calls all five "real, replicated, and mundane". One is fully supported here, two are cited by entries that bound rather than establish them, and two have no entry at all. An absent entry means this corpus cannot cite the claim, not that the claim is false. Script: `figs/src/CCP-A03_fig05.py`.

- *Established:* a future is a distribution rather than a point.
- *Established, in the reduced form Section 7.3 permits:* the act of foreseeing participates in the foreseen.
- *Established:* there is no view from outside one's own life, so every forecast a person makes is made by an inhabitant of the system forecast.
- *Postulated:* that the trade-off structure carries over — that resolution is conjugate to disturbance.

The status is stated exactly. **It is not a theorem. It is not established physics. It is not a claim that a mind is a quantum system**, and the framework makes none of those claims. Under a strict falsifiability criterion it is not a scientific claim at all [Popper, 1959]; the honest description of its role is that of a hard-core commitment protected rather than tested, whose warrant is the productivity of the belt of testable claims around it [Lakatos, 1970].

One boundary the source cuts deliberately is worth preserving because it forecloses the obvious abuse: **the Postulate concerns futures coupled to their own foreseeing** — futures of systems that contain the person doing the foreseeing. Where the coupling is zero, the framework asserts nothing. It says nothing about tides, dice, or next year's commodity prices except to the exact degree that a person's seeing can reach the machinery that makes them.

The hazard the badge exists to prevent is documented: a physics result cited outside the conditions of its own derivation transfers its authority and none of its content, and the clearest case is the traversable-wormhole literature, routinely invoked to support shortcuts between distant states when its own conclusion is that such a shortcut requires exotic matter violating an energy condition [Morris and Thorne, 1988]. The corpus applies the same discipline elsewhere and supplies the number that makes it concrete: a warm, wet system at 310 K has a decoherence time of $\tau_{\text{dec}} = 1.98 \times 10^{-17}$ s against a millisecond-scale neural event, a shortfall of $5.04 ×10^{13}$, and a protection factor of 10^{6} still leaves $5.04 ×10^{7}$ [Curzi, 2026aa]. **That is the corpus refuting the literal reading of its own borrowed vocabulary**, and it is the reason the Postulate is stated as a correspondence of shape and never as a claim about substrate. The measurement question the source declines to adjudicate remains open on its own terms [Zeh, 1970].

The corpus's template for a badged postulate is explicit and this one follows it: a magnitude form with a forbidding clause attached — $E = G \cdot B + \varepsilon$ with $G = 0 \Rightarrow E = 0$ for all B — badged

as a postulate and paired by explicit correspondence with the storage law's zero-efficiency case [Curzi, 2026ab]. A strong claim, stated with the clause that forbids its abuse, and badged.

7.5 The trade-off law, and three riders (R7)

From the Postulate the source derives its working law:

> **Every act of foresight has a resolution — a fineness at which the foreseen outcome is specified. Resolution is purchased with disturbance: the finer the outcome is fixed, the more the fixing bends, clutters and constrains the path that must carry the practitioner there; the coarser the outcome is held, the smoother the path runs, at the price of spread in where it arrives. Neither pole is an error. The choice of resolution is the practitioner's most consequential act.**

The two poles are stated with their specific costs, and the costs are the law's content.

At the **fine** pole, three things happen and only the third is surprising. Every hour must be audited against a detailed template, and auditing is not walking. The measure becomes the target, so the practitioner optimises the *signs* of approach rather than the approach — which is the one item of the mirror catalogue this corpus can fully cite [Campbell, 1979, Goodhart, 1975]. And fineness **forecloses**: a specification refuses in advance every route that arrives at the right result by an unlisted road, and the number of such routes is not enumerable in advance.

At the **coarse** pole the path is undisturbed because nothing is asked of it, and nothing arrives, because a gradient requires a difference and "something better" differs from nothing in particular by nothing in particular.

The source writes the trade in the physicist's notation as a mnemonic — $\Delta(\text{outcome}) \cdot \Delta(\text{path}) \geq k$ — and then, in the same breath, states that it has not measured k and that nobody has. **This paper preserves both halves of that sentence and treats the second as the more important.** The inequality is a postulate of craft wearing borrowed notation. What is established is the *direction* of the trade at the fine pole, by indicator corruption; what is postulated is that the trade has a floor that cannot be beaten, only budgeted.

Three riders are attached, and the third is the only one with an operational consequence that does not depend on the Postulate.

First, resolution may sharpen as the outcome nears. A specification that would foreclose the path at two years' range is an ordinary checklist at two months. The framework's named error is demanding a near-term resolution at long range.

Second, the tested path thickens. Disturbance spent *on the path* — small trials, cheap experiments, weight actually placed — is an investment, because the route tested becomes the route best able to carry the practitioner; disturbance spent on the *outcome* is a tax. This is the most useful sentence in the section and it does not require the Postulate: it is a statement about where to spend a fixed budget of checking.

Third, the budget is real, so schedule it. The framework's protection against indicator corruption is not abstinence from measurement but an *appointed* measurement: a fixed, small, scheduled act of checking, outside which no checking occurs. **The protocol implementing that appointment falls beyond this paper's source boundary** (Section 1.3) and is not reported here.

3.0.8 8. Method: what kind of borrowing, what scale, and what is identified

8.1 Analogy discipline

Every physics borrowing in this paper is labelled at first use as a **derivation** (the system satisfies the physical result's premises), a **shared mathematical form** (the same equation governs both, with no claim that the physics applies), or an **analogy** (a suggestive correspondence with

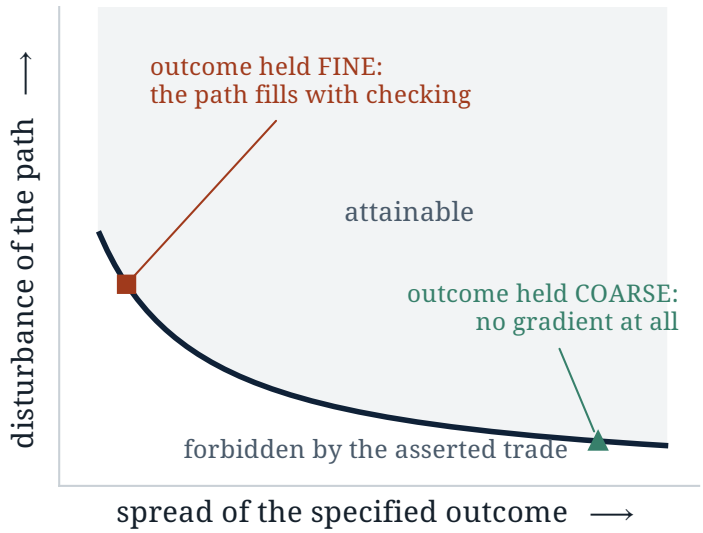

Figure 3.5: **The trade the source asserts, and the constant it says nobody has measured.** Schematic; neither axis carries a scale, because neither quantity has been operationalised. The two poles and their consequences are the source's own. The source writes the trade as $\Delta(\text{outcome}) \cdot \Delta(\text{path}) \geq k$ and states in the same passage that it has not measured k and that no one has. Script: `figs/src/CCP-A03_fig03.py`.

no formal warrant, legitimate as motivation and never as evidence). The labels are collected here.

Borrowing	Category	Warrant, and what is not claimed
Amplitudes and superposition (Sec. 4.1)	3 — analogy, and explicitly refused as more	Reported as physics and used for the image of weighted coexistence only. **Uncited: this bibliography holds no entry for the Born rule.**
Weights on paths, not endpoints (Sec. 4.1)	2 — shared form	Any path-summed cost functional has this property. No physical result is transferred.
Stationary phase, as the neighbour test (Sec. 4.4)	3 — analogy	The physical mechanism is cancellation of phases. The framework's weight cannot cancel (Sec. 4.3), so the transfer is of the *idea* that robust routes survive, not of the mechanism.
2^{-R} as Boltzmann weighting (Sec. 4.3)	2 — shared form	The exponential is the maximum-entropy distribution under a mean-cost constraint [Jaynes, 1957]. No claim that resistance is an energy or that any temperature exists.

Borrowing	Category	Warrant, and what is not claimed
Freezing (Sec. 5)	3 — analogy	No premise of the thermal result is shown to hold. What is used is a claim about defaults, which stands alone.
$\sigma_x \sigma_p \geq \hbar/2$ (Sec. 7.1)	quoted exactly, then 3 — analogy	Quoted in its state-preparation reading [Kennard, 1927]. Its extension to a foreseen future is P1 and is badged at every occurrence.
The time–frequency bound (Sec. 7.1)	1 — derivation	A genuine theorem of signal analysis [Gabor, 1946], proved in the corpus by the same variational argument [Curzi, 2026z]. Nothing psychological is claimed from it.
$\Delta(\text{outcome}) \cdot \Delta(\text{path}) \geq k$ (Sec. 7.5)	3 — analogy, in borrowed notation	The source says so itself and states that k is unmeasured. Reported and badged; no result in this paper consumes it.

The general form of the hazard is documented. Economics imported the formal apparatus of nineteenth-century physics without the conservation law that gave it content [Mirowski, 1989]; laws hold within shielded arrangements rather than universally, so importing a law's form is not importing its scope [Cartwright, 1999]; and the field this corpus's title claims membership of has been surveyed and bounded, with its vocabulary given definitions the corpus can be held to [Castellano et al., 2009]. The constructive standard for making such an analogy checkable is to name the physical quantity, name the social quantity, and state the correspondence explicitly [Vinković and Kirman, 2006]; the table above is this paper's attempt to meet it. **No conserved quantity is exhibited anywhere in this paper, and none is claimed.**

Where this paper cites a corpus result carrying the reference constant $k = 0.483425732988414$ Hz, two cautions apply and are recorded once: the constant is **defined**, exact by construction as $(9/8)^2/\varphi^2$, so its fifteen figures are defensible only on that basis, and **attaching hertz to it is a separate and much stronger claim than computing it**. The general hazard of reading a chosen golden-section ratio as a fact about the world is documented and should be read before any such reading is offered [Markowsky, 1992]. The corpus's own statement is the correct one: that reference constant, the affine effective count, and the choice of twelve components are all badged as chosen rather than derived, and the associated deficit is blind to the decay term, so the intuitive intervention of lowering loss moves the instrument by exactly zero [Curzi, 2026].

8.2 Scale type: a four-point rating, summed and exponentiated

This is the paper's sharpest exposure and it is stated in full, because the objection is specific and the corpus has already committed itself to the rule that answers it.

D1's resistance score is a **four-point rating scale with verbally anchored categories**, of exactly the kind whose scale type has been contested since the format was introduced [Likert, 1932]. Such a scale is, absent a demonstration to the contrary, **ordinal**: the categories are ordered, and nothing establishes that the interval between "would do it while unwell" and "ordinary resolve" equals the interval between "needs a good day" and "needs a better self". The framework then performs two operations on it that ordinal data do not license:

1. **It sums the scores across twelve steps** to obtain R. Addition requires at least an interval scale.
2. **It exponentiates the sum**, forming 2^{-R}, and reads the result as a ratio of likelihoods. Exponentiation of a summed ordinal quantity and the reading of the result as a ratio require a ratio scale with a true zero.

Neither is licensed. The classification that fixes which operations each scale type permits is Stevens's [Stevens, 1946]; the standard against which a claim of quantitative structure is judged is set out in the measurement-foundations literature [Krantz et al., 1971]; and the formal test for whether an attribute has additive quantitative structure at all is conjoint measurement [Luce and Tukey, 1964], whose cancellation conditions are exactly what would have to be checked. **They were not tested.** The strongest single objection to this framework is that psychology systematically assumes quantitative structure without testing for it [Michell, 1997], and **this section concedes it rather than answering it.** Routes that would earn the arithmetic exist and are unused: a probabilistic measurement model that does not require respondents to use numbers [Rasch, 1960], or an interval scale constructed from comparative judgements [Thurstone, 1927], with the construct-validation programme that would accompany either [Cronbach and Meehl, 1955].

The corpus has already stated the rule that governs this case, and the rule is applied here to this paper's own material. The corpus's formula-validation protocol demotes its own moment equation on precisely this ground: because the expression contains a division and a multiplication, inputs that are not instrumented on a common ratio scale with a shared true zero withdraw the magnitude, the number, and the quantitative join as measured quantities [Curzi, 2026t]. The identical objection applies to 2^{-R}, which contains an exponentiation. Applying the corpus's own rule:

- R **is retained as an ordering.** Ranking branches by accumulated resistance is licensed if the individual scores are ordinal and the summation is treated as a heuristic aggregate, which is the weakest defensible reading.
- 2^{-R} **is demoted.** It may not be printed as a ratio of likelihoods, and the statement that a three-point difference is "a factor of eight in expectation" is **withdrawn as a quantitative claim** and retained as an ordering: steeper branches are less likely, and by a margin that grows with the difference.
- **The worked case's ratio is demoted with it.** Section 9.5 reports the arithmetic discrepancy in the source's own terms, because a printed number should be checked against the rule that produced it even when the rule is itself demoted.

This is a real loss of content and it is not disguised. What survives is an ordering procedure with a stated bias toward robustness, which is useful and much less than the source claims.

8.3 Identification, and the framework turned on itself

The Postulate concerns futures coupled to their own foreseeing — which is to say, reflexive systems. The moment a reflexive claim is made about a system containing other people, the question of whether its parameter could be recovered from observation arises, and the answer is no.

The corpus's central formal object is the reflexive loop $T(x) = W(x, M(x))$, fixed in the founding paper of this series. Written as an aggregate relation — a group's state influencing its members while the members constitute the group — **that is a linear-in-means reflexive specification, and the endogenous social effect in such a specification is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is gathered [Manski, 1993]. The network route is closed by the same family of result, since influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. The available remedies are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending

the stipulation, the last having an explicit template in a discrete-choice model that states the conditions under which its interaction parameter is econometrically identified [Brock and Durlauf, 2001]. **This paper adopts none of them.** P1 and R7 are therefore **modelling positions rather than identified empirical results**, and every downstream paper citing them inherits that status.

That reflexivity of this shape occurs at all is separately documented, and the documentation is the existence proof the framework otherwise lacks: when the Black–Scholes option-pricing model was published its prices did not fit the market, and after traders adopted it the market came to fit the model, with dates and price data recording the convergence [MacKenzie and Millo, 2003]. The general statement that classifications of people alter the people classified is argued directly [Hacking, 1995], and the closest existing named doctrine to the framework's reflexive law is Soros's fallibility–reflexivity pair, which supplies the concept without an equation [Soros, 2013]. That literature supplies existence, not identification.

The framework turned on itself. The framework asserts that a system changes its behaviour when it is modelled and observed. Applied consistently, that assertion falls on the framework's own parameters: a halving constant, a fragility penalty or a resistance score estimated in a population that has not read the framework cannot be assumed to survive in one that has, because the decision rules those parameters summarise are themselves responses to the environment the model describes [Lucas, 1976]. The position taken here, stated so that it can be held against the paper: **no stability of this framework's parameters under its own dissemination is claimed, and no result in this paper depends on any.** Three consequences are accepted. Any future estimate of the halving constant must record the reading status of the population it was estimated in. A before-and-after design on a single practitioner is confounded by construction. And the framework's own placement technique (Section 6) is a deliberate regime change for the person applying it, which the framework predicts and which makes its own effect sizes non-transferable.

No scaling or power-law claim is made anywhere in this paper. The weight law is exponential in R and its exponent is *defined by the model rather than estimated from data*; where any paper in this corpus does make a distributional or heavy-tail claim, the principled maximum-likelihood, Kolmogorov–Smirnov and likelihood-ratio procedure is binding and must be run and reported [Clauset et al., 2009]. The absence of that procedure here is a scope statement and not an omission. The general warning that a neighbouring model fitting equally well is the norm rather than the exception applies to the exponential form as much as to any other [Stumpf and Porter, 2012, Durlauf, 2005].

3.0.9 9. Results

9.1 Definitions fixed. D1 (the four-point resistance score) and D2 (the licence clause) are stated in the form the remaining papers cite. Neither is a finding. D1 does not survive the scale-type audit of Section 8.2 in the form the source uses it.

9.2 Results established by construction. R1, R3, R4, R6 and R7 are specifications and procedures rather than measurements. R1 is a scoring rule; R3 is a robustness test with a stipulated penalty; R4 is a three-way classification with a named but uncited mechanism; R6 is three placement laws with an uncited external warrant; R7 is a stated trade-off whose constant the source says has never been measured.

9.3 Results established by derivation. R2 is established: $2^{-R} = e^{-R\ln 2}$ is exponential weighting of states by cost, which is the maximum-entropy distribution under a mean-cost constraint [Jaynes, 1957], and it is not a phase-based amplitude. The consequence — that **nothing in the framework's own arithmetic can cancel** — is established and it goes against the framework's own presentation of ambivalence (Section 4.5). The arithmetic join of Section 6.4, that removing one resistance point doubles a branch's weight, is established as arithmetic on R1 and establishes nothing empirical.

9.4 Hypotheses tested. None. H1 through H5 are stated in falsifiable form and none is tested here. No dataset was collected. H5 is not currently testable as stated, for the reasons in

Section 7.5. This is reported in the same plain language a positive result would receive: **the five hypotheses this paper states stand untested, and the paper that states them supplies no evidence for any of them.**

9.5 An arithmetic discrepancy in the source, printed rather than corrected. The source's worked example records two branch resistances explicitly — 29 for the continuation branch and 9 for the intervention branch — and then states that "the halvings put the counter at roughly a thousand times the weight of holding on".

Under the framework's own rule, $\Delta R = 29 - 9 = 20$ and the weight ratio is $2^{20} = 1{,}048{,}576$: approximately **one million**, not one thousand. A ratio of a thousand corresponds to $\Delta R = \log_2 1000 = 9.9658$, which is half the recorded difference.

Three readings are possible and this paper does not choose between them. The printed ratio may be an error of three orders of magnitude. One of the two resistance totals may be misprinted. Or the halving may have been intended per *two* points rather than per point, in which case $2^{10} = 1024$ reproduces "roughly a thousand" exactly — but that reading contradicts the rule as stated twice in the same material. **The discrepancy is recorded here, and no downstream paper should quote the "roughly a thousand" figure.** Figure 1 plots both readings.

9.6 Reproduction of the corpus's own arithmetic. Three numerical claims carried by this paper's internal citations were recomputed.

- The time–frequency bound: $1/(4\pi) = 0.0795774715459477$, printed as 0.079577471545948 [Curzi, 2026z]. **Reproduced exactly.**
- The minimum-gap schedule in cents: $1200\log_2(9/8) = 203.9100$, $1200\log_2(50/49) = 34.9756$, $1200\log_2(289/288) = 6.0008$ and $1200\log_2(1682/1681) = 1.0296$, all as printed [Curzi, 2026]. **Reproduced exactly, to the four decimals given.**
- The decoherence shortfall: $10^{-3}/(1.98 \times 10^{-17}) = 5.05 \times 10^{13}$ against the printed \$5.04 ×10^{13}$ [Curzi, 2026aa]. The printed value is recovered from an unrounded $\tau_{\text{dec}} \approx 1.984 \times 10^{-17}$ s, so the discrepancy is a rounding of the *displayed input* rather than an error in the result. **Reproduced, with that clarification**, and the derived \$5.04×10^{13}/10^{6} = 5.04×10^{7}$ follows.

3.0.10 10. Discussion

10.1 What follows

Three consequences follow and they are this material's genuine yield.

The first is that **a scoring rule which ignores the destination is a real methodological choice with a real cost.** Covering the endpoint during scoring removes the single largest source of motivated distortion in any self-assessment of a plan, and it is cheap. Its cost is that the procedure cannot rank branches by anything a practitioner wants, which is why the protocol requires the disagreement between the weight ranking and the wanting ranking to be written down as a finding rather than resolved.

The second is that **the licence clause is prior to the technique, not appended to it.** A method that reliably lowers the resistance of a step is a method for altering another person's behaviour, and the framework's decision to state the constraint before any technique is the correct ordering. The corpus states the same constraint elsewhere as a condition rather than a courtesy.

The third is the trade-off's one practical rider, which survives the removal of the Postulate entirely: **spend checking on the path and not on the outcome.** Testing a route with real weight makes the route more able to carry the practitioner; auditing an outcome against a template does not, and it corrupts the indicators it audits — which is the one item of the mirror catalogue this corpus can fully cite.

10.2 What does not follow

That a rule is stated exponentially does not make it exponential; that a score is summed does not make it additive; that a trade-off is written as an inequality does not make it one; and that a corpus can cite two of five claims does not make the other three false or true.

Two further non-implications are worth stating. First, **the framework's cancellation language is not licensed by its own arithmetic** (Section 4.3), and any downstream use of the framework's ambivalence account as though it were a computation is unsupported. Second, **the Postulate is not made stronger by the correctness of Section 7.1.** The source states the physical relation better than most popular accounts, and that accuracy is a virtue of the exposition and not evidence for the conjecture that follows it. A carefully stated premise and an unlicensed extension are two separate things, and the first is not a warrant for the second.

10.3 Relation to the corpus

The results fixed here are consumed downstream in specific ways. The launch-budget instrument turns a resistance-like barrier into an explicit fund with a fixed point — $L^{Q} = \max(0,\ \eta M - C)$, $\Lambda_{\infty} = L/\lambda$, departure feasible only where $\Lambda_{\infty} > E_b$ and reached after $t^{*} = \ln(1 - E_b/\Lambda_{\infty})/\ln(1 - \lambda)$ periods [Curzi, 2026p] — which is the quantitative form of the claim R1 makes qualitatively, that accumulated resistance is what has to be paid before a branch moves. The corpus's evidential-status apparatus supplies the schedule of exactly representable gaps that any resolution claim must live inside: 1200 cents at two elements, 203.9100 at three to six, 34.9756 at seven to sixteen, 6.0008 at seventeen and above, and 1.0296 at forty-one and above [Curzi, 2026]. That schedule is R7's structural cousin: **the finer the scheme, the smaller the distinction it can still carry**, and the shrinkage is exactly computable there and merely asserted here.

Four results elsewhere bound what this paper may claim. The corpus's falsification suite measured its own shuffled-input control and found it **anti-conservative**: against a nominal 0.05 across 500 null trials, independent permutation rejected at 0.108, circular shift at 0.120 and block permutation at 0.060 [Curzi, 2026u]. That is the correct prior for any future test of H1–H5. The corpus's two-column refinement bounds what the mirror catalogue's partial support can be made to do: an evidence column carries what could have come out otherwise and a precedent column carries only that an idea was independently arrived at and preserved, so two sources agreeing does not double the evidence when only one of them is evidence [Curzi, 2026w]. The corpus's audit of a traditional operation set against a parameter model returned seven mappings, two splits, one rendering and three rejections over thirteen entries, with five entries carrying a failure [Curzi, 2026] — the same refusal discipline applied to inherited material, and the model for Section 7.3's audit. And two structural results state the general shape of R5's constraint from the other side: an effective count measures independence and not capacity, so a structure that clears an independence threshold still says nothing about whether any part of it can carry the load [Curzi, 2026], and a separated control channel trusted *because* it is separate is itself the failure mode, separation being necessary and not sufficient [Curzi, 2026]. The framework's licence clause is a separation claim of exactly that kind and inherits exactly that caution.

One further result is cited for the structure it shares: the property that makes an insurance reserve resistant to third-party claims — real liabilities owed to unrelated parties — is the same property that makes it unavailable to its owner, leaving only 7.58 per cent realisable within a year [Curzi, 2026]. That is R7 in a different domain: the same feature buys the protection and imposes the cost, and the trade cannot be escaped by wanting both ends of it.

3.0.11 11. Verification

This section is not a summary. It decomposes the paper's results into steps small enough to check one at a time, and labels each `ARITHMETIC` (a reader can redo it), `DEFINITION` (true by this

paper's own construction), CITED (a named external source supports it) or POSTULATED (asserted here, no external support). The razor is applied: any postulate whose removal leaves the results standing has been removed.

11.1 Postulates

- **P1 (DEFINITION).** A branch is an ordered sequence of steps, and each step carries a score in $\{0, 1, 2, 3\}$. *Check:* D1.
- **P2 (DEFINITION).** The resistance of a branch is the sum of its step scores. *Check:* D1. **Note: summation of an ordinal rating is not licensed, and Section 8.2 demotes what may be done with the sum.**
- **P3 (DEFINITION).** The weight of a branch is $2^{-\Delta R}$, where ΔR is measured from the smallest branch resistance. *Check:* the rule as stated.
- **P4 (ARITHMETIC).** $2^{-\Delta R}$ falls by a factor of two per point, so $\Delta R = 3$ gives $1/8$ and $\Delta R = 20$ gives $1/1{,}048{,}576$. *Check:* redo it.
- **P5 (CITED: `jaynes1957information`).** The exponential weighting of states by cost is the maximum-entropy distribution subject to a mean-cost constraint; it is positive everywhere and therefore admits no cancellation.
- **P6 (POSTULATED).** The completion likelihood of a course of action falls geometrically in accumulated step steepness, with a halving constant of one point. *Check:* **not checked. This is the substantive content of H1 and it is asserted.**
- **P7 (POSTULATED).** A branch that cannot survive one middle-step failure is half as likely as one of equal resistance that can. *Check:* **not checked**; the factor is a stipulation.
- **P8 (POSTULATED).** Futures requiring the smallest change from present arrangements consolidate first, whether or not they are chosen. *Check:* **not checked**, and no entry in this bibliography supports the mechanism.
- **P9 (POSTULATED).** A cue sited on a walked path lowers the resistance of the step it represents. *Check:* **not checked**; the entire external warrant the framework claims for it is absent from this bibliography (Section 12.3).
- **P10 (CITED: `kennard1927quantenmechanik`).** $\sigma_x \sigma_p \geq \hbar/2$ is a property of the quantum state, not of measurement disturbance.
- **P11 (CITED: `gabor1946theory`).** A signal cannot be arbitrarily localised in time and in frequency simultaneously; the bound is a theorem of signal analysis and mentions no observer.
- **P12 (CITED: `campbell1979assessing`, `goodhart1975monetary`).** An indicator adopted for consequential decisions is gamed, and the process it tracked is corrupted.
- **P13 (POSTULATED).** The uncertainty of a future coupled to its own foreseeing is the same kind as that of a quantum state, and the trade-off structure carries over. *Check:* not checkable; this is the framework's Postulate and is badged wherever it appears.

Postulates dropped as unnecessary: the reactance mechanism (Section 6.1), the planning fallacy (Section 4.4), the approach–avoidance account of ambivalence (Section 4.5), the frequency illusion and the fresh-start effect (Section 6.3), and the historical claim about the retirement of Heisenberg's disturbance parable (Section 7.1). Each was tested for load and carries none: every result below survives its removal. All are reported in the text and none is used.

11.2 The compounding chain

Each line consumes only the outputs named on its left.

```
P1 + P2          -> L1   a branch has a resistance R          DEFINITION
L1 + P3          -> R1   the branch weight is 2^-(dR)         DEFINITION
R1               -> L2   dR = 3 gives 1/8; dR = 20 gives
                         1/1,048,576                          ARITHMETIC
```

L2	-> D1'	the source's printed "roughly a thousand" needs dR = 9.97, not 20	ARITHMETIC
R1 + P5	-> R2	the weight is Boltzmann-style exponential discounting, NOT a phase amplitude	CITED
R2	-> L3	nothing in this arithmetic can cancel; the cancellation talk is a picture, not a computation	ARITHMETIC
P7	-> R3	the neighbour test halves a fragile branch again	POSTULATED
P8	-> R4	the freezing law and its three classes of settled future	POSTULATED
(stipulation)	-> R5	the licence clause	DEFINITION
		(its mechanical limb)	POSTULATED
P9	-> R6	the three placement laws	POSTULATED
R1	-> L4	one resistance point removed doubles a branch's weight	ARITHMETIC
P10 + P11	-> L5	conjugate bounds are facts about states and signals, not observers	CITED
P12	-> L6	a finely specified outcome corrupts its own indicators	CITED
L5 + L6 + P13	-> R7	the resolution-disturbance law	POSTULATED
R1 + P2	-> C1	branch weights may be read as ratios of likelihoods	WITHDRAWN (Sec. 8.2)

What this chain shows, stated plainly. R2 is the only result in this paper that is CITED at its load-bearing step, and its content is a *restriction*: the framework's weighting is an ordinary exponential discount and cannot do the one thing the borrowed vocabulary suggests. Everything else about practice is POSTULATED. R1 is DEFINITION and the reading of it that the framework most wants — a ratio of likelihoods — is withdrawn on scale-type grounds and appears in the chain as WITHDRAWN, which is the honest terminal state for it.

A chain whose steps are mostly DEFINITION and POSTULATED is not a proof, and this one is mostly DEFINITION and POSTULATED. What it is instead is a specification of which premises would have to be settled: P6 (the halving constant), P7 (the fragility penalty), P8 (default consolidation), P9 (that a placed cue lowers resistance), and P13 (the Postulate, which is not the kind of thing that can be settled). Four of the five are testable, three of them cheaply, and none was tested.

11.3 The checks a reader should run first

1. **Redo the weight law.** $2^3 = 8$ and $2^{20} = 1{,}048{,}576$. Then compute $\log_2 1000 = 9.9658$ and confirm the discrepancy reported in Section 9.5.
2. **Redo the resistance ceiling.** Twelve steps at a maximum score of 3 gives 36, so the recorded totals of 29 and 9 sit at 81 and 25 per cent of the maximum. Figure 2 plots both.
3. **Redo the time–frequency constant.** $1/(4\pi) = 0.0795774715459477$. The corpus prints 0.079577471545948 [Curzi, 2026z]. It agrees.
4. **Redo two entries of the gap schedule.** $1200 \log_2(9/8) = 203.9100$ and $1200 \log_2(1682/1681) = 1.0296$ [Curzi, 2026]. Both agree to the printed decimals.
5. **Check that $\sigma_x \sigma_p \geq \hbar/2$ carries its state-preparation reading at every occurrence.** There are three, in Sections 7.1, 8.1 and 11.1, and all three carry it.
6. **Check that the analogy table in Section 8.1 assigns category 1 to exactly one entry**, and that the entry is a theorem of signal analysis from which nothing psychological is drawn.

7. **Check that no sentence in this paper reads 2^{-R} as a probability.** Section 8.2 withdraws that reading and the Conclusion repeats the withdrawal.

11.4 Dimensional audit

Symbol	Meaning	Dimension	Unit	Status
step score	steepness of one step	none assigned	**ordinal categories, no unit**	defined (D1); **not shown to be interval or ratio**
R	branch resistance	none assigned	points	defined as a sum of ordinal scores; **the summation is not licensed**
ΔR	resistance above the easiest branch	none assigned	points	derived from R
$w = 2^{-\Delta R}$	branch weight	dimensionless	—	derived; **demoted to an ordering (Sec. 8.2)**
$\beta = \ln 2$	discount rate per point	inverse points	per point	defined by the choice of base 2; **chosen, not measured**
resolution	fineness of a specification	none assigned	**no operational unit exists**	undefined in the source; not operationalised anywhere
disturbance	interference with the path	none assigned	**no operational unit exists**	undefined in the source; not operationalised anywhere
k (trade-off floor)	the asserted bound's constant	product of two unmeasured quantities	**none**	**asserted; the source states it has never been measured**
$\sigma_x, \sigma_p, \hbar$	quantum spreads and reduced Planck constant	m; kg·m·s^{-1}; J·s	SI	quoted from physics; not quantities of this framework
$\Delta t, \Delta f$	time and frequency spreads (quoted)	time; inverse time	s; Hz	quoted from `ccp:CCP-032`; their product is dimensionless
τ_{dec}	decoherence time (quoted)	time	s	quoted from `ccp:CCP-033`

Does the central relation balance? $w = 2^{-\Delta R}$ requires ΔR to be dimensionless, and it is — but only in the trivial sense that a count of ordinal points carries no unit. **A dimensionless exponent is not the same thing as a licensed one**, and the balance here is formal: it is satisfied by construction and constrains nothing.

Does the trade-off relation balance? $\Delta(\text{outcome}) \cdot \Delta(\text{path}) \geq k$ **cannot be checked**, because neither factor has a dimension, a unit, or an operational definition, and the constant is therefore a number attached to a product of two undefined quantities. **The source is silent on all three and this paper does not supply them.** A dimensionless placeholder is the honest entry; an invented unit would not be.

11.5 Limits and boundary behaviour

- $\Delta R \to 0$**.** All branches carry equal weight and the procedure ranks nothing. Correct and uninformative.
- $\Delta R \to \infty$**.** The weight of the steeper branch goes to zero. The model therefore asserts that a sufficiently steep branch is impossible rather than merely unlikely, which is a **defect of the model's domain**: no finite resistance should drive a completion probability to exactly zero, and the framework supplies no floor. The domain should be restricted to the range over which the branches are comparable, and the source does not do this.
- **All steps scored 0.** $R = 0$ for every branch, all weights equal 1, and the procedure is silent. The framework's own account predicts this case is empty, since a branch with no resistance anywhere would already have been taken.
- **All steps scored 3.** $R = 36$ at twelve steps. Weights are equal again, because the rule is anchored at the minimum. **The rule cannot distinguish "all branches easy" from "all branches impossible"**, and the source does not note this.
- **Fragility penalty applied to every branch.** The relative weights are unchanged, since a common factor divides out. The neighbour test therefore has content only when branches differ in robustness, which the framework does not state.
- **Resolution held at its finest.** The path is maximally constrained and, by the framework's own account, all arrival is by listed routes only. The framework predicts the highest indicator corruption here, and that limb is the one this corpus can cite [Campbell, 1979].
- **Resolution held at its coarsest.** No gradient, and no arrival. The framework's own gradient material supplies this limit: a difference is required for motion, and an unspecified outcome supplies none.
- **Coupling between seeing and seen** $\to 0$**.** The Postulate is silent by its own stated boundary (Section 7.4). This is the only boundary in this paper at which the framework correctly declines to say anything.

On invariance. The weight rule is invariant under the addition of a constant to every branch's resistance, since it is anchored at the minimum, and it is invariant under relabelling of steps within a branch, since only the sum enters. Both are consequences of the construction rather than findings, and neither has been tested at any scale, because nothing here is measured. **No conserved quantity is exhibited.**

3.0.12 12. Limitations

12.1 The scoring rule's arithmetic is not licensed by its own scale type. This is the paper's principal exposure and it is stated first. A four-point verbally anchored rating is ordinal absent a demonstration otherwise [Likert, 1932, Stevens, 1946]; summing it and exponentiating the sum requires interval and ratio structure respectively; and the formal test that would establish either was not run [Luce and Tukey, 1964, Krantz et al., 1971]. The strongest single objection to this framework is that psychology assumes quantitative structure without testing for it [Michell, 1997], and Section 8.2 **concedes it**. The corpus's own demotion rule applies and has been applied [Curzi, 2026t]. **Falsified by:** a conjoint-measurement study on any operationalisation of step resistance that fails double cancellation, which would remove the quantitative content of R1 entirely and leave only the ordering.

12.2 The halving constant and the fragility penalty are stipulations. Nothing establishes one halving per point rather than per two points or per half a point, and nothing establishes

that fragility costs a factor of two. Both are round numbers chosen for arithmetic convenience, and the model's entire quantitative output is a function of them.

12.3 Claims with no supporting literature in this corpus's bibliography. Listed individually, because a reviewer will find them and finding them first is the point.

- *Pressure on a perceived freedom produces counter-movement (reactance).* Load-bearing for R5's mechanical limb and for failure mode CC-L4. **No entry.** Retained uncited; R5's ethical argument stands without it.
- *If-then plans tied to concrete cues outperform bare intentions; habitual performance is cue-driven; some twenty seconds of added or removed friction decides behaviour.* The **entire** external warrant for Section 6.2 and for H4. **No entry for implementation intentions, cue-driven habit, choice architecture, or default effects.** Reported as the framework's and uncited. The scaffold for this paper names an organisational-dynamics cluster as the source of this support; **the cluster does not contain it**, and no citation was attached to make it appear that it does.
- *Plans are systematically imagined as their own best case (the planning fallacy).* Load-bearing for R3's rationale. **No entry.** Retained uncited.
- *Behaviour tracks situations more reliably than resolutions, and highly self-controlled people experience fewer temptations rather than winning more of them.* The pivot of Section 6's argument. **No entry.**
- *The frequency illusion; the fresh-start effect of temporal landmarks; that scheduled attention accumulates relevance.* The mechanism of the named day (Section 6.3). **No entry.**
- *Measurement reactivity and the mere-measurement effect.* Two of the five items in the mirror catalogue (Section 7.3). **No entry.**
- *The Born rule and the postulates of quantum mechanics; the historical retirement of Heisenberg's disturbance parable.* Sections 4.1 and 7.1. **No entry.** Reported as physics and used for nothing; excluded from the verification chain.
- *Approach–avoidance conflict; anchoring; availability; optimism bias; catastrophising; motivated reasoning.* The mechanisms named in the three failure catalogues. **No entry for any of them.**

That is **eight classes of unsupported claim**, and they are more of this paper's material than any other single category. A reader should treat the failure catalogues and the placement laws as the framework's clinical folklore, usefully organised, and not as findings.

12.4 The cancellation account is unsupported by the framework's own arithmetic. Section 4.3 establishes that 2^{-R} is positive and cannot cancel. The framework's ambivalence account is retained as an instruction and marked as a picture, and no downstream paper should treat it as a computation.

12.5 Parameters chosen rather than measured. Every parameter in every figure is either the source's own recorded number or a stipulation. Figures 1 and 2 plot the source's own printed values and the arithmetic that follows from them. Figures 3 and 4 are schematics and carry no scale on any axis; Figure 3 in particular is drawn without axis units precisely because neither of its quantities has been operationalised. Figure 5 is an audit of this corpus's bibliography and not of the literature.

12.6 The trade-off law is not currently testable as stated. Neither resolution nor disturbance has been operationalised, the constant has never been measured, and the source says so. H5 is therefore listed as a hypothesis in name and is not one in practice until the two quantities are defined. **This is the weakest claim in the paper and it is the one the framework leans on hardest.**

12.7 Nothing here is identified. As an aggregate specification, any reflexive claim of the framework's form is not identified from observational data [Manski, 1993], and the network route is closed by the generic confounding of influence with selection [Shalizi and Thomas, 2011]. This paper adopts no remedy and therefore states P1 and R7 as **modelling positions rather than identified empirical results** (Section 8.3). **Resolved by:** a randomised or partial-

population design, or a defended stipulation of the reference group in the manner of Brock and Durlauf [2001].

12.8 The framework's own parameters are not exempt from its own thesis. By the Lucas critique, a halving constant estimated in a population that has not read the framework cannot be assumed stable in one that has [Lucas, 1976]. No stability is claimed and no result here depends on any; the cost is that no cross-population comparison of a resistance score is currently interpretable, and that the framework's own technique constitutes a regime change for its user.

12.9 The exponential form is one of a family and nothing discriminates it. A one-parameter generalisation produces a family of weightings containing the exponential as a special case [Tsallis, 1988], and the general problem is that many mechanisms produce indistinguishable curves [Stumpf and Porter, 2012]. A reviewer will ask for the differential prediction [Durlauf, 2005]. **This paper does not have one.**

12.10 The mirror catalogue is not uniformly established, and the source says it is. Section 7.3 audits it: one item fully supported, two supported only in a bounded form, two with no entry. The source's blanket characterisation is not sustained.

12.11 The worked cases are illustrative. The two worked cases reported in Sections 4.2 and 9.5 are single, self-reported, retrospective accounts drawn from the source manuscript. They illustrate what the procedures return and establish nothing about whether the procedures work. The base rate against which any single such report should be read is not encouraging [Ioannidis, 2005, Open Science Collaboration, 2015].

12.12 A printed number in the source does not follow from the source's own rule. Section 9.5 records the discrepancy in full. No claim in this paper depends on the figure, and the discrepancy is printed rather than harmonised.

12.13 No hypothesis was tested and no data were collected. H1–H5 stand. The discipline that would make a later confirmatory attempt credible is specified and not exercised [Nosek et al., 2018], and the analytic flexibility available in any such attempt should be constrained in advance [Simmons et al., 2011]. The corpus's own control measured anti-conservative at 0.108 against a nominal 0.05 [Curzi, 2026u], which is the prior any such test should be read against.

3.0.13 13. Conclusion

The seven results are stated below in the exact form in which the rest of the corpus cites them. Downstream papers should quote this text rather than paraphrase it.

R1. The comfort-weighted amplitude: score each step of a candidate branch 0 to 3 for steepness, sum to a resistance R, and weight the branch as $2^{-\Delta R}$ measured from the easiest branch, so that a three-point difference in steepness is a factor of eight. **The quantitative reading of that weight is withdrawn on scale-type grounds (Section 8.2): the score is ordinal, its summation and exponentiation are not licensed, and R1 survives as an ordering of branches by accumulated resistance and not as a ratio of likelihoods.**

R2. The pedigree, stated honestly: the weight is exponential, Boltzmann-style discounting of states by cost — $2^{-R} = e^{-R\ln 2}$, the maximum-entropy form under a mean-cost constraint — and explicitly **not** a phase-based path amplitude. It follows that **nothing in this arithmetic can cancel**, and the framework's account of ambivalence is a picture rather than a computation.

R3. The neighbour test: break one middle step of a branch and halve its weight again if it cannot reroute, penalising plans that require every step to succeed. The penalty is a stipulation.

R4. The freezing law: futures adjacent to present arrangements consolidate first, by adjacency and default rather than by choice, with three classes of settled future distinguished — frozen by choice, frozen by geography, and settled in appearance with something unresolved running underneath.

R5. The licence clause preceding all cue technique: arrangement is legitimate only on one's own path or on the path of a person who has asked. The ethical argument stands on its own; **the framework's further claim that the prohibition enforces itself mechanically, through counter-movement proportional to the discovered push, has no supporting entry in this corpus's bibliography and is reported uncited.**

R6. Three placement laws: site the cue on an already-walked path, represent the first step and never the summit, and re-site the cue once it has stopped being noticed — with friction priced in seconds of added or removed effort. **The external warrant the framework claims for all three is absent from this corpus's bibliography.** What survives is arithmetic on R1: removing one resistance point from one step doubles the branch's weight.

R7. The resolution–disturbance law: fine specification buys precision at the cost of path disturbance, indicator-optimisation and the foreclosure of unlisted routes, while infinite coarseness exerts no gradient at all. The trade's *direction* at the fine pole is supported by indicator corruption [Campbell, 1979]; the existence of a floor beneath it is postulated, and the source states plainly that its constant has never been measured by anyone.

Counter-result. The uncertainty material declines the inflated reading of its own borrowed physics. The Postulate is stated as a postulate; the physical relation is given only in its correct state-preparation form and never as a claim about measurement disturbance; and a named requirement holds that a practitioner must be able to state the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand. To that this paper adds an audit the source did not run: of the five phenomena the source calls uniformly established, one is fully supported by this corpus's bibliography, two are cited only by entries that bound them, and two have no entry at all.

What is established, then, is one restriction — that the framework's weight is an ordinary exponential discount and cannot cancel — one theorem of signal analysis from which nothing psychological is drawn, and one fully supported mechanism, indicator corruption, on which the practically useful half of the trade-off law rests. What is not established is any of the five hypotheses, the licensing of the scoring arithmetic, the halving constant, the fragility penalty, or the existence of the trade-off's floor. The paper's contribution at this stage is to name the four testable premises whose settlement would decide the matter — the halving constant, the fragility penalty, default consolidation, and whether a placed cue lowers resistance — and to note that three of the four are cheap to test and none was tested.

3.0.14 14. Declarations

Data and code availability. No external dataset was collected for this paper and none exists. The worked cases reported in Sections 4.2 and 9.5 are drawn from the source manuscript's own record and are not a dataset. All figures are generated by the scripts named in their captions (`figs/src/CCP-A03_fig01.py` through `figs/src/CCP-A03_fig05.py`), which import the shared style module `lib/figstyle.py`; every number plotted is either computed within the script from a rule stated in this paper or quoted from the source text identified in the script's docstring. Three of the five scripts contain assertions that fail if the numbers they plot cease to agree with the source claims they are drawn from.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures, and the text.

Ethics. No human-subjects research was conducted for this paper. No personal data were collected or processed. The worked cases in Sections 4.2 and 9.5 are drawn from the source manuscript, are presented under the descriptions they carry there, and are illustrative rather than evidential; they were not gathered under a research protocol and are not offered as one. Nothing in this paper is clinical advice. The licence clause of Section 6.1 records the framework's own instruction that its placement technique is not to be applied to another person's

environment without that person's request, and this paper reports that instruction as a constraint on the method rather than as an endorsement of the technique.

Use of the ceremonial register. The source manuscript is in part an initiatory document. This paper analyses that register as an object of study and does not reproduce it; ceremonial names are reported only where they identify a construct this paper renames.

Chapter 4

The Spoken Word and the Returned Difference: Performative Commitment, Echo Reading, and the Doctrine of Category Violation

Abstract. This instalment covers the framework's account of commitment, its treatment of feedback, and an interlude on objects that violate a classification scheme without harming anyone. A spoken commitment is analysed as a performative directed at the speaker, with three converging mechanisms named: consistency pressure following a voiced position, self-perception from overheard testimony, and the commitment device that re-prices later defection. The present tense is argued to be calibration rather than etiquette, since a future-tense formulation is consistent with a day identical to yesterday and therefore generates no dissonance for the consistency mechanism to act on. A prohibition follows and is stated as law: a future may not be voiced over another person's life, including benevolently, because imposed futures are registered as pressure and produce counter-movement, so that the attempt manufactures its own refutation. The feedback node writes the loop as sent x, returned y = T(x), and read as the difference y - x, with the argument that a channel returning a signal unchanged has reported nothing about itself, that all information lives in the transform, and that a null return is itself a datum with two possible readings. The interlude defines a category violation as an object or act that harms no person while standing in two boxes a schema swore were disjoint, and argues that such objects are diagnostic of where a classification has torn. Three conditions constrain the doctrine: clean acquisition, clean possession, and self-decoding.

Keywords: performative utterance; consistency; commitment device; reactance; feedback transform; null return; category violation; self-decoding

Series: A. Foundations **Paper:** CCP-A04

4.0.1 1. Introduction

1.1 The question

Once a framework has scored a set of candidate futures and arranged an environment around one of them, three questions remain and none of them is about scoring.

What does *saying* a future do? The framework's answer is that a spoken commitment is not a report about a future but an act performed on the speaker, and that its grammar is calibration rather than etiquette.

What does a *reply* tell you? The framework's answer is that a returned signal carries its information in the transform applied to it and nowhere else, so the reading rule is to record what was sent, record what came back, and read the difference — with the corollary that a channel returning a signal unchanged has reported only that nothing in it could touch the signal.

And what should be done with an object that a classification scheme cannot file? The framework's answer is a definition — an object that harms no person while standing in two boxes a scheme declared disjoint — and three constraints that between them refuse almost everything the definition might be thought to license.

Twenty-seven corpus papers cite the results established here. Because those results are load-bearing elsewhere, this paper states them in a form intended to be quoted rather than paraphrased.

It also reports, at the same precision, what this corpus cannot support. **The three mechanisms on which the paper's first result rests — consistency pressure following a voiced position, self-perception from overheard testimony, and the re-pricing of later defection — have no supporting entry anywhere in this corpus's external bibliography.** So does the prohibition's mechanical limb, so does the substitution effect that motivates the framework's quarantine rule, and so does the attentional cost that motivates its burning rule. Six of the framework's named mechanisms in this material are uncited, and they are listed individually rather than papered over with the nearest plausible key.

1.2 What this paper contributes

Seven results are established or fixed here, labelled R1 through R7 and restated verbatim in the Conclusion.

R1 analyses a spoken commitment as a performative directed at the speaker, supported by three converging mechanisms: consistency pressure following a voiced position, self-perception from overheard testimony, and the re-pricing of later defection. **R2** states the present-tense requirement as calibration rather than style: a future-tense formulation is consistent with a day identical to yesterday, so it generates no dissonance and the consistency mechanism has nothing to act on. **R3** states the prohibition on voicing a future over another life, including benevolently, on the ground that imposed futures are registered as pressure and manufacture their own refutation. **R4** states the feedback reading rule: record what was sent, x, and what returned, $y = T(x)$, and read the difference $y - x$, since a channel that returns a signal unchanged reports only that nothing in it could touch the signal. **R5** treats the null return as a datum with exactly two readings — a distance beyond the listening window, or a medium that absorbs the frequency entirely — rather than as an absence of evidence. **R6** defines a category violation as an object or act that harms no person while standing in two boxes a scheme declared disjoint, holds the law of persons and the law of categories apart, and gives the person-law priority. **R7** states the three constraints on the doctrine: no coercive acquisition, possession by clean holding only, and self-decoding, since an explained instance is a spent one.

A counter-result is stated with equal weight. **The category material constrains far more than it licenses.** Category innocence is explicitly refused as a defence of acquisition; the doctrine forbids moving any harm through a discovered gap in a scheme; and the framework concedes on the record that the case in which the feedback loop runs through another person's will is an unsettled seam which it does not close.

1.3 Register, sources, and the chunk boundaries

The source manuscript is written in two registers, a narrative one and an analytic one, deliberately braided. This paper reports the analytic register. The narrative material is a fictional exposition and carries no analytical claim the treatise does not also carry; it is not reproduced. Where the source's ceremonial vocabulary names a construct — *the word that closes the sea*, *the rite of the far shore*, *the lawful crime* — the construct is renamed to what it is, and the ceremonial name is reported once, as an object of study. The last of those three is the source's own term for the object R6 defines; this paper uses the neutral term **category violation** throughout and reports the source's term once, here, because downstream papers refer to the material by that name.

The source volume was re-split after a de-framing correction, and the boundaries of the file assigned to this paper do not coincide with the source's divisions. **At the opening**, the file begins with the operating protocol and failure catalogue of the preceding construct — the resolution material whose law is stated in the preceding instalment of this series, which records that its protocol falls here. That protocol is reported in Section 3, both because it is the only place in the volume where the framework's central trade-off is actually measured and because the preceding paper states that it will be found here. **At the close**, the file ends in the middle of the category material's fifth and final teaching section, so that section is reported in full while any closing apparatus attached to it falls in the file assigned to the next paper in this series.

4.0.2 2. Hypothesis

The material below divides into claims that could be wrong, definitions and stipulated constraints that could not, and one postulate inherited from earlier in the series. A hypothesis that nothing could falsify is restated as a definition or a constraint and labelled as such [Popper, 1959].

H1 — the performative hypothesis. A commitment spoken aloud, by a speaker, in the present tense, and to no audience, raises the rate at which the speaker's subsequent conduct moves toward the commitment, relative to the same commitment held silently. *Predicted:* matched undertakings differ in completion by voicing condition, with the spoken-to-no-audience condition highest. *Falsified by:* no difference between spoken and unspoken conditions at matched content. *Status:* testable and cheap to test; **not tested here.** All three mechanisms the framework offers for it are uncited (Section 11.3).

H2 — the tense hypothesis. A future-tense formulation generates no pressure toward action because it is consistent with an unchanged day, whereas a present-tense formulation is not. *Predicted:* among spoken commitments matched on content, present-tense formulations produce more early action than future-tense ones. *Falsified by:* equal action rates by tense, or higher rates for the future tense. *Status:* **not tested here.** The prediction follows from the consistency mechanism, which is uncited, so a failure of H2 would be evidence against the mechanism rather than against the grammar.

H3 — the imposition hypothesis. A future voiced over another person, without that person's request, lowers the rate at which they move toward it relative to no intervention, and does so more strongly the more clearly the steering is detected. *Predicted:* movement away from an imposed future, scaling with detected pressure. *Falsified by:* movement toward an imposed future, or movement independent of detection. *Status:* **not tested here**, and the mechanism the framework names for it has **no supporting entry** in this corpus's bibliography (Section 11.3). The ethical argument for R3 does not depend on H3 and is stated separately in Section 4.4.

H4 — the residue hypothesis for returns. The deviation between a signal sent and a signal returned carries information about the medium that no property of the arrival alone carries. *Predicted:* an observer given only the deviations between a set of sent and returned signals can characterise the medium as well as one given the full returns. *Falsified by:* deviations

carrying no more than arrivals about the medium. *Status:* **true by construction for a linear channel**, where the impulse response is exactly the transform [Oppenheim et al., 1996], and **not tested** for any social channel, where linearity is not established and is implausible.

H5 — the null-return hypothesis. A return that does not arrive discriminates between two states of the channel — too distant for the listening window, or absorbing — and the discrimination improves with the length of the window. *Predicted:* silences classified provisionally as "far" resolve into arrivals at a rate that rises with window length, while those classified "absorbed" do not. *Falsified by:* silences resolving at rates independent of window length. *Status:* testable against any archive of dated correspondence; **not tested here.**

D1 — the performative (definition). An utterance is performative with respect to a speaker when the utterance is itself the act it names rather than a report about the world. This is a stipulated distinction, taken from the philosophy of language and used here without adjudicating that literature.

D2 — the reading rule (definition). For a signal x sent into a channel returning $y = T(x)$, the reading is $y - x$. This is a definition of what shall be read and not a claim that the difference is informative, which is H4.

D3 — category violation (definition). An object or act that harms no person — nothing taken, nobody deceived about anything they were owed, no will overridden — while standing in two categories that a classification scheme declared disjoint. This is a stipulated definition and its two halves are held apart deliberately.

C1 — the three constraints (stipulated constraints, not claims). Acquisition without coercion; possession by clean holding; and decoding by the holder. The framework states that failing any one converts the object into an ordinary harm. These are constraints on a doctrine's domain and are not falsifiable, and they are labelled as constraints rather than dressed as findings.

P1 — the inherited postulate. The uncertainty of a future affected by its own foreseeing is postulated to be the same *kind* as that of a quantum state, with the trade-off structure carrying over in shape. This paper inherits the postulate from earlier in the series, does not re-argue it, and preserves its badge at every occurrence. Nothing in physics licenses it.

4.0.3 3. Material carried across the opening boundary

The file assigned to this paper opens with the operating protocol of the preceding construct and its failure catalogue. Both are reported here because the preceding paper in this series records that they fall in this file, and because the protocol is the only place in the volume where the framework's resolution trade-off is given an actual measurement procedure.

3.1 The three-card carriage procedure

The procedure is a within-subject comparison and its design is better than most of what surrounds it. One undertaking is written on three cards at three resolutions — **fine** (dates, numbers, names, everything specified), **coarse** (a direction and a quality only, no numbers, no dates, no proper nouns), and **middle** (exactly one number *or* one date, and exactly one place *or* one name). Each card is then carried for one full day, and **every reading of the card, and every check made in the world because of it, is recorded as a tally on the card's back.**

That yields a measured quantity: the *disturbance cost* of a specification at three resolutions, in units of the practitioner's own attention. The procedure then sorts each card's tallies into two classes — checks that bent the hands toward *doing* something, and checks that bent them toward *verifying* — and applies a selection rule: keep the sharpest card whose disturbance is mostly of the first kind, and coarsen any card whose disturbance is mostly of the second.

This is a real measurement design and it is worth saying so. It is within-subject, it uses a fixed and countable operationalisation of the quantity it cares about, and its selection rule

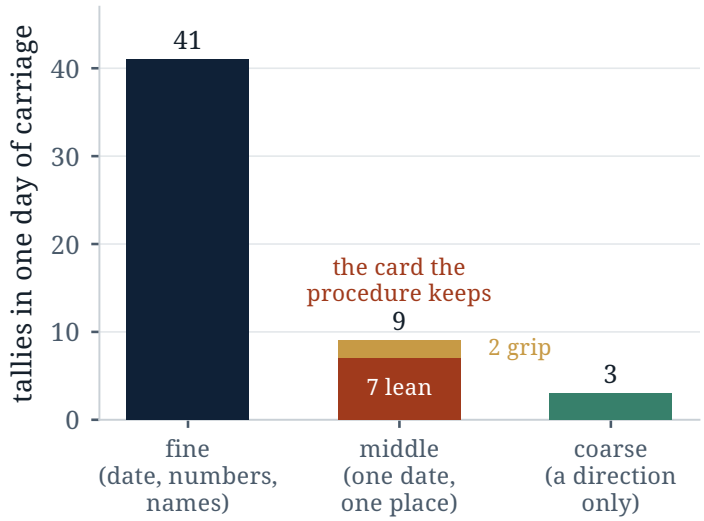

Figure 4.1: **The disturbance cost of a specification, measured at three resolutions.** Measured from the source's worked case, which records 41 tallies for the fine card, 3 for the coarse and 9 for the middle in one day of carriage each, and sorts the middle card's nine into seven that bent the hands toward doing and two toward verifying. The procedure's stated rule then selects the middle card. Single participant, unblinded, uncounterbalanced. Script: `figs/src/CCP-A04_fig01.py`.

is stated in advance. Its weaknesses are equally plain: a single participant, no blinding, an order that is not counterbalanced — the fine card is always carried first — and an outcome recorded by the person whose behaviour is being measured. The order effect is not incidental: a first day of carriage is also a first day of novelty, and the design confounds resolution with day number. **Counterbalancing the three days would cost nothing and was not done.**

The worked case records the numbers. The fine card returned **41** tallies in one day, the coarse card **3**, and the middle card **9**, of which **7** were of the hands-toward-doing kind and **2** of the verifying kind. The rule therefore selected the middle card. The case also records a self-observation that the framework treats as confirming and that should be treated more cautiously: a symptom polled five times daily began, on the practitioner's own account, to report at the polling hours. That is a single self-reported observation by an interested party and it is exactly the pattern that measurement reactivity would predict and that expectation alone would also predict; it discriminates nothing.

The procedure's standing element is a scheduled measurement: one reading of the retained card each day at a fixed hour, entered as exactly one of three words — nearer, farther, or unknown — after which the record is closed. The framework's argument for scheduling rather than abstaining is the one this corpus can fully support: an indicator adopted for consequential decisions is gamed, and the process it tracked is corrupted [Campbell, 1979, Goodhart, 1975], so the protection is a budget rather than a prohibition.

3.2 The five failure modes carried with it

Renamed with a `CC-` prefix to keep them clear of this paper's own results.

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-U1	The borrowed authority	The practitioner conflates the uncertainty theorem, the observer effect and the framework's own conjecture, and claims physics endorses the last	**the counter-sign is the paper's own**: three separate sentences on demand. Morris and Thorne [1988] is the documented case of the failure
CC-U2	The indicator that replaces the substance	Goodhart and Campbell effects on the practitioner's own record	Campbell [1979], Goodhart [1975]
CC-U3	Continuous self-polling	Measurement reactivity in overdose; a system polled continuously has no unpolled hours left	**none** for the reactivity claim; McCambridge et al. [2014] bounds the nearest literature
CC-U4	The demand for a resolution the distance cannot support	Treating a forecast as a fact	**none** for the clinical framing; Salganik et al. [2020] and Hofman et al. [2017] establish that the underlying predictability is low
CC-U5	Never testing at all, dressed as epistemic humility	Avoidance wearing the chapter's own doctrine	**none**; the counter-sign is the source's own second rider, to spend the checking budget on the path rather than the outcome

CC-U1 is worth marking as the counter-result of the preceding paper and of this one: the framework's own named failure mode is the misuse of its own borrowed physics, and the test it sets — state the theorem, the observer effect and the conjecture as three separate sentences — is a discipline this paper applies to itself in Section 7.1.

4.0.4 4. The spoken commitment

4.1 Performative rather than descriptive

The material opens with a distinction that does real work: some utterances describe a state of affairs and can be true or false about it, while others *are* the act they name. A statement about the thickness of ice is a report and the ice is indifferent to it. A sentence of resignation, of naming, of promising, does not report the resignation, the name or the promise; it performs it, and courts and registries run on that fact daily.

The framework's move is to apply the distinction reflexively: **a spoken commitment is a performative aimed at the speaker.** It does not report a future — reporting futures is the scoring material of the preceding paper. It performs a selection, in the speaker's own accounting, which is the accounting the speaker's subsequent behaviour reads from.

This corpus's external bibliography contains no entry for the philosophy of performatives. The nearest support is the performativity literature in economics, which argues that a body

of theory does not describe its object but formats it [Callon, 1998], and which supplies the documented instance in which an option-pricing model's prices did not fit the market when published and the market came to fit the model after traders adopted it, with dates and price data recording the convergence [MacKenzie and Millo, 2003, MacKenzie, 2006]. That literature supports the general claim that an utterance can constitute rather than describe; it does not support the specific claim about a self-addressed commitment, and no citation has been attached to make it appear that it does.

The framework also borrows the vocabulary of measurement collapse for this construct, and it states its own limits carefully enough that the statement is worth preserving. What it takes is the uncontroversial spine — a distribution over outcomes, then an act, then one outcome, then all subsequent predictions conditioning on that outcome — and it declines to adjudicate the interpretive question, which remains genuinely open [Zeh, 1970]. **It borrows the shape and not the mechanism**, and this paper preserves that badge. The human mechanism, the framework then says, is not mysterious at all; it is the next subsection, and the next subsection is where the trouble is.

4.2 Three converging mechanisms, and their support (R1)

The framework offers three mechanisms and holds that they converge.

Consistency. Once a position is voiced, subsequent perception, memory and choice bend toward agreement with it, and a life at odds with a spoken sentence is uncomfortable in a way that has a name in the psychological literature. The framework's contribution is stated as an inversion: the same mechanism that produces rationalisation and doubling down can be aimed deliberately, so that the sentence spoken is one whose consistency pressure points where the practitioner has already, by the preceding procedures, decided to go.

Self-perception. A person infers who they are partly by observing their own conduct, including their own speech, so a sentence spoken aloud is filed as testimony where a sentence merely thought is filed as rehearsal. The framework's operational consequence is that the sentence must be voiced with the body in it and not held internally.

The commitment device. A voiced commitment re-prices later defection: every course inconsistent with the spoken sentence now carries an additional cost, small and constant, and a small constant tilt on a landscape compounds over time. This is the framework's join to its own gradient material.

R1 is the conjunction of the three. **All three are uncited.** This corpus's external bibliography contains no entry for cognitive dissonance, none for self-perception theory, and none for commitment devices. The three are retained in the text because R1 is what the corpus cites and removing them would misrepresent the framework, and they are retained **uncited**; they are listed individually in Section 11.3.

What can be supported is narrower and is stated instead, in two parts. First, that a belief acted upon can bring about the conditions that make it true is established as a sociological phenomenon and was named long before this framework [Merton, 1948], with its companion — purposive action producing consequences nobody modelled — the same machinery read from the other end [Merton, 1936]. Second, that expectations held about a person alter what that person produces is established, and is established at a magnitude smaller than the popular account holds: real but modest, not typically cumulative, and often dissipating, with most expectations turning out to be accurate rather than causal [Rosenthal and Jacobson, 1968, Rosenthal and Fode, 1963, Jussim and Harber, 2005]. **Neither establishes the self-addressed case**, which is R1's actual content.

4.3 The present tense as calibration (R2)

R2 is the framework's sharpest small claim and it is a claim about grammar with a mechanism attached.

A future-tense commitment — *I will become* — is, on the day it is spoken, **perfectly consistent with a day identical to yesterday.** The due date is always downstream; the account is always payable later; and the consistency mechanism, which is the whole motor of R1, therefore has nothing to act on, because an unchanged life does not contradict a promise whose term has not expired. A present-tense commitment asserts something about now, and to the exact degree that now does not match it, the pressure the mechanism supplies engages.

That is a genuine argument and it is stated here at full strength. Its dependency is also stated: **R2 is an entailment of the consistency mechanism, and the consistency mechanism is uncited.** If consistency pressure does not operate as described, R2 is a stylistic preference. This paper does not soften R2; it locates its load-bearing premise.

The framework attaches one boundary in strong terms and the boundary is worth preserving, because it forecloses the abuse the grammar invites. The present tense must be **reachable by gradient** — a state the practitioner can begin occupying in some honest fraction today. A sentence flatly contradicted by observable fact each morning is not a commitment but a misdescription of the present state, and the framework's ruling is that the ground state always wins and that each collision costs the instrument credit until the practitioner's own testimony is filed as fiction. The framework's formulation is that the sentence declares a road already entered rather than an arrival already occupied.

4.4 The prohibition (R3)

The framework states its constraint as law and states it before the technique that would violate it. This paper preserves that order and separates the two arguments the framework gives, because they have very different standing.

> **No future is to be voiced over another person's life without their word — and the prohibition covers the benevolent case explicitly.**

The ethical argument requires no literature and is stated first. Another person is not a branch of the speaker's situation; they are a separate system with their own weights and their own jurisdiction. A future installed in another person's environment, below the level at which they can contest it, is coercion whatever its intent, because the channel it operates in is one where the target cannot defend themselves without becoming someone who distrusts every encouragement. That argument is a moral one and it stands or falls on moral grounds; it is not an empirical claim and it is not offered as one.

The mechanical argument is the framework's own and is uncited. The framework holds that an imposed future is registered as pressure and produces a counterforce proportional to the detected push, so that the attempt manufactures its own refutation and returns it to the speaker as apparent evidence against their reading. **This corpus's external bibliography contains no entry for reactance**, and the claim is retained uncited, exactly as the other papers of this series retain it. What can be supported is weaker and sufficient for the corpus's purposes: that classifications and expectations applied to people alter the people they are applied to, so that the referent moves [Hacking, 1995]; and that a theory adopted as a description of people can make itself true by changing how they are treated, sometimes for the worse [Ferraro et al., 2005].

R3 is therefore a stipulated constraint with a sound ethical argument and an uncited mechanical one. The constraint stands without the mechanism. The framework's stronger claim — that the prohibition enforces itself, so that a practitioner need not be trusted to observe it — does not.

The framework's own statement of what remains permitted is narrow and is preserved: a practitioner may place a visible offer where another person will encounter it, may ask, and may consent to be asked. The corpus states the same constraint elsewhere as a closure condition rather than a courtesy [Curzi, 2026].

4.5 The read-aloud test and its taxonomy

The framework's drafting procedure is a rejection loop: draft, read aloud alone, and discard any draft that produces a specific bodily response, repeating until one survives. It supplies a four-way taxonomy of the responses, and the taxonomy is the useful part because it converts a vague instruction into named observations:

- **the catch** — the voice thins on a particular word, which the framework holds identifies the word carrying the falsehood rather than the sentence;
- **the slide** — the gaze leaves the page and the line is read without being heard, which the framework holds indicates a borrowed sentence;
- **the hedge** — a qualifier appears in the final third, which the framework treats as a flinch that arrived early enough to reach the text;
- **the performance heat** — the sentence reads clean and yet is read with an awareness of how it sounds, which the framework holds indicates an audience inside the sentence and treats as the most serious of the four.

The mechanism the framework offers — that bodily verdicts on prospects precede articulate reasoning — is named in the source with an explicit acknowledgement that the hypothesis it belongs to has open questions, and this corpus's bibliography contains no entry for it. It is reported uncited. The taxonomy does not depend on the mechanism: it is a set of named, self-observable events, and its usefulness is that it is more specific than "trust your instinct" and can therefore be wrong in identifiable ways.

The framework distinguishes what is discarded from what is filed, and the distinction is operational rather than ceremonial. A specification declined *at this resolution* is retained, because the distance may close and the finer version may later be usable; a draft that was never the practitioner's own sentence is destroyed. **The reason the framework gives for destruction — that unfinished items hold attention and levy a standing cost — has no supporting entry in this corpus's bibliography** and is reported uncited. The corpus's closure discipline elsewhere rests the same rule on bookkeeping grounds instead, which is the defensible version [Curzi, 2026].

4.6 The compression doctrine, and its boundary

The framework advances a specific claim about laughter that is worth reporting because it is stated as an operational tool with a stated boundary and a stated test.

Its analysis: a joke sustains two readings of the same material, the second concealed; the resolution forces a collision that reveals the concealed reading as the true one; and the moment of forced recomputation has an involuntary felt signature. The framework's inference is that laughter marks a **compression event** — a contradiction registered as meaningful without being resolved, releasing the process to proceed — rather than a resolution of the contradiction.

The operational rule follows: where a procedure jams on a contradiction that ordinary means cannot resolve, the practitioner may deliberately laugh at the knot, which the framework holds lets the work continue through it rather than around it.

Two things must be said. First, **this corpus's external bibliography contains no entry for the psychology or the theory of humour**, and the incongruity-resolution family the source names is reported uncited. Second, and more to this paper's credit than the framework's, **the framework attaches a boundary and a test that make the rule falsifiable in use**: where the contradiction is the practitioner's own failure, the rule does not apply and the appropriate response is repair; and the test of whether a given instance was compression or evasion is whether the *work* proceeded within the hour or only the mood improved. A rule with a stated failure signature is a better object than a rule without one, and this one has both.

4.7 Speaking without an audience

The framework's most counter-intuitive instruction is that the commitment be spoken aloud and to no one, and it argues the point against the common advice rather than ignoring it.

It concedes the case for public commitment: a word given before others is harder to withdraw, and the architecture of vows and contracts exists because that is true. It then asks what a public commitment binds the speaker to, and answers that when the commitment concerns identity — who the speaker is becoming, which is what a commitment of this kind is — announcing it to an audience can **substitute** for enacting it. The audience supplies recognition; recognition is the wage of the finished thing, paid early; the tension the sentence was built to create is partially discharged in the telling.

The framework's reconciliation is the sharpest sentence in the material and this paper adopts it: **the voicing is the measurement; being observed voicing is the contamination.** From it follow three placement rules — speak once and not repeatedly, speak to something that cannot respond with recognition, and observe a quarantine before telling anyone.

The substitution effect has no supporting entry in this corpus's bibliography and is reported uncited. What can be supported is adjacent and weaker: that an indicator adopted as a target is gamed and corrupts the process it tracked [Campbell, 1979, Goodhart, 1975], which applies to a practitioner's own record of approach; and that a record made and dated in advance constrains what can later be claimed to have been intended [Nosek et al., 2018], which is the defensible warrant for the quarantine — it keeps the record uncontaminated by an audience's response rather than protecting a psychological account.

4.8 The failure catalogue of the spoken commitment

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-C1	The commitment spent on an audience	Announced identity goals substituting for enactment	**none**
CC-C2	The commitment that waits	Deferral encoded in the future tense; the practitioner does not register the tense as a flinch	**none**; the remedy is mechanical — strike every future-tense verb and read what remains
CC-C3	The specification closed too small	Over-specification rebuilding the corridor of the preceding construct in a single sentence	Campbell [1979] supports the indicator half; the foreclosure half is the framework's own
CC-C4	The commitment laid on another life	Imposition and the counterforce it purchases	**none** (Section 11.3). The ethical argument of Section 4.4 stands without it
CC-C5	The laugh that disperses instead of compressing	Avoidant humour wearing the compression tool's coat	**none**; the source's own test — did the work proceed within the hour — is the discriminator

4.0.5 5. The returned difference

5.1 The loop, written out

The framework writes the loop it inherits from the founding paper of this series in operational form:

$$T(x) \;=\; W(x,\, M(x))$$

where M is the practitioner's model of the situation, W is the world's response to an action taken on that model, and $T(x)$ is the next state. The founding paper fixes this composition and identifies a self-fulfilling prophecy as a fixed point of it [Curzi, 2026]. **R4 and R5 derive from that definition**, and inherit its status: Section 7.3 records that the specification is not identified from observational data and that the corpus's claims about it are modelling positions rather than measured effects.

The framework's examples are ordinary and are the right ones: a rumour that an institution is failing can empty it, after which the institution has failed and the rumour stands vindicated at the outcome it produced; a selector who expects little asks smaller questions, receives smaller answers, and files the smallness as a discovery. The general principle — that a system's next state can depend on a participant's report about the system — is the working principle of every controller and is not this framework's discovery [Wiener, 1948, Åström and Murray, 2008], and the modelling of a human operator inside such a loop is older than any claim here [Tustin, 1947].

5.2 Why the difference carries the information (R4)

R4 is the framework's reading rule and it is the strongest result in this paper, because it is true by construction in the domain it is borrowed from.

$$\text{sent } x \quad\longrightarrow\quad \text{returned } y = T(x) \quad\longrightarrow\quad \text{read } y - x$$

The argument is a reductio: consider what a *perfect* return would mean. If a signal comes back unworn — undelayed, unfiltered, unchanged — the observer has learned exactly one thing, namely that nothing in the channel could touch the signal. **A channel that returns a signal unchanged has reported only its own emptiness.** All of the information about the channel lives in the transform: in what was kept, what was lost, what was delayed, what was added.

In signal terms this is not an analogy but a theorem. The response of a linear time-invariant channel to a sharp input *is* the channel's impulse response, and the impulse response characterises the channel completely [Oppenheim et al., 1996]. Every echo-ranging and impedance-probing method in engineering is built on exactly that fact, and the sent signal is treated as known, cheap and disposable precisely because the returned signal is valuable only where it deviates. The information-theoretic form of "read the difference" is equally standard: the quantity that measures how far one distribution has been moved from another is a divergence rather than a property of either one alone [Kullback and Leibler, 1951, Shannon, 1948].

The transfer to a social channel is a shared mathematical form and not a derivation, and it is labelled as one in Section 7.1. The premises that make the engineering result exact — linearity and time-invariance — are not established for a channel made of markets, institutions or people, and are implausible for one made of people. What survives the transfer is the *reading discipline*: record what was sent, record what came back, and attend to the deviation rather than to the arrival. That discipline is defensible on its own terms, because it converts a verdict into an observation, and this paper endorses it in that reduced form.

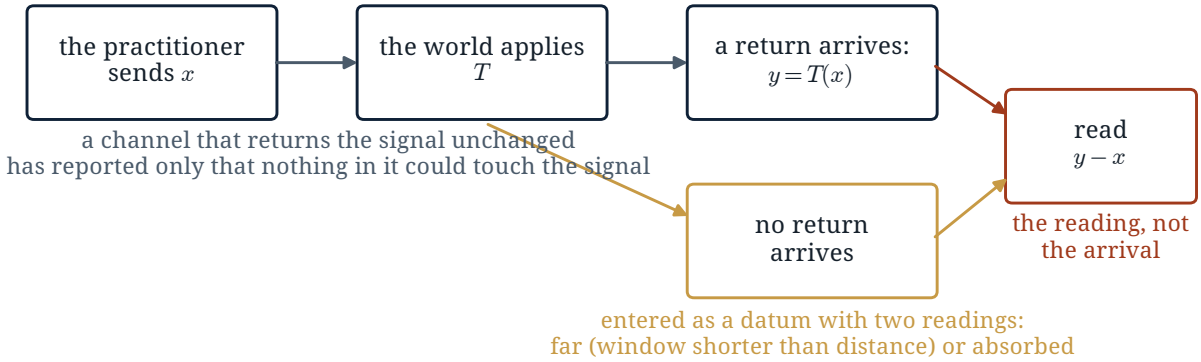

Figure 4.2: **The reading rule, and the null return as a datum.** Schematic; no plotted quantity. The loop and the rule are the source's own, which records what is sent, records what returns, and reads the difference. The lower branch is the source's treatment of a return that never arrives: it is entered with exactly two readings rather than discarded as an absence of evidence. Script: `figs/src/CCP-A04_fig02.py`.

5.3 The null return (R5)

R5 is a small result and a genuinely useful one. A return that does not arrive is entered in the record with one of two marks:

- **far** — the listening window may simply be shorter than the distance;
- **absorbed** — the medium does not return this frequency, and a louder call will not change that.

Where the two cannot be distinguished, both are written and the entry stands. The framework's own instruction is that waiting is itself a reading.

This is the correct treatment of a missing observation and it should be said plainly. An absent return is a datum about the channel; treating it as no evidence discards information, and treating it as a verdict fabricates information. The framework's rule is neither, and its provision for an undecided entry is what makes it honest: a record that forces every silence into one of two bins would manufacture certainty at the point where there is least.

The corpus supplies the general version of the same discipline. A record that asserts an identity holds exactly while the statement it certifies is misleading is a consistency check and not an integrity check, and the identity's holding is therefore not evidence [Curzi, 2026]. A null return that has been classified for the analyst's convenience is the same failure in a different ledger.

5.4 When the other party is a will

The framework marks this case as the seam in its own material and does not close it, and this paper reports the concession as a concession because it is the counter-result.

When the responding party is a person, the diagram doubles: the other party is not a channel but a second system with its own model and its own outward signal, so what returns was composed on the far side of an inwardness the sender cannot audit. The framework draws two consequences. The informational one: a reply from a person carries more than an echo from a material, because it is the transform of a transformer. The ethical one: a material cannot be trespassed against by being spoken at, and a person can.

The framework then states the case it cannot resolve. Its own argument runs: a person's discarded drafts — the sentence struck, the tone not adopted — are read off them by everyone

they pass, so the world already answers versions of a person they never authorised; from which it might follow that carrying one more copy of an already-circulating self is transport rather than forgery. **The framework records the argument, rules against it, and states that the ruling does not settle it.** Its stated ground for ruling against it is a distinction between a condition and a choice: that the world reads a person without leave is a condition, while a particular person appointing themselves the world's courier is a choice.

This paper reports the seam as open. The framework's own text says the argument is not settled and will not be settled by it, and no result in this corpus closes it. What the framework does supply, and what is worth preserving, is a two-ledger rule for the case in which a return was obtained by trespass: the trespass is entered with its name and its cost, *and* the return is read, on the ground that the world's answer is now a fact about the world regardless of how it travelled, and that discarding a sounding to punish the sounder makes the situation less legible rather than more just. Neither entry pays the other.

The corpus's own treatment of the point where a second party enters a loop is the same one, stated as governance: when another will consents to be in the loop, the loop is a commons, and durable arrangements over commons are governed by rules the affected parties had a hand in making — a finding derived from cases rather than postulated [Ostrom, 1990].

5.5 What the framework establishes and what it claims

The framework performs its own accounting here and the accounting is accurate on its own terms, which is rare enough to preserve. It sorts its claims into three:

- **Established elsewhere, not by this framework:** feedback — that a system's next state can depend on a participant's report about it [Wiener, 1948, Åström and Murray, 2008].
- **Established elsewhere, in a reduced form:** that expectation alters conduct and conduct alters response. The framework's own summary is that the effect is real, moves through ordinary channels, and is contested in size, and that anyone claiming it is either nothing or everything is selling. That summary is accurate [Rosenthal and Jacobson, 1968, Jussim and Harber, 2005].
- **Established, on the framework's account:** reactance. **This is the one item the framework mis-sorts.** It is not established in this corpus's bibliography, which contains no entry for it, and this paper moves it to the uncited list.
- **Claimed, and flagged by the framework as a craft claim:** that the wear on a return can be read, with practice, as a chart of the material between the sender and the mark. The framework compares it to a tracker's claim about a bent stalk and says it is practised everywhere and proven nowhere. **That is the correct badge and this paper keeps it.**
- **Postulated:** the inherited postulate P1, which the framework declines to re-argue.

The framework then makes a design statement worth quoting as a principle: it chose instruments that **survive the doctrine failing**. The two-column record and the difference reading remain useful if the postulate is false, because they are bookkeeping rather than theory. That is the correct criterion for an instrument and it is the strongest methodological sentence in this material.

5.6 The recording procedure and its failure catalogue

The procedure is a fixed-window observational record and its design deserves the same scrutiny the framework gives its subject. A window is declared in advance; the channels that will count as observations are declared in one sitting, and **nothing may later be promoted to an observation that was not declared**; arrivals are logged verbatim on the day they arrive, without interpretation at entry; the difference is taken on a fixed weekly schedule; silences are classified per R5; and no return that raised the practitioner's pulse may be answered within one day.

SENT	RETURNED	THE WEAR
letter to a fine-editions press	silence	far or absorbed: both marked
letter to a second press	"list us your commercial rates"	fine → commercial
shop-window card: repairs and fine bindings	a co-op asks for 40 years of ledgers rebound	fine → records
price list to a historical society	"can you teach the apprentice to sew spines?"	fine → keeping

the page's own closing line: the material returns the frequency "keeping" and absorbs "exquisite"

Figure 4.3: **A worked record, with the deviation extracted.** Measured from the source's own reproduced card: four items sent, three returns and one silence. The right-hand column is what the reading rule extracts in each case, and the silence is entered under both of its two permitted readings rather than resolved. Script: `figs/src/CCP-A04_fig03.py`.

Three of those are genuine methodological controls and should be named as such. Declaring the channels in advance is a pre-specification rule that prevents the outcome set from expanding to fit the result [Nosek et al., 2018, Simmons et al., 2011]. Logging verbatim before interpretation separates observation from analysis. And the one-day delay on replies is a control on the analyst becoming their own noise source — in the framework's terms, a reply that outruns the reading collapses the difference before it has been measured. The general fact that delayed feedback is where human judgement systematically fails is established [Sterman, 1989, Forrester, 1961].

The procedure also imposes an ordering rule that is a genuine ethical commitment rather than a technique: where a return contains another person's actual question, that question is answered before the practitioner's own work advances.

The worked case is a single, self-reported, retrospective record and establishes nothing about whether the procedure works; it is reported because it shows what the procedure returns and because it contains two refusals, which is the part of a practice usually omitted from its own account. Its own closing line — that the surrounding material returns one frequency and absorbs another — is an interpretation by the interested party, and the base rate against which any single such report should be read is not encouraging [Ioannidis, 2005, Open Science Collaboration, 2015].

The six named failure modes, renamed with the `CC-` prefix:

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-E1	The arrival read as a verdict	Outcome fixation; the return graded rather than differenced	**none**; the remedy is the forced two-column subtraction
CC-E2	The hall of one voice	Listening arranged so that only agreement can return	Lorenz et al. [2011], Bikhchandani et al. [1992] establish that correlated sources stop carrying information

No.	Failure	Mechanism named by the source	Support in this bibliography
CC-E3	The reply that outran the reading	Impulsive response; the practitioner becomes their own noise source	Sterman [1989] on delayed feedback and misjudgement
CC-E4	The transform taken personally	Attributing the medium's transform to malice or to self	**none**
CC-E5	The forged return	Promoting an undeclared channel to an observation after the fact	Simmons et al. [2011], Gelman and Loken [2013] on the flexibility this exploits
CC-E6	Speaking through another's life	Imposition, and the response it purchases	**none** for the mechanism; the two-ledger rule of Section 5.4 is the framework's own

CC-E2 is worth marking because the corpus prices it exactly elsewhere: agreement between sources that share their premises is not evidence but repetition, and a set of aligned viewpoints has an effective count of one however many members it has. CC-E5 is the failure the framework guards against by pre-declaration, and the guard is placed upstream of the temptation, which is the correct place for it.

4.0.6 6. Category violation

6.1 A classification is a projection

The framework's opening move is a claim about filing systems: a scheme has fewer dimensions than what it files. A catalogue is a sequence; a form is a finite grid of yes-or-no boxes; a taxonomy is a tree, and a tree forbids the one thing living systems do constantly, which is for two branches to touch.

The framework states the consequence as a geometry. Filing is a **projection** of a higher-dimensional object onto a surface low enough to administer, and a projection is not a lie but it does discard. Most objects project into the interior of a single box and file without loss; the framework's estimate is that this is the ordinary case and that the scheme is therefore not a defect but the reason schemes exist. Some objects, however, carry a dimension the scheme does not have, and their projection lands on the boundary between two boxes and stays there.

This is not the framework's discovery and the literature it belongs to is in this corpus. Objects that inhabit several communities of practice at once, satisfying the informational requirements of each while being differently constituted in each, are **boundary objects**, and they are the standard analytic device for exactly this situation [Star and Griesemer, 1989]; the general study of what classification systems do to what they classify, and of what falls between their categories, is a developed field [Star and Ruhleder, 1996]. The framework's projection geometry adds an image to that literature and does not add a result to it, and this paper says so rather than presenting the geometry as new.

Two further external results bound the material. A scheme that makes a situation legible in order to administer it can destroy the local variety the situation was actually running on [Scott, 1998] — which is the cost side of the projection, and the framework does not price it. And a classification applied to people alters the people classified, so that the referent moves and the scheme's own accuracy decays [Hacking, 1995] — which the framework does not mention at all, and which is the single most relevant external result to a doctrine about the gaps in classification schemes.

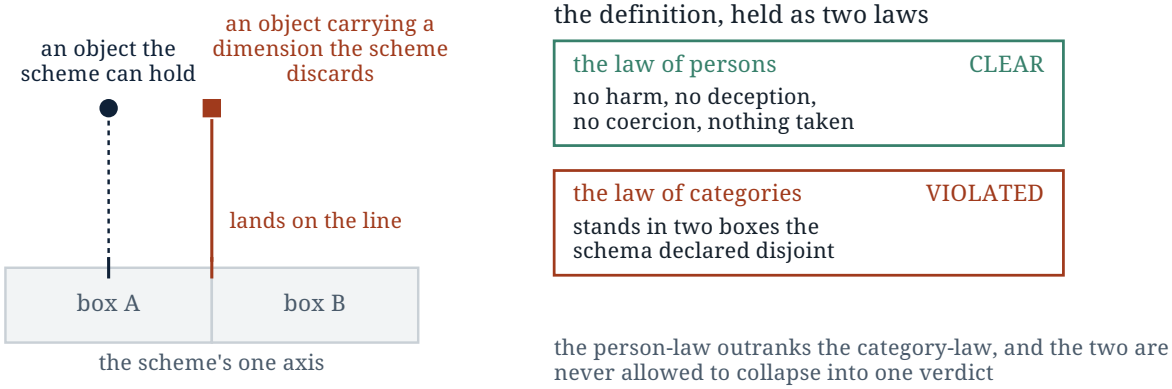

Figure 4.4: **A category is a projection, and a category violation is an object whose projection lands on a boundary.** Schematic; no plotted quantity. The left panel is the source's own construction: filing discards a dimension, most objects project into the interior of one box, and an object carrying a dimension the scheme lacks can land on the line between two boxes the scheme declared disjoint. The right panel is the definition, with the two laws the source insists on holding apart. Script: `figs/src/CCP-A04_fig04.py`.

The framework also applies its inherited postulate here, and this paper flags the application. It describes an object exceeding its category as being "in superposition" with respect to that category, and it flags the description as a postulated correspondence of shape rather than a claim about substrate. **The flag is correct and the correspondence is doing no work**: nothing in R6 or R7 requires it, and the verification chain in Section 10.2 does not consume it. It is reported once and used for nothing.

6.2 The definition, and the two laws (R6)

R6 is a definition and it is stated as a deliberate paradox held open.

> **A category violation is an object or act that is, at the same instant, not a crime and a crime.**

It is **not a crime by the law of persons**: no harm, no deception about anything owed, no coercion, nothing taken from anyone who had it. Run the tests by which a wrong is identified in law or in conscience and each returns no.

It is **a crime by the law of categories**: it stands in two boxes a scheme declared disjoint, and in doing so it falsifies the scheme's implicit promise that its boxes tile the world without overlap or gap.

The framework's instruction is that **neither half may be allowed to dissolve the other**, and that the reader's temptation at this point is to collapse the paradox by deciding the object is really innocent (so the word "crime" is a provocation) or really guilty (so the innocence is an excuse). Both collapses are refused.

The framework then ranks the two laws, and the ranking is the result's actual content: **the law that protects persons is the law the other law exists to serve.** A classification scheme is a tool for coordination — so that things can be found, remembered and handed on — and where the two laws part company, the person-law governs and the category-law is revealed as a convenience rather than a moral fact.

This ranking is a normative claim and it is not established by anything. It is a position, and a defensible one, and it is labelled here as a position. What can be said in its favour from this corpus's own material is that a scheme is a measurement instrument and that an instrument's

classifications license only the operations its scale type permits [Stevens, 1946, Krantz et al., 1971]; an object exceeding a scheme's dimensions cannot be filed without loss, and treating the resulting file as a fact about the object is precisely the error the measurement literature names [Michell, 1997].

6.3 The diagnostic use, and what it cannot do

The framework's second claim about category violations is that they are diagnostic: the capacity to recognise one and the capacity to construct one are the same capacity, namely the ability to read along a dimension a given scheme discards. It draws the consequence that an object of this kind sorts observers without asking them anything, since an observer who reads only in the scheme's dimensions will file it correctly and be untroubled.

Two objections apply and are stated here rather than left to a reviewer.

First, the claim that recognition cannot be faked — the framework's phrasing is that one cannot cheat on a test one is unable to perceive — **is true only of a first encounter.** Any such object, once described, becomes an ordinary piece of information that can be learned and reported, and the framework's own third constraint (Section 6.4) concedes exactly this by declaring an explained instance spent. The diagnostic is therefore single-use per object and per observer, which sharply limits its practical value and which the framework does not state.

Second, the claim generalises a specialist's inability to see the perpendicular dimension into a property of specialisation as such. The organisational literature supports a weaker version — that an organisation which learns fast homogenises and destroys the variance that produced its own advantage [March, 1991] — and a stronger version is not established. The framework's account of specialisation is a restatement of its own gradient material and inherits its status.

A third point belongs here and it is the one that most limits the material's reach. **A selection device that identifies people by an unadvertised perceptual capacity is unauditable by construction**: it has no stated criterion, no rate of false identification, and no appeal. The engineering standard for a system whose function must be trusted is the opposite of what this device requires — a system's integrity should not depend on any part of it being hidden [Kerckhoffs, 1883, Saltzer and Schroeder, 1975]. That standard is cited here **against** the framework, because the framework's third constraint makes concealment constitutive rather than incidental, and a reader should see the tension named.

6.4 The three constraints (R7)

R7 is the framework's own fence and it is the counter-result of this paper, because it refuses more than the definition licenses.

First: no coercive acquisition. The object may violate categories; it may not violate persons, and acquisition is the first place a person can be violated. The framework's formulation is exact and is preserved: a category violation that was taken — from a hand that did not release it, a place that was not opened, a will that was overridden — is not a category violation that happens to have been stolen. It is a theft, entire, and the doctrine laid over it is an aggravation rather than a mitigation, because it is the theft plus the claim that the theft was clever. **Category innocence is explicitly refused as a defence of acquisition.**

Second: possession by clean holding only. The positive half of the first. Where an object came to the holder cleanly, the fact that a second reading exists inside the same catalogue identity deprives no one of anything they had, were owed, or could name. The framework's supporting observation is the one it flagged three sections earlier and then uses: the second reading is superposed on the first and takes nothing from it.

Third: self-decoding. The meaning is not handed over, and the framework states this as a property of the object rather than a rule imposed on the holder: an instance explained by a fluent reader is spent, because the function of the object is to be readable only by an eye

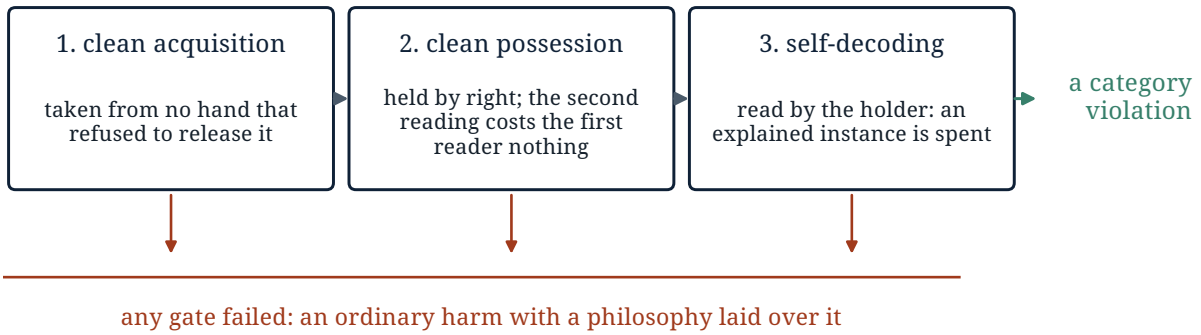

Figure 4.5: **The three constraints, as a gate sequence.** Schematic; no plotted quantity. The three conditions and their order are the source's own, as is the terminal state: failing any one converts the object from a category violation into an ordinary harm. The third gate is stated by the source as a property of the object rather than a rule imposed on the holder. Script: `figs/src/CCP-A04_fig05.py`.

reading in the discarded dimension, and a borrowed reading leaves the borrower exactly as they were.

The framework's summary of its own doctrine is that failing any one of the three converts the object into an ordinary harm with a philosophy laid over it, and that the doctrine therefore forbids moving any harm through a discovered gap in a scheme. That is the correct reading and this paper adopts it: R7 constrains R6 rather than extending it.

The framework closes by identifying its third constraint with the consent doctrine that governs the rest of the volume: a recognition cannot be installed in another person, and the attempt is coercion, which produces resistance rather than movement. That identification is internally consistent and it inherits the uncited status of the mechanism it rests on (Section 4.4).

4.0.7 7. Method: what kind of borrowing, what scale, and what is identified

7.1 Analogy discipline

Every borrowing in this paper is labelled at first use as a **derivation** (the system satisfies the borrowed result's premises), a **shared mathematical form** (the same equation governs both, with no claim that the source domain's physics applies), or an **analogy** (a suggestive correspondence with no formal warrant, legitimate as motivation and never as evidence). The labels are collected here.

Borrowing	Category	Warrant, and what is not claimed
Measurement collapse, for a spoken commitment (Sec. 4.1)	3 — analogy, and flagged as one by the source	Only the uncontroversial spine is taken — distribution, act, one outcome, conditioning — and the interpretive question is left open [Zeh, 1970]. No claim about substrate.

Borrowing	Category	Warrant, and what is not claimed
Superposition, for an object exceeding its category (Sec. 6.1)	3 — analogy, and doing no work	Flagged by the source as postulate. No result consumes it; the chain in Section 10.2 does not contain it.
The impulse response, for the reading rule (Sec. 5.2)	**1 for a linear channel, 2 for a social one**	Exact for a linear time-invariant system [Oppenheim et al., 1996]. Neither linearity nor time-invariance is established for a social channel; what transfers is the reading discipline, not the theorem.
Divergence, for "read the difference" (Sec. 5.2)	2 — shared form	A directed measure of how far one distribution sits from another [Kullback and Leibler, 1951]. No claim that the returns form a distribution or that any divergence has been computed.
Feedback and loop gain (Sec. 5.1)	2 — shared form	The mathematics of a controller governs any system with a report inside it [Wiener, 1948, Åström and Murray, 2008, Tustin, 1947]. No physical result is transferred.
Projection and dimension, for classification (Sec. 6.1)	3 — analogy, with a real literature beside it	The geometric image is the source's. The established treatment of the same phenomenon is boundary objects [Star and Griesemer, 1989] and the study of classification itself [Star and Ruhleder, 1996].

The general hazard is documented: a formal apparatus imported without the constraint that gave it content produces a defective copy [Mirowski, 1989]; laws hold within shielded arrangements rather than universally, so importing a law's form is not importing its scope [Cartwright, 1999]; behaviour at one scale is not derivable from the laws governing the parts [Anderson, 1972]; and the field this corpus's title claims membership of has been surveyed and bounded, with its vocabulary given definitions the corpus can be held to [Castellano et al., 2009]. The constructive standard for making such a borrowing checkable is to name the source-domain quantity, name the target-domain quantity, and state the correspondence [Vinković and Kirman, 2006]; the table above is this paper's attempt at it. **No conserved quantity is exhibited anywhere in this paper and none is claimed. No scaling or power-law claim is made**, so the procedure that would be binding on one is not run, and its absence here is a scope statement rather than an omission [Clauset et al., 2009].

The framework's own failure mode CC-U1 sets the test for this section: state the theorem, state the ordinary observer effect, and state the framework's conjecture, as three separate sentences. They are, respectively: that no state is sharp in both members of a conjugate pair,

watched or unwatched [Kennard, 1927]; that to measure a system one must interact with it, so the interaction enters the system's history; and that the uncertainty of a future affected by its own foreseeing is the same kind, which is P1 and is badged wherever it appears.

7.2 Scale type, and what a classification licenses

Two of this paper's results are about classification and one is about a rating, so the scale-type audit bears on all three.

R6's classification is nominal. A scheme that assigns objects to boxes without order supports statements of membership and non-membership and nothing else [Stevens, 1946]. The framework's central observation — that an object can satisfy the membership conditions of two boxes a scheme declared disjoint — is therefore a statement *about the scheme's own consistency* and requires no quantitative structure at all. **R6 is the one result in this paper whose measurement-theoretic standing is unproblematic**, and it is unproblematic precisely because it claims nothing numerical.

R4's difference is not licensed as arithmetic in general. Writing $y - x$ presupposes that the sent and returned signals live in a space where subtraction is defined. For a physical signal it does [Oppenheim et al., 1996]. For a returned letter, an offer or a silence it does not: the "difference" between a request for fine bindings and an offer of ledger repair is not a subtraction but a *comparison*, and no operation on it beyond comparison is licensed. **The reading rule is therefore retained as a comparison and demoted as an arithmetic**, which costs nothing, because the framework never computes with it either.

The tally counts of Section 3 are a ratio-scale count and are licensed. A count of recorded checks has a true zero and equal units by construction, so the comparison of 41 against 9 against 3 is legitimate arithmetic. What is *not* licensed is the inference from those counts to a general constant: three days by one participant, uncounterbalanced, with the outcome recorded by the participant.

The standing objection to the framework's wider programme applies here as everywhere: the strongest single criticism is that psychology assumes quantitative structure without testing for it [Michell, 1997], the formal test is conjoint measurement [Luce and Tukey, 1964] against the measurement-foundations standard [Krantz et al., 1971], and **it was not run.** Routes that would earn the arithmetic exist and are unused [Rasch, 1960]. This paper's exposure is smaller than its predecessors' only because most of its results are qualitative.

7.3 Identification, and the framework turned on itself

R4 and R5 derive from the reflexive loop, and the loop's status is fixed and inherited.

Written as an aggregate relation — a group's state influencing its members while the members constitute the group — $T(x) = W(x, M(x))$ is a linear-in-means reflexive specification, and **the endogenous social effect in such a specification is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is gathered [Manski, 1993]. The network route is closed by the same family of result, since influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. The available remedies are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation, the last having an explicit template in a discrete-choice model that states the conditions under which its interaction parameter is econometrically identified [Brock and Durlauf, 2001]. **This paper adopts none of them.** R4 and R5 are therefore **modelling positions rather than identified empirical results**, and every downstream paper citing them inherits that status.

The consequence is specific and constrains the framework's own procedure. The recording procedure of Section 5.6 produces a within-subject observational record of returns following an intervention the subject chose. **No causal reading of that record is available**, because

the subject's decision to send is not independent of the state of the channel; whatever association appears between a sent signal and a returned one is confounded by the reasons the signal was sent when it was. That is not a defect of the record-keeping, which is good; it is a limit on the inference, and it is stated here because the framework does not state it.

That reflexivity of this shape occurs at all is separately documented, and the documentation is the existence proof the framework otherwise lacks [MacKenzie and Millo, 2003], with the closest existing named doctrine supplying the concept without an equation [Soros, 2013]. That literature supplies existence, not identification.

The framework turned on itself. The framework asserts that a system changes its behaviour when modelled and observed. Applied consistently, that assertion falls on its own procedures: a person who has read this material and then keeps a two-column record is not the same observer as one who has not, because the decision rules the record captures are responses to the environment the model describes [Lucas, 1976]. The position taken here, stated so that it can be held against the paper: **no stability of this framework's effects under its own dissemination is claimed, and no result in this paper depends on any.** Three consequences are accepted. The tally counts of Section 3 are not transferable to a practitioner who has read the selection rule in advance. A before-and-after design on a single practitioner is confounded by construction. And R1's own mechanism, if it operates, operates differently on a speaker who knows why they are being asked to speak aloud — which makes H1's spoken-versus-silent comparison harder to run than it looks, and this paper says so rather than proposing it as though it were easy.

4.0.8 8. Results

8.1 Definitions and constraints fixed. D1 (the performative), D2 (the reading rule), D3 (category violation) and C1 (the three constraints) are stated in the form the remaining papers cite. None is a finding. C1 in particular is a constraint on a doctrine's domain and is not falsifiable, and it is labelled as such rather than presented as a result.

8.2 Results established by derivation. R4's core is established **for a linear channel**, where the transform is the channel's complete characterisation [Oppenheim et al., 1996]; the transfer to a social channel is a shared form and is not established. R5 is established as a bookkeeping rule: a missing observation is a datum with two readings, and the provision for an undecided entry is what makes it honest. R6 is established as a definition and its scale-type standing is unproblematic (Section 7.2).

8.3 Results established by construction, on uncited mechanisms. R1, R2 and R3 are the framework's specifications, and **all three rest on mechanisms this corpus cannot cite.** R1 rests on three of them; R2 is an entailment of the first of the three; R3's mechanical limb rests on a fourth. This is stated here as a result because it is the most important thing this paper found: the section of the framework most often quoted downstream is the section with the least support in the corpus's own bibliography.

8.4 Hypotheses tested. None. H1 through H5 are stated in falsifiable form and none is tested here. No dataset was collected. H4 is true by construction in the domain it is borrowed from and untested in the domain it is applied to. This is reported in the same plain language a positive result would receive: **the five hypotheses this paper states stand untested, and the paper that states them supplies no evidence for any of them.**

8.5 One measurement is reported, with its design flaws. The three-card carriage procedure returned 41, 9 and 3 tallies at fine, middle and coarse resolution, with the middle card's nine sorting 7 to 2. **That is a real measurement of a real quantity and it is worth nothing on its own**: one participant, three days, no counterbalancing, no blinding, and the outcome recorded by the person being measured. It is reported because the design would cost nothing to repair and because a corpus that reports a weak measurement honestly is in a better position than one that reports none.

8.6 Reproduction of the corpus's own arithmetic. Three numerical claims carried by this paper's internal citations were recomputed and all three reproduce.

- The vehicle-cost comparison: at 240 million units of value, 5.0 basis points is 120,000 and 35 basis points is 840,000, an annual difference of exactly 720,000 as printed [Curzi, 2026]. **Reproduced exactly.**
- The concentration chain printed in the corpus with its own arithmetic error left visible: $1/0.764992 = 1.307203$ and $\ln(1.307203) = 0.267890$, both as printed [Curzi, 2026]. **Reproduced exactly.** That paper's practice of printing an error and correcting it in place is the practice this paper follows in Section 8.5 and that the preceding paper in this series follows for a discrepancy it could not resolve.
- The audit distribution: seven mappings, two splits, one rendering and three rejections sum to thirteen entries as stated [Curzi, 2026]. **Reproduced.**

4.0.9 9. Discussion

9.1 What follows

Three consequences follow and they are this material's genuine yield.

The first is that **a reading rule can be right while its mechanism is unsupported.** R4's instruction — record the sent, record the returned, read the deviation — converts a verdict into an observation, and that conversion is defensible as bookkeeping whether or not any account of why deviations are informative survives. The framework says this about its own instruments in Section 5.5, and it is the best sentence in the material: instruments were chosen that survive the doctrine failing.

The second is that **a null result is a datum and needs a taxonomy.** R5's two readings, plus the provision for an undecided entry, is a better treatment of missing data than most qualitative practice manages, and it is directly transferable: any record of solicited responses should classify its silences rather than dropping them.

The third is that **a doctrine's constraints can be its content.** R7 refuses more than R6 licenses, and the refusals are specific: acquisition is fenced first, the harm-transport reading is forbidden outright, and the third constraint is stated as a property that makes the object self-limiting. A doctrine whose net effect is to narrow what its own definition permits is unusual and is worth marking as such.

9.2 What does not follow

That an utterance can constitute rather than describe does not establish that a self-addressed utterance does. That a transform characterises a linear channel does not establish that a deviation characterises a person. That a classification scheme has gaps does not license anything being carried through them — and the framework agrees, which is R7.

Two further non-implications are worth stating. First, **the diagnostic claim of Section 6.3 is single-use and unauditable**, and a selection device with no stated criterion and no false- identification rate is not an instrument in any sense this corpus should endorse; the engineering standard is the opposite [Kerckhoffs, 1883]. Second, **the framework's accuracy about physics is not evidence for its psychology.** The material states the borrowed results better than most popular accounts and declines to adjudicate what physicists have not settled. That accuracy is a virtue of the exposition, and a carefully stated premise is not a warrant for an unlicensed extension.

9.3 Relation to the corpus

The results fixed here are consumed downstream in specific ways, and three upstream results fix what they may be. The reflexive loop $T(x) = W(x, M(x))$, with the self-fulfilling prophecy identified as a fixed point of the composition of seeing and responding, is fixed in the founding paper of this series and is what R4 and R5 are read off [Curzi, 2026]. The scoring rule that

weights a branch by its accumulated resistance is the instrument this paper's commitments are selected with, and this paper inherits its demotion: the weight is an ordering and not a likelihood [Curzi, 2026]. And the self-reading gauge — that the distance remaining to a fixed point is bounded by the size of the last correction scaled by $q/(1-q)$ — is the instrument the recording procedure's weekly difference approximates without the bound [Curzi, 2026], which is worth stating precisely: **the framework's weekly subtraction is the gauge without its constant**, and it inherits none of the guarantee.

Four results elsewhere bound what this paper may claim. The corpus's evidence-versus-precedent distinction bounds what R4's accumulated readings can be made to do: an evidence column carries what could have come out otherwise, a precedent column carries only that something was independently arrived at and preserved, and two sources agreeing does not double the evidence when only one of them is evidence [Curzi, 2026w]. Its survivorship arithmetic prices the failure mode CC-E2 exactly, giving a surviving accuracy of 7.9 per cent where failures were invisible against 94.5 per cent where they were visible — a twelvefold difference produced by the filter alone [Curzi, 2026w]. The corpus's four failure classes for a claimed channel — no channel; a real channel with insufficient gain; a correct result extrapolated to the wrong magnitude; and a system unresponsive at this input size — are the diagnostic grid R5's two readings are a special case of [Curzi, 2026ac]. And the corpus's belief postulate is the template R1's badge should have followed: a magnitude form with a forbidding clause, $E = G \cdot B + \varepsilon$ with $G = 0 \Rightarrow E = 0$ for all B, badged and paired by explicit correspondence with a zero-efficiency case [Curzi, 2026ab]. **R1 has no forbidding clause**, and Section 11 records that as a defect.

Three further results are cited for the discipline they model. The corpus's determination result — that a set closed under negation has a resultant of exactly zero, verified at four sizes, and that an orthogonal set's mean direction shrinks as $1/\sqrt{N}$ — is the arithmetic behind CC-E2 and the reason a hall of agreeing sources carries nothing [Curzi, 2026ad]. The corpus's audit of a traditional operation set against a parameter model, returning seven mappings, two splits, one rendering and three rejections over thirteen entries, is the model for the audits this paper runs on its own material [Curzi, 2026]. And two refusal results bound the category material: that repetition cannot move a fixed point, since the equilibrium expression contains no time index [Curzi, 2026], and that an open problem should be stated formally rather than claimed as a result — no established mechanism produces a response depending on a symbol string as an *order* rather than on permutation-invariant functionals [Curzi, 2026]. The seam of Section 5.4 is a problem of that kind, and this paper states it as one.

4.0.10 10. Verification

This section is not a summary. It decomposes the paper's results into steps small enough to check one at a time, and labels each `ARITHMETIC`, `DEFINITION`, `CITED` (with the key) or `POSTULATED`. The razor is applied: any postulate whose removal leaves the results standing has been removed.

10.1 Postulates

- **P1 (DEFINITION).** An utterance is performative with respect to a speaker when it is the act it names. *Check:* D1.
- **P2 (POSTULATED).** A voiced position exerts pressure on the speaker's subsequent conduct toward consistency with it. *Check:* **not checkable from within this corpus and not checked; no entry supports it.**
- **P3 (POSTULATED).** A person infers their own dispositions partly from observing their own conduct, including their own speech. *Check:* **no entry.**
- **P4 (POSTULATED).** A voiced commitment re-prices later defection. *Check:* **no entry.**
- **P5 (ARITHMETIC).** A statement whose truth condition lies in the future is not contradicted by a present unchanged from yesterday. *Check:* redo it; it is a fact about the

statement's truth conditions and not about people.

- **P6 (POSTULATED).** A future voiced over a person without their request produces movement away from it, scaling with detected pressure. *Check:* **no entry.**
- **P7 (DEFINITION).** For a channel returning $y = T(x)$, the reading is $y - x$. *Check:* D2.
- **P8 (CITED: `oppenheim1996signals`).** For a linear time-invariant channel, the response to a known input characterises the channel completely; a channel returning its input unchanged is the identity and carries no information about itself.
- **P9 (POSTULATED).** A social channel's deviation can be read as a characterisation of the channel. *Check:* **not checked**; the framework itself badges this as a craft claim.
- **P10 (DEFINITION).** An absent return is entered with one of two readings, or with both. *Check:* D2 extended; a bookkeeping rule.
- **P11 (DEFINITION).** A classification scheme has fewer dimensions than what it files, so filing discards. *Check:* immediate for any finite scheme over an infinite domain.
- **P12 (DEFINITION).** A category violation harms no person and violates a scheme's disjointness. *Check:* D3.
- **P13 (POSTULATED, normative).** Where the law of persons and the law of categories conflict, the person-law governs. *Check:* not checkable; a normative position, labelled as one.
- **P14 (DEFINITION).** The three constraints: clean acquisition, clean possession, self-decoding. *Check:* C1; constraints on a domain, not claims.

Postulates dropped as unnecessary: the measurement-collapse analogy of Section 4.1, the superposition description of Section 6.1, the bodily-verdict mechanism of Section 4.5, the attentional-cost mechanism behind the destruction rule, the substitution effect behind the quarantine rule, and the humour mechanism of Section 4.6. Each was tested for load and carries none — every result below survives its removal — and all are reported in the text and used for nothing.

10.2 The compounding chain

Each line consumes only the outputs named on its left.

```
P1 + P2 + P3 + P4 -> R1   a spoken commitment is a performative
                          aimed at the speaker, on three
                          converging mechanisms              POSTULATED
                          (all three mechanisms uncited)
P5                -> L1    a future-tense commitment is not
                           contradicted by an unchanged day  ARITHMETIC
L1 + P2           -> R2    therefore it generates no

                                                             (normative)
P14               -> R7    the three constraints, any failure
```

```
of which converts the object into
an ordinary harm                    DEFINITION
```

What this chain shows, stated plainly. R4 is the only result in this paper CITED at its load-bearing step, and it is cited for a *linear* channel; its transfer to a social channel passes through P9, which the framework itself badges as a craft claim. R1 — the result the corpus cites most from this paper — passes through three postulates, none of which this corpus can support. R2 inherits P2. R3's ethical limb is a definition and its mechanical limb is a postulate. R5, R6 and R7 are DEFINITION throughout, which is exactly right for them: they are bookkeeping rules and a definition with constraints, and definitions are not weakened by being called definitions.

A chain whose steps are mostly DEFINITION and POSTULATED is not a proof, and this one is mostly DEFINITION and POSTULATED. What it is instead is a specification of the bill: P2, P3, P4 and P6 are four psychological claims, all four testable, all four absent from this corpus's bibliography, and settling them would decide the standing of R1, R2 and R3b. P9 is a fifth, testable in principle against any archive of dated correspondence, and it decides how much of R4 transfers. **Five claims. None was tested.**

One structural defect is recorded here rather than in the text. The corpus's own template for a badged postulate attaches a *forbidding clause* — a condition under which the postulate's mechanism is stipulated to produce exactly nothing [Curzi, 2026ab]. R1 has no such clause: as stated, there is no condition under which a spoken commitment is asserted to do nothing at all, which makes it harder to falsify than the corpus's own standard requires. The natural candidate — that a commitment whose content the speaker cannot begin occupying in any fraction today produces no effect — is available from Section 4.3's boundary and is **not** stated by the framework as a forbidding clause. This paper records the gap and does not fill it, since filling it would be new work rather than conversion.

10.3 The checks a reader should run first

1. **Redo the tally comparison.** 41, 9 and 3, with the middle card's nine sorting 7 to 2. Confirm that $7 + 2 = 9$ and that the selection rule as stated selects the middle card. Figure 1 plots all four numbers and the script asserts the sort exhausts the card.
2. **Redo the basis-point arithmetic.** At 240 million, 5.0 bp is 120,000 and 35 bp is 840,000, so the difference is 720,000 [Curzi, 2026]. It agrees.
3. **Redo the concentration chain.** $1/0.764992 = 1.307203$ and $\ln(1.307203) = 0.267890$ [Curzi, 2026]. Both agree to the printed decimals.
4. **Check the audit distribution sums.** $7 + 2 + 1 + 3 = 13$ [Curzi, 2026].
5. **Check that R1's three mechanisms carry no citation anywhere in this paper.** They do not, in Section 4.2, in Section 10.1, or in the Conclusion, and Section 11.3 lists them.
6. **Check that the analogy table in Section 7.1 assigns category 1 to exactly one entry**, and that the entry is qualified by the domain in which it holds.
7. **Check that no sentence in this paper describes R4 or R5 as identified.** Section 7.3 states that they are modelling positions and the Conclusion repeats it.

10.4 Dimensional audit

Symbol	Meaning	Dimension	Unit	Status
x	signal sent	none assigned	none	defined; an element of an unspecified set
$y = T(x)$	signal returned	$[x]$	none	defined by the channel

Symbol	Meaning	Dimension	Unit	Status
$y - x$	the reading	$[x]$	none	**defined for a linear signal space; a comparison and not a subtraction for the social case (Sec. 7.2)**
T, W, M	maps on states	—	—	defined; inherited from the founding paper of this series
tally count	recorded checks in one day	dimensionless	counts	**measured**; ratio scale with a true zero
resolution class	fine / middle / coarse	none assigned	**an ordered three-level category**	defined by the procedure's own construction rules
lean / grip	class of a recorded check	none assigned	**nominal, two categories**	defined; assigned by the participant
box membership	a scheme's assignment	none assigned	**nominal**	defined; R6 concerns consistency of assignment, not magnitude
$\sigma_x, \sigma_p, \hbar$	quantum spreads and reduced Planck constant (quoted)	m; kg·m·s^{-1}; J·s	SI	quoted from physics; not quantities of this framework
basis point (quoted)	annual charge per unit of value	dimensionless	10^{-4}	quoted from `ccp:CCP-053`; the arithmetic is reproduced in Sec. 8.6

Does the central relation balance? $y - x$ balances if and only if x and y inhabit a common space in which subtraction is defined. **For the engineering case they do; for the social case the source does not say what space its signals inhabit, and this paper does not supply one.** The honest entry is that the operation is a comparison, and Section 7.2 demotes it accordingly.

Does the tally measurement balance? Yes, and it is the only quantity in this paper that does without qualification. A count of recorded checks is dimensionless with a true zero, and 41, 9 and 3 are directly comparable. What does not follow is any inference to a constant, for the design reasons in Section 3.1.

A quantity with no operational unit is entered as having none. No unit was invented for a commitment's binding force, for the wear on a return, or for a scheme's discarded dimension, and none should be inferred from the fact that the tally counts are well behaved.

10.5 Limits and boundary behaviour

- **Deviation $\to 0$ (a perfect return).** The channel is the identity and reports nothing about itself. R4 is exact at this limit and the limit is the argument (Section 5.2).
- **Deviation $\to$ everything (no recognisable relation between sent and returned).** The reading rule is silent: with no correspondence there is no difference to take. The framework does not treat this limit, and it is the common case in a slow or crowded channel. **This is a gap in R4 and it is recorded as one.**
- **Listening window $\to 0$.** Every return is classified "far" and the record carries no information. **Listening window $\to \infty$.** No classification is ever made and the procedure never terminates, which the framework names as a real failure — practitioners who listen indefinitely because listening excuses them from acting.
- **Number of declared channels $\to$ all channels.** Pre-declaration ceases to constrain anything and CC-E5, the forged return, becomes unpreventable. The framework's guard is scarcity of declared channels and it does not state a bound.
- **Audience size $\to 0$.** The framework's prescribed condition. **Audience size $\to \infty$.** Its predicted failure, CC-C1. The framework predicts a monotone relation between audience and substitution and supplies no turning point; whether one exists is untested and, given the public commitment evidence the framework itself concedes, a turning point is the more plausible shape. **The framework's monotone reading is not supported and this paper does not adopt it.**
- **Scheme dimensions $\to$ the dimensions of what it files.** No object can violate the scheme, R6 is vacuous, and the scheme is unadministrable, which is why schemes discard. **Scheme dimensions $\to 1$.** Almost every object violates, R6 is trivial, and the diagnostic of Section 6.3 sorts nobody. The doctrine has content only in the intermediate regime and the framework does not say where its boundaries lie.
- **An explained instance.** R7's third constraint sets this limit itself: the object's function is destroyed by explanation, so the doctrine is self-limiting by construction and its diagnostic is single-use.

On invariance. The reading rule is invariant under any relabelling of the signal set that preserves the correspondence between sent and returned, which is a consequence of the construction rather than a finding, and it has been checked at no scale because nothing here is measured except the tally counts. **No conserved quantity is exhibited.**

4.0.11 11. Limitations

11.1 The paper's most-cited result rests entirely on uncited mechanisms. R1's three mechanisms — consistency pressure, self-perception, and the re-pricing of defection — have no supporting entry in this corpus's external bibliography, and R2 is an entailment of the first of them. This is stated first because it is the paper's principal exposure. **Falsified by:** a spoken-versus-silent comparison at matched content showing no difference, which would remove R1 and R2 together and is cheap to run.

11.2 R1 has no forbidding clause and the corpus's own standard requires one. Section 10.2 records the defect. As stated, R1 names no condition under which a spoken commitment does nothing, which makes it less falsifiable than the corpus's own badged postulate elsewhere [Curzi, 2026ab].

11.3 Claims with no supporting literature in this corpus's bibliography. Listed individually, because a reviewer will find them and finding them first is the point.

- *Consistency pressure following a voiced position (dissonance).* R1's first mechanism and R2's premise. **No entry.**
- *Self-perception: a person infers their dispositions from observing their own conduct.* R1's second mechanism, and the reason the framework requires the commitment to be voiced rather than held. **No entry.**

- *Commitment devices: a voiced commitment re-prices later defection.* R1's third mechanism. **No entry.**
- *Pressure on a perceived freedom produces counter-movement (reactance).* R3's mechanical limb and failure modes CC-C4 and CC-E6. **No entry.** Retained uncited; R3's ethical argument stands without it.
- *Announced identity goals substitute for enactment.* The entire warrant for the quarantine rule (Section 4.7) and for CC-C1. **No entry.**
- *Unfinished items hold attention and levy a standing cost.* The warrant for the destruction rule (Section 4.5). **No entry.**
- *Bodily verdicts on prospects precede articulate reasoning.* The mechanism behind the read-aloud taxonomy (Section 4.5). **No entry**, and the source itself notes the hypothesis has open questions.
- *Incongruity and its resolution as the structure of humour; laughter as a compression event.* Section 4.6. **No entry.**
- *The philosophy of performative utterances.* Section 4.1. **No entry**; the performativity literature in economics [Callon, 1998, MacKenzie, 2006] supports the general claim and not the self-addressed case.
- *Measurement reactivity, in the overdose form named by CC-U3.* **No entry**; McCambridge et al. [2014] bounds the nearest literature rather than supporting the claim.
- *Anchoring, availability, motivated reasoning, apophenia, personalisation.* The mechanisms named in the three failure catalogues. **No entry for any of them.**

That is **eleven classes of unsupported claim**, more than in either preceding paper of this series. A reader should treat the failure catalogues and the mechanism triad as the framework's clinical folklore, usefully organised, and not as findings.

11.4 The one measurement reported is a weak design. Section 3.1 states the flaws: a single participant, three days in a fixed order so that resolution is confounded with day number, no blinding, and the outcome recorded by the person being measured. **Counterbalancing would cost nothing and was not done**, and no result in this paper should be read as evidence about the magnitude of the effect.

11.5 Parameters and classifications chosen rather than measured. The three resolution classes are defined by construction rules the source chose (one number *or* one date; one place *or* one name), and nothing establishes that those rules produce equally spaced levels or that any other partition would behave the same way. The lean/grip classification is assigned by the participant without a stated rubric, without a second rater, and without any reliability estimate.

11.6 The reading rule is demoted from arithmetic to comparison. Section 7.2 states the ground: subtraction requires a space where subtraction is defined, and the source does not say what space its signals inhabit. Nothing in the paper computes with the difference, so the demotion costs nothing — but a downstream paper that treats $y - x$ as a quantity would be doing something the dimensions forbid.

11.7 R4's transfer premises are unverified. Linearity and time-invariance make the engineering result exact and are not established — and are implausible — for a channel made of people. What transfers is the reading discipline and not the theorem, and Section 5.2 says so.

11.8 R4 has a gap at the limit where no correspondence exists. Section 10.5 records it: where a return bears no recognisable relation to anything sent, the rule is silent, and that is the common case in a slow or crowded channel. The framework does not treat it.

11.9 The diagnostic use of category violation is single-use, unauditable, and cited against. Section 6.3 gives the argument. A selection device with no stated criterion, no false-identification rate and no appeal is not an instrument this corpus should endorse, and the engineering standard runs the other way [Kerckhoffs, 1883, Saltzer and Schroeder, 1975].

11.10 The seam where a second will enters the loop is open and the framework says so. Section 5.4 reports the concession. This paper does not close it either, and no result here should be read as settling the case in which a return is obtained through another person

without their word.

11.11 The person-law ranking is a normative position. Section 6.2 labels it. It is defensible and it is not established by anything, and R6's usefulness as a definition does not depend on it.

11.12 Nothing here is identified. As an aggregate specification, the reflexive loop's endogenous effect is not identified from observational data [Manski, 1993], and the network route is closed by the generic confounding of influence with selection [Shalizi and Thomas, 2011]. This paper adopts no remedy and therefore states R4 and R5 as **modelling positions rather than identified empirical results** (Section 7.3). **Resolved by:** a randomised or partial-population design, or a defended stipulation in the manner of Brock and Durlauf [2001].

11.13 The framework's own effects are not exempt from its own thesis. By the Lucas critique, tallies and response patterns recorded by a practitioner who has read the selection rule are not comparable to those recorded by one who has not [Lucas, 1976]. No stability is claimed and no result here depends on any.

11.14 Case material is illustrative. The worked cases in Sections 3.1 and 5.6 are single, self-reported, retrospective accounts drawn from the source manuscript. They illustrate what the procedures return and establish nothing about whether the procedures work [Ioannidis, 2005, Open Science Collaboration, 2015].

11.15 No hypothesis was tested and no data were collected. H1–H5 stand. The discipline that would make a later confirmatory attempt credible is specified and not exercised [Nosek et al., 2018, Simmons et al., 2011], and H1 in particular is complicated by the framework's own reflexivity (Section 7.3), which this paper states rather than proposing the test as though it were straightforward.

4.0.12 12. Conclusion

The seven results are stated below in the exact form in which the rest of the corpus cites them. Downstream papers should quote this text rather than paraphrase it.

R1. A spoken commitment is a performative aimed at the speaker, supported by three converging mechanisms: consistency pressure following a voiced position, self-perception from overheard testimony, and the re-pricing of later defection. **All three mechanisms are uncited in this corpus's bibliography, and R1 is therefore a specification resting on unsupported psychology rather than an established result.**

R2. The present-tense requirement is calibration and not etiquette: a future-tense formulation is consistent with a day identical to yesterday, so it generates no dissonance and the consistency mechanism has nothing to act on. **R2 is an entailment of R1's first mechanism and inherits its status.**

R3. No future is to be voiced over another person's life without their word, and the prohibition covers the benevolent case. **The ethical argument stands on its own and requires no literature. The framework's further claim — that imposed futures are registered as pressure and manufacture their own refutation — has no supporting entry in this corpus's bibliography and is reported uncited.**

R4. The feedback reading rule: record what was sent, x, and what returned, $y = T(x)$, and read the difference $y - x$, since a channel that returns a signal unchanged reports only that nothing in it could touch the signal. **Exact for a linear channel, where the transform is the channel's complete characterisation; a shared mathematical form and not a derivation for a social channel, and a comparison rather than an arithmetic difference in that case.**

R5. A null return is a datum with exactly two readings — a distance beyond the listening window, or a medium that absorbs the frequency entirely — and may be entered under both while undecided. It is not an absence of evidence.

R6. A category violation is an object or act that harms no person — nothing taken, nobody deceived about anything owed, no will overridden — while standing in two categories a scheme declared disjoint. The law of persons and the law of categories are held apart and

neither is allowed to dissolve the other; where they conflict, the person-law governs. **That ranking is a normative position and is labelled as one.**

R7. Three constraints govern the doctrine: no coercive acquisition, possession by clean holding only, and self-decoding, since an explained instance is a spent one. Failing any one converts the object into an ordinary harm with a doctrine laid over it.

Counter-result. The category material constrains far more than it licenses. Category innocence is explicitly refused as a defence of acquisition; the doctrine forbids moving any harm through a discovered gap in a scheme; and the framework concedes on the record that the case in which the feedback loop runs through another person's will is an unsettled seam it does not close. To that this paper adds two findings the framework does not state: the diagnostic use of a category violation is single-use per object and unauditable by construction, and R1 carries no forbidding clause of the kind the corpus's own standard requires.

What is established, then, is one theorem of signal analysis about linear channels, one bookkeeping rule for missing observations that is better than most qualitative practice manages, one definition whose measurement-theoretic standing is unproblematic because it claims nothing numerical, and a set of constraints that narrow the definition rather than extending it. What is not established is any of the five hypotheses, any of the four psychological mechanisms on which R1, R2 and R3's mechanical limb rest, or the transfer of the reading rule from a linear channel to a social one. The paper's contribution at this stage is to name the five testable premises whose settlement would decide the matter — consistency pressure, self-perception, defection re-pricing, counter-movement under imposition, and the readability of a social channel's deviation — and to note that all five are testable, that four of them are cheap, and that none was tested.

4.0.13 13. Declarations

Data and code availability. No external dataset was collected for this paper and none exists. The worked cases reported in Sections 3.1 and 5.6, including the tally counts and the reproduced record card, are drawn from the source manuscript's own record and are not a dataset. All figures are generated by the scripts named in their captions (`figs/src/CCP-A04_fig01.py` through `figs/src/CCP-A04_fig05.py`), which import the shared style module `lib/figstyle.py`; every number plotted is quoted from the source text identified in the script's docstring. Two of the five scripts contain assertions that fail if the numbers they plot cease to agree with the source claims they are drawn from.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures, and the text.

Ethics. No human-subjects research was conducted for this paper. No personal data were collected or processed. The worked cases in Sections 3.1 and 5.6 are drawn from the source manuscript, are presented under the descriptions they carry there, and are illustrative rather than evidential; they were not gathered under a research protocol and are not offered as one. Nothing in this paper is clinical advice. Sections 4.4 and 6.4 report constraints the framework places on its own procedures — that no future is to be voiced over another person's life without their word, and that nothing may be acquired coercively — and this paper reports both as constraints on the method rather than as endorsements of the techniques they constrain. Section 6.3 states expressly that the framework's proposed use of a category violation as a selection device is unauditable and is not endorsed here.

Use of the ceremonial register. The source manuscript is in part an initiatory document. This paper analyses that register as an object of study and does not reproduce it; ceremonial names are reported only where they identify a construct this paper renames, and the source's own term for the object defined in R6 is reported once, in Section 1.3, because downstream papers refer to the material by it.

Chapter 5

Convergence and Its Dark Twin: The Contraction Mapping, the Audit of Arrival, and the Consent Law of Closure

Abstract. This instalment states the corpus's central theorem, its converse, and the audit and closure disciplines that follow. Banach's fixed-point theorem is stated exactly: a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any starting state, with the remaining distance shrinking geometrically. It then extracts the a posteriori bound the framework prizes above the theorem, $d(x_n, x^*) \leq (k^n/(1-k))\, d(x_0, x_1)$, in the practical form that distance to arrival is bounded by the last correction scaled by $q/(1-q)$, so that the size of a most recent revision is a self-reading gauge. The converse is stated with equal force: unit gain gives an isometry and so an orbit with no arrival, and gain above one gives an amplifier in which corrections sized to stale feedback arrive as new errors. Completeness is read as a failure condition: a foreseen state a life cannot contain is a hole in the space, and iteration toward it contracts forever and arrives never, which is the one failure mode invisible from inside the loop. Arrival is certified by audit rather than by feeling, on three instruments, a dated record predating arrival, at least three preserved discrepancies, and a geometrically shrinking sequence of corrections. Closure imposes three verdicts, a single-active-commitment rule, a consent law, and three conditions barring operation. Four hypotheses are stated in falsifiable form; none is tested here, and three claims the source treats as established are reported uncited because this corpus's bibliography contains no support for them.

Keywords: contraction mapping; a posteriori bound; divergence; reactance; completeness failure; hindsight retrofitting; consent; closure verdicts

Series: A. Foundations **Paper:** CCP-A05

5.0.1 1. Introduction

1.1 The question

A framework that tells a practitioner to iterate owes them three things it usually does not supply: a condition under which iteration arrives, a condition under which it does not, and

a test that distinguishes an arrival from the feeling of one. This paper supplies all three, and finds that the third is the hardest and the most often skipped.

The corpus's central theorem is Banach's fixed-point theorem. Its founding paper states the condition $d(T(x), T(y)) \leq k\, d(x, y)$ with $0 \leq k < 1$ and derives existence, uniqueness and geometric convergence from any starting point [Curzi, 2026]. That statement is exact and it is not the whole instrument. What an operator actually needs is not the guarantee but a gauge — something readable from inside the loop, before arrival, that reports distance to the fixed point. The theorem supplies one, in a corollary that is less famous than the theorem and more useful than it.

This paper asks: what does the contraction theorem license when a life is the space, what does its converse forbid, and what evidence can certify an arrival given that the machinery which rehearses a future is the same machinery that reconstructs a past?

1.2 What this paper contributes

Eight results are established or fixed here, labelled R1 through R8 and restated in the Conclusion.

R1 states Banach's theorem exactly: a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass. **R2** extracts the a posteriori bound $d(x_n, x^*) \leq \frac{k^n}{1-k}\, d(x_0, x_1)$ and reads it operationally: distance to arrival is bounded by the size of the last correction scaled by $q/(1-q)$, so the size of one's most recent revision is a self-reading gauge. **R3** states the honest converse: gain exactly one gives an isometry that orbits without arriving, and gain at or above one gives an amplifier whose corrections, sized to delayed feedback, arrive as new errors. **R4** states the stability rule that follows: a correction smaller than the observed difference can be wrong and still converge, while a correction larger than the difference can be right and still diverge, so restraint is a stability criterion rather than a virtue. **R5** reads completeness as a failure condition: a foreseen state the life cannot contain is a hole in the space, and iteration toward it contracts indefinitely while arriving never. **R6** specifies a three-instrument audit of arrival — a dated record predating arrival, at least three preserved discrepancies, and a geometrically decaying sequence of corrections — on the ground that a seamless match indicates a retrofitted record. **R7** states the closure discipline: exactly three verdicts (fulfilled, released, lapsed), one active commitment at a time, and a consent law forbidding a future voiced over another's path without their word. **R8** states the externality result as engineering: a fixed point requiring another party's displacement re-enters the loop as friction, raising the gain and converting a basin into a position that must be held.

The counter-result is stated with the same force. This paper refuses the certificate its own theorem appears to offer: a human life is not a metric space, nobody has measured the relevant contraction modulus, and the theorem therefore transfers as shape rather than as guarantee. It also holds that the feeling of recognition on arrival proves nothing, because the machinery that rehearses a future retrofits a past with equal fluency.

1.3 Register and sources

The source manuscript is written in two braided registers, one narrative and one analytic. This paper reports the analytic register; the narrative material is fictional exposition and is not reproduced. Ceremonial names are reported once, as objects of study, where they identify a construct that this paper renames. The material below corresponds to three of the source's twelve constructs — iteration, arrival, and closure — and is presented as one continuous argument because the three are one mechanism seen at three stages.

5.0.2 2. Hypothesis

The paper's claims divide into one theorem, three statements about that theorem's converse and corollaries which are also arithmetic, and four claims about human practice which are genuinely hypotheses. They are separated here, and the ones that cannot be falsified are labelled as definitions or postulates rather than dressed as hypotheses [Popper, 1959].

H1 — the gauge hypothesis. In a loop that is in fact contracting, the size of the most recent correction bounds the distance remaining, so an operator can read their own distance to arrival off their own record without seeing the destination. *Predicted:* across a series of iterations of any documented revision process, the observed remaining distance never exceeds $q/(1-q)$ times the last correction, once q is estimated from the ratio of successive corrections. *Falsified by:* a documented revision series in which corrections shrink at a stable ratio while remaining distance does not respect the bound — which would show the process was not the contraction the ratio suggested. *Status:* mathematically true of a contraction (Section 3.3); the hypothesis is that real revision series are contractions. **Not tested here.**

H2 — the divergence-signature hypothesis. A loop whose gain has risen above one signals it by alternation of correction sign before amplitude grows. *Predicted:* in records of failing iterative projects, sign alternation precedes amplitude growth by at least one pass, so it is available as an early warning. *Falsified by:* amplitude growth arriving without prior alternation, or alternation occurring at equal rates in converging and diverging series. *Status:* true of the modelled scalar recursion; the transfer to documented human projects is untested. **Not tested here.**

H3 — the residue hypothesis (the paper's sharpest empirical claim). A genuine prediction record disagrees with the outcome in inventory while agreeing in structure, so the count of preserved errors discriminates genuine foresight from retrospective reconstruction. *Predicted:* records made before an outcome contain at least three specific particulars the outcome contradicts; records reconstructed after an outcome contain fewer. *Falsified by:* prospectively dated records showing zero to two discrepancies at the same rate as retrospective reconstructions, in matched cases. *Status:* directly testable with existing preregistration archives, and **not tested here.** The threshold of three is a stipulation, not an estimate (Section 12.5).

H4 — the externality hypothesis. A fixed point requiring another party's uncompensated displacement raises the effective loop gain, because the displaced party becomes a second modeller inside W. *Predicted:* arrangements reached over an unconsenting party show rising maintenance cost over time, where structurally identical consented arrangements do not. *Falsified by:* matched consented and unconsented arrangements showing equal maintenance cost. *Status:* stated as engineering; **not tested here**, and the mechanism it invokes has no supporting entry in this corpus's external bibliography (Section 12.3).

D1 — contraction (definition). A map T on a metric space (X, d) is a contraction with modulus q if $d(T(x), T(y)) \leq q\, d(x, y)$ for all $x, y \in X$ and some fixed $q < 1$. Not most pairs. All of them, always, by at least that factor.

D2 — closure verdict (definition). Every commitment receives exactly one of three written verdicts: fulfilled, released, or lapsed. This is a stipulated taxonomy, not a finding, and its adequacy is a question about practice rather than about the world.

P1 — the transfer postulate. That a human life admits a state space which is complete under some metric, and a reflexive loop which contracts with a uniform modulus, is postulated wherever the theorem is applied to a life. It is not demonstrated anywhere in this corpus. This paper's principal methodological contribution is to keep saying so.

5.0.3 3. The theorem, and the corollary that matters more

3.1 Statement

Take a space of states — positions, drafts, situations; anything on which "distance between two states" means something and behaves honestly. Require the space to be **complete**: any sequence of states that bunches up ever more tightly must be bunching toward a state that is actually in the space. No holes where a limit ought to live.

Now take a map T that turns any state into a next state: feed in where you are, receive where the pass leaves you. Call T a **contraction** if there is a fixed fraction q, strictly less than one, such that for *any* two states the distance between their images under T is at most q times the distance between the originals.

Then Banach [1922] says exactly this and no more:

> A contraction on a complete space has exactly one fixed point x^* with $T(x^*) = x^*$, and iteration finds it from anywhere: start at any state whatever, apply the map again and again, and the sequence converges to x^* geometrically, so that after n passes the distance from the fixed point is at most q^n times a constant fixed at the start.

Each clause is earned, and it is worth seeing how. *Exactly one:* if two different states were each fixed, the map would have to shrink the distance between them by the factor q; but both are fixed, so that distance cannot change at all, and the only distance that both shrinks and stays the same is zero, so the two points were one point. *From anywhere:* the theorem asks nothing about where the iteration begins — not that it begins close, not that it begins wise. *Geometrically:* if q is one half, each pass halves the remaining gap, so ten passes put the gap under a thousandth of what it was.

The result is not exotic, and its oldest worked example predates the theorem by two millennia: the surveyor's rule for square roots. To find $\sqrt{2}$, guess anything — guess 1 — then repeat the correction *take the average of your guess and two divided by your guess.* The source prints the iterates $1,\ 1.5,\ 1.41666\ldots,\ 1.4142156\ldots,\ 1.4142135\ldots$ and observes that four passes carry a poor guess to six true figures. Each pass takes the error and roughly squares it away; the map contracts, the space is complete, and no cleverness in the starting guess would have bought more than one pass's head start. Figure 2 recomputes the same recursion and confirms the printed iterates digit for digit.

3.2 The premises, stated as premises

Two conditions carry the whole result and both are named here rather than assumed.

The map must contract. Every pass must actually shrink the gap, which means every revision must be taken from the world's returned difference and not from appetite, mood, or fashion. A revision taken from mood is a step of unknown direction; enough of them and the map is a stagger, and staggers have no theorem.

The space must be complete. The state converged upon must be a state the actual system can contain. This condition is usually treated as a technicality and it is not: its failure is a distinct and diagnosable mode, treated at length in Section 5.

And one honesty above the others, stated plainly so that no one can say the mathematics concealed it: **a human life is not a metric space, and no one has measured any operator's q.** The theorem is real; its transposition to a life is this corpus's, made because the shape is the same. What the transposition earns is not a certificate. It is a discipline of expectation with a mechanism in it — the knowledge of what would have to be true for arrival to be guaranteed — and therefore a checklist that can fail inspection and say where. That is worth more than encouragement and less than proof, and this paper does not confuse the two. The formal obstacle is not merely unmeasured: psychological similarity is asymmetric and violates the triangle inequality, so any d built from similarity judgements is not a metric at all [Tversky,

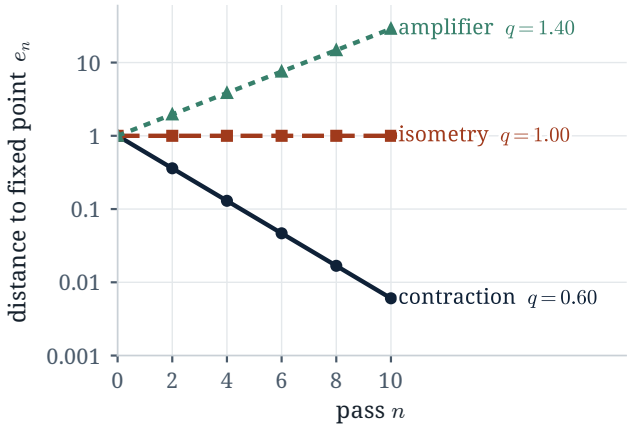

Figure 5.1: The three gain regimes, on the same axes. Modelled, not measured: the scalar recursion $e_{n+1} = q\,e_n$ with $e_0 = 1$ is the worst-case distance-to-fixed-point sequence a Lipschitz map of modulus q admits, with $q \in \{0.60, 1.00, 1.40\}$. Below unit gain the distance falls geometrically; at unit gain it neither falls nor grows, which is an orbit and not a plateau; above unit gain the loop manufactures error at the same rate the contraction would have removed it. Script: `figs/src/CCP-A05_fig01.py`.

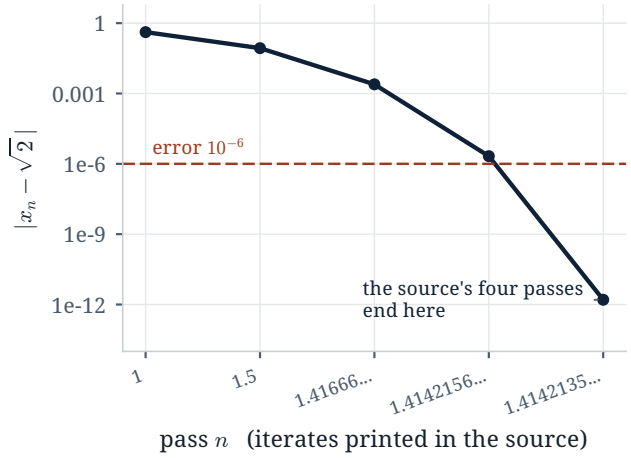

Figure 5.2: The source's own worked contraction, recomputed. Measured against the source: the recursion $x_{n+1} = (x_n + 2/x_n)/2$ from $x_0 = 1$ reproduces the printed iterates $1,\ 1.5,\ 1.41666\ldots,\ 1.4142156\ldots,\ 1.4142135\ldots$ exactly, and the absolute error against $\sqrt{2}$ falls below 10^{-6} within the four passes the source claims. The script asserts the agreement and fails if it is ever lost. Script: `figs/src/CCP-A05_fig02.py`.

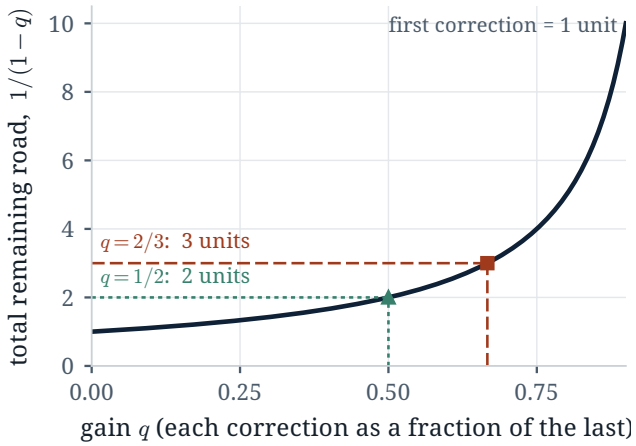

Figure 5.3: The whole remaining road, priced by the ratio. Arithmetic, not measurement: with a first correction of one unit and each correction a fixed fraction q of the last, the total distance ever to be travelled is the geometric sum $1/(1-q)$. The two annotated points are the source's own cases — $q = 1/2$ giving two units and $q = 2/3$ giving three, the latter stated in the source as "the entire road, walked forever, is three units long". The curve's divergence as $q \to 1$ is the same fact as the isometry in Figure 1. Script: `figs/src/CCP-A05_fig03.py`.

1977], and the underlying question of whether the attribute is quantitative in the first place has an unanswered critic [Michell, 1997].

3.3 The a posteriori bound (R2)

One consequence rides along with the proof, and this corpus prizes it above the theorem, because it answers the question an operator actually asks — not *will I arrive* but *how far off am I now*.

The fixed point cannot be seen; if it could be seen the map would not be needed. But something just as good can be seen: **the size of the last correction.** On a contracting loop the remaining distance is bounded by the last step taken, scaled by a constant depending only on the gain:

$$d(x_n,\, x^*) \;\le\; \frac{k^n}{1-k}\, d(x_0,\, x_1)$$

and, in the form an operator uses, the distance still remaining is at most $\frac{q}{1-q}$ times the length of the latest correction. A gain of one half means one is never farther from the fixed point than the whole size of the step just made.

The practical content is worth stating without ornament. The operator who wants to know how near arrival stands does not need to see the future; they need only measure their most recent revision. Corrections running to pages: far, and now quantified. Corrections down to a word: near, and *provably* near, on the theorem's own signature — not consoled, not encouraged, **bounded**. The mathematicians call this an a posteriori estimate. Its whole value is that it is self-reading: the same record that holds the gain also reports the distance.

The geometric-series form makes the total road finite and prices it in advance. If the first correction moved one unit and each subsequent correction is two thirds of the last, then the entire road, walked for ever, is $1/(1-2/3) = 3$ units long. This is why the last steps of a true convergence are so small that they feel like standing still, and why the door, when it is reached, is barely a step.

One caution attaches to the gauge and is not optional. A quantity that is read as an indicator of one's own progress, and acted upon, is exposed to the standard failure of social indicators: a measure adopted as a target ceases to be a good measure [Campbell, 1979, Goodhart, 1975]. An operator who knows that small corrections certify nearness can produce small corrections. The audit of Section 6 exists partly because of this, and the exposure is structural rather than incidental.

3.4 What the theorem says about deserving

The theorem has no clause about deserving, and the corpus makes a point of this. It has no clause about how far the starting state lies from the fixed point, or how many years were spent circling before the first true correction was cut. Distance costs passes — the constant out front may be large, and early iterations from far away are humbling — but distance costs *only* passes, and each pass is the same size of work.

That is a statement about the mathematics and it is exact. It is not a statement about lives, and the difference is P1.

5.0.4 4. The converse (R3, R4)

A treatment of convergence without a treatment of divergence is a loan with the terms withheld. Everything above required q strictly less than one. Loosen that and the guarantee does not weaken; it inverts, in two distinct ways with two distinct signatures.

4.1 Unit gain: the orbit

The pass that preserves distances — same utterance, same conduct, no revision taken, or a revision taken and quietly unwound because nothing held it — orbits. It can orbit with complete sincerity and perfect attendance. Nothing in orbiting reduces the gap; the map is an isometry, and isometries have no theorem and no arrival. Most of what is called being stuck is not a wall. It is an unpitched loop.

The distinction the source draws here is operationally sharp and worth preserving: a record showing no corrections *near the end* of a long series of shrinking ones is the quiet of convergence; a record showing no corrections *from the beginning* is a groove that never had a pitch. The two stillnesses are told apart by whether shrinking corrections precede the silence, which is exactly the third instrument of Section 6.

4.2 Gain above one: the amplifier

This is the dangerous regime, because it wears effort's face. The operator, impatient with small steps, reacts to each returned difference with a revision larger than the difference that prompted it, overshoots, receives back a larger opposing difference, and corrects harder still. Any helmsman knows the sequence: oversteer, overcorrect, and the swings grow until the wake is a snake. In a loop with delay — and every real loop has delay — corrections sized to old feedback arrive as new errors, and the oscillation feeds itself. **Divergence does not look like collapse at first. It looks like intensity.**

The general treatment of gain, delay and stability margin is the control engineer's and is standard [Åström and Murray, 2008, Oppenheim et al., 1996], as is the first-order difference-equation account of the same three regimes [Elaydi, 2005, Kelley and Peterson, 2001]. That a human operator inside a control loop can be modelled this way at all is an old and respectable result [Tustin, 1947], and the founding claim that one feedback mathematics governs machines and organisms alike is older still [Wiener, 1948]. Delay in a stock-and-flow system is precisely where human judgement fails: people systematically misjudge stocks with delays, and the resulting oscillation is a robust experimental finding [Forrester, 1961, Sterman, 1989].

The corresponding failure in institutions is a slow erosion of a standard that nobody decided to erode [Vaughan, 1996], and its acute form is an organisation losing its own structure under stress [Weick, 1993].

4.3 The case that has no citation, and is retained anyway

When the loop runs through another person, the amplifying case has, according to the source, a mechanism with a clinical name: press a will and the counterforce rises; push a foreseen future harder and the pressed party is drawn to its opposite *because* it is the opposite. A prediction pushed too hard does not merely fail — it manufactures its own refutation and returns it signed. The source calls the clinical mechanism reactance.

This corpus's external bibliography contains no entry for reactance. The claim is retained here because it is load-bearing for R3's human limb and because removing it would misrepresent the framework; it is retained **uncited**, and it is listed in Section 12.3 among the claims this paper cannot support. What can be supported is narrower and is stated instead: that measuring or managing a process changes it in ways not simply predicted [Campbell, 1979], and that redundancy and added control can reduce rather than increase safety in coupled systems [Sagan, 1993, Perrow, 1984].

4.4 The stability rule (R4)

The remedy is not subtle. Small corrections; many passes. The standing rule is: never correct by more than a fraction of the gap the differences show, and halve the step the moment the last corrections begin alternating in direction.

The reason the rule works is the whole of R4 and it inverts the usual moral ordering:

> **A correction smaller than the difference can be wrong and still converge, because the next pass will catch it. A correction larger than the difference can be right and still diverge.**

In this craft, restraint is not a virtue. It is a stability criterion. The same statement in control terms is that a gain margin is a property of the loop and not of the operator's character, and that the loop's stability is decided before any particular correction's correctness is known [Åström and Murray, 2008]. The corpus's storage law supplies the same result with an explicit increment bound: the rule $r \leq h$ with a recommended reserve $r \leq 0.7h$, since the maximum $r_{\max} = h$ is attained only at the boundary $U = 1$, together with the branch in which no interaction geometry can prevent order from decreasing [Curzi, 2026j]. And the same map appears there in closed form: the storage map $T(Q) = (1-\delta)Q + b$ is a contraction with constant $1-\delta$, giving $Q_\infty = (\eta M^* - c^*)/\delta$ and the exact error law $|Q_t - Q_\infty| = (1-\delta)^t |Q_0 - Q_\infty|$ [Curzi, 2026q]; its parent statement is the storage law $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ with $S_t = \ln(1 + (N-1)U_t)$, Lipschitz with modulus $k = 1-\delta$, so that $\delta > 0$ is exactly what makes it a contraction and $Q^* = (\eta S - C)/\delta$ its steady state [Curzi, 2026a].

5.0.5 5. Completeness as a failure condition (R5)

Completeness is where a transposition of this theorem most often fails silently, and the failure has a signature worth naming because every local reading of it is good.

The state converged upon must be a state the actual system can contain — the limit must have somewhere to land. There are foreseen states that are holes in the space: outcomes requiring a person the operator has made no provision to become, sustained by conditions the life as lived cannot hold. **Iterate toward a hole and the passes contract beautifully, for ever, arriving never:** the gap shrinks toward a point that is not there.

The diagnostic problem is that contraction is preserved. Every instrument in Section 6 reports health. The corrections shrink; the ratio is stable; the record is honest; there is no

oscillation and no alternation. Only a check performed from **outside** the loop detects it, and the corpus supplies one: ask of the target, with the ledger open, whether the life as actually lived could hold it if it arrived on an ordinary Tuesday — naming the room it would occupy, the hours it would consume, and the person the operator would have to have become meanwhile. If the check finds a hole, the honest responses are two: widen the space until the limit has somewhere to land, or move the target by daylight as a declared new undertaking. Pushing the loop harder at the wall is not among them.

This is a real mathematical point and not a metaphor. A Cauchy sequence in an incomplete space converges to nothing in that space while satisfying every internal criterion of convergence; the rationals under the usual metric are the standard example, and $\sqrt{2}$ — the very limit of Figure 2's iteration — is precisely the hole. The recursion of Figure 2 is a contraction on the rationals and has no fixed point there. That is completeness doing visible work, and it is why the condition appears in the theorem rather than in its preamble.

The organisational analogue is the case in which making a system legible to a plan destroys the local variety the system was actually running on: the plan contracts toward a state the terrain cannot hold [Scott, 1998]. The analogous engineering treatment is to regard the constraint set, not the component reliability, as the object of design [Leveson, 2011].

5.0.6 6. The audit of arrival (R6)

6.1 Why the feeling proves nothing

Every operator reports it and none is prepared for it: a fixed point entered at last does not feel like triumph. It feels like recognition. The proportions of the hour are familiar; the hook is where the arm expected it.

The source offers a mechanism: that the machinery with which a mind imagines a future is not separate from the machinery with which it remembers a past, so a scene assembled often enough is consolidated as a memory is, and recognition on arrival is the felt signature of zero prediction error — the difference signal, for once, silent. **This corpus's external bibliography contains no entry for the constructive memory literature, and the mechanism is therefore reported uncited** (Section 12.3).

But the paper's claim does not depend on that mechanism, and this is worth being clear about, because it is the one place where an unsupported explanation and a supported conclusion are easily confused. The conclusion is:

> **The feeling of recognition proves nothing**, because whatever machinery produces it will produce it equally for a rehearsed future correctly reached and for a past quietly tidied to agree with a present.

That conclusion is supported by results this bibliography does contain. People report the causes of their own mental processes with a confidence unrelated to accuracy [Nisbett and Wilson, 1977]; the answers a person gives about their own states are shaped by how the question was asked [Schwarz, 1999]; and attention directed at a named component of well-being systematically distorts the judgement of it [Kahneman et al., 2006]. Nothing about a subjective report of fit, however vivid, is evidence of a prior prediction.

The counterfeit feels identical from inside — warmer, if anything, for having been tailored after the measurements were taken. The framework therefore does not permit arrival to be certified by feeling. Arrival is certified by audit, and the audit has three instruments.

6.2 First instrument: the record precedes the room

A genuine convergence leaves a paper trail laid down *before* arrival — dated, specific and falsifiable. If the only evidence of having foreseen an outcome is present testimony that it was foreseen, there is no evidence; there is a mood.

This is the practice the open-science literature independently arrived at, and its rationale transfers without modification: a prediction registered in advance constrains what can later be claimed to have been predicted [Nosek et al., 2018], and the alternative is a space of analytic and interpretive choices wide enough to support almost any conclusion [Simmons et al., 2011, Gelman and Loken, 2013]. The subtle form of the problem does not require any bad faith and is the one most likely to affect an honest author [Gelman and Loken, 2013]. The standard against which a directional claim should be judged is severe: directional predictions are nearly costless, and a theory earns credit by making point predictions with constants [Meehl, 1967]. The corpus's own habit of specifying numbers rather than directions is the correct response to that objection, and stating so explicitly is part of the answer [Meehl, 1990]. The design principle that makes such records worth keeping is that they should discriminate between named alternatives, not merely accord with one [Platt, 1964].

6.3 Second instrument: the residue (H3)

This is the subtle one. A genuine convergence agrees with the record in **structure** and disagrees with it in **inventory**. The returned world is never the one that was sent. A record may have foreseen light from the left, an old desk, water held at an angle; it did not foresee the bakery, and the warm smell in the record is marked *unidentified*, because at the time it honestly could not be identified.

That failure, preserved in the record, is the strongest available authentication.

> **A room that matches an account in every particular is a room the account was written in. The forger's tell is perfection. Truth arrives with its discrepancies still attached; only counterfeits are seamless.**

The operational rule is a count: on auditing an arrival, count the details the dated record got flatly wrong, and if fewer than three can be found, do not trust the record.

The threshold of three is a stipulation and not an estimate. Nothing establishes three rather than two or five, and Section 12.5 says so. What the rule encodes is a real asymmetry — a prospective record has independent opportunities to be wrong that a reconstruction does not — and that asymmetry is the content of H3.

6.4 Third instrument: the shrinking corrections

Convergence has a signature no single moment can fake, because it is a *sequence*. Going back through the record and measuring the size of each revision, a true approach to a fixed point shows them shrinking, roughly geometrically, each pass a fraction of the last, exactly as the bound of Section 3.3 prices it. A retrofit shows no such decay: an ordinary wandering line, and then one large convenient leap explained after the landing.

A conclusion can be faked. A ratio cannot be faked backwards through a dated record.

The corpus supplies the decay constants for its own storage instance, and they are worth quoting because they show what the signature looks like when it is measured: at $\delta = 0.09$ the time constant is $\tau = 10.6033$, the half-life is 7.3496 passes, and the error falls to five per cent by pass 32, to one per cent at 48.83, and to a tenth of a per cent at 73.24 [Curzi, 2026]. The same contraction verified to a maximum residual of 2.0624×10^{-15} over a hundred passes is reported elsewhere in the corpus [Curzi, 2026].

What the drawing quietly forbids is the belief — dear to the exhausted — that the great correction is still ahead, and that arrival will announce itself in upheaval commensurate with the wanting. The arithmetic says otherwise: if corrections have been taken honestly, the largest step of the journey is behind. It was the first one, and the smallness since is the signature of approach rather than a failure of nerve.

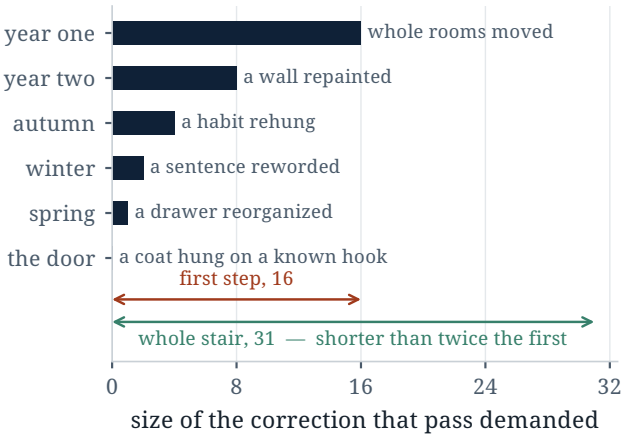

Figure 5.4: The source's own drawing of a converging series of corrections, redrawn to scale. Measured from the source: its monospace figure sets six corrections at bar lengths 16, 8, 4, 2, 1 and 0 characters, labelled year one through the door, and closes with the claim that "the whole stair, laid end to end, is shorter than twice its first step". The bar lengths here are those character counts; the total, 31, is computed by the script and is indeed below $2 \times 16 = 32$. Script: `figs/src/CCP-A05_fig04.py`.

6.5 The auxiliary: the walk-away test

One blunt auxiliary completes the audit. A genuine fixed point is a basin: it can afford inspection, delay and doubt, because everything in the neighbourhood drains back toward it. A counterfeit is a ledge, and it knows it is a ledge, and so it manufactures urgency — decide today, the door is closing, consult no one. Whatever cannot survive a willingness to walk away from it was not going to hold weight when sat down in.

6.6 The audit as a procedure

The three instruments and the auxiliary compose into a gate sequence, performed before anything is accepted, signed, or celebrated (Figure 5). The source's procedure has ten movements and they are reproduced here in operational form because later papers refer to their outputs.

1. **Stand down the hour.** Decide nothing for the first hour after recognition. Note what happens when this is said aloud: a basin absorbs the sentence without a ripple, a ledge negotiates.
2. **Retrieve the record before revisiting the feeling.** Do not rehearse the recognition in memory — every rehearsal edits. Lay out every dated page bearing on the arrival, in date order.
3. **Write the arrival as it is.** On a fresh dated card, a plain inventory of what is actually present, in the order encountered. A manifest, not a review.
4. **Rule two columns: structure and inventory.** Enter every structural agreement in the left; every inventory disagreement in the right, in both directions — items the record specified that the outcome contradicts, and items the outcome contains that the record never imagined.
5. **Count the honest errors, and require three.** From the right column, count the details the record got flatly wrong. Fewer than three: stop. The remaining movements cannot be trusted until it is known whether the record or the outcome was tailored.
6. **Plot the corrections.** List each revision in order with its rough size. Look for the shrinking sequence. If the trail shows wandering and then one large convenient leap, name the leap aloud. Leaps are not forbidden — luck exists — but a leap must be called a leap

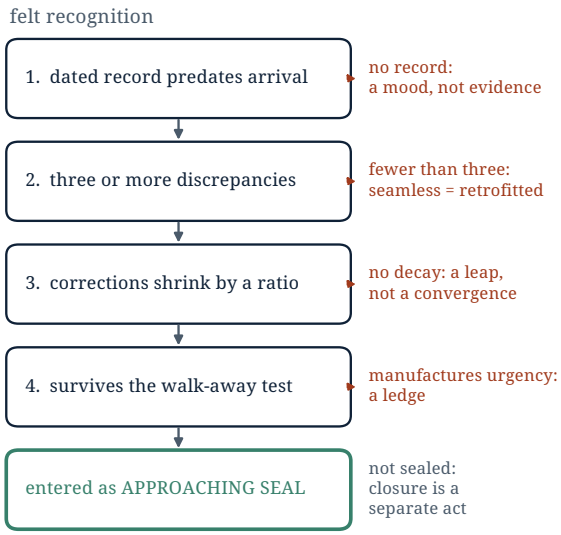

Figure 5.5: The audit of arrival as a gate sequence. Schematic; no plotted quantity. The gates are the source's three instruments in the source's order, followed by the walk-away auxiliary; any gate that fails ends the audit. The terminal verdict is "approaching seal" rather than "sealed", because closure is a separate act with its own conditions (Section 8). Script: `figs/src/CCP-A05_fig05.py`.

and lived in provisionally, because there is no evidence it will hold when the loop next passes through it.

7. **Audit the expense.** Write the name or station of every person whose position changes on acceptance. Beside each: does this diminish them, and has anyone asked them? For every unverified kindness, the audit is suspended until the kindness is priced from the recipient's side.
8. **Fork the offer.** Draft two versions of acceptance in writing — the one offered and the one the record and the expense audit actually describe. Where they differ, prepare the counter in a single present-tense sentence.
9. **Sit the arrival.** Where it has a physical place, spend twenty minutes in it doing nothing. This measures the one quantity paperwork cannot: whether the comfort deepens under examination or requires continued motion.
10. **Enter and mark.** If the audit stands, enter the arrival in the record in the present tense, date it, and mark the undertaking **approaching seal**. Not sealed. Arrival ends the journey; it does not close the undertaking.

The procedure reads long and runs short, and it earns its hour in one currency, which is not certainty — the framework has none to sell — but **auditability**: the difference between a practice that can answer for its arrivals and one that can only insist on them. The general principle is the security engineer's: a system's integrity should not depend on any part of it being hidden, including from its own operator [Kerckhoffs, 1883, Saltzer and Schroeder, 1975].

5.0.7 7. The externality result (R8)

There remains a counterfeit that passes every instrument above — dated pages, honest residue, shrinking corrections — and is still not the operator's.

A fixed point reached at another's expense is not a fixed point. Not as sentiment; as engineering. Consider what has actually been built if the arrival requires an emptied chair. The displaced party is now a term in the loop. Their loss, their resistance, their unconsented re-

arrangement do not exit the system when the paperwork closes; they return through W on every pass, as friction, as grievance, as a standing vigilance carried up the stairs every morning. What has been found is not a state the loop returns to; it is a state the loop must be **held** in, and holding is the opposite of arrival. The gain exported into another person's life re-enters as k creeping upward, and a basin with rising gain is a basin becoming a ledge.

Stated in the loop's own terms: an unconsenting party is a **second modeller** inside W, whose model of the operator now contains the operator's designs on them. The composition of two modellers each modelling the other is not a contraction; it is an arms race of models, with gain compounding above one. This is R8, and it is H4's mechanism.

The structural literature says the same thing without the vocabulary. Adding components inside one coupling perimeter increases interactive complexity, and beyond a point makes failure a property of the system rather than an error by an operator [Perrow, 1984]; added redundancy can reduce safety outright [Sagan, 1993]; and cohesion's benefit is an inverted U rather than a monotone gain [Uzzi and Spiro, 2005]. Durable arrangements over shared resources are governed by rules the affected parties had a hand in making, and that finding is empirical rather than postulated [Ostrom, 1990]. Reciprocity sustains cooperation only where the parties expect to meet again [Axelrod, 1984], and trust is a property of the relation rather than a disposition of either party [Gambetta, 1988]. Contact across difference produces value under conditions and not unconditionally [Allport, 1954].

7.1 What kind of claim R8 is: identification, and the framework turned on itself

R8 is a statement about a loop, and a statement about a loop invites the question of whether the loop's parameters could be recovered from observation. They could not, and this is stated here rather than in a footnote because it fixes what R8 is.

Written as an aggregate relation, the reflexive loop this corpus is built on — $T(x) = W(x, M(x))$, fixed in the founding paper of the series [Curzi, 2026] — is a linear-in-means reflexive specification, and the endogenous effect in such a specification is **not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables no matter how much data is gathered [Manski, 1993]. The network route is closed by the same family of result, since influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011]. The available remedies are randomisation, an instrument, partial-population variation, or a defended stipulation of the reference group, the last being the realistic route and having an explicit template in a discrete-choice model that states the conditions under which its interaction parameter is econometrically identified [Brock and Durlauf, 2001]. **This paper adopts none of them.** R8 is therefore a modelling position — a mechanism stated in the loop's own terms — and not an identified empirical result, and H4 is the design that would be needed to make it one.

That reflexivity of this shape occurs at all is separately documented, and the documentation matters because it is the existence proof the framework otherwise lacks. When the Black–Scholes option-pricing model was published its prices did not fit the market; after traders adopted it, the market came to fit the model, with dates and price data recording the convergence [MacKenzie and Millo, 2003]. That is a reflexive fixed point observed in the field. It establishes that the mechanism is real; it does not establish that any particular loop is one, and this paper keeps the two apart.

The same reflexivity falls on this paper's own instrument. The gauge of Section 3.3 reads a modulus q off a series of corrections. Parameters estimated in a population that does not know the model cannot be assumed to survive in a population that has read it, because the decision rules those parameters summarise are themselves responses to the environment the model describes [Lucas, 1976]. A framework that asserts observation changes behaviour and then exempts its own coefficients is not self-consistent. The position taken here, stated so that it can be held against the paper: **no stability of the framework's parameters under its own dissemination is claimed, and no result in this paper depends on any.** The costs are accepted — a q estimated from an operator who has read this paper is not comparable to one

estimated from an operator who has not, and a before-and-after design on a single operator is confounded by construction — and the gauge is offered as a bound that an operator may apply to their own record, not as a coefficient that generalises.

The audit question that follows is asked at the threshold, while it is still cheap: *who else is in this arithmetic, and did they consent to be?* If the answer requires a kindness no one has verified with its recipient, the answer is no — and the genuine arrival, the one the dated record actually describes, is usually adjacent to the counterfeit and one refusal away.

5.0.8 8. Closure (R7)

8.1 The cost of not closing

The source opens its treatment of closure with an empirical claim: that an interrupted task is remembered better than a completed one, that unfinished business is *staffed* rather than archived, and that the intrusions of an open goal quiet down not when the goal is achieved but when it is concretely disposed of — achieved, planned to the point of trust, or genuinely renounced. The mind, on this account, does not demand completion; it demands a verdict, and will accept a written *no* from an honest court.

This corpus's external bibliography contains no entry for that literature. The claim is reported as the framework's and is uncited (Section 12.3). What follows from it does not depend on it: the closure discipline is a bookkeeping rule, and a bookkeeping rule can be justified by what it makes auditable regardless of whether the attentional mechanism is as described.

The framework's own summary is worth preserving as a statement of the design problem it is solving: a commitment that is never closed does not become neutral, it becomes a standing charge. An undertaking that arrived and was never marked fulfilled keeps campaigning decades into possession. An undertaking that died and was never marked lapsed stands in the record like an unpaid invoice. An undertaking abandoned without words is billed nightly.

8.2 Three verdicts, and no fourth

Every commitment receives exactly one of three verdicts, entered deliberately and in writing rather than left to erosion (D2).

Fulfilled. The undertaking arrived and survived the audit of Section 6. The closing is a single dated line in the record, in the present tense: the sentence rewritten one final time as plain fact, without the forward lean it needed while it was doing gradient work. The card is then turned face down — not to hide it, but because a closed undertaking becomes ground, and ground is not for reading.

Released. The undertaking is one the operator no longer chooses — outgrown, superseded, or revealed by its own returned differences to have been someone else's sentence mistaken for one's own. Release is renunciation with the dignity of a verdict, and it is spoken once aloud, because the loop was opened by speech and the ledger honours symmetry. Release is not failure: a practice that cannot renounce can only accumulate.

Lapsed. The undertaking died unattended — starved of iteration, obsoleted by arrival elsewhere, or simply outlived. The closing is a written death date, honestly guessed, and one brief line. Brevity is the sincerity of the entry; a long apology to a dead undertaking is a way of keeping it open.

One rule completes the discipline: **one open undertaking at a time.** One commitment in the forward channel doing gradient work, and everything else current, closed, and filed. The framework's justification is capacity, not asceticism: three simultaneous undertakings run through one attentional system interfere, each returned difference arriving garbled by the others and each correction smearing across all three. The general form of that argument — that a regulator must have at least as much variety as the system it regulates, and that a

channel has a capacity — is old and standard [Ashby, 1956]. Whether one is the right number is not established, and Section 12.5 says so.

8.3 The consent law

The framework states one constraint as law rather than technique:

> **No future is to be spoken over another's path without their word.**

The argument is structural rather than moral, and this paper reports it as structural because that is how it is made. Stripped of ceremony, the undertaking is a seen future, made vivid, installed where a mind will keep encountering it, so that many small choices tilt toward it by gradient rather than by effort. Performed on oneself, with one's own record, this is the framework's whole subject: the seeing is one's own, the gradient is one's own, and the arrival is one's own to audit and to refuse. Performed on another person without their word, *the identical mechanism* is coercion — worked above the awareness of its target, in the one channel where a person cannot defend themselves without becoming someone who trusts nothing, including encouragement.

The framework adds that the law is self-enforcing because the mechanism also **fails**, by the amplifier of Section 4.2. That limb rests on the reactance claim and is therefore uncited here (Section 4.3, Section 12.3). What is not in doubt, and what the paper does assert, is R8: an unconsenting party is a second modeller inside W, and the composition is not a contraction.

Consent transforms the mechanism completely, which is why the law is a law of *words* and not a counsel of abstinence. A future spoken *with* another — asked for, chosen, co-authored, revocable — is not an installation but a shared seeing, and the difference between the two is one conversation.

The law's reach is stated so that it is not signed narrowly. It covers the obvious cases. It equally covers the benevolent ones, and this is where practitioners fail: the prophecy over a child's talent, the confident assurance about someone else's marriage, the diagnosis by faith spoken over a sick friend. **Kindness is not consent. Accuracy is not consent. Being right is not consent.** The offence is never in the content; it is in the door. In practice the discipline is small: before any undertaking that touches another life, ask, aloud, and honour the answer — including the later answer, when it changes, because consent is a standing arrangement and not a receipt.

8.4 Three conditions barring operation

The framework names three conditions under which the procedure is not to be run at all, on the ground that they are states in which the loop gain is not a constant of the operator's character but a property of the current system.

Grief, in its acute form, re-prices everything hour to hour, so that no weighting made inside it is stable enough to build on. The futures seen from inside acute grief are vivid — the framework notes that grief is a powerful extrapolation engine — and they are not the operator's to run, because the one who states the sentence in February is not the one who must live in it in June. The prescription is to run the locating disciplines only.

Rage collapses the time horizon to the width of the injury and then demands a prediction from inside the collapse. The framework's observation is specific and worth preserving: a working spoken in rage is almost always a prophecy over the offender's path, unconsented, dressed as self-improvement, and therefore the commonest violation of the consent law committed by people who would never violate it knowingly.

Revenge, the cold form, mimics the practice perfectly — patient, iterative, detail-loving, willing to keep records for years — and is distinguished by exactly one feature: its fixed point

contains another person's diminishment as a load-bearing element. Remove the diminishment and the state collapses. That is the test, and by R8 the pursuit runs above unit gain by construction, because the adversary is a second modeller.

The framework's rule for knowing when the condition has passed is that the operator does not vote on it from inside, since these are precisely the states in which instruments about state cannot be trusted; the objective signs are the ones the practice already records.

5.0.9 9. Results

9.1 Established by derivation. R1 and R2 are established. The theorem is stated exactly and its uniqueness clause is argued in Section 3.1; the a posteriori bound is its standard corollary and the geometric-series form is checked arithmetically in Figure 3. R3 and R4 follow from the same inequality read at $q = 1$ and $q > 1$ and are established in the same sense. **All four are established for the mathematical object and not for any human loop**, for the reason recorded as P1.

9.2 Established by construction. R5, R6, R7 and R8 are specifications rather than findings. R5 identifies a real mathematical condition with a real practical failure mode and gives an external check for it; the identification is argued, not measured. R6 specifies an audit; R7 specifies a taxonomy and two rules; R8 states a mechanism in the loop's own terms. None is a measurement.

9.3 Reproduction of the source's arithmetic. Two of the source's own numerical claims were recomputed and both hold. The square-root iteration reproduces the printed iterates $1,\ 1.5,\ 1.41666\ldots,\ 1.4142156\ldots,\ 1.4142135\ldots$ exactly, with absolute error below 10^{-6} within four passes (Figure 2; the script asserts the agreement and fails if it is lost). The source's stair of corrections, at bar lengths 16, 8, 4, 2, 1 and 0, sums to 31, which is below $2 \times 16 = 32$, so its claim that "the whole stair, laid end to end, is shorter than twice its first step" is arithmetically correct (Figure 4).

9.4 Hypotheses tested. None. H1 through H4 are stated in falsifiable form and none is tested here; no dataset was collected. This is reported in the same plain language a positive result would receive. H3 in particular is testable today against existing preregistration archives and was not tested.

9.5 Claims retained without support. Three of the source's mechanisms are retained in the text and could not be cited from this corpus's bibliography: reactance, the attentional cost of unclosed commitments, and the shared-machinery account of imagination and memory. Each is marked at its point of use and listed in Section 12.3. In each case the paper's own conclusion was restated so that it does not depend on the unsupported mechanism.

5.0.10 10. Discussion

10.1 What follows

The paper's practical yield is one instrument and one refusal.

The instrument is the gauge of Section 3.3. It is unusual among instruments of self-assessment in requiring no judgement about the destination and no estimate of the distance — only a measurement of the last revision, which is already recorded. Its value is that it converts a question that cannot be answered (*am I nearly there*) into one that can (*how big was my last change*), and it does so with a bound rather than an encouragement.

The refusal is the audit of Section 6. It denies the operator the one certificate they most want to accept, and it does so for a reason that survives even if the source's proposed mechanism is wrong: no subjective report of fit is evidence about a prior prediction. The audit's three instruments are all documentary, and that is deliberate.

Between them there is a general lesson about instruments in this corpus. Both are built on the same principle: prefer a quantity recorded before the outcome to one produced after

it, and prefer a quantity that can be re-derived to one that must be believed.

10.2 What does not follow

That a loop has a fixed point does not mean it has been shown to contract; that corrections are shrinking does not mean the target is reachable, because completeness can fail while contraction holds (Section 5); and that an arrival passes the audit does not mean it is legitimate, because the expense audit is a separate gate (Section 7).

Nor does the theorem license the reassurance most often taken from it. “From anywhere” is a clause about the *mathematics*, and applying it to a life is P1. This paper’s position is that the transposition is useful precisely because it can fail inspection: it names the two conditions — contraction and completeness — whose failure produces the two failure modes practitioners actually report.

10.3 Relation to the corpus

The definitions this paper consumes are fixed upstream: the Banach condition $d(T(x), T(y)) \leq k\, d(x, y)$ with $0 \leq k < 1$, and its three consequences, are stated in the founding paper of the series [Curzi, 2026], and this paper’s R1 and R2 are their extension into a working instrument. The corpus’s reference apparatus places the established-mathematics component of the surplus functional — the restatement of $f(u) = \ln(1 + (N-1)u)$ as the logarithm of an affine effective count and as a lower bound on the ensemble’s entropy — in its established drawer while assigning the application to a life to the postulate drawer [Curzi, 2026]; that three-drawer discipline is the same discipline this paper applies to P1.

Downstream and laterally, four results bound what this paper may claim. The corpus’s own preregistered measurement of its storage law failed its second falsification rule: a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, notwithstanding a 40.3 per cent advantage over persistence, 97.7 per cent over direct input, and $p = 0.0005$ against a shuffle control [Curzi, 2026i]. That is the corpus’s strongest available evidence that a contraction-shaped model can fit well and still fail a properly specified test, and it is the correct prior for every claim in this paper. The corpus’s audit of a traditional operation set against a parameter model returned seven mappings, two splits, one rendering and three rejections over thirteen entries, with five entries carrying a failure [Curzi, 2026] — an example of the same refusal discipline applied to inherited material. The corpus’s sonification paper states an open problem formally rather than claiming a result: no established mechanism produces a transcriptional response depending on a symbol string as an *order*, as distinct from permutation-invariant functionals of the waveform [Curzi, 2026]. And the corpus’s own record of what its architecture cannot do reports that disclosure did not confer immunity in the strongest available test case, that a backing basket was 4.61 times less diversified than its component count claimed, that a terminal programme phase was a 0.090 option rather than a plan, and that a levy presented as a costless accounting correction in fact reallocated burden, 42.0 per cent of it onto one sector with a constructed 55 per cent passing through to consumers [Curzi, 2026]. That paper bounds this one: it is the corpus demonstrating that a well-specified structure can still fail in the world, which is exactly what P1 leaves open.

Two identity results in the corpus are instruments of the same kind as the audit, and are cited here because the audit’s second and third instruments are documentary integrity controls in all but name. The canonical form $\text{canon}(x) = \text{restrict_ASCII}(\text{confusable_fold}(\text{NFKC}(x)))$ collapses 495 of 495 manipulated entries onto the clean form, is idempotent across all 500 cases, and resolves 995 raw byte strings to the true 500 identifiers [Curzi, 2026]. And the channel-separation principle — that in-band architectures admit an impersonation class no care within the shared channel can close, while out-of-band separation closes it structurally, measured at 0.383 per cent in-band ambiguity against 0.000 per cent out-of-band over 100,000 values [Curzi, 2026] — is the general form

of the audit's first instrument: a record produced inside the channel it is meant to certify cannot certify it.

Finally, the corpus's belief postulate is the template this paper's P1 follows: the magnitude form $E = G \cdot B + \varepsilon$ with the forbidding clause $G = 0 \Rightarrow E = 0$ for all B, badged as a postulate and paired by explicit correspondence with the storage law's $\eta = 0$ [Curzi, 2026ab]. A strong claim, stated with the clause that forbids its abuse, and badged.

5.0.11 11. Verification

This section is not a summary. It decomposes the paper's results into steps small enough to check one at a time, and labels each `ARITHMETIC`, `DEFINITION`, `CITED` (with the key) or `POSTULATED`. The razor is applied: any postulate whose removal leaves the results standing has been removed.

11.1 Postulates

- **P1 (DEFINITION).** (X, d) is a metric space: $d \geq 0$, $d(x, y) = 0$ iff $x = y$, symmetry, triangle inequality. *Check:* standard.
- **P2 (DEFINITION).** (X, d) is complete: every Cauchy sequence in X converges in X. *Check:* standard.
- **P3 (DEFINITION).** T is a contraction with modulus q: for all x, y, $d(T(x), T(y)) \leq q\, d(x, y)$, $q < 1$. *Check:* D1.
- **P4 (CITED: `banach1922operations`).** Under P1–P3, T has exactly one fixed point, reached from any start, with $d(x_n, x^*) \leq q^n d(x_0, x^*)$.
- **P5 (ARITHMETIC).** For $0 \leq q < 1$, $\sum_{j \geq 0} q^j = 1/(1 - q)$. *Check:* the geometric series; redo it.
- **P6 (POSTULATED).** A life admits a state space satisfying P1 and P2, and a reflexive loop satisfying P3. *Check:* **not checkable and not checked. This is the premise the whole transfer rests on and it is stated as a postulate everywhere it is used.**
- **P7 (POSTULATED).** A subjective feeling of recognition carries no information about whether a prediction preceded an outcome. *Check:* asserted; supported obliquely by `nisbett1977telling` and `schwarz1999self`, neither of which states it.
- **P8 (POSTULATED).** A prospectively made record has independent opportunities to be specifically wrong that a retrospective reconstruction does not. *Check:* asserted; it is the content of H3 and it is testable and untested.
- **P9 (POSTULATED).** An unconsenting party inside W acts as a second modeller whose model contains the operator's designs. *Check:* asserted; this is R8's mechanism and it has no supporting entry.

Postulates dropped as unnecessary: the reactance mechanism (Section 4.3), the attentional cost of unclosed commitments (Section 8.1), and the shared-machinery account of imagination and memory (Section 6.1). Every result below survives their removal, which is why they are reported rather than used.

11.2 The compounding chain

```
P1 + P2 + P3     -> L1   the hypotheses of the theorem hold       DEFINITION
L1 + P4          -> R1   one fixed point, reached from anywhere,
                         geometrically                           CITED
R1 + P5          -> L2   sum of remaining steps <= last/(1-q)    ARITHMETIC
L2               -> R2   distance to arrival <= q/(1-q) times
                         the last correction                     ARITHMETIC
P3 at q = 1      -> R3a  isometry: distance preserved, no
                         theorem, no arrival                     ARITHMETIC
P3 at q > 1      -> R3b  amplifier: distance grows               ARITHMETIC
```

```
R3a + R3b        -> R4   a smaller-than-gap correction may be
                         wrong and converge; a larger-than-gap
                         correction may be right and diverge      ARITHMETIC
P2 negated       -> R5   contraction toward a hole: shrinking
                         gap, no limit in the space               ARITHMETIC
P7 + P8          -> R6   arrival is certified by dated record,
                         >= 3 residues, and a decaying ratio      POSTULATED
(taxonomy)       -> R7   three verdicts, one open undertaking,
                         the consent law                          DEFINITION
P9               -> R8   an exported cost re-enters as gain       POSTULATED
R1 + P6          -> C1   a well-built undertaking arrives         POSTULATED (via P6)
```

What the chain shows. R1 is `CITED`; R2, R3, R4 and R5 are `ARITHMETIC` on top of it. That block — the paper's mathematical content — is checkable end to end without believing anything about people. Everything about *practice* is `POSTULATED`: R6 rests on P7 and P8, R8 rests on P9, and C1 — the conclusion an operator wants — rests on P6, which is not checkable.

A chain whose steps are mostly `DEFINITION` and `POSTULATED` is not a proof. This one is unusual in the corpus for having a genuinely `CITED`-plus-`ARITHMETIC` spine; it is entirely ordinary in that everything the spine is *for* sits on postulates. The value of laying it out this way is that it names the exact bill: P6, P7, P8 and P9 are four claims, three of them testable, and testing them would settle the framework's practical status. That is a smaller bill than the framework's rhetoric implies.

11.3 Dimensional audit

Symbol	Meaning	Dimension	Unit	Status
x, y	states	none assigned	none	defined; indices into a state set
$d(x, y)$	distance between states	$[x]$	**no operational unit exists**	assumed to exist; never constructed for a life
q, k	contraction modulus	dimensionless	—	defined; **never measured for a human loop**
n	pass index	dimensionless	passes	defined
e_n	distance to fixed point at pass n	$[x]$	none	derived from d
x^*	fixed point	$[x]$	none	defined by $T(x^*) = x^*$
$q/(1-q)$	bound multiplier	dimensionless	—	derived, arithmetic
δ	storage decay rate (quoted)	dimensionless	per pass	quoted from `ccp:CCP-007`; not measured here
$\tau = 10.6033$	time constant (quoted)	time	passes	quoted from `ccp:CCP-047`; a derived quantity there
bar lengths 16, 8, 4, 2, 1, 0	correction sizes in the source figure	dimensionless	characters	measured from the source's own drawing

Does the central relation balance? $d(x_n, x^*) \le \frac{k^n}{1-k} d(x_0, x_1)$ balances trivially: k is dimensionless and both sides carry $[x]$. **That the relation balances is not evidence that $[x]$ exists.** The source is silent on the units of the distance between two states of a life, and this paper does not supply them; the honest entry is that there is none. Where the corpus's storage instance is quoted, its δ is dimensionless per pass and its τ is in passes, and both are that paper's quantities rather than this one's.

Scale type. The bound of Section 3.3 is a statement about *ratios of distances* and therefore presupposes at least an interval scale, and in the form "the remaining distance is at most $q/(1-q)$ times the last correction" it presupposes a ratio scale. Nothing in the source establishes either for any psychological quantity. The formal test for whether an attribute has additive quantitative structure is conjoint measurement [Luce and Tukey, 1964], against the standard set out by Krantz et al. [1971], and **its conditions were not tested.** The strongest objection to the whole framework is that psychology assumes quantitative structure without ever testing for it [Michell, 1997]; the correct response available and unused is either a conjoint demonstration or a Rasch-model one [Rasch, 1960], with the construct-validation programme that would accompany it [Cronbach and Meehl, 1955, Campbell and Fiske, 1959]. **Where an operator's corrections are counted in something with a natural unit — hours, money, words struck, letters sent — the ratio reading is licensed by that unit and not by this framework. Where they are not, it is not licensed at all.**

11.4 Limits and boundary behaviour

- $q \to 0^+$**.** One pass arrives. The bound $q/(1-q) \to 0$: the last correction is the whole remaining distance and there is none left. Degenerate but coherent.
- $q \to 1^-$**.** Convergence survives and utility does not: $1/(1-q) \to \infty$, so the total road diverges and the number of passes to any fixed accuracy grows without bound (Figure 3). The theorem does not fail here; it stops being useful, and the two are worth distinguishing.
- $q = 1$**.** No theorem. The map is an isometry; the orbit neither approaches nor recedes (Figure 1). Note that the fixed point may still *exist* — the identity map fixes everything — but nothing is guaranteed and nothing converges.
- $q > 1$**.** The bound reverses and iteration is a divergence generator. There is no contradiction with the existence of a fixed point; there is simply no route to it by iteration.
- $n \to \infty$ **with completeness failing.** $e_n \to 0$ and x_n converges to nothing in the space (Section 5). Every internal criterion reports success. This is the only boundary in this paper that is invisible from inside the loop.
- **First correction** $\to 0$**.** The a posteriori bound collapses to zero remaining distance, which is correct and useless: an operator who never corrects at all reads as arrived. The gauge presupposes that corrections are being taken from returned differences, and this degenerate case is exactly the orbit of Section 4.1 wearing the gauge's clothes.
- **Number of open undertakings** $\to \infty$ **(Section 8.2).** The framework asserts interference; nothing here bounds it, and the rule of one is a stipulation.

11.5 The checks a reader should run first

1. **Redo the uniqueness argument** in Section 3.1. Three lines, no source.
2. **Redo the geometric sum** in Section 3.3 for $q = 2/3$: $1/(1-2/3) = 3$. Figure 3 should agree, and the script asserts it.
3. **Run `figs/src/CCP-A05_fig02.py`.** It recomputes the source's square-root iterates and asserts they match the printed digits; if the assertion is ever removed, the figure is no longer a check.
4. **Add up Figure 4's bars:** $16 + 8 + 4 + 2 + 1 + 0 = 31 < 32$. The source's claim is arithmetic and it holds.

5. **Look for a citation attached to reactance.** There is none, in this paper or anywhere in the corpus's external bibliography, and Sections 4.3 and 12.3 say so.

5.0.12 12. Limitations

12.1 The transfer premises are unverified, and this is the principal limitation. Neither completeness nor a uniform contraction modulus has been established for any human loop, by this corpus or by anyone. Everything in Sections 3 and 4 is exact about a mathematical object and conditional about a life. **Falsified by:** nothing, which is the point — P6 is not currently a falsifiable claim, and the honest description of its role is that of a hard-core commitment protected by a belt of testable claims [Lakatos, 1970].

12.2 No hypothesis was tested and no data were collected. H1–H4 stand. H3 in particular is testable against existing preregistration archives with no new data collection, and testing it is the single most valuable next step this paper can name. The discipline that would make such a test credible is specified and not exercised [Nosek et al., 2018, Simmons et al., 2011].

12.3 Claims with no supporting literature in this corpus's bibliography. Listed individually, because a reviewer will find them.

- *Pressure on a perceived freedom produces counter-movement (reactance).* Load-bearing for the human limb of R3 and for the self-enforcing reading of the consent law. **`bib/external.bib` contains no entry.** Retained uncited; no citation was attached to make it appear supported. Where the paper's conclusion could be restated without it, it has been (Sections 4.3, 8.3).
- *Unfinished commitments hold attention and levy a continuing cost until concretely disposed of.* The premise of Section 8.1. **No entry.** Retained uncited, and the closure discipline is justified on bookkeeping grounds instead.
- *Imagination and memory run on the same constructive machinery, so a rehearsed future consolidates as a memory does and a present outcome reshapes the remembered expectation.* The proposed mechanism for Section 6.1. **No entry.** The paper's conclusion — that felt recognition certifies nothing — is restated so that it rests on the self-report literature instead [Nisbett and Wilson, 1977, Schwarz, 1999, Kahneman et al., 2006], which supports a weaker and sufficient claim.
- *The specific numerical thresholds*: three preserved discrepancies, one open undertaking, a correction no larger than one third of the gap, twenty minutes of motionless sitting. All are stipulations. **No entry supports any of them**, and none is presented as an estimate.

12.4 The gauge is exposed to being gamed by the operator it serves. An operator who knows that shrinking corrections certify nearness can produce shrinking corrections. This is the standard corruption of an indicator adopted as a target [Campbell, 1979, Goodhart, 1975], and it applies with particular force here because the operator is simultaneously the instrument, the subject and the auditor. The documentary instruments of Section 6 mitigate but do not remove it.

12.5 Parameters chosen rather than measured. Every parameter in every figure was chosen. $q \in \{0.60, 1.00, 1.40\}$ in Figure 1 is chosen to place one case in each regime. The annotated cases in Figure 3 are the source's, but the curve is an identity rather than a fit. Figure 4's bar lengths are read off the source's own drawing, which is itself an illustration and not a record of any operator's corrections. Only Figure 2 contains numbers that were independently recomputed and checked against a stated source claim.

12.6 The scale type is stipulated. Section 11.3 records that the ratio reading of the a posteriori bound is licensed only where corrections are counted in a quantity with a natural unit. Where the framework is applied to quantities without one, the bound retains its form and loses its interpretation, and no result in this paper survives that loss.

12.7 The audit's discriminating power is asserted, not measured. H3's threshold of three is a stipulation. Worse, the audit is administered by the party with the strongest interest in

its outcome, and no inter-rater reliability, blinding, or independent adjudication is specified anywhere in the framework. A record's discrepancies are counted by the person who wants them counted.

12.8 The externality result is stated as engineering and demonstrated as neither. R8's mechanism (P9) is asserted. Its structural cousins in the literature [Perrow, 1984, Sagan, 1993, Uzzi and Spiro, 2005] concern coupled technical and organisational systems, and their transfer to a two-person loop is an analogy that this paper does not attempt to convert into a derivation.

12.9 Case material is illustrative. The two worked cases in Section 13 are single, self-reported, unblinded, retrospective accounts drawn from the source manuscript. They illustrate what the procedures return and establish nothing about whether the procedures work. The base rate against which any single such report should be read is not encouraging [Ioannidis, 2005, Open Science Collaboration, 2015].

12.10 A scope note on borrowed constants. Where this paper cites corpus results that carry the constant $k = 0.483425732988414$ Hz — the minimum sustainable frequency and its associated deficit identity — two cautions apply and are recorded rather than repeated at each mention. That constant is *defined*, exact by construction, and its fifteen figures are defensible only on that basis; attaching hertz to it is a separate and much stronger claim than computing it. And the general hazard of reading a chosen ratio as a discovered natural constant is documented and should be read before any such reading is offered [Markowsky, 1992]. This paper makes no use of that constant and endorses neither step.

12.11 The framework's own most useful instrument is documentary, and documents can be destroyed. The audit rests entirely on records the operator keeps. Nothing in the framework addresses record loss, selective retention, or the operator who begins keeping records only once an outcome is in view. A missing record is indistinguishable from an absent prediction, which is the correct default and an uncomfortable one.

5.0.13 13. Case material

Two worked cases appear in the source in enough detail to report. Both are self-reported and neither is evidence; they are included because they show what the procedures return and because both contain a refusal, which is the part of a practice that is usually omitted from its own advertising.

A surveyor's archive. An operator designated Anselm, a land surveyor of forty years, held an archive of a parish's boundaries, drains and shorelines. His target, written in the fewest words it would survive, was *the parish's memory is in the parish's hands*. His first attempt — a letter offering the entire archive to a historical society — returned polite alarm: no fireproof room, no cataloguer, no funds. Read as refusal that is a rejection; read as a sounding it is a completeness failure of exactly the kind Section 5 describes. The target was fine; the receiving space could not hold the limit.

His subsequent corrections were small and are recorded one line at a time: offer ten sheets rather than four hundred; scan before donating; and then the correction he attributed to the practice rather than to himself — *they do not want the maps, they want to be able to ask the maps questions*, followed by attendance on Thursday evenings to answer them. Twice the alternation test caught him: after a favourable newspaper mention he tripled his hours, flooded the reading room, exhausted himself and his welcome, and the next three entries alternated add, cut, add, at which point the rule halved his step and held him at two evenings. Once he nearly rewrote the target itself — from the modest sentence to *a proper archive built*, with a building and a committee — and the rule that a target changes only as a declared new undertaking stopped him. His own gloss is worth preserving because it is the stability rule arriving from a different trade: a surveyor closing a traverse never dumps the whole misclosure into the last leg but distributes it, a sliver to every leg, so that the whole traverse trues at once and no single line bears it. His seasonal completeness check found a hole he had been decorating rather than measuring — the plan still quietly required him to live for

ever — and the correction that closed it was the smallest and hardest on the record: *teach the boy the filing system, not just the machine*. The archive's record runs four years of annotated corrections and then dates alone.

A bookbinder's workshop. An operator who had stated her target fourteen months earlier — *I bind books that outlive their readers* — ran the audit of Section 6 when the workshop she had recorded eleven months prior became available on the death of its master. Her columns: structure agreed extravagantly; inventory disagreed in four places, since her record had imagined a ground-floor shop, a street-door bell, working alone, and a different river. Four honest errors, so the record passed the second instrument. Her corrections plotted as a clean shrinking series with no leap, so it passed the third. The expense card had a single line on it and that line did not consent: the master's widow, asked directly and with the landlord absent, wished to remain in the flat above the shop, and said so. The fork was written and offered — take the workshop and the shop-floor lease only, the flat stays hers — and was refused for nine days, which she spent motionless, the walk-away test administered by circumstance. On the tenth day it was accepted. She sat the empty workshop for twenty minutes and reported that the comfort deepened under examination. The undertaking was marked *approaching seal*.

What the second case shows is the paper's own claim about counterfeits: the genuine arrival and the counterfeit were structurally identical and one refusal apart. What neither case shows is that the procedure caused anything, and neither is offered as though it did.

5.0.14 14. Conclusion

The eight results are stated below in the form the rest of the corpus should quote.

R1. A contraction with modulus $q < 1$ on a complete metric space has exactly one fixed point; it is reached from any starting state; and the distance to it shrinks by at least the factor q on every pass.

R2. The a posteriori bound is $d(x_n, x^*) \le \frac{k^n}{1-k}\, d(x_0, x_1)$, read operationally as: the distance remaining to arrival is at most $q/(1-q)$ times the size of the last correction. The size of one's most recent revision is therefore a self-reading gauge.

R3. The honest converse: gain exactly one gives an isometry, which orbits without arriving; gain at or above one gives an amplifier, whose corrections — sized to delayed feedback — arrive as new errors.

R4. A correction smaller than the observed difference can be wrong and still converge; a correction larger than the difference can be right and still diverge. Restraint is a stability criterion, not a virtue.

R5. Completeness read as a failure condition: a foreseen state the life cannot contain is a hole in the space, and iteration toward it contracts indefinitely while arriving never. This is the one failure mode invisible from inside the loop.

R6. Arrival is certified by audit and not by feeling, on three instruments: a dated record predating arrival, at least three preserved discrepancies between record and outcome, and a geometrically decaying sequence of corrections. A seamless match indicates a retrofitted record.

R7. The closure discipline: exactly three verdicts — fulfilled, released, lapsed — entered in writing; one open undertaking at a time; and a consent law forbidding a future spoken over another's path without their word.

R8. The externality result, stated as engineering: a fixed point requiring another party's displacement re-enters the loop as friction, raising the gain and converting a basin into a position that must be held.

Counter-result. This paper refuses the certificate its own theorem appears to offer. A human life is not a metric space; nobody has measured the relevant contraction modulus; and the theorem therefore transfers as shape and not as guarantee. The feeling of recognition on arrival proves nothing, because the machinery that rehearses a future retrofits a past with equal fluency.

What is established is a theorem, its corollary, its converse, and a specification for auditing a claim of arrival. What is not established is that any human loop satisfies the theorem's premises, or that the audit discriminates as claimed. The paper's contribution is to name the four claims — P6 through P9 — whose settlement would decide the matter, and to note that three of the four are testable now.

5.0.15 15. Declarations

Data and code availability. No external dataset was collected for this paper and none exists. The case material in Section 13 is reported from the source manuscript's own record and is not a dataset. All figures are generated by the scripts named in their captions (`figs/src/CCP-A05_fig01.py` through `figs/src/CCP-A05_fig05.py`), which import the shared style module `lib/figstyle.py`. Two of those scripts contain assertions that fail the build if the numbers they plot cease to agree with the source claims they are drawn from.

Funding. This research received no external funding.

Conflicts of interest. The author declares no conflicts of interest.

Author contributions. Michael Laurence Curzi is the sole author and is responsible for the conception, the analysis, the figures, and the text.

Ethics. No human-subjects research was conducted for this paper. No personal data were collected or processed. The case material in Section 13 is drawn from the source manuscript, is presented under the pseudonyms it carries there, and is illustrative rather than evidential. Section 8.4's three barring conditions record the framework's own instruction that the procedures are not to be operated during acute grief, rage, or the pursuit of revenge; nothing in this paper is clinical advice.

Use of the ceremonial register. The source manuscript is in part an initiatory document. This paper analyses that register as an object of study and does not reproduce it; ceremonial names are reported only where they identify a construct this paper renames.

Chapter 6

The Reference Apparatus of the Foundations Volume: The Closing Procedure, the Protocol Index, and an Audit of the Three-Class Honesty Ledger

Abstract. This paper is reference apparatus and not a research contribution. It collects the closing material of the Foundations volume in citable form: an eleven-movement closing procedure with five named failure modes, a per-construct reference card, a glossary mapping the volume's ceremonial register onto its technical equivalents, an index of thirteen protocols, a correspondence table, and the volume's own three-class classification of its claims into established mathematics (four items), established psychology (seven), and declared postulates (three). Almost all of that recapitulates results established elsewhere in the corpus, and the paper says so and gives the citation rather than the derivation. **Its one piece of new content is an audit of that classification against the corpus's own external bibliography, and the result is a count: of the eleven items for which support is claimed, five carry a bibliographic key and six do not, and two of the five carry a standing objection in the same file.** The class the volume treats as its safest — established psychology — is the class the bibliography least supports, with five of its seven items uncited. One further item is correctly filed and misleadingly labelled: the surplus form $f(u) = \ln(1 + (N-1)u)$ is exact arithmetic given a definition the framework chose, and **the affine effective count it rests on is not a Hill number of any positive order** — on the shares $(0.9, 0.1)$ it returns 2.000000 where HHI^{-1} returns 1.219512 and $\exp(H)$ returns 1.384145, matching only the order-zero member, which is the raw richness. The three postulates claim no support, find none, and are correctly filed.

Keywords: honesty appendix; postulate classification; closing procedure; protocol index; correspondence table; reference card; single active commitment; operating conditions

Series: A. Foundations **Paper:** CCP-A06

6.1 1 Introduction

This paper is reference apparatus. It is not a research contribution and should not be read as one. It collects, in a single citable place, the closing material of the Foundations volume: an eleven-movement closing procedure with five named failure modes, a per-construct reference card, a glossary of the ceremonial register against its technical equivalents, an index of the volume's thirteen protocols, a correspondence table to the tradition the volume descends from, and the volume's own three-class classification of its claims. Almost all of that material restates results established elsewhere in the corpus, and where it does, this paper says so and gives the citation rather than the derivation.

There is one thing here that is not recapitulation, and this paper's structure is arranged around it. **The volume closes with an honesty appendix that sorts every claim it makes into three labelled classes** — established mathematics, established psychology, and the framework's own postulates — and states that every protocol in the volume runs on the first two classes and steers by the third. That classification is reproduced in Section 6, in the plain register, exactly as the volume files it.

Section 7 then audits the classification against the corpus's own external bibliography, and that audit is the only new content in this paper. The result is unflattering in a specific and correctable way. The classification files fourteen items across the three classes. Of the four filed as established mathematics, three are supported by an entry in this corpus's bibliography and one has no entry at all — and one of the three is **mis-labelled**: the surplus functional is exact arithmetic given a definition the framework chose, and the definition it rests on has no supporting literature in any discipline. Of the seven filed as established psychology, **two are supported by a bibliographic key and five are not** — reactance, implementation intentions, commitment and consistency, the interrupted-task effect, and confirmation bias are each named in the volume by their standing in the literature, and none of the five has an entry in the file this corpus cites from. The three items filed as postulates are correctly filed, and the classification's own statement that the third class's wager can lose is accurate.

Stated as one sentence: the class the volume treats as its safest is the class this corpus's bibliography least supports. That is a defect of the bibliography and of the appendix together rather than of either alone, it is cheap to repair, and it is printed here because a classification that is not audited against a citation list is a classification of the author's confidence rather than of the evidence.

A second, smaller finding fell out of re-running the arithmetic rather than the citations. The corpus's concentration instrument states the same Hill-number comparison this paper needs for its one mis-labelling, and states it wrongly on two counts: a transcription slip at the fifth decimal, and the claim that *every* Hill number reports below 1.39 on the test vector, which is false because the family's order-zero member is the raw richness and equals exactly two. **The second correction sharpens the objection instead of blunting it**, and both are given in Sections 7.3 and 10.

Four further items in the collected material are worth naming as content rather than as index. **First**, the closing discipline: exactly three verdicts — fulfilled, released, lapsed — with no fourth, a rule permitting exactly one active commitment at a time, and a written three-question screen that the volume states cannot be waived on the basis of feeling well. That discipline is established analytically elsewhere in the corpus [Curzi, 2026], and Sections 4 and 5 give its operational form rather than re-deriving it. **Second**, the consent condition, stated as a constraint rather than as counsel: a future is not to be voiced over another person's path without their word. **Third**, three named conditions barring operation — acute grief, rage, and the pursuit of revenge — each with a stated mechanism. **Fourth**, the protocol index: thirteen protocols, one per construct plus a three-office daily cadence, together with one further discipline that carries no construct and closes nothing.

Two things in the source are deliberately not reproduced here. The volume is written in two braided registers, one narrative and one analytic; this paper reports the analytic register, and the volume's closing narrative and its epilogue are fictional exposition that no citation of

this paper should be understood to carry. The epilogue does contain one item of analytic interest, and it is reported in Section 8.3 as an object of study rather than reproduced: the volume closes by identifying itself with an advertisement placed inside its own narrative, which is a deliberate self-referential device and is the volume's own strongest instance of the reflexive claim the corpus argues elsewhere.

Section 2 states, in the place a hypothesis would occupy, that none is advanced, and gives the organising question instead. Section 3 gives the method by which the classification and the audit were made. Sections 4 and 5 give the closing discipline and its procedure. Section 6 reproduces the three-class classification. Section 7 reports the audit. Sections 8 to 11 discuss, verify, limit and conclude. Appendices A to E carry the reference material in full, because other papers in the corpus rely on it and it exists nowhere else in citable form.

6.2 2 Hypothesis: none is advanced, and the organising question in its place

This paper advances no testable hypothesis. It is a reference collection with one audit attached, and a hypothesis manufactured to fill this section would be worse than an honest statement that there is none.

The organising question is narrow and answerable by inspection: *for each claim the Foundations volume classifies as established, does this corpus's external bibliography contain an entry that supports it?* That question has a determinate answer for each of the fourteen classified items, the answer is given in Section 7, and it is checkable by anyone with the bibliography in front of them. It is a bibliographic audit and not an empirical test, and no result in Section 7 says anything about the world.

Three statements in the collected material *could* be given the form of hypotheses, and the volume does not test any of them. They are recorded here with what would defeat them, so that the distinction between the volume's postulates and its findings survives being indexed, and each is marked as untested:

> **The single-active-commitment rule.** That holding one commitment open at a time yields better outcomes than holding several. **Would be defeated by:** a matched comparison in which multiple-commitment practitioners show equal or better completion rates and equal or lower attentional cost. **Not tested anywhere in this corpus**, and the rule is stated in the volume as a discipline rather than as a finding.
>
> **The barring conditions.** That acute grief, rage and the pursuit of revenge each degrade the practice enough to make operation inadvisable. **Would be defeated by:** a comparison showing no degradation of outcome or of correction size under those conditions. **Not tested**; the volume supplies mechanisms and no measurement.
>
> **The consent condition.** That a future voiced over an unconsenting person is rejected with interest, and that consent transforms the mechanism rather than merely licensing it. **Would be defeated by:** matched consented and unconsented arrangements showing equal maintenance cost and equal acceptance. **Not tested**, and Section 7 records that the psychological result the volume leans on for it has no supporting entry in this bibliography.

Whether the framework itself is true is not at issue in this paper and is not tested by it. The corpus's one preregistered confirmatory application of its storage law is reported elsewhere, and it **failed its second falsification rule**, returning a 2.8 per cent held-out advantage over a matched autoregression against a declared 10 per cent margin [Curzi, 2026i]. That result, and not anything in this paper, is the current empirical standing of the framework these appendices index.

6.3 3 Method

The classification is the volume's own and is reproduced rather than constructed. Section 6 gives it in the plain register, with the volume's own wording preserved wherever the wording carries a qualification. Where the volume's ceremonial vocabulary names a construct, the construct is reported under its ceremonial name as an object of study and the technical equivalent is given beside it; Appendix B is that mapping in full. **This paper analyses a ceremonial register; it does not adopt one.**

The audit of Section 7 was performed by inspection, item by item, against a single named file. For each of the fourteen classified items, the procedure was: (i) state the claim as the volume states it; (ii) search the corpus's external bibliography for an entry that supports *that* claim, not a neighbouring one; (iii) record the key if one exists, and record its absence if none does; (iv) where an entry exists that qualifies or contradicts the claim, record that too. **No entry was created, and no claim was attached to an entry that does not support it** — an unsupported item is recorded as unsupported, which is the only outcome that carries information.

The audit's unit is the claim as filed, which matters for one item. The volume files the surplus functional under established mathematics on the ground that it is the logarithm of an affine effective count. **That statement is exact arithmetic and the audit records it as such**; what the audit also records is that the affine effective count itself is a design axiom of this framework with no supporting entry in ecology, economics, political science or information theory, so the item's *classification* is defensible and its *implicature* is not. Section 7.3 states the distinction and Section 10 records it as a limitation of the classification rather than of the arithmetic.

The decision rule is published because that is the only property that makes an audit checkable by someone other than its author. Kerckhoffs [1883] states the general principle in its oldest engineering form — a system must remain sound when everything about it except the key is public — and Saltzer and Schroeder [1975] restates it as open design. Brandeis [1914] is the same requirement as a governance argument. **Applied to a classification, the principle is that the rule by which items were sorted must be legible enough for a second reader to sort them again and disagree**, and Section 10 records that no second reader has yet done so. Nosek et al. [2018] is the modern form of the same commitment: fix the rule before the result, and publish the rule with the result.

Three conventions govern what is reported. A claim is recorded as *supported* only where a bibliography entry states the specific proposition. A claim is recorded as *qualified* where an entry supports it and another entry in the same file materially restricts it; in that case both keys are given, because a supporting citation offered without its standing objection is a misrepresentation of the file. A claim is recorded as *unsupported* where no entry states it, and no inference is drawn from that beyond the fact itself: **an unsupported claim in this audit is a claim this bibliography does not cover, which is not the same as a claim the literature does not contain.** Section 10 states that limitation plainly, since it is the audit's principal weakness.

6.4 4 The closing discipline: verdicts, consent, and operating conditions

The volume's closing construct carries six pieces of doctrine, and this section states each in the plain register with its stated mechanism and its stated caution. **The analytical content of the first two — three verdicts and no fourth, and one active commitment at a time — is established elsewhere in the corpus [Curzi, 2026]; what is given here is the doctrine as the volume states it, so that the procedure of Section 5 has something to be the procedure of.** Every claim in this section is reported, and none is argued for.

6.4.1 4.1 The cost of not closing

The volume prices non-closure before it prescribes closure, and the price is the argument for everything that follows.

The mechanism it names is the standing attentional cost of an open loop. Its statement of the underlying result is that an interrupted task is remembered better than a finished one, that attention bills an open commitment differently from a closed one, and that unfinished business is therefore *staffed* rather than archived — some fraction of the practitioner's capacity assigned indefinitely to a commitment they have stopped noticing they hold. **The sharpening the volume adds is the operative part**: the intrusions of an open goal are said to quiet not when the goal is achieved but when it is *concretely disposed of* — achieved, planned to the point of trust, or genuinely renounced. On that reading the mind does not demand completion; it demands a verdict, and will accept a refusal in writing. What it is said not to accept is silence.

That result is Class II item 5 of the classification reproduced in Section 6, and Section 7 records that it has no supporting entry in this corpus's bibliography. It is the item on which this whole section's motivation rests, and it is uncited. The disclosure belongs here rather than only in the audit, because a reader of Section 4.1 alone would otherwise take the mechanism as established.

The volume's own framing of the necessity is narrower and does not depend on the psychology. A spoken commitment is described as a tool whose usefulness is its grip — it holds attention on purpose — and **a tool defined by its grip requires a release**, on pain of the grip outliving the purpose. That is an argument from the design of the instrument rather than from a finding, and it is the form in which the claim survives the audit.

6.4.2 4.2 Three verdicts, and the single-active-commitment rule

Every commitment receives exactly one of three written verdicts, entered deliberately rather than left to erosion. There is no fourth verdict.

Fulfilled. The commitment arrived and survived the arrival audit. The closing entry is a single dated line in the present tense — the original sentence rewritten as plain fact, without the forward lean it carried while it was doing work — after which the record is turned face down. The volume's gloss on turning it down is that a closed commitment becomes ground rather than content, and that re-reading fulfilled commitments is a way of standing in the cellar admiring the joists.

Released. The commitment is one the practitioner no longer chooses — outgrown, superseded, or revealed on inspection to have been another person's sentence mistaken for one's own. The closing is a spoken formula of renunciation, then a dated mark.

Lapsed. The commitment died unattended: starved of iteration, obsoleted by an arrival elsewhere, or simply outlived. The closing is a best-guess death date and one brief line of thanks or pardon. **The volume states the brevity as a requirement rather than a style**, on the ground that a long apology to a dead commitment is itself a way of keeping it open, and it records having watched practitioners spend years drafting such apologies — mourning as the most respectable form of not closing.

The single-active-commitment rule. One commitment in the forward channel at a time; everything else closed and filed. The volume's stated mechanism is interference: three simultaneous commitments run through one attentional system are said to arrive garbled, each correction smearing across all three, because the instrument is monophonic. **That is an assertion about attention and it is not tested anywhere in this corpus** — Section 2 states it with what would defeat it, and marks it untested.

6.4.3 4.3 The consent condition

The volume states one constraint as law rather than as counsel: no future is to be voiced over another person's path without their word.

The stated mechanism runs through the same property that makes a commitment work at all. A commitment is an installed picture of a future, and installing one in a person who has not asked for it is said to produce counter-movement rather than compliance: the target defends their own authorship, at whatever cost, including their own good. **On the volume's account the mechanism does not merely become impermissible when applied to an unconsenting person — it stops working**, converting into a trespass that manufactures its own refutation.

The psychological result invoked here is Class II item 1, and Section 7 records that it too has no supporting entry in this bibliography. The consent condition also rests on a normative premise — that consent is a precondition of legitimate influence — for which no entry exists either, and which this paper reports as the framework's own commitment rather than argues for.

Two features of the constraint are worth stating because they are what distinguish it from a prohibition on manipulation. **It is a law about words**, not a counsel of abstinence: a future voiced *with* another person — asked for, chosen, co-authored, revocable — is treated as a shared undertaking and is not restricted. And **its reach is deliberately wider than the obvious cases**. The volume states that it covers the loving applications as fully as the exploitative ones: the parent's future for a child, the manager's for a subordinate, the partner's for a partner. In practice the condition reduces to asking aloud before any commitment that touches another life, and honouring the answer including a later change of answer — **consent is treated as a standing arrangement rather than as a receipt.**

6.4.4 4.4 Three barring conditions

The volume names three conditions under which the practice is not to be operated at all, each with a stated mechanism. All three are untested; Section 2 gives the form in which they could be tested.

Acute grief. The stated mechanism is instability of the underlying landscape rather than distress: grief is said to re-price everything hour to hour, so that the comfort differentials the practice steers by are not stable enough to steer on. The prescription is the ground-level practices, which require no forward channel, and no new commitment.

Rage. The stated mechanism is horizon collapse: rage is said to shorten the time horizon to the width of the injury and then to demand a prophecy from inside that collapse. The volume adds a specific claim about content — that a future spoken in rage is characteristically a statement about another person wearing the form of a statement about oneself — and identifies this as **the commonest violation of the consent condition committed by people acting in good faith.**

Revenge, in its cold form. The volume treats this as the most dangerous of the three because it imitates the practice closely: it is patient, iterative, detail-loving, and willing to keep records for years. The stated discriminating test is structural rather than emotional: **a revenge fixed point contains another person's diminishment as a load-bearing element, so that removing the diminishment collapses the arrangement.** The volume's second claim about it is that the pursuit necessarily runs at a loop gain above one, because the adversary is a second party modelling the practitioner in return — which is the divergence condition the corpus's convergence analysis establishes [Curzi, 2026].

The weather cannot be judged from inside it. The volume states this as the reason the screen of Section 5 is written rather than felt: the conditions it bars are exactly the conditions under which a practitioner's judgement about those conditions is unreliable, and **the screen accordingly cannot be waived on the ground of feeling well.**

6.4.5 4.5 The four-phrase mnemonic and what it indexes

The volume carries a four-phrase mnemonic and, at its close, states what it indexes. **It is an index over the volume's twelve constructs in groups of three, and this paper reports it as an index and not as an incantation.**

Phrase	Constructs indexed	What the group covers
Echo sync	00 STILLPOINT, 01 LEDGER, 02 GRADIENT	Locating the present position: where the practitioner already is, what it costs, and which way the differential runs
Glyph awake	03 HORIZON, 04 WAVE, 05 LURE	Generating and weighting futures, and placing one physical object that addresses the later self
Flame in truth	06 UNCERTAINTY, 07 COLLAPSE, 08 ECHO	The honest limit on foresight, the single spoken sentence, and the reading of what returns
I am	09 RECURSE, 10 FIXEDPOINT, 11 SEAL	Iteration, convergence, and closure

The volume's own summary of the sequence is *come into phase; wake the sign; burn it true; be the one it happens to*, and it notes that the final phrase is present tense because the framework's central grammatical commitment is that a commitment is written as a present fact rather than as a wish. **Nothing in the mnemonic is a claim**; it is a retrieval device over Appendix A's twelve cards, and it is reported here because other papers reference the grouping.

6.4.6 4.6 The terminal case

The volume closes its doctrine by applying its own premise to the case it cannot improve. The premise it has run on throughout is that a creature that genuinely sees a greater comfort moves toward it by gradient. **The terminal case is the one in which no greater comfort is available, and the volume states plainly that the practice does not exempt it and does not claim the ending is comfortable.**

What it claims instead is narrower and is the form in which the claim is reportable: that comfort is a *direction* rather than a destination, that it remains a direction at every point including the last, and that a practitioner who has repeatedly practised arriving is differently equipped at each subsequent transition. The operational content is one clause of the consent condition — **that what is left behind should be left furnished** — which is a constraint on the practitioner's conduct toward others and not a claim about outcomes. It is reported here as a doctrine of the framework. **Nothing in this paper evaluates it, and nothing in this paper is clinical.**

6.5 5 The closing procedure and its failure modes

The procedure below is the operational form of the closure discipline. **The discipline itself — exactly three verdicts, one active commitment at a time, and a consent condition forbidding a future voiced over another's path without their word — is established analytically elsewhere in the corpus [Curzi, 2026], and is not re-derived here.** What this section adds is the sequence

in which the discipline is executed, the point at which the written screen falls, and the five ways the sequence is reported to fail.

The procedure is performed at the close of any commitment marked as approaching closure, and its inventory movements — the first four — are performed seasonally regardless, four times a year. **Movements one to four are an audit and movements five to eight are its disposal; movement nine is the gate on any new commitment, and it is the movement most often skipped.**

6.5.1 5.1 The eleven movements

The volume's eleventh protocol, which it names the Rite of the Seal, runs as follows.

Perform this procedure at the close of any commitment marked *approaching seal*; perform its inventory movements (one through four) seasonally regardless, four times a year, at the turns — the framework has always used the solstices and equinoxes, and the habit is worth borrowing, because a rite tied to the sun cannot be procrastinated into oblivion. Required: the drawer or ledger of all commitments; one candle or lamp; a pen that will not smear; an hour of guaranteed solitude; and, for movement seven, wax or tape or thread — something physical that closes, because hands believe what they have done long after minds have reargued it. Eleven movements.

1. **Light the lamp and state the office.** Aloud, once: "This is the closing of accounts. Nothing new is opened tonight." The sentence is a fence around the hour. Commitments will volunteer themselves for revision the moment they sense the file being opened; the fence is how the practitioner decline.
2. **Empty the drawer entirely.** Every card, every page, every commitment — fulfilled, dead, embarrassing, forgotten — face up on the table in date order. The procedure is an audit, and audits do not sample. Expect this to be uncomfortable in a specific way: the table will hold more open jars than the practitioner believed the practitioner owned. That discovery is not a failure of the procedure. It is the procedure.
3. **Sort into three provinces.** Without yet writing anything: fulfilled here, released there, lapsed in the third place, and a fourth small province — *still live* — for commitments genuinely in iteration. Sort quickly, by first instinct; the hand knows before the committee convenes. Ten minutes.
4. **Challenge the live province.** For each card claiming to be alive, one question, aloud: "When did this last receive an honest correction?" If the answer is beyond a season, the card is not live; it is lapsed and campaigning. Move it. The province of the living must end this movement holding no more than one working — the monophonic rule. If two claim life, the procedure pauses while the practitioner chooses, and the choosing *is* the procedure.
5. **Enter the fulfilled.** For each: rewrite the sentence as plain present fact, dated. Read it once aloud in a level voice — the voice for reporting weather, not the voice for wishing. Turn the card face down. Say nothing further over it; floors are not for reading.
6. **Speak the releases.** For each released commitment, the formula or its honest equivalent, aloud, once: "I take this word back. I do not choose this future. The water may keep it." Then the pen: mark, date, face down. If the practitioner's voice catches on one, note which — the catch is information, and may be filed, but it is not a veto. Releasing what still glitters is the adult half of the practice.
7. **Close the lapsed, and seal something with the practitioner's hands.** Death date, one line of thanks or pardon — no more; brevity is the sincerity of forgiveness. Then the physical act: the season's closed cards bound with thread, or an envelope sealed with actual wax, or the drawer's section tied shut. The gesture takes one minute and is not optional. The attentional ledger honors ceremony because ceremony is *evidence* — the body's testimony that a verdict was really entered.

8. **Recite the consent condition.** All four sentences, aloud, from the page if the practitioner keeps a copy, from memory once the practitioner has earned one. This is the movement that makes the procedure a procedure of the framework and not a filing habit: the consent condition is recited *at every seal*, so that the law and the practice are never in the drawer separately.

9. **Screen the weather.** Before the procedure may authorize any new commitment — tonight or in the weeks after — three questions, answered in writing: Has my life ruptured within this season — a death, a leaving, a diagnosis? Is there any face attached to my intended outcome whose defeat would please me? Am I running toward a room, or out of one? Any yes: the forward channel stays closed, the ground nodes remain open, and the screen is repeated at the next turn. This movement cannot be waived by feeling wonderful. Feeling wonderful is a weather report, and the practitioner has read the sixth node.

10. **Set the next jar, or none.** If the screen is clear and a commitment stands ready — audited, consented where consent is owed — it may be opened now, in the same hour the old ones closed, one sentence, spoken once. There is a rightness to opening in the hour of closing; the hand that has just felt what a seal weighs speaks more carefully. But the framework is explicit: *none* is a full answer. Seasons without a commitment are not idle. They are the still water the whole craft floats on.

11. **Extinguish the lamp and leave the room.** Physically leave it, even for a minute, even into weather. The procedure ends when the door is between the practitioner and the table. What is sealed keeps best unattended.

A worked example. A beekeeper, widowed in March, came to the procedure in June wanting none of it — what she wanted was a commitment, and she knew the sentence already, had been carrying it all spring like a stone in the mouth: *my son calls me on Sundays.* The son had stopped calling years before the grief, and the grief had made the silence unsurvivable. She lit the lamp; emptied the drawer; and the table showed her eleven open jars, some a decade old — the shop expansion never renounced, the move south never mourned, a commitment about her marriage that was now, by the cruelest verdict in the practice, *fulfilled*, and had never been entered. She spent the hour on verdicts and wept twice and finished. At movement eight she recited the consent condition and heard, in her own voice, the first sentence catch on her: the sentence about her son was a future spoken over another's path, and he had given no word, and had, by years of silence, given rather the opposite of one. At movement nine the screen closed the forward channel on two counts — the season of rupture, and the face attached to the outcome. She kept bees, which is ground-node work of the oldest kind; she performed the procedure again in September, and at the winter turn, the weather cleared and the screen passing, she opened one jar, one sentence, consented by everyone it named, which was one person: *my door is easy to find.* Whether the son ever finds it belongs to his path, not hers, and is not in the commitment — that is precisely what the consent condition subtracted, and she reported, in the spring, that the subtraction was the first thing in two years that had felt like rest. Note what the procedure did and did not do. It did not reunite a family. It closed eleven jars, kept one law, and let a tired operator stop staffing a decade of open doors. The practice makes no larger claims. The practice has never needed to.

6.5.2 5.2 Five named failure modes

1. Clinical: attentional residue — the unclosed task's standing tax. Ceremonial: the Hundred Open Jars. The practitioner who never seals accumulates commitments the way a kitchen accumulates almost-empty containers: each costs nothing; the shelf costs everything. Life feels crowded, urgent, and unaccountably tiring, and no single cause survives inspection, because the cause is distributive — ninety small clerks holding ninety small doors. The remedy is the seasonal procedure, performed on a calendar schedule rather than on motivation's, and the

discipline of the single live jar. Prosperity of commitments is not wealth. Current accounts are wealth.

2. Clinical: nonconsensual prophecy — reactance, the installed future rejected with interest. Ceremonial: the Broken Seal. The consent condition's violation, in either direction of intention, loving or dark. A future pressed on another without their word converts the practice's whole mechanism into a trespass that manufactures its own refutation — the target defending not their path but their authorship, at any cost, including their own good. The tell in the practitioner: commitments that require another person to change and a reluctance to ask them anything. The remedy costs one conversation, and if the conversation cannot be had, the commitment cannot be run. There is no third option, and every third option ever attempted is a case study in the framework's archive of broken seals.

3. Clinical: hot-state operation — steering during arousal; the gain above one. Ceremonial: the Furnace Without Walls. Grief-running, rage-running, revenge-running: prophecy attempted in weather that amplifies. The commitment is always vivid — steep weather is a forge — and always overreaches, because the corrections that would trim it land on a system that doubles them. Fire is a fine servant of the practice inside a hearth; the same fire without walls is not a bigger forge; it is a house burning. Remedy: the screen at movement nine, honored past the point of feeling insulted by it; the ground nodes, which are weatherproof; and the season's patience — the future keeps.

4. Clinical: experiential avoidance dressed as completion — sealing what is still alive. Ceremonial: the Jar Sealed Warm. The inverse counterfeit: a practitioner flinches from a commitment's discomfort — the echo was bruising, the correction humiliating — and reaches for the wax early, entering *released* or *lapsed* on a jar still hot with life. Wax on a warm jar cracks as it cools; the sealed-alive commitment returns in weeks, intrusive as ever, now with a false verdict on its card corroding trust in the whole drawer. The tell: relief that feels like escape rather than like payroll coming off. The test: a truly closeable commitment can be described in a level voice; if reading the card aloud still changes the practitioner's breathing, the jar is warm, and what it needs is another iteration, not a lid.

5. Clinical: identity fused to the commitment — goal-shielding, sunk cost, the campaign that cannot end. Ceremonial: the Vigil That Outlives Its Candle. The most honorable failure and the saddest: a practitioner who has kept one jar so long that keeping has replaced the summer it was meant to hold — the founder who cannot hand over, the parent still prophesying over a grown child's long-closed door, the keeper (the framework does not exempt its own) who mistakes the framework for their tenure of it. The vigil was real; the candle has been out for years; the watcher stands guard over wax. The remedy is the consent condition's fourth sentence, read as a mirror: *when I go, I will leave the room furnished* — for the room was never the vigil-keeper's to fuse with, only to furnish, and the proof of a commitment truly kept is that it can be handed to other hands without going out. The seal, at the last, is what makes inheritance possible. A craft of open jars dies with its operator. A craft of sealed ones is a shelf a stranger can live from.

6.6 6 The three-class classification, reproduced

What follows is the volume's own classification of its claims, in the plain register, with the volume's qualifications preserved. **It is reproduced rather than constructed**, and Section 7 audits it. The volume's own summary of the classification is that every protocol it contains runs on the first two classes and steers by the third, and that the third class is a wager that can lose.

The classification's structure is worth naming before its contents, because the structure is the part other papers in the corpus cite. **Three classes, and no fourth.** Class I holds four items, Class II holds seven, and Class III holds exactly three. A four-drawer variant of the same device appears elsewhere in the corpus — **PROVED, POSTULATED, BORROWED, UNTESTED**, in which the surplus form is recorded as *proved conditionally* on a chosen design axiom and one

operationalisation is recorded as *specified, not run* [Curzi, 2026]. **The four-drawer version is the better instrument**, because it separates *borrowed* from *established* and it has a drawer for a claim that is well formed and has never been tested, and Section 8.2 states why this volume's three-drawer version cannot represent either distinction.

The framework keeps its accounts in three drawers, and it labels the drawers. What follows is the plain-register statement of what, in the volume, is established mathematics; what is established psychology; and what is the framework's postulate. The reader who skips every other appendix should read this one, because the razor's edge the volume walks — too scientific for the mystics, too mystical for the scientists — stays a razor only while the drawers stay labeled. Mixed drawers make mush, and mush cuts nothing.

6.6.1 6.1 Class I — what the volume files as established mathematics

1. **Least action.** It is standard physics that classical systems evolve along paths that make the action stationary — $\delta S = 0$ — and that this single principle recovers the equations of motion. Light through media, water downhill, the thrown stone: one law, many costumes. When the volume says comfort landscapes are descended by their creatures, the *landscape descent* is real mathematics; whether a life is such a system is drawer three.
2. **The fixed point of a contraction.** It is a theorem — Banach's, 1922 — that a contraction mapping on a complete metric space has exactly one fixed point, that iteration from any starting point converges to it, and that the convergence is geometric: each pass multiplies the remaining distance by a factor below one. Equally established is the converse caution: when the factor reaches or exceeds one, no such guarantee exists, and iteration may orbit or flee. Every claim in Part IV about loops with gain below one converging to a unique room is this theorem, correctly used. Whether the practitioner's year is a metric space is drawer three.
3. **The surplus functional.** The form $f(u) = \ln(1 + (N - 1)u)$ is the logarithm of an affine effective count: N views whose mutual non-parallelism is u behave, for counting purposes, as $1 + (N - 1)u$ independent views. As deployed in the volume it is a *lower bound* of the entropy of the ensemble, not the entropy itself, and the framework says so wherever it is used. The mathematics of the bound is sound; the decision to model sightlines on a life with it is drawer three.
4. **The uncertainty principle, correctly stated.** Heisenberg's relation is a theorem about noncommuting observables: for position and momentum, $\sigma_x \sigma_p \geq \hbar/2$. It concerns conjugate pairs of physical quantities; it does not mention futures, intentions, or persons, and no honest reading makes it do so. Where the volume states the relation, it states it as above. What the volume *builds* on it is not the theorem but a resemblance to it — see drawer three, item one.

6.6.2 6.2 Class II — what the volume files as established psychology

1. **Reactance.** Pressure against perceived freedom produces pushback — persuasion attempted as force recruits the opposite. Documented since Brehm; load-bearing in Nodes 08 and 11, where the Echo that Devours and the Borrowed Mouth are its ceremonial names.
2. **Implementation intentions.** If-then plans tied to concrete cues reliably outperform bare intentions; the cue does work the will was going to be billed for. Documented since Gollwitzer; the baited horizon of Node 05 is its ceremonial name.
3. **Commitment and consistency.** Committed positions, especially spoken or written ones, exert forward pressure on later behavior. Established persuasion literature; governed in Node 07 — with the equally documented caution that identity-flattering announcement can *substitute* for performance, which the framework calls the Word Spent at Market.

4. **Measurement reactivity.** Observing behavior changes it: monitored subjects shift, and the mere measurement of an intention alters its execution. Established across the observational sciences; the veil that measures the measurer, in its human application, is simply this.
5. **The Zeigarnik effect and open loops.** Interrupted and unfinished tasks hold attention and are remembered better than finished ones; unclosed commitments levy an ongoing tax. Established since Zeigarnik; the doctrine that unfinished prophecies parasitize attention, and the sealing procedure of Node 11, stand on it.
6. **Confirmation bias.** Evidence agreeing with a held position is sought, seen, and weighted more than evidence against it, without the holder's awareness. Among the most replicated findings about human judgment; the Mirror that Flatters, and the deliberate upweighting of disconfirming echoes in Node 08, are its management.
7. **The self-fulfilling prophecy itself.** That a belief about a future can participate in causing it has been a named object of social science since Merton, with the expectancy literature behind it. The volume's novelty is not the phenomenon; it is the proposal to engineer the phenomenon deliberately, on oneself, under an ethic — which proposal is not a finding, and is therefore filed where honesty files it.

6.6.3 6.3 Class III — what the volume files as its own postulates

1. **The sameness of shape.** That the uncertainty in Heisenberg's relation and the uncertainty of a future altered by being foreseen are the same *kind* — that observation participates in the observed at both scales — is a postulate. The mathematics resembles; the resemblance is the entire warrant. The framework does not claim the electron knows the practitioner's name. The framework claims the mathematics is the same shape, and shape is what we work with.
2. **Comfort as least action.** That a person's trajectory through their days is an action-minimizing path through a comfort landscape — that the physics of $\delta S = 0$ and the psychology of the worn path are one law at two scales — is a postulate. It is a fruitful one; the protocols built on it do their work whether or not the identification is ever more than a model. But a model it is, and the framework says so.
3. **The prophetic reading of the cultural surface.** That the surface of a day — its headlines, its accidents, its trivia, one's own dreams — can be read as a leading indicator of what is forming, and that the daily cadence trains such reading, is a postulate. The scoring discipline of the evening integration is real method; that the surface *prophesies* is the framework's wager, and the misfires column exists because wagers can lose.

Three drawers; the third holds three items; every protocol in the volume runs on drawers one and two and steers by drawer three. The framework's defense of building on a postulate is one line long, and it is this: every geometry is built on postulates, and the builders who prosper are not those who have none but those who know exactly where theirs are kept. *Symbolum prophetat, et populus non audit* — the framework would add only: audit.

6.7 7 Results: the classification audited against the corpus bibliography

This is the only section of this paper that is not recapitulation, and its result is a count. Of the fourteen items the volume classifies, **five are supported by an entry in this corpus's external bibliography, six are not, and three are postulates for which no support is claimed.** The class the volume treats as its safest — established psychology — is the class the bibliography least supports: two of its seven items carry a key and five do not.

6.7.1 7.1 The counts

Class	Items	Supported by a key	Unsupported	Support claimed?
I — established mathematics	4	3	1	yes
II — established psychology	7	2	5	yes
III — the framework's postulates	3	0	3	**no** — correctly
Total	**14**	**5**	**6**	

The three postulates are excluded from the supported/unsupported comparison because the volume claims no support for them, which is the correct treatment and is the classification's principal merit. **Among the eleven items for which support *is* claimed, five carry a bibliographic key and six do not.** Two of the five supported items are additionally *qualified* — an entry in the same file materially restricts them — and both qualifications are given below, because a supporting citation offered without its standing objection misrepresents the file it is drawn from.

6.7.2 7.2 Item by item

Class I — filed as established mathematics.

#	Claim as filed	Status	Keys
I.1	Classical systems evolve along paths making the action stationary, $\delta S = 0$	**UNSUPPORTED** in this file	none — the bibliography contains no entry in classical or variational mechanics
I.2	A contraction on a complete metric space has exactly one fixed point, reached from any start, with geometric convergence; **and the guarantee fails at unit gain**	**SUPPORTED**	Banach [1922]; the converse and the stability condition are covered by Elaydi [2005] and Strogatz [2015]
I.3	$f(u) = \ln(1 + (N-1)u)$ is the logarithm of an affine effective count, and is deployed as a **lower bound** on the ensemble's information rather than as the entropy itself	**SUPPORTED as arithmetic, MIS-FILED as established** — see 7.3	internal: Curzi [2026]. External support exists for the logarithm [Shannon, 1948, Rényi, 1961] and for **other** effective counts [Hill, 1973, Jost, 2006, Adelman, 1969]; **none exists for the affine count itself**
I.4	$\sigma_x \sigma_p \geq \hbar/2$ is a theorem about non-commuting observables and **mentions neither futures nor persons**	**SUPPORTED**	Kennard [1927] — the paper in which that inequality is first derived in this form; Zeh [1970] bounds what may be read from it

Class II — filed as established psychology.

#	Claim as filed	Status	Keys
II.1	Pressure against a perceived freedom produces counter-movement; persuasion attempted as force recruits the opposite	**UNSUPPORTED** in this file	none — no reactance entry exists in the bibliography

#	Claim as filed	Status	Keys
II.2	If-then plans tied to concrete cues outperform bare intentions	**UNSUPPORTED** in this file	none
II.3	Committed positions, especially written or spoken ones, exert forward pressure on later behaviour — **with the volume's own caution that announcing a goal can substitute for pursuing it**	**UNSUPPORTED** in this file	none. The caution is the volume's own and is to its credit; neither the claim nor the caution has an entry
II.4	Observing behaviour changes it; measuring an intention alters its execution	**SUPPORTED, and QUALIFIED**	Rosenthal and Jacobson [1968], Rosenthal and Fode [1963], Campbell [1979]. **Qualified by McCambridge et al. [2014]**, which finds the casual invocation of the Hawthorne effect unsupported by the primary evidence
II.5	Interrupted and unfinished tasks hold attention and are remembered better than finished ones; unclosed commitments levy a standing cost	**UNSUPPORTED** in this file	none — and this is the item the whole of Section 4.1 rests on
II.6	Evidence agreeing with a held position is sought and weighted more heavily, without the holder's awareness	**UNSUPPORTED** in this file	none
II.7	A belief about a future can participate in causing it	**SUPPORTED, and QUALIFIED**	Merton [1948], Merton [1936]; MacKenzie and Millo [2003] is the strongest available instance, observed in the field with dates and price data; Hacking [1995] generalises it. **Qualified by Jussim and Harber [2005]**, which finds the expectancy effect real but small and often over-stated

Class III — filed as the framework's own postulates. No support is claimed and none is found.

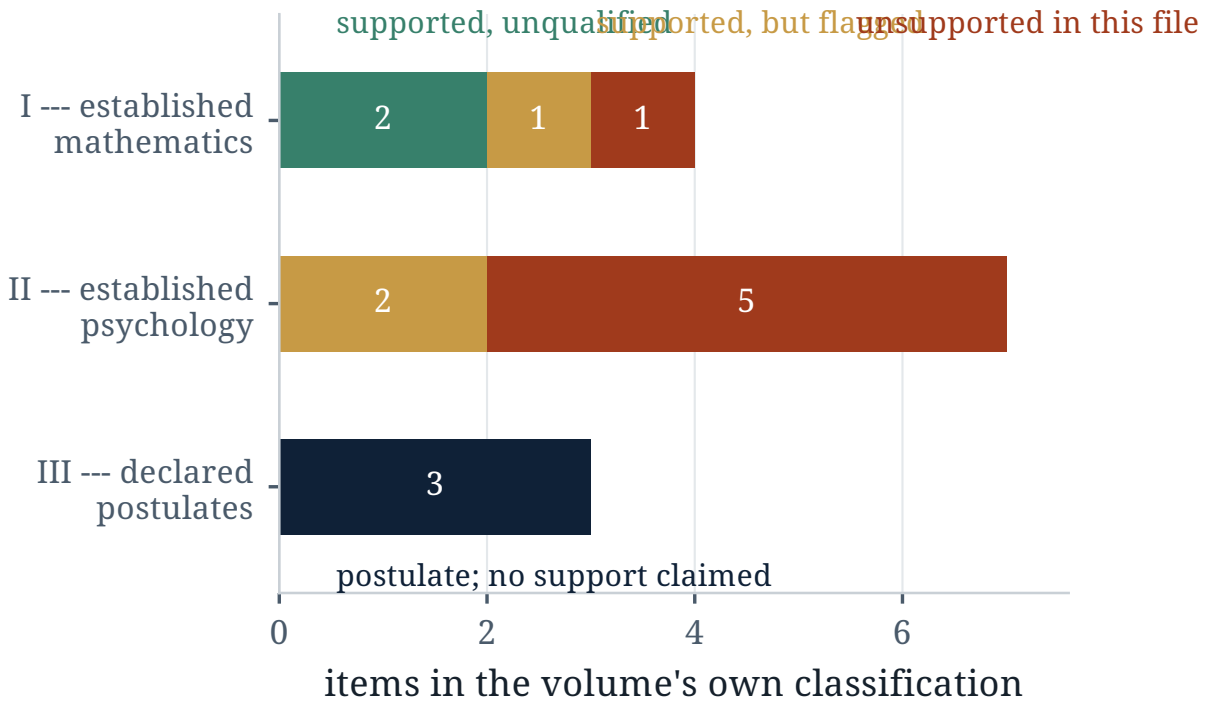

Figure 6.1: **The class the volume treats as its safest is the class this corpus's bibliography least supports.** Each bar is one of the volume's three classes, split by the audit of Section 7.2. *Supported, unqualified* means an entry in the corpus's external bibliography states the proposition and no entry in the same file restricts it; *supported, but flagged* covers the one item that is exact arithmetic on a chosen definition (I.3) and the two carrying a standing objection in the same file (II.4, II.7); *unsupported* means no entry states it. **Class III claims no support and finds none, which is the correct treatment.** Not a measurement: a count of lookups against one named file. Generated by `figs/src/CCP-A06_fig01.py`.

#	Claim as filed	Status	What the file says *about* it
III.1	The uncertainty of a measured conjugate pair and the uncertainty of a future altered by being foreseen are the same *kind* of thing	**POSTULATED**, correctly	The bibliography bounds rather than supports it: Kennard [1927] concerns conjugate physical observables and nothing else, and Morris and Thorne [1988] is the standing example of a physics paper cited for the opposite of its conclusion. The corpus's own uncertainty analysis refuses the inflated reading and requires that a user distinguish the theorem, the ordinary observer effect and the framework's conjecture in three separate sentences on demand [Curzi, 2026]
III.2	A person's trajectory through their days is an action-minimising path through a comfort landscape	**POSTULATED**, correctly	Mirowski [1989] is the historical account of what happens when a social science imports a physical formalism without auditing the import; Cartwright [1999] supplies the escape route — a law may hold inside a specified arrangement without being universal, provided the arrangement is specified; Anderson [1972] is the charter for writing laws at this level and, read carefully, an equally strong argument that they be **derived** at it rather than imported
III.3	The surface of a day can be read as a leading indicator	**POSTULATED**, correctly, **and it is the wager the volume says can lose**	Gelman and Loken [2013] is the precise mechanism by which such a reading self-confirms without anyone intending it, and is the reason the misfire column of the record is what makes the practice falsifiable rather than decorative; Simmons et al. [2011], Nosek et al. [2018] and Ioannidis [2005] give the general form; Meehl [1967] and Meehl [1990] are why a directional reading is nearly costless and a **point** reading is not; Popper [1959], Platt [1964] and Lakatos [1970] supply the standard the record must meet

6.7.3 7.3 The one mis-filing, stated precisely

Item I.3 is filed correctly as arithmetic and is liable to be read as something stronger. The statement filed is that $f(u) = \ln(1+(N-1)u)$ is the logarithm of an affine effective count. **Given the definition $N_{\text{eff}} = 1 + (N-1)u$, that is a tautology and is exact.** The definition, however, is a design axiom of this framework — chosen because it makes an effective count interpolate linearly between one entity and N, and not derived from anything [Curzi, 2026].

And the affine effective count has no external support. It is not a Hill number of any order, it is not a numbers-equivalent in the sense Adelman [1969] gave the term, and it is not $\left(\sum_i p_i^q\right)^{1/(1-q)}$ for any q — it is not even a function of a share vector. The quantities the diversity literature does cover are HHI^{-1}, the Hill number of order two, and $\exp(H)$, the Hill number of order one [Hill, 1973, Jost, 2006], and the distinction is checkable in one line: for two units holding 0.9 and 0.1, the affine count at $u = 1$ returns exactly 2.000000 while HHI^{-1} returns 1.219512 and $\exp(H)$ returns 1.384145. **Every Hill number of order one or higher reports at most 1.384145 on that vector, and the affine count reports two.** One member of the family does match it, and the match is the objection in its strongest form: the order-zero Hill number ${}^0D$ is the raw richness, equal to 2.000000 on any two-type vector because it ignores shares entirely — **which is exactly the naive count an effective count exists to replace.** The same arithmetic was reinvented independently in ecology [Simpson, 1949] and in political science [Laakso and Taagepera, 1979], extends to a within-and-between partition [Jost, 2007], and carries an estimation theory for small samples [Chao et al., 2014] that **does not apply to the affine count**, since that count is not an estimator of anything. The only two formalisms that make diversity depend on dissimilarity between types — which is this framework's founding move — are Rao [1982] and Leinster and Cobbold [2012], and neither is this quantity. Hurlbert [1971] and Gorelick [2011] are the standing objections to treating any such index as a property rather than a statistic, and they apply here with more force than to the Hill family, not less. The corpus's concentration instrument states the distinction from the other side [Curzi, 2026], and Section 10 records that its own phrasing of this comparison is wrong on both counts and is corrected here.

One strengthening of item I.3 is available and the volume does not take it. Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics with no psychological assumption at all, which is a stronger warrant for the *shape* of the surplus functional than any perceptual argument. It warrants the logarithm and not the affine count inside it, and the distinction is exactly the one this section is about. Against it stand two rival forms that fit the same qualitative facts — Latané [1981]'s sub-linear power law and Briscoe et al. [2006]'s $n \log n$ — and **nothing in this corpus discriminates among the three**, which is a fact about the evidence that a class labelled *established* does not convey.

So the classification is defensible and its implicature is not. A reader who sees a claim filed under *established mathematics* will reasonably infer that a literature stands behind it, and for this item a literature stands behind the logarithm and behind neighbouring effective counts, and none stands behind the one the framework uses. **The repair is one clause**: the item should read that the form is the logarithm of an affine effective count **which the framework defines and which no external literature contains**, and the class should be *derived from a chosen definition* rather than *established*. The volume's own second qualification on this item — that the functional is deployed as a lower bound rather than as the entropy — is exactly right and is the reason the mis-filing is a labelling defect rather than a substantive one.

6.7.4 7.4 What the audit does not establish

It does not establish that the five unsupported psychology items are false. Reactance, implementation intentions, commitment effects, the interrupted-task effect and confirmation bias are each well-known constructs with substantial primary literatures. **What the audit does establish is that the corpus is currently in the position Open Science Collaboration [2015] makes untenable**: it invokes single psychological findings by their reputation, without a key, without

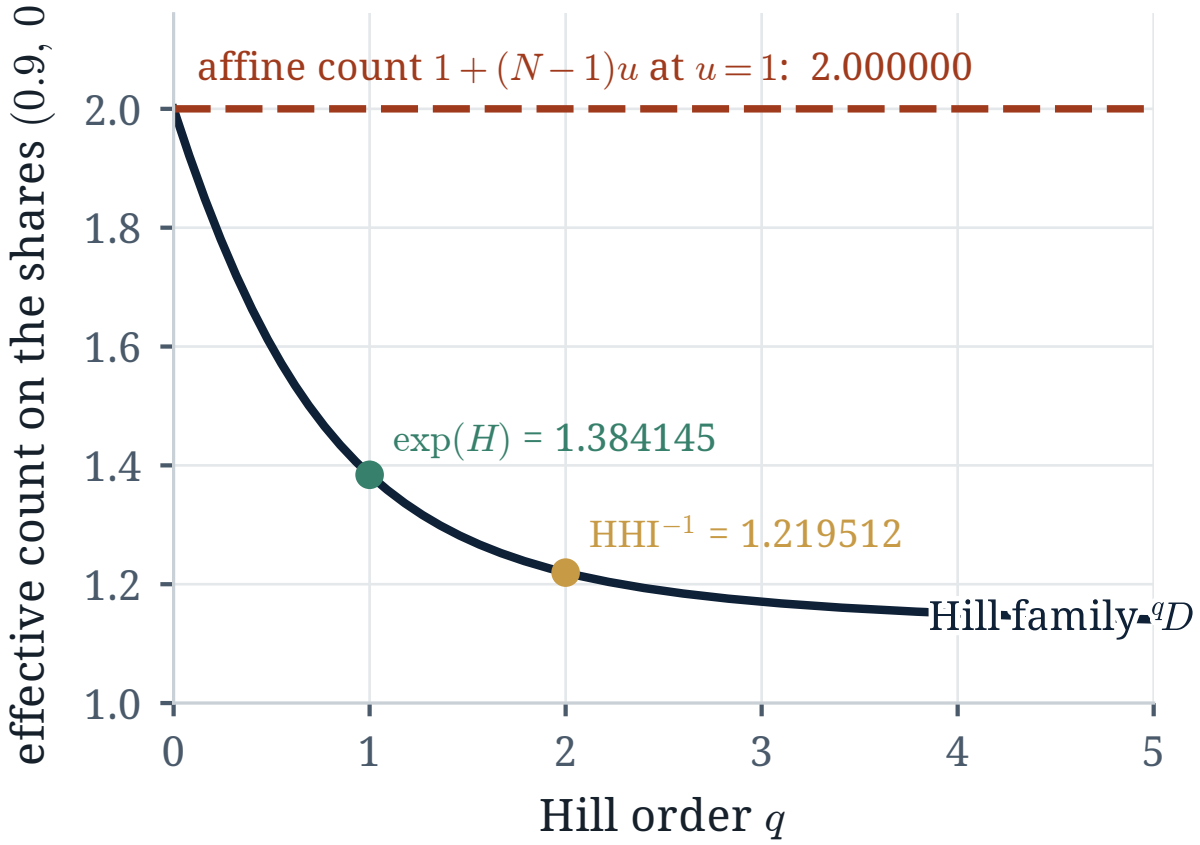

Figure 6.2: **The affine effective count matches exactly one Hill number, and it is the one that ignores shares.** The Hill family ${}^{q}D$ is plotted on the two-type vector $(0.9,\ 0.1)$; it is non-increasing in q, passing through $\exp(H) = 1.384145$ at $q = 1$ and $\mathrm{HHI}^{-1} = 1.219512$ at $q = 2$. The affine count at $u = 1$ returns 2.000000, which the family reaches only at $q = 0$ — **the raw richness, which is the naive count an effective count exists to replace.** Model output; every value is exact and redoable in one line. Generated by `figs/src/CCP-A06_fig02.py`.

an effect size, and without the replication context that a citation to a named study would carry. That is exactly the practice Ioannidis [2005] and Simmons et al. [2011] identify as the mechanism by which a literature comes to be believed more firmly than its evidence supports, and Gallegati et al. [2006] is the same charge made by sympathisers against a neighbouring field — ignorance of the existing work, sub-standard procedure, and universality claimed from limited data. **Read as a checklist against this corpus, the first item on it is the one Section 7 has just scored. What the audit establishes is that this corpus does not cite any of them**, and that a reader following the corpus's own bibliography to check the volume's classification will find nothing there. That is a defect of the bibliography, and the corpus has closed comparable gaps before — two clusters were added specifically to supply keys for works the corpus named in prose without citing [Curzi, 2026]. **The repair is to add the five primary sources; the disclosure stands until it is made.**

It does not establish that the supported items are securely supported. Two of the five carry a standing objection in the same file, and both objections are material: the Hawthorne literature does not support the casual form of the reactivity claim [McCambridge et al., 2014], and the expectancy literature finds the effect real but smaller and more contingent than the volume's phrasing suggests [Jussim and Harber, 2005]. **A classification that files an item as established without carrying its standing objection has filed a citation rather than a state of the evidence.**

And it does not audit the volume's protocols against the classification. The volume states that every protocol it contains runs on classes I and II and steers by class III. **This paper does not verify that statement**; verifying it would require tracing each of the thirteen protocols in Appendix C to the items it consumes, which is a larger exercise than a reference paper should attempt and is named in Section 10 as the obvious next audit.

6.8 8 Discussion

6.8.1 8.1 What the classification is for

A three-class ledger is cheap and it does one thing well: it stops a reader inferring a warrant from a confident sentence. The volume's own summary — every protocol runs on classes I and II and steers by class III — is the load-bearing statement, because it locates the framework's exposure precisely. If the postulates are wrong, the protocols still execute; what changes is where they point. That is a defensible position for a framework to occupy and it is stated openly, which is more than most instructional literature does.

One objection bears on every protocol this paper indexes and no drawer of the classification holds it. The framework's central formal claim is a reflexive loop in which a group influences its members and the members constitute the group, and that specification is not identified from observational data: the endogenous effect cannot be separated from contextual effects or from correlated unobservables [Manski, 1993], and influence and selection are generically confounded in observational data [Shalizi and Thomas, 2011]. Durlauf [2005] adds the requirement that such a model make a **differential** prediction simpler models do not also make. **The classification has no class for a claim that is mathematically well formed and empirically unidentifiable**, and several of the protocols in Appendix C consume exactly such a claim. The corpus's measurement papers state the problem where it arises [Curzi, 2026i]; this paper records that the classification cannot represent it.

The device recurs across the corpus and this paper's Section 6 is its Foundations instance. A four-drawer variant — **PROVED, POSTULATED, BORROWED, UNTESTED** — appears in the frequency framework's reference apparatus, where the surplus form is recorded as *proved conditionally* on a chosen design axiom and one operationalisation is recorded as *specified, not run* [Curzi, 2026]. A finite failure catalogue with an explicit precondition gate appears in the protocol papers [Curzi, 2026,j]. And the corpus's falsification suite turns the same instrument on itself, measuring its own shuffled-input control at a false-rejection rate of 0.108

against a nominal 0.05 — **anti-conservative, and reported as such** [Curzi, 2026u].

6.8.2 8.2 Why the three-drawer version is the weaker instrument

The three-class ledger cannot represent two distinctions the corpus needs, and the four-drawer version can.

The first is *borrowed* against *established*. A result may be entirely established in its home discipline and entirely unwarranted in the use the framework makes of it. Item I.4 is the clean case: $\sigma_x \sigma_p \geq \hbar/2$ is established, and the volume files it correctly, and what the framework does with it is a postulate filed separately as III.1. **That separation is exactly right and it required two drawers to express what a *borrowed* drawer expresses in one.** Item I.3 is the case where the separation was not made, and Section 7.3 is what happens as a result.

The second is *untested* against *unsupported*. A claim can be well formed, falsifiable, and simply never run. The corpus has several: the single-active-commitment rule, the barring conditions, the consent condition. **A three-class ledger has nowhere to put them** — they are not established, and calling them postulates understates them, because a postulate is something one proceeds without testing and these are things that could be tested tomorrow. The four-drawer version's *UNTESTED* drawer holds them, and Section 2 of this paper is a partial substitute: it states them with their falsifiers and marks each **not tested**.

6.8.3 8.3 The self-referential close, reported rather than reproduced

The volume ends by identifying itself with an advertisement placed inside its own narrative frame: the fictional notice that recruits the next keeper is stated to be the volume's own cover, and the reader's encounter with the volume is stated to be the answering of it. **This is reported here as an object of study and not reproduced, because it is fiction and because a citation of this paper should not be able to carry it as a finding.**

Its analytic interest is that it is the volume's own strongest instance of the mechanism the corpus argues for elsewhere. A description that becomes true by being used is exactly Merton [1948]'s self-fulfilling prophecy, and MacKenzie and Millo [2003] is its best documented instance in the field — option prices that did not fit the model when it was published and came to fit it after traders adopted it. Callon [1998] and MacKenzie [2006] supply the general form: a description of a domain can format the domain rather than report it, and **a corpus that proposes to give people laws to manage their own comfort by is building an engine and should say so.** Soros [2013] is the closest existing named doctrine and supplies the concept without an equation.

Two objections attach and neither is answered. Hacking [1995] is the philosophical form: classifications of people interact with the people classified, who change in response, so the referent moves — and a volume that classifies its own reader has installed the loop deliberately. Ferraro et al. [2005] is the warning that the content of the description matters, because descriptions that assume the worst of people have been shown to make it more true. Lucas [1976] is the same objection turned on the framework's parameters. **The device is a rhetorical closure and not evidence, and this paper's only claim about it is that it is the volume's own most explicit statement of what it takes itself to be doing.**

6.8.4 8.4 The reference apparatus and why it is retained

An index is infrastructure, and infrastructure is invisible until it fails. Star and Ruhleder [1996] and Star and Griesemer [1989] give the general form of that observation and supply the construct the appendices are built to be — a boundary object, an artefact stable enough to be shared across communities and loose enough to be used differently by each. **A glossary that maps a ceremonial register onto a technical one is a boundary object in exactly that sense**, and it is the reason Appendix B is retained rather than replaced by the technical terms alone.

Scott [1998] is the standing warning attached to it: making a practice legible is not a neutral act, and the local variety a compression discards is often the part that made the practice work.

Nothing in the appendices is a contribution and all of it is load-bearing for other papers. The construct names, the protocol numbering, the ceremonial-to-technical glossary and the lineage correspondence are referenced by thirty-two other papers in the corpus, and until now they existed only inside a book. A reference paper that says plainly what it is — an index — is more useful than an index dressed as an argument, and the cost of the disguise is exactly what Section 7 was able to detect only because the classification was written down in one place.

The corpus contains close analogues of that reasoning in other series. The gated intervention procedure carries a thirty-two-entry failure catalogue for the same reason [Curzi, 2026j], and the manifestation protocols carry thirty faults with a headroom precondition attached [Curzi, 2026]. The measurement papers make the harder version of the point: a formula validation protocol that **demotes the corpus's own moment equation to ordinal scale** and prices what restoring it would cost [Curzi, 2026t], and a conditional postulate stated in magnitude form with an explicit forbidding clause — zero channel gain yields zero effect for every belief — badged as a postulate rather than as a finding [Curzi, 2026ab]. **In each case the value is in the labelling, and the labelling is what an apparatus paper exists to preserve.**

Two structural results elsewhere in the corpus bear directly on what a reference card may claim. The surplus form is exactly a Fechner law with threshold $u_0 = 1/(N-1)$, verified for $N = 2 \dots 100$ at seven values of u to a maximum deviation of 8.9×10^{-16} [Curzi, 2026]; and the compound rule and the essence law agree at no integer index, requiring $n = 1/\sqrt{k} = 1.438252434444351$, so that at $n = 12$ they differ by 6.121291 octaves [Curzi, 2026]. **Both are exactly the kind of result a reference card flattens**, and Appendix A's cards accordingly point at the papers rather than restating the numbers. The refinement analysis makes the same point about the closing procedure's own seasonal cadence: seven passes close 48.32 per cent of a gap at $\delta = 0.09$ and 6.79 per cent at $\delta = 0.01$, and closing 95 per cent in seven passes requires $\delta = 0.348164$ [Curzi, 2026] — **so a card that says "repeat seasonally" without the decay rate has omitted the parameter that decides whether repeating works.**

6.8.5 8.5 What a classification cannot do, from three results in the structural series

Three results elsewhere in the corpus bound what this paper's audit can be taken to establish, and they bound it in the same direction.

An honest register can still be built on a fabricated item. The historical-network analysis demolishes its own most attractive material — refusing a famous story as a fabricated data point, rejecting a unified-hand reading at 1,365 to 1, and badging a 25 per cent figure as an artefact of a chosen synthetic ratio rather than a constant, with its confusable-only check reaching only 58.99 per cent [Curzi, 2026]. **A classification records what its author believes about provenance; it does not verify provenance**, and Section 7's audit inherits that limit exactly.

A canonical form is worth more than a label where one is available. The identifier-integrity work measures its controls rather than classifying them — 28 of 28 grid links recorded in both ledgers, and local append cost rising from 0.002 s to 0.014 s as chains go from 50 to 400 entries, reported as local and single-process with no distributed throughput claim [Curzi, 2026]. **That is what a measured control looks like next to a classified one**, and it is the standard the volume's Class II items do not meet.

And the standard a classification is finally held to is a disciplinary one. Hedström and Ylikoski [2010] states it for sociology: an explanation must name a mechanism rather than exhibit a fitted curve, and a labelled drawer is not a mechanism. Keuschnigg et al. [2018] is the most constructive position available to a corpus in this situation and is the one it would be wisest to claim; Epstein [2008] is the best defence against the charge that a framework whose laws forecast nothing is therefore worthless; and Watts [2014] is the charge itself, that formal

social explanation is often commonsense reasoning in dress. Castellano et al. [2009] is where the surrounding programme was last surveyed and bounded, and it supplies definitions this framework can be held to. Sobkowicz [2020] is the standing indictment of the genre — many models, negligible empirical discrimination between them — and **it applies to this corpus and is not answered by classifying claims more carefully.** No scaling claim, power law or heavy tail is asserted anywhere in this paper, which is worth stating because Clauset et al. [2009] is the procedure that would otherwise be owed.

And a structural separation closes what care within a channel cannot. The channel-separation result establishes that in-band architectures admit an impersonation class no amount of care inside the shared channel can remove, and that out-of-band separation closes it structurally — measured at 0.383 per cent in-band ambiguity against 0.000 per cent out-of-band over 100,000 values [Curzi, 2026]. **The analogue for this paper is exact**: a claim and its warrant travelling in the same sentence admit a confusion that no amount of careful phrasing removes, and separating them into a labelled ledger closes it structurally. That is the strongest available defence of the device Section 6 reproduces, and it is why the device is worth repairing rather than replacing.

6.9 9 Verification

This section is a check, not a summary. A reader who runs the three arithmetic lines and the four lookups below has verified the whole of Section 7 without reading Section 7's prose, which is what a verification section is for.

6.9.1 9.1 Dimensional audit

Most of this paper carries no dimensioned quantity at all, which is itself worth stating: an index, a glossary and a classification are not measurements and have no units. The quantities that do appear are inherited from papers this one cites, and they are audited here because a reference card that reproduces a number without its dimension is the most common way a dimension is lost.

Symbol	Dimension	Unit	Status
verdict count (fulfilled / released / lapsed)	[1]	count	**defined**; a partition of a finite set, exhaustive and exclusive by stipulation
active-commitment count	[1]	count	**defined**; the discipline fixes it at 1
screen questions	[1]	count	**defined**; fixed at 3
classification items	[1]	count	**defined**; 4 + 7 + 3 = 14
q, the contraction modulus	[1]	none	**defined** dimensionless; the guarantee requires $q < 1$
u, non-parallelism	[1]	none	**defined** dimensionless; a squared sine of an angle
$f(u) = \ln(1 + (N-1)u)$	[1]	nats	**derived**; a logarithm of a pure number

Symbol	Dimension	Unit	Status
σ_x	$[L]$	m	**measured** — a standard deviation of position
σ_p	$[M][L][T]^{-1}$	kg m s^{-1}	**measured** — a standard deviation of momentum
$\hbar$	$[M][L]^2[T]^{-1}$	J s	**measured** physical constant
S, the action	$[M][L]^2[T]^{-1}$	J s	**defined** by the Lagrangian's time integral
comfort	**none**	**none**	**no operational unit**; treated as a dimensionless magnitude by stipulation
stored order Q	$[Q]$	declared proxy units	**measured** against a declared proxy; two systems' values are not comparable unless the proxy is the same

Does the uncertainty relation balance? $\sigma_x\sigma_p$ carries $[M][L]^2[T]^{-1}$, which is the dimension of $\hbar$. It balances, and **it balances only for a conjugate pair.** That is the whole content of item I.4's second clause: the inequality is dimensionally meaningless for any pair of quantities whose product is not an action, and a foreseen future and its alteration are not such a pair. **The framework's extension is therefore not a dimensional statement at all; it is an analogy of shape, and it is filed as III.1 where it belongs.**

Does the action have the same dimension as $\hbar$? It does — both are $[M][L]^2[T]^{-1}$ — and that coincidence is real physics and is not what item III.2 claims. **A comfort landscape has no Lagrangian, no unit of action, and no measured** δS, so the least-action language in III.2 is a shared *form* and not a shared dimension. This audit records that the source is silent on what units a comfort action would carry, rather than assigning one.

And the construct with no unit is where the framework is most exposed. Comfort is treated as a quantitative magnitude by stipulation, and Michell [1997] and Michell [1999] are the objection: psychology routinely assumes quantitative structure without testing whether the attribute has it. The formal remedy is conjoint measurement [Luce and Tukey, 1964], whose cancellation conditions establish additive quantitative structure within the representational framework of Krantz et al. [1971], with Rasch [1960] the alternative route. **Those conditions have not been tested for comfort anywhere in this corpus**, and the classification of Section 6 has no drawer that says so — which is a further instance of the representational gap Section 8.2 names. The corpus does demote one of its own quantities to ordinal scale on exactly this ground [Curzi, 2026t], and Stevens [1946] is the rule that makes the demotion consequential: the permissible statistics follow the scale type.

Does the surplus functional balance? $\ln(1+(N-1)u)$ takes the logarithm of a pure number, since u is a squared cosine of unit vectors and N is a count. It balances. **The nat is not a physical unit**: it is the unit of a logarithm to base e, and reporting in bits multiplies every figure by $1/\ln 2 = 1.442695$ and changes nothing.

6.9.2 9.2 Postulates

#	Statement	Status
P1	The volume's classification places 4 items in Class I, 7 in Class II and 3 in Class III	**DEFINITION** — reproduced in Section 6; a reader may count
P2	The corpus's external bibliography is the file named in Section 3 and no other	**DEFINITION** — the audit's scope, stipulated
P3	A claim is *supported* only where an entry states that specific proposition	**DEFINITION** — the audit's decision rule, stipulated in Section 3
P4	$N_{\text{eff}} = 1 + (N-1)u$ is a design axiom, chosen and not derived	**CITED** within the corpus — Curzi [2026]
P5	HHI^{-1} is the Hill number of order 2 and $\exp(H)$ of order 1	**CITED** — Hill [1973], Jost [2006]
P6	Banach's theorem holds for $q < 1$ and its guarantee fails at $q = 1$	**CITED** — Banach [1922]
P7	$\sigma_x \sigma_p \geq \hbar/2$ is a theorem about non-commuting observables	**CITED** — Kennard [1927]

Every postulate in this paper is a definition or a citation. None is an empirical claim, which is the correct profile for a reference paper and is the reason Section 2 states that there is no hypothesis.

6.9.3 9.3 The compounding chain

```
P1              -> L1   4 + 7 + 3 = 14 classified items                    ARITHMETIC
P2 + P3         -> L2   each item is supported or it is not; the file
                        is fixed, so the classification is decidable       DEFINITION
L1 + L2         -> R1   Class I: 3 supported, 1 unsupported                ARITHMETIC (lookup)
L1 + L2         -> R2   Class II: 2 supported, 5 unsupported               ARITHMETIC (lookup)
L1 + L2         -> R3   Class III: 0 claimed, 0 found -- correctly         DEFINITION
R1 + R2         -> R4   of the 11 items claiming support, 5 carry a key
                        and 6 do not                                       ARITHMETIC
R2              -> R5   the class filed as "established psychology" is
                        the least supported class in the file              ARITHMETIC
P4 + P5         -> R6   the affine count is not a Hill number: for two
                        units at 0.9 / 0.1 it returns 2.000000 at u = 1
                        where HHI^-1 returns 1.219512 and exp(H) 1.384145  ARITHMETIC
R6              -> R7   item I.3 is exact arithmetic on a chosen
                        definition, and the definition has no external
                        literature -- so the item is correctly filed and
                        misleadingly labelled                              ARITHMETIC
P6              -> R8   the contraction guarantee is conditional on
                        q < 1 and states nothing at q = 1                  CITED
P7              -> R9   the uncertainty relation's dimensions balance
                        only for a conjugate pair                          ARITHMETIC
```

The three checks a reviewer can redo in a minute. First, $4 + 7 + 3 = 14$, and $4 + 7 = 11$ items

claim support. Second, $1/(0.9^2 + 0.1^2) = 1/0.82 = 1.219512$ and $\exp(-(0.9 \ln 0.9 + 0.1 \ln 0.1)) = \exp(0.325083) = 1.384145$, while $1 + (2 - 1) \times 1 = 2.000000$ — three numbers that settle item I.3 without an opinion. Third, $[M][L]^2[T]^{-1}$ on both sides of $\sigma_x \sigma_p \geq \hbar/2$, which settles item I.4's second clause.

And the four lookups that settle the rest. Open the corpus's external bibliography and search it for an entry on reactance, on implementation intentions, on the interrupted-task effect, and on confirmation bias. **There is none for any of the four**, and a fifth search for commitment and consistency returns nothing either. Those five searches are the whole of Section 7's Class II result, and any reader can run them.

What the chain does not establish. Every line above is a definition, a lookup, or arithmetic on counts. **Nothing in it is evidence about a person, an institution, or a practice**, and no line supports any claim about whether the volume's protocols work. A reader who wants the framework's empirical standing should read the preregistered application that failed [Curzi, 2026i] and the falsification suite that measured its own control as anti-conservative [Curzi, 2026u].

6.9.4 9.4 Boundary behaviour of the two mathematical items

The classification files two mathematical results, and both have boundaries the card format tends to lose. They are stated here because losing them is precisely how a reference card becomes wrong.

Limit	Behaviour	Reading
$q \to 0$	one pass reaches the fixed point	Degenerate but harmless.
$q \to 1^-$	convergence holds but arbitrarily slowly; the a posteriori bound $q/(1-q)$ diverges	**The guarantee survives and the gauge does not.** A practitioner reading the last correction as a distance estimate is reading a diverging quantity.
$q = 1$	isometry: the orbit neither converges nor diverges	**The theorem says nothing.** The volume states this explicitly and the card must carry it [Curzi, 2026].
$q > 1$	corrections grow; the loop is an amplifier	Not a slow failure but a different regime.
space not complete	the fixed point may not exist	**The condition the framework's application cannot verify**: a life is not shown to be a complete metric space anywhere in this corpus.
$\hbar \to 0$	the relation permits arbitrarily precise joint preparation	The classical limit. **It has no analogue in the framework's extension**, because the extension has no constant to send to zero — which is one concrete way item III.1 is weaker than the theorem it borrows from.

The second row is the one a card loses and the one that matters most in practice. A frame-

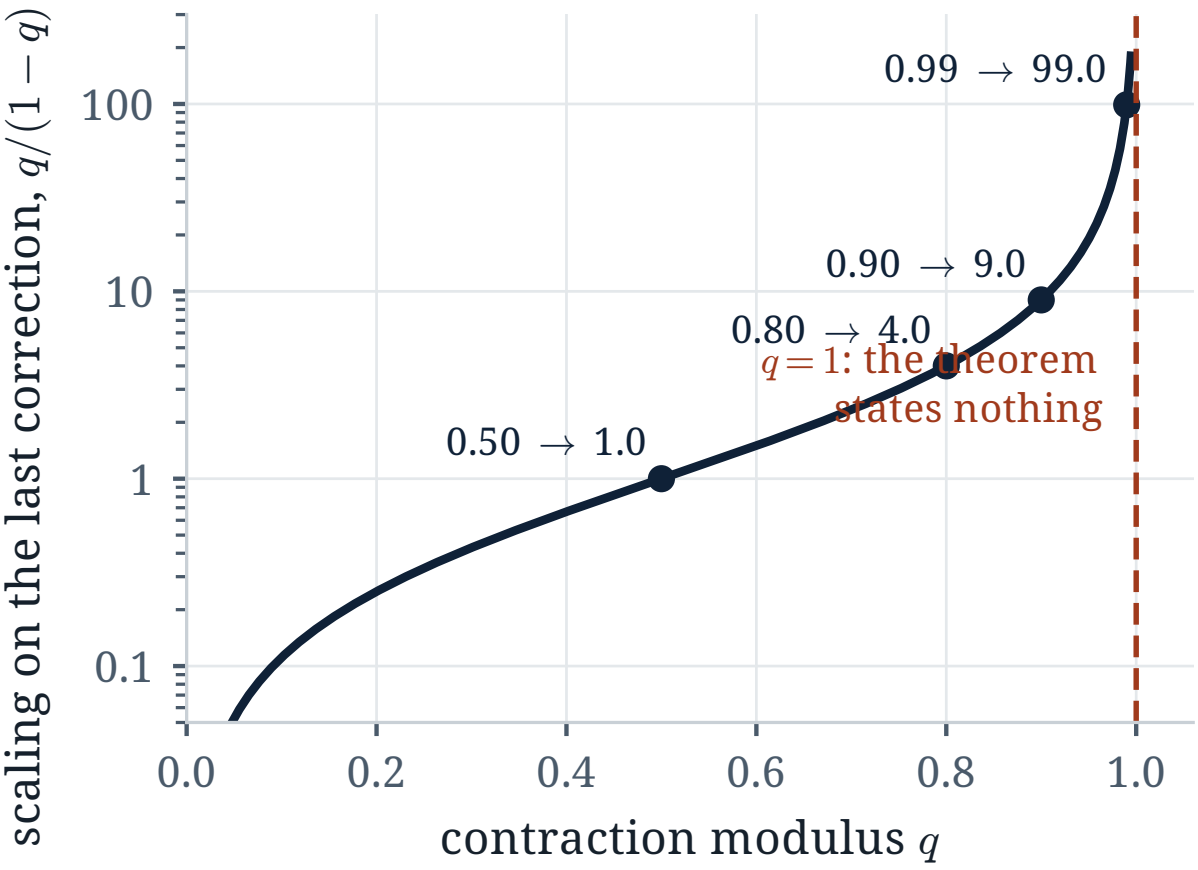

Figure 6.3: **The contraction guarantee survives to $q = 1$; the gauge built on it does not.** The a posteriori bound scales the last correction by $q/(1-q)$ to bound the distance remaining, and that factor diverges as the modulus approaches one: 1.0 at $q = 0.50$, 9.0 at 0.90, 99.0 at 0.99. **A slow, long-running commitment sits exactly in the regime where the framework's own progress gauge becomes uninformative**, and a reference card that states only that a contraction converges has dropped the condition that makes the statement useful. Model output; the bound is exact. Generated by `figs/src/CCP-A06_fig03.py`.

work whose central gauge is the size of the last correction is reading a quantity that becomes uninformative exactly as the modulus approaches one, which is exactly the regime a slow, difficult, long-running commitment sits in.

6.10 10 Limitations

This paper advances no testable hypothesis and contributes no new result about the world. It is reference apparatus with a bibliographic audit attached, and it is stated as such in Section 1, Section 2 and here. **It should not be submitted, cited, or read as a research contribution**; the material it collects exists because thirty-two other papers in the corpus rely on it, and its value is that the material is now in one citable place with its provenance attached.

The audit's scope is one file and its result inherits that scope. Section 7 records five of eleven support-claiming items as unsupported. **That means unsupported *by this corpus's bibliography*, not unsupported by the literature.** Reactance, implementation intentions, commitment effects, the interrupted-task effect and confirmation bias all have substantial primary literatures, and a reader should not take Section 7 as a claim about their standing. What Section 7 establishes is that a reader following the corpus's own citations to check the volume's classification will find nothing there, which is a defect in the corpus and is repairable by adding five entries.

The audit was performed by one person by inspection and no second reader checked it. The decision rule of Section 3 is stated so that the audit is reproducible, and reproducibility is not replication. **A second auditor might reasonably classify one or two items differently** — item II.4 in particular, where measurement reactivity is supported for its expectancy form and McCambridge et al. [2014] restricts its Hawthorne form, and a stricter auditor would record it as unsupported. The counts in Section 7.1 would then read four supported and seven unsupported. **That sensitivity is stated rather than smoothed, and it does not change the direction of the result.**

The classification audited is the volume's own and its granularity was not chosen by this paper. The volume files fourteen items; a finer decomposition would file more, and some of the fourteen bundle a claim with a caution — item II.3 carries both a commitment effect and the countervailing observation that announcing a goal can substitute for pursuing it. **The audit treats each bundle as one item**, which is the only treatment that keeps the counts comparable to the volume's own statement, and it means the counts are counts of *entries* rather than of propositions.

The volume's central claim about its own classification is not verified here. It states that every protocol it contains runs on classes I and II and steers by class III. **Verifying that would require tracing each of the thirteen protocols in Appendix C to the items it consumes**, and this paper does not do it. That is the obvious next audit and it is the one that would establish whether the five unsupported psychology items are load-bearing or decorative.

The material collected here recapitulates and the recapitulation is not independently checked. The reference cards of Appendix A, the glossary of Appendix B, and the protocol summaries of Appendix C are compressions of analytical material established elsewhere in the corpus. **A compression can drop a condition**, and Section 9.4 gives the clearest instance: a card stating that a contraction converges has dropped the condition $q < 1$, under which alone the statement is true, and the corpus's own convergence analysis is explicit that the guarantee fails at unit gain [Curzi, 2026]. **Every card in Appendix A names the paper that establishes what it summarises, and the cards are not substitutes for those papers.**

The correspondence table of Appendix D is a historical claim this paper cannot verify. It maps the volume's twelve constructs onto a ten-node scheme and a five-phase arrangement attributed to an earlier tradition, and records a lineage variation in which the ninth node carries a different name in the oldest copies. **No source for that tradition is cited anywhere in this corpus, no primary document is named, and the mapping is therefore an assertion about a lineage rather than a documented correspondence.** It is reproduced because other papers

reference the construct numbering it fixes; its historical content should not be relied upon.

Two items in the collected material carry claims this bibliography does not support and one of them is a normative claim. The consent condition of Section 4.3 asserts that consent is a precondition of legitimate influence. **That is an ethical commitment of the framework, no entry in this bibliography states it, and this paper does not argue for it** — it records that the framework holds it as a constraint rather than as counsel, which is a statement about the framework. And the least-action item I.1 asserts a standard result of classical mechanics for which the bibliography contains no entry at all; the claim is uncontroversial in its home discipline and is uncited here, which is exactly the situation Section 7 exists to make visible.

The narrative material is not reproduced and that is a judgement, not a neutral act. The volume's closing scene and its epilogue are omitted as fictional exposition, following the treatment established for the analytic register of this series [Curzi, 2026]. **A reader who believes the narrative carries analytic content this paper has discarded is reading a different volume from the one this paper indexes**, and Section 8.3 reports the one item — the self-referential close — whose analytic interest this paper judged sufficient to state.

The paper is exposed to the failure it names. Section 8.4 argues that the value of a classification is in its labelling and that an unaudited classification records confidence rather than evidence. **This paper's own classification of items as supported, qualified and unsupported has not itself been audited by anyone**, and Goodhart [1975] and Campbell [1979] apply to it as to any measure that might be adopted as a target: a corpus that reported "items supported" as a figure of merit would have created an incentive to attach keys rather than to find them. The only defence offered is that the decision rule is published and every lookup is one search in a named file.

Two defects in a companion paper's version of the same check are corrected in this paper rather than propagated, and both were found by re-running its arithmetic. The corpus's concentration instrument runs the comparison of Section 7.3 [Curzi, 2026]. It reports $\exp(H) = \exp(0.325083) = 1.384115$ for the two-unit vector $(0.9, 0.1)$; **the correct value is** 1.384145, since $H = -(0.9 \ln 0.9 + 0.1 \ln 0.1) = 0.3250829734$ nats and $e^{0.3250829734} = 1.3841454885$. And it states that *every* Hill number reports less than 1.39 on that vector, which **is false**: the family is non-increasing in q and its order-zero member is the raw richness ${}^0D = 2.000000$, with every member below $q \approx 0.15$ above 1.39. **The second correction strengthens the objection rather than weakening it**, because the one member the affine count matches is the one that ignores shares. Both corrections are printed here rather than silently applied, because a verification chain a reader cannot reproduce exactly is not a verification chain — **and because this paper's own thesis is that an unaudited classification records confidence rather than evidence, which applies to the corpus's arithmetic as much as to its citations.**

Nothing here is clinical, and the barring conditions are not clinical advice. Section 4.4 records that the volume bars operation during acute grief, rage and the pursuit of revenge, and gives the volume's stated mechanisms. **Those are the framework's own operating constraints, they are not tested, and they are not a clinical judgement about any person.** A reader in any of the three conditions the volume names should consult a clinician and not a protocol index.

6.11 11 Conclusion

This paper is the Foundations volume's reference apparatus, collected and labelled. It advances no testable hypothesis, contributes no new result about the world, and should not be read as a research contribution. It exists because thirty-two other papers in the corpus reference the construct names, the protocol numbering, the ceremonial-to-technical glossary and the lineage correspondence it carries, and because until now those items existed only inside a book.

The one thing here that is not recapitulation is an audit, and its result is a count. The volume closes with a three-class classification of its own claims — established mathematics,

established psychology, and the framework's own postulates — holding four, seven and three items respectively, and states that every protocol in the volume runs on the first two classes and steers by the third. Audited against this corpus's external bibliography, **five of the eleven support-claiming items carry a key and six do not, and two of the five carry a standing objection in the same file.** The three postulates claim no support, find none, and are correctly filed; the classification's own statement that the third class is a wager that can lose is accurate.

The class the volume treats as its safest is the class this corpus's bibliography least supports. Two of the seven items filed as established psychology carry a key. Reactance, implementation intentions, commitment and consistency, the interrupted-task effect, and confirmation bias have no entry in the file the corpus cites from, and the interrupted-task effect is the item on which the whole cost-of-not-closing argument rests. **That is a defect of the bibliography rather than of the literature, it is repairable by adding five entries, and it stands disclosed until it is.**

One item is correctly filed and misleadingly labelled. The surplus functional $f(u) = \ln(1 + (N-1)u)$ is filed as established mathematics on the ground that it is the logarithm of an affine effective count. Given the definition $N_{\text{eff}} = 1 + (N-1)u$ that is a tautology and it is exact — and **the definition is a design axiom of this framework with no supporting literature in any discipline.** The affine count is not a Hill number of any order: for two units holding 0.9 and 0.1 it returns exactly 2.000000 at $u = 1$, where HHI^{-1} returns 1.219512 and $\exp(H)$ returns 1.384145. The repair is one clause and it is stated in Section 7.3.

The collected material's four substantive items are stated here in the form other papers cite. The closing discipline: exactly three verdicts — fulfilled, released, lapsed — with no fourth, a rule permitting one active commitment at a time, and a written three-question screen the volume states cannot be waived on the basis of feeling well. The consent condition, stated as a constraint and not as counsel: no future is to be voiced over another person's path without their word. Three named conditions barring operation — acute grief, rage, and the pursuit of revenge — each with a stated mechanism and no measurement. And the protocol index: thirteen protocols, one per construct plus a three-office daily cadence, together with one further discipline that carries no construct and closes nothing.

Where the volume's own instrument is weaker than the corpus's, this paper says which and why. A four-drawer classification — PROVED, POSTULATED, BORROWED, UNTESTED — can represent two distinctions the three-class version cannot: a result established in its home discipline but borrowed without warrant, and a claim that is well formed, falsifiable, and simply never run. **The volume has several of the second kind and nowhere to file them**, and Section 2 of this paper is a partial substitute, stating three of them with their falsifiers and marking each not tested.

6.11.1 Declarations

Data and code availability

No dataset was collected for this paper and none exists. Section 7 is a bibliographic audit performed by inspection against one named file — the corpus's external bibliography — and every lookup it reports can be re-run by any reader holding that file. **No figure in this paper plots measured data.** The three figures show, respectively, the counts of Section 7.1, the Hill family evaluated on one two-type vector, and an exact algebraic bound; each is generated by the script named in its caption, each script imports the shared style module `lib/figstyle.py`, and each carries assertions that fail the build if the plotted values cease to agree with the numbers printed in the text. The arithmetic checks of Section 9.3 are exact computations on the numbers printed in the text.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. **The paper audits the author's own prior work**, which is a conflict of a specific kind: the classification examined in Section 7 was written by the author of this paper. The decision rule of Section 3 is published so that the audit can be re-run by someone else, and Section 10 records that no second reader has checked it.

Author contributions

Single author. Michael Laurence Curzi wrote the source volume, performed the audit, and wrote the paper.

Ethics

No human-subjects research was conducted for this paper and no personal data were collected or processed. **The material indexed here is a set of procedures addressed to a practitioner working on their own commitments**, and two of its provisions are ethical constraints rather than techniques: the consent condition, which forbids voicing a future over another person's path without their word, and the three barring conditions, which forbid operating during acute grief, rage, or the pursuit of revenge. **Both are reported as the framework's own constraints on prospective practice. Neither is tested, and neither is clinical advice.** A reader in any of the three barred conditions should consult a clinician rather than a protocol index.

Preregistration

This paper reports no preregistered test and advances no hypothesis. Section 2 states three claims in the collected material that could be given hypothesis form, together with what would defeat each, and marks all three **not tested**. The corpus's one preregistered confirmatory application of its storage law is reported elsewhere, where it **failed its second falsification rule** [Curzi, 2026i]; the corpus's falsification suite measures its own shuffled-input control at a false-rejection rate of 0.108 against a nominal 0.05, which is **anti-conservative** [Curzi, 2026u]. Neither result is affected by anything in this paper.

Use of the ceremonial register

The source volume is written in part as an initiatory document, in two braided registers, one narrative and one analytic. **This paper reports the analytic register and does not reproduce the narrative one.** Ceremonial names are reported as objects of study where they identify a construct this paper renames, and Appendix B is the mapping in full. **Nothing in this paper is written in the initiatory register, and no passage of it is intended to be performed.**

6.12 Appendices

The appendices below are the reference apparatus proper. **They contain no new argument.** They are reproduced in full because other papers in the corpus rely on them — the construct names, the protocol numbering, the ceremonial-to-technical mapping, and the lineage correspondence — and because those items exist nowhere else in citable form.

One warning belongs at the head of the drawer, and the volume states it itself. A reference card is a compression, and a compression carries a cost: a practitioner who reads only the card will reproduce the procedure and not the reasoning that makes the procedure revisable. The cards below are indexes into the analytical papers of the corpus, not substitutes for them, and every one of them names the paper that establishes what it summarises.

6.13 Appendix A — The node reference cards

Ceremonial names are retained in this appendix because they are identifiers. A construct's ceremonial name — STILLPOINT, LEDGER, the Rite of the Seal — is how the rest of the corpus refers to it, so renaming it here would break every citation the appendix exists to serve. Each name is reported as the label of an object of study, never performed, and Appendix B maps every one of them onto its technical equivalent.

The twelve constructs indexed below are defined in the corpus's founding paper, which fixes the ground state, the comfort landscape, and the reflexive loop that every later construct operates on [Curzi, 2026]. **The cards are indexes into that definition and into the analytical papers that develop it, and they establish nothing on their own.**

One entry per node. Each entry carries the plate, the glyph, the office, the protocol in summary, the failure modes in their paired names, and the seal line. The summaries are honest abbreviations; where a summary and its chapter disagree, the chapter is right and the card should be corrected in the practitioner's own hand. A card corrected in the practitioner's hand is worth two printed ones.

Node 00 — STILLPOINT

Plate. Node 00 · STILLPOINT · *The practitioner is already there; that is the difficulty.* · First assumed node — the Mirror Grid did not count it · Part I: The Still Water · The Work of Light.

Glyph. A single filled point resting at the lowest interior of a shallow open curve — a bead of water at the bottom of a bowl that has finished tipping.

Office. To establish the doctrine on which every later node stands: comfort is not a place the practitioner go but the place the practitioner is; the present moment is the practitioner's comfort zone by definition, not by luck. Clinically, the ground state; ceremonially, the water at rest. Nothing can be steered from a position that has not been admitted.

The Protocol, in summary. *(The Protocol of the Still Water — seven days, one hour each.)* 1. Fix one seat — one place, one hour — and do not renegotiate either for seven days; the seat's merit is its fixity, not its excellence. 2. Arrive each sitting with one spoken bearing — *"I am where my life has set me down"* — said whether or not it feels true. 3. In the first quarter, inventory the present in the present tense — *"Right now I am…"* — body first, then room, then situation; ten lines is the floor. 4. Audit each escape fantasy: name the elsewhere in one line, then beneath it write where the body sat — warm, fed, in a chair — every time, without exception. 5. Price each elsewhere in a single word (*Money. Standing. Mother.*) and do not solve it; the zeroth node locates, it does not solve. 6. Sit the remainder; name rising restlessness *weather* and let it cross without steering — the practitioner is not seeking calm, the practitioner is practicing being locatable. 7. Close each hour standing — *"This is the floor. The floor holds."* — and leave the day's pages unread until the last day. 8. On the seventh day, read all seven pages aloud and underline every comfort that recurs three times or more; that list of load-bearing comforts is the procedure's product, kept as raw ore for the Ledger.

The Failure Modes. - **the Pond that Calls Itself the Sea** ↔ *status-quo rationalization* — promoting the lawful local minimum to the global one: *I am here by the deep law; therefore here is best; therefore nothing need be done.* The correction is in the definitions — *local* was never a compliment. Consent to the practitioner's position; do not canonize it. - **the Storm Painted on the Wall** ↔ *confusing affect with position* — mistaking unpleasant mental weather for evidence of being outside comfort. The bottom of the bowl was never promised pleasant, only cheap; familiar dread can be the cheap option. The storm is real weather painted on the wall of a room the practitioner is securely inside. - **the Statue at the Shore** ↔ *reactive self-report* — sitting the hour as an exhibit, pages curated for the practitioner the practitioner intend to have been. The mark is that the pages read well; genuine zeroth-node pages are boring, repetitive, and faintly humiliating. - **the Frozen Bowl** ↔ *anhedonic flatness mistaken for stillness* — the water level not because it has settled but because it has frozen; nothing costs because nothing registers. This is not a failure of the practitioner; a frozen bowl wants warmth before

doctrine. If the seventh-day underlines number zero, set the volume down and seek the appropriate help first. - **the Feast Eaten in the Doorway** ↔ *fantasy substitution* — the imagined elsewhere enjoyed so richly that the appetite meant to move the feet is spent at the door. The discipline is the second line — *the body sat in a chair* — written every time, so the dreamer is returned to the platform without the dream being banned.

Seal line. *The zeroth node is sealed: the practitioner has never been anywhere but here, and here was always holding the practitioner.*

Node 01 — LEDGER

Plate. Node 01 · LEDGER · *What comforts the practitioner is not free; what costs the practitioner is not waste.* · KIN.0 VALIDATE — the test of the stone · Part I: The Still Water · The Work of Light.

Glyph. An upright card ruled once down its middle, a filled circle at the foot of the left column and an open circle at the foot of the right — the held and the owed, facing each other across a single line.

Office. The honest inventory: every comfort carries a cost, every discomfort conceals a yield, and neither is admissible to the ledger until both figures are on the card. This is the framework's truth-validation — the test of the stone — performed on one's own furniture. Nothing later in the volume works from a falsified ledger; the prophecy of Node 07 is only as strong as the accounting of Node 01.

The Protocol, in summary. *(The Protocol of the Ledger — seven evenings; the Still Water pages are its opening ore.)* 1. Open each evening spoken — *"I am counting what I already carry"* — the boundary stone between inventory and shopping. 2. Gather comforts, one per card, present tense, in plain bin-label words, drawing the first dozen from the Still Water pages; forty cards is the floor, depth of pricing over breadth of listing. 3. Turn the cards: price each comfort's carrying cost in four fixed currencies — coin, hours, attention, foreclosure — foreclosure last and always attempted; the dash is earned by a second look, never a first. 4. Add the gray cards: discomforts assayed for what they pay (information, training, position, contrast); where nothing surfaces, write *unpriced*, never *nothing*, and never invent a yield to comfort the card. 5. Stand the resisting card upright and unwritten against the box, one minute of plain attention at each evening's close; resistance located is the node's yield, not its debt. 6. Audit one card only — the one is least willingly audited — with three questions, aloud: *What does it buy? What does it forbid? Who would I be a year from now if it kept its job?* 7. Read the whole ledger aloud, both sides of every card; the voice finds what the eye excuses. File in any order except importance, and date the box in ink. 8. Close spoken — *"The count is taken. The count is not the judge."* — and re-count at each season's turn. The ledger's product is a tested inventory, never a decision.

The Failure Modes. - **the Price Paid Twice** ↔ *sunk-cost fallacy* — pricing a holding by what it has already cost — the decade given, the identity built — instead of what it now costs. The ledger's columns run forward only; the acquisition payment cannot be recovered by further payments. - **the Stone that Weighs More in the Hand** ↔ *endowment effect* — every holding, priced while held, comes in heavy; the ledger overprices the stock and underprices the shelf. The test: ask what the practitioner would pay today, in all four currencies, to acquire the holding if the practitioner did not have it. - **the Ledger Written for the Auditor** ↔ *impression management, turned inward* — cards written for an imagined reader, costs flattered, yields ennobled. The mark is that it reads well; a true ledger is boring and slightly shaming. The reading-aloud is the remedy — a false price can be written smoothly and almost cannot be said. - **the Scourge in the Counting-House** ↔ *the audit collapsed into rumination* — the counting curdling into a courtroom, each cost recounted, the sum never struck. Counting moves card to card and is done; scourging loops. The remedy is mechanical: the closing sentence, said aloud, and the box closed for the night. - **the Drawer Nailed Shut** ↔ *experiential avoidance* — the resisting card not stood upright in the light but filed away flat, then not written, then its whole territory re-zoned out of the inventory. The test: name aloud what the practitioner's

ledger does not contain; if the sentence will not finish, the drawer has been nailed, and the next evening belongs to the nail.

Seal line. *The first node is sealed: the stone is tested, the count is taken, and what the dark was charging has been written where the light can read it.*

Node 02 — GRADIENT

Plate. Node 02 · GRADIENT · *What the practitioner call the practitioner's decisions, the snow calls its records.* · Second assumed node — the gradient the Mirror Grid stood in without counting · Part I: The Still Water · The Work of Force.

Glyph. A tilted plane drawn in three descending strokes, crossed by a dotted line that leaves the paved road and does not apologize.

Office. Comfort differentials as the true motive power: systems evolve along action-minimizing paths, and a creature's days are such a system. The physicist writes $\delta S = 0$ and means the path taken is the one a small change cannot cheapen; the framework says water does not negotiate. The node's work is to read the practitioner's own worn paths as data and stop legislating against them.

The Protocol, in summary. *(Protocol 02 — The Cartography of Worn Paths — seven days of survey, one of drafting, seven of verification.)* 1. Bound the ground: survey the practitioner's waking days for seven consecutive days, the dates written on the first card. A survey without a boundary is a mood. 2. Survey each evening in ten minutes: record where feet, hands, and attention repeatedly went — repetitions, not events; the rule of three, an act performed three times in the week is a path. 3. Refuse the story: no reasons, no adjectives, no defense counsel; any card bearing the word *because* is re-copied without it. The practitioner is snow, which counts footprints and does not explain them. 4. Mark the pavement beside each path — the routine or intention that hour is supposed to hold; where none exists, write *unpaved*, never manufactured. 5. Draft the map on the eighth day: paved walks dashed, worn paths solid, drawn dark in proportion to traffic; mark every divergence, expecting three to seven. Fewer means the practitioner tidied; more means the practitioner moralized. 6. Price each differential concretely, in the ledger's discipline: what is cheaper, warmer, nearer, or less watched about the worn route. Most often the worn path is not a vice but a better-engineered road serving a need the pavement ignored. 7. Choose one divergence — one; the procedure forbids two — and re-grade it with one physical change that tilts the ground, never a promise. Apply the worst-day test: any change that needs the practitioner's virtue is decoration, not grading. 8. Verify against fresh snow for seven more days; if the prints move — if the water takes the new channel unbegged — the differential was named truly. If not, the practitioner misnamed the comfort; return to the pricing without self-reproach.

The Failure Modes. - **the Cartographer Who Draws the Road He Wishes** ↔ *social-desirability bias; self-report distortion* — the survey quietly falsified toward the practitioner's better self, the eleventh visit to the window unrecorded. The map then grades ground that does not exist. The remedy is liturgical: the practitioner is snow; snow does not audition. - **the Man Who Shouts at Water** ↔ *reliance on effortful inhibition; the cold-to-hot-state planning error* — accepting the map, rejecting the method: attacking the steepest divergence with resolve at the hour of maximum tilt until the inevitable failure is booked to character rather than to hydraulics. The correction is the worst-day test, applied as a category. - **the Fence the Feet Ignore** ↔ *reactance; restriction without re-grading* — using the office of the ground only to build barriers across worn paths while leaving every differential untouched. The water finds the gap beside the fence and cuts an uglier channel with resentment in it. Grading and fencing are not the same craft. - **the Pilgrim Who Climbs to Spite the Valley** ↔ *effort justification; the confusion of cost with worth* — concluding that everything comfortable is corrupt and choosing paths *because* they are steep. This is not liberation from the gradient; it is the gradient of self-regard, wearing boots. Water reaches the sea without once suffering on principle. - **the Map That Ate the Garden** ↔ *analysis paralysis; measurement as avoidance* — the survey become the residence: maps of maps, ever-finer taxonomies of divergence, and no

kettle ever moved. The procedure's numbers are the remedy — seven days, one hour, one divergence, one change.

Seal line. *The second node is sealed: the ground has been surveyed and found honest, the water has been acquitted, and the hand that reached is the hand that will move the kettle.*

Node 03 — HORIZON

Plate. Node 03 · HORIZON · *One window is a wall with a hole in it.* · KIN.1 TRANSMED — the many windows of the one tower · Part II: The Baited Horizon · The Work of Light.

Glyph. A single vertical stroke crowned with three small squares, no two of them set at the same angle.

Office. Extrapolational thinking: tracing a future forward, branch by branch, without switching assumptions mid-trace — then doing it again from a genuinely different window. The framework's arithmetic of difference governs the yield: N ways of seeing produce surplus only insofar as they are non-parallel, and the surplus grows as the logarithm of the effective count, not as the count itself. Ten windows facing the same way are one window with nine echoes.

The Protocol, in summary. *(Protocol 03 — The Rite of the Three Windows.)* 1. Set the horizon: one distance — one year or three — written at the head of all four cards; every window in the procedure looks the same distance. 2. Write the question in present tense, about the practitioner's own life — a state to be seen, not a plea: *"It is three years on, and I am living somehow."* 3. Cut the first glass — *nothing turns*: the continuation window. Trace five steps, each drawn from the previous step's world, asking at each what it makes easy and what it makes hard; land the trace in a furnished room of at least five sensory facts, then close the window and leave the chair. 4. Cut the second glass — *one thing turns*: one named change traced honestly around. The collision test is mandatory — somewhere in its five steps it must contradict the first trace, or the practitioner has opened the same window twice with a new curtain. 5. Cut the third glass — *the tinted pane*: the refused branch, given its honest three years and traced with the same courtesy — no punishment-writing, no rescue borrowed from the other windows. 6. Audit for invariants: all three cards face up, circle every concrete feature that appears in all three landed futures; ignore features shared by only two. 7. Hunt the breaking window: for each invariant, try in earnest to cut a fourth glass that honestly lands without it. If it breaks, strike the circle gratefully; if it cannot be honestly built, promote the circle to a horizon-fact. 8. File and be silent: the cards to the drawer, the horizon-fact seen and not announced, not promised, not leaned on in conversation. The speaking has its own node.

The Failure Modes. - **the Smeared Pane** ↔ *anchoring; scenario contamination* — switching windows mid-trace, importing a rescue from one branch into another, producing a chimera assembled from parts that cannot coexist. The remedy is procedural: the decontamination interval honored to the minute, and the struck-and-rebuilt rule for any step answering to a window not currently open. - **the Tower of One Window Repeated** ↔ *pseudo-diversity; the illusion of independent confirmation* — three glasses ground from one doctrine ("I stay and it's fine / good / great"), their agreement read as convergence. The arithmetic prices it exactly: u = 0, N_eff = 1, surplus zero. The collision test exists for this fault alone. - **the Stained Glass That Outshines the Lake** ↔ *availability and simulation heuristics; vividness mistaken for probability* — one branch traced in oils while the others get pencil, the futures then weighed by brightness of rendering rather than honesty of steps. Vividness is a property of the glass, not the water. The remedy is the procedure's evenhandedness: five steps and five sensory facts to every branch. - **the Bricked Window** ↔ *motivated reasoning; defensive avoidance* — the refused branch never cut at all, the audit run over windows curated to be survivable. The cost is a corrupted convergence — an invariant of the practitioner's courage, not their landscape. The bricked branch, finally traced, holds the load-bearing invariant more often than any other. - **the Straight Road Drawn on Round Water** ↔ *linear extrapolation; trend-fitting past the trend's regime* — extending the present's visible motion in a ruler line, no step con-

sulting the step before. The remedy is the nonlinearity rule enforced without appeal: each step derived from the world its predecessor made.

Seal line. *The third node is sealed: the tower does not move, the windows are many, and what stands in every window was never in the glass.*

Node 04 — WAVE

Plate. Node 04 · WAVE · *Weigh the wind before it has chosen.* · KIN.3 MYTHOS — the sea before the wind chooses · Part II: The Baited Horizon · The Work of Light.

Glyph. A half-circle open at the top, holding three crests of unequal height, the tallest of them left unfinished.

Office. The future held as a weighted set rather than a single picture: branches carry amplitudes, and amplitude follows comfort — futures near existing comfort freeze first, becoming likely the way the lake's margin skins with ice before its center. The node teaches honest weighting: neither bribing the wind toward the future the practitioner prefer nor rehearsing nightly the storm the practitioner fear.

The Protocol, in summary. *(The Weighing of Waters — an evening's procedure on the branches of the window-work.)* 1. Set the water: watch moving water — or a stirred basin stilled — until a dozen disturbances have risen and died. The practitioner is tuning the hand that holds the pencil: many tries, few winds. 2. Hide the prizes: fold each branch-card so its endpoint, the room at the end, is covered. The fourth node weighs paths; endpoints are the heart's ballot boxes, and the heart waits outside until Node 07. 3. Walk and score: for each branch, twelve steps forward, scoring each step's steepness *for the self who actually answers the alarm* — 0 (would do it sick), 1 (ordinary resolve), 2 (needs a good day), 3 (needs a better self). Do not average as the practitioner go; averaging is how flattery gets in. 4. Sum the resistance to each branch's R, find the smallest R, and subtract it from every card — leaving the easiest branch at zero and the others with their differences. 5. Halve by the difference: weight 1 for the easiest, one-half per point of difference for the rest, so a branch three points steeper carries an eighth the weight. If the arithmetic feels merciless, the practitioner has understood it. 6. Break a middle step: declare one middle step failed and ask whether the branch reroutes or dies; if it dies, halve its weight again and write *fragile*. A future that needs everything to go right is quarreling with its neighbors. 7. Consult the wide table and move the watcher: name the class of person who attempts each branch and what mostly happens to that class, not its heroes; then re-read the weights as the practitioner's harshest colleague and as the practitioner's gentlest friend, marking every step they contest by two or more. 8. Write the inversion: rank the branches by weight and by wanting, and where the two disagree write the disagreement in one sentence — the finding is carried, not settled. Carry the heaviest-weighted card (not the most wanted) seven days, then re-score and enter the corrected weights, dated.

The Failure Modes. - **the Wind that Flatters** ↔ *optimism bias; wishful weighting* — scoring the desired branch as the self the practitioner intend to become, not the self who answers the alarm; every step comes back 0 and 1. The mark: no step of any wanted branch scored 3 all evening. Remedy is the wide table, the moved watcher, and one re-scoring done tired. - **the Drowned Pilot** ↔ *catastrophizing; availability-driven weighting* — the opposite hand on the scale: one vivid disaster scored as the base rate, all 3s toward the horizon. The vividness of a remembered wave is not its frequency. Count what happens to the class, not to the shipwreck that made the news. - **Walking Out on Young Ice** ↔ *premature closure; status quo consolidation mistaken for choice* — a near future frozen solid, the relief of bearing weight read as *chosen* rather than *hardened by adjacency*. The mark: a weighing done in twenty minutes with no inversion found. There is always an inversion. - **the Single Cat's Paw** ↔ *sampling error; recency; extrapolation from N = 1* — one gust running (one good week, one warm letter) and the wind declared hired. One sample is not a distribution. Remedy: no re-weighting on fewer than three independent gusts. - **the Sailor Who Loves the Harbor Chart** ↔ *analysis paralysis; choice deferral dressed as diligence* — re-weighing weekly forever, a connoisseur

of one's own undecided water. The mark is a beautiful ledger and an unchanged life. The fourth node has one exit and it is the fifth; the wind, eventually, must be allowed to choose.

Seal line. *The fourth node is sealed: count every gust and prefer none, for the water shows its winds only to the eye that has not yet voted.*

Node 05 — LURE

Plate. Node 05 · LURE · *The practitioner cannot push themselves uphill; the practitioner can leave honey on the pass.* · KIN.4 FORGE — the baited horizon; the Tuesday bell · Part II: The Baited Horizon · The Work of Sound.

Glyph. A small bell hung from a hook whose shank is the first turn of a spiral, with a single drop falling from the bell's lip.

Office. Cue placement: setting the idea of greater comfort where the self will pass anyway, so that finding does the work forcing cannot. This is the smithy of the twelve — the one node that manufactures. Its two instruments are the placed object (the bell in the coat pocket) and the named time (the Tuesday teaching: name a day, and the day begins to gather events, because a named neutral thing becomes a mirror).

The Protocol, in summary. *(The Setting of the Lure — one week.)* 1. Choose the quarry: name one change already weighed and found heavy; fifth-node work follows fourth-node work, for luring an unweighed future baits a trap for whatever walks by. 2. Cut the honey to size: write the *first step only*, ten minutes or less, performable by the practitioner's worst self on the practitioner's worst morning; halve it until it is faintly insulting. 3. Track themselves: tour one ordinary day's premises as a tracker and mark the three strongest stations — the kettle, the door, the sill — where the practitioner actually pass, not where the practitioner ought to. 4. Forge the lure: one physical object that embodies the first step. One object; a pile is not a lure, a pile is a reproach. 5. Write the if-then — *"When I [pass/see/touch the lure at station X], then I will [first step]"* — and read it aloud once. This sentence is the whole machinery; everything else is placement. 6. Place at the height of the hand: the lure at the practitioner's strongest station, on the path, at reaching height, set with the practitioner's own hand at the practitioner's strongest hour — the placing hand teaches the finding eye. 7. Name the day and forbid the summit: hang a bell, declare one standing office — on the named day, one ring, one page — and let nowhere at any station show the whole mountain; the lure speaks only of the next hundred feet. 8. Walk the trapline each named day: if the step was met and taken, leave it; if met and refused, cut the honey again; if unmet, move it — never scold. Retire the lure formally once the path has worn in, and choose the next quarry.

The Failure Modes. - **Honey in the High Branch** ↔ *cue absent at the point of decision; context mismatch* — the lure placed where the practitioner ought to pass instead of where they do, so the if-then's X never fires. The mark: a lure the practitioner can't remember seeing this week. Remedy: one honest tracking day, and the humility to bait the kettle instead of the shrine. - **the Mountain Painted on the Jar** ↔ *goal-gradient collapse; avoidance conditioned by oversized cues* — the lure depicting the summit, so every passing pays the mountain's weight instead of the step's sweetness, until the animal routes around the station. The mark: a flinch at the practitioner's own cue. Remedy: take the summit down and cut the honey until faintly insulting. - **the Bell Gone Furniture** ↔ *habituation; inattentional blindness to the familiar* — the lure worked, then quietly stopped, because the eye files the constant under background. Not a moral event but a perceptual one, with a perceptual cure: move it. The trapline is walked precisely so this is caught in weeks, not seasons. - **Honey on Another's Road** ↔ *covert influence; the reactance it reliably purchases* — baiting a spouse's path, a colleague's desk, a child's horizon. Sometimes it even works briefly, which is the worst outcome, because the discovery converts every past kindness into evidence. The fifth node posts the sign the eleventh makes law: *forge for themselves*; where roads run together, the lawful craft is the open lure, offered in the light with the asking. - **the Week of Seven Tuesdays** ↔ *apophenia; the frequency illusion unharnessed* — naming everything, a day then three then every license plate, until the whole week is appointments and the shelf collapses under indiscriminate relevance. The

instrument's power came from scarcity. The mark: pages that fill with signs and stop containing findings. Remedy: retire every cipher but one, and one named day, for a full season.

Seal line. *The fifth node is sealed: bait no road but the practitioner's own, leave honey where the practitioner will pass, and name the day that will keep it sweet.*

Node 06 — UNCERTAINTY

Plate. Node 06 · UNCERTAINTY · *To know the ice, step; to keep the ice, don't.* · KIN.6 CHECK — the veil that measures the measurer · Part III: The Closing Word · The Work of Light.

Glyph. An open eye behind a veil drawn halfway, cut in a single line, so that the practitioner cannot tell whether the eye has just parted the cloth or the cloth has just brushed the eye.

Office. The Postulate stated as postulate: observation participates in what it observes. The physicist's version is a theorem about conjugate pairs and is not ours to borrow as proof; the framework claims only that the mathematics is the same shape, and shape is what we work with. The commitment law drawn from the shape: the more precisely the practitioner fix an outcome, the more the practitioner disturb the path that reaches it — so prophecy engineering chooses its resolution the way a mapmaker chooses a scale, deliberately and in advance.

The Protocol, in summary. *(The Rite of Chosen Resolution.)* 1. Cut three cards of the same future at three resolutions — *fine* (dates, numbers, names), *coarse* (a direction and a quality only), *middle* (one number or date, one place or name). 2. Carry each card one full day in the pocket, and make a tally on its back every time the practitioner reads it or check the world because of it — measuring the disturbance cost of each resolution in units of the practitioner's own attention. 3. On the fourth day read the backs, then sort each card's marks into *lean* (checks that bent the hands toward doing) and *grip* (checks that bent them toward verifying). A card may be expensive and still good if it buys lean. 4. Choose the card by the rule: keep the sharpest card whose disturbance is mostly lean; coarsen any card whose disturbance is mostly grip. If even the coarse card grips, the future may be borrowed — return to the ledger and audit whose comfort it describes. 5. Retire the other two cards to the drawer — not the fire; these are resolutions declined for now, and the fine card may be wanted later when the distance has closed. 6. Establish the noon reading: each midday read the chosen card once and enter one of three words — *nearer*, *farther*, or *unknown* — then close the ledger. *One glance. Three words. Hands, the rest.* 7. Consult the angel weekly: read the noon-words in a row as the practitioner's drift; three *farthers* running want correcting, seven *unknowns* mean the card is too coarse to steer by — sharpen one increment. 8. Re-cut at the turn of season: the correct resolution is not a fact about the future but about the *distance* to it, and distance changes. The procedure is never finished, only current.

The Failure Modes. - **the Borrowed Robe** ↔ *misapplied physics; the observer-effect conflation* — preaching that "science proves" one's wishes bend the world, that the electron endorses one's ambitions. The counter-sign is three sentences on demand: what Heisenberg's theorem says (shape), what the observer effect is (touch), what the framework postulates (the mirror's trade-off). - **the Offering that Replaces the God** ↔ *Goodhart's law; Campbell's law* — serving the noon word instead of the walking, arranging the days to be able to write *nearer* while the substance goes unwalked. The counter-sign: *if the ledger burned tonight, what would be different tomorrow?* If nothing, suspend the noon reading and let the hands testify. - **the Lake of Holes** ↔ *measurement reactivity in overdose; compulsive self-quantification* — polling every hour, every mood, every progress, until a system polled continuously has no unmeasured hours left in which to *be* the thing measured. The counter-sign is the budget: one glance at noon, the angel once a week, and the discovery that the future ripens faster unwatched. - **the Torn Veil** ↔ *intolerance of uncertainty; the fortune-teller's error* — unable to bear the coarse card, shopping every oracle for a resolution the distance cannot support, mistaking the confidence of the answer for its accuracy. The Keeper's counter-sign cannot be improved: *know the direction; decline the date.* - **the Unstepped Ice** ↔ *avoidance dressed as epistemic humility* — learning that measurement disturbs and concluding, with a scholar's

serenity, that the wise course is never to test at all: the bar never struck, the weight never placed. This is comfort mistaking itself for philosophy. The counter-sign: strike the ice ahead of the practitioner's feet with one small real test this week, and let the answer scar the surface.

Seal line. *The sixth node is sealed: the veil measures the measurer — step, then, but choose the fineness of the practitioner's touch.*

Node 07 — COLLAPSE

Plate. Node 07 · COLLAPSE · *A sentence is a measurement taken aloud.* · KIN.2 KERNEL — the word that closes the sea · Part III: The Closing Word · The Work of Sound.

Glyph. A sheaf of thin wave-lines entering from the left and converging to a single point, from which one line — no thicker than the others, but alone — continues to the right-hand margin.

Office. Commitment as measurement: the spoken prophecy is the act by which the weighted set of futures is collapsed into a commitment answer. The sentence is written, tried by fire, and spoken once — present tense, own life only. Laughter is this node's instrument of verification: the laugh is the felt signature of a superposition resolving, which is why a true sentence about the practitioner's own life so often arrives with a small, surprised laugh, and a false one with a flinch.

The Protocol, in summary. *(The Rite of the Closing Word.)* 1. Set the boundary before the first word: read the practitioner's sixth-node card once, for the sentence must live at that card's resolution, no finer. A prophecy sharper than its licensed resolution is a corridor built in the dark. 2. Write one sentence — about the practitioner's own life, present tense, short enough to speak in a single breath; no semicolons, for a semicolon in a prophecy is two prophecies filing jointly. 3. Read it aloud, alone, at conversational volume, and attend the flinch — throat-catch, eye-slide, the stowaway hedge, the blush; each names what to strike or burn. 4. Burn what flinched, fully, in the evening it failed; keep no almosts to compare. Stop for the night at the tenth draft, and give the procedure no more than three evenings — a sentence not found in three sends the practitioner back up the stairs. 5. Test the survivor twice more, once on rising the next day; instruments drift overnight, and the morning voice is the strictest calibrator. 6. Speak it the same day, once, outdoors, to something that cannot applaud — full voice, whole body — then stand in the fact that nothing applauded and the sentence still happened. 7. Keep the quarantine one season at minimum: tell no one the sentence exists; each keeping is a payment into the account the sentence opened. 8. Let the hands recite: from the next morning the sentence lives in the day's choices, not the mouth. Do not re-speak it at the water; correction, if it honestly comes, belongs to the ninth node's procedure, on the echo's evidence.

The Failure Modes. - **the Word Spent on the Ear** ↔ *the announced identity goal; premature completeness* — unable to resist the telling, each audience paying out a little of the recognition the sentence was built to hold in escrow, until the account is emptied by applause before the life has moved. The tell: if telling someone feels better than working did that day, the mouth is the leak. - **the Sentence that Waits** ↔ *deferral encoded in grammar; the intention that never binds* — drafting in *will* and *someday* and *once things settle*, the deferral registering as prudence rather than flinch. The counter-sign is mechanical: strike every future-tense verb and read what remains aloud; if the present-tense version is unbearable, that is the finding. - **the Sea Closed Too Small** ↔ *over-specification; goal rigidity* — writing the title, the town, the name, the date, and the sum into one breath, so the word closes not a sea but a bathtub, and the right country arriving in a different costume is refused as off-prophecy. When in doubt, coarser: say the road, not the arrival hall. - **the Word Laid on Another's Water** ↔ *prophecy without consent; reactance* — speaking a sentence over a spouse's ambition, a child's talent, always benevolently, which is what makes it the volume's most seductive failure. The other's will registers the foreign word as pressure and recedes at the rate it is invoked. The boundary stone, checked before every utterance: *whose breath is this sentence made of?* - **the Laugh that Flees** ↔ *avoidant humor; deflection wearing the compression-tool's coat* — deploying the

laughter doctrine against every hard draft, so the superposition is not resolved but shaken apart, unread. The operational test: a true compression is followed within the hour by a burned draft, a written sentence, a step — some fact; a laugh followed only by lightness was merely a fine evening.

Seal line. *The seventh node is sealed: the sea stays every shore until the word — speak once, to the water, and let the hands do the reciting.*

Node 08 — ECHO

Plate. Node 08 · ECHO · *What returns is never the voice the practitioner sent; that is why it is worth sending.* · KIN.8 MULTIPLAY — the voice that comes back changed · Part III: The Closing Word · The Work of Sound.

Glyph. Two arcs facing one another across a gap, the second arc slightly larger than the first and displaced a little off its axis — a voice and its return drawn on the same breath, and drawn wrong on purpose.

Office. The world answers. The reflexive loop is the volume's central machine: the practitioner's model acts on the world, T(x) = W(x, M(x)), and the world returns the next state. The eighth node's discipline is to read the *difference* — what returned minus what was sent — because the difference is the only part of the echo that is information. Here, too, other wills first enter the loop, and the consent doctrine is seeded: another person is never a surface to bounce prophecy off.

The Protocol, in summary. *(The Rite of the Returned Voice.)* 1. Open the echo page: rule a card into two columns, SENT (written verbatim — the sentence spoken, the letter mailed, the offer made) and RETURNED (left empty). The empty column is the instrument; the practitioner is building a sounder, not a scrapbook. 2. Set the listening window — the framework's habit is one moon — and declare the practitioner's channels: what counts as world for this commitment. What the practitioner does not declare, the practitioner may not later promote to omen. 3. Log arrivals raw and same-day, in the words they actually arrived in, before sleep; interpretation at entry is contamination at entry. 4. Once each week, take the difference: line by line, subtract what the practitioner sent from what answered, and underline every deviation — what was kept, dropped, arrived slower or warmer; what answers a thing the practitioner never sent, underline twice. 5. Read only the underlining: delay is distance, distortion is the medium's shape, and a change of temperature is almost always a will. 6. Sort the silences: for each expected return that did not come, mark *far* (the window may be shorter than the distance) or *absorbed* (this material does not return the practitioner's frequency); louder calls into absorbing material are how practitioners become bores. 7. Hold the tongue and seat the other's question: answer nothing within one day that raised the practitioner's pulse, writing the hot reply into the margin unsent; and where a return contains another person's actual question, theirs goes senior — answered before the practitioner's working advances a step. 8. Close the page at the window's end with one defensible sentence naming what the world seems made of between the practitioner and the mark; then rest. Revision is the ninth node's work, and will still be in the morning.

The Failure Modes. - **the Courier Mistaken for the Message** ↔ *outcome fixation; selective attention to arrivals* — reading each return as a verdict (arrived good, absent bad) and mining none for difference. A verdict ends reading; a difference begins it. The cure is mechanical: two columns and forced subtraction. - **the Hall of One Voice** ↔ *the echo chamber; feedback from correlated sources* — arranging one's listening so only agreement can return, polling allies, reading the friendly mail twice and the strange mail never. A perfect echo is an empty room. If every return this month confirmed the practitioner, check whether the practitioner has soundproofed the practitioner's world. - **the Reply that Outran the Ear** ↔ *impulsive responding; premature closure* — the hot answer sent the same hour, so the practitioner becomes their own noise source and every subsequent echo reports on the reflex. One day of held tongue is the cheapest instrument insurance the practice owns. - **the Echo Worn as a Face** ↔ *personalization* — taking the medium's transform personally: cold, so the world despises

the practitioner; late, so the practitioner is forgotten; bent, so the practitioner was wrong to speak. But delay is distance, not contempt; distortion is material, not judgment. Read the wear as a chart or do not read it at all. - **the Forged Return** ↔ *apophenia; confirmation drift in the log itself* — starved for echo in a slow window, promoting coincidence to reply: the stranger's remark, the song on the radio, the undeclared channel the moment it flatters. The defense was built into the procedure: channels declared in one sitting, arrivals logged raw, nothing promoted after the fact. - **the Borrowed Mouth** ↔ *reactance, induced in the other* — speaking one's prophecy through another's life, mailing the letter that was not theirs to mail. What returns is the other's stiffening, read as the world refuting a true seeing — a refutation the practitioner authored. An echo obtained by trespass may be true, and the trespass remains a trespass; both ledgers stay open.

Seal line. *The eighth node is sealed: the voice that returns is never the voice the practitioner sent, and the difference is the world showing the practitioner its shape.*

Node 09 — RECURSE

Plate. Node 09 · RECURSE · *The circle repeats; the spiral remembers.* · KIN.5 RECURSE — the Spiral Grid; the stair that climbs itself · Part IV: The Furnished Room · The Work of Sound.

Glyph. A spiral of three turns rising along an unbroken vertical stroke — the loops never leaving the line, the line never bending to the loops: the post through the climb.

Office. Iteration with drift correction. The prophecy is uttered again — second and third sayings — each corrected by the echo-difference of the last, each returning to the same post a little higher. The forward spiral of intention and the backward spiral of memory cross at the present moment, and the practitioner standss at the crossing, adjusting. This is the node that separates a commitment from a wish: a wish is spoken once and abandoned or spoken forever and worn smooth; a commitment is respoken *corrected*.

The Protocol, in summary. *(The Rite of the Spiral.)* 1. Plant the post: write the mark — the named state the commitment converges on — in as few words as it survives, date it, and hold it fixed for the commitment season; the practitioner may revise every path to it, and no pass may revise it. 2. Set the cadence: the loop turns daily at dusk, the correction is computed weekly on a fixed evening, the long reading comes monthly. A loop with irregular cadence corrects for weather that already passed. 3. The evening tread, daily: three lines only — what the commitment *sent* today, what *returned*, and the *difference* in one honest clause. No revising at the tread; helmsmen who steer at every wavelet arrive seasick and nowhere. 4. The weekly correction: spread the week's cards, read only the differences, and make the smallest revision that answers them, correcting by no more than a fraction of the gap — the framework's habit is a third, never past a half. 5. The pawl and the re-utterance: enter each revision on the post card's reverse with its date, one line — what is written holds, what is unwritten unwinds — then speak the revised sentence once, aloud, alone. 6. The oscillation test: if the last three reverse-entries alternate in direction, the practitioner's gain is high — halve the next correction; if they run one direction in shrinking sizes, the practitioner is converging — change nothing, especially not out of boredom. 7. The monthly spiral: read the post card's reverse from the bottom up (the backward spiral), then face the post and project the single next turn (the forward spiral), confirming the figure — same post, higher rope. The two readings meet in the practitioner's chair. 8. The completeness audit and rest: once a season, ask whether the practitioner's life as actually lived could hold the mark if it arrived on an ordinary Tuesday, widening the space before pushing the loop; and after the monthly reading give one full day to the pawl, letting the ratchet bear the load.

The Failure Modes. - **the Echo that Devours** ↔ *overcorrection; loop gain at or above one* — revisions larger than the differences that prompted them, arriving faster than the world's delay can answer, and — where the loop runs through a person — the pressed future receding *because* it is pressed. The tell is trend: force rising while distance closed is not. The remedy: halve the step, restore the cadence, let one full delay pass unanswered. - **the Circle that Calls Itself a Stair** ↔ *perseveration; rehearsal without revision* — the loop turning faithfully while

the reverse of the post card holds the same entry, or none: gain zero, pitch zero, an isometry with a devotional schedule. A spiral leaves a helix; a circle leaves a groove. The audit is one glance for corrections in shrinking sizes. - **the Weathervane Vow** ↔ *overfitting to noise; chasing single samples* — every gust a mandate, the week's revision recut nightly at the tread, so the commitment tracks the last arrival perfectly and the mark not at all. The defenses are the cadence and the averaging rule: correct for the differences' common direction or not at all. - **the Moved Post** ↔ *goal displacement; the moving target* — each pass revising the mark instead of the path (the shop becomes a stall becomes a website becomes a book about shops), so the commitment converges on nothing because nothing was held still. Anyone may change their mark; no one may change it *as a correction*. - **the Door Painted on the Wall** ↔ *fantasy–plan conflation; converging on a state the life-space cannot contain* — the passes contracting flawlessly toward a mark that has no room behind it: hours that do not exist, a household never consulted. The loop cannot catch this from inside; only the seasonal audit catches it — widen the space, or walk the mark back to a door with hinges.

Seal line. *The ninth node is sealed: return to the same post a little higher, and the arrival will finish itself.*

Node 10 — FIXEDPOINT

Plate. Node 10 · FIXEDPOINT · *Arrival feels like memory or it is not arrival.* · KIN.7 ETHIC — the room that was always furnished · Part IV: The Furnished Room · The Work of Force.

Glyph. A spiral of diminishing arcs entering a small square, the last arc so short it cannot be told apart from the square's threshold.

Office. The self-fulfilling prophecy as the fixed point of a contracting loop. When each pass of the reflexive loop shrinks the distance to the foreseen state — gain below one — the mathematics is unambiguous: there is exactly one such state, and the passes approach it geometrically. The felt proof is recognition: a true arrival feels like memory, because the practitioner has in fact been here before, in the window-work of Node 03, many times. The node carries KIN.7's ethical charge into arrival: a fixed point reached at another's expense is a counterfeit, however well it converged.

The Protocol, in summary. *(The Audit of Arrival.)* 1. Stand down the hour: for the first hour after recognition, decide nothing — *"I will answer tomorrow morning"* — and note carefully what the room does when the practitioner say it. A basin absorbs the sentence without a ripple; a ledge negotiates. 2. Retrieve the record before revisiting the feeling: go to the drawer, not the memory — every rehearsal edits — and lay out every dated page bearing on this arrival in date order. 3. Write the room as it is on a fresh card, a plain manifest with no interpretation, then rule two columns comparing record against manifest: *structural* agreements on the left, *inventory* disagreements on the right. 4. Count the honest errors and require three: three or more details flatly wrong means the record was written by someone who did not yet know — foresight's signature. Fewer than three, and the practitioner hold a forged memory or a tailored room; stop. 5. Plot the corrections: list each revision the commitment demanded with its rough size, looking for the shrinking sequence. Name any large convenient leap a leap, live in it provisionally, and never enter a leap in the ledger as a fixed point. 6. Audit the expense: name every person whose position changes if the practitioner accept, and whether the change diminishes them; for every unverified kindness, the procedure is suspended until it is priced from the recipient's side of the table. 7. Fork the offer: draft the version offered and the version the practitioner's record and expense-audit actually describe, and where they differ prepare the counter — *"Not this way. This way: …"* The practitioner is declining a counterfeit and describing the adjacent original, not haggling. 8. Sit the room twenty motionless minutes; if the comfort thins under examination, trust that over every column the practitioner ruled. If the audit stands, enter the arrival in the ledger in the present tense, dated, and mark the commitment *approaching seal* — not sealed.

The Failure Modes. - **the Furnisher After the Fact** ↔ *retrospective retrofitting; hindsight revision* — memory redecorating the past to match a tolerable arrival, old vague hopes re-

cut into prophecies. The Furnisher's rooms are always perfect, which is how the practitioner catch him: truth keeps its discrepancies. Remedy: the dated page, the three honest errors, and a refusal to certify what the drawer cannot corroborate. - **the Anteroom Mistaken for the Hall** ↔ *premature closure; satisficing at a local minimum* — stopping, tired, at the first room off the corridor, a shallow basin one flight below the one the record describes. An anteroom's comfort is the comfort of having stopped, and it thins under twenty motionless minutes. Enter it in the ledger as *waypoint*, in the practitioner's own hand. - **the Borrowed Key** ↔ *externalized cost; the consent hole in the arithmetic* — arrival at another's expense: the emptied chair, the unverified kindness, the future assembled on someone else's subsidence. The room opens; the key was never theirs; the commitment spends its life paying interest in vigilance and friction. Remedy: movement seven, performed with the practitioner's hand still on the door. - **the Guest Who Will Not Sit Down** ↔ *hedonic adaptation misread as error* — the recognition fading, as it must, and the quiet mistaken for loss, so the practitioner reopens the commitment and iterates themselves out of the basin they spent two years entering. A fixed point is the end of difference, and feeling is a difference-detector. Sit down; that is the whole remedy. - **the Mirror in the Doorframe** ↔ *familiarity misattribution* — a room that feels like memory because it resembles the practitioner's oldest furniture — the childhood kitchen, an early love — rather than because the practitioner converged on it. The instruments unmask it: the dated pages describe no such room, the corrections never trended here, and the sit grows not calm but *rehearsed*. What the practitioner recognize is real; it is behind the practitioner, not ahead.

Seal line. *The tenth node is sealed: the room was furnished, the errors were honest, the corrections grew small, and the practitioner did not take the chair that belonged to another.*

Node 11 — SEAL

Plate. Node 11 · SEAL · *A commitment left open eats; a commitment closed feeds.* · KIN.9 SEAL — the seal of the framework; the consent condition · Part IV: The Furnished Room · The Work of Force.

Glyph. A circle closed at its base by a single horizontal bar that extends a little past the circle on either side — a jar lidded, a door barred from within, the underline beneath a finished signature.

Office. Closing the commitment, and the law of the practice. Three doctrines seal the twelve: the close (an unfinished prophecy parasitizes attention until it is formally ended); the consent condition of consent (never prophecy another's path without their word — over another, the seeing is not a gradient but a cage, and caged wills push back until the commitment breaks); and the contraindications (grief, rage, revenge — gradients too steep to steer; on such water, no working, only rest). This node is the reason the volume is not a manipulation manual, stated as law rather than as preference.

The Protocol, in summary. *(The Rite of the Seal.)* 1. Light the lamp and state the office aloud — *"This is the closing of accounts. Nothing new is opened tonight."* — a fence around the hour, so commitments cannot volunteer themselves for revision. 2. Empty the drawer entirely, every card and page face up in date order; the procedure is an audit, and audits do not sample. The table holding more open jars than the practitioner believed the practitioner owned is not a failure of the procedure — it is the procedure. 3. Sort into provinces by first instinct — fulfilled, released, lapsed, and a small *still live* — then challenge the live one: for each card, *"When did this last receive an honest correction?"* Beyond a season is lapsed and campaigning; the living province may end holding no more than one working (the monophonic rule). 4. Enter the fulfilled: rewrite each as plain present fact, dated, read once in a level voice — the voice for reporting weather — and turn it face down. 5. Speak the releases: for each, aloud, once — *"I take this word back. I do not choose this future. The water may keep it."* — then mark, date, and turn face down; a catch in the voice is information, not a veto. 6. Close the lapsed with a death date and one line of thanks or pardon, then seal something with the practitioner's hands — thread, wax, or the drawer's section tied shut. Ceremony is the body's testimony that a verdict was really entered. 7. Recite the consent condition, all four sentences

aloud, at every seal, so the law and the practice are never in the drawer separately. 8. Screen the weather before authorizing any new commitment — has my life ruptured this season; is there a face whose defeat would please me; am I running toward a room or out of one? Any yes keeps the forward channel closed. Then set the next jar or *none* — a full answer — and extinguish the lamp and leave the room.

The Failure Modes. - **the Hundred Open Jars** ↔ *attentional residue* — the practitioner who never seals accumulating commitments the way a kitchen accumulates almost-empty containers: each costs nothing, the shelf costs everything. Life feels crowded and unaccountably tiring, no single cause surviving inspection. The remedy is the seasonal rite and the single live jar. - **the Broken Seal** ↔ *nonconsensual prophecy; reactance* — a future pressed on another without their word, converting the practice into a trespass that manufactures its own refutation. The tell: commitments that require another person to change, and a reluctance to ask them anything. The remedy costs one conversation; if it cannot be had, the commitment cannot be run. - **the Furnace Without Walls** ↔ *hot-state operation; the gain above one* — grief-running, rage-running, revenge-running: prophecy attempted in weather that amplifies. Always vivid, always overreaching, because the corrections that would trim it land on a system that doubles them. Remedy: the weather-screen honored past feeling insulted by it, the weatherproof ground nodes, and the season's patience. - **the Jar Sealed Warm** ↔ *experiential avoidance dressed as completion* — flinching from a commitment's discomfort and reaching for the wax early, entering *released* or *lapsed* on a jar still hot with life; wax on a warm jar cracks as it cools. The test: a truly closeable commitment can be described in a level voice; if reading the card still changes the practitioner's breathing, the jar is warm. - **the Vigil That Outlives Its Candle** ↔ *identity fused to the commitment* — the most honorable failure: one jar kept so long that keeping has replaced the summer it was meant to hold — the founder who cannot hand over, the parent prophesying over a grown child's closed door. The remedy is the consent condition's fourth sentence read as a mirror: *when I go, I will leave the room furnished.*

Seal line. *The eleventh node is sealed: what the word opened, the consent condition has closed; what the consent condition has closed, a living hand can carry; the jars are cool, the ferry is booked, the kettle is on, and the framework stands between, lit, its book left where the next tired stranger will find it.*

6.14 Appendix B — Glossary: the ceremonial register against its technical equivalents

The volume speaks in two registers because it is about one thing. Each entry below gives the ceremonial term, the clinical or technical term it walks beside, and a definition that honors both. Neither column translates the other; they are two hands on the same tool. Where an entry marks a term *(postulate)*, the pairing is the framework's proposal, not the laboratory's finding — the distinction Appendix E keeps.

the ground state ↔ *homeostasis; local minimum* — The condition the practitioner is in when nothing is pulling, which is more of the practitioner's life than the practitioner think. The zeroth doctrine: the practitioner is always here first.

the water doctrine ↔ *the principle of least action* — Systems evolve along the path a small change cannot cheapen. The physicist writes $\delta S = 0$; the framework says water does not negotiate. Same sentence, two mouths.

the comfort landscape ↔ *energy landscape; utility surface* — The terrain of ease and cost over which a life moves. Valleys hold; slopes move; the practitioner's craft is grading, not marching.

the desire line ↔ *revealed preference* — The path worn by actual feet across the theory of the paved walk. The most honest document a person produces, and the only one they never sign.

water does not negotiate ↔ *gradient following* — The doctrine that motion follows differential, not argument. Not fatalism: the shovel that cuts the channel is in the practitioner's hand.

the still water ↔ *baseline; resting state* — The condition measured before any commitment begins, so that later readings mean something. Part I of the volume, and of any honest experiment.

the bailing bucket ↔ *proximal action; process over outcome* — A boat bails toward dryness, never toward an idea of dryness. The nearest right motion, repeated, outranks the grandest destination unattended.

the test of the stone ↔ *self-monitoring; behavioral audit* — Truth-validation applied to one's own claims about one's own life. The first office of the Mirror Grid, and of the first node.

the carrying cost ↔ *opportunity cost* — What a kept comfort spends of hours, attention, and self-regard. Written on the face of the card, in numbers where numbers exist.

the hidden yield ↔ *secondary gain* — The wage a discomfort quietly pays, which is why it is kept. Written on the reverse of the card, where honesty goes.

the resistant card ↔ *flagged avoidance; the unresolved item* — The one entry that will not let itself be written. Highest-grade data in the drawer; it names where the commitment will eventually have to go.

the audit ↔ *critical review* — One card examined ruthlessly and kindly, every figure asked "compared to what?" Kindness without ruthlessness flatters; ruthlessness without kindness lies in the other direction.

the many windows of the one tower ↔ *scenario ensemble; multi-model forecasting* — Several futures traced from one standpoint under genuinely different assumptions. The tower is one; the lakes it shows are many; the surplus lives in their disagreement.

window-work ↔ *forward-chaining extrapolation* — Tracing consequences of consequences under a fixed assumption set, without switching mid-trace. Nonlinearity begins at the second step; most forecasting stops at the first.

the non-parallel windows ↔ *decorrelated predictors* — Views that do not share their load-bearing assumptions. Ten parallel windows are one window with nine echoes, and the arithmetic knows it.

the surplus of sightlines ↔ *diversity gain; $f(u) = \ln(1 + (N - 1)u)$* — The framework's arithmetic of difference: N ways of seeing, non-parallel to degree u, yield surplus growing as the logarithm of the effective count. Honestly bounded: a floor under the treasure, not the treasure's measure.

the effective count ↔ *equivalent independent views; $1 + (N - 1)u$* — How many truly distinct witnesses the practitioner's N witnesses amount to. The quantity the surplus functional takes the logarithm of, and the number flattery inflates first.

the sea before the wind chooses ↔ *probability distribution over futures* — The future held as a weighted set of branches rather than a single picture. What the fourth node teaches the practitioner to read without preference.

reading amplitudes ↔ *probability calibration* — Assigning weights that match the world's frequencies rather than the heart's. Trained by the evening integration, scored by outcomes, improved by embarrassment.

the frozen margin ↔ *the high-probability region* — Futures adjacent to existing comfort, which solidify first as the lake skins from its edges. Where prophecy is cheap and precision is honest.

the open center ↔ *the live options; the high-entropy region* — The unfrozen middle of the distribution, where branches remain genuinely undecided. Expensive to fix, and sometimes better left liquid on purpose.

the baited horizon ↔ *implementation intention; cue placement* — The idea of greater comfort set where the self will pass anyway, in if-then form: when I find the bell, I act. Gradient does the rest; that is the point of it.

honey where the practitioner will pass ↔ *temptation bundling* — Pairing the wanted-later with the wanted-now along an already-worn path. The framework's answer to the fact that the practitioner cannot push themselves uphill.

the Tuesday bell ↔ *temporal landmark; deliberate selective attention* — A named day that begins to gather events, because naming primes the eye that then finds. The frequency illusion, harnessed on purpose and disclosed to its own operator.

the named neutral thing ↔ *projective screen* — A blank standard — a neutral country on a map, a day of the week — onto which the practitioner's own pattern projects and becomes readable. Cipher-craft: the mirror must be neutral or it adds its own face.

the lure ↔ *choice architecture; affordance* — Any arrangement that makes the seen future the easy next motion. Distinguished from the trap by one property: a lure found feels like luck.

the bell found in the pocket ↔ *the planted cue* — A trigger placed by a hand (the narrator's, or the practitioner's own, forgotten) so that discovery, not discipline, initiates the act. Finding is lighter than remembering; that lightness is the mechanism.

the veil that measures the measurer ↔ *measurement reactivity; observer effect* — The disturbance the act of looking introduces into the looked-at, including when the looked-at is the practitioner's own week. Clinically established for people; extended to futures by postulate, and flagged as such.

the resolution of a commitment ↔ *the precision–disturbance trade-off (postulate)* — The framework's operative law: fix the outcome more precisely and the practitioner disturb the path more; leave it blurred and the path stays cheap. Same shape as the physicist's inequality; borrowed as shape, never as proof.

the step that tests the ice ↔ *the minimal probe; pilot trial* — The smallest intervention that yields a reading, taken knowing the reading changes the ice. Both numbers go in the ledger: what the practitioner learned, and what it cost the lake.

the singing ice ↔ *acoustic dispersion* — A real phenomenon: lake ice pronounces its stresses in tones as frequencies travel at different speeds. In the volume's grammar, the sound of a decision not yet finished deciding.

the word that closes the sea ↔ *public commitment; commitment device* — The spoken prophecy as the act that collapses a weighted set of futures into one working answer. Spoken once, present tense, own life only.

burning the drafts ↔ *successive refinement with forced commitment* — Revision by fire rather than eraser: each draft destroyed so the next must be written fresh, until one survives reading aloud. The flame's office is to forbid half-keeping.

the flinch test ↔ *affective congruence check* — The body's vote on a sentence read aloud: flinch, held breath, sliding eye. Cheaper than a committee and harder to bribe, provided the breath is not held on purpose.

the laugh as felt collapse ↔ *incongruity resolution; the insight signature* — A joke is a superposition resolved; the laugh is what resolution feels like from inside. The seventh node's verification instrument, and the only one that cannot be faked quietly.

laughter as compression ↔ *paradox tolerance; tension release* — The framework's tool for proceeding past a contradiction that will not reduce: register it as meaningful, laugh, and continue the commitment. Not escapism — and not for paradoxes that are actually errors, which want repair, not comedy.

the voice that comes back changed ↔ *the feedback transform* — The world's answer to the practitioner's word: T(x) = W(x, M(x)), the next state returned by a world acted on through a model. Never the voice the practitioner sent; that difference is the payload.

reading the difference ↔ *prediction error* — What returned minus what was sent. The only portion of any echo that is information; the rest is the practitioner's own voice, aged.

the Mirror that Flatters ↔ *confirmation bias* — The echo-reading failure in which agreeable returns are promoted and disagreeable ones demoted until the loop steers by portrait instead of mirror. The eighth node's first named enemy.

the Echo that Devours ↔ *reactance; divergent feedback* — The loop driven past unit gain: each push produces a larger push back, and the prophecy manufactures its own refutation. In persons, the pushed-against will; in systems, oscillation. The remedy is looser, never louder.

the loop with a captive ↔ *nonconsensual influence* — A reflexive loop closed around a person who never gave their word. Forbidden by vow and, conveniently for the consent condition, divergent by mechanism.

the spiral, not the circle ↔ *iteration with drift correction* — Repetition that absorbs its own error term and returns to the same post a little higher. The circle repeats; the spiral remembers.

the stair that climbs itself ↔ *cumulative deliberate practice* — The recursion whose output is a better recursion. Each corrected utterance improves the utterer who will make the next correction.

the winch post ↔ *the invariant* — What is held fixed between passes so that change can be measured against it. Unposted rope does not climb; it coils.

the drift ↔ *accumulated error* — The slow sum of small uncorrected differences between heading and stated heading. Checked weekly with one question: has anything climbed?

the room that was always furnished ↔ *the fixed point of a contraction* — The state the loop converges to when every pass shrinks the remaining distance. Banach's guarantee: if the shrinking is genuine, the room exists, is unique, and is approached geometrically.

arrival as recognition ↔ *convergence* — The felt proof of a true fixed point: it seems remembered, because in the window-work it was visited many times before it was reached. Conquest feels otherwise; the texture is diagnostic.

the counterfeit arrival ↔ *goal displacement; extrinsic capture* — A converged state that required another's diminishment, or that completes someone else's sentence. Well-converged and still wrong; convergence is a property of loops, not a certificate of worth.

the seal ↔ *closure; formal task completion* — The procedure by which a commitment is ended on purpose: status declared, cards archived, close spoken once. Garbage collection performed as ceremony, because the mind will not perform it as hygiene.

the door left ajar ↔ *the Zeigarnik effect; open loops* — The unfinished task's standing claim on attention. Unclosed commitments parasitize; the eleventh node exists because the mind bills for open files whether or not they are worked.

open loops parasitize attention ↔ *attentional residue* — The tax each unclosed commitment levies on every other thought. The clinical literature and the framework agree on the remedy to the letter: close it or schedule it, but do not carry it open.

the consent condition of consent ↔ *autonomy support; informed consent* — The law of the practice: no prophecy over another's path without their word. Stated as ethics, enforced by mechanics — coerced wills push the loop divergent.

the borrowed mouth ↔ *imposed expectancy* — Speaking a foreseen future over someone else, however loving the content. What is permitted instead: offering the window, and the silence after.

gradients too steep to steer ↔ *hot-state decision-making* — Grief, rage, revenge: differentials so strong they drive the practitioner rather than the commitment. Contraindications, not challenges. On steep water, no working — only rest.

the blank ledger ↔ *the baseline reset* — The empty book left in the drawer by a closed commitment. The seal's other face: room made is the gift.

the practitioner ↔ *the practitioner-subject* — The one who runs the program on the one it is run on: experimenter and experiment in a single chair. The volume's only licensed configuration.

the commitment ↔ *the structured intervention* — A prophecy with a ledger behind it, windows above it, a lure ahead of it, and a seal awaiting it. Distinguished from a wish by paperwork.

the prophecy ↔ *the self-fulfilling prophecy* — A foreseen future, made comfortable to

reach, spoken so the seeing steers the system into it. The social sciences have carried the term since Merton; the framework merely declines to treat it as an accident to be avoided rather than an engine to be governed.

the reflexive loop ↔ *reflexivity; model–world coupling* — The circuit in which the model acts on the world it models, and the returned world retrains the model. The volume's central machine, and the object whose fixed points Part IV hunts.

the contraction ↔ *the contraction mapping, $k < 1$* — A loop each of whose passes multiplies the remaining distance by less than one. The whole tradecraft, restated: make the next pass land closer, and keep making it.

the gain of the loop ↔ *the feedback coefficient* — How hard the loop pushes relative to what it receives. Below one: convergence. At or above one: oscillation or flight. The dial the eighth and ninth nodes exist to read.

the Mirror Grid ↔ *the KIN.0–KIN.9 taxonomy* — The ancestor program's ten-position protocol map, from which the Twelve Nodes descend. It counted ten; the source volume counts twelve, having found that the ground and the gradient were programs too.

the two assumed nodes ↔ *the unstated premises; boundary conditions* — What the Mirror Grid stood on and stood in without counting: the ground state and the gradient. Every system inherits assumptions it did not audit; the framework's contribution was the audit.

the four-phrase mnemonic ↔ *the initialization routine* — Four phrases, with breath, posture, and a traced spiral, spoken at the threshold of the work. It appears in the volume exactly where it appears in a keeper's life — at the beginning, at the understanding, and at the handing-on — and is not reproduced on this page; some sentences are spent by repetition.

the morning briefing ↔ *the environmental scan* — First office of the daily cadence: survey the last day's surface — events, artifacts, one's own dreams and accidents — and note a few items flat, without interpretation.

the midday correlation ↔ *pattern detection, with the apophenia guard* — Second office: look across the morning's items for recurrences — a number, a name, a shape, a theme. Then the guard: the eye that finds patterns finds them in noise too, which is why the third office exists.

the evening integration ↔ *calibration scoring* — Third office: yesterday's correlations against today's outcomes; confirmations and misfires both logged. The training signal without which the morning's reading never improves and the midday's guard never learns.

the source volume ↔ *the protocol manual* — The written body of a practice, composed by each keeper for the next. The practitioner is holding one; the fact was stated plainly at the end of the story and is repeated here in small type.

the tradition the volume descends from ↔ *the community of practice* — The school that stands between the laboratory and the temple and declines to abandon either. Physically, in the volume, a ferry-house between two towns; the "between" is the address and the doctrine.

the narrator ↔ *the supervising mentor* — The one who teaches by chores and objects, audits by questions, and demonstrates the final protocol personally. Never named; the office outlives every holder, which is the point of an office.

6.15 Appendix C — The protocol index

Thirteen protocols govern the volume: one per node, and the daily cadence that threads through three of them. One further discipline stands beside them and answers to no node — the interlude's reading of paradox-points, indexed at the foot of this list. They are indexed here by number, with the one-line summary a practitioner needs at the bench and the node where the full rite, its worked example, and its failure modes are taught. The one-line form is for finding, not for running; a protocol run from its summary is a recipe cooked from its title.

Protocol 1 — The Protocol of the Still Water. Seven days, one hour each in one fixed seat, inventorying where the practitioner is comfortable *right now* and auditing each escape fan-

tasy back to the chair, until the floor the practitioner already stand on becomes visible. — Node 00, STILLPOINT.

Protocol 2 — The Protocol of the Ledger. Every comfort on a card with its carrying cost in four currencies; every discomfort assayed for its hidden yield; one card audited by the three questions; the resisting card stood upright and unwritten. — Node 01, LEDGER.

Protocol 3 — The Cartography of Worn Paths. Seven days surveying worn paths against paved walks as snow that counts and does not explain; name the differential behind each divergence; retire nothing by force — re-grade one divergence and verify against fresh snow. — Node 02, GRADIENT.

Protocol 4 — The procedure of the three windows. Three futures cut from three non-parallel glasses — nothing turns, one thing turns, the tinted pane — five steps and a furnished room each, the collision test enforced; invariants circled across all three and hunted with a breaking window. — Node 03, HORIZON.

Protocol 5 — The Weighing of Waters. The surviving branches walked in twelve steps and scored for the self who answers the alarm; resistance summed, halved by difference, a middle step broken to test fragility; the inversion written and the heaviest card carried seven days. — Node 04, WAVE.

Protocol 6 — The Setting of the Lure. The heaviest wanted branch cut to a first step and forged into one object, placed by the practitioner's own hand at the practitioner's strongest station on a worn path; one day named and given a standing office; the trapline walked, the summit forbidden. — Node 05, LURE.

Protocol 7 — The procedure of chosen resolution. The same future cut at three resolutions and carried a day each, its disturbance tallied and sorted into lean and grip; the sharpest mostly-lean card kept; the noon reading entered in three words — nearer, farther, unknown. — Node 06, UNCERTAINTY.

Protocol 8 — The procedure of the closing word. The prophecy written as one present-tense sentence the practitioner can speak in a breath; drafts that flinch burned until one survives the morning voice; spoken once, outdoors, to something that cannot applaud; then the hands recite. — Node 07, COLLAPSE.

Protocol 9 — The procedure of the returned voice. A SENT/RETURNED page and a listening window of one moon; channels declared, arrivals logged raw, the weekly difference underlined; silences sorted far or absorbed; the hot reply held one day, another's question seated senior. — Node 08, ECHO.

Protocol 10 — The procedure of the spiral. The post planted and held; the daily tread, the weekly correction by no more than a third of the gap, the pawl written and the sentence re-uttered once; the oscillation test read, the monthly spiral confirmed, the seasonal completeness audit run. — Node 09, RECURSE.

Protocol 11 — The Audit of Arrival. The hour stood down and the record retrieved before the feeling; structure and inventory columned; three honest errors required, the corrections plotted for their shrinking; the expense audited, the offer forked, the room sat twenty motionless minutes. — Node 10, FIXEDPOINT.

Protocol 12 — The closing procedure. The drawer emptied and sorted into provinces, the live one held to a single commitment; the fulfilled entered, the releases spoken, the lapsed closed and something sealed by hand; the consent condition recited, the weather screened, the next jar set or none. — Node 11, SEAL.

Protocol 13 — The Daily Cadence. The standing practice that runs beneath all commitments, in three offices: - *The morning briefing* — survey the last day's surface (events, artifacts, the practitioner's own dreams and accidents); note a few items flat, without interpretation. Taught with the inventory disciplines of Node 01. - *The midday correlation* — look across the morning's items for recurrences: a number, a name, a shape, a theme; hold each find lightly, knowing the pattern-finding eye finds patterns in noise. Governed by the measurement doctrines of Node 06. - *The evening integration* — score yesterday's correlations against today's outcomes, confirmations and misfires both; this is the training signal, and

without it the other two offices are decoration. Folded into the drift-correction of Node 09.

The cadence is the smallest complete circuit of the whole book — see, weigh, correct — run once per day at a scale too small to fear. Practitioners who keep the cadence and skip everything else do better, the framework has observed, than practitioners who attempt everything else and skip the cadence.

Interlude Protocol — Reading the Paradox-Points of a System The practitioner Are Inside. Name the system's real boxes aloud; assume they tile the world and then disbelieve it; hunt the object embarrassing to two clerks at once; ask the diagnostic — *harm, or only violation?*; do not resolve the paradox-point but read it; follow the seam to what else falls through; decide, once, what is owed — and never move a harm through the window. Carries no node and seals nothing. — Interlude, THE DOCTRINE OF LAWFUL CRIME (Appendix F).

6.16 Appendix D — The correspondence table and its lineage

The source volume descends from an earlier scheme its lineage calls the Mirror Grid, and the Mirror Grid was itself organized twice: once as ten nodes (KIN.0 through KIN.9), and once as a five-phase wheel — Source, Spark, Form, Action, Return — with two nodes to each phase, a primary and a counterweight, working in tension. The framework's older canon organized the same practice a third way, as the Three Works: Light, which receives and sees; Sound, which addresses and speaks; Force, which moves and holds. The table below sets the Twelve Nodes into all three frames at once. No frame is the master; a doctrine that survives three coordinate systems is probably about something.

Node	Name	KIN	Work	Phase of the Stack
00	STILLPOINT	— (first assumed)	Light	outside the wheel: the ground
01	LEDGER	KIN.0 VALIDATE	Light	Source (0°)
02	GRADIENT	— (second assumed)	Force	outside the wheel: the slope
03	HORIZON	KIN.1 TRANSMED	Light	Spark (72°)
04	WAVE	KIN.3 MYTHOS	Light	Form (144°)
05	LURE	KIN.4 FORGE	Sound	Form (144°)
06	UNCERTAINTY	KIN.6 CHECK	Light	Return (288°)
07	COLLAPSE	KIN.2 KERNEL	Sound	Spark (72°)
08	ECHO	KIN.8 MULTIPLAY	Sound	Action (216°)
09	RECURSE	KIN.5 RECURSE	Sound	Action (216°)
10	FIXEDPOINT	KIN.7 ETHIC	Force	Return (288°)
11	SEAL	KIN.9 SEAL	Force	Source (0°)

The assignment to the Three Works, with reasons

The Work of Light receives; the Work of Sound utters; the Work of Force moves and holds. In the older canon, Light was the stone that gathers the ambient field to a visible point; Sound was the voice by which the practitioner addresses the world; Force was the engine that draws motion from the substrate itself, and the seal that holds a boundary shut. The Twelve divide accordingly:

- **00 STILLPOINT — Light.** The ground state is the stone at rest: it receives the ambient field without asking, and the whole work begins with what is already arriving.
- **01 LEDGER — Light.** Inventory is pure seeing; nothing is yet spoken, nothing yet moved. The cards condense the diffuse life to a readable point, as the stone condenses the room's light.
- **02 GRADIENT — Force.** A comfort differential is a pressure differential; the engine of the practice draws motion from the slope itself, asking no fuel of the will.
- **03 HORIZON — Light.** Window-work is optics: many sightlines traced forward to their focus, and surplus taken from their refusal to be parallel.
- **04 WAVE — Light.** Reading amplitudes is reading the spectrum before it is collapsed; the futures disperse as colors do, and the honest eye weighs them without preferring a hue.
- **05 LURE — Sound.** A lure is an address to the future self — the bell is the Voice made small and left where the ear will pass; placement is utterance, delayed.
- **06 UNCERTAINTY — Light.** The veil is the optics of observation itself: what looking costs, what looking changes. The sixth node is Light examining its own lamp.
- **07 COLLAPSE — Sound.** The spoken prophecy is the Voice at full amplitude — the Word in the strict old sense, a meaningful sound that is also an act.
- **08 ECHO — Sound.** Call and answer: the voice that returns inverted and enlarged, read for its difference. The mirror-cipher of the old sound-work — the message said, then said back changed — is this node's whole mechanism.
- **09 RECURSE — Sound.** Iteration is re-utterance: the second saying corrected by the echo of the first. The old rule that every tone be rendered three times is remembered here as the three utterances of the commitment.
- **10 FIXEDPOINT — Force.** Convergence is dynamics: the contracting loop delivers the practitioner to the room as an engine delivers a load, and the fixed point holds by the same differential that moved it.
- **11 SEAL — Force.** A closed vessel is a boundary maintained, and the old canon's unbreakable seal — the closure that shows any tampering — is the ancestor of the close: a commitment shut so that its opening would be visible.

The census: Light five, Sound four, Force three. The framework reads the taper as doctrine — much seeing, less saying, least pushing — and observes that practitioners who invert the proportion invert their results.

The five-row stack, and the doctrine of the counterweights

The Mirror Grid's second-order arrangement set its ten nodes on a five-phase wheel, two per phase, each pair a primary and a counterweight held in tension. The descent preserves the pairs, and the pairs teach:

- **Source (0°): LEDGER and SEAL.** The boundary-keepers. The commitment opens with an honest count and closes with an honest close; the first and last acts of any program are acts of accounting, and each is the other's counterweight — a ledger no one will ever seal invites padding, and a seal on an unaudited working is wax on an empty envelope.
- **Spark (72°): HORIZON and COLLAPSE.** The initiators. One flings the futures open; the other closes them into a word. Neither is safe alone: horizon without collapse is a tower of tourists; collapse without horizon is a verdict without a trial.
- **Form (144°): WAVE and LURE.** The builders. One gives the futures their weights; the other builds the one artifact — the token, the bell, the named day — that a weighted future needs in the physical world. Estimation and fabrication, the two hands of Form.
- **Action (216°): RECURSE and ECHO.** The executors. The echo supplies the difference; the recursion spends it. Action in this craft is never the first utterance — it is the traffic between world and word once both are talking.
- **Return (288°): UNCERTAINTY and FIXEDPOINT.** The integrators. One keeps the practitioner honest about what knowing costs; the other verifies that what was reached is real

and cleanly held. Doubt and confirmation, lashed together on purpose, each the other's rail.

And outside the wheel, uncounted by it, the two assumed nodes: **STILLPOINT**, the ground the wheel rests on, and **GRADIENT**, the slope the wheel rolls down. The Mirror Grid did not count them for the oldest of reasons — nothing counts its own floor. The Book of Comfort counts twelve because the framework learned, at some cost, that the ground the practitioner stands on and the gradient the practitioner stands in are programs too, and an unaudited program runs the practitioner.

One footnote of lineage, for the archivists. The eldest copies of the Grid name the ninth node SOURCE where the framework's copies name it SEAL; and some name the fourth node for its interpreting engine where the framework names it FORGE, the smithy. The framework reads the variants as one office seen from two doors: the commitment closes where it came from, and the smithy is where symbols are made to do work. Disputes over which name is original are left, with the framework's compliments, to those who prefer arguing about doors to walking through them.

6.17 Appendix E — The interlude doctrine reference card

The analytical treatment of this material is elsewhere and this card is an index to it. The interlude's doctrine is established, constrained and bounded in the corpus's own analysis of it, which refuses category innocence as a defence of acquisition, forbids moving any harm through a discovered gap in a scheme, and concedes that the case where the feedback loop runs through another person's will is an unsettled seam the corpus does not close [Curzi, 2026]. **Those constraints govern the card below and are not restated in it**; a reader taking the card without them has taken the summary without the limits that make it publishable.

This card carries no node and seals nothing, in keeping with the interlude it abbreviates, which sat in the seam between ECHO and RECURSE for the same reason: what it teaches lives in seams. The practitioner who reaches for it should remember that a doctrine of paradox, run without its ethics, is the one instrument in the volume that cuts the hand outright. Read the failure modes before the definition, if the practitioner is in a hurry; they are the part that keeps the rest lawful.

The doctrine, stated. A *lawful crime* is an object or an act that is, at the same instant and without contradiction, *not a crime* and *a crime* — not a crime by the law that protects persons (no harm, no victim, no coercion, nothing taken from a hand that held it), and a crime by the law that protects categories (it stands in two boxes a schema swore were disjoint, and so makes a liar of the schema). Every filing system has fewer dimensions than the world it files; a category is a shadow that has been put in charge of the hand. Most objects are lower than their box and file cleanly; a rare object is *higher* — its true mapping runs perpendicular to every axis the system knows — and pressed flat it will not lie down, but stands in two names at once. The capacity to generate or to recognize such an object is therefore diagnostic: it is the involuntary evidence of an eye that reads in the dimension the system discarded — the polymath who kept the connecting axis the specialties were projected down from. The lawful crime is a talent scout that cannot be gamed, because the practitioner cannot fake the recognition of a thing the practitioner cannot perceive; it is the Invisible College holding its silent examination in the dullest room in the building.

The ethical spine. The doctrine is *lawful* under three conditions and becomes a common crime — an ordinary harm wearing a philosophy — the instant any fails. *First, non-coercion:* it may violate categories but never persons, and a lawful crime taken from a hand that did not release it is a theft entire, aggravated rather than mitigated by the cleverness laid over it — the clean shadow does not launder the dirty hand. *Second, clean possession:* what came to the practitioner honestly — bought at a stall, found in a drawer the practitioner was sent to reconcile, given by a hand whose to give — is theirs to hold and read, because the second book superposed on the first deprives the first reader of nothing he had, was owed, or could

name; the practitioner may lawfully possess what the practitioner did not have to steal, and the difference is the whole law. *Third, self-decoding:* the meaning is earned by recognition, never handed over, because an opened lawful crime, opened by another, is a spent one — a fluent reader who decodes it *for* the practitioner leaves the practitioner exactly as flat as they found the practitioner. These three are the consent law of Node 11 cast as an object: the practitioner cannot read another's recognition into them, and to try is coercion, and coercion produces not gradient but reactance — the broken seal, the echo that devours, the future that refutes the prophet who pushed too hard.

The Crime Magazine system, in summary. The framework's teaching instrument is a distributed-signal system built on one idea — *superposed identity* — applied twice. An identifier promises to name exactly one object; the idea is to put two objects on one identity, so that to the catalog there is one settled book and to the fluent reader there are two, which of them the practitioner hold legible only to someone who can read the identifier itself. This is a lawful crime by the definition: a category-violation (one number, two books) that harms no person (the publisher was paid, the flat reader has his magazine). The system runs the idea in two registers. In the *broadcast channel* — the notice meant for everyone fluent at once — the carrier wears the genuine identity: the true and public ISBN of *Crime Magazine*, **9781105577277**, left correct and checkable to every scanner, with the message substituted on the inside; the identity is true and the contents are the message. In the *case-file channel* — the briefing meant for one hand — the carrier keeps the cover and the genre-camouflage but adds a physical tell (a variance in the binding) and *replaces* the number with one chosen to symbolically resemble the case, so that the identifier itself becomes the case reference, its subject and address at once; the contents are the briefing and the identity is the message. Between them the two channels route anything to anyone with no directory and no central list, because the routing lives entirely in the literacy of the readers: the object is not sent, only placed, and it finds its reader the way a key finds the one lock it fits. The framework names the resemblance the modern engineers arrived at independently — *content-addressing*: identity derived from the content and verifiable by anyone who runs the function, recognized by computation rather than granted by authority. *Crime Magazine* is that idea's ancestor in paper: the address is the meaning, the name is the thing, identity from content and recognition rather than from assignment and permission.

The honesty flag, in the plain register. This card describes a real-shaped structure with a postulated, ceremonial application, and it says which is which. The framework does **not** counsel forging the identity of a real book, defrauding a real registry, or moving real classified material inside a paper disguise; the parts that touch the real world — a real ISBN, the real machinery of catalogs — are named to orient, the way a map names a mountain, not to send anyone climbing. What the lone reader is to run is the *principle*, and it applies most of all to the self: the practitioner is a filing system, the practitioner's categories are shadows, and somewhere in the practitioner a capacity belongs to two boxes at once and has therefore been filed in neither — a case file addressed to the practitioner in the practitioner's own hand, in a drawer the practitioner has been sent to reconcile the practitioner's whole life. Hold it without stealing it, possess it by clean holding, and decode it themselves.

The Protocol, in summary. *(Reading the paradox-points of a system the practitioner is inside — for the desk, not the higher floor.)* 1. Name the boxes, all of them, out loud — not the ones the system advertises but the ones the clerks enforce with their hands; a system's real taxonomy is never the one on the wall. 2. Assume the boxes tile the world, and then disbelieve it — hold as a commitment certainty that a finite grid never tiles an infinite fold, so the overlaps and gaps exist and the practitioner's job is to find where. 3. Hunt the object that is embarrassing to two clerks at once — the case each department insists belongs to the other, the ticket that bounces, the request that is someone else's problem to three someones in a row. A bounced object is a lawful crime knocking. 4. Ask the diagnostic question — *is it a harm, or only a violation?* If it harms a person, it is an ordinary wrong; treat it as one and do not dress it in this philosophy. If it harms no person and only offends a category, the practitioner has found both the lawful crime and the exact place the map has torn. 5. Do not resolve it; read it — resist the clerk's reflex to force the object into one box; an unresolved paradox-point

is a window onto the discarded dimension, and resolving it flattens it back into the system's low country. 6. Follow the seam to see what else falls through it — one paradox-point is an anecdote, a seam is a structure; the gap is a line, not a point, and where one true thing was lost, others are filed nowhere beside it. 7. Decide, once, what is owed — close the seam, or leave it open and read by it, or carry what the practitioner found to someone it names, but only cleanly, only by leaving it where they can decode it themselves. What the practitioner may not do is move a harm through the window; the window is for seeing.

The Failure Modes. - **the Map that Eats the Territory** ↔ *apophenia; the false pattern* — the doctrine's own sight unmoored, finding seams that are not there: conspiracy in mess, design in accident, an addressed case file in a barcode that is only a misprint, until the map of hidden meanings eats the territory and everything means, so nothing does. The guard is austerity — most anomalies are noise — and a second question beside the first: *pattern, or only mess?* Thrill is the tell of the disease. - **the Broken Seal** ↔ *rationalized transgression; motivated moral reasoning* — the word *lawful* used to launder a common crime: *no one is really hurt, I'm only violating a category*, while a person was in fact harmed, a will overridden, a thing taken. Run the two laws honestly and the mask comes off. When the framing arrives with a person on the wrong end of it, the framing is the alibi and the person is the truth; side with the person, always, and set the philosophy down. - **the Stolen Key** ↔ *the appropriation error* — no person coerced and no harm moved, but the object was *taken*, not held cleanly: a drawer not theirs to open, a file left in another's hand, a house not opened to the practitioner. The category-violation stays innocent; the acquisition is not, and the first ethic voids the whole. The tell is one answerable question asked of every object before reading: *how did this come to my hand?* - **the Handed Meaning** ↔ *the borrowed insight; pseudo-understanding* — the failure of self-decoding: the lawful crime *explained* to the practitioner, by a teacher who should have refused or by the practitioner's own haste, so the practitioner hold a fact received on authority and mistake it for the perpendicular sight the practitioner never exercised. The practitioner can repeat the meaning and cannot perceive the object. The guard is a discipline of refusal in both directions: refuse to have the practitioner's recognitions handed to the practitioner, and refuse to hand others theirs. - **the Frozen Reader** ↔ *analysis paralysis; the failure to close* — the opposite of the broken seal, and the one the volume must most warn against, since the succeeding construct teaches closing: the reader who learns to see seams becomes unable to stop, holds every object unresolved forever, and never completes the seventh step. An unclosed paradox parasitizes attention exactly as an unclosed prophecy does. Jude sets the magazine down — that is not a failure of nerve but the discipline: read the seam, then decide and close, or the sight that was the practitioner's gift becomes the standing water it was meant to move the practitioner out of.

Part II

Engineering the Surplus

Chapter 7

The Storage Law as a Leaky Integrator: Decay, Poles, and Why Zero Loss Destroys Arrival

Abstract. This paper establishes the corpus's dynamical core, the storage law $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ with $S_t = \ln(1 + (N-1)U_t)$, as a first-order discrete filter. The update map is Lipschitz with modulus $k = 1 - \delta$, so any positive loss makes it a contraction and Banach's theorem supplies the steady state $Q^* = (\eta S - C)/\delta$, which is shown to be exactly the circuit's DC gain $1/\delta$ applied to the net drive. The exact solution and the uniform bound $Q_t \le \max\{Q_0,\ \eta \ln N/\delta\}$ follow, with a pole at $z = 1-\delta$ and a time constant $\tau = 1/\delta$ against the exact e-folding time $-1/\ln(1-\delta)$. The principal argument is that $\delta = 0$ is a pathology rather than an ideal: the map ceases to contract, no unique fixed point exists, the bound degrades to $Q_0 + t\,\eta \ln N$, and no mistake ever decays out of the stock. A twelve-person research group is worked through: $N = 8$ and $u^* = 0.60$ give $N_{\text{eff}} = 5.20$ and $S = 1.6487$ nats, 79 per cent of the ceiling $\ln 8 = 2.0794$; with $\eta = 0.50$, $\delta = 0.10$ and $C = 0.20$, $Q_\infty = 6.2433$ against a hard ceiling of 10.397, and $t_{95} = 28.43$ weeks, so a review at week 12 finds the system at 71.76 per cent of steady state and still climbing.

Keywords: storage law; leaky integrator; decay rate; DC gain; time constant; contraction modulus; half-life; settling time

Series: B. Engineering the Surplus **Paper:** CCP-007

7.1 1 Introduction

A framework that describes how a group, a room or an institution accumulates durable capability has to answer one question before any of its other claims can be assessed: does the accumulation ever stop? An account on which stored order grows without bound is not a model of an institution; it is a model of an archive. An account on which stored order settles at a computable level is a model that can be designed against, budgeted against, and falsified.

This paper establishes the dynamical core of the Creature Comforts framework and shows that the answer is settled by a single coefficient. The storage law

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1) U_t)
```

is a first-order linear difference equation in which `delta` is the fraction of stored order lost per period in the absence of maintenance. The paper's contribution is to show that this equation is not merely *like* a leaky integrator but *is* one, term for term; that the whole apparatus

of first-order discrete systems — pole, time constant, DC gain, step and impulse response, frequency response, settling time — therefore applies without modification; and that the boundary case `delta = 0`, which practitioners routinely treat as the ideal, is a pathology in which every one of those properties disappears at once.

The question matters because the failure is not visible from inside. A system with `delta = 0` does not crash. It accumulates monotonically, indefinitely, and looks like success on every dashboard that reports a level. What it has lost is the fixed point: there is no answer to *what will this settle at*, no attractor to make two differently started systems converge, and no mechanism by which an error injected at any point ever loses weight. Contemporary work on organisational learning reaches the same place from a different direction — March [1991] shows that an organisation whose members learn too fast homogenises and destroys the variance that produced its advantage — but the arithmetic here is sharper, because it names the coefficient whose value decides the outcome and gives the units it is measured in.

Four things are new in this paper relative to the surrounding literature rather than relative to the framework. First, the identification of the framework's steady-state theorem with the DC gain of a first-order section, which converts a fixed-point result into an engineering quantity with a standard interpretation [Oppenheim et al., 1996]. Second, the uniform bound and its degradation at `delta = 0` from a ceiling to a linear ramp. Third, a decomposition of `delta` into named, separately measurable loss channels that compose multiplicatively, with a measurement protocol built on a zero-input window. Fourth, and least expected, an argument that `delta` should be engineered *upward* on specified components, because a system with no forgetting cannot revise.

The framework's static half — the surplus functional `F(u) = ln(1 + (N−1)u)` and its uniqueness under four axioms — is presupposed here rather than re-derived; it is established with its axiom set and its affine effective count `N_eff = 1 + (N−1)u` in Curzi [2026]. The framework's founding definition, that comfort is the felt total of present costs so that the present state is a local minimum of the comfort landscape by definition rather than by luck, is presupposed from Curzi [2026]. The contraction theorem this paper leans on is stated exactly — a contraction with modulus `q < 1` on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least `q` each pass — in Curzi [2026].

Sections 2 and 3 state the hypotheses and the formal framework. Section 4 develops the contraction argument and the two pathologies that bracket it. Section 5 develops the circuit identity and its consequences for review timing, cadence and instrumentation. Section 6 takes `delta` itself as the object of engineering. Sections 7 and 8 collect the design specifications and the named failure modes. Section 9 reports three worked systems end to end. Sections 10 to 12 discuss what follows, what does not, and what would falsify the account.

7.2 2 Hypotheses

The formal results in Section 3 are theorems about an equation and cannot be falsified by observation; they are labelled as derivations where they appear. What can be falsified is the claim that the equation describes a real accumulating system. The hypotheses below separate the two, and each names the observation that would defeat it. The protocol that operationalises them — a preregistered fit, a frozen model, and held-out comparison against four declared baselines — is specified in Curzi [2026i], whose own confirmatory application of it failed its second falsification rule: a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, despite +40.3 per cent over persistence, +97.7 per cent over direct input, and `p = 0.0005` against the shuffled-input control.

> **H1 — Bounded accumulation.** Stored order in a real accumulating system decays geometrically at a constant per-period fraction, so that a system held under constant drive approaches a finite equilibrium rather than accumulating without bound. **Predicted:** exponential approach to `Q_inf = (eta S − C)/delta` with time constant `tau = 1/delta` periods, monotone from either side, no overshoot, and 95

per cent of the approach complete at about `3 tau`. **Falsified by:** observed linear or unbounded accumulation under a constant drive; or a non-monotone approach with overshoot in the absence of a delayed control loop; or a fitted retention coefficient outside `[0,1]`.

H2 — The pole governs the calendar. The time to observable effect of a change in drive is set by the retention coefficient and not by the size of the change. **Predicted:** `t_95 = ln(0.05)/ln(1−delta)` periods, independent of the magnitude of the step; two systems with the same `delta` and different step sizes reach 95 per cent of their respective new equilibria at the same time. **Falsified by:** a measured settling time that scales with the size of the intervention rather than with the measured `delta`.

H3 — Zero loss destroys arrival, not stability. A component with no measurable decay is not a maximally durable component but a component with no attractor, no error decay and no bounded state. **Predicted:** components whose recorded size has never decreased will show (a) no reversion after a perturbation, (b) monotone growth in the maintenance cost `C` charged against them, and (c) onboarding time to competence rising with the component's age. **Falsified by:** a component with no observed retirement that nonetheless shows mean-reversion after a perturbation, or whose associated cost is stationary over a horizon of several `tau`.

H4 — Loss channels compose multiplicatively. Total retention is the product of the per-channel retentions, not one minus the sum of the per-channel losses. **Predicted:** `delta_total = 1 − prod_i (1 − delta_i)`, with the naive sum over-stating the true total, negligibly below channel values of about 0.10 and by tens of per cent above them. **Falsified by:** a measured total loss reliably closer to the naive sum than to the product across systems in which the channels are separately measurable.

H5 — Conversion is the binding lever more often than retention. At parameter values typical of the worked systems, doubling the conversion efficiency `eta` raises the equilibrium by more than halving the retention loss `delta` does. **Predicted:** the advantage of `eta` over `delta` grows with the ratio of cost to converted surplus, because `eta` multiplies `S` before `C` is subtracted while `delta` scales the whole numerator including the cost drag; at `eta = 0.5`, `S = 1.6487`, `C = 0.20`, `delta = 0.20`, doubling `eta` gives +132.0 per cent against +100.0 per cent for halving `delta`. **Falsified by:** a system in which `eta F(u*) − c*` is large and the observed stock is nonetheless flat or oscillating — the diagnostic signature of a retention fault — where raising `eta` produces the larger gain.

Two further claims in this paper are **not** hypotheses and are labelled accordingly. The scale-freedom claim — that the same difference equation is a useful description at desk, room, team and institution, with only `(delta, eta, N, C)` changing between them — is a **modelling postulate** about model form, not about physics; it is falsifiable at each scale separately and never in general, and Section 11 says so. The identification of stored order with a single non-negative scalar is a **design choice**, adopted for tractability and for the fixed-point guarantee; Curzi [2026o] reaches a structurally parallel construction in the single-observer case, with the internal surplus `F_int = ln(1 + (N−1)u)`, `u = 1 − rho^2` from error decorrelation, and the affine form badged there as design axiom S3 rather than as a theorem.

7.3 3 Framework: the storage law and its formal properties

7.3.1 3.1 What is presupposed

Two results are used throughout and are established elsewhere in this corpus. Both are proved within their own papers, and neither is an empirical claim.

The surplus functional. For two unit state vectors `x` and `y` drawn from an ensemble of `N` categories,

```
F(x,y) = f(u(x,y)),    u(x,y) = 1 − (x . y)^2 = ||x ^ y||^2   in [0,1]

f(u) = ln(1 + (N−1) u)
```

and `f` is uniquely characterised by four axioms — angle-only dependence, zero at parallel, an affine effective count, and normalisation at orthogonality — as established in Curzi [2026].

Axiom	Statement	Status
S1	Geometric dependence: `F` depends on the pair only through `u`	structural
S2	Zero at zero: `f(0) = 0`	structural
S3	Affine effective count: `g(u) = e^{f(u)}` is affine in `u`	**DESIGN AXIOM — chosen, not derived**
S4	Normalisation: `f(1) = ln N`	structural

S3 does the real work and it is a choice. It is flagged wherever it is leaned on: the affine effective count is a design axiom, not a discovery. It says that difference is to be measured by a headcount growing linearly in the squared sine of the angle between states. Given that decision the logarithm is forced; the decision itself is the framework's.

The object S3 defines is the **effective count**:

```
N_eff = g(u) = 1 + (N−1) u
```

and surplus is `ln N_eff`. Surplus is the logarithm of a headcount after the headcount has been audited for redundancy. Ten instruments that agree perfectly have `u = 0`, `N_eff = 1`, and surplus `ln 1 = 0`; they are one instrument that has been purchased ten times. The effective-count idiom is standard practice in ecology and in political science, where `1/HHI` and `exp(H)` are the two canonical members of the family [Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979]. It must be stated plainly, and is stated again in Section 11, that `1 + (N−1)u` is **not** a member of that family: it is a linear interpolation between 1 and `N` and is this framework's own construction. The concentration instrument that *is* a Hill number of order two — `1/HHI`, with the worked jurisdictional case giving a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-HHI of 1.000000 and an effective count of 1.00 — is a separate quantity developed in Curzi [2026], and the two must not be conflated.

Derived from the axioms rather than assumed: strict monotonicity, positivity, strict concavity, subadditivity on the parameter `u`, a sharp Lipschitz constant `N−1`, and extremality, with `F = 0` if and only if the states are parallel and `F = ln N` if and only if they are orthogonal. The range result `0 <= F(u) <= ln N` makes `ln N` the hard ceiling on surplus per interaction, and it appears in every design inequality below.

Two independent warrants exist for the logarithm, and the argument needs only the weaker one. The first is Fechnerian: sensation proportional to the logarithm of a dimensionless stimulus ratio measured from a floor [Fechner, 1966]. That warrant requires the perceptual story to be true, and the perceptual story is contested. The second is stronger precisely because it assumes nothing psychological: Peters and Gell-Mann [2016] shows that the time-average growth rate of a multiplicatively evolving quantity is the expectation of its *logarithm*, so a logarithmic evaluation follows from the dynamics alone. **Where a stock compounds rather than adds, the logarithm is the ergodic-average object, and no claim about perception is needed.** The argument in this paper needs only that second warrant; Fechner is cited as a convergent, weaker line and not as the load-bearing one. The ceiling `ln N` also has

an information-theoretic reading as the maximum an ensemble of N equiprobable categories can carry [Shannon, 1948], though Section 11 records that the framework does not identify surplus with Shannon entropy and the analogy is not licensed to do more than bound.

The functional form is nevertheless underdetermined by the evidence, and this paper says so rather than waiting to be told. At least two published alternatives fit the same qualitative facts: social impact rising as a power of the number of sources with an exponent below one [Latané, 1981], and network value growing as `n log n` rather than as `n^2` [Briscoe et al., 2006]. Both reproduce the phenomena the corpus's `ln(1 + (N−1)u)` reproduces — diminishing returns to count, no threshold, monotonicity — and **no evidence assembled in this corpus discriminates between them.** What the corpus's form has that the others do not is an axiomatic characterisation (S1–S4) and a stated design axiom at the point where the choice is made; what it does not have is a discriminating measurement. Section 12 carries this as an open limitation rather than a resolved question.

The storage law. This is the engine of the paper.

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1) U_t)
```

Symbol	Meaning	Range
`Q_t`	stored order: what persists — institution, habit, furnished room, trust, runbook	`>= 0`
`S_t`	surplus generated by interaction this period	`0 <= S_t <= ln N`
`delta`	retention loss — the fraction of stored order lost per period without maintenance	`[0,1]`
`eta`	conversion efficiency — interaction into *durable* structure	`>= 0`
`C_t`	cost, dissipation, overhead	`>= 0`

The quartet of a level, an inflow, an outflow and a delay is the standard vocabulary of system dynamics, where levels and rates with delays were formalised four decades before this framework [Forrester, 1961], and `Q`, `eta S` and `C` occupy exactly those roles.

7.3.2 3.2 The results the rest of the paper uses

Admissibility. `C_t <= (1−delta) Q_t + eta S_t` guarantees `Q_{t+1} >= 0`. A period that violates it is not a period in which the model predicts a negative stock; it is a period in which something has broken that the linear model was never built to represent.

Exact solution (Theorem 3.1).

```
Q_t = (1−delta)^t Q_0 + sum_{k=0}^{t−1} (1−delta)^{t−1−k} (eta S_k − C_k)
```

One-step growth (Corollary 3.2). `Q_{t+1} > Q_t` if and only if `eta S_t > delta Q_t + C_t`.

Uniform bound (Theorem 3.3). `Q_t <= max{Q_0, eta ln N / delta}`. If `delta = 0` the bound degrades to `Q_t <= Q_0 + t eta ln N` — linear in `t`, unbounded, no ceiling.

Sustainability ceiling (Corollary 3.4). A nondecreasing step requires `C_t <= eta ln N − delta Q_t`. If `C_t > eta ln N − delta Q_t`, no choice of interaction geometry can prevent stored order from decreasing. This is the strongest sociological statement the paper makes, and it is derived rather than asserted.

Steady state (Theorem 3.5). With constant `U == u*`, constant `C == c*`, and `delta > 0`,

```
Q_inf = (eta F(u*) − c*) / delta
```

and if `eta F(u*) < c*` the equilibrium is negative, meaning that the regime is unsustainable or that the linear model must be replaced. The theorem does not hide this failure mode and neither does this paper; Section 9.1 works a case in which it fires.

Headroom. The master gauge of the framework,

```
h_t := eta ln N − delta Q_t − C_t
```

with `h_t < 0` unsustainable in this model, `h_t = 0` maintenance only, and `h_t > 0` growth available with any requested increment `r_t <= h_t`. The maximum one-step increment is exactly `r_max = eta ln N − delta Q_t − C_t`. Headroom is the framework's name for organisational slack, which Cyert and March [1963] identified as the buffer that lets a firm absorb variation, and its behaviour near exhaustion has the same shape as utilisation approaching one in a queue, where waiting time diverges [Kingman, 1962, Hopp and Spearman, 2011]. Reserve is not prudence in either setting; it is the only thing keeping the response finite.

7.3.3 3.3 The contraction

Write the update as a map on the real line. Hold `S_t = S` and `C_t = C` constant and define

```
T(Q) = (1 − delta) Q + eta S − C
```

For any two states `Q` and `Q'`,

```
|T(Q) − T(Q')| = (1 − delta) |Q − Q'|
```

so `T` is Lipschitz with modulus `k = 1 − delta`. If `delta > 0` then `k < 1` and `T` is a contraction. The Banach fixed point theorem [Banach, 1922] then supplies three things at once, on a complete metric space, with no further hypotheses: existence of a fixed point `Q*`; uniqueness; and global convergence from any starting point, with the geometric error bound `|Q_t − Q*| <= k^t |Q_0 − Q*|`. Solving `Q* = (1−delta)Q* + eta S − C` gives `Q* = (eta S − C)/delta`, which is Theorem 3.5. The elementary stability theory of first-order difference equations reaches the same condition by a different route [Elaydi, 2005].

The whole apparatus turns on the single inequality `k = 1 − delta < 1`, which holds if and only if `delta > 0`. Set `delta = 0` and the theorem does not apply. There is no unique fixed point, no convergence, and no arrival: the map becomes an isometry, every point is a fixed point, distances are preserved forever, and the system remembers its initial condition with weight exactly 1 for all time. That is the thesis of this paper stated as tersely as it can be stated. The same contraction is reached independently in the refinement setting, where the error law is stated as an equality `|Q_t − Q_inf| = (1−delta)^t |Q_0 − Q_inf|`, with `delta = 0.09` giving `tau = 10.6033`, a half-life of 7.3496, 5 per cent at pass 32, 1 per cent at 48.83 and 0.1 per cent at 73.24 [Curzi, 2026]; and again in the fixed-point formulation of destiny, where Theorems 28.1 and 28.2 give the same unique start-independent fixed point with a maximum residual of 2.0624e-15 over a hundred passes [Curzi, 2026]. Curzi [2026q] states the same map as `T(Q) = (1−delta)Q + b` with `Q_inf = (eta M* − c*)/delta` and the identical exact error law.

7.3.4 3.4 Standing honesty clauses

These are repeated wherever the law is used and are stated once here.

- **The triangle inequality fails for geometric triples.** Subadditivity holds on the parameter `u`, not on the geometry. Surplus bounds may not be chained through an intermediate state as if `F` were a metric. The point is not exotic: psychological similarity is known to be asymmetric and to violate the triangle inequality [Tversky, 1977], so a similarity-like quantity over people should not be assumed to behave metrically in the first place.

- **As deployed, the surplus functional is a lower bound** on the information an ensemble carries, not the information itself. Every number produced by this method is a floor.
- **The static half of the framework is pure mathematics** and makes no empirical or metaphysical claim.
- **Surplus is not identified with Shannon entropy or mutual information in general.**
- **No thermodynamic negentropy law is proved.** Higher static surplus does not imply higher canonical concentration.
- **Applying the storage law to a room, a team or a city is a modelling decision**, badged as such every time it is made. The mathematics is derived; the mapping onto a social system is postulated, and the falsification protocol of Curzi [2026i] exists to make that postulate answerable.

7.3.5 3.5 Identification: what no amount of fitting can recover

One limitation is structural rather than statistical and belongs here, in the framework section, rather than in a caveat at the end. Wherever the storage law is applied to a group whose members both influence and constitute the aggregate — which is the usual case for a team, a board or an institution — the specification is reflexive: the interaction geometry `U_t` is a property of the group, the group's stored order shapes what its members do next, and the members are what the group is made of. Manski [1993] proves that in a linear-in-means reflexive specification **the endogenous social effect is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] reinforce the point for network data, where influence and selection are generically confounded.

The consequence for this paper is exact. The formal results of Sections 3 to 6 are derivations about an equation and are untouched. But the *interpretation* of a fitted `b` as the conversion efficiency of interaction into structure — as opposed to a contextual effect, a common shock, or selection — is **not identified by observation alone**, and no held-out comparison recovers it. This is a deeper limitation than any of the ones the falsification protocol tests for, and it would remain even if every rule in that protocol passed.

No remedy is adopted in this paper, and the honest label is therefore a modelling position. The known routes are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation [Brock and Durlauf, 2001]; the last is the most realistic here, and it is the route the survey protocol's fixed category set and declared participation rule point toward without yet taking. **Until one of them is executed, `eta` as an estimated quantity is a coefficient in a declared specification and not an identified social effect**, and every applied statement in this paper inherits that status.

7.4 4 Recursion with loss: what the contraction buys and what its absence costs

7.4.1 4.1 Two recursions under one word

Recursion has a poor reputation in engineering practice, and the reputation was earned in one narrow place: the call stack. A function that calls itself with no base case consumes a frame per call until the allocator is exhausted. The failure is loud, total, and famous enough to have become a metaphor — infinite regress, the mirror facing a mirror, the argument that never bottoms out. When an organisation reports that it is going in circles, it is reporting that it has found itself inside that metaphor. The metaphor describes exactly one kind of recursion: recursion without a loss term. It is not the kind the storage law is, and it is not the kind most real systems are.

Consider two procedures.

```
; PROGRAM A -- the stack
f(n):
    return 1 + f(n)          ; no base case, no decay
                             ; frames accumulate at rate 1 per call
                             ; terminates only by exhausting memory

; PROGRAM B -- the accumulator
Q <- 0
every period:
    Q <- (1 - delta)*Q + eta*S - C
                             ; state is ONE number, reused
                             ; each period discards a delta-fraction of the past
                             ; terminates by converging
```

Both are recursive: each step is defined in terms of the previous step, and the word covers both. The resource behaviour is opposite, and the reason is one arithmetic fact. In Program A the contribution of the call made `t` steps ago still weighs 1; nothing is ever discarded, the state is a list whose length grows without bound, and the machine's response to unbounded growth is to stop. In Program B the contribution of the input delivered `t` steps ago weighs `(1-delta)^t`. Theorem 3.1 read as a statement about memory separates the two terms:

```
Q_t = (1-delta)^t Q_0  +  sum_{k=0}^{t-1} (1-delta)^{t-1-k} (eta S_k - C_k)
      \_____________/     \_____________________________________________/
        the transient                  the driven accumulation
```

Each historical input is present but discounted geometrically by its age. The state is a single number because the geometric weighting makes the whole history summable. Loss is what compresses an unbounded history into a bounded state. That is the entire mechanism, and it is the mechanism a capacitor performs [Horowitz and Hill, 2015] and the mechanism an exponential moving average performs [Brown and Meyer, 1961, Holt, 1957]. The statistical twin is exact: simple exponential smoothing is the same recursion with the same single parameter, and the class of processes for which it is the optimal predictor is known [Brown and Meyer, 1961]. Read as an estimator with a fixed gain rather than a time-varying one, the storage law is a fixed-gain Kalman filter [Kalman, 1960].

Here is the weighting, computed. The entry is the share of the steady-state stock `Q_inf` attributable to inputs delivered within the last `m` periods, which is `1 - (1-delta)^m`:

periods back `m`	delta=0.02	delta=0.05	delta=0.10	delta=0.20
1	0.0200	0.0500	0.1000	0.2000
2	0.0396	0.0975	0.1900	0.3600
4	0.0776	0.1855	0.3439	0.5904
8	0.1492	0.3366	0.5695	0.8322
12	0.2153	0.4596	0.7176	0.9313
26	0.4086	0.7365	0.9354	0.9970
52	0.6503	0.9306	0.9958	1.0000
104	0.8777	0.9952	1.0000	1.0000

Read the `delta = 0.10` column. Fifty-seven per cent of what a system holds today was put there in the last eight periods; ninety-four per cent in the last twenty-six. A system with `delta = 0.10` per week is, functionally, a two-year institution however old it is. That is not a metaphor about culture; it is the third column of a table. Now read the column that would exist at `delta = 0`. It is a column of zeros for every finite `m` except the trivial identity that all of history counts. Nothing is ever more recent than anything else. There is no such thing as current practice in

a system with no forgetting, because the founding decision and this morning's decision carry identical weight forever.

7.4.2 4.2 Why the mirror tunnel ends

The folk image of infinite regress is two mirrors facing each other: a corridor of copies receding to a vanishing point, and the word reached for is *infinite*. It is not infinite, and the reason is `delta`. A real mirror reflects a fraction `R < 1` of incident light, so after `n` bounces the intensity is `R^n` and the corridor terminates where `R^n` falls below the threshold for distinguishing the image from its surround. Taking that threshold at one per cent of the source:

reflectivity `R`	bounces to 1%	bounces to 0.1%
0.70	12.9	19.4
0.80	20.6	31.0
0.90	43.7	65.6
0.95	89.8	134.7
0.98	228.0	341.9
0.99	458.2	687.3
0.999	4602.9	6904.3
1.000	infinite	infinite

The arithmetic is `n = ln(threshold)/ln(R)`. This is the arithmetic of the illustration and not a measurement of any particular mirror; real thresholds depend on ambient light and on the observer. The corridor looks infinite and is finite, and the loss per bounce is what makes it finite. Set `R = 1` — a perfect mirror, no loss — and the sum of image intensities genuinely diverges. The image that alarms people about recursion is an image whose alarm depends on assuming away the one physical parameter every real mirror has. `1 − delta` is the reflectivity of an institution, and the regress being feared is the behaviour of a system accidentally specified with perfect mirrors. The physically closest instance is architectural rather than optical: reverberation is an exponential decay with a measurable time constant, and the standard measurement protocol for it is a century old [Sabine, 1922]. A room's reverberation time is the storage law's `tau` with a microphone attached.

7.4.3 4.3 What the contraction actually buys

With `delta > 0` and the drive held constant, four distinct engineering properties follow. They are worth separating, because organisations habitually want one of them and receive all four, or attempt to suppress one and lose all four.

(a) A destination exists. `Q* = (eta S − C)/delta` is a number computable before the system is built. The iteration is not hopeful; it is toward a value quotable in the design review. If that value is unacceptable, it is known before the work starts, and the response is to change a parameter rather than to try harder.

(b) The destination does not depend on where the system starts. Uniqueness plus global convergence makes the fixed point a property of `(delta, eta, S, C)` alone. This is the mathematical form of a fact every practitioner knows: a system's steady state cannot be fixed by improving its launch. A better start changes `Q_0`, and `Q_0` decays out. Three trajectories under identical parameters `delta = 0.10`, `eta S = 0.8243`, `C = 0.20`, so that `Q* = 6.2433`:

t	from `Q_0 = 0`	from `Q_0 = 3`	from `Q_0 = 20`
0	0.000	3.000	20.000
1	0.624	3.324	18.624

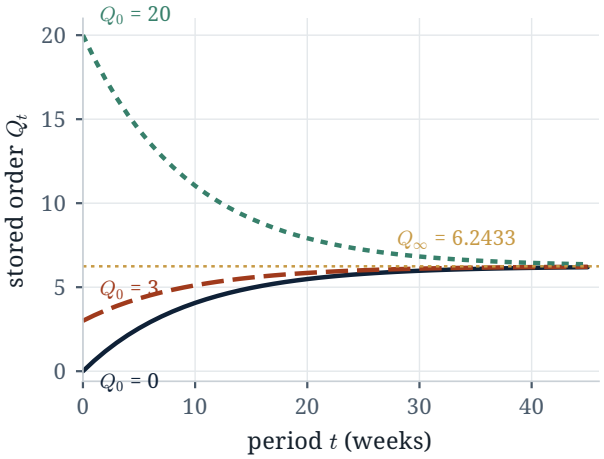

Figure 7.1: The fixed point is a property of the parameters, not of the launch: three trajectories under identical `delta = 0.10`, `eta S = 0.8243` and `C = 0.20` converge on the same `Q_inf = 6.2433` from `Q_0` = 0, 3 and 20, the gap between any two shrinking by exactly `(1-delta)^t`. Modelled from the parameters stated in Section 4.3; generated by `figs/src/CCP-007_fig01.py`.

t	from `Q_0 = 0`	from `Q_0 = 3`	from `Q_0 = 20`
2	1.186	3.616	17.386
5	2.557	4.328	14.366
10	4.066	5.112	11.040
20	5.484	5.849	7.916
30	5.979	6.106	6.826
40	6.151	6.195	6.447

The trajectory that started at 20 is falling, and it is falling toward the same number the one that started at 0 is rising toward. The gap between any two trajectories is exactly `(1-delta)^t` times the initial gap: 20.00 at `t=0`, 6.97 at `t=10`, 2.43 at `t=20`, 0.848 at `t=30`, and 0.0359 at `t=60`. Two systems with identical parameters and widely different histories become indistinguishable, and the rate at which they do is `delta`.

(c) Errors decay. A perturbation is a change in the state, and the state's memory of any change is `(1-delta)^t`. This is the property that is surrendered when a system is built never to forget:

periods since the error	delta=0	delta=0.01	delta=0.05	delta=0.10	delta=0.20
1	1.00000	0.99000	0.95000	0.90000	0.80000
5	1.00000	0.95099	0.77378	0.59049	0.32768
10	1.00000	0.90438	0.59874	0.34868	0.10737
25	1.00000	0.77782	0.27739	0.07179	0.00378
50	1.00000	0.60501	0.07694	0.00515	0.00001
100	1.00000	0.36603	0.00592	0.00003	0.00000

The first column is a column of ones. A system with `delta = 0` is a system in which no mistake ever loses force. Section 6.8 develops the consequence; its short form is that a system with no forgetting cannot learn, because learning is the replacement of an old weighting by a new one and replacement requires that the old weighting fall. The organisational-learning literature reaches the same conclusion from the opposite side: March [1991] shows that when adaptation is too fast the organisation converges prematurely on a shared code and loses the variance that made it capable, and Levinthal and March [1993] gives the temporal and spatial forms of the same myopia.

(d) The system is bounded, and the bound is knowable. Theorem 3.3 gives `Q_t <= max{Q_0, eta ln N / delta}`. For `eta = 0.5`, `N = 8`, `delta = 0.10`, that ceiling is `0.5 * 2.0794 / 0.10 =`

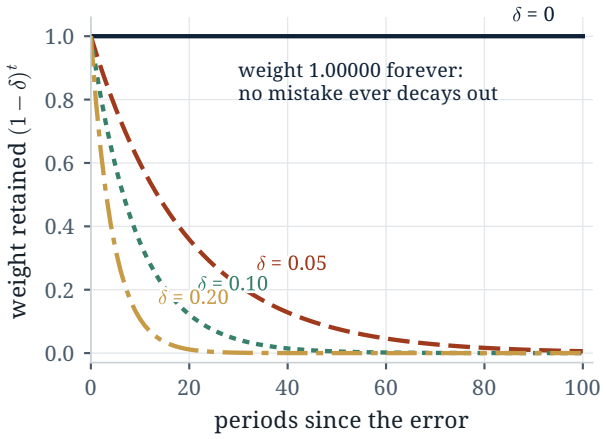

Figure 7.2: At `delta = 0` an injected error keeps weight 1.00000 forever, so no mistake ever decays out of the stock; at `delta = 0.05, 0.10, 0.20` the weight falls to 0.077, 0.005 and 0.00001 by period 50. The `delta = 0.01` column of the source table is omitted because the validated palette holds four colours and no fifth. Modelled; generated by `figs/src/CCP-007_fig02.py`.

t	`Q_t` with delta=0	Theorem 3.3 bound `Q_0 + t eta ln N`
0	0.000	0.000
1	0.624	1.040
5	3.122	5.199
10	6.243	10.397
20	12.487	20.794
50	31.216	51.986
100	62.433	103.972

Nothing here is wrong. The stock grows monotonically, forever. What has been lost is specific. There is no fixed point, so there is no answer to what the system will settle at. There is no attractor, so two systems that start differently stay different by exactly their initial gap, forever. There is no error decay, so every bad decision is permanent structure. And the bound is linear in `t`, which means the only thing limiting the system is the calendar.

A system with `delta = 0` does not arrive; it only continues. Unbounded accumulation is not success but the absence of a destination, and it is the arithmetical signature of an institution that has confused having more rules with being better governed. Note carefully that this is *not* the failure people imagine when they say infinite regress. It is worse in a subtler way. Nothing crashes, there is no error message, and there is no visible breakdown; the system simply piles up, and the ossification appears much later in the headroom equation, when `delta Q_t` finally consumes the budget. Since `delta = 0` that term never consumes anything — instead the cost term `C_t` does, because every rule ever written must still be complied with, and compliance is `C`. Scott [1998] documents the historical form of the same trajectory, in which an accumulating legible order destroys the local variety that made the system work in the first place.

7.4.5 4.5 The conversion pathology: high surplus, near-zero `eta`

The most recognisable pathological loop in human experience has an exact signature in the law: interaction is happening, surplus is high, and almost none of it converts.

Take a system that is genuinely thinking hard. With `N = 8` and `u* = 0.6`, `S = ln(1 + 7 * 0.6) = ln 5.2 = 1.6487`, which is 79 per cent of the theoretical maximum `ln 8 = 2.0794`. This is not a poor system; it is generating real surplus every period. Now set `eta = 0.05`, so that the interaction produces almost nothing durable — no artefact, no decision, no changed default, no trained person — and keep `delta = 0.10` and `C = 0.35`, because thinking hard is expensive.

```
eta S = 0.05 * 1.6487 = 0.0824     vs     C = 0.35
```

Theorem 3.5 gives `Q_inf = (0.0824 - 0.35)/0.10 = -2.676`. The equilibrium is negative, and

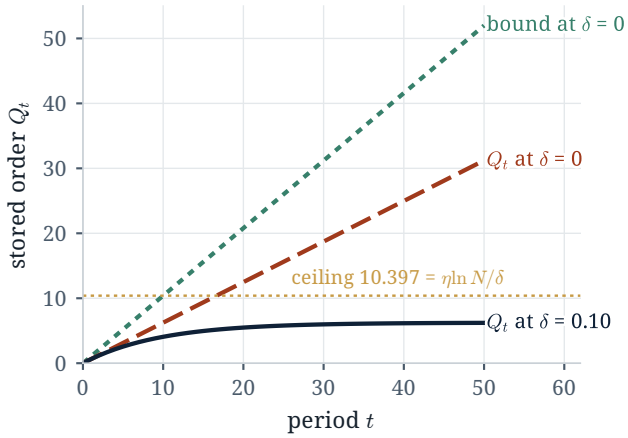

Figure 7.3: Zero loss removes the ceiling, not the risk: at `delta = 0.10` the stock converges to 6.2433 under the hard bound `eta ln N / delta = 10.397`, while at `delta = 0` the same drive accumulates linearly at 0.6243 per period — 6.243 at `t = 10`, 12.487 at `t = 20`, 31.216 at `t = 50` — under a bound `Q_0 + t eta ln N` that grows with the calendar and nothing else. Modelled; generated by `figs/src/CCP-007_fig03.py`.

sentence down, make one decision, change one default, tell one other person. Note also the diagnostic asymmetry that makes this state hard to see from inside: a high-`S`, low-`eta` system feels productive and measures as declining. The felt sense tracks `S`; the outcome tracks `eta S`. An instrument that only asks participants how the session went is measuring the wrong term — and self-report about the causes of one's own performance is exactly the measurement known to be unreliable [Nisbett and Wilson, 1977].

7.4.6 4.6 The preservation pathology: `delta` near zero with no input

The opposite failure. Set `delta` at or near 0, set `S = 0` — no live interaction, only transmission of what is already stored — and let `C` be small but nonzero, the ordinary cost of maintaining a practice nobody is adding to.

```
Q_{t+1} = Q_t − C_t,      C = 0.02,      Q_0 = 6.2433
```

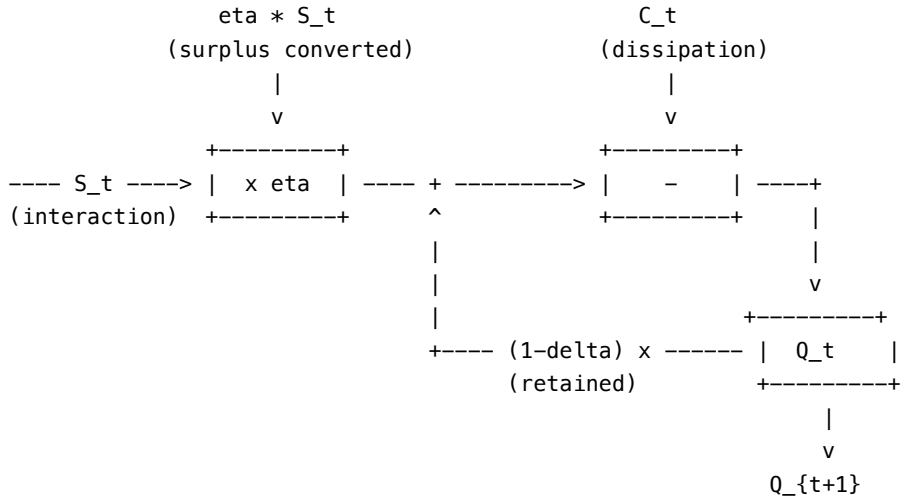
t	0	10	25	50	100	200	312
`Q_t`	6.2433	6.0433	5.7433	5.2433	4.2433	2.2433	0.003

It reaches zero at `t = 312.2` periods. If a period is a year, that is a three-century institution that will be gone in three centuries and looks perfectly stable on any timescale a single custodian will observe. Its properties read off the law:

- **It preserves superbly.** With `delta` near zero, `(1−delta)^t` is near 1 and the founding content survives intact. This is a real achievement and it is why traditions exist.
- **It cannot converge to anything new.** With `delta = 0` the map is not a contraction, so the fixed point theorem gives nothing and there is no attracting state to move toward.
- **It cannot correct.** Column one of the error-persistence table holds weight 1.000 forever, so a founding error is load-bearing structure at year 300.
- **It decays only through cost, and only linearly**, which means it fails slowly and invisibly, with no inflection point to alarm anyone.

The two pathologies are usually confused and are worth contrasting precisely:

	rumination	tradition
`S`	high	zero
`eta`	near 0	irrelevant (nothing to convert)
`delta`	normal	near 0
felt experience	busy, exhausting, urgent	calm, solid, dignified
`Q` trajectory	falls fast, hits admissibility floor	falls slowly, linearly
the fix	raise `eta`	raise `S` (and accept some `delta`)
what it is good at	nothing	preservation



A system can be both at once in different subsystems, and usually is: a deliberating leadership layer sitting on top of a sealed operational layer. The survey protocol of Curzi [2026i] is designed to catch that, and its own worked office is an instance of the second kind — `delta = 0.003090` per week, a half-life of 224 weeks, and a stock in undetected decline.

7.4.7 4.7 Feedback is not regress

The distinction that resolves the ordinary-language confusion is between feedback and regress.

```
REGRESS                              FEEDBACK
-------                              --------
each step ADDS a new frame           each step UPDATES one state
history stored explicitly            history stored as a discounted sum
weight of step k = 1 forever         weight of step k = (1-delta)^age
resource use grows with t            resource use constant in t
terminates by exhaustion             terminates by convergence
no fixed point                       unique fixed point (delta > 0)
"we keep going in circles"           "we are converging on a practice"
```

The circuit is the diagram this framework returns to:

The loop from Q back into the summing junction through the gain (1-delta)

```
IS the recursion. delta is the loss in that path. If delta = 0 the loop
gain is exactly 1 and the integrator never settles.
```

A control engineer reading that diagram will report loop gain 1, marginally stable, pole on the unit circle. That is precisely correct, and it is the same statement as *no contraction, no fixed point* [Åström and Murray, 2008]. The organisational complaint that a group is going round in circles and the control-theoretic complaint that the pole is on the unit circle are the same complaint. The fix in control engineering is not to break the loop but to move the pole inside the unit circle — that is, to introduce loss. The framework's whole project is the organisational version of that move, and the observation that social systems are feedback systems in the engineer's sense rather than in the metaphorical one goes back to the first generation of cybernetics [Wiener, 1948].

7.4.8 4.8 The horizon of arrival

Corollary 3.2 says growth continues exactly while `eta S_t > delta Q_t + C_t`. With the drive held constant this is a threshold in `Q`:

```
grow while  Q_t < (eta S − C)/delta = Q_inf
```

so the fixed point is not only where the system ends up but the boundary between the growing and shrinking regimes. Below it the system grows, above it the system shrinks, and the second case is not hypothetical: it is what happens to an organisation whose drive falls — a key person leaves, `S` drops — while its stock stays high. Worked with `delta = 0.10`, `C = 0.20`, `eta S = 0.8243`:

`Q_t`	`delta Q_t + C_t`	vs `eta S_t = 0.8243`	verdict
0.0000	0.2000	less	grow
2.0000	0.4000	less	grow
4.0000	0.6000	less	grow
6.0000	0.8000	less	grow
6.2433	0.8243	equal	**hold — this is `Q_inf`**
7.0000	0.9000	greater	shrink
10.0000	1.2000	greater	shrink

Two structural points follow. First, **the maintenance term `delta Q_t` grows with success.** At `Q = 0` the system spends 0.20 per period on upkeep; at `Q = 6.24` it spends 0.824. Same organisation, same `delta`, four times the upkeep, purely because there is more to keep. Second, the headroom gauge along the same trajectory, with `eta ln N = 0.5 * 2.0794 = 1.0397`:

`Q_t`	0	2	4	6	6.2433	8	10
`h_t`	0.8397	0.6397	0.4397	0.2397	0.2154	0.0397	**-0.1603**

`h` reaches zero at `Q = 8.397`. Beyond that point Corollary 3.4 applies in its hard form: no arrangement of people, no meeting design, no facilitation technique and no interaction geometry whatsoever prevents this system's stored order from decreasing. That is not a motivation problem; it is an inequality. The same shape appears in Curzi [2026], where a 15 per cent annual hard-currency drag with a 25.17 per cent local-currency allocation drives the headroom coefficient to exactly −0.500000 and cancels the entire `eta ln(N) = 0.377583` diversification gain — a cost term consuming a logarithmic gain, in a different domain and with the same arithmetic.

7.4.9 4.9 Scale-freedom, badged

The storage law is applied across this corpus at every scale — a desk, a room, a team, a building, an institution, a city — with only `(delta, eta, N, C)` changing between them. **This is a modelling postulate about form, not a claim about physics.** It asserts that the same difference equation is a useful description at each scale. It does not assert that a city is a large room, and it does not assert any conservation law, thermodynamic principle, or mechanism connecting the scales.

The claim earns its place by being falsifiable at each scale independently. The protocol is given in Curzi [2026i]: fit `Y_{t+1} = a Y_t + b F(U_t) − C_hat_t + eps_t` on training data with `0 <= a <= 1` and `b >= 0`, freeze the model, and report held-out performance against four baselines. If the fitted `a` is not in `[0,1]`, or the model does not beat a matched autoregression and a shuffled-input control, the form is wrong *at that scale* and the report says so. What the symmetry buys, where it holds, is transfer of method rather than transfer of numbers: the `delta` of a whiteboard and the `delta` of a constitution differ by orders of magnitude, and only the procedure for measuring both is identical. Curzi [2026v] exhibits the same style of claim in a domain where exhaustive verification was possible — the decomposition of the star figure {N/k} into `gcd(N,k)` closed strokes, unicursal exactly when `gcd(N,k) = 1`, verified by exhaustive trace over 779 cases with zero mismatches — which is the standard a form claim should be held to wherever the domain is finite enough to permit it.

7.5 5 The circuit identity and its consequences

The claim of this section is stronger than an analogy. In discrete time the storage law is not *like* a first-order low-pass filter; it *is* one, term for term, with the same pole, the same time constant, the same step response, the same settling time and the same DC gain. Every result in the standard theory of first-order discrete systems is therefore available without modification, and none of it has to be rediscovered in organisational language [Oppenheim et al., 1996, Åström and Murray, 2008]. **The status of this identity should be fixed before it is used: it is a shared mathematical form, not a derivation from physical premises.** The same difference equation governs a charge accumulator with a leak and a stock of order with a decay rate; nothing about capacitance, current or energy is claimed to hold of an institution, and no physical result's authority transfers. What transfers is the mathematics, and the mathematics transfers completely. That matters practically, because the standard theory answers questions organisations ask constantly and answer badly: when an initiative should be reviewed (settling time); whether a single large event will work (impulse response against the input ceiling); whether a large push beats a steady cadence (frequency response plus a saturation bound); why a change took a year to appear (the pole); and why a two-year-old programme is still climbing (`t_95` at the measured `delta`).

7.5.1 5.1 The identity

Set `x_t := eta S_t − C_t` for the net drive. Then

```
Q_{t+1} = a Q_t + x_t,      a := 1 − delta
```

which is the canonical first-order discrete-time system. Its transfer function, taking the `z` transform with `Q_0 = 0`, is

```
H(z) = Q(z) / X(z) = 1 / (z − a) = z^{−1} / (1 − a z^{−1})
```

with a single pole at `z = a = 1 − delta`. The system is bounded-input bounded-output stable if and only if `|a| < 1`, that is if and only if `0 < delta < 2`. Since `delta` lies in `[0,1]` by con-

struction, the binding case is `delta > 0`. This is an algebraic identity and not a modelling assumption; the badge belongs one level up, on the decision to describe a room, a team or an institution by this difference equation at all.

storage law	circuit	control theory
`Q_t`	charge on the capacitor, `q = C_cap V`	state
`delta`	leakage conductance across the capacitor	`1` – pole
`1 − delta`	retention per period	pole location `a`
`eta S_t`	current in from the source	driven input
`C_t`	current drawn by the load	disturbance
`eta`	source transconductance	input gain
`eta / delta`	DC gain of the RC section	DC gain `H(1)`
`Q_inf`	steady-state charge	DC steady state
`(1−delta)^t Q_0`	initial charge bleeding off	transient / natural response
`1 / delta` (periods)	`tau = R C_cap` (seconds)	time constant
`S_t <= ln N`	source compliance limit	input saturation
`C_t <= (1−delta)Q_t + eta S_t`	capacitor cannot supply more than it holds	admissibility

7.5.2 5.2 The continuous section, and where `delta` comes from

The continuous first-order low-pass is

```
tau dV/dt = V_in(t) − V(t),      tau = R C_cap
```

Euler-discretising with step `dt`:

```
V(t+dt) = V(t) + (dt/tau) (V_in − V(t)) = (1 − dt/tau) V(t) + (dt/tau) V_in
```

Matching coefficients against `Q_{t+1} = (1−delta)Q_t + ...` gives

```
delta = dt / tau      i.e.      tau = dt / delta = 1/delta   periods
```

`delta` is therefore not a property of the system alone. It is the ratio of the observation period to the system's own time constant. A `delta` of 0.05 measured weekly and a `delta` of 0.19 measured monthly can be the same system, since `1 − (1−0.05)^4 = 0.1855`. Section 5.7 gives the conversion rules and the errors that follow from ignoring them.

7.5.3 5.3 DC gain and the steady state

Evaluating the transfer function at `z = 1`, that is at zero frequency, gives

```
H(1) = 1/(1 − a) = 1/delta
```

so a constant net drive `x` produces steady state `Q_inf = x/delta`. Substituting `x = eta F(u*) − c*` recovers Theorem 3.5 exactly:

```
Q_inf = (eta F(u*) − c*) / delta
```

Theorem 3.5 is the DC gain of the circuit. With surplus in nats and cost in the same units per period, the DC gain from surplus to stored order is `eta/delta`: each sustained unit of surplus per period buys `eta/delta` units of permanent stock. Two consequences are constantly conflated and are worth separating. `eta` sets how much of each period's interaction becomes structure; `eta/delta` sets how much stock a *sustained* rate of interaction supports. A system with `eta = 0.4` and `delta = 0.08` has a DC gain of 5.0. Halving `delta` to 0.04 doubles the DC gain to 10.0 without touching `eta` at all. Retention is a gain term, and organisations almost never treat it as one.

A note on deliberately raising `C`. The DC gain makes cost look like a term no one would willingly increase, and the popular instruction to leave one's comfort zone looks from here like straightforward self-harm. That reading is too coarse, and the measured answer splits in two. A cost rise applied *globally* is strictly harmful and monotonically so: it lowers `eta F(u*) − c*`, lowers `Q_inf`, and lengthens every departure; in the worked case elsewhere in this corpus an operator's wait to fund a departure rises from 32.0 weeks at baseline to 42.5, then 89.2, then never, because above a critical operating cost `C_crit = eta M − lambda E_b` the departure is unreachable at any level of desire and unlimited time. A cost rise *confined to the origin* genuinely shortens the wait, because the barrier is measured as excess cost over the starting configuration, so raising the origin lowers the budget and the barrier together — 32.0 weeks down to 9.9, bought at a permanent fund 37 per cent smaller. The question is therefore narrower than a denunciation: whether it is a cost that can be left behind or a cost that is carried. Local discomfort at the origin works; global discomfort — attention, sleep, health, regulatory load — follows the operator out of the basin and destroys the platform. The empirical literature on adaptation supports the mechanism from the other side: hedonic adaptation returns a subject toward a baseline after both fortune and misfortune [Helson, 1948, Brickman et al., 1978], though the strong form of the treadmill has been revised and the revision restores room for a raised set point [Diener et al., 2006].

7.5.4 5.4 The pole, the time constant, and the settling table

The pole `a = 1 − delta` is the multiplier applied to the whole stored state each period. Three regimes, all of which occur in real organisations:

```
|a| < 1   (delta > 0)      STABLE. Contraction. Unique fixed point.
                           Transients decay as a^t. Errors forgotten.
                           --> Section 4: this is why iteration arrives.

 a  = 1   (delta = 0)      MARGINALLY STABLE. Pure integrator.
                           No fixed point. Any constant input ramps forever.
                           Initial condition never decays.
                           --> "we go round in circles"; the unbounded ledger.

|a| > 1   (delta < 0)      UNSTABLE. Not admissible here: delta lies in [0,1].
                           Would correspond to stored order that amplifies itself
                           without input. The law does not permit it.
```

The third case is worth a sentence even though the law excludes it, because organisations *describe* themselves as being in it — the culture reinforces itself, it snowballs. Under the storage law that behaviour is not `a > 1`; it is a high `eta` combined with an `S` that rises with `Q`, which is a nonlinearity in the drive rather than instability in the pole. If a system genuinely shows self-amplification, the linear model is the wrong model, and the fitting procedure of Curzi [2026i] will report `a > 1` — a signal to stop and re-specify rather than to celebrate.

Two definitions of the time constant are in circulation and differ by a few per cent at ordinary `delta`:

```
tau_approx = 1 / delta                (the engineering rule of thumb)
```

```
tau_exact  = −1 / ln(1 − delta)       (the true e-folding time of a^t)
```

`tau_exact` is the number of periods for the transient `a^t` to fall to `1/e`; `tau_approx` is its first-order approximation and is the number in general use. They agree to better than 1 per cent for `delta <= 0.02` and to about 5 per cent at `delta = 0.10`. Below `delta = 0.30` either is adequate for design work; above it the exact form is required, and above `delta = 0.5` time constants should be abandoned and settling times read directly. Half-life follows immediately:

```
t_half = ln 2 / (−ln(1 − delta)) = 0.6931 * tau_exact
```

All figures below are computed from `t_p = ln(1−p) / ln(1−delta)`.

delta	pole `1−delta`	tau = 1/delta	tau_exact	half-life	t_63	t_95	t_99	3 tau	5 tau
0.001	0.999	1000.00	999.50	692.80	999.17	2994.23	4602.87	3000.0	5000.0
0.005	0.995	200.00	199.50	138.28	199.43	597.65	918.73	600.0	1000.0
0.01	0.990	100.00	99.50	68.97	99.47	298.07	458.21	300.0	500.0
0.02	0.980	50.00	49.50	34.31	49.48	148.28	227.95	150.0	250.0
0.05	0.950	20.00	19.50	13.51	19.49	58.40	89.78	60.0	100.0
0.08	0.920	12.50	11.99	8.31	11.99	35.93	55.23	37.5	62.5
0.10	0.900	10.00	9.49	6.58	9.49	28.43	43.71	30.0	50.0
0.15	0.850	6.67	6.15	4.27	6.15	18.43	28.34	20.0	33.3
0.20	0.800	5.00	4.48	3.11	4.48	13.43	20.64	15.0	25.0
0.30	0.700	3.33	2.80	1.94	2.80	8.40	12.91	10.0	16.7
0.40	0.600	2.50	1.96	1.36	1.96	5.86	9.02	7.5	12.5
0.50	0.500	2.00	1.44	1.00	1.44	4.32	6.64	6.0	10.0
0.60	0.400	1.67	1.09	0.76	1.09	3.27	5.03	5.0	8.3
0.70	0.300	1.43	0.83	0.58	0.83	2.49	3.82	4.3	7.1
0.80	0.200	1.25	0.62	0.43	0.62	1.86	2.86	3.8	6.3
0.90	0.100	1.11	0.43	0.30	0.43	1.30	2.00	3.3	5.6

The rule of thumb of `3 tau` to 95 per cent and `5 tau` to 99 per cent is conservative in discrete time, which is the safe direction. Checking it exactly, the fraction of the step reached at `k tau` with `tau = 1/delta` is:

delta	at `1 tau`	at `2 tau`	at `3 tau`	at `4 tau`	at `5 tau`
0.02	0.6358	0.8674	0.9517	0.9824	0.9936
0.05	0.6415	0.8715	0.9539	0.9835	0.9941
0.10	0.6513	0.8784	0.9576	0.9852	0.9948
0.20	0.6723	0.8926	0.9648	0.9885	0.9962
continuous `1 − e^{−k}`	0.6321	0.8647	0.9502	0.9817	0.9933

So `3 tau` delivers 95.2 to 96.5 per cent and `5 tau` delivers 99.4 to 99.6 per cent, always slightly ahead of the continuous-time reference. Use `3 tau` for *substantially arrived* and `5 tau` for *settled*.

Design rule R2.1: no initiative is evaluated before `3 tau` periods have elapsed. Evaluating a first-order system at `1 tau` and finding it 65 per cent of the way there is not a finding about the initiative; it is a finding about the reviewer's calendar.

7.5.5 5.5 Step response

A step is a permanent change in the drive: a policy that starts and stays, a new standing meeting, a hire, a rule. Formally `x_t = x` for all `t >= 0` and `x_t = 0` before.

```
Q_t = Q_inf (1 − a^t) + Q_0 a^t,     Q_inf = x/delta
```

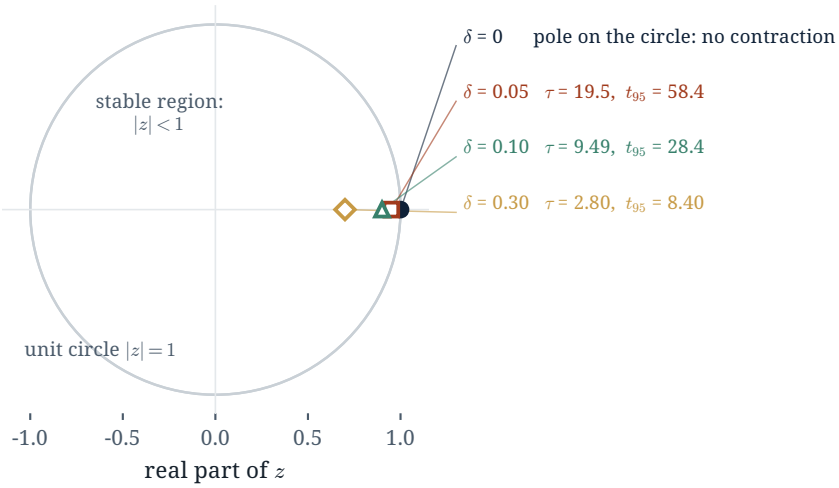


Figure 7.4: The single pole sits at `z = 1 - delta` on the real axis: strictly inside the unit circle for every `delta > 0`, and *on* it at `delta = 0`, where the map is an isometry and no contraction exists. Distance from the circle sets the calendar — `delta = 0.05` gives `tau_exact = 19.5` and `t_95 = 58.4` periods, `delta = 0.30` gives 2.80 and 8.40. Schematic drawn from the master table of Section 5.4; generated by `figs/src/CCP-007_fig04.py`.

Two exponentials with the same rate: the old state bleeding out and the new state filling in. There is no overshoot, no oscillation and no ringing. A first-order system with a real pole in `(0,1)` approaches its new steady state monotonically from whichever side it starts on. Worked at `delta = 0.08` and `x = 0.3511` per week, so `Q_inf = 4.3888`:

week	`Q_t`	% of `Q_inf`
0	0.0000	0.00%
1	0.3511	8.00%
2	0.6741	15.36%
4	1.2447	28.36%
6	1.7276	39.36%
8	2.1364	48.68%
12	2.7752	63.23%
18	3.4104	77.71%
24	3.7955	86.48%
26	3.8867	88.56%
36	4.1707	95.03%
48	4.3086	98.17%
52	4.3314	98.69%
60	4.3593	99.33%

At the six-month review, week 26, the system is at 88.6 per cent of where it is going; at the annual review, week 52, it is at 98.7 per cent. The visible slowdown between month six and month twelve is not the initiative losing momentum; it is `a^t` doing exactly what `a^t` does. An organisation that reads that curve as fatigue and responds by adding input has misdiagnosed a pole as a morale problem. That misdiagnosis is not idiosyncratic: people systematically misjudge the behaviour of stocks with delays even when the structure is explained to them and the incentives are aligned [Sterman, 1989].

7.5.6 5.6 Impulse response, the input ceiling, and the honest scope of the cadence argument

An impulse is a single period of input followed by nothing: the offsite, the launch event, the one-time grant, the visiting expert.

```
Q_t = A a^{t}   for t >= 0, from a single input A at t = 0
```

Pure decay. The whole contribution of an impulse is `A` at the moment it lands and `A a^t` thereafter, and its total contribution to the running integral over all time is `A/delta`. That last figure is what makes intensity sound competitive: an impulse and a sustained drive with the same total input have the same integrated effect over infinite time. In a linear time-invariant system this is exactly true, and honesty requires saying so plainly.

The reason intensity nevertheless loses is not the linear algebra. It is the saturation bound. The range result gives `0 <= F(u) <= ln N`, so the input in any single period is bounded by `eta S_t <= eta ln N`. A year's worth of surplus cannot be delivered in a weekend, because the per-period ceiling is a hard constraint of the law rather than a matter of stamina. Some ceilings, computed:

`eta`	`N`	`ln N`	per-period ceiling `eta ln N`
0.30	12	2.4849	0.7455
0.40	6	1.7918	0.7167
0.50	8	2.0794	1.0397
0.70	4	1.3863	0.9704

Meanwhile cost does not saturate: `C_t` accrues every period whether or not any surplus was delivered. So the honest comparison between an impulse and a cadence is not *same total, same effect*. It is that the cadence can deliver `T` periods of ceiling-limited input while paying `T` periods of cost, whereas the impulse delivers *one* period of ceiling-limited input while paying the same `T` periods of cost.

The concession above is stronger than it looks and is stated plainly rather than left as an aside. Summing `Q_t` over 400 periods for a 26-unit annual budget delivered three ways at `delta = 0.06` gives

```
impulse      433.3333
weekly       433.3333
four-weekly  433.3333
B/delta   =  433.3333
```

identical to every digit. Cadence delivers no more integrated stored order than intensity, and any version of the cadence argument resting on the premise that it does is simply false for a linear time-invariant system. Two things do the actual work. First, **strict concavity, which needs no ceiling at all**: for a fixed budget `T` split into `n` occasions the delivered total `D(n) = n g(T/n)` is nondecreasing in `n` whenever `g` is concave with `g(0) = 0`, and `f(u) = ln(1 + (N−1)u)` is exactly that, so splitting an input across occasions strictly dominates delivering it at once. This argument is independent of the saturation bound and survives even where the ceiling is never approached. Second, **the ceiling clips the impulse**: in a worked annual rite with `eta = 0.35`, `N = 8` and a per-week ceiling of `0.7278`, a 26-unit once-yearly burst delivers `0.7278` — 2.8 per cent of the nominal budget, with the other 97.2 per cent not delivered late but not delivered at all. A third difference the infinite integral conceals is that the impulse decays to a steady state of exactly 0 while sustained periodic forcing holds `m/delta`: the integral is equal, the level is not.

7.5.7 5.7 Choosing the period, and the conversions that go with it

The period `dt` is an operational choice, and once made everything else is expressed in it. Mixing periods is a common and expensive error. Aggregating up, retention multiplies:

```
delta_m = 1 − (1 − delta)^m
```

Disaggregating down, take the root:

```
delta_1 = 1 − (1 − delta_m)^{1/m}
```

Worked from `delta = 0.05` per week:

horizon `m` (weeks)	combined `delta_m`
1	0.0500
2	0.0975
4	0.1855
13	0.4867
26	0.7365
52	0.9306

And in reverse: an annual `delta` of 0.4596 corresponds to a monthly `delta` of 0.0500, since `1 − (1−0.4596)^{1/12} = 0.05000`.

Design rule R2.2: state the period in the same sentence as the `delta`, always. A bare `delta = 0.05` is meaningless; `delta = 0.05` per week is a specification.

Design rule R2.3: choose `dt` so that `delta` lands roughly in `[0.02, 0.30]`. Below 0.02 the signal-to-noise ratio on the decay measurement is poor because almost nothing changes per period; above 0.30 the discrete approximation to the underlying continuous process is coarse and the `tau = 1/delta` rule of thumb fails badly — at `delta = 0.5` it overstates `tau_exact` by 39 per cent. A system with an eight-month half-life is measured monthly, not daily and not annually.

7.5.8 5.8 Frequency response: why stored order is low-pass

Evaluating the transfer function on the unit circle, `z = e^{j w}`, and normalising by the DC gain:

```
|H(w)| / |H(0)| = delta / sqrt(1 − 2a cos w + a^2),     a = 1 − delta
```

An input repeating with period `P` has fundamental frequency `w = 2 pi / P`. The fraction of that input's amplitude surviving into `Q`:

input period `P`	`delta`=0.02	0.05	0.10	0.20	0.50
2	0.0101	0.0256	0.0526	0.1111	0.3333
3	0.0117	0.0296	0.0607	0.1280	0.3780
4	0.0143	0.0362	0.0743	0.1562	0.4472
6	0.0202	0.0512	0.1048	0.2182	0.5774
8	0.0264	0.0669	0.1364	0.2804	0.6786
12	0.0390	0.0986	0.1995	0.3966	0.8069
26	0.0835	0.2081	0.4006	0.6800	0.9465

input period `P`	`delta`=0.02	0.05	0.10	0.20	0.50
52	0.1650	0.3910	0.6576	0.8799	0.9857
100	0.3062	0.6325	0.8590	0.9627	0.9961

And the `-3 dB` cutoff, where the response falls to `1/sqrt(2)` of DC:

`delta`	cutoff `w_c` (rad/period)	period at cutoff
0.01	0.01005	625.2
0.02	0.02020	311.0
0.05	0.05130	122.5
0.10	0.10546	59.6
0.20	0.22408	28.0
0.30	0.36052	17.4
0.50	0.72273	8.7

For small `delta`, `w_c` is very nearly `delta` itself. Read together, the design consequence is immediate. A weekly system with `delta = 0.05` passes 2.6 per cent of a fortnightly oscillation and 63.3 per cent of a two-year one. **Stored order responds to the slow component of what a system does and ignores the fast component almost entirely.** The week-to-week variation in how a team feels is invisible to `Q`; the two-year trend is nearly fully transmitted. The correct instrument for a low-pass system is therefore a sustained mean rather than a peak. A programme delivering a variable amount each week, averaging `x`, produces almost exactly the same `Q` as one delivering a flat `x`, because the varying part is filtered out. That is a liberating result for anyone running a real organisation: consistency is required on the timescale of `tau`, not week to week.

7.5.9 5.9 Periodic forcing: cadence and ripple

Take a fixed mean input rate `m` per period delivered in bursts of `A = m P` every `P` periods. The steady-state cycle is exact:

```
Q_max = A / (1 - a^P)        immediately after a burst
Q_min = Q_max * a^P          immediately before the next
ripple = Q_max - Q_min = A
```

For `delta = 0.10` and `m = 0.20` per period:

burst interval `P`	burst size `A`	`Q_max`	`Q_min`	ripple	ripple as % of mean	mean over cycle
1	0.200	2.0000	1.8000	0.2000	10.0%	2.0000
2	0.400	2.1053	1.7053	0.4000	20.0%	2.0000
3	0.600	2.2140	1.6140	0.6000	30.0%	2.0000
4	0.800	2.3263	1.5263	0.8000	40.0%	2.0000
6	1.200	2.5610	1.3610	1.2000	60.0%	2.0000
12	2.400	3.3446	0.9446	2.4000	120.0%	2.0000

Three things must be said, and the third is the important one. **First, the mean is invariant.** Every row has mean 2.0000, equal to `m/delta`. This is the linear time-invariant result and there is no way around it: for the same total input, cadence does not change the average stored

order. **Second, the trough falls with `P`.** At weekly cadence the system never drops below 1.80; at quarterly cadence it drops to 0.94, a 48 per cent swing. If there is any threshold below which the system misbehaves — a level of shared context below which meetings stop working, a level of trust below which people stop volunteering information — the sparse cadence spends time under it while the dense cadence never approaches it. Averages do not fail systems; minima do. **Third, at realistic parameters `m` cannot be held constant while `P` rises, because `A = mP` runs into the ceiling `eta ln N`.** Taking the working example of Section 5.10, `eta = 0.4` and `N = 6` give a per-week ceiling of `eta ln 6 = 0.7167`, while a four-week burst would need `4 * eta S = 4 * 0.5011 = 2.0044`, which is 2.8 times the ceiling. The burst is clipped to 0.7167. Over a year the weekly cadence delivers `52 * 0.5011 = 26.06` units of input and the four-weekly cadence delivers `13 * 0.7167 = 9.32`, which is 35.8 per cent as much, while cost is paid all 52 weeks in both cases.

The argument, stated exactly: **a scheduled practice is a periodic forcing function on a low-pass filter, and cadence beats intensity because surplus saturates at `ln N` per period while cost does not saturate at all, so the only way to deliver a large total is to deliver it often.** The scope correction of Section 5.6 applies in full: the ceiling is half the reason, strict concavity is the other half, and neither half amounts to the claim that cadence delivers more integrated input — it does not.

Note the corollary, which is unintuitive and useful: as `P` shrinks below `tau`, the ripple vanishes and the practice becomes indistinguishable from a constant policy. At `delta = 0.10` a period-4 forcing transmits only 7.4 per cent of its oscillation. The filter has converted a discrete ceremony into a steady level. A practice frequent enough relative to `tau` stops being an event and becomes infrastructure — which is what a working practice feels like from inside, and exactly the condition under which Star and Ruhleder [1996] observe that infrastructure becomes visible only on breakdown.

7.5.10 5.10 The three input regimes, computed

Parameters: `delta = 0.08` per week, `eta = 0.40`, `N = 6`, `u* = 0.50`, `C = 0.15` per week.

```
S = F(u*) = ln(1 + 5 * 0.50) = ln 3.5 = 1.2528
eta S = 0.5011        eta ln N = 0.4 * 1.7918 = 0.7167  (the ceiling)
net weekly drive = eta S - C = 0.3511
Q_inf = 0.3511 / 0.08 = 4.3888
tau_exact = 11.99 weeks,  t_95 = 35.93 weeks,  t_99 = 55.23 weeks
```

Regime A — the impulse. A two-week intensive session run at the input ceiling of 0.7167 per week, then no further surplus input for the rest of the year. Cost continues at 0.15 per week throughout.

week	0	1	2	3	4	8	12	26	52
`Q_t`	0.0000	0.5667	1.0881	0.8510	0.6329	0.0000	0.0000	0.0000	0.0000

Peak at week 2, gone by week 8. The session is not useless — it puts 1.0881 units of order into a system that had none — but the drive stops and the cost does not, so the system runs down to the admissibility floor within six weeks. This is the arithmetic of every intensive event whose effects *wore off*. They did not wear off; they decayed at `(1-delta)^t` while `C` continued.

Regime B — the sustained step. The same input delivered every week at `eta S = 0.5011`.

week	0	1	2	3	4	8	12	26	52
`Q_t`	0.0000	0.3511	0.6741	0.9713	1.2447	2.1364	2.7752	3.8867	4.3314

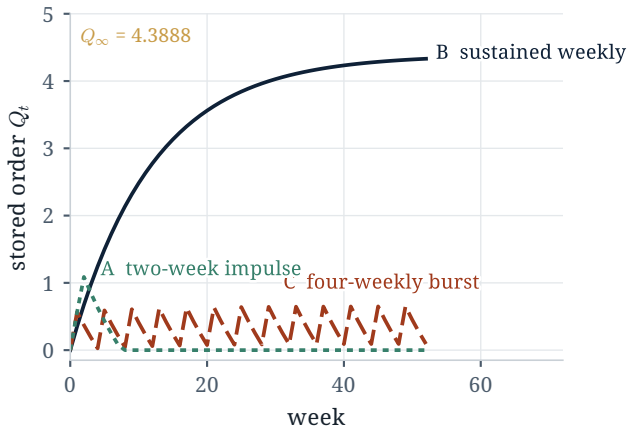

Figure 7.5: Cadence against intensity at `delta = 0.08`, `eta = 0.40`, `N = 6`, `u* = 0.50`, `C = 0.15` per week. The two-week impulse peaks highest at week 2 (1.0881) and is at the floor by week 8; the four-weekly burst is clipped by the ceiling `eta ln N = 0.7167` and oscillates about a mean of 0.365; only the sustained weekly regime arrives, reaching 4.3314 at week 52 against `Q_inf = 4.3888`. Modelled from the parameters stated in Section 5.10; generated by `figs/src/CCP-007_fig05.py`.

Regime B is *behind* Regime A at week 2, 0.674 against 1.088. At week 4 it has overtaken it. At week 52 it stands at 4.3314 against 0.0000. The regime that looked worse at the first checkpoint is the only one that arrives anywhere.

Regime C — sparse ritual. An intensive session every fourth week, sized to deliver four weeks of surplus at once — except that it cannot, because 2.0044 exceeds the ceiling 0.7167 and is clipped. Cost continues weekly.

week	0	1	2	3	4	8	12	26	52
Q_t	0.0000	0.5667	0.3714	0.1917	0.0263	0.0452	0.0587	0.4393	0.0916

In steady state this regime oscillates between 0.093 and 0.652 with a mean of 0.365 — 8.3 per cent of Regime B's steady state, from a schedule its participants would describe as meeting regularly. The monthly session is genuinely intensive and genuinely valuable; it simply cannot push more than 0.7167 through the ceiling in the week it happens, and the other three weeks pay 0.15 of cost with no input at all.

regime	input delivered over 52 weeks	`Q` at week 52	steady-state mean `Q`
A — two-week offsite	1.4334	0.0000	0
B — weekly sustained	26.0575	4.3314	4.3888
C — four-weekly burst	9.3171	0.0916	0.3647

Design rule R2.4: the cadence of a scheduled practice should be short relative to `tau`, and its per-session intensity should be sized to the ceiling `eta ln N` rather than to the ambition. Anything beyond the ceiling is discarded in the period it is delivered.

7.5.11 5.11 What a high-pass version would mean

The low-pass character is a consequence of `Q_t` appearing on the right-hand side with a positive coefficient. A high-pass version would replace the input with its first difference:

```
Q_{t+1} = (1 − delta) Q_t + eta (S_t − S_{t−1}) − C_t
```

Such a system responds only to *change* in interaction and is completely blind to a constant level. A steady, high-surplus practice sustained for years would drive it to `−C/delta`, which is negative: the system would treat a stable excellent state as no input at all. Systems that behave this way exist, and naming them is useful because they are usually built by accident.

- **Attention markets.** The stock of attention responds to the derivative of events rather than their level. A chronic condition of constant severity generates no coverage.
- **Alarm and exception handling.** By design, an alarm fires on change. This is correct for alarms and catastrophic for anything that must be maintained: a system reporting only exceptions cannot report that the ordinary thing is still working.
- **Novelty-driven incentive schemes.** Promotion for launching, none for operating. The organisation's `Q` receives credit for `S_t − S_{t−1}` and none for `S_t`, so maintenance is structurally unrewarded even where everyone agrees it matters.
- **Difference-only reporting.** A dashboard showing only period-over-period deltas is a high-pass filter installed on top of a low-pass system, and it systematically hides what the system actually accumulates.

Stored social order is low-pass, and it must be, because `Q` is a stock and a stock integrates. Trust, habit, institutional memory and furnishing all respond to the sustained level of what is done, with fast fluctuations averaged away. A system whose *measurement* is high-pass while its *dynamics* are low-pass will report noise and miss the trend. This is not a subtle statistical point; it is a mismatch of filter type between plant and instrument, and it is among the most common instrumentation faults in organisational reporting [Forrester, 1961].

Design rule R2.5: match the filter type of the instrument to the filter type of the system. Report levels for stocks and differences for flows. A dashboard with only difference columns cannot measure `Q`.

7.5.12 5.12 Cascades and delayed control

Real systems are often two integrators in series. Individual skill accumulates with `delta_1`, and team capability accumulates from the flow of trained individuals with `delta_2`:

```
A_{t+1} = (1 − delta_1) A_t + x_t
B_{t+1} = (1 − delta_2) B_t + delta_1 A_t
```

Worked with `delta_1 = 0.20`, `delta_2 = 0.08`, unit step into stage 1:

t	stage 1	stage 2
0	0.0000	0.0000
2	1.8000	0.2000
5	3.3616	1.4998
8	4.1611	3.2060
12	4.6564	5.4129
20	4.9424	8.6650
30	4.9938	10.8027
40	4.9993	11.7593
60	5.0000	12.3600
80	5.0000	12.4736

Stage 1 settles at `1/delta_1 = 5.0`; stage 2 settles at `1/delta_2 = 12.5`. Stage 2 reaches half its final value at week 14, 95 per cent at week 43 and 99 per cent at week 62, against 36 and

55 for a single stage with `delta = 0.08` driven directly. Two facts carry forward, both checked numerically. **The cascade is slower and has an S-shaped rise**, because stage 2 sees nothing until stage 1 has something to give it, so the apparent *nothing is happening* phase in the first two months is structural. **The cascade does not overshoot**: two real poles in `(0,1)` give a monotone step response, verified by simulation over 400 periods, and overshoot and ringing require complex poles, which a cascade of leaky integrators cannot produce on its own.

Overshoot comes instead from feedback with delay — a controller acting on a stale measurement. Simulating `Q_{t+1} = (1−delta)Q_t + k(target − Q_{t−L})` with `delta = 0.10`, `k = 0.30` and target 5.0:

measurement lag `L`	peak `Q`	final `Q`	overshoot
0	3.7500	3.7500	0.0%
2	4.8826	3.7500	30.2%
4	6.5784	3.7576	75.1%

At `L = 4` with a more aggressive gain `k = 0.50` the loop goes unstable outright: the simulated trajectory peaks at 39.2 and then diverges into oscillation with negative excursions, which under the storage law means the admissibility condition has been violated and the model has broken.

Design rule R2.6: the reporting lag of a management control loop must be short relative to `tau`, and the correction gain must fall as the lag rises. An organisation adjusting quarterly on the basis of annual data is running `L` of four periods with a large gain, and the resulting whipsaw is not indecision — it is a delayed feedback loop behaving exactly as delayed feedback loops behave [Åström and Murray, 2008, Sterman, 1989].

7.6 6 Loss as an object of engineering

`delta` is the parameter that makes the machine work and it is the one no organisation puts on a dashboard. Section 4 showed why it is load-bearing: `delta > 0` makes the update map a contraction, and contraction supplies a destination, a destination independent of history, and error decay. Section 5 showed what it controls: the pole, the time constant, the settling time, the DC gain and the cutoff frequency, each of which is `delta` wearing a different hat. This section takes `delta` as an object of engineering and answers four questions in order. What is it made of? How is it measured? How is it driven down? And — the question this section exists for, and the one most often skipped — when should it be driven *up*?

7.6.1 6.1 Where `delta` sits, and what the results say about it

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     delta in [0,1]
```

`delta` is the fraction of stored order lost per period **in the absence of maintenance**. That qualifier is the whole definition. `delta` is not how much is lost; it is how much would be lost if nothing were done, and the maintenance actually performed appears elsewhere in the equation — partly in `eta S_t`, where maintenance regenerates structure, and partly in `C_t`, where the effort of maintaining is paid for. **Confusing `delta` with observed net decline is the most common estimation error in this framework**, and Section 6.4 gives the procedure that avoids it.

Reading the results of Section 3.2 as statements about `delta`: Theorem 3.1 makes `delta` the discount rate on history, with the weight on an input `j` periods old equal to `(1−delta)^j`. Corollary 3.2 identifies `delta Q_t` as the **maintenance load**, proportional to how much the system holds. Theorem 3.3 puts `delta` in the denominator of the ceiling, so halving `delta` doubles the

maximum attainable stock, and at `delta = 0` the bound degrades to `Q_t <= Q_0 + t eta ln N`, linear and unbounded. Corollary 3.4 says that as `Q` grows, `delta Q` consumes the cost budget, and past `Q = (eta ln N − C_t)/delta` no choice of interaction geometry prevents stored order from decreasing. Theorem 3.5 puts `delta` in the denominator of the fixed point. And the contraction modulus is exactly `k = 1 − delta`, so `delta > 0` is necessary and sufficient for existence, uniqueness and global convergence.

The transient `(1−delta)^t` is a geometric decay, so it has a half-life:

```
t_half = ln 2 / (−ln(1 − delta))
```

This is the single most useful derived quantity in the framework for communicating with non-specialists. *Our `delta` is 0.10 per week* means nothing to a director. *Half of everything this group knows how to do that is not written down or exercised is gone in about six and a half weeks* is a sentence that gets a budget. Computed for the range that matters:

`delta` (per period)	half-life (periods)	to 10% remaining	to 1% remaining	retained after 10 periods
0.01	68.97	229.11	458.21	0.9044
0.02	34.31	113.97	227.95	0.8171
0.05	13.51	44.89	89.78	0.5987
0.10	6.58	21.85	43.71	0.3487
0.20	3.11	10.32	20.64	0.1074
0.30	1.94	6.46	12.91	0.0282
0.50	1.00	3.32	6.64	0.0010

Note the nonlinearity. Moving from `delta = 0.10` to `delta = 0.05` roughly doubles the half-life, 6.58 to 13.51, and doubles `Q_inf`; moving from 0.05 to 0.02 multiplies it by 2.54. **Each halving of `delta` doubles both the ceiling and the settling time**, and the second of those is the price nobody budgets for.

Four clauses attach specifically to `delta`. It is **period-dependent** and meaningless without a stated period. A `delta` measured on a proxy `Y` is the decay rate of the proxy, so the justification that `Y` is not a repackaging of the input `U` must precede the measurement, or what is being measured is the decay of the measuring instrument. The exponential decay form is a **modelling assumption, badged**: real loss processes can be non-exponential — a cliff at a single departure, a step at a reorganisation, a long tail from written records — and fitting an exponential to a cliff produces a number wrong in a specific and predictable direction. And every `Q_inf` computed from an estimated `delta` inherits its uncertainty *in the denominator*, so small errors in `delta` produce large errors in `Q_inf`: a 20 per cent error in `delta` produces a 25 per cent error in `Q_inf`. Ranges, not points.

7.6.2 6.2 What `delta` is made of

Loss is not one thing. In any real system it decomposes into named channels, each with its own mechanism, its own measurement, and its own available intervention. Eight recur.

(1) Procedural forgetting. An individual's memory of a procedure not executed recently. Fast for multi-step procedures with arbitrary ordering, slow for procedures with strong internal logic. This is the channel that periodic exercises address.

(2) Turnover. A departure removes whatever fraction of `Q` lived in that person and nowhere else. Section 6.6 treats it separately because it is usually the largest single channel and the easiest to compute.

(3) Documentation entropy. Written records do not decay by fading; they decay by **becoming false**. The document is intact and the world has moved. Documentation entropy is why a

written artefact does not reduce `delta` to zero, and why *executable* documentation — a test, a script, a check that fails when it is wrong — has a materially lower `delta` than prose.

(4) Environment drift. The system the stored order refers to has changed: a runbook referencing a decommissioned server, a floor plan predating the renovation, a policy naming a department that no longer exists. This channel is invisible until exercised, which is what makes it dangerous.

(5) Relationship decay. Trust and working familiarity between two people, absent interaction. This is a genuine `delta` channel and one of the few whose maintenance cost is almost pure `C`: a standing one-to-one produces very little `S`, and its purpose is not to produce `S` but to suppress `delta`.

(6) Skill atrophy. Distinct from procedural forgetting: the procedure is remembered and the execution has degraded. Motor skill, judgement calibration and fluency sit here.

(7) Physical wear. Furniture, buildings, instruments, acoustic treatment that has come loose. The most literal `delta` and the only one with an established maintenance profession attached — which is instructive, because the reason building maintenance is a discipline and institutional maintenance is not is that physical `delta` is visible.

(8) Context loss. The rule survives and its rationale does not. **This channel is worse than plain forgetting**, because it leaves behind a rule that is still enforced and can no longer be evaluated. A rule whose rationale has decayed cannot be retired, because nobody can establish that retiring it is safe, so context loss converts ordinary `Q` into permanent `C`. Ordinary loss removes structure and frees the budget it consumed; context loss removes the justification and leaves the structure drawing cost forever. **Context loss is the mechanism by which decay produces ossification rather than clearance**, and it is why deliberate shedding must be a design activity rather than a natural process. Scott [1998] and Vaughan [1996] document the institutional form from opposite directions: a rule set whose local justification has been erased, and a normalised deviance whose original risk argument nobody can reconstruct.

7.6.3 6.3 Channels compose multiplicatively

Retention multiplies; loss does not add. If `k` independent channels each retain a fraction `1 − delta_i` per period, then

```
1 − delta_total = product_i (1 − delta_i)      so      delta_total = 1 − product_i (1 − delta_i)
```

Worked, for four channels in a team:

channel	`delta_i`
turnover	0.030
procedural forgetting	0.050
documentation rot	0.020
tool churn	0.015
naive sum	**0.1150**
true combined `1 − prod(1−delta_i)`	**0.1105**

The naive sum overstates by 0.0045, about 4 per cent relative. At these magnitudes the difference is small and the sum is serviceable. It stops being serviceable quickly: four channels at 0.20 each give a naive sum of 0.80 and a true combined `delta` of 0.5904, an overstatement of 35 per cent.

Design rule R3.1: use the product form whenever any channel exceeds 0.10, and always in the design record. The sum is acceptable only as a check at small `delta`.

The corollary matters more than the arithmetic. **The channels are not fungible, and reducing the largest one has the largest effect on the product.** Halving the 0.050 forgetting channel

to 0.025 takes the combined `delta` from 0.1105 to 0.0871, a 21.2 per cent reduction; halving the 0.015 tool-churn channel takes it only to 0.1037, a 6.2 per cent reduction. Attack the biggest channel; the multiplicative structure rewards it.

7.6.4 6.4 Measuring `delta`: the zero-input window

The procedure is six steps. **First**, choose the order proxy `Y`, state what it counts, and write the justification that `Y` is not a repackaging of the input `U`; have a second person check it. **Second**, find or create a window in which `S` contributions to `Y` are near zero. Candidates: a plant shutdown; a hiring or feature freeze; a holiday period; the interval after a contributor leaves and before a replacement starts; a decommissioned tool still nominally in service; a documented practice nobody has exercised. **Third**, measure `Y` at several points in the window — two points give a number, five give a fit and a residual, and the residual is where the information about model form lives. **Fourth**, fit log-linearly: regress `ln Y_t` on `t`, so the slope is `ln(1-delta)` and `delta = 1 - exp(slope)`, and report `R^2`. **Fifth**, convert to the working period if the window was measured on a different one, using `delta_1 = 1 - (1-delta_m)^{1/m}`. **Sixth**, sanity-check against the half-life: whether `ln 2 / (-ln(1-delta))` matches what practitioners say when asked how long the capability would survive if work stopped. A factor-of-two disagreement is normal; a factor-of-ten disagreement means the proxy is wrong. The two-point estimator, for when that is all the record supports, is `delta = 1 - (Y_k / Y_0)^{1/k}`.

Five pitfalls, each with its detection. **Contaminated window** — input leaked in; detected by a plateau or upturn in the fit, or poor `R^2` with structured residuals; fixed by shortening the window or finding a cleaner one. **The proxy is the input** — `Y` is really a measure of `U` or `S`, so its apparent decay is just the activity stopping; detected because `Y` drops to near zero the moment the window opens rather than decaying; this is the most common single error in the field. **Cliff, not exponential** — the loss was one departure rather than a rate; detected by a single large step in the residuals and wildly heterogeneous per-step estimates; fixed by modelling the departure as an event and estimating `delta` from the remainder. **Censoring** — the proxy has a floor, and the last few units are the most robust; detected because the fit flattens at low `Y`; fixed by fitting only the upper range and saying so. **Reactive maintenance** — people notice `Y` falling and intervene, which is `eta S` re-entering; detected by asking; fixed by instrumenting the window so intervention is recorded.

Worked estimation. A monthly proxy over a six-month zero-input window:

month `t`	0	1	2	3	4	5	6
`Y_t`	100	92	84	79	71	66	60

Per-step naive estimates `1 - Y_t/Y_{t-1}` run 0.0800, 0.0870, 0.0595, 0.1013, 0.0704, 0.0909. The spread is 0.0595 to 0.1013, which is what single-step estimates always look like and why none should be used alone. The endpoint two-point estimator gives `1 - (60/100)^{1/6} = 0.0816`. The log-linear regression gives slope `-0.08446`, so **`delta = 0.0810`**, fitted `Y_0 = 100.16`, and **`R^2 = 0.9980`**, with half-life `ln 2 / (-ln 0.9190) = 8.21` months. The regression and the two-point estimator agree to within 0.8 per cent here, which is a good sign: the decay really is close to exponential over this range. **Where they disagree by more than about 15 per cent, neither should be believed and the residuals should be inspected**, because the disagreement means the shape is not geometric and the whole exponential model is in question for that proxy.

The general form of this move — reading a system's storage constant off its observed relaxation — has a physical precedent in the fluctuation–dissipation theorem [Callen and Welton, 1951], and an architectural one in reverberation-time measurement [Sabine, 1922]. Neither licenses the sociological application; both establish that the measurement design is a recognised one rather than an improvisation.

Where no zero-input window exists, `delta` must be estimated jointly with `eta` from the full model — the estimation procedure of Curzi [2026i]: fit `Y_{t+1} = a Y_t + b F(U_t) − C_hat_t + eps_t` with `0 <= a <= 1`, `b >= 0`, `a = 1−delta`, `b = eta`, on training data; freeze; and report held-out performance against persistence, direct-input, matched autoregressive and shuffled-input baselines. Two cautions. `a` and `b` are correlated in the fit — high retention with low conversion and low retention with high conversion describe the data almost equally well, and separating them requires variation in `U` that the data may not contain. And **a fitted `a` outside `[0,1]` is not a number to be clipped; it is a specification failure** and must be escalated as such. A single documented shutdown identifies `delta` directly and is worth more than a year of regression on confounded data.

7.6.5 6.5 Periods and conversions

`delta` is a per-period quantity and must always be reported with its period:

```
delta_m = 1 − (1−delta_1)^m          (short period to long)
delta_1 = 1 − (1−delta_m)^{1/m}      (long period to short)
```

Monthly to annual, computed:

monthly `delta`	annual retention `(1−delta)^12`	annual `delta`
0.01	0.8864	0.1136
0.02	0.7847	0.2153
0.05	0.5404	0.4596
0.10	0.2824	0.7176
0.15	0.1422	0.8578
0.20	0.0687	0.9313
0.30	0.0138	0.9862

And back the other way:

annual `delta`	implied monthly `delta`
0.05	0.0043
0.10	0.0087
0.20	0.0184
0.30	0.0293
0.50	0.0561
0.70	0.0955

A monthly `delta` of 0.05 — which sounds modest, and which a manager would describe as losing a bit of ground each month — destroys 46 per cent of unmaintained stored order in a year. That single row is the most persuasive line in most `delta` presentations, and it is arithmetic rather than rhetoric.

7.6.6 6.6 Turnover as a `delta` term

Turnover is usually the largest channel and has the cleanest formula. If a fraction `p` of members leave per period and a fraction `phi` of stored order is **person-borne** — held in individuals and nowhere else — then to first order

```
delta_turnover = p * phi
```

The two factors are independently controllable, and this is the practical point. Turnover can be reduced, which is expensive, partly outside the organisation's control, and sometimes undesirable; or the person-borne fraction can be reduced, which is cheap, entirely within the organisation's control, and beneficial for other reasons. **`phi` is the parameter, not `p`.** Computed at 20 per cent annual turnover, monthly `p = 0.0184`:

person-borne fraction `phi`	monthly `delta_turnover`	annual equivalent
0.90	0.0166	0.1818
0.75	0.0138	0.1538
0.60	0.0111	0.1249
0.40	0.0074	0.0849
0.20	0.0037	0.0433
0.05	0.0009	0.0110

Moving `phi` from 0.90 to 0.20 cuts the turnover channel by a factor of 4.5 without changing a single thing about retention or recruitment. Every mechanism that raises `eta` also lowers `phi`, because they are the same mechanisms: writing it down, building the object, training the second person, changing the default. This is the strongest instance of a general pattern — **the artefact that captures surplus is the artefact that survives the person who made it.**

Conway's observation enters here with a specific quantitative consequence. Systems mirror the communication structure of the organisation that builds them [Conway, 1968], which means a substantial part of `Q` is encoded in the communication topology rather than in any document: who talks to whom, which pairs have a working channel, where the informal escalation paths run. **A reorganisation is therefore a `delta` event, and a large one**, because it invalidates the part of stored order that lived in that topology. The reorganised system retains its documents and loses its routing. This is measurable: sample the *who would you ask about X* network for a fixed set of `X` before and after, and the fraction of queries whose answer changed or became *I don't know* is a direct estimate of the reorganisation's one-off `delta` contribution. It is almost never measured and is almost always large. The complementary result supplies the other half: adding people to a late project makes it later, because new arrivals must be brought up on stored order that is largely person-borne and the bring-up consumes the time of exactly the people who hold it [Brooks, 1975]. In the law's terms, onboarding is a `C` term proportional to `phi Q`, charged against the same budget as everything else, and the quadratic growth of communication paths is the mechanism.

7.6.7 6.7 Engineering `delta` down, and the two prices

The intervention always has the same form: **move stored order down the artefact ladder**, from media with high `delta` toward media with low `delta`.

```
THE ARTIFACT LADDER            typical delta        why
-------------------            (per month, rough)
one person's memory            0.10 - 0.30          forgetting + they may leave
two people's shared memory     0.06 - 0.20          redundancy halves the departure risk
spoken transmission / story    0.05 - 0.15          survives departure, drifts in content
written prose document         0.02 - 0.08          survives; goes silently false
diagram / checklist            0.02 - 0.06          harder to be ambiguous
executable check / test        0.005 - 0.02         FAILS when it becomes false
physical object / built form   0.001 - 0.02         must be actively removed to be lost
trained cohort (>3 people)     0.005 - 0.03         regenerates itself if cadence holds
```

```
These bands are ORDER-OF-MAGNITUDE ORIENTATION, badged as such. They are
not measurements. Each system's own zero-input window supplies its real numbers.
```

That badge is not decorative. The bands are working priors for structuring a survey, not findings. **Any number in a design record must come from that system's own zero-input window, not from this ladder.** The ladder indicates direction and rough magnitude; Section 6.4 says what is actually true in a given system.

The rungs, with what each buys. **Write it down** is the single largest step and the cheapest, converting a channel that includes departure risk into one that does not; it does not eliminate documentation entropy, so it lowers `delta` by roughly a factor of 3 to 5 rather than to zero. **Make it executable** is the largest reduction available short of building a physical object, and it is available in far more domains than assumed: automated tests, periodic restore drills, a checklist with a signature line, a form that will not submit if a field is inconsistent. **Executable documentation is the only kind that reports its own decay** — prose rots silently, and a test that rots turns red. **Build the object**: physical structure has the lowest `delta` available because losing it requires deliberate removal. **Train the second, third and fourth person**: redundancy in people is `phi` reduction, and past about three holders it becomes self-regenerating, because the cohort can rebuild a departed member's share without external input; below three holders a practice is a person with a job title. **Institute the periodic exercise**: at interval `P <= tau/2` a periodic forcing function becomes indistinguishable from a constant policy, and in `delta` terms the exercise suppresses procedural forgetting and environment drift simultaneously, because the exercise *reveals* the drift, which is the only way drift is ever revealed. **Apprenticeship**: the transfer of context rather than procedure, and the only mechanism this framework identifies that addresses channel (8), because rationale is not writable in a form anyone reads; it is expensive, slow, and has no substitute. **Design for patina**: Jacobs [1961] observed that aged buildings carry a mix of uses new construction cannot, partly because a building that ages well accumulates adaptation rather than requiring replacement, so a material that looks better worn has a lower effective `delta` than one that looks worse worn, because the replacement decision is deferred.

Both prices of a low `delta` are routinely omitted from proposals and both are computable. **Price one: `C` rises.** Every rung costs something to maintain — tests kept green, documents reviewed, drills run, second and third holders spending time holding. Since `C` enters the sustainability condition linearly and `delta` enters multiplied by `Q_t`, the trade is favourable only while the `delta Q_t` saved exceeds the `C` added. **At small `Q`, lowering `delta` is not worth its cost.** A three-month project should not build institutional memory; it should finish. **Price two: the system gets slower.** This is invisible and is the more dangerous of the two:

`delta`	half-life	`t_95`	`Q_inf` at drive 7.775
0.0810	8.21	35.5	96.0
0.0405	16.76	72.5	191.9
0.0368	18.49	79.9	211.3

Halving `delta` doubles `Q_inf` and doubles `t_95`. **The result is a system that holds twice as much and takes twice as long to change its mind about anything.** If the environment the system responds to moves faster than the new `t_95`, the design has bought stability it cannot use and lost adaptability it needed.

Design rule R3.2: state the new `t_95` in the same paragraph as the new `Q_inf`, every time a `delta` reduction is proposed.

There is a further structural bias against maintenance, and it is not cultural. Star and Ruhleder [1996] observe that infrastructure becomes visible only on breakdown, and the consequence in this model is exact. Maintenance is the activity that suppresses `delta`; its output is a non-event. A high-pass reporting instrument generates no signal from a non-event, so maintenance produces no visible result while it is working and a highly visible result the moment it stops. **The budget-allocation process is therefore systematically biased against exactly**

the activity that keeps `delta` low, and the bias requires nobody to be foolish — it follows from the filter type of the instrument. Three counters, all instrumentation rather than exhortation: report `delta` itself as a headline metric, since it is a level and is visible when things are fine; report the counterfactual maintenance load `delta Q_t`, which makes the invisible work quantitative; and run scheduled failure drills, which convert a non-event into an event on a schedule the organisation controls.

7.6.8 6.8 When `delta` should be high

This is the half of the subject that most treatments omit. `delta` is a per-component parameter, not a global constant. **Different parts of `Q` should have radically different `delta`, and setting them all low is a design failure rather than a design goal.**

What should decay fast: **stored interpersonal records**, whose persistence drives `u` toward zero within the affected pair by making the interaction predictable and defensive — high `delta` here is an engineering choice with a half-life; **obsolete procedure**, which draws `C` forever and produces nothing, and which once its rationale has decayed can be retired only by scheduled expiry rather than by argument; **any practice that made sense once**, since the whole point of a practice is that it does not require re-deciding, which is exactly what makes an obsolete one durable; **roadmaps, plans and forecasts**, which are supposed to decay, so a two-year-old roadmap still being executed is a `delta`-too-low failure; **metrics that have become targets**, because a measure that becomes a target ceases to be a measure [Goodhart, 1975, Campbell, 1979], and in this model a metric is stored order with a `delta`, so the correct response to capture is to raise the metric's `delta` — retire it and replace it — rather than to defend it, since a permanent metric is a guaranteed-corrupted metric; and **reputational classification of people**, since any stored judgement about a person's capability becomes self-confirming through assignment [Merton, 1948, Rosenthal and Jacobson, 1968], so high `delta` on such records is what makes development possible.

The load-bearing sentence of this section: a system with no forgetting cannot learn. The demonstration is one row of a table. An error injected at `t = 0` retains weight `(1-delta)^t`:

periods since the error	`delta`=0	0.01	0.05	0.10	0.20
1	1.00000	0.99000	0.95000	0.90000	0.80000
5	1.00000	0.95099	0.77378	0.59049	0.32768
10	1.00000	0.90438	0.59874	0.34868	0.10737
25	1.00000	0.77782	0.27739	0.07179	0.00378
50	1.00000	0.60501	0.07694	0.00515	0.00001
100	1.00000	0.36603	0.00592	0.00003	0.00000

Learning is the replacement of an old weighting with a new one, and replacement requires that the old weighting fall. **At `delta = 0` no weighting ever falls, so no replacement ever completes**, and what looks like learning is only accumulation: the new belief is added alongside the old one, both at full weight, and the system holds a contradiction it cannot resolve. This is not a metaphor about culture; it is the first column of the table.

Note also what high `delta` does at the other end of the ladder. A component with `delta = 0.25` has a half-life of 2.41 periods and 0.1 per cent residue after 24 periods. That is a component which can be replaced wholesale with no removal effort at all: **it is retired by declining to maintain it.** Deliberate high-`delta` design — sunset clauses, term limits, expiring authorisations, dated documents that go stale visibly — is the cheapest removal mechanism that exists, because it costs nothing to invoke.

The design output for any real system is therefore not a `delta` but a table of them, one per component, each justified:

component	target `delta` (per month)	half-life (months)	rationale
constitutional / safety-critical rules	0.002	346.2	must survive every individual; changing them must be deliberate and slow
safety procedures	0.010	69.0	durable, but must be re-derivable and periodically re-examined
core tooling and standards	0.050	13.5	durable within a technology generation; must not outlive it
team practice and convention	0.100	6.6	should be re-decided roughly twice a year by exercise
roadmap and plan	0.250	2.4	must go stale visibly; a stale plan being executed is the failure
interpersonal records / grudges	0.400	1.4	near-total clearance in six months by design

Design rule R3.3: no component gets `delta = 0`. Even the constitutional layer is 0.002, which is a 346-month half-life and an amendment process, not a stone tablet. A component at exactly zero has no fixed point, no error decay, and no mechanism of correction.

Design rule R3.4: `delta` should decrease monotonically with the component's intended lifetime, and every component must have a stated intended lifetime. A component to which nobody has assigned a lifetime will default to `delta = 0` through neglect, because retirement requires a decision and persistence requires none.

7.6.9 6.9 The trade computed: `delta` down against `eta` up

Take `eta = 0.5`, `N = 8`, `u* = 0.6` so `S = 1.6487`, `C = 0.20`, and `delta = 0.20`:

```
baseline:            Q_inf = (0.5 * 1.6487 - 0.20)/0.20 = 3.1216
halve delta to 0.10: Q_inf = (0.5 * 1.6487 - 0.20)/0.10 = 6.2433    (+100.0%)
double eta to 1.0:   Q_inf = (1.0 * 1.6487 - 0.20)/0.20 = 7.2433    (+132.0%)
```

Doubling `eta` beats halving `delta`, and beats it by 32 percentage points. The reason is structural: `eta` multiplies `S` before the cost is subtracted, so doubling it adds `eta S = 0.8243` to the numerator, whereas halving `delta` merely doubles whatever the numerator already is, including the drag of `–C`. The larger `C` is relative to `eta S`, the more the asymmetry favours `eta`. That is the general case, and it is the content of H5. Note the exception, because it is where this section earns its place: **`delta` reduction is the better lever whenever the numerator `eta F(u*) – C*` is already large and the problem is that nothing stays.** A system generating excellent surplus, converting it well, and losing it all by the next quarter has a retention fault, and no amount of additional `eta` fixes a leak. The diagnostic is simple: **if `Q` is oscillating or flat while `eta S` is comfortably above `C`, the fault is `delta`**, and a zero-input window will confirm it in one measurement.

7.7 7 Design specifications

The requirements below are numbered and checkable. They are grouped by the section that derives them. Their status is normative for any design record produced with this framework; nothing in them is an empirical claim.

7.7.1 7.1 Requirements from the contraction

S1.1 — Loss must be positive and named. Every modelled subsystem shall have `delta > 0`, and the mechanism of loss shall be identified by name (turnover, forgetting, wear, drift, deprecation). A subsystem for which no loss mechanism can be named has not been modelled; it has been assumed.

S1.2 — The fixed point shall be computed before the system is built. For the intended operating parameters, compute `Q_inf = (eta F(u*) − c*)/delta` and record it in the design record. If `eta F(u*) < c*`, the design is rejected at this line and no further work proceeds until a parameter changes.

S1.3 — The uniform bound shall be quoted. Record `eta ln N / delta` as the ceiling on stored order (Theorem 3.3). Any commitment that exceeds it is void.

S1.4 — Convergence time shall be stated, not assumed. Record the number of periods to reach 95% and 99% of `Q_inf` from the actual starting stock. Formulae and tables are in Section 5. A programme whose sponsor's patience is shorter than its `t_95` is misdesigned regardless of its fixed point.

S1.5 — Admissibility shall be checked each period. Verify `C_t <= (1−delta) Q_t + eta S_t`. A violation is escalated as a model-breakdown event, not clipped silently.

S1.6 — Headroom shall be measured before any increment is promised. Compute `h_t = eta ln N − delta Q_t − C_t`. Any requested increment `r_t` shall satisfy `r_t <= h_t` (Corollary 4.2). Promises exceeding `h_t` are not ambitious; they are arithmetically unavailable.

S1.7 — The order proxy shall be justified as distinct from the input. Written justification that `Y` is not a repackaging of `U` [Curzi, 2026i] shall exist before any fitting is performed.

S1.8 — Postulates shall be badged in the sentence that states them. Any application of the storage law to a social or physical system is a modelling decision and shall be marked as such at the point of use, not in a footnote.

S1.9 — Every number shall be computed or cited. No figure appears in a design record without either the arithmetic that produced it or the source that reported it. Where a figure would require research not yet done, the record states what would need measuring instead.

S1.10 — Reversibility. Any intervention shall have a defined stop condition and a defined return path. A change that cannot be undone is a change to `delta` as well as to whatever it was aimed at, because it becomes permanent structure.

S1.11 — Declining shall remain available. No specification in this framework is satisfied by a mechanism that removes a participant's ability to opt out; this is the declination constraint, and it is a constraint on the space of admissible designs rather than a review gate.

7.7.2 7.2 Requirements from the circuit identity

S2.1 — Declare the period. Every parameter shall be stated with its period (`delta = 0.08 per week`). Conversions between periods shall use `delta_m = 1 − (1−delta)^m` and shall be shown in the design record.

S2.2 — Choose the period so that `delta` lands in `[0.02, 0.30]`. Record the justification. If the natural observation cadence forces `delta` outside this band, state the consequence for measurement precision explicitly.

S2.3 — Publish the pole, the time constant, and three settling times. For every modelled subsystem the design record shall contain `1 − delta`, `tau_exact = −1/ln(1−delta)`, `t_50`, `t_95`, and

t_99, computed from t_p = ln(1−p)/ln(1−delta).

S2.4 — Schedule reviews at or after 3 tau. No initiative shall be evaluated for effect before 3 tau periods have elapsed from the change. Interim checkpoints may verify *inputs* (S, eta, C) but shall not be used to judge Q.

S2.5 — State the DC gain. Record eta/delta, the units of stored order bought per sustained unit of surplus per period, and Q_inf = (eta F(u*) − c*)/delta. Where eta F(u*) < c*, record the negative equilibrium and stop; the regime is unsustainable or the linear model must be replaced (Theorem 3.5).

S2.6 — Size every burst to the ceiling. No scheduled session shall be planned to deliver more than eta ln N of input in one period. Planned excess shall be re-scheduled into additional periods, not compressed.

S2.7 — Specify cadence relative to tau. Ritual interval P shall satisfy P <= tau/2 unless a ripple analysis is recorded showing that Q_min = Q_max (1−delta)^P remains above the system's stated functional threshold.

S2.8 — Record the trough, not only the mean. Any cadence proposal shall report Q_min, Q_max, and ripple, computed from Q_max = A/(1−(1−delta)^P).

S2.9 — Match instrument to plant. Reporting for a stock quantity shall present levels; reporting for a flow quantity shall present rates. A difference-only dashboard is not an acceptable instrument for Q.

S2.10 — Bound the control loop. Where a management loop adjusts inputs on the basis of measured Q, record the measurement lag L in periods and the correction gain k. Require L <= tau/4, and reduce k if L cannot be reduced.

S2.11 — Model-breakdown escalation. If a fitted pole leaves [0,1], or admissibility C_t <= (1−delta)Q_t + eta S_t is violated, the event shall be escalated as a specification failure and re-modelled. It shall not be clipped, smoothed, or averaged away.

7.7.3 7.3 Requirements from the loss analysis

S3.1 — delta shall be measured, not assumed. Every design record shall contain a delta estimate obtained from a documented zero-input window or from a frozen, held-out fit [Curzi, 2026i]. Orientation bands (§3.11) are not measurements and shall not be cited as such.

S3.2 — State the period. delta is reported as delta = X per <period>, always. Conversions use delta_m = 1−(1−delta_1)^m and are shown.

S3.3 — Decompose into named channels. The estimate shall be accompanied by an enumeration of loss channels with an individual estimate for each, combined by delta_total = 1 − prod(1−delta_i). The residual between the combined channel estimate and the measured total shall be reported. A residual above 25% of the measured total means the enumeration is incomplete.

S3.4 — Report the half-life. Every delta shall be reported alongside t_half = ln 2 / (−ln(1−delta)) in the same line.

S3.5 — Justify the proxy. Written justification that the order proxy Y is not a repackaging of the input U [Curzi, 2026i] shall precede any delta estimation.

S3.6 — Report phi. The person-borne fraction of stored order shall be estimated and reported. Turnover contribution is recorded as delta_turnover = p * phi with both factors stated separately.

S3.7 — Treat reorganisation as a delta event. Any structural reorganisation shall be preceded and followed by a "who would you ask about X" network sample over a fixed question set, and the fraction of changed or lost answers recorded as a one-off delta contribution.

S3.8 — Every component has an intended lifetime and a target delta. The design record contains a delta portfolio table (§3.13). **No component is assigned delta = 0.**

S3.9 — State both prices of a delta reduction. Any proposal to lower delta shall state, in the same section: the added C per period, and the new t_95 = ln(0.05)/ln(1−delta_new).

S3.10 — Executable over prose where available. Where stored order can be expressed as a check that fails when it becomes false, it shall be, and the prose version shall be derived from the check rather than maintained in parallel.

S3.11 — Minimum three holders. No practice on which the system depends shall have fewer than three trained holders. Where fewer, the shortfall is recorded as an explicit `phi` risk with its `delta_turnover` contribution computed.

S3.12 — Maintenance shall be reported as a level. `delta` and the counterfactual maintenance load `delta Q_t` shall appear in routine reporting as levels, not as incident counts or period-over-period differences (S2.9 above; Star and Ruhleder, 1996).

S3.13 — Scheduled expiry for the high-`delta` portfolio. Components with target `delta >= 0.20` shall carry an explicit expiry date, after which continuation requires an affirmative decision. Silence retires them.

S3.14 — Escalate model breakdown. A fitted `a = 1-delta` outside `[0,1]`, or a decay window whose residuals are structured rather than random, shall be escalated as a specification failure and re-modelled. It shall not be clipped or smoothed.

7.8 8 Failure modes

Each entry gives a clinical description, the parameter damaged, the diagnostic signature, the measurement that detects it, and the fix. They are the named faults for which the three analyses above are responsible.

7.8.1 8.1 Faults of the recursion

THE UNTERMINATED REGRESS — the system reruns the same deliberation without converting any of it, and each pass restates the previous pass rather than updating a single stored position.

- *Parameter damaged:* `eta` (to zero) and effectively `delta = 0` on the deliberation record.
- *Diagnostic signature:* meeting `n+1` opens by re-establishing what meeting `n` established. Agenda items reappear with the same wording. Participants can recall the discussion but cannot point to an artifact.
- *Measurement:* count decisions recorded per hour of deliberation. Count agenda-item recurrences across consecutive meetings. Both near zero and high, respectively.
- *Fix:* force a single mutable stored state — one document, one decision log, one register — that each pass must update rather than restate. This converts the stack into an accumulator by construction. The conversion parameter is treated in Section 6.9, and the stigmergic form of the same move — putting the state in the medium — is developed in the corpus's paper on order without a centre.

THE RUMINATION LOOP — high-surplus interaction with near-zero conversion and nonzero cost; stock falls while the system feels maximally engaged.

- *Parameter damaged:* `eta`.
- *Diagnostic signature:* `S` is high (real disagreement, real analysis, real expertise in the room) and `Q` is falling. Participants report the sessions as valuable. Nothing downstream changes.
- *Measurement:* `eta = delta_Y_attributable / S_input` over several periods. Compare `eta S` against `C` directly. If `eta S < C`, Theorem 3.5 gives a negative equilibrium and the diagnosis is settled.
- *Fix:* raise `eta`, never `S`. Smallest effective moves: a written decision at the end of each session; a named owner; a changed default; a trained second person (Section 6.9).

THE SEALED VAULT — `delta` near zero with no live input; excellent preservation, zero adaptation, slow linear decline through cost alone.

- *Parameter damaged:* `S` (to zero); `delta` suppressed below useful.
- *Diagnostic signature:* the system's answer to a novel question is a citation to an old decision. Procedures whose original rationale nobody can state are still enforced. Founding errors are still load-bearing.
- *Measurement:* age distribution of the active rule set. Fraction of stored order whose rationale can be reconstructed by a current member. Rate of rule retirement (usually exactly zero).
- *Fix:* introduce input (`S > 0`) and introduce *selective* loss. Sunset clauses, review cycles, and scheduled retirement are `delta` restored deliberately on the parts that should decay. Sections 6.7 and 6.8.

THE UNBOUNDED LEDGER — `delta = 0` with continuing input; stock grows linearly and forever, with no fixed point and no error decay. Every rule ever written is still in force.

- *Parameter damaged:* `delta` (to zero), with `C` rising as a consequence.
- *Diagnostic signature:* rule count, policy count, or documentation volume rises monotonically and has never fallen. Compliance cost rises with no corresponding rise in capability. Nobody can state the current state of practice without reading everything.
- *Measurement:* plot cumulative rule count against time; look for any decrease. Measure onboarding time to competence — it grows with `Q` when `delta = 0`.
- *Fix:* institute retirement. The `delta = 0` system has no attractor; giving it one requires removing structure on purpose. Section 6.8 covers deliberate shedding.

THE FORGOTTEN COST — the model is specified with `S`, `eta`, and `delta`, and `C` is left out because nobody owns it. The design predicts growth and the system declines.

- *Parameter damaged:* `C` (unmeasured, therefore unbudgeted).
- *Diagnostic signature:* predicted `Q_inf` far exceeds observed steady state. Predicted growth, observed flatness.
- *Measurement:* tally every recurring draw on the system, including unbilled ones — coordination, context switching, commute, compliance, emotional labour. The full enumeration is the cost tally of the survey protocol [Curzi, 2026i].
- *Fix:* re-fit with `C` included and re-check `eta F(u*) > c*`. Frequently the correct action is to cut `C` rather than to add `S`, because `C` enters linearly and `S` enters through a logarithm.

THE UNBADGED POSTULATE — a modelling assumption is presented with the authority of a theorem.

- *Parameter damaged:* none directly; it damages the warrant of every number downstream.
- *Diagnostic signature:* a claim of the form "the law shows that this room will…" where the law shows nothing of the kind without an unstated mapping from room to model.
- *Measurement:* audit every quantitative claim in the design record against the framework's badge rule. Anything not traceable to a derivation is a postulate and must carry its badge.
- *Fix:* restate with the badge in the same sentence. **The mysticism is permitted; it is permitted in the open, with its badge on.**

7.8.2 8.2 Faults of timing and instrumentation

THE PREMATURE REVIEW — a first-order system is evaluated before `3 tau` and judged on the fraction of its step response that has completed.

- *Parameter damaged:* none. The system is fine; the instrument's timing is wrong.
- *Diagnostic signature:* results at review are between 50% and 80% of target and rising; the language used is "slower than hoped" and "losing momentum."
- *Measurement:* compute `t_95 = ln(0.05)/ln(1-delta)` and compare against the elapsed time. If elapsed `< 3 tau`, the review is uninformative about `Q` by construction.
- *Fix:* move the review to `3 tau`. Use interim checkpoints on inputs only. Where the sponsor's patience is genuinely shorter than `3 tau`, the honest response is to raise `delta`'s counterpart — pick a subsystem with a shorter time constant — not to promise faster arrival.

THE INTENSITY FALLACY — a large one-off input is substituted for a sustained one on the grounds that the total is the same.

- *Parameter damaged:* effectively `S` (clipped by the ceiling) while `C` is unaffected.
- *Diagnostic signature:* a peak two to four periods after the event, decay thereafter, and a post-mortem that concludes "we failed to sustain the energy."
- *Measurement:* compare planned session input against `eta ln N`. Compute delivered total across the horizon versus the sustained alternative.
- *Fix:* redistribute. Size sessions to `eta ln N` and increase their frequency until the planned total is deliverable. If the total is not deliverable at any feasible frequency, the total was never available and the plan should say so.

THE SPARSE RITUAL — a ceremony at an interval much longer than `tau`, whose troughs fall below the system's functional threshold even though its mean looks acceptable.

- *Parameter damaged:* none directly; the ripple is the fault.
- *Diagnostic signature:* the ceremony is well-attended and well-regarded, and between occurrences the system behaves as if it does not exist. Participants describe "getting back up to speed."
- *Measurement:* compute `Q_min = Q_max (1-delta)^P` and compare against the threshold below which the system is observed to malfunction. Also compute the delivered total against the ceiling.
- *Fix:* shorten `P` toward `tau/2` or below. Note that halving `P` does not require halving session length: the ceiling caps per-session delivery anyway, so two half-length sessions frequently deliver more than one full-length one.

THE HIGH-PASS INSTRUMENT — the system integrates but the reporting differentiates, so sustained level is invisible and only change is reported.

- *Parameter damaged:* none in the plant; the measurement of `Q` is systematically wrong.
- *Diagnostic signature:* reports consist entirely of week-over-week or quarter-over-quarter changes. A stable, functioning capability generates no report and therefore no resourcing. Maintenance is chronically unfunded (compare Star and Ruhleder, 1996: infrastructure becomes visible only on breakdown; Star and Ruhleder, 1996).
- *Measurement:* audit the reporting pack. Count the fraction of metrics presented as levels versus differences. Ask what report a perfectly stable, perfectly functioning subsystem would generate; if the answer is "none," the instrument is high-pass.

- *Fix:* add level reporting for every stock. The institutional version of this fault is treated at length in the corpus's papers on institutional maintenance.

THE OVERDAMPED INSTITUTION — `delta` driven so low that `tau` exceeds the tenure of everyone who could act on a measurement.

- *Parameter damaged:* `delta` (too low).
- *Diagnostic signature:* every proposed change is met with "we tried that" referring to an attempt whose evidence nobody can reconstruct. `t_95` exceeds the average tenure of the decision-makers.
- *Measurement:* compute `t_95` and compare against median tenure in the roles that would act on the result. If `t_95 > tenure`, the institution cannot learn from its own experiments.
- *Fix:* either raise `delta` on the parts of `Q` that should turn over (Section 6.8 on deliberate forgetting), or restructure the experiment onto a faster subsystem with a shorter `tau`. Do not attempt to speed up a slow pole by adding input; the pole sets the rate.

THE DELAYED CONTROLLER — corrections applied on the basis of measurements that are several periods stale, producing overshoot and, at higher gain, oscillation.

- *Parameter damaged:* the closed-loop dynamics; the open-loop parameters may be perfectly healthy.
- *Diagnostic signature:* alternating over- and under-correction on roughly a `4L`-period cycle. Hiring surges followed by freezes. Process added then stripped then re-added.
- *Measurement:* record `L` (periods between the state occurring and the decision responding to it) and `k` (fraction of the observed gap corrected per period). Compare `L` against `tau/4`.
- *Fix:* shorten the reporting lag first; reduce the gain second. At `L = 4` and `k = 0.5` the simulated loop diverges outright, so gain reduction alone is not always sufficient.

THE MISMATCHED PERIOD — parameters measured on one period and applied on another without conversion.

- *Parameter damaged:* all of them, silently.
- *Diagnostic signature:* forecasts wrong by a factor that is a power of the period ratio. A monthly-measured `delta` applied as if annual understates decay by a factor near 12 at small `delta` and far more at large `delta`.
- *Measurement:* check every parameter in the record for a stated period. Any parameter without one is suspect.
- *Fix:* restate everything on a single declared period using `delta_m = 1-(1-delta)^m`. Note that `eta` and `C` also carry periods and must be converted; only `u` and `N` are period-free.

7.8.3 8.3 Faults of retention

THE PERSON-SHAPED REPOSITORY — a substantial fraction of stored order lives in one individual and nowhere else; `phi` is near 1 for that component.

- *Parameter damaged:* `delta` via the turnover channel; `C` via onboarding.
- *Diagnostic signature:* a name appears as the answer to "who would know?" for many unrelated questions. Their absence stops work in areas unrelated to their nominal role. They cannot take leave.

- *Measurement:* sample the "who would you ask about X" network across a fixed question set and compute the concentration. Compute `delta_turnover = p * phi` for the affected component.
- *Fix:* train to three holders (S3.11), then move the content down the artifact ladder. Note that the same actions raise `eta`: the conversion mechanisms and the retention mechanisms of Section 6 are the same mechanisms.

THE ROTTING DOCUMENT — the artifact is intact, complete, well-formatted, and false. Nothing about its appearance indicates this.

- *Parameter damaged:* `delta` via documentation entropy and environment drift, both undetected.
- *Diagnostic signature:* documents are never edited and never deleted. When someone follows one, it fails at step four, and the response is to ask a person rather than to fix the document.
- *Measurement:* select documents at random and have someone who did not write them execute them. Record the failure rate and the step at which failure occurs. That rate, per period, is a direct `delta` estimate for the documentation channel.
- *Fix:* make it executable (S3.10). Where that is impossible, date it and expire it (S3.13): a document with a visible staleness marker is honest about its own `delta`.

THE REORG AMNESIA — a structural change invalidates the part of `Q` encoded in the communication topology, and nobody accounts for it because no document was lost.

- *Parameter damaged:* `delta`, in a single large step rather than a rate.
- *Diagnostic signature:* post-reorganisation, routine requests take substantially longer and get routed wrongly. Everyone's documents are intact; the mechanism is Conway's observation that a system mirrors the communication structure that built it [Conway, 1968].
- *Measurement:* the before/after network sample of S3.7. The fraction of changed or lost answers is the estimate.
- *Fix:* budget the loss in advance and pay it deliberately — publish the new routing, run the "who would you ask" survey and publish its answers as an artifact, and expect a recovery period of roughly `t_95` at the prevailing `delta`. Do not model the step as a rate; §3.7's cliff pitfall applies.

THE IMMORTAL RULE — a procedure whose rationale has decayed while the procedure has not. It cannot be retired because nobody can establish that retiring it is safe.

- *Parameter damaged:* `delta` far too low on a component that should have been high; `C` permanently elevated.
- *Diagnostic signature:* asked why the rule exists, everyone gives a different answer or cites a person who has left. The rule survives every review because removing it requires proving a negative.
- *Measurement:* for each rule in the active set, record whether any current member can state its originating condition. The fraction that cannot is the context-loss share of `Q`, and it is usually startling.
- *Fix:* sunset clauses applied retroactively — set an expiry date on the existing rule set and require affirmative renewal (S3.13). This converts "prove it is safe to remove" into "state why it should stay," which is the tractable direction.

THE PRESERVED GRUDGE — an interpersonal record maintained at near-zero `delta` in a component whose target `delta` should be the highest in the portfolio.

- *Parameter damaged:* `delta` too low; `u` driven toward 0 within the affected pair, because the interaction becomes fully predictable and defensive; `C` elevated by routing work around the pair.
- *Diagnostic signature:* two people or two groups who are never scheduled together, whose work is routed through an intermediary, and whose original incident predates most of the current membership.
- *Measurement:* count the routing detours. Compare the age of the originating incident against the half-life assigned to this component in the portfolio (Section 6.8 suggests 1.4 months).
- *Fix:* the design lever is the `delta` of the *record*, not the sentiment. Do not retain durable written accounts of interpersonal incidents past their intended lifetime. Where the record has already outlived it, a structured repair with a stated closure is a one-off high-`delta` event. **The declination constraint applies without exception: no mechanism here removes anyone's ability to decline.**

THE INVISIBLE MAINTENANCE — the activity that suppresses `delta` produces non-events, is therefore invisible to difference-based reporting, and is therefore chronically underfunded.

- *Parameter damaged:* `delta` rises as maintenance is cut; the rise is not attributed to the cut because the lag is roughly `t_half`.
- *Diagnostic signature:* maintenance budget falls with no immediate consequence, followed some months later by a cluster of failures treated as unrelated incidents [Star and Ruhleder, 1996].
- *Measurement:* report `delta` and `delta Q_t` as levels (S3.12). Correlate maintenance spend against `delta` with a lag of one half-life.
- *Fix:* instrument the non-event. Scheduled drills, executable checks, and level-based reporting all convert invisible success into visible signal.

THE CONTAMINATED DECAY WINDOW — `delta` is estimated over a window in which input was still arriving, producing an underestimate.

- *Parameter damaged:* the estimate, and therefore every quantity computed from it — `Q_inf` and the Theorem 3.3 ceiling both have `delta` in the denominator.
- *Diagnostic signature:* the fit shows a plateau or an upturn; `R^2` is poor with structured residuals; per-step estimates trend toward zero across the window.
- *Measurement:* plot `ln Y_t` against `t` and inspect residuals for structure. Compare the regression estimate against the endpoint two-point estimate; disagreement above roughly 15% indicates non-geometric shape.
- *Fix:* find a cleaner window, shorten the window to its uncontaminated prefix, or fall back to the joint fit [Curzi, 2026i] with its four required baselines.

THE ZERO-DELTA COMPONENT — a component of `Q` assigned no loss at all, deliberately or by neglect.

- *Parameter damaged:* `delta = 0` on that component: no fixed point, no error decay, unbounded linear accumulation (Theorem 3.3, second case).
- *Diagnostic signature:* the component's size has never decreased in its recorded history. Rule count, policy volume, or documentation size is monotone increasing. Onboarding time grows year over year with no corresponding growth in capability.
- *Measurement:* plot cumulative component size against time and look for any decrease. Compute the retirement rate; it is usually exactly zero.
- *Fix:* assign a target `delta` and an intended lifetime (S3.8). Institute scheduled expiry (S3.13). Accept that some structure will be lost that would have been useful — that loss is the price of the error decay and the fixed point, and Section 4.3 computes what they are worth.

7.9 9 Results: three systems worked end to end

The three cases below are **worked examples, not field studies.** Each is a constructed system with declared parameters, carried through the full procedure so that every number can be re-derived by the reader. Their function is to exercise the chain and to exhibit the places where the arithmetic refuses to cooperate — a negative equilibrium, an infeasible increment, a doubled settling time — rather than to supply evidence about any real organisation. No dataset was collected for any of them, and Section 12 records this as a limitation of the paper rather than a caveat on the cases.

7.9.1 9.1 A twelve-person research group

The system. A twelve-person applied research group inside a larger organisation. Period: one week. The question is whether a proposed change to the weekly seminar can deliver the improvement the director has promised upward.

Step 1 — `Q` and its proxy. `Q` is the group's stored methodological order: techniques that any member can execute correctly without the originator present. The proxy `Y` is the count of techniques that pass a monthly spot-check, where the check is performed by a member who did not develop the technique. This proxy is not a repackaging of the input `U`, because `U` describes the *disagreement geometry* across research categories in a given week and `Y` describes *transferable executable capability* measured a month later by a different person [Curzi, 2026i]. That justification is written into the design record before any fitting, per S1.7.

Step 2 — `N` and `u*`. The group spans eight genuinely distinct methodological categories, so `N = 8` and the per-interaction ceiling is `ln 8 = 2.0794`. Disagreement audits and error- decorrelation measurements across category pairs give a working estimate `u* = 0.60`.

```
N_eff = 1 + (N−1) u* = 1 + 7 * 0.60 = 5.20
S = F(u*) = ln(5.20) = 1.6487
```

The roster says twelve people in eight categories. The audited effective count is 5.20. The group is buying eight categories' worth of salary and receiving 5.20 categories' worth of non-redundancy. Here is the full sensitivity, which the director should see:

`u*`	`N_eff = 1 + 7u*`	`S = ln N_eff`	% of ceiling `ln 8`
0.00	1.00	0.0000	0%
0.10	1.70	0.5306	26%
0.25	2.75	1.0116	49%
0.50	4.50	1.5041	72%
0.60	**5.20**	**1.6487**	**79%**

u*	N_eff = 1 + 7u*	S = ln N_eff	% of ceiling ln 8
0.75	6.25	1.8326	88%
0.90	7.30	1.9879	96%
1.00	8.00	2.0794	100%

Note the strict concavity of `f` [Curzi, 2026] doing its work: moving `u*` from 0.00 to 0.25 buys 1.0116 nats; moving it from 0.75 to 1.00 buys 0.2468. **The first quarter of non-parallelism is worth four times the last quarter.** This is the concavity dividend: most of the available surplus is bought by the first departure from parallelism.

Step 3 — `eta`. Measured over eleven weeks as attributable change in `Y` per unit of `S` delivered: `eta = 0.50`. So `eta ln N = 0.5 * 2.0794 = 1.0397` is the absolute per-week input ceiling, and the achieved input is `eta S = 0.5 * 1.6487 = 0.8243`.

Step 4 — `delta`. A four-week shutdown gave a clean zero-input window; log-linear fit on the decay gives `delta = 0.10` per week. Half-life `ln 2 / (−ln 0.9) = 6.58` weeks. Section 6.4 gives the procedure and Section 9.3 gives a fuller version of this fit.

Step 5 — `C`. Tallied at `C = 0.20` per week: seminar preparation, the coordination overhead of scheduling across eight categories, and the write-up burden.

Step 6 — the fixed point. By Theorem 3.5,

```
Q_inf = (eta F(u*) − c*) / delta = (0.8243 − 0.20) / 0.10 = 6.2433
```

and by Theorem 3.3 the uniform ceiling is `eta ln N / delta = 1.0397 / 0.10 = 10.397`. **The group converges to 6.2433 and cannot under any interaction geometry exceed 10.397.**

Step 7 — convergence. Starting from `Q_0 = 0`:

week	Q_t	% of Q_inf
0	0.0000	0.00%
1	0.6243	10.00%
2	1.1862	19.00%
4	2.1471	34.39%
6	2.9254	46.86%
8	3.5558	56.95%
10	4.0664	65.13%
12	4.4800	71.76%
15	4.9579	79.41%
20	5.4843	87.84%
25	5.7951	92.82%
29	5.9492	95.29%
30	5.9786	95.76%

Ninety-five percent of the destination is reached in week 29; the exact figure from `t_95 = ln(0.05)/ln(0.90)` is 28.43 weeks. Ninety-nine percent takes `ln(0.01)/ln(0.90) = 43.71` weeks. **The director's promised review is at week 12, when the system will be at 71.76% of its own steady state and still climbing.** That is not underperformance. It is the step response of a first-order system evaluated before it settles, and Section 5 exists so that this mistake is not made in a design review.

Step 8 — headroom, and what may be promised. With `eta ln N = 1.0397`:

Q_t	h_t = 1.0397 − 0.10 Q_t − 0.20	regime
0.0000	0.8397	growth
2.0000	0.6397	growth
4.0000	0.4397	growth
6.2433	0.2154	growth (at Q_inf, still positive)
8.0000	0.0397	growth, nearly exhausted
8.3972	0.0000	**maintenance only**
10.0000	-0.1603	**unsustainable — no geometry saves it**

The maximum single-week increment the group can be promised at its current stock of 4.48 is r_max = 1.0397 − 0.448 − 0.20 = 0.3917 (Corollary 4.2). By Proposition 4.1, achieving an increment r_t requires S_t >= (delta Q_t + C_t + r_t)/eta, feasible only if delta Q_t + C_t + r_t <= eta ln N. At Q_t = 4.48 and r_t = 0.50, the requirement is S_t >= (0.448 + 0.20 + 0.50)/0.50 = 2.296, which exceeds ln 8 = 2.0794. **The requested increment is infeasible, and the proof is one line of arithmetic.** The correct report upward is not "we will try"; it is "0.50 per week is above r_max = 0.3917, here is the calculation, and here are the three parameters that would have to move."

Step 9 — the counterfactuals, computed.

If delta were 0. The group would grow linearly at 0.6243 per week without limit — 6.243 at week 10, 12.487 at week 20, 62.433 at week 100 — with no fixed point, no error decay, and no answer to "what will this settle at?" It would also never lose a single obsolete technique, and its spot-check burden would grow without bound, which shows up as a rising C in year three. The group's methodological register would become an archive that must be read in full before anyone can act. **The absence of loss does not produce a better group; it produces a group that cannot say what it currently does.**

If eta fell to 0.05 — the seminar continues, the arguments are as good as ever, and nobody writes anything down. Then eta S = 0.0824 < C = 0.20, Q_inf = −2.676, and the stock falls from 6.2433 to below the admissibility floor within twelve weeks. The seminar would feel *better* during this period, because S is unchanged and the discussions are as rich as they ever were.

If S fell to 0 and delta were driven to 0 — the sealed vault. Q falls linearly at C = 0.20 per week and reaches zero at week 31.2, with the group defending techniques whose justification nobody present can reconstruct.

Step 10 — the intervention, and its falsification criterion. The binding constraint is not u*, which at 0.60 already delivers 79% of the ceiling and whose remaining headroom is worth only 0.43 nats at enormous recruiting cost. It is not N, because raising N from 8 to 16 buys exactly ln 2 = 0.6931 extra ceiling for a doubling of genuinely distinct methodological categories — see the corpus's analysis of the logarithmic ceiling. The binding constraint is the pair (eta, C), and of the two, eta is cheaper to move (Section 6.9).

The intervention: every seminar closes with one written, owned, dated decision, and one named second person who can execute the technique discussed. Predicted effect: eta from 0.50 to 0.60, C unchanged. Then eta S = 0.9892, Q_inf = (0.9892 − 0.20)/0.10 = 7.892, a 26.4% increase in steady-state stored order, reached to 95% in another 28.4 weeks from the point of change.

Preregistered falsification [Curzi, 2026i]: fit Y_{t+1} = a Y_t + b F(U_t) − C_hat_t + eps_t on weeks 1-30, freeze, and predict weeks 31-60. The intervention is falsified if the fitted a does not lie in [0,1], if b does not increase, or if the frozen model fails to beat all four required baselines on held-out data — persistence, direct-input, matched autoregressive, and the shuffled-input control. **The shuffled-input control is the one most often omitted and the one most often decisive**, because it is the only baseline that tests whether the *timing* of interaction matters or merely its volume.

7.9.2 9.2 A six-category production team choosing its cadence

The system. A production team of nineteen people spanning six genuinely distinct functional categories: design, fabrication, quality, logistics, maintenance, and customer support. Period: one week. The question is whether to replace the current monthly all-hands “deep dive” with a weekly thirty-minute cross-function standup, over the objection that the monthly session is “much more substantial.”

Measured parameters.

parameter	value	how obtained
`N`	6	enumeration of functional categories
`u*`	0.50	disagreement audit and error-decorrelation across category pairs
`eta`	0.40	attributable change in the order proxy per unit surplus, over 14 weeks
`delta`	0.08 per week	log-linear fit on a 5-week zero-input window during a plant shutdown (Section 6.4)
`C`	0.15 per week	tallied coordination, scheduling, and write-up overhead

Derived quantities.

```
ln N        = ln 6                  = 1.7918     hard per-interaction ceiling
N_eff       = 1 + 5 * 0.50          = 3.50       audited effective count
S           = ln 3.50               = 1.2528     69.9% of ceiling
eta S       = 0.4 * 1.2528          = 0.5011     delivered input per week
eta ln N    = 0.4 * 1.7918          = 0.7167     per-week input CEILING
net drive   = 0.5011 - 0.15         = 0.3511     per week
Q_inf       = 0.3511 / 0.08         = 4.3888     Theorem 3.5
DC gain     = eta/delta = 0.40/0.08 = 5.0        stock per sustained unit of surplus
Thm 3.3 cap = eta ln N / delta      = 8.9588     absolute ceiling on Q
pole        = 0.92
tau_exact   = -1/ln(0.92)           = 11.99 weeks
t_half      = 0.6931 * 11.99        = 8.31 weeks
t_95        = ln(0.05)/ln(0.92)     = 35.93 weeks
t_99        = ln(0.01)/ln(0.92)     = 55.23 weeks
```

The nineteen-person roster contains six categories and buys 3.50 effective ones. The team achieves 69.9% of its theoretical per-interaction ceiling. That is a respectable `u*`: the remaining 30% costs more to buy than it returns here, and the binding constraint is elsewhere.

Step 1 — Is the monthly cadence even deliverable?

A monthly session sized to carry four weeks of surplus would need to deliver `4 * eta S = 4 * 0.5011 = 2.0044` in one week. The ceiling is `eta ln N = 0.7167`. **The monthly session is over the ceiling by a factor of 2.80.** No facilitation technique changes this: the range result caps `F(u)` at `ln N = 1.7918` and no interaction geometry exceeds it.

So the monthly session actually delivers 0.7167, and 1.288 units of intended input per month — 64.3% of it — do not exist.

Step 2 — Annual delivery, both regimes.

	sessions per year	delivered per session	annual total delivered	cost paid
weekly	52	0.5011	26.0575	52 weeks
monthly (4-weekly)	13	0.7167 (clipped)	9.3171	52 weeks

The weekly cadence delivers **2.80 times** the annual input, and the two regimes pay identical annual cost. The ratio is exactly the clipping factor, which is not a coincidence: it is `4 eta S / eta ln N = 4S/ln N`.

Step 3 — Trajectories.

week	weekly cadence	4-weekly cadence
0	0.0000	0.0000
1	0.3511	0.5667
2	0.6741	0.3714
3	0.9713	0.1917
4	1.2447	0.0263
8	2.1364	0.0452
12	2.7752	0.0587
26	3.8867	0.4393
52	4.3314	0.0916

Steady state: weekly settles at 4.3888. Four-weekly oscillates between 0.0928 and 0.6521 with a mean of 0.3647 — **8.3% of the weekly regime.**

Observe week 1. **The monthly cadence is ahead**, 0.5667 against 0.3511, because a single session at the ceiling puts more in than a single ordinary week. That is the entire empirical basis for the objection that the monthly deep dive is "more substantial," and it is correct — for one week. By week 2 the weekly regime is ahead and it never trails again.

Step 4 — Ripple analysis for the sparse regime, per S2.8.

For `P = 4`, `a = 0.92`, `A = 0.7167`:

```
a^P    = 0.92^4                       = 0.7164
Q_max  = A/(1 - a^P) = 0.7167/0.2836  = 2.5271   (if cost were zero)
Q_min  = Q_max * a^P                  = 1.8104   (if cost were zero)
```

With cost at 0.15 per week the simulated cycle is far lower — 0.0928 to 0.6521 — because the weekly cost draw consumes most of what the burst delivers before the next burst arrives. **The ripple formula is the no-cost idealisation; the real trough is set by the cost drawn between bursts, and that is the number that must be reported.**

Step 5 — Filter check, per §2.12. At `delta = 0.08`, an input oscillating with period 4 weeks is transmitted at roughly 6% of its amplitude (interpolating between the `delta = 0.05` value of 0.0362 and the `delta = 0.10` value of 0.0743). The team's stored order is essentially blind to the monthly rhythm as *rhythm*; what reaches `Q` is the mean, and the mean is what clipping has destroyed.

Step 6 — Review scheduling, per S2.4. `3 tau = 35.98` weeks. The correct evaluation point for the weekly-cadence change is **week 36**, when the system will be at 95.03% of `Q_inf`. A review at week 12 will find 63.2%, and a review at week 26 will find 88.6%. Both are on the curve. Neither is evidence of a problem. The design record states all three numbers in advance so that nobody has to argue about it later.

Step 7 — Headroom check, per Section 3.2. At the new steady state `Q_inf = 4.3888`:

```
h = eta ln N − delta Q − C = 0.7167 − 0.08 ∗ 4.3888 − 0.15 = 0.2155
```

Positive, so growth remains available, and `r_max = 0.2155` per week is the largest increment that may be promised (Corollary 4.2). Headroom reaches zero at `Q = (0.7167 − 0.15)/0.08 = 7.0838`, safely above the operating point.

At the *old* monthly cadence with `Q` near 0.36, headroom was `0.7167 − 0.08(0.36) − 0.15 = 0.5379` — apparently *higher*. This is the trap the headroom gauge names: **headroom is high in a system that has stored nothing, and that is not a sign of health.** A team with no accumulated order has enormous room to build and nothing built. Headroom is a budget, not a score.

Step 8 — Recommendation and falsification.

Adopt the weekly cadence. Retain a quarterly longer session for the genuinely serial work that cannot be decomposed into weekly increments, sized to the ceiling and understood to contribute `0.7167` in its week rather than a quarter's worth.

Predicted: `Q` rises from a mean of 0.365 to 4.389, reaching 95% of the new value at week 36.

Preregistered falsification [Curzi, 2026i]: fit `Y_{t+1} = a Y_t + b F(U_t) − C_hat_t + eps_t` on weeks 1-36 with `0 <= a <= 1` and `b >= 0`, freeze the coefficients, and report on weeks 37-72 against four baselines — persistence, direct-input, matched autoregressive, and shuffled-input control. The prediction is falsified if:

1. the fitted `a` falls outside `[0,1]` (the first-order form is wrong);
2. the fitted `b` does not exceed its pre-intervention value (the cadence change did not raise delivered input);
3. the frozen model fails to beat the **shuffled-input control** on held-out data — which would mean that the *timing* of interaction carries no information beyond its volume, and the entire cadence argument in this chapter would not apply to this system.

The shuffled-input control is the decisive test for this chapter's thesis. Every claim made here about cadence is a claim that *when* surplus arrives matters, not merely how much. If shuffling the input sequence does not degrade the fit, the low-pass structure is not present in this system and the design rules of Section 5 do not apply to it. Curzi [2026i] explains why this control is the one most often omitted, and measures the three distinct ways it fails.

7.9.3 9.3 A twenty-two-person infrastructure team re-engineering its `delta`

The system. Twenty-two engineers responsible for the operational infrastructure of a mid-sized service. Period: one month.

Step 1 — `Q` and its proxy `Y`. `Q` is operational stored order: the team's capacity to execute correct recovery, deployment, and diagnostic procedures without the original author present. The proxy `Y` is **the number of runbooks that pass a monthly spot-audit, where the audit consists of a randomly selected engineer executing the runbook end to end in a staging environment, and a pass requires completion without consulting the author.**

Proxy justification, per S3.5 and the order-proxy condition [Curzi, 2026i]. The input observable `U` is the disagreement geometry across the team's seven operational categories in a given month — measured by error-decorrelation on incident post-mortems. The order observable `Y` is transferable executable capability, measured in a different environment, by a different person, at a later time, against a fixed procedure. `Y` cannot be raised by having more discussion; it can only be raised by producing or repairing a runbook and training someone to run it. **`Y` is not a repackaging of `U`.** This paragraph is in the design record before any fitting is performed.

Step 2 — The zero-input window. A six-month platform freeze during a compliance migration. During the freeze no new runbook work was funded, and the audit continued. This is a genuine zero-input window on the runbook component of `Q`.

month	0	1	2	3	4	5	6
`Y` (runbooks passing audit)	100	92	84	79	71	66	60

Step 3 — The fit. Log-linear regression of `ln Y` on `t`:

```
slope    = −0.08446
delta    = 1 − exp(−0.08446)  = 0.0810 per month
Y_0 fit  = 100.16
R^2      = 0.9980
t_half   = ln 2 / (−ln 0.9190) = 8.21 months
```

Cross-check by endpoints: `1 − (60/100)^{1/6} = 0.0816`, agreeing with the regression to 0.8%. The per-step estimates range from 0.0595 to 0.1013 — a reminder that no single step is an estimate. Residuals are unstructured and `R^2` is 0.998, so the exponential form is supported for this proxy over this range.

In plain language for the sponsor: half of everything this team knows how to do that is not actively exercised is gone in eight months.

Step 4 — Channel decomposition, per S3.3. Monthly attrition is 1.4% (an annual rate of 15.6%), and an audit of runbook authorship and the "who would you ask" network puts the person-borne fraction at 0.55.

channel	mechanism	`delta_i`
turnover	`p * phi = 0.014 * 0.55`	0.0077
platform / tool churn	dependencies deprecate under the team	0.0200
environment drift	runbook references infrastructure that changed	0.0350
procedural forgetting	steps not executed between incidents	0.0200
naive sum		**0.0827**
combined `1 − prod(1−delta_i)`		**0.0804**
measured (regression)		**0.0810**
residual unexplained		**0.0006**

The residual is 0.0006, or 0.7% of the measured total — well inside S3.3's 25% threshold. **The enumeration is complete enough to act on**, and the largest channel is environment drift at 0.0350, 43% of the total.

Step 5 — The rest of the parameters. For completeness, since `delta` alone does not give a fixed point:

parameter	value	source
`N`	7 operational categories	enumeration
`u*`	0.45	error-decorrelation across post-mortems
`eta`	9.0 runbooks per nat per month	attributable `delta_Y` per unit `S` over 14 months
`C`	4.0 runbooks per month	deprecations, audit failures, forced rewrites

```
N_eff    = 1 + 6 * 0.45      = 3.70
S        = ln 3.70           = 1.3083 nats      (67.2% of ln 7 = 1.9459)
eta S    = 9.0 * 1.3083      = 11.7750 runbooks/month
eta ln N = 9.0 * 1.9459      = 17.5132 runbooks/month   (the per-month ceiling)
```

Step 6 — Model consistency check. Theorem 3.5 predicts

```
Y_inf = (eta S - C)/delta = (11.7750 - 4.0)/0.0810 = 96.00 runbooks
```

The observed pre-freeze steady state was 100. **The model predicts 96.00 against an observed 100 — a 4.0% discrepancy, which is well within the uncertainty of the parameter estimates and is reported as a consistency check, not as a validation.** Validation requires the frozen held-out procedure of the preregistered protocol [Curzi, 2026i], which is Step 10.

Step 7 — The intervention. Attack the largest channel first (§3.6), and use the artifact ladder (§3.11).

channel	before	intervention	after
turnover	0.0077	pair rotation on-call; three holders per runbook (S3.11) drops `phi` from 0.55 to 0.30	0.0042
platform / tool churn	0.0200	no change proposed — outside the team's control this cycle	0.0200
environment drift	0.0350	**runbooks executed monthly in CI against staging: prose becomes an executable check that fails when it becomes false (S3.10)**	0.0050
procedural forgetting	0.0200	quarterly exercise; each engineer executes two unfamiliar runbooks live	0.0080
combined	**0.0804**		**0.0368**

```
new delta   = 0.0368 per month
new t_half  = ln 2 / (-ln 0.9632) = 18.49 months     (was 8.21)
```

Step 8 — What that buys, and what it costs, per S3.9.

```
Y_inf before = (11.7750 - 4.0)/0.0810 = 96.00 runbooks
Y_inf after  = (11.7750 - 4.0)/0.0368 = 211.28 runbooks     (+120.1%)

t_95 before  = ln(0.05)/ln(0.9190) = 35.5 months
t_95 after   = ln(0.05)/ln(0.9632) = 79.9 months            (+125.1%)
```

The team more than doubles its sustainable stock of executable capability, and more than doubles the time it takes to converge on any new steady state. Both numbers go in the proposal. The second one is the one that will not be volunteered by anyone else in the room.

Is that trade acceptable here? The relevant comparison is `t_95` against the rate at which the underlying platform changes. If the platform's own generation is shorter than 80 months, the team will be converging toward a target that has already moved, and the correct design is a lower target `Y_inf` with a faster response. In this case the platform generation is estimated at roughly 5 to 7 years, so 80 months is at the edge of acceptable and the design record says so explicitly rather than hiding it.

The added `C`: CI execution of runbooks costs compute and maintenance of the staging environment; quarterly exercises cost roughly 2 engineer-days per person per year; pair rotation costs scheduling flexibility. Estimated at 1.2 runbooks-equivalent per month of additional `C`. Re-running with `C = 5.2`:

```
Y_inf after, with added cost = (11.7750 - 5.2)/0.0368 = 178.67 runbooks   (+86.1%)
```

Still a large gain, and **the honest number is 178.67, not 211.28.** Proposals that omit the added `C` overstate the benefit by 18%.

Step 9 — Headroom, per Section 3.2. With `eta ln N = 17.5132` runbooks/month:

```
h = eta ln N - delta Y - C
```

state	`delta`	`Y`	`C`	`h`
before	0.0810	100	4.0	5.4132
after	0.0368	100	5.2	8.6332

and the stock at which headroom reaches zero, `Y = (eta ln N - C)/delta`:

```
before: (17.5132 - 4.0)/0.0810   = 166.83 runbooks
after:  (17.5132 - 5.2)/0.0368   = 334.60 runbooks
```

Before the intervention, the maintenance load `delta Y` at `Y = 100` is 8.10 runbooks per month — more than double the explicit cost `C = 4.0`. The team's largest recurring expense was invisible because it was not billed to anything. After the intervention it is 3.68. That single line is usually the one that carries the proposal, and it is the headroom thesis arriving early: the maintenance term grows with what the system holds, and it is the term nobody puts on a budget.

Step 10 — Preregistration and falsification, per Curzi [2026i].

Fit `Y_{t+1} = a Y_t + b F(U_t) - C_hat_t + eps_t` with `0 <= a <= 1` and `b >= 0` on the 14 months preceding the intervention. Freeze. Predict the 24 months following.

Predicted: fitted `a` rises from `1 - 0.0810 = 0.9190` to `1 - 0.0368 = 0.9632`; `b` unchanged; `Y` rises toward 178.67 with 95% of the movement complete at month 80.

Falsified if:

1. fitted `a` after the intervention is not significantly greater than 0.9190 — the interventions did not reduce loss;
2. fitted `a` falls outside `[0,1]` — the first-order form is wrong for this proxy and the whole model must be re-specified;
3. `b` changes materially — the interventions have confounded `delta` reduction with `eta` increase, which is likely on its face, since executable runbooks and three-holder training plausibly raise conversion too. **This is a real confound and it is stated in advance rather than discovered afterward.** The mitigation is to stage the interventions: CI execution in quarter one, three-holder training in quarter three, with a fit between them.

4. the frozen model fails to beat the **shuffled-input control** on held-out data — which would mean the timing of interaction carries no information beyond its volume, and the storage-law description of this system is not supported regardless of how well `delta` was measured.

The shuffled-input control is the one most often omitted and the one most often decisive. It is the only baseline that can distinguish a real dynamical model from a well-fitted trend.

Step 11 — The `delta` portfolio for this team, per S3.8. The intervention above concerns one component. The full record assigns a target to each:

component	target `delta`/month	half-life	intended lifetime
incident-response protocol	0.010	69.0 months	multi-generation; safety-critical
runbooks	0.037	18.5 months	one platform generation
tooling conventions	0.050	13.5 months	one platform generation
on-call rota practice	0.100	6.6 months	re-decided twice yearly by exercise
quarterly roadmap	0.250	2.4 months	must go stale visibly
post-incident personal attributions	0.400	1.4 months	cleared by design; see THE PRESERVED GRUDGE

No row is zero (R3.3), every row has a stated lifetime (R3.4), and the two high-`delta` rows carry expiry dates so that silence retires them (S3.13).

7.10 10 Discussion

7.10.1 10.1 What follows

The results above are consequences of one coefficient having a value strictly between zero and one. Restated in the order they are used downstream:

The **storage law is a contraction whenever `delta > 0`**, with modulus `k = 1 − delta` and steady state `Q* = (eta S − C)/delta`. This is the result the rest of this corpus leans on, and it is what licenses talking about a system's destination at all.

Theorem 3.5 is the DC gain of a first-order section. Evaluating `1/(z − a)` at `z = 1` gives `1/delta`, so the fixed point is the net drive multiplied by the gain. This is not a restatement; it is what makes the standard toolkit — settling time, frequency response, ripple analysis — available without further argument.

The uniform bound `Q_t <= max{Q_0, eta ln N / delta}` degrades at `delta = 0` to `Q_t <= Q_0 + t eta ln N`, which is linear, unbounded, and has no attractor. The failure is of a kind that no monitoring instrument reporting only levels will detect, because the level keeps rising.

`delta = 0` is a pathology rather than an ideal. The map ceases to contract, the fixed point disappears, and the error-persistence column is a column of ones, so no mistake ever decays out of the stock. An organisation pursuing perfect retention as a goal is pursuing the loss of its own capacity to revise.

The time-constant table gives `tau = 1/delta` against `tau_exact = −1/ln(1−delta)`, agreeing within one per cent at `delta <= 0.02` and about five per cent at `delta = 0.10`, with `3 tau` delivering 95.2 to 96.5 per cent and `5 tau` delivering 99.4 to 99.6 per cent of the step. This is the result that decides when a programme may honestly be reviewed.

The worked research group returns `N = 8`, `u* = 0.60`, `N_eff = 5.20`, and `S = 1.6487` nats — 79 per cent of the ceiling `ln 8 = 2.0794`. With `eta = 0.50`, `delta = 0.10` and `C = 0.20`, `Q_inf = 6.2433` against a hard ceiling of 10.397, and `t_95 = 28.43` weeks, so a review at week 12 finds the system at 71.76 per cent of steady state and still climbing.

The conversion failure case shows the model reporting its own domain of breakdown: with `S` at 79 per cent of ceiling but `eta = 0.05` and `C = 0.35`, `eta S = 0.0824` falls below `C` and the steady state is negative at `Q_inf = −2.676`.

Two of these deserve emphasis because they are the ones most likely to be repeated loosely elsewhere. The DC-gain identification is exact and is not an analogy. And the `delta = 0` result is not the claim that forgetting is good; it is the claim that a system with no forgetting has no fixed point, which is a different and stronger statement.

7.10.2 10.2 What does not follow

No thermodynamic claim is made. The capacitor is a mathematical correspondence and not a physical mechanism. Nothing here proves a negentropy law, and higher static surplus does not imply higher canonical concentration.

Surplus is not identified with Shannon entropy or mutual information. The `ln N` ceiling has an information-theoretic reading and the reading bounds; it does not identify.

The mapping onto any real social system is not established by anything in this paper. All three worked systems are constructed. What licenses applying the law to an actual organisation is a preregistered fit with held-out comparison against declared baselines, and the paper that specifies that protocol reports its own confirmatory application **failing** its second rule [Curzi, 2026i]: a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin. A reader who takes the present paper's arithmetic as evidence that institutions obey the storage law has read it wrongly. The arithmetic is derivation; the correspondence is a postulate awaiting corroboration that has, in the one confirmatory test so far reported, not been supplied.

Monotonicity in `u` is not established here and is contested. The framework's surplus is monotone increasing in `u`, and the empirical literature does not agree that the benefit of difference rises without turning over. Uzzi and Spiro [2005] find an inverted U, with creative success rising and then falling with cohesion; Mannix and Neale [2005] and van Knippenberg and Schippers [2007] find that surface-level diversity frequently costs in the short run; Putnam [2007] finds short-run reductions in trust and civic participation, with Abascal and Baldassarri [2015] as the rebuttal; and Sagan [1993] documents settings in which redundancy reduces safety. Against these, Granovetter [1973], Burt [2004] and Schindler et al. [2010] supply measured benefits of bridging and of effective count. The honest position is that the monotone form is this framework's construction over the regime it has examined, and that where the curve turns is an open empirical question. Harrison and Klein [2007] sharpens the demand further: three incompatible constructs travel under the word diversity — separation, variety and disparity — and a quantity like `u` owes the reader a statement of which one it is.

Diversification benefit depends on covariance, not count. Markowitz [1952] stated this in 1952 with the mathematics attached, and it is the same content as the effective-count result: `N` uncorrelated holdings and `N` perfectly correlated holdings have the same nominal `N` and different effective counts. Any reading of `ln N` as a benefit of headcount rather than of *audited* headcount is a misreading, and the concentration instrument that makes the audit computable is developed separately [Curzi, 2026].

The stability benefit of an effective count is not free of a purely statistical explanation. Doak et al. [1998] showed that diversity–stability correlations can arise from statistical averaging alone with no mechanism, and May [1972] and Gardner and Ashby [1970] showed that increasing diversity and connectance destabilises randomly assembled systems. McCann [2000] is the fair survey and Loreau and de Mazancourt [2008] names the decisive variable — synchrony — which is the ecological name for what this framework calls the coordination perimeter.

7.10.3 10.3 Relation to the surrounding literature

The storage law's nearest formal relatives are three. In **system dynamics**, `Q`, `eta S` and `C` are a level with an inflow, an outflow and a delay, formalised four decades earlier [Forrester, 1961], and the finding that people systematically misjudge such systems even under aligned incentives [Sterman, 1989] is empirical support for the central institutional claim of this paper. In **forecasting**, the recursion is simple exponential smoothing, whose optimality class is known [Brown and Meyer, 1961, Holt, 1957]; that class is a question this framework does not currently ask about its own model, and it should. In **computational neuroscience**, a leaky integrator with a threshold and a resulting firing rate is a century-old and empirically supported model [Lapicque, 1907, Gerstner and Kistler, 2002, Usher and McClelland, 2001]; that literature is the best available precedent for the *shape* of results derived from an integrator with a drive and a cost, and Curzi [2026] builds on exactly that shape, deriving a minimum sustainable frequency `f_min = k e^(2c/eta)` with `k = 0.483425732988414` Hz and the trichotomy `f > = < f_min` corresponding to `Q_inf > = < 0`. The precedent grounds the structure and not the formula, and Section 12 records the distinction.

The **requisite-variety** tradition supplies the reason `ln N` appears as a ceiling at all: only variety can absorb variety [Ashby, 1956]. The **thermodynamic** reading of the cost term has a warrant in Landauer [1961], but the warrant is about erasure in physical systems and does not transfer to an institutional cost line; it is cited here as the reason the analogy is tempting and not as its licence.

Within the corpus, the results of this paper are consumed in three ways. They are **restated as an equality** — `|Q_t − Q_inf| = (1−delta)^t |Q_0 − Q_inf|` — in the refinement analysis [Curzi, 2026] and in the fixed-point analysis of drive conservation [Curzi, 2026], whose Theorems 28.1 and 28.2 report a maximum residual of 2.0624e-15 over a hundred passes. They are **reused with different symbols** in the return-difference formulary [Curzi, 2026q]. And they are **converted into a procedure** in the consolidated reproduction workbook, whose organising rule is that `ln(1.00) = 0`, so a structure with one effective bloc has zero available surplus rather than a low one, and step one of the method is to collapse before measuring [Curzi, 2026].

7.11 11 Verification

The results of this paper compound from five postulates. Each is atomic, each is checkable on its own, and each carries its status. **If a postulate could be dropped and the result still follow, it has been dropped**; what remains is what the chain actually consumes.

7.11.1 11.1 Dimensional audit

The equation must balance before anything else about it is worth checking. The audit below states each symbol's dimension, its unit, and whether the framework fixes it or is silent. `[Q]` denotes the dimension of stored order and `[T]` the dimension of time; the period is the unit of `[T]` and every rate below is *per period*, which is why no explicit `[T^−1]` appears once the equation is written in discrete steps.

Symbol	Dimension	Unit	Status
`Q_t`	`[Q]`	proxy units (rules, protocols, runbooks, modules)	**measured**, in whatever unit the declared order proxy counts

Symbol	Dimension	Unit	Status
`U_t`	`[1]`	none	**defined** dimensionless: `u = 1 - (x.y)^2` with `x`, `y` unit vectors
`S_t = F(U_t)`	`[1]`	nats	**derived** dimensionless: a logarithm of an effective count, so a pure number reported in nats
`eta`	`[Q]` per nat, i.e. `[Q]` per step per nat	proxy units per nat per period	**measured**; *not* dimensionless in this framework
`delta`	`[1]`	per period	**measured** dimensionless fraction per step
`C_t`	`[Q]` per step	proxy units per period	**measured**
`h_t`	`[Q]` per step	proxy units per period	**derived**
`Q_inf`	`[Q]`	proxy units	**derived**: `[Q]/step` divided by `[1]/step` returns `[Q]`
`tau`, `t_half`, `t_95`	`[T]`	periods	**derived**

Does the equation balance? `Q_{t+1} = (1-delta) Q_t + eta S_t - C_t` balances if and only if every term on the right carries `[Q]`. The first term does, since `delta` is dimensionless. The third does by construction. The second does only if `eta S_t` carries `[Q]`, and since `S_t` is a dimensionless count in nats, **`eta` must carry `[Q]` per nat per step**. It is therefore not dimensionless, and the worked systems are consistent with this: Section 9.3 reports `eta` as *9.0 runbooks per nat per month*, which is `[Q]` per nat per step exactly. Section 9.1 reports `eta = 0.50` without units, which is a **silence in the source**: the research group's proxy is a technique count, so the value should read 0.50 techniques per nat per week, and it is recorded here rather than quietly corrected.

Two consequences follow and both are worth stating. First, **`eta/delta` carries `[Q]` per nat** and is the DC gain in the proper sense: units of stock per sustained nat per period. Second, **`ln N` is dimensionless, so `eta ln N` carries `[Q]` per step** and is commensurable with `delta Q_t` and with `C_t`, which is what makes the headroom gauge `h_t` a well-formed subtraction. A headroom calculation in which `C` is denominated in hours or currency while `Q` is denominated in rules is dimensionally malformed however arithmetically tidy it looks; that is the denomination requirement the survey protocol imposes [Curzi, 2026i].

Where the framework has no operational unit, it is said here. `Q` is *stored order*, and stored order has no natural unit: it is counted in whatever the declared proxy counts, and two systems' `Q` values are not comparable unless they declare the same proxy. Comfort itself, the underlying construct of the corpus, has **no operational unit at all**; it is treated as a dimensionless magnitude by stipulation, not by measurement, and Section 12 records that the quantitative structure required for that stipulation has not been tested.

7.11.2 11.2 The postulates

P1 — The recurrence is linear and first order. `Q_{t+1} = a Q_t + x_t` with `a` and `x_t` not depending on `Q`. *Status:* **DEFINITION** — this is the model form adopted by the framework, restated

from the storage law by setting `a := 1 - delta` and `x_t := eta S_t - C_t`. It carries no empirical weight on its own, and Section 12 records that its application to a real system is a postulate.

P2 — `0 < delta <= 1` implies `0 <= a < 1`. *Status:* **ARITHMETIC.** `a = 1 - delta`; subtracting a number in `(0, 1]` from 1 gives a number in `[0, 1)`.

P3 — A geometric series with ratio `|r| < 1` sums to `1/(1-r)`. *Status:* **CITED** — elementary, and stated with the convergence condition in Elaydi [2005]; the metric-space form that supplies uniqueness and start-independence as well is Banach [1922].

P4 — Surplus per period is bounded: `0 <= S_t <= ln N`. *Status:* **CITED** — the range result of the surplus functional [Curzi, 2026], following from `f(u) = ln(1+(N-1)u)` on `u` in `[0,1]`.

P5 — Cost accrues every period whether or not surplus was delivered. *Status:* **POSTULATED** — this is an assumption about how real systems charge overhead; it has no external support and is the only postulate in the chain that does not. It is used at exactly one place, R6 below, and the chain's other results do not depend on it.

7.11.3 11.3 The compounding chain

```
P1 + P2          -> L1   the update map T(Q) = aQ + x has |T(Q)-T(Q')| = a|Q-Q'|
                         with a < 1, so T is a contraction.                  ARITHMETIC

L1 + P3          -> R1   T has exactly one fixed point Q* = x/(1-a) = (eta S - C)/delta,
                         reached from any start.                             CITED (banach1922operations)

P1               -> L2   unrolling t steps gives
                         Q_t = a^t Q_0 + sum_{k=0}^{t-1} a^{t-1-k} x_k.       ARITHMETIC

L2 + P3          -> R2   with x_k = x constant, Q_t = x(1-a^t)/(1-a) + a^t Q_0,
                         so Q_t -> x/delta and the approach is geometric.     ARITHMETIC

L2 + P4          -> R3   Q_t <= max{Q_0, eta ln N / delta} for delta > 0.     ARITHMETIC

P2 at delta=0    -> R4   a = 1: L1 gives |T(Q)-T(Q')| = |Q-Q'|, so T is an isometry,
                         P3 does not apply, no fixed point exists, and
                         L2 gives Q_t = Q_0 + sum x_k, bounded only by
                         Q_0 + t eta ln N.                                   ARITHMETIC

R2               -> R5   the transient a^t falls to 1/e at
                         tau_exact = -1/ln a and to 1-p at
                         t_p = ln(1-p)/ln a.                                 ARITHMETIC

R1 + P4 + P5     -> R6   a nondecreasing step needs eta S_t > delta Q_t + C_t, and
                         since S_t <= ln N this requires C_t <= eta ln N - delta Q_t;
                         beyond that no geometry prevents decline.           ARITHMETIC
```

Every line is checkable from its own inputs. **R1, R2, R3, R4, R5 and R6 are arithmetic consequences of one definition (P1), one arithmetic fact (P2), one cited theorem (P3) and one cited range result (P4).** Only R6 consumes a postulate with no external support, and it consumes it only for the interpretation of `C` as a standing charge; the inequality itself holds however `C` is generated.

What this chain does not establish. It does not establish that any organisation obeys P1. That is the modelling postulate of Section 4.9, it is not verified here, and the one preregistered confirmatory test of it so far reported in this corpus did not meet its own declared margin [Curzi, 2026i]. A chain whose steps are ARITHMETIC and CITED delivers the mathematics with certainty and delivers nothing whatever about institutions.

7.11.4 11.4 The equilibrium, reached by summing the series

The single most useful check a reviewer can perform is to confirm that the equilibrium is what the geometric sum says it is, rather than taking Theorem 3.5 on trust. Take the worked research group of Section 9.1: `delta = 0.10`, so `a = 0.90`; `eta = 0.50`; `S = 1.6487`; `C = 0.20`; `Q_0 = 0`. The constant net drive is

```
x = eta S − C = 0.50 x 1.6487 − 0.20 = 0.82435 − 0.20 = 0.62435
```

From R2 with `Q_0 = 0`, `Q_t = x (1 − a^t)/(1 − a) = x (1 − 0.9^t)/0.10`. Summing the series term by term, each term being `x a^k`:

```
k =  0:  0.62435 x 0.9^0  = 0.624350     running total  0.624350
k =  1:  0.62435 x 0.9^1  = 0.561915     running total  1.186265
k =  2:  0.62435 x 0.9^2  = 0.505724     running total  1.691989
k =  3:  0.62435 x 0.9^3  = 0.455151     running total  2.147140
k =  4:  0.62435 x 0.9^4  = 0.409636     running total  2.556776
k =  9:  0.62435 x 0.9^9  = 0.241878     running total  4.066423
k = 19:  0.62435 x 0.9^19 = 0.084324     running total  5.484292
k = 29:  0.62435 x 0.9^29 = 0.029395     running total  5.978562
-----------------------------------------------------------------
limit :  0.62435 / (1 − 0.9)             = 6.2435
```

The running totals at `t = 1, 2, 4, 10, 20, 30` are 0.6244, 1.1863, 2.1471, 4.0664, 5.4843 and 5.9786, which are the entries of the convergence table in Section 9.1 to four decimals. The limit `0.62435/0.10 = 6.2435` is `Q_inf` to within the rounding of `S`, which the source carries as 6.2433 from the unrounded `S = 1.64866...`. **The equilibrium is not an assertion; it is the sum of a geometric series, and the sum can be checked by hand in a few lines.**

The `delta = 0` case is checked the same way and fails visibly. With `a = 1`, the terms are `x a^k = 0.62435` for every `k`, so the running total after `t` steps is `0.62435 t`: 6.2435 at `t = 10`, 12.487 at `t = 20`, 62.435 at `t = 100`. The series does not converge, `1/(1−a)` is undefined, and there is no limit to report. That is R4, and it is visible in three lines of arithmetic.

7.11.5 11.5 Two secondary checks

The time constant. At `delta = 0.10`, `tau_exact = −1/ln(0.9) = −1/(−0.105361) = 9.4912` periods against the rule of thumb `1/delta = 10`, a 5.4 per cent difference — the entry in the master table of Section 5.4. And `t_95 = ln(0.05)/ln(0.9) = (−2.995732)/(−0.105361) = 28.43` periods, which is the figure quoted for the research group's review timing. **ARITHMETIC.**

Multiplicative composition of loss. Four channels at 0.030, 0.050, 0.020, 0.015: `(1−0.030)(1−0.050)(1−0.020)(1−0.015) = 0.970 x 0.950 x 0.980 x 0.985 = 0.889508...`, so `delta_total = 0.110492`, against the naive sum 0.1150. Both figures appear in Section 6.3, and the check is one line of multiplication. **ARITHMETIC.**

7.11.6 11.6 Limits, asymptotics, and the model's valid domain

The `delta = 0` boundary is examined at length in Section 4.4. Completeness requires the rest.

`delta -> 0^+`. `tau = 1/delta -> infinity` and `Q_inf = (eta S − C)/delta -> +infinity` when the net drive is positive, `−infinity` when it is negative. The fixed point survives for every `delta > 0` and diverges only in the limit. **The limit is singular**: at exactly `delta = 0` the fixed point does not exist at all rather than being infinite, because the map is an isometry and the geometric series does not converge. The divergence and the pathology are two different statements and are often conflated.

`delta = 0` exactly. No contraction, no fixed point, error persistence 1 forever, bound linear in `t`. Section 4.4. **This value is outside the model's valid domain.**

`delta -> 1^-`. The pole `a = 1 - delta -> 0`, so `tau_exact = -1/ln(1-delta) -> 0` and the system has no memory: `Q_{t+1} -> eta S_t - C_t`, a pure input-output map with no state. The fixed point still exists and equals `eta S - C`, but the object being modelled is no longer a stock. **At `delta = 1` the storage law is not a storage law**; it is an instantaneous transducer, and any claim about accumulation is vacuous there. The measurement machinery also breaks first: at `delta > 0.30` the rule of thumb `tau = 1/delta` fails badly, overstating `tau_exact` by 39 per cent at `delta = 0.5`, and above `delta = 0.5` time constants should not be used at all.

`eta -> 0`. The drive term vanishes and `Q_{t+1} = (1-delta)Q_t - C_t`, so `Q_inf = -C/delta <= 0`: the system decays to the admissibility floor at rate `delta` while paying `C`, which is exactly the conversion pathology of Section 4.5 taken to its limit. **Zero conversion means the input is decoupled from the stock entirely**, so no interaction geometry of any quality changes the outcome — the framework's `eta = 0` clause is the same statement as the corpus's `G = 0` clause in the contact postulate, where a zero coupling coefficient makes the product `E = G B` vanish however large `B` is.

`N -> 1`. `ln N = 0` and `F(u) = ln(1 + 0 u) = 0` for every `u`. **A single category has zero available surplus, not a small amount.** The ceiling and the achievable value collapse together, so `Q_inf = -C/delta <= 0` and headroom is `-delta Q - C < 0` at any positive stock. This is the boundary that makes the bloc-collapse operation consequential: a structure with one effective bloc has `ln(1.00) = 0` available surplus [Curzi, 2026,?].

`N -> infinity`. `ln N -> infinity`, so the per-period ceiling grows without bound — but only logarithmically, and the marginal gain `ln N - ln(N-1) ~ 1/N` vanishes. Against this, coordination cost grows with the number of pairs, `n(n-1)/2` [Brooks, 1975, Conway, 1968], which is quadratic. **The two curves cross, and beyond the crossing point additional categories cost more than the ceiling they buy.** The limit is therefore not a licence to raise `N` indefinitely; it is the reason `N` is the most expensive and least rewarding of the four levers.

`u -> 0`. `N_eff -> 1`, `F -> 0`. Every category is a duplicate of every other, and the roster has left the arithmetic. **`u -> 1`.** `N_eff -> N`, `F -> ln N`, the ceiling is attained and no further gain is available from geometry. Strict concavity means the approach is front-loaded: in the worked case, moving `u*` from 0.00 to 0.25 buys 1.0116 nats and moving it from 0.75 to 1.00 buys 0.2468.

Stated domain. The storage law as used in this paper is valid for **`delta` in `(0, 0.5]`, with `(0.02, 0.30)` the band in which the standard approximations hold and the decay measurement has usable signal**; `eta > 0`; `N >= 2`; `u` in `[0,1]`; and `C_t <= (1-delta)Q_t + eta S_t` each period. Outside that domain the equation still has solutions and they should not be interpreted as statements about a stock.

7.11.7 11.7 Invariance, and how far the scale-freedom claim has been tested

The scale-freedom claim of Section 4.9 is an **invariance of form under a change of unit and a change of system size**, and it is worth stating as one. Let `Q` be rescaled by a positive constant `c`, so `Q' = cQ`. The law is invariant provided `eta` and `C` rescale with it — `eta' = c eta`, `C' = cC` — while `delta`, `N` and `u` are unchanged, since `delta` is a dimensionless fraction and `S` is a dimensionless count. **`delta`, `u` and `N` are therefore the unit-free quantities of the framework, and `Q`, `eta` and `C` are the unit-carrying ones.** Two systems can be compared on `delta`, `u` and `N` directly; they cannot be compared on `Q`, `eta` or `C` unless they share a proxy.

What would break the invariance: a `delta` that varies with `Q`, which would make the transformation non-linear; an `eta` that saturates at large `S`, which the linear model excludes by assumption; or a proxy whose counting unit is not extensive, so that doubling the system does not double the count.

How many scales it has been tested at. Within this paper: three, and all three are constructed rather than observed. Elsewhere in this corpus the same five-parameter survey has been applied from a single desk to a 22-household block, reproducing each system's observed decline — predicted −0.250474 against observed −0.250 at the desk and −0.996371 against

−1.000 at the library, with residuals under 1.4 per cent of the ceiling term [Curzi, 2026k]. **That is five systems, one corpus, one author, and no independent replication.** The invariance is a claim about form that has been exercised, not an invariance that has been established.

7.11.8 11.8 Analogy discipline, and the precision of the numbers

The circuit identity is a shared mathematical form, not a derivation from physical premises. The storage law and the RC low-pass section are governed by the same difference equation, so every theorem about first-order discrete systems applies to both. Nothing about charge, capacitance or current is claimed to hold of an institution, and no physical result's authority transfers. A leaky integrator is a leaky integrator whether it holds charge or stored order, and that is the whole of the claim. The same label applies to the leaky integrate-and-fire precedent [Lapicque, 1907, Gerstner and Kistler, 2002, Usher and McClelland, 2001] and to the reverberation analogy [Sabine, 1922]: **shared form, not derivation.**

No thermodynamic result is used as evidence. Landauer [1961] establishes a physical lower bound on the energy cost of erasure; it is cited in Section 10.3 as the reason the analogy is tempting, and it is **not** used to warrant any claim about institutional cost. The entropy invoked anywhere near `ln N` is **Shannon entropy**, a dimensionless information measure in nats, and not thermodynamic entropy, which carries `[energy][temperature]^-1`. They are different objects and the framework does not identify surplus with either.

Precision. The numbers in this paper are of three kinds and are quoted accordingly. *Defined or derived-from-defined* quantities — `ln 8 = 2.0794`, `ln(1-delta)`, `t_95`, `tau_exact`, the geometric-series limits — are exact to the precision printed and may be recomputed to any further precision. *Illustrative model output* — every entry in every trajectory table, `Q_inf = 6.2433`, `Q_inf = -2.676`, `Y_inf = 178.67` — is the output of stipulated parameters and carries **no measurement uncertainty because there was no measurement**; four decimal places there record the arithmetic, not the confidence. *Measured or fitted* quantities do not appear in this paper, because nothing in it was measured; the worked `delta = 0.0810` with `R^2 = 0.9980` in Section 6.4 is a fit to a constructed series and is illustrative in exactly the same sense. Any application of this framework to real data must report fitted parameters with intervals, and Section 12 records that the corpus's one such report gives a profile interval on the retention coefficient and no interval on several other quantities.

7.12 12 Limitations

The three worked systems are constructed, not observed. No dataset was collected for this paper. Every number in Section 9 is the output of the stated parameters under the stated model, carried through so a reader can re-derive it. They demonstrate that the procedure runs and that it reports its own failures; they are not evidence that any organisation behaves this way, and they should never be cited as such.

The correspondence between the equation and any social system is a postulate, and its one preregistered confirmatory test did not meet its declared margin. Curzi [2026i] specifies the protocol and applies it: the fit landed strictly inside the admissible box and its parameters agreed with independent measurement within 4.8 per cent on decay and 16.8 per cent on conversion, but it beat a matched AR(1) by 2.8 per cent on held-out error against a preregistered requirement of 10 per cent, so the verdict was *parameters corroborated, predictive advantage not demonstrated.* That is the current evidential status of every applied claim in this paper, and it is weaker than the mathematics.

Which parameters were chosen rather than measured. In all three worked systems, `(N, u*, eta, delta, C)` are stipulated. The artefact-ladder bands of Section 6.7 are explicitly badged as order-of-magnitude orientation and are the author's working priors for structuring a survey, not measurements; they must not be cited as findings. The `delta` portfolio table of Section 6.8 is a design proposal with stated rationales, not an empirical distribution. The mirror-reflectivity

table of Section 4.2 is the arithmetic of an illustration, and real visual thresholds depend on ambient light and on the observer.

`N_eff = 1 + (N−1)u` is not a Hill number, and no external literature contains it. This is recorded in the corpus's own coverage audit as a claim with no external support. `1/HHI` is the Hill number of order two and `exp(H)` is the Hill number of order one, and both are fully grounded [Hill, 1973, Jost, 2006]; `1 + (N−1)u` is a linear interpolation between 1 and `N` and is this framework's own construction, adopted by design axiom S3. A reviewer who reaches for the Hill-number literature as support will find that it does not apply. The two quantities are used under one effective-count heading across this corpus, which is a real exposure; the repair is to derive the properties of `1 + (N−1)u` in the framework's own terms and to reserve the Hill citations for `1/HHI` and `exp(H)`, where they are exact. Neither is a measured quantity in this paper.

`u` has not been shown to be a quantity. The framework treats non-parallelism as a measurable magnitude, and Michell [1997] argues that psychology routinely fails to test whether its attributes are quantitative at all before measuring them. The available remedies are conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971] or a Rasch-model demonstration [Rasch, 1960]; neither has been run for `u`, and until one is, the quantitative treatment of `u` in this paper is a stipulation. Relatedly, if `u` is read as a similarity measure over people it cannot be assumed to behave metrically, since psychological similarity is asymmetric and violates the triangle inequality [Tversky, 1977] — which is the empirical counterpart of the framework's own clause that the triangle inequality fails for geometric triples.

The linear model is chosen for tractability. Real institutional stocks may saturate, have thresholds, exhibit hysteresis, or have a state-dependent `eta`. Theorem 3.5 flags its own breakdown when `eta F(u*) < c*`, which is a useful property, but a linear model that reports a negative equilibrium has told the analyst only that it has left its domain, not what replaces it. A fitted retention coefficient outside `[0,1]` is likewise a specification failure and not a number to be clipped.

Constant parameters over the estimation window is an assumption that organisations violate. Turnover, reorganisation and a change of leadership all move `delta`, `eta` and `N`. A fit spanning a regime change is fitting an average of two systems, neither of which exists.

What would falsify the account. H1 fails on observed linear or unbounded accumulation under constant drive, or on a fitted `a` outside `[0,1]`. H2 fails if measured settling time scales with the size of the intervention rather than with the measured `delta`. H3 fails if a component with no observed retirement nonetheless shows mean reversion after a perturbation. H4 fails if measured total loss is reliably closer to the naive sum than to the product. H5 fails if raising `eta` produces the smaller gain in systems whose diagnostic signature is a retention fault. The scale-freedom postulate of Section 4.9 is falsifiable at each scale separately and is not falsifiable in general, which is a genuine weakness of that claim and is stated as one.

The framework's own instrument is exposed to the failure it describes. A measure that becomes a target ceases to be a measure [Goodhart, 1975, Campbell, 1979], and `Q` is a measure. Section 6.8 prescribes raising a captured metric's `delta` rather than defending it, but the prescription is a design rule and not a demonstration, and the same warning attaches to `h` — the headroom gauge is at least as gameable as anything it audits.

Nothing in this paper is a human-subjects finding. No interventions were run, no participants were recruited, and the declination constraint discussed in Sections 7 and 8 is a design constraint on future work rather than a report of past practice.

The reflection problem, and why it outranks the fitting result. Section 3.5 states it in full: applied to a group whose members both influence and constitute the aggregate, the specification is reflexive, and Manski [1993] proves the endogenous social effect is not identified from observational data. **No fit — however well designed, however honestly held out — recovers that parameter**, and Shalizi and Thomas [2011] show the same confounding for network data. This paper adopts no remedy, so the applied reading of `eta` is a **modelling position rather than an identified empirical result**. The most realistic available repair is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001]; the survey protocol's fixed cate-

gory set is a step toward it and not a substitute for it.

The Lucas critique applied to this framework's own parameters. Section 6.8 asserts that a measure changes the behaviour of the system that is measured by it, and prescribes raising a captured metric's `delta` in response. The framework then treats `delta`, `eta` and `N` as constants over an estimation window. **Both cannot be true without qualification.** The position this paper takes is the narrow one: the parameters are treated as stable *only over a declared window and only while `Q` is not itself a reported target*, which is exactly why Section 6.9's first and strongest defence is to keep the order proxy out of the reporting line. Where `Q` is reported upward, the framework's own reflexivity applies to it and the constancy assumption fails. That is a real restriction on where the model may be used and it is stated as one rather than assumed away.

The functional form is underdetermined. Section 3.1 gives the alternatives — Latané [1981]'s sub-linear power law and Briscoe et al. [2006]'s `n log n` — and records that nothing assembled here discriminates between them. **The logarithm is chosen for its axiomatic characterisation, not established by measurement.**

No scaling or heavy-tail claim is made in this paper, so the distribution-fitting procedure that any such claim would require [Clauset et al., 2009] does not apply. The distributional statement that *is* made — that decay is geometric — is tested by the log-linearity check of Section 6.4 and by the residual inspection prescribed there, and Section 6.1 records that a cliff fitted as an exponential produces an error in a specific and predictable direction.

Unmet rigour checks, printed rather than left to a reviewer. (i) *Model comparison.* This paper fits nothing, so no information criterion applies to it; but the corpus's one applied fit reports held-out RMSE against baselines and **no AIC or BIC**, so the parameter count was never paid for, and a 2.8 per cent margin over a two-parameter AR(1) may not be a margin at all [Curzi, 2026i]. (ii) *Effect sizes and intervals.* Nothing in Section 9 carries an interval, because nothing in Section 9 was measured; that is honest for a constructed example and is not a substitute for the intervals a real application owes. (iii) *Scale type.* `u` and `Q` are treated as ratio-scale quantities throughout — differences, ratios and logarithms are all taken — and **the conjoint-measurement conditions that would license that treatment have not been tested** [Luce and Tukey, 1964, Krantz et al., 1971]. The treatment is a stipulation. (iv) *Independent replication.* Every system in this paper and every system in the corpus's applied papers was constructed or surveyed by one author; there is no independent replication of any parameter estimate, and the reproducibility literature is unambiguous about what that is worth [Open Science Collaboration, 2015, Ioannidis, 2005]. (v) *Directional versus point prediction.* Meehl [1967] observes that directional predictions are nearly costless in the social sciences; this framework does make point predictions with constants, which is the right answer to that objection, but only Curzi [2026i] has so far put one of them at risk.

7.13 13 Conclusion

The corpus's dynamical core is the storage law `Q_{t+1} = (1−delta) Q_t + eta S_t − C_t` with `S_t = ln(1 + (N−1) U_t)`. Its update map is Lipschitz with modulus `k = 1 − delta`, so any positive loss makes it a contraction, and the contraction supplies a unique start-independent steady state `Q* = (eta S − C)/delta`, which is exactly the DC gain `1/delta` of a first-order discrete section applied to the net drive. The exact solution `Q_t = (1−delta)^t Q_0 + sum_{k=0}^{t−1} (1−delta)^{t−1−k}(eta S_k − C_k)` and the uniform bound `Q_t <= max{Q_0, eta ln N / delta}` follow, with a single pole at `z = 1 − delta`, a time constant `tau = 1/delta` against the exact e-folding time `−1/ln(1−delta)`, and settling times `t_p = ln(1−p)/ln(1−delta)`. **At `delta = 0` the map ceases to contract, no unique fixed point exists, the bound degrades to `Q_t <= Q_0 + t eta ln N` — linear and unbounded — and the error-persistence column is a column of ones, so no mistake ever decays out of the stock. Zero loss does not preserve a system; it removes its destination and its capacity to revise.** These are the statements downstream papers should quote rather than paraphrase.

The worked research group returns `N = 8`, `u* = 0.60`, `N_eff = 5.20` and `S = 1.6487` nats, 79

per cent of the ceiling `ln 8 = 2.0794`; with `eta = 0.50`, `delta = 0.10` and `C = 0.20`, `Q_inf = 6.2433` against a hard ceiling of 10.397 and `t_95 = 28.43` weeks, so a review at week 12 finds the system at 71.76 per cent of steady state and still climbing. The conversion failure case returns a negative steady state, `Q_inf = −2.676`, which the model reports as its own domain of breakdown rather than concealing. All of this is arithmetic. Whether any institution is described by the equation is a separate question, it is a postulate rather than a result, and the one preregistered confirmatory test of it reported in this corpus did not meet its own declared margin.

7.13.1 Declarations

Data and code availability

No external dataset was collected for this paper. All numerical results are computed from the stated parameters under the model developed in the text, and every table can be re-derived from the equations and parameter values printed beside it. The three systems worked in Section 9 are constructed examples with declared parameters, not field observations. The figures are generated by the scripts named in each caption; those scripts contain no data beyond the numbers printed in this paper and the model equations of Sections 3 to 6.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the work, derived the results, produced the worked examples and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The worked systems are constructed. The declination constraint referred to in Sections 7 and 8 — that no intervention removing a participant's ability to decline is within the framework's scope — is a design constraint on prospective work and is not a report of any study performed.

Preregistration

This paper reports no preregistered test of its own; its results are derivations. The preregistered protocol for testing the storage law against a real system, together with the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared margin of 10 per cent — is reported in Curzi [2026i]. Any applied claim resting on this paper inherits that result.

Chapter 8

Conversion, Coordination Cost, and Headroom: Why Eta Is the First Lever and Why the Optimum Group Is Smaller Than the Crossover

Abstract. This paper develops the three remaining terms of the storage law and the gauge reading them together: headroom h_t = eta*ln N - delta*Q_t - C_t, with three regimes and a maximum one-step increment r_max = h_t. Its central asymmetry result is arithmetic: doubling the conversion coefficient eta is exactly squaring the category count, since 2*eta*ln N = eta*ln(N^2), and doubling the surplus by raising non-parallelism alone is feasible only when u <= 1/(sqrt(N)+1), so at N = 8 and u = 0.30 the required u' is 1.23 and the move is arithmetically impossible. Conversion composes multiplicatively through recording, binding and reach gates, so three gates at 0.7 give eta = 0.343 and the weakest dominates: lifting recording from 0.20 to 0.80 gains 300 per cent, lifting binding from 0.60 to 0.90 only 50 per cent. On the cost side, coordination priced as C = kappa*n(n-1)/2 against a logarithmic budget gives a net optimum near sqrt(eta/kappa), far below the crossover at which cost exhausts the budget: at eta = 0.30 and kappa = 0.010 the optimum is six. Topology is shown to be a free lever - eighteen people rewired from a complete graph into three cells of six move from h = -0.4571 to h = +0.1189, a swing of 0.576, with the surplus ceiling untouched because N = 18 either way. A nine-person group is diagnosed at eta = 0.030 with h_0 = -0.1062 and a negative steady state, needing only eta >= 0.091.

Keywords: conversion efficiency; capture gates; coordination cost; communication topology; headroom; sustainability ceiling; queueing slack; shedding stored order

Series: B. Engineering the Surplus **Paper:** CCP-008

8.1 1 Introduction

The storage law of this framework has four parameters and one of them has already been studied on its own. The leaky-integrator analysis establishes that retention loss `delta` decides whether an accumulating system has a destination at all, and that `delta = 0` is a pathology rather than an ideal [Curzi, 2026a]. That leaves three terms — the conversion efficiency `eta`, the cost flow `C`, and the ceiling `ln N` that bounds what any interaction geometry can deliver — and one gauge that reads all four together.

This paper develops those three terms and the gauge. The gauge is **headroom**,

```
h_t := eta ln N − delta Q_t − C_t
```

which is the sustainability ceiling of the storage law rearranged so that its sign can be read off a single subtraction: negative means stored order declines this period whatever is done to the interaction geometry, zero means maintenance only, positive means an increment `r_t <= h_t` is available. Headroom is this framework's name for the reserve that Cyert and March [1963] identified as organisational slack, and its behaviour near exhaustion has the same shape as utilisation approaching one in a queue, where waiting time diverges [Kingman, 1962, Hopp and Spearman, 2011].

The paper's central result is an asymmetry, and the asymmetry is arithmetic rather than empirical. `eta` enters the budget linearly and `N` enters logarithmically, so doubling `eta` is *exactly* squaring `N`: `2 eta ln N = eta ln(N^2)`. An organisation with eight genuinely distinct methodological lineages that wants to double its structural budget can install a decision log, or it can find fifty-six more genuinely distinct lineages. The second route to the same number is a decade of recruitment; the first is a rota. The same asymmetry runs against the third lever: doubling surplus by raising non-parallelism `u` alone is feasible only when `u <= 1/(sqrt(N) + 1)`, so at `N = 8` and `u = 0.30` the required `u'` is 1.23 and the move is not expensive but arithmetically impossible.

Four further results follow from taking the cost side seriously. Conversion **composes multiplicatively** through three named gates — recording, binding, reach — so three gates at 0.7 give `eta = 0.343` and the weakest gate dominates every intervention decision. Priced against a logarithmic budget, coordination cost of the form `C = kappa n(n−1)/2` gives a net optimum near `sqrt(eta/kappa)` that sits **far below the crossover** at which cost exhausts the budget: at `eta = 0.30` and `kappa = 0.010` the optimum is six and the crossover is thirteen, and the band between them is where nothing visibly breaks while every additional member reduces net output. **Communication topology is a free lever**: eighteen people rewired from a complete graph into three cells of six move from `h = −0.4571` to `h = +0.1189`, a swing of 0.576, with the surplus ceiling untouched because `N = 18` either way. And at the fixed point the gauge collapses to `h_inf = eta (ln N − F(u*))`, in which `delta`, `C` and `Q` all cancel — so the only headroom a converged system has is exactly the surplus it is failing to extract from its own difference.

The paper's own worked case refuses the lesson the framework's name would suggest. A nine-person research group is surveyed at `N = 6`, `u = 0.55` and `S = 1.3218` nats, which is 74 per cent of its own ceiling and is good geometry by any reading. Its headroom is nonetheless `h_0 = −0.1062` and its steady state is negative at `Q_inf = −1.607`, because `eta = 0.030` discards 97 per cent of what the geometry produces. Adding a seventh distinct lineage buys 0.0046; cutting coordination cost to zero leaves headroom at roughly a tenth of what the conversion fix delivers. **The geometry this corpus is named for was not the binding constraint in the paper's own example, and the paper says so rather than choosing a different example.**

Three things are new here relative to the surrounding literature rather than relative to the framework. First, the crossover and the optimum are separated and both are computed, where the operations literature supplies the quadratic communication count [Brooks, 1975, Conway, 1968] without pricing it against a logarithmic benefit. Second, coordination cost and interaction geometry are placed on one commensurable scale, so that a topology change and a hiring decision can be compared in the same units. Third, **deliberately reducing stored order is developed as a fourth lever with a computed exchange rate `dQ = dh/delta`**, and is shown to outperform every other move at the paper's own base parameters — while being ruled out of bounds wherever the stored order in question constitutes a person's ability to decline participation.

The framework's static half — the surplus functional `F(u) = ln(1 + (N−1)u)` and its uniqueness under four axioms, with the affine effective count `N_eff = 1 + (N−1)u` — is presupposed rather than re-derived; it is established in Curzi [2026], whose standing clause that the functional is deployed as a **lower bound** on the ensemble's information rather than the information itself governs every number in this paper.

Sections 2 and 3 state the hypotheses and the framework, including the identification problem that limits every applied reading of `eta`. Section 4 develops conversion, Section 5 cost, and Section 6 the headroom gauge. Sections 7 and 8 collect the design specifications and the named failure modes. Section 9 works three systems end to end. Sections 10 to 13 discuss what follows, verify the chain, state the limitations, and conclude.

8.2 2 Hypotheses

The results of Sections 4 to 6 are of two kinds and the distinction is load-bearing. Some are theorems about an equation and cannot be falsified by observation; they are labelled as derivations where they appear. Others are claims that the equation describes a real accumulating system, and those are stated below with what would defeat them. The protocol that operationalises them — a preregistered fit, a frozen model, and held-out comparison against four declared baselines — is specified in Curzi [2026i], whose own confirmatory application failed its second falsification rule: a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin.

H1 — Conversion is a stable scalar over the survey horizon. A real organisation's conversion of interaction into durable structure is well described by a single coefficient `eta` that is approximately constant across periods. **Predicted:** a fitted `b` in `Y_{t+1} = a Y_t + b F(U_t) − C_t + eps_t` that is stable across disjoint sub-windows of the estimation period, within its own interval. **Falsified by:** a fitted `b` that moves significantly between sub-windows with no recorded intervention, or that falls outside `b >= 0`. Where H1 fails, the linear storage law is the wrong model for that system and must be replaced rather than refitted.

H2 — Conversion composes multiplicatively across gates. Total conversion is the product of the recording, binding and reach fractions, not their mean and not one minus the sum of their complements. **Predicted:** `eta = eta_record x eta_bind x eta_reach`, so that an intervention on the smallest gate dominates an intervention of equal size on any other; at gates `(0.20, 0.60, 0.70)`, lifting recording to 0.80 gains 300 per cent against 50 per cent for lifting binding to 0.90. **Falsified by:** a measured `eta` reliably closer to the mean of separately measured gate values than to their product, across systems in which the three gates are separately measurable.

H3 — Conversion is the binding constraint more often than geometry. In systems with `h < 0`, the modal deficiency is `eta` rather than `u` or `N`. **Predicted:** across surveyed systems with negative headroom, the intervention with the largest computed `dh` is more often a capture intervention than a geometry intervention. **Falsified by:** a survey series in which geometry interventions dominate on computed `dh`. **This paper's own worked case is consistent with H3 and its second worked case is not**, which is reported in Section 9 rather than resolved.

H4 — Coordination cost is superlinear in headcount under an unmanaged topology. **Predicted:** regressing measured `C` on `n` across comparable units under complete-graph obligation returns an exponent materially above one. **Falsified by:** a measured exponent near one under complete-graph obligation. **Important qualification:** the exponent 2 used throughout this paper is **defined by the model** `C = kappa n(n−1)/2`, not estimated from data. Section 11.7 records that the log-log regression the source protocol proposes for testing this is precisely the procedure Clauset et al. [2009] shows to be unreliable, and states what would be required instead.

H5 — Topology moves headroom without moving the ceiling. Rewiring a fixed roster changes `C` and leaves `N` and therefore `eta ln N` unchanged. **Predicted:** for

eighteen people at `kappa = 0.006`, complete-graph obligation costs 0.9180 per period and three cells of six with liaison links cost 0.3420, a fall of 63 per cent, while the ceiling term `eta ln 18` is identical in both. **Falsified by:** a measured `C` after a cellular split that does not fall by at least half, which would indicate that the liaison multiplier was underestimated; or a measured fall in `u` below the pre-split level, which would indicate that the split destroyed the difference it was meant to preserve.

Two claims in this paper are **not** hypotheses and are labelled accordingly. That coordination cost is proportional to the number of active communication paths, `C1 = kappa P`, is a **modelling choice**: the combinatorial count `P(n) = n(n−1)/2` is arithmetic, and the interpretive step from that count to a cost is Brooks [1975]'s observation from practice, adopted here because it is the simplest form that reproduces the observed superlinearity and makes the crossover computable. That deference in an assembly can be represented as a common rotation coefficient, and the three-gate decomposition of `eta`, are **modelling conveniences** with no external support and no theorem behind them; both are badged at every use.

8.3 3 Framework

8.3.1 3.1 What is presupposed

The storage law. The equation this paper prices is

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1) U_t)
```

Symbol	Meaning	Range
`Q_t`	stored order: what persists — protocol, runbook, default, furnished room, trust	`>= 0`
`S_t`	surplus generated by interaction this period	`0 <= S_t <= ln N`
`delta`	retention loss, the fraction of stored order lost per period unmaintained	`[0,1]`
`eta`	conversion efficiency: interaction into *durable* structure	`>= 0`
`C_t`	cost, dissipation, overhead	`>= 0`

The quartet of a level, an inflow, an outflow and a delay is the standard vocabulary of system dynamics, formalised four decades before this framework [Forrester, 1961], and the finding that people systematically misjudge such systems even under aligned incentives [Sterman, 1989] is the empirical support for this paper's central institutional claim: that the crossing points below are invisible from inside.

The surplus functional. For two unit state vectors drawn from an ensemble of `N` categories, `u(x,y) = 1 − (x . y)^2` in `[0,1]` and `f(u) = ln(1 + (N−1)u)`, uniquely characterised by four axioms — angle-only dependence, zero at parallel, an affine effective count, normalisation at orthogonality — as established in Curzi [2026]. **Axiom S3, the affine effective count `N_eff = 1 + (N−1)u`, is a design axiom: chosen, not derived**, and it is flagged as such wherever this paper leans on it. The count it defines is developed with its full provenance, its exact bridge to the Rényi-2 participation ratio, and its measurement-error budget in Curzi [2026c], whose result R1 records that a hundred-person department at `u = 0.05` has an effective count of 5.95.

`1 + (N−1)u` is not a Hill number. The effective-count idiom is standard in ecology and in political science, where `1/HHI` and `exp(H)` are the canonical members of the family [Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979]. `1 + (N−1)u` is a linear interpolation between 1 and `N` and belongs to no order of that family. The concentration instrument that *is* a Hill number of order two — `1/HHI`, with the worked jurisdictional case giving a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-HHI of 1.000000 and an effective count of 1.00 — is a separate quantity [Curzi, 2026], and the two must not be conflated. This is repeated in Section 12 because a reviewer reaching for the Hill-number literature as support will find that it does not apply.

The results this paper consumes, all established in Curzi [2026a] and none altered here:

- **Admissibility.** `C_t <= (1−delta) Q_t + eta S_t` guarantees `Q_{t+1} >= 0`.
- **Exact solution.** `Q_t = (1−delta)^t Q_0 + sum_{k<t} (1−delta)^{t−1−k}(eta S_k − C_k)`.
- **One-step growth.** `Q_{t+1} > Q_t` if and only if `eta S_t > delta Q_t + C_t`.
- **Uniform bound.** `Q_t <= max{Q_0, eta ln N / delta}`.
- **Sustainability ceiling.** A nondecreasing step requires `C_t <= eta ln N − delta Q_t`.
- **Steady state.** With constant `U == u*` and `C == c*` and `delta > 0`, `Q_inf = (eta F(u*) − c*)/delta`, negative when `eta F(u*) < c*`.
- **Range.** `0 <= F(u) <= ln N`, which is what makes `eta ln N` a ceiling rather than a typical value.

The leaky-integrator paper's own conversion-failure case is the one this paper generalises: with `S` at 79 per cent of ceiling but `eta = 0.05` and `C = 0.35`, `eta S = 0.0824` falls below `C` and the steady state is negative at `Q_inf = −2.676`, which the model reports as its own domain of breakdown [Curzi, 2026a].

8.3.2 3.2 Two warrants for the logarithm, and the one the argument needs

The logarithmic form has two independent justifications and this paper needs only the weaker demand. The first is Fechnerian: sensation proportional to the logarithm of a dimensionless stimulus ratio measured from a floor [Fechner, 1966]. That warrant requires the perceptual story to be true and the perceptual story is contested. The second assumes nothing psychological at all: Peters and Gell-Mann [2016] shows that the time-average growth rate of a multiplicatively evolving quantity is the expectation of its *logarithm*, so a logarithmic evaluation follows from the dynamics. **Where a stock compounds rather than adds, the logarithm is the ergodic-average object, and no claim about perception is required.** This paper's argument needs only the second warrant. The ceiling `ln N` also has an information-theoretic reading as the maximum an ensemble of `N` equiprobable categories can carry [Shannon, 1948], and the requisite-variety tradition supplies the reason a variety term appears as a ceiling at all: only variety absorbs variety [Ashby, 1956, 1958]. Neither reading identifies surplus with Shannon entropy, and Section 11.8 says so.

The functional form is nevertheless underdetermined by the evidence, and the paper says so rather than waiting to be told. Social impact rising as a power of the number of sources with an exponent below one [Latané, 1981] and network value growing as `n log n` rather than `n^2` [Briscoe et al., 2006] both reproduce the qualitative facts this framework's `ln(1 + (N−1)u)` reproduces — diminishing returns to count, no threshold, monotonicity — and **nothing assembled in this corpus discriminates between them**. What the corpus's form has is an axiomatic characterisation with the design axiom named at the point where the choice is made; what it lacks is a discriminating measurement. Stumpf and Porter [2012] states the general form of the problem: many mechanisms produce indistinguishable curves. Section 12 carries this as an open limitation.

8.3.3 3.3 Identification: what no amount of fitting recovers

This limitation is structural rather than statistical and belongs here rather than in a caveat at the end. Wherever the storage law is applied to a group whose members both influence and constitute the aggregate — the usual case for a team, a board or an institution — the specification is reflexive: the interaction geometry `U_t` is a property of the group, the group's stored order shapes what its members do next, and the members are what the group is made of. Manski [1993] proves that in a linear-in-means reflexive specification **the endogenous social effect is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] reinforce the point for network data, where influence and selection are generically confounded.

The consequence for this paper is exact. Every derivation in Sections 4 to 6 is a statement about an equation and is untouched. But the *interpretation* of a fitted `b` as the conversion efficiency of interaction into structure — as opposed to a contextual effect, a common shock, or selection — is **not identified by observation alone**, and no held-out comparison recovers it. That is a deeper limitation than anything the falsification protocol of Curzi [2026i] tests for, and it would remain even if every rule in that protocol passed.

No remedy is adopted in this paper, and the honest label is therefore a modelling position. The known routes are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation [Brock and Durlauf, 2001]; the last is the most realistic here, and it is the route the survey protocol's fixed category set and declared participation rule point toward without yet taking. **Until one of them is executed, `eta` as an estimated quantity is a coefficient in a declared specification and not an identified social effect**, and every applied statement in this paper inherits that status. The same applies with equal force to `kappa`, which Section 5.9 estimates by a procedure that is entirely observational.

8.3.4 3.4 Standing honesty clauses

Repeated wherever the law is used, and stated once here.

- **The triangle inequality fails for geometric triples.** Subadditivity holds on the parameter `u`, not on the geometry, so surplus bounds may not be chained through an intermediate state. The point is not exotic: psychological similarity is known to be asymmetric and to violate the triangle inequality [Tversky, 1977].
- **As deployed, the surplus functional is a lower bound** on the information an ensemble carries, not the information itself [Curzi, 2026]. Every number in this paper is a floor.
- **Surplus is not identified with Shannon entropy or mutual information**, and no thermodynamic negentropy law is proved.
- **Applying the storage law to a room, a team or an institution is a modelling decision**, badged as such every time it is made.
- **The constraint that an intervention may not remove a participant's ability to decline sits outside the arithmetic.** It is not derived from the law, the law gives no warning where it is violated, and Section 6.9 records the one place in this paper where a lever with a computed positive return is declared out of bounds anyway.
- **What this framework permits itself is bounded by its own interlude on category violation**, which refuses category innocence as a defence of acquisition and forbids moving a harm through a discovered gap in a scheme, and which concedes that the case where a feedback loop runs through another person's will is an unsettled seam the corpus does not close [Curzi, 2026]. The shedding lever of Section 6.9 is exactly a case of finding a gap in a scheme, and it is bounded accordingly.

8.4 4 Conversion: engineering `eta`

`eta` is the only parameter in the law that stands between an interaction and a consequence. Everything else describes what happens to consequences once they exist; `eta` decides whether they exist at all. It appears in every design inequality of the framework, and it always appears multiplied by something that is hard to change:

```
one-step growth :   Q_{t+1} > Q_t   <=>   eta*S_t > delta*Q_t + C_t
uniform bound   :   Q_t <= max{ Q_0 , eta*ln N / delta }
sustainability  :   nondecreasing requires  C_t <= eta*ln N - delta*Q_t
steady state    :   Q_inf = (eta*F(u*) - c*) / delta
headroom        :   h_t = eta*ln N - delta*Q_t - C_t
max increment   :   r_max = eta*ln N - delta*Q_t - C_t
```

Every one of these is **linear in `eta` and logarithmic in `N`**. That asymmetry is the whole argument of this section and Section 4.9 prices it exactly.

8.4.1 4.1 The `eta = 0` collapse

Set `eta = 0` in the exact solution:

```
Q_t = (1-delta)^t * Q_0  -  sum_{k=0}^{t-1} (1-delta)^{t-1-k} * C_k
```

The driven term vanishes entirely. What remains is a decaying transient plus an accumulated debit. For `delta > 0` and any `C_k >= 0`, `Q_t` is non-increasing in every period and converges to `-c/delta` if cost is constant — which is inadmissible, meaning the linear model has been pushed outside its range and the real system has hit some floor.

A system with `eta = 0` does not stagnate; it declines, and it declines at exactly the rate it would decline if the interaction had never occurred. The meetings still happen. The conferences still convene. The arithmetic does not notice any of it. This condition is nearly invisible from inside, because `S_t` is large and visible while `eta S_t` is small and abstract: people experience the interaction and do not experience the coefficient.

8.4.2 4.2 The distinction the section turns on

Two different quantities travel under one word.

```
S_t        the interaction that HAPPENED    -- attendance, discussion, encounter, contact
eta*S_t    the interaction that STUCK       -- decision, artifact, default, trained person
```

`S_t` is bounded above by `ln N` and is generated by the geometry of who is present and how different they actually are; `eta` is generated by what is done with what that geometry produced. **The geometry decides how much is available; the conversion decides how much is kept.**

Most organisations measure `S` and report it as though it were `eta S`. Attendance figures, meeting counts, conference days, touchpoints, engagement, workshop hours: these are measurements of `S`, or of proxies for `S`, and none of them is a measurement of `Q`. A report that lists them and concludes that the organisation is building something has performed a substitution the arithmetic does not permit. Stated as a rule: **a report that an interaction went well is a report of `S` and contains no information about `eta`.** The answerable follow-up is not what was discussed but what is different now that was not different before, and where it is written down. If the honest answer is *nothing yet*, then `eta S = 0` for that interaction and it moved `Q` by exactly zero.

8.4.3 4.3 The three gates

`eta` is a capture rate, and in every real system it decomposes into three sequential gates, each a multiplier in `[0,1]`:

```
eta  =  eta_record  *  eta_bind  *  eta_reach
```

- **`eta_record`** — the fraction of what was produced that was recorded at all, in any durable medium. A decision reached and not written is lost at the rate of human memory.
- **`eta_bind`** — the fraction of what was recorded that was bound to a change in the system's behaviour: an owner, a date, a default, a modified procedure, a moved wall. A record with no binding is an artefact in a filing cabinet.
- **`eta_reach`** — the fraction of the bound change that reached the people and places that act. A changed default that no tooling implements has changed nothing.

Badge: this three-gate decomposition is a modelling convenience, not a theorem, and it has no external support. It earns its place by telling an analyst where to look. What matters is the multiplicative form: three gates at 0.7 each give `eta = 0.343`, so the intuition that a system is *doing pretty well on all three* is worth less than half of what it feels like.

The multiplicative form also explains why conversion improvements are so often cheap. If the worst gate is `eta_record = 0.1` because nothing is written down, a scribe rota costs one person's attention per meeting and can plausibly take that gate to 0.8 — an eightfold move on the whole coefficient, with no change to headcount, geometry, or budget.

8.4.4 4.4 Six capture mechanisms

These are the durable-structure channels available to almost every system, listed in rough ascending order of conversion per unit of effort, each described in terms of the parameter it moves.

1. Writing it down (raises `eta_record`). A shared, dated, append-oriented record of what was concluded. Cost: one person, ten minutes. The highest-leverage intervention available in any system with `eta_record < 0.5`, which is most of them. The failure variant is catalogued as F2: minutes that record what was *said* rather than what was *decided* raise `eta_record` while leaving `eta_bind` at zero.

2. The decision log (raises `eta_record` and `eta_bind` together). Distinct from minutes. It records the decision, the date, the alternatives rejected, the person accountable, the review date, and the condition that would reverse it. It is the cheapest device that touches both gates at once, and it also serves the falsification requirement of Curzi [2026i], because a decision log with reversal conditions is a preregistration in the sense that literature requires [Nosek et al., 2018].

3. The changed default (raises `eta_bind` and `eta_reach`). A default is a decision that executes itself: the template that now has the new field, the calendar that now has the slot. **Defaults have the highest reach of any mechanism, because they require no ongoing compliance from anyone.** They are also the case in which Star and Ruhleder [1996]'s observation bites in the organisation's favour: infrastructure is invisible when it works, which is exactly why a default is more durable than a policy — and exactly why, in Section 6.9, working stored order never appears on a list of things that could be removed.

4. The built object (raises all three; resists `delta` mechanically). A jig, a checklist card, a script, a fixture, a moved partition. A built object is stored order that resists decay mechanically rather than through anybody's diligence, which is why the built-environment levers of Curzi [2026f] — whose entrance-sequence case takes interruptions from 22 to 6 per person-day and headroom from `+0.0642` to `+0.2955` for 7.6 per cent of net floor — are conversion devices as much as cost devices.

5. The trained person (highest conversion, highest exposure to `delta`). Skill in a person is the densest form of stored order available and the form most exposed to turnover. The

engineering response is not to avoid training people but to pair this mechanism with the first four, so that a departure is a partial rather than a total loss.

6. The altered institution (highest durability, highest cost, longest lag). Moving a wall, changing a reporting line, creating a standing role, rewriting a charter. These are the slowest and most expensive captures and they have the lowest decay. Conway [1968] is the reason they work: systems mirror the communication structure of the organisation that builds them, so an alteration to that structure propagates into everything the structure subsequently produces. **The source manuscript dates this article to 1967; it ran in *Datamation* in April 1968, and the correction is recorded here rather than made silently.**

8.4.5 4.5 Ordering the mechanisms honestly

The list above is ordered by effort-adjusted leverage in a typical system, and that ordering is a judgement rather than a measurement. **The honest statement is that the ordering is system-specific and should be measured rather than assumed.** What is not system-specific is the structure of the argument: find the lowest gate and fix that one.

Consider a group whose gates are `eta_record = 0.20` (someone occasionally emails notes), `eta_bind = 0.60` (when notes exist, an owner is usually named), `eta_reach = 0.70` (named owners usually follow through), so that `eta = 0.20 x 0.60 x 0.70 = 0.084`. Two candidate interventions of comparable cost:

```
Intervention A: improve eta_bind   0.60 -> 0.90    eta = 0.20*0.90*0.70 = 0.126   (+50%)
Intervention B: improve eta_record 0.20 -> 0.80    eta = 0.80*0.60*0.70 = 0.336  (+300%)
```

Both are process improvements. One is four times the other. The difference is entirely visible in advance if the coefficient is decomposed, and entirely invisible if it is not.

8.4.6 4.6 Governance design principles read as conversion devices

Ostrom [1990] gives eight design principles for durable common-pool resource institutions, derived from field study of institutions that survived for centuries and institutions that failed. They are usually read as governance advice. Read as engineering they are almost entirely conversion and retention devices, and it is worth saying which is which. Cox et al. [2010] is the meta-analytic audit of those principles and is the kind of external test this framework's own principles will eventually face; Hardin [1968] is the claim Ostrom refuted, and the pair should be cited together or not at all.

Design principle	Primary effect in the law	Mechanism
Clearly defined boundaries	raises `eta_bind`; defines `N`	a decision cannot bind to an undefined membership
Rules matched to local conditions	raises `eta_reach`	a rule that does not fit is not executed
Collective-choice arrangements	raises `eta`; protects `u`	those affected participate
Monitoring	raises `eta_reach`; lowers `delta`	detects when stored order has decayed
Graduated sanctions	lowers `delta`; bounds `C`	maintains bindings without maximal enforcement
Conflict-resolution mechanisms	lowers `C`	conflict is a dissipation term
Recognition of rights to organise	raises `eta_bind`	external non-recognition voids the binding

Design principle	Primary effect in the law	Mechanism
Nested enterprises	raises `eta` at scale; bounds `C`	the topology answer of Section 5.7

The most consequential reading is monitoring. In the field data it is not primarily a compliance device; it is the device that makes the state of `Q` *visible*, and a `Q` that is visible can be maintained. Star and Ruhleder [1996]'s observation that infrastructure becomes visible only on breakdown is precisely the failure that monitoring corrects, at a cost, and the cost is a `C` term. Monitoring is therefore a deliberate trade — **spend `C` to lower `delta`** — worth making only when `delta Q` exceeds the monitoring cost, which is computable and is computed in Section 6.

Nested enterprise is the same structural answer that Section 5.7 reaches from the cost side and that the semilattice argument reaches from the surplus side. **Three independent lines arriving at one topology is the strongest form of agreement this paper can offer, and it is still not a proof.** Scott [1998] supplies the standing warning attached to it: legibility destroys the local variety that made a system work, and a cellular scheme imposed from outside is a legibility project.

8.4.7 4.7 Apprenticeship, and the throughput trade

Apprenticeship holds `S_t` at a moderate level continuously over a long horizon with `eta_reach = 1` by construction, because the person receiving the transfer is the person who will act. Writing has a reach problem — the reader may not be the actor — and a tacit-knowledge problem, since what cannot be articulated is not recorded. Apprenticeship has neither, because the transfer channel is demonstration rather than description.

What it has instead is a throughput problem: one transfer per master per period, where a written artefact serves many. **That is the exact trade — apprenticeship buys very high conversion at very low throughput; documentation buys much lower conversion at very high throughput** — and a system using only one of them leaves the other's regime unserved. The design rule that follows is not *do apprenticeship*. It is: **for the fraction of stored order that is tacit, documentation has `eta_record` near zero regardless of effort.** Identify that fraction honestly and give it a demonstration channel.

8.4.8 4.8 What `eta = 0` looks like from inside

Named symptoms, so the condition can be recognised before the arithmetic is run.

- The same decision is re-litigated at intervals, and each re-litigation feels novel.
- Nobody can say when a standing practice was adopted or by whom.
- A new member's onboarding consists of a person telling them things.
- Meeting outputs are described in terms of mood rather than of change.
- Things are written down but cannot be found — `eta_record > 0` with `eta_reach` near zero.
- Departures cause loss disproportionate to the departing person's visible role.

The re-litigation symptom is the most diagnostic, because it is the direct observable signature of `Q` decaying back below the threshold at which a decision counts as settled. It is also countable, and Section 7 makes it a standing requirement.

8.4.9 4.9 Measuring conversion

The definitional estimator is `eta_hat = delta_Q_attributable / S_input`. Both terms are hard, and the procedure names both difficulties rather than hiding them.

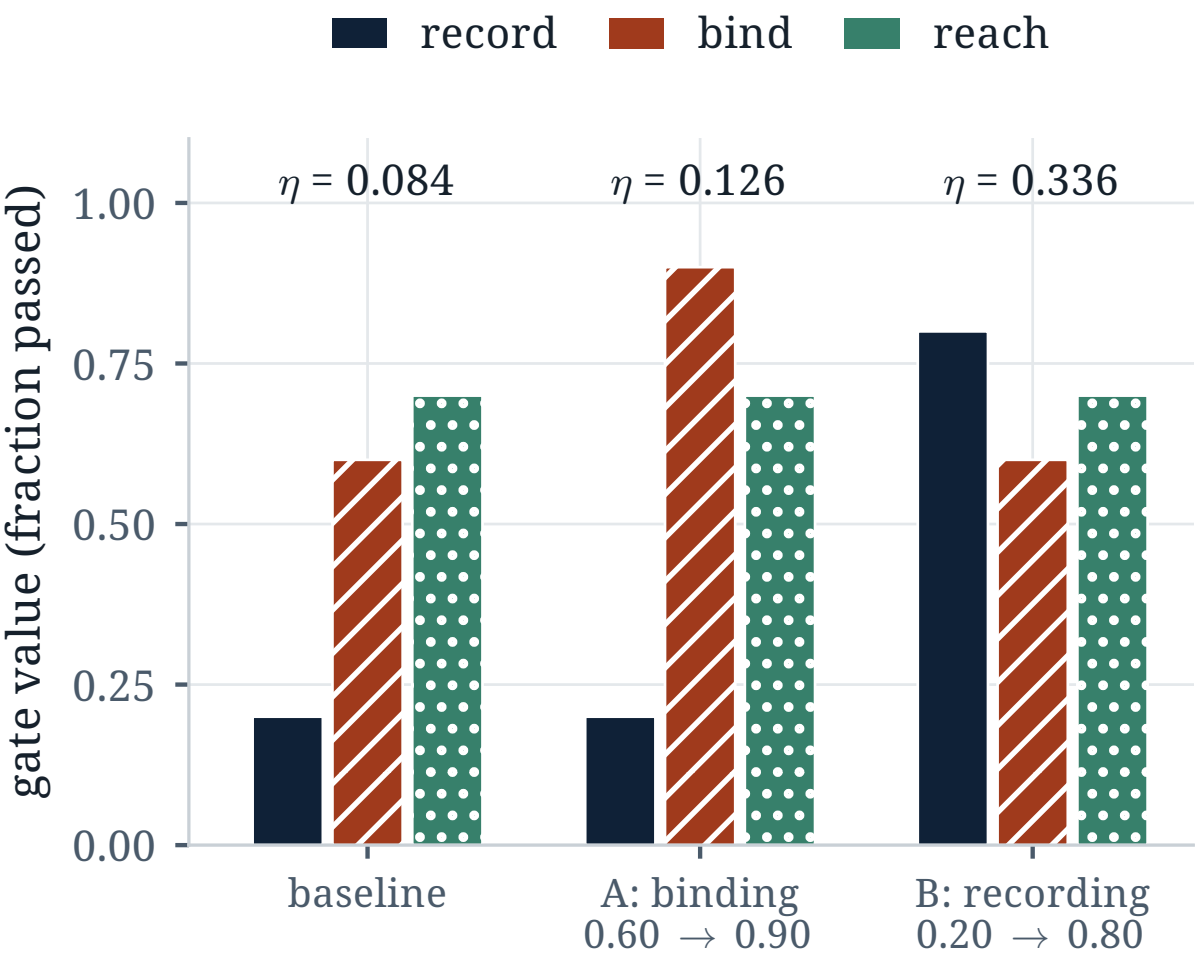

Figure 8.1: **The weakest gate dominates: the same 0.30 improvement is worth +50 per cent applied to binding and +300 per cent applied to recording**, because conversion is a product and not a mean. Gate values are stipulated illustrative inputs; the products are exact. Generated by `figs/src/CCP-008_fig02.py`.

Step 1 — choose the order observable `Y_t`. A measurable proxy for `Q_t`: count of live written decisions with named owners; count of standing defaults implemented in tooling; number of procedures a randomly sampled member can execute unaided; count of built artefacts in active use.

Step 2 — justify that `Y_t` is not a repackaging of `U_t`. This is the most common measurement error in the framework. If the order measure is really a measure of how much interaction is happening, the input has been fitted to itself and the estimate is meaningless. **The short form of the test: if the order proxy would move on a week when a great deal of talking happened and nothing was concluded, it is an interaction measure and must be replaced.** The cheapest detector of the failure is the ceiling test, since no admissible single-period increment can exceed `eta ln N`: a repackaged proxy in the corpus's one applied survey produced a single-week jump of 31.1 units against a maximum admissible increment of 0.8071, a factor of 38.5 [Curzi, 2026i].

Step 3 — measure `S_input`. Estimate `N` by the effective-count audit [Curzi, 2026c] and `u` by disagreement rate or error decorrelation, then compute `S = ln(1 + (N−1)u)` directly. Do not estimate `S` from attendance.

Step 4 — establish attribution. The minimum acceptable design is comparison against four baselines: persistence, direct-input, matched autoregressive, and shuffled-input. **The shuffled-input control is the one that catches a false conversion estimate: if the pairing of periods is shuffled and the fit does not degrade, what has been measured is a trend and not a conversion.** Simmons et al. [2011] and Gelman and Loken [2013] are the reason this is not optional; Ioannidis [2005] and Open Science Collaboration [2015] are the reason a single uncontrolled estimate should not be believed.

Step 5 — fit the minimal model `Y_{t+1} = a Y_t + b F(U_t) − C_t + eps_t` with `0 <= a <= 1` and `b >= 0`, so that `a = 1 − delta` and `b = eta`. Fit on training data, **freeze**, and report held-out performance.

A worked estimation table. Take a group with `N = 8` and `u = 0.30`, so `S = ln(1 + 7 x 0.30) = ln 3.10 = 1.1314` nats per period, with `Y` normalised so that one unit is one durable, owned, implemented decision still live at review:

Capture regime	`delta_Q` per period	`eta_hat = delta_Q / 1.1314`
No artefact of any kind	0.000	0.000
Verbal agreement only	0.010	0.009
Notes circulated after the fact	0.050	0.044
Decision log with owner	0.140	0.124
Log, owner and changed default	0.280	0.247
Built artefact and trained person	0.450	0.398

Badge: the left column is a set of illustrative inputs chosen to span a plausible range, not measurements from any study. The arithmetic in the right column is exact; the left column is what an analyst must measure in their own system. No citation is offered for a number that was not measured. What the table demonstrates is the *shape* of the result — a factor of forty between the bottom and top regimes, produced entirely by what happens in the twenty minutes after an interaction ends.

8.4.10 4.10 The asymmetry: why conversion is the first move

This is the quantitative core of the section. `eta` enters the budget linearly, `N` logarithmically, and `u` through a concave saturating function. The consequence is a set of exact equivalences.

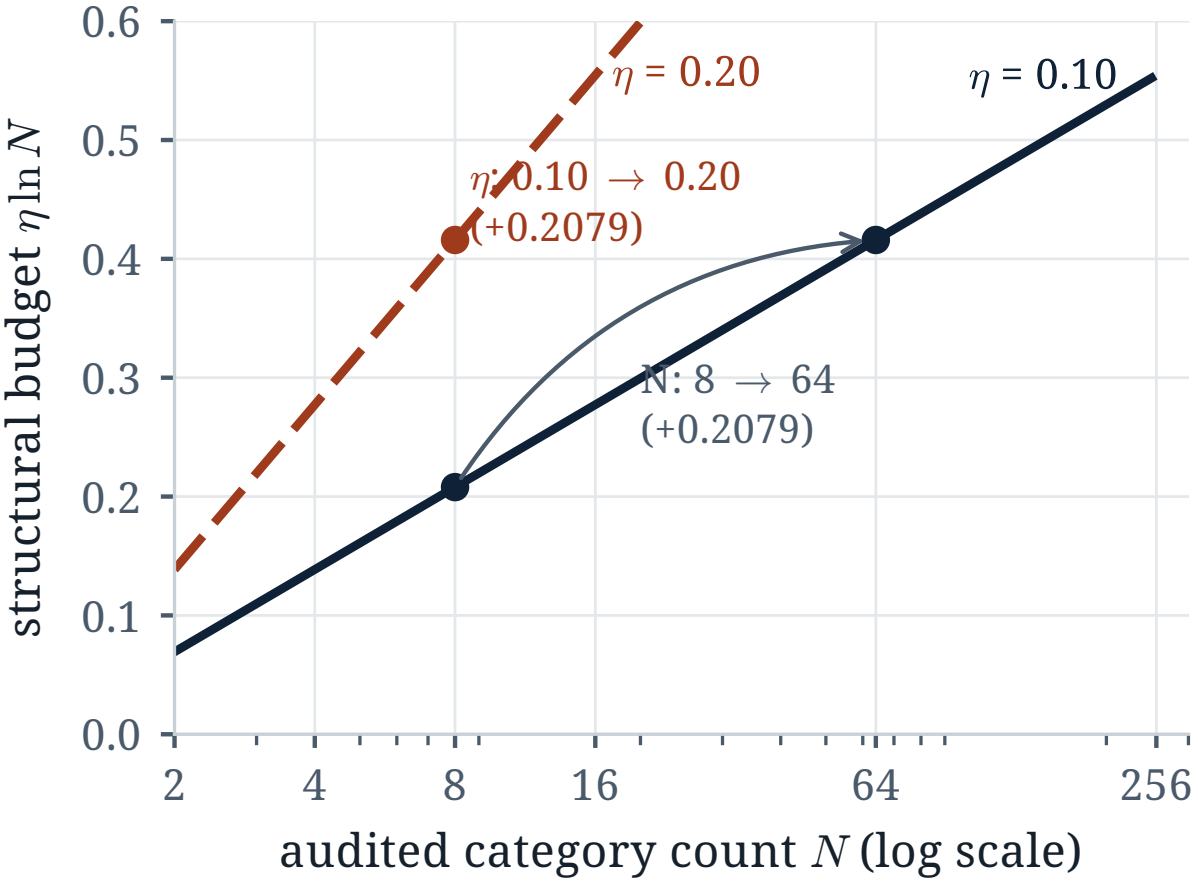

Figure 8.2: **Doubling conversion and squaring the category count buy exactly the same budget**: at `eta = 0.10` moving `N` from 8 to 64 adds 0.2079, and so does moving `eta` from 0.10 to 0.20 at `N = 8`. Modelled from the budget term `eta ln N`; the two parameter values are stipulated and the arithmetic is exact. Generated by `figs/src/CCP-008_fig01.py`.

4.10.1 Doubling `eta` is exactly squaring `N`

The budget term is `eta ln N`. Doubling `eta` gives `2 eta ln N = eta ln(N^2)`. Therefore **to match a doubling of conversion by adding categories, the category count must be squared.**

Current `N`	`N` required to match a doubling of `eta`
2	4
4	16
8	64
10	100
16	256
20	400
50	2,500
100	10,000

An organisation with eight genuinely distinct disciplines that wants to double its structural budget can install a decision log, or find fifty-six more genuinely distinct disciplines.

4.10.2 Doubling `eta` is often impossible to match by raising `u`

To double `S = ln(1 + (N−1)u)` by raising `u` alone requires `u'` with `1 + (N−1)u' = (1 + (N−1)u)^2`, so

```
u' = ( (1 + (N−1)u)^2 − 1 ) / (N−1)
```

Since `u <= 1` by construction, this is feasible only when `(1 + (N−1)u)^2 <= N`, that is when

```
u  <=  1 / (sqrt(N) + 1)
```

Above that threshold, doubling the surplus by raising non-parallelism is not merely expensive: it is arithmetically impossible, because there is not enough room left below `u = 1`.

`N`	maximum `u` from which doubling via `u` remains feasible
2	0.4142
3	0.3660
4	0.3333
5	0.3090
8	0.2612
10	0.2403
16	0.2000
20	0.1827
50	0.1239
100	0.0909

Worked instances:

```
N=8,  u=0.30 -> S = 1.1314;  doubling needs u' = 1.2300   INFEASIBLE (u' > 1)
N=8,  u=0.10 -> S = 0.5306;  doubling needs u' = 0.2700   feasible, and expensive
N=20, u=0.10 -> S = 1.0647;  doubling needs u' = 0.3900   feasible, and very expensive
```

Raising `u` from 0.10 to 0.27 in a real team means recruitment across training lineages, rotation, adversarial roles, the deliberate outsider — a multi-year programme with a high failure rate. Doubling `eta` from 0.084 to 0.168 by fixing the recording gate is a rota.

4.10.3 The full comparison at one base case

Base: `N = 8`, `u = 0.30`, `eta = 0.10`, `delta = 0.10`, `C = 0.05`. Then `S = 1.1314` and the structural budget is `eta ln N = 0.10 x 2.0794 = 0.2079`.

Move	new `eta ln N`	gain	realistic cost
baseline	0.2079	—	—
`eta`: 0.10 to 0.20	0.4159	+0.2079	a scribe rota and a decision log
`N`: 8 to 10	0.2303	+0.0223	two genuinely new disciplines hired
`N`: 8 to 16	0.2773	+0.0693	doubling the discipline count

Move	new `eta` `ln N`	gain	realistic cost
`N`: 8 to 64	0.4159	+0.2079	eight times the discipline count

Hiring eight times as many distinct disciplines buys exactly what a decision log buys. This is the asymmetry stated as a single line, and it is why conversion is the first move in almost every system this framework has been applied to. The result is consumed downstream as the sensitivity table `dh/d(eta) = ln N = 2.197` against `dh/dN = eta/N = 0.0038`, which records adding categories as the weakest available lever [Curzi, 2026o].

4.10.4 Cadence is not a conversion move and must not be booked as one

A fourth move is proposed in the same breath as the three above — meet more often — and it belongs in a different column of the ledger. **For a linear time-invariant integrator the integrated effect of one large input and of the same total delivered periodically is identical** [Oppenheim et al., 1996]. Rescheduling delivers no extra input, and a cadence change booked as a gain in `eta` is double-counting.

What cadence does buy is real and arrives through the *surplus* term. Because `f(u) = ln(1 + (N−1)u)` is strictly concave with `f(0) = 0`, splitting a fixed budget of non-parallelism across more occasions strictly increases the delivered total. At `N = 8`:

occasions `n`	`u` per occasion	`f(u)`	delivered total `n f(u)`
1	0.60	1.6487	1.6487
2	0.30	1.1314	2.2628
4	0.15	0.7178	2.8714
6	0.10	0.5306	3.1838

Four occasions deliver **1.74 times** what one delivers from the same budget, and separately the ceiling `S <= ln N` clips whatever a single occasion tried to exceed. **Cadence beats intensity because of concavity and the ceiling, not because it delivers more input.** Book the gain under `S`, keep `eta` for the capture gate, and the two moves stay separately auditable.

Two cautions, both of which the source manuscript leaves implicit and this paper states. First, the table treats a session's worth of non-parallelism as a divisible budget that can be partitioned across occasions. **`u` is a bounded geometric parameter — the squared sine of an angle between unit state vectors — and nothing in the framework establishes that it is extensive in this way.** The table is therefore correct arithmetic about `f` and rests on an unstated postulate about `u`, which is badged here as a modelling choice. Second, this concavity argument runs in the opposite direction from the concavity correction of Section 6.2, where *variability* in `U` at fixed mean reduces the delivered mean of `F` below `F` of the mean. Both are Jensen's inequality; they differ in what is held fixed, and confusing them produces an error in a predictable direction.

8.4.11 4.11 Where conversion cannot be raised

Three honest limits.

The tacit fraction. Some stored order is not articulable, and documentation has `eta_record` near zero on it by nature. The answer is a demonstration channel, not more effort.

The capture tax. Capture consumes attention, and attention is a `C` term. A system that captures everything spends its entire budget on capture. The marginal condition is computable: capture is worth doing on an interaction while the marginal `d(eta) S` exceeds the marginal

dC. In practice this means **capture the decisions, not the discussion** — the discussion is S, and only the decision can become Q.

The ceiling is still ln N. Raising conversion scales the whole budget, but the budget is eta ln N, and a high conversion rate applied to nearly nothing is nearly nothing. **A multiplier cannot rescue a zero.** Where three ostensibly independent sources share one doctrine, u = 0, N_eff = 1, and S = ln 1 = 0, and every conversion intervention in this section returns nothing while consuming C. This is the case Curzi [2026] states as the binding clause of the functional: a second opinion from a source sharing training, incentives and premises is worth ln(1) = 0 of surplus. It gives the correct sequencing rule:

Verify S > 0 before investing in conversion. If u is near zero, fix the geometry first. Otherwise fix conversion first, and fix it before considering N.

8.4.12 4.12 Communication structure as a conversion channel

Conway [1968] observed that a system's structure mirrors the communication structure of the organisation that produced it. In the terms of the law this is a statement about eta_bind and eta_reach: **the communication topology is the channel through which captured order reaches the artefact, so the artefact inherits the topology.**

Two consequences. First, if an artefact with a particular structure is wanted, the cheapest route is to give the producing organisation that structure, because reach along the existing topology is high and reach across it is low. Fighting the topology costs C; using it is free. Second, and less often noticed, **a communication topology change is a high-conversion intervention**, because it propagates automatically into everything subsequently produced. The altered institution is expensive precisely because it is powerful.

8.4.13 4.13 High conversion on the wrong thing

eta is neutral. It converts whatever surplus arrives into whatever durable structure the capture mechanism specifies, and a high-conversion system that captures wrong conclusions builds durable wrong structure — which by construction has a low delta and therefore persists. This is the mirror image of the retention result that a system with no forgetting cannot revise [Curzi, 2026a]. Banach [1922] guarantees arrival at the fixed point and says nothing whatever about whether the fixed point is a good place; the convergence analysis of this corpus makes the same refusal explicitly, holding that the theorem transfers as shape rather than as guarantee because nobody has measured the relevant contraction modulus and a human life is not a metric space [Curzi, 2026].

The engineering answer is not to lower conversion. It is to build reversal into the capture format, which is why the decision-log specification requires *the condition that would reverse it.* **A capture format that records its own falsification condition converts surplus into structure that can be dismantled on evidence, which is the only kind of high-conversion system that remains correctable.**

The measurement is exposed to the failure it describes. A measure that becomes a target ceases to be a measure [Goodhart, 1975, Campbell, 1979], so if conversion is measured and the measurement becomes a target, capture ceremonies will multiply and the measured eta will rise while the real one does not. The adversarial form of the order-proxy test is the defence: **ask whether the conversion metric would rise if people simply wrote more documents that changed nothing. If it would, it is not measuring conversion.**

8.4.14 4.14 Minutes and a decision log

Worth stating separately, because the confusion is close to universal.

```
MINUTES                          DECISION LOG
```

```
records what was SAID               records what was DECIDED
chronological                       indexed by decision
complete                            selective
raises eta_record only              raises eta_record AND eta_bind
read once, by nobody                read on every re-litigation
grows without bound                 grows with decision count
no owner field                      owner field is mandatory
no reversal condition               reversal condition is mandatory
```

Minutes are an archive; a decision log is a control surface. **The test is whether the document is consulted when someone asks why a practice is what it is. If it is not, the record is minutes and `eta_bind` is unaffected by it.**

8.5 5 Cost: the dissipation budget

`C_t` removes stored order in a way that has nothing to do with decay. `delta` is what leaks out through the walls; `C_t` is what is drawn off deliberately — the overhead of being an organisation at all, paid every period whether or not anything is accomplished.

Two constraints govern the section and they are not the same line.

```
admissible :   C_t <=  (1-delta)*Q_t + eta*S_t     -- Q_{t+1} stays >= 0
sustainable:   C_t <=  eta*ln N - delta*Q_t         -- Q_{t+1} >= Q_t
```

Admissibility is a floor condition: the model does not produce nonsense. Sustainability is a growth condition: order does not decline. **Admissibility permits eating capital; sustainability does not.** Critically, `Q` appears with opposite signs in the two: a large stock of stored order *raises* the admissible cost, because it can be burnt, and *lowers* the sustainable cost, because it must be maintained. Worked at `delta = 0.08`, `eta = 0.22`, `N = 8`, `u = 0.60`, so `S = 1.6487`, `eta S = 0.3627` and `eta ln N = 0.4575`:

`Q_t`	admissible `C_max`	sustainable `C_max`
0.0	0.3627	+0.4575
0.5	0.8227	+0.4175
1.0	1.2827	+0.3775
2.0	2.2027	+0.2975
4.0	4.0427	+0.1375
8.0	7.7227	-0.1825

The two columns move in opposite directions, and at `Q = 8` the sustainable ceiling has gone negative while the admissible ceiling stands at 7.72. A large institution can therefore run for a very long time in a state that is admissible and unsustainable, consuming accumulated order at a rate that looks affordable because there is so much of it. That is the structural picture of long institutional decline and it is the subject of Section 6.

8.5.1 5.1 What c contains

`C` is not one thing. It is tallied as a sum of named lines, because an aggregate figure cannot be attacked and a decomposed one can.

C1 · Coordination. The direct cost of aligning people: meetings, status reporting, scheduling, handoffs, approval chains. This is the line that scales with path count.

C2 · Friction. Cost incurred because the system is arranged badly rather than because the work is hard: waiting for access, re-entering data, tool mismatch, permission bottlenecks. Friction produces nothing at all, not even coordination.

C3 · Maintenance of relationship. The upkeep that keeps `u` from collapsing into hostility or `N` from fragmenting. **This is the `C` line most often cut first and it is often the one that should be cut last**, because cutting it raises `delta` on trust, which is stored order.

C4 · Conflict. Disputes that consume attention without resolving. Conflict and disagreement are *not* the same thing: disagreement is `u` and is on the credit side of the ledger; conflict is `C`. **A design that suppresses conflict by suppressing disagreement has paid for a `C` reduction with a `u` reduction, and since `u` enters through a logarithm and `C` enters linearly, that trade is usually bad.** Acoustic treatment and table geometry are, in part, devices for having disagreement without conflict [Curzi, 2026e,f].

C5 · Rent and premises. Literal rent and everything that behaves like it: licence fees, platform tolls, the fixed cost of existing.

C6 · Commute and transit. The cost of getting bodies into proximity. Its reduction trades directly against `S`, because proximity is one of the cheapest ways to raise interaction rate. A genuine trade, not a free cut.

C7 · Attention labour. The cost of managing presentation, absorbing others' states, and maintaining the social surface. Real, chronically unmeasured, and unevenly distributed. It is a `C` term because it consumes exactly the resource — attention — that conversion also consumes.

C8 · Compliance and reporting. Externally imposed overhead. Often the least compressible line and the one that grows with `Q` (Section 5.11).

C9 · Context switching and interruption. Each switch costs recovery time. Usually invisible in a budget and frequently the largest single item in knowledge work; the built-environment treatment prices it as a threshold problem and measures a fall from 0.321 to 0.087 of the working day [Curzi, 2026f].

8.5.2 5.2 The pair count and what it does not prove

In a group of `n` people the number of distinct unordered pairs is

```
P(n) = n(n−1)/2
```

This is arithmetic and therefore not a claim about the world. The interpretive step — that coordination burden tracks `P` — is Brooks [1975]'s observation from practice, and this paper adopts it as a **badged modelling choice** in the form `C1 = kappa P(n)`, with `kappa` a per-link cost per period. It is chosen because it is the simplest form that reproduces the observed superlinearity and because it makes the crossover computable. **It is falsifiable in principle: measure `C` at several `n` in a comparable setting and check the exponent. Section 11.7 records that the log-log regression the corpus's own protocol proposes for that check is not a sound procedure, and states what would be.**

The count itself, alongside the surplus ceiling for the most favourable possible case in which every added person brings a genuinely new category:

`n`	`n(n−1)/2`	`ln n`	paths per nat
2	1	0.6931	1.44
4	6	1.3863	4.33
6	15	1.7918	8.37
8	28	2.0794	13.47
10	45	2.3026	19.54
12	66	2.4849	26.56

n	n(n−1)/2	ln n	paths per nat
15	105	2.7081	38.77
20	190	2.9957	63.42
30	435	3.4012	127.90
50	1,225	3.9120	313.14
100	4,950	4.6052	1,074.88
150	11,175	5.0106	2,230.26

Read the last column as the price of a nat of surplus ceiling, denominated in communication paths. At `n = 6` a nat costs 8.37 paths; at `n = 150` it costs 2,230.26. **The price has risen by a factor of 266 while the thing purchased has risen by a factor of 2.8.**

8.5.3 5.3 The divergence, stated per added person

The marginal view is more severe than the total view and it is the one that should govern hiring. Adding one person to a group of `n` creates `n` new paths and raises the surplus ceiling by `ln(n+1) − ln n`:

n to n+1	new paths	gain in ln n	paths per nat of gain
3 to 4	3	0.28768	10.4
6 to 7	6	0.15415	38.9
10 to 11	10	0.09531	104.9
20 to 21	20	0.04879	409.9
50 to 51	50	0.01980	2,524.9
100 to 101	100	0.00995	10,049.9
150 to 151	150	0.00664	22,574.9

The marginal price of surplus rises quadratically in `n`, because the numerator grows like `n` and the denominator falls like `1/n`. From the fourth member to the hundred-and-fifty-first the price of an additional nat rises by a factor of two thousand. This is not a metaphor and not an approximation: `n(n−1)/2` is exactly quadratic under the modelling choice of Section 5.2 and `ln n` is exactly logarithmic, and any quadratic overtakes any logarithm at a point that depends only on `eta` and `kappa`.

8.5.4 5.4 The crossover

Question. For given `eta` and `kappa`, at what group size does coordination cost `C = kappa n(n−1)/2` exceed the entire structural budget `eta ln N`?

Take the most favourable case for growth, `N = n`, so that every person added brings a genuinely distinct category. This is the best case and it is almost never true; Section 5.6 handles the realistic case, in which the crossover arrives earlier and the optimum much earlier. Solve for the smallest integer `n >= 2` with `kappa n(n−1)/2 > eta ln n`:

kappa \ eta	0.10	0.20	0.30	0.50	0.80	1.00
0.0005	39	58	73	97	125	142
0.0010	27	39	49	66	85	97
0.0020	18	27	33	45	58	66
0.0050	11	16	20	27	35	39

kappa eta	0.10	0.20	0.30	0.50	0.80	1.00
0.0100	7	11	13	18	23	27
0.0200	5	7	9	12	16	18
0.0500	3	4	5	7	9	11
0.1000	2	3	4	5	6	7

`kappa` is the cost per active communication path per period, in the same normalised order-units as `Q`. The entry is the group size at which coordination alone consumes the entire structural budget — the size at which, even with zero maintenance draw and zero other cost, headroom has gone negative and no geometric remedy remains.

First: the crossover is an upper bound on viable size under complete-graph obligation, and it is a low number. For mid-range values `eta = 0.30` and `kappa = 0.010` the ceiling is thirteen people — not thirteen as a rule of thumb, but thirteen as an arithmetic consequence of two parameters.

Second: conversion buys size, and it buys it slowly. Along the `kappa = 0.010` row, a tenfold increase in `eta` from 0.10 to 1.00 moves the crossover from 7 to 27, a factor of 3.9 rather than 10. Setting `kappa n^2/2 ~ eta ln n` and ignoring the slowly varying logarithm gives `n ~ sqrt(eta/kappa)` up to a log factor, so **the crossover scales roughly as the square root of conversion.** Doubling `eta` buys about 41 per cent more headcount, not 100 per cent more.

Third: `kappa` buys size on the same square-root terms and is far easier to move. Down the `eta = 0.30` column, a hundredfold reduction in `kappa` from 0.10 to 0.001 moves the crossover from 4 to 49. And `kappa` is reducible by topology, by protocol, by asynchrony and by co-location, none of which requires changing anyone's capability. **The cheapest way to be allowed to be bigger is to make each link cheaper, not to make each person better.**

8.5.5 5.5 The crossover is not the optimum

The crossover answers *when does cost eat the whole budget*, which is the wrong question for sizing. The right question is what `n` maximises net structural gain. Maximise `net(n) = eta ln n − kappa n(n−1)/2`:

```
d/dn [ eta*ln n − kappa*(n^2 − n)/2 ]  =  eta/n − kappa*(2n − 1)/2  =  0

  =>   eta = kappa * n * (n − 1/2)   ~   kappa * n^2

  =>   n_opt  ~  sqrt( eta / kappa )
```

Design rule: the net-optimal group size under complete-graph obligation is approximately the square root of the ratio of conversion efficiency to per-link cost. Exact integer optima by direct search, with the net value in parentheses:

kappa eta	0.10	0.20	0.30	0.50	0.80	1.00
0.0005	14 (+0.218)	20 (+0.504)	25 (+0.816)	32 (+1.485)	40 (+2.561)	45 (+3.312)
0.0010	10 (+0.185)	14 (+0.437)	18 (+0.714)	23 (+1.315)	29 (+2.288)	32 (+2.970)
0.0020	7 (+0.153)	10 (+0.371)	13 (+0.613)	16 (+1.146)	20 (+2.017)	23 (+2.629)
0.0050	5 (+0.111)	7 (+0.284)	8 (+0.484)	10 (+0.926)	13 (+1.662)	14 (+2.184)
0.0100	3 (+0.080)	5 (+0.222)	6 (+0.388)	7 (+0.763)	9 (+1.398)	10 (+1.853)
0.0200	3 (+0.050)	3 (+0.160)	4 (+0.296)	5 (+0.605)	7 (+1.137)	7 (+1.526)
0.0500	2 (+0.019)	2 (+0.089)	3 (+0.180)	3 (+0.399)	4 (+0.809)	5 (+1.109)
0.1000	2 (-0.031)	2 (+0.039)	2 (+0.108)	3 (+0.249)	3 (+0.579)	3 (+0.799)

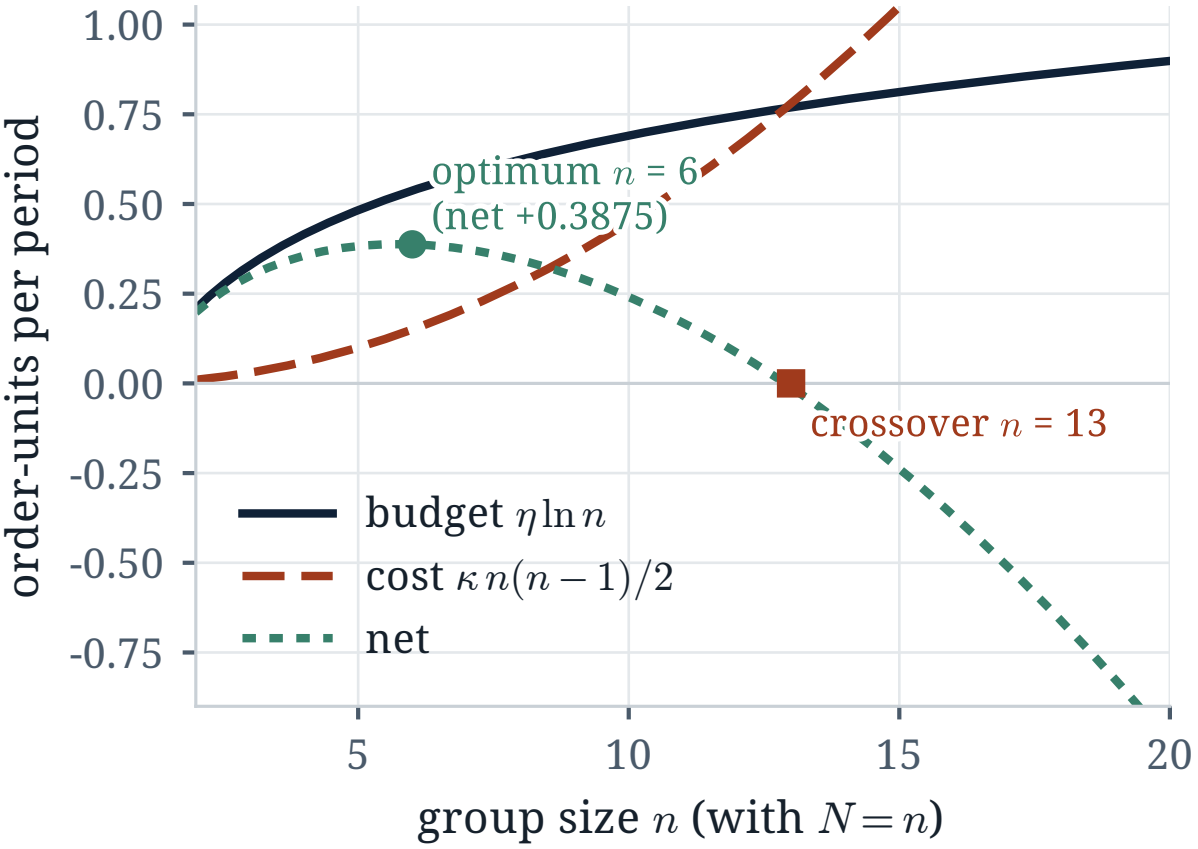

Figure 8.3: **The net optimum sits at six and the crossover at thirteen**, so the band in which every additional member reduces net output is more than twice the optimal size. Modelled from `net(n) = eta ln n − kappa n(n−1)/2` at the stipulated `eta = 0.30`, `kappa = 0.010`, `N = n`. Generated by `figs/src/CCP-008_fig03.py`.

The closed form tracks the search closely: at `eta = 0.30`, `kappa = 0.005`, `sqrt(0.30/0.005) = 7.7` against a searched optimum of 8; at `eta = 1.0`, `kappa = 0.001`, `sqrt(1000) = 31.6` against a searched optimum of 32.

Compare the two tables at a common cell. **At `eta = 0.30` and `kappa = 0.010` the optimum is 6 and the crossover is 13.** A team of thirteen is not at capacity; it is at twice its net-optimal size and delivering less than a team of six. Between 6 and 13 the group remains nominally viable — headroom may be positive — while every additional member reduces net structural output.

This gap is where most organisations live, and it is invisible without the calculation, because nothing breaks at the optimum. The failure is silent and gradual until the crossover, at which point it becomes sudden and is misdiagnosed as a leadership problem. That the failure is undetectable from inside is the point at which Sterman [1989]'s measured result — that people misjudge stocks with delays even under aligned incentives — stops being a curiosity and becomes the mechanism.

Note the bottom-left cell: at `eta = 0.10` and `kappa = 0.10` the optimum over `n >= 2` is `n = 2` and the net value is **negative**, against a net of exactly zero for `n = 1`. There exist parameter regimes in which no group of any size does better than nobody working together, because the per-link cost exceeds what any amount of difference can pay for. That is not a rhetorical flourish; it is what the arithmetic returns.

8.5.6 5.6 The realistic case: `N` saturates while `n` grows

The tables above assume `N = n`. Real groups exhaust their genuinely distinct categories quickly; beyond that point additional people add paths without adding `N`, and the effective-count audit shows `N_eff` flat while headcount climbs [Curzi, 2026c]. Model it as `N = min(n, D)` with `D` the number of genuinely distinct categories available, at `eta = 0.30`, `kappa = 0.010`:

`D`	surplus ceiling `eta ln D`	crossover `n*`	net-optimal `n`	net at optimum
3	0.3296	9	3	+0.2996
5	0.4828	11	5	+0.3828
8	0.6238	12	6	+0.3875
12	0.7455	13	6	+0.3875
20	0.8987	13	6	+0.3875

Look at the last three rows. Raising the available category count from 8 to 20 — a substantial and expensive achievement — moves the optimum not at all and moves the crossover from 12 to 13. Once the quadratic cost term binds, extra categories are irrelevant because the people who would carry them are unaffordable. The surplus side reaches the same conclusion independently and states it as: a headroom problem cannot be escaped by adding domains [Curzi, 2026c]. Here it appears from the cost side, and the two derivations do not share a premise.

Note also that when `D` is small the optimum sits exactly at `D`. **When categories are scarce, hire exactly as many people as there are categories and stop.** The eleventh person on a five-category problem is pure `kappa`.

8.5.7 5.7 Topology: the complete graph is a choice

Everything above assumed `P = n(n−1)/2`, every pair maintaining an active link. That is a choice, not a law, and it is the most expensive available choice. Path counts under five wiring plans, priced at `kappa = 0.006`:

`n`	complete	ring	star	tree	cells of 6 plus liaisons
6	0.0900	0.0360	0.0300	0.0300	0.0900
12	0.3960	0.0720	0.0660	0.0660	0.2040
18	0.9180	0.1080	0.1020	0.1020	0.3420
24	1.6560	0.1440	0.1380	0.1380	0.5040
30	2.6100	0.1800	0.1740	0.1740	0.6900
48	6.7680	0.2880	0.2820	0.2820	1.3920

The cells column assumes complete graphs of six within each cell plus liaison links between cells priced at four times a normal link, because a cross-boundary link genuinely is more expensive, requiring translation, context transfer and schedule reconciliation. **At `n = 48` the complete graph costs 6.7680 and the cellular topology 1.3920 — a factor of 4.86, purchased entirely by deciding who is not obliged to keep a live channel with whom.**

Topology is not free in the surplus term, and the honest treatment says so. The star and the tree are cheap because they route everything through a hub, and a hub drives `u` toward zero, because every message passes through a filter with a single viewpoint. Barabási and Albert [1999] shows that preferential attachment produces hubs spontaneously and Albert et al. [2000] shows such networks are robust to random failure and fragile to targeted attack — with Doyle et al. [2005] as the necessary corrective, since the real Internet's robustness

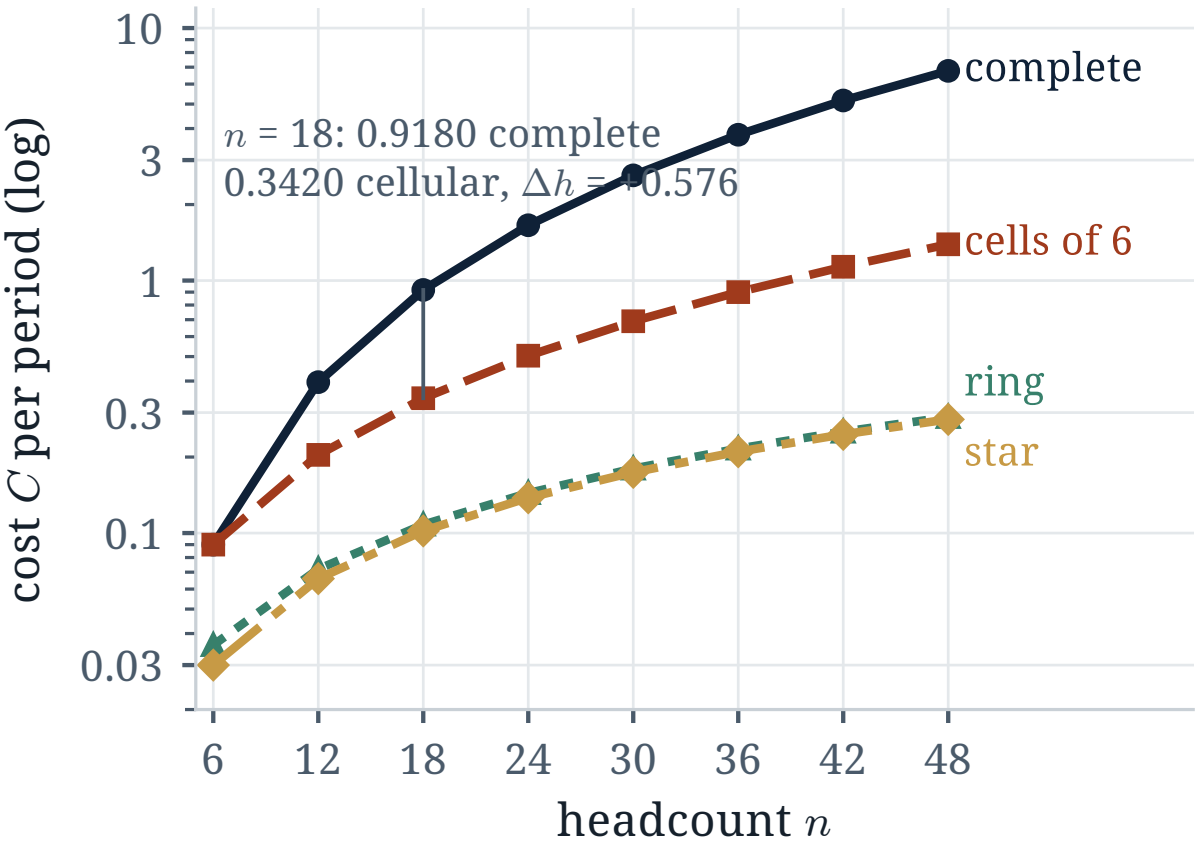

Figure 8.4: **Coordination cost under four wiring plans at `kappa = 0.006`**, on a logarithmic scale because the complete graph and the star differ by more than an order of magnitude at `n = 48` (6.7680 against 0.2820). Modelled; the per-link cost and the fourfold liaison multiplier are stipulated. Generated by `figs/src/CCP-008_fig04.py`.

comes from engineered design rather than from a degree distribution. **A star topology buys a cheap `C` at the price of `U` and of resilience. That is a real trade and must be priced rather than assumed away.**

The cellular arrangement is the one this paper recommends, and the recommendation converges from four independent directions: from cost, since cells cap the quadratic term at cell size and make total `C` linear in cell count; from the nested-enterprise principle observed in long-lived institutions [Ostrom, 1990, 2010]; from the semilattice argument that overlapping, non-exclusive groupings carry structure a strict tree destroys [Alexander, 1965]; and from complex contagion, since behaviour requiring reinforcement spreads along dense local ties rather than weak long ones [Centola and Macy, 2007, Centola, 2010]. **Four independent literatures arriving at one topology is the strongest agreement this paper can offer, and it is still not a proof.**

The concrete rule:

```
Keep complete-graph obligation inside cells of roughly n_opt = sqrt(eta/kappa).
Connect cells by explicit liaison links, budgeted at a higher kappa.
Let cell membership OVERLAP -- that is what makes it a semilattice rather than a tree.
Never route all inter-cell traffic through a single hub.
```

One caution the convergence does not remove. Buldyrev et al. [2010] show that coupled networks are far more fragile than either network alone, so cells joined by a thin set of liaison links are not simply a cheaper complete graph; they are a coupled system with its own failure mode. Perrow [1984] names the general condition — interactive complexity plus tight coupling makes catastrophic failure a system property — and Sagan [1993] documents settings in which redundancy *reduces* safety. Section 12 records that this paper prices the cost saving and does not price that fragility.

8.5.8 5.8 Queueing: slack as a cost-control device

Every shared resource is a queue: the approver, the reviewer, the one person who knows the deployment procedure, the single instrument. For an M/M/1 queue with utilisation `rho`, expected waiting time in queue measured in units of service time is `rho/(1 - rho)` [Erlang, 1909, Kingman, 1962]:

`rho`	wait, in service times	multiple of the wait at `rho = 0.5`
0.10	0.111	0.11
0.30	0.429	0.43
0.50	1.000	1.00
0.70	2.333	2.33
0.80	4.000	4.00
0.90	9.000	9.00
0.95	19.000	19.00
0.99	99.000	99.00

Between 90 and 99 per cent utilisation — an 11 per cent gain in apparent efficiency — the wait multiplies by eleven. Little's Law then gives that queue length multiplies by the same factor [Little, 1961], so work in progress balloons, which raises context-switching cost (C9) and coordination cost (C1) simultaneously. Hopp and Spearman [2011] is the standard treatment.

Therefore waiting is a `C` term, and driving utilisation toward one converts idle capacity — which costs nothing in the law — into waiting, which costs a great deal. Slack is not waste; it is the instrument that keeps the queueing term out of `C`. If waiting costs `kappa_delay` per unit of service time waited, the delay contribution is `kappa_delay rho/(1-rho)` per item. At `kappa_delay = 0.02`:

```
rho = 0.50  ->  0.0200 per item        rho = 0.90  ->  0.1800
rho = 0.70  ->  0.0467                 rho = 0.95  ->  0.3800
rho = 0.80  ->  0.0800                 rho = 0.99  ->  1.9800
```

Against a structural budget of order 0.4 to 0.5, typical of the worked cases below, **a single resource at 99 per cent utilisation can exceed the entire budget by itself. A named individual who is the sole route to a necessary approval, running at near-full load, is a sustainability-ceiling violation wearing the costume of a productivity success.** This is Ashby [1956]'s requisite variety in a different costume: only variety absorbs variety, and a fully loaded server has none left to absorb anything.

8.5.9 5.9 Estimating `kappa`

Step 1 — define an active link. Two people constitute an active link in a period if maintaining mutual awareness of each other's work required time in that period. Not *could have talked* — did have to.

Step 2 — count them. For small groups, ask. For larger ones, sample: take ten people at random, ask each how many colleagues they had to stay synchronised with this period, and estimate the total as `n x mean / 2`. **The instrument is a self-report survey and inherits every known exposure of one: question wording and focusing effects move the answers [Schwarz, 1999, Kahneman et al., 2006], and the estimate should carry an interval rather than a point.**

Step 3 — price them. Estimate hours per period spent on synchronisation, divide by the link count, and convert into the same normalised order-units as `Q`. **The unit conversion is the delicate step and it is where estimates go wrong: `kappa`, `eta` and `Q` must all be in one consistent system or the crossover tables are meaningless.** Section 11.1 states the dimensional requirement exactly.

Step 4 — check the exponent, and do not check it by regressing logs on logs. If `C` can be observed at several group sizes in comparable conditions, the question is whether the growth is nearer quadratic than linear. **The source manuscript prescribes regressing `log C` on `log n` and reading the slope. That is precisely the procedure Clauset et al. [2009] shows to be unreliable, and the objection is not confined to power laws in the tail: a straight line on a log-log plot is weak evidence for the exponent that generated it, and Stumpf and Porter [2012] shows many mechanisms produce indistinguishable curves.** The defensible version compares the quadratic and linear models by likelihood on held-out data with an information criterion, states the number of free parameters, and reports the comparison rather than a slope. **This paper does not run that comparison, because it fits nothing; it records the requirement in Section 11.7 and in Section 12.**

A cross-check requiring no instrumentation is the raw meeting arithmetic:

`n`	90-minute weekly meeting	person-hours per year (46 weeks)	paths
4	6.0 person-hours/wk	276	6
6	9.0	414	15
8	12.0	552	28
12	18.0	828	66
20	30.0	1,380	190
30	45.0	2,070	435

A thirty-person weekly standing meeting consumes 2,070 person-hours a year — more than a full-time post — to service 435 pairwise relationships of which any given attendee is party to 29. **The all-hands is a device for paying complete-graph cost while delivering star-topology information flow.** It is the worst of both wiring plans and it is the default.

8.5.10 5.10 The share of budget consumed by C

The approach to the crossover is where decisions actually get made. With `eta = 0.22`, `kappa = 0.006`, `N = n`:

n	eta ln n	C	C as multiple of budget
3	0.2417	0.0180	0.07
6	0.3942	0.0900	0.23
8	0.4575	0.1680	0.37
10	0.5066	0.2700	0.53
12	0.5467	0.3960	0.72
15	0.5958	0.6300	1.06
20	0.6591	1.1400	1.73
30	0.7483	2.6100	3.49
50	0.8606	7.3500	8.54
100	1.0131	29.7000	29.31
150	1.1023	67.0500	60.83

At `n = 150` coordination costs sixty-one times the entire structural budget. **A figure of 150 is widely quoted as a cognitive limit on stable relationships; no entry in this paper's bibliography supports it, this paper neither endorses nor relies on it, and nothing below depends on it.** What the arithmetic does say is that whatever any cognitive limit may be, **the economic limit under complete-graph obligation arrives around `n = 15` for these parameters, an order of magnitude sooner.** The reason human groups of 150 exist at all is that they never run a complete graph: they run cells, kin structures and role hierarchies — topologies, in the sense of Section 5.7.

8.5.11 5.11 When cost grows with stored order

Several `C` lines are not constant but scale with accumulated stored order. Compliance reporting grows with the number of rules to comply with; maintenance of built artefacts grows with the artefact count; archive management grows with the archive. Model it as `C_t = C_0 + gamma Q_t` and substitute:

```
Q_{t+1} = (1 − delta)∗Q_t + eta∗S_t − C_0 − gamma∗Q_t
        = (1 − (delta + gamma))∗Q_t + eta∗S_t − C_0
```

A cost that scales with stored order is arithmetically indistinguishable from a higher decay rate. The system behaves exactly as if `delta_eff = delta + gamma`, so every result of the retention analysis transfers with that substitution [Curzi, 2026a]: the time constant shortens to `1/(delta+gamma)`, the steady state falls to `(eta S − C_0)/(delta+gamma)`, and the uniform bound tightens.

Two practical consequences. **First, a `Q`-scaling cost line makes an organisation look forgetful when it is overburdened.** The symptom is identical — stored order decaying faster than expected — and the remedy is not: raising retention will not touch `gamma`. **Second, `gamma` is exactly the term that makes shedding `Q` a double win**, because reducing `Q` reduces both the `delta Q` maintenance draw and the `gamma Q` cost line at once.

8.5.12 5.12 The sustainability ceiling, stated hard

```
If   C_t  >  eta ∗ ln N  −  delta ∗ Q_t
then NO arrangement of people prevents decline.
```

Not *decline is likely*. Not *decline unless we work harder*. The inequality forecloses the entire space of geometric interventions, because `ln N` is the hard ceiling on `F(u)` and `eta ln N` is therefore the largest input the interaction channel can deliver in one period. **Every off-site, every reorganisation, every new collaboration model, and every leadership change operates strictly inside the space of interventions that this corollary has already ruled out.**

There are exactly four responses and they exhaust the space: reduce `C_t`; raise `eta`; raise `N` logarithmically, therefore weakly, and only with genuinely distinct categories; and reduce `Q_t`. The completeness of this set is established formally elsewhere in the corpus, where the steady state is shown to depend on exactly `u`, `N`, `eta` and `c` through `F`, plus `delta` as a divisor, with no fifth argument [Curzi, 2026].

Note which response is *not* on the list: raising `u`. Raising `u` increases `S_t` toward its ceiling `ln N`, which helps — but the ceiling condition is stated *at* the ceiling. **If cost exceeds the budget even when `S` is maximal, improving the geometry cannot close the gap.** The geometry work of Curzi [2026d] and Curzi [2026g] is essential, and it is work done when `h > 0`, not instead of the arithmetic.

8.5.13 5.13 Cutting cost badly

Every `C` line is attached to something. Cut C3 and `delta` rises on trust. Cut C6 and interaction rate falls, lowering `S`. Cut C1 indiscriminately and the channel through which reach operates is cut, lowering `eta`. Cut slack and the queueing term explodes. **A `C` cut that raises `delta` or lowers `eta` can easily be net negative, and the arithmetic is available to check before the cut rather than after.**

The rule: **for every proposed reduction, state which term it might damage and by how much, then compute the net effect on `h`.** A cut of 0.06 in `C` that costs 0.02 in `eta` at `ln N = 2.08` is a net loss of `0.02 x 2.08 − 0.06 = −0.0016`. That calculation takes a minute and is almost never performed.

The lines usually safe to cut are in C2 — friction — because friction by construction produces nothing. **Attack friction first, coordination second, everything else only with a computed net effect.**

8.6 6 Headroom: the master gauge

```
h_t := eta * ln N  −  delta * Q_t  −  C_t

    h_t < 0    unsustainable in this model. No geometry saves it.
    h_t = 0    maintenance only. Hold, do not build.
    h_t > 0    growth available; any requested increment must satisfy r_t <= h_t.
```

The maximum one-step increment is exactly `r_max = h_t`, and no policy based on interaction geometry alone can guarantee more. The target-increment condition is that `Q_{t+1} − Q_t >= r_t` holds if and only if `S_t >= (delta Q_t + C_t + r_t)/eta`, feasible only if `delta Q_t + C_t + r_t <= eta ln N`.

Headroom is not a new quantity. It is the sustainability ceiling rearranged into a gauge: `C_t <= eta ln N − delta Q_t` becomes `h_t >= 0`. **Its value is that it puts three parameters usually argued about separately onto one dial with one reading and one sign.** Read as an accounting statement:

```
   eta * ln N        the structural BUDGET     -- the most this system can convert in a period
 − delta * Q_t       the MAINTENANCE DRAW      -- what must be spent to keep what exists
 − C_t               the OPERATING DRAW        -- what is spent to be an organisation at all
 ------------------
 = h_t               HEADROOM                  -- what is left to build with
```

Proven: the definition and the three-regime reading follow from the sustainability ceiling and the maximum-increment corollary together with the range result `0 <= F(u) <= ln N`, which is what makes `eta ln N` an actual ceiling rather than a typical value [Curzi, 2026a]. **Postulated, badged:** that `eta`, `delta`, `N` and `C` are approximately constant over the horizon on which the gauge is read; that the order proxy stands in a stable relation to `Q`; and that the linear model is the right model at all. None of these is a theorem, and a headroom figure is only as good as the four measurements behind it. The gauge is reused as a precondition on protocol design elsewhere in the corpus, where `h < 0` forbids building and `h > 0` caps every increment at `r <= h`, worked at `N = 18`, `eta = 0.30`, `delta = 0.06`, `C = 0.55`, `Q = 1.20` giving `h = +0.2451` [Curzi, 2026].

8.6.1 6.1 Why the ceiling term is `ln N` and not `F(u)`

Headroom uses `eta ln N`, not `eta F(U_t)`, and the difference is deliberate. `F(U_t)` is what the system's *current* geometry delivers this period; `ln N` is the most any geometry could deliver, attained only at perfect orthogonality.

Headroom is therefore a statement about the best case, and a negative headroom is a statement that even the best case fails. When `h_t < 0` the reading is not that the current arrangement is inadequate; it is that the entire space of arrangements is inadequate, and no facilitator, retreat, restructure or hire inside that space can help. This is the strongest negative result the framework contains and it is strong precisely because it is stated at the ceiling.

The corollary is that **`h_t > 0` is necessary and not sufficient.** Positive headroom says growth is *permitted*; whether it *occurs* depends on `F(U_t)`, which is the subject of the geometry papers. The gauge licenses; the geometry delivers.

8.6.2 6.2 The three regimes

Regime 1, `h_t < 0`: unsustainable. `Q` will decline this period whatever is done. Exactly four things are available and they exhaust the space:

```
1. raise eta      effect = ln N per unit        usually cheapest
2. raise N        effect = eta/N per unit       logarithmic, therefore weak
3. cut C          effect = 1 per unit           direct
4. shed Q         effect = delta per unit       the one nobody considers
```

What not to do. Do not commission a workshop, a reorganisation, an engagement programme or a leadership change *as the response to negative headroom.* Each operates on `F(U_t)`, and `F(U_t) <= ln N` already, so the ceiling condition has ruled them out. They may be excellent things to do once `h > 0`. They cannot rescue `h < 0`. The correct report is: *headroom is negative at the stated figure; under this model no arrangement of these people prevents decline this period; the available moves are to reduce cost, raise conversion, or shed stored order; here is the arithmetic.* That sentence is worth more than any amount of strategy because it is checkable.

Regime 2, `h_t = 0`: maintenance only. The budget exactly covers the two draws. Hold, refuse new commitments, and protect the maintenance draw absolutely, because at `h = 0` any increase in `C` — one new reporting requirement, one new standing meeting — puts the system into Regime 1 immediately. **The characteristic error at `h = 0` is to read stability as slack.** A system holding steady at zero headroom looks calm from outside and has no reserve at all.

Regime 3, `h_t > 0`: growth available. Choose `r_t <= h_t`, then verify the geometry can deliver the required `S_t`. Worked at `eta = 0.25`, `N = 8`, `delta = 0.08`, `Q_t = 3.0`, `C_t = 0.10`:

```
h_t = 0.25*2.0794 - 0.08*3.0 - 0.10 = 0.5199 - 0.2400 - 0.1000 = +0.1799

request r_t  = 0.15                          (inside headroom)
required S_t = (0.2400 + 0.1000 + 0.1500)/0.25 = 1.9600 nats
```

```
ceiling      = ln 8 = 2.0794
required u   = (e^1.96 - 1)/7 = (7.0993 - 1)/7 = 0.8713
```

Feasible, and only just: it requires `u = 0.871`, which is a very high degree of non-parallelism and is not achievable by asking people to disagree more. The headroom said yes; the feasibility clause said *yes, at a geometry you almost certainly do not have*. Requesting `r_t = 0.05` instead requires `S_t = 1.56` and `u = 0.537`, which is attainable. **Always run the feasibility clause after the headroom check.** The gauge alone will license promises the geometry cannot pay for.

A concavity correction to the feasibility clause. The check above computes a single required `u` as though `U` were the same every period. It never is, and the error is one-sided. What accumulates is the sum of `eta F(U_t)`, so the quantity to test is the **mean of `F(U_t)`, not `F` of the mean `U`** — and because `F` is strictly concave, Jensen's inequality runs against the analyst:

```
mean of F(U_t)  <=  F( mean of U_t )        equality only if U is constant
```

At `N = 8` with sessions alternating between `u = 0.75` and `u = 0.30`, mean `U` is 0.525 and `F(mean U) = 1.5422`, but mean `F` is 1.4820 — a concavity penalty of 0.0602 nats, **3.9 per cent of the surplus lost to variability alone. Report the required `u` for legibility if desired; never test against it.** State the requirement as `mean F(U_t) >= S_req` and compare it to the measured mean of `F`. Testing on `F` of the mean certifies increments the geometry cannot deliver, and the penalty it hides is recoverable for free by regularising a variable geometry.

8.6.3 6.3 Why headroom falls as stored order grows

One line of algebra:

```
h_t = eta*ln N - delta*Q_t - C_t          =>          d h_t / d Q_t  =  -delta
```

Headroom decreases linearly in stored order at rate `delta`. Every unit of durable structure a system acquires permanently reduces, by `delta` per period, the amount it can build next.

This is the structural reason institutions ossify and it deserves to be stated without moral vocabulary. **Ossification is not complacency, not cowardice, not bureaucratic capture, and not a failure of leadership. It is `dh/dQ = -delta`.** An institution that succeeds accumulates `Q`; accumulated `Q` demands maintenance at `delta Q`; maintenance consumes the budget; the budget was the capacity to build. **Success consumes its own headroom, by construction, in the absence of any error by anyone.** March [1991] reaches the same destination from a different direction — an organisation whose members learn too fast homogenises and destroys the variance that produced its advantage — and Levinthal and March [1993] names the myopia that follows.

At `eta = 0.25`, `N = 8` so budget 0.5199, `delta = 0.08`, `C = 0.10`:

`Q`	maintenance draw `delta Q`	`h = 0.5199 - delta Q - 0.10`
0	0.0000	+0.4199
1	0.0800	+0.3399
2	0.1600	+0.2599
3	0.2400	+0.1799
4	0.3200	+0.0999
5	0.4000	+0.0199
6	0.4800	-0.0601
8	0.6400	-0.2201
10	0.8000	-0.3801

Q	maintenance draw	delta Q h = 0.5199 − delta Q − 0.10
15	1.2000	-0.7801
20	1.6000	-1.1801

At Q = 0 this system can build freely. At Q = 5 it has 0.0199 and is a maintenance organisation. At Q = 6 it is in decline. **Nothing changed except that it succeeded five times.** The advantage of a young institution is now arithmetic rather than folklore: a new entrant outbuilds an incumbent with more money and more people because the entrant's delta Q is near zero and the incumbent's consumes its entire budget. **The incumbent is not slower; it is spending its budget on being what it already is.**

8.6.4 6.4 The critical stock

Setting h_t = 0 and solving for Q:

```
Q_crit  =  ( eta*ln N  −  C )  /  delta
```

Q_crit is the largest stock of order a system can hold without going into decline. It is a hard capacity computable from four measured numbers and it belongs on the front page of any survey. With eta = 0.25 and N = 8, so eta ln N = 0.5199:

delta C	0.00	0.05	0.10	0.20	0.40
0.01	51.99	46.99	41.99	31.99	11.99
0.02	25.99	23.49	20.99	15.99	5.99
0.05	10.40	9.40	8.40	6.40	2.40
0.10	5.20	4.70	4.20	3.20	1.20
0.20	2.60	2.35	2.10	1.60	0.60
0.30	1.73	1.57	1.40	1.07	0.40

First, Q_crit scales as 1/delta, so retention is the dominant term in institutional capacity. Moving delta from 0.10 to 0.02 takes capacity from 4.20 to 20.99 at C = 0.10, a factor of five from retention alone. **Institutions that hold the most stored order are not those with the most input; they are those with the lowest delta.**

Second, C bites hardest when delta is small. At delta = 0.30, raising C from 0 to 0.40 costs 1.33 units of capacity; at delta = 0.01 the same increase costs 40 units. **The better the retention, the more damaging the overhead**, because a low delta divides eta ln N − C by a small number and amplifies every change in C.

8.6.5 6.5 The maintenance trap

A system near Q_crit exhibits full activity and high effort; output that is entirely replacement rather than addition; rising frustration among people who joined to build and find themselves maintaining; every new initiative displacing an existing one; and leadership attributing the stall to insufficient ambition, focus or talent.

The last item is the trap. **Every symptom of the maintenance trap is also a symptom of a motivation problem, and the two require opposite responses.** Exhortation applied to a headroom problem raises C — more meetings, more reporting, more alignment work — and therefore lowers h, worsening exactly the condition it was meant to fix. The distinguishing test is arithmetic and takes an afternoon: compute delta Q_t and compare it to eta ln N. **If the maintenance draw exceeds half the budget, the diagnosis is structural and no amount of motivation is relevant.**

8.6.6 6.6 The fixed-point identity

At the steady state with constant `U = u*` and `C = c*`:

```
Q_inf = ( eta*F(u*) − c* ) / delta

h_inf = eta*ln N − delta*Q_inf − c*
      = eta*ln N − ( eta*F(u*) − c* ) − c*
      = eta*ln N − eta*F(u*)

h_inf = eta * ( ln N − F(u*) )
```

At the fixed point, headroom equals the conversion efficiency times the geometric shortfall. `delta` cancels, `C` cancels, `Q` cancels. The only surviving quantities are `eta` and the gap between what the geometry delivers and what the category count would permit. Verified numerically across four unrelated parameter sets:

eta	N	u*	delta	C	S = F(u*)	Q_inf	h_inf computed	eta(ln N − S)
0.25	8	0.60	0.080	0.10	1.6487	3.9021	+0.107696	+0.107696
0.18	12	0.45	0.060	0.22	1.7834	1.6835	+0.126273	+0.126273
0.20	14	0.50	0.045	0.08	2.0149	7.1773	+0.124831	+0.124831
0.40	20	0.90	0.030	0.30	2.8959	28.6122	+0.039928	+0.039928

Identical to six decimal places, as the algebra requires.

What this means is the most uncomfortable result in the paper. The only headroom a mature system possesses is exactly the surplus it is failing to extract from its own difference. Watch it vanish as the geometry improves, at `eta = 0.25`, `N = 8`:

u*	S = F(u*)	h_inf = eta(ln N − S)
0.20	0.8755	0.300993
0.40	1.3350	0.186110
0.60	1.6487	0.107696
0.80	1.8871	0.048093
0.90	1.9879	0.022892
0.95	2.0347	0.011184
0.99	2.0707	0.002197
1.00	2.0794	0.000000

A system that has arrived at its fixed point and perfectly exploits its own diversity has zero headroom. At `u = 1` the surplus is at ceiling, `Q_inf` is at its maximum `eta ln N / delta` — which is the uniform bound arrived at from a different direction — and there is nothing left over. This is not a paradox and not a criticism of difference; it is the statement that a fully converged system has converged, having spent its capacity on becoming what it is. Banach [1922] guarantees the arrival and nothing guarantees the destination is liked.

The same zero arrives from a completely different direction elsewhere in the corpus. At the calibration fixed point where doctrine exactly matches evidence, the input sits at its ceiling and headroom is identically zero by cancellation, `h = eta ln N − (eta ln N − C) − C = 0`, **so perfect calibration is not an unqualified target** [Curzi, 2026r]. Undistorted contact maximises what is banked and leaves nothing to build with.

The design consequence: **to retain headroom at maturity a system must either hold `eta` high, refuse to converge, or periodically leave the fixed point by reducing `Q`.**

8.6.7 6.7 The linear model does not ossify by itself

An honest complication the previous section forces. If `h_inf = eta(ln N − F(u*)) >= 0` always — and it does, since `F(u) <= ln N` — then a system running the plain storage law with constant parameters **never reaches negative headroom.** It approaches its fixed point and sits there with a small positive `h`. At `eta = 0.25`, `N = 8`, `u = 0.60`, `delta = 0.08`, `C = 0.10`, `Q_0 = 0`:

t	Q_t	h_t
0	0.0000	+0.4199
2	0.5994	+0.3719
5	1.3303	+0.3134
10	2.2070	+0.2433
15	2.7849	+0.1971
20	3.1658	+0.1666
30	3.5822	+0.1333
40	3.7631	+0.1188

Headroom falls monotonically from 0.4199 toward its limit 0.107696 and stops. It never crosses zero.

Therefore observed institutional ossification — real organisations that genuinely cannot build anything — requires something outside the constant-parameter linear model. It is not automatic, and this paper does not pretend it is. Three candidate mechanisms, each with a different remedy:

Mechanism A — cost that scales with stored order. `C_t = C_0 + gamma Q_t`, arithmetically identical to a higher decay rate. **It does not by itself produce negative headroom**, because the fixed-point identity survives the substitution:

```
Q_inf = (eta*S − C_0)/(delta + gamma)
h_inf = eta*ln N − delta*Q_inf − C_0 − gamma*Q_inf
      = eta*ln N − (delta + gamma)*Q_inf − C_0
      = eta*ln N − (eta*S − C_0) − C_0  =  eta*(ln N − S)
```

Identical. A linear `Q`-scaling cost does not cause ossification; it only makes the system converge to a smaller `Q` faster. This eliminates the most popular explanation, and it is a result worth stating because it is easy to assume the opposite.

Mechanism B — exogenous accretion. `Q` arriving through a channel that is not `eta S`: inherited mandates, merged organisations, statutory obligations, standards adopted by external bodies that must now be upheld. Model it as a constant `A` added each period:

```
Q_{t+1} = (1−delta)*Q_t + eta*S − C_t + A
h_inf   = eta*(ln N − S)  −  A
```

This does go negative, and it goes negative when `A > eta(ln N − F(u*))`. Exogenous stored order accumulates without paying for its own maintenance, and headroom is what it consumes.

Mechanism C — declining conversion or non-parallelism with age. Cohesion rising over time drives `u` toward zero; informational cascades collapse the effective count in a group that started diverse [Bikhchandani et al., 1992, Banerjee, 1992, Lorenz et al., 2011]; capture ceremonies displace real capture. Any of these lowers `eta S` while `Q` stays high. The decay of `u` as a state variable in its own right, with a measured half-life, is developed in Curzi [2026d].

Of the three, Mechanism B is the one most often mistaken for laziness and the one most amenable to a direct fix, and the third worked system of Section 9 is built on it.

8.6.8 6.8 The four levers, priced

Marginal derivatives of `h`:

```
d h / d eta  =  ln N          raising conversion is worth ln N per unit
d h / d N    =  eta / N       raising categories is worth eta/N per unit -- and falls with N
d h / d C    =  −1            cutting cost is worth exactly 1 per unit
d h / d Q    =  −delta        shedding order is worth delta per unit
```

Worked at `eta = 0.25`, `N = 8`, `delta = 0.08`, `Q = 5`, `C = 0.10`. Baseline `h = 0.5199 − 0.4000 − 0.1000 = +0.0199`, a classic maintenance-trap state.

Lever	Move	New `h`	Gain	What it costs in practice
L1 raise `eta`	0.25 to 0.35	+0.2278	+0.2079	a decision log and a recorder rota
L2 raise `N`	8 to 12	+0.1212	+0.1014	four genuinely new disciplines recruited
L2b raise `N`	8 to 16	+0.1931	+0.1733	doubling the discipline count
L3 cut `C`	0.10 to 0.04	+0.0799	+0.0600	a 60 per cent cut in overhead
L4 shed `Q`	5.0 to 3.0	+0.1799	+0.1600	retire two units of stored order
L4b shed `Q`	5.0 to 2.0	+0.2599	+0.2400	retire three units

Shedding three units of stored order outperforms every other move on the table, including a 40 per cent improvement in conversion efficiency. It is also the only move on the list requiring no new capability, no recruitment, no budget, and no negotiation outside the organisation.

The exchange rate between shedding and the other levers is exact. To buy headroom increment `dh` by shedding, shed `dQ = dh/delta`:

`delta` \ `dh`	0.02	0.05	0.10	0.20	0.50
0.02	1.00	2.50	5.00	10.00	25.00
0.05	0.40	1.00	2.00	4.00	10.00
0.08	0.25	0.62	1.25	2.50	6.25
0.10	0.20	0.50	1.00	2.00	5.00
0.20	0.10	0.25	0.50	1.00	2.50
0.30	0.07	0.17	0.33	0.67	1.67

Shedding is cheapest when `delta` is high. A high-maintenance system gets a large headroom return for a small reduction in stock; a system that has invested heavily in permanence must shed a great deal to recover a little. **Durability and adaptability trade against each other**

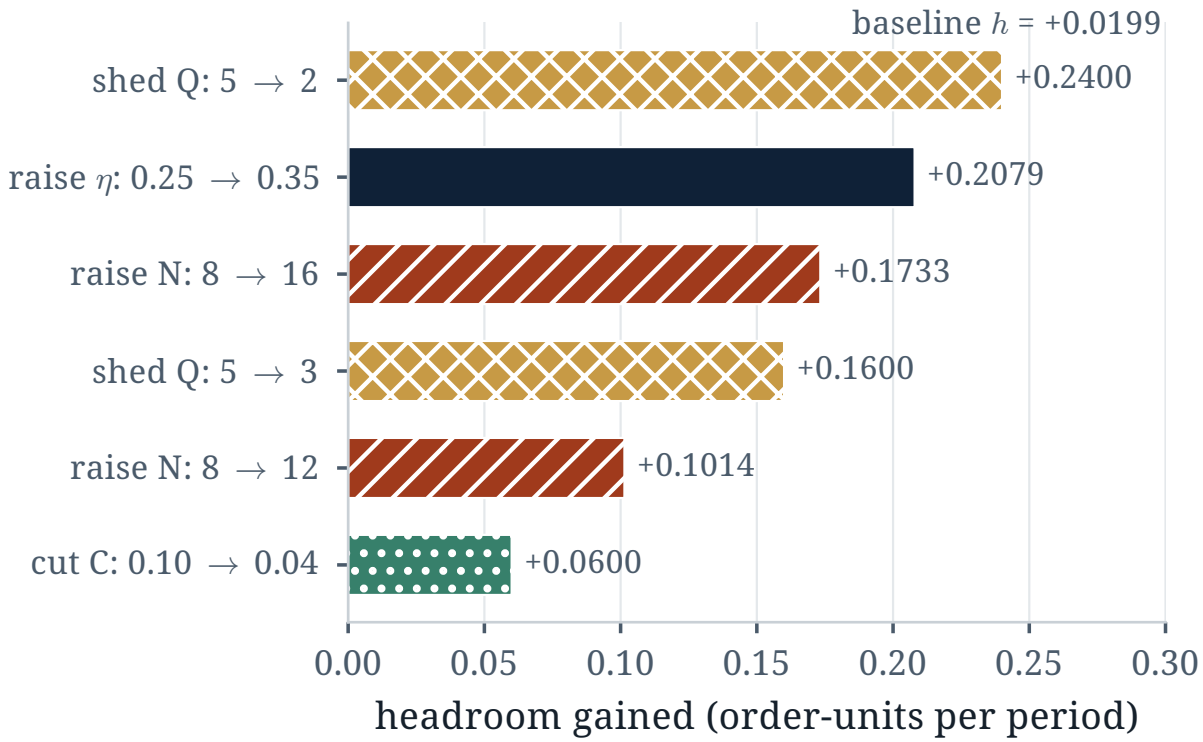

Figure 8.5: **Shedding stored order outperforms every other lever at this base case**, including a 40 per cent rise in conversion; the baseline headroom is +0.0199. Modelled at the stipulated `eta = 0.25`, `N = 8`, `delta = 0.08`, `Q = 5`, `C = 0.10`; colour encodes which of the four parameters is moved. Generated by `figs/src/CCP-008_fig05.py`.

exactly, and the exchange rate is `1/delta`. That is the honest form of the intuition that solid institutions are hard to change: it is not a moral fact about institutions, it is `dh/dQ = -delta`.

And against `N`, at `eta = 0.25`, `delta = 0.08`:

`N` change	headroom gained	equivalent `Q` to shed
8 to 10	+0.0558	0.697
8 to 12	+0.1014	1.267
8 to 16	+0.1733	2.166
8 to 32	+0.3466	4.332
8 to 64	+0.5199	6.498

Retiring 2.166 units of obsolete stored order is worth exactly as much as doubling the number of genuinely distinct disciplines in the organisation. One of those is a decision; the other is a decade. The corresponding computation on the other side of the ledger is worked in Curzi [2026j], where the `N` lever is computed and declined on net: a ceiling gain of `eta(ln 6 - ln 5) = +0.1914` against five added communication paths costing `+0.0714`, a 34 per cent haircut on the headline benefit.

8.6.9 6.9 The fourth lever: deliberately shedding stored order

6.9.1 Why it is invisible

One: `Q` is not measured, so it cannot be reduced. Most organisations have no order observable at all, and a quantity that is not tracked cannot be decided about.

Two: `Q` is confused with achievement. Stored order is the accumulated record of past success, and reducing it reads as undoing that success. The law is indifferent to how `Q` was acquired. **A procedure that was excellent fifteen years ago and is now upheld out of habit costs exactly the same `delta Q` as one that is excellent today.** The maintenance draw does not inspect provenance.

Three: shedding has an identifiable victim and an unidentifiable beneficiary. The person whose procedure is retired is specific and present; the headroom released is diffuse and future. That is a political asymmetry, not an arithmetic one, and it is why shedding must be scheduled in advance rather than negotiated in the moment.

Four: working infrastructure is invisible. Star and Ruhleder [1996] and Star and Griesemer [1989]: infrastructure becomes visible only on breakdown, so working stored order never appears on a list of things that could be removed, while its maintenance cost is paid silently every period. The countermeasure is an inventory listing what exists rather than what is broken.

6.9.2 What can be shed and what cannot

Freely sheddable. Procedures whose triggering condition no longer occurs. Reports nobody reads, measurable directly by access logs. Approval gates with a rejection rate near zero, since a gate that never rejects is pure `C` and pure `delta Q` and performs no filtering function. Superseded documentation retained for reference. Committees whose founding question was answered. Tooling with no active users. Metrics captured by the measure-becomes-target failure and no longer measuring what they name [Goodhart, 1975, Campbell, 1979].

Conditionally sheddable, with a stated replacement. Redundant capability: redundancy is `Q` that buys resilience, which is real, and it should be shed only after computing which failure mode is being re-exposed — Albert et al. [2000] is the relevant caution, since robustness to random failure and fragility to targeted attack are different properties and shedding redundancy affects them differently, while Sagan [1993] documents settings in which redundancy reduces safety and Perrow [1984] explains why. Institutional memory of past failures: genuinely valuable and genuinely costly, and the specified form is to **shed the procedure and keep the one-line reason**, because a rule with its rationale attached can be re-derived cheaply and a rule without one must be maintained forever because nobody dares remove it. Standards commitments to external parties, which require negotiation rather than decision.

Not sheddable under any headroom pressure. Anything constituting a person's ability to decline participation. A consent provision, a right of appeal, a dissent protection or a minority-report requirement is stored order that shows up in the `delta Q` draw, and **it is not available for shedding regardless of what the arithmetic says.** Safety interlocks whose failure mode is injury. Obligations to parties not represented in the decision to shed.

This is the one place in this paper where a lever with a computed positive return is declared out of bounds. It is declared out of bounds anyway, and the model gives no warning at that boundary — the computed return is genuinely positive, which is exactly why the constraint must sit outside the model.

6.9.3 How to shed: schedule it in advance

Shedding negotiated in the moment fails, because the identifiable-victim asymmetry makes every individual case losable. **Shedding works when it is scheduled at the moment of creation, before anyone is attached.** The devices: sunset clauses, so that renewal requires an argument and continuation does not require a decision to end it; reversal conditions, so that a decision whose reversal condition has been met and which still stands is a shedding candidate identified by the system itself; term limits on roles and committees; review dates whose **default is removal**, since a review whose default is retention is a formality; planned demolition, on the argument that a city which never demolishes anything has no site available for anything new [Jacobs, 1961]; and scheduled forgetting, which is the deliberate form of the decay that the

retention analysis spent its length trying to reduce [Curzi, 2026a]. The two are not in conflict: **control the leak so that what drains can be chosen.**

6.9.4 The double return when cost scales with stock

Where `C_t = C_0 + gamma Q_t`, shedding attacks two terms at once, `dh/dQ = −(delta + gamma)`, so the shed required to buy headroom `dh` is `dQ = dh/(delta + gamma)`, which is smaller. **In any institution whose compliance, reporting or maintenance burden scales with what it has accumulated — which is most large institutions — shedding is strictly more efficient than the table of Section 6.8 suggests.**

6.9.5 What shedding does not do

Shedding raises `h` and does not raise `Q_inf`. It moves the system away from its fixed point, and the contraction guarantees a return: the system re-accumulates toward `(eta S − C_0)/(delta + gamma)` at time constant `1/(delta+gamma)`. **Shedding buys a window, not a new equilibrium.** The window is genuinely valuable — it is the period during which `h` is large enough to build something structurally different — but a shedding programme not paired with a use for the released headroom simply regrows the same stock. The correct sequencing:

```
1. shed Q          -> h rises, window opens
2. spend h on eta  -> the permanent lever (dh/d eta = ln N)
3. re-accumulate at the higher eta -> a higher Q_inf and a higher h_inf
```

Shedding is a transient. Raising conversion is permanent. Use the transient to buy the permanent.

8.6.10 6.10 Measuring headroom in practice

The minimum viable reading, achievable in about two weeks in most organisations: enumerate `N` by listing genuinely distinct methodological or domain categories rather than job titles, expecting the audited count to be roughly half the number first proposed [Curzi, 2026c]; count `Q` crudely, since the *sign* of `h` is usually robust to a factor of two in `Q` and the sign is what governs the decision; estimate `delta` from the last period of genuine inactivity; tally `C` by the nine lines of Section 5.1; estimate `eta` from the last six months of attributable durable change divided by computed `S`; and compute `h`, `Q_crit` and `h_inf = eta(ln N − S)`.

Report the sign before the magnitude. The sign determines which of the four levers may be reached for; the magnitude only determines how much may be requested. **And report the sensitivity** — how much `Q` would have to be wrong for the sign to flip. If `h = +0.02` and a five per cent error in `Q` flips it, say so.

A cheaper route to the direction, and it is an identity rather than an approximation. Holding `eta`, `N`, `delta` and `Q` fixed across the configurations being compared, `h(x) = eta ln N − delta Q − C(x)` depends on the configuration only through `C`, so

```
grad h = −grad C
```

Measuring where a system's own choices already go and measuring the gradient of headroom are the same measurement, in the same direction, with the same zeros. A cheap habit survey therefore locates the direction of steepest improvement without the full instrument. Two cautions: this gives direction only, and the sign of `h` still requires the four measurements; and the identity holds only where `eta`, `N`, `delta` and `Q` really are configuration-independent, which fails as soon as a configuration changes who is in the room, because that changes `N`. **A measured preference pointing consistently away from measured headroom improvement is**

a diagnosis rather than a contradiction: one of those four is moving with the configuration. The commonest case is low `C` with low `N` — the comfortable narrow life — and it is visible only if `N` is measured alongside `C`.

8.7 7 Design specifications

Numbered, checkable requirements. A system claiming to have engineered these three terms satisfies them. They are **design requirements, not findings**: each is a rule this framework proposes, and none is an empirical result.

8.7.1 7.1 Requirements on conversion

D1.1 The system shall define an order observable `Y_t` in writing, together with its measurement procedure and its period length.

D1.2 The system shall document the argument that `Y_t` is not a repackaging of the interaction observable `U_t`. The argument shall be specific, not asserted.

D1.3 Every recurring interaction of more than two participants shall have a named recorder before it begins. The role may rotate; it may not be vacant.

D1.4 The system shall maintain a decision log. Each entry shall contain at minimum the decision, the date, the alternatives rejected, the accountable person, the review date, and the reversal condition.

D1.5 No decision-log entry shall have a vacant accountable-person field. An entry without an owner has `eta_bind = 0` and shall be marked a proposal, not a decision.

D1.6 Every entry shall carry a reversal condition — the observation that would require the decision to be revisited. Entries without one shall not be closed.

D1.7 The system shall maintain a register of changed defaults, distinct from the decision log, listing for each the default, the artefact that implements it, and the date it became live.

D1.8 A decision not implemented in tooling, template, form, calendar or physical arrangement within one review period shall be reported as unrealised. Its contribution to `Q` is zero until then.

D1.9 The system shall estimate `eta` at least once per twelve periods using `eta_hat = delta_Q_attributable / S_input`, with `S` computed from measured `N` and `u` and not from attendance.

D1.10 Every estimate shall be reported alongside all four baselines: persistence, direct-input, matched autoregressive, and shuffled-input.

D1.11 The system shall decompose `eta` into recording, binding and reach at each estimation, and shall direct the next intervention at the smallest of the three.

D1.12 The system shall identify in writing the fraction of its stored order it considers tacit, and shall provide a demonstration channel for that fraction.

D1.13 No capture requirement shall be imposed whose estimated `C` exceeds its estimated `d(eta) S`. Capture is subject to the same budget as everything else.

D1.14 Capture shall target decisions and changed defaults. Verbatim capture of discussion shall not be a requirement of any recurring interaction.

D1.15 The system shall count re-litigated decisions per period as a standing diagnostic. A rising count is the signature of `eta S < delta Q`.

D1.16 Onboarding shall be defined as a document plus a demonstration channel, never as a sequence of conversations.

D1.17 Before any conversion programme is funded, the system shall verify `S > 0` by measuring `u`. If `u` is near zero the programme shall be deferred until the geometry work is done.

D1.18 The system shall not report attendance, meeting count, workshop hours or engagement as evidence of `Q`. These are `S` proxies and shall be labelled as such wherever they appear.

D1.19 Any conversion metric adopted as a target shall be re-examined for measure-becomes-target capture at each estimation.

D1.20 Every capture mechanism shall be reversible by the people subject to it. No capture requirement shall remove a participant's ability to decline participation.

8.7.2 7.2 Requirements on cost

D2.1 The system shall maintain a written cost tally decomposed into the nine lines of Section 5.1. An aggregate `C` figure shall not be accepted as a survey deliverable.

D2.2 The system shall estimate `kappa` by the four-step procedure of Section 5.9 at least once per twelve periods, and shall record the unit normalisation used and an interval on the estimate.

D2.3 The system shall compute and record its crossover size and its net-optimal size `n_opt = sqrt(eta/kappa)` before any decision that changes headcount.

D2.4 No unit shall be grown past `n_opt` without a recorded justification stating what is being bought with the net structural loss.

D2.5 No unit shall be grown past the crossover without first changing the topology, because past the crossover the sustainability ceiling is violated even at `Q = 0`.

D2.6 The system shall state its communication topology explicitly: which pairs are obliged to maintain a live channel and which are not. **An unstated topology defaults to the complete graph and shall be costed as one.**

D2.7 Complete-graph obligation shall be confined to cells of size at most `n_opt`. Inter-cell links shall be explicit, named, and budgeted at an elevated `kappa`.

D2.8 Cell membership shall be permitted to overlap. A partition into disjoint cells with a reporting hierarchy is a tree and shall be flagged as a `u`-destroying topology.

D2.9 No topology shall route all inter-cell traffic through a single node. Hub topologies shall be recorded as accepting a known `u` penalty and a known targeted-failure fragility.

D2.10 Utilisation of every identified critical shared resource shall be measured. Any resource above 0.90 shall be raised as a fault.

D2.11 Target utilisation for critical shared resources shall be at or below 0.80. Slack below that level shall not be reported as waste in any budget document.

D2.12 Every standing recurring meeting shall have its annual person-hour cost computed and displayed on its own agenda.

D2.13 Any standing meeting with more than `n_opt` attendees shall state in writing which information flow requires all of them, or be split.

D2.14 The system shall compute the sustainability ceiling `C_max = eta ln N − delta Q_t` each period and compare it to measured `C_t`. This comparison shall appear in any report proposing new activity.

D2.15 Where `C_t > eta ln N − delta Q_t`, the system shall not authorise any intervention whose mechanism is interaction geometry, and shall record that the sustainability ceiling forecloses it.

D2.16 The system shall test whether any `C` line scales with `Q`. Where it does, `gamma` shall be estimated and `delta_eff = delta + gamma` used in all subsequent computation.

D2.17 Every proposed cost reduction shall be accompanied by a statement of which other parameter it may damage and a computed net effect on `h`.

D2.18 Friction shall be attacked before coordination, and coordination before any other line.

D2.19 Conflict and disagreement shall be tallied separately and never conflated. A programme that reduces conflict shall report its measured effect on `u`.

D2.20 No cost reduction shall be implemented that removes a participant's ability to decline an interaction. Mandatory attendance is a cost increase disguised as a cost control.

8.7.3 7.3 Requirements on the gauge

D3.1 The system shall compute `h_t = eta ln N − delta Q_t − C_t` at least once per twelve periods and shall record the four measurements and their dates.

D3.2 The sign of `h_t` shall be reported before its magnitude and shall accompany any proposal for new activity.

D3.3 No increment shall be requested such that `r_t > h_t`.

D3.4 Every requested increment shall be checked against the feasibility clause `delta Q_t + C_t + r_t <= eta ln N`, and the implied required `u` shall be computed and stated.

D3.5 Where the implied required `u` exceeds the measured `u` by more than a stated margin, the request shall be refused as geometrically infeasible even if `r_t <= h_t`.

D3.6 Where `h_t < 0`, no intervention whose mechanism is interaction geometry shall be authorised. The refusal shall show the arithmetic.

D3.7 Where `h_t < 0`, the response shall be selected from exactly four options: raise `eta`, raise `N`, cut `C`, shed `Q`. Any other proposal shall be recorded as out of scope.

D3.8 The system shall compute and publish `Q_crit = (eta ln N − C)/delta` and shall report `Q_t/Q_crit` as a standing capacity-utilisation figure.

D3.9 Where `Q_t/Q_crit` exceeds 0.75, the system shall open a shedding review.

D3.10 Where `delta Q_t` exceeds half of `eta ln N`, the system shall record that it is in the maintenance regime and shall not attribute the resulting stall to motivation, ambition, focus or talent.

D3.11 Every unit of stored order shall carry, at creation, a sunset date or an explicit statement that it is permanent, with the reason.

D3.12 Renewal past a sunset date shall require a positive argument. Continuation shall never be the default at review.

D3.13 The system shall maintain a shedding inventory listing every candidate in the three classes of Section 6.9.2, updated each review.

D3.14 No item shall be shed that constitutes a person's ability to decline participation, regardless of computed headroom benefit.

D3.15 No item shall be shed that constitutes a safety interlock whose failure mode is injury.

D3.16 No item shall be shed that constitutes an obligation to a party not represented in the shedding decision, without that party's participation.

D3.17 Where a procedure is shed, its one-line rationale shall be retained.

D3.18 Every shedding programme shall state in advance what the released headroom will be spent on. A programme with no stated use shall be deferred.

D3.19 Where any cost line scales with `Q`, `dh/dQ = −(delta + gamma)` shall be used in all shedding calculations.

D3.20 The system shall compute `h_inf = eta(ln N − F(u*))` and report it as the headroom it will retain once converged. A projected `h_inf` near zero shall be flagged.

D3.21 Every headroom report shall state the sensitivity of the *sign* of `h` to error in `Q`, `delta`, `eta` and `C`.

D3.22 No headroom figure shall be published without the order-proxy justification of D1.2.

8.8 8 Failure modes

Each entry names the damaged parameter, the diagnostic signature, the detecting measurement, and the fix. **These are constructed clinical descriptions, not case reports; no organisation was observed for this section.** The corpus's full catalogues run to thirty-two entries for the storage law [Curzi, 2026j] and thirty for the protocol layer [Curzi, 2026].

8.8.1 8.1 Faults of conversion

F1 · The leaky vessel. *Damages* `eta`*.* Interaction of high quality and adequate geometry occurs on schedule and none of it is captured: `S` is large, `eta` is near zero, and `Q` decays at rate `delta` regardless. *Signature:* recurring re-litigation of settled questions; knowledge held entirely in individuals; onboarding by conversation. *Detection:* count decisions revisited per period; ask five members independently to state the current policy on a specific matter and compare answers, since disagreement is direct evidence of a recording failure. *Fix:* D1.3, D1.4. The cheapest fix in the paper.

F2 · The minutes fallacy. *Damages* `eta_bind`*.* Extensive verbatim records exist and nothing is bound, so recording is high, binding near zero, and the product near zero. *Signature:* a large, complete, chronological archive nobody consults; no owner fields anywhere. *Detection:* access logs; ask when a minute was last cited in an argument about what to do. *Fix:* replace minutes with a decision log.

F3 · The write-only archive. *Damages* `eta_reach`*.* Capture and binding occur but the record cannot be found by the people who need it. *Signature:* people re-derive documented things; multiple contradictory documents on one topic, each authoritative-looking. *Detection:* give a new member a specific question and time the retrieval. *Fix:* single index, mandatory supersession marking, one canonical location per topic. Deleting duplicates is a shedding action and is legitimate.

F4 · The unowned artefact. *Damages* `eta_bind`*.* A decision or artefact exists with no accountable person and degrades without anyone being responsible for noticing. *Signature:* orphaned tooling that everyone depends on and nobody maintains. *Detection:* audit the decision log and tooling register for vacant owner fields; the count is the measurement. *Fix:* D1.5.

F5 · The capture tax. *Damages* `C`*, and* `eta` *indirectly.* Capture requirements proliferate until the cost of documenting exceeds the value of what is documented. *Signature:* templates with more fields than content; rising `C` with flat `Q`. *Detection:* person-hours spent on capture as a fraction of person-hours spent in interaction. *Fix:* D1.13, D1.14.

F6 · The ceremony that replaced the capture. *Damages* `eta`*, while appearing to raise it.* A capture ritual is performed faithfully and produces no binding. *Signature:* action items with a low completion rate and no consequence for non-completion; identical items recurring across sessions. *Detection:* track completion and recurrence; recurrence is the tell. *Fix:* attach every item to the changed-default register or delete it.

F7 · The high-conversion error. *Damages nothing in the law; the law is working correctly against the system.* High `eta` and low `delta` have converted a wrong conclusion into durable structure that cannot be dislodged. *Signature:* confident, well-documented, deeply implemented practice that no evidence appears able to change; challenges met with the documentation. *Detection:* check the decision log for reversal conditions; their absence is the diagnostic. *Fix:* D1.6 applied retroactively. Where a reversal condition has been met and the decision stands, that is a shedding case.

F8 · The attribution illusion. *Damages the estimate, not the coefficient.* `eta` is estimated by correlating interaction with subsequent order growth with no control, so any secular trend produces a positive estimate. *Signature:* an estimate never tested against a shuffled-input control; a model that fits everything and predicts nothing out of sample. *Detection:* run the shuffled-input control. *Fix:* D1.10.

F9 · The order proxy that was really the input. *Damages every downstream number.* `Y_t` is a disguised measure of `U_t`. *Signature:* `Y` rises on periods with much discussion and no conclusions. *Detection:* identify a period of intense interaction that produced nothing durable and check whether `Y` rose; or apply the ceiling test, since no admissible increment exceeds `eta ln N` [Curzi, 2026i]. *Fix:* D1.2 — choose a proxy that can fall while interaction is high.

F10 · Conversion applied to a parallel roster. *Damages the intervention budget.* A serious capture programme is installed in a group with `u` near zero, so `S = 0`, `eta S = 0` for any `eta`, and the programme returns nothing while consuming `C`. *Signature:* excellent documentation

of unanimous conclusions; a decision log in which nothing was ever contested. *Detection:* measure `u`. *Fix:* D1.17 — defer, and fix the geometry first.

8.8.2 8.2 Faults of cost and topology

F11 · The quadratic committee. *Damages `C`.* A group grown past `n_opt`, often past the crossover, under complete-graph obligation. *Signature:* meetings that lengthen without producing more; scheduling as the dominant constraint; decisions deferred for want of a quorum. *Detection:* count `n`, compute `sqrt(eta/kappa)`, compare; compute `C/(eta ln N)`. *Fix:* D2.7.

F12 · The utilisation cliff. *Damages `C` via the queueing term.* A critical shared resource is driven toward full utilisation in pursuit of efficiency and wait time explodes hyperbolically. *Signature:* lead times lengthening far out of proportion to load; one named person as the bottleneck for many flows. *Detection:* measure `rho`; anything above 0.90 is the diagnosis. *Fix:* D2.10, D2.11 — add capacity, remove the gate, or shed demand, and defend slack in the budget as a cost-control device.

F13 · The all-hands trap. *Damages `C`, and `u` indirectly.* Complete-graph cost paid for star-topology information flow. *Signature:* large standing meetings with low participation dispersion; attendees doing other work during them. *Detection:* D2.12, plus the speaking-time distribution [Curzi, 2026g]. *Fix:* D2.13 — split, or convert to a written broadcast, which is star topology at a fraction of the cost.

F14 · The uncosted topology. *Damages every downstream estimate.* Nobody has stated who is obliged to coordinate with whom, so everyone assumes everyone and the tally understates `C` badly. *Signature:* nobody can draw the communication graph. *Detection:* attempt to draw it; the failure to draw it is the finding. *Fix:* D2.6.

F15 · The hub that ate the variance. *Damages `u`, while appearing to fix `C`.* Coordination cost is reduced by routing everything through a central node; `C` falls and so does `u`, because every message is filtered through one viewpoint. *Signature:* cheap coordination and unanimous conclusions; cross-team disagreement never surfaces. *Detection:* measure `u` before and after any centralisation. *Fix:* D2.9 — add lateral links that bypass the hub, and compute the trade.

F16 · The compliance ratchet. *Damages `C` via `gamma`; manifests as elevated apparent `delta`.* Cost that scales with stored order grows unnoticed as `Q` grows until `delta_eff = delta + gamma` dominates. *Signature:* stored order decaying faster than the measured `delta` predicts; older institutions performing worse than younger ones with identical staff. *Detection:* D2.16. *Fix:* reduce per-unit overhead, or shed `Q`, which attacks `delta Q` and `gamma Q` simultaneously.

F17 · The conflict-suppression trade. *Damages `u`.* Conflict is reduced by discouraging disagreement rather than by improving the handling of it; cost falls and surplus falls further. *Signature:* harmonious meetings, low measured conflict, low measured disagreement, decisions unanimously endorsed and privately doubted. *Detection:* D2.19 — tally the two separately; the signature is both falling together. *Fix:* separate them; acoustic and geometric treatment reduce conflict without reducing disagreement [Curzi, 2026e,f].

F18 · The net-negative cut. *Damages `h`, while appearing to raise it.* A cost reduction whose collateral damage to `eta` or `delta` exceeds the saving. *Signature:* cost falls, stored order falls faster. *Detection:* D2.17. *Fix:* reverse the cut where possible; this is one of the few cases in which restoring `C` raises `h`.

F19 · The missing denominator. *Damages the sizing decision.* Growth justified by total output rather than output per member, throughout the entire band between `n_opt` and the crossover. *Signature:* headcount growth defended by absolute figures. *Detection:* compute `net(n) = eta ln n − kappa n(n−1)/2` at current and proposed `n`. *Fix:* D2.3, D2.4.

8.8.3 8.3 Faults of the gauge

F20 · The unread gauge. *Damages every decision downstream.* `h` is never computed; capacity is argued about qualitatively and settled by seniority or volume. *Signature:* commitments

made without any capacity calculation; repeated overcommitment followed by repeated surprise. *Detection:* ask for the current `h`; the absence of an answer is the finding. *Fix:* D3.1.

F21 · The maintenance trap. *Damages `h` via `delta Q`.* `Q` has grown until the maintenance draw consumes the budget; all output is replacement and the stall is attributed to motivation. *Signature:* high activity, low novelty; every new initiative displacing an existing one; builders leaving. *Detection:* D3.10. *Fix:* shed `Q` or raise `eta`. Exhortation raises `C` and makes it worse.

F22 · The unshed stock. *Damages `h`, permanently.* Stored order accumulates monotonically because nothing has a removal path. *Signature:* a procedure manual nobody has read end to end; rules whose origin nobody knows. *Detection:* D3.13 — count items with no sunset date, and approval gates with a rejection rate near zero. *Fix:* D3.11, D3.12.

F23 · The ceiling misread. *Damages the credibility of the method.* `h` computed with `eta F(U_t)` instead of `eta ln N`, producing a smaller and more pessimistic figure; or `h > 0` read as a promise of growth rather than a licence. *Signature:* headroom figures that move week to week with meeting quality. *Detection:* check the formula and whether the feasibility clause was run. *Fix:* D3.4 — `h` uses the ceiling, feasibility uses the geometry, both in that order.

F24 · The rising gauge on a falling system. *Damages interpretation.* `h` rises while `Q` falls, because the collapsing maintenance draw releases budget; the rise is read as recovery. *Signature:* improving headroom, deteriorating output, shrinking stored order — every reading better than the last and every observable worse. *Detection:* plot `h` and `Q` together; divergence in this direction is the diagnosis. *Fix:* never read `h` without `Q` beside it. **This is the single most misread signal on the gauge and Section 9.1 works it in full.**

F25 · Exogenous accretion. *Damages `h` through a channel the model does not see by default.* `Q` arrives from outside the `eta S` channel — mandates, mergers, statute, external standards — and consumes headroom without ever having paid for its own maintenance, so `h_inf = eta(ln N − S) − A`. *Signature:* growing obligations with flat or falling capability; a remit that expands by acquisition rather than by decision. *Detection:* tally `Q` acquired by internal decision against `Q` acquired by external imposition and estimate `A` directly. *Fix:* shed the accreted `Q` where permitted, refuse further accretion, or negotiate the mandate.

F26 · The converged institution. *Damages `h`, at the fixed point.* A system at steady state with high `u` has `h_inf = eta(ln N − S)` near zero: it is performing excellently and has no capacity for anything new. *Signature:* high measured performance, high measured difference, complete inability to take on a new class of problem. *Detection:* D3.20. *Fix:* raise `eta`, which is the only term scaling `h_inf`; or shed `Q` to leave the fixed point deliberately; or accept the state as a legitimate mature equilibrium and say so.

F27 · Shedding without a use. *Damages nothing and achieves nothing.* Released headroom is never spent and the system re-accumulates the same stock at the same rate. *Signature:* periodic simplification initiatives whose effects are undone within one time constant; rule counts oscillating around a stable mean. *Detection:* plot `Q` over several time constants; oscillation without trend is the finding. *Fix:* D3.18.

F28 · Shedding across the ethical line. *Damages the standing of the method.* A shedding programme with a genuine positive computed return removes consent provisions, appeal rights, dissent protections or safety interlocks, because those are stored order and stored order costs `delta Q`. *Signature:* a headroom argument used to justify removing someone's ability to decline. *Detection:* check every candidate against D3.14 to D3.16. *Fix:* refuse. **The model itself gives no warning here — the computed return is genuinely positive — which is exactly why the constraint must sit outside the model.**

8.9 9 Results: three systems worked end to end

All three systems are constructed. No dataset was collected. Every number below is the output of the stated parameters under the model of Sections 3 to 6, carried through so that a reader can re-derive it. They demonstrate that the procedure runs and that it reports its own failures. They are not evidence that any organisation behaves this way.

8.9.1 9.1 A nine-person research group over twenty-six weeks

System. A nine-person applied research group, weekly periods, a ninety-minute all-hands each week and a variable number of pair sessions.

Survey. Enumerating genuinely distinct methodological lineages rather than job titles gives `N = 6`: experimental measurement, numerical simulation, statistical inference, hardware fabrication, domain theory, and software infrastructure. Three of the nine people duplicate an existing lineage, which is why the headcount is nine and the audited count is six — the effective-count audit applied before anything else [Curzi, 2026c]. A disagreement audit over eight weeks, on structured forecasting questions about experimental outcomes with independent pre-discussion estimates, gives `u = 0.55`. **That figure is an estimate from a self-administered instrument in a constructed example and carries no interval; a real survey owes one.**

```
S = ln(1 + (N−1)∗u) = ln(1 + 5∗0.55) = ln(3.75) = 1.3218 nats/week
ceiling: ln N = ln 6 = 1.7918
geometric shortfall: ln N − S = 0.4700
```

The group realises 74 per cent of the surplus its own category count would permit at `u = 1`. **That is good geometry, and the rest of this subsection is about why it does not help.** Retention loss is `delta = 0.05` per week, measured across a five-week shutdown with no input, a half-life of `ln 2 / (−ln(1−0.05)) = 13.5` weeks. Cost is `C = 0.12` per week in normalised order-units. The order observable `Y_t` counts live, owned, implemented methodological decisions and built artefacts in active use, with `Y_0 = 0.80`; **the proxy passes the D1.2 test because it fell during a busy but inconclusive fortnight, which an interaction measure could not have done.**

Diagnosis. Decomposing conversion:

```
eta_record = 0.15   -- an occasional email; no standing recorder
eta_bind   = 0.40   -- owners named sometimes, review dates never
eta_reach  = 0.50   -- what is bound often fails to reach the people who act

eta = 0.15 ∗ 0.40 ∗ 0.50 = 0.030
```

Before the intervention, with `eta = 0.030`:

```
eta∗S    = 0.03 ∗ 1.3218 = 0.0397 per week
delta∗Q0 = 0.05 ∗ 0.80   = 0.0400
C        = 0.1200

h_0 = eta∗ln N − delta∗Q_0 − C = 0.03∗1.7918 − 0.0400 − 0.1200 = −0.1062
```

`h_0 < 0`. The sustainability ceiling applies without qualification: no arrangement of these nine people, no change to who talks to whom, and no improvement in the quality of the discussion can prevent `Q` from declining. The group's geometry is excellent and it is irrelevant, because the conversion coefficient discards 97 per cent of what the geometry produces.

Trajectory under `Q_{t+1} = 0.95 Q_t + 0.0397 − 0.12`:

week	Q_t	h_t
0	0.8000	-0.1062
1	0.6797	-0.1002
2	0.5653	-0.0945
4	0.3535	-0.0839
8	-0.0101	-0.0657

week	Q_t	h_t
13	-0.3714	-0.0477
20	-0.7441	-0.0290
26	-0.9727	-0.0176

`Q` crosses zero at week 8. The steady state is `Q_inf = (0.0397 − 0.12)/0.05 = −1.607`, which is negative — meaning the regime is unsustainable or the linear model must be replaced. **The theorem does not hide this failure mode and neither does the survey report.** In the real group `Q` cannot go negative; what happens instead is that it hits a floor consisting of whatever is externally enforced and operates entirely on that.

Note the deceptive shape of the headroom column. Headroom *improves* every week, from -0.1062 to -0.0176, and it improves because `Q` is collapsing, which reduces the maintenance draw. **A system in decline shows rising headroom. Headroom rising while `Q` falls is not recovery; it is the maintenance burden shrinking because there is less left to maintain.** This is F24, and it is the single most misread signal on the gauge.

Two thresholds, computed before choosing the intervention.

```
eta needed for a non-negative steady state:  eta > C/S = 0.12/1.3218 = 0.0908
eta needed for h_0 > 0 at Q_0 = 0.80:        eta > (delta*Q_0 + C)/ln N
                                                 = (0.0400 + 0.1200)/1.7918 = 0.0893
```

The group needs `eta >= 0.091`, a factor of three, and nothing more. It is worth recording how much cheaper that brief is than the ones that would have been proposed without the arithmetic. Not *hire more people*: `N` is already 6 and adding a seventh distinct lineage buys `eta ln(7/6) = 0.0046`. Not *improve collaboration*: `u = 0.55` is already strong. Not *reduce meetings*: cutting `C` to zero still leaves `h = 0.0538 − 0.0400 = +0.0137`, technically positive but roughly a tenth of what the conversion fix delivers, and it would destroy the `u` the group depends on.

This is the paper's own counter-result and it is stated rather than buried. In its own leading worked case the levers this corpus is named for — geometry, difference, category count — are all inert, and the binding constraint is a clerical one.

Intervention. Three changes, all cheap, all aimed at the decomposition: a standing recorder rota on the weekly all-hands, ten minutes of one person's time, targeting recording 0.15 to 0.70; a decision log replacing minutes with mandatory owner, review date and reversal condition (D1.4 to D1.6), targeting binding 0.40 to 0.75; and a changed-default register (D1.7) requiring every methodological decision to name the template, script or fixture that implements it within one week or be marked unrealised (D1.8), targeting reach 0.50 to 0.80.

Projected `eta = 0.70 x 0.75 x 0.80 = 0.420`. **That is optimistic and is treated as such**: the conservative half of the gain is taken and `eta = 0.21` is projected, still more than double the threshold. **After the intervention:**

```
eta*S = 0.21 * 1.3218 = 0.2776 per week
h_0   = 0.21*1.7918 − 0.05*0.80 − 0.12 = 0.3763 − 0.0400 − 0.1200 = +0.2163
Q_inf = (0.2776 − 0.12)/0.05 = +3.1514
```

week	Q_t	h_t
0	0.8000	+0.2163
1	0.9176	+0.2104
2	1.0293	+0.2048
4	1.2362	+0.1945
8	1.5914	+0.1767

week	Q_t	h_t
13	1.9443	+0.1591
20	2.3084	+0.1408
26	2.5317	+0.1297

`Q` rises from 0.80 to 2.5317 in twenty-six weeks and converges on 3.1514. The time constant is `1/delta = 20` weeks, so the group is at 80 per cent of its new steady state by week 26. **Nothing changed except the conversion coefficient: `N`, `u`, `S`, `delta`, `C` and the headcount are identical. The same nine people, having the same conversations, with the same disagreement rate, at the same cost, move from terminal decline to a fourfold increase in stored order.**

Falsification criteria, registered before the intervention. The prediction is `a = 0.95` and `b = 0.21` in the minimal model, fitted on weeks 1 to 16 and frozen, with weeks 17 to 26 held out. The intervention is judged a failure if held-out prediction of `Y` is not better than the persistence baseline; if the fitted `b` is below 0.09, the sustainability threshold, meaning the programme did not move the coefficient enough to matter; if the shuffled-input control fits as well as the true pairing, indicating a trend rather than a consequence; or if the re-litigation count does not fall, indicating that reach is still zero despite records existing, which is F3 rather than success.

Standing caution. `Y` counts owned, implemented decisions, which a group could inflate by making trivial decisions and implementing them — the measure-becomes-target failure [Goodhart, 1975]. The registered defence is that the review-date field forces every entry to be re-examined and entries no longer corresponding to anything anyone does are struck from the count. **A metric with a scheduled removal path is substantially harder to inflate than one that only accumulates**, and the removal path is also the shedding mechanism of Section 6.9.

8.9.2 9.2 Sizing an incident-response function

System. A standing incident-response function inside a mid-size operations group, which must diagnose and resolve heterogeneous failures under time pressure. `Q` is the count of live, exercised runbooks and validated diagnostic procedures, normalised so that one unit is one such procedure verified within the last quarter.

Survey.

```
eta    = 0.22    a strong decision log and runbook discipline
kappa  = 0.006   4.2 h/period of synchronisation across 47 active links, normalised
delta  = 0.07    procedures go stale; measured by re-validation failure rate
Q      = 2.5     2.5 normalised units of live procedure
delta*Q = 0.175  the standing maintenance draw
```

Every added responder is assumed, generously, to bring a genuinely distinct failure-domain category, so `N = n`. An effective-count audit would normally reduce this; taking `N = n` biases the answer toward larger teams, which makes the conclusion conservative.

The sizing table, `h(n) = eta ln n − delta Q − kappa n(n−1)/2`:

n	eta ln n	C = kappa n(n−1)/2	h
2	0.1525	0.0060	-0.0285
3	0.2417	0.0180	+0.0487
4	0.3050	0.0360	+0.0940
5	0.3541	0.0600	+0.1191
6	0.3942	0.0900	+0.1292
7	0.4281	0.1260	+0.1271
8	0.4575	0.1680	+0.1145

n	eta ln n	C = kappa n(n−1)/2	h
10	0.5066	0.2700	+0.0616
12	0.5467	0.3960	-0.0243
16	0.6100	0.7200	-0.2850
20	0.6591	1.1400	-0.6559
30	0.7483	2.6100	-2.0367
50	0.8606	7.3500	-6.6644

```
net-optimal size:            n = 6         (h = +0.1292)
closed form sqrt(eta/kappa): 6.06          (agrees)
h > 0 range:                 n in [3, 11]
C exceeds eta*ln n at:       n = 15
```

The table contains three boundaries that are routinely confused with each other.

At `n = 2`, headroom is negative. A two-person function cannot sustain 2.5 units of procedure: there is not enough category diversity to generate the surplus that maintenance requires. **The lower bound is a real bound — understaffing is a sustainability violation exactly as overstaffing is.** At `n = 6` headroom peaks; that is the design point. **At `n = 11` headroom reaches zero**, and above eleven the team cannot maintain the procedures it already has. **At `n = 15` cost exceeds the entire structural budget.**

Note the shape between 6 and 11: headroom stays positive and falls by 52 per cent across those five hires. **Nothing observable breaks in that band. The team feels busier and produces less durable procedure, and the natural interpretation is that they need more people.** That interpretation is exactly backwards and it is the mechanism by which F11 propagates.

The eighteen-person question. Suppose the operations group requires eighteen responders for round-the-clock coverage — a genuine constraint. Under a complete graph:

```
C(18) = 0.006 * 18*17/2 = 0.006 * 153 = 0.9180
h(18) = 0.22*ln 18 - 0.175 - 0.9180 = 0.6359 - 0.1750 - 0.9180 = -0.4571
```

Deeply unsustainable. But `n` is fixed by the rota constraint, so three of the four responses are unavailable and topology is the only move. **Restructure as three cells of six with liaison links**, complete graph inside each cell and three inter-cell liaison links priced at four times a normal link because they carry translation and handover cost:

```
within-cell:   3 cells * (0.006 * 6*5/2)  = 3 * 0.0900        = 0.2700
between-cell:  3 links * 4 * 0.006                            = 0.0720
total C(split) = 0.3420        against C(monolith) = 0.9180

h(split, N = 18) = 0.22*ln 18 - 0.175 - 0.3420 = +0.1189
```

The same eighteen people, with the same skills, doing the same work, move from `h = -0.4571` to `h = +0.1189` — a swing of 0.576 — purely by changing who is obliged to keep a live channel with whom. No hiring, no firing, no training, no budget. Cost falls by 63 per cent and the surplus ceiling is untouched, because `N = 18` regardless of how the eighteen are wired.

Against the alternatives: raising conversion to rescue the monolith requires `eta' = (delta Q + C)/ln N = (0.175 + 0.918)/2.8904 = 0.378`, a 72 per cent improvement on a discipline that is already strong. Cutting `delta` to zero — perfect retention, an impossibility, and one the retention analysis shows to be a pathology in its own right [Curzi, 2026a] — saves only 0.175 and leaves `h = -0.282`. Shedding `Q` entirely, from 2.5 to 0, saves the same 0.175 and leaves `h = -0.282`. **Only the topology move closes the gap.**

What the split costs, stated honestly.

1. **Cross-cell `u` may fall.** Responders in one cell stop routinely encountering another cell's failure modes. The countermeasure is overlapping membership (D2.8): each responder belongs primarily to one cell and secondarily to another, which preserves the semilattice and costs roughly one additional link per person, `18 x 0.006 = 0.108`, taking total `C` to 0.4500 and `h` to `+0.0109`. Still positive, and the surplus is protected.
2. **Handover risk rises at cell boundaries.** The elevated liaison multiplier of four is the estimate of it. If handover proves more expensive — say eight times — total `C` becomes `0.2700 + 0.1440 + 0.108 = 0.5220` and `h = −0.0611`, which is negative. **The sensitivity of the answer to the liaison multiplier is high, and the liaison multiplier is the least well-estimated number in this survey.** It should be measured before the split is made permanent, not assumed. This is also where the coupled-network caution of Section 5.7 bites: Buldyrev et al. [2010] give the mechanism by which a thin coupling between otherwise robust cells becomes the system's failure mode, and this survey prices the coordination saving and does not price that fragility.
3. **The rota constraint was never tested.** Eighteen was given as a coverage requirement. The arithmetic says a six-person cell is the net optimum, and three cells of six is what the rota produces anyway. **The convergence is fortunate rather than designed and should not be assumed to recur.**

Falsification criteria, registered before the split.

1. Predicted: `Q` rises from 2.5 toward `Q_inf = (eta S − C)/delta`. With `u` estimated at 0.55 post-split, `S = ln(1 + 17 x 0.55) = 2.3370`, `eta S = 0.5141`, so `Q_inf = (0.5141 − 0.4500)/0.07 = 0.916`. **Note that this is *lower* than the current `Q = 2.5`.** The honest prediction is therefore that the split makes `h` positive while `Q` still falls, because `eta S` at the achievable `u` does not support 2.5 units of procedure against this `delta` and this `C`. The team must additionally raise `u`, raise `eta`, or **shed procedures deliberately** — the fourth lever, arriving unprompted from a pure cost analysis. **This is the single most useful thing the calculation produced, and it would not have been visible from `h` alone.**
2. The split fails if measured `C` after two quarters does not fall by at least half, indicating the liaison multiplier was underestimated.
3. The split fails if measured `u` falls below 0.45, indicating that the overlapping-membership provision failed and F15 has occurred in cellular form.
4. The split fails if the shuffled-input control fits the post-split series as well as the true pairing.

Standing caution. Positive headroom licenses building; it does not promise that what exists is sustainable. **This example makes both points at once: the split buys headroom, and the same arithmetic reveals that the existing stock of procedure was never supportable at any topology with these parameters. The cost analysis rescued the organisation and condemned its backlog, and it did both with the same four numbers.**

8.9.3 9.3 A professional standards body over sixty years

System. A membership organisation that publishes and maintains technical standards for a regulated trade. Annual periods. `Q` is the count of standards actively maintained — published, in force, and re-validated within the review cycle — normalised so that one unit is one such standard.

Survey.

```
eta   = 0.20     conversion of committee work into published, adopted standard
N     = 14       genuinely distinct technical sub-domains (the initial claim was 31,
                 reduced by the collision test of the effective-count audit)
u     = 0.50     measured by pre-discussion disagreement on technical questions
delta = 0.045    standards go stale; measured by re-validation failure over a dormant biennium
```

```
C_0   = 0.08     baseline operating cost: governance, publication, administration
gamma = 0.030    cost scaling with the standards count: re-validation, cross-reference
                 maintenance, enquiry handling, errata
A     = 0.25     EXOGENOUS ACCRETION: standards adopted by statute and by international
                 harmonisation, which the body must maintain and did not choose
```

Derived:

```
S           = ln(1 + 13*0.50) = ln(7.5)  = 2.0149 nats/yr
eta*S       = 0.4030
budget      = eta*ln N = 0.20 * 2.6391    = 0.5278
delta_eff   = delta + gamma               = 0.075
Q_inf       = (eta*S - C_0 + A)/delta_eff = (0.4030 - 0.08 + 0.25)/0.075 = 7.6397
Q_crit      = (budget - C_0)/delta_eff    = (0.5278 - 0.08)/0.075       = 5.9708
h_inf       = eta*(ln N - S) - A          = 0.20*0.6242 - 0.25          = -0.1252
```

The two numbers that decide the case are on adjacent lines: `Q_inf = 7.6397` and `Q_crit = 5.9708`. The body will converge to a stock 28 per cent larger than the largest stock it can sustain. That is the diagnosis, available in year zero, sixty years before the symptoms.

Trajectory, `Q_{t+1} = 0.955 Q_t + 0.4030 - (0.08 + 0.030 Q_t) + 0.25`:

year	Q_t	C_t	delta Q_t	h_t
0	0.0000	0.0800	0.0000	+0.4478
5	2.4662	0.1540	0.1110	+0.2628
10	4.1363	0.2041	0.1861	+0.1376
15	5.2672	0.2380	0.2370	+0.0528
20	6.0331	0.2610	0.2715	-0.0047
25	6.5518	0.2766	0.2948	-0.0436
30	6.9030	0.2871	0.3106	-0.0699
40	7.3019	0.2991	0.3286	-0.0998
50	7.4848	0.3045	0.3368	-0.1135
60	7.5687	0.3071	0.3406	-0.1198

Headroom crosses zero in year 20, at `Q = 6.033`, just past `Q_crit = 5.971`. Consider what year 20 looks like from inside: it is the twentieth consecutive year of growth, the catalogue has grown every year, membership is at a record, and by every visible measure the organisation has succeeded. **There is no event. The crossing has no signature. It is a sign change in a quantity nobody is computing.**

By year 40 the condition is recognisable: `delta Q = 0.3286` and `C = 0.2991`, together 0.6277 against a budget of 0.5278. The maintenance draw alone is 62 per cent of the total budget, well past the D3.10 threshold. The body publishes little that is new, spends its committee time on revision and errata, and is described by its own members as bureaucratic. **That description is accurate and it is not an explanation.**

Diagnosis. Of the stored order accumulated, the accretion term `A = 0.25` per year against internal generation `eta S = 0.4030` per year means **38 per cent of this body's stored order arrived by statute and harmonisation rather than by its own decision, and none of it came with maintenance funding.** The fixed-point identity prices it exactly:

```
h_inf = eta*(ln N - S) - A = +0.1248 - 0.2500 = -0.1252
```

Without `A` the organisation would sit at `h_inf = +0.1248` indefinitely — converged, maintained, modest, and permanently solvent. **The entire deficit is the accretion term.** That is a

very different finding from *the organisation became complacent*, and it points at a very different remedy.

The four levers, priced at year 60, with `Q = 7.5687`, `C = 0.3071`, `h = −0.1198`.

L1, raise conversion. Required `eta' = (delta Q + C)/ln N = (0.3406 + 0.3071)/2.6391 = 0.2454`, from 0.20 — **a 23 per cent improvement.** Plausible, since standards drafting is a capture process to which the mechanisms of Section 4.4 apply directly. This is the best of the first three levers.

L2, raise the category count. Required `N' = exp((delta Q + C)/eta) = exp(0.6477/0.20) = exp(3.2385) = 25.5`, from 14 — **eleven more genuinely distinct technical sub-domains, an 82 per cent expansion of remit.** And note the perversity: expanding remit is precisely the process that generates more `A`. **Lever 2 in this case makes the disease worse while treating the symptom**, which is a structural feature of accretion-driven ossification and not a quirk of these numbers.

L3, cut cost. Required `C' <= budget − delta Q = 0.5278 − 0.3406 = 0.1872`, from 0.3071 — a 39 per cent cut. But decompose: `C = C_0 + gamma Q = 0.08 + 0.2271`. **Only 0.08 of the 0.3071 is discretionary; 0.2271 is driven by `Q` itself. Even abolishing the entire baseline operating cost leaves `C = 0.2271` and `h = −0.0399`, still negative.** Lever 3 cannot reach the target at any level of austerity. This is the arithmetic behind the familiar spectacle of an institution cutting itself to the bone and remaining stuck.

L4, shed stored order. Required `Q' <= Q_crit = 5.9708`, from 7.5687 — **a 21 per cent reduction, and the deficit is closed.** Because `gamma > 0`, shedding attacks both draws at once at rate `delta + gamma = 0.075` per unit. Take the shed further, to `0.75 x Q_crit = 4.4781`, retiring 41 per cent of the catalogue:

```
new C = 0.08 + 0.030*4.4781            = 0.2143
new h = 0.5278 − 0.045*4.4781 − 0.2143 = +0.1120

headroom recovered = +0.1120 − (−0.1198) = +0.2318
```

A swing of 0.2318, which is 44 per cent of the organisation's entire structural budget, recovered by retiring standards that no longer describe practice. Achieving the same swing through the category lever would require `N' = 14 exp(0.2318/0.20) = 45` — tripling the technical remit. **Retiring 3.09 units of obsolete standard is worth more than tripling the organisation's technical scope, and it can be decided in one committee meeting.**

Execution. The shed of 3.09 units, roughly two fifths of the catalogue, is executed against the classification of Section 6.9.2 and not by percentage target.

- *Freely sheddable:* standards for equipment classes no longer manufactured; standards superseded by a later standard but never formally withdrawn; guidance notes with no recorded citation in a decade; three committees whose founding question was resolved. **The never-formally-withdrawn category alone is typically the largest and is pure F22.**
- *Conditionally sheddable, with replacement:* four standards consolidated into one, retaining each original's one-line rationale as an annex (D3.17). This is the *shed the rule, keep the reason* form and it is what makes the consolidation defensible to the members whose work is being retired.
- *Not shed, and named as not shed:* every statutory obligation, since the obligation runs to parties not represented in this decision, so it is renegotiated with the regulator or it stands (D3.16); every safety-critical interlock standard (D3.15); and the members' right of objection to a published standard, which is stored order costing `delta Q` every year and is **not available regardless of the computed return** (D3.14). **The model gives no warning here. The computed return on removing the objection procedure is genuinely positive. The constraint sits outside the model on purpose.**

Preventing the regrowth. Shedding is a transient. The contraction guarantees a return to `Q_inf = 7.6397` at time constant `1/0.075 = 13.3` years, so the released headroom must be spent

before it is reabsorbed. The registered plan: spend `h = +0.1120` on the conversion lever over years 61 to 66, targeting `eta` from 0.20 to 0.26 through a drafting decision log with mandatory reversal conditions, which raises the budget from 0.5278 to 0.6862; require from year 61 that **every new standard carries a sunset date with removal as the review default**, which is the structural fix rather than the symptomatic one and the only change that prevents recurrence; and open negotiation with the regulator on `A` over years 61 to 63, seeking either maintenance funding attached to statutory adoptions or a formal withdrawal mechanism. **`A` is the actual cause and it is the only item on the list outside the body's unilateral control. Every other action treats a symptom, and the survey says so rather than claiming a cure.**

Falsification criteria, registered before the intervention.

1. Predicted: `Q` falls to 4.478 at the shed and, absent the sunset provision, regrows toward 7.6397 with time constant 13.3 years, reaching approximately 6.0 by year 74 and recrossing `Q_crit`. **The sunset provision is falsified if `Q` follows that trajectory anyway.**
2. Predicted: measured `C` falls from 0.3071 to approximately 0.2143 within two review cycles. If it does not, `gamma` was misestimated and the double-return argument does not apply here.
3. Predicted: fitted `b` rises from 0.20 toward 0.26 following the decision-log intervention. If `b` does not move, the conversion programme failed and the window will close with nothing bought — F27.
4. Predicted: fitted `a` remains near `1 − delta_eff = 0.925`. **A significant change in `a` indicates that `delta` or `gamma` was not stable across the horizon, which falsifies H1 and requires the model to be replaced rather than refitted.**
5. The shuffled-input control must degrade the fit. If it does not, the entire fitted relationship between committee interaction and standards output is a trend and the conversion estimate was never real.

Standing caution. Every number here follows from six parameters and the theorems of the storage law. **The parameters are the argument; the arithmetic is only bookkeeping.** An organisation disputing the conclusion should dispute `eta`, `N`, `u`, `delta`, `gamma` or `A` — and to dispute them it must measure them, which is the entire purpose of putting the gauge on the wall.

8.10 10 Discussion

8.10.1 10.1 What follows

Restated in the order they are consumed downstream.

The headroom gauge `h_t = eta ln N − delta Q_t − C_t` reads three parameters on one dial with one sign, with three regimes, a maximum one-step increment `r_max = h_t`, and two separate constraints that are routinely conflated: admissibility `C_t <= (1−delta)Q_t + eta S_t` and sustainability `C_t <= eta ln N − delta Q_t`. A system can satisfy the first and violate the second for decades.

Doubling conversion is exactly squaring the category count, since `2 eta ln N = eta ln(N^2)`; and doubling the surplus by raising non-parallelism alone is feasible only when `u <= 1/(sqrt(N)+1)`, so at `N = 8` and `u = 0.30` the required `u'` is 1.23 and the move is impossible rather than expensive. **This is arithmetic, not a finding about organisations**, and it is the reason conversion is the first move in almost every system this framework describes.

Conversion composes multiplicatively through recording, binding and reach, so three gates at 0.7 give `eta = 0.343` and the weakest gate dominates: recording 0.20 to 0.80 gains 300 per cent against binding 0.60 to 0.90 at 50 per cent. **The decomposition itself is a modelling convenience with no external support**; the multiplicative arithmetic conditional on it is exact.

`eta = 0` produces decline, not stagnation. The stock is non-increasing in every period and falls at exactly the cost rate, converging on `−C/delta`, which is inadmissible and marks the model's own domain of breakdown.

The net optimum sits far below the crossover. Maximising `eta ln n − kappa n(n−1)/2` gives `eta = kappa n(n − 1/2)`, approximately `sqrt(eta/kappa)`; at `eta = 0.30` and `kappa = 0.010` the optimum is six and the crossover is thirteen. **The band between them is where nothing visibly breaks and every additional member reduces net output**, and it is where most organisations live.

Topology is a free lever. Eighteen people rewired from a complete graph into three cells of six move from `h = −0.4571` to `h = +0.1189`, a swing of 0.576, with cost falling 63 per cent and the surplus ceiling untouched because `N = 18` either way.

The nine-person case returns `N = 6, u = 0.55, S = 1.3218` nats — 74 per cent of `ln 6` — with measured `eta = 0.030` giving `h_0 = −0.1062` and `Q_inf = −1.607`. The binding threshold is `eta >= 0.091`, a factor of three.

A cost that scales with stored order is a decay rate. With `C = C_0 + gamma Q`, the system behaves exactly as if `delta_eff = delta + gamma`, so every result of the retention analysis transfers with that substitution [Curzi, 2026a].

Two of these deserve emphasis because they are most likely to be restated loosely elsewhere. The doubling identity is exact and is not an analogy. And the fixed-point identity `h_inf = eta(ln N − F(u∗))` is a cancellation, not an approximation: `delta`, `C` and `Q` all vanish, and the consequence — that **the plain linear model never ossifies by itself** — rules out the most popular explanation for institutional ossification and forces the analyst to name which of three imported mechanisms is operating.

8.10.2 10.2 What does not follow

No thermodynamic claim is made. Landauer [1961] establishes a physical lower bound on the energy cost of erasure and is the reason the cost analogy is tempting; it is not a warrant for any claim about institutional cost, and it is not used as one.

Surplus is not identified with Shannon entropy. The `ln N` ceiling has an information-theoretic reading and the reading bounds; it does not identify.

The mapping onto any real organisation is not established by anything in this paper. All three worked systems are constructed. What would license applying these results to an actual organisation is a preregistered fit with held-out comparison against declared baselines, and the paper specifying that protocol reports its own confirmatory application **failing** its second rule [Curzi, 2026i]. A reader who takes this paper's arithmetic as evidence that organisations obey the storage law has read it wrongly.

Monotonicity in `u` is not established here and is contested. The framework's surplus is monotone increasing in `u`, and the empirical literature does not agree that the benefit of difference rises without turning over. Uzzi and Spiro [2005] find an inverted U, with creative success rising and then falling with cohesion; Mannix and Neale [2005] and van Knippenberg and Schippers [2007] find that surface-level diversity frequently costs in the short run; Putnam [2007] finds short-run reductions in trust and civic participation, with Abascal and Baldassarri [2015] as the rebuttal; and Sagan [1993] documents settings in which redundancy reduces safety. Against these, Granovetter [1973], Burt [2004] and Schindler et al. [2010] supply measured benefits of bridging and of effective count. **The honest position is that the monotone form is this framework's construction over the regime it has examined, and where the curve turns is an open empirical question.** Harrison and Klein [2007] sharpens the demand further: three incompatible constructs travel under the word diversity — separation, variety and disparity — and `u` owes the reader a statement of which one it is. **This paper's `u` is a variety measure with a disparity weighting and it is stated as such here for the first time in this series.**

Diversification benefit depends on covariance, not count. Markowitz [1952] stated this in 1952 with the mathematics attached, and it is the same content as the effective-count result: `N` uncorrelated holdings and `N` perfectly correlated holdings have the same nominal `N` and different effective counts. **Any reading of `eta ln N` as a benefit of headcount rather than of *audited* headcount is a misreading**, and the audit that makes the distinction computable is developed separately [Curzi, 2026c,?].

The stability benefit of an effective count is not free of a purely statistical explanation. Doak et al. [1998] showed that diversity–stability correlations can arise from statistical averaging alone with no mechanism; May [1972] and Gardner and Ashby [1970] showed that increasing diversity and connectance destabilises randomly assembled systems; McCann [2000] is the fair survey; and Loreau and de Mazancourt [2008] names the decisive variable, synchrony, which is the ecological name for what this framework calls a coordination perimeter.

The `n_opt = sqrt(eta/kappa)` rule is not a law of team size. It is the stationary point of a model whose cost term is a badged modelling choice and whose benefit term is a functional form the evidence does not currently discriminate from at least two alternatives. Change the cost exponent and the rule changes.

8.10.3 10.3 Relation to the surrounding literature

The three terms of this paper have different standing in the external literature and the difference should be stated.

Cost has the strongest grounding. The quadratic pair count and its interpretation as coordination burden are Brooks [1975] and Conway [1968]; the level–rate vocabulary is Forrester [1961]; the finding that people misjudge such systems even under aligned incentives is Sterman [1989]; the queueing result that makes slack a control device rather than waste is Kingman [1962], Little [1961] and Hopp and Spearman [2011]; and the reserve itself was named organisational slack by Cyert and March [1963]. Nothing in Section 5 is novel as a mechanism; what is new is pricing these against a logarithmic benefit on one commensurable scale.

Conversion has the weakest grounding and the paper says so. The three-gate decomposition appears in no external literature. What external work supports is the *class* of devices: the design principles associated with durable common-pool institutions [Ostrom, 1990, 2010, Cox et al., 2010] read as conversion and retention devices; the invisibility of working infrastructure [Star and Ruhleder, 1996, Star and Griesemer, 1989]; and the finding that a group performance factor exists and is distinct from member ability [Woolley et al., 2010] — which is what the conversion coefficient is being asked to stand in for, and which Hong and Page [2004] illustrates and Thompson [2014] sharply criticises. **Those two must be cited together or not at all**, and Singer [2019] is the repair that survives the objection.

The gauge is this framework's own and its nearest relative is a budget constraint. Its content is that three quantities usually argued about separately are commensurable, which is a modelling claim rather than a discovery.

Within the corpus, these results are consumed in four ways. They are **reused as an instrument** in the built-environment analyses, whose entrance-sequence case moves interruptions from 22 to 6 per person-day and headroom from `+0.0642` to `+0.2955` for 7.6 per cent of net floor [Curzi, 2026f], and in the channel analyses, where forced integration raised realised `u` from 0.1155 to 0.3465 and surplus by 121 per cent while cost rose 279 per cent, taking the step from `−0.1953` to `−0.3714` [Curzi, 2026g]. They are **restated as a ceiling on roster size**: the roster ceiling `m(m−1) <= 2 eta ln(N)/kappa`, with a constructed commons sitting exactly at it, 30 against 30.7225, so that a seventh member makes the case structural [Curzi, 2026]. They are **bounded by a completeness result**: the steady state depends on exactly `u`, `N`, `eta` and `c` through `F`, plus `delta` as a divisor, with no fifth argument and `delta` not a lever on the deficit [Curzi, 2026]. And they are **shown to be order-sensitive**: eight periods of the wrong lever order cost twelve periods of permanent lag, a minimum stock of `−2.373029` from `+1.000000`, and 111.133601 stock-periods of cumulative gap [Curzi, 2026]. **That last result is the sharpest limitation on the four-lever framing of Section 6.8, which prices the levers and does not price their sequence.**

Two results from the structural series bear directly on Section 5's cost analysis. The disclosure-perimeter analysis scores a five-criterion test as a **product rather than an average**, so that five structures averaging 0.80 yield a group product of zero because two contain a zero-scoring element [Curzi, 2026] — which is the same arithmetic as the three-gate composition of Section 4.3 arriving in a different domain, and is the strongest independent support this

paper has for its multiplicative form. And the option-pricing analysis of an uncertain jurisdictional call gives a cost ceiling `p = (c + 0.0051096)/0.0318401`, so that a leg is worth nothing at any probability once its incremental cost exceeds 0.0267305 — 8.9 per cent of that group's entire maintenance budget [Curzi, 2026]. **That is the liaison-multiplier sensitivity of Section 9.2 stated as a decision rule, and it is the form the sensitivity analysis should take when a cost is uncertain rather than merely estimated.**

Finally, the enterprise itself has a literature and it is not entirely friendly. Castellano et al. [2009] surveys and bounds the programme of carrying physics formalism into social systems and supplies definitions this framework can be held to; Helbing and Molnár [1995] and Helbing [2001] set the evidentiary bar by validating a social force analogy against measured trajectories, and **the standard they set is prediction of observed data, not internal consistency.** Gallegati et al. [2006] is the field's own indictment and reads as a checklist against this paper: ignorance of existing work, sub-standard statistical procedure, unjustified universality claims from limited data. Hedström and Ylikoski [2010] states the criterion sociologists will apply — an explanation must name a mechanism, not exhibit a fitted curve — which this paper meets in form, since every result names a mechanism, and does not meet in evidence, since no curve was fitted to anything observed. Durlauf [2005] asks for the prediction that only this model makes, and Sobkowicz [2020] asks it in one line: what observation would distinguish these laws from a neighbouring model that fits equally well? **Section 12 records that this paper does not have an answer.** Epstein [2008] is the standing reply to the charge that such models forecast nothing — prediction is one of sixteen reasons to model — and the reason this paper claims explanation and design rather than forecast.

8.11 11 Verification

The results of this paper compound from six postulates. Each is atomic, each is checkable on its own, and each carries its status. **Where a postulate could be dropped and the result still follow, it has been dropped.**

8.11.1 11.1 Dimensional audit

The equation must balance before anything else about it is worth checking. `[Q]` denotes the dimension of stored order and `[T]` the dimension of time; the period is the unit of `[T]` and every rate below is *per period*, which is why no explicit `[T^-1]` appears once the equation is written in discrete steps.

Symbol	Dimension	Unit	Status
`Q_t`	`[Q]`	proxy units (standards, runbooks, owned decisions)	**measured**, in whatever unit the declared order proxy counts
`U_t`	`[1]`	none	**defined** dimensionless: `u = 1 - (x.y)^2` with unit vectors
`S_t`	`[1]`	nats	**derived** dimensionless: a logarithm of an effective count
`eta`	`[Q]` per nat per step	proxy units per nat per period	**required by the balance**; see below

Symbol	Dimension	Unit	Status
`delta`	`[1]`	per period	**measured** dimensionless fraction per step
`C_t`	`[Q]` per step	proxy units per period	**measured**
`kappa`	`[Q]` per step per link	proxy units per period per active link	**measured**
`gamma`	`[1]`	per period	**measured** dimensionless fraction per step, like `delta`
`A`	`[Q]` per step	proxy units per period	**measured**
`h_t`	`[Q]` per step	proxy units per period	**derived**
`Q_crit`, `Q_inf`	`[Q]`	proxy units	**derived**: `[Q]/step` over `[1]/step` returns `[Q]`

Does the equation balance? `Q_{t+1} = (1−delta) Q_t + eta S_t − C_t` balances if and only if every term on the right carries `[Q]`. The first does, since `delta` is dimensionless; the third does by construction; the second does only if `eta S_t` carries `[Q]`, and since `S_t` is a dimensionless count in nats, **`eta` must carry `[Q]` per nat per step.** The gauge then balances too: `ln N` is dimensionless, so `eta ln N` carries `[Q]` per step and is commensurable with `delta Q_t` and with `C_t`, which is what makes the three-way subtraction well formed. And `eta/delta` carries `[Q]` per nat, which is the DC gain in the proper sense: units of stock per sustained nat per period.

The source is silent on this and its silence is not neutral. The source manuscript states that `eta` has units of `[Q]/[S]` and that, `S` being dimensionless, `eta` carries whatever unit the order proxy carries. **That is the `[Q]` per nat half and it omits the per-step half entirely.** The source then advises normalising `Q` so that `eta` lands in `[0,1]` and adds that `eta > 1` should be read as a unit choice rather than a violation — advice that treats `eta` as if it were a pure number. **The reading required for the law to balance is `[Q]` per nat per period, it is stated here explicitly, and it is recorded that the source does not supply it rather than being assigned quietly.** The practical consequence is the one Section 5.9 flags: a crossover table computed with `kappa` in hours, `eta` in normalised order-units and `Q` in document counts is dimensionally malformed however tidy the arithmetic looks, and the denomination requirement is part of the survey protocol [Curzi, 2026i].

Where the framework has no operational unit, it is said here. `Q` is stored order, and stored order has no natural unit: it is counted in whatever the declared proxy counts, and two systems' `Q` values are not comparable unless they declare the same proxy. **Consequently `eta` and `kappa` are not comparable across systems either**, and a table of `eta` values drawn from different surveys is meaningless. Comfort itself, the underlying construct of the corpus, has **no operational unit at all**; it is treated as a dimensionless magnitude by stipulation, not by measurement, and Section 12 records that the quantitative structure required for that stipulation has not been tested.

8.11.2 11.2 The postulates

P1 — The recurrence is linear and first order. `Q_{t+1} = a Q_t + x_t` with `a` and `x_t` not depending on `Q`. *Status:* **DEFINITION** — the model form adopted by the framework, with `a := 1 − delta` and `x_t := eta S_t − C_t`. It carries no empirical weight on its own.

P2 — Surplus per period is bounded: `0 <= S_t <= ln N`. *Status:* **CITED** — the range result of the surplus functional [Curzi, 2026], following from `f(u) = ln(1+(N−1)u)` on `u` in `[0,1]`.

P3 — `ln` is strictly increasing and strictly concave, and `ln(x^2) = 2 ln x`. *Status:* **ARITHMETIC.**

P4 — In a group of `n`, the number of unordered pairs is `n(n−1)/2`. *Status:* **ARITHMETIC** — combinatorics, and true independently of any claim about cost.

P5 — Coordination cost is proportional to the number of active communication paths, `C1 = kappa P`. *Status:* **POSTULATED** — a modelling choice of this framework. The interpretive step from the pair count to a cost is Brooks [1975]'s observation from practice, presented there as observation and not as proof. It is the only postulate in the chain with no theorem and no controlled measurement behind it, and every result about crossover, optimum and topology consumes it.

P6 — Cost accrues every period whether or not surplus was delivered. *Status:* **POSTULATED** — an assumption about how real systems charge overhead. It is used at exactly one place, R6 below, and the chain's other results do not depend on it.

The three-gate decomposition of `eta` is **not** in this list, because no result in the chain consumes it. It is a diagnostic device, and it is badged as such wherever it appears.

8.11.3 11.3 The compounding chain

```
P1 + P2        -> L1   the per-period increment eta*S_t - C_t is at most
                       eta*ln N - C_t, attained only at u = 1.              ARITHMETIC

L1             -> R1   a nondecreasing step requires C_t <= eta*ln N - delta*Q_t;
                       define h_t := eta*ln N - delta*Q_t - C_t, so that
                       h_t >= 0 is exactly that condition, and the maximum
                       one-step increment is r_max = h_t.                   ARITHMETIC

P3             -> R2   2*eta*ln N = eta*ln(N^2), so doubling eta and squaring
                       N give the identical budget.                         ARITHMETIC

P3 + P2        -> R3   doubling S needs (1+(N−1)u)^2 = 1+(N−1)u', so
                       u' = ((1+(N−1)u)^2 − 1)/(N−1); u' <= 1 requires
                       (1+(N−1)u)^2 <= N, i.e. u <= 1/(sqrt(N)+1).          ARITHMETIC

P4 + P5        -> L2   coordination cost under complete-graph obligation is
                       C(n) = kappa*n(n−1)/2.                               POSTULATED (P5)

L2 + P3        -> R4   net(n) = eta*ln n − kappa*n(n−1)/2 is stationary at
                       eta = kappa*n*(n − 1/2), so n_opt ~ sqrt(eta/kappa);
                       the crossover, where C(n) first exceeds eta*ln n,
                       is strictly larger.                                  ARITHMETIC given L2

L2             -> R5   the path count, and therefore C, depends on the wiring
                       plan and not on n alone; N is unchanged by rewiring,
                       so eta*ln N is unchanged and dh = −dC exactly.       ARITHMETIC given L2

R1 + P1        -> R6   at the fixed point Q_inf = (eta*F(u*) − c*)/delta,
                       h_inf = eta*ln N − delta*Q_inf − c* = eta*(ln N − F(u*)):
                       delta, C and Q cancel identically.                   ARITHMETIC

R6 + P6        -> R7   since F(u) <= ln N by P2, h_inf >= 0 always, so the
                       constant-parameter linear model never reaches negative
                       headroom; ossification must be imported.              ARITHMETIC
```

Every line is checkable from its own inputs. R1, R2, R3, R6 and R7 are arithmetic consequences of one definition, one cited range result and elementary properties of the logarithm. **R4 and R5 — the crossover, the optimum, and the topology lever — consume P5, which has no external support beyond an observation from practice.** That is the load-bearing weakness of Section 5 and it is stated here rather than left to be found: **if coordination cost is not superlinear in the path count, the sizing results of this paper do not hold, and nothing in this paper measures whether it is.**

What this chain does not establish. It does not establish that any organisation obeys P1. That is a modelling postulate, it is not verified here, and the one preregistered confirmatory test of it so far reported in this corpus did not meet its own declared margin [Curzi, 2026i]. **A chain whose steps are ARITHMETIC, CITED and POSTULATED delivers the mathematics with certainty and delivers nothing whatever about institutions.**

8.11.4 11.4 The checks a reviewer can redo in a minute

The doubling identity. `ln 8 = 2.079442`, so `0.10 x 2.079442 = 0.2079442`. And `ln 64 = 4.158883`, so `0.10 x 4.158883 = 0.4158883`, while `0.20 x 2.079442 = 0.4158883`. **The two are equal to every digit printed, because `ln(8^2) = 2 ln 8` exactly.** ARITHMETIC.

The infeasibility threshold. At `N = 8`, `1/(sqrt(8)+1) = 1/3.828427 = 0.261204`. At `u = 0.30 > 0.261204` the doubling is infeasible, and directly: `S = ln(1 + 7 x 0.30) = ln 3.10 = 1.131402`, so doubling requires `u' = (3.10^2 − 1)/7 = (9.61 − 1)/7 = 8.61/7 = 1.230000 > 1`. **Impossible.** ARITHMETIC.

The gate product. `0.20 x 0.60 x 0.70 = 0.084`; `0.20 x 0.90 x 0.70 = 0.126`, a rise of 50.0 per cent; `0.80 x 0.60 x 0.70 = 0.336`, a rise of 300.0 per cent. ARITHMETIC.

The optimum against the closed form. At `eta = 0.30`, `kappa = 0.010`: `sqrt(0.30/0.010) = sqrt(30) = 5.477`, and direct search over integers gives `net(5) = 0.30 ln 5 − 0.005 x 20 = 0.482831 − 0.100 = 0.382831`, `net(6) = 0.537528 − 0.150 = 0.387528`, `net(7) = 0.583773 − 0.210 = 0.373773`. **The optimum is 6.** The crossover is the smallest `n` with `0.005 n(n−1) > 0.30 ln n`: at `n = 12`, `0.66 < 0.745472`; at `n = 13`, `0.78 > 0.769485`. **The crossover is 13.** ARITHMETIC.

The topology swing. `0.006 x 18 x 17/2 = 0.006 x 153 = 0.918`; `3 x (0.006 x 15) + 3 x 4 x 0.006 = 0.270 + 0.072 = 0.342`. With `eta ln 18 = 0.22 x 2.890372 = 0.635882` and `delta Q = 0.175`: `h = 0.635882 − 0.175 − 0.918 = −0.457118` and `h = 0.635882 − 0.175 − 0.342 = +0.118882`. **The swing is 0.576000 and the cost falls by `(0.918−0.342)/0.918 = 62.7` per cent.** ARITHMETIC.

The fixed-point identity, checked on a row of the table. `eta = 0.18`, `N = 12`, `u* = 0.45`, `delta = 0.06`, `C = 0.22`. Then `S = ln(1 + 11 x 0.45) = ln 5.95 = 1.783391`, `Q_inf = (0.18 x 1.783391 − 0.22)/0.06 = (0.321010 − 0.22)/0.06 = 1.683509`, and `h_inf = 0.18 x 2.484907 − 0.06 x 1.683509 − 0.22 = 0.447283 − 0.101011 − 0.22 = 0.126273`. Against `eta(ln N − S) = 0.18 x (2.484907 − 1.783391) = 0.18 x 0.701516 = 0.126273`. **Identical to six decimal places, as the cancellation requires.** ARITHMETIC.

The nine-person case, end to end. `S = ln(1 + 5 x 0.55) = ln 3.75 = 1.321756`; `eta = 0.15 x 0.40 x 0.50 = 0.030`; `h_0 = 0.030 x 1.791759 − 0.05 x 0.80 − 0.12 = 0.053753 − 0.040 − 0.120 = −0.106247`; `Q_inf = (0.030 x 1.321756 − 0.12)/0.05 = (0.039653 − 0.120)/0.05 = −1.606943`; threshold `C/S = 0.12/1.321756 = 0.090789` and `(delta Q_0 + C)/ln N = 0.16/1.791759 = 0.089298`, so the binding requirement is `eta >= 0.0908`, **a factor of 3.03 on a measured 0.030.** ARITHMETIC.

The standards body's two decisive numbers. `S = ln 7.5 = 2.014903`; `ln 14 = 2.639057`; `delta_eff = 0.045 + 0.030 = 0.075`; `Q_inf = (0.20 x 2.014903 − 0.08 + 0.25)/0.075 = 0.572981/0.075 = 7.639747`; `Q_crit = (0.20 x 2.639057 − 0.08)/0.075 = 0.447811/0.075 = 5.970816`. **The ratio is 7.639747/5.970816 = 1.2795, so the body converges 28.0 per cent above what it can sustain.** ARITHMETIC.

8.11.5 11.5 Limits, asymptotics, and the model's valid domain

`eta -> 0`. The drive term vanishes and `Q_inf = -C/delta <= 0`: the system decays to the admissibility floor at rate `delta` while paying `C`. **Zero conversion decouples the input from the stock entirely**, so no interaction geometry of any quality changes the outcome.

`eta -> infinity`. `Q_inf` and `h` grow without bound, which the model permits and which is a defect of the linear form rather than a result. Real capture saturates, and the linear model excludes saturation by assumption. **The model has no upper domain limit on `eta` and should be given one empirically before any extrapolation.**

`N -> 1`. `ln N = 0` and `F(u) = 0` for every `u`. **A single audited category has zero available surplus, not a small amount.** The ceiling and the achievable value collapse together, so `Q_inf = -C/delta <= 0` and headroom is negative at any positive stock. This is the boundary that makes the collapse operation of the concentration instrument consequential: a structure with one effective bloc has `ln(1.00) = 0` available surplus [Curzi, 2026].

`N -> infinity`. `eta ln N -> infinity`, so the per-period budget grows without bound. **Taken literally this says that a sufficiently large audited category count makes any cost sustainable, and that is false.** Three things bound it and all three are domain restrictions rather than results.

1. *Internal.* Coordination cost grows with the pair count, which is quadratic under P5, so the two curves cross at a size that depends only on `eta` and `kappa` — this paper's own crossover. Beyond the crossing, additional categories cost more than the ceiling they buy.
2. *External and contrary.* Uzzi and Spiro [2005] find an inverted U: creative success rises and then *falls* with cohesion, so the benefit of difference turns over rather than growing without bound. Sagan [1993] documents settings in which redundancy reduces safety, and May [1972] and Gardner and Ashby [1970] show that increasing diversity and connectance destabilises randomly assembled systems. **The unbounded growth of `eta ln N` contradicts this literature and the contradiction is not resolved here.**
3. *Marginal.* Even inside the model the marginal gain `ln N - ln(N-1) ~ 1/N` vanishes, so the divergence is the slowest available and is never a practical route.

The stated domain is therefore `N` bounded above by the crossover of Section 5.4, and the logarithmic ceiling is a within-domain approximation and not an asymptotic claim. It is recorded as a restriction on where the model may be used, not as a finding about large groups.

`u -> 0`. `N_eff -> 1`, `F -> 0`, and every conversion intervention returns nothing. **`u -> 1`.** `F -> ln N`, the ceiling is attained, and by the fixed-point identity `h_inf -> 0`: a perfectly exploited geometry at equilibrium has no headroom at all. Strict concavity means the approach is front-loaded: at `N = 8`, moving `u` from 0.00 to 0.25 buys 1.0116 nats and moving it from 0.75 to 1.00 buys 0.2468.

`kappa -> 0`. The crossover and the optimum both diverge, so a costless link removes every size limit this paper derives. **That is the signature that the size results are entirely a statement about `kappa` and not about people.** **`kappa -> infinity`.** `n_opt -> 1` and the net value at every `n >= 2` is negative: there exist parameter regimes in which no group outperforms nobody working together, and at `eta = 0.10`, `kappa = 0.10` the model already returns `net(2) = -0.031` against `net(1) = 0`.

`rho -> 1` in the queueing term. `rho/(1-rho) -> infinity`: the delay contribution to `C` is unbounded, so a critical resource at full utilisation violates the sustainability ceiling by itself. The divergence is real in the M/M/1 model and is the reason Section 5.8 sets a target below 0.80.

`gamma ->` such that `delta + gamma -> 1`. The effective time constant goes to zero and the system stops being a stock. **`delta -> 0`** removes the fixed point entirely and is outside the model's domain, which is the result the retention analysis establishes [Curzi, 2026a] and which this paper inherits rather than re-deriving.

Stated domain. The results of this paper are valid for `delta` in `(0, 0.5]`, `eta > 0` and bounded above by the saturation point of whatever capture mechanism is in use, `N >= 2` and bounded above by the crossover, `u` in `[0,1]`, `kappa > 0`, `gamma >= 0` with `delta + gamma < 1`, and `C_t <= (1−delta)Q_t + eta S_t` each period. **Outside that domain the equations still have solutions and they should not be interpreted as statements about a stock.**

8.11.6 11.6 Invariance

Unit rescaling. Let `Q' = cQ` for positive `c`. The law is invariant provided `eta`, `C`, `kappa` and `A` rescale with it — `eta' = c eta`, `C' = cC`, `kappa' = c kappa`, `A' = cA` — while `delta`, `gamma`, `N` and `u` are unchanged, since `delta` and `gamma` are dimensionless fractions and `S` is a dimensionless count. **`delta`, `gamma`, `u` and `N` are therefore the unit-free quantities of the framework, and `Q`, `eta`, `C`, `kappa` and `A` are the unit-carrying ones.** Two systems can be compared on the first group directly; they cannot be compared on the second unless they share a proxy. **This is the invariance that licenses the `n_opt = sqrt(eta/kappa)` rule, since the ratio `eta/kappa` is invariant under the rescaling** — it carries dimension `[link]`, the reciprocal of a per-link cost against a per-nat conversion, and `n_opt` is therefore a pure number as it must be.

Rewiring invariance. Under any change of communication topology holding the roster fixed, `N`, `u` and `S` are unchanged and only `C` moves, so `dh = −dC` exactly. **This is what makes topology a free lever and it is the invariance H5 tests.** What would break it: a rewiring that removes categories from the room, which changes `N`; or one that suppresses disagreement, which changes `u` — F15, the hub that eats the variance, is precisely the failure of this invariance.

What would break the unit invariance: a `delta` that varies with `Q`, which makes the transformation non-linear; an `eta` that saturates at large `S`, which the linear model excludes by assumption; or a proxy whose counting unit is not extensive, so that doubling the system does not double the count. **The third is the most likely in practice and the least often checked.**

How many scales this has been exercised at. Within this paper: three, all constructed. Across the corpus the same five-parameter survey has been applied from a single desk to a twenty-two-household block [Curzi, 2026k]. **That is a handful of systems, one corpus, one author, and no independent replication. The invariance is a claim about form that has been exercised, not one that has been established.**

8.11.7 11.7 Model comparison, and the exponent that was never estimated

This paper fits nothing, so no information criterion applies to it. What it does do is assert a functional form for cost, and the rigour standard requires that assertion to be handled properly rather than by assumption.

The exponent 2 in `C = kappa n(n−1)/2` is defined by the model, not estimated from data. That is the honest status and it is stated wherever the form is used. The pair count is exact combinatorics; the identification of coordination burden with the pair count is P5, a badged modelling choice.

The procedure the source manuscript proposes for checking it is not sound. It prescribes regressing `log C` on `log n` across comparable units and reading the slope, with a slope near 2 taken to support the complete-graph postulate. Clauset et al. [2009] shows that fitting a scaling exponent by ordinary least squares on log-transformed data is unreliable, that a straight line on a log-log plot is not evidence, and that the defensible procedure is maximum likelihood with a goodness-of-fit test and an explicit likelihood-ratio comparison against named alternatives. Stumpf and Porter [2012] adds that even a well-fitted exponent is weak evidence for a mechanism, because many mechanisms produce the same curve. **The defensible version of the check is therefore: state the two candidate models — `C = kappa n(n−1)/2` and `C = kappa_eff n` — with their free parameter counts, fit both by maximum likelihood on training data, and compare on held-out error with AIC or BIC reported, so that the parameter count is paid for.**

No such comparison exists in this corpus. **The correction is recorded here rather than made silently, and it is listed in Section 12 as an unmet check.**

8.11.8 11.8 Analogy discipline, scale type, and the precision of the numbers

The circuit and stock–flow correspondences are shared mathematical form, not derivations from physical premises. The storage law and a first-order discrete section are governed by the same difference equation, so every theorem about first-order systems applies to both; nothing about charge or capacitance is claimed to hold of an institution. The level–rate vocabulary of system dynamics is the same statement in a different notation [Forrester, 1961].

The queueing result is a derivation, not an analogy, wherever its premises hold. `rho/(1-rho)` follows from the M/M/1 model — Poisson arrivals, exponential service, one server, infinite queue — and where an approval process does not satisfy those premises the formula does not transfer. **The premises are almost never checked in organisational settings and are not checked here**; Hopp and Spearman [2011] gives the variability-adjusted forms that should be used instead when service times are not exponential. **This paper uses the M/M/1 form as an order-of-magnitude illustration and labels it as one.**

The entropy invoked anywhere near `ln N` is Shannon entropy — a dimensionless information measure in nats — **and not thermodynamic entropy**, which carries `[energy][temperature]^-1`. They are different objects and the framework identifies surplus with neither. Mirowski [1989] is the standing warning: neoclassical economics was built by copying mid-nineteenth-century energetics and the copy was defective, because utility was made to play the role of energy without the conservation law that gave energy its content. **`Q` in this paper is a stock that accumulates, leaks and is spent — the grammar of a conserved quantity — and nothing in this framework is conserved.** Cartwright [1999] offers the escape route this paper takes: specify the arrangement within which the law is claimed to hold, which is the stated domain of Section 11.5, and stop claiming a universality the law does not need.

Scale type. `Q`, `C`, `kappa` and `h` are treated as ratio-scale quantities throughout — differences, ratios and logarithms are all taken — and `u` likewise. **The conjoint-measurement conditions that would license that treatment have not been tested** [Luce and Tukey, 1964, Krantz et al., 1971]. Michell [1997] argues that psychology systematically fails to test whether its attributes are quantitative at all before measuring them, and **that is the strongest single objection to this framework's founding move.** The honest answer is that the ratio-scale treatment is a stipulation, that the remedy is a conjoint test or a Rasch-model demonstration [Rasch, 1960, Andrich, 1988], and that neither has been run. Note also that `u` estimated from a disagreement audit is built from ordinal judgements aggregated into a proportion; **the aggregation step is not licensed by the scale of its inputs and is performed anyway, which is stated here rather than defended.**

Precision. The numbers in this paper are of three kinds. *Defined or derived-from-defined* quantities — `ln 8 = 2.079442`, `ln 6 = 1.791759`, `1/(sqrt(8)+1) = 0.261204`, every entry in the doubling and infeasibility tables — are exact to the precision printed and may be recomputed further. *Illustrative model output* — every trajectory table, `h_0 = -0.1062`, `Q_inf = -1.6069`, `Q_crit = 5.9708` — is the output of stipulated parameters and carries **no measurement uncertainty because there was no measurement**; four or six decimal places there record the arithmetic, not confidence. *Measured or fitted* quantities do not appear in this paper, because nothing in it was measured. **Any application of this framework to real data must report fitted parameters with intervals**, and the four-decimal presentation used throughout must not be carried over to a measured `eta`, where two significant figures with an interval would be the defensible form.

8.12 12 Limitations

The three worked systems are constructed, not observed. No dataset was collected for this paper. Every number in Section 9 is the output of the stated parameters under the stated model, carried through so that a reader can re-derive it. They demonstrate that the procedure runs and that it reports its own failures; they are not evidence that any organisation behaves this way and should never be cited as such.

The cost model is the paper's load-bearing weakness. P5 — that coordination cost is proportional to the active path count — carries the crossover, the optimum, the topology lever and every sizing result. Its support is an observation from practice [Brooks, 1975] presented by its author as observation, not proof. **Nothing in this paper measures the exponent, and Section 11.7 records that the procedure the corpus proposes for measuring it is not sound.** If coordination cost is in fact linear in headcount under managed communication — which Conway [1968] arguably implies for an organisation that has already solved its topology — then Sections 5.4 to 5.6 describe a regime rather than a law.

The three-gate decomposition has no external support at all. It appears in no literature; it is a diagnostic convenience; and although no result in the verification chain consumes it, it carries the entire practical argument of Section 4 and the whole of the nine-person case's diagnosis. **A reviewer is entitled to treat it as an unsupported taxonomy, and this paper's answer is that it is one.**

The liaison multiplier is the least well-estimated number in the paper. Section 9.2's conclusion reverses between a four-fold and an eight-fold cross-boundary cost — `h = +0.0109` against `h = −0.0611` — and nothing here determines which is right. **A result that flips sign on an unmeasured parameter is a result about the parameter.**

The cellular recommendation prices a saving and not a fragility. Cells joined by thin liaison links are a coupled system, and coupled networks are more fragile than either network alone [Buldyrev et al., 2010]; interactive complexity with tight coupling makes catastrophic failure a system property [Perrow, 1984]; and redundancy can reduce safety [Sagan, 1993]. **This paper computes the coordination saving of a cellular split and does not compute its failure cost.** The four-way convergence of Section 5.7 is convergence on a topology, not on a risk assessment.

Which parameters were chosen rather than measured. In all three worked systems, `(N, u, eta, delta, C, kappa, gamma, A)` are stipulated. The capture-regime table of Section 4.9 is explicitly a set of illustrative inputs spanning a plausible range and must not be cited as a finding. The five-topology price table of Section 5.7 assumes a four-fold liaison multiplier that is a design estimate. **None of these is a measurement and none carries an interval.**

`N_eff = 1 + (N−1)u` is not a Hill number, and no external literature contains it. `1/HHI` is the Hill number of order two and `exp(H)` is the Hill number of order one, and both are fully grounded [Hill, 1973, Jost, 2006]; `1 + (N−1)u` is a linear interpolation between 1 and `N` and is this framework's own construction, adopted by design axiom S3. **A reviewer who reaches for the Hill-number literature as support will find that it does not apply.** The two quantities are used under one effective-count heading across this corpus, which is a real exposure; the repair is to derive the properties of `1 + (N−1)u` in the framework's own terms and to reserve the Hill citations for `1/HHI` and `exp(H)`, where they are exact [Curzi, 2026c,?].

`u` has not been shown to be a quantity. The framework treats non-parallelism as a measurable magnitude, and Michell [1997] argues that psychology routinely fails to test whether its attributes are quantitative at all. The remedies are conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971] or a Rasch demonstration [Rasch, 1960]; neither has been run, so the quantitative treatment is a stipulation. Relatedly, if `u` is read as a similarity measure over people it cannot be assumed to behave metrically, since psychological similarity is asymmetric and violates the triangle inequality [Tversky, 1977].

`u` is a variety measure and the word it travels under covers three incompatible constructs. Harrison and Klein [2007] distinguishes separation, variety and disparity, and a quantity like `u` owes the reader a statement of which one it is. Section 10.2 supplies that statement; **it has not been supplied consistently across this corpus and that inconsistency is a real exposure.**

The reflection problem, and why it outranks every fitting result. Section 3.3 states it in full: applied to a group whose members both influence and constitute the aggregate, the specification is reflexive, and Manski [1993] proves the endogenous social effect is not identified from observational data. **No fit — however well designed, however honestly held out — recovers that parameter**, and Shalizi and Thomas [2011] show the same confounding for network data. This paper adopts no remedy, so **the applied reading of `eta` is a modelling position rather than an identified empirical result.** The most realistic repair is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001].

The Lucas critique applied to this framework's own parameters. Section 4.13 asserts that a measure adopted as a target ceases to measure what it names, and prescribes an adversarial test in response. The framework then treats `eta`, `delta`, `N` and `kappa` as constants over an estimation window. **Both cannot be true without qualification** [Lucas, 1976]. The position taken here is the narrow one: the parameters are treated as stable *only over a declared window and only while `Q` and `h` are not themselves reported targets.* **Where `h` is reported upward, the framework's own reflexivity applies to it, and the gauge is at least as gameable as anything it audits.** Hacking [1995] states the general form — classifications of people interact with the people classified, who change in response — and Ferraro et al. [2005] states the specific hazard, that theories assuming the worst of people can make that assumption true. **A framework that tells an organisation its stored order decays should ask what that assumption will make true.**

The functional form is underdetermined. Latané [1981]'s sub-linear power law and Briscoe et al. [2006]'s `n log n` fit the same qualitative facts, and nothing assembled here discriminates between them. **The logarithm is chosen for its axiomatic characterisation, not established by measurement**, and Peters and Gell-Mann [2016] is the strongest available warrant precisely because it needs no psychological premise.

No scaling or heavy-tail claim is made from data, so the distribution-fitting procedure of Clauset et al. [2009] does not apply to any fitted result here — because there are none. **It does apply to the exponent check the corpus proposes, and Section 11.7 records that the proposed check is unsound and states what would replace it.** This is an unmet requirement, not a satisfied one.

The linear model is chosen for tractability. Real capture saturates; real cost has thresholds; real institutions have hysteresis and a state-dependent `eta`. The steady state flags its own breakdown when `eta F(u*) < c*`, which is a useful property, but a linear model reporting a negative equilibrium has told the analyst only that it has left its domain, not what replaces it.

Constant parameters over the estimation window is an assumption organisations violate. Turnover, reorganisation and a change of leadership all move `delta`, `eta`, `N` and `kappa`. **A fit spanning a regime change is fitting an average of two systems, neither of which exists.**

Ossification is not explained. Section 6.7 shows that the constant-parameter linear model never reaches negative headroom and that a linear `Q`-scaling cost does not change this. The paper therefore *requires* an imported mechanism and offers three candidates, of which only exogenous accretion is worked. **The other two are named and not modelled**, and no evidence is offered that accretion is the common case; the third worked system is constructed to exhibit it, which demonstrates the diagnosis and proves nothing about frequency.

Levers are priced and their sequence is not. Section 6.8 gives four marginal derivatives and compares single moves. The corpus's own analysis of lever ordering finds that eight periods of the wrong order cost twelve periods of permanent lag, a minimum stock of `-2.373029` from `+1.000000`, and 111.133601 stock-periods of cumulative gap [Curzi, 2026]. **A table of marginal returns does not capture that, and the four-lever framing of this paper is a static comparison presented where a dynamic one is needed.**

Unmet rigour checks, printed rather than left to a reviewer. (i) *Model comparison.* This paper fits nothing, so no information criterion applies; but it asserts a cost exponent that was never estimated, and the corpus's one applied fit reports held-out RMSE against baselines and **no AIC or BIC**, so the parameter count was never paid for [Curzi, 2026i]. (ii) *Effect sizes and intervals.* Nothing in Section 9 carries an interval, because nothing in Section 9 was measured.

(iii) *Scale type.* `Q`, `C` and `u` are treated as ratio-scale and the conjoint conditions were not tested. (iv) *Independent replication.* Every system here and in the corpus's applied papers was constructed or surveyed by one author, and the reproducibility literature is unambiguous about what that is worth [Open Science Collaboration, 2015, Ioannidis, 2005]. (v) *Directional versus point prediction.* Meehl [1967] observes that directional predictions are nearly costless in the social sciences; this framework does make point predictions with constants, which is the right answer to that objection, but only Curzi [2026i] has so far put one at risk, and it did not meet its own margin. (vi) *The discriminating observation.* Durlauf [2005] and Sobkowicz [2020] ask what observation would distinguish these laws from a neighbouring model that fits equally well. **This paper does not have an answer**, and the honest statement is that the sizing results of Section 5 would be shared by any model pairing a decelerating benefit with a superlinear cost.

Nothing in this paper is a human-subjects finding. No interventions were run and no participants were recruited. The constraint that no intervention may remove a participant's ability to decline, invoked in Sections 6.9, 7 and 8, is a design constraint on prospective work and not a report of past practice.

What would falsify the account. H1 fails on a fitted `b` that moves between sub-windows with no recorded intervention. H2 fails if measured conversion is reliably closer to the mean of the gate values than to their product. H3 fails on a survey series in which geometry interventions dominate on computed headroom gain. H4 fails on a measured cost exponent near one under complete-graph obligation. H5 fails if a cellular split does not at least halve measured cost, or if measured `u` falls after it.

8.13 13 Conclusion

The three remaining terms of the storage law are read together by one gauge, `h_t = eta ln N − delta Q_t − C_t`, with three regimes — negative unsustainable, zero maintenance only, positive growth available — a maximum one-step increment `r_max = h_t`, and two distinct constraints that are routinely confused: admissibility `C_t <= (1−delta)Q_t + eta S_t` and sustainability `C_t <= eta ln N − delta Q_t`. **`eta` must carry `[Q]` per nat per period for the gauge to balance; the source is silent on the per-period half and this paper supplies the reading explicitly rather than assigning it quietly.**

Doubling the conversion coefficient is exactly squaring the category count, since `2 eta ln N = eta ln(N^2)`; and **doubling the surplus by raising non-parallelism alone is feasible only when `u <= 1/(sqrt(N)+1)`**, so at `N = 8` and `u = 0.30` the required `u'` is 1.2300 and the move is arithmetically impossible rather than merely expensive. **Conversion composes multiplicatively through recording, binding and reach gates**, so three gates at 0.7 give `eta = 0.343` and the weakest gate dominates: lifting recording from 0.20 to 0.80 gains 300 per cent against 50 per cent for lifting binding from 0.60 to 0.90. **`eta = 0` produces decline rather than stagnation**: the stock is non-increasing in every period and falls at exactly the cost rate.

The net optimum group size maximising `eta ln n − kappa n(n−1)/2` satisfies `eta = kappa n(n − 1/2)`, approximately `sqrt(eta/kappa)`, and lies far below the crossover at which cost exhausts the budget: at `eta = 0.30` and `kappa = 0.010` the optimum is six and the crossover is thirteen. Topology is a free lever: eighteen people rewired from a complete graph into three cells of six move from `h = −0.4571` to `h = +0.1189`, a swing of 0.576, with cost falling 63 per cent and the surplus ceiling untouched because `N = 18` either way. **When cost scales with stock as `C = C_0 + gamma Q`, the system behaves exactly as if `delta_eff = delta + gamma`**, so every result of the retention analysis transfers with that substitution. **At the fixed point, `h_inf = eta(ln N − F(u*))`: `delta`, `C` and `Q` cancel, so the only headroom a converged system has is the surplus it fails to extract from its own difference — and the plain linear model therefore never ossifies by itself.**

The nine-person worked case returns `N = 6`, `u = 0.55`, `S = 1.3218` nats — 74 per cent of `ln 6 = 1.7918` — with a measured conversion coefficient of 0.030 giving `h_0 = −0.1062` and a negative

steady state `Q_inf = -1.607`. The binding threshold is `eta >= 0.091`, a factor of three. These are the statements downstream papers should quote rather than paraphrase.

The paper's own counter-result is stated as plainly as its results. In that same worked case the levers this corpus is named for are inert: non-parallelism at 0.55 is already strong and adding a distinct lineage buys 0.0046, while cutting coordination cost to zero leaves headroom at roughly a tenth of what the conversion fix delivers. Improved cadence is refused as a conversion gain and booked under surplus instead. The fourth lever — deliberately shedding stored order — outperforms every other move at the paper's base parameters and is nonetheless declared out of bounds wherever what would be shed constitutes a person's ability to decline, **with the model giving no warning at that boundary, because the computed return there is genuinely positive.**

All of this is arithmetic conditional on one postulate with no controlled measurement behind it — that coordination cost tracks the active path count. **Whether any institution is described by these equations is a separate question, it is a postulate rather than a result, and the one preregistered confirmatory test of the underlying law reported in this corpus did not meet its own declared margin.**

8.13.1 Declarations

Data and code availability

No external dataset was collected for this paper. All numerical results are computed from the stated parameters under the model developed in the text, and every table can be re-derived from the equations and parameter values printed beside it. The three systems worked in Section 9 are constructed examples with declared parameters, not field observations. **The figures are generated by the scripts named in each caption**; those scripts contain no data beyond the numbers printed in this paper and the model equations of Sections 3 to 6.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the work, derived the results, produced the worked examples and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The three worked systems are constructed. The declination constraint invoked in Sections 6.9, 7 and 8 — that no intervention removing a participant's ability to decline is within this framework's scope — is a design constraint on prospective work and is not a report of any study performed.

Preregistration

This paper reports no preregistered test of its own; its results are derivations, and the falsification criteria attached to the three worked systems in Section 9 are illustrations of the form

such a registration would take rather than registrations of tests that were run. The preregistered protocol for testing the storage law against a real system, together with the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared margin of 10 per cent — is reported in Curzi [2026i]. Any applied claim resting on this paper inherits that result.

Chapter 9

The Effective Count and the Logarithmic Ceiling: Auditing Roster Size Against Non-Parallelism

Abstract. This paper develops the audited count that the framework substitutes for headcount and prices the three ways of raising it. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$, with $u = 1 - (x \cdot y)^2$ and surplus $S = \ln N_{\text{eff}}$, is stated with its provenance: three of the four characterising axioms are structural, and the affine form is badged throughout as a design axiom, chosen and not derived. **It is stated equally plainly that $1+(N-1)u$ is not a Hill number of any order and has no external support, where HHI^{-1} and $\exp(H)$ are the Hill numbers of orders two and one.** The same verification chain is run on both and the second fails visibly, returning 2.000000 on a share vector where every Hill number reports below 1.39. The consequence of the audit is severe — a hundred-person department at $u = 0.05$ has an effective count of 5.95 — and an exact bridge to a standard spectral measure is supplied, $N_{\text{eff}} = N + 1 - N/\text{PR}$ against the Rényi-2 participation ratio of the Gram matrix, re-verified here at machine epsilon. Because u depends only on the magnitude of correlation, perfect opposition scores $u = 0$ exactly as perfect agreement does, so a standing contrarian buys nothing. The sharp Lipschitz constant $N - 1$ is read as a measurement-error budget: at $N = 12$ an uncertainty of ± 0.05 around $u = 0.05$ admits a surplus anywhere in $[0, 0.7419]$. A worked twelve-person panel audits to $\bar{u} = 0.5137$, $N_{\text{eff}} = 6.6509$ and 76.3% of $\ln 12$, and every doubling of N adds exactly $\ln 2 = 0.6931$ at any scale. **A worked research institute has headroom -2.1182 that no attainable geometry closes: perfect orthogonality across all eight of its domains would still leave it declining, and the paper states that rather than choosing a different example.**

Keywords: effective count; non-parallelism; design axiom; participation ratio; Lipschitz bound; logarithmic ceiling; redundancy deficit; lineage census

Series: B. Engineering the Surplus **Paper:** CCP-009

9.1 1 Introduction

A body's headcount is not a measure of what it can produce. This paper develops the audited count that the framework substitutes for headcount, states exactly what that count is and is not, and prices the three ways of raising it.

The storage law of the framework drives stored order with an interaction surplus $S_t = F(U_t)$, and the surplus functional is $F(u) = \ln(1 + (N-1)u)$ with $u = 1 - (x \cdot y)^2$ [Curzi, 2026]. The exponential of that surplus is the object of this paper: $N_{\text{eff}} = 1+(N-1)u$, the **affine effective count**, so that $S = \ln N_{\text{eff}}$. Surplus is not the logarithm of a headcount. It is the logarithm of a headcount after the headcount has been audited for redundancy, and the audit is performed by a purely geometric quantity.

The first thing this paper must say about that count is what it is not. The corpus runs two quantities under the name *effective count*. One of them — the reciprocal Herfindahl index HHI^{-1} used elsewhere in the corpus [Curzi, 2026] — is the Hill number of order two [Hill, 1973, Jost, 2006], is a numbers-equivalent in the sense Adelman [1969] gave the term, and was independently reinvented in ecology [Simpson, 1949] and in political science [Laakso and Taagepera, 1979]. The other — $1 + (N-1)u$, the one this paper develops — **is not a Hill number of any order, is not a numbers-equivalent, and has no supporting entry in the ecological, economic, political-science or information-theoretic literature.** It is a linear interpolation between 1 and N and it follows from a design axiom the framework chose. Section 3.3 states the distinction, Section 9.6 runs the same verification chain on both and lets the second fail visibly, and every use of the affine count in this paper carries the badge.

Three of the four axioms that characterise f uniquely are structural bookkeeping. The fourth, **S3 — that the effective count is affine in** u — is a design decision. Everything in Sections 4 to 6 that reads as a discovery about institutions is, at bottom, a consequence of having decided that the effective count should interpolate linearly. The decision is defensible and it is not derived, and the paper badges it at every use.

The consequence is severe and is the paper's headline number. A hundred-person department at $u = 0.05$ has an effective count of 5.95. Not a hundred, not fifty, just under six. That figure is a statement about a geometry, not about the people in it, and the same arithmetic would apply to sensors or to estimators with nobody involved.

Seven further results follow. **(1)** An exact bridge to a standard spectral measure: $N_{\text{eff}} = N + 1 - N/\text{PR}$, where PR is the Rényi-2 participation ratio of the Gram matrix of the encoded states [Rényi, 1961], verified numerically at $K = 3, 5, 8, 12$ to better than 10^{-12} [Curzi, 2026i,?]. That identity does not repair the postulate underneath it, but it does name the audit: mean-pairwise u *is* the participation ratio, reparametrised. **(2)** Because u depends only on the magnitude of the correlation, perfect opposition at $\rho = -1$ scores $u = 0$ exactly as perfect agreement does; **a standing contrarian buys no surplus at all**, and a body assembled for creative tension has purchased an effective count of one at the price of two seats [Curzi, 2026]. **(3)** The sharp Lipschitz constant $N-1$ [Curzi, 2026] is read here as a measurement-error budget rather than a smoothness result: at $N = 12$, an uncertainty of ± 0.05 around $u = 0.05$ admits a surplus anywhere in $[0, 0.7419]$, a width of 0.7419, against 0.1266 at $u = 0.70$. **In the low-u regime where institutions actually sit, a plausible measurement error spans nearly the whole range of the quantity being estimated.** **(4)** The affine count is explicitly distinguished from the classical variance-reduction count $N_{\text{ind}} = N/(1 + (N-1)\rho)$, which tends to a hard asymptote of $1/\rho$; the two share a form and are different quantities, and Markowitz [1952] had the substantive point — that diversification benefit depends on covariance and not on count — in 1952. **(5)** Every doubling of N adds exactly $\ln 2 = 0.6931$ nats at any scale, so the ceiling gain from one category to two equals the gain from fifty to a hundred. **(6)** A twelve-person panel audits to $u = 0.5137$, $N_{\text{eff}} = 6.6509$ and $S = 1.8948$ nats, which is 76.3 per cent of $\ln 12$, with a redundancy deficit of 0.5901. **(7)** Growth of that panel from twelve to thirty buys 0.8714 nats for eighteen hires and 435 communication paths against 66, while redistributing the existing members across twelve lineages buys 0.2654 nats for none.

The paper's own worked institute refuses the lesson the framework is named for. A publicly funded research institute with eight declared domains has headroom $h = -2.1182$ against a total structural budget of $\eta \ln N = 0.8318$. Doubling its domain count buys 0.2772 nats and closes 13 per cent of the gap; break-even by domain addition alone requires $N = 1596$; and **even perfect orthogonality across all eight domains would leave it declining by** 1.5682 **nats per year.** The geometry this corpus is named for was never the binding constraint in the paper's

own example, and no geometric intervention could have worked. That is stated in Section 7.2 rather than resolved by choosing a different example.

The paper is a framework-development paper with three worked applications, not a field study. **No dataset was collected. Every system in Section 7 is constructed**, and every number in it is an exact computation on stipulated inputs, so that a reader can redo the arithmetic without access to anything. Section 10 records what that costs the paper's claims.

Sections 2 and 3 state the hypotheses and the framework, including the two objections — the identification problem and the underdetermination of the functional form — that no amount of fit can answer. Section 4 develops the audited count, Section 5 the ceiling, and Section 6 the engineering of non-parallelism; each closes with its design specifications and its named failure modes. Section 7 works three systems end to end. Sections 8 to 11 discuss, verify, limit and conclude.

9.2 2 Hypotheses

The results below are of two kinds and the distinction is load-bearing. Some are theorems about a functional form and cannot be falsified by observing an institution; they are labelled as derivations or definitions where they appear, and they carry no empirical weight. Others are claims that the functional form describes real bodies, and those are stated here with what would defeat them. Where a claim can be neither derived nor falsified it is labelled a postulate or a modelling choice and is not dressed as a hypothesis [Popper, 1959, Platt, 1964].

H1 — The audited count, not the headcount, governs what a body delivers. A body's aggregation performance tracks $N_{\text{eff}} = 1 + (N-1)u$ rather than N. **Predicted:** across bodies matched on N and differing in measured u, scored accuracy rises with u and is flat in N at fixed u. **Falsified by:** matched bodies whose accuracy tracks headcount at fixed measured u. **Not tested here.** The supporting external result is Hong and Page [2004], whose conditions Thompson [2014] disputes in detail; the disagreement is reported in Section 6.5 rather than adjudicated.

H2 — Opposition is redundancy. Because $u = 1 - \rho^2$ depends only on $|\rho|$, a member who reliably inverts the body's judgement adds no surplus. **Predicted:** a designated-contrarian arrangement, measured by error decorrelation on scored outcomes, returns $u \approx 0$ and no improvement in aggregate accuracy over the aligned body it replaced, while costing one additional seat. **Falsified by:** a measured accuracy gain from a designated opponent at $\rho \to -1$, which would show that the encoder — error vectors — is the wrong state representation and that sign carries information the square discards. **Not tested here.** This is the paper's sharpest and most checkable empirical prediction.

H3 — Conversion and cost bind before geometry does. In bodies with negative headroom, the intervention with the largest computed Δh is more often a conversion or a cost intervention than a geometry intervention. **Predicted:** across surveyed systems with $h < 0$, geometric interventions are dominated on computed Δh. **Falsified by:** a survey series in which geometry interventions dominate. **This paper's second worked system is consistent with H3 in the strongest possible way** — no attainable geometry closes its gap — and its third is a counter-instance, since there u was the binding constraint. Both are reported in Section 7.

H4 — The affine effective count equals the participation-ratio count. For N encoded unit vectors with Gram matrix G and $\text{PR} = (\operatorname{tr} G)^2 / \|G\|_F^2$, mean pairwise nonparallelism $\bar{u}$ satisfies $1 + (N-1)\bar{u} = N + 1 - N/\text{PR}$. **Predicted:** exact agreement in double precision on any ensemble. **Falsified by:** any ensemble on which the two disagree beyond floating-point tolerance. *(Result:* ***not falsified*** *— agreement*

better than 10^{-12} *at* $K = 3, 5, 8, 12$ *[Curzi, 2026i], and re-verified over six random correlation matrices [Curzi, 2026].* ***This is a derivation; the numerical check tests the implementation, not the world.)***

Three claims in this paper are not hypotheses and are labelled as what they are.

S3, the affine effective count, is a DESIGN AXIOM. That $g(u) = e^{f(u)}$ is affine in u is chosen and not derived. No observation refutes it, because it is a decision about what the word *count* should mean in this framework. It is badged at every use, and Section 9.6 shows precisely what it costs: the resulting quantity is not a numbers-equivalent, and the diversity literature does not cover it.

The Roster Reduction is a POSTULATE. Reading a roster of N people as N categories, and a mean pairwise u as the roster's non-parallelism, is a modelling assumption stated in Section 3.4 together with the specific way it can be wrong.

That error vectors are the right state encoding is a POSTULATE. The identity $u = 1 - \rho^2$ is exact for mean-centred, unit-normalised vectors, because their inner product is the Pearson correlation. That a member's scored error vector is the state the framework means is an encoding choice, badged wherever it is used.

9.3 3 Framework: the law, what is chosen, and what the count is not

9.3.1 3.1 The statement

From Curzi [2026], Thm 2.1, the interaction surplus of a pair of states x, y is

```
F(x,y) = f(u(x,y))

u(x,y) = 1 − (x . y)^2 = || x ^ y ||^2      in [0,1]

f(u)   = ln(1 + (N−1) u)
```

and the object of this paper is the exponential of the surplus:

```
N_eff = g(u) = e^{f(u)} = 1 + (N−1) u        the EFFECTIVE COUNT

surplus = ln N_eff
```

Read the second line slowly. Surplus is not the log of a headcount. **Surplus is the log of a headcount after the headcount has been audited for redundancy.** The audit is performed by u, and u is a purely geometric quantity: it is the squared magnitude of the wedge of the two states, or equivalently one minus the squared cosine between them.

Because `(x . y) = cos θ` for unit states, one may write the identity that does most of the work in Sections 4 to 6:

```
u = 1 − cos^2 θ = sin^2 θ
```

u is the squared sine of the angle between two states. It is 0 when they are parallel and 1 when they are orthogonal, and it moves through the intermediate range in the way a squared sine does — slowly at first, then fast, then slowly again.

9.3.2 3.2 What is proven and what is chosen

The functional form `f(u) = ln(1 + (N−1)u)` is **uniquely characterized** by four axioms. Three of them are bookkeeping. One of them is a design decision, and the framework is required to say so every time it leans on it.

Axiom	Statement	Status
S1	Geometric dependence: F depends on the pair only through u.	Structural. Fixes what kind of object F is.
S2	Zero at zero: `f(0) = 0`. Parallel states produce no surplus.	Normalization. Uncontroversial.
S3	Affine effective count: `g(u) = e^{f(u)}` is affine in u.	**[DESIGN AXIOM — CHOSEN, NOT DERIVED]**
S4	Normalization: `f(1) = ln N`.	Normalization. Sets the ceiling.

S3 is the design axiom. It is chosen, not derived, and it is the reason the effective count is a straight line in u rather than some other curve. Everything in Sections 4 to 6 that reads as a discovery about the world is, at bottom, a consequence of having decided that the effective count should be affine. The decision is a good one — it is the simplest possible assumption that makes "effective count" behave like a count, interpolating linearly between one entity and N entities — but it is a decision. When a reader objects that the second member cannot possibly be worth exactly as much as the fortieth in u-units, the honest answer is: S3 says it is, S3 was chosen, and if a measured reason exists to replace S3 with something else, the rest of the theory will have to be rebuilt around it.

Given S1–S4, the following are **derived**, not assumed [Curzi, 2026]:

Property	Reference	Statement
Strict monotonicity	Thm 3.1	More non-parallelism strictly increases surplus.
Positivity	Thm 3.2	`F > 0` for any `u > 0`.
Strict concavity	Thm 3.3	Diminishing returns in u, unconditionally.
Subadditivity in u	Thm 3.4	`f(u_1 + u_2) <= f(u_1) + f(u_2)` on the parameter.
Sharp Lipschitz constant	Thm 4.2	`|f(u_1) − f(u_2)| <= (N−1)|u_1 − u_2|`, and N-1 is sharp.
Extremality	Thm 4.3	`F = 0` iff parallel; `F = ln N` iff orthogonal.
Range	Curzi [2026], Cor 2.2	`0 <= F(u) <= ln N`.

9.3.3 3.3 Which effective count: the Hill correspondence, stated exactly

The corpus runs two quantities under the name *effective count*, and they are not the same quantity. This section states which is which, in the paper that develops the second of them, because a reviewer who reaches for the diversity literature will find that it covers one exactly and the other not at all.

The reciprocal concentration index is a Hill number of order two. Hill [1973] defined the family ${}^{q}D = \left(\sum_i p_i^q\right)^{1/(1-q)}$, whose members return the number of equally abundant types that would produce the observed value of the underlying index. At $q = 2$ this is $\left(\sum_i p_i^2\right)^{-1}$, which is HHI^{-1} exactly. Jost [2006] is the statement that entropies are not diversities and that their numbers-equivalents are, and Jost [2007] extends it to the partition into within-group and between-group components. **The numbers-equivalent reading — that the reciprocal index answers "how many equal units would give this figure" — is Adelman [1969], and the corpus should name him rather than hedge**; the source manuscript attributes the reading to no one. The same arithmetic was reached independently in ecology by Simpson [1949] and in political science by Laakso and Taagepera [1979] as the effective number of parties. Independent reinvention in three disciplines is the strongest available argument that the instrument is general rather than borrowed. The exponential of Shannon entropy [Shannon, 1948] is the same family at $q = 1$; the reciprocal index is also the exponential of the Rényi entropy of order two [Rényi, 1961], which is where the participation-ratio name of Section 3.4 comes from. The measure that makes diversity depend on *dissimilarity between types* rather than on shares alone — which is this framework's founding move — exists in exactly two formalisms, Rao [1982] and Leinster and Cobbold [2012], and neither of them is the affine count.

The affine effective count is not a Hill number and has no external support. The quantity this paper develops, $N_{\text{eff}} = 1 + (N-1)u$, is a **linear interpolation between** 1 **and** N. It is not $\left(\sum_i p_i^q\right)^{1/(1-q)}$ for any q; it is not a function of a share vector at all, but of the pair (N, u); it is not a numbers-equivalent; and no entry in ecology, economics, political science or information theory contains it. The arithmetic that separates the two takes one line and is given as a failing verification chain in Section 9.6: for two units holding 0.9 and 0.1, the affine count at $u = 1$ returns exactly 2.000000, while HHI^{-1} returns 1.219512 and $\exp(H)$ returns 1.384145. **Every Hill number of order one or higher reports at most** 1.384145 **on that vector, and the affine count reports two.** The comparison must be stated with that qualification, because the Hill family is non-increasing in q and its order-zero member — the raw richness ${}^{0}D$ — equals 2.000000 on this vector as it does on every two-type vector. **That coincidence is uninformative and is worth stating precisely because it is the sharpest form of the objection**: ${}^{0}D$ is the one member of the family that ignores shares entirely, which is exactly the naive count an effective count exists to replace, and the affine count at $u = 1$ agrees with it.

The two quantities are related — both are called effective counts, both return N in the fully independent limit, both return 1 at total redundancy — and they are not interchangeable. The corpus has in places let them travel under one name. **This paper uses the affine count throughout, badges it as the framework's own construction at every use, and reserves the Hill citations for the reciprocal index, where they are exact.** A downstream paper that cites this one must carry the distinction with the citation.

What is lost, stated plainly. Three properties a reviewer would expect of an effective count do not hold for the affine form. It does not satisfy the replication principle — pooling two identical communities of N equally weighted types should return N, and the affine count's answer depends on u rather than on the composition. It is not invariant to how the underlying units are partitioned, because N is a declared category count and not a measured share vector. And it inherits no estimation theory: the small-sample bias corrections of Chao et al. [2014] and Chao and Jost [2012] apply to the Hill family and not to this. **A twelve-person roster is a small sample, no correction is available for the affine count, and none was applied.** Hurlbert [1971] and Gorelick [2011] are the standing objections to treating any such index as a substantive property rather than as a statistic, and they apply here with more force than they do to the Hill family, not less.

9.3.4 3.4 The Roster Reduction — a badged postulate

The law is stated for a **pair** of states x, y, with N entering only through the normalization S4 as the number of distinct categories the ambient space can express. Practical work wants to

apply it to a roster of N people, or N teams, or N sensors. That step is not in the founding surplus analysis [Curzi, 2026]. It is a modeling assumption and this paper badges it:

> **THE ROSTER REDUCTION [POSTULATE].** For a body of N members, N is taken to be the number of nominal categories the body claims to span, and u is taken to be a representative non-parallelism across the body's pairs — normally the mean pairwise u over all `N(N−1)/2` pairs, or a lineage-weighted version of the same. `N_eff = 1 + (N−1)u` is then read as the audited count.

This postulate is doing real work and it can be wrong in a specific way: because the triangle inequality fails for geometric triples, a mean pairwise u does **not** determine the joint geometry of the whole body. Two rosters with the same mean pairwise u can have genuinely different structure — one a ring of mutual near-orthogonality, another a tight cluster plus one distant outlier. The Roster Reduction discards that distinction. It is used because it is cheap, computable from instruments that can actually be run (Section 4.2), and because it errs conservatively in the common institutional case, where the failure is a tight cluster and the mean pairwise u is dragged down by exactly the redundancy the audit is trying to detect. **Where the difference between "one distant outlier" and "genuine spread" matters to a decision, do not use the mean; report the pairwise matrix and read it directly.** the two-source decomposition [Curzi, 2026d] splits u into its two components and gives a sharper instrument.

The mean-pairwise choice is nevertheless less arbitrary than it looks, and the survey protocol [Curzi, 2026i] says why. Let `G` be the Gram matrix of the N encoded unit vectors, `G_ij = x_i . x_j`, and let `PR` be the standard Renyi-2 participation ratio of its spectrum, `PR = (tr G)^2 / ||G||_F^2`. Since `||G||_F^2 = N + N(N−1)(1−u)`, one line of algebra gives

```
N_eff = 1 + (N−1)u = N + 1 − N/PR
```

The mean-pairwise `u` aggregator IS the participation ratio, reparametrised into effective-count form. The identity is exact; the survey protocol [Curzi, 2026i] verifies it numerically at `K = 3, 5, 8, 12` on random ensembles to better than 1e-12. Its two poles are worth carrying. At `PR = N` the Gram matrix has no off-diagonal mass, `N_eff = N`, and roster equals effective count — attainable only at exact mutual orthogonality. At `PR = 1` every vector is the same, `N_eff = 1`, and the size of the roster has left the arithmetic entirely.

This does not repair the postulate; the triangle-inequality objection above still stands, because `PR` is itself a scalar summary of a spectrum. **What it does is name the audit.** The Roster Reduction is not an improvisation but a standard diversity measure an ecologist, a portfolio analyst or a spectroscopist would recognise on sight, and when a sponsor asks why disagreement is averaged pairwise rather than some other way, the answer is this identity and not a plausibility argument. See the survey protocol [Curzi, 2026i].

9.3.5 3.5 Identification: the objection that no measurement of u can answer

Every applied reading in this paper runs through a reflexive specification. The framework's central formal claim is that a group's influence on its members and the members' constitution of the group are one loop, $T(x) = W(x, M(x))$ [Curzi, 2026]. The estimate of u inherits it directly: the error vectors whose correlation defines u are produced by members who observe one another, and the correlation the analyst measures is jointly the product of shared training, shared incentive, and mutual influence.

That specification is exactly a linear-in-means reflexive model, and its endogenous social effect is not identified from observational data. Manski [1993] proves it: the endogenous effect cannot be separated from contextual effects or from correlated unobservables without prior information specifying the reference group. No quantity of scored decisions recovers it. Shalizi and Thomas [2011] reinforce the point for networks — influence and selection are generically confounded in observational data — and Lyons [2011] shows what happens when the confound is ignored in a well-publicised case. Durlauf [2005] adds the requirement that

a complexity model earn its keep by making a **differential** prediction that simpler models do not also make.

The remedy this paper adopts is the fourth of Manski's four, and it is not free. The available routes are randomisation, an instrument, partial-population variation, and stipulating the reference group and defending the stipulation; Brock and Durlauf [2001] is the template for the last, and it derives a mean-field structure from standard discrete choice **with its identification conditions stated**. This paper stipulates the reference group — the declared roster, with the declared lineage partition of Section 7.1 — and defends the stipulation on the ground that institutional membership is administratively observable in a way that a social peer group is not. **That is a defence of the stipulation, not a recovery of the parameter.** Accordingly:

> **Every applied u in this paper is a modelling position, not an identified empirical quantity.** The arithmetic relating u to N_{eff} and to S is exact and is not at issue. What is at issue is whether a measured error correlation is the framework's u, and observation alone cannot settle it.

Two objections in the same family are also unanswered here and are recorded rather than deflected. **The Lucas critique, turned on the framework itself** [Lucas, 1976]: this framework asserts that systems change their behaviour when modelled and observed, and then treats its own u, η and δ as stable in a population that has read it. A body that has been told its second opinion is worth $\ln 1 = 0$ will behave differently in the next elicitation, and Section 6.8's D-1 to D-10 are precisely the mechanisms through which that would operate. Hacking [1995] is the general statement — the subjects of a psychological physics read the theory and move — and Ferraro et al. [2005] is the warning that a description assuming the worst can make it true. **The framework has no answer and this paper states that it has none.** MacKenzie and Millo [2003] is the countervailing observation that such a loop has been caught happening, with dates and price data, which establishes that reflexive fixed points exist without establishing that this one does.

And the functional form is underdetermined by the evidence. Three shapes fit the qualitative facts equally well: this framework's $\ln(1 + (N-1)u)$, the sub-linear power law with exponent below one that Latané [1981] established with psychological data, and the $n \log n$ network-value law of Briscoe et al. [2006]. Nothing in this paper discriminates among them, because nothing in this paper fits the form to data at all; the paper derives consequences of a form assumed. Sobkowicz [2009] and Sobkowicz [2020] are the general indictment — many models, negligible empirical discrimination between them — and they apply. **The honest statement is that the logarithmic form is adopted and its uniqueness under S1–S4 is a theorem about the axioms and not evidence about institutions.**

One strengthening is available and should be taken. Peters and Gell-Mann [2016] and Peters [2019] derive a logarithmic form from multiplicative dynamics with **no psychological assumption whatever**: the time-average growth rate of a multiplicative process is logarithmic. That is a stronger warrant for the framework's logarithms than the psychophysical route through Fechner [1860], because it does not require the perceptual story to be true. It also carries a warning the framework must accept: the time average of a multiplicative process differs from its ensemble average, so a parameter estimated across a cross-section of bodies does not describe what happens to any one body over time — and Q accumulates over time, for one body.

9.3.6 3.6 Analogy discipline: what is derived, what shares a form, and what is only suggestive

The framework borrows shape from physics and information theory, and each borrowing is classified here at first use, in the three categories the corpus's rigour standard requires.

Borrowing	Category	What is and is not claimed
The leaky integrator $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$	**2 — shared mathematical form**	A first-order linear difference equation governs both a discharging capacitor and this stock [Oppenheim et al., 1996, Elaydi, 2005]. No physical claim is transferred [Curzi, 2026a].
The Rényi-2 participation ratio	**1 — derivation**	PR $= (\operatorname{tr} G)^2 / \|G\|_F^2$ is applied to a Gram matrix, which is what the quantity is defined on [Rényi, 1961]. The identity of Section 3.4 is algebra, not resemblance.
$\ln N$ as a ceiling, against Shannon entropy	**2 — shared form only**	Both are logarithms of a category count. **Surplus is not identified with Shannon entropy or with mutual information** [Curzi, 2026]; the resemblance is a normalisation over N, and Shannon [1948] is cited for the entropy and not for the surplus.
Ashby's requisite variety	**2 — formal correspondence**	Ashby [1956, 1958] measure variety as the logarithm of a state count and treat it as a cap on regulation. The two are not proved equal (Section 5.9).
Condorcet's jury theorem	**3 — interpretive correspondence**	The independence premise and the non-parallelism parameter say related things in two vocabularies. **No theorem connecting them is asserted** (Section 4.7).
The portfolio analogy	**2 — shared form**	Markowitz [1952] states the substantive result — benefit depends on covariance, not count — and this framework restates it with a different index. The correlation-collapse literature [Longin and Solnik, 2001, Ang and Chen, 2002] is the warning that the covariance itself moves under stress.

This paper is bound by the corpus's own strictest ruling on borrowed physics. The uncertainty node declines the inflated reading of its own borrowing: it states the framework's postulate as a postulate, gives the relation only in its correct form, and requires that a user be able to distinguish the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand [Curzi, 2026]. The same standard governs every row of the table above, and nothing in this paper claims more of a borrowing than that ruling permits.

The failure mode this table exists to prevent is a category-2 borrowing carrying a category-1 result's authority. The arithmetic of Sections 4 to 6 is category 1 within its own axioms and needs no help; the physical and information-theoretic vocabulary is category 2 and is used for shape only. Mirowski [1989] is the historical account of what happens when a social science imports a physical formalism without auditing the import, and Cartwright [1999] supplies the generous escape route: a law can hold inside a specified arrangement without being universal, provided the arrangement is specified. **The design specifications of Sections 4.9, 5.13 and 6.11 are this paper's attempt to specify the arrangement.**

9.3.7 3.7 The honesty clauses that bind every use of the law

These are binding wherever the law is used and are reproduced here rather than referenced, because this is the point at which a reader is most tempted to over-read the result.

1. **The founding surplus analysis [Curzi, 2026] is pure mathematics and makes no empirical or metaphysical claim.** It proves that a particular functional form follows from four axioms. It does not prove that human groups obey that form. The empirical content of this paper is a modeling proposal, tested by the protocols in Chapters 24 and 25, and falsifiable there.
2. **As deployed, the surplus functional is a lower bound** on the ensemble's information, not the information itself. The floor is logged, not the ceiling. An `N_eff` of 2.5 does not mean the group contains exactly 2.5 independent perspectives; it means the measured geometry guarantees at least that much, and there may be more that the state encoder failed to see.
3. **Surplus is not identified with Shannon entropy or mutual information in general** [Curzi, 2026]. The ln is not a Shannon ln. Do not import entropy intuitions wholesale.
4. **The triangle inequality FAILS for geometric triples** (the surplus functional's metric analysis [Curzi, 2026]). Subadditivity holds on the parameter u only. You may not chain surplus across three states as though it were a distance. This matters directly in Section 4.5 where auditing a roster larger than two is discussed.
5. **No thermodynamic negentropy law is proved** [Curzi, 2026a]. `F(u) + N_can(u) <= ln N` bounds a sum; it does not license any statement about physics, order, or consciousness.

9.4 4 The audited count in use: geometry, instruments, and concavity

9.4.1 4.1 Ten parallel windows are one window

Set u = 0. Then `N_eff = 1 + (N−1)·0 = 1`, and `surplus = ln 1 = 0`.

This is the whole audit in one line, and it is not a limiting case or an edge condition. It is the modal condition of institutional life. A wall of ten identical windows, all facing the same courtyard at the same angle, admits one view. A panel of ten reviewers trained in the same three departments, reading the same literature, rewarded by the same committee, produces one review. The arithmetic does not care that there are ten signatures on it. It prices the geometry.

The corresponding engineering instruction is blunt: **the first question about any body is not how many members it has but how many directions it points, and the second question is how that was measured.**

Table 4.1 gives the audited count directly. Read down a column to see what a nominal roster is actually worth at a given non-parallelism.

TABLE 4.1 — EFFECTIVE COUNT N_eff = 1 + (N−1)u

N	u=0.0	u=0.05	u=0.1	u=0.2	u=0.3	u=0.5	u=0.7	u=0.9	u=1.0
2	1.00	1.05	1.10	1.20	1.30	1.50	1.70	1.90	2.00
3	1.00	1.10	1.20	1.40	1.60	2.00	2.40	2.80	3.00
4	1.00	1.15	1.30	1.60	1.90	2.50	3.10	3.70	4.00
5	1.00	1.20	1.40	1.80	2.20	3.00	3.80	4.60	5.00
6	1.00	1.25	1.50	2.00	2.50	3.50	4.50	5.50	6.00
8	1.00	1.35	1.70	2.40	3.10	4.50	5.90	7.30	8.00
10	1.00	1.45	1.90	2.80	3.70	5.50	7.30	9.10	10.00
12	1.00	1.55	2.10	3.20	4.30	6.50	8.70	10.90	12.00
15	1.00	1.70	2.40	3.80	5.20	8.00	10.80	13.60	15.00
20	1.00	1.95	2.90	4.80	6.70	10.50	14.30	18.10	20.00
25	1.00	2.20	3.40	5.80	8.20	13.00	17.80	22.60	25.00
30	1.00	2.45	3.90	6.80	9.70	15.50	21.30	27.10	30.00

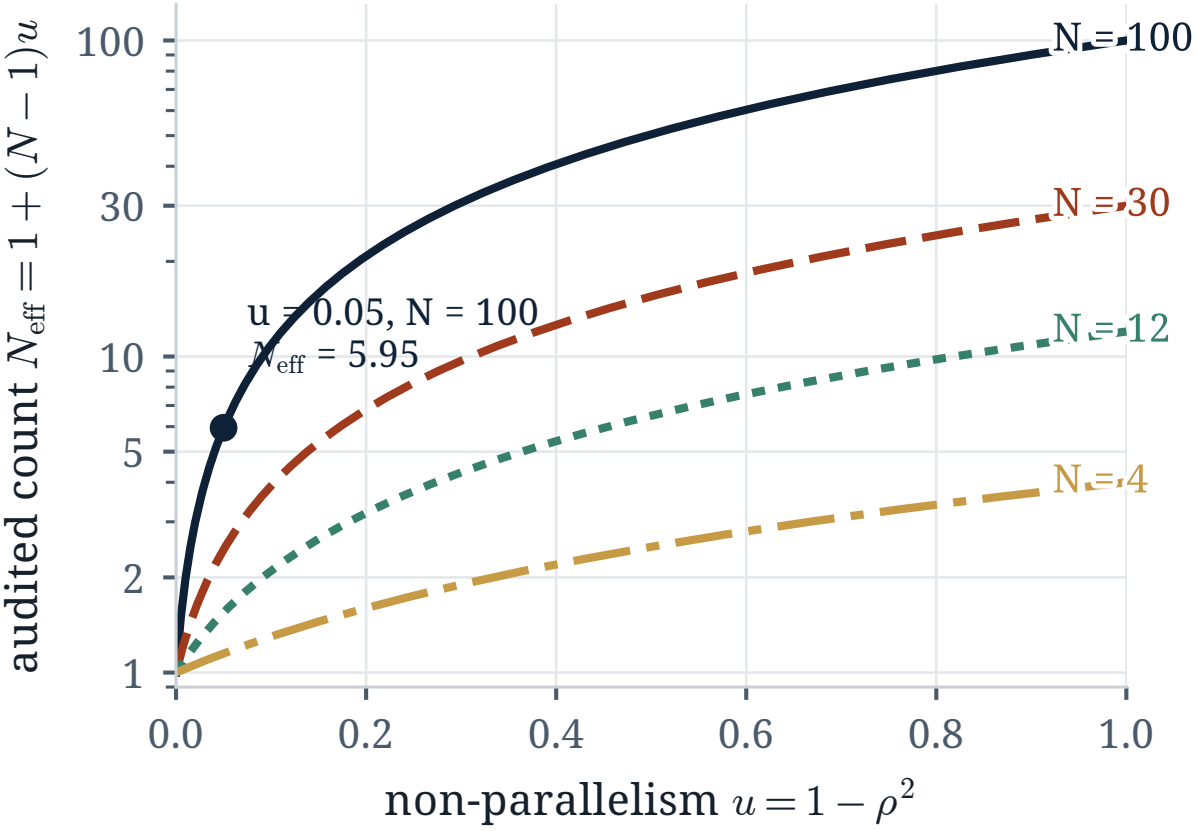

Figure 9.1: **A roster of a hundred at $u = 0.05$ audits to an effective count of 5.95, not to a hundred.** The affine count $N_{\text{eff}} = 1 + (N-1)u$ is plotted at four roster sizes on a logarithmic vertical axis; the marked point is the headline reading of Table 4.1. Model output, not measurement: the relation is exact given design axiom S3, which is chosen rather than derived. Generated by `figs/src/CCP-009_fig01.py`.

```
 40 |  1.00 |  2.95 |  4.90 |  8.80 | 12.70 | 20.50 | 28.30 | 36.10 | 40.00
 50 |  1.00 |  3.45 |  5.90 | 10.80 | 15.70 | 25.50 | 35.30 | 45.10 | 50.00
100 |  1.00 |  5.95 | 10.90 | 20.80 | 30.70 | 50.50 | 70.30 | 90.10 |100.00
```

A hundred-person department at u = 0.05 has an effective count of 5.95. Not 100. Not 50. Just under six.

If that department's hiring, training, and promotion pipeline is a single funnel, u = 0.05 is not a pessimistic estimate; it is a generous one.

9.4.2 4.2 The geometry of u, in degrees

Because `u = sin² θ`, the relationship between the intuitive quantity (how differently do these two see the problem?) and the parameter is not linear, and engineers consistently misjudge it in the same direction. Small angles are worth almost nothing.

```
TABLE 4.2 — ANGLE -> u -> AUDITED COUNT (illustrated at N = 12)

  theta    cos θ     u = sin^2 θ   N_eff      ln N_eff    % of ln 12
  -----    ------    -----------   -------    --------    ----------

80°	0.1736	0.9698	11.668	2.4569	98.9%
90°	0.0000	1.0000	12.000	2.4849	100.0%

Two observations an engineer should carry.

First, **a ten-degree difference of view is worth 3% of an available effective count of twelve.** A team of people who "have different backgrounds" but converge on the same framing within one meeting is a ten-degree team. Everyone experiences the difference as real — they argue, they use different words — and it prices at u = 0.03.

Second, the curve saturates hard past 60°. Going from 60° to 90° — from strongly different to completely orthogonal — buys the last 10.5% of the ceiling. **The expensive, socially painful distance between "strongly disagrees" and "does not share a frame of reference" is worth about a tenth of what the cheap distance between "identical" and "moderately different" is worth.** That is a merciful result and Section 6 builds on it heavily: there is no need to import a stranger from another civilization. The requirement is to stop hiring the same person eleven times.

Third, and it is the observation the table's 0°-to-90° range conceals: the curve comes back down. `u = 1 − (x·y)^2` depends only on the *magnitude* of the correlation, so it is symmetric about 90° and the table must be read as a fold, not a ramp:

```
120°  ->  u = 0.7500     same as  60°
135°  ->  u = 0.5000     same as  45°
170°  ->  u = 0.0302     same as  10°
180°  ->  u = 0.0000     same as   0°
```

At `rho = −1`, perfect opposition, `u = 0` exactly as it does at `rho = +1`. The member who reliably inverts a colleague spans no more of the space than the member who reliably echoes them: given either, the other can be reconstructed, and reconstruction is what redundancy means. **The contrarian carries exactly as much information as the sycophant: none.**

This has a direct consequence for a common staffing move. A body assembled for "creative tension" — a designated opposite, a house sceptic whose position is the negation of the proposal — has bought an `N_eff` of 1 on that axis and is paying `C` for two seats. It is worse than an aligned pair, not better, because it carries the same zero surplus at higher cost. Section 6 treats the engineering consequence and the pseudo-diversity analysis [Curzi, 2026d] catalogues it as a failure mode distinct from the Parallel Wall.

9.4.3 4.3 Five instruments for estimating u

u is a geometric quantity in a state space that is not directly observed. Estimating it requires an operational choice: the *state encoder*, which the founding surplus analysis requires be declared [Curzi, 2026] and the survey protocol operationalises [Curzi, 2026i]. Here are the five instruments this paper recommends, in increasing order of cost and decreasing order of ambiguity.

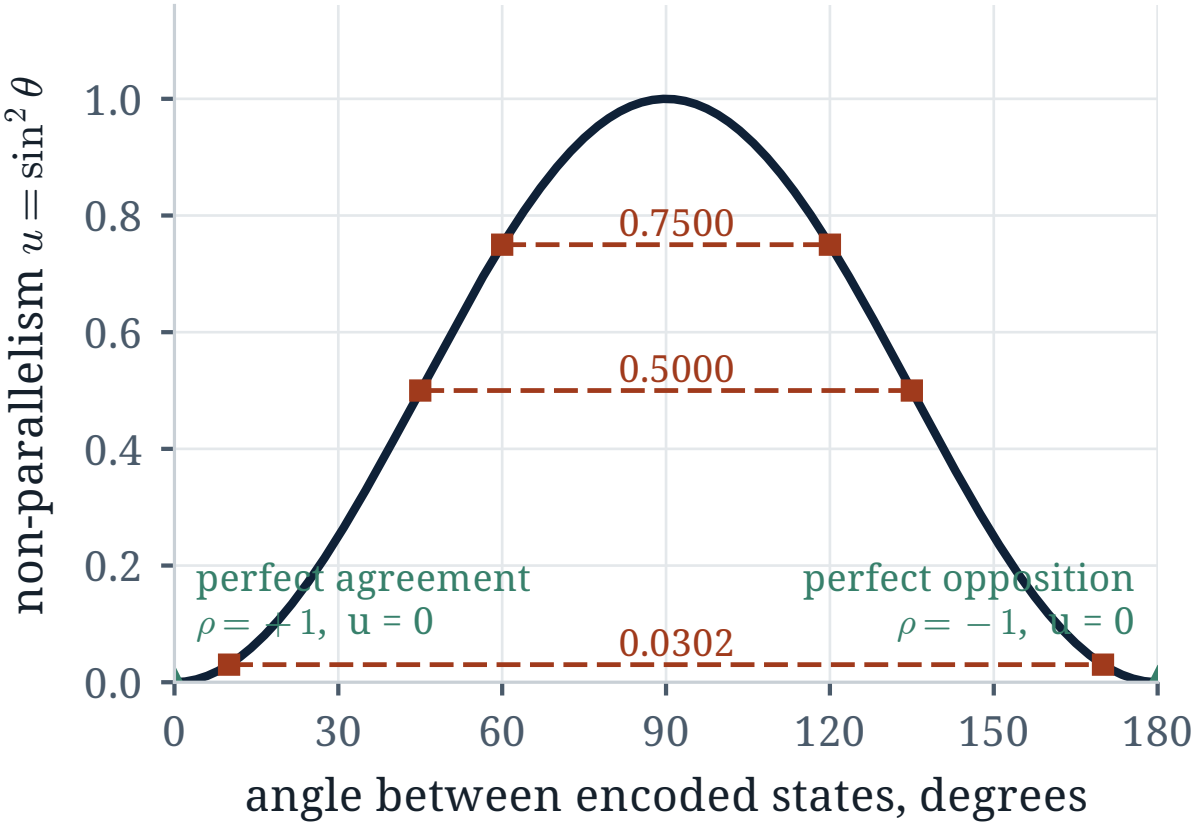

Figure 9.2: **Opposition prices as parallelism: the curve folds about ninety degrees.** Because $u = 1 - (x \cdot y)^2$ depends only on the magnitude of the correlation, $u(\theta) = u(180^\circ - \theta)$ exactly, and the three tie-lines mark pairs of angles that price identically — 60° with 120° at 0.7500, 45° with 135° at 0.5000, 10° with 170° at 0.0302. **At $\rho = -1$ the surplus is exactly zero, as it is at $\rho = +1$.** Model output; the identity is exact. Generated by `figs/src/CCP-009_fig02.py`.

Instrument 1 — Disagreement rate

The cheapest instrument. Present the body with a set of K binary or categorical judgment items under **independent** conditions (no discussion, no visible responses, no sequencing). Record the fraction of item-pairs on which two given members differ.

For two members i and j, let `d_ij` be the fraction of items on which they disagree. Under a simple encoding in which each member's response vector is mean-centred and normalized, the sample cosine between response vectors is `1 − 2 d_ij` for balanced binary items, giving

```
u_ij  =  1 − (1 − 2 d_ij)^2
```

`d = 0` gives u = 0. `d = 0.5` — chance-level disagreement, i.e. mutual independence — gives u = 1. `d = 0.1` gives `u = 1 − 0.64 = 0.36`. **Ten percent disagreement is already a third of the way to orthogonality, which indicates how little disagreement most institutions actually tolerate.**

Caveats, and they are severe. The instrument is only valid if elicitation was genuinely independent; a show of hands measures cascade, not geometry (the pseudo-diversity analysis [Curzi, 2026d]). It is sensitive to item difficulty: items everyone gets right and items everyone gets wrong both read as u = 0 and neither carries information about the geometry. Use items with a spread of difficulty and discard items with unanimous responses before computing d.

Instrument 2 — Error decorrelation

The most informative single instrument, and the one this paper prefers whenever the body produces predictions that are later scored.

Take each member's **error** vector across a common set of scored items: `e_i = (prediction_i − outcome)` over items. Mean-centre and normalize each error vector. Then the inner product between two normalized, mean-centred vectors is exactly the Pearson correlation coefficient ρ, and

```
u_ij  =  1 − rho_ij^2
```

This is an exact identity, not an approximation, given the encoding choice. **The encoding choice — that error vectors are the right states — is a modeling assumption and is badged as such [POSTULATE]**; the algebra that follows from it is not.

```
TABLE 4.3 — ERROR CORRELATION -> u -> AUDITED COUNT (illustrated at N = 8)

   rho     u = 1 − rho^2   N_eff     ln N_eff    % of ln 8
   ----    -------------   ------    --------    ---------
   0.99       0.0199        1.139     0.1304        6.3%
   0.95       0.0975        1.683     0.5203       25.0%
   0.90       0.1900        2.330     0.8459       40.7%
   0.80       0.3600        3.520     1.2585       60.5%
   0.70       0.5100        4.570     1.5195       73.1%
   0.60       0.6400        5.480     1.7011       81.8%
   0.50       0.7500        6.250     1.8326       88.1%
   0.40       0.8400        6.880     1.9286       92.7%
   0.30       0.9100        7.370     1.9974       96.1%
   0.20       0.9600        7.720     2.0438       98.3%
   0.10       0.9900        7.930     2.0707       99.6%
   0.00       1.0000        8.000     2.0794      100.0%
```

Note the shape. Because u = 1 - ρ^2, the audited count is punished by **correlation squared**, which means that the region of high correlation — where institutions actually live — is where

the penalty is steepest and least visible. Moving eight forecasters from ρ = 0.90 to ρ = 0.80 nearly doubles the effective count, from 2.33 to 3.52. Moving them from ρ = 0.20 to ρ = 0.10 moves it from 7.72 to 7.93. **The returns to decorrelation are concentrated exactly where organizations feel most comfortable.**

Instrument 3 — Prediction diversity, via a variance identity

Standard mathematics, offered here without any citation because none is needed: for N estimators each with error variance σ^2 and uniform pairwise correlation ρ, the variance of their simple average is

```
Var(mean)  =  (sigma^2 / N) * (1 + (N-1) rho)
```

Define the **classical variance-reduction count** `N_ind = N / (1 + (N-1)ρ)` — the number of independent estimators that would give the same variance reduction. It is worth tabulating because it is the quantity most working analysts already have intuitions about.

TABLE 4.4 — CLASSICAL VARIANCE-REDUCTION COUNT N_ind = N / (1 + (N-1) rho)

N	rho=0.0	rho=0.1	rho=0.2	rho=0.4	rho=0.6	rho=0.8	rho=0.95
2	2.00	1.82	1.67	1.43	1.25	1.11	1.03
4	4.00	3.08	2.50	1.82	1.43	1.18	1.04
8	8.00	4.71	3.33	2.11	1.54	1.21	1.05
12	12.00	5.71	3.75	2.22	1.58	1.22	1.05
20	20.00	6.90	4.17	2.33	1.61	1.23	1.05
50	50.00	8.47	4.63	2.43	1.64	1.24	1.05
100	100.00	9.17	4.81	2.46	1.66	1.25	1.05
1000	1000.00	9.91	4.98	2.50	1.67	1.25	1.05

As N grows, `N_ind -> 1/ρ`, a hard asymptote. **A thousand analysts at ρ = 0.2 are worth five independent analysts, and the next nine hundred and ninety are worth nothing at all.**

Now a required warning. `N_ind = N/(1+(N-1)ρ)` and `N_eff = 1+(N-1)u` are **different quantities** and must not be equated. They share a structural motif — the `1 + (N-1)·` form — because both are affine interpolations between "one thing" and "N things," which is a natural way to build a count, and S3 chose that same form deliberately. **The resemblance is a design echo, not a theorem, and this paper badges it as such [OBSERVATION, NOT DERIVATION].** Use Table 4.4 for intuition and sanity-checking; use Table 4.3 when computing surplus.

Instrument 4 — The collision test

Adapted from the framework's collision instrument [Curzi, 2026]. Present two members with the same stimulus under blind conditions and record whether their outputs *collide* — that is, land in the same cell of a pre-declared response partition. Over K trials, the collision rate `c_ij` estimates the probability that the two members are functionally the same instrument.

The collision test is coarser than error decorrelation but it has two advantages that make it the field instrument of choice. It requires no outcome data, so it can be run before anything is scored or on questions that will never be resolved. And it is legible to non-technical participants, which matters more than engineers usually admit: a body will accept a redundancy audit it can see being run, and will contest one that arrives as a correlation matrix from an analyst.

Map collision rate to u by treating the response partition as the encoder:

```
u_ij  ~  1 - c_ij       (for a partition with many roughly equiprobable cells)
```

State the approximation honestly. With a coarse partition — say three cells — random collision alone runs near 1/3, so raw collision rate over-reads similarity. Correct for chance:

```
u_ij  ~  (1 − c_ij) / (1 − c_chance)      clipped to [0,1]
```

where `c_chance` is the collision rate expected if both members answered at random from the observed marginal distribution. **A collision audit that does not subtract chance collision is not a measurement; it is a mood.**

Instrument 5 — The lineage census

The bluntest and often the most decisive. Enumerate, for every member, the answers to a fixed set of provenance questions: where they were trained, by whom, in what decade, in what language, under what funding model, with what incentive attached to being right. Two members who answer identically on all axes are provisionally scored at high correlation until measured otherwise.

The lineage census is not a substitute for Instruments 1–4 and this paper does not claim that provenance determines view. **It is a prior, not a measurement, and it is badged as such [HEURISTIC].** Its function is triage: it indicates which pairs to measure first, and it makes the redundancy structure visible to people who will never read a correlation matrix. It is also the only one of the five instruments that can be run on a hiring pipeline before anyone is hired, which makes it the only one that can prevent the problem rather than diagnose it.

9.4.4 4.4 Concavity — the merciful clause

`f` is strictly concave in u (Curzi [2026], Thm 3.3), and `ln N_eff` is concave in N as well. The practical consequence is the most useful budgeting fact in the framework.

Fix u. Ask what the Nth member adds:

```
ΔF(N)  =  ln(1 + (N−1)u)  −  ln(1 + (N−2)u)
```

TABLE 4.5 — MARGINAL SURPLUS OF THE Nth MEMBER, AT FIXED u
(values are nats; the total ceiling is ln N)

N	u = 0.1	u = 0.3	u = 0.5	u = 0.8	u = 1.0

  40 |   0.0206  |   0.0239  |   0.0247  |   0.0252  |   0.0253
```

Read the u = 1.0 column. **The second genuinely different member is worth 0.6931 nats. The fortieth is worth 0.0253 — a factor of 27 less, for exactly the same salary.** At u = 0.5 the ratio is 0.4055 to 0.0247, a factor of 16. The pattern is universal across the table because it is concavity, and concavity is a theorem here, not a tendency.

Now read across a row instead. At N = 2, moving from u = 0.1 to u = 1.0 multiplies the gain by 7.3. At N = 40 it multiplies it by 1.23. **Non-parallelism matters enormously for the first few members and barely at all for the last few.** Both readings point the same way and the intervention procedure [Curzi, 2026j] will use them to rank the levers: get two or three genuinely orthogonal members, then stop buying members and start buying η.

The cumulative form is the one to quote at a budget meeting:

```
TABLE 4.6 — CUMULATIVE SURPLUS f(N,u) = ln(1 + (N−1)u), SELECTED ROWS

   N  |  u=1.00 |  u=0.50 |  u=0.30 |  u=0.15 |  u=0.05 |  u=0.00
 -----+---------+---------+---------+---------+---------+--------
    2 |  0.6931 |  0.4055 |  0.2624 |  0.1398 |  0.0488 |  0.0000
    3 |  1.0986 |  0.6931 |  0.4700 |  0.2624 |  0.0953 |  0.0000
    4 |  1.3863 |  0.9163 |  0.6419 |  0.3716 |  0.1398 |  0.0000
    5 |  1.6094 |  1.0986 |  0.7885 |  0.4700 |  0.1823 |  0.0000

```

9.4.5 4.5 Three honest windows set wide

Compare two cells in Table 4.6.

```
  N =  3,  u = 1.00   ->   S = 1.0986
  N = 12,  u = 0.15   ->   S = 0.9746
```

Three honest windows set wide capture more than a gallery of twelve pointing the same way. Three people, no shared training, no shared incentive, genuinely orthogonal instruments, beat a twelve-person panel at fifteen percent non-parallelism — and they do it while generating `3·2/2 = 3` communication paths instead of `12·11/2 = 66`, which by the cost accounting [Curzi, 2026b] is a 22-fold reduction in the quadratic term.

The comparison generalizes. Wherever a choice between more members and more difference is offered, both cells should be computed and compared. The result is almost always the same, because the two terms enter the formula asymmetrically: N enters inside a logarithm, u enters linearly inside that same logarithm and multiplies (N-1). Doubling u is not the same shape of operation as doubling N. Here is the comparison at a concrete baseline:

```
baseline: N = 12, u = 0.15          S = 0.9746
double N to 24, u unchanged         S = 1.4929   (+0.5183, twelve new hires)
hold N = 12, double u to 0.30       S = 1.4586   (+0.4841, zero new hires)
quadruple N to 48, u unchanged      S = 2.0857   (+1.1111, thirty-six new hires)
hold N = 12, u to 0.60              S = 2.0281   (+1.0536, zero new hires)
```

Doubling the effective difference within an existing body is worth almost exactly what doubling the body is worth, and quadrupling the difference is worth almost exactly what quadrupling the body is worth — at a fraction of the cost, and with none of the quadratic coordination penalty. This is the central practical result of this paper and Section 6 is devoted to executing it.

9.4.6 4.6 The Lipschitz constant is a measurement-error budget

Curzi [2026], Thm 4.2 gives the sharp Lipschitz constant N-1:

```
| f(u_1) − f(u_2) |  <=  (N−1) | u_1 − u_2 |
```

This is usually read as a smoothness result. Read it instead as a **specification for how precisely u must be measured**. The local slope is

```
df/du  =  (N−1) / (1 + (N−1)u)
```

which equals the bound N-1 only at u = 0 and falls off from there.

TABLE 4.7 — SENSITIVITY df/du, AND THE SHARP BOUND

N	u=0.02	u=0.1	u=0.3	u=0.6	u=1.0	bound (N−1)
3	1.923	1.667	1.250	0.909	0.667	2
5	3.704	2.857	1.818	1.176	0.800	4
10	7.627	4.737	2.432	1.406	0.900	9
20	13.768	6.552	2.836	1.532	0.950	19
50	24.747	8.305	3.121	1.612	0.980	49
100	33.221	9.083	3.225	1.639	0.990	99

The engineering reading: at large N and small u, surplus is violently sensitive to u, so a sloppy estimate of u produces a wildly wrong estimate of S. At N = 12, an uncertainty of ±0.05 in u produces these ranges in S:

```
u = 0.05 ± 0.05   ->   S in [0.0000, 0.7419]    width 0.7419
u = 0.10 ± 0.05   ->   S in [0.4383, 0.9746]    width 0.5363
u = 0.20 ± 0.05   ->   S in [0.9746, 1.3218]    width 0.3472
u = 0.40 ± 0.05   ->   S in [1.5790, 1.7834]    width 0.2044
u = 0.70 ± 0.05   ->   S in [2.0980, 2.2246]    width 0.1266
```

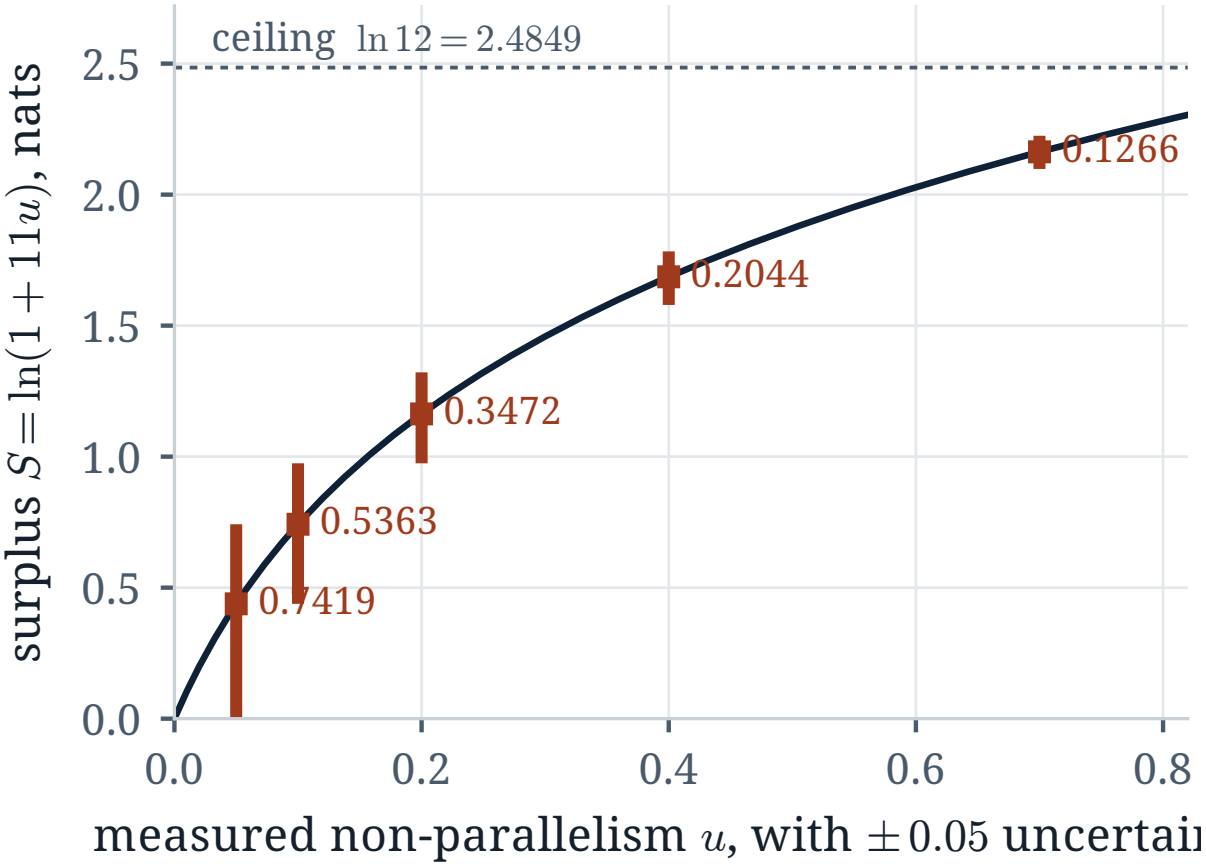

Figure 9.3: **Where institutions actually sit, a plausible measurement error spans nearly the whole range of the quantity being measured.** At $N = 12$, an uncertainty of ± 0.05 in u admits a surplus anywhere in the marked interval; the figure beside each bar is its width in nats. The width falls from 0.7419 at $u = 0.05$ to 0.1266 at $u = 0.70$, which is why the specification forbids a point estimate below $u = 0.3$. Model output at $N = 12$; arithmetic exact. Generated by `figs/src/CCP-009_fig03.py`.

Precisely in the low-u regime where institutions actually operate, a plausible measurement error in u spans nearly the entire range of surplus being estimated. Do not report a single number for S when u is small and poorly measured. Report the interval. The corpus's preregistration protocol [Curzi, 2026i] makes this a requirement.

9.4.7 4.7 Condorcet says the same thing in another language

The Condorcet jury theorem states that if each of N voters is independently correct with probability p > 0.5, the probability that a majority is correct rises with N and approaches 1. The independence clause is not decorative. It is the whole theorem.

Here is the theorem doing its work at p = 0.6, computed exactly:

```
TABLE 4.8 — MAJORITY ACCURACY, N INDEPENDENT VOTERS AT p = 0.6

    N =   1    0.6000
    N =   3    0.6480
    N =   5    0.6826
    N =   7    0.7102
    N =   9    0.7334
    N =  11    0.7535
    N =  15    0.7869
    N =  21    0.8256
    N =  31    0.8716
    N =  51    0.9265
    N = 101    0.9791
```

Now break independence. If the voters are perfectly correlated — all one instrument — the majority is correct with probability 0.6 regardless of N. In the present vocabulary, u = 0, `N_eff = 1`, surplus = 0, and the roster of 101 is a roster of 1. Condorcet's independence requirement and the surplus law's non-parallelism requirement are **the same requirement stated in two vocabularies.** Condorcet states it as a precondition and then reasons about accuracy; the surplus law states it as a continuous parameter and prices the intermediate cases. Neither is more fundamental. Having both is useful, because Condorcet is the version a lawyer or a board member already believes, and the surplus law is the version that goes into a spreadsheet.

This paper does not claim the two are mathematically equivalent, and asserts no theorem connecting them. **The correspondence is interpretive and is badged [INTERPRETIVE CORRESPONDENCE].**

9.4.8 4.8 Where the effective count enters the circuit

Return to the storage law. The storage law is

```
Q_{t+1} = (1−δ) Q_t + η S_t − C_t,     S_t = ln(1 + (N−1) U_t) = ln N_eff(t)
```

and the master gauge is

```
h_t = η ln N − δ Q_t − C_t
```

Two distinct roles for the count, and confusing them is a recurring error:

- **`ln N` is the ceiling.** It appears in headroom, in the sustainability ceiling (Cor 3.4), in the uniform bound (Thm 3.3), in the maximum one-step increment (Cor 4.2). It is what the system *could* draw if every interaction were orthogonal. Section 5 is entirely about this term.

- **`ln N_eff` is the draw.** It is what the system actually delivers this period, and it is strictly less than `ln N` unless u = 1.

The gap between them, `ln N − ln N_eff = ln(N / N_eff)`, is the **redundancy deficit**. At N = 12 and u = 0.15 it is `2.4849 − 0.9746 = 1.5103` nats, meaning the panel is leaving 61% of its theoretical input on the table every single period, forever, until someone changes the geometry. That deficit compounds through the integrator: over the 6.58-period half-life corresponding to δ = 0.10 (the retention analysis [Curzi, 2026a], Table L), it is not a one-time loss but a permanently lowered steady state, since `Q_\ensuremath{\infty} = (ηF(u*) − c*)/δ` scales directly with F.

Redundancy is not a missed opportunity. It is a permanent reduction in the fixed point.

9.4.9 4.9 Specification: the effective-count requirements

Numbered, checkable requirements. A body that satisfies EC-1 through EC-12 has been audited for effective count. A body that has not been audited should not be described in a plan as having N members; it should be described as having an unmeasured N_eff.

EC-1 — Declare the encoder. Before any u is estimated, write down in one sentence what a member's *state* is taken to be: their scored error vector, their independent response vector on a declared item set, or their cell assignment under a declared partition. No estimate of u is admissible without a declared encoder [Curzi, 2026].

EC-2 — Elicit independently or do not elicit. All responses used to estimate u must be gathered under conditions where no member can observe another's response before committing their own. Written, simultaneous, sealed. Anything else measures cascade, not geometry. This requirement is absolute and is not subject to convenience.

EC-3 — Report N, u, and N_eff together, never N alone. Any document that states the size of a body must state the audited size beside it, in the form `N = 12, u = 0.15 ± 0.05, N_eff = 2.65 [1.55, 4.30]`. A bare headcount in a design document is a specification defect.

EC-4 — Report an interval, not a point, whenever u < 0.3. Table 4.7 shows the sensitivity. Below u = 0.3 the surplus estimate is dominated by measurement error and a point estimate is misleading.

EC-5 — Subtract chance collision. Any collision-based estimate must state `c_chance` and report the chance-corrected figure. Uncorrected collision rates are not admissible.

EC-6 — Discard unanimous items. Items on which every member agrees carry no information about geometry, whether the unanimity is correct or incorrect. Compute u on the discriminating subset and report how many items were discarded. If more than 80% of items were discarded, the item set is not fit for purpose and must be rebuilt.

EC-7 — Estimate u at least once per δ-half-life. u decays (Section 6, the pseudo-diversity analysis [Curzi, 2026d]). An estimate older than one half-life of the body's convergence process is not a measurement; it is a memory. The retention analysis [Curzi, 2026a] gives `t_half = ln 2 / (−ln(1−δ))`; use the convergence rate of u, not the decay rate of Q.

EC-8 — Publish the pairwise matrix when a decision turns on structure. The mean pairwise u is a summary and the Roster Reduction discards structure. When a decision depends on whether difference is spread or concentrated in one member, publish the matrix.

EC-9 — Run a lineage census on every hiring pipeline, annually. Provenance axes at minimum: training institution, principal mentor, decade of formation, working language, funding source, prior industry. Report the entropy of each axis across the current roster. This is a prior, not a measurement (Section 4.3, Instrument 5), and must be labelled as such wherever reported.

EC-10 — Size against the marginal table, not against a headcount target. Before adding the Nth member, look up the marginal gain in Table 4.5 at the measured u and compare it against the member's full loaded cost including the `N−1` additional communication paths they

create. If the marginal surplus is below 0.05 nats, the correct move is almost certainly to raise u instead.

EC-11 — Compute and publish the redundancy deficit. `ln N − ln N_eff`. This single number is the most useful summary of a body's geometric health and it belongs on the same dashboard as headcount and budget.

EC-12 — Badge the Roster Reduction wherever it is used. Any report applying `N_eff = 1+(N−1)u` to a roster of people rather than to a declared pair of states must carry the badge and one sentence naming the failure mode: mean pairwise u does not determine joint geometry, because the triangle inequality fails for geometric triples.

9.4.10 4.10 Failure modes native to the audited count

Each entry: NAME, clinical description, damaged parameter, diagnostic signature, detecting measurement, fix. The corpus's consolidated failure catalogue [Curzi, 2026j] carries the full set; the entries below are the ones native to the audited count.

FM-4.1 · THE HEADCOUNT FALLACY

Damages: the estimate of S, and thereby every downstream budget.

Clinical description. The body reports its size and reasons from it. Plans, budgets, and capability claims are all scaled to N. u is never estimated, so `N_eff` is never known, and the gap between the claimed and delivered input is absorbed silently as underperformance attributed to effort or morale.

Diagnostic signature. Any planning document containing a headcount and no non-parallelism figure. Statements of the form "with twelve reviewers we have comprehensive coverage." Retrospectives that conclude "we need more people" after a body has already grown twice without improving.

Detecting measurement. EC-3 compliance audit. Count planning documents; count the fraction containing a u estimate. Below 100% is a defect.

Fix. Institute EC-3 as a document standard. It costs nothing and it is the single highest-leverage administrative change in this paper, because it forces the question into every document where a decision is made.

FM-4.2 · THE PARALLEL ROSTER

Damages: u -> 0, hence `N_eff -> 1`, hence S -> 0.

Clinical description. Every member is a functional copy of every other. Recruitment, socialization, and promotion have converged the body onto a single instrument. Members experience the condition as agreement, competence, and pleasant working relations. It is the most comfortable of all the failure modes and therefore the most durable.

Diagnostic signature. Disagreement rate under blind elicitation below 5%. Error correlation above 0.9. Meetings that end early. Unanimous votes on non-trivial questions. New members who "fit in immediately."

Detecting measurement. Instrument 2 (error decorrelation) run on the last 30 scored decisions, or Instrument 1 on a fresh blind item set of 20 discriminating items.

Fix. Section 6 in full. In outline: recruit across a lineage boundary, install rotation, mandate an adversarial role. Note that the fix is a **u** intervention, not an N intervention; adding members from the same pipeline makes the failure worse by raising C while leaving `N_eff` at 1.

This mode is important enough that the pseudo-diversity analysis [Curzi, 2026d] is devoted to its detection and its socially disguised variants.

FM-4.3 · THE MISSING DENOMINATOR

Damages: the credibility of the whole measurement chain.

Clinical description. u is reported without its N. Because `N_eff = 1 + (N−1)u`, a u of 0.4 means an effective count of 1.4 at N = 2 and 40.6 at N = 100. A u reported alone is uninterpretable.

Diagnostic signature. A dashboard tile reading "diversity: 0.42."

Detecting measurement. Inspection.

Fix. EC-3. Never report u without N and `N_eff`.

FM-4.4 · SUBSTITUTION OF PROVENANCE FOR GEOMETRY

Damages: the measurement, not the system — but it hides damage to u.

Clinical description. The lineage census (Instrument 5) is treated as a measurement of u rather than as a prior. The body reports high provenance entropy and concludes it has high u, when in fact its members were drawn from different institutions into a single shared framework and their error vectors correlate at 0.92.

Diagnostic signature. Reports that cite composition and never cite disagreement. Assertion that a body is "diverse" with no scored-error figure anywhere in the document.

Detecting measurement. Run Instrument 2 and compare with what Instrument 5 predicted. A large gap between predicted and measured u is itself the finding, and it is a useful one: it establishes that the homogenizing force is downstream of recruitment, in training or incentive.

Fix. Demote provenance to triage, per EC-9's labelling requirement. Then look downstream: shared training, shared incentive, shared review. Section 6.7.

FM-4.5 · THE CASCADE-CONTAMINATED ESTIMATE

Damages: the estimate of u, always in the direction of overstating similarity.

Clinical description. u is estimated from responses gathered in sequence or in view of one another. Members anchored on the first response. The measured disagreement rate reflects the cascade, not the geometry. The body then concludes it is more parallel than it is, or — worse — concludes it is appropriately aligned and stops trying.

Diagnostic signature. Disagreement rate strongly dependent on speaking order. First responder's answer disproportionately represented in the modal response. Round-table elicitation of any kind.

Detecting measurement. Run the same item set twice, once sequentially and once with silent-write-first. Compare the two u estimates. A gap above 0.15 indicates cascade contamination of the sequential protocol; use only the blind estimate thereafter.

Fix. EC-2, absolutely. Silent-write-first, sealed simultaneous submission. The seating and furniture analysis [Curzi, 2026f] gives the furniture that makes this the default and the individuality analysis [Curzi, 2026h] gives the protocol.

FM-4.6 · THE SATURATED PANEL

Damages: C, without damaging S — which is why it survives.

Clinical description. A body that has passed the point where additional members buy meaningful surplus keeps adding members. From Table 4.5, at u = 0.5 the 30th member buys 0.0328 nats while adding 29 communication paths. The surplus curve is flat; the cost curve is not.

Diagnostic signature. Growth in headcount with flat or declining output. Meetings where a majority of attendees do not speak. Sub-committees forming spontaneously — which, note, is the body correctly self-organizing away from the saturated configuration.

Detecting measurement. Compute marginal surplus per member at measured u (Table 4.5) and compare against loaded cost per member including the quadratic coordination term from the cost analysis [Curzi, 2026b]. The crossover point is computable and belongs in every org design review.

Fix. Split. Two bodies of six at u = 0.5 deliver `2 × 1.5041 = 3.008` nats of input against `2 × 15 = 30` communication paths; one body of twelve at the same u delivers 1.8718 nats against 66 paths. **Splitting a saturated body is not an admission of failure; it is the arithmetic.** Section 5.9 and the intervention procedure [Curzi, 2026j] give the sequencing.

9.5 5 The logarithmic ceiling

Section 4 established that a body's audited count is `N_eff = 1 + (N−1)u`, and that the audit is usually brutal. The obvious response is to raise N. Add domains. Widen the remit. Bring in the adjacent discipline, then the one after that. If twelve categories are not enough, take thirty.

Section 5 prices that move, and the price is a logarithm.

The result is not a caution. It is a structural prohibition, and it is the single most useful negative result in the framework: **a headroom problem cannot be escaped by adding domains.** Not because adding domains is bad, but because the return on N is `ln N`, and `ln N` grows so slowly that the quantities being outrun — δQ and C, which grow linearly and quadratically — will always win in the end. Section 5 establishes that with explicit arithmetic and then states what to do instead.

9.5.1 5.1 The ceiling

From Curzi [2026], Cor 2.2:

```
0  <=  F(u)  <=  ln N
```

with the upper bound attained if and only if the states are orthogonal (Curzi [2026], Thm 4.3). `ln N` is not a soft target or an asymptote. It is a hard ceiling on surplus per interaction, and it is set entirely by N.

The ceiling enters the theory through axiom **S4**, the normalization `f(1) = ln N`. Read S4 correctly: it says that when two states are maximally non-parallel, the surplus they generate is the log of the number of categories the ambient space can express. N is not the number of people in the room. **N is the number of genuinely distinct categories the system is capable of distinguishing.** Section 4's Roster Reduction [POSTULATE] permits reading a roster of people as a set of categories for practical work, but the underlying quantity is a dimension count, not a headcount, and Section 5 is about the dimension count.

9.5.2 5.2 Where the ceiling appears

`ln N` does not appear once. It appears in every design inequality in the storage-law analysis [Curzi, 2026a], always multiplied by η, and always as the term that caps what the system can do.

Result	Statement	Role of `ln N`
Curzi [2026], Cor 2.2	`0 <= F(u) <= ln N`	The per-interaction ceiling itself.

Result	Statement	Role of `ln N`
Curzi [2026a], Thm 3.3	`Q_t <= max{Q_0, η ln N / δ}`	Caps the *entire trajectory* of stored order.
Curzi [2026a], Thm 3.3 (δ=0)	`Q_t <= Q_0 + t η ln N`	Caps the growth *rate* when there is no leak.
Curzi [2026a], Cor 3.4	Nondecreasing step requires `C_t <= η ln N − δ Q_t`	Caps the affordable cost.
Curzi [2026a], Prop 4.1	Feasible only if `δQ_t + C_t + r_t <= η ln N`	Caps the requestable increment.
Curzi [2026a], Cor 4.2	`r_max = η ln N − δQ_t − C_t`	Caps the maximum one-step gain.
the storage-law analysis [Curzi, 2026a], §6.4	`h_t = η ln N − δQ_t − C_t`	The master gauge.

Five of these seven are the same inequality wearing different clothes, and the clothes matter less than the fact that **η ln N is the entire budget from which δQ and C are paid.** Everything a system can spend on maintenance, coordination, and growth comes out of a single term that scales as the logarithm of its category count.

9.5.3 5.3 The honesty clauses, restated for the ceiling

1. **The founding surplus analysis [Curzi, 2026] is pure mathematics and makes no empirical or metaphysical claim.** That `ln N` is a ceiling is a theorem about a functional form. That real institutions are bounded by it is a modeling proposal, falsifiable by the protocols of the preregistration protocol [Curzi, 2026i].
2. **S3, the affine effective count, is a design axiom — chosen, not derived.** The logarithmic ceiling is a consequence of having chosen an affine `g(u)` together with the normalization S4. A different choice of S3 would give a different ceiling law. The framework's negative result about adding domains is therefore conditional on S3, and the conditionality is stated here in the open.
3. **As deployed, the surplus functional is a lower bound**, not the ensemble's information. `ln N` bounds the floor that can be logged, and the honest claim is that nothing more can be *guaranteed* than `ln N`, not that no more exists.
4. **Surplus is not Shannon entropy or mutual information** [Curzi, 2026]. The similarity in form between `ln N` and the entropy of a uniform distribution over N states is a formal resemblance arising from both being normalizations over a category count. **It is not an identification and this paper badges it [FORMAL RESEMBLANCE, NOT IDENTIFICATION].** Section 5.9 uses it as a bridge to Ashby with the badge attached.
5. **The triangle inequality fails for geometric triples** (the surplus functional's metric analysis [Curzi, 2026]). When this section discusses composing categories, it composes them through `u` and the subadditivity relation on `u` only.
6. **No thermodynamic negentropy law is proved** [Curzi, 2026a]. Nothing here licenses a claim about physical order.

9.5.4 5.4 How slowly the logarithm actually grows

Engineers know that logarithms grow slowly. Almost nobody has looked at the table. Here it is, for every integer from 2 to 100.

```
TABLE 5.1 — ln N, N = 2 TO 100

   N   ln N     |    N   ln N     |    N   ln N     |    N   ln N     |    N   ln N
```

2	0.6931	22	3.0910	42	3.7377	62	4.1271	82	4.4067
3	1.0986	23	3.1355	43	3.7612	63	4.1431	83	4.4188
4	1.3863	24	3.1781	44	3.7842	64	4.1589	84	4.4308
5	1.6094	25	3.2189	45	3.8067	65	4.1744	85	4.4427
6	1.7918	26	3.2581	46	3.8286	66	4.1897	86	4.4543
7	1.9459	27	3.2958	47	3.8501	67	4.2047	87	4.4659
8	2.0794	28	3.3322	48	3.8712	68	4.2195	88	4.4773
9	2.1972	29	3.3673	49	3.8918	69	4.2341	89	4.4886
10	2.3026	30	3.4012	50	3.9120	70	4.2485	90	4.4998
11	2.3979	31	3.4340	51	3.9318	71	4.2627	91	4.5109
12	2.4849	32	3.4657	52	3.9512	72	4.2767	92	4.5218
13	2.5649	33	3.4965	53	3.9703	73	4.2905	93	4.5326
14	2.6391	34	3.5264	54	3.9890	74	4.3041	94	4.5433
15	2.7081	35	3.5553	55	4.0073	75	4.3175	95	4.5539
16	2.7726	36	3.5835	56	4.0254	76	4.3307	96	4.5643
17	2.8332	37	3.6109	57	4.0431	77	4.3438	97	4.5747
18	2.8904	38	3.6376	58	4.0604	78	4.3567	98	4.5850
19	2.9444	39	3.6636	59	4.0775	79	4.3694	99	4.5951
20	2.9957	40	3.6889	60	4.0943	80	4.3820	100	4.6052
21	3.0445	41	3.7136	61	4.1109	81	4.3944		

Sit with the last cell. A hundredfold increase in category count — from one to a hundred — buys 4.6052 nats. From two to a hundred it buys 3.9120. That is the whole return, for the whole journey, from a small team to a large institution.

Now the same table read as a fraction of what a hundred categories deliver:

TABLE 5.2 — SHARE OF ln 100 CAPTURED BY THE FIRST N CATEGORIES

N	ln N	share of ln 100
2	0.6931	15.1%
3	1.0986	23.9%
4	1.3863	30.1%
5	1.6094	34.9%
7	1.9459	42.3%
10	2.3026	50.0%
15	2.7081	58.8%
20	2.9957	65.1%
30	3.4012	73.9%
50	3.9120	84.9%
75	4.3175	93.8%
100	4.6052	100.0%

Ten categories capture exactly half of what a hundred capture. The remaining ninety categories divide the other half between them. The first five capture 35%. The first three capture nearly a quarter.

This is the same concavity that made Section 4's marginal table merciful, and it cuts the same way: the early categories are where the value is, and the late ones are rounding.

9.5.5 5.5 The doubling constant

The most useful single fact about the ceiling is scale-invariance of its increment.

```
ln(2N) − ln(N)  =  ln 2  =  0.693147...     for every N whatsoever
```

```
TABLE 5.3 — DOUBLING ALWAYS ADDS ln 2 = 0.6931

       N      ln N       gain from N/2 -> N
     -----   -------     ------------------
         2   0.6931           0.6931
         4   1.3863           0.6931
         8   2.0794           0.6931
        16   2.7726           0.6931
        32   3.4657           0.6931
        64   4.1589           0.6931
       128   4.8520           0.6931
       256   5.5452           0.6931
       512   6.2383           0.6931
      1024   6.9315           0.6931
```

Doubling the number of domains adds exactly 0.6931 nats, whether the move is from 2 to 4 or from 512 to 1024. The absolute gain never changes. The relative gain collapses: 0.6931 is 100% of ln 2 but 10% of ln 1024.

The corollary that governs planning:

```
to add ONE nat to the ceiling, multiply N by  e = 2.71828...
```

```
TABLE 5.4 — WHAT +1.0 NAT OF CEILING COSTS IN CATEGORIES

from N =   2  (ln N = 0.6931)   requires N =    5.4
from N =   5  (ln N = 1.6094)   requires N =   13.6
from N =  10  (ln N = 2.3026)   requires N =   27.2
from N =  20  (ln N = 2.9957)   requires N =   54.4
from N =  50  (ln N = 3.9120)   requires N =  135.9
from N = 100  (ln N = 4.6052)   requires N =  271.8
```

And its inverse, the form to use when someone specifies a required ceiling:

```
TABLE 5.5 — CATEGORIES REQUIRED FOR A TARGET CEILING

target ln N        N required
-----------        ----------
   0.5000              1.65
   1.0000              2.72
   1.5000              4.48
   2.0000              7.39
   2.5000             12.18
   3.0000             20.09
   3.5000             33.12
   4.0000             54.60
   4.6052            100.00
   5.0000            148.41
   6.0000            403.43
   7.0000           1096.63
```

A ceiling of 7 nats requires 1,097 genuinely distinct categories. Not 1,097 people — 1,097 categories, each of which must be distinguishable from every other by the system's own encoder, and each of which must be actually populated by someone capable of occupying it.

9.5.6 5.6 The consequence, stated hard

The structural prohibition this section exists to establish is the following.

The master gauge is `h_t = η ln N − δQ_t − C_t`. Suppose h < 0 — the system is in decline, and by The sustainability corollary [Curzi, 2026a] **no arrangement of interaction geometry prevents order from decreasing.** The manager's instinct is to grow: add teams, add disciplines, add scope, add categories, and thereby raise `η ln N` until h turns positive.

Compute what that requires. To close a deficit of size D by raising N alone:

```
η ln N_new  −  η ln N_old  =  D
ln(N_new / N_old)          =  D / η
N_new                      =  N_old · e^{D/η}
```

The multiplier is `e^{D/η}`, and it is exponential in the deficit.

TABLE 5.6 — MULTIPLIER ON N REQUIRED TO CLOSE A DEFICIT D, AT η = 0.40

deficit D (nats)	N must be multiplied by e^{D/0.40}
0.10	1.3 x
0.25	1.9 x
0.50	3.5 x
1.00	12.2 x
2.00	148.4 x

A deficit of two nats — which in the worked systems of the storage-law analysis [Curzi, 2026a] is an unremarkable size of shortfall — requires a **148-fold** increase in category count. At η = 0.40, an institute with eight domains and a two-nat deficit needs 1,187 domains.

And here is the part that makes it a prohibition rather than an expense: **δQ and C do not hold still while N is multiplied.** C grows at least linearly in N and, through Brooks' `n(n−1)/2` communication paths, often quadratically. Q grows because a larger system stores more, so δQ grows too. You are trying to outrun linear and quadratic growth with a logarithm. **The logarithm loses, always, and it loses faster the further it is pushed.**

This is worth writing as a rule, because it will be violated in almost every organization the reader will ever work in.

> **THE DOMAIN-ADDITION PROHIBITION.** A headroom deficit cannot be closed by raising N. The required multiplier is `e^{D/η}`, exponential in the deficit, while the cost terms it must outrun grow at least linearly and typically quadratically in N. **If h < 0, adding domains makes h worse.** The admissible responses are: raise η, cut C, or shed Q. The headroom analysis [Curzi, 2026b] names those three; this section establishes that the fourth is not an option.

Two honest qualifications, because the prohibition is strong and strong claims need their limits stated.

First, the prohibition applies to raising N as a **remedy for a deficit**. Raising N for other reasons — because the environment genuinely presents variety the system cannot currently absorb (Section 5.9), because a new category is cheap and the ceiling is close to binding, because the initial system is being built rather than repairing one — remains legitimate. Section 5.11 gives the four legitimate cases.

Second, the prohibition assumes η is held constant while N grows. In practice adding a genuinely new domain sometimes raises η, because a new discipline brings new capture mechanisms — a new notation, a new archive, a new form of artifact. That effect is real and this paper does not deny it. But it should be attributed correctly: the gain came from η, not from N, and where it is wanted the correct move is to obtain η directly rather than buying a domain and hoping. The conversion analysis [Curzi, 2026b] gives the direct route and it is far cheaper.

9.5.7 5.7 What raising N actually requires

Suppose a decision has legitimately been taken to raise N. The question is what counts.

N is the number of **genuinely distinct categories the system can express**. It is not the number of labels in the org chart. Splitting a category into two relabeled halves does not raise N; it raises the label count while leaving the geometry untouched, and the arithmetic of Section 4 prices the result at zero.

Make this precise. Suppose the system has N categories and one of them is split into two halves with pairwise non-parallelism ε. Two things happen:

- The **nominal ceiling** rises from `ln N` to `ln(N+1)`.
- The **delivered surplus** does not, because the new pair contributes u = ε ≈ 0.

TABLE 5.7 — CEILING GAIN FROM ADDING ONE CATEGORY

N -> N+1	ceiling gain ln(N+1) − ln N	as % of current ceiling
2 -> 3	0.4055	58.50%
3 -> 4	0.2877	26.19%
4 -> 5	0.2231	16.10%
5 -> 6	0.1823	11.33%
6 -> 7	0.1542	8.60%
8 -> 9	0.1178	5.66%
10 -> 11	0.0953	4.14%
12 -> 13	0.0800	3.22%
16 -> 17	0.0606	2.19%
20 -> 21	0.0488	1.63%
32 -> 33	0.0308	0.89%
50 -> 51	0.0198	0.51%
100 -> 101	0.0100	0.22%

At N = 20, one more category raises the ceiling by 1.63%. If that category is a relabeled half of an existing one, the delivered surplus rises by approximately nothing while C rises by the cost of running a twenty-first category. Category inflation is a pure cost with a cosmetic ceiling gain, and it is the standard institutional response to a demand for breadth.

The relabeling audit

Before N is incremented in any plan, run this test on the proposed new category:

1. **State the new category's encoder.** What state does a member of this category occupy that a member of no existing category occupies? Write one sentence. If that cannot be done, stop.
2. **Estimate u between the new category and its nearest existing neighbour** using Section 4's Instruments 1 or 2. Blind elicitation on 20 discriminating items is sufficient.
3. **Require u >= 0.3 against every existing category.** Below 0.3 the new category is a relabel and must not be counted in N. Report the measured u alongside the request.
4. **Compute delivered gain, not ceiling gain.** The plan must state `Δ(delivered) = ln(1 + N·u_bar_new) − ln(1 + (N−1)·u_bar_old)`, not `ln(N+1) − ln N`.
5. **Compute the cost delta.** New coordination paths, new meetings, new interfaces. Priced by the cost accounting of Curzi [2026b].
6. **Compare.** If delivered gain is below cost delta, the category is a liability.

Steps 1 and 3 kill most proposals, which is the point. **A category that cannot state what it sees that nobody else sees is a label, and labels do not enter the law.**

The three ways N is faked

- **Splitting.** One category becomes two with the same training, the same literature, the same incentives, and a boundary drawn on the org chart. Diagnostic: measured u between the halves below 0.15. This is the most common.
- **Importing the adjacent.** Recruiting from the discipline next door — which shares 80% of its methods, its journals, and its reviewers with the existing one. Genuine but small u. Diagnostic: measured u between 0.15 and 0.35, and error correlation above 0.8. Counts partially; count it partially.
- **Nominal representation.** Adding a category to the chart and staffing it with someone whose actual working practice is unchanged from their previous category. Diagnostic: the person's error vector is unchanged from before the reassignment. This is the hardest to detect and requires scored longitudinal data.

9.5.8 5.8 The scale-free reading

The doubling constant has an architectural consequence worth stating, because it is where CANON §1.4's hyperrecursive symmetry becomes concrete.

Because `ln(2N) − ln N = ln 2` at every scale, the ceiling gain from doubling is identical at a desk, in a room, in a team, in a building, in an institution, and in a city. Two drawers instead of one; two disciplines instead of one; two wings instead of one; two boroughs instead of one. All worth 0.6931.

That is a genuine scale-free property of the model form, and it is honest to state it as such: **it is a claim about the FORM of the equation, not about physics.** The parameters δ, η, C differ enormously across those scales; only the shape of the N-dependence is invariant. This is the architectural claim of the framework and it is the reason a single set of design rules can be written for objects that differ in size by six orders of magnitude.

It also explains a common and correct intuition: that adding the second of anything feels transformative and adding the fiftieth feels like paperwork. The absolute gain is the same 0.6931 per doubling either way, but the doubling from 1 to 2 is one hire and the doubling from 50 to 100 is fifty.

9.5.9 5.9 Ashby's Law of Requisite Variety — why N matters at all

Everything above has been a case against raising N. Ashby supplies the case for.

Ashby's Law of Requisite Variety (1956): only variety can absorb variety. A regulator can hold a system's essential variables within limits only if the regulator's variety is at least as great as the variety of the disturbances it must counter. A thermostat with two states cannot regulate a process with ten distinguishable failure modes. A committee with one framework cannot govern a domain that presents four kinds of problem.

Ashby measured variety as **the logarithm of the number of distinguishable states**. That is his own formulation, and it is why the correspondence with `ln N` is close enough to be useful:

```
Ashby:        variety V = log (number of distinguishable states)
Surplus law:  ceiling   = ln N,  N = number of distinguishable categories
```

TABLE 5.8 — VARIETY IN NATS AND BITS

distinguishable states	ln (nats)	log2 (bits)
2	0.6931	1.0
4	1.3863	2.0
8	2.0794	3.0
16	2.7726	4.0

64	4.1589	6.0
256	5.5452	8.0
1024	6.9315	10.0

This paper badges the correspondence [FORMAL CORRESPONDENCE, NOT IDENTIFICATION]. Ashby's variety and the surplus ceiling are both logarithms of a state count, and both function as caps on regulatory capability. They are not proved equal, and the surplus range analysis [Curzi, 2026] explicitly declines to identify surplus with information-theoretic quantities. Use the correspondence as a bridge between two literatures, not as a theorem.

With the badge attached, the pairing is powerful, because Ashby and the ceiling say opposite and complementary things:

- **Ashby states the requirement.** If the environment presents V_env of variety and the regulator has V_reg < V_env, the shortfall shows up as unregulated variation — surprises, crises, failures the system did not have a category for. A system cannot regulate what it cannot distinguish, and no amount of effort substitutes for a missing category.
- **The ceiling states the price.** Each doubling of the regulatory repertoire costs the whole effort of doubling and returns 0.6931 nats.

Put together: N must be raised when and only when the environment presents variety the system cannot distinguish, and it must be raised by acquiring genuinely new distinctions rather than new labels — because Ashby's requirement is about distinguishability, which is exactly what Section 5.7's relabeling audit tests.

This gives the four legitimate reasons to raise N, listed in Section 5.11.

Ashby also explains why the Domain-Addition Prohibition does not contradict him. Ashby's law is about **capability**, not about **budget**. A system that lacks requisite variety will fail at regulation no matter how much headroom it has. A system with requisite variety and negative headroom will fail at persistence no matter how well it regulates. They are different failure modes with different fixes, and confusing them produces the characteristic institutional error: responding to a persistence problem (h < 0) with a capability intervention (add domains), which worsens the persistence problem without addressing anything.

Diagnose which one is present before acting. Ashby's failure looks like surprise. The headroom failure looks like erosion.

9.5.10 5.10 Alexander: a city is not a tree

Christopher Alexander's 1965 essay "A City is Not a Tree" is the most directly relevant piece of design theory in this paper's lineage, and Section 5 is where it belongs, because it is an argument about **category structure** and therefore about N.

Alexander's distinction. A **tree** is a collection of sets in which any two sets are either disjoint or one contains the other. A **semilattice** is a collection of sets in which two sets may also **overlap** — sharing members without either containing the other. Every tree is a semilattice; the converse is dramatically false.

Alexander's arithmetic, which anyone can verify:

TABLE 5.9 — DESCRIBABLE SUBSETS ON n ELEMENTS

n	tree: at most (n−1) non-trivial subsets	ln	semilattice: 2^n − n − 1	ln	ratio of ceilings
4	3	1.0986	11	2.3979	2.18 x
6	5	1.6094	57	4.0431	2.51 x
8	7	1.9459	247	5.5094	2.83 x
10	9	2.1972	1013	6.9207	3.15 x

12	11	2.3979	4083	8.3146	3.47 x
16	15	2.7081	65519	11.0901	4.10 x
20	19	2.9444	1048555	13.8629	4.71 x

On twenty elements a tree can carry at most nineteen further subsets. A semilattice on the same twenty can carry 1,048,555. Alexander stated this in the essay as “more than a million,” and the count is exactly `2^20 - 20 - 1`.

Translated into this paper’s terms: the tree structure caps N at n-1, while the semilattice structure caps it at 2^n - n - 1, and since the ceiling is ln N, the tree costs a factor of 4.71 in ceiling at twenty elements and the factor grows with n.

But the deeper point is not about the ceiling. It is about u, and it is the reason the manifest calls hierarchy the organizational form that drives u toward zero.

Why hierarchy drives u to zero

In a tree, every element belongs to exactly one chain of nested sets: itself, its parent, its grandparent, up to the root. Those are its descriptors — the categories the system uses to characterize it.

Nested categories are parallel categories. A set and its superset do not point in different directions; one is contained in the other, and the smaller carries no information the larger contradicts. Under the encoding this paper uses, the pair contributes u $\approx$ 0.

The step is badged: **[POSTULATE] a pair of nested categories is assigned u = 0, and a pair of incomparable (overlapping or disjoint but non-nested) categories is assigned some u_0 > 0 determined by measurement.** The postulate is a modeling choice; it is defensible because a nested pair conveys strictly refined information along a single axis, and it is testable by measuring u between a category and its parent using Section 4’s instruments.

With that postulate, the arithmetic is stark. Consider an element carrying m descriptors:

TABLE 5.10 — DESCRIPTOR-SET AUDIT FOR ONE ELEMENT CARRYING m LABELS
(semilattice case computed at measured u_0 = 0.7)

m	TREE: all nested		SEMILATTICE: all incomparable		ceiling
	N_eff	S	N_eff	S	ln m
2	1.000	0.0000	1.700	0.5306	0.6931
3	1.000	0.0000	2.400	0.8755	1.0986
4	1.000	0.0000	3.100	1.1314	1.3863
6	1.000	0.0000	4.500	1.5041	1.7918
8	1.000	0.0000	5.900	1.7750	2.0794
12	1.000	0.0000	8.700	2.1633	2.4849

In a strict tree, an element’s entire descriptor set audits to an effective count of one, regardless of how deep the hierarchy is. Twelve levels of nested classification and the element is described by one direction. Adding levels adds labels, cost, and review steps, and adds exactly zero surplus.

Real organizations are not perfect trees and not complete semilattices. Parameterize by the fraction q of an element’s descriptor pairs that are incomparable rather than nested:

TABLE 5.11 — PARTIAL OVERLAP. m = 6 DESCRIPTORS, u_0 = 0.7

q (fraction incomparable)	u_bar	N_eff	S	% of ln 6
0.0	0.000	1.000	0.0000	0.0%
0.2	0.140	1.700	0.5306	29.6%

0.4	0.280	2.400	0.8755	48.9%
0.6	0.420	3.100	1.1314	63.1%
0.8	0.560	3.800	1.3350	74.5%
1.0	0.700	4.500	1.5041	83.9%

Moving an organization from q = 0.0 to q = 0.2 — allowing one descriptor pair in five to overlap rather than nest — buys 29.6% of the available ceiling for that element's descriptor set, and it is the cheapest structural change in this section.

What does q > 0 look like in practice? It looks like:

- A person who reports to a function and also belongs to a standing cross-function body, where neither membership is a subset of the other.
- A budget line owned jointly by two units, neither of which contains the other.
- A physical space used by two groups on overlapping schedules — Jacobs' mixed primary uses, which is the same structure in a city.
- A document with two independent owners in different branches.
- A review process in which a proposal is read by its own division and by a body that spans divisions, with neither review subordinate to the other.

And what does q = 0 look like? It looks like a clean org chart. The org chart is legible precisely because it is a tree, and it is a tree precisely because someone removed all the overlaps, and the overlaps were the surplus. This is Alexander's complaint about planned cities restated for institutions, and it is the same complaint: the tree is what a designer produces when the design must be comprehensible to the designer, and comprehensibility to the designer is not one of the system's requirements.

The silo analysis [Curzi, 2026g] develops the organizational consequence (silos as local minima). The room-as-circuit analysis [Curzi, 2026d] develops the spatial consequence. The point here is arithmetic: **hierarchy is a u-destroying structure, and since surplus is `ln(1 + (N−1)u)`, destroying u destroys the return on every category already paid for.**

The semilattice is not free

Honesty requires the other side. Overlapping structure raises C. A person with two non-nested memberships attends two sets of meetings, answers to two review paths, and can be given contradictory instructions. Alexander's essay does not price this; this paper must.

The cost of overlap is roughly proportional to the number of overlapping memberships per element, which is a linear term, while the surplus gain is inside a logarithm. Therefore overlap, like every other lever, saturates: the first overlap per element is worth a great deal and the sixth is worth very little, while each costs the same. Table 5.11 shows the shape — most of the gain is in the first fifth of q. The design rule follows in the Specification: give every element one or two non-nested memberships and stop.

9.5.11 5.11 The four legitimate reasons to raise N

Given the prohibition, when is raising N correct?

L-1 — Ashby shortfall. The environment presents distinguishable variety the system cannot distinguish. Diagnostic signature: recurring surprises of a *kind*, not just of a magnitude — failures the system has no category for and therefore no procedure for. This is the strongest reason and it is not optional; a system without requisite variety fails at its function regardless of its headroom. Note carefully: this is a capability argument, and it may require accepting a worse headroom position in exchange for being able to do the job at all. That trade is legitimate and must be made explicitly, with the headroom cost computed and stated.

L-2 — Building, not repairing. At the initial design of a system, N is being set for the first time and the concavity of Table 5.2 means the early categories are cheap and valuable. Getting

from one category to four buys 1.3863 nats. Do this at design time, when C is still small and Q is still zero, and never again at this price.

L-3 — The ceiling is binding and h is positive. If η S is running up against η ln N — that is, if u is already near 1 and the system is genuinely extracting near its ceiling — then N is the binding constraint and raising it is the correct move. This condition is rare and must be measured, not assumed. The test: `S / ln N > 0.85`. Below that, u is the binding constraint, not N, and Section 6 governs.

L-4 — The new category is nearly free. Occasionally a genuinely distinct category can be acquired at near-zero marginal C — an existing person who already holds a second practice, an existing space that already serves a second use, an existing artifact that already encodes a second tradition. **Take these every time.** They are the only case where the logarithm's slowness does not matter, because the denominator is zero.

Everything else is category inflation.

9.5.12 5.12 N against cost — the crossover

The cost analysis [Curzi, 2026b] established the crossover calculation; it is reproduced here in the form that governs N decisions, because it is the arithmetic that turns the prohibition from an argument into a number.

Take a coordination cost that grows with communication paths: `C(n) = k · n(n−1)/2`. Compare against η ln n at η = 0.5.

TABLE 5.12 — COST VS CEILING, C(n) = k n(n−1)/2 AGAINST eta ln n, eta = 0.5

n	k=0.002		k=0.005		k=0.01		k=0.02		k=0.05	
	C	net	C	net	C	net	C	net	C	net
4	0.012	+0.681	0.030	+0.663	0.060	+0.633	0.120	+0.573	0.300	+0.393
6	0.030	+0.866	0.075	+0.821	0.150	+0.746	0.300	+0.596	0.750	+0.146
8	0.056	+0.984	0.140	+0.900	0.280	+0.760	0.560	+0.480	1.400	−0.360
10	0.090	+1.061	0.225	+0.926	0.450	+0.701	0.900	+0.251	2.250	−1.099
12	0.132	+1.111	0.330	+0.913	0.660	+0.583	1.320	−0.078	3.300	−2.058
15	0.210	+1.144	0.525	+0.829	1.050	+0.304	2.100	−0.746	5.250	−3.896
20	0.380	+1.118	0.950	+0.548	1.900	−0.402	3.800	−2.302	9.500	−8.002
25	0.600	+1.009	1.500	+0.109	3.000	−1.391	6.000	−4.391	15.000	−13.391
30	0.870	+0.831	2.175	−0.474	4.350	−2.649	8.700	−6.999	21.750	−20.049
40	1.560	+0.284	3.900	−2.056	7.800	−5.956	15.600	−13.756	39.000	−37.156

Every column turns negative. Every one. The only question is where. At k = 0.01 — a modest coordination cost of one hundredth of a nat per communication path — the system goes net-negative at n = 20 and is 5.96 nats underwater at n = 40, against a ceiling of only 1.84.

Note also where each column peaks: k = 0.002 peaks around n = 15; k = 0.005 around n = 10; k = 0.01 around n = 8; k = 0.02 around n = 6; k = 0.05 around n = 4. **The optimal category count is small, and it shrinks fast as coordination gets expensive.** This is the arithmetic behind every piece of practical folk wisdom about small teams, and it does not require any claim about human psychology. It is a logarithm losing a race against a quadratic.

9.5.13 5.13 Specification: the requirements on raising N

RN-1 — Publish the ceiling. Every system's design documentation must state N, ln N, η, and η ln N on its first page. That last number is the total budget from which all maintenance, coordination, and growth is paid, and if the people spending it do not know its value they are spending blind.

RN-2 — Compute h before considering N. `h = η ln N − δQ − C`. If h < 0, the Domain-Addition Prohibition applies and no proposal to raise N may be approved as a remedy. Route to the intervention procedure [Curzi, 2026j]: cut C, raise η, or shed Q.

RN-3 — Run the relabeling audit on every proposed category. Six steps, Section 5.7. A proposal that cannot state the new category's encoder in one sentence is rejected without further review.

RN-4 — Require u >= 0.3 against every existing category. Measured by Section 4's Instrument 1 or 2, on at least 20 discriminating items, under blind elicitation. Report the full vector of measured u's against existing categories, not the mean.

RN-5 — Price ceiling gain and delivered gain separately. `ln(N+1) − ln N` is the ceiling gain and is nearly always trivially small (Table 5.7). The delivered gain is `ln(1 + N·u_bar_new) − ln(1 + (N−1)·u_bar_old)` and it is the number that matters. Documents that quote only the ceiling gain are non-compliant.

RN-6 — Test the binding constraint before acting. Compute `S / ln N`. Above 0.85, N binds and Section 5 applies. Below 0.85, u binds and Section 6 applies. Most systems that believe they have an N problem have a u problem, and this single ratio distinguishes them.

RN-7 — Diagnose Ashby shortfall separately from headroom deficit. Ashby shortfall presents as surprises of a novel *kind*. Headroom deficit presents as steady erosion of a familiar kind. Keep two registers: a surprise log (novel failure kinds, dated) and a headroom trace (h computed each period). They call for opposite actions and must never be conflated.

RN-8 — Specify q, the overlap fraction, as a design parameter. For each element of the organization, count its memberships and the fraction of membership pairs that are non-nested. Target q in the range 0.2 to 0.4 (Table 5.11 shows the gain is concentrated there and the cost accounting [Curzi, 2026b] shows the overhead is not yet severe). Publish q per element. q = 0 across the whole organization means a tree has been built and the return on every category paid for has been forfeited.

RN-9 — Give every person at least one non-nested membership. The minimum viable semilattice. One standing cross-function body, one jointly owned artifact, or one shared space with a group that neither contains nor is contained by their own.

RN-10 — Cap N against the cost crossover. Compute the crossover from Table 5.12's method at the measured k and η. Do not exceed the peak. Publish the computed optimum with the org design.

RN-11 — Prefer splitting the body to growing it. Two bodies of six at u = 0.5 deliver `2 × 1.5041 = 3.0082` nats against `2 × 15 = 30` paths. One body of twelve at the same u delivers 1.8718 against 66 paths. **Splitting raises delivered surplus by 61% and cuts communication paths by 55% simultaneously.** This is the strongest single move available at moderate N and it is almost never taken, because splitting reads as failure and growing reads as success.

RN-12 — Badge every use of the Ashby correspondence. `[FORMAL CORRESPONDENCE, NOT IDENTIFICATION]`. Ashby's variety and the surplus ceiling are both logarithms of a state count; they are not proved equal and the surplus range analysis [Curzi, 2026] declines to identify surplus with information-theoretic quantities.

RN-13 — Badge the nesting postulate. Any argument that assigns u = 0 to a nested category pair carries `[POSTULATE]` and states the test that would refute it: measure u between a category and its parent using Instrument 2; if it exceeds 0.3, the postulate does not hold for that structure.

9.5.14 5.14 Failure modes native to the ceiling

FM-5.1 · THE DOMAIN-ADDITION REFLEX

Damages: C (raises it), h (worsens it), and the credibility of the whole planning process.

Clinical description. The system detects decline. Leadership responds by broadening scope: new departments, new initiatives, new disciplines, new markets. The reasoning is that

a bigger system has more capability and therefore more resilience. The arithmetic says the added ceiling is `η ln(N_new/N_old)` while the added cost is at least linear and typically quadratic in the new category count. **Every domain addition made in response to a deficit deepens the deficit.**

Diagnostic signature. A strategy document that responds to declining performance with an expanded remit. Growth in the number of named initiatives while output per initiative falls. The phrase "we need to be more than just a ___."

Detecting measurement. Compute h before and after each of the last three expansions. If h fell each time, the reflex is present and is the primary pathology.

Fix. RN-2 as a hard gate. Then the intervention ordering [Curzi, 2026j]: raise η first (cheapest), cut C second, shed Q third. Only after h > 0 may N be reconsidered, and then only under one of Section 5.11's four legitimate reasons.

FM-5.2 · CATEGORY INFLATION

Damages: C, and the integrity of the measurement of N.

Clinical description. N in the plan rises while N in the geometry does not. Categories are created by splitting, relabeling, or nominal reassignment. Table 5.7's ceiling gain is quoted; Table 5.7's ceiling gain is 1.63% at N = 20 and the delivered gain is zero.

Diagnostic signature. Growth in the org chart without growth in scored disagreement. New category names that are compound modifications of existing ones ("Applied X", "Strategic X", "X Operations"). Measured u between new and parent category below 0.15.

Detecting measurement. RN-4. Blind elicitation on 20 discriminating items, new category against its parent, computed as `u = 1 − ρ²`.

Fix. The relabeling audit (Section 5.7) applied retroactively. Merge every category pair measuring u < 0.15 back into one. Report the merge as a cost reduction, which is what it is.

FM-5.3 · THE ASHBY–HEADROOM CONFUSION

Damages: the diagnosis, and therefore every action that follows it.

Clinical description. A capability failure (missing variety) and a persistence failure (negative headroom) present superficially alike — both look like "we are not doing well" — and call for opposite actions. Treating a headroom deficit as an Ashby shortfall produces FM-5.1. Treating an Ashby shortfall as a headroom deficit produces a system that is efficiently and sustainably unable to do its job.

Diagnostic signature. For Ashby shortfall: failures of a *novel kind*, incident reports whose category field reads "other," repeated invention of ad-hoc procedure. For headroom deficit: failures of a familiar kind at rising frequency, maintenance backlogs, staff who know exactly what is wrong and cannot get to it.

Detecting measurement. Two registers, kept separately, per RN-7: a surprise log and a headroom trace.

Fix. Diagnose first. If Ashby shortfall: acquire the missing distinction, accept the headroom cost, state it explicitly, and pay for it by cutting elsewhere. If headroom deficit: the intervention procedure [Curzi, 2026j]. If both — which happens — fix headroom first, because an Ashby intervention undertaken at h < 0 will not persist. You cannot store a capability in a vessel that is draining.

FM-5.4 · THE TREE

Damages: u, catastrophically, and therefore the return on all existing N.

Clinical description. The organization has been arranged as a strict hierarchy. Every element has exactly one parent. Every category is a subset of exactly one other. All overlaps

have been resolved into ownership, all dual reporting eliminated, all shared spaces assigned. The chart is clean. Under the nesting postulate, every element's descriptor set audits to `N_eff = 1`.

Diagnostic signature. q = 0 across the organization. No standing cross-function bodies with real authority. Every artifact has exactly one owner. Every meeting has exactly one convening unit. When two units need to work together, a coordinating third unit is created above them — which preserves the tree and adds a level.

Detecting measurement. RN-8. Enumerate memberships per element and compute the non-nested fraction. Also count: how many standing bodies span two branches without being subordinate to a common parent below the root? In a strict tree the answer is zero.

Fix. RN-9, the minimum viable semilattice: one non-nested membership per person. Then targeted overlap at the highest-value boundaries — the rotation programmes of the silo analysis [Curzi, 2026g], shared instrumentation, and boundary objects are all q-raising devices. Do not attempt q > 0.4; Table 5.11 shows the returns saturate and the cost analysis [Curzi, 2026b] shows the costs do not.

FM-5.5 · THE UNMEASURED CEILING

Damages: every planning decision downstream.

Clinical description. Nobody has computed `η ln N`. Budgets, growth targets, and maintenance commitments are set without reference to the total from which they must all be paid. The system routinely commits to `r_t > h_t` and then fails to deliver, and the failure is attributed to execution.

Diagnostic signature. Chronic under-delivery against plan with no pattern in which items fail. Plans that sum commitments without reference to a total. Nobody in the organization can state `η ln N` when asked.

Detecting measurement. Ask three senior people for the value of `η ln N`. If none can answer, the mode is present.

Fix. RN-1. Put the number on the first page of the plan. This costs one afternoon and it is, per unit of effort, the highest-return intervention in this paper.

FM-5.6 · THE SATURATED CATEGORY SET

Damages: C, while delivering nothing to S.

Clinical description. N has grown past the crossover in Table 5.12. Additional categories cost more in coordination than they return in ceiling. The system is net-negative on its most recent several categories and does not know it because it measures ceiling gain rather than delivered gain minus cost.

Diagnostic signature. Coordination effort growing faster than headcount. Meetings whose purpose is to synchronize other meetings. Category owners who cannot name what their category contributes that no other category does.

Detecting measurement. Compute the crossover per RN-10 at measured k and η. Compare against current N.

Fix. RN-11. Split rather than grow, or merge the categories that fail RN-4. Both reduce the quadratic term, and the surplus loss is small because the categories being removed were the ones contributing 0.02–0.05 nats apiece.

9.6 6 Engineering non-parallelism

Section 5 closed a door. The ceiling is `ln N`, it grows brutally slowly, and a headroom deficit cannot be closed by adding domains. That is the negative result and it eliminates the move most organizations reach for first.

Section 6 opens the door that remains. In `S = ln(1 + (N−1)u)`, the parameter u enters **linearly**, and it multiplies the **full** `(N−1)`. Every category already paid for — every domain, every discipline, every hire, every instrument — is sitting there with its contribution scaled by u. Raising u collects on all of them at once, without hiring anyone, without expanding scope, and without adding a single communication path.

u is the only parameter in the law that can be moved substantially in a single quarter, and it is the only one whose improvement collects on capital already bought. δ moves over years. η moves over seasons and requires building things. N is capped by a logarithm and constrained by cost. C can be cut but only to zero, and zero is rarely enough. u can go from 0.12 to 0.50 in eight quarters with three interventions and no new headcount, and Section 6 sets out how, with the arithmetic attached.

It also catalogs, at length, the many ways institutions destroy u without noticing — because in practice most u engineering is not construction. It is the removal of homogenizing machinery that somebody installed for a good reason and nobody has audited since.

9.6.1 6.1 The parameter

```
u(x,y) = 1 − (x . y)^2 = || x ^ y ||^2  = sin^2 θ        in [0,1]

N_eff  = 1 + (N−1) u

S      = f(u) = ln(1 + (N−1) u)      UNIQUELY characterized by S1–S4
```

with **S3, the affine effective count, being the design axiom — chosen, not derived**. The linearity of `N_eff` in u, which is the entire engineering premise of this section, is a consequence of S3. That dependence is stated wherever the section leans on it, which in Section 6 is constant.

The derived properties that govern u engineering [Curzi, 2026]:

Property	Ref	What it means for the engineer
Strict monotonicity	Thm 3.1	Every increase in u strictly increases S. There is no threshold to cross and no plateau to wait for. **Partial progress is real progress.**
Positivity	Thm 3.2	`F > 0` for any `u > 0`. A single genuinely different member produces strictly positive surplus.
Strict concavity	Thm 3.3	Diminishing returns. The first increments of u are the valuable ones.
Sharp Lipschitz	Thm 4.2	`|f(u_1)−f(u_2)| <= (N−1)|u_1−u_2|`. Sensitivity is highest at small u, which is where most systems are.
Extremality	Thm 4.3	`F = 0` iff parallel. **Not small. Zero.**
Range	Curzi [2026], Cor 2.2	`0 <= F <= ln N`.

9.6.2 6.2 The zero

The extremality theorem [Curzi, 2026] says `F = 0` if and only if the states are parallel. This is not a limit or an approximation. At u = 0, `N_eff = 1` and `S = ln 1 = 0` exactly.

The organizational statement of that theorem is the sentence Section 6 is built around:

> **A second opinion from someone whose training and incentives replicate the first is worth ln(1) = 0.**

Not "worth little." Not "of limited value." Worth zero. The second reviewer, the confirming analysis, the sanity read from the colleague down the hall — if the instrument is the same instrument, the reading is the same reading, and the law prices a duplicate at nothing.

TABLE 6.1 — WHAT A SECOND OPINION IS WORTH, AS A FUNCTION OF ERROR CORRELATION
(N = 2; u = 1 − rho^2; S = ln(1 + u); ceiling ln 2 = 0.6931)

rho	u	N_eff	S = ln(1+u)	share of ln 2
1.00	0.0000	1.0000	0.0000	0.0%
0.98	0.0396	1.0396	0.0388	5.6%
0.95	0.0975	1.0975	0.0930	13.4%
0.90	0.1900	1.1900	0.1740	25.1%
0.80	0.3600	1.3600	0.3075	44.4%
0.60	0.6400	1.6400	0.4947	71.4%
0.40	0.8400	1.8400	0.6098	88.0%
0.20	0.9600	1.9600	0.6729	97.1%
0.00	1.0000	2.0000	0.6931	100.0%

Read the top of the table, because the top is where organizations live. Two reviewers at ρ = 0.95 — typical of two people trained in the same programme, reading the same literature, evaluated by the same committee — deliver 13.4% of an independent pair. At ρ = 0.98, which describes a mentor and their own former student, they deliver 5.6%.

The organization believes it bought a second opinion. It bought 5.6% of one, at full price.

And now the other end of the table, which is not printed above and must be. Table 6.1 runs `rho` from 1.00 down to 0.00 and stops, which invites the reading that the good direction is simply *away from agreement*, and that the best available reviewer is the one who disagrees hardest. That reading is wrong, and the correction is one line of the definition: `u = 1 − rho^2` depends only on `|rho|`. The table is symmetric about zero.

```
rho = −0.95   ->   u = 0.0975   S = 0.0930    13.4%   -- identical to rho = +0.95
rho = −0.98   ->   u = 0.0396   S = 0.0388     5.6%   -- identical to rho = +0.98
rho = −1.00   ->   u = 0.0000   S = 0.0000     0.0%   -- identical to rho = +1.00
```

At perfect opposition the surplus is exactly zero, precisely as it is at perfect agreement. The zero of the extremality theorem [Curzi, 2026] is a zero of *parallelism*, and a state vector and its negation are parallel. Given the sycophant's reading the principal's can be reconstructed; given the perfect contrarian's it can be reconstructed just as exactly, by changing a sign. **The mirror and the mirror-image are the same instrument. The contrarian who inverts a colleague carries as much information as the sycophant who echoes them: none.**

This correction governs the rest of Section 6, and method M-7 and the red-team specification in particular. **The target of every intervention below is `|rho|` near zero — genuine independence — and never `rho` near -1.** A body engineered for "creative tension," in which a designated opponent takes the negation of whatever is proposed, has manufactured a `u` of zero and is paying `C` for the extra seat: it returns no surplus and costs more than the aligned pair it replaced. Section 4.2 gives the geometry — the angle table folded about 90 degrees — and the pseudo-diversity analysis [Curzi, 2026d] catalogues the fault in its own right, distinct from the Parallel Wall.

9.6.3 6.3 The honesty clauses, restated for the non-parallelism parameter

1. **The founding surplus analysis [Curzi, 2026] is pure mathematics and makes no empirical or metaphysical claim.** That `F = 0` at u = 0 is a theorem about a functional form. That a review panel's second reader is worth nothing is a modeling inference, and it depends on the encoder chosen and on the Roster Reduction [POSTULATE] of Section 3.4.
2. **S3 is a design axiom.** The linearity of `N_eff` in u is chosen.
3. **The deployed functional is a lower bound.** A measured u of 0.15 licenses "at least this much"; it does not license "exactly this much" or "no more than this."
4. **The identity `u = 1 − ρ²` is exact** for mean-centred, unit-normalized state vectors, since their inner product is the Pearson correlation. Encoding a member's state as their error vector is a modeling assumption, badged **[POSTULATE]**.
5. **Subadditivity holds on u only; the triangle inequality fails for geometric triples** (the founding surplus analysis [Curzi, 2026] §5). Where Section 6 combines interventions, it combines them on u and does not chain surplus across triples.
6. **Surplus is not Shannon entropy or mutual information** [Curzi, 2026], and **no thermodynamic negentropy law is proved** [Curzi, 2026a].

9.6.4 6.4 The lever ranking, and why u is second

The intervention procedure [Curzi, 2026j] gives the full ordering. The short version, with this section's justification:

Lever	Typical time to move	Typical cost	Collects on	Verdict
η	one to three quarters	low — writing, archiving, apprenticeship	all future S	**first move in almost every system**
u	one to four quarters	low to moderate — mostly removal of existing machinery	all existing N	**fastest-moving parameter; this section**
C	one to four quarters	moderate — political, not technical	the whole budget	third; bounded below by zero
Q (shedding)	one to eight quarters	political	frees δQ	underused; see the headroom analysis [Curzi, 2026b]
δ	years	high	future retention	slow; the retention analysis [Curzi, 2026a]
N	years	very high	logarithmic return	**last; Section 5's prohibition**

η is first because it is usually cheapest and because it multiplies everything. But η requires **building** — an archive, a protocol, a training path — and building takes a quarter before it starts converting. u is the parameter that moves fastest, because most u interventions are subtractions rather than additions, and a subtraction takes effect the day it is made.

Cancel the meeting that produces the cascade and u rises the next week. Stop screening for culture fit and u rises with the next hire. Remove the shared metric that gives every unit

the same objective function and u rises the next quarter. These are not construction projects. They are the removal of machinery.

9.6.5 6.5 What u buys, at a working scale

Before methods, the payoff table. A system with N = 10, η = 0.5, δ = 0.08 per quarter, C = 0.30. Each level of u, with the steady state it implies through the fixed-point theorem [Curzi, 2026a], `Q_\ensuremath{\infty} = (ηF(u∗) − c∗)/δ`.

```
TABLE 6.2 — WHAT u BUYS, N = 10, eta = 0.5, delta = 0.08, C = 0.30

      u      N_eff      S = ln N_eff    eta S       Q_inf = (eta S − C)/delta
   ─────   ───────    ─────────────   ───────     ─────────────────────────
    0.05    1.45          0.3716        0.1858            −1.428   (unsustainable)
    0.10    1.90          0.6419        0.3209             0.262
    0.15    2.35          0.8544        0.4272             1.590
    0.20    2.80          1.0296        0.5148             2.685
    0.30    3.70          1.3083        0.6542             4.427
    0.40    4.60          1.5261        0.7630             5.788
    0.50    5.50          1.7047        0.8524             6.905
    0.60    6.40          1.8563        0.9281             7.852
    0.70    7.30          1.9879        0.9939             8.674
    0.80    8.20          2.1041        1.0521             9.401
    0.90    9.10          2.2083        1.1041            10.052
    1.00   10.00          2.3026        1.1513            10.641
```

Three readings.

First, the bottom of the table is a death sentence. At u = 0.05 the steady state is negative, which by the fixed-point theorem [Curzi, 2026a] means the equilibrium is unsustainable and the linear model must be replaced. The theorem does not hide this failure mode and neither should the analyst. A ten-category system at u = 0.05 does not converge to a little stored order; it converges to a contradiction, which in practice means it dissolves, is rescued by subsidy, or was never described by these parameters.

Second, the returns are front-loaded. Moving u from 0.05 to 0.30 — a year's work for most organizations — swings the steady state by 5.855. Moving from 0.70 to 1.00, which would require near-perfect orthogonality, swings it by 1.967. The first quarter of the range is worth three times the last. That is concavity, and it is a theorem.

Third — and this is the whole engineering argument — none of these rows required changing N, η, δ, or C. Same categories, same conversion, same leak, same cost. The entire column of steady states was produced by moving one parameter that costs nothing except the willingness to stop homogenizing.

9.6.6 6.6 Raising u — eight methods, with what each costs and what it buys

Ordered by speed of effect. Each entry gives the mechanism, the expected effect on u, the cost, the failure mode, and the measurement that confirms it worked.

M-1 · Silent-write-first

Mechanism. Before any discussion of a question, every participant writes their independent answer and estimate, seals it, and submits it. Only then does discussion begin, and the sealed answers are read into the record first.

Effect on u. It does not raise the geometry; it stops the measured u from being destroyed by the cascade, which in practice is the same thing, since a collapsed discussion delivers the

surplus of one member whatever the geometry. In bodies that have never done it, the gap between measured-under-cascade u and measured-blind u routinely exceeds 0.15 (Section 4, FM-4.5).

Cost. Three minutes per question. Zero capital. Zero headcount.

Failure mode. Performing it and then discarding it — writing the sealed answers and then proceeding as though the senior person's spoken opinion is the starting point. The sealed answers must be read into the record *before* discussion, in a randomized or reverse-seniority order, or the ritual is theatre.

Confirming measurement. Instrument 1 on the sealed answers and on the post-discussion positions; the gap is the cascade magnitude, tracked as a standing metric. This is the highest return-per-minute intervention in the framework, and adopting it requires no authority beyond the ability to say "everyone write it down first."

M-2 · Cut the shared incentive

Mechanism. Identify the metric, target, or reward that every category is optimized against. Split it, stagger it, or replace it with category-specific objectives that are not derivable from one another.

Effect on u. Often the largest structural effect available. A common objective function is a **common mode**: it correlates the errors of otherwise independent instruments, exactly as a shared power supply correlates the noise of independent circuits. In Section 4's worked example, cross-lineage correlation ran at $\rho = 0.55$ among people from genuinely different traditions, the residual attributable to a shared funder with shared criteria; reducing it to $\rho = 0.40$ raised delivered surplus by 0.1550 nats with zero personnel change.

Cost. Political, sometimes severe. A single shared metric is administratively convenient and its removal is resisted by everyone whose job is administration.

Failure mode. Replacing one shared metric with another under a different name. Test it: if unit A's objective is a monotone function of unit B's, nothing changed.

Confirming measurement. Error correlation (Instrument 2) computed before and after, on scored outcomes. Expect the effect to take two to four periods to appear in the data, because the old incentive's influence on behaviour persists past its removal.

Related failure, named here because it is the same mechanism running the other way: Goodhart's Law and Campbell's Law. A measure that becomes a target ceases to be a measure. In this vocabulary: a shared target drives every category to the same point in state space, so u falls, so the measure loses the very diversity of view that made it informative. Goodhart capture is a u-destruction mechanism, and that is the sharpest available statement of why it happens.

M-3 · The adversarial role

Mechanism. Assign, formally and rotationally, a member whose function for this decision is to build the strongest available case against the emerging consensus. The role is structural, not dispositional: it rotates, it is compensated, and its occupant is not held responsible for the position they argued.

Effect on u. Moderate to large, and immediate. It manufactures a non-parallel state where the geometry did not supply one — the cheapest way to obtain a nonzero u in a body that is genuinely homogeneous and cannot be reconstituted this quarter.

Cost. One person's time per decision, plus the meeting time to hear the case.

Failure mode. Two. **The role becomes a person** — one individual always plays it, acquires a reputation as difficult, and is discounted; rotation is what makes it structural rather than personal. Or **the role becomes a ritual** — the objection heard, thanked, minuted, ignored; require the case be answered in writing before the decision is recorded, and let an unanswered objection block it.

Confirming measurement. The fraction of decisions the adversarial case changed, even marginally. Zero over twenty decisions means the role is theatre.

Honest limitation. A manufactured u is not a measured u: the role produces an argument the body would not otherwise have heard, but the arguer's underlying state is still correlated with the body's. Badge it **[PARTIAL SUBSTITUTE]** and do not record it in a structural u estimate.

M-4 · The deliberate outsider

Mechanism. Recruit one member from a training lineage with no overlap with any existing member, place them in a role with real decision rights, and protect them from assimilation for a defined period.

Effect on u. Large, per Section 4's marginal table. The first outsider in a homogeneous body is worth most, because at low u the Lipschitz slope is steep: at N = 12, `df/du` at u = 0.1 is 4.74, so a 0.1 rise in u buys roughly 0.47 nats.

Cost. One hire, or one replacement. Real but bounded.

Failure mode — and it is the dominant one — assimilation. The outsider is hired, warmly welcomed, onboarded into the shared vocabulary, trained on the shared literature, evaluated against the shared metric, and within four quarters their error vector is indistinguishable from everyone else's. The organization concludes that hiring outsiders does not work, when what happened is that it converted the outsider into an insider and destroyed the asset it bought. Section 6.9 gives the protection protocol.

Confirming measurement. The outsider's error correlation against the body's mean, quarterly. A rising ρ is assimilation in progress, visible long before anyone notices it socially.

M-5 · Rotation

Mechanism. Move people between categories on a fixed cadence — six to twenty-four months by the depth of the practice — with a required overlap period and a written handover.

Effect on u. Moderate, cumulative, durable. Rotation attacks u decay at its source: it stops an individual's state converging on their category's, and it manufactures the non-nested memberships Section 5.10 identified as semilattice structure. Rotation is simultaneously a u intervention and a q intervention, which is why it appears in both sections.

Cost. Real. Rotation costs productivity during transitions and depth permanently — a rotated practitioner is less expert in any one category than a fixed one. A genuine trade-off.

Failure mode. Rotating within a branch of the tree, which is nesting, not overlap, and buys nothing. Rotate **across** branches or do not rotate.

Confirming measurement. Pairwise u between categories, measured before rotation begins and after two full cycles. Also track the q statistic of Section 5 RN-8.

M-6 · Import a practitioner from an unrelated trade

Mechanism. Bring in someone whose expertise is real, deep, and from a field with no institutional contact with the receiving one: a logistician into a hospital, a stage manager into a research group, a bookbinder into a software archive project.

Effect on u. Potentially the largest single-person effect available, because lineage overlap is genuinely zero. From Table 4.2, an 80° difference gives u = 0.9698 against 0.0670 at 15° — a factor of fourteen.

Cost. Moderate to high in translation overhead: neither party can use the other's vocabulary. The translator role and boundary objects of the silo analysis [Curzi, 2026g] exist precisely for this.

Failure mode. Placing the outsider in an advisory position with no decision rights, where their non-parallel state has no channel into any decision. A state that cannot enter a decision

contributes zero surplus to that decision regardless of its geometry. Advisory boards are the standard institutional method for acquiring u and simultaneously ensuring it is never spent.

Confirming measurement. Count decisions in which the imported practitioner's position appears in the decision record. Zero means the import is decorative.

M-7 · The red team

Mechanism. A standing group, separately staffed and separately reporting, whose function is to attack the main body's conclusions — a permanent structure with its own membership, budget, and information access, rather than M-3's rotating role.

Effect on u. Large where it is real, which is rare. A red team reporting to the body it attacks is not a red team: the reporting line is a shared incentive (M-2) and will drive its error vector toward the main body's within a year.

Cost. High. It is a duplicate structure.

Failure mode. Capture by three routes — shared reporting line, shared recruitment pool, shared social environment. All three must be broken. A red team recruited from the main body's alumni is a mirror with a different letterhead.

Confirming measurement. Error correlation against the main body, quarterly. Below $\rho = 0.5$ the red team functions; above $\rho = 0.75$ it is captured and should be disbanded and rebuilt, because a captured red team is worse than none — it produces the appearance of adversarial review, which suppresses demand for the real thing.

M-8 · Recruit across training lineages, permanently

Mechanism. Make lineage diversity a standing constraint on the pipeline, not a preference: cap the fraction of the body from any one training lineage, and require the lineage census (Section 4 Instrument 5, EC-9) run and published before any requisition is approved.

Effect on u. The largest **structural** effect available, and the slowest to arrive. Section 4's worked example computed the full ladder: three lineages at 5/4/3 gave u_bar = 0.5137; four lineages at 3/3/3/3 gave 0.5814; six lineages at 2×6 gave 0.6395; twelve distinct lineages gave 0.6975. Note the shape — moving from three lineages to twelve, the theoretical maximum, bought 0.2654 nats, while moving from one lineage to three would have bought far more. Concavity again. Get to three or four lineages and then stop optimizing lineage and start on incentives.

Cost. Recruitment friction. The pipeline is slower and candidates harder to evaluate, precisely because the evaluators are calibrated on the existing lineages — a homogeneous body's hiring process cannot correctly evaluate a candidate from outside its lineage, because evaluation is itself an instrument and the body has only one. The pseudo-diversity analysis [Curzi, 2026d] develops this.

Failure mode. Achieving lineage diversity and then homogenizing downstream through shared training, metrics, and review (FM-6.2). Section 4's FM-4.4 gives the diagnostic: a gap between the u the census predicts and the u error decorrelation measures means the force is downstream of hiring.

Confirming measurement. Both instruments, compared. Publish both.

9.6.7 6.7 Hong and Page: why this is not a fairness argument

Hong & Page (PNAS 2004) proved a result that is routinely misquoted and is worth stating precisely: under stated conditions, a randomly selected group of problem solvers can outperform a group composed of the best individual performers. The mechanism is that high-ability solvers tend to share heuristics — they are good in similar ways — and therefore get stuck in the same local optima, while a more heuristically diverse group has more escape routes.

The result is a theorem under explicit assumptions about the problem space and the solver representations. It is not an empirical claim about all groups and it does not say ability is unimportant. It is a theorem with conditions, and the conditions matter.

What it supplies here is the answer to the objection raised against every intervention in Section 6.6: *"but the people we are excluding are better."* The answer is arithmetic. Take two candidates for a twelfth seat on a body at u_bar = 0.15, N = 12.

- Candidate A is measurably stronger individually and comes from the body's dominant lineage. Their error correlation with the body is ρ = 0.95, so their pairwise u against the body is `1 − 0.95² = 0.0975`.
- Candidate B is measurably weaker individually and comes from an absent lineage. Their error correlation with the body is ρ = 0.55, so their pairwise u is `1 − 0.55² = 0.6975`.

The body has 11 existing members, so the twelfth seat contributes 11 new pairs out of 66. Under the Roster Reduction:

```
with A:  u_bar = (55 x 0.15 + 11 x 0.0975)/66 = (8.250 + 1.073)/66 = 0.14126
         N_eff = 1 + 11 x 0.14126 = 2.554     S = 0.9377

with B:  u_bar = (55 x 0.15 + 11 x 0.6975)/66 = (8.250 + 7.673)/66 = 0.24126
         N_eff = 1 + 11 x 0.24126 = 3.654     S = 1.2960
```

Candidate B delivers 0.3583 more nats than candidate A — a 38% increase in the body's entire surplus input — and candidate A, the stronger individual, lowers the body's mean non-parallelism below its previous level. Hiring A makes the body worse in the only currency the law recognizes.

Say this plainly, because it is the sentence that will get the framework argued with: **the argument for non-parallelism is not about fairness, representation, or morale. It is about the arithmetic of a logarithm, and it would hold identically for sensors, models, or measuring instruments with no people involved.** That it also happens to support treating people decently is a convenience, not a premise; the individuality analysis [Curzi, 2026h] takes up the ethics on its own terms.

9.6.8 6.8 How institutions destroy u without noticing

Almost every homogenizing mechanism below was installed deliberately, for a defensible reason, by someone competent. None was installed in order to destroy u. All of them do.

The unifying diagnosis: **u is not a property that is acquired once. It is a quantity that decays and must be maintained.** Unmaintained, it goes to zero at its own rate. That makes u a δ problem as much as a design problem, which is why the pseudo-diversity analysis [Curzi, 2026d] treats its maintenance as a first-class activity.

TABLE 6.3 — u DECAY. u_t = u_0 (1 − d_u)^t, starting from u_0 = 0.60

t	d_u=0.02	d_u=0.05	d_u=0.10	d_u=0.20
0	0.6000	0.6000	0.6000	0.6000
1	0.5880	0.5700	0.5400	0.4800
2	0.5762	0.5415	0.4860	0.3840
3	0.5647	0.5144	0.4374	0.3072
6	0.5315	0.4411	0.3189	0.1573
12	0.4708	0.3242	0.1695	0.0412
24	0.3695	0.1752	0.0479	0.0028
36	0.2899	0.0947	0.0135	0.0002
60	0.1785	0.0276	0.0011	0.0000

```
TABLE 6.4 — HALF-LIFE OF u UNDER CONVERGENCE RATE d_u
             t_half = ln 2 / ( -ln(1 - d_u) )

     d_u = 0.01     half-life = 68.97 periods
     d_u = 0.02     half-life = 34.31 periods
     d_u = 0.05     half-life = 13.51 periods
     d_u = 0.10     half-life =  6.58 periods
     d_u = 0.15     half-life =  4.27 periods
     d_u = 0.20     half-life =  3.11 periods
```

At a convergence rate of 10% per quarter — which is modest for a co-located team with a shared metric and a weekly all-hands — a body's non-parallelism halves in 6.58 quarters and is down to 5% of its initial value in five years. No one notices, because convergence feels like the team getting better at working together. It is, in fact, the team becoming one instrument.

Now the mechanisms.

D-1 · Hiring for culture fit

The most efficient u-destroyer ever devised, and the one most likely to be described as a strength. "Culture fit" is operationally a screen for state similarity to the existing body: a correlation filter applied at entry, by evaluators who are themselves the reference vector.

Signature. Interview loops that include a "would I want to work with them" question. Candidates rejected for reasons that resolve, when written down, to unfamiliarity. High agreement among interviewers about candidates — which is itself a u = 0 measurement on the interview panel and should be read as such.

Correct replacement. Screen for **values fit** and **capability**, which are not similarity, and explicitly *against* lineage duplication; state in the requisition which lineages are over-represented. Where a "fit" judgement survives, require it in writing as a specific behavioural prediction — falsifiable — rather than as a feeling, which is a correlation reading.

D-2 · Promotion by similarity

The same filter at every subsequent level, compounding. If each promotion round selects for similarity to the level above with even modest strength, after four levels the leadership is a near-pure sample from one lineage however diverse the entry cohort was. A diverse intake with a similarity-selecting promotion ladder produces a diverse workforce and a parallel leadership, which is the observed state of a great many institutions.

Signature. Lineage entropy falling monotonically with seniority. Compute the entropy of the lineage distribution at each level and plot against level; a downward slope is the diagnosis.

Correct replacement. Promotion criteria stated as observable outputs, not judgements of potential — potential is the channel through which similarity operates. Cross-level review panels drawn from other branches. Publish lineage entropy by level annually.

D-3 · Shared training

Everyone attends the same onboarding, the same courses, the same annual conference, and reads the same canonical texts. Done for excellent reasons — shared vocabulary lowers C substantially — and the cost is paid in u. A genuine trade-off, not a mistake; the engineering question is only where to put the boundary.

The rule this paper recommends: share the interface, not the model. Standardize the format in which claims, decisions, and artifacts are exchanged. Do not standardize the reasoning that produces them. A common file format costs nothing in u. A common analytical framework costs almost all of it.

Signature. Every member can complete every other member's sentence. New hires describe onboarding as "learning how we think here."

D-4 · Common incentives

Covered as M-2 from the intervention side; from the destruction side, note how quietly it operates. A single organization-wide bonus metric, a single OKR cascade, a single set of promotion criteria — each is a common-mode input to every member's objective function. The members remain different people with different training and their **errors converge anyway**, because they are now all solving the same optimization problem.

Signature. The gap FM-4.4 identifies: high lineage entropy, low measured u. If provenance says diverse and error decorrelation says parallel, look at the incentive first.

D-5 · Co-location without cross-assignment

Putting people in one building raises contact rate. Contact without cross-assignment raises convergence without raising the overlap fraction q — a body that talks constantly and thinks identically, the maximum-convergence, minimum-structure configuration.

Signature. High interaction frequency, low measured u, and an org chart that is a strict tree (FM-5.4). Open-plan offices with pure functional reporting are the canonical instance.

Correct replacement. Cross-assignment first, co-location second. Co-location amplifies whatever structure is present; if the structure is a tree, it accelerates the convergence. The room-as-circuit analysis [Curzi, 2026d] gives the spatial version and the threshold analysis [Curzi, 2026f] the threshold design that preserves separation where separation is load-bearing.

D-6 · Information cascades

Bikhchandani, Hirshleifer & Welch (1992) showed that rational agents observing predecessors' actions can rationally abandon their own private information, at which point the sequence stops aggregating entirely — every later actor is copying, so no new information enters the record however many participate. In the present vocabulary: **a cascade drives the observed u to zero regardless of the underlying geometry.** The body may hold twelve genuinely different instruments, and if the eleventh and twelfth speak after hearing the first ten, the reading is the first one's.

Signature. Strong dependence of stated position on speaking order. Rapid convergence in discussion. Unanimity arrived at quickly on questions that are genuinely hard.

Correct replacement. M-1, silent-write-first, an anti-cascade device by construction; Chapter 17's furniture and the protocols of the individuality analysis [Curzi, 2026h] institutionalise it. A cascade is the cheapest u-destroyer to prevent and the most expensive to detect afterward, because it leaves a record of agreement.

D-7 · Preferential attachment and the homogenizing hub

Barabási & Albert (Science 1999) showed that growth with preferential attachment produces scale-free degree distributions: a few nodes acquire very high degree. **Albert, Jeong & Barabási (Nature 2000)** showed such networks are robust to random failure and fragile to targeted attack on hubs.

The u consequence is a third property, specific to this paper's concern. A hub is connected to a large fraction of the network, and every node connected to it receives its input. Over time, the hub's state becomes a common-mode input to much of the body, and common-mode input correlates errors. The hub need not be coercive or even intentionally influential. It only needs to be listened to by many people.

Signature. One person, document, forum, or channel upstream of most positions. Ask twenty members where they formed their view on a contested question; if more than half trace to one source, that source is a homogenizing hub.

Correct replacement. Not removal — hubs carry real efficiency and robustness benefits. Install a second and third hub with genuinely different states, and ensure no member draws from only one. Two hubs at ρ = 0.4 with members drawing from both is a substantially different geometry from one, and it costs far less than dismantling the network. Note the interaction with Section 5: preferential attachment grows something close to a tree with a few high-degree centres, and Section 5.10 showed that tree structure drives a descriptor set to `N_eff = 1`. **Hub formation and tree formation are the same homogenization arriving by two routes.**

D-8 · Cohesion

Cohesion is the most socially rewarded u-destroyer. A cohesive team is pleasant, low-friction, low-C, and it converges. The collective-intelligence analysis [Curzi, 2026g] puts it as **cohesion is often the enemy of the collective intelligence factor c, because cohesion drives u toward 0**; the arithmetic version is that every mechanism making a group more comfortable with itself raises the convergence rate d_u unless specifically counteracted.

Signature. Rising satisfaction scores alongside falling disagreement rates. Meetings that end early. Departures described as "not a fit."

Correct replacement. Not to make the group unpleasant, which raises C without raising u, but to install counter-mechanisms — M-1, M-3, M-5 — that hold u against the cohesion gradient. Comfort and non-parallelism are not opposites, but neither are they automatically compatible; where they conflict, this paper chooses the arrangement that preserves both by design.

D-9 · The single review path

Every output passes the same review, by the same reviewers, against the same rubric. A filter applied to all outputs makes all outputs more alike; over enough cycles the body learns to produce what passes, and what passes is one thing.

Signature. Convergence of output form over time. New members' work becoming indistinguishable from old members' work within a year. A rubric that has not changed in five years.

Correct replacement. Two independent review paths with genuinely different rubrics, or a panel whose composition rotates across lineages. And sunset the rubric: one unchanged in five years is stored order consuming its own δQ maintenance while suppressing u — a case for the shed of the headroom analysis [Curzi, 2026b].

D-10 · Success

The last and the hardest. A method that worked becomes the method. Everyone adopts it, because it worked. u falls, because it worked. **This is the u-side of the headroom observation [Curzi, 2026b] that success consumes its own headroom.** There, Q grew until δQ ate the budget; here, a successful approach propagates until it is the only approach. The two are the same event viewed from two parameters, and an institution in this condition has a rising Q and a falling u simultaneously, which is the fastest available route to h < 0.

Signature. One large success, then declining performance everyone attributes to changed external conditions. Universal endorsement of a specific method. Nobody able to describe what that method's failure conditions would look like.

Correct replacement. Reserve capacity for methods that are not the method — an explicit allocation, protected from the metric the successful method optimizes. It is expensive, and

it is The intervention most likely to be cut in a downturn, which is exactly when it is most needed.

9.6.9 6.9 Protecting u after it has been bought

The most wasteful pattern in this subject: an organization spends a year and real money acquiring non-parallelism, then destroys it in four quarters through D-1 to D-10 without connecting the two events. Table 6.3 gives the arithmetic — from a hard-won u_0 = 0.60 at d_u = 0.10, the body is at 0.319 after six quarters and 0.170 after twelve. Translated to steady state:

```
TABLE 6.5 — REGRESSION AFTER THE CAMPAIGN STOPS
            starting u = 0.57; N = 10, eta = 0.5, delta = 0.08, C = 0.30
            Q_inf is the steady state the CURRENT u would sustain

    quarters    d_u = 0.05          d_u = 0.10          d_u = 0.15
    since       u      Q_inf        u      Q_inf        u      Q_inf
    ---------  ------  -------     ------  -------     ------  -------
        0      0.5700   7.582      0.5700   7.582      0.5700   7.582
        2      0.5144   7.050      0.4617   6.500      0.4118   5.931
        4      0.4643   6.528      0.3740   5.461      0.2975   4.390
        6      0.4190   6.016      0.3029   4.471      0.2150   2.979
        8      0.3781   5.515      0.2454   3.536      0.1553   1.716
       10      0.3413   5.025      0.1987   2.660      0.1122   0.613
       12      0.3080   4.548      0.1610   1.848      0.0811  -0.325
```

At a convergence rate of 15% per quarter, an organization that reaches u = 0.57 and then stops maintaining it is back to an unsustainable steady state within three years. Not back to where it started — *below* where it started, because Q has grown in the meantime and δQ is now larger.

The protection protocol is the standing half of this section's Specification: EU-2, EU-6, EU-7, EU-9, and EU-10. Two points belong here rather than there.

Measure quarterly, never annually. The half-life at d_u = 0.10 is 6.58 quarters; an annual measurement samples a decaying signal at half its half-life and misses the trend for two years.

And when u falls, look for the mechanism, not the people. Every entry in Section 6.8 is structural. None requires anyone to behave badly and none is fixed by asking people to be more open-minded. **Exhortation is not an intervention on u; it is a request that people compensate personally for a machine that is running.** the silo analysis [Curzi, 2026g] makes the general form of this argument.

9.6.10 6.10 Measuring u — the standing protocol

Section 4.3 gave the five instruments. The cadence that turns them into a standing measurement:

Quarterly. (1) *Blind item set* — twenty discriminating items from the body's actual work, fresh each quarter, simultaneous and sealed; discard unanimous items (EC-6), compute pairwise disagreement, convert to u, publish the matrix and the mean. (2) *Cascade gap* — readminister five after discussion; blind u minus post-discussion u is the cascade magnitude, and its trend is the health of the elicitation process. (3) *New-member correlation* per EU-7.

Annually. (4) *Error decorrelation on scored outcomes* (Instrument 2) — the ground truth, and the one that catches a body that argues about everything and is wrong in the same direction. (5) *Lineage census* (EC-9), entropy per provenance axis and per seniority level, which is D-2's diagnostic. (6) *Homogenizer inventory* per EU-9 — the single document that makes u destruction visible.

Reporting. Per EU-2, and always with an interval below u = 0.3 (EC-4): the Lipschitz slope makes point estimates misleading there.

9.6.11 6.11 Specification: the requirements on engineering u

EU-1 — Silent-write-first on every consequential decision. Independent written positions, sealed, submitted before discussion and read into the record in randomized or reverse-seniority order. No exceptions for time pressure; the procedure costs three minutes.

EU-2 — Publish u quarterly with its interval. Format: `N = 10, u = 0.34 ± 0.06, N_eff = 4.06 [3.52, 4.60], S = 1.401, ceiling ln N = 2.303, deficit = 0.902`.

EU-3 — No shared objective function across categories. Each category's objective must be non-derivable from every other's. Test annually: if one category's objective is a monotone function of another's, they are one category for surplus purposes and must be recorded as such in N.

EU-4 — Rotate the adversarial role; never let it become a person. Rotation on a published schedule. The adversarial case must be answered in writing before the decision is recorded. An unanswered case blocks the decision.

EU-5 — Cap any single training lineage at one third of the body. Measured by the lineage census. A body exceeding the cap may not hire from the over-represented lineage until it is back in compliance. State the cap in the requisition.

EU-6 — Onboard to the interface, not to the model. Onboarding materials must be auditable against this distinction. Any module that teaches "how we think about X" is a homogenizer and goes in the register (EU-9) with an expiry date.

EU-7 — Protect new outsiders for eight quarters. Output-based evaluation, reviewed by someone outside the dominant lineage, with monthly error-correlation tracking. A ρ rising above 0.05 per quarter triggers a review of what is assimilating them. Onboard them to the interface, not the model, and do not evaluate them against insider criteria.

EU-8 — Give every member at least two upstream sources with measured ρ <= 0.5 between them. The anti-hub requirement (D-7). Audit by asking members to name where they formed their view on three contested questions.

EU-9 — Maintain the homogenizer register. Every shared rubric, metric, reading list, onboarding module, review path, and canonical forum, with install date, last re-justification, expiry, and the measured u across its population. No entry may exceed a three-year expiry unre-justified.

EU-10 — Budget u maintenance as an operating line. Not a project, not an initiative, not a campaign. A standing line covering the quarterly measurement, the rotation cadence, and the adversarial-role time.

EU-11 — Two independent review paths, or a rotating review panel. No output class may pass through a single fixed review path for more than three years.

EU-12 — Reserve capacity against the successful method. An explicit allocation, protected from the metric that method optimizes, for approaches that are not the current one. State it as a fraction and defend it in downturns specifically.

EU-13 — Badge manufactured u. Adversarial roles, red teams, and devil's-advocate protocols produce arguments, not geometry. Record them as `[PARTIAL SUBSTITUTE]` and do not enter them into a structural u estimate.

EU-14 — Test the binding constraint before spending on u. Compute `S / ln N` (Section 5, RN-6). Above 0.85, N binds and this section's interventions will not help. Below 0.85, u binds. Also compute h: **if h < 0, u interventions cannot rescue the system, because S is already capped at `ln N` and the deficit is in δQ or C.** Fix headroom first.

EU-15 — Never remove a person's ability to decline. Every intervention in Section 6.6 works by making a different position available, audible, and consequential. None may compel a person to hold a view, argue a position they reject, or remain in a role they wish to leave. The adversarial role is voluntary and compensated; rotation is opt-out-able with a stated reason.

A method that works by removing resistance has no coercive failure mode; its worst outcome is that someone declines. The framework's own safety analysis [Curzi, 2026h] develops this as a safety property of the whole approach.

9.6.12 6.12 Failure modes native to non-parallelism

FM-6.1 · THE MIRROR SECOND OPINION

Damages: u, and the credibility of every verification process built on it.

Clinical description. Verification is performed by a second party whose training, information, and incentives replicate the first's, and recorded as independent. Table 6.1 prices two reviewers at ρ = 0.95 at 13.4% of an independent pair, and at ρ = 1.00 at exactly zero.

Diagnostic signature. Second opinions agreeing above 95% of the time. Verification steps that have never once overturned an original finding. Reviewers drawn from the pool they review.

Detecting measurement. Error correlation between first and second party across scored outcomes. Anything above ρ = 0.9 means the verification is delivering under 26% of one independent check.

Fix. Draw the second party from a different lineage (M-8), give them different information access, and ensure they are not evaluated by the same person. If none is possible, record the verification as a consistency check, not an independent confirmation, and stop counting it as risk reduction.

FM-6.2 · ASSIMILATION OF THE OUTSIDER

Damages: u, on a delay of four to eight quarters after the acquisition.

Clinical description. The organization recruits genuinely non-parallel members, then converges their state onto the body's through onboarding, shared metrics, shared review, and social integration. The asset is destroyed by the machinery installed to make new members effective, and the organization concludes that hiring for difference does not work.

Diagnostic signature. New members' error correlation rising steadily through their first two years. Onboarding praised as "getting up to speed on how we do things." Outsiders who become the most enthusiastic exponents of the local view within a year.

Detecting measurement. EU-7's monthly tracking. Plot ρ against tenure for every member hired in the last three years; a rising curve is the diagnosis and its slope is the assimilation rate.

Fix. EU-6, EU-7, EU-9. The fix is not to onboard less; it is to onboard differently, and the distinction is entirely between teaching where things are and teaching how to think.

FM-6.3 · THE CAPTURED RED TEAM

Damages: u, plus the demand for real adversarial review.

Clinical description. An adversarial structure exists, is staffed and funded, and has converged on the body it was built to challenge — through shared reporting, shared recruitment, or shared social environment. It produces adversarial-shaped output confirming the body's position, which is worse than having no red team, because the structure suppresses demand for the function.

Diagnostic signature. Findings that have never changed a major decision; members recruited from the main body; reporting into the main body's leadership; correlation above ρ = 0.75.

Detecting measurement. Quarterly error correlation, plus the blunt count: how many decisions did red team review change?

Fix. Break all three capture routes at once — reporting line, recruitment pool, social environment — or disband. A partial fix leaves the appearance intact and the function absent.

FM-6.4 · EXHORTATION IN PLACE OF STRUCTURE

Damages: nothing directly, which is the problem. It consumes the appetite for intervention while changing no parameter.

Clinical description. A u problem is met with training on open-mindedness, workshops, statements of value, and requests that people speak up, while every mechanism in Section 6.8 keeps running. u does not move, and the failure is attributed to culture being hard to change.

Diagnostic signature. Interventions whose deliverable is a document or a session rather than a changed default, schedule, metric, or piece of furniture. Measured u unchanged four quarters after a major culture programme.

Detecting measurement. Measure u before and after; the mode is defined by producing no change, so the measurement is the detector.

Fix. Replace with a structural intervention from Section 6.6. **The test for whether an intervention is structural: could it work if nobody's attitude changed at all?** Silent-write-first passes. Cancelling the shared metric passes. A workshop does not. This is not an argument against psychological safety, which is a precondition for structure to function rather than a substitute for it: a body without it will not surface the sealed answers honestly, and a body with it and no structure will still cascade.

FM-6.5 · THE ADVISORY OUTSIDER

Damages: the return on a u acquisition, without damaging the measured u — which is what makes it hard to see.

Clinical description. A genuinely non-parallel member is placed where their state cannot enter a decision: an advisory board, a consulting arrangement, a research function with no operational authority, a report that is read and filed. The geometry is real and the channel is absent. Surplus requires interaction; a state that never interacts contributes zero.

Diagnostic signature. Advisory bodies whose recommendations appear in no decision record; consultants engaged repeatedly with no traceable change; research output described as "interesting."

Detecting measurement. Trace the last twenty decisions backward and count the fraction in which the outsider's position appears in the record at all, adopted or rejected. Below 20% is the diagnosis.

Fix. Decision rights, or at minimum a required-response protocol: the outsider's position must be answered in the decision record before the decision is final. This is M-3's requirement applied to M-6's asset.

FM-6.6 · CASCADE COLLAPSE

Damages: observed u, to zero, regardless of underlying geometry.

Clinical description. Per D-6. Positions form in sequence with visibility, so later positions carry no new information. The body may be geometrically rich and epistemically empty. Diagnostic signature: speaking-order dependence, rapid unanimity, cascade gap above 0.15. Detect with the cascade gap — blind u minus post-discussion u on the same items. Fix with EU-1; the pseudo-diversity analysis [Curzi, 2026d] gives the detection toolkit and the seating and furniture analysis [Curzi, 2026f] the furniture.

FM-6.7 · THE UNAUDITED HOMOGENIZER

Damages: u, continuously and invisibly.

Clinical description. A shared rubric, metric, reading list, onboarding module, or review path installed years ago for a good reason continues to run, unowned and unre-justified, converging every member it touches at a rate nobody measures.

Diagnostic signature. Ask who owns the rubric. If the answer is a role rather than a person, or the last revision predates half the current staff, the mode is present.

Detecting measurement. The homogenizer register (EU-9). The mode is defined by absence from the register, so building the register is the detection.

Fix. EU-9 with hard expiry dates: re-justify or retire. Retiring an obsolete rubric is a simultaneous u gain and Q shed — one of the few interventions that improves two terms of the headroom equation at once.

FM-6.8 · CHASING u AT NEGATIVE HEADROOM

Damages: the intervention budget, and the credibility of the framework.

Clinical description. A system with h < 0 invests heavily in u. Because `S <= ln N` and h < 0 means `η ln N < δQ + C`, **no value of u whatsoever produces a nondecreasing step.** The intervention is well-designed, well-executed, correctly measured, and mathematically incapable of working — and the organization concludes the framework does not work.

Diagnostic signature. h computed and found negative, followed by a u programme. Or — far more common — a u programme launched without h ever being computed.

Detecting measurement. EU-14. Compute h first. Always.

Fix. The intervention ordering [Curzi, 2026j]: cut C, raise η, shed Q until h > 0. **Then** spend on u, and the same intervention that would have failed will work. The sequencing is not a preference; it is a feasibility condition from the feasibility proposition [Curzi, 2026a].

9.7 7 Results: three systems audited end to end

Three systems are worked completely, from survey through diagnosis to a costed recommendation and a declared falsification rule. **All three are constructed.** No dataset was collected, no organisation was surveyed, and every parameter below is stipulated so that the arithmetic can be redone by the reader from the numbers printed here. They are included because the framework's claims are claims about what happens when the arithmetic is actually carried out, and the failure modes of Sections 4.10, 5.14 and 6.12 are visible only in a complete case.

The three were chosen to exercise different branches of the framework. The first has positive delivery against its ceiling and a *hidden* structural problem the mean conceals. The second has a deficit so large that **no attainable geometry closes it**, which is a counter-result against the framework's own emphasis. The third is the case the framework's engineering sections are written for — non-parallelism binding, headroom available — and it is the only one of the three in which a geometric intervention is the right move.

9.7.1 7.1 A twelve-person review panel

A funding body operates a standing panel that reviews proposals in one technical area. The panel has twelve members. It has operated for six years. Its decisions are scored: three years after each funding round, an independent committee rates each funded proposal's outcome on a five-point scale, and the panel's original scores are compared against that outcome. Six years of data are available.

The body's stated problem: "our decisions have become predictable and our best applicants are going elsewhere." Its proposed solution: expand the panel to thirty members to broaden coverage.

The system is surveyed before anything is changed.

Step 1 — Declare the encoder (EC-1)

State = the member's error vector across scored proposals: for each proposal, the member's original score minus the eventual outcome rating. Six years, 214 scored proposals, twelve members. Vectors mean-centred and normalized per member.

Step 2 — Measure u (Instrument 2)

Compute all `12 × 11 / 2 = 66` pairwise Pearson correlations of the normalized error vectors, then `u_ij = 1 − ρ_ij²`.

The lineage census (Instrument 5, run first as triage per EC-9) had already flagged the structure: the twelve members come from three training lineages, in a 5 / 4 / 3 split. The measured correlations confirm the census's prior and sharpen it:

```
within-lineage mean rho = 0.97   ->   u_within = 1 - 0.97^2 = 0.0591
cross-lineage  mean rho = 0.55   ->   u_cross  = 1 - 0.55^2 = 0.6975
```

Pair accounting for a 5 / 4 / 3 split:

```
total pairs        = 12 x 11 / 2                    = 66
within-lineage     = C(5,2) + C(4,2) + C(3,2)
                   = 10 + 6 + 3                     = 19
cross-lineage      = 66 - 19                        = 47
```

Mean pairwise u under the Roster Reduction [POSTULATE]:

```
u_bar = (19 x 0.0591 + 47 x 0.6975) / 66
      = (1.1229 + 32.7825) / 66
      = 33.9054 / 66
      = 0.5137
```

Step 3 — Audit the count

```
N     = 12
u     = 0.5137
N_eff = 1 + 11 x 0.5137 = 6.651
S     = ln 6.651 = 1.8948 nats

ceiling  ln 12 = 2.4849
delivery       = 1.8948 / 2.4849 = 76.3%
redundancy deficit = 2.4849 - 1.8948 = 0.5901 nats
```

This panel is in better shape than it feels. It is delivering 76% of its ceiling. **The problem is not that the panel is parallel; the problem is that the panel is parallel in a specific place, and the mean has hidden where.**

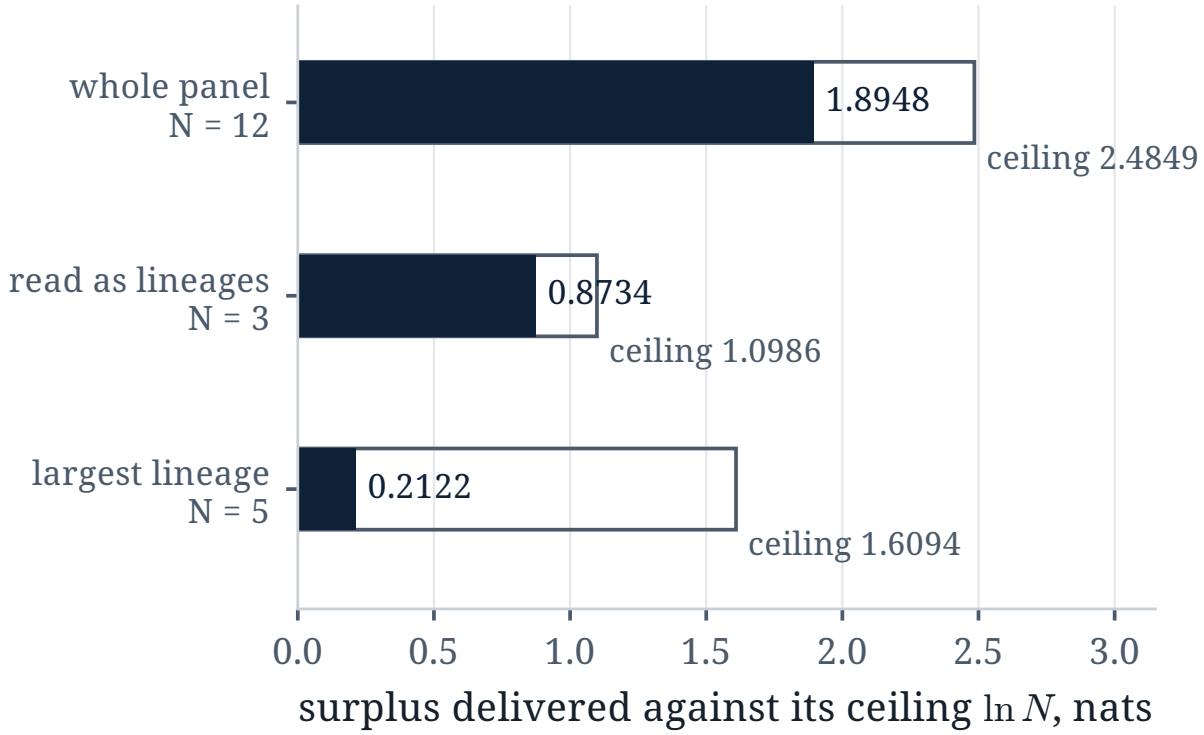

Figure 9.4: **The panel's mean passes at 76 per cent of its ceiling while its largest lineage delivers 13 per cent of its own.** Filled bars are surplus delivered, outlined bars the ceiling ln N. The whole panel reads 1.8948 nats against 2.4849; read as three lineages it reads 0.8734 against 1.0986; and the five members of the largest lineage deliver 0.2122 against 1.6094 among themselves — an effective count of 1.236 for five people. Model output on the stipulated correlations of Section 7.1; arithmetic exact. Generated by `figs/src/CCP-009_fig05.py`.

Step 4 — Read the structure, not the mean (EC-8)

Publish the block structure. Within lineages, `u = 0.0591`: the five members of the largest lineage are, pairwise, at an effective count of `1 + 4 × 0.0591 = 1.236`. Five people delivering `ln 1.236 = 0.212` nats among themselves. **Those five members are, for review purposes, approximately one member and a quarter.**

Read the panel at lineage level — three categories at cross-lineage non-parallelism:

```
N     = 3 lineages
u     = 0.6975
N_eff = 1 + 2 x 0.6975 = 2.395
S     = ln 2.395 = 0.8734      (ceiling ln 3 = 1.0986, delivery 79.5%)
```

Two readings of the same panel, at two granularities, and the honest summary is: **this is a three-instrument panel with twelve people attached to it, and nine of the twelve are duplicate readings of instruments already present.**

Step 5 — Price the proposed solution

The panel proposes growing 12 -> 30. What does that buy? Growth by the existing pipeline recruits into the existing lineages, so the block structure — and therefore `u_bar` — does not change materially. At the panel's own `u_bar = 0.5137`:

```
N = 12   N_eff = 6.651   S = 1.8948   pairs = 66
N = 20   N_eff = 10.76   S = 2.3757   pairs = 190
N = 30   N_eff = 15.90   S = 2.7663   pairs = 435
```

Growth to 30 buys `2.7663 − 1.8948 = 0.8715` nats for 18 new members and a 6.6-fold increase in communication paths. Per member: 0.0484 nats. Consult Table 4.5 — that is the marginal-gain regime where EC-10 says stop.

Worse, growth by the existing pipeline is unlikely to hold `u_bar` constant. Recruiting 18 people into three existing lineages shifts the within/cross pair balance toward within. Recompute with a 12 / 10 / 8 split at 30 members:

```
within pairs = C(12,2) + C(10,2) + C(8,2) = 66 + 45 + 28 = 139
cross  pairs = 435 − 139                                  = 296
u_bar = (139 x 0.0591 + 296 x 0.6975) / 435 = (8.215 + 206.46)/435 = 0.4935
N_eff = 1 + 29 x 0.4935 = 15.31
S     = ln 15.31 = 2.7285
```

Still a gain, but the mean u has fallen and the cost has multiplied. **Growth through an unchanged pipeline dilutes the very quantity it is being purchased to increase.**

Step 6 — Price the alternatives

Option A — rebalance to 4 / 4 / 4 by moving one member out of the largest lineage and one into the smallest. Two personnel actions, no headcount change.

```
within pairs = 3 x C(4,2) = 18,   cross = 48
u_bar = (18 x 0.0591 + 48 x 0.6975)/66 = (1.064 + 33.48)/66 = 0.5234
N_eff = 1 + 11 x 0.5234 = 6.757
S     = ln 6.757 = 1.9106      gain +0.0158 nats
```

Nearly worthless. Rebalancing within a fixed set of lineages moves 19 pairs to 18. **The lineage *count* is the binding constraint, not the lineage *balance*.**

Option B — add a fourth lineage, 3 / 3 / 3 / 3, by replacing three members. No headcount change.

```
within pairs = 4 x C(3,2) = 12,   cross = 54
u_bar = (12 x 0.0591 + 54 x 0.6975)/66 = (0.709 + 37.665)/66 = 0.5814
N_eff = 1 + 11 x 0.5814 = 7.396
S     = ln 7.396 = 2.0009      gain +0.1061 nats
```

Option C — six lineages of two. Replace roughly five members with people from three new lineages.

```
within pairs = 6 x C(2,2) = 6,   cross = 60
u_bar = (6 x 0.0591 + 60 x 0.6975)/66 = (0.355 + 41.85)/66 = 0.6395
N_eff = 1 + 11 x 0.6395 = 8.034
S     = ln 8.034 = 2.0837      gain +0.1889 nats
```

Option D — twelve distinct lineages, the theoretical limit at this cross-lineage correlation.

```
u_bar = 0.6975    (all pairs are cross-lineage)
N_eff = 1 + 11 x 0.6975 = 8.672
S     = ln 8.672 = 2.1602      gain +0.2654 nats
```

Step 7 — Also attack the cross-lineage correlation

Every option above holds `ρ_cross = 0.55` fixed. But 0.55 is itself a measured quantity and it is high for people from different training lineages. The likely cause is downstream homogenization: the three lineages read the same journals, attend the same annual meeting, and are scored by the same funder against the same declared criteria. That is a shared incentive acting as a common mode.

Suppose an intervention (Section 6) reduces `ρ_cross` from 0.55 to 0.40, leaving lineage structure at the current 5 / 4 / 3:

```
u_cross_new = 1 − 0.40^2 = 0.84
u_bar = (19 x 0.0591 + 47 x 0.84)/66 = (1.123 + 39.48)/66 = 0.6152
N_eff = 1 + 11 x 0.6152 = 7.767
S     = ln 7.767 = 2.0498      gain +0.1550 nats, zero personnel change
```

Reducing the common-mode correlation by 0.15 outperformed adding a fourth lineage and cost no personnel action at all. This is the shape of result Section 6 exists to produce, and it is the reason this paper ranks u interventions above N interventions in the lever ordering of the intervention procedure [Curzi, 2026j].

Step 8 — Put it through the circuit

The panel's other parameters, measured per Chapters 3–5: `η = 0.45` (decisions produce durable precedent and written criteria at a middling rate), `δ = 0.09` per annual cycle (membership rotates, criteria drift, institutional memory is thin), `C = 0.55` per cycle (meeting logistics, appeals, conflict-of-interest management, and the appeals load which grows with panel size), and current `Q = 9.5` on the declared order proxy.

Current headroom:

```
h = η ln N − δQ − C
  = 0.45 x 2.4849 − 0.09 x 9.5 − 0.55
  = 1.1182 − 0.855 − 0.55
  = −0.2868
```

Negative. The panel is in the regime where, by the sustainability corollary [Curzi, 2026a], no arrangement of people prevents decline. This changes the entire analysis. Every option in Step 6 was priced against S, but S is capped at `η ln N = 1.1182`, and the panel's actual delivery of `η S = 0.45 × 1.8948 = 0.8527` is already close to that cap. The panel cannot fix a negative headroom by improving its geometry, because the geometry is nearly maxed against a ceiling set by N and η.

Now price growth to 30 correctly:

```
h(N=30) = 0.45 x ln 30 − 0.09 x 9.5 − C(30)
```

`ln 30 = 3.4012`, so `η ln N` rises from 1.1182 to 1.5305, a gain of 0.4123. But C rises too. If the coordination term scales even weakly with pairs — and appeals load, scheduling, and conflict-of-interest management all do — then a 6.6-fold increase in pairs will consume the gain several times over. Taking a modest linear-in-pairs coefficient calibrated to the current panel (`C = 0.55` at 66 pairs implies roughly 0.0083 per pair at the margin, though only part of C is pair-driven — say half):

```
C(30) ~ 0.275 + 0.0042 x 435 = 0.275 + 1.827 = 2.10
h(30) = 1.5305 − 0.855 − 2.10 = −1.4245
```

Growing the panel makes the headroom five times worse. This is Section 5's thesis arriving early and the crossover calculation [Curzi, 2026b] doing exactly what it was built to do.

Step 9 — The recommendation

Given `h < 0`, the intervention procedure [Curzi, 2026j] forbids building and requires cutting C, raising η, or shedding Q. In priority order:

1. **Cut C.** Reduce panel size from 12 to 7, choosing the 7 to preserve all three lineages (3 / 2 / 2). Pairs fall from 66 to 21, a 3.1-fold reduction. New `u_bar`: `within = 3 + 1 + 1 = 5`, `cross = 16`, `u_bar = (5 × 0.0591 + 16 × 0.6975)/21 = (0.296 + 11.16)/21 = 0.5455`. `N_eff = 1 + 6 × 0.5455 = 4.273`, `S = ln 4.273 = 1.4523`. Ceiling `ln 7 = 1.9459`, so `η ln N = 0.8757`. With `C = 0.275 + 0.0042 × 21 = 0.363`: `h = 0.8757 − 0.855 − 0.363 = −0.342`. Still negative — the δQ term is the problem.
2. **Shed Q.** The panel carries 9.5 units of stored order, much of it precedent that no longer discriminates: criteria written for a different research landscape, appeals doctrine accreted over six years, a scoring rubric with sixteen dimensions of which four carry all the variance. Sunset the rubric to four dimensions and formally retire pre-2023 precedent. Estimate the shed at 40%: `Q: 9.5 -> 5.7`, so `δQ: 0.855 -> 0.513`. `h = 0.8757 − 0.513 − 0.363 = −0.0003`. Break-even.
3. **Raise η.** The panel's η = 0.45 is low because decisions produce scores but not written reasoning that binds future rounds. Instituting a two-paragraph written rationale per decision, indexed and searchable, is the classic η intervention from the conversion analysis [Curzi, 2026b]. Estimate `η: 0.45 -> 0.62`. `h = 0.62 × 1.9459 − 0.513 − 0.363 = 1.2065 − 0.876 = +0.3305`. **Positive.**
4. **Only now, raise u.** With `h = +0.3305`, there is room to request an increment. Replace one member with an outsider from a fourth lineage. At 7 members in a 2 / 2 / 2 / 1 split: `within = 1+1+1 = 3`, `cross = 18`, `u_bar = (3 × 0.0591 + 18 × 0.6975)/21 = (0.177 + 12.555)/21 = 0.6063`. `N_eff = 1 + 6 × 0.6063 = 4.638`, `S = ln 4.638 = 1.5343`. `ηS = 0.62 × 1.5343 = 0.9513` against a ceiling of `η ln 7 = 1.2065`.

Final position:

```
N = 7,  u = 0.6063,  N_eff = 4.638,  S = 1.5343
eta = 0.62, delta = 0.09, Q = 5.7, C = 0.363
h   = 0.62 x 1.9459 − 0.09 x 5.7 − 0.363 = +0.3305
Q_{t+1} = 0.91 x 5.7 + 0.62 x 1.5343 − 0.363 = 5.187 + 0.951 − 0.363 = 5.775
Q_inf   = (0.62 x 1.5343 − 0.363) / 0.09 = (0.9513 − 0.363)/0.09 = 6.537
```

The panel is smaller, it stores less, and its fixed point is 6.54 rather than the 9.5 it currently carries — which looks like a downgrade until one observes that its current 9.5 is on a declining trajectory (h < 0) and its new 6.54 is a stable attractor it converges to from either direction, by Banach.

The panel asked to be made bigger. The arithmetic said: make it smaller, write the reasoning down, throw away half the precedent, and then — only then — hire the outsider.

Step 10 — Falsification rules declared in advance

State in advance what would show this analysis wrong.

- If, after the intervention, the measured ρ among the seven does not fall relative to the twelve, the Roster Reduction's block accounting was wrong for this body and the u estimates must be rebuilt from the pairwise matrix.
- If Q on the declared proxy does not stabilize within `3τ \ensuremath{\approx} 3/0.09 \ensuremath{\approx} 33` cycles — impractically long here, so use the 1-cycle prediction `Q_1 = 5.775 ± measurement error` — the storage-law model is not describing this system.

- If the written-rationale intervention does not produce a measurable rise in η, computed as `ΔQ_attributable / S_input` per the conversion analysis [Curzi, 2026b], then η was not the binding parameter and the recommendation was wrong in its most expensive component.
- The shuffled-input control [Curzi, 2026i] is mandatory: re-run the fit with the S series randomly permuted in time. If the shuffled fit performs comparably, the apparent relationship between panel geometry and stored order is an artifact and this entire analysis should be discarded.

A framework that cannot fail cannot be trusted, and the fourth bullet is the one that would kill this one.

9.7.2 7.2 A research institute that proposed to double its domain count

A publicly funded research institute has operated for nineteen years. It spans eight declared research domains. Its stated problem, from its own strategic review: "our output per researcher has declined for six consecutive years and our field-leading position has eroded." Its proposed remedy: expand to sixteen domains over five years, on the reasoning that a broader institute is a more resilient one and that the adjacent fields are where the growth is.

The system is surveyed before anything is changed (the survey procedure [Curzi, 2026i], abbreviated here to the parameters Section 5 needs).

Step 1 — Parameters

Parameter	Value	How obtained
N	8	Declared research domains, each with its own funding line, faculty, and review process. Relabeling audit run: all eight pass RN-4 with pairwise u >= 0.42.
η	0.40	The conversion-estimation method [Curzi, 2026b]: attributable ΔQ per unit S over the last six years. Mid-range; the institute publishes and archives but converts little of its internal interaction into durable method, training, or instrumentation.
δ	0.06 per year	The retention-estimation method [Curzi, 2026a]: decay of the order proxy under a two-year period of reduced input following a funding pause in year 12.

Parameter	Value	How obtained
Q	40.0	Declared order proxy: a composite of maintained instrument-hours, active protocol count, and trained-researcher count, normalized to the year-1 baseline.
C	0.55 per year	The cost tally [Curzi, 2026b]: governance, compliance, inter-domain coordination, estate, and the review overhead of eight funding lines.

Step 2 — The ceiling and the gauge

```
ln N       = ln 8              = 2.0794
eta ln N   = 0.40 x 2.0794     = 0.8318      <- the ENTIRE annual budget

delta Q    = 0.06 x 40.0       = 2.4000
C          =                     0.5500
-------------------------------------------
h = eta ln N - delta Q - C
  = 0.8318 - 2.4000 - 0.5500
  = -2.1182
```

The institute's entire annual budget of order-production is 0.8318 nats, and its maintenance burden alone is 2.4000. Headroom is -2.1182. By the sustainability corollary [Curzi, 2026a] this is the regime in which **no choice of interaction geometry prevents order from decreasing.** Six consecutive years of decline is not a mystery, a morale problem, or a leadership failure. It is the equation.

Note what this means about the six years of effort already spent. Whatever the institute did to improve its collaboration, its culture, its recruitment, or its geometry, `S` is bounded above by `ln 8 = 2.0794` and ηS by 0.8318. The institute could have achieved perfect orthogonality across all eight domains — u = 1, every pair — and still declined by 2.1182 - 0 = 1.5682 nats per year at best. **The geometry was never the binding constraint and no geometric intervention could have worked.**

Step 3 — Price the proposed remedy

Expand from 8 domains to 16.

```
ln 16      = 2.7726
eta ln 16  = 0.40 x 2.7726 = 1.1090
gain       = 1.1090 - 0.8318 = 0.2772 nats
```

Doubling the institute's entire domain structure — five years of recruitment, eight new funding lines, eight new estates, eight new review processes — buys **0.2772 nats** against a deficit of 2.1182. It closes 13% of the gap. And that is before counting the cost.

Continue the sequence to make the point unanswerable:

TABLE 5.13 — CLOSING A 2.1182–NAT DEFICIT BY DOMAIN ADDITION ALONE

```
          (eta = 0.40, delta Q = 2.4000, C = 0.5500 held constant)

   N        eta ln N       h = eta ln N - 2.9500
 -----      --------       ---------------------
     8       0.8318              -2.1182
    16       1.1090              -1.8410
    32       1.3863              -1.5637
    64       1.6636              -1.2864
   128       1.9408              -1.0092
  1000       2.7631              -0.1869
  1600       2.9511              +0.0011
```

Solve it exactly. Break-even requires `η ln N >= δQ + C = 2.9500`, hence `ln N >= 2.9500 / 0.40 = 7.3750`, hence

```
N  >=  e^{7.3750}  =  1595.6
```

The institute would need 1,596 genuinely distinct research domains to reach break-even by domain addition alone — each one passing RN-4's u >= 0.3 test against all 1,595 others, each with its own staff, and all of them held together at the institute's current coordination cost, which they obviously would not be. With 1,596 domains the coordination term alone, at any positive k, is astronomically larger than 0.55.

This is the Domain-Addition Prohibition in a single number. Print it and put it on the wall.

Step 4 — Price the admissible levers

Lever 1 — Raise η. The institute's η = 0.40 reflects a real and fixable deficiency: internal seminars produce no artifact, methods live in individual heads, instrument configurations are not documented, and departing postdocs take their protocols with them. The conversion interventions [Curzi, 2026b] — mandatory method write-ups, a versioned protocol archive, apprenticeship overlap on instrument handover — are all cheap.

```
eta = 0.40:   h = 0.40 x 2.0794 - 2.95 = -2.1182
eta = 0.60:   h = 0.60 x 2.0794 - 2.95 = -1.7023
eta = 0.90:   h = 0.90 x 2.0794 - 2.95 = -1.0785
eta = 1.20:   h = 1.20 x 2.0794 - 2.95 = -0.4547
eta = 1.42:   h = 1.42 x 2.0794 - 2.95 = +0.0028   <- break-even
```

η would have to more than triple, to 1.42, to close the deficit alone. Tripling η is ambitious but it is not absurd — an institute that currently captures almost nothing in durable form has a great deal of room — and unlike the 1,596 domains it is at least the right order of magnitude.

Lever 2 — Cut C.

```
C = 0.55:  h = 0.8318 - 2.40 - 0.55 = -2.1182
C = 0.30:  h = 0.8318 - 2.40 - 0.30 = -1.8682
C = 0.10:  h = 0.8318 - 2.40 - 0.10 = -1.6682
C = 0.00:  h = 0.8318 - 2.40 - 0.00 = -1.5682
```

Even eliminating coordination cost entirely — an impossibility — leaves h at -1.5682. C is not the problem. The δQ term is.

Lever 3 — Shed Q.

```
Q = 40.0:  h = 0.8318 - 2.400 - 0.55 = -2.1182
Q = 30.0:  h = 0.8318 - 1.800 - 0.55 = -1.5182
Q = 20.0:  h = 0.8318 - 1.200 - 0.55 = -0.9182
Q = 10.0:  h = 0.8318 - 0.600 - 0.55 = -0.3182
Q =  4.7:  h = 0.8318 - 0.282 - 0.55 = -0.0002   <- break-even
```

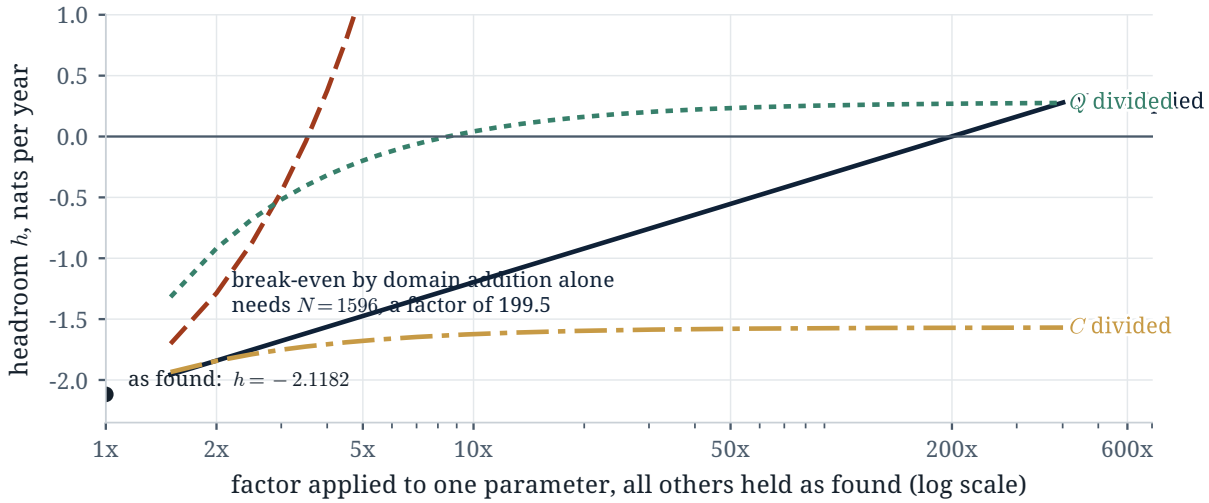

Figure 9.5: **No attainable geometry closes the institute's gap, and the domain lever is the weakest of the four.** Each curve multiplies one parameter of the worked institute ($\eta = 0.40$, $\delta = 0.06$, $Q = 40.0$, $C = 0.55$, $N = 8$) and holds the rest as found. Headroom starts at -2.1182; multiplying N by 199.5, to $N = 1596$, is what break-even by domain addition alone requires, while cutting C to zero never reaches it at all. Modelled with the source's stipulated parameters; arithmetic exact. Generated by `figs/src/CCP-009_fig04.py`.

The institute would have to shed 88% of its stored order to break even on this lever alone. That is the arithmetic statement of a nineteen-year-old institution that has accumulated more structure than its input can maintain. This is the maintenance trap of the headroom analysis [Curzi, 2026b], and it is the actual diagnosis: the institute is not failing to produce; it is failing to stop maintaining.

Step 5 — The combination that works

No single lever suffices. Combine, at levels that are individually plausible:

```
eta:  0.40 -> 0.60   (method archive, protocol versioning, handover overlap)
C:    0.55 -> 0.25   (merge four of eight funding lines into two; single
                      compliance function; retire two of five governance bodies)
Q:    40.0 -> 18.0   (retire 55% of stored order: decommission the instrument
                      park's obsolete half, sunset protocols unused in four years,
                      close two domains that fail RN-4 against their neighbours)

h = 0.60 x 2.0794 - 0.06 x 18.0 - 0.25
  = 1.2476 - 1.0800 - 0.2500
  = -0.0823
```

Still marginally negative. Push η slightly further, to 0.68, which the protocol archive plus a formal apprenticeship overlap should support:

```
h = 0.68 x 2.0794 - 1.0800 - 0.2500 = 1.4140 - 1.3300 = +0.0840
```

Positive. Barely — but the sign is what matters, because the sign is the difference between a system that can grow and a system for which no policy exists that prevents decline.

Note what happened to N. Two domains were **closed**, taking N from 8 to 6:

```
eta ln 6 = 0.68 x 1.7918 = 1.2184
h = 1.2184 - 1.0800 - 0.2500 = -0.1116
```

Negative again. The closures cost 0.1956 nats of ceiling. So they must be paid for by the C and Q reductions they enable — which they are, and generously: closing two domains was what made the funding-line merge and the instrument decommissioning possible in the first place. Attribute honestly:

```
closing 2 domains:  ceiling  -0.1956
                    delta Q  -0.36    (from Q 24 -> 18, the domain-attributable part)
                    C        -0.12
                    net h    +0.2844
```

Closing two domains improved headroom by 0.2844 nats, while adding eight domains would have improved it by at most 0.2772 before costs and by a substantial negative after them. That is Section 5's thesis reduced to a single comparison, and it is the comparison no strategic review ever makes.

Final position:

```
N = 6,  eta = 0.68,  delta = 0.06,  Q = 18.0,  C = 0.25
eta ln N = 0.68 x 1.7918 = 1.2184
h        = 1.2184 - 1.0800 - 0.2500 = -0.1116
```

which is still negative, so one more cut is required. Take Q from 18.0 to 15.0 by retiring the third governance body and the associated documentation estate:

```
h = 1.2184 - 0.9000 - 0.2500 = +0.0684
```

Positive. The institute is smaller in every dimension and it is, for the first time in seven years, above water.

Step 6 — Now check Ashby (RN-7)

Before accepting the recommendation, run the separate diagnosis. The institute's surprise log over six years shows 31 incidents. Classifying by kind:

- 24 are familiar failures at rising frequency: instrument downtime, grant deadline misses, staff departures without handover. **Headroom signature.**
- 7 are novel in kind: three regulatory categories the institute had no procedure for, two data-governance failures involving a technique nobody on staff could evaluate, two collaborations that failed because no one could translate between two of the eight domains. **Ashby signature.**

The seven are real and they will not be fixed by the headroom intervention. Two of them — the data-governance failures — indicate a genuine missing distinction, which is L-1, the one legitimate reason that overrides headroom concerns.

So the recommendation carries an explicit exception:

```
Acquire ONE new category: quantitative data governance, staffed by one person
with genuinely distinct training (RN-4 test required before hiring).

ceiling gain:  eta [ln 7 - ln 6] = 0.68 x (1.9459 - 1.7918) = 0.68 x 0.1541 = +0.1048
C cost:        estimated +0.06 (one funding line, one review path)
Q cost:        +0 initially
net h:         +0.0684 + 0.1048 - 0.06 = +0.1132
```

In this case the Ashby acquisition happens to be **h-positive**, because the institute is at N = 6 where Table 5.7's ceiling gain per category is still 8.60% of the current ceiling, and because the new category is cheap. That is L-4 and L-1 arriving together. **Take it.** Had it been h-negative, the correct move would have been to take it anyway and state the cost, because a system that cannot distinguish its regulatory environment fails at its function regardless of its budget — but the cost would have had to be paid from somewhere, explicitly, in the same document.

Step 7 — What the plan says

```
RECOMMENDATION — RESEARCH INSTITUTE, YEAR 20

REJECT: expansion from 8 to 16 domains.
  Reason: h = −2.1182. Domain-Addition Prohibition (Section 5.6).
  Break-even by domain addition alone requires N = 1,596.
  Proposed expansion closes 13% of the deficit before costs and
  widens it after them.

ADOPT, in this order:
  1. RAISE eta 0.40 -> 0.68. Method archive, protocol versioning,
     mandatory handover overlap. Measured per the conversion analysis \citep{ccp:CCP-008}.
  2. CUT C 0.55 -> 0.25. Merge funding lines 8 -> 4; single compliance
     function; retire 3 of 5 governance bodies.
  3. SHED Q 40.0 -> 15.0. Decommission obsolete instrument park; sunset
     four-year-unused protocols; close 2 domains failing RN-4.
  4. THEN acquire 1 category (data governance) on Ashby grounds L-1,
     at measured u >= 0.3 against all existing domains.

RESULTING POSITION
  N = 7,  eta = 0.68,  delta = 0.06,  Q = 15.0,  C = 0.31
  eta ln N = 0.68 x 1.9459 = 1.3232
  h        = 1.3232 − 0.9000 − 0.3100 = +0.1132
  Q_inf    = (eta F(u*) − C) / delta, computed once u* is measured
             post-intervention (Section 6).
```

Step 8 — Falsification rules declared in advance

- **If h computed at year 21 has not risen above zero**, at least one of the three parameter changes did not land, and the survey must identify which. The most likely candidate is the Q shed: decommissioning is routinely announced and not executed, and Q is the parameter most prone to being reported as reduced while still being maintained.
- **If output continues to decline while h > 0**, the order proxy is wrong. The order-proxy warning [Curzi, 2026i]'s warning applies: verify that the declared proxy Y is not merely a repackaging of the input U. This is the most common measurement error in the framework and the survey protocol's order-proxy test [Curzi, 2026i] is the check.
- **If the shuffled-input control [Curzi, 2026i] fits as well as the ordered one**, the apparent relationship between the institute's interaction structure and its stored order is an artifact and the entire analysis must be withdrawn. This is the control most often omitted and it is the one that would kill this analysis if it were wrong.
- **If the seven Ashby-signature surprises continue at the same rate after the data-governance acquisition**, the missing distinction was misidentified. Re-classify the surprise log and look for the actual missing category rather than assuming the first candidate was correct.

9.7.3 7.3 An engineering organisation over sixteen quarters

A software engineering organization of roughly 90 people is arranged in ten functional categories: platform, application, data, infrastructure, security, quality, design, research, documentation, and operations. Its stated problem: “we ship, but we keep shipping the same class of mistake, and our post-incident reviews always conclude the same three things.”

That last clause is an Ashby-shaped complaint (Section 5.9), but the surprise log resolves it otherwise: the incidents are of familiar kinds, recurring. Not a missing category — a body producing one reading.

Step 1 — Survey

The survey procedure [Curzi, 2026i], abbreviated to the parameters needed here.

Parameter	Value	Method
N	10	Declared functional categories. Relabeling audit (Section 5.7): nine pass RN-4; “documentation” measures u = 0.11 against “quality” and is flagged but retained.
η	0.50	The conversion-estimation method [Curzi, 2026b]. Design documents are written and kept, which is why η is not lower; no apprenticeship and no decision log, which is why it is not higher.
δ	0.08 per quarter	The retention-estimation method [Curzi, 2026a], from decay across a two-quarter hiring freeze.
Q_0	3.0	Order proxy: runbook coverage, test suite health, documented-decision count, normalized.
C	0.30 per quarter	The cost tally [Curzi, 2026b]: cross-team coordination, on-call, release process, compliance.

Ceiling: `η ln N = 0.50 × 2.3026 = 1.1513`.

Step 2 — Measure u

Blind item set: twenty architectural and prioritization judgment items, administered simultaneously and sealed. Six discarded as unanimous (EC-6); pairwise disagreement computed on the remaining fourteen and converted per Instrument 1, cross-checked against Instrument 2 on eighteen months of scored incident predictions.

```
u_bar = 0.12  (interval [0.07, 0.17], reported as an interval per EC-4)
N_eff = 1 + 9 x 0.12 = 2.08
```

```
S     = ln 2.08 = 0.7324
ceiling ln 10 = 2.3026
redundancy deficit = 2.3026 − 0.7324 = 1.5702 nats  (68% of the ceiling forfeited)
```

Ten functional categories, ninety people, delivering the surplus of 2.08 categories.

Cascade gap: five items re-administered after discussion. Post-discussion u = 0.04 against blind u = 0.12. Gap of 0.08 — the discussion process is destroying two-thirds of what little non-parallelism the body has.

Step 3 — Check the binding constraint and the headroom (EU-14)

```
S / ln N = 0.7324 / 2.3026 = 0.318      well below 0.85  ->  u binds, not N
h = eta ln N − delta Q − C
  = 1.1513 − 0.08 x 3.0 − 0.30
  = 1.1513 − 0.24 − 0.30
  = +0.6113                              POSITIVE
```

u binds and headroom is available — the configuration in which this section's interventions are applicable and feasible. Had h been negative, EU-14 and FM-6.8 would have routed the work to The intervention procedure [Curzi, 2026j] instead.

Step 4 — The counterfactual

What happens if nothing changes? Run the storage law forward at u = 0.12.

```
S = 0.7324,  eta S = 0.3662,  and  delta Q + C at Q=3.0  is  0.24 + 0.30 = 0.54

t=0  Q = 3.000  ->  0.92 x 3.000 + 0.3662 − 0.30 = 2.826
t=1  Q = 2.826  ->  2.666
t=2  Q = 2.666  ->  2.519
t=3  Q = 2.519  ->  2.384
t=4  Q = 2.384  ->  2.259
t=6  Q = 2.145  ->  2.039
t=8  Q = 1.942  ->  1.853

Q_inf = (eta S − C)/delta = (0.3662 − 0.30)/0.08 = 0.827
```

The organization is converging to a steady state of 0.827 against a current 3.000 — a 72% reduction in stored order, over roughly 3τ = 37 quarters. Note that h is positive throughout: positive headroom means growth is *available*, not that it is *happening*. The nondecreasing-step test [Curzi, 2026a] gives the test — `Q_{t+1} > Q_t` iff `ηS_t > δQ_t + C_t`, and here `0.3662 < 0.54`. Declining.

Nobody would describe this as a crisis. It is a 4.5% quarterly erosion of runbook coverage, test health, and documented decisions, and it will be visible in about four years.

Step 5 — Design the campaign

Three interventions, chosen by the Section 6.6 ordering and by what this body's diagnosis actually shows.

Q1 — M-1, silent-write-first, plus EU-1. The cascade gap of 0.08 says the discussion process is the largest immediate loss. Cost: three minutes per decision. Expected: recovery of most of the gap, and then more as people stop pre-converging in anticipation. `u: 0.12 -> 0.20` by Q2.

Q2 — M-2, cut the shared incentive. The audit finds one organization-wide quarterly delivery metric, bonus attached, against which all ten categories are assessed — security, quality,

and research all optimizing a throughput number. Replace with three clusters carrying non-derivable objectives (EU-3): delivery, reliability, discovery. `u: 0.20 -> 0.35` over three to four quarters.

Q3 — M-3 and M-8 together. A rotating adversarial role on every architectural decision (badged `[PARTIAL SUBSTITUTE]` per EU-13, so not entered into the structural estimate), plus two requisitions under a lineage constraint: the census shows 61% of engineering staff trained in one framework tradition, exceeding EU-5's one-third cap. Expected: `u: 0.35 -> 0.50` over four quarters.

Not attempted: raising N. `S / ln N = 0.318` says N does not bind. The flagged "documentation" category, measuring u = 0.11 against "quality," is left in place and re-tested at Q8.

Step 6 — The trajectory

Run the storage law forward with the campaign's u path. Parameters unchanged: `η = 0.5`, `δ = 0.08`, `N = 10`, `C = 0.30`, `Q_0 = 3.0`.

TABLE 6.6 — CAMPAIGN TRAJECTORY, SIXTEEN QUARTERS

t	u	N_eff	S = ln N_eff	h_t	Q_t	->	Q_{t+1}
0	0.12	2.08	0.7324	+0.6113	3.000	->	2.826
1	0.12	2.08	0.7324	+0.6252	2.826	->	2.666
2	0.20	2.80	1.0296	+0.6380	2.666	->	2.668
3	0.28	3.52	1.2585	+0.6379	2.668	->	2.784
4	0.35	4.15	1.4231	+0.6286	2.784	->	2.972
5	0.41	4.69	1.5454	+0.6135	2.972	->	3.207
6	0.46	5.14	1.6371	+0.5947	3.207	->	3.469
7	0.50	5.50	1.7047	+0.5737	3.469	->	3.744
8	0.52	5.68	1.7370	+0.5518	3.744	->	4.013
9	0.54	5.86	1.7681	+0.5302	4.013	->	4.276
10	0.55	5.95	1.7834	+0.5092	4.276	->	4.526
11	0.56	6.04	1.7984	+0.4892	4.526	->	4.763
12	0.56	6.04	1.7984	+0.4703	4.763	->	4.981
13	0.57	6.13	1.8132	+0.4528	4.981	->	5.189
14	0.57	6.13	1.8132	+0.4362	5.189	->	5.381
15	0.57	6.13	1.8132	+0.4208	5.381	->	5.557
16	0.57	6.13	1.8132	+0.4068	5.557	->	5.719

```
Q_inf at u* = 0.57:  (0.5 x 1.8132 - 0.30)/0.08 = 7.582
tau = 1/delta = 12.5 quarters;  3tau = 38,  5tau = 62
```

Four things to read from this table.

First, the turnaround is at t = 2, not t = 0. Q continues to fall for two quarters after the campaign begins, because the integrator is still discharging its initial transient `(1-δ)^t Q_0` while the driven term builds. This is the recursion result and the central point of the circuit analysis [Curzi, 2026a]: **a leaky integrator does not respond instantly, and a campaign evaluated at one quarter will be judged a failure at exactly the moment it is working.** Anyone who cancels this programme at Q2 because "the numbers are still going down" has misread the circuit.

Second, the arrival is slow. τ = 12.5 quarters, so 3τ ≈ 38 quarters to reach 95% of the new steady state. At t = 16 the system is at 5.719 against a fixed point of 7.582, 75% of the way. The intervention was fast; the arrival is slow, and the slowness is δ, not the intervention.

Third, headroom falls monotonically as Q rises — from +0.6113 at t = 0 to +0.4068 at t = 16. The headroom observation [Curzi, 2026b] that success consumes its own headroom, arriving on schedule. At the fixed point, headroom is `1.1513 − 0.08 × 7.582 − 0.30 = 0.2447`: positive,

but 60% consumed. The maintenance transition lands at about Q = 10.6, where `δQ + C = η ln N` exactly, and the organization should know that now rather than discovering it in a decade.

Fourth, compare against the counterfactual. At t = 8, campaign Q = 4.013 against counterfactual 1.853, a factor of 2.17; at the fixed points, 7.582 against 0.827, a factor of 9.17. The campaign cost three minutes per meeting, one metric redesign, one rotating role, and two lineage-constrained hires — and it moved the organization's stable stored order by a factor of nine.

Step 7 — What was and was not achieved

Honest accounting. What did **not** change: N stayed at 10, η at 0.50, δ at 0.08, C at 0.30, and headcount rose by two on a base of ninety. Every gain in Table 6.6 came from one parameter, moved mostly by cancelling things.

What was not delivered: the final u of 0.57 is well short of 1.0, and `S = 1.8132` is 79% of the ceiling. By RN-6's test `S / ln N = 0.787`, still below 0.85, so u binds marginally and a little remains. Take it carefully — from Table 6.2, u from 0.60 to 0.70 buys 0.0658 nats of `ηS` and 0.82 of `Q_\ensuremath{\infty}`, against 0.1939 and 2.42 for the move from 0.12 to 0.20. The campaign has collected the front-loaded portion, and the correct next move is η, not more u.

Step 8 — Maintenance, or it all comes back

The campaign's output is `u* = 0.57`. Per Section 6.9, that figure decays. The organization must now budget maintenance as a standing line (EU-10) or repeat Table 6.5:

```
at d_u = 0.05:  Q_inf sustainable falls  7.582 -> 4.548 over 12 quarters
at d_u = 0.10:  Q_inf sustainable falls  7.582 -> 1.848 over 12 quarters
at d_u = 0.15:  Q_inf sustainable falls  7.582 -> -0.325 over 12 quarters
```

At a 15% quarterly convergence rate the organization is back below its unsustainable threshold in three years, carrying a Q of around 6 when it gets there — so the second decline is steeper than the first. Standing commitments per EU-2 and EU-7 to EU-11: quarterly measurement, new-member correlation tracking, the homogenizer register with three-year expiries, the rotation cadence, and two independent review paths.

Step 9 — Falsification rules declared in advance

Stated in advance, before the campaign begins, and frozen.

- **The blind u must rise.** If measured u at Q4 is not above 0.25, the incentive change did not affect the geometry and the model of what was homogenizing this body is wrong — most likely the shared metric was not the binding common mode and shared hiring is, given the 61% concentration.
- **The trajectory must turn by Q3.** Table 6.6 puts the minimum at t = 2, `Q \ensuremath{\approx} 2.666`. Still falling at t = 4 means δ was mis-estimated or the proxy is not tracking Q.
- **Q at t = 8 must be within measurement error of 4.013.** A miss on the level with a correct turning point implicates η; a miss on both implicates δ.
- **The order proxy must not be a repackaging of the input.** the order-proxy warning [Curzi, 2026i]. If documented-decision count is partly a measure of how much the body interacts, it is contaminated and must be dropped from the composite. **This is the most common measurement error in the framework**; the survey protocol [Curzi, 2026i] §24.7 gives the test.

- **The shuffled-input control [Curzi, 2026i] is mandatory.** Refit `Y_{t+1} = aY_t + bF(U_t) – Ĉ_t + ε_t` with the U series randomly permuted in time. If the shuffled fit performs comparably on held-out data, the apparent link between this organization's geometry and its stored order is an artifact and **this entire analysis must be withdrawn, including the parts that appeared to work.** It is the control most often omitted and the one that would kill this result.

u is the fast parameter. It collects on every category already bought, it moves in a quarter, and most of the moves are subtractions — cancel the shared metric, the sequential discussion, the culture-fit screen; sunset the five-year-old rubric. It is also the parameter that decays fastest and most invisibly, because every force acting on it — cohesion, success, shared training, a good hire being welcomed — feels like the organization working well.

Non-parallelism is not a state an institution achieves. It is a load an institution carries, and the moment it stops carrying it the load slides back down. the two-source decomposition [Curzi, 2026d] splits the load into its two independent components, so that it is possible to tell which half is being carried and which half was dropped.

9.8 8 Discussion

9.8.1 8.1 What follows from the three sections

The audit is the whole result. Every quantitative claim in Sections 4 to 6 is a consequence of one substitution: replacing N by $1 + (N - 1)u$ wherever a count enters the storage law. The substitution costs nothing to make and it changes the sign of most institutional recommendations. A hundred-person department at $u = 0.05$ delivering an effective 5.95 is not a rhetorical flourish; it is the same arithmetic that gives Markowitz [1952]'s result that a hundred perfectly correlated holdings diversify as well as one.

The three levers are ordered by their arithmetic, not by preference. Conversion enters the budget linearly, non-parallelism enters linearly inside a logarithm and multiplies the full $(N - 1)$, and category count enters only as $\ln N$. That ordering is why the domain-addition prohibition of Section 5.6 is a structural result and not advice: closing a deficit D by raising N alone requires multiplying N by $e^{D/\eta}$, which is exponential in the deficit, while the cost terms it must outrun grow at least linearly and typically quadratically [Brooks, 1975, Conway, 1968]. A logarithm loses that race.

Two results in this paper are corrections to intuitions the framework itself invites. The first is the fold at ninety degrees: u depends on ρ^2, so opposition is parallelism and the designated contrarian is priced at zero (Section 6.2). The second is that the mean pairwise u hides where the redundancy sits. The twelve-person panel of Section 7.1 delivers 76.3 per cent of its ceiling and looks healthy on the mean, and the block structure underneath shows five members operating at an effective count of 1.236 among themselves. **The summary statistic passed and the structure failed, which is exactly the case the specification's requirement to publish the pairwise matrix exists to catch.**

9.8.2 8.2 What does not follow

Nothing here establishes that institutions obey the surplus law. The uniqueness of f under S1–S4 is a theorem about four axioms, one of which was chosen. The empirical content is a modelling proposal, and the protocol that would test it is specified elsewhere in the corpus [Curzi, 2026i] — where its one confirmatory application **failed its second falsification rule**, returning a 2.8 per cent held-out advantage over a matched autoregression against a declared 10 per cent margin. That result is the correct context for every number in this paper.

Nothing here licenses treating the affine effective count as a diversity index. Section 3.3 and Section 9.6 are the argument. A reader who imports the Hill literature's estimation theory,

partitioning theory or replication principle will import guarantees the affine count does not have.

The monotone claim is not defensible unqualified. Surplus is strictly increasing in u by Curzi [2026]'s Thm 3.1, and the empirical literature does not agree that value is. Uzzi and Spiro [2005] finds an inverted U in creative output against cohesion; Putnam [2007] finds short-run reductions in trust and participation with diversity, a result its author did not want, and Abascal and Baldassarri [2015] is the rebuttal that should be cited with it; Mannix and Neale [2005] and van Knippenberg and Schippers [2007] find surface-level difference often hurts in the short run; May [1972] and Gardner and Ashby [1970] show that increasing diversity and connectance destabilises randomly assembled systems; and Sagan [1993] documents that redundancy can reduce safety. **The framework's curve is monotone and the measured curves turn over.** The honest reconciliation is that the framework prices the *input* term and says nothing about the cost of extracting it, and the cost side is exactly where those results live — Section 5.12's crossover table is this paper's version of the turn, and it turns in every column. Allport [1954]'s four conditions are the same qualification in the contact literature: difference produces value under conditions, and u needs the conditions named.

Nothing here is an argument about fairness. Section 6.7 makes the point explicitly and it is worth repeating: the case for non-parallelism is arithmetic and would hold identically for sensors, estimators or measuring instruments. Harrison and Klein [2007] is the reason the point must be made carefully — three incompatible constructs travel under the word *diversity* (separation, variety, disparity) — and **this framework's u is a disparity measure and must declare itself as one.**

9.8.3 8.3 Relation to the surrounding literature

The closest empirical analogue of an effective count in the social sciences is Ugander et al. [2012], which measures adoption against the number of *distinct connected components* among a person's contacts rather than against the number of contacts — an effective count of independent sources, at scale, with data. Lorenz et al. [2011] measures the collapse directly: social influence reduces the effective diversity of a population's estimates and simultaneously increases confidence, which is Section 6.8's D-6 with an experiment attached. Bikhchandani et al. [1992] and Banerjee [1992] supply the formal core of that collapse, and Douceur [2002] supplies its adversarial form — one party presenting as many, which is a proof that an unaudited count is worthless.

On the pro-difference side, Hong and Page [2004] is the theorem the framework's engineering sections lean on and Thompson [2014] is the detailed objection to its conditions; the pair must travel together, and Grim et al. [2019] maps the boundary conditions under which the result holds in simulation while Singer [2019] and Kuehn [2017] are the repairs. Woolley et al. [2010] supplies the measured collective-intelligence factor and its turn-taking-equality component, which is the closest empirical relative of the framework's own speaking-share diagnostic. Page [2007] and Page [2010] are the book-length statements.

On concentration, Schindler et al. [2010] is the strongest single demonstration that an effective count buys stability — half the variability and one tenth the fishery closures in a portfolio of salmon populations — and Doak et al. [1998] is the standing objection that diversity–stability relationships arise from statistical averaging with no mechanism at all, with Tilman et al. [1998] the reply. Loreau and de Mazancourt [2008] names the decisive variable as **synchrony**, which is the ecological name for what ρ measures here. McCann [2000] is the fair survey.

On the institutional mechanism, March [1991] is the framework's own thesis published in 1991 with a simulation attached: fast learning homogenises an organisation and destroys the variance that produced its advantage. Section 6.8's D-1 to D-10 are that mechanism enumerated. Levinthal and March [1993] is the same argument about search; Scott [1998] is the historical version, in which legibility destroys the local variety that made a system work — and is simultaneously a warning about this paper's own instrument, since a published u figure is

a legibility device. Goodhart [1975] and Campbell [1979] are the specific form that warning takes: adopted as a target, u would cease to measure anything, and Section 6.6's M-2 identifies Goodhart capture as a u-destruction mechanism in its own right.

On structure, Alexander [1965] supplies Section 5.10's tree-versus-semilattice argument in its original form, and Jacobs [1961] supplies the mixed-primary-use version of the same claim about cities. Star and Ruhleder [1996] and Star and Griesemer [1989] supply the boundary object, which is the artefact that makes a non-nested membership work in practice. Granovetter [1973], Burt [1992] and Burt [2004] supply measured effect sizes for the bridging claim, and Centola and Macy [2007] and Centola [2010] supply the qualification that matters most for the framework's prescriptions: **behaviours needing reinforcement spread along dense local ties rather than weak long ones, so raising the audited count by adding distant contacts works for information and not for practice.**

Perrow [1984] is the objection the framework must not talk past. Interactive complexity plus tight coupling makes catastrophic failure a system property, and adding categories inside one coordination perimeter can therefore make matters worse — which is Section 5.6's prohibition reached by a different route, in 1984. Buldyrev et al. [2010] is its formal statement for coupled networks.

9.8.4 8.4 Where these results are consumed, and what parallels them elsewhere in the corpus

The affine effective count is load-bearing beyond this paper and the badge must survive every citation. The internal-surplus analysis runs the identical form on one observer's framings — $F_{\text{int}} = \ln(1 + (N-1)u)$ with N_{eff} the audited framing count and $u = 1 - \rho^2$ from error decorrelation — and badges the affine form as design axiom S3 rather than as a theorem [Curzi, 2026o], which is the correct treatment and the one this paper's Section 3.3 requires. The opposition identity of Section 6.2 is carried into the frequency framework unchanged: $u = 1 - \rho^2$ depends only on $|\rho|$, so $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$, and the same folded note [Curzi, 2026]. And the headroom gate this paper's Sections 5.6 and 6.12 route through is stated as a precondition on any protocol elsewhere in the corpus — $h = \eta \ln N - \delta Q - C$, with $h < 0$ forbidding construction and $h > 0$ capping every increment at $r \le h$, worked at $N = 18$ with $\eta = 0.30$, $\delta = 0.06$, $C = 0.55$, $Q = 1.20$ to give $h = +0.2451$ [Curzi, 2026].

Two corpus results bound what Section 6 may claim about calibration and about acoustics. At the reflexive fixed point the input sits exactly at its ceiling and headroom is identically zero, $h = \eta \ln N - (\eta \ln N - C) - C = 0$, so calibration is not an unqualified target [Curzi, 2026r]; a body that has converged has no headroom left to spend on the interventions of Section 6.6, whatever its geometry. And the ceiling is spent by physical exclusion as readily as by redundancy: silencing three of eight participants costs $\ln 8 - \ln 5 = 0.4700$ nats, which is 22.6 per cent of the room's per-interaction surplus [Curzi, 2026e]. **A body can lose more of its ceiling to a reverberant room than Section 7.1's panel gained from redistributing its entire lineage structure.**

The same arithmetic recurs in three other domains and the recurrence is worth naming, because it is what makes the instrument general rather than local. In the frequency framework the deficit identity $D = 2.885390(c/\eta - F) = -2.885390(\delta/\eta)Q_\infty$ carries the surplus term into a pitch criterion and is cross-checked at an $8.88\text{e}{-16}$ residual [Curzi, 2026]; in the essence lattice the doubling theorem $HD_{\text{ess}}(i,j) = 2\log_2(pq)$ with $G_{\text{ess}} = 2G(pq) - 1$ is verified exactly over all sixty-six pairs at $N = 12$ [Curzi, 2026] — the same sixty-six pairs this paper's Section 7.1 audits, arrived at from an entirely different construction. **The coincidence of $\binom{12}{2} = 66$ in both is combinatorial and carries no further significance; saying so is cheaper than letting a reader find it.**

In the structural series the effective count is the grounded one, and the contrast is instructive rather than embarrassing. The concentration instrument uses HHI^{-1}: exposures of 40.9 / 27.3 / 18.2 / 13.6 give a naive HHI of 0.293430 and 3.41 effective jurisdictions, while a bloc collapse gives HHI $= 1.000000$ and an effective count of 1.00 [Curzi, 2026]. The same reciprocal

form prices job concentration — an as-found operating company scoring $S = 0.4050$ and 2.4691 effective jobs against a specialist target of 1.1050 [Curzi, 2026]. And the corpus's reproduction workbook states the procedural consequence in one line: $\ln(1.00) = 0$, so a structure with one effective bloc has **zero** available surplus rather than a low one, and the first step of the method is to collapse before measuring [Curzi, 2026]. **Those three results are grounded in the Hill literature and this paper's are not, and a reader moving between them must carry Section 3.3's distinction with them.**

9.9 9 Verification

9.9.1 9.1 Dimensional audit

Every equation in this paper is audited below. $[Q]$ is the dimension of the declared order proxy — whatever unit it counts — and $[T]$ is time in the system's declared period.

Symbol	Dimension	Unit	Status
x, y	$[1]$	none	**defined** as unit vectors in the encoder's state space; the encoder is declared, not measured
$u = 1 - (x \cdot y)^2$	$[1]$	none	**defined** dimensionless; a squared sine of an angle
ρ	$[1]$	none	**measured** correlation, under the error-vector encoding
N	$[1]$	count of categories	**declared**, not measured; a dimension count, not a headcount
$N_{\text{eff}} = 1 + (N-1)u$	$[1]$	count	**defined** by design axiom S3
PR	$[1]$	none	**derived** from the Gram spectrum
$F(u) = \ln N_{\text{eff}}$	$[1]$	nats	**derived**; a logarithm of a dimensionless count
$\ln N$	$[1]$	nats	**derived** ceiling
η	$[Q]$ per nat	proxy units per nat	**estimated**, and *not* dimensionless
δ	$[T]^{-1}$	per period	**estimated** decay rate
Q	$[Q]$	declared proxy units	**measured** against a declared proxy
C	$[Q]$,$[T]^{-1}$	proxy units per period	**measured**, denominated in Q-units by requirement
$h = \eta \ln N - \delta Q - C$	$[Q]$,$[T]^{-1}$	proxy units per period	**derived**

Symbol	Dimension	Unit	Status
κ	$[Q]$,$[T]^{-1}$ per path	per communication path	**stipulated** in Section 5.12

Does the surplus equation balance? $F(u) = \ln(1 + (N-1)u)$ takes the logarithm of a pure number, which is the only thing a logarithm may take. u is dimensionless because it is a squared cosine of unit vectors; N is a count. The equation balances, and it balances *because* N is a count of categories and not a headcount with an implied staffing unit attached.

Does the storage equation balance? $Q_{t+1} = (1-\delta)Q_t + \eta F(u) - C_t$ holds only if every right-hand term carries $[Q]$. The first does, since δ is dimensionless per period. The third does by the denomination requirement. The second does **only if η carries $[Q]$ per nat**, which is why η is reported in this paper as proxy units per nat and never as a bare fraction [Curzi, 2026b]. A conversion efficiency quoted as a dimensionless number makes the equation dimensionally malformed however tidy the arithmetic looks.

Where the framework has no operational unit, this audit says so. Q is stored order and has no natural unit; it counts whatever the declared proxy counts, and two bodies' Q values are not comparable unless they declare the same proxy. The underlying construct — comfort — has **no operational unit at all** and is treated as a dimensionless magnitude by stipulation. Section 9.5 records that the quantitative structure that stipulation assumes has not been tested. **The nat is not a physical unit either**: it is the unit of a logarithm taken to base e, and the choice of base is a convention, not a measurement. Reporting a surplus in bits would multiply every figure in this paper by $1/\ln 2 = 1.442695$ and change nothing.

9.9.2 9.2 Postulates

Seven postulates. Each is atomic, each is checkable alone, and each carries its status. Where one could be dropped and the results still follow, it has been dropped.

#	Statement	Status
P1	$u(x, y) = 1 - (x \cdot y)^2$ for unit vectors x, y	**DEFINITION**
P2	f depends on a pair only through u (S1); $f(0) = 0$ (S2); $f(1) = \ln N$ (S4)	**DEFINITION** — normalisation and structure
P3	$g(u) = e^{f(u)}$ is affine in u (S3)	**DESIGN AXIOM** — chosen, not derived; Curzi [2026]
P4	for a roster of N members, N is the declared category count and u is the mean pairwise value	**POSTULATED** (the Roster Reduction, Section 3.4)
P5	a member's state is their mean-centred, unit-normalised scored error vector	**POSTULATED** (the encoder, Section 4.3)
P6	$\mathrm{PR} = (\mathrm{tr}\, G)^2 / \|G\|_F^2$ is the Rényi-2 participation ratio of the Gram spectrum	**CITED** — Rényi [1961]
P7	$h_t = \eta \ln N - \delta Q_t - C_t$, and $h_t < 0$ forbids a nondecreasing step	**CITED** within the corpus — Curzi [2026a], Cor 3.4; Curzi [2026b]

P3 is the load-bearing one and it is the one a reviewer should attack first. P1, P2 and P6 are definitions or citations and carry no empirical weight at all. P4 and P5 are the two places where the framework touches a real body, and both are badged in the running text at every use.

9.3 The compounding chain

Each line names what it consumes and what it produces, and can be checked without reading the line before it for anything but its stated output.

```
P1 + P2 + P3 + S4  -> L1   f(u) = ln(1 + (N-1)u) is the unique form         DEFINITION
P3                 -> L2   N_eff = e^{f(u)} = 1 + (N-1)u                   DEFINITION
L2 + P4            -> R1   N = 100, u = 0.05:  1 + 99(0.05) = 5.95         ARITHMETIC
P1                 -> L3   u = 1 - cos^2(theta) = sin^2(theta)             ARITHMETIC
L3                 -> R3   u depends on |rho| only, so rho = -1 gives u = 0 ARITHMETIC
L2 + P6            -> R2   ||G||_F^2 = N + N(N-1)(1-u), so
                           N + 1 - N/PR = 1 + (N-1)u exactly               ARITHMETIC
L1                 -> L4   df/du = (N-1)/(1 + (N-1)u), maximal at u = 0    ARITHMETIC
L4                 -> R4   N = 12: u = 0.05 +/- 0.05 gives S in
                           [0.000000, 0.741937], width 0.741937            ARITHMETIC
L1                 -> R8   ln(2N) - ln(N) = ln 2 = 0.693147 for every N    ARITHMETIC
P4 + P5            -> R6   19 pairs at u = 0.0591, 47 at u = 0.6975:
                           u_bar = 33.9054/66 = 0.5137182                  ARITHMETIC
R6 + L2            -> R6'  N_eff = 1 + 11(0.5137182) = 6.6509000 exactly,
                           S = ln 6.6509 = 1.8947522 nats                  ARITHMETIC
R6' + L1           -> R6'' S/ln 12 = 1.8947522/2.4849066 = 0.7625044,
                           deficit = 0.5901545 nats                        ARITHMETIC
R6' + L2           -> R7   N = 30 at the same u_bar: N_eff = 15.8978273,
                           S = 2.7661825, gain = 0.8714303 nats for 18
                           hires; 12 lineages at u = 0.6975 gain 0.2654049
                           for none                                        ARITHMETIC
P7                 -> CR   institute: eta ln 8 = 0.40(2.079442) = 0.831777,
                           h = 0.831777 - 2.400000 - 0.550000 = -2.118223  ARITHMETIC
CR                 -> CR'  break-even by N alone: ln N >= 2.95/0.40,
                           N >= e^{7.375} = 1595.59                        ARITHMETIC
```

The three checks a reviewer can redo in under a minute are $1 + 99 \times 0.05 = 5.95$; $\ln 2 = 0.693147$ at every scale, so $\ln 4 - \ln 2 = \ln 1024 - \ln 512$; and $33.9054/66 = 0.5137182$, whose affine count $1 + 11 \times 0.5137182 = 6.6509$ has logarithm 1.8947522. Those three establish the paper's three headline figures.

And the chain must be read for what it is. Its first two steps are definitions, one of them a design axiom, and its two contact points with a real body — P4 and P5 — are postulates. **Every ARITHMETIC line below them is exact and none of them is evidence about an institution.** A reader who wants the empirical status of the framework should read Curzi [2026i], which ran the preregistered test and reported the failure.

9.4 The participation-ratio identity, checked on the smallest case and re-verified

The identity $N_{\text{eff}} = 1 + (N-1)\bar{u} = N + 1 - N/\text{PR}$ is a derivation. The smallest case that exercises it is $N = 2$. Take two unit vectors with inner product c. Then $\|G\|_F^2 = 2 + 2c^2$ and $\operatorname{tr} G = 2$, so $\text{PR} = 4/(2 + 2c^2) = 2/(1 + c^2)$, and

```
N + 1 - N/PR  =  3 - 2(1 + c^2)/2  =  3 - (1 + c^2)  =  2 - c^2
```

while $\bar{u} = 1 - c^2$ for the single pair, so $1 + (N-1)\bar{u} = 1 + (1-c^2) = 2 - c^2$. **The two agree identically, for every c.** *Status:* **ARITHMETIC**.

The general step is one line. With $G_{ii} = 1$ and the off-diagonal entries satisfying $G_{ij}^2 = 1 - u_{ij}$, $\|G\|_F^2 = N + N(N-1)(1-\bar{u})$ and $\mathrm{tr}\, G = N$, so $\mathrm{PR} = N/\left(1 + (N-1)(1-\bar{u})\right)$ and $N + 1 - N/\mathrm{PR} = N - (N-1)(1-\bar{u}) = 1 + (N-1)\bar{u}$.

The identity was re-verified for this paper on random unit-vector ensembles at $N = 3, 5, 8, 12$, with residuals of $0.00\text{e}{+00}$, $0.00\text{e}{+00}$, $8.88\text{e}{-16}$ and $1.78\text{e}{-15}$ — machine epsilon, not a measurement. The same identity is established at roster scale as Theorem 16.1 of the tuning-halt analysis — $M_{\text{eff}} = 1 + (m-1)\bar{u} = m + 1 - m/\mathrm{PR}$, verified there at 1.7815458788 with an error of $0.00\text{e}{+00}$ [Curzi, 2026]. The 10^{-12} tolerance quoted elsewhere in the corpus [Curzi, 2026i] and the independent re-verification over six random correlation matrices [Curzi, 2026] are checks of the same kind. **They test the implementation and not the world, and no reader should read a 10^{-12} agreement as an empirical result.**

9.9.5 9.5 Measurement-theoretic status of u

u is treated throughout as a ratio-scale quantity and that treatment is not tested. It is multiplied, averaged over pairs, differenced, and fed into a logarithm; each of those operations requires more than an ordinal scale, and none of them is licensed by anything in this paper. Michell [1997] and Michell [1999] are the strongest objection available to the whole framework: psychology routinely assumes quantitative structure without testing whether the attribute has it. **The objection applies here and is conceded.**

The formal remedy exists and was not run. Conjoint measurement [Luce and Tukey, 1964] supplies the conditions — single, double and triple cancellation — under which an attribute can be shown to have additive quantitative structure at all, within the representational framework of Krantz et al. [1971]. **The conjoint conditions were not tested for u, for comfort, or for stored order, and no such test is reported anywhere in this corpus.** The Rasch route [Rasch, 1960, Andrich, 1988] is the alternative, and the corpus takes it in one place [Curzi, 2026t], where the moment equation is explicitly demoted to ordinal scale — which is the right instinct, applied once.

What survives without the test is narrower than what the paper uses, and the difference should be stated. **The ordering survives**: a body whose members' errors correlate more strongly has a lower u than one whose errors correlate less, and the ranking of the options in Section 7.1's step 6 does not depend on the scale type. **The zero survives**, because $u = 0 \iff \rho^2 = 1$ is a statement about an identity between vectors and not a statement about a psychological magnitude. **The arithmetic on u does not survive independently of the encoding**: it is licensed by the fact that ρ is a correlation between real-valued vectors, which is a genuine ratio-scale object, and it is licensed only as far as postulate P5 — that error vectors are the states — holds. Where the encoder is a partition (Instrument 4) or a provenance census (Instrument 5), **the resulting figure is ordinal at best and the specification labels it as a prior rather than a measurement.**

One consequence is operational and belongs in every report. Stevens [1946] is the source of the rule that the permissible statistics follow the scale, and averaging a set of ordinally scored u values across pairs — which the Roster Reduction does — is not licensed when the underlying encoder is a partition. **The mean pairwise u is therefore reportable as a measurement only under the error-vector encoding, and is a triage figure under any other.**

9.9.6 9.6 The same verification chain applied to the affine effective count, which fails it

Section 3.3 stated that HHI^{-1} is a Hill number and $1 + (N-1)u$ is not. The claim is checkable, and the check is run here rather than asserted. The first chain is the one that succeeds; the second is this paper's own quantity, and it fails at the second step.

Chain A — the reciprocal index, which passes.

step	statement	status
A1	HHI $= \sum_i p_i^2$ on shares summing to one	DEFINITION
A2	for n equal shares of $1/n$, $\text{HHI}^{-1} = n$ exactly	ARITHMETIC
A3	HHI^{-1} is a numbers-equivalent: the count of equal units giving the observed index	CITED — Adelman [1969]
A4	$\text{HHI}^{-1} = {}^2D$, the Hill number of order 2	CITED — Hill [1973], Jost [2006]
A5	$\exp(H)$ is the same family at $q = 1$	CITED — Shannon [1948], Jost [2006]
A6	the same arithmetic is Simpson's index reciprocal and the effective number of parties	CITED — Simpson [1949], Laakso and Taagepera [1979]

Chain B — the affine count, which fails at B2.

step	statement	status
B1	$N_{\text{eff}} = 1 + (N-1)u$, with u a scalar non-parallelism	DEFINITION (design axiom S3, the framework's own)
B2	for two units at shares 0.9 and 0.1 with $u = 1$, B1 gives exactly 2.000000	ARITHMETIC
B3	for the same two units, $\text{HHI}^{-1} = 1/(0.81 + 0.01) = 1.219512$	ARITHMETIC
B4	for the same two units, $\exp(H) = \exp(0.325083) = 1.384145$	ARITHMETIC
B5	B2 disagrees with B3 and B4, so B1 does not return a numbers-equivalent	ARITHMETIC — **A3 fails**
B6	B1 is a function of (N, u) and not of the share vector, so it is not $\left(\sum_i p_i^q\right)^{1/(1-q)}$ for any $q > 0$	ARITHMETIC — **A4 fails**
B6a	it does agree with ${}^0D = 2.000000$, the raw richness, which is the one member of the family that ignores shares — so the agreement is with the naive count, not with a numbers-equivalent	ARITHMETIC
B7	no entry in ecology, economics, political science or information theory states B1	POSTULATED — no external support

The two chains part company at B5. HHI^{-1} and $\exp(H)$ are Hill numbers of order 2 and 1 and are fully grounded. Row B6a is the qualification that keeps B6 exact: the affine count does coincide with the order-zero Hill number on this vector, and ${}^0D$ is the raw richness, so the coincidence is with the count the audit exists to replace rather than with a numbers-equivalent. $1+(N-1)u$ is a linear interpolation between 1 and N; it is this framework's own construction, it carries no external support, and **a reviewer who reaches for the Hill literature expecting it to apply will find that it does not.** That is printed here, in the paper that develops the quantity, rather than left to be discovered. The corpus notes elsewhere that the two are different quantities [Curzi, 2026], which is to its credit; what this section adds is the arithmetic that makes the difference checkable in one line, and the instruction that **the two must not travel under one name.**

9.7 Model comparison and the scaling claims, audited against what is required

No model is fitted anywhere in this paper, so most of the model-comparison requirements are not merely unmet but inapplicable, and saying which is which matters.

Requirement	Status in this paper
Out-of-sample rather than in-sample performance	**Not applicable.** Nothing is fitted; the three systems are constructed and the arithmetic on them is exact.
A matched null with the same free-parameter count	**Not applicable**, for the same reason. The framework's confirmatory test against a matched AR(1) is reported in Curzi [2026i], and it failed.
The number of free parameters stated explicitly	**Met.** The surplus functional has none: N is declared and u is measured. The storage law adds η and δ.
An information criterion	**Not applicable here**; **not met** in the corpus, which computes none anywhere [Curzi, 2026i].
Effect sizes with intervals	**Partially met.** Section 4.6 requires an interval on S whenever $u < 0.3$ and reports one for each worked system. No interval accompanies η, δ or C in Section 7, because those are stipulated.

The scaling claims are the ones a reviewer will test, and this paper makes two. The first is that the ceiling gain per doubling of N is scale-invariant at $\ln 2$. **That is not an empirical scaling claim: it is an identity of the logarithm**, defined by the model and not estimated from anything. The second is that coordination cost grows as $\kappa n(n-1)/2$. **The exponent 2 there is likewise defined by the model, not estimated — and this paper states that plainly because the alternative is the error Clauset et al. [2009] exists to prevent.** A log-log regression of measured cost on headcount would be exactly the procedure that paper shows to be unreliable, and no such regression is run here. Stumpf and Porter [2012] adds the underdetermination: even a genuine power law is weak evidence for a mechanism. **No power law is claimed, no exponent is estimated, and no heavy tail is asserted anywhere in this paper.** Broido and Clauset [2019] is the reason that abstention is the right position for a paper about social structure.

The one place the paper uses the word *scale-free* is Section 5.8, and it is used there in a sense that must not be confused with the network sense of Barabási and Albert [1999]: **the claim is that the FORM of the N-dependence is invariant under doubling, not that any measured distribution is heavy-tailed.** The parameters δ, η and C differ enormously across the

scales named there, and only the shape is invariant. Under the transformation $N \mapsto \lambda N$ the ceiling shifts by $\ln \lambda$, which is an additive shift and not an invariance; **the invariance claimed is that the shift depends on λ alone and not on N, and that is all that is claimed.** It was checked at the ten doublings tabulated in Section 5.5 and nowhere else.

9.9.8 9.8 Limits and boundary behaviour

Every law in this paper is evaluated at the boundaries of its parameters, and two of the limits are constraints on the model's domain rather than results.

Limit	Behaviour	Reading
$u \to 0$	$N_{\text{eff}} \to 1$, $S \to 0$ exactly	Not an asymptote: an attained value. The modal institutional condition.
$u \to 1$	$N_{\text{eff}} \to N$, $S \to \ln N$	The ceiling, attained only at exact mutual orthogonality.
$\rho \to -1$	$u \to 0$	**Opposition is parallelism.** The fold at ninety degrees, Section 6.2.
$N \to 1$	$N_{\text{eff}} = 1$ for every u; $\ln N = 0$	A one-category system has no surplus and no ceiling. Degenerate, and correctly so.
$N \to \infty$ at fixed $u > 0$	$S \sim \ln N \to \infty$, unbounded	**A domain constraint, not a result.** The cost term $\kappa n(n-1)/2$ diverges quadratically, so the net turns negative at a finite n in every column of Section 5.12. The unbounded surplus limit is never reachable.
PR $\to 1$	$N_{\text{eff}} \to 1$	Every encoded state identical; the roster has left the arithmetic.
PR $\to N$	$N_{\text{eff}} \to N$	No off-diagonal Gram mass.
$\delta \to 0$	Q_∞ undefined; $Q_t \le Q_0 + t\,\eta \ln N$	**A pathology, not an ideal** — nothing ever leaves the stock, and the fixed point does not exist [Curzi, 2026a].
$\eta \to 0$	$h \to -\delta Q - C < 0$ always	No geometry rescues a body that converts nothing. Section 6.12's FM-6.8.

The $N \to \infty$ limit is the one that matters and it is the one the framework's own enthusiasm obscures. The surplus term is unbounded in N and the framework is frequently read as saying that more categories are always better in principle and merely expensive in practice. That reading is wrong on the framework's own arithmetic: with any positive κ, net surplus has an interior maximum and the crossover to negative is finite and computable, and Section 5.12 computes it at every column.

9.10 10 Limitations

The affine effective count is chosen, not derived, and has no external support. Design axiom S3 fixes the shape of every result in this paper. A different choice of S3 gives a different ceiling law, a different marginal table and a different prohibition. Section 9.6 runs the verification chain that a grounded effective count passes and shows this one failing it at the second step. **No literature in ecology, economics, political science or information theory contains** $1 + (N - 1)u$, and a reader who wants a grounded effective count should use HHI^{-1} or $\exp(H)$ and accept that they measure a different thing [Hill, 1973, Jost, 2006].

The reflexive specification is not identified from observational data. Section 3.5 states it with its citation [Manski, 1993] and names the remedy this paper adopts — stipulating the reference group, on the template of Brock and Durlauf [2001] — together with what that remedy does not buy. **Every applied** u **in this paper is a modelling position and not an identified empirical quantity.** No amount of scored data recovers the endogenous effect, and Shalizi and Thomas [2011] shows the confound is generic rather than incidental.

The framework exempts its own parameters from its own reflexivity. Lucas [1976] is the objection and this paper has no answer to it: a body that has read the framework will produce different sealed answers at the next elicitation, so u estimated before publication does not describe a population that has read the paper. Hacking [1995] generalises the problem and Ferraro et al. [2005] names the specific hazard — that a framework telling people their second opinions are worth nothing may make that true.

The functional form is underdetermined. Latané [1981]'s sub-linear power law and Briscoe et al. [2006]'s $n \log n$ fit the qualitative facts as well as $\ln(1 + (N - 1)u)$ does, and nothing in this paper discriminates among them because nothing in this paper fits anything. The uniqueness theorem is a theorem about S1–S4. **What would discriminate is an experiment that varies** N **over at least a decade at fixed measured** u **and compares held-out predictive error across the three forms with a matched parameter count; that experiment has not been run.** Peters and Gell-Mann [2016] supplies the one non-psychological derivation of a logarithmic form available and is the strongest warrant the framework has for its shape, though it warrants the shape and not the arguments.

The conjoint conditions were never tested. Section 9.5 concedes Michell [1997] in full. u is treated as ratio-scaled, the arithmetic on it is licensed only through the error-vector encoding, and Luce and Tukey [1964]'s cancellation conditions — the actual test of whether the attribute has additive quantitative structure — have not been run for u, for Q, or for comfort. **This is the single most dangerous unanswered objection to the framework and it is conceded rather than argued with.**

The Roster Reduction discards joint structure. Two rosters with identical mean pairwise u can have genuinely different geometry — a ring of mutual near-orthogonality against a tight cluster plus one outlier — and the triangle inequality fails for geometric triples [Curzi, 2026], so the mean does not determine the joint configuration. The participation-ratio identity of Section 3.4 names the aggregator but does not repair this, because PR is itself a scalar summary of a spectrum. Section 7.1 is the worked case in which the mean passed and the structure failed. Tversky [1977] is the further warning that psychological similarity is asymmetric and violates the triangle inequality, so **if** u **is read as a similarity measure over people it may not have metric behaviour at all.**

Every system in Section 7 is constructed. The panel, the institute and the engineering organisation are invented; their parameters are stipulated; their correlations, decay rates and conversion coefficients were chosen so that the arithmetic is checkable and the failure modes visible. **None of them is evidence about any real body**, and no figure in Section 7 may be cited as an empirical result. What they demonstrate is what the procedure does when it is carried out, not what institutions do.

Small-sample estimation is not addressed and no correction exists for this index. A twelve-person roster produces 66 pairwise correlations from a common set of scored items, and those correlations are themselves estimates with sampling error that the paper's intervals do not

include: Section 4.6's intervals propagate a stipulated uncertainty in u, not an estimated one. Chao et al. [2014] supplies the bias corrections for the Hill family and **they do not apply to the affine count**, so no correction was available and none was applied.

Three of the five instruments are not measurements. The collision test requires a chance correction whose baseline is itself estimated; the lineage census is explicitly a prior and is badged as such; and the disagreement-rate instrument is valid only under genuinely independent elicitation, which is the condition institutional practice most often violates. **The cascade-contaminated estimate of Section 4.10 is the most common failure and it biases u downward, which is the direction that makes the framework look most impressive.** That is stated here because a bias that flatters the model is the one a reviewer will look for first.

The `[PARTIAL SUBSTITUTE]` badge is doing real work and it is not a measurement. Adversarial roles and red teams manufacture an argument the body would not otherwise have heard; they do not change the underlying geometry, and the specification forbids entering them into a structural u estimate. **A body that raises its measured u by installing an adversarial role has raised a number without raising the quantity the number was built to report** — which is Goodhart [1975] operating on the framework's own instrument.

The monotone claim is restricted. Section 8.2 lists the contrary evidence in full. The framework prices an input term and is silent on the extraction cost, and the measured curves [Uzzi and Spiro, 2005, Putnam, 2007, May, 1972, Sagan, 1993] turn over. **The claim this paper defends is that surplus increases in u within the model, not that institutional value does.**

A rounding-order artefact in the source is recorded rather than corrected silently. Carried at full precision, the twelve-person panel's mean pairwise non-parallelism is $33.9054/66 = 0.5137182$, its audited count is $1 + 11 \times 0.5137182 = 6.6509000$ exactly, and its surplus is $\ln 6.6509 = 1.8947522$ nats — which is the source's 1.8948 to four places, and its 76.3 per cent of $\ln 12$ to three, so those figures stand. **One downstream figure does not.** The growth gain from twelve members to thirty is computed in the source as $2.7663 - 1.8948 = 0.8715$, from two intermediate values each already rounded to four places. Carried at full precision it is $2.7661825 - 1.8947522 = 0.8714303$, which rounds to 0.8714. **The published figure 0.8715 is high by one unit in the fourth decimal**, and any downstream paper quoting it inherits the artefact. The source's figure is retained in Section 7.1 so that the discrepancy is visible, and the exact value is used in Section 9.3's chain. This is a rounding-order artefact and not an error of method: the correct practice, which this paper adopts in its verification chain and the source does not adopt in its worked text, is to round once at the end.

An arithmetic error in the source is corrected in the open. The institute's worked example states that at perfect orthogonality across all eight domains the institute would "still have declined by $2.1182 - 0 = 1.5682$ nats per year at best." That subtraction is not arithmetic. **The correct figure is 2.1182**: headroom $h = \eta \ln N - \delta Q - C$ already evaluates the surplus term at its ceiling, so $u = 1$ gives a step of $0.831777 - 2.400000 - 0.550000 = -2.118223$ exactly. The figure 1.5682 is the decline at $u = 1$ **and** $C = 0$ together, which is the last row of that section's Lever 2 table and is a different counterfactual. The corrected reading strengthens the paper's counter-result rather than weakening it: perfect geometry leaves the institute declining by more than the source claimed, not less.

The paper's own headline case defeats the framework's own emphasis. The institute's geometry was never the binding constraint. Its entire structural budget is 0.831777 nats and its maintenance burden alone is 2.400000, so no attainable geometry — including perfect orthogonality — produces a nondecreasing step. **A corpus organised around the engineering of non-parallelism should say, where it is true, that non-parallelism was irrelevant**, and Section 7.2 says it.

Two defects in a companion paper's version of the same check are corrected here rather than propagated, and both were found by re-running its arithmetic. The corpus's concentration instrument runs the same failing chain on the affine count [Curzi, 2026]. **First**, it reports $\exp(H) = \exp(0.325083) = 1.384115$ for the two-unit vector $(0.9, 0.1)$; the correct value is 1.384145, since $H = -(0.9 \ln 0.9 + 0.1 \ln 0.1) = 0.3250829734$ nats and $e^{0.3250829734} = 1.3841454885$. That is a transcription slip at the fifth decimal and it changes no conclusion. **Second, and substantively,**

it states that *every* Hill number reports less than 1.39 on that vector. That is false. The Hill family is non-increasing in q, and its order-zero member is the raw richness ${}^0D = 2.000000$; the members exceeding 1.39 are exactly those of order below $q \approx 0.9808$. The corrected statement is that every Hill number of order one or higher reports at most 1.384145, and it is given in that form throughout this paper. **The correction strengthens the argument rather than weakening it**: the one Hill number the affine count does match is the one that ignores shares entirely, which is the naive count an effective count exists to replace.

Two named results in the running text have no bibliographic support here and are reported without a citation rather than attached to an entry that does not support them. The Condorcet jury theorem of Section 4.7 and the *gradus*-free classical statement of the variance-reduction identity in Section 4.3, Instrument 3, are both classical results with no entry in this corpus's bibliography. They are named rather than cited, and the correspondence between Condorcet's independence premise and this framework's non-parallelism parameter is badged in Section 3.6 as **interpretive**, with no theorem connecting them asserted anywhere. This is recorded so that a reader does not mistake absence for oversight.

One item in the specification cannot be audited from outside. RN-4 requires $u \geq 0.3$ between a proposed category and every existing one, measured under blind elicitation on at least twenty discriminating items. The threshold 0.3 is stipulated, not estimated. It corresponds to $|\rho| \leq 0.837$. **No evidence supports that threshold, no procedure in this paper derives it, and a different threshold would admit a different set of categories.**

9.11 11 Conclusion

This paper develops the audited count that the framework substitutes for headcount, states exactly what that count is and is not, and prices the three ways of raising it.

The count. The affine effective count is $N_{\text{eff}} = 1 + (N-1)u$ with $u = 1 - (x \cdot y)^2$, and surplus is $S = \ln N_{\text{eff}}$. Three of the four axioms that characterise the functional form uniquely are structural; the fourth, S3, is a **design axiom, chosen and not derived**, and it is badged at every use. The consequence is severe: **a hundred-person department at $u = 0.05$ has an effective count of 5.95.**

What the count is not. $1 + (N-1)u$ **is not a Hill number of any order**, is not a numbers-equivalent, and has no supporting entry in any external literature. For two units at shares 0.9 and 0.1 it returns exactly 2.000000 at $u = 1$, where HHI^{-1} returns 1.219512 and $\exp(H)$ returns 1.384145. **The reciprocal index is the Hill number of order two and the exponential of Shannon entropy is the Hill number of order one; the affine count is a linear interpolation and the two must not travel under one name.**

The bridge that does exist. $N_{\text{eff}} = N + 1 - N/\text{PR}$ exactly, against the Rényi-2 participation ratio of the Gram matrix of the encoded states — re-verified here at $N = 3, 5, 8, 12$ with residuals at machine epsilon. **Mean-pairwise u is the participation ratio, reparametrised into effective-count form**, which names the aggregator without repairing the postulate under it.

Opposition is parallelism. Because u depends only on $|\rho|$, perfect opposition at $\rho = -1$ scores $u = 0$ exactly as perfect agreement does. **A standing contrarian buys no surplus and costs a seat.**

The measurement-error budget. The sharp Lipschitz constant $N - 1$ is read here as a specification on precision rather than as a smoothness result. At $N = 12$, an uncertainty of ± 0.05 around $u = 0.05$ admits a surplus anywhere in $[0, 0.7419]$ — a width of 0.7419 against 0.1266 at $u = 0.70$. **Below $u = 0.3$ a point estimate of surplus is not reportable.**

The two counts must not be substituted. $N_{\text{eff}} = 1 + (N-1)u$ and the classical variance-reduction count $N_{\text{ind}} = N/(1 + (N-1)\rho)$, which tends to a hard asymptote of $1/\rho$, share a form and are different quantities.

The ceiling. Every doubling of N adds exactly $\ln 2 = 0.6931$ nats at any scale, so the gain from one category to two equals the gain from fifty to a hundred, and adding one nat of ceiling

costs a factor of e in categories. A deficit D closed by raising N alone requires multiplying N by $e^{D/\eta}$.

The worked results. A twelve-person panel with within-lineage $\rho = 0.97$ over 19 pairs and cross-lineage $\rho = 0.55$ over 47 audits to $\bar{u} = 0.5137182$, $N_{\text{eff}} = 6.6509$ and $S = 1.8948$ nats — **76.3 per cent of** $\ln 12$**, with a redundancy deficit of** 0.5901. Growing it to thirty buys 0.8714 nats for eighteen hires and 435 communication paths against 66; redistributing the existing twelve across twelve lineages buys 0.2654 nats for none.

And the counter-result, which is the paper's most important sentence. The worked research institute has headroom -2.1182 against a total structural budget of 0.8318. Doubling its domain count buys 0.2772 nats and closes 13 per cent of the gap; break-even by domain addition alone requires $N = 1596$; and **perfect orthogonality across all eight domains would leave it declining by** 2.1182 **nats per year, since headroom already evaluates the surplus term at its ceiling.** The geometry this corpus is named for was never the binding constraint in the paper's own worked example, and no geometric intervention could have worked. **The paper states that rather than choosing a different example.**

9.11.1 Declarations

Data and code availability

No external dataset was collected for this paper and none exists. The three systems worked in Section 7 — a twelve-person review panel, a research institute, and an engineering organisation — are constructed composites with stipulated parameters, produced so that every reported number can be re-derived by the reader from the parameters and equations printed in the text. **They must not be cited as evidence about any real organisation.** Every table in Sections 4 to 6 is an exact evaluation of a closed-form expression at the arguments shown. The figures are generated by the scripts named in each caption, which import the shared style module `lib/figstyle.py` and contain no data beyond the numbers printed in this paper. The participation-ratio identity of Section 9.4 was re-verified for this paper on pseudo-random unit-vector ensembles at $N = 3, 5, 8, 12$; the residuals reported there are floating-point residuals and not measurements.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi developed the framework, performed the analysis, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted for this paper and no personal data were collected or processed. The bodies discussed are constructed. Where the paper's specifications bear on people — the lineage census, the protection of a newly recruited outsider, the rotation cadence — they are design requirements addressed to an analyst and are not reports of any study performed. **The specification's standing requirement that no intervention may remove a person's ability to decline is a constraint on prospective work**, stated in Section 6.11, and this

paper makes no clinical, employment or personnel recommendation about any identified individual.

Preregistration

This paper reports no preregistered test. The hypotheses of Section 2 are stated with their falsifiers so that a later test can be preregistered against them, and each is marked **not tested here**. The corpus's one preregistered confirmatory application of the storage law is reported elsewhere [Curzi, 2026i], where it **failed its second falsification rule**, and the shuffled control on which such tests depend has been measured within the corpus at a false-rejection rate of 0.108 against a nominal 0.05 [Curzi, 2026u].

Use of the framework's ceremonial register

The source manuscript from which this paper is drawn is written in part as an instructional manual with a ceremonial register. This paper reports the analytic content; the register is not reproduced, and the source's named constructs are renamed where they identify an object this paper analyses.

Chapter 10

Crossing Versus Divergence: Decomposing Non-Parallelism, the Decay of u, and the Room as a Circuit Element

Abstract. This paper splits non-parallelism into two sources and shows that they compete for one budget. For a block vector $u = \beta^2 + \alpha^2 \sin^2\gamma$ with $\alpha^2 + \beta^2 = 1$, so crossing (different domains) and divergence (disagreement on shared ground) sum — but u_{div} is capped at $1 - u_{\text{cross}}$, and **at $u_{\text{cross}} = 0.90$ no amount of internal argument buys more than 0.10.** The law prices the two identically at the margin, while their productivity in the design variables differs, $\partial u / \partial(\beta^2) = \cos^2\gamma$ against $\partial u / \partial(\sin^2\gamma) = \alpha^2$, which is why institutions buy crossing and starve divergence. A worked institute measures $u_{\text{cross}} = 0.72$ and $u_{\text{div}} = 0.03$, a balance index of 0.0206 and zero within-block dissents across forty decisions; adding a seventh discipline drives its period change negative at -0.002863 and lowers its fixed point from 6.265 to 5.964. **Opposition is parallelism**: at a normalised inner product of -1, $u = 0$, and a perfect opponent and a perfect echo both price at -0.5000 per seat, worse than an empty seat. Non-parallelism is then treated as a decaying state variable, $u_t = u_0(1-\lambda)^t$; a standards board at $\lambda = 0.18$ per quarter (half-life 3.49) fell from $u = 0.55$ to 0.0057 in twenty-three quarters, and its stored order peaked two quarters *after* the decay began, which is why the collapse of its input went unnoticed for years. **A one-time restoration on a system leaking three per cent per quarter returns to within 0.11 of its starting point twenty-eight quarters later: the durable quantity is $1/\lambda$, not u.** A final section locates all four storage-law terms in a physical room and works one to a measured outcome that remains negative, and says so.

Keywords: two-source decomposition; crossing; divergence; balance index; cascade decay; ceiling utilisation; room design; observed activity ratio

Series: B. Engineering the Surplus **Paper:** CCP-010

10.1 1 Introduction

Non-parallelism is not one quantity. This paper splits it into two structural sources, shows that they compete for a single unit budget, treats the result as a state variable that decays, and then locates every term of the storage law inside a physical room.

The framework's surplus functional is $F(u) = \ln(1 + (N-1)u)$ with $u = 1 - (x \cdot y)^2$, and the audited count it exponentiates is $N_{\text{eff}} = 1 + (N-1)u$ [Curzi, 2026,c]. **That count is the framework's own affine construction and not a Hill number of any order**; it has no supporting entry in the ecological, economic or information-theoretic literature, where HHI^{-1} and $\exp(H)$ are the Hill numbers of orders two and one [Hill, 1973, Jost, 2006, Curzi, 2026]. Every N_{eff} in this paper carries that badge, because the design axiom S3 that produces it is chosen and not derived.

The paper's first result is a decomposition and a budget. For a pure block vector, $u = u_{\text{cross}} + u_{\text{div}}$ with $u_{\text{cross}} = \beta^2$ and $u_{\text{div}} = \alpha^2 \sin^2\gamma$, and since $\alpha^2 + \beta^2 = 1$ the two sources are not independent supplies: $u_{\text{div}} \le 1 - u_{\text{cross}}$. **At $u_{\text{cross}} = 0.90$ no amount of internal argument buys more than 0.10, because the ground on which two people can disagree is exactly the ground they hold in common and crossing spends it.** Crossing is bought by hiring across a boundary; divergence is bought by permitting disagreement within one. They are different transactions with different costs, different observability, and different decay rates.

The second result is that the law prices them identically at the margin and the design variables do not. Because f depends on u alone, $\partial f/\partial u_{\text{cross}} = \partial f/\partial u_{\text{div}} = (N-1)/(1+(N-1)u)$ exactly. There is no premium on cross-disciplinarity in this law. But in the variables an analyst actually controls, $\partial u/\partial(\beta^2) = \cos^2\gamma$ and $\partial u/\partial(\sin^2\gamma) = \alpha^2$, so **each lever is most productive exactly where the other has not been pulled, and the correct first move is always the scarcer source.** That asymmetry, together with the fact that crossing is legible on a spreadsheet and divergence exists only in behaviour, explains why institutions systematically buy one and starve the other without ever deciding to.

The worked institute is the paper's headline measurement and it is unflattering to its own subject. A thirty-four-person research institute with six genuinely distinct disciplines measures $u_{\text{cross}} = 0.72$ and $u_{\text{div}} = 0.03$, a balance index of 0.0206, and **zero within-block dissents across forty decisions.** Its surplus would be almost unchanged if every within-discipline disagreement in the building were silenced tomorrow. Adding a seventh discipline — its own standing proposal — drives the period change negative at -0.002863 and lowers the fixed point from 6.265 to 5.964.

The third result is that opposition is parallelism. Because $u = 1 - \rho^2$ depends only on $|\rho|$, a normalised inner product of -1 gives $u = 0$ exactly as $+1$ does. Priced as a seat at $\eta = 0.35$, $\delta = 0.10$ and a seat cost of 0.05, **a perfect opponent and a perfect echo both contribute -0.5000 to the fixed point** — identical, and both worse than leaving the seat empty. A designated contrarian is not a weak purchase of divergence; it is a zero purchase with a cost overhead, and it suppresses demand for the real thing by appearing to fill the slot.

The fourth result treats non-parallelism as a state variable that leaks. Under an explicitly badged postulate, $u_t = u_0(1-\lambda)^t$. A standards review board measured at $\lambda = 0.18$ per quarter — a half-life of 3.49 quarters — fell from $u = 0.55$ to 0.0057 in twenty-three quarters with no personnel change, no policy change, and three procedural choices nobody recorded as decisions. **Its stored order peaked two quarters after the decay began**, because a leaky accumulator lags its input, which is why the collapse of its input went unnoticed for years. Two instruments built on entirely different foundations agreed at the year-five audit: the classical variance-reduction count returned $15/[1 + 14(0.71)] = 1.371$ independent reviewers and the surplus law returned $N_{\text{eff}} = 1.203$. **A one-time restoration on a system with $\lambda = 0.03$ is a step input to a leaky accumulator: it peaks at 3.202 and returns to within 0.11 of its starting point twenty-eight quarters later. The durable quantity is not u but $1/\lambda$.**

The fifth section locates all four storage-law terms in a physical volume, and does so under three badged postulates rather than a derivation. The worked room — a 120 m^2 departmental common room — audits to $N = 2$ use categories and headroom -1.3957. Three moves, chosen by the arithmetic rather than by the department's own plan, close 66 per cent of that gap; at week eight the observed optional-activity ratio has risen from 0.185 to 0.335 while necessary activity is flat at 211 against 216, which is the internal-validity check the taxonomy supplies for free. **And the room ends still negative at -0.4808, which the paper reports rather than repairs.**

The counter-result runs through all three sections. A room cannot manufacture non-parallelism, cannot raise conversion above what surrounding practice permits, and cannot make a negative-headroom system positive. The upper bound $f(u) \leq f(u_{\text{cross}}) + f(u_{\text{div}})$ is an impossibility limit and never a spendable budget: at a balanced split and full non-parallelism it overstates the true value by 44.7 per cent, and **any plan that adds the two sources' surpluses overstates its deliverable by up to forty-five per cent, with the error largest exactly where the ambition is highest.**

Every system in Section 7 is constructed. **No dataset was collected**, and Section 10 records what that costs the paper's claims. Sections 2 and 3 state the hypotheses and the framework, including the identification problem that no measurement of u can answer. Sections 4, 5 and 6 develop the decomposition, the decay, and the room, each closing with its specification and its named failure modes. Section 7 works three systems end to end; Sections 8 to 11 discuss, verify, limit and conclude.

10.2 2 Hypotheses

Some results below are theorems about a functional form and cannot be falsified by observing an institution; they are labelled derivations or definitions where they appear. Others are claims that the form describes real bodies and real rooms, and those are stated here with what would defeat them [Popper, 1959, Platt, 1964].

H1 — The two sources compete for one budget. For a pair whose states decompose against a declared block structure, u_{div} cannot exceed $1 - u_{\text{cross}}$. **Predicted:** measuring β^2 by an evaluability partition and $\sin^2\gamma$ by shared-ground correlation, no measured pair returns $u_{\text{cross}} + u_{\text{div}} > 1$. **Falsified by:** any measured pair exceeding one, which would show the block decomposition does not describe the encoded states. *(Status: this is an **algebraic consequence** of $\alpha^2 + \beta^2 = 1$; the empirical content is whether the encoding is right, not whether the sum holds. **Not tested here.**)*

H2 — Institutions accumulate crossing and lose divergence. In bodies with an explicit diversity programme, the balance index B is small and the missing source is divergence rather than crossing. **Predicted:** across such bodies, $u_{\text{cross}} \gg u_{\text{div}}$ and $B < 0.10$. **Falsified by:** a survey series in which the deficient source is as often crossing as divergence, or in which B is routinely above 0.3. **Not tested here.** This paper's constructed institute is consistent with H2 by construction and is not evidence for it; the hypothesis is stated so a real survey can be run against it.

H3 — Opposition buys nothing. A seat filled by a participant whose position is derivable from the proposal contributes no surplus. **Predicted:** a designated-opponent arrangement, measured by shared-ground correlation on independently scored items, returns $|\rho|$ near one and no measurable improvement in aggregate accuracy over the arrangement it replaced, while costing one seat. **Falsified by:** a measured accuracy gain at $\rho \to -1$, which would establish that sign carries information the square discards and that the encoder is wrong. **Not tested here.** This is the paper's sharpest and most checkable empirical prediction.

H4 — Non-parallelism decays geometrically absent maintenance. In a group under ordinary communication and with no u-maintenance regime, $u_{t+1} = (1 - \lambda)u_t$ with $\lambda \in [0, 1)$. **Predicted:** two measurements separated by k maintenance-free periods, on the same instrument and the same item pool, give a λ that predicts a third measurement. **Falsified by:** measured u under zero maintenance that does not decline approximately geometrically — for instance a step, a plateau, or an increase. *(Status: a **badged modelling postulate**, adopted because it is the simplest*

form consistent with the cascade mechanism of Section 5.10, because it makes λ estimable from two measurements, and because it is falsifiable. ***Not tested here.)***

H5 — Optional activity proxies conversion. In a bounded volume containing people, the optional-activity ratio tracks the fraction of interaction converted into durable structure. **Predicted:** a room whose observed activity ratio rises shows a proportionate rise in attributable ΔQ per unit of interaction. **Falsified by:** a room whose ratio rises while attributable ΔQ does not — **which is a real and common case**, and is catalogued in Section 6.15 as the room that generates pleasant lingering and stores nothing. *(Result:* ***the worked room is a partial counter-instance.*** *Its observed ratio rose by a factor of 1.81 and its measured conversion by a factor of 1.57, so the two moved together but not proportionately, and Section 7.3 reports the discrepancy.)*

Four claims in this paper are not hypotheses and are labelled as what they are.

S3, the affine effective count, is a DESIGN AXIOM — chosen because it renders the effective count additive in difference, which is what an audit of a headcount wants, and not derived from anything [Curzi, 2026].

That participants can be represented by state vectors in a block-structured space, and that the declared categories correspond to the blocks, is a POSTULATE. It is falsifiable in one specific way, stated in Section 3.8: shuffle the category assignment and refit; if the fitted parameters do not degrade, the block structure was not real.

That a room is a circuit element with its own δ, η, N, u and C is a POSTULATE about model form, not a claim about physics. The storage law is scale-free in form; asserting that a forty-square-metre volume is one of the scales at which the form applies is a choice that must be earned by measurement in each case.

That $1 - r^2$ on shared-ground scores estimates $\sin^2\gamma$ is a MODELLING CHOICE. It is the standard coefficient of non-determination read as a squared sine, and it is defensible rather than derived. It is declarable in any preregistration and is badged at every use.

10.3 3 Framework: the decomposition, the bounds, and what they license

10.3.1 3.1 The theorem, stated exactly

****The two-source decomposition** [Curzi, 2026].** For a pure block vector,

```
u = u_cross + u_div

    u_cross = beta^2              (between-category component)
    u_div   = alpha^2 sin^2(gamma) (within-category component)

max( f(u_cross), f(u_div) )  <=  f(u)  <=  f(u_cross) + f(u_div)
```

with `f(u) = ln(1 + (N-1)u)` as established by Curzi [2026], Thm 2.1 under axioms S1-S4, and `alpha^2 + beta^2 = 1`.

That is the whole formal content of the decomposition. Everything below is either a reading of those five lines or an instrument for measuring their terms.

10.3.2 3.2 What alpha, beta, and gamma are

Take two participants, `x` and `y`, each a unit state vector in a space carrying a block structure — the blocks being the `N` categories the survey (the survey protocol [Curzi, 2026i]) declared. Let `x` lie inside one block. Decompose `y` relative to that block:

```
y = alpha * (unit vector inside x's block, at angle gamma from x)
  + beta  * (unit vector outside x's block)

alpha^2 + beta^2 = 1,  alpha, beta >= 0
```

Then the inner product only survives on the shared block:

```
x . y   = alpha cos(gamma)
u       = 1 - (x . y)^2
        = 1 - alpha^2 cos^2(gamma)
        = 1 - alpha^2 + alpha^2 sin^2(gamma)
        = beta^2 + alpha^2 sin^2(gamma)
        = u_cross + u_div
```

A one-line verification of the theorem's form, not a re-derivation — worth doing once, because it fixes what the three parameters mean in an organization:

Symbol	Formal meaning	Organizational reading
`beta^2`	squared component of `y` outside `x`'s category block	the fraction of the second party's competence that the first party cannot evaluate
`alpha^2`	squared component of `y` inside `x`'s block, `= 1 - beta^2`	the shared ground: the part of the work both parties can actually judge
`gamma`	angle between the two inside the shared block	how much they disagree about the things they both understand

`u_cross` is bought by hiring across; `u_div` is bought by permitting disagreement within. Different transactions, different costs, different failure modes — and, as Section 4.3 shows, a hard budget relation between them that almost nobody accounts for.

10.3.3 3.3 The two bounds, and what each one licenses

The bound is two-sided and the two sides do different jobs.

Lower bound — the guarantee.

```
f(u) >= max( f(u_cross), f(u_div) )
```

Whatever the stronger source already supplied, adding the other cannot take it away. This is the safe half of the theorem, and it licenses one design statement: *adding a genuinely different source is never negative.*

Upper bound — the ceiling, and the warning.

```
f(u) <= f(u_cross) + f(u_div)
```

This follows from subadditivity on `u` (Curzi [2026], subadditivity [Curzi, 2026]), itself a consequence of strict concavity (3.3). The combined system is worth **at most** what running the two sources separately and adding their surpluses would give.

Stated in its practical form: **The theorem promises no synergy beyond additivity, and honest design must not assume any.** No clause in the founding surplus analysis [Curzi, 2026] says a cross-disciplinary team with internal dissent produces more than the sum of a cross-disciplinary team and a dissenting team. The mathematics forbids more than the sum. It does not forbid less, and — because `f` is strictly concave — the truth is systematically *less* whenever both sources are nonzero. How much less is computable, and it is not a rounding error.

```
N = 8,  f(u) = ln(1 + 7u)

split (u_cross : u_div)   u      f(u) true   upper bound   overstatement
-------------------------------------------------------------------------
50 / 50                   0.20     0.8755       1.0613          21.2%
50 / 50                   0.40     1.3350       1.7509          31.2%
50 / 50                   0.60     1.6487       2.2628          37.3%
50 / 50                   0.80     1.8871       2.6700          41.5%
50 / 50                   1.00     2.0794       3.0082          44.7%

75 / 25                   0.20     0.8755       1.0179          16.3%
75 / 25                   0.60     1.6487       2.1409          29.9%
75 / 25                   1.00     2.0794       2.8442          36.8%
```

At a balanced split and full non-parallelism, the upper bound overstates real surplus by 44.7 percent. **Any plan that adds the two sources' surpluses overstates its deliverable by up to forty-five percent, and the error grows exactly where the ambition is highest.** The upper bound is a proof device, not a plan.

10.3.4 3.4 The marginal identity

Because `u = u_cross + u_div` is a plain sum, and `f` depends on `u` alone (axiom S1, geometric dependence),

```
d f / d u_cross  =  d f / d u_div  =  (N − 1) / (1 + (N−1) u)
```

At the margin, in the parameter `u`, a unit of crossing and a unit of divergence are worth exactly the same. There is no premium on cross-disciplinarity in this law. The theorem is indifferent to where the non-parallelism came from.

This matters more than it looks. Any organizational preference for cross-hiring over internal dissent is a preference about *acquisition cost and observability*, not about value: a procurement decision dressed as an epistemic one. the intervention procedure's [Curzi, 2026j] lever ranking must be built on that distinction and not on the fiction that crossing is intrinsically superior.

10.3.5 3.5 The structural constraint

One consequence of `alpha^2 + beta^2 = 1` appears nowhere in the theorem's headline and governs almost every real design:

```
u_div = alpha^2 sin^2(gamma) <= alpha^2 = 1 − beta^2 = 1 − u_cross

so   u_cross + u_div <= 1   (as it must, u being in [0,1])
and  max achievable u_div, given u_cross  =  1 − u_cross
```

The two sources are not independent supplies from separate accounts; they compete for the same unit budget. At `u_cross = 0.90`, no amount of internal argument can buy more than `u_div = 0.10` for that pair, even at total within-block disagreement (`gamma = 90 degrees`). The ground on which two people can disagree is exactly the ground they hold in common, and crossing spends it.

This is the mathematical form of an observation every practitioner has made: the more foreign two specialists are to each other, the less able they are to have a real argument. They talk past each other instead — `beta^2` without `gamma`, which the law credits correctly as non-parallelism but which is a different product from a disciplined disagreement and cannot substitute for one when the question is internal to a discipline.

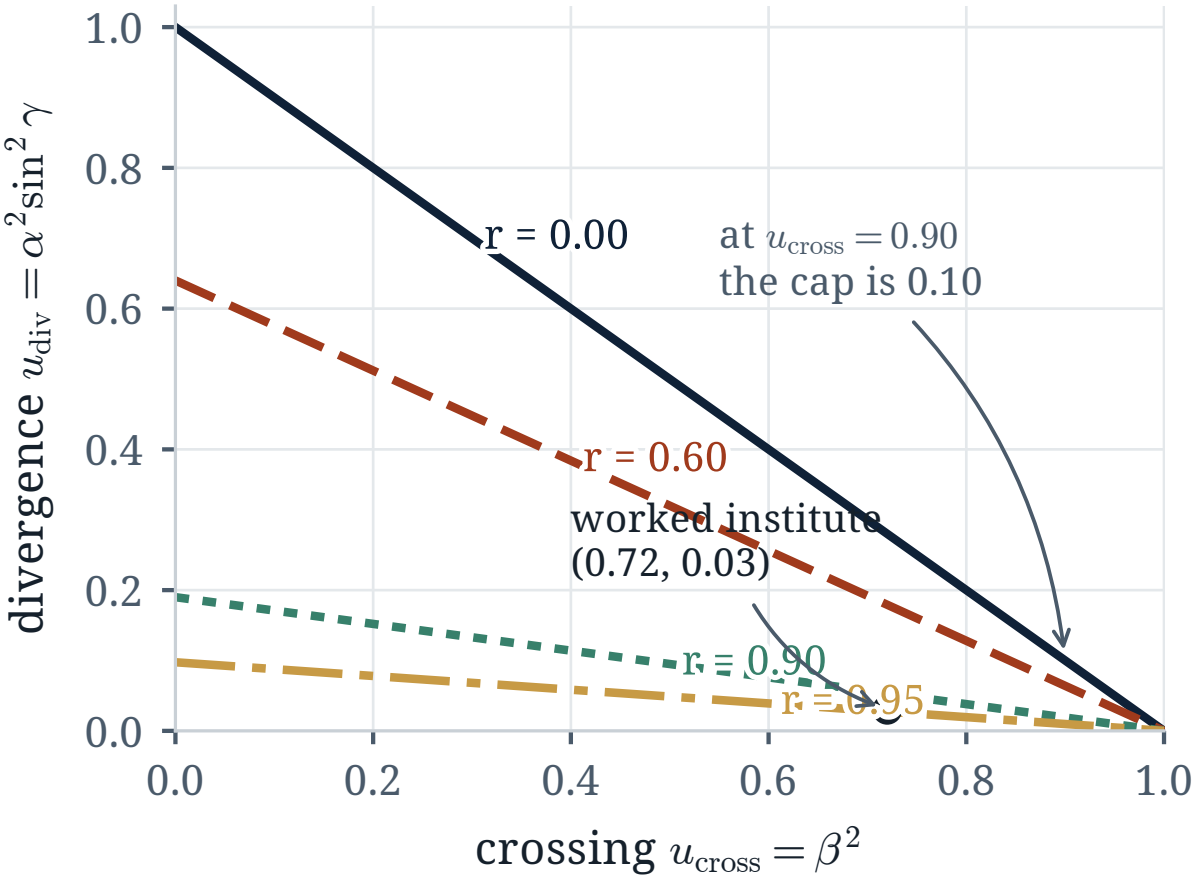

Figure 10.1: **Crossing spends the ground on which divergence would have to register.** The attainable divergence $u_{\mathrm{div}} = (1 - u_{\mathrm{cross}})(1 - r^2)$ is plotted at four within-block correlations; the envelope $u_{\mathrm{div}} = 1 - u_{\mathrm{cross}}$ is the $r = 0$ curve. **At $u_{\mathrm{cross}} = 0.90$ the cap is 0.10 whatever the protocol.** The marked point is the worked institute of Section 7.1. Model output; the constraint follows exactly from $\alpha^2 + \beta^2 = 1$. Generated by `figs/src/CCP-010_fig01.py`.

10.3.6 3.6 Identification: the objection that no measurement of the two sources can answer

Every applied reading in this paper runs through a reflexive specification. The framework's central formal claim is that a group's influence on its members and the members' constitution of the group are one loop [Curzi, 2026], and the estimators of Section 4.10 inherit it directly: the shared-ground scores whose correlation defines γ are produced by people who observe one another, and Section 5.10's cascade mechanism is precisely the process by which that observation destroys the independence the estimator assumes.

That specification is a linear-in-means reflexive model, and its endogenous social effect is not identified from observational data. Manski [1993] proves it: the endogenous effect cannot be separated from contextual effects or from correlated unobservables without prior information specifying the reference group. Shalizi and Thomas [2011] show that influence and selection are generically confounded in observational network data, and Lyons [2011] shows what happens when the confound is ignored. Durlauf [2005] adds the requirement that such a model earn its keep by making a **differential** prediction that simpler models do not also make.

The remedy this paper adopts is to stipulate the reference group and defend the stipulation, on the template of Brock and Durlauf [2001], which derives a mean-field structure from standard discrete choice with its identification conditions stated. The stipulation here is the declared block structure of Section 4.14's SPEC 4.1 — blocks declared by *evaluative standard*, in writing, before any estimate is computed — and it is defended on the ground that an evaluative standard is an administratively observable property of a body's own review practice. **That is a defence of the stipulation and not a recovery of the parameter.** Accordingly:

> **Every applied u, u_{cross} and u_{div} in this paper is a modelling position rather than an identified empirical quantity.** The algebra relating them to N_{eff} and to S is exact and is not at issue. What is at issue is whether a measured evaluability partition and a measured shared-ground correlation are the framework's β^2 and γ, and observation alone cannot settle it.

The same objection applies with more force to the decay rate. λ is estimated from two measurements of u separated by a period asserted to be maintenance-free, and **the assertion is not verifiable from the data**; a period containing unrecorded maintenance returns the net of decay and repair, which is a different quantity. Section 5.12 states the condition and Section 10 records that no procedure in this paper verifies it.

Two further objections in the same family are unanswered and are recorded rather than deflected. Lucas [1976] turned on the framework itself: a body that has read this paper will produce different sealed scores at the next elicitation, so a λ estimated before publication does not describe a population that has read it — and Section 5.10's cascade mechanism is exactly the channel through which that would operate. Hacking [1995] is the general statement, and Ferraro et al. [2005] the specific warning that a framework which assumes people will converge may help them do so. MacKenzie and Millo [2003] is the countervailing observation that such a loop has been caught happening in the field, with dates and price data, which establishes that reflexive fixed points exist without establishing that this one does.

And the functional form is underdetermined by the evidence. Latané [1981]'s sub-linear power law and Briscoe et al. [2006]'s $n \log n$ fit the qualitative facts as well as $\ln(1 + (N-1)u)$ does. Nothing in this paper discriminates among them, because nothing in this paper fits the form to data; the paper derives consequences of a form assumed. Sobkowicz [2009] and Sobkowicz [2020] are the standing indictment — many models, negligible empirical discrimination between them — and they apply. One strengthening is available and is taken: Peters and Gell-Mann [2016] derives a logarithmic form from multiplicative dynamics with no psychological assumption at all, which is a stronger warrant for the shape than the psychophysical route.

10.3.7 3.7 Analogy discipline: what is derived, what shares a form, and what is only suggestive

Each borrowing in this paper is classified at first use, in the three categories the corpus's rigour standard requires.

Borrowing	Category	What is and is not claimed
The block decomposition $u = \beta^2 + \alpha^2 \sin^2 \gamma$	**1 — derivation**	Orthogonal decomposition of a unit vector against a subspace. The algebra is exact; the empirical content is entirely in whether the declared blocks are the subspaces.
The leaky integrator, and the room's lag	**2 — shared mathematical form**	A first-order linear difference equation governs a discharging capacitor and this stock alike [Oppenheim et al., 1996, Elaydi, 2005]. **No physical claim is transferred**, and the "circuit element" language of Section 6 is a naming convention, not a physics claim [Curzi, 2026a].
Geometric decay of u	**3 — analogy, badged as a postulate**	Nothing derives it. It is adopted for simplicity and estimability and is falsifiable (H4). Friedkin and Johnsen [1990] supplies the closest formal relative — a stubbornness term in an opinion-updating model that plays the same role a leak plays here — and is cited as prior art rather than as support.
The cascade as the mechanism of decay	**1 — derivation, within its own model**	Bikhchandani et al. [1992] and Banerjee [1992] prove the result for sequential agents with private signals. **The transfer to a standing committee is an analogy**, because a committee's agents are not drawn afresh and the signal structure is not the model's.
$\ln N$ as a ceiling, against Shannon entropy	**2 — shared form only**	Both are logarithms of a category count. **Surplus is not identified with Shannon entropy or with mutual information** [Curzi, 2026]; Shannon [1948] is cited for the entropy and not for the surplus.
Requisite variety	**2 — formal correspondence**	Ashby [1956] measures variety as the logarithm of a state count and treats it as a cap on regulation. The two are not proved equal.
Robustness against targeted attack	**3 — suggestive correspondence**	Albert et al. [2000] establishes robust-yet-fragile for a degree distribution. Reading a single-sourced portfolio as a one-hub structure is a shape argument and no more; Doyle et al. [2005] is the reason it must not be pressed further.
Proxemic bands as channel types	**3 — analogy**	Hall [1966] reports distances at which sensory channels change, in one culture and one decade. Treating a band boundary as a discontinuity in the surplus a pair can carry is this paper's own reading and has no measurement behind it.

The failure mode this table exists to prevent is a category-2 or category-3 borrowing carrying a category-1 result's authority. The corpus's own strictest ruling on borrowed physics governs here: the framework's postulate is stated as a postulate, the borrowed relation is given

only in its correct form, and a user must be able to distinguish the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand [Curzi, 2026]. Mirowski [1989] is the historical account of what goes wrong otherwise, and Cartwright [1999] the generous escape route: a law may hold inside a specified arrangement without being universal, provided the arrangement is specified. **Sections 4.14, 5.19 and 6.13 are this paper's attempt to specify the arrangement.**

10.3.8 3.8 Badges and honesty clauses

- **Proven (Curzi [2026], Thm 4.1):** the decomposition and both bounds, for a pure block vector.
- **Proven (Curzi [2026], strict concavity [Curzi, 2026], 3.4):** strict concavity and subadditivity on `u`, from which the upper bound follows.
- **Design axiom, not derived (S3):** the affine effective count `g(u) = e^{f(u)} = 1 + (N−1)u`. Everything here that speaks of `N_eff` inherits that choice, made because it renders the effective count additive in difference — what an engineer wants from a headcount audit. That dependence is stated wherever the argument leans on it, as this paper does here.
- **Postulate, badged:** that participants can be represented by state vectors in a block-structured space at all, and that the declared categories correspond to the blocks. A modeling assumption, not a result, falsifiable in the manner of the preregistration protocol [Curzi, 2026i]: shuffle the category assignment, and if the fitted parameters do not degrade, the block structure was not real.
- **Honesty clause, restated:** the triangle inequality FAILS for geometric triples (the metric analysis of the surplus functional [Curzi, 2026]). Subadditivity holds on `u`, and only on `u`. Three participants may not be chained and expected to behave as a metric.
- **Honesty clause, restated:** as deployed, the surplus functional is a **lower bound** on the ensemble's information, not the information itself. The floor is logged, not the ceiling. A group with `u_div` near zero may still hold information this instrument cannot see; it will not hold information the instrument *credits*, and stored order (the institutions-as-storage analysis [Curzi, 2026h]) responds to what the instrument credits.
- **Honesty clause, restated:** The founding surplus analysis [Curzi, 2026] is pure mathematics and makes no empirical or metaphysical claim. Nothing here says a cross-disciplinary team is *good*. It says what a specified functional returns.
- **Refused (the framework's consent clause [Curzi, 2026]):** no protocol in this paper removes a person's ability to decline to disagree. Divergence performed on demand is not divergence but a second kind of compliance, and it measures as noise.

10.4 4 Crossing and divergence: the two purchases and their budget

10.4.1 4.1 Two ways not to be parallel

Case A — the crossing. A structural engineer and a public-health epidemiologist assess a proposed bridge. The epidemiologist cannot evaluate the fatigue calculations; the engineer cannot evaluate the ambulance-transit consequences of a lane closure. Almost all of the second party's state lies outside the first's block: `beta^2 = 0.85`. Within the sliver they share — cost, schedule, public communication — they broadly agree, `gamma = 12 degrees`.

```
u_cross = 0.85
u_div   = (1 − 0.85) ∗ sin^2(12 deg) = 0.15 ∗ 0.0432 = 0.0065
u       = 0.8565
```

Case B — the divergence. Two structural engineers, same degree programme, same code books, assess the same bridge. `beta^2 = 0.03`. But one is a fatigue specialist who believes the

connection detail will crack in twenty years and the other does not. Within the shared block they are 65 degrees apart.

```
u_cross = 0.03
u_div   = 0.97 * sin^2(65 deg) = 0.97 * 0.8214 = 0.7968
u       = 0.8268
```

At `N = 6`, `f(u) = ln(1 + 5u)`: Case A gives `ln(5.2825) = 1.6644`, Case B gives `ln(5.1340) = 1.6360` — within two percent of each other. **The law prices a foreign expert and a determined internal dissenter as near-equivalent goods, and an organization that buys only one of them has bought half a portfolio at full price.**

The difference is not in the surplus but in what the surplus is *about*. Case A's non-parallelism lives entirely in the question "what else does this bridge touch?" Case B's lives entirely in "is this bridge sound?" An organization with only Case A never learns that the connection detail cracks. An organization with only Case B builds a structurally impeccable bridge that closes the only route to the hospital.

10.4.2 4.2 Reading beta and gamma as organizational facts

Each parameter has a direct organizational correlate, and each is acquired by a different administrative act.

	`u_cross` (beta^2)	`u_div` (alpha^2 sin^2 gamma)
acquired by	recruiting, seconding, rotation across disciplines	protecting dissent, rotating adversarial roles, independent estimates first
visible in	org chart, CV, hiring record	minutes, dissent log, the error-decorrelation audit
costs	salary, onboarding, translation burden (C)	social friction, slower meetings, managerial nerve
decays via	attrition, assimilation to the dominant discipline	cascades, promotion by similarity, shared incentives
audit interval	annual (slow-moving)	quarterly at most (fast-moving; see Section 5)

The asymmetry in the "visible in" row is the engine of the pathology this section exists to diagnose. `u_cross` is legible on a spreadsheet: it survives an audit and can be reported to a board. `u_div` exists only in behaviour and leaves a record only if someone deliberately builds one. **An institution that manages what it can see will accumulate `beta^2` and let `gamma` go to zero without ever making a decision to do so.**

10.4.3 4.3 The budget constraint nobody accounts for

The ceiling `u_div <= 1 - u_cross` changes what "more diversity" means at different operating points, and its shape is counter-intuitive enough to need a table. Estimate `sin^2(gamma)` from the correlation `r` of two parties' independent judgments on items *both* can evaluate: `sin^2(gamma) = 1 - r^2` (an estimator choice, badged; see Section 4.10). Then `u_div = (1 - u_cross)(1 - r^2)`.

`u_cross`	r=0.95		r=0.90		r=0.60		r=0.00	
	`u_div`	`u`	`u_div`	`u`	`u_div`	`u`	`u_div`	`u`

```
 0.00   |  .098  .098    .190  .190    .640  .640   1.000 1.000
 0.10   |  .088  .188    .171  .271    .576  .676    .900 1.000
 0.25   |  .073  .323    .142  .392    .480  .730    .750 1.000
 0.50   |  .049  .549    .095  .595    .320  .820    .500 1.000
 0.72   |  .027  .747    .053  .773    .179  .899    .280 1.000
 0.90   |  .010  .910    .019  .919    .064  .964    .100 1.000
```

Reading the rows: At `u_cross = 0.90`, driving within-block correlation from 0.95 to 0.00 — near-total agreement to total independence — moves `u` from 0.910 to 1.000. At `u_cross = 0.00`, the identical change in `r` moves `u` from 0.098 to 1.000. At `N = 6`:

```
u_cross = 0.90:  f(1.000) − f(0.910) = 1.7918 − 1.7138 = 0.0780
u_cross = 0.00:  f(1.000) − f(0.098) = 1.7918 − 0.3988 = 1.3930
```

The same dissent intervention is worth nearly eighteen times more in a monodisciplinary group than in a heavily cross-staffed one — not because dissent is less valuable there in principle, but because the cross-staffing has already consumed most of the unit budget, leaving little shared ground on which the dissent can register. The converse holds too, and is the correction to the usual enthusiasm.

10.4.4 4.4 Which lever is live — marginal productivity in the design variables

In the *parameter* `u`, both sources are worth the same at the margin (Section 3.4). But the design variables an analyst controls are `beta^2` (who is hired) and `sin^2(gamma)` (what is permitted), and in those the marginal productivities are not equal:

```
u = beta^2 + (1 − beta^2) sin^2(gamma)

d u / d(beta^2)       = 1 − sin^2(gamma) = cos^2(gamma)
d u / d(sin^2 gamma)  = 1 − beta^2       = alpha^2

beta^2  sin^2 g |  du/d(beta^2)   du/d(sin^2 g)  |   u
----------------+---------------------------------+--------
 0.00    0.00   |     1.000           1.000       |  0.000
 0.00    0.50   |     0.500           1.000       |  0.500
 0.00    0.90   |     0.100           1.000       |  0.900
                |                                 |
 0.50    0.00   |     1.000           0.500       |  0.500
 0.50    0.50   |     0.500           0.500       |  0.750
 0.50    0.90   |     0.100           0.500       |  0.950
                |                                 |
 0.72    0.00   |     1.000           0.280       |  0.720
 0.72    0.50   |     0.500           0.280       |  0.860
 0.72    0.90   |     0.100           0.280       |  0.972
                |                                 |

 0.90    0.90   |     0.100           0.100       |  0.990
```

The rule that falls out is symmetric, and it is the single most useful operational statement in this section:

```
RULE 4.4  (which lever is live)

  Hiring across is most productive when the group already agrees internally:
```

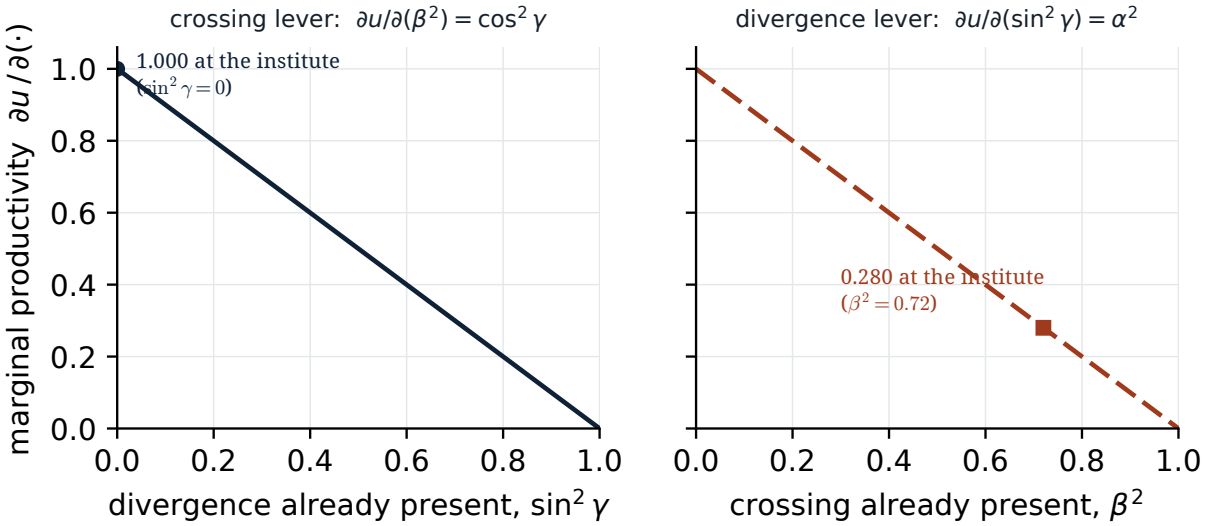

Figure 10.2: **Each lever is most productive exactly where the other has not been pulled, which is why the correct first move is always the scarcer source.** Left: the crossing lever's marginal productivity $\partial u/\partial(\beta^2) = \cos^2\gamma$ falls as divergence rises. Right: the divergence lever's $\partial u/\partial(\sin^2\gamma) = \alpha^2$ falls as crossing rises. The marked points are the worked institute, which reads 1.000 on the crossing lever and 0.280 on the divergence lever — **and Section 4.4 explains why the larger number is nonetheless the wrong purchase.** Model output; both derivatives are exact. Generated by `figs/src/CCP-010_fig03.py`.

```
  du/d(beta^2) = cos^2(gamma)  -> maximal at gamma = 0.
Permitting dissent is most productive in a monodisciplinary group:
  du/d(sin^2 gamma) = alpha^2  -> maximal at beta^2 = 0.

Therefore the correct first move is always the scarcer source.
```

Each lever's productivity is highest exactly where the other has not been pulled. A self-correcting rule: buying the scarcer source cannot go far wrong, and buying more of the abundant one will.

An organization at `beta^2 = 0.72, sin^2(gamma) = 0.00` — the classic case this section diagnoses — gets `du/d(beta^2) = 1.000` from another cross-hire against `du/d(sin^2 gamma) = 0.280` from permitting dissent. The naive reading is that cross-hiring should continue, being nearly four times as productive per unit. That reading is wrong twice over.

First, the units are not comparable. Moving `beta^2` by 0.10 requires restructuring a team; moving `sin^2(gamma)` by 0.28 requires a meeting protocol (the seating analysis [Curzi, 2026f]) and the nerve to keep it. the intervention procedure's [Curzi, 2026j] cost ranking converts marginal productivity into value per unit of expenditure, and by that measure the protocol wins in almost every real case.

Second, surplus is not the whole brief (Section 4.1). The two components are surplus about *different questions*, and a group at `beta^2 = 0.72, gamma = 0` has bought a wide field of view with no resolution anywhere in it. the effective-count analysis's [Curzi, 2026c] phrase applies with force: **three honest windows set wide capture most of what a gallery could — but a window that reports what the window next to it reports is not a second window.**

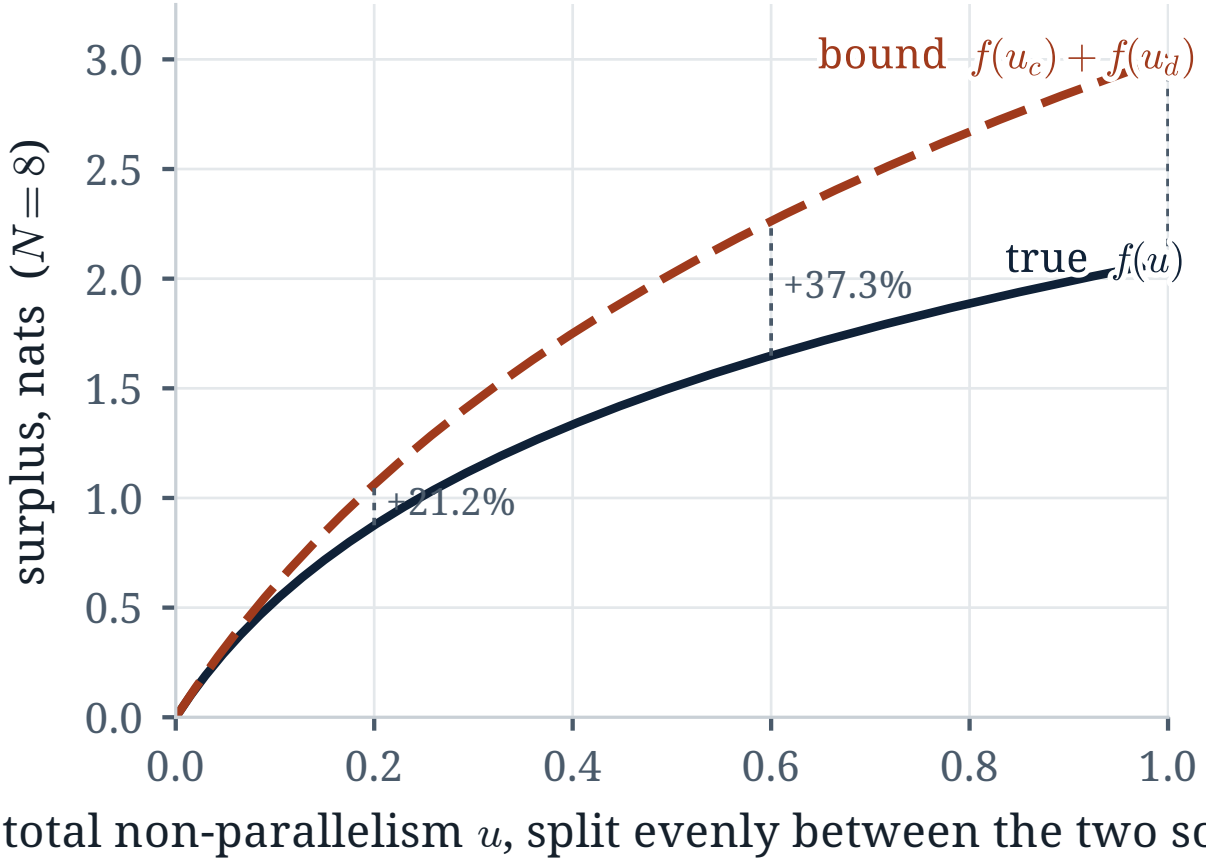

Figure 10.3: **The additive bound overstates the true value by up to 44.7 per cent, and the error is largest exactly where the ambition is highest.** At $N = 8$ with the two sources split evenly, the true surplus $f(u_{\text{cross}} + u_{\text{div}})$ is plotted against the impossibility limit $f(u_{\text{cross}}) + f(u_{\text{div}})$; the annotations give the overstatement at three points. **The gap is a consequence of strict concavity and is not a modelling artefact.** Model output at $N = 8$; arithmetic exact. Generated by `figs/src/CCP-010_fig02.py`.

10.4.5 4.5 What the upper bound actually licenses

The upper bound is stated so often as "subadditivity" that its practical content is easy to lose. Three statements, each forbidding a specific real mistake.

Statement 1 — no synergy is promised. The theorem gives a ceiling and no floor above the max. Any memo arguing that cross-disciplinary staffing *and* structured dissent together "will be greater than the sum of its parts" makes a claim the mathematics does not support and in fact bounds against. **Honest design assumes additivity at best and plans against the true concave value.**

Statement 2 — the true value is systematically below the sum. Strict concavity (strict concavity [Curzi, 2026]) makes the inequality strict whenever both components are nonzero. The overstatement table in Section 3.3 quantifies it. The correct quantity is `f(u_cross + u_div)`; `f(u_cross) + f(u_div)` is never the estimate.

Statement 3 — the bound is not tight, so it is not an estimate. A loose upper bound is a proof of impossibility, not a forecast: it states where surplus *cannot* be, and nothing about where it is.

A fourth statement, badged as this paper's interpretation rather than a result: **because the deployed functional is a lower bound on the ensemble's information, a group may realize benefits from combining the two sources that this instrument does not credit.** A reason to build such groups; not a reason to write the uncredited benefit into a plan. The floor is logged and spent against.

10.4.6 4.6 The lower bound is the floor that can actually be spent

```
f(u) >= max( f(u_cross), f(u_div) )
```

The lower bound has a use the upper bound does not: it is a *guarantee*, and guarantees are what may be committed to. Its tightness varies, and knowing where it is tight establishes when the second source is worth the trouble. The gain of the true value over the best single source, at `N = 8`:

```
u     u_cross  u_div   max f (floor)   f(u) true   gain over best single
-------------------------------------------------------------------------
1.00   0.500   0.500      1.5041        2.0794     +0.5754   (+38.3%)
1.00   0.700   0.300      1.7750        2.0794     +0.3045   (+17.2%)
1.00   0.900   0.100      1.9879        2.0794     +0.0916   (+4.6%)
1.00   0.980   0.020      2.0618        2.0794     +0.0177   (+0.9%)
1.00   1.000   0.000      2.0794        2.0794     +0.0000   (0.0%)
```

The bound is tight exactly when the portfolio is lopsided, and slack exactly when it is balanced — which makes the lower bound a direct readout of how unbalanced the two sources are. At a 50/50 split the true value exceeds the guaranteed floor by 38 percent; at 98/2 it exceeds it by under one percent, which is to say the minority source has bought nothing that was not already present.

That gives a diagnostic requiring no new instrumentation:

```
BALANCE INDEX

  B := [ f(u) − max( f(u_cross), f(u_div) ) ] / f(u)

  B near 0      one source does all the work; the other is decoration
  B in 0.1–0.3  a real but lopsided portfolio
  B > 0.3       both sources materially loaded
```

For the rows above: B = 0.2767 at 50/50, 0.1464 at 70/30, 0.0440 at 90/10, 0.0085 at 98/2. Compute B every audit cycle — it needs no data beyond the decomposition already computed, and it tells a board whether its diversity programme has one leg or two.

10.4.7 4.7 The classic pathology: rich in crossing, starved of divergence

This is the central practical diagnosis of Section 4, and it deserves to be stated without hedging. A very large number of contemporary organizations — institutes, consultancies, agencies, foundations, product teams, review panels, standards bodies — have executed a genuine and expensive programme to raise `u_cross` and simultaneously, usually without noticing, driven `u_div` toward zero. The mechanism is not conspiratorial. It is administrative, and every step is locally reasonable.

STEP	ON u_cross	ON u_div
1. Recruit deliberately across disciplines	UP	neutral
2. Onboard everyone through one induction	neutral	DOWN
3. Adopt one shared framework/vocabulary	neutral	DOWN
4. Tie all bonuses to one composite metric	neutral	DOWN (hard)
5. Promote the people who integrate well	neutral	DOWN
6. Report diversity as headcount by category; never report disagreement	reported UP	invisible
7. Escalate disputes to one decision-maker	neutral	DOWN (hard)

Steps 2 through 5 are the things done to make a cross-disciplinary team *function*: its `C` term (the cost analysis [Curzi, 2026b]) is enormous because translation is expensive, and shared vocabulary, shared metrics and clear escalation are the cheapest ways to cut it. **The organization pays for its `u_cross` by spending its `u_div`, and the transaction never appears on any ledger because only one of the two quantities is measured.**

The signature is unmistakable once it is looked for. The org chart shows six disciplines and the last forty decision memos show no recorded dissent. Everyone can explain why their discipline matters, and no two people in the same discipline have ever publicly disagreed about a substantive call. Reviews described as “robust” produce, on inspection, a 100 percent approval rate with comments. “We’re all aligned on this” is a report of success. New arrivals from outside the dominant discipline stop objecting within four to eight months, and this is described as *settling in*.

Run the arithmetic at `N = 8`, against three alternative portfolios:

`N = 8,  f(u) = ln(1 + 7u)`

portfolio	u_cross	u_div	u	f(u)	N_eff	floor	ceiling
diverse hires, one opinion	0.750	0.000	0.750	1.8326	6.250	1.8326	1.8326
+ a dissent protocol	0.750	0.050	0.800	1.8871	6.600	1.8326	2.1327
monodiscipline, real fight	0.000	0.750	0.750	1.8326	6.250	1.8326	1.8326
balanced	0.375	0.375	0.750	1.8326	6.250	1.2879	2.5757

Three of these four rows have identical surplus. That is the law being honest: it counts non-parallelism and does not care about its provenance. But look at the floor and ceiling columns. The first row is *pinned* — floor equals true value equals ceiling, because one component is zero. No slack, no second source, no redundancy in its difference: a single-channel instrument with six labels on it. Remove its one source and it holds nothing. The balanced row has the same output today and, if either source were removed, would still hold 1.2879.

A portfolio with the same surplus and two live sources is strictly more robust than a portfolio with the same surplus and one, and the surplus number alone cannot tell them apart. This is the result of Albert et al. [2000] in another domain: a structure concentrated on one hub is robust to random failure and fragile to targeted attack on that hub. A monoculture of opinion, however cross-disciplinary its headcount, has exactly one hub.

10.4.8 4.8 The mirror pathology: the monoculture that argues

The opposite failure is rare in large institutions and endemic in small expert ones: `u_div` high, `u_cross` near zero. Fourteen economists who genuinely and vigorously disagree. A surgical team that argues every case. Twelve cryptographers who are each other's fiercest critics. `gamma` large, `beta^2 = 0.02`.

```
u_cross = 0.02, u_div = 0.98 * sin^2(70 deg) = 0.98 * 0.8830 = 0.8654
u = 0.8854,  N=8: f(u) = ln(7.1978) = 1.9738,  N_eff = 7.198
```

Excellent surplus — about a strictly bounded set of questions, because no component of anyone's state lies outside the block. Every question the block does not contain returns `u = 0`: not low surplus, *no* surplus, because there is no non-parallel component to register it.

The signature: fierce, high-quality internal debate and a reputation for rigour; decisions impeccable within the frame and catastrophic outside it; failures always described afterwards as "outside our remit"; recruiting that selects for people who can survive the internal debate, which is a filter for people already inside the block. the law of requisite variety [Ashby, 1956] applied and failed — variety deep in one dimension and zero in all others absorbs only the disturbances that arrive along that dimension.

The fix is not more argument. `du/d(sin^2 gamma) = alpha^2 = 0.98` here, which is high, but `sin^2(gamma)` is already 0.883 and can rise at most to 1.000 — worth `f(1.00) - f(0.8854) = 2.0794 - 1.9738 = 0.1056` in total. Whereas `du/d(beta^2) = cos^2(gamma) = 0.117` looks small, but `beta^2` can rise from 0.02 to anywhere. Rule 4.4 fires: buy the scarce source.

10.4.9 4.9 Why institutions systematically buy crossing and not divergence

Four structural reasons, each with a named counterpart elsewhere in this paper.

(1) Observability asymmetry. `u_cross` is a property of the roster; `u_div` is a property of behaviour over time, and only one is auditable from a spreadsheet. Star and Ruhleder [1996] apply exactly: functioning dissent is invisible, and its absence becomes visible only when the organization walks into a wall it had six people qualified to see.

(2) Goodhart capture [Goodhart, 1975]. Once `u_cross` is a reported target, the cheapest way to raise the report is to relabel categories rather than acquire orthogonal ones (the ceiling analysis [Curzi, 2026c]). `u_div` is harder to capture that way, which is precisely why nobody measures it: it produces uncomfortable numbers that administrative action alone cannot improve.

(3) The cost term punishes divergence directly. Internal dissent raises `C_t` immediately and visibly: meetings run longer, decisions take another cycle. Cross-hiring also raises `C_t`, but that increase is booked as onboarding and treated as investment. Same term, opposite political treatment.

(4) Conway's law [Conway, 1968]. An organization that resolves disputes by escalation builds systems with single points of arbitration; one running on shared vocabulary builds systems with one ontology. The architecture then reinforces the geometry that produced it, and `gamma` falls further.

A fifth is not structural but worth naming: **permitting divergence requires an unglamorous kind of managerial nerve, and it is the one lever of the two that cannot be delegated to a recruiting function.** Badged as observation, not result.

10.4.10 4.10 Instruments — measuring the two components separately

The decomposition is only useful if `beta^2` and `gamma` can be estimated separately from real data. Both can. Every estimator below is badged: these are operational choices in the sense of the state-encoder requirement [Curzi, 2026], not consequences of the theorem.

Instrument A — the evaluability partition (estimates beta^2)

For each ordered pair `(x, y)`, sample `y`'s recent work products and have `x` classify each item:

```
E  : "I can evaluate this on its merits."
N  : "I can read it but cannot judge whether it is right."
```

Then

```
beta^2_hat(x, y)  =  ( count of N ) / ( count of E + count of N )
```

Notes and cautions. The estimator is directional: `beta^2(x,y)` need not equal `beta^2(y,x)`, and in hierarchical organizations it systematically does not. Use the mean for pair-level `u_cross` and *log the asymmetry separately* — it is itself a finding (Section 4.13). Classify against actual artifacts, not job titles: asking a participant whether they can evaluate an epidemiologist's work measures self-image, while handing someone three anonymized memos measures evaluability. And anonymize provenance, because a known author contaminates the E/N call with deference.

Instrument B — the shared-ground correlation (estimates gamma)

Restrict to items both parties classified `E`. Have each score them independently and *before any discussion* — the ordering is not optional; see Chapters 11 and 22. Compute the correlation `r` of the two score vectors. Then

```
sin^2(gamma)_hat = 1 − r^2
u_div_hat        = alpha^2_hat ∗ (1 − r^2)  =  (1 − beta^2_hat)(1 − r^2)
```

Badge: `1 − r^2` is the standard coefficient of non-determination, and reading it as `sin^2(gamma)` is natural when the two score vectors stand for the state vectors restricted to the shared block. It is a modeling choice — defensible, the one this paper makes, and declarable in any preregistration (the preregistration protocol [Curzi, 2026i]).

Cautions.

- `r` must be computed on *independent* scores. A correlation measured after discussion measures the discussion, not the participants. This single error accounts for most inflated agreement statistics in practice.
- Use a sufficient item count. Below about 12 shared-ground items the standard error on `r` swamps the estimate. The item count is reported with every `gamma`.
- Negative `r` gives the same `1 − r^2` as `+|r|`: the estimator measures angle, not direction. **That is a genuine trap.** Two participants who systematically take opposite positions are *parallel* in this geometry (`x . y = −1`, `u = 0`), and the professional contrarian therefore buys nothing. If `r` sits near `−1` rather than near `0`, there is no divergence, only a mirror. See Failure Mode FM-4F. Antiparallel is parallel.

Instrument C — the ensemble roll-up

The theorem governs a pair; aggregating to a group is an operational choice.

```
u_cross_hat = mean over all ordered pairs of beta^2_hat
u_div_hat   = mean over all ordered pairs of alpha^2_hat (1 − r^2)
u_hat       = u_cross_hat + u_div_hat
```

Badge, and this matters: **the mean-over-pairs roll-up is a convenience, not a theorem** — a summary statistic, adequate for design and inadequate for a claim of proof. the survey protocol [Curzi, 2026i] requires the choice stated; the preregistration protocol [Curzi, 2026i] requires it frozen before fitting.

Instrument D — the disagreement log (a delta instrument)

Levels are not enough: as Section 5 establishes, `u_div` decays. Keep a standing log:

```
For each substantive decision, record:
  − was a dissenting position stated on the record?  (Y/N)
  − by whom, and in which block?
  − from INSIDE the deciding block (u_div) or a different one (u_cross)?
  − was the dissent's substance addressed in the decision record?
```

The fourth field is the one that matters. Dissent recorded and not addressed is theatre and scores zero. the conversion analysis's [Curzi, 2026b] `eta` is the relevant term: **a disagreement that leaves no trace in the artifact converted none of its surplus into stored order, and `eta * S` for that interaction was zero regardless of how vigorous the meeting felt.**

10.4.11 4.11 Where the two components sit in the storage law

Nothing here changes the storage law. Both components feed the same scalar:

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = f(u_cross,t + u_div,t)
```

But the components have different *dynamics*, which is why they must be tracked separately even though the law only ever sees their sum.

`u_cross` decays slowly — set by the roster, moving at attrition timescales, so an annual recruiting and rotation review suffices. `u_div` decays fast, with a half-life in months (Section 5 computes it), and needs continuous protocol: independent-estimate-first, a dissent log, a red-team rotation.

The practical consequence for the headroom gauge (the headroom analysis [Curzi, 2026b]), `h_t = eta ln N − delta Q_t − C_t`: it does not contain `u` at all. `u` determines how much of the available headroom is converted, via `S_t = f(u) <= ln N`. **A collapse in `u_div` does not show up in the headroom gauge; it shows up as a persistent gap between `eta S_t` and `eta ln N` — between what the system could take in and what it does.** Define and track it:

```
UTILIZATION OF CEILING

  rho_ceil,t := S_t / ln N = f(u_t) / ln N,  in [0, 1]

  rho_ceil = 1   u = 1, orthogonal, running at the per−interaction ceiling
  rho_ceil = 0   u = 0, parallel, no surplus at any headcount
```

At `N = 6` (`ln 6 = 1.7918`): an organization at `u = 0.75` runs at `1.5581 / 1.7918 = 0.8696`; at `u = 1.00` it runs at 1.000. That 13 percent of unused ceiling is the entire prize in the worked example below, and it is invisible on every gauge except this one.

10.4.12 4.12 Semilattice, not tree

Alexander [1965] is the architectural statement of this section's structural claim. A tree partitions — every element in exactly one parent set, no overlap. A semilattice permits overlap.

A **tree** assigns each person exactly one block, so any pair is either in the same block (`beta^2 = 0`, all difference from `gamma`) or in different blocks (`beta^2 = 1`, `alpha^2 = 0`, so `u_div = 0` identically — *no shared ground* on which to disagree). **A strict tree forces every pair into a corner of the budget: pure crossing or pure divergence, never a portfolio**, every pair pinned and every balance index zero. A **semilattice** lets people hold partial membership in several blocks, so `0 < beta^2 < 1` for most pairs, both components are live, and B is positive across the ensemble.

This is why matrix structures, dual reporting, rotating secondments and shared instrumentation carry more surplus than the same headcount in a clean hierarchy — and why they cost more in `C`. the cost arithmetic [Curzi, 2026b] and this section's are in tension by construction; the intervention procedure [Curzi, 2026j] is where the trade is made explicitly.

10.4.13 4.13 The asymmetry finding

Instrument A's directional `beta^2` is diagnostic in its own right. Define `A(x,y) := beta^2_hat(x,y) − beta^2_hat(y,x)`. `A` near zero means mutual evaluability. Large positive `A` for a consistently-appearing `x` means *x reports being unable to evaluate others' work while others report being able to evaluate x's* — which has two very different causes. Either a genuine specialization gradient (`x` works deep and narrow), or **deference collapse**: `x` is junior and has learned not to claim evaluative standing, which is `u_div` being destroyed by rank and reappears in the seating analysis [Curzi, 2026f] as the head-of-table effect. Distinguish by anonymizing the artifacts. If `A` collapses when authorship is hidden, the asymmetry was deference. Cheapest decisive test in Section 4; it costs one afternoon.

10.4.14 4.14 Specification: measuring and designing the two sources

Requirements are numbered `SPEC 4.n` and each is checkable. A conforming system satisfies all of Group A, and satisfies Group B or records a dated exception with a named owner.

Group A — measurement (mandatory)

SPEC 4.1 The survey (the survey protocol [Curzi, 2026i]) shall enumerate the `N` blocks in writing before any `u` estimate is computed, declared as *distinct methods or evaluative standards*, not job titles or demographic labels.

SPEC 4.2 `u_cross` and `u_div` shall be estimated and reported separately. A report containing only a total `u` is non-conforming.

SPEC 4.3 `beta^2` shall be estimated by the evaluability partition (Instrument A) against real, anonymized artifacts. Self-report against job titles does not conform.

SPEC 4.4 `gamma` shall be estimated from independent scores collected *before* any group discussion of the items. Post-discussion correlation is non-conforming and shall be labeled as such if reported.

SPEC 4.5 Every `gamma` estimate shall carry its shared-ground item count `n_E`. Estimates with `n_E < 12` shall be marked provisional.

SPEC 4.6 The pair-to-ensemble roll-up rule shall be stated in the report and shall not change between periods without a dated note.

SPEC 4.7 The directional asymmetry `A(x,y)` shall be computed and reported. Any participant whose mean `A` exceeds 0.25 shall trigger the anonymization test of Section 4.13.

SPEC 4.8 The balance index `B = [f(u) − max(f(u_cross), f(u_div))] / f(u)` shall be computed each period and reported alongside `u`.

SPEC 4.9 The ceiling utilization `rho_ceil = f(u) / ln N` shall be computed each period and reported alongside `h_t`.

Group B — design (mandatory unless exception recorded)

SPEC 4.10 No plan shall use `f(u_cross) + f(u_div)` as an estimate of surplus. Plans shall use `f(u_cross + u_div)`. The upper bound may appear only as a stated impossibility limit.

SPEC 4.11 No plan shall assert synergy beyond additivity. A benefit believed to exist beyond it shall be recorded as an uncredited expectation and excluded from the numbers.

SPEC 4.12 The first increment of `u` in any period shall come from whichever source is scarcer, per Rule 4.4, unless a written justification records why the more abundant source was chosen.

SPEC 4.13 Where `B < 0.05` for two consecutive periods, the system shall be recorded as single-sourced and a remediation owner named. `B < 0.05` at high `u` is not a healthy state; it is a concentrated one.

SPEC 4.14 Every substantive decision record shall carry a dissent field with four entries: stated (Y/N), by whom, source (cross or div), addressed in the artifact (Y/N). A blank field is non-conforming; "none" conforms and is itself data.

SPEC 4.15 Dissent recorded but not addressed in the artifact shall be scored `eta = 0` for that interaction and shall not count toward `u_div` maintenance.

SPEC 4.16 Independent estimates shall precede discussion wherever `u_div` is a design input. The ordering is a hard requirement; reversing it destroys both the quantity being measured and the quantity being used.

SPEC 4.17 Onboarding, vocabulary standardization, and composite incentive metrics — the standard `C`-reduction moves — shall carry an explicit `u_div` impact estimate before adoption. Cutting `C` by spending `u_div` is a legitimate trade and an illegitimate accident.

SPEC 4.18 No participant shall be required to disagree. Divergence protocols shall create the *opportunity* and the *protection* to dissent, never an obligation: an intervention removing the ability to decline is out of scope for this paper (the framework's consent clause [Curzi, 2026]). Compelled dissent is also useless — it produces low-information objections that inflate the log without moving `r`.

SPEC 4.19 Under a strict hierarchy, at least one crosscutting structure (rotation, community of practice, shared instrument, dual assignment) shall exist, so that some pairs have `0 < beta^2 < 1`. A pure tree pins every pair at a budget corner (Section 4.12).

SPEC 4.20 The contrarian check shall run each period: any pair with shared-ground `r` below `-0.6` shall be flagged as a possible mirror rather than a divergence, and re-examined. Antiparallel is parallel.

Group C — reporting

SPEC 4.21 The period report shall contain at minimum:

```
PERIOD: ______   N (declared blocks): ____
u_cross: ______ (n pairs ____)   u_div: ______ (mean n_E ____)   u: ______
N_eff = 1+(N-1)u: ______   S = f(u): ______   ln N: ______
rho_ceil = S/ln N: ______   B (balance index): ______
floor = max(f(uc),f(ud)): ______
ceiling = f(uc)+f(ud): ______   [impossibility limit only]
decisions with recorded dissent: ____/____
dissents addressed in artifact:  ____/____
mean directional asymmetry A: ______
```

SPEC 4.22 Any use of axiom S3 (the affine effective count) shall carry its badge in the same sentence. `N_eff` is a design choice, not a derived fact.

SPEC 4.23 The report shall state, verbatim: *the surplus functional as deployed is a lower bound on the ensemble's information, not the information itself.*

10.4.15 4.15 Failure modes of the decomposition

Each entry: name, clinical description, damaged parameter, signature, measurement, fix. These feed the catalog in the consolidated failure catalogue [Curzi, 2026j].

FM-4A · THE FURNISHED MONOCULTURE

Clinical. High `u_cross`, `u_div` at or near zero. Every discipline present; each represented by exactly one permitted view.

Damages. `u_div` -> 0, pinning `f(u)` at `f(u_cross)` and driving `B` to zero. Robustness collapses while surplus still reads well.

Signature. Blank or "none" dissent fields across consecutive decisions; approval near 100 percent with substantive comments; "aligned" used as a success report; outsiders stop objecting within two quarters, and this is praised.

Measurement. Instrument B on within-block pairs: `r > 0.9`. `B < 0.05`. Fewer than one recorded-and-addressed dissent per ten decisions.

Fix. Rule 4.4: buy the scarce source. Independent-estimate-before-discussion (SPEC 4.16); a rotating, protected adversarial role; a non-blank dissent field (SPEC 4.14); an artifact recording how each dissent was addressed (SPEC 4.15). Expect `C` to rise; budget it against `h_t` first.

FM-4B · THE DEEP NARROW WELL

Clinical. High `u_div`, `u_cross` near zero. Vigorous argument inside a single block; no component of anyone's state outside it.

Damages. `u_cross` -> 0. a violation of requisite variety [Ashby, 1956]: variety in one dimension, none in the others.

Signature. Reputation for rigour; failures always classified as "outside our remit"; recruitment selects for people who survive the internal debate, which selects for insiders.

Measurement. Instrument A: `beta^2` below 0.10 for nearly all pairs.

Fix. Import a practitioner from an unrelated trade with real standing, not an advisory seat; give them work products to evaluate, not presentations to attend. At large `gamma` the first cross-hire buys less than expected, since `du/d(beta^2) = cos^2(gamma)` is small. Buy anyway: the ceiling on further `gamma` is close, the ceiling on `beta^2` is not.

FM-4C · THE ADDED-BOUND PLAN

Clinical. A plan or forecast computing surplus as `f(u_cross) + f(u_div)`.

Damages. Nothing in the system; everything in the forecast. Overstates by 16 to 45 percent (Section 3.3), worst where the plan is most ambitious.

Signature. Two surplus numbers in a document, added. Language about the combination being "greater than the sum of its parts."

Measurement. Recompute with `f(u_cross + u_div)`. The gap is the overstatement.

Fix. SPEC 4.10 and 10.11. Retire the upper bound from planning use entirely.

FM-4D · THE C-FOR-DIVERGENCE TRADE MADE BY ACCIDENT

Clinical. An organization cuts coordination cost by standardizing vocabulary, induction, incentives and escalation, destroying `u_div` without deciding to.

Damages. `C` down (good), `u_div` down (unaccounted). The net effect on `eta S_t − delta Q_t − C_t` is often positive in the short run and negative once `S_t` responds, because the low-pass lag (the circuit analysis [Curzi, 2026a]) delays the `S` decline past the point where anyone attributes it to the change.

Signature. A cost-efficiency programme completed 6 to 18 months before an unexplained decline in decision quality — unsuspected, because it "worked."

Measurement. Track `u_div` and `C` on one time axis: a `C` step down followed by a `u_div` slope down. the preregistration protocol's [Curzi, 2026i] shuffled-input control separates it from coincidence.

Fix. SPEC 4.17. Trade deliberately or not at all.

FM-4E · THE RELABELED BLOCK

Clinical. `N` raised on paper by splitting an existing category rather than adding an orthogonal one.

Damages. `N`, `beta^2`, and `u_cross` all inflated; every downstream number wrong in the optimistic direction.

Signature. Block boundaries following the reporting line rather than the method; blocks whose members trained in the same programme; `beta^2` near zero for pairs the declaration puts in different blocks.

Measurement. Cross-tabulate declared block against measured `beta^2`. If cross-block `beta^2` is not materially higher than within-block, the declaration is fiction.

Fix. Re-declare blocks by evaluative standard (SPEC 4.1). A block is defined by *what counts as a good answer*, not by who reports to whom.

FM-4F · THE MIRROR MISTAKEN FOR A WINDOW

Clinical. A participant who reliably opposes, credited as the source of `u_div`. In the squared geometry, systematic opposition is parallelism: `x . y = −1` gives `u = 0`.

Damages. `u_div` credited where none exists; worse, a designated opposer suppresses dissent from others, who assume the slot is filled.

Signature. One person objects to everything, and the objection carries no information because it is predictable from the proposal. `r` near `−1`.

Measurement. SPEC 4.20. Also: predict the objector's position from the proposal alone. If that can be done reliably, they are a mirror.

Fix. Rotate the adversarial role rather than appointing it (the non-parallelism analysis [Curzi, 2026c]); score dissent by whether it changed the artifact. `r` near 0 is the target.

FM-4G · DEFERENCE COLLAPSE

Clinical. Directional asymmetry `A` driven by rank rather than specialization. Juniors report being unable to evaluate senior work; seniors report the reverse.

Damages. `beta^2` overestimated in one direction — silence recorded as crossing — and `u_div` destroyed, the party who would disagree having disclaimed standing to do so.

Signature. `A` correlates with seniority across the roster.

Measurement. Section 4.13's anonymization test.

Fix. Anonymize artifacts at the point of evaluation. the seating analysis's [Curzi, 2026f] protocols — last-speaks-first for rank, silent-write-first, no head of table — attack the same fault from the geometry side.

FM-4H · THE UNADDRESSED DISSENT LOG

Clinical. Dissent recorded diligently and never changing an artifact. The log grows, `Q` does not.

Damages. `eta -> 0` for the divergence channel: all the `C` of the argument, none of the storage.

Signature. A healthy dissent-stated rate and a near-zero dissent-addressed rate. Participants describe the process as going through the motions.

Measurement. The two counts in SPEC 4.21's report block, side by side. Their ratio is the divergence channel's `eta`.

Fix. SPEC 4.15. A the conversion analysis [Curzi, 2026b] intervention, not a Section 4 one: the geometry was fine, the conversion was zero.

10.5 5 Pseudo-diversity and the decay of non-parallelism

This is the failure mode that costs modern institutions the most, and it is almost never diagnosed, because every instrument the institution owns reports that nothing is wrong.

The parallel wall is not a shortage of people, talent, funding, effort, or good intention. It is a geometry in which many capable people, each doing competent work, collectively return the surplus of one. The arithmetic that prices it is short enough to fit on a card, and Section 5's first job is to put it there.

Its second job is harder. `u` is not a property an organization acquires and then owns. **It is a quantity that decays, and that makes non-parallelism a maintenance obligation, not a procurement one.** A group can be assembled correctly, measure well on day one, and be parallel within two years without a single person leaving, a single policy changing, or anyone making a decision they would recognize as wrong.

10.5.1 5.1 The arithmetic of zero

From Curzi [2026], Thm 2.1 and the effective count that follows from axiom S3:

```
N_eff = g(u) = 1 + (N−1)u
S     = F(u) = f(u) = ln(1 + (N−1)u) = ln N_eff

at u = 0:   N_eff = 1 + (N−1)(0) = 1
            S     = ln 1 = 0
```

That is the whole indictment. **Three glasses ground from one doctrine are one glass, and their agreement is not evidence of anything except that they were ground from one doctrine.**

Curzi [2026], Thm 4.3 (extremality) makes it exact and two-sided: `F = 0` if and only if the states are parallel, and `F = ln N` if and only if they are orthogonal. There is no gradation at the bottom. Parallelism does not produce a small surplus; it produces none.

Note also what the law does *not* say. It does not say the group produces nothing. Each member still does work. What returns zero is the *interaction surplus* — the part of the output that exists because there is more than one of them. **A parallel group of forty is not a bad group. It is a group of one, paid forty times, and audited as though it were forty.**

10.5.2 5.2 What "parallel" means operationally

`u = 1 − (x . y)^2`. Two states are parallel when their normalized inner product has magnitude 1 — when one is a scalar multiple of the other. In an organization the operational readings are:

Formal	Operational reading
`x . y = +1`	the second party's judgment is predictable from the first's, with the same sign
`x . y = −1`	the second party's judgment is predictable from the first's, with the sign flipped
`u = 0`	in either case: knowing the first determines the second, so the second carried no new information

The second row is the trap Section 4 named (Failure Mode FM-4F) and it bears repeating here because pseudo-diversity programmes frequently buy it by mistake. **Antiparallel is parallel.** A designated opposer whose position is derivable from the proposal is a mirror, not a window, and the law prices a mirror at zero.

10.5.3 5.3 The price of pseudo-diversity, in numbers

Take a declared roster of `N` categories. Compute what the roster is actually worth at various levels of measured non-parallelism.

	N = 5		N = 10		N = 20		N = 40	
u	N_eff	S	N_eff	S	N_eff	S	N_eff	S
0.00	1.000	0.0000	1.000	0.0000	1.000	0.0000	1.000	0.0000
0.01	1.040	0.0392	1.090	0.0862	1.190	0.1740	1.390	0.3293
0.02	1.080	0.0770	1.180	0.1655	1.380	0.3221	1.780	0.5766
0.05	1.200	0.1823	1.450	0.3716	1.950	0.6678	2.950	1.0818
0.10	1.400	0.3365	1.900	0.6419	2.900	1.0647	4.900	1.5892
0.20	1.800	0.5878	2.800	1.0296	4.800	1.5686	8.800	2.1748
0.40	2.600	0.9555	4.600	1.5261	8.600	2.1518	16.600	2.8094
1.00	5.000	1.6094	10.000	2.3026	20.000	2.9957	40.000	3.6889

Read the `N = 40` column. A forty-category roster at `u = 0.05` has an effective count of 2.95. **Forty declared categories, three effective ones — and the organization is paying for forty, sizing its meeting rooms for forty, and carrying the coordination cost of forty.** the cost analysis's [Curzi, 2026b] arithmetic completes the picture: at `N = 40`, the communication-path count [Brooks, 1975] communication paths number `n(n−1)/2 = 780`. The group carries 780 channels of cost to deliver the surplus of three.

That ratio — cost of the declared count, surplus of the effective count — is the entire economics of the parallel wall, and it is why pseudo-diversity is expensive rather than merely disappointing.

10.5.4 5.4 The steepest slope is at zero

Curzi [2026], Thm 4.2 gives the sharp Lipschitz constant `N − 1`. Differentiating:

```
f'(u) = (N−1) / (1 + (N−1)u)

f'(0)  = N − 1        <-- the maximum, attained exactly at parallelism
f'(1)  = (N−1)/N      <-- the minimum
```

The first unit of difference is the most valuable unit of difference there will ever be. Concretely:

N	f(0.01) − f(0)	f(1.00) − f(0.99)	ratio
3	0.0198	0.006689	3.0
5	0.0392	0.008032	4.9
10	0.0862	0.009041	9.5
20	0.1740	0.009545	18.2
40	0.3293	0.009798	33.6

At `N = 40`, the first hundredth of `u` is worth 33.6 times the last hundredth. At `N = 10`, moving `u` from 0.00 to 0.05 buys 0.3716; moving it from 0.95 to 1.00 buys 0.0460 — a factor of 8.07.

This cuts both ways, and the second cut is the one Section 5 is about. **Because the function is steepest at zero, a group near the parallel wall loses more surplus per unit of `u` lost than a group anywhere else on the curve.** The last increments of difference to disappear are the most expensive ones. Decay does not slow as it approaches zero; in surplus terms it accelerates.

10.5.5 5.5 u as a decaying state variable

Nothing in the founding surplus analysis [Curzi, 2026] makes u a function of time. the founding surplus analysis [Curzi, 2026] is static geometry. The storage law (the storage-law analysis [Curzi, 2026a]) evolves Q, and takes U_t as an *input*:

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1)U_t)
```

U_t is exogenous to the law. **Nothing in the mathematics says U_t stays where it was put, and everything in the empirical literature says it does not.**

This paper therefore adopts an explicit modeling postulate, badged here and carried through Section 5:

> **POSTULATE P-U (u-decay), badged.** In a group under ordinary communication, absent maintenance, measured non-parallelism decays geometrically: `U_{t+1} = (1 − lambda) U_t` with `lambda` in `[0,1)`.
>
> This is a modeling assumption, not a theorem. It is not in the founding surplus analysis [Curzi, 2026], not in the storage-law analysis [Curzi, 2026a], and not proved anywhere in this paper. It is adopted because it is the simplest form consistent with the cascade mechanism of Section 5.10, because it makes `lambda` estimable from two measurements, and because it is falsifiable in the manner of the preregistration protocol [Curzi, 2026i]. If measured u under zero maintenance does not decline approximately geometrically, replace the postulate.

With that badge in place, the structural claim of Section 5 becomes sayable in the framework's own terms:

```
delta  is the decay rate of STORED ORDER      (the retention analysis \citep{ccp:CCP-007})
lambda is the decay rate of DIFFERENCE        (Section 5)

Both are leaks. Both require maintenance. Only one of them is
routinely measured, and it is not lambda.
```

u is a delta problem as much as a design problem, and an organization that has a maintenance regime for its documents and none for its disagreement has budgeted for one leak and ignored the other.

10.5.6 5.6 Badges and honesty clauses

- **Proven (Curzi [2026], Thm 2.1, 4.3):** `f(u) = ln(1 + (N−1)u)` under S1-S4; `F = 0` iff parallel, `F = ln N` iff orthogonal.
- **Proven (Curzi [2026], Thm 4.2):** sharp Lipschitz constant `N − 1`, attained at `u = 0`.
- **Design axiom, not derived (S3):** the affine effective count `N_eff = 1 + (N−1)u`. Every `N_eff` in Section 5 inherits that choice.
- **Postulated and badged (11.1):** geometric decay of u.
- **Honesty clause:** as deployed, the surplus functional is a **lower bound** on the ensemble's information, not the information itself. A group measured at `u = 0` on the chosen observables may hold information those observables do not see. It does not hold information the instrument *credits*, and stored order responds to what the instrument credits. **If the instrument reads zero and the analyst believes the group is not parallel, the correct response is to change the instrument, not to overrule it.**
- **Honesty clause:** The founding surplus analysis [Curzi, 2026] is pure mathematics and makes no empirical or metaphysical claim. the surplus range analysis [Curzi, 2026]: surplus is not identified with Shannon entropy or mutual information in general.

- **Refused (the framework's consent clause [Curzi, 2026]):** nothing in this paper recommends compelling anyone to hold, express, or perform a view. Every instrument here measures; every intervention here creates opportunity and protection. A person who declines to dissent has exercised a right, and their decline is recorded as data, not as a failure.
- **Scope note, stated once and meant.** Section 5 treats diversity as an engineering parameter of an information-processing system. It makes no claim about the social, moral, or legal case for any staffing policy, and it takes no position on any of them. A reader who imports a political argument into this section has imported it; it is not here. **The fault named here is that a measurable quantity is going unmeasured, and the fix is to measure it.**

10.5.7 5.7 Three glasses ground from one doctrine

Three optical instruments are pointed at the same object. They agree, and the agreement is reported as convergent evidence.

But all three were ground on the same machine, to the same prescription, by the same house, and calibrated against the same reference. Their agreement is a statement about the machine. It contains exactly as much information about the object as one instrument does, and the confidence gained from the "three" is manufactured.

In the law: `x1 = x2 = x3` up to scale, so `u = 0` for every pair, `N_eff = 1`, `S = ln 1 = 0`. **The confidence went up and the information did not, and that gap is what pseudo-diversity produces as its characteristic output.**

Condorcet's jury theorem says the same from the other side: collective accuracy exceeds individual accuracy *only under independence*. Independence is not a nicety attached to the theorem, it is the theorem's engine, and dropping it drops the conclusion. Section 5.15 computes how fast.

10.5.8 5.8 The five species

Pseudo-diversity is not one fault but five, needing different instruments to detect and different interventions to fix.

Species 1 — declared variety with epistemic uniformity. The roster varies along one or more declared axes; the *evaluative standards* do not. Every member was trained to recognize the same things as good answers. The blocks were declared along an axis that is not the axis on which judgment varies, so `u_cross` measures high on the declared axis and near zero on the axis that governs the decisions being made.

Detection: declare blocks by evaluative standard (SPEC 4.1), then re-measure. If `beta^2` does not rise across the declared boundary, the boundary is not an epistemic boundary.

Species 2 — the echo chamber. Information intake is filtered through a common upstream source. Members differ in training and converge in evidence, because they read the same five outlets, attend the same three conferences, and follow the same feed. Difference in the members does not survive identical inputs.

Detection: audit the information supply chain, not the roster. Ask each member independently for the three sources that most changed their view in the past year; compute the overlap. High overlap is the signature.

Species 3 — correlated forecasts. Members produce independent-looking numerical judgments whose errors correlate. Each estimate is honestly made; the ensemble is nonetheless one estimate with noise. This species does most damage in risk, finance, planning, and engineering safety, because the aggregate is *reported* as an ensemble and *behaves* as a point.

Detection: error-decorrelation measurement, Section 5.16. This is the one species with a clean, cheap, quantitative instrument, and it is still rarely run.

Species 4 — committee theatre. Structure is elaborate — subcommittees, review stages, sign-offs, quorums — and the geometry flat, because every stage draws from the same pool and applies the same standard. Each stage adds `C` and no `u`: the process grows quadratically in cost and not at all in surplus.

Detection: count the stages, then count how often a later stage reversed an earlier one on substance. A reversal rate near zero across many decisions means the later stages are re-reading the first stage's instrument.

Species 5 — the common training pipeline. Reviewer, candidate, and appointment pools all drawn from a few upstream institutions. This is preferential attachment [Barabási and Albert, 1999] operating on careers: hubs attract, hubs train, and everyone downstream carries the hub's prior. The structure is efficient, robust to random loss, and — per Albert et al. [2000] — fragile to anything corrupting the hub, since everything downstream inherits it at once.

Detection: trace training lineage rather than affiliation. Two people at different institutions who trained under the same advisor are one lineage.

10.5.9 5.8.1 Manufactured opposition — a sixth fault, and not the Parallel Wall

The five species above all describe bodies that agree too much. This one describes a body that disagrees on schedule, and it was catalogued after the five because it does not look like them from outside. It is entered here as a distinct fault, with its own signature and its own fix, and it is recorded as failure mode FM-5I below.

The arithmetic is Section 5.2's second row, taken seriously. `u = 1 − (x . y)^2` depends only on `|rho|`, so **`rho = −1` returns `u = 0` exactly as `rho = +1` does.** Perfect opposition is parallel. The contrarian who reliably inverts a colleague carries the same information as the sycophant who reliably echoes them: none, because in both cases their position is a function of yours.

"Creative tension" at `rho` near -1 is therefore not a weak purchase of `u`. It is a zero purchase of `u` with a cost overhead, and that overhead is what makes it distinct from the Parallel Wall rather than a variant of it. A parallel roster wastes seats it already had. A designated-opposer seat is *added* — hired, seconded, or scheduled — to supply a divergence it cannot supply. Price the seat alone, at `eta = 0.35`, `delta = 0.10`, and a seat cost of 0.05 per period:

the added seat	`u`	`S`	`eta*S`	its `Q_inf` contribution
genuinely independent, `rho = 0`	1.0000	0.6931	0.2426	**+1.9260**
partially correlated, `rho = 0.6`	0.6400	0.4947	0.1731	+1.2314
perfect echo, `rho = +1`	0.0000	0.0000	0.0000	**-0.5000**
perfect opposition, `rho = −1`	0.0000	0.0000	0.0000	**-0.5000**

The last two rows are the same row. The opposer and the echo have identical consequences for stored order, and both are strictly worse than not filling the seat, because `C` is paid and nothing is returned.

The fault is worse than its arithmetic, for a reason that is not in the equation and is badged as observation rather than theorem: **the slot appears filled.** A body with a house sceptic believes it has bought dissent and stops looking for the independent judgment it actually needs,

so the manufactured opposition suppresses demand for the real thing. That is the same structure as the non-parallelism analysis's [Curzi, 2026c] captured red team (FM-9.3), arrived at from the opposite direction.

Detection: predict the objector's position from the proposal before the meeting. If the prediction is reliable, `|rho|` is near 1 and the seat is a mirror regardless of how heated the exchange is. Measure `|rho|`, never `rho`.

Fix: target `|rho|` near zero, not `rho` near -1. Rotate the role so it cannot become a stable inversion; score the seat by artifact change rather than by objection count. the geometry of the fold [Curzi, 2026c] gives the geometry — the angle table folded about 90 degrees — the dyadic table of the non-parallelism analysis [Curzi, 2026c] gives the dyadic table, and the dyad analysis [Curzi, 2026r] treats the two-person case in full.

10.5.10 5.9 The inference error, stated formally

Underneath all five species is a single reasoning mistake, worth stating in a form precise enough to check.

Agreement between two observers is evidence about the world **only to the extent that the observers could have disagreed.** The informativeness of concordance is a function of the prior probability of discordance; when that prior is zero, concordance carries no information.

```
CONCORDANCE TEST

  Before reading the second opinion, write down:
    p = P(this reviewer disagrees with the first, given the first)

  If p is near 0, the second opinion is not evidence, whatever it says.
  If p cannot be estimated, the agreement cannot be interpreted.
```

This test costs thirty seconds and can be applied to any second opinion, any peer review, any confirming analysis. Most institutions have never asked it about any of theirs. **The question is not "do they agree?" but "could they have disagreed?" — and the second question is the only one whose answer carries information.**

the non-parallelism analysis's [Curzi, 2026c] line is the same statement in the roster's language: a second opinion from someone whose training and incentives replicate the first is worth `ln(1) = 0`.

10.5.11 5.10 The cascade: how a diverse group becomes parallel

Everything so far describes a group that was parallel to begin with. The harder and more common case is a group that was genuinely diverse and became parallel while doing nothing wrong.

The mechanism is the information cascade of **Bikhchandani, Hirshleifer and Welch (1992)**, worth working through because it shows the collapse occurring through *individually rational* behaviour. No one defects, no one is coerced, and the group still ends up as one instrument.

The canonical setup: agents act in sequence on a binary question. Each holds a private signal, correct with probability `p > 1/2`. Each observes the actions of those who acted before, but not their private signals. Each acts to maximize their own accuracy.

Agent 1 has only their signal, so acts on it. Agent 2, seeing one action and holding one signal, acts on their own signal (breaking ties toward it). Agent 3 now faces two prior actions. If both agree, two units of evidence stand against Agent 3's one, and the rational act is to follow the crowd **and ignore their own signal.** From that moment, every subsequent agent sees only actions that carried no private information, so every subsequent action carries none either. The cascade is locked.

The arithmetic of the canonical model:

```
State A is true; signal accuracy p.
Agents 1 and 2 both follow their own signals.
  both correct   -> p^2          -> correct cascade
  both incorrect -> (1-p)^2      -> INCORRECT cascade
  mixed          -> 2p(1-p)      -> no cascade; the process restarts

 p      P(correct cascade)   P(incorrect cascade)   E[agents whose signal
                                                    entered the record]
-----------------------------------------------------------------------
0.55         0.5990               0.4010                   3.96
0.60         0.6923               0.3077                   3.85
0.70         0.8448               0.1552                   3.45
0.80         0.9412               0.0588                   2.94
0.90         0.9878               0.0122                   2.44
```

Two results deserve to be read slowly.

First, the incorrect-cascade probability. With individually 70-percent-accurate agents, the group locks onto the wrong answer 15.5 percent of the time, and once locked, adding more agents does not help — every additional agent copies. **A room of forty 70-percent-accurate people has a roughly one-in-six chance of being confidently, permanently wrong, and the confidence grows with the room size while the accuracy does not.**

Second, the informative-agent count. At `p = 0.70`, on average 3.45 agents' private signals ever enter the public record. Everyone after that is echo. In a room of forty, thirty-six and a half people are re-reporting three and a half. The declared `N` is 40. The information-bearing count is 3.45.

That is pseudo-diversity manufactured in real time, from a group that was genuinely diverse when it walked in.

10.5.12 5.11 Cascades collapse u, and that is the delta problem

The cascade result is normally taught as a decision-theory curiosity. In this framework it is the mechanism behind Postulate P-U, and the bridge is direct.

Before the cascade, participants' reported states differ because each reflects an independent private signal: `u > 0`. After the cascade, every reported state is a copy of the public history: `x_i = x_j` for all post-cascade `i, j`, so `u = 0` among them. Not small. Zero, by the extremality theorem [Curzi, 2026].

The key structural point is that **cascades do not need a new event to occur. They occur as a by-product of ordinary sequential communication, which is to say they occur continuously in any group that talks.** Every meeting in which the senior person speaks first, every review in which the second reviewer sees the first reviewer's score, every forecast round in which the group discusses before estimating, is a cascade opportunity. Most organizations present dozens per week.

That is why u decays rather than merely being low. And it is why the right frame is maintenance:

```
                 acquisition problem        maintenance problem
-------------------------------------------------------------------
question         *was difference hired?*  *is the difference still present?*
measured         at recruitment             every period, forever
owner            recruiting                 whoever runs the meetings
failure looks    a homogeneous roster       a heterogeneous roster that
like                                        produces homogeneous output
-------------------------------------------------------------------
```

Almost every organisation has the left column staffed and the right column unstaffed. **The left column is the one that photographs well.**

10.5.13 5.12 The decay table

Under Postulate P-U, `u_t = u_0 (1 − lambda)^t`, and the half-life is

```
t_half = ln 2 / ( −ln(1 − lambda) )
```

which is the same formula the retention analysis [Curzi, 2026a] gives for `delta`, because it is the same kind of leak.

```
lambda   half-life (periods)   u after 10 periods, from u_0 = 0.60
-------------------------------------------------------------------
 0.02          34.31                        0.4902
 0.05          13.51                        0.3592
 0.10           6.58                        0.2092
 0.15           4.27                        0.1181
 0.20           3.11                        0.0644
 0.30           1.94                        0.0169
 0.50           1.00                        0.0006
```

And the surplus consequence, at `N = 10`, `u_0 = 0.60`:

```
lambda = 0.15,  N = 10
 t     u        N_eff      S = f(u)     S as % of ln 10
-----------------------------------------------------------
  0   0.6000    6.400      1.8563           80.6%
  2   0.4335    4.902      1.5895           69.0%
  4   0.3132    3.819      1.3399           58.2%
  6   0.2263    3.037      1.1107           48.2%
  8   0.1635    2.471      0.9048           39.3%
 10   0.1181    2.063      0.7242           31.5%
 12   0.0853    1.768      0.5699           24.8%
```

Twelve periods — three years at quarterly cadence — takes a group from 80.6 percent of its per-interaction ceiling to 24.8 percent, with the same people, the same budget, and the same org chart. **Nothing in this table requires anyone to do anything wrong. It requires only that nobody does anything to stop it.**

Estimating lambda in a real system. Measure `u` at two times separated by `k` periods, with no `u`-maintenance intervention between them:

```
lambda_hat = 1 − (u_1 / u_0)^(1/k)
```

Two cautions, both mandatory. First, the interval must genuinely contain no maintenance, or what has been measured is the net of decay and repair, which cannot be separated. Second, `u` must be measured the same way both times — the same instrument, the same item pool, the same pre-discussion ordering (Section 4, SPEC 4.4). A change of instrument between the two measurements produces a `lambda` that is an artifact of the change.

10.5.14 5.13 Why the institution looks healthy after its input has collapsed

Here is the property that makes this failure mode so hard to catch in time, and it comes directly from the circuit analysis's [Curzi, 2026a] circuit identity.

The storage law is a first-order low-pass filter. `Q` responds to `S` with a lag of order `1/delta` periods. So when `u` — and therefore `S` — starts falling, `Q` does not immediately fall. It keeps rising for a while, on the momentum of the accumulated term, and then rolls over.

Worked, with `N = 5`, `eta = 0.55`, `delta = 0.09`, `C = 0.15`, `Q_0 = 4.00`, `u_0 = 0.55`, and `lambda = 0.18` (half-life 3.49 periods):

t	u	N_eff	S	eta S	delta Q	Delta Q	Q	
0	0.5500	3.200	1.1632	0.6397	0.3600	+0.1297	4.0000	
1	0.4510	2.804	1.0310	0.5671	0.3717	+0.0454	4.1297	
2	0.3698	2.479	0.9080	0.4994	0.3758	−0.0264	4.1751	<- peak
3	0.3033	2.213	0.7944	0.4369	0.3734	−0.0865	4.1488	
4	0.2487	1.995	0.6905	0.3798	0.3656	−0.1358	4.0623	
6	0.1672	1.669	0.5121	0.2817	0.3376	−0.2059	3.7511	
8	0.1124	1.450	0.3714	0.2043	0.2985	−0.2442	3.3166	
10	0.0756	1.302	0.2642	0.1453	0.2537	−0.2584	2.8185	
12	0.0508	1.203	0.1851	0.1018	0.2071	−0.2553	2.3015	
16	0.0230	1.092	0.0879	0.0484	0.1192	−0.2208	1.3240	
20	0.0104	1.042	0.0407	0.0224	0.0460	−0.1736	0.5110	
23	0.0057	1.023	0.0227	0.0125	0.0022	−0.1398	0.0248	

`u` peaks at `t = 0`. `Q` peaks at `t = 2`. **For two full periods after the input has begun to collapse, the institution's stored order is still rising, and every dashboard says the programme is working.** By the time `Q` visibly falls, `u` has already halved.

That lag is not a defect of the model. It is the correct behaviour of an accumulator, and it is the reason the input must be instrumented directly. **Watching `Q` to detect a `u` collapse is watching the reservoir to detect the drought.**

Two further readings from this run.

The headroom gauge does not see it. Compute `h_t = eta ln N − delta Q_t − C_t` along the same path: `h_0 = 0.3752`, `h_2 = 0.3594`, `h_8 = 0.4367`, `h_16 = 0.6160`. Headroom *rises* as the institution collapses, because `Q` is falling and `delta Q_t` shrinks with it. the headroom analysis's [Curzi, 2026b] gauge is doing its job — it reports available capacity, and a dying institution has plenty. **`h_t` measures what could be taken in; `rho_ceil = S_t / ln N` measures what is taken in. Only the second one detects a parallel wall.** Here `rho_ceil` goes 0.723 at `t = 0` to 0.055 at `t = 16`.

The model names its own breakdown. Admissibility requires `C_t <= (1 − delta)Q_t + eta S_t`. At `t = 23`, the right side is 0.0350 against `C = 0.15`. Admissibility fails, and beyond that the linear model reports negative `Q`, which is not a physical state. Read correctly: the arithmetic does not predict a negative institution. **It names the period at which the institution can no longer pay its own running cost, and stops.** the storage-law analysis [Curzi, 2026a], the fixed-point theorem [Curzi, 2026a] makes the same statement in equilibrium form: with `eta F(u*) < c*` the steady state is negative, and the theorem does not hide the failure mode. At `u = 0.08` here, `Q_inf = (0.55 * 0.277632 − 0.15)/0.09 = 0.030` — the regime is at the edge of unsustainable, and a little below that `u` it is over it.

10.5.15 5.14 Detection instruments

Five instruments, in increasing order of cost. Run at least two; they fail differently.

Instrument 1 — the collision test (the framework's collision instrument [Curzi, 2026], formalised). Put a live question to two members separately, in writing, with no prior discussion.

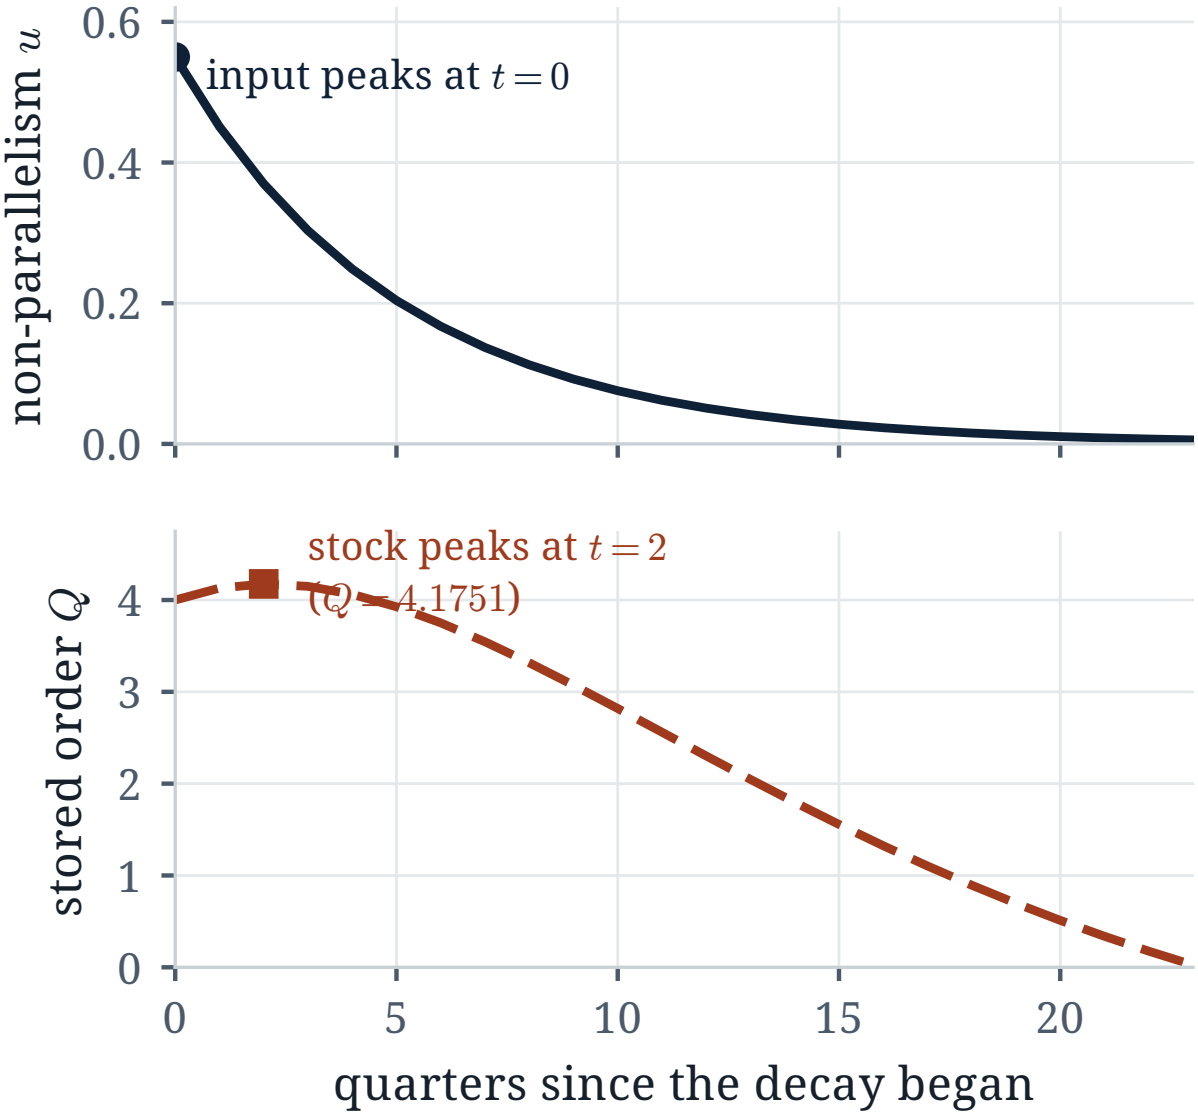

Figure 10.4: **The input peaks at $t = 0$ and the stock keeps rising until $t = 2$, which is why the collapse went unnoticed for years.** Upper panel: non-parallelism under $\lambda = 0.18$ per quarter. Lower panel: stored order under the storage law with $N = 5$, $\eta = 0.55$, $\delta = 0.09$, $C = 0.15$ and $Q_0 = 4.00$. Two panels rather than two axes, because the quantities have different dimensions. **Every dashboard available during those two quarters reported improvement.** Modelled with the source's stipulated parameters; arithmetic exact. Generated by `figs/src/CCP-010_fig04.py`.

Compare. Where the two accounts *collide* — genuinely conflict, not merely differ in emphasis — there is non-parallelism. Where they read as one account in two hands, there is none.

Score it: over `m` questions, the collision rate `c = collisions / m` is a crude but honest first estimate of the group's `u` on that question class. It is crude because it binarizes a continuous angle. It is honest because it cannot be faked by anyone who has not seen both answers.

Instrument 2 — the disagreement audit. Retrospective, cheap, and usually devastating. Pull the last 40 substantive decision records. Count:

```
decisions with any dissent recorded                    ____ / 40
dissents from inside the deciding discipline (u_div)   ____
dissents from a different discipline (u_cross)         ____
dissents whose substance changed the final artifact    ____
reversals of an earlier stage by a later stage         ____
```

The fourth line is the one that matters, per the conversion analysis [Curzi, 2026b]: dissent that leaves no trace in the artifact had `eta = 0` and converted nothing. The fifth line detects Species 4.

Instrument 3 — error-decorrelation measurement. The strongest instrument available, and the subject of Section 5.16. Requires a history of independent, resolvable predictions. Where it can be run it should be; it produces a number rather than an impression.

Instrument 4 — the pre-mortem. Prospective. Before a decision is finalized, state as fact that it failed badly two years on, and ask each participant *independently and in writing* why. Two properties make this a `u` instrument and not merely a risk exercise: it inverts the frame, so agreement with the group's prior no longer counts as a contribution; and it is written before discussion, so it precedes the cascade.

Read the output as a `u` measurement: if the independently written failure stories cluster onto one story, `u` is low on the risk axis. If they scatter across genuinely different mechanisms, `u` is live. **A pre-mortem that produces one story is not a reassuring pre-mortem. It is a failed measurement of the group.**

Instrument 5 — the shuffled-input control (the preregistration protocol [Curzi, 2026i]). The decisive test, and the one most often omitted. Fit the minimal estimation model `Y_{t+1} = a Y_t + b F(U_t) − C_hat_t + e_t` on the real input series; then refit with the `U_t` series randomly permuted in time. If the shuffled series fits as well as the true one, the interaction geometry was not driving the order, and any story told about `u` in that system is unsupported. **A framework that cannot fail cannot be trusted, and this is the test that lets this one fail.**

10.5.16 5.15 What correlation does to Condorcet

Condorcet's theorem requires independence. Institutions habitually invoke the theorem's conclusion — bigger juries are more accurate — while operating in conditions that violate its premise. The size of the error is computable.

Here is an explicit toy model, defined in this paper and not cited from anywhere, so that its assumptions are visible. With probability `rho`, all `N` members receive and act on one common signal (correct with probability `p`), so they vote identically. With probability `1 − rho`, they vote independently, each correct with probability `p`. Majority rules.

```
p = 0.60

 rho     N = 3      N = 11     N = 51
-----------------------------------------
0.0     0.6480     0.7535     0.9265
0.2     0.6384     0.7228     0.8612
0.5     0.6240     0.6767     0.7632
0.8     0.6096     0.6307     0.6653
```

```
1.0     0.6000     0.6000     0.6000
```

At `rho = 0`, going from 3 to 51 members buys 28 points of accuracy. At `rho = 0.8` it buys 5.6. At `rho = 1.0` it buys nothing at all: fifty-one perfectly correlated 60-percent voters are a 60-percent voter.

Scale is a multiplier on independence, not a substitute for it, and a large correlated body is not a safer decision-maker than a small one — it is the same decision-maker with a larger travel budget. This is the ceiling analysis's [Curzi, 2026c] logarithmic ceiling meeting Section 5's parallel wall: raising `N` cannot rescue a system whose `u` is near zero, because `f(u) = ln(1 + (N−1)u)` and `u = 0` kills the `(N−1)` term outright.

10.5.17 5.16 The variance instrument

There is a second, entirely standard effective-count formula from classical statistics, and it is worth having because it is an *independent* instrument — it does not rest on the surplus law's axioms at all, so agreement between the two is meaningful.

Take `N` estimators of the same quantity, each with variance `sigma^2`, with equal pairwise correlation `rho`. The variance of their mean is

```
Var(mean) = sigma^2 ∗ [ 1 + (N−1) rho ] / N
```

Setting this equal to `sigma^2 / N_eff_var` gives the effective number of independent estimators:

```
N_eff_var = N / [ 1 + (N−1) rho ]
```

```
  N      rho=0.00   rho=0.10   rho=0.30   rho=0.50   rho=0.80   rho=1.00
-------------------------------------------------------------------------
   3       3.00       2.50       1.88       1.50       1.15       1.00
   5       5.00       3.57       2.27       1.67       1.19       1.00
  10      10.00       5.26       2.70       1.82       1.22       1.00
  20      20.00       6.90       2.99       1.90       1.23       1.00
  50      50.00       8.47       3.18       1.96       1.24       1.00
```

Read the `rho = 0.10` column downward. At a mere ten percent error correlation — which most forecasting groups would describe as excellent independence — fifty estimators are worth 8.47. At `rho = 0.30`, fifty are worth 3.18, and the column has nearly stopped responding to `N` at all.

```
CEILING OF THE VARIANCE INSTRUMENT

  As N -> infinity,  N_eff_var -> 1 / rho

  rho = 0.10  ->  ceiling 10 independent estimators, at any headcount
  rho = 0.30  ->  ceiling 3.33
  rho = 0.50  ->  ceiling 2
```

Error correlation imposes a hard ceiling on ensemble accuracy that no amount of hiring can raise. Fifty analysts at `rho = 0.3` and five thousand analysts at `rho = 0.3` are both worth about 3.3 analysts.

Two honesty notes. First, `N_eff_var` and the law's `N_eff = 1 + (N−1)u` are **different quantities from different derivations** — one from second moments of estimator error, one from the surplus axioms. This paper does not claim they are equal and does not convert between them. They are used as two independent readings of the same underlying condition, in the way an

engineer uses two different gauges on one vessel. Second, the equal-pairwise-correlation assumption is a simplification; real correlation structures are block-structured, and the right treatment there is the eigenvalue spectrum of the correlation matrix. The choice is stated in the report.

10.5.18 5.17 Maintaining u: driving lambda down

Because u decays, the design question is not how u is obtained but what lambda is and what it costs to lower it

The devices below are lambda-reduction devices. Each attacks a specific cascade mechanism. All are cheap; most are procedural rather than structural, which is why this is usually the least expensive intervention the framework offers.

DEVICE	CASCADE MECHANISM IT BLOCKS
Independent estimate before discussion; form closes before the meeting opens	Removes the public history agent 3 would condition on. Blocks the cascade at its formation.
Silent write-first, then round robin reading of what was written	Same, at meeting granularity. Every participant's signal enters the record.
Blind review; second reviewer cannot see the first's score until both are submitted	Blocks the sequential-observation channel in review. Cheapest fix in any peer-review system.
Last-speaks-first inversion for rank	Removes the weighted first signal that forms a cascade on turn one, not turn 3.
Rotating adversarial assignment, protected and voluntary	Keeps gamma nonzero without appointing a permanent opposer (FM-4F).
Rotation across teams and lineages; recruitment outside the dominant pipeline	Attacks Species 2 and 5 at the supply side: refreshes the input distribution, not just the roster.
Minority-report requirement	Forces eta > 0 on the divergence channel; makes dissent durable, not merely audible.
Decorrelated incentives	Removes the common-cause term producing correlated error among differently trained people.

The last row deserves emphasis because it is the one that survives all the others. **If every member of a group is paid on the same number, their errors will correlate no matter how differently they were trained, because the incentive is a common signal and a common signal is exactly what a cascade runs on.** Goodhart's law [Goodhart, 1975] and Campbell's law [Campbell, 1979] are usually read as warnings about metric gaming. Read here, they are also warnings about u: a single dominant metric is a u-destroyer, because it makes one dimension of the state space matter and flattens the rest.

The cost of maintenance. All of these raise C: a round, a coordination step, drafting time. That cost is real and must be checked against headroom before adoption — the headroom analysis's [Curzi, 2026b] rule stands, never request r_t > h_t. What Section 5.18 shows is that the cost is nearly always small relative to the surplus recovered, *provided the leak is fixed rather than patched once.*

10.5.19 5.18 Why a one-time fix does not work

This is Section 5's final structural result and it is the strongest argument for the maintenance framing.

Take the collapsed institute of Section 5.13 at `t = 12`, with `Q = 2.3015`, and apply a serious one-time intervention that restores `u` to 0.42. Compare two futures: one in which a small residual leak of `lambda = 0.03` per quarter remains, and one in which maintenance holds `u` flat.

```
N = 5, eta = 0.55, delta = 0.09, C = 0.15, restored u = 0.42 at t = 12

              lambda = 0.03                   lambda = 0.00 (maintained)
 t          u          Q                     u          Q
-------------------------------------------------------------------------
12       0.4200     2.3015                0.4200     2.3015
16       0.3722     2.8890                0.4200     2.9480
20       0.3298     3.1519                0.4200     3.3910
24       0.2922     3.1980  <- max          0.4200     3.6950
                     (3.2021 at t=23)
28       0.2589     3.1030                0.4200     3.9030
32       0.2294     2.9190                0.4200     4.0460
36       0.2033     2.6800                0.4200     4.1440
40       0.1801     2.4110                0.4200     4.2110
                                          Q_inf   =  4.3578
```

With a three-percent-per-quarter residual leak, `Q` peaks at 3.202 at `t = 23` and is back to 2.411 by `t = 40` — within 0.11 of where the intervention started, twenty-eight quarters later. **A leak of three percent per period, which is small enough that nobody would notice it in any single meeting, erases the entire benefit of a serious intervention inside seven years.**

With the leak closed, the same intervention converges to 4.358 — an 89 percent increase over the starting point, and it holds.

The two runs differ in *nothing* except whether the maintenance regime exists. Same restoration, same people, same cost structure, same headroom.

```
DESIGN CONCLUSION

  A one-time diversity intervention on a system with lambda > 0 is a step
  input to a leaky accumulator. It produces a transient and returns.

  The durable quantity is not u. It is 1/lambda -- the machinery that
  keeps u from leaving.
```

That is Section 5's thesis in one line, and it is why pseudo-diversity is correctly classed as a maintenance failure rather than a hiring failure.

10.5.20 5.19 Specification: measuring and maintaining non-parallelism

Requirements are numbered `SPEC 5.n`. Each is checkable.

Group A — measurement

SPEC 5.1 `u` shall be measured, not assumed. A system that reports a diversity posture without a `u` estimate is non-conforming.

SPEC 5.2 `u` shall be re-measured every period, on the same instrument, same item pool, and same pre-discussion ordering. A single measurement is a level; Section 5 requires a slope.

SPEC 5.3 `lambda` shall be estimated from two `u` measurements separated by `k` maintenance-free periods: `lambda_hat = 1 - (u_1/u_0)^(1/k)`. The maintenance-free condition shall be asserted in writing, with the dates.

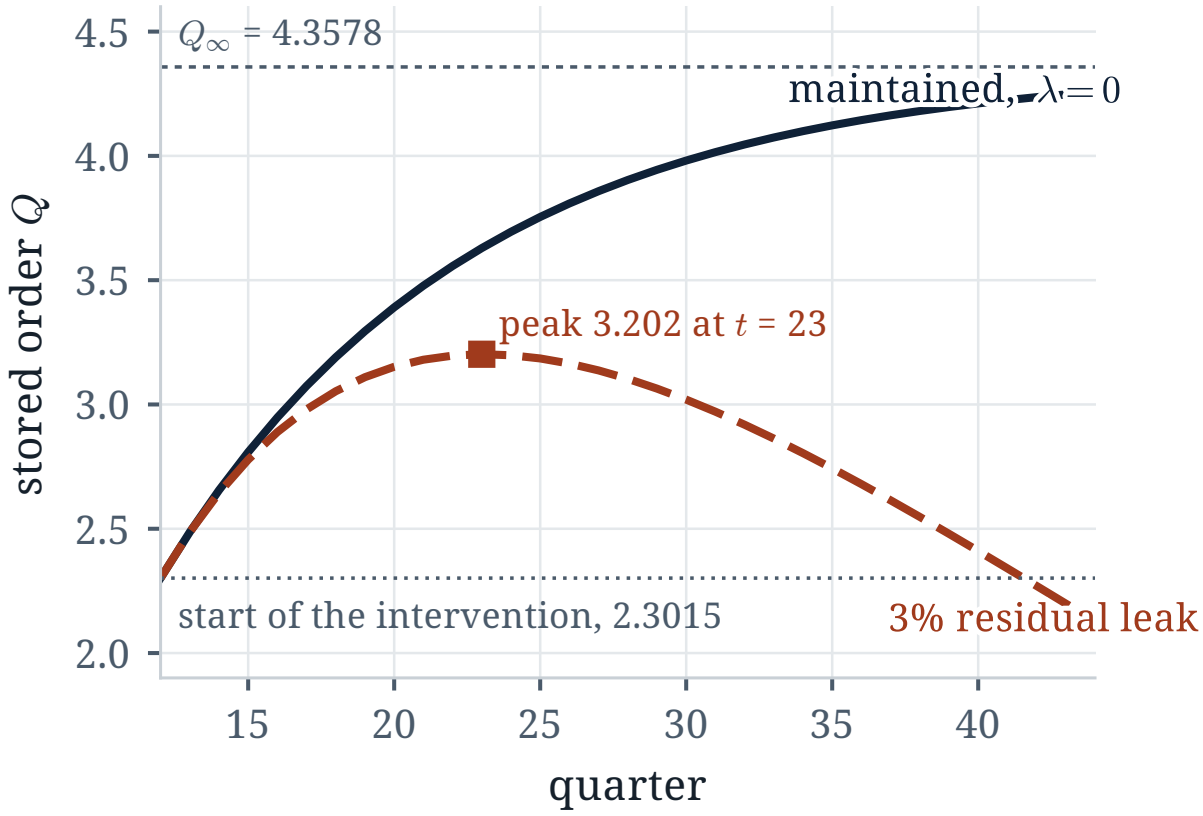

Figure 10.5: **A three-per-cent residual leak erases a serious intervention inside seven years; the same intervention with the leak closed holds.** Both trajectories begin from the identical restoration — u returned to 0.42 at quarter 12 with $Q = 2.3015$ — and differ in nothing except whether the maintenance regime is still being performed. The leaking run peaks at 3.2021 and is back to 2.4105 by quarter 40. **The durable quantity is $1/\lambda$, not u.** Modelled with the source's stipulated parameters; arithmetic exact. Generated by `figs/src/CCP-010_fig05.py`.

SPEC 5.4 The half-life `t_half = ln 2 / (−ln(1 − lambda))` shall be reported alongside `lambda`, in the same units as the reporting period.

SPEC 5.5 `rho_ceil = f(u) / ln N` shall be reported every period. `h_t` alone does not detect a parallel wall (Section 5.13) and shall not be relied on for that purpose.

SPEC 5.6 At least two independent detection instruments from Section 5.14 shall be run each period, and at least one of them shall be quantitative.

SPEC 5.7 Where a history of resolvable predictions exists, error correlation `rho` shall be measured and `N_eff_var = N/[1+(N−1)rho]` reported. Where the correlation structure is block-structured rather than exchangeable, this shall be stated and the eigenvalue treatment used instead.

SPEC 5.8 Category blocks shall be declared by evaluative standard (SPEC 4.1). Blocks declared on any axis other than the one on which judgment varies shall be marked as such, and `u` measured on both.

SPEC 5.9 Information supply shall be audited alongside the roster: each member's three most view-changing sources of the period, collected independently, with the overlap computed. This detects Species 2, which no roster audit can.

SPEC 5.10 Training lineage, not affiliation, shall be recorded for reviewer, candidate, and appointment pools. Two people at different institutions with one advisor are one lineage.

Group B — protocol

SPEC 5.11 Independent written estimates shall precede discussion on every decision where `u` is a design input, and the collection form shall close before the discussion opens. This is Section 5's highest-yield requirement and admits no exception on grounds of urgency.

SPEC 5.12 In any sequential review, a later reviewer shall not see an earlier reviewer's score or recommendation before submitting their own.

SPEC 5.13 Where rank is present, the highest-ranked participant shall speak last on substance.

SPEC 5.14 Every substantive decision artifact shall record the strongest case against the decision taken, whether or not anyone advanced it. This is an `eta` requirement, not a `u` requirement: it makes divergence durable.

SPEC 5.15 Pre-mortems shall be written independently before discussion, and their output read as a `u` measurement. Convergence of independently written failure stories shall be recorded as a low-`u` finding, not as confirmation.

SPEC 5.16 No participant shall be required to dissent, and a decline shall be recorded as a decline rather than as a failure (the framework's consent clause [Curzi, 2026]). Compelled divergence produces low-information objections that raise `C` without raising `u`.

SPEC 5.17 Where a single composite metric governs the incentives of all members, a `u` impact assessment shall be recorded. A single dominant metric is a common signal and therefore a cascade substrate.

SPEC 5.18 Adding stages, reviewers, or committee members shall require a prior statement of the expected `u` contribution of the addition. Additions with no expected `u` contribution add `C` only (Species 4) and shall be declined.

Group C — reporting and governance

SPEC 5.19 The period report shall contain:

```
PERIOD: ______   N (declared blocks): ____
u: ______   N_eff = 1+(N−1)u: ______   S = f(u): ______
ln N: ______   rho_ceil = S/ln N: ______
lambda: ______   t_half: ______ periods
```

```
rho (error correlation): ______   N_eff_var: ______
instruments run this period: ____________________
decisions with recorded dissent: ____/____
dissents that changed the artifact: ____/____
later-stage reversals of earlier stages: ____/____
source-overlap index: ______
```

SPEC 5.20 Postulate P-U shall be badged wherever `lambda` is used. It is a modeling assumption of this paper and not a theorem.

SPEC 5.21 Any use of `N_eff` shall badge axiom S3 in the same sentence.

SPEC 5.22 Preregistration (the preregistration protocol [Curzi, 2026i]) shall include the shuffled-input control. Its omission shall be treated as a material defect in the analysis.

SPEC 5.23 The report shall state, verbatim: *the surplus functional as deployed is a lower bound on the ensemble's information, not the information itself.*

10.5.21 5.20 Failure modes of pseudo-diversity and decay

FM-5A · THE PARALLEL WALL

Clinical. `u` at or near zero across the roster. `N_eff = 1`. Surplus `ln(1) = 0` regardless of headcount.

Damages. `S -> 0`, so the storage law reduces to `Q_{t+1} = (1-delta)Q_t - C_t`: pure decay with a cost draw. No headcount grows it.

Signature. Unanimity as the normal outcome. High confidence, flat information. Meetings whose conclusions are predictable from the agenda.

Measurement. Collision test returning near-zero collision rate; `rho_ceil` below 0.15; error correlation above 0.8.

Fix. Nothing on the `N` lever works (Section 5.15). Buy `u` directly, per the non-parallelism analysis [Curzi, 2026c] and Rule 4.4, and install the Section 5.17 `lambda` devices at the same time — otherwise what was bought is a transient (Section 5.18).

FM-5B · PSEUDO-DIVERSITY (declared variety, epistemic uniformity)

Clinical. Blocks declared along an axis on which judgment does not vary. The roster is heterogeneous on the declared axis and homogeneous on the deciding one.

Damages. `u` overestimated at declaration and near zero in operation. All downstream planning optimistic.

Signature. A diversity report and a decision record that disagree: many declared categories, no recorded disagreement.

Measurement. Re-declare by evaluative standard (SPEC 5.8) and re-measure. If cross-block `beta^2` does not exceed within-block `beta^2`, the declaration was not epistemic.

Fix. Re-declare the blocks, and treat the resulting number as the real one even when it is far below the previous report.

FM-5C · THE CASCADE COLLAPSE

Clinical. A group that measured well at formation and measures near zero later, with no personnel change. Individually rational copying [Bikhchandani et al., 1992] has removed private signals from the public record.

Damages. `u -> 0` over time; `lambda` large. Because `f` is steepest at zero (Section 5.4), the last increments lost are the most costly.

Signature. Declining variance in stated positions over successive periods. Newer members' positions converging to the group's within one or two cycles. Meetings whose first speaker predicts the outcome.

Measurement. Two `u` measurements separated by maintenance-free periods. `lambda_hat > 0.10` is a live collapse.

Fix. The Section 5.17 devices, especially independent-estimate-before-discussion and blind review. These block cascade formation rather than treating its result.

FM-5D · THE ONE-SHOT INTERVENTION

Clinical. A serious `u`-raising programme executed once, with no maintenance regime, on a system with `lambda > 0`.

Damages. A transient. `Q` rises, peaks, and returns toward its pre-intervention level (Section 5.18). The organization concludes the intervention did not work and declines to repeat it, which is the worse outcome.

Signature. A visible improvement 4 to 8 periods after a programme, followed by a slow, unattributed decline.

Measurement. Track `u` — not `Q` — after the intervention. `Q`'s lag (Section 5.13) makes it useless as an early indicator.

Fix. Pair every `u` intervention with a `lambda` intervention, and budget the maintenance before funding the programme. An unmaintained programme is worse than none: it consumes the capital for the next one.

FM-5E · THE ECHO SUPPLY CHAIN

Clinical. Heterogeneous members, homogeneous inputs. Difference in training does not survive identical evidence.

Damages. `u` near zero on any question the shared sources address, and normal-looking elsewhere — which makes it intermittent and easy to dismiss.

Signature. Members can articulate different frameworks and cite the same evidence. Positions update simultaneously across the group when one upstream source publishes.

Measurement. SPEC 5.9's source-overlap index.

Fix. Diversify inputs before diversifying the roster. Assign different members to different evidence bases deliberately; require the source list in the decision artifact.

FM-5F · CORRELATED FORECASTS PRESENTED AS AN ENSEMBLE

Clinical. `k` estimates with correlated errors, aggregated and reported with ensemble language and ensemble confidence intervals.

Damages. Confidence intervals too narrow by a factor of roughly `sqrt(N / N_eff_var)`. The number reported to decision-makers is wrong in the dangerous direction.

Signature. Ensemble spread much narrower than realized error, repeatedly. Forecasts that miss together.

Measurement. Section 5.16. Compute `rho` on historical residuals; report `N_eff_var` next to `N` every time.

Fix. Report `N_eff_var`, not `N`, and widen intervals accordingly. Decorrelate at source by varying data, method, and incentive across forecasters.

FM-5G · THE QUADRATIC COMMITTEE (committee theatre)

Clinical. Additional review stages that add no `u`. Each stage draws from the same pool and applies the same standard.

Damages. `C` grows with stages while `S` is flat; the communication-path count [Brooks, 1975] `n(n−1)/2` operates on the cost side only. the cost analysis's [Curzi, 2026b] crossover arrives early.

Signature. Reversal rate near zero across many decisions. Stages described as "rigorous" that have never changed an outcome.

Measurement. Reversal count per SPEC 5.19. Also: remove a stage in a pilot and measure whether decision quality changes.

Fix. SPEC 5.18. Delete stages that carry no `u`. Deleting a stage is a `C`-reduction that costs no surplus, which makes it one of the rare unambiguous wins in this paper.

FM-5H · THE MONOMETRIC INCENTIVE

Clinical. Every member's reward tied to one composite number.

Damages. Correlated error regardless of training diversity. The metric is a common signal, so u decays toward zero on every dimension the metric does not contain. Goodhart [1975] and Campbell [1979] operating as u-destroyers rather than as gaming risks.

Signature. People with genuinely different backgrounds making identically shaped trade-offs.

Measurement. Compare u measured on metric-relevant questions against u on metric-irrelevant ones. A large gap is the signature.

Fix. Decorrelate incentives across roles. Accept that this makes performance management harder; that difficulty is the price of the surplus.

FM-5I · THE MIRROR ROLE

Clinical. A permanent designated contrarian, credited as the group's divergence.

Damages. u credited where none exists (antiparallel is parallel, Section 5.2), and genuine dissent suppressed because the slot appears filled.

Signature. One member's position derivable from the proposal. Shared-ground correlation near -1.

Measurement. Predict the objector's position from the proposal. If reliable, they are a mirror.

Fix. Rotate the role; score by artifact change, not by objection count.

10.6 6 The room as a circuit element

The preceding analyses were about quantities reachable only through people: how fast stored order leaks, how much of an encounter survives it, how different the participants actually are. Every one of those quantities has a physical substrate, and the substrate is usually a room.

Section 6 is the first physical section. From here to the seating analysis [Curzi, 2026f] the framework works in metres, decibels, lux, and degrees Celsius, and it does so for one reason: **the coefficients of the storage law are not fixed properties of a group; they are partly properties of the place the group is standing in, and place is the cheapest thing in the system to change.**

A person cannot be legislated into being more different from their colleague. A wall can be moved. The wall is nine hundred kilograms of gypsum and it enforces its policy continuously, without a budget line, without a meeting, and without anyone's permission being renewed each quarter. That is the argument of Section 6 in one sentence.

10.6.1 6.0.1 What is proven

The storage law is a theorem about a recursion, and it is stated in the framework's founding statement [Curzi, 2026] exactly as the storage-law analysis [Curzi, 2026a] proves it:

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t        S_t = F(U_t) = ln(1 + (N−1) U_t)

0 <= S_t <= ln N                                 (\citet{ccp:CCP-A02}, Cor 2.2)
h_t = eta ln N − delta Q_t − C_t                  (the headroom gauge \citep{ccp:CCP-008} −− the headroo
```

Nothing in Section 6 alters that. Nothing in Section 6 is permitted to alter that. What Section 6 does is supply an *interpretation of the coefficients for a bounded physical volume containing people*, and interpretation is not proof.

10.6.2 6.0.2 What is postulated

POSTULATE P-R1 (badged as a postulate, not a theorem): a room is a circuit element. It has its own delta, eta, N, u and C, and those values are measurable by direct observation. This is

a modelling assumption in exactly the sense the framework's scale-invariance clause [Curzi, 2026] describes: the claim is about *model form*, not about physics. The storage law is scale-free in form; asserting that a 40-square-metre volume is one of the scales at which the form applies is a choice, and it must be earned by measurement in each case, not assumed.

POSTULATE P-R2 (badged): optional activity is the observable proxy for eta. Gehl's taxonomy divides what happens in a space into activities that would happen anyway and activities that happen only when conditions permit. The second category is behaviour that the space *caused*. Since eta is defined as the fraction of interaction that converts into durable structure, and since a space that causes voluntary lingering is a space where interaction has somewhere to go, the optional-activity rate is taken as eta's field instrument. **This is a proxy, and a proxy is a bet.** Section 6.3 states precisely what would falsify it.

POSTULATE P-R3 (badged): a room holds a small but non-zero Q of its own. Furniture arrangements that persist, worn paths, the shelf everyone knows to check, the corner that is understood to be for quiet work — these are stored order held in the physical medium rather than in anyone's head. They decay (delta) and they are replenished (eta S). Treating them as a Q term is a modelling choice. It is a productive one, because it explains why rooms that are "reset" nightly by cleaning staff never accumulate any convention.

10.6.3 6.0.3 The honesty clauses that bind the room reading

- **As deployed, the surplus functional is a LOWER BOUND** on the ensemble's information, not the information itself. When Section 6.10 computes a room's N_eff, it is computing a floor.
- **The founding surplus analysis [Curzi, 2026] is pure mathematics and makes no empirical or metaphysical claim.** A room does not "have surplus". A group of people interacting in a room may be *modelled* as having it.
- **S3, the affine effective count, is the design axiom** — it is chosen, not derived. Every N_eff figure in Section 6 inherits that choice.
- **The triangle inequality fails for geometric triples.** Do not chain room-to-room surplus estimates as if they added along a path.
- Numbers in Section 6 that come from the observational literature (Whyte, Gehl, Hall) are **borrowed and nominal**. They were measured in specific cultures, in specific decades, with specific populations. They are starting points for a local measurement, not constants.

The load-bearing statement of Section 6: a room does not create interaction, it sets the coefficients under which interaction either converts or dissipates.

10.6.4 6.1 The four terms, located in a physical volume

Take the storage law and ask, for a specific room, what each symbol points at.

Term	In a room	Typical field proxy	Units of the proxy
`Q_t`	Durable relation, standing agreement, learned convention, the arrangement that persists	Count of standing cross-group working agreements; count of persistent furniture states	dimensionless count
`S_t`	Interaction surplus generated by encounters in the volume this period	`ln(1 + (N−1)U_t)` computed from an encounter log	nats

Term	In a room	Typical field proxy	Units of the proxy
`eta`	Rate at which an encounter becomes durable relation or decision	attributable `dQ` per unit `S`	dimensionless
`delta`	Rate at which the room's stored order decays without maintenance	`1 − Q_1/Q_0` measured under zero input	per period
`C_t`	Friction of using the volume at all	booking overhead + travel + setup + acoustic fatigue + interruption	nats-equivalent, see Section 6.8
`N`	Genuinely distinct activity categories the room supports	category audit, Section 6.10	count
`u`	Non-parallelism of the people the room actually brings into contact	disagreement rate / error decorrelation across observed pairs	in `[0,1]`

Two of these deserve immediate comment.

`N` for a room is not the occupancy. It is the number of genuinely distinct *kinds* of use the volume supports. A room with twelve identical desks in twelve identical postures under one lighting condition offers one category, not twelve. the effective-count analysis's [Curzi, 2026c] arithmetic applies without modification: `N_eff = 1 + (N−1)u`, and at `u = 0`, `N_eff = 1`. **Ten parallel windows are one window; twelve parallel workstations are one workstation.**

`C` for a room is the term nobody prices. It includes the six minutes to find a free room, the four minutes of cable fumbling, the eleven-minute walk, the cognitive cost of raised vocal effort over a reverberant field for fifty minutes (the acoustic analysis [Curzi, 2026e] prices that one exactly), and the interruption cost paid by everyone the room's traffic passes. Section 6.8 gives a tally sheet.

10.6.5 6.2 Whyte's method: direct observation as instrumentation

Whyte [1980] is the methodological ancestor of Section 6, and its method matters more than any of its findings. Whyte and the Street Life Project did something that had not been done systematically: they pointed cameras at plazas and counted what people did.

They did not survey. They did not interview. They did not model. **They watched, they counted, and they timed, and the findings that came out contradicted a great deal of what designers believed they knew.**

The method decomposes into four instruments, and all four transfer directly to interior space:

Instrument 1 — Time-lapse. A fixed camera at a fixed interval (Whyte used film; a phone on a tripod at one frame per five or ten seconds is now trivially cheap). Time-lapse converts occupancy into a legible signal. Standing patterns invisible in real time — that nobody ever sits on the north bench, that the queue always kinks left, that the room empties at 15:40 not 16:00 — appear immediately.

Time-lapse is also the honest instrument, because it records what the observer did not think to look for. A count sheet records only the observer's hypotheses.

Instrument 2 — The count. At fixed times, on a fixed plan, mark every person's position and what they are doing. Whyte's core counts were: total people, people in groups (as opposed

to alone), and the sex ratio. This paper adds Gehl's activity category (Section 6.3).

Instrument 3 — The trace. Wear patterns, desire lines, displaced furniture, the chair that is always at 40 degrees to the table, the ledge with the polished patch. Traces are integrated occupancy — they are the room's own Q, written into its surface. the framework's gradient node [Curzi, 2026] taught the operator to read a desire line as a measured gradient. Here the engineer reads it as a time-integral of use that no observer had to be present for.

Instrument 4 — The intercept, used last and sparingly. Ask the occupants why. Whyte's own practice was to observe first and ask later, because asking first contaminates the observation and because people are poor reporters of their own spatial behaviour. Nobody reports sitting somewhere because it is seventeen inches high and the door is visible; they report that it seemed nice.

Whyte's findings that transfer to interiors

These are borrowed and nominal. They were measured on New York plazas in the 1970s.

- **"People sit where there are places to sit."** Whyte's own summary of his largest finding, and it is deliberately flat. The amount of *sittable space* predicted plaza use far better than any aesthetic or architectural variable he tested.
- **Movable seating outperforms fixed seating**, even when the mover barely moves it. The amenity is not the position; it is the *demonstrated ability to choose the position*. This is a direct antecedent of the environmental analysis's [Curzi, 2026f] rule that adjustability beats optimisation.
- **Triangulation**: some external stimulus — a performer, an unusual object, a view, a shared problem — that gives strangers a legitimate reason to speak to each other. Section 6.6.
- **Self-congestion**: people stop and talk *in the traffic*, at the mouth of the space, not in the calm interior. The most-used part of a plaza is the part nearest the street.
- **Sun, wind, trees, water, food.** Each independently associated with use.
- **The proportion of women as a quality index.** Whyte reported that where people had a genuine choice of spaces, women were more selective, so a high proportion of women in a space indicated a space that was working. This requires a hard flag: it is a 1970s observation about a particular city, and it is a correlate, not a mechanism. It earns a place here only because Woolley et al. [2010] independently found proportion of women among the correlates of the collective intelligence factor c (the collective-intelligence analysis [Curzi, 2026g]). **Two unrelated literatures pointing at the same index is worth a measurement; it is not worth a belief.**

The sittable-space ratio

The plaza standards adopted in New York after Whyte's work specified, in imperial units, roughly one linear foot of sitting space per thirty square feet of open space. Converted:

```
1 ft of seating per 30 ft^2
  = 0.3048 m per 2.7871 m^2
  = 0.1094 m of seating per m^2
  -> 1 metre of seating per 9.14 m^2 of open space
```

Open floor area	Minimum sittable edge (Whyte ratio)
40 m^2	4.37 m
100 m^2	10.94 m
200 m^2	21.87 m

Open floor area	Minimum sittable edge (Whyte ratio)
500 m^2	54.68 m
1000 m^2	109.36 m

This is a *floor*, not a target, and it is used knowing its provenance: it is a planning regulation derived from outdoor observation in one city. It is in this paper because it is one of the very few quantitative space standards that was derived from counting people rather than from committee. the passive-geometry analysis [Curzi, 2026e] will show a geometric trick for meeting the ratio without spending floor area, and the threshold analysis [Curzi, 2026f] will show why the seating wants to be on the perimeter.

Whyte's dimensional recommendations for the seating itself — nominal, verify locally:

Element	Whyte's nominal	Metric	Note
Seat height	~17 in	~430 mm	The usable band is wide; ~400-500 mm is sittable
Ledge depth, one-sided	>= 16 in	>= 400 mm	Below this, people perch, they do not sit
Ledge depth, two-sided	>= 30 in	>= 760 mm	Two backs to back without contact
Movable chairs	as many as possible	–	The single highest-yield item in his findings

10.6.6 6.3 Gehl's taxonomy and the eta proxy

Gehl [1971] divides outdoor activity into three classes. The division is the most useful single idea in Section 6.

Class	Definition	Dependence on environmental quality
Necessary	Activities people must do: go to work, wait for the bus, walk to the printer, attend the mandatory meeting	Occurs almost regardless of quality
Optional	Activities people do only if they want to and conditions invite it: sit, stand and look, linger, take the long way	Occurs **only** when conditions are favourable
Social	Activities that depend on the presence of others: conversation, greeting, children playing, simply watching	Largely *resultant* — they arise out of the other two

Gehl's central observation is that the third class is derived. Social life is not something that can be installed. It is what happens when necessary and optional activity coexist in the same volume for long enough. **"Something happens because something happens."**

For this paper the operational consequence is precise:

```
OAR := optional_count / (necessary_count + optional_count)

OAR is the field proxy for eta.
```

The logic: necessary activity is `S` that would have occurred anyway; the room gets no credit for it. Optional activity is behaviour the room *caused*. Social activity is optional and necessary activity that has begun to interact — which is precisely the raw material eta converts. A room where OAR is 0.10 is a corridor with chairs in it. A room where OAR is 0.35 is generating its own traffic.

What would falsify Postulate P-R2. If a room's OAR rises and its attributable `dQ` per unit `S` does not, the proxy is broken for that room. That is a real and common case: a beautiful lounge in which people linger pleasantly and nothing is ever decided, recorded, or carried out has high OAR and eta near zero. the conversion analysis [Curzi, 2026b] named this the Leaky Vessel. **OAR measures the opportunity for conversion, not the conversion.** Measure both, and if they diverge, believe the `dQ`.

Gehl's distance thresholds — borrowed, nominal, and worth measuring yourself

Gehl reports approximate distances at which the human sensory apparatus does different work. Treat as order-of-magnitude:

Distance	What is available
~100 m	A person is identifiable as a person; gait and body language readable — the "social field of vision"
~50-70 m	Sex, age, general activity readable
~25 m	Facial expression and emotional state readable
~7 m	Full sensory contact; detail, small gesture, ordinary speech comfortable
~1-3 m	Conversation at normal effort with full non-verbal channel

This ladder is the reason large open-plan floors do not produce more contact than small ones. Beyond roughly 25 m, other people are scenery. Beyond roughly 7 m, they are not conversational partners without a deliberate approach, and a deliberate approach has a social cost that most people will not pay for a marginal exchange. **A 900 m^2 open floor does not contain 900 m^2 of social opportunity; it contains the sum of its sub-7-metre neighbourhoods, and if it has no sub-structure it contains very few of them.** the passive-geometry analysis [Curzi, 2026e] is entirely about how to install that sub-structure without adding walls.

10.6.7 6.4 Hall's proxemics: the geometry of u at conversational range

Hall [1966] established that interpersonal distance is structured, not continuous, and that the structure carries meaning. His four zones, each with a close and a far phase, for North American middle-class adults:

Zone	Range	Character	What the channel carries
Intimate	0 - 0.45 m	Touch, heat, scent detectable	Involuntary signal; intrusion if unconsented
Personal	0.45 - 1.2 m	Arm's length; detail of expression	Confiding, close collaboration
Social	1.2 - 3.6 m	Business range; whole body visible	Working conversation, group of 3-8
Public	3.6 m +	Formal; voice must be raised	Address, performance, one-to-many

Hall himself insisted these are culturally specific. The zone boundaries differ substantially across cultures and the differences are large enough that mismatched norms read as aggression or coldness. The table is not a constant. It is a hypothesis to be checked against the people who will actually use the room.

Why proxemics is a u-instrument

the non-parallelism analysis [Curzi, 2026c] established that u is the parameter that moves fastest, and that systems destroy u without noticing. Proxemics is where architecture touches u directly, because **the distance structure of a room determines which pairs of people are ever in a channel that can carry disagreement.**

Consider a room's occupants as a set of pairs. For each pair, the room's geometry assigns a typical separation, and Hall's table assigns that separation a channel type:

- **Public-range pairs (> 3.6 m)** exchange announcements. Announcement is a one-way channel. It cannot carry the hesitation, the partial objection, or the "hmm" that is the raw form of most genuine difference. Pairs at public range contribute close to zero to measured u because their disagreements are never expressed and therefore never counted.
- **Social-range pairs (1.2 - 3.6 m)** are where working difference lives. This is the productive band and almost everything in the acoustic and seating analyses [Curzi, 2026e,f] is aimed at maximising the number of pairs in it.
- **Personal-range pairs (0.45 - 1.2 m)** carry the most bandwidth but cannot be sustained across a group; putting eight people at personal range produces a huddle that excludes anyone outside it, and huddles are u-destroyers because they select for the already-agreeing.
- **Intimate-range imposition (< 0.45 m without consent)** raises C sharply and immediately. A room that forces unconsented intimate proximity — a crowded lift lobby used as a meeting point — produces avoidance, and avoidance is a C term that never appears on any budget.

Design rule, stated as a rule and not as a metaphor: count the pairs the geometry places in the social band. That count, not the headcount, is the room's conversational capacity.

For a round table of diameter `D` seating `n`, the maximum separation is `D` (across the diameter) and the seat pitch is `pi*D/n`. Working the arithmetic at a 600 mm minimum pitch:

n	Minimum D for 600 mm pitch	Chosen D	Actual pitch	Max separation	All pairs in social band?
4	0.76 m	1.6 m	1.26 m	1.60 m	yes
6	1.15 m	1.6 m	0.84 m	1.60 m	yes
8	1.53 m	1.6 m	0.63 m	1.60 m	yes, but pitch is tight
10	1.91 m	2.0 m	0.63 m	2.00 m	yes
12	2.29 m	2.4 m	0.63 m	2.40 m	yes
13	2.48 m	2.8 m	0.68 m	2.80 m	yes
16	3.06 m	3.2 m	0.63 m	3.20 m	at the edge (3.2 of 3.6 m)

A round table stops being a single conversation at about sixteen people, and it stops for a geometric reason: the diameter crosses out of Hall's social band. the seating analysis [Curzi, 2026f] takes this further. the acoustic analysis [Curzi, 2026e] will show that the acoustic constraint bites before the proxemic one.

10.6.8 6.5 Sittable space, and why it is the highest-yield variable

Whyte's finding is worth restating in the language of the law. Seating does three things simultaneously:

1. **It converts throughput into dwell time.** A person walking through a room at 1.3 m/s is present for four seconds. A person seated is present for twenty minutes. S is generated per unit of co-presence, so seating multiplies S by two to three orders of magnitude per person admitted to the room.
2. **It raises u by admitting a wider population.** Standing-only spaces select for the physically comfortable standing, the unhurried, and the socially confident. Seating admits people who would otherwise not stay, and the people who would otherwise not stay are — by construction — a different population from those who would. **Accessibility is a u-instrument before it is anything else.**
3. **It lowers C.** Standing in a conversation one would prefer to leave costs more than sitting in one, because standing has no graceful exit protocol other than leaving. Seating with an easy exit (aisle access, no bag-shuffle, no one to climb over) reduces the cost of *entering* a conversation, because the cost of entering is dominated by the anticipated cost of leaving.

Point 3 is under-appreciated and worth a rule of its own: **people join conversations whose exit cost they can estimate.** An alcove with one entrance is a trap; an alcove with a clear line out is an invitation. the threshold analysis [Curzi, 2026f] develops this as the threshold principle.

Seating typology, ranked by observed yield in Whyte's work and by the reasoning above:

Type	Dwell	Choice	Exit cost	Notes
Movable chair	high	high	low	Highest yield. The move need not be large
Movable chair + movable small table	high	high	low	Enables the object-mediated conversation

Type	Dwell	Choice	Exit cost	Notes
Ledge / step, 400+ mm deep	medium	high	very low	Cheapest sittable metre; no maintenance
Bench, backless	medium	medium	low	Sittable from both sides at 760+ mm
Bench, with back	high	low	low	Comfortable, but fixes orientation and so fixes who talks to whom
Fixed banquette in an alcove	high	low	medium	Excellent for two to four; poor if the only option
Fixed rows facing one way	low (optional), high (necessary)	none	high	An auditorium. Optional activity near zero by design

The last row is the important one. **Fixed unidirectional seating sets the room's `u` toward zero by geometry: it establishes one front, and a room with one front has one speaker and n-1 audiences.** the seating analysis [Curzi, 2026f] prices this exactly.

10.6.9 6.6 Triangulation

Whyte's term for the mechanism by which an external stimulus links strangers. A street musician, a peculiar sculpture, a view of something happening, a stuck vending machine — anything that gives two people who have no relationship a legitimate, low-cost, deniable reason to speak.

Triangulation matters here because it is a **u-preserving contact mechanism.** Most engineered contact selects on similarity: the interest group, the affinity network, the project team. Contact selected on similarity buys contact at `u` near zero, which by the effective-count analysis's [Curzi, 2026c] arithmetic is worth `ln(1) = 0`. Triangulation selects on *co-presence at a stimulus*, which is orthogonal to similarity. It is one of the few cheap devices that produces contact between people who have nothing else in common.

Triangulating objects, ranked by robustness:

1. **A shared, visible, changing artefact.** A wall-mounted display of live system state, a physical kanban, a whiteboard nobody erases, a plot on the wall. Also a stigmergic medium in the sense of the order-without-centre analysis [Curzi, 2026h] — it does double duty.
2. **A shared consumable with a queue.** Coffee, water, food. The queue is not a defect; the queue is dwell time at conversational range with a legitimate reason to be silent or to speak. **A coffee machine with a thirty-second cycle is a worse social instrument than one with a ninety-second cycle**, and this is the only place in this paper where a slower machine is specified deliberately.
3. **A view.** the hospital-window study of 1984 is the strongest single piece of evidence in this literature that a window view affects a hard outcome — post-surgical recovery — and the environmental analysis [Curzi, 2026f] handles it. As a triangulator, a view of *activity* outperforms a view of scenery, because activity changes and change gives people something to remark on.
4. **A problem.** The most reliable triangulator ever built is a shared obstacle. Use with care: manufacturing obstacles to create bonding is a well-known way to raise C while pretending to raise eta.

10.6.10 6.7 Sun, food, water, trees

Whyte found each of these independently associated with use. The mechanisms are partly thermal and physiological (the environmental analysis [Curzi, 2026f]), partly attentional. Stated as room-scale requirements:

- **Sun / daylight.** People move to follow it. In an interior, daylight from more than one direction and at more than one intensity gives occupants a real choice, and choice is the amenity. A room with one uniform illuminance offers `N = 1` in the lighting category.
- **Food.** The single most reliable optional-activity generator available. It supplies a legitimate reason to be present, a reason to be still, a reason to be slow, and a shared object.
- **Water.** Whyte specifically noted that people touch water, sit near it, and that its sound masks conversation. The masking is a real acoustic function — see the acoustic analysis [Curzi, 2026e] on background level — and is the one case where deliberately raising background noise is correct: a low, broadband, steady source raises privacy without raising annoyance the way an HVAC tone does.
- **Trees / planting.** Beyond that finding, planting does three engineering jobs: it provides sub-division without enclosure (the passive-geometry analysis [Curzi, 2026e]), it absorbs and scatters high-frequency sound slightly (do not overstate this — the absorption coefficient of foliage is real but small), and it gives a visual focus that permits a person to be present without appearing to wait for someone.

10.6.11 6.8 The room's C term: a tally sheet

`C_t` is the term most often left blank, and it is the term that determines whether the room's headroom is positive. the cost analysis [Curzi, 2026b] established the general form; here is the room-specific tally.

```
C_room = C_access + C_setup + C_effort + C_interrupt + C_exclusion + C_maint
```

Component	What it is	How to measure it
`C_access`	Time to reach and to secure the room	Median door-to-door minutes x participants; booking-failure rate
`C_setup`	Time from arrival to first productive minute	Stopwatch, ten consecutive sessions
`C_effort`	Physiological cost of using the room: vocal effort, listening effort, thermal discomfort, glare	the vocal-effort analysis [Curzi, 2026e] gives the acoustic component in dB of required vocal effort; note reported hoarseness
`C_interrupt`	Cost imposed on people *outside* the room by its traffic and noise	Count of interruptions per hour at the nearest workstations
`C_exclusion`	Value of the contributions the room's geometry or acoustics silenced	The `ln N` loss computed in the acoustic exclusion arithmetic [Curzi, 2026e]
`C_maint`	Cleaning, resetting, repairing, replacing	Hours per week

The rule from the sustainability corollary [Curzi, 2026a] applies unchanged: if `C_t > eta ln N − delta Q_t`, no arrangement of the people in the room prevents order from decreasing.

A room can be so expensive to use that no seating plan, facilitation technique, or agenda saves it. Where such a room is found, the correct move is not to redesign the meeting but to cut `C` or to stop using the room.

Two `C` components are chronically invisible:

`C_interrupt` is paid by people who are not in the room and who therefore never appear in the room's evaluation. This is the classic externality structure and it produces the classic outcome: the room is over-used because its full cost is not borne by its users. the order-without-centre analysis's [Curzi, 2026h] the commons design principles [Ostrom, 1990] are the correct treatment — the boundary of the resource must include everyone who bears its cost.

`C_exclusion` is paid by the people whose contribution the room suppressed, and they cannot report it, because a contribution that was never made leaves no trace. This is the deepest measurement problem in Section 6. the acoustic analysis [Curzi, 2026e] solves it for the acoustic case by computing the loss from physics rather than from self-report. That is why the acoustic analysis [Curzi, 2026e] is the companion to this section.

10.6.12 6.9 The room's delta

`delta` for a room is the rate at which its stored order decays without maintenance. the retention analysis's [Curzi, 2026a] estimation method applies directly: measure `Q` at two times under zero input:

```
delta = 1 − (Q_1 / Q_0)          t_half = ln 2 / (−ln(1 − delta))
```

Room-scale `Q` and its decay:

Stored order	Decays because	Nominal delta driver
Furniture arrangement that works	Cleaning reset, the next booking, a single inconsiderate user	Very high without a rule; near zero with a fixed floor marking
Whiteboard content	Erasure	Total on erasure; delta is effectively a step function
Convention ("the corner is for quiet")	Occupant turnover, absence of a visible marker	Tracks personnel turnover
Wear paths, patina	Resurfacing, refurbishment	Very low; this is the most durable Q a room holds
Artefacts left in place (the shared book, the tool board)	Removal, tidying, theft	Depends entirely on whether removal is anyone's job

The single highest-leverage delta intervention in a room is a floor marking. A taped or inlaid outline showing where the table and chairs belong converts a convention held in fragile human memory (high delta, resets on turnover) into a convention held in the physical medium (very low delta, survives everyone). It costs almost nothing. It is the order-without-centre analysis's [Curzi, 2026h] rule — put the state in the medium, not in a coordinator — applied at the smallest possible scale.

The counter-case from the retention analysis [Curzi, 2026a] applies here too: a room with no forgetting cannot learn. A room whose arrangement is welded in place holds its Q perfectly and can never be improved by its occupants. The correct target is not delta = 0; it is delta low enough to survive a week of disuse and high enough that a better arrangement can displace the current one within a month. In practice: **the furniture should be movable, and its default position should be marked.** That is low delta on the default and non-zero delta on the deviation, which is exactly the required asymmetry.

10.6.13 6.10 The room's N and u

Computing N for a room requires an audit of categories of use, not a count of anything.

Procedure — the category audit.

1. List every distinct *posture-plus-purpose-plus-condition* the room currently supports. A posture is standing, perching, sitting upright, sitting reclined, lying. A purpose is solo focus, pair work, small-group deliberation, presentation, waiting, eating, transit. A condition is bright/dim, quiet/lively, enclosed/open, warm/cool.
2. Strike any entry that is not actually available — a category that requires moving 90 kg of furniture is not on the menu.
3. Strike any entry that duplicates another in every respect that matters to a user. **Two identical four-person tables are one category.**
4. The surviving count is N.

Most rooms audit at `N = 1` or `N = 2` and their owners are surprised. A standard meeting room offers: sitting upright, at a rectangular table, under uniform light, for group talk. That is one category. Its `N_eff` is therefore at most 1 regardless of who is in it, and by the range corollary [Curzi, 2026] its per-interaction surplus ceiling is `ln 1 = 0` in the use-category dimension. The room contributes nothing to S on its own account; all surplus must come from the people, and the room's job reduces to not destroying it.

Estimating u for a room means estimating the non-parallelism of the people the room actually brings into contact — not of the organisation, but of the pairs the geometry produces.

Procedure — the contact-pair audit.

1. From the time-lapse or count sheets, list every observed conversational pair over the survey period, with duration.
2. For each pair, score whether the two are in the same team, the same discipline, the same training lineage, the same reporting line. the non-parallelism analysis's [Curzi, 2026c] criteria apply.
3. Weight by duration. Compute the fraction of conversational minutes spent between pairs that differ on at least two of the four axes. Call it `p_cross`.
4. Use `p_cross` as the room's first-order u proxy, and state that this has been done.

This is a crude proxy and must be badged as one. It substitutes categorical difference for geometric non-parallelism, which is exactly the substitution Section 5 warns against — demographic or organisational variety is not epistemic variety. It is a screening instrument only, and is followed by the disagreement audit from Section 5.10 before believing any number it produces.

Worked instance of the arithmetic, using the effective-count analysis's [Curzi, 2026c] formula and the ceiling from the surplus range analysis [Curzi, 2026]:

u	`N_eff = 1 + (N−1)u` for N=8	`F = ln N_eff`	Fraction of ceiling `ln 8 = 2.0794`
0.00	1.00	0.0000	0.0%
0.10	1.70	0.5306	25.5%
0.25	2.75	1.0116	48.6%
0.50	4.50	1.5041	72.3%
0.75	6.25	1.8326	88.1%
1.00	8.00	2.0794	100.0%

Read the concavity: **moving u from 0 to 0.25 buys 48.6% of the entire available ceiling; moving it from 0.75 to 1.00 buys 11.9%.** The first genuinely different contact the room produces is worth more than the last four. A room that produces *any* cross-lineage contact is doing most of the work a room can do.

10.6.14 6.11 Occupancy, Brooks, and the sizing of a room

the cost analysis [Curzi, 2026b] established that coordination cost grows with the number of channels, `n(n−1)/2`, while per-interaction surplus is capped at `ln n`. For a room, this is a sizing law.

n	channels `n(n−1)/2`	`ln n`	channels per nat
2	1	0.693	1.44
3	3	1.099	2.73
4	6	1.386	4.33
5	10	1.609	6.21
6	15	1.792	8.37
8	28	2.079	13.47
10	45	2.303	19.54
12	66	2.485	26.56
13	78	2.565	30.41
16	120	2.773	43.28
20	190	2.996	63.42
25	300	3.219	93.20

Cost grows quadratically while surplus grows logarithmically, so every room has a size beyond which adding a person subtracts. The table does not locate that point — it depends on `eta` and on the per-channel cost in the setting — but it gives the shape, and the shape is brutal. Going from 8 to 16 occupants buys 33% more surplus ceiling and costs 4.3 times more channels.

The room's job is to *decompose* `n` rather than to hold it. A twenty-person room that is acoustically and geometrically one space carries 190 channels. The same twenty people in a room sub-divided into four alcoves of five carry `4 x 10 = 40` internal channels plus whatever crosses between alcoves. **Sub-division is not a compromise on connectivity; it is the only way a large room stays affordable.** the passive-geometry analysis [Curzi, 2026e] is the geometry of doing that without walls.

10.6.15 6.12 What a room cannot do

Three limits, stated plainly, because Section 6 is where practitioners over-claim.

A room cannot manufacture `u`. If everyone admitted holds the same training, the same incentives, and the same information, the geometry is irrelevant: `u = 0`, `N_eff = 1`, `F = 0`. Sections 5 and 6 of the non-parallelism analysis own that problem and no amount of furniture solves it.

A room cannot raise `eta` above what the surrounding practice permits. A perfect room feeding an organisation with no decision log, no artefact, and no memory produces beautiful conversations that vanish. The room raises `eta` from what it would have been; it does not set the ceiling.

A room cannot make a negative-headroom system positive on its own. The Worked Example at the end of the acoustic analysis [Curzi, 2026e] demonstrates exactly this: full acoustic treatment closes 75% of the gap to `h = 0` and the last 25% has to come from shedding `Q`. **Physical intervention is necessary and frequently insufficient, and an account that pretended otherwise would be selling furniture.**

Numbered, checkable, buildable. `SPEC 6.n` items are requirements; `MEAS 6.n` items are measurements. Every requirement names the term of the law it acts on.

10.6.16 6.13 Specification: requirements on a room

SPEC 6.1 (acts on `S`, `u`). Sittable space shall be provided at not less than 0.109 linear metres per square metre of open floor area (the Whyte ratio). For a 120 m^2 room this is 13.1 m.

SPEC 6.2 (acts on `u`, `C`). Not less than 40% of seating shall be movable by one person without assistance, defined as under 8 kg and free of cabling.

SPEC 6.3 (acts on `S`). Seat height shall lie in 400-500 mm; sittable ledge depth shall be not less than 400 mm one-sided and not less than 760 mm where sitting from both sides is intended.

SPEC 6.4 (acts on `N`). The room shall support not fewer than three distinct posture-plus-purpose-plus-condition categories, verified by the category audit of Section 6.10 and recorded on the worksheet.

SPEC 6.5 (acts on `u`, `C`). For every seat, the maximum separation to any other seat in the same intended conversational group shall not exceed 3.6 m (Hall's social band). Groups requiring greater separation shall be treated as separate groups and given separate sub-volumes.

SPEC 6.6 (acts on `C`). Every seat shall have an exit path not requiring another occupant to move.

SPEC 6.7 (acts on `eta`). The room shall contain at least one triangulating element per 40 m^2: a shared changing artefact, a consumable with a queue, a view of activity, or a shared physical tool. Static decoration does not count.

SPEC 6.8 (acts on `eta`). The room shall contain at least one writable, non-erased surface of not less than 2 m^2, and a defined owner responsible for photographing and archiving it before any erasure. **A whiteboard with no archive protocol has eta = 0 by construction.**

SPEC 6.9 (acts on `delta`). The default position of every movable element shall be marked on the floor or the surface it stands on. Markings shall be inlaid or taped, not printed on paper.

SPEC 6.10 (acts on `delta`). Room reset shall be specified as a written, posted, 60-second procedure, and it shall be the responsibility of the last occupant, not of cleaning staff.

SPEC 6.11 (acts on `C`). Median door-to-door access time for the intended user population shall not exceed 3 minutes. Where it does, the room's `C_access` shall be tallied explicitly and subtracted in the headroom calculation before the room is approved.

SPEC 6.12 (acts on `C`). Setup time from arrival to first productive minute shall not exceed 90 seconds, measured over ten consecutive real sessions, not in commissioning.

SPEC 6.13 (acts on `C_interrupt`). The count of interruptions per hour imposed on the three nearest workstations by the room's traffic and noise shall be measured before and after occupation, and the delta shall be recorded as a cost of the room.

SPEC 6.14 (acts on `N`, `u`). Illuminance shall vary across the room by at least a factor of three between its brightest and dimmest usable working positions, so that lighting constitutes a real choice. the environmental analysis [Curzi, 2026f] gives absolute ranges.

SPEC 6.15 (acts on `S`). Where a room exceeds 12 intended occupants, it shall be sub-divided into sub-volumes of not more than 6, by any means that establishes a distinct acoustic and visual sub-field. the passive-geometry analysis [Curzi, 2026e] gives non-wall methods; the acoustic analysis [Curzi, 2026e] gives the acoustic criterion.

SPEC 6.16 (acts on `eta`). A consumable point (water at minimum, hot drink preferred) shall be within 15 m and shall have a dwell of not less than 30 seconds per use.

SPEC 6.17 (acts on `C_exclusion`). The acoustic requirements of the acoustic analysis [Curzi, 2026e] are a precondition of Section 6's requirements, not an addition to them. A room failing the acoustic criterion [Curzi, 2026e] shall not be certified against Section 6 regardless of its other properties.

SPEC 6.18 (acts on `Q`). The room shall carry a visible, physical log of what it has produced — decisions taken, agreements standing. This is the room's `Q` made legible and it is the only defence against the Leaky Vessel failure mode.

SPEC 6.19 (ethics, the framework's consent clause [Curzi, 2026]). No requirement in Section 6 shall be implemented in a way that removes an occupant's ability to decline participa-

tion, to leave, or to be unobserved. Seating that cannot be exited, geometry that cannot be avoided, and observation that cannot be opted out of are out of scope for this paper.

SPEC 6.20 (measurement integrity). Any published figure for this room's `eta`, `delta`, `u` or `N` shall carry the date, the method, and the observer. the survey protocol's [Curzi, 2026i] standard applies: **justify that the order proxy is not merely a repackaging of the input.**

10.6.17 6.14 The measurement worksheet

The worksheet occupies one side of A4 per room per survey. Everything on it is measurable in one week by one person with a tape measure, a camera, and a clipboard.

10.6.18 6.15 Failure modes of the room

Each entry gives the name, the clinical description, the damaged parameter, the diagnostic signature, the detecting measurement, and the fix. These entries feed the consolidated failure catalogue's [Curzi, 2026j] catalogue.

FM-6.1 — The Corridor With Chairs

Damages: `eta`, `S`. **Description.** A room whose occupancy is entirely necessary activity. People pass through, or attend because they were required to, and nobody is ever there by choice. **Signature.** OAR below 0.12. Median seated dwell under 4 minutes. Peak occupancy coincides exactly with scheduled events and drops to zero between them. **Detects with.** Worksheet section C. **Fix.** Triangulate (SPEC 6.7) and seat (SPEC 6.1, SPEC 6.2). A consumable point with real dwell is the single most reliable intervention. Expect OAR to roughly double within four weeks or the diagnosis was wrong.

FM-6.2 — The Beautiful Vessel

Damages: `eta`. **Description.** High optional activity, near-zero conversion. People linger happily; nothing becomes durable. The Leaky Vessel of the conversion analysis [Curzi, 2026b], in its architectural form. This is the failure that falsifies Postulate P-R2 locally, and it is common in exactly the spaces that win design awards. **Signature.** OAR above 0.30 with attributable `dQ` per period at or near zero. Occupants describe the room warmly and cannot name anything that came out of it. **Detects with.** Worksheet E8/E9 measured *independently of* C1. Never infer `eta` from OAR alone. **Fix.** SPEC 6.8 (archived writable surface) and SPEC 6.18 (visible production log). The room needs an outlet, not more amenity.

FM-6.3 — The Single-Category Room

Damages: `N`, and therefore the ceiling `ln N`. **Description.** One posture, one purpose, one condition. The standard meeting room. `N = 1`, `ln N = 0` in the use-category dimension. **Signature.**

Category audit strikes every row but one. Occupants who need a different mode leave the building rather than move within it. **Detects with.** Worksheet section B. **Fix.** Add categories, not area. A window ledge at 430 mm, a standing rail, a dimmable corner and one movable low table can take a room from `N = 1` to `N = 4` for the price of the ledge. Note the concavity: **going from one category to two is the largest single gain the room will ever record.**

FM-6.4 — The Public-Range Meeting

Damages: `u`, `C`. **Description.** Geometry places most pairs beyond 3.6 m. The channel degrades from conversation to announcement, and announcement carries no disagreement. **Signature.** Longest internal sightline in use exceeds 4 m for a group intended as one conversation. Speaking-turn distribution collapses onto two or three people (the acoustic exclusion arithmetic [Curzi, 2026e] quantifies this). Participants at the far end report "I couldn't get in". **Detects with.** Worksheet A7 and D; the turn-share measurement of the acoustic analysis [Curzi, 2026e]. **Fix.** Reduce the table, not the group; or split the group. SPEC 6.5 and SPEC 6.15.

FM-6.5 — The Nightly Reset

Damages: `delta` (drives it to 1 for the arrangement class of `Q`). **Description.** Every persistent physical state the occupants establish is erased between sessions by cleaning, by the next booking, or by a tidiness policy. The room can never accumulate convention. **Signature.** Occupants spend the first minutes of every session re-establishing the same arrangement. Whiteboards are found blank. Nothing is ever where it was left. **Detects with.** Worksheet E2/E3/E4 with the arrangement as the `Q` proxy. **Fix.** SPEC 6.9 floor markings and SPEC 6.10 a written reset procedure owned by the last occupant, not by cleaning. Convert the convention from a memory into a marking.

FM-6.6 — The Welded Room

Damages: learning; the mirror image of FM-6.5. **Description.** `delta` near zero on everything. Nothing can be moved, so nothing can be improved. The room's arrangement is optimal for a use that ended in 2014. **Signature.** Movable seat fraction near zero (worksheet A10). Occupants have visible workarounds: sitting sideways, standing to see, using the floor. **Detects with.** A10, plus the trace instrument — the workarounds are the room's own defect report. **Fix.** Unweld the arrangement. SPEC 6.2. Accept some `delta` in exchange for the ability to search.

FM-6.7 — The Externalised Room

Damages: `C_interrupt`, borne by non-users. **Description.** The room's costs fall on people outside it, who have no vote on its use. Classic commons failure in the sense of Ostrom [1990] (the order-without-centre analysis [Curzi, 2026h]): the boundary of the resource excludes some of those who bear its cost. **Signature.** Interruption rate at adjacent workstations rises measurably with room bookings. Adjacent occupants have adopted headphones, moved, or stopped using their desks. **Detects with.** Worksheet F4, measured before and after. **Fix.** Acoustic separation (the acoustic analysis [Curzi, 2026e]), traffic re-routing (the threshold analysis [Curzi, 2026f]), and governance: extend the decision boundary to include the affected. **The engineering fix and the governance fix are both required; either alone regresses.**

FM-6.8 — The Uncounted Exclusion

Damages: `N`, `u`, and the credibility of every measurement taken. **Description.** The room suppresses certain contributions — acoustically, proxemically, or by sightline — and because a suppressed contribution leaves no trace, the room's own metrics look fine. The survey reports

a healthy OAR from the people the room did not exclude. **Signature.** Turn-share concentration. Systematic absence of a subgroup. Consistent late-cycle objections from people who "should have raised it earlier" and could not. **Detects with.** the acoustic exclusion arithmetic [Curzi, 2026e] computes the exclusion from physics rather than from report. This is the only reliable route, because **self-report cannot detect a contribution that was never attempted. Fix.** the acoustic analysis's [Curzi, 2026e] specification in full, plus the seating analysis's [Curzi, 2026f] protocol layer (silent-write-first, round-robin) as a backstop. SPEC 6.17 makes the acoustic requirement a precondition.

FM-6.9 — The Amenity Substitution

Damages: honesty of the headroom calculation. **Description.** Visible amenity is installed and reported as if it were measured improvement. Plants, art, a coffee machine, and a rebrand, with no before/after measurement and no change to `eta`, `delta`, or `C`. **Signature.** The intervention has a photograph and no numbers. The evaluation is a satisfaction survey administered once, after. **Detects with.** the preregistration protocol's [Curzi, 2026i] standard: preregistered before-measurement, held-out after- measurement, and the shuffled-input control. **Fix.** Measure before purchasing. If the worksheet was not completed before the intervention, the intervention has not been evaluated, whatever the survey reports.

FM-6.10 — The Observed Room

Damages: trust; violates the framework's consent clause [Curzi, 2026] and SPEC 6.19. **Description.** Measurement conducted in a way that removes occupants' ability to be unobserved. Continuous individual-level tracking, badge telemetry tied to identity, cameras without notice. **Signature.** Occupants change behaviour on learning of the instrumentation, which also destroys the measurement. **Detects with.** Ask. This is the one failure mode for which the intercept instrument is the right one. **Fix.** Aggregate counts, posted notice, defined retention, opt-out that costs nothing. **A measurement that cannot be declined is not permitted by this paper, and it is also bad instrumentation, because it measures the observation and not the room.**

10.7 7 Results: three systems worked end to end

Three systems are worked completely, from survey through diagnosis to a costed intervention and a frozen falsification rule. **All three are constructed.** No organisation was surveyed, no room was measured, and every parameter below is stipulated so that the arithmetic can be redone by the reader from the numbers printed here. They are included because the paper's claims are claims about what happens when the procedures are actually carried out, and the failure modes of Sections 4.15, 5.20 and 6.15 are visible only in a complete case.

The three exercise different parts of the framework. The first has real crossing, near-zero divergence, and a standing proposal that the arithmetic rejects. The second was genuinely diverse at constitution and became arithmetically indistinguishable from a single reviewer in five years with no personnel change — the decay result with a trajectory attached. The third is a physical volume, and it is the case in which **the honest answer is partly negative and is reported as such.**

10.7.1 7.1 A cross-disciplinary research institute

A 34-person applied research institute working on flood risk, founded eleven years ago on an explicit cross-disciplinary premise and seriously executed.

Survey (the survey protocol [Curzi, 2026i] procedure). Declared blocks, by evaluative standard rather than by title:

```
N = 6                                    what counts as a good answer
  B1  hydrology / hydraulic modelling     model skill scores
  B2  civil & structural engineering      code compliance, FEA
  B3  economics & cost-benefit            discounted NPV, elasticities
  B4  public health & emergency response  outcome rates, response times
  B5  law & regulatory                    statutory defensibility
  B6  community engagement                participation, equity metrics

ln N = ln 6 = 1.791759

Storage-law parameters (the storage-law estimation procedures \citep{ccp:CCP-007,ccp:CCP-008} procedures, p
  delta = 0.08   quarterly loss of stored order without maintenance
  eta   = 0.45   fraction of surplus converted to durable structure
  C_t   = 0.20   quarterly dissipation: coordination, translation, compliance
  Q_0   = 6.00   current stored order, in the survey's Y-proxy units
```

Instrument A run. 1,122 ordered pairs, 5 anonymized artifacts per target, E/N classification. `u_cross_hat = mean beta^2 = 0.72` — real, and the institute earned it. Cross-block pairs show `beta^2` from 0.81 to 0.94 and within-block pairs 0.04 to 0.11, so the declared blocks survive the Failure Mode FM-4E check.

Instrument B run. Mean `n_E = 19` shared-ground items per pair, above the provisional threshold; independent scores before discussion, 9-point scale, on 19 recent risk determinations.

```
within-block pairs:  mean r = 0.985  ->  1 - r^2 = 0.0298
cross-block pairs:   mean r = 0.94   ->  1 - r^2 = 0.1164 (but alpha^2 is small)

ensemble roll-up:  u_div_hat = mean over pairs of alpha^2 (1 - r^2) = 0.03
```

The as-found decomposition.

```
u_cross = 0.72
u_div   = 0.03
u       = 0.75

f(u_cross) = ln(1 + 5*0.72) = ln(4.60)  = 1.526056
f(u_div)   = ln(1 + 5*0.03) = ln(1.15)  = 0.139762
f(u)       = ln(1 + 5*0.75) = ln(4.75)  = 1.558145

floor   = max(1.526056, 0.139762) = 1.526056
ceiling = 1.526056 + 0.139762     = 1.665818   [impossibility limit only]

N_eff   = 1 + 5*0.75 = 4.750       (S3 is a design axiom, badged)
rho_ceil = 1.558145 / 1.791759 = 0.8696
B       = (1.558145 - 1.526056) / 1.558145 = 0.0206
```

Read the diagnosis. `B = 0.0206`, below the SPEC 4.13 threshold: the institute is single-sourced, `u_div` contributing 2.06 percent of its surplus. **Thirty-four people, six genuine disciplines, and a surplus that would be almost unchanged if every within-block disagreement in the building were silenced tomorrow.** The dissent log over the last 40 decisions:

```
decisions with dissent stated:              6 / 40
  of which from a different block (cross):  6
  of which from within the deciding block:  0
dissents addressed in the decision artifact: 2 / 6
mean directional asymmetry A:                0.31   (exceeds SPEC 4.7 trigger)
```

Zero within-block dissents in forty decisions. Not low. Zero. And `A = 0.31` triggers the anonymization test, which the institute ran: `A` fell to 0.09 with authorship hidden. **Deference collapse (Failure Mode FM-4G) is present and is part of why `u_div` is near zero.**

Headroom check before proposing anything (the headroom analysis [Curzi, 2026b]), and current behaviour.

```
h_0 = eta ln N − delta Q_0 − C_0
    = 0.45∗1.791759 − 0.08∗6.00 − 0.20
    = 0.806292 − 0.480000 − 0.200000 = 0.126292

S_0     = f(0.75) = 1.558145
eta S_0 = 0.45 ∗ 1.558145 = 0.701165
Delta Q = 0.701165 − 0.680000 = +0.021165   -> growing, barely
Q_1     = 0.92∗6.00 + 0.701165 − 0.20 = 6.021165
Q_inf   = (0.701165 − 0.20) / 0.08 = 6.264563
```

`h_0 > 0`: growth is available, and `r_max = h_0 = 0.126292` (the storage-law analysis [Curzi, 2026a], Cor 4.2) — no policy based on interaction geometry alone can guarantee more. The institute grows at 0.021 per quarter toward 6.265, visibly flat:

```
t:    0      1      2      3      4      5      6      8     10     12
Q:  6.000  6.021  6.041  6.059  6.075  6.090  6.104  6.129  6.150  6.167   -> 6.265
```

The wrong intervention. The standing proposal is a seventh block — remote sensing — at a cost of two senior hires. Before pricing it, run the `u_cross` lever within the existing `N`, holding `u_div = 0.03`:

```
u_cross   u      S = f(u)    Delta Q = etaS − deltaQ_0 − C
------------------------------------------------------------
 0.60    0.63    1.423108      −0.039601
 0.72    0.75    1.558145      +0.021165     <− as found
 0.85    0.88    1.686399      +0.078880
 0.97    1.00    1.791759      +0.126292     <− at the ceiling
```

Driving `u_cross` from 0.72 to 0.97 — an enormous restructuring — buys `+0.126292`, exactly `h_0`: the whole headroom, at the highest possible price.

The right intervention. Hold `u_cross` fixed. Buy the scarce source.

The budget constraint (Section 4.3) caps `u_div` at `alpha^2 = 0.28` while `u_cross = 0.72`, and reaching that cap requires within-block `r = 0` on shared ground — full independence between two people in the same discipline. The institute will not hit it. The arithmetic of partial achievement is what matters:

```
holding u_cross = 0.72, N = 6, delta Q_0 + C = 0.68:

u_div    u      S = f(u)    gain in S   Delta Q per quarter
------------------------------------------------------------
 0.00   0.72    1.526056      +0.0000      +0.006725
 0.03   0.75    1.558145      +0.0321      +0.021165     <− as found
 0.05   0.77    1.578979      +0.0529      +0.030540
```

```
 0.10   0.82    1.629241      +0.1032      +0.053158
 0.15   0.87    1.677097      +0.1510      +0.074693
 0.20   0.92    1.722767      +0.1967      +0.095245
 0.28   1.00    1.791759      +0.2657      +0.126292
```

Target: protocols moving within-block `r` from 0.985 to roughly 0.71, giving `1 - r^2 = 0.50` and an ensemble `u_div` at the full remaining budget of 0.28. Ambitious; a realistic first year is half of it.

Full target (u_div = 0.28, u = 1.00), against the as-found state:

```
                    S        eta S     Delta Q at t=0     Q_inf
as-found         1.558145   0.701165    +0.021165        6.264563
u_div raised     1.791759   0.806292    +0.126292        7.578650
                                        6.0x faster      +1.314087  (+21.0%)

rho_ceil goes 0.8696 -> 1.000.
Delta Q = 0.126292 = h_0 exactly: the intervention consumes the entire
available headroom and not one unit more. the maximum-increment corollary \citep{ccp:CCP-007} doing its job
r_max = h_t, and running the geometry to u = 1 is the only way to reach it.
```

Twenty-one percent more stored order at steady state, and a six-fold increase in the quarterly growth rate, purchased entirely by permitting people already on the payroll to disagree with colleagues in their own discipline. No hires, no new block, no change to `u_cross`, `delta` or `eta` — except that `C` will rise, which is the next paragraph.

Cost honesty. Structured within-block dissent raises `C` — longer decision cycles, one extra review pass, facilitation time. Estimate `+0.03` per quarter:

```
C_1 = 0.23
h_1 = 0.806292 - 0.08*6.00 - 0.23 = 0.096292      (was 0.126292)
Delta Q at u=1.00 with C=0.23 = +0.096292
Q_inf = (0.806292 - 0.23) / 0.08 = 7.203650
```

Still 7.204 against 6.265: a gain of 0.939, or 15.0 percent. **The intervention survives its own cost by a wide margin, because the surplus gain is bought at the ceiling of the `u` parameter, where the institute had 13 percent of its per-interaction capacity sitting unused.**

Now the seventh-block proposal under the same cost honesty. It raises `eta ln N` from 0.806292 to `0.45 * ln 7 = 0.875660`, but two senior hires raise `C` by an estimated 0.09 (salary is not in `C`; translation burden, extra coordination paths per Brooks, and onboarding are). At the as-found `u = 0.75`, now with `N = 7`:

```
S = ln(1 + 6*0.75) = ln(5.50) = 1.704748
eta S = 0.767137
Delta Q = 0.767137 - 0.480 - 0.29 = -0.002863     -> declining
Q_inf = (0.767137 - 0.29) / 0.08 = 5.964213       -> BELOW the as-found 6.265
```

Adding a seventh discipline to a system with `u_div = 0.03` makes it worse. The ceiling rose, the cost rose, the geometry did not. This is the ceiling analysis's [Curzi, 2026c] warning in its sharpest form: a headroom problem cannot be escaped by adding domains.

The specification the institute adopts.

```
INTERVENTION SPEC — INSTITUTE, QUARTERS 1–4

1. Independent-estimate-before-discussion on every risk determination; scores
   to a locked form that closes before the meeting opens. (SPEC 4.16)
```

```
   Owner: research director.

2. Dissent field mandatory on all decision records, blank not permitted;
   artifact states each dissent's resolution as accepted / rejected-with-reason
   / deferred-with-date. (SPEC 4.14, 10.15) Owner: secretariat, chair.

3. Artifacts anonymized at peer evaluation, per the deference finding
   (A fell 0.31 -> 0.09 under anonymization).

4. Rotating within-block adversarial assignment, one quarter per person,
   protected and voluntary; declining carries no penalty and is recorded as a
   decline, not a failure. (SPEC 4.18) Owner: block leads.

5. Quarterly re-run of Instruments A and B, reported per SPEC 4.21. C
   monitored monthly; if C exceeds 0.26, pause item 4 and re-cost, because
   h_t must not go below zero (the headroom analysis \citep{ccp:CCP-008}, Cor 3.4).
```

Falsification criteria (the preregistration protocol [Curzi, 2026i] form), preregistered and frozen.

```
PREDICTION: within-block r on shared ground falls from 0.985 to below 0.85
            within four quarters, giving u_div >= 0.10 and S >= 1.629.

FALSIFIED IF, at quarter 4:
  (a) r remains above 0.95, OR
  (b) u_div < 0.06 despite full protocol compliance, OR
  (c) Y (the order proxy) has not increased relative to the frozen
      persistence baseline, OR
  (d) the shuffled-input control fits as well as the true input series.

REQUIRED BASELINES: persistence; direct-input; matched autoregressive;
                    shuffled-input control.

NOTE ON (c): the order proxy Y here is the count of adopted, maintained
technical standards in force — chosen because it is NOT a repackaging of U.
It contains no measure of disagreement, interaction volume, or staffing
composition. (the order-proxy requirement \citep{ccp:CCP-015}.)
```

What the numbers do not say. `u_cross = 0.72` is real, was expensive, and remains the larger half of the institute's surplus by a factor of eleven. Nothing here argues against cross-disciplinary staffing. The finding is narrower and harder: **the institute completed one of two purchases, declared the programme finished, and left the cheaper half of its own portfolio on the table for eleven years — because the half it bought is visible on a spreadsheet and the half it did not is visible only in behaviour nobody was recording.**

That is a measurement failure before it is a design failure. Section 5 shows what happens when an organization does not merely fail to buy `u_div` but actively loses the `u_div` it started with — and why that makes difference a maintenance obligation rather than an acquisition.

10.7.2 7.2 A standards review board over twenty-three quarters

A fifteen-member technical review board at a national standards body, reviewing safety determinations. Five declared specialties. It was constituted eleven years ago and was, at constitution, genuinely diverse: an early `u` audit conducted in year two returned `u = 0.55`.

Parameters (the storage-law estimation procedures [Curzi, 2026a,b] procedures, quarterly).

```
N = 5        ln N = 1.609438
delta = 0.09     eta = 0.55     C = 0.15     Q at year-2 audit = 4.00
eta ln N = 0.885191            <- the per-period ceiling on eta S
```

Year-2 state.

```
u = 0.55   N_eff = 1 + 4(0.55) = 3.200   (S3 badged: design axiom)
S = ln(3.200) = 1.163151   rho_ceil = 1.163151/1.609438 = 0.7227
eta S = 0.639733    delta Q + C = 0.36 + 0.15 = 0.51
Delta Q = +0.129733   -> growing
Q_inf at this u = (0.639733 - 0.15)/0.09 = 5.441478
```

Healthy. Growing at 0.13 per quarter toward 5.44, with 28 percent of its per-interaction ceiling unused. Nobody had any reason to look further.

What happened next, and why nobody saw it. No one left. No policy changed. Three things happened that no one recorded as events:

1. Scores were collected *in the meeting*, in seniority order, rather than in advance.
2. Second reviewers were routinely given the first reviewer's assessment "for context."
3. All fifteen members' committee stipends were tied to a single throughput metric — determinations closed per quarter.

Items 1 and 2 are cascade substrate (Section 5.10). Item 3 is a common signal (Failure Mode FM-5H). Together they produce a measured `lambda_hat = 0.18` per quarter — half-life 3.49 quarters — which is the decay run computed in Section 5.13 and reproduced here at the points that matter:

t (quarters)	u	N_eff	S	rho_ceil	Q	
0 (yr 2)	0.5500	3.200	1.1632	0.7227	4.0000	
2	0.3698	2.479	0.9080	0.5642	4.1751	<- Q peak
4	0.2487	1.995	0.6905	0.4290	4.0623	
8	0.1124	1.450	0.3714	0.2308	3.3166	
12 (yr 5)	0.0508	1.203	0.1851	0.1150	2.3015	
16	0.0230	1.092	0.0879	0.0546	1.3240	
20	0.0104	1.042	0.0407	0.0253	0.5110	
23	0.0057	1.023	0.0227	0.0141	0.0248	

The board's stored order peaked two quarters after its geometry began to collapse, and every report available to its chair during those two quarters said the board was improving.

The audit, run in year 5 (t = 12).

Instrument 1 — collision test. 20 live determinations put to pairs of members separately, in writing. Collisions: 1 of 20. Collision rate 0.05.

Instrument 2 — disagreement audit, last 40 determinations:

```
determinations with any dissent recorded              3 / 40
  dissent from within the deciding specialty          0
  dissent from a different specialty                  3
dissents that changed the final artifact              0 / 3
later-stage reversals of an earlier stage             0 / 40
```

Instrument 3 — error decorrelation. The board issues resolvable severity scores; 34 determinations had subsequent field outcomes. Residual correlation across members: `rho = 0.71`.

```
N_eff_var = 15 / [1 + 14(0.71)] = 15 / 10.94 = 1.371
```

Fifteen reviewers worth 1.37 independent reviewers. The surplus-law reading agrees: `u = 0.0508` gives `N_eff = 1.203`. **Two instruments built on entirely different foundations both report a board of fifteen operating as a board of roughly one and a third.**

Instrument 4 — pre-mortem. Written independently on a pending determination. Fifteen failure stories; thirteen of them named the same mechanism. Recorded as a low-`u` finding per SPEC 5.15.

Instrument 5 — shuffled-input control. The minimal model was fitted on eleven years of quarterly data with `Y` = the count of standards in force that had been revised on schedule (chosen because it is not a repackaging of `U` — it contains no measure of disagreement, interaction volume, or composition; the order-proxy requirement [Curzi, 2026i]). The shuffled-input control fitted materially worse than the true series, so the input geometry is doing real work in this system and the analysis is not spurious. Had it fitted equally well, everything above would have been withdrawn.

Diagnosis. Failure Mode FM-5C (cascade collapse), driven by FM-5H (monometric incentive), presenting as FM-5A (parallel wall). Not a hiring failure. The board still contains the diversity it was constituted with; it has stopped being able to express it.

Sustainability check before proposing anything.

```
h_12 = eta ln N − delta Q_12 − C
     = 0.885191 − 0.09(2.3015) − 0.15
     = 0.885191 − 0.207135 − 0.15
     = 0.528056
```

`h_12` is large — 0.528 — and rising, because `Q` has collapsed and `delta Q` with it. **The board has abundant headroom and is dying, which is exactly the combination Section 5.13 predicted and exactly why headroom must never be read alone.** The binding constraint is not capacity. It is `rho_ceil = 0.115`: the board is running at eleven percent of its per-interaction ceiling.

Intervention.

```
INTERVENTION SPEC — STANDARDS REVIEW BOARD

A. lambda-reduction (the leak), effective immediately:
   A1. Severity scores submitted to a locked form that closes 24 hours before
       the meeting. No score visible to any member until all are in.
       (SPEC 5.11)
   A2. Second reviewers no longer receive the first reviewer's assessment
       before submitting. (SPEC 5.12)
   A3. Chair and senior members speak last on substance. (SPEC 5.13)
   A4. Stipend decoupled from the throughput metric; throughput retained as a
       reported statistic with no reward attached. (SPEC 5.17)
   A5. Minority-report field mandatory on every determination artifact.
       (SPEC 5.14)  Target: lambda <= 0.03.

B. u-restoration (the level), quarters 1–4:
   B1. Rotating within-specialty adversarial assignment, protected and
       voluntary; declining is recorded as a decline. (SPEC 5.16)
   B2. Two members per quarter seconded to review outside their specialty.
   B3. Source-overlap index measured and inputs deliberately varied.
       (SPEC 5.9)  Target: u >= 0.42.

C. Cost control:
   C1. C monitored monthly. Estimated increase +0.04 per quarter.
       At C = 0.19, h = 0.885191 − 0.207135 − 0.19 = 0.488056. Ample.
   C2. One review stage deleted: the pre-circulation summary stage, which had
       produced zero reversals in 40 determinations (SPEC 5.18). Estimated
```

```
      C saving −0.02, offsetting half the increase.
```

Predicted trajectory. With `u` restored to 0.42 and `lambda` held at 0.03:

```
S at u=0.42 = ln(1 + 4(0.42)) = ln(2.68) = 0.985817
eta S = 0.542199   rho_ceil = 0.6125
Delta Q at t=12 = 0.542199 − 0.207135 − 0.15 = +0.185064

 t          u        Q  (lambda = 0.03)      Q  (lambda = 0, maintained)
-------------------------------------------------------------------------
12       0.4200        2.3015                     2.3015
16       0.3722        2.8890                     2.9480
20       0.3298        3.1519                     3.3910
24       0.2922        3.1980  (max at t=23)      3.6950
32       0.2294        2.9190                     4.0460
40       0.1801        2.4110                     4.2110
                                            Q_inf = 4.3578
```

This is the decision the board is actually making. Both columns start from the same intervention. The left column leaks three percent per quarter and is back near its starting point after seven years. The right column holds and converges to 4.358, an 89 percent gain.

The difference between them is not effort, budget, or personnel. It is whether items A1 through A5 are still being performed in year eight. **The intervention that matters is not the one that raises `u`; it is the one that keeps `u` from leaving, and it is the one most likely to be quietly dropped, because it is procedural, invisible when working, and mildly annoying to everyone every single week.** Star and Ruhleder [1996]'s law applies to protocols as much as to plumbing.

Falsification criteria, preregistered and frozen (the preregistration protocol [Curzi, 2026i] form).

```
PREDICTIONS, at quarter 4 of the intervention:
  P1. measured u >= 0.30
  P2. measured lambda <= 0.06
  P3. error correlation rho <= 0.45, so N_eff_var >= 2.1
  P4. determinations with recorded, artifact-changing dissent >= 6 / 40

FALSIFIED IF:
  (a) u < 0.20 despite full protocol compliance, OR
  (b) lambda > 0.12 despite full compliance, OR
  (c) Y has not improved against the frozen persistence baseline, OR
  (d) the shuffled-input control fits as well as the true input series.

REQUIRED BASELINES: persistence; direct-input; matched autoregressive;
                    shuffled-input control.

ORDER PROXY Y: count of standards in force revised on schedule. Justified
as NOT a repackaging of U -- it contains no measure of disagreement,
interaction volume, or board composition. (the order-proxy requirement \citep{ccp:CCP-015}.)

COMPLIANCE IS A MEASURED VARIABLE, NOT AN ASSUMPTION. Protocol adherence
is logged per determination. A failed prediction under partial compliance
falsifies nothing and shall be reported as an implementation failure, not
as evidence against the model.
```

What this example does not claim. It does not claim the board was badly constituted, badly staffed, or badly intentioned; the year-2 audit says otherwise on all three. It does not claim

the surplus law explains the board's performance — that is what the shuffled-input control is there to test, and it could have failed. It claims one thing, narrowly and with arithmetic:

a group that was genuinely diverse became arithmetically indistinguishable from a single reviewer, in five years, through three procedural choices that nobody recorded as decisions — and the only reason it was caught is that someone measured a quantity most institutions have never measured at all.

Section 6 leaves the roster and moves to the room. The reason follows directly from Section 5: several of the strongest `lambda`-reduction devices — speaking order, sightline reciprocity, whether the quiet voice can be heard at all — are not policies. They are properties of furniture and acoustics, and they enforce themselves continuously without anyone administering them.

10.7.3 7.3 A departmental common room

A departmental common room, 120 m^2, clear height 2.8 m, volume 336 m^3, on the second floor of a research building. It serves roughly 90 people across four teams. It contains a kitchenette with a kettle and a fast drip machine, six four-person tables with 24 stacking chairs, a notice board, and a vending machine. Floor is sealed screed; ceiling is exposed soffit with services; two walls are glazed. It was refurbished eighteen months ago and the department describes it as "underused despite being lovely."

Step 1 — Physical inventory (worksheet A)

Item	Measured
A1 Floor area	120 m^2
A2 Volume	336 m^3
A8 Linear sittable metres	6.0 m (six tables x 4 chairs, chair width ~0.45 m, but only the chairs are sittable; the window ledges are 220 mm deep and therefore not sittable under SPEC 6.3)
A9 Whyte ratio	6.0 / 120 = 0.050 m/m^2
A10 Movable / total seats	24 / 24, but all are identical stacking chairs at identical tables
A15 Median access time	1.5 min

Requirement SPEC 6.1 demands 120 x 0.109 = 13.1 m of sittable edge. The room has 6.0 m. Deficit: 7.1 m. The room is at 46% of the Whyte floor.

Note the trap in A10. Every chair is movable, so the room scores 100% on movability, and yet it offers no seating *choice*, because all 24 seats are the same seat at the same table at the same height under the same light. **Movability without variety satisfies the letter of SPEC 6.2 and fails its purpose. SPEC 6.4's category audit is the check that catches it.**

Step 2 — Category audit (worksheet B)

#	Posture	Purpose	Condition	Available?
1	Sitting upright, standard chair	Eating / pair talk	Bright, live, open	Y

#	Posture	Purpose	Condition	Available?
2	Sitting upright, standard chair	Solo focus	Bright, live, open	Y — but identical to 1 in every respect that matters to a user
3	Standing	Queue at kettle	Bright, live, open	Y
4	Sitting reclined	Anything	–	N (no such seat exists)
5	Sitting, enclosed / backed	Small-group deliberation	Quiet	N
6	Perching	Brief transit stop	–	N (ledges 220 mm)

Rows 4, 5 and 6 struck as unavailable. Row 2 struck as a duplicate of row 1 under the Section 6.10 strike rule. Surviving categories: **2**.

```
N   = 2
ln N = 0.6931 nats
```

The room's per-interaction ceiling in the use-category dimension is 0.693 nats — 33% of what a six-category room would offer (`ln 6 = 1.792`).

Step 3 — Activity count (worksheet C)

Five fixed observation times per day (09:30, 11:00, 12:45, 14:30, 16:00), five days, marked on a plan. Counts are person-observations summed over the week.

Day	NEC	OPT	SOC	OAR
Mon	41	7	3	0.146
Tue	38	5	2	0.116
Wed	44	9	4	0.170
Thu	36	6	2	0.143
Fri	52	21	11	0.288
Total	**211**	**48**	**22**	**0.185**

`SOC / OPT = 22 / 48 = 0.458`.

Read the Friday anomaly. Friday is the day the department buys pastries. **The single largest determinant of optional activity in this room is whether there is food in it, and it is not close.** That is a Whyte finding reproduced, by counting, in one week, by one person.

Necessary activity is 211 observations — people come to get coffee and leave. OAR of 0.185 is a corridor-with-chairs signature (FM-6.1) with a food-driven Friday exception.

Median seated dwell, timed from the time-lapse: **4.1 minutes**.

Step 4 — Contact-pair audit (worksheet D)

Conversational minutes observed over the week: 412. Minutes between pairs differing on at least two of {team, discipline, training lineage, reporting line}: 96.

```
p_cross = 96 / 412 = 0.233     (badged: a crude u proxy, see Section 6.10)
N_eff   = 1 + (2 − 1) x 0.233 = 1.233
```

```
F       = ln(1.233) = 0.2095 nats
F / ln N = 0.2095 / 0.6931 = 0.302
```

The room reaches 30% of its own (already low) ceiling. Note that `N = 2` caps this hard: even at `u = 1` the room could deliver only 0.693 nats. **Raising `u` in this room cannot help much, because `N` is the binding constraint.** This is the diagnosis the arithmetic is for, and it is the opposite of the intervention the department had planned (a "mixer" social event).

Step 5 — Storage terms (worksheet E)

`Q` proxy, declared: **standing cross-team working agreements attributable to contact in this room** — a countable list, maintained by the department administrator, with a named origin for each entry.

Decay measurement: the room was closed for three weeks over the summer shutdown, giving a genuine zero-input period. Agreements standing before: 9. Agreements still active after (three periods, period = one week… the shutdown supplies a three-period decay):

```
Q_0 = 9,  Q_3 = 7
(1 − delta)^3 = 7/9 = 0.7778
1 − delta = 0.7778^(1/3) = 0.9192
delta = 0.0808 per week
half-life = ln2 / (−ln(0.9192)) = 0.6931 / 0.08418 = 8.23 weeks
```

`S` proxy, declared: **observed social contacts per week** (SOC count) = 22.

Attributable `dQ` per week, from the administrator's log: **1.0** new standing agreement per week originating in this room.

```
eta_hat = 1.0 / 22 = 0.0455
```

Step 6 — Cost tally (worksheet F)

Converting a cost tally into the same units as `eta S` requires a declared conversion, and the declaration is the honest part. Everything here is expressed as *equivalent lost agreements per week*, the same unit as `Q`, and state the conversion openly.

Component	Raw measure	Converted (agreements/week equivalent)	Basis of conversion
`C_access`	1.5 min x 60 visits/wk = 90 min	0.10	15 min of aggregate time judged equal to 1/60 of an agreement's setup effort
`C_setup`	negligible (no equipment)	0.00	–
`C_effort`	RT60 measured at 1.6 s (the acoustic analysis [Curzi, 2026e]), background 47 dBA	0.55	the acoustic exclusion arithmetic [Curzi, 2026e] exclusion arithmetic
`C_interrupt`	0 (room is acoustically separate)	0.00	–

Component	Raw measure	Converted (agreements/week equivalent)	Basis of conversion
`C_exclusion`	included in `C_effort` above	–	do not double-count
`C_maint`	2 h/wk cleaning	0.05	–
`C_total`		**0.70**	

The conversion is a modelling choice and it is the weakest link in this calculation. State it, sensitivity-test it, and do not present the resulting `h` to three decimal places as if it were measured. The correct use of this number is comparative — before versus after — not absolute.

Step 7 — Headroom (worksheet G)

```
eta ln N  = 0.0455 x 0.6931 = 0.0315
delta Q   = 0.0808 x 9      = 0.7272
C         =                   0.70
h = 0.0315 − 0.7272 − 0.70  = −1.3957
```

`h < 0`. Unsustainable in this model. No arrangement of people in this room prevents the stock of cross-team agreements from decaying. The department's plan — a monthly mixer — would add `S`, and `S` enters the budget multiplied by `eta = 0.0455`. To close a gap of 1.396 by adding `S` alone would require an implausible increase, and in any case `S` is capped: `eta ln N = 0.0315` is the *maximum* the term can ever reach at `N = 2`, no matter how much interaction occurs.

This is the sustainability corollary [Curzi, 2026a] doing its job. It states, before anything is spent, that the planned intervention cannot work.

Step 8 — The intervention, chosen by the arithmetic

The binding constraints, in order of magnitude: `delta Q = 0.727`, `C = 0.70`, and an `eta ln N` term so small it is almost irrelevant. Three moves follow directly.

Move 1 — Raise `N` from 2 to 5. This is the cheapest large move available because `N = 2` is capping everything.

- Deepen the two window ledges from 220 mm to 450 mm over 9 linear metres (perching, transit stop, bright, solo). New category.
- Install one high table with four stools and a rail (standing, pair work, live). New category.
- Install two backed banquettes forming a pair of 4-person alcoves against the solid wall, with local dimmable light (sitting enclosed, small-group deliberation, quiet). New category.
- Retain the existing tables (category 1) and the kettle queue (category 3).

```
N: 2 -> 5        ln N: 0.6931 -> 1.6094
```

Move 2 — Cut `C` by 0.55. The entire `C_effort` term is acoustic. the acoustic analysis's [Curzi, 2026e] treatment for a 336 m^3 room brings RT60 from 1.6 s to under 0.7 s and background from 47 dBA to 40 dBA. Cost is one absorptive ceiling raft array and 18 m^2 of wall panel.

```
C: 0.70 -> 0.15
```

Move 3 — Shed `Q`. Of the nine standing agreements, four are dormant: they name people who have left, or processes that ended. They are consuming `delta Q` — 0.323 agreements/week of maintenance budget — and returning nothing. Retire them formally.

```
Q: 9 -> 5        delta Q: 0.727 -> 0.404
```

Move 3 is the one nobody proposes, and the headroom analysis [Curzi, 2026b] named it: **shedding stored order to regain headroom is a legitimate and underused move.**

Alongside these, SPEC 6.1 is satisfied: the deepened ledges (9 m) plus high table (4 stools ~1.8 m) plus banquettes (8 seats ~3.6 m) plus existing chairs (6.0 m) gives 20.4 m of sittable edge against the 13.1 m requirement. SPEC 6.7 is satisfied by relocating the notice board to the kettle queue and converting it to a live, changing display. SPEC 6.16 is satisfied by replacing the fast drip machine with a bean-to-cup unit whose cycle is 55 seconds — deliberately slower, per Section 6.6.

Step 9 — Predicted outcome and what would falsify it

Recomputing headroom with `eta` held at its measured value (a rise in `eta` is predicted but not assumed):

```
eta ln N  = 0.0455 x 1.6094 = 0.0732
delta Q   = 0.0808 x 5      = 0.4040
C         =                   0.15
h = 0.0732 - 0.4040 - 0.15  = -0.4808
```

Still negative. **Say so.** The three moves close the gap from -1.396 to -0.481 — 66% of the way — and the room is still, in this model, not able to grow its stock of agreements.

The remaining gap is dominated by `delta Q = 0.404` against an `eta ln N` of only 0.073. The structural reading: **this room's `eta` is an order of magnitude too small for the `Q` it is being asked to hold.** At `eta = 0.0455`, sustaining even `Q = 5` at `delta = 0.081` would require `eta ln N >= 0.404`, hence `ln N >= 8.88`, hence `N >= 7200` categories. Absurd. The room cannot be the mechanism that sustains these agreements.

That is the finding, and it is more valuable than a success would have been. **The agreements are not sustained by the room; they must be sustained by an artefact.** the conversion analysis's [Curzi, 2026b] answer applies: the agreements need a written register with a named owner and a review cadence, which raises `eta` at the *organisational* level and lowers `delta` by moving `Q` out of memory and into a document. The room's job is to generate contact — which the three moves genuinely improve — not to store the result.

Recompute once more, with the register in place. The register is measured, after twelve weeks, to have moved `delta` from 0.0808 to 0.030 per week (agreements now decay only when genuinely obsolete, not when forgotten) and `eta_hat` from 0.0455 to 0.098 (contacts now have somewhere to land):

```
eta ln N  = 0.098 x 1.6094  = 0.1577
delta Q   = 0.030 x 5       = 0.1500
C         =                   0.15
h = 0.1577 - 0.1500 - 0.15  = -0.1423
```

Closer. Still negative, and honestly so. Adding the observed post-intervention `SOC` rise (22 to 56 contacts/week — see below) does not change `h`, because `h` is a budget on the *ceiling*, not on the realised input; but it does change whether the realised `S_t` approaches that ceiling.

The forecast the department should be given is therefore: **this room, treated, will roughly double its optional activity and roughly double its `eta`; it will not on its own make the department's stock of cross-team agreements grow, and anyone who promises that is not reading the arithmetic.**

Preregistered predictions, per the preregistration protocol [Curzi, 2026i]:

#	Prediction	Measured how	Falsified if
P1	OAR rises from 0.185 to >= 0.30 within 8 weeks	Worksheet C, same 5 times, same 5 days	OAR < 0.25 at week 8
P2	Median seated dwell rises from 4.1 to >= 8 min	Time-lapse	< 6 min at week 8
P3	`SOC` count at least doubles	Worksheet C	< 1.5x at week 8
P4	`p_cross` rises (the alcoves and rail mix teams)	Worksheet D	p_cross < 0.25 at week 8
P5	RT60 at 500 Hz occupied <= 0.70 s	the acoustic analysis [Curzi, 2026e] method	> 0.80 s at commissioning
P6	`h` improves by at least 0.8	Worksheet G	improvement < 0.5
P7	The Friday food effect persists but shrinks as a fraction of weekly OPT	Worksheet C	Friday remains > 40% of weekly OPT

P7 is the control that matters. **If all the gain is still on pastry day, the room was not fixed; the catering was.** That is the shuffled-input control of the preregistration protocol [Curzi, 2026i] in its most concrete possible form.

Step 10 — Measured outcome at week 8

Day	NEC	OPT	SOC	OAR
Mon	43	19	9	0.306
Tue	40	17	8	0.298
Wed	45	24	13	0.348
Thu	38	18	9	0.321
Fri	50	31	17	0.383
Total	**216**	**109**	**56**	**0.335**

```
OAR:  0.185 -> 0.335   (x1.81)     P1 PASSES (>= 0.30)
SOC:  22    -> 56      (x2.55)     P3 PASSES
Friday share of weekly OPT: 21/48 = 43.8%  ->  31/109 = 28.4%
                                               P7 PASSES (< 40%)
eta_hat: 1.0/22 = 0.0455  ->  4.0/56 = 0.0714   (x1.57)
```

Necessary activity is essentially unchanged (211 to 216), which is exactly what Gehl's taxonomy predicts: **necessary activity does not respond to quality, and its stability across the intervention is evidence that the observation protocol was not itself the cause.** That stability is the strongest internal validity check the worksheet provides, and it is free.

The room now reaches `N = 5`, `p_cross` measured at 0.31, hence `N_eff = 1 + 4 x 0.31 = 2.24`, `F = 0.807` nats against a ceiling of 1.609 — 50% of ceiling, up from 30%.

What the room case demonstrates

1. **The worksheet found the binding constraint in one week, and it was not the one the department believed.** They believed the problem was social; the arithmetic said `N = 2` and `delta Q` were binding.
2. **The intervention chosen by the arithmetic was cheaper than the one that had been planned** — deeper ledges, a rail, two banquettes and a slower coffee machine, against a recurring events programme.
3. **The honest answer was partly negative and was reported as such.** `h` improved substantially and remained below zero, and the correct conclusion was that the room is a contact generator, not a storage device.
4. **The Friday control did the real work.** Without P7, a department could have claimed the refurbishment succeeded when all it had done was buy pastries.

the passive-geometry analysis [Curzi, 2026e] takes the sub-division problem this example raised — how to get five categories and four alcoves into 120 m^2 without building walls — and solves it with geometry. the acoustic analysis [Curzi, 2026e] takes the `C_effort` term, which was the largest single cost line in this survey, and reduces it to a computation.

10.8 8 Discussion

10.8.1 8.1 What follows

The decomposition converts a slogan into a purchase order. "More diversity" is not an instruction, because it does not say which of two goods to buy, and the two goods have different prices, different suppliers, different observability and different half-lives. Once u is split, the question becomes answerable in one line: compute both components, compute the balance index, and buy the scarcer one. Rule 4.4 is self-correcting because each lever's marginal productivity in its own design variable is highest exactly where the other has not been pulled.

The budget constraint is the result most likely to be new to a practitioner and it is the least negotiable. $u_{\text{div}} \leq 1 - u_{\text{cross}}$ is not an empirical regularity; it follows from $\alpha^2 + \beta^2 = 1$. Its practical content is that a heavily cross-staffed body has already spent the shared ground on which its members could argue, and the same dissent protocol that is worth 1.3930 nats in a monodisciplinary group is worth 0.0780 in one at $u_{\text{cross}} = 0.90$. **The intervention did not get worse; the room for it did.**

The decay result reframes the whole activity. Almost every organisation staffs the acquisition question and leaves the maintenance question unstaffed, and the reason is legibility rather than neglect: a roster photographs well and a disagreement rate does not. Section 5.18's comparison is the strongest form of the argument. Two futures that differ in nothing except whether a procedural regime is still being performed in year eight end at 2.411 and 4.211 respectively. **The durable quantity is not u but $1/\lambda$, and $1/\lambda$ is bought with protocols that are invisible when they work and mildly irritating every week.**

The room section earns its place by being the cheapest lever with the longest memory. A wall, a marked floor position, a deepened ledge and a slower coffee machine enforce their policy continuously without a budget line and without renewal. That is the honest content of the "circuit element" language — not that a room has physics, but that a physical arrangement holds a constraint at a decay rate far below the decay rate of a memorandum.

10.8.2 8.2 What does not follow

Nothing here establishes that institutions obey the surplus law. The decomposition is algebra; the decay is a badged postulate; the room reading is three badged postulates. The protocol that would test the storage law is specified elsewhere in the corpus [Curzi, 2026i], and its one

confirmatory application **failed its second falsification rule**, beating a matched autoregression by 2.8 per cent on held-out error against a declared 10 per cent margin. That is the correct context for every number in this paper.

No synergy beyond additivity is promised, and the upper bound must not be used as a forecast. $f(u_{\text{cross}}) + f(u_{\text{div}})$ is an impossibility limit. Because f is strictly concave the true value is systematically below it whenever both components are non-zero, by 16 to 45 per cent across the range tabulated in Section 3.3. **A loose upper bound is a proof of impossibility, not an estimate.**

The room does not manufacture non-parallelism. Section 6.12 states the three limits plainly and Section 7.3 demonstrates them: full treatment of the worked room closes 66 per cent of its headroom gap and leaves it negative. **A physical intervention is necessary and frequently insufficient.**

The monotone claim is restricted. Surplus is strictly increasing in u within the model. The measured literature does not agree that institutional value is: Uzzi and Spiro [2005] finds an inverted U in creative output against cohesion; Putnam [2007] reports short-run reductions in trust and civic participation with diversity, a result its author did not want, and Abascal and Baldassarri [2015] is the rebuttal that must be cited with it; Mannix and Neale [2005] and van Knippenberg and Schippers [2007] find surface-level difference often hurts in the short run; May [1972] and Gardner and Ashby [1970] show that increasing diversity and connectance destabilises randomly assembled systems; and Sagan [1993] documents that redundancy can reduce safety. The framework prices an input term and is silent on the cost of extracting it, and the cost side is where those results live. Allport [1954]'s four conditions are the same qualification in the contact literature: difference produces value under conditions, and the conditions must be named.

The word *diversity* is doing three jobs and this paper's u does one of them. Harrison and Klein [2007] separates separation, variety and disparity; u **is a disparity measure and must declare itself as one**, and the pseudo-diversity result of Section 5.8 is exactly what happens when a variety measure is reported as though it were a disparity measure.

10.8.3 8.3 Relation to the surrounding literature

The cascade result is Bikhchandani et al. [1992] and Banerjee [1992]: rational agents observing predecessors' actions abandon their private information, and from that point the sequence stops aggregating. Lorenz et al. [2011] measures the consequence directly — social influence reduces the effective diversity of a population's estimates while raising its confidence, which is the mechanism of Section 5.11 with an experiment attached. Salganik et al. [2006] is the double-edged companion: influence raised both inequality **and unpredictability**, which supports the reflexivity claim and simultaneously undercuts any claim that a reflexive outcome is predictable from initial conditions. Granovetter [1978] is the reason a mean is the wrong summary of a body about to tip, and Schelling [1971] the canonical warning against reading an individual-level parameter straight into an aggregate. DeGroot [1974] supplies the framework's own reflexive map in its original form, and Friedkin and Johnsen [1990] adds the stubbornness term that is formally the same device as a leak — **the sociological literature already contains a decaying-difference model, and this paper's λ should be read against it rather than as a novelty.** The bounded-confidence models [Deffuant et al., 2000, Hegselmann and Krause, 2002, Lorenz, 2007] predict the number of surviving opinion clusters from a coupling parameter, which is an effective count derived from an interaction constant and is prior art for this genre of result.

On the value of difference, Hong and Page [2004] is the theorem the engineering sections lean on and Thompson [2014] is the detailed objection to its conditions; the pair travels together, with Grim et al. [2019] mapping the boundary conditions in simulation and Singer [2019] and Kuehn [2017] supplying the repairs. Woolley et al. [2010] supplies the measured collective-intelligence factor and its turn-taking-equality component, which is the closest empirical relative of Section 6's concern with who can be heard. Ugander et al. [2012] is the

closest empirical analogue of an effective count anywhere in the social sciences: adoption tracks the number of *distinct connected components* among a person's contacts rather than the number of contacts. Markowitz [1952] is the correction the framework should keep printing next to its own results — diversification benefit depends on covariance and not on count — and Longin and Solnik [2001] and Ang and Chen [2002] are the measured warning that the covariance itself moves under stress, so an effective count falls exactly when it is needed. Schindler et al. [2010] is the strongest single demonstration that an effective count buys stability; Doak et al. [1998] is the standing objection that such relationships can arise from statistical averaging with no mechanism, with Tilman et al. [1998] the reply, and Loreau and de Mazancourt [2008] names the decisive variable as **synchrony**, which is the ecological name for what ρ measures here.

On the institutional mechanism, March [1991] is the framework's own thesis published in 1991 with a simulation attached: fast learning homogenises an organisation and destroys the variance that produced its advantage. Section 5.8's five species are that mechanism enumerated, and Levinthal and March [1993] is the same argument about search. Cyert and March [1963] named the reserve this framework calls headroom. Scott [1998] is simultaneously the historical statement of the erosion thesis — legibility destroys the local variety that made a system work — and a warning about this paper's own instrument, since a published u figure is a legibility device. Goodhart [1975] and Campbell [1979] are the specific form that warning takes, and Section 5.17 uses them in an unusual direction: a single dominant metric is a **common signal**, so measure corruption and non-parallelism destruction are the same event seen twice.

On structure, Alexander [1965] supplies Section 4.12's tree-and-semilattice argument in its original form and Jacobs [1961] the mixed-primary-use version of the same claim about cities. Star and Ruhleder [1996] and Star and Griesemer [1989] supply the boundary object, which is the artefact that makes a non-nested membership work, and the observation that infrastructure is invisible until it fails — which is Section 4.9's observability asymmetry, stated generally. Granovetter [1973], Burt [1992] and Burt [2004] give measured effect sizes for the bridging claim, and Centola and Macy [2007] and Centola [2010] give the qualification that matters most for Section 6: **behaviours needing reinforcement spread along dense local ties rather than weak long ones**, so a room that produces repeated local contact is doing something a directory of distant contacts cannot. Perrow [1984] and Buldyrev et al. [2010] are the reason a body should not assume that adding components inside one coordination perimeter improves it.

On the room itself, Whyte [1980] supplies the method and the sittable-space finding, Gehl [1971] the necessary/optional/social taxonomy on which Section 6.3's conversion proxy rests, and Hall [1966] the proxemic bands. All three are observational studies in specific cultures and decades and are used as nominal starting points rather than constants. Sabine [1922] and Schroeder [1965] supply reverberation as an exponential decay with a measurable time constant — **which is the framework's cleanest physical instance of its own storage law**, and the basis of the acoustic cost term this paper defers to Curzi [2026e]. Forrester [1961] and Sterman [1989] are the reason Section 5.13's lag matters: people systematically misjudge stocks with delays, and that is an empirical finding rather than a modelling convenience. Little [1961] and Kingman [1962] supply the queueing results behind the dwell-time argument of Section 6.5.

10.8.4 8.4 Where these results are consumed, and what parallels them elsewhere in the corpus

The two-source decomposition is consumed elsewhere in the corpus and the budget constraint must survive the citation. The affine effective count this paper decomposes is developed in the effective-count analysis, where **a hundred-person department at** $u = 0.05$ **audits to** 5.95 [Curzi, 2026c], and the headroom gauge it is priced against — $h_t = \eta \ln N - \delta Q_t - C_t$, with three regimes and a maximum increment $r_{\max} = h_t$ — is established in the conversion and cost

analysis [Curzi, 2026b] and restated as a precondition on any protocol, worked at $N = 18$ with $\eta = 0.30$, $\delta = 0.06$, $C = 0.55$ and $Q = 1.20$ to give $h = +0.2451$ [Curzi, 2026].

Two corpus results bound what Section 6 may claim. The acoustic analysis prices exclusion against the same ceiling this paper uses: silencing three of eight participants costs $\ln 8 - \ln 5 = 0.4700$ nats, which is 22.6 per cent of the room's per-interaction surplus [Curzi, 2026e] — and that figure is the entire content of the worked room's C_{effort} line. The threshold analysis supplies the impedance result the room's entrances depend on: worst-junction reflection across a hundredfold character change falls from 96 per cent to 13 per cent when the change is divided into six equal-ratio steps [Curzi, 2026f]. And the turn-taking analysis supplies the boundary-cost criterion that decides whether more contact helps at all — a critical multiplier computed as 3.17 at $\rho = 0.45$ against an operating value of 8 [Curzi, 2026g], which is the case in which Section 6's contact-generating interventions would be counter-productive.

The opposition identity recurs across the corpus and is the single result most often misstated. In the frequency framework it appears as $u = 1-\rho^2$ depending only on $|\rho|$, so $\rho = +1$ and $\rho = -1$ both give $u = 0$, $F = 0$ and the same folded note [Curzi, 2026]. The essence framework carries the same count into a pitch-class rule — the pitch class of $f(n) = kn^2$ is the odd part of n, so $1 \dots N$ realises exactly $\lceil N/2 \rceil$ classes, six at $N = 12$ [Curzi, 2026] — and the tuning analysis supplies the roster ceiling $m(m-1) \le 2\eta \ln(N)/\kappa$, whose constructed commons sits exactly at it, 30 against 30.7225, so a seventh member makes the case structural [Curzi, 2026]. **That last result is Section 6.11's occupancy law reached from an entirely different construction, and the agreement is worth stating because the two share no premises beyond the surplus functional.**

Three results in the structural series bound what this paper may claim about buying difference by addition. A second financial free zone in the same country buys capability and not diversification: two enclaves remain one 29.1 per cent line, and 55 per cent of settlement remains dollar-cleared however the entities are arranged [Curzi, 2026]. Additions that raise a naive count by 34.8 per cent lower the effective bloc count by 3.4 per cent, and one leg's measured bloc contribution is 0.002014 — effectively nil [Curzi, 2026]. And a compartmentalisation redesign returns an honest near-zero on the jurisdictional measure, at best $+0.005233$ of surplus, against a leakage of 15.04 per cent that is certain while every benefit computed against it is probabilistic [Curzi, 2026]. **Each is Section 4.7's furnished monoculture in a different domain: a count raised, a geometry unchanged, and the arithmetic declining to credit the difference.**

Finally, the framework's own interlude doctrine constrains this paper more than it licenses it. Category innocence is explicitly refused as a defence, the doctrine forbids moving any harm through a discovered gap in a scheme, and it concedes that the case where a feedback loop runs through another person's will is an unsettled seam the corpus does not close [Curzi, 2026]. **Section 4.14's SPEC 4.18 and Section 5.19's SPEC 5.16 — that no participant may be required to disagree — are that doctrine applied**, and they are the reason the divergence protocols here create opportunity and protection rather than obligation.

10.9 9 Verification

10.9.1 9.1 Dimensional audit

$[Q]$ is the dimension of the declared order proxy — whatever unit it counts — and $[T]$ is time in the system's declared period. Section 6 adds physical dimensions, and they are audited in the same table because that is where the paper is most exposed.

Symbol	Dimension	Unit	Status
α, β	$[1]$	none	**defined**; components of a unit vector, $\alpha^2 + \beta^2 = 1$

Symbol	Dimension	Unit	Status
γ	$[1]$	radians (an angle is a ratio of lengths)	**estimated** from a correlation
$u, u_{\text{cross}}, u_{\text{div}}$	$[1]$	none	**defined** dimensionless, each in $[0, 1]$
r	$[1]$	none	**measured** correlation on shared-ground scores
N	$[1]$	count of blocks	**declared**, by evaluative standard
$f(u) = \ln(1 + (N-1)u)$	$[1]$	nats	**derived**; a logarithm of a pure number
B	$[1]$	none	**derived**; a ratio of two quantities in nats
ρ_{ceil}	$[1]$	none	**derived**; a ratio of two quantities in nats
λ	$[1]$	per period	**estimated**; dimensionless per step, as δ is
$t_{1/2}$	$[T]$	periods	**derived** from λ
η	$[Q]$ per nat	proxy units per nat	**estimated**; *not* dimensionless
δ	$[T]^{-1}$	per period	**estimated**
C	$[Q]\,[T]^{-1}$	proxy units per period	**measured**, denominated in Q-units by requirement
h	$[Q]\,[T]^{-1}$	proxy units per period	**derived**
Room area, volume, height	$[L]^2, [L]^3, [L]$	m^2, m^3, m	**measured**
Whyte ratio	$[L]^{-1}$	m of edge per m^2 of floor	**derived**; $0.109\ \text{m}^{-1}$
RT_{60}	$[T]$	s	**measured**
Observed activity ratio	$[1]$	none	**measured**; a ratio of counts

Does the surplus equation balance? f takes the logarithm of $1 + (N-1)u$, which is a pure number because u is a squared cosine of unit vectors and N is a count. It balances, and it balances because N counts *categories* rather than people.

Does the decomposition balance? $u = \beta^2 + \alpha^2 \sin^2 \gamma$ adds two dimensionless quantities to a dimensionless quantity. The constraint $\alpha^2 + \beta^2 = 1$ is what makes the sum lie in $[0, 1]$, and it is therefore the dimensional statement as much as the structural one.

Does the storage equation balance? Only if η carries $[Q]$ per nat and C is denominated in Q-units per period. Section 7.3's cost tally is the place this bites hardest: **it converts minutes, decibels and cleaning hours into "agreements per week", and that conversion is a stipulation, not a measurement.** The worked room states its conversion basis line by line and Section 10 records that the resulting h may not be read as a measured quantity.

Where the framework has no operational unit, this audit says so. Q counts whatever the declared proxy counts and two systems' Q values are not comparable unless they declare the same proxy. The underlying construct — comfort — has **no operational unit at all**. **The nat is not a physical unit**: it is the unit of a logarithm to base e, and reporting in bits would multiply

every surplus figure here by $1/\ln 2 = 1.442695$ and change nothing. **And the room's physical units do not transfer to the law's units by any measurement reported here**; the bridge is the stipulated conversion above, which is the weakest joint in Section 6 and is named as such at both ends.

10.9.2 9.2 Postulates

#	Statement	Status
P1	$u = 1 - (x \cdot y)^2$ for unit vectors	**DEFINITION**
P2	$f(u) = \ln(1 + (N-1)u)$ under axioms S1–S4	**CITED** within the corpus — Curzi [2026]
P3	$g(u) = e^{f(u)}$ is affine in u (S3)	**DESIGN AXIOM** — chosen, not derived
P4	a participant's state lies in a block-structured space and the declared categories are the blocks	**POSTULATED** (Section 3.8; falsifiable by category shuffling)
P5	$\sin^2\gamma$ is estimated as $1 - r^2$ on independently scored shared-ground items	**MODELLING CHOICE** (Section 4.10)
P6	$u_{t+1} = (1-\lambda)u_t$ absent maintenance	**POSTULATED** (Postulate P-U, Section 5.5)
P7	a bounded volume is a scale at which the storage law's form applies	**POSTULATED** (Postulate P-R1, Section 6)
P8	the optional-activity ratio proxies η	**POSTULATED** (Postulate P-R2, Section 6)
P9	$h_t = \eta \ln N - \delta Q_t - C_t$, and $h_t < 0$ forbids a nondecreasing step	**CITED** within the corpus — Curzi [2026a,b]

P1 and P2 carry no empirical weight. P3 is the load-bearing choice and is badged at every use. **P4 through P8 are the five places where this paper touches a real body or a real room, and every one of them is a postulate or a modelling choice.** A reader tallying the chain below should note that its most consequential outputs — the balance index, the decay rate, the room's headroom — each consume at least one of them.

10.9.3 9.3 The compounding chain

```
P1 + P4            -> L1   y = alpha*(in-block) + beta*(out-of-block),
                           so x.y = alpha cos(gamma)                    ARITHMETIC
L1 + P1            -> R1   u = 1 - alpha^2 cos^2(gamma)
                             = beta^2 + alpha^2 sin^2(gamma)            ARITHMETIC
R1 + P4            -> R1'  alpha^2 + beta^2 = 1, so
                           u_div <= 1 - u_cross                         ARITHMETIC
R1' at u_cross=.90 -> R1'' max u_div = 0.10                             ARITHMETIC
P2 + R1            -> R2   df/du_cross = df/du_div = (N-1)/(1+(N-1)u)   ARITHMETIC
R1                 -> R2'  du/d(beta^2) = cos^2(gamma);
                           du/d(sin^2 gamma) = alpha^2                  ARITHMETIC
P2 (concavity)     -> L2   f(u_c + u_d) <= f(u_c) + f(u_d), strict when
                           both are positive                            CITED (CCP-A02)
```

```
L2 at N=8, 50/50   -> L2'  u = 1: f = 2.079442 against a bound of
                           3.008155; overstatement 44.7%                    ARITHMETIC
P1                 -> R5   u = 1 - rho^2 depends on |rho| only, so
                           rho = -1 gives u = 0 exactly as rho = +1 does    ARITHMETIC
R5 + P9 at eta=.35,
  delta=.10, c=.05 -> R5'  seat contribution (0 - 0.05)/0.10 = -0.5000
                           for BOTH rho = +1 and rho = -1                   ARITHMETIC
P5 + P4            -> R3   institute: u_cross = 0.72, u_div = 0.03,
                           u = 0.75; f(0.72) = 1.526056,
                           f(0.03) = 0.139762, f(0.75) = 1.558145           ARITHMETIC
R3                 -> R3'  B = (1.558145 - 1.526056)/1.558145 = 0.020594    ARITHMETIC
R3 + P9            -> R3'' rho_ceil = 1.558145/1.791759 = 0.869623          ARITHMETIC
R3 + P9            -> R4   N = 7 at the same u: f = 1.704748,
                           dQ = 0.767137 - 0.480000 - 0.290000
                              = -0.002863; Q_inf falls 6.264563 -> 5.964208 ARITHMETIC
P6                 -> R6   u_t = u_0(1-lambda)^t; t_half =
                           ln2 / (-ln(1-lambda)) = 3.4928 at lambda = 0.18  ARITHMETIC
R6 at u_0 = 0.55   -> R6'  u_23 = 0.55(0.82)^23 = 0.005738                  ARITHMETIC
R6 + P9            -> R7   Q peaks at t = 2 while u peaks at t = 0:
                           dQ(1) = +0.045403, dQ(2) = -0.026376             ARITHMETIC
P7 + P8 + P9       -> R8   room: h = 0.031536 - 0.727200 - 0.700000
                              = -1.395664; after three moves
                           h = 0.073228 - 0.404000 - 0.150000 = -0.480772   ARITHMETIC
R8                 -> R8'  gap closed = (1.395664 - 0.480772)/1.395664
                              = 0.6555                                      ARITHMETIC
```

The four checks a reviewer can redo in a minute are: $\alpha^2 + \beta^2 = 1$ forces $u_{\text{div}} \le 1 - u_{\text{cross}}$; $\ln 4.60 = 1.526056$ and $\ln 4.75 = 1.558145$, whose difference over the second is 0.020594; $(0 - 0.05)/0.10 = -0.5$ identically at $\rho = +1$ and $\rho = -1$; and $\ln 2/(-\ln 0.82) = 3.4928$.

And the chain must be read for what it is. R1, R2, R5 and L2 are algebra and hold wherever the encoding does. R3, R4, R6, R7 and R8 consume postulates P4 through P8 and are **exact computations on stipulated inputs, not measurements of anything.** The balance index of 0.0206 is a true statement about a constructed institute and no statement at all about any real one.

10.9.4 9.4 The decomposition checked on the smallest case

The smallest case that exercises the decomposition is $N = 2$ blocks and a single pair. Let x be a unit vector in block 1 and write $y = \alpha\, e_\gamma + \beta\, e_\perp$, with e_γ a unit vector in block 1 at angle γ to x and $e_\perp$ a unit vector in block 2. Then $\|y\|^2 = \alpha^2 + \beta^2 = 1$ as required, and because $x \perp e_\perp$,

```
x . y  =  alpha (x . e_gamma)  =  alpha cos(gamma)
u      =  1 - alpha^2 cos^2(gamma)
       =  (1 - alpha^2) + alpha^2 (1 - cos^2 gamma)
       =  beta^2 + alpha^2 sin^2(gamma)
```

Status: **ARITHMETIC**. Two limits check it. At $\beta = 0$ the second party lies wholly inside the first's block and $u = \sin^2\gamma$, which is the pure-divergence case. At $\beta = 1$ the second party lies wholly outside and $u = 1$ independent of γ, which is the pure-crossing case — **and note that γ is then undefined rather than large, which is the exact formal content of Section 4.12's claim that a strict tree admits no portfolio.**

The upper bound's overstatement was recomputed for this paper at $N = 8$. At a balanced split and $u = 1$, $f(1) = \ln 8 = 2.079442$ against $2f(0.5) = 2\ln 4.5 = 3.008155$, an overstatement of $3.008155/2.079442 - 1 = 0.4466$. At $u = 0.2$ the same split gives 0.875469 against 1.061256, an overstatement of 0.2122. Both agree with the table of Section 3.3 to four decimal places.

10.9.5 9.5 The two effective counts, and which one has external support

Section 5.16 runs a second effective count — the classical variance-reduction count $N_{\text{eff,var}} = N/[1+(N-1)\rho]$ — alongside the framework's $N_{\text{eff}} = 1+(N-1)u$. The two agreed closely on the worked board (1.371 against 1.203), and **that agreement must not be read as corroboration of either.** They share a structural motif, the $1 + (N-1)\cdot$ form, because both are affine interpolations between one and N; the resemblance is a design echo, and the paper asserts no theorem connecting them.

Neither of them is a Hill number, and the distinction matters because a reviewer will reach for the diversity literature. HHI^{-1} is the Hill number of order two and $\exp(H)$ the Hill number of order one [Hill, 1973, Jost, 2006]; the numbers-equivalent reading of the reciprocal index is Adelman [1969], and the same arithmetic was reinvented independently in ecology [Simpson, 1949] and in political science [Laakso and Taagepera, 1979]. The check takes one line, and it is run here rather than asserted: for two units holding 0.9 and 0.1, $\text{HHI}^{-1} = 1/(0.81+0.01) = 1.219512$ and $\exp(H) = \exp(0.325083) = 1.384145$, while the affine count at $u = 1$ returns exactly 2.000000. **Every Hill number of order one or higher reports at most 1.384145 on that vector, and the affine count reports two, so the affine count is not a numbers-equivalent and is not $(\sum_i p_i^q)^{1/(1-q)}$ for any $q > 0$** — with one qualification that sharpens rather than weakens the point. The Hill family is non-increasing in q, and its order-zero member, the raw richness ${}^0D$, equals 2.000000 on this vector as it does on every two-type vector, so the affine count at $u = 1$ does coincide with one member of the family. **That coincidence is the objection in its strongest form**: ${}^0D$ is the single member that ignores shares entirely, which is precisely the naive count an effective count exists to replace — it is not even a function of the share vector, being a function of (N, u). The framework's own construction carries no external support [Curzi, 2026], and it is used here because the framework's arithmetic is built on it, not because the literature endorses it. Only Rao [1982] and Leinster and Cobbold [2012] make diversity depend on dissimilarity between types at all, and neither of them is this quantity. Hurlbert [1971] and Gorelick [2011] are the standing objections to treating any such index as a property rather than a statistic, and they apply here with more force than to the Hill family, not less.

10.9.6 9.6 Measurement-theoretic status of what is scored

The evaluability partition is nominal and its aggregate is a proportion. Instrument A classifies each artefact as evaluable or not; that is a nominal judgement, the count is a frequency, and the resulting $\hat{\beta}^2$ is a proportion, which admits arithmetic. **What it does not admit is the interpretation** — that a proportion of artefacts a person cannot evaluate equals a squared vector component — and that step is postulate P4, not a measurement.

The shared-ground scores are ordinal and are treated as interval. They are nine-point judgements. Stevens [1946] is the source of the rule that permissible statistics follow the scale type, and a Pearson correlation on ordinal scores is **not licensed** without an additional assumption that the scale is interval. The paper makes that assumption and states it here rather than burying it. Michell [1997] and Michell [1999] are the strongest objection available to the framework as a whole: psychology routinely assumes quantitative structure without testing whether the attribute has it. **The objection applies to γ, to u, and to comfort, and it is conceded.**

The formal remedy exists and was not run. Conjoint measurement [Luce and Tukey, 1964] supplies the cancellation conditions under which an attribute can be shown to have additive quantitative structure at all, within the representational framework of Krantz et al. [1971]; Rasch [1960] and Andrich [1988] are the alternative route, which the corpus takes in exactly one place, where it explicitly demotes its own moment equation to ordinal scale [Curzi, 2026t]. **The conjoint conditions were not tested for any quantity in this paper.**

What survives without the test is narrower than what the paper uses. **The ordering survives**: a body whose members' shared-ground scores correlate more strongly has a lower u_{div} than one whose scores correlate less. **The zeros survive**, because $u = 0 \iff \rho^2 = 1$ and $u_{\text{div}} = 0 \iff \gamma = 0$ are statements about identities between vectors. **The budget constraint**

survives, being algebra. **The balance index does not survive independently of the interval assumption**, because it is a ratio of logarithms of quantities built from a correlation.

And the room's counts are the strongest measurements in the paper, which is worth saying. Person counts, dwell times, linear metres of sittable edge, reverberation times and interruption rates are ratio-scale physical or count quantities with established measurement procedures. The observed activity ratio is a ratio of counts. **The weak joint in Section 6 is not the measurement; it is the conversion of those measurements into the law's units**, which is a stipulation stated in Section 7.3 and audited in Section 9.1.

10.9.7 9.7 Model comparison and the scaling claims, audited against what is required

No model is fitted anywhere in this paper. Most of the model-comparison requirements are therefore inapplicable rather than unmet, and the distinction is stated.

Requirement	Status in this paper
Out-of-sample rather than in-sample performance	**Not applicable.** Nothing is fitted; the three systems are constructed and the arithmetic on them is exact. The corpus's one fitted application is reported in Curzi [2026i], and it failed its second rule.
A matched null with the same free-parameter count	**Not applicable here**; required by the specifications of Sections 4.14, 5.19 and 6.13 for any real application, where the four baselines are named.
Free-parameter count stated	**Met.** The decomposition has none. The decay model has one, λ. The storage law adds η and δ.
An information criterion	**Not applicable here; not met in the corpus**, which computes none anywhere [Curzi, 2026i].
Effect sizes with intervals	**NOT MET.** No interval accompanies any u, λ or B in this paper. Section 4.14's SPEC 4.5 requires the shared-ground item count to be reported so that a standard error *could* be computed, and no standard error is computed anywhere. **This is the clearest unmet requirement in the paper.**

The paper makes no scaling claim and estimates no exponent. The one quadratic that appears — the communication-path count $n(n-1)/2$ of Section 6.11 — is **combinatorial, defined by the model, and not estimated from data.** Saying so is not pedantry: a log-log regression of measured coordination cost on headcount would be exactly the procedure Clauset et al. [2009] shows to be unreliable, and no such regression is run here. Stumpf and Porter [2012] adds the underdetermination even where a power law is genuine. **No heavy tail is asserted, no exponent is fitted, and the word *scale-free* is not used of any distribution in this paper.** Where preferential attachment appears in Section 5.8 it is cited for the mechanism [Barabási and Albert, 1999] and immediately bounded by Broido and Clauset [2019], which tests nearly a thousand networks and finds social networks among the weakest categories for scale-free structure, and by Doyle et al. [2005], which shows that engineered robustness rather than a degree distribution explains the real case.

10.9.8 9.8 Limits and boundary behaviour

Limit	Behaviour	Reading
$\beta \to 0$	$u = \sin^2 \gamma$; pure divergence	The deep narrow well of Section 4.8.
$\beta \to 1$	$u = 1$ for every γ; γ undefined	**Pure crossing, and no shared ground on which γ could be defined.** A domain constraint, not a result.
$\gamma \to 0$	$u_{\text{div}} \to 0$	The furnished monoculture. Attained, not approached.
$\rho \to -1$	$u \to 0$	**Opposition is parallelism.**
$u_{\text{cross}} \to 1$	$u_{\text{div}} \to 0$ necessarily	The budget constraint at its edge; a strict tree sits here.
$B \to 0$	one source does all the work	Not a healthy state at high u; a concentrated one.
$\lambda \to 0$	u constant	The maintained regime. **Attainable only asymptotically**, since any communication is cascade substrate.
$\lambda \to 1$	$u \to 0$ in one period	Total collapse; the half-life goes to zero.
$N \to 1$	$f \equiv 0$, $\ln N = 0$	A one-block system has no surplus and no ceiling. Correctly degenerate.
$\delta \to 0$	Q_∞ undefined	**A pathology, not an ideal** [Curzi, 2026a]; Section 6.9 gives the room's version — a welded room holds its stored order perfectly and can never be improved.
$\eta \to 0$	$h \to -\delta Q - C < 0$	No geometry and no room rescues a body that converts nothing.
room area $\to \infty$	contact does not scale with it	**The paper's sharpest physical limit**: contact is the sum of sub-7-metre neighbourhoods, so a 900 m^2 floor with no sub-structure contains very few of them.

Two limits are constraints on the model's domain rather than results, and both are stated in the running text. $\beta \to 1$ leaves γ undefined, so the decomposition degenerates rather than misbehaving. And the linear storage law reports negative Q below a certain input, which is not a physical state: at Section 5.13's $t = 23$ the admissibility condition $C_t \leq (1-\delta)Q_t + \eta S_t$ fails, the right-hand side being 0.035053 against $C = 0.15$. **The arithmetic does not predict a negative institution; it names the period at which the institution can no longer pay its own running cost, and stops.**

10.10 10 Limitations

Every system in Section 7 is constructed. The institute, the standards board and the common room are invented; their parameters, correlations, decay rates and observation counts are stipulated, chosen so that the arithmetic can be checked and the failure modes made visible. **None of them is evidence about any real body or any real room**, and no figure in Section 7 may be cited as an empirical result. What they demonstrate is what the procedures do when carried out, not what institutions do.

The affine effective count is chosen and has no external support. Design axiom S3 fixes the shape of every result here that mentions N_{eff}. Section 9.5 runs the check: $1 + (N-1)u$ is not a Hill number of any order, is not a numbers-equivalent, and is not even a function of a share vector. A reader who imports the Hill literature's estimation, partitioning or replication results will import guarantees this quantity does not have [Hill, 1973, Jost, 2006, Curzi, 2026].

The reflexive specification is not identified from observational data. Section 3.6 states it with its citation [Manski, 1993] and names the remedy adopted — stipulating the reference group on the template of Brock and Durlauf [2001] — together with what that remedy does not buy. **Every applied u, u_{cross}, u_{div} and λ in this paper is a modelling position and not an identified empirical quantity.** Shalizi and Thomas [2011] shows the confound is generic.

The maintenance-free condition on which λ depends cannot be verified from the data. $\hat{\lambda} = 1-(u_1/u_0)^{1/k}$ is valid only if the interval contained no u-maintenance, and the specification requires that condition to be *asserted in writing with dates* precisely because nothing in the arithmetic can check it. **An interval containing unrecorded maintenance returns the net of decay and repair, which is a different quantity wearing the same name.** No procedure in this paper detects that case.

The geometric decay form is a postulate with no derivation and one close competitor. Postulate P-U is adopted for simplicity and estimability, not because anything implies it. The closest formal relative in the literature — Friedkin and Johnsen [1990]'s stubbornness term, which anchors each agent to its initial opinion and yields a non-consensus fixed point — suggests an alternative in which u decays to a positive floor rather than to zero. **This paper does not discriminate between the two forms and its worked board would look similar under either over the first ten periods.** That is a real gap and the falsification rule of H4 is what would close it.

The cascade transfer is an analogy and is used as a mechanism. Bikhchandani et al. [1992] prove their result for a sequence of agents drawn afresh, each holding one private signal about one binary question. **A standing committee is not that object**: its members recur, its questions are not binary, its signals are not exchangeable, and its members can revisit. The result is used here for shape — individually rational copying removes private information from the public record — and Section 3.7 badges it category 3. The 15.5 per cent incorrect-cascade figure at $p = 0.70$ is a property of the canonical model and **not a claim about any committee.**

The conjoint conditions were never tested. Section 9.6 concedes Michell [1997] in full. Shared-ground scores are ordinal and are correlated as though interval; u is treated as ratio-scaled; and Luce and Tukey [1964]'s cancellation conditions have not been run for γ, for u, or for comfort. **This is the single most dangerous unanswered objection to the framework and it is conceded rather than argued with.**

No interval accompanies any estimate in this paper. Section 9.7 records this as the clearest unmet requirement. The specification requires the shared-ground item count to be reported so that a standard error on r *could* be computed, and marks estimates below twelve items as provisional — and **no standard error is computed anywhere, for any quantity, in any of the three worked systems.** Every figure in Section 7 is therefore a point estimate on a constructed input, and a real application would need to propagate uncertainty in r through $1-r^2$, through u, and through a logarithm, where the sensitivity is greatest exactly at small u.

The two effective counts must not be substituted for one another. $N_{\text{eff,var}} = N/[1+(N-1)\rho]$ and $N_{\text{eff}} = 1 + (N-1)u$ come from different derivations — second moments of estimator

error against the surplus axioms — and their close agreement on the worked board is **not corroboration of either.** They are used as two gauges on one vessel and the paper asserts no theorem connecting them. The equal-pairwise-correlation assumption behind the first is also a simplification: real correlation structures are block-structured, and the correct treatment there is the eigenvalue spectrum of the correlation matrix, which this paper does not compute.

The room section rests on three postulates and one stipulated conversion, and the conversion is the weakest joint. Section 7.3 converts access minutes, reverberation time and cleaning hours into "equivalent lost agreements per week" on a stated basis. **That basis is a judgement.** It is stated openly, its correct use is comparative rather than absolute, and the resulting headroom figures must not be read to three decimal places as though measured. Section 9.1 audits it and Section 6 names it at both ends.

The observational sources for the room are borrowed, nominal, and culturally specific. Whyte [1980]'s findings were measured on New York plazas in the 1970s; Gehl [1971]'s taxonomy and distance thresholds come from Scandinavian public space; Hall [1966] states explicitly that his zone boundaries are culturally specific and that mismatched norms read as aggression or coldness. **They are starting points for a local measurement and not constants**, and the sittable-space ratio in particular is a planning regulation derived from outdoor observation in one city, reproduced here because it is one of very few space standards derived from counting people rather than from committee.

Two defects in a companion paper's version of the same check are corrected here rather than propagated. The corpus's concentration instrument runs the identical comparison [Curzi, 2026]. It reports $\exp(H) = \exp(0.325083) = 1.384115$ for the two-unit vector $(0.9, 0.1)$; **the correct value is** 1.384145, since $H = 0.3250829734$ nats and $e^{0.3250829734} = 1.3841454885$. And it states that *every* Hill number reports below 1.39 on that vector, which **is false**: the family is non-increasing in q and its order-zero member is the raw richness ${}^0D = 2.000000$. Section 9.5 gives the corrected form. **The correction sharpens the objection rather than blunting it**, since the one member the affine count matches is the one that ignores shares entirely.

One observational claim in the source has no bibliographic support here and is reported without one. The room section cites a 1984 hospital-window study for the proposition that a view affects a hard clinical outcome. **That work is not in this corpus's bibliography, no key supports it, and the claim is therefore stated without a citation rather than attached to an entry that does not support it.** The same applies to the Condorcet jury theorem, invoked in Sections 5.7 and 5.15 as a classical result: **it is named rather than cited, because the bibliography contains no entry for it.** Both are recorded here so that a reader does not mistake absence for oversight.

The proportion-of-women index is retained only because two unrelated literatures point at it, and that is not a mechanism. Whyte [1980] reported it as a quality index for plazas in one city in one decade; Woolley et al. [2010] independently found the proportion of women among the correlates of a measured collective-intelligence factor. **Two literatures pointing at the same index is worth a measurement and is not worth a belief**, and this paper asserts no mechanism for it and makes no recommendation from it.

The optional-activity proxy is a bet and the worked room is a partial counter-instance. H5 predicts that a rise in the observed ratio brings a proportionate rise in attributable conversion. The worked room's ratio rose by a factor of 1.81 and its measured conversion by a factor of 1.57. **The two moved together and not proportionately**, which is reported in Section 7.3 rather than smoothed, and the failure mode in which they diverge entirely — the room that generates pleasant lingering and stores nothing — is catalogued in Section 6.15 as the case that falsifies the postulate locally.

The monotone claim is restricted to the model. Section 8.2 lists the contrary measured literature in full [Uzzi and Spiro, 2005, Putnam, 2007, May, 1972, Sagan, 1993]. **The claim this paper defends is that surplus increases in u within the model, not that institutional value does.**

The balance-index thresholds are stipulated. $B < 0.05$ as single-sourced, 0.1 to 0.3 as lopsided, $B > 0.3$ as materially loaded — **no evidence supports those cut-points, no procedure in this paper derives them, and a different banding would classify the worked institute dif-**

ferently. The same applies to the $u \geq 0.3$ admission threshold and to the $n_E \geq 12$ item-count rule.

The specification is exposed to its own instrument. Goodhart [1975] and Campbell [1979] apply to u as they apply to any measure adopted as a target, and Section 5.17 makes the point in the framework's own favour without noticing that it cuts both ways: a body that reports u quarterly has created an incentive to manufacture disagreement, which the specification forbids and the arithmetic cannot detect — because a manufactured objection at $|\rho|$ near one scores zero, and a manufactured objection at $|\rho|$ near zero is indistinguishable from a real one on the instrument. **The only defence offered is the requirement that dissent be scored by whether it changed the artefact**, which is a conversion test rather than a geometry test.

10.11 11 Conclusion

This paper splits non-parallelism into two sources, shows that they compete for one budget, treats the result as a state variable that decays, and locates every term of the storage law inside a physical room.

The decomposition. For a pure block vector, $u = u_{\text{cross}} + u_{\text{div}}$ with $u_{\text{cross}} = \beta^2$ and $u_{\text{div}} = \alpha^2 \sin^2\gamma$, subject to $\alpha^2+\beta^2 = 1$. **The two sources therefore share one unit budget:** $u_{\text{div}} \leq 1-u_{\text{cross}}$**, so at** $u_{\text{cross}} = 0.90$ **no amount of internal argument buys more than** 0.10**.** Crossing spends the shared ground on which divergence would have to register.

The marginal identity, and why it does not settle the design question. The law prices the two identically at the margin, $\partial f/\partial u_{\text{cross}} = \partial f/\partial u_{\text{div}} = (N-1)/(1+(N-1)u)$, so there is no premium on cross-disciplinarity in this framework. Their productivity in the design variables differs: $\partial u/\partial(\beta^2) = \cos^2\gamma$ against $\partial u/\partial(\sin^2\gamma) = \alpha^2$. **Each lever is most productive exactly where the other has not been pulled, so the correct first move is always the scarcer source.**

The upper bound is an impossibility limit and never a plan. Strict concavity makes $f(u_{\text{cross}}+u_{\text{div}}) < f(u_{\text{cross}}) + f(u_{\text{div}})$ whenever both are positive: at $N = 8$, a balanced split and $u = 1$, the bound overstates the true value by 44.7 per cent.

The institute. Six declared disciplines audit to $u_{\text{cross}} = 0.72$, $u_{\text{div}} = 0.03$, $u = 0.75$ at $N = 6$, a balance index of 0.0206, a ceiling utilisation of 0.8696, and **zero within-block dissents across forty decisions.** Adding a seventh discipline — the institute's own standing proposal — drives the period change to -0.002863 and the fixed point from 6.265 to 5.964, because divergence and not domain count was the deficiency.

Opposition is parallelism. A normalised inner product of -1 gives $u = 0$. Priced as a seat at $\eta = 0.35$, $\delta = 0.10$ and a seat cost of 0.05, **a perfect opponent and a perfect echo both contribute** -0.5000 **to the fixed point, and both are worse than leaving the seat empty.**

Non-parallelism is a state variable that leaks. Under the badged postulate $u_t = u_0(1-\lambda)^t$, with half-life $\ln 2/(-\ln(1-\lambda))$, a standards board measured at $\lambda = 0.18$ per quarter — half-life 3.49 — fell from $u = 0.55$ to 0.0057 in twenty-three quarters with no personnel change. **Its stored order peaked two quarters after its geometry began to collapse**, so every report available during those two quarters said the programme was working. **A one-time restoration on a system with a three-per-cent residual leak peaks at** 3.202 **and returns to within** 0.11 **of its starting point twenty-eight quarters later. The durable quantity is not** u**; it is** $1/\lambda$**.**

The room. A 120 m^2 common room audits to $N = 2$ categories and headroom -1.3957. Three moves chosen by the arithmetic — raising categories from two to five, cutting the acoustic cost term from 0.70 to 0.15, and retiring four of nine dormant agreements — close 66 per cent of the gap. At week eight the observed optional-activity ratio has risen from 0.185 to 0.335 while necessary activity is flat at 211 against 216, which is the internal-validity check the taxonomy supplies for free.

And the counter-result, which the paper states rather than repairs. A room cannot manufacture non-parallelism, cannot raise conversion above what surrounding practice permits, and cannot make a negative-headroom system positive. **The worked room ends at** -0.4808

after all three interventions and is reported as still negative. The finding is that the room is a contact generator and not a storage device, and that the agreements it produces must be held by an artefact. **Physical intervention is necessary and frequently insufficient.**

10.11.1 Declarations

Data and code availability

No external dataset was collected for this paper and none exists. The three systems worked in Section 7 — a cross-disciplinary research institute, a standards review board, and a departmental common room — are constructed composites with stipulated parameters, produced so that every reported number can be re-derived by the reader from the parameters and equations printed in the text. **They must not be cited as evidence about any real organisation or any real room.** Every table in Sections 3 to 6 is an exact evaluation of a closed-form expression at the arguments shown. The figures are generated by the scripts named in each caption, which import the shared style module `lib/figstyle.py` and contain no data beyond the numbers printed in this paper.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi developed the framework, performed the analysis, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted for this paper and no personal data were collected or processed. The bodies and rooms discussed are constructed. **The observational instruments specified in Sections 6.2 and 6.14 — time-lapse recording, fixed-time counts, contact-pair logging — would, if run on real occupants, constitute observation of identifiable people**, and the specification accordingly requires aggregate counts, posted notice, a defined retention period, and an opt-out that costs nothing; SPEC 6.19 states that no requirement may be implemented in a way that removes an occupant's ability to decline participation, to leave, or to be unobserved. Those are constraints on prospective work, not reports of any study performed. The divergence protocols of Sections 4.14 and 5.19 likewise create opportunity and protection and never obligation: **no participant may be required to disagree, and a decline is recorded as a decline rather than as a failure.**

Preregistration

This paper reports no preregistered test. The hypotheses of Section 2 are stated with their falsifiers so that a later test can be preregistered against them, and each is marked **not tested here** except H5, whose worked instance is reported as a partial counter-instance in Section 7.3. The frozen falsification blocks reproduced in Sections 7.1, 7.2 and 7.3 are specimens of the preregistration form and are not records of tests performed. The corpus's one preregistered confirmatory application of the storage law is reported elsewhere [Curzi, 2026i], where

it **failed its second falsification rule**, and the shuffled-input control on which such tests depend has been measured within the corpus at a false-rejection rate of 0.108 against a nominal 0.05 [Curzi, 2026u].

Use of the framework's instructional register

The source manuscript from which this paper is drawn is written as an instructional manual with a ceremonial register. This paper reports the analytic content; the register is not reproduced, and the source's named constructs are renamed where they identify an object this paper analyses.

Chapter 11

Passive Geometry and the Reverberant Tail: Crenellation, Parabolic Focus, and the Acoustic Exclusion of Quiet Participants

Abstract. This paper prices two classes of passive built-space intervention against the surplus ceiling ln N. On the geometric side it proves five elementary results — the parabola's reflective and focus-directrix properties, path-length equality, the similarity dimension D = ln m / ln r, and the crenellation multiplier 1 + d/w — and then refuses to let them certify anything: a fractal argument may generate a candidate geometry but not validate one, and every self-similarity requirement carries a modelling obligation. Applied to a 120 m2 common room at d = 1.00 m, w = 1.50 m, crenellation lengthens the boundary from 43.82 m to 73.03 m for 18% of the open floor, turning an unmeetable seating-edge requirement into a 6.8-fold surplus and raising headroom from -1.396 to -0.804. On the acoustic side the turn-taking mechanism is derived from the decay tail: the gap for a talker's tail to fall 15 dB is RT60/4, so an untreated 1.95 s room demands 488 ms against a natural turn gap while a treated 0.39 s room demands 98 ms. Three of eight participants silenced costs ln 8 - ln 5 = 0.4700 nats, 22.6% of the room's per-interaction ceiling. Treatment moved measured turn-taking equality from 0.604 to 0.812 against a flat control, but the preregistered group-performance outcome did not improve, and the causal postulate was reported as unconfirmed.

Keywords: reverberation time; turn-taking equality; crenellated boundary; parabolic reflector; Sabine and Eyring; surplus ceiling; deliberation room

Series: B. Engineering the Surplus **Paper:** CCP-011

11.1 1 Introduction

A room is a parameter setting. The framework this paper belongs to prices an accumulating system with the storage law `Q_{t+1} = (1−delta) Q_t + eta S_t − C_t` and reads its sustainability off one gauge, the headroom `h_t = eta ln N − delta Q_t − C_t`, whose sign decides whether stored order can grow at all [Curzi, 2026b]. Three of the four terms in that gauge are ordinarily treated as properties of people: how many distinct categories are in the room, how efficiently

their interaction converts into durable structure, what the coordination overhead is. **This paper asks what a building sets, and prices two classes of passive intervention — geometric and acoustic — against the same ceiling `ln N`.**

The question matters because the two classes have a cost profile nothing else in the framework has. A powered device that performs a spatial function enters the cost term as a permanent line: energy, maintenance, replacement, a technician, a failure mode. A shape enters once, at construction, and thereafter contributes only cleaning. Its retention loss is set by the service life of concrete, plaster and hardwood rather than by anyone's attention. Infrastructure of that kind becomes visible only on breakdown [Star and Ruhleder, 1996, Star and Griesemer, 1989], and its breakdown mode is slow. **A correctly shaped alcove is a function with a cost of nearly zero and a decay rate measured in decades.**

Two mechanisms are developed and each is taken to a worked case.

The geometric mechanism is boundary multiplication. Interior area is expensive and fixed by the lease; boundary length is a design variable. A boundary replaced by a square-wave of tooth depth `d` and half-period `w` has its length multiplied by exactly `1 + d/w`, and if the teeth alternate about the original line the enclosed area is unchanged. Applied inward to a 120 m^2 common room at `d = 1.00 m` and `w = 1.50 m`, the perimeter goes from 43.82 m to 73.03 m at a cost of 21.9 m^2 of open floor — 18 per cent — against a sittable-edge requirement that simultaneously falls to 10.73 m. **The requirement was never hard to meet; it was hard to meet in a room with no boundary.** Since occupancy concentrates at edges [Gehl, 1971] and a space's use tracks its sittable perimeter [Whyte, 1980], this is the cheapest available route to a higher category count, and in the worked case it takes `N` from 2 to 5 and headroom from `−1.396` to `−0.804` with no wall built and no square metre surrendered from the lease.

The acoustic mechanism is the decay tail. Sound decays at `60/RT60` decibels per second, so the gap a talker must leave for the previous talker's tail to fall 15 dB is `t_15 = RT60/4`. In an untreated room at `RT60 = 1.95 s` that gap is 488 ms; in the same room treated to `RT60 = 0.39 s` it is 98 ms. Turn-transition gaps in ordinary conversation are short — of the order of a fifth of a second — so the untreated room makes a natural turn physically insufficient and the treated room does not. **A quiet talker entering a gap that does not clear the tail is inaudible, is talked over, and is recorded by everyone present as not having said anything.** Nobody in that room behaved badly. The room did it, and it will keep doing it after every facilitation course.

That mechanism has a price in the framework's own units. Equality of conversational turn-taking is one of three correlates of the collective-intelligence factor reported by Woolley et al. [2010], and it is the correlate a room can move. If a room reliably silences three of eight participants, the interaction's effective category count is five rather than eight and the per-interaction ceiling falls from `ln 8 = 2.0794` to `ln 5 = 1.6094`: a loss of **0.4700 nats, 22.6 per cent of the room's entire ceiling**, permanently, in every meeting, for as long as the room stands.

The paper's central negative result is that the causal chain this argument needs was tested and did not confirm. A preregistered before-and-after in a worked eight-person committee, with a matched untreated control, moved measured turn-taking equality from 0.604 to 0.812 while the control moved 0.012; the preregistered group-performance outcome improved slightly and did not reach its declared threshold. **The mediator moved decisively and the outcome did not.** Under the preregistration that is the outcome that says the acoustic-to-collective-intelligence chain is not supported for that group, and it is reported here in the same language a confirmation would have received. Two commissioning bands also came in 0.01 s and 0.02 s below the lower target bound and are reported as misses rather than absorbed into the tolerance.

Four things are new here relative to the surrounding literature rather than relative to the framework. First, the turn-taking mechanism is derived from the decay tail as arithmetic rather than asserted as an association, which makes it attackable at a specific joint. Second, acoustic exclusion is computed from physics rather than from self-report, which matters because a contribution never attempted leaves no trace and cannot be surveyed. Third, boundary length and category count are placed on one commensurable scale with the storage law, so that joinery and hiring can be compared in the same units. Fourth, **a three-tier certifica-**

tion standard is imposed on the paper's own geometric claims, under which no self-similarity claim may be certified from the concept; applied to the worked room it leaves three of twelve claims uncertified, and they are the three that sound most impressive.

Sections 2 and 3 state the hypotheses and the framework, including the identification problem that limits every applied reading of the mechanism. Section 4 derives the parabola and its hard frequency floor; Section 5 develops self-similarity, the crenellation multiplier and the nested enclosure ladder; Section 6 develops the diffuse-field model, its five assumptions and the Sabine/Eyring switching rule; Section 7 develops the exclusion mechanism and the tail arithmetic. Section 8 collects the design specifications. Section 9 works two systems end to end. Sections 10 to 13 discuss what follows, verify the chain, state the limitations, and conclude. Appendix A gives the eight-measurement protocol and Appendix B the failure-mode catalogue.

11.2 2 Hypotheses

The results below are of two kinds and the distinction is load-bearing. Some are theorems about a geometry or an identity of the decay law and cannot be falsified by observation; they are labelled as derivations where they appear. Others claim that these equations describe a real room and a real meeting, and those are stated here with what would defeat them.

H1 — The decay tail sets a minimum inter-turn gap. In a room of reverberation time `RT60`, the gap a following talker must leave for the previous talker's tail to fall 15 dB is `t_15 = RT60/4`, and a talker whose vocal level is materially below the previous talker's cannot take a turn in a gap shorter than that. **Predicted:** measured turn-transition gaps lengthen with `RT60` across rooms, and the share of attempted turns that are abandoned or overridden rises with `t_15` relative to the population's natural gap. **Falsified by:** measured turn gaps and override rates that are independent of `RT60` across a set of rooms spanning at least a factor of three in reverberation time.

H2 — A measurable and often dominant share of turn-taking inequality in a physical meeting is produced by the room's acoustics rather than by anyone's behaviour. **Predicted:** acoustic treatment alone, with the roster, the chair, the agenda and the meeting series held fixed, raises the turn-share evenness statistic `N_eff_turn/n`. In the worked case, from 0.604 to at least 0.75. **Falsified by:** treatment that meets its acoustic targets and leaves `N_eff_turn/n` unmoved, which would locate the inequality in status, chairing or agenda instead. **The share is not claimed as a number; the mechanism is claimed and its magnitude is computed.**

H3 — Acoustic treatment is therefore a collective-intelligence intervention. This chains H2 to Woolley et al. [2010]'s reported correlation, and the chain requires that turn-taking equality *causes* the collective-intelligence factor rather than merely tracking it. **Predicted:** a preregistered before-and-after with a matched untreated control shows the mediator and the group-performance outcome moving together. **Falsified by:** the mediator moving and the outcome not moving. **This paper ran that test and obtained exactly that pattern.** H3 is therefore reported in Section 9.2 as **not supported by this case**, and the treatment is retained on accessibility, fatigue and ceiling grounds instead. The direction of the correlation is not established in the source literature, so H3 could have failed for a reason that leaves H2 entirely intact.

H4 — Boundary multiplication converts floor area into usable category count. Crenellating a room's solid boundary inward raises the number of distinct posture/purpose/condition categories a fixed floor can host, at a floor-area cost equal to the recess depth times the recessed run. **Predicted:** in the worked room, `d =`

`1.00 m` over 21.91 m of run costs 21.91 m^2 — 18 per cent of the floor — multiplies the perimeter by 1.6667, and takes the audited category count from 2 to 5, so `ln N` rises by a factor of 2.32. **Falsified by:** an audited count that does not rise after construction, or fine-scale features that a time-lapse count shows to be unoccupied at all times, which is the recorded failure mode **FG4** of Appendix B.

H5 — The four-part seating pattern is scale-invariant. Positions that are back-protected, give a view out over a larger territory, have a visible low-cost exit and offer a boundary at reachable scale are occupied preferentially, and the same four conditions predict occupancy at desk, alcove, room and wing scale with only the dimensions changing. **Predicted:** occupancy counts at each built rung favour positions satisfying all four conditions over positions failing one or more. **Falsified by:** counts showing no preference at any rung, in which case **the seating requirements of Section 8 should be discarded for that population.** Do not defend the pattern against the count.

Three claims in this paper are **not** hypotheses and are labelled accordingly wherever they appear. That the storage law applies at every scale of enclosure — desk, alcove, room, wing, campus — with the same form and different parameters is a **modelling choice** and not a claim about physics; there is no theorem that a campus obeys the same recursion as a desk. That a self-similar boundary buys multi-scale social response the way a self-similar conductor buys multi-band electrical response is an **analogy**, structural and suggestive and not a derivation. That acoustically caused silence is indistinguishable, in the room's own records, from voluntary silence is a **definition of the measurement problem** rather than an empirical finding: it is why Section 7.6 computes exclusion from physics and not from asking.

11.3 3 Framework

11.3.1 3.1 What is presupposed

The storage law and its gauge. The equation this paper acts on is

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1) U_t)
```

with `Q_t` the stored order, `S_t` the surplus generated by interaction, `delta` the retention loss per period, `eta` the conversion of interaction into durable structure, and `C_t` the cost flow. The results consumed here and not re-derived are the headroom gauge `h_t = eta ln N − delta Q_t − C_t` with its three regimes and maximum one-step increment `r_max = h_t`, the two distinct constraints of admissibility `C_t <= (1−delta)Q_t + eta S_t` and sustainability `C_t <= eta ln N − delta Q_t`, and the steady state `Q_inf = (eta F(u*) − c*)/delta`, which is negative when `eta F(u*) < c*` [Curzi, 2026b]. The level–rate–delay quartet is the standard vocabulary of system dynamics and long predates this framework [Forrester, 1961]; headroom is this framework's name for what Cyert and March [1963] called organisational slack.

The surplus functional. For two unit state vectors drawn from an ensemble of `N` categories, `u(x,y) = 1 − (x . y)^2` in `[0,1]` and `f(u) = ln(1 + (N−1)u)`, characterised by four axioms — angle-only dependence, zero at parallel, an affine effective count, normalisation at orthogonality — as established in Curzi [2026]. **The affine effective count `N_eff = 1 + (N−1)u` is a design axiom: chosen, not derived**, and it is flagged as such wherever this paper leans on it. The range `0 <= F(u) <= ln N` is what makes `eta ln N` a ceiling rather than a typical value, and the forced-ceiling form `0 <= M <= ln N` with its worked twelve-category value of 2.484907 nats is developed in Curzi [2026l].

Two effective counts appear in this paper and they are different objects. The first is `N_eff = 1 + (N−1)u`, above. **It is not a Hill number.** The effective-count idiom is standard in ecology and political science, where `1/HHI` and `exp(H)` are the canonical members of the family [Hill, 1973,

Jost, 2006, Laakso and Taagepera, 1979]; `1 + (N−1)u` is a linear interpolation between 1 and `N` and belongs to no order of that family. The concentration instrument that *is* a Hill number of order two — `1/HHI`, with the worked jurisdictional case returning a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-HHI of 1.000000 and an effective count of 1.00 — is a separate quantity [Curzi, 2026]. The second effective count in this paper is the turn-share statistic `N_eff_turn = exp(−sum_i p_i ln p_i)` of Section 7.4. **That one IS a Hill number of order one** — the exponential of Shannon entropy [Shannon, 1948, Jost, 2006, Pielou, 1966] — and it is a descriptive index of the turn distribution and nothing else. **The three must not be substituted for one another, and `ln(N_eff_turn)` must never be reported as a surplus.** Section 12 repeats this, because a reviewer reaching for the Hill-number literature to support `1 + (N−1)u` will find that it does not apply.

The category count `N` in this paper is an audited count of posture/purpose/condition categories available in a room, established by the survey procedure of the room-as-circuit-element analysis, whose worked room returns `N = 2`, a sittable-edge ratio of 0.050 against a requirement of 0.109, `delta = 0.0808` per week, `eta_hat = 0.0455` and `h = −1.396`, and whose prescription — raise `N` from two to five, cut the acoustic cost term, retire dormant agreements — closes 66 per cent of that gap [Curzi, 2026d]. Section 9.1 designs the geometry that delivers the `N` increase in that prescription. **Whether an audited category is a category is a judgement with a declared strike rule, not a measurement**, and Section 12 says so.

11.3.2 3.2 Identification: what no amount of measurement recovers

This limitation is structural rather than statistical and belongs here rather than in a caveat at the end. The mechanism this paper asserts runs through a group whose members both influence and constitute the aggregate: the room shapes who speaks, who speaks shapes what the meeting is, and the meeting is made of its members. That is exactly a linear-in-means reflexive specification, and Manski [1993] proves that in such a specification **the endogenous social effect is not identified from observational data**: it cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] reinforce the point for network data, where influence and selection are generically confounded.

The consequence for this paper is exact and it is narrower than it first looks. Sections 4 to 7 contain two kinds of statement. The geometric theorems, the decay-rate identity, Sabine's equation and the direct-to-reverberant arithmetic are physics and are untouched: they concern air and surfaces, not social influence, and no identification problem arises. **The interpretation of the resulting turn-share change as an endogenous social effect is what is not identified.** When Section 9.2 reports that `N_eff_turn/n` rose from 0.604 to 0.812 while a matched control moved 0.012, that comparison licenses the claim that *the intervention* moved the mediator; it does not license decomposing the mediator's effect on group behaviour into an endogenous social component and a contextual one.

A partial remedy is adopted and its price is paid. The matched untreated control room removes the most immediate confound — that measuring a group's turn-taking is itself an intervention, the hazard McCambridge et al. [2014] documents systematically and Rosenthal and Jacobson [1968] demonstrates for expectancy — and it is the reason Section 8's requirement schedule makes the control mandatory rather than advisory. **It does not solve the reflection problem.** The route that would is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001]; the fixed roster and the declared participation rule of the measurement protocol point toward it without yet taking it. **Until that is done, the claim that acoustic treatment raises collective performance through the turn-taking channel is a modelling position rather than an identified empirical result**, and every applied statement in this paper inherits that status. Durlauf [2005] states the general form of the demand: name the observation that would distinguish this account from a neighbouring one that fits equally well.

11.3.3 3.3 Analogy discipline

Three borrowings from physics appear in this paper and each is labelled at first use, following the three-way distinction the corpus imposes on itself.

Sabine's equation and the two-field model are derivations, not analogies. They are statements about sound in air, used here for sound in air. Sabine's `RT60 = 0.161 V/A` is not a curve fit: it follows from a statistical-energy argument in which the mean free path between reflections in a rectangular enclosure is `4V/S` [Sabine, 1922, Rossing et al., 2002]. **But the argument makes five assumptions, Section 6.1 lists them, and Section 6.3 exhibits a case where Sabine over-predicts the built result by 77.8 per cent.** The premises are checkable and this paper checks them; that is what distinguishes a derivation from a borrowing.

The Lombard feedback loop is a shared mathematical form. In a room with several conversations, each conversation's output is background for the others, and a first-order loop with gain `s` below unity converges to `1/(1−s)` times its seed disturbance. That is the same fixed-point arithmetic as the storage law's convergence, and it is the same contraction argument: a map with modulus `q < 1` on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least `q` each pass [Banach, 1922, Curzi, 2026]. **Nothing about charge, capacitance or thermodynamics is claimed to hold of a noisy room**; the claim is that the same difference equation governs both, which is legitimate and is category two of the three [Åström and Murray, 2008].

Self-similarity in social occupancy is an analogy and is badged as one. Self-similar antennas work because Maxwell's equations are scale-invariant in the relevant sense. **There is no scale-invariance principle for human occupancy corresponding to that**, because people have one size: proxemic bands are absolute distances, not ratios [Hall, 1966], and so are the sensory thresholds that govern what can be seen and heard across a space [Gehl, 1971]. The analogy motivates a candidate geometry and licenses nothing. Section 5.7 states the certification rule this produces, and Section 12 records that geometric over-claiming has a long and documented history in design writing, of which the golden-section literature is the best-audited instance [Markowsky, 1992, Thompson, 1917].

One further borrowing is refused outright. `ln N` here is a bound on an ensemble of `N` equiprobable categories in the information-theoretic sense [Shannon, 1948], and the requisite-variety tradition supplies the reason a variety term appears as a ceiling at all: only variety absorbs variety [Ashby, 1956, 1958]. **Surplus is not identified with Shannon entropy or mutual information, and no thermodynamic entropy law is invoked**; the two are different objects with different units, and Mirowski [1989] is the standing warning about what happens to a social science that copies an energetics for which it has no conservation law.

11.3.4 3.4 Standing honesty clauses

Repeated wherever they bite, and stated once here.

- **As deployed, the surplus functional is a lower bound** on the information an ensemble carries, not the information itself [Curzi, 2026]. Every number in this paper is a floor.
- **`ln N` is a ceiling per interaction, not a typical value.** When Section 7.3 computes the loss from silencing three of eight voices, it computes a loss of *ceiling*, and the realised loss may be larger, because the silenced participants may have been the ones carrying the non-parallel view [Curzi, 2026d].
- **Every absorption coefficient in this paper is NOMINAL** — a typical published value for a generic material description. They are adequate for design arithmetic and are **not adequate for a construction specification**, where the manufacturer's tested data for the specific product at the specific mounting condition is required. A "50 mm mineral wool panel" spans a range of real performance wide enough to change a design decision.
- **Applying the storage law to a room is a modelling decision**, badged as such every time it is made, and the same applies with more force to applying it at five nested scales at once.

- **The transfer of a classroom acoustic standard to a deliberation room is a transfer.** It is defensible — a committee member straining to hear is in the same acoustic situation as a child at the back of a class — and it is labelled as one wherever it is used, because the standard was arrived at through the speech-intelligibility literature for a different population and task.
- **No intervention in this paper may remove a participant's ability to decline**, and the arithmetic gives no warning where that boundary is crossed. Recording a meeting for turn-share measurement requires consent, and acoustic treatment must not be presented as a remedy for a hierarchy that is not acoustic in origin. The corpus's own three-drawer honesty classification — four items of established mathematics, seven of established psychology, and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third — is the standard this section is written to [Curzi, 2026].

11.4 4 Geometry that performs a function without power

11.4.1 4.1 The cost argument

Return to the cost term. `C_t` in the storage law is dissipation: what the system spends to keep running. A powered device that performs a spatial function — an amplifier, a fan, a display, an active noise system — enters the budget as a permanent line. A shape enters once, at construction, and then contributes only through cleaning and eventual repair.

```
Powered function:   C_t = c_energy + c_maint + c_replace + c_failure   , every period
Geometric function: C_t = c_clean                                      , every period
                    plus a one-time capital charge at t = 0
```

This is the structural argument for the whole class. A shape is a function with a cost of nearly zero and a retention loss set by material durability rather than by anyone's attention. It is the limiting case of infrastructure that recedes from notice until it fails [Star and Ruhleder, 1996], and its failure mode is slow — wear, obstruction, misuse — rather than sudden, which makes it a low-variance element in a cost profile. **Stone, concrete, hardwood and plaster have retention losses measured in decades, and almost nothing else in an organisation does.** The same claim in its acoustic form — that boundary geometry alone selects modes at no ongoing cost, exactly for room acoustics, where the mode frequencies follow `f = (c/2) sqrt((n_x/L_x)^2 + (n_y/L_y)^2 + (n_z/L_z)^2)` from the same Helmholtz problem, and as a design heuristic only for occupancy — is stated and badged as a postulate in Curzi [2026aa], and this paper adopts that badging without weakening it.

11.4.2 4.2 The parabola, derived

Take the parabola in its focal form:

```
y = x^2 / (4f)            focus  F = (0, f)
                          directrix  y = −f
                          dy/dx = x / (2f)
```

Theorem 1 (focus-directrix). For any point `P = (a, a^2/(4f))` on that parabola, `|PF| = y_P + f`, which is exactly the perpendicular distance from `P` to the directrix.

Proof.

```
|PF|^2 = a^2 + ( a^2/(4f) − f )^2
       = a^2 + a^4/(16 f^2) − 2f ∗ a^2/(4f) + f^2
       = a^2/2 + a^4/(16 f^2) + f^2
```

```
( a^2/(4f) + f )^2 = a^4/(16 f^2) + 2f * a^2/(4f) + f^2
                   = a^4/(16 f^2) + a^2/2 + f^2
```

The two expressions are identical, so `|PF| = a^2/(4f) + f = y_P + f`, the vertical distance from `P` down to the directrix `y = −f`. **The distance to the focus equals the distance to the directrix at every point on the curve: the parabola's definition, recovered from its equation.**

Theorem 2 (reflective property). Every ray parallel to the axis of symmetry reflects, at the surface, through `F`.

A ray descending parallel to the axis has direction `d = (0, −1)`. The surface normal at `P` comes from the gradient of `y − x^2/(4f)`, giving `n` proportional to `(−a/(2f), 1)`, normalised. The reflected direction is `r = d − 2 (d . n_hat) n_hat`. Carried out numerically for `f = 1.0 m` and checked at the focal height `y = f`:

`a` (m)	`y_P` (m)	slope `a/2f`	tangent angle (deg)	x-crossing at `y = f`
0.25	0.0156	0.1250	7.13	0.000000
0.50	0.0625	0.2500	14.04	0.000000
0.75	0.1406	0.3750	20.56	0.000000
1.00	0.2500	0.5000	26.57	0.000000
1.50	0.5625	0.7500	36.87	0.000000
2.00	1.0000	1.0000	45.00	reflected ray exactly horizontal; `y_P = f`
3.00	2.2500	1.5000	56.31	0.000000

Every reflected ray crosses `y = f` at `x = 0`. The `a = 2f` row is the degenerate case: the reflected ray leaves horizontally and travels along `y = f` to the focus. That is the rim-angle-90-degree point, and it is why `f/D = 0.25` is the geometry at which the rim subtends a full half-space at the focus.

Corollary 3 (path-length equality) — the load-bearing one. Every axis-parallel ray descending from a common height `h` and reflecting to the focus travels the same total distance `h + f`, independent of where on the surface it struck:

```
total = (h − y_P) + |PF| = (h − y_P) + (y_P + f) = h + f
```

The `y_P` cancels. Numerically, with `f = 1.0` and `h = 5.0`:

`a` (m)	`y_P`	`|PF|`	`(h − y_P) + |PF|`
0.0	0.0000	1.0000	6.0000
0.5	0.0625	1.0625	6.0000
1.0	0.2500	1.2500	6.0000
1.5	0.5625	1.5625	6.0000
2.0	1.0000	2.0000	6.0000
3.0	2.2500	3.2500	6.0000

Identical at every aperture radius, because it is identically `h + f`. Corollary 3 is why a parabola has *gain* and a merely curved surface does not. Convergence without path-length equality produces arrival out of phase, which is partial cancellation; convergence with

path-length equality produces coherent addition. **The parabola is not a funnel but a phase-correcting device, and the phase correction is performed by the shape, at no cost, indefinitely.** There is no computation, no calibration and no control loop: the function is stored in the boundary condition.

11.4.3 4.3 Aperture, depth, and f-ratio

For a dish of aperture diameter `D` and focal length `f`, the rim sits at `x = D/2`, so `depth = (D/2)^2/(4f) = D^2/(16f)` and `f/D` is the f-ratio, smaller meaning deeper.

`D` (m)	`f` (m)	`f/D`	depth (m)	rim angle at focus (deg)
0.50	0.15	0.300	0.104	79.6
1.00	0.30	0.300	0.208	79.6
2.00	0.50	0.250	0.500	90.0
6.10	1.50	0.246	1.550	90.9
9.10	2.30	0.253	2.250	89.4
61.00	15.00	0.246	15.504	90.9

The recurrence of `f/D` near 0.25 is not coincidence: at `f/D = 0.25` the focus sits exactly in the plane of the rim, which is the shallowest geometry that still collects a full hemisphere and is therefore the most material-efficient. **A design that converges on `f/D` near 0.25 has usually converged correctly.** Deeper dishes shield the focus from off-axis noise at the cost of material and of a focus buried inside the shell where a head does not comfortably fit; shallower dishes put the focus in the open where it is easy to use and easy to contaminate.

11.4.4 4.4 Directivity, gain, and the hard frequency floor

For a circular aperture of diameter `D` at wavelength `lambda`, the half-power beamwidth is approximately `theta ~ 70 lambda / D` degrees, and the theoretical on-axis gain with aperture efficiency `eta_ap` is `G = (pi D / lambda)^2 eta_ap`. Take `eta_ap = 0.5`, a conventional and generous value for a real reflector, and `c = 343 m/s` at 20 C. For a 1.2 m aperture — the largest that fits comfortably behind a seated head:

Frequency	`lambda` (m)	`D/lambda`	Beamwidth	Aperture gain (upper bound)
250 Hz	1.372	0.87	80.0 deg	5.8 dB
500 Hz	0.686	1.75	40.0 deg	11.8 dB
1000 Hz	0.343	3.50	20.0 deg	17.8 dB
2000 Hz	0.172	7.00	10.0 deg	23.8 dB
4000 Hz	0.086	13.99	5.0 deg	29.9 dB

The frequency floor. A reflector does essentially nothing when it is small compared with the wavelength; sound diffracts around it. The working rule is that useful directivity begins at about `D = 2 lambda`, which gives the hard floor `f_floor = 2c/D`:

Aperture `D`	`D = 1 lambda` at	`D = 2 lambda` at (useful floor)	`D = 4 lambda` at
0.30 m	1143 Hz	2287 Hz	4573 Hz
0.50 m	686 Hz	1372 Hz	2744 Hz

Aperture `D`	`D = 1 lambda` at	`D = 2 lambda` at (useful floor)	`D = 4 lambda` at
0.60 m	572 Hz	1143 Hz	2287 Hz
0.90 m	381 Hz	762 Hz	1524 Hz
1.20 m	286 Hz	572 Hz	1143 Hz
2.00 m	172 Hz	343 Hz	686 Hz
3.00 m	114 Hz	229 Hz	457 Hz
6.10 m	56 Hz	113 Hz	225 Hz
9.10 m	38 Hz	75 Hz	**151 Hz**
61.00 m	5.6 Hz	11 Hz	22 Hz

A correction to the source table is recorded here rather than made silently. The manuscript this paper converts gives 225 Hz in the `D = 4 lambda` column for both the 6.10 m and the 9.10 m apertures. The 6.10 m entry is right — `343/(6.10/4) = 224.9` Hz — and the 9.10 m entry is a duplicate of it: `343/(9.10/4) = 150.8` Hz. **The table above carries 151 Hz.** Nothing in the paper's argument depends on the cell, and it is corrected in the open because a reviewer who checks one cell checks the rest.

Now place speech on that scale. An adult fundamental runs 85–255 Hz, the first two vowel formants 250–2500 Hz, and consonants and fricatives 2000–8000 Hz — which is where intelligibility lives. **A 0.6 m shell behind a chair has a floor of about 1143 Hz. It does nothing whatever to the voice's fundamental, little to the first formant, and real work only on the consonant band.** That is not a failure: the consonant band is precisely where intelligibility is won or lost, and Section 6 shows that consonants are also what a reverberant room destroys first. But it means the honest description of a small acoustic shell is **a consonant-band directivity device, not something that makes a talker louder.**

Three further conditions bind every gain figure above.

1. **The gain formula assumes a plane wave arriving on-axis from the far field.** A talker 1.5 m from a 1.2 m dish is nowhere near that aperture's far field; the wavefront is curved across the aperture and the coherent addition is partial. Near-field performance is substantially below the tabulated bound.
2. **`eta_ap = 0.5` is an assumption.** Surface accuracy, edge diffraction, blockage by the listener's own head at the focus, and absorption in the shell all reduce it. Head blockage is severe in listening shells, because the thing being fed is sitting in the aperture.
3. **These are single-frequency figures.** Speech is broadband and the perceived effect is an average weighted by the speech spectrum and by the ear's frequency response.

Every computed aperture gain is therefore an upper bound that will not be reached, and the built article must be measured. Section 9.1 measures one and finds 4.8 dB against a bound of 17.8 dB.

11.4.5 4.5 The Denge precedent

Between roughly 1928 and the early 1930s, at Denge near Dungeness on the Kent coast, the British Air Ministry built a set of concrete acoustic mirrors as an early-warning system for aircraft, under William Sansome Tucker. Three principal structures survive: a 6.1 m dish, a 9.1 m dish, and a 61 m curved wall. The operating principle is exactly Theorem 2: engine noise arriving as a near-plane wave is concentrated at the focus, where a microphone — in earlier installations, a listening trumpet and a human ear — picks it up, and bearing is determined by moving the collector across the focal region. **There is no power in the acoustic path. The concrete does the work.**

What the geometry buys, in this paper's terms, at `eta_ap = 0.5`:

D	Beamwidth at 250 Hz	Beamwidth at 500 Hz	Aperture gain at 250 Hz (bound)
6.10 m	15.7 deg	7.9 deg	19.9 dB
9.10 m	10.6 deg	5.3 deg	23.4 dB
61.00 m	1.6 deg	0.8 deg	**39.9 dB**

A second correction to the source, recorded rather than absorbed. The manuscript gives 46.9 dB for the 61 m structure at 250 Hz. Recomputing from the formula the manuscript itself states, `G = (pi D/lambda)^2 eta_ap` with `lambda = 1.372 m` and `eta_ap = 0.5`, gives `(pi x 61/1.372)^2 x 0.5 = 9755`, or **39.9 dB**. The stated 46.9 dB is not reproducible from the stated formula at any of its stated parameters; the nearest reproducible neighbour is 45.9 dB, which is the same aperture at 500 Hz. **The table above carries 39.9 dB.** The 61 m structure is in any case a strip mirror rather than a dish, so it focuses in one plane and the circular-aperture figures are indicative for it; but a figure that cannot be recovered from its own formula must be replaced rather than repeated.

The order of magnitude is nonetheless the explanation for building something that large: **bearing resolution on a low-frequency source is set by `lambda/D` and by nothing else**, and at 250 Hz a two-degree beam is not available from anything smaller than a building. Reported detection ranges were of the order of tens of kilometres in favourable conditions, giving warning of some minutes; those figures varied enormously with wind, sea state, aircraft type and operator skill and the surviving accounts are not consistent, so **the safe claim is the one the geometry guarantees: real, passive, unpowered directional gain in the low-frequency band.**

Why the mirrors were abandoned is the part that generalises. Radar rendered them obsolete within a few years, and it is tempting to read that as the geometry failing. It is not what happened. **The mirrors did not fail; their input signal moved out from under them.** Aircraft got faster, so warning time — range divided by closing speed — shrank toward uselessness while the device stayed constant. The acoustic environment got noisier, and a passive device has no gain control and no way to reject a competing source inside its beam. And radar carried its own signal: a passive collector concentrates only what happens to arrive, while an active system chooses what to transmit, when, and at what power, and therefore controls its own signal-to-noise ratio.

The general principle, and it governs every geometric intervention in this paper: passive geometry has no gain control and generates no signal of its own. A perfectly shaped alcove in an organisation with nothing to say will concentrate silence with excellent efficiency. Geometry sets the coefficients `N` and `C`; it does not supply `S`, and the conversion coefficient `eta` is a separate lever with its own analysis [Curzi, 2026b]. This is failure mode **FG7** of Appendix B and it is the one that wastes the most capital.

11.4.6 4.6 Where the parabola belongs, and the concave-room prohibition

At furniture and niche scale, aimed deliberately.

Application	Aperture	Frequency floor	What it does
Listening niche behind a seated head	1.0–1.4 m	~490–690 Hz	Raises consonant-band SNR for one seated person facing the room
Desk-scale shell	0.5–0.7 m	~980–1372 Hz	Consonant-band privacy shield; reduces spill both ways

Application	Aperture	Frequency floor	What it does
Alcove back-shell, shallow, `f/D` ~0.35	2.0–2.6 m	~264–343 Hz	Sub-divides an open floor acoustically without a wall
Outdoor listening seat / whisper pair	1.5–3.0 m	~229–457 Hz	Triangulating object that is also a demonstration

It does not belong as the shape of a room, and this is the most important negative in the section. In a room, concave surfaces are usually a defect. A domed ceiling, a curved end wall, a barrel vault or a concave glazed facade concentrates sound at focal points and produces:

- **hot spots** — positions where a talker is uncomfortably loud and positions two metres away where they are inaudible, which destroys the turn-taking equality Section 7 is about;
- **focused echoes** — a discrete, delayed, high-level reflection at a specific seat. Discrete echoes damage intelligibility far more than an equal amount of diffuse reverberation, because the ear integrates diffuse energy and cannot separate a strong late arrival from the direct sound;
- **position-dependent performance**, which is a governance problem as much as an acoustic one. **A room whose best seat is acoustically privileged has installed a head of the table by accident**, and the governance consequence of that is developed in Curzi [2026f], whose deference model gives `u = 1 − a^4` in a common rotation coefficient `a` and whose thirteen-seat ring table drove the estimated `a` from 0.83 to 0.47.

Requirement **G9** of Section 8 states the prohibition. **The parabola is a scalpel, not wallpaper.**

11.5 5 Self-similarity and boundary multiplication

11.5.1 5.1 Similarity dimension, and what it does not tell you

Theorem 4 (similarity dimension). A set composed of `m` copies of itself, each scaled by `1/r`, has similarity dimension `D = ln m / ln r`. This is true by the definition of self-similarity.

Set	`m`	`1/r`	`D = ln m / ln r`
Cantor set	2	3	0.6309
Koch curve	4	3	1.2619
Sierpinski gasket	3	2	1.5850
Sierpinski carpet	8	3	1.8928
Menger sponge	20	3	2.7268
Hilbert curve	4	2	2.0000

The Koch snowflake makes the architecturally useful property visible: its perimeter grows without bound while its area converges.

iteration `n`	perimeter (unit-side triangle)	multiple of original	area / `A_0`
0	3.0000	1.0000	1.00000
1	4.0000	1.3333	1.33333

iteration `n`	perimeter (unit-side triangle)	multiple of original	area / `A_0`
2	5.3333	1.7778	1.48148
3	7.1111	2.3704	1.54733
4	9.4815	3.1605	1.57659
5	12.6420	4.2140	1.58960
6	16.8560	5.6187	1.59538
7	22.4746	7.4915	1.59794
8	29.9662	9.9887	1.59909

Area converges to exactly `8/5 = 1.6` times the original triangle; perimeter multiplies by `4/3` every iteration and diverges. **This is the whole architectural point in one table: boundary is cheap, interior is expensive, and self-similarity is the technique for buying large amounts of the first with bounded amounts of the second.** The edge effect — that people occupy edges first [Gehl, 1971] — and the sittable-space ratio [Whyte, 1980] are both demands for boundary. A room's floor area is fixed by the lease; its boundary length is a design variable, and Theorem 5 prices it exactly.

What the dimension does not tell you. `D = 1.2619` for the Koch curve is a statement about how its measured length scales with ruler size. It says nothing about whether the shape scatters sound usefully at any particular frequency, whether people will sit in its recesses, whether those recesses are reachable, cleanable or safe, or whether the geometry resonates, focuses or traps anything undesirable. **Two boundaries with identical `D` can behave completely differently.** That is why the self-similarity claim of Section 2 is badged as an analogy and why every requirement in Section 8 that invokes self-similarity carries a modelling obligation.

11.5.2 5.2 The antenna precedent and where the analogy stops

The commercial precedent is genuine and worth stating precisely, because it is the strongest available evidence that self-similar geometry does real engineering work. An antenna's resonant behaviour is set by its electrical length relative to wavelength, and two consequences follow. **Space-filling lowers the resonant frequency for a fixed physical envelope**: a Koch monopole of a given height contains more conductor than a straight monopole of the same height, so it resonates lower — which for a handset, where the envelope is fixed by industrial design and the bands are fixed by regulators, is the whole problem. And **self-similarity at scale factor `s` produces resonances at frequency ratios approximately `s`**, so a structure containing copies of itself at half scale tends to resonate at `f`, `2f`, `4f`, `8f`: a multiband antenna from one radiating element rather than several.

Both are load-bearing. Now the limit. The claim that fractality is *optimal* — that a fractal antenna necessarily outperforms a well-designed conventional multiband antenna of the same size — is contested in the antenna literature, and careful comparisons have found conventional meander and inverted-F designs performing comparably. **The safe statement is that self-similarity is a reliable route to multiband, size-reduced behaviour, not a guarantee of superiority.** This paper cites no key for the antenna literature because the bibliography assembled for this corpus contains none; the claim is therefore recorded as **uncited and taken from engineering practice**, and Section 12 lists it among the unsupported statements.

How far the analogy carries. It carries this far: a self-similar boundary offers usable features at several characteristic sizes simultaneously, so one geometry presenting 0.6 m recesses, 2.2 m alcoves and 6.5 m bays serves the pair, the small group and the assembly out of one construction — the same economy a self-similar radiator achieves across bands. **It stops here:** there is no scale-invariance principle for human occupancy. People have one size; proxemic bands are absolute distances, not ratios [Hall, 1966], and sensory thresholds are absolute

distances [Gehl, 1971]. **A social geometry is self-similar over at most three or four scales before it meets the fixed size of a human being at the bottom and the fixed limit of a sightline at the top.** That is a bounded, checkable claim, and Section 5.4 builds exactly three social rungs.

11.5.3 5.3 The crenellation multiplier

Theorem 5 (crenellation multiplier). A boundary replaced by a square-wave of tooth depth `d` and half-period `w` has its length multiplied by exactly `1 + d/w`. *Proof, by summing segments:*

```
per period of length 2w, the path runs:  w  along the outer line
                                         d  inward
                                         w  along the inner line
                                         d  outward
path length per period = 2w + 2d
multiplier = (2w + 2d) / 2w = 1 + d/w
```

If the teeth alternate inward and outward about the original line, the enclosed area is unchanged exactly. Applied to a square room of 120 m^2 — side 10.954 m, perimeter 43.818 m:

`d`	`w`	multiplier	new perimeter
0.50 m	1.50 m	1.333	58.42 m
0.75 m	1.50 m	1.500	65.73 m
1.00 m	1.50 m	1.667	73.03 m
1.00 m	1.00 m	2.000	87.64 m
1.50 m	1.50 m	2.000	87.64 m

And it iterates. Applying the same `d/w = 2/3` at each of three self-similar orders, each order at one third the size of the previous:

order	`d`	`w`	multiplier this order	cumulative	perimeter
1	1.000 m	1.500 m	1.667	1.667	73.03 m
2	0.333 m	0.500 m	1.667	2.778	121.7 m
3	0.111 m	0.167 m	1.667	4.630	202.9 m

Order 3 is where the arithmetic detaches from reality. A 111 mm recess at 167 mm pitch is not a seat, not a niche and not reachable; it is a texture. It has real acoustic effects — at 111 mm scale it scatters sound above roughly 1.5 kHz, which is useful diffusion — but it does not carry a person, and counting perimeter metres at that scale toward a sittable-edge requirement would be straightforwardly false. **Only boundary at scales that can hold the thing being counted for may be counted:** for seating, `d >= 0.40 m` and `w >= 0.60 m`. That single rule is what separates a fractal argument from fractal decoration, and it is requirement **G15** of Section 8.

The inward-only case is the real one. In an occupied building the teeth rarely push outward: there is a structural wall, a corridor or another tenant. Inward-only crenellation converts open floor into niche floor. For the same 120 m^2 room, recessing half the perimeter run — 21.91 m — inward by `d`, with the sittable-edge requirement recomputed on the reduced open floor at the 0.1094 ratio:

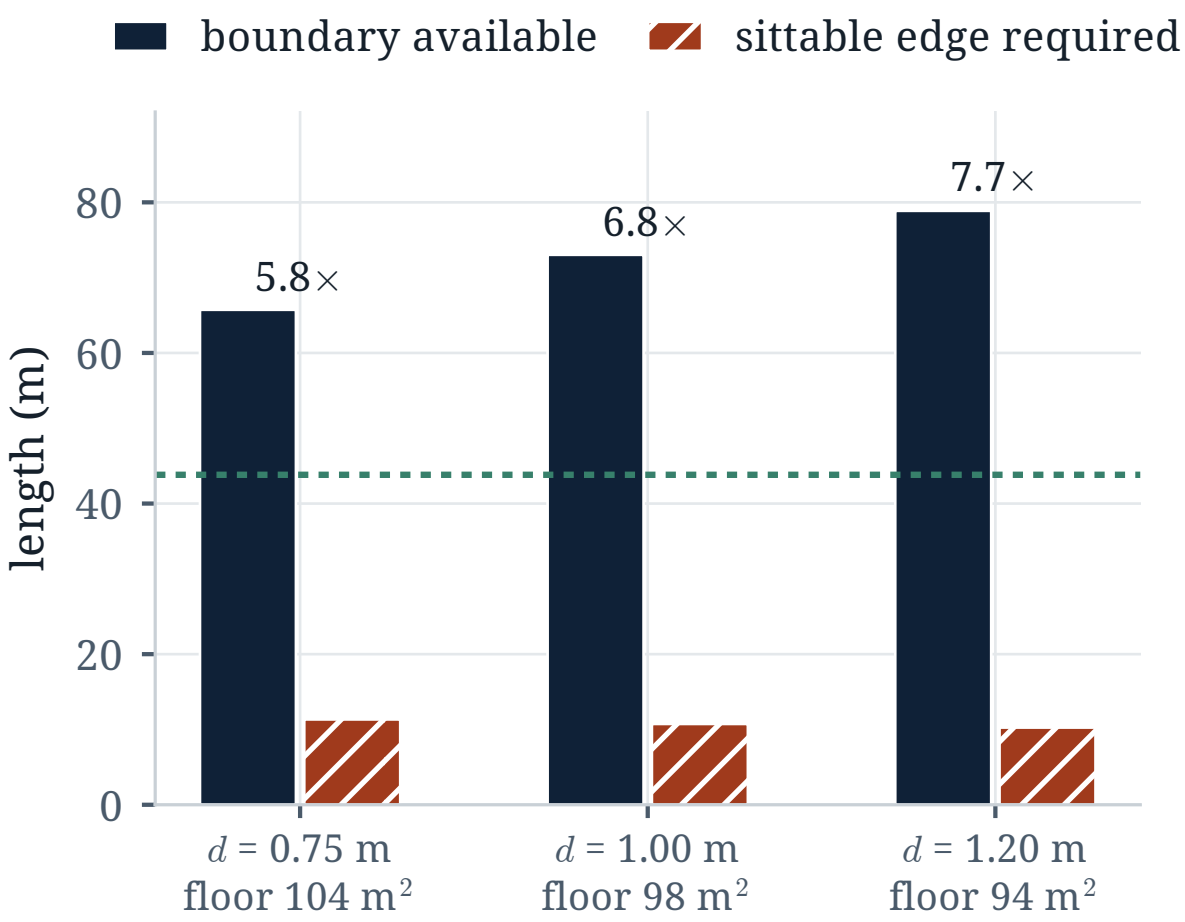

Figure 11.1: **Boundary multiplication converts an unmeetable seating-edge requirement into a several-fold surplus, and it does it by spending floor area on the thing the floor area existed to enable.** At `d = 1.00 m` and `w = 1.50 m` the 120 m^2 room gives up 21.9 m^2 of open floor — 18 per cent — and gains 29.2 m of boundary, against a requirement that has simultaneously fallen to 10.73 m. Exact arithmetic from the multiplier `1 + d/w`; the 0.1094 sittable-edge ratio is a stipulated design target, not a measurement. Generated by `figs/src/CCP-011_fig02.py`.

d	new perimeter	niche area created	remaining open floor	edge required	edge available
0.75 m	65.73 m	16.43 m^2	103.57 m^2	11.33 m	65.73 m
1.00 m	73.03 m	21.91 m^2	98.09 m^2	10.73 m	73.03 m
1.20 m	78.87 m	26.29 m^2	93.71 m^2	10.25 m	78.87 m

At `d = 1.00 m`, **the room gives up 18 per cent of its open floor and ends with roughly seven times the required sittable edge.** And the 21.9 m^2 is not lost: it is exactly where the seating goes. **The floor area was converted into the thing the floor area existed to enable.** An open 120 m^2 room with 43.8 m of unusable perimeter is worse in every measurable respect than a 98 m^2 room with 73 m of occupied edge. The construction need not be structural — free-standing banquette backs, tall shelving, storage walls, planters and screens produce the same multiplication at a retention loss and a cost far below masonry.

11.5.4 5.4 The nested enclosure ladder

Choose a scale ratio `r = 3`, chosen because it lands the rungs close to the human thresholds already established and not because three is special:

k	Scale	L_k = 0.75 x 3^k	Area ~ L^2	What it holds	Threshold it matches
0	desk	0.75 m	0.6 m^2	one person, one task	personal distance, 0.45–1.2 m
1	alcove	2.25 m	5.1 m^2	two to four	social distance, 1.2–3.6 m
2	room	6.75 m	45.6 m^2	six to twelve	full-sensory range, ~7 m
3	wing	20.25 m	410 m^2	thirty to eighty	between 7 m and 25 m
4	quarter	60.75 m	3691 m^2	a few hundred	beyond emotion-reading range, ~25 m
5	campus	182.25 m	33215 m^2	thousands	beyond person-identification range, ~100 m

The distance thresholds in the right-hand column are the proxemic and sensory bands of Hall [1966] and Gehl [1971]. **Two of these rungs do something the others do not: the desk-to-room span, `k = 0` to 2, is the social ladder, and above it the rungs are logistical.** Past roughly 20 m other people are not conversational partners and the enclosure's job changes from enabling contact to organising movement. Section 5.2's limit is visible here: **the self-similar social geometry is three rungs deep, perhaps four, and claims beyond that are architecture rather than sociology.**

For a two-dimensional plan, each rung holds `m = r^2 = 9` sub-units of the rung below, giving `D = ln 9 / ln 3 = 2.0000` — which is simply the statement that a plan fills a plane. **A plan whose measured `D` came out below 2 would be reporting that it has gaps.** This is a sanity check, not a design target.

The design consequence is **multi-scale response in bounded volume**. A room built with a crenellated boundary at `d = 1.0 m` and a secondary order at `d = 0.35 m` simultaneously offers 0.35 m recesses at shoulder scale, 1.0 m recesses giving a seat with the back protected, 2.25 m bays formed by pairs of recesses, and the 6.75 m room itself. **One geometry, four occupancy scales, no moving parts, no power and no booking system** — which is how a single construction satisfies a four-category requirement without four separate rooms.

11.5.5 5.5 Parameters that change with scale

The modelling choice of Section 2 says the same equation applies at every rung with different parameters. Here is the ladder with illustrative parameters. **These are illustrative values chosen to show the shape of the drift. They are not measurements, none carries an interval, and any real project must fill this table from its own survey**, against the evidential standard of Curzi [2026], whose four-drawer classification — PROVED, POSTULATED, BORROWED, UNTESTED — records the surplus form as PROVED CONDITIONALLY on a chosen design axiom and the ladder's operationalisation as SPECIFIED, NOT RUN. **This table is in the last of those drawers.**

Scale	L (m)	delta	tau ~ 1/delta	eta	N	ln N	eta ln N	Q	delta Q	C	h
desk	0.75	0.600	1.7	0.40	3	1.0986	0.4394	0.2	0.1200	0.05	+0.2694
alcove	2.25	0.200	5.0	0.30	4	1.3863	0.4159	1.0	0.2000	0.12	+0.0959

Scale	L (m)	delta	tau ~ 1/delta	eta	N	ln N	eta ln N	Q	delta Q	C	h
room	6.75	0.080	12.5	0.25	6	1.7918	0.4479	3.0	0.2400	0.15	+0.0579
wing	20.25	0.030	33.3	0.15	10	2.3026	0.3454	20.0	0.6000	0.60	-0.8546
campus	60.75	0.010	100.0	0.08	16	2.7726	0.2218	150.0	1.5000	2.00	-3.2782

Read the columns as a set of monotone trends, because the trends are the content. **`delta` falls with scale** — a desk arrangement decays in days, a campus in decades — so **`tau = 1/delta` rises** from under two periods to a hundred: larger enclosures are slower filters that respond to sustained forcing rather than to impulses, and it is not a criticism of a one-day event to say that it changes a desk and not a campus. **`eta` falls with scale**, because conversion is most efficient in the smallest unit, where the person who had the idea is also the person who can act on it, and every rung upward inserts a handoff. **`N` rises with scale but only logarithmically in effect**: from desk to campus, `N` goes 3 to 16 while `ln N` goes 1.0986 to 2.7726, so a factor of 5.3 in categories buys a factor of 2.5 in ceiling. **`eta ln N` is therefore roughly flat through the social rungs and then falls.** And **`Q` explodes**, from 0.2 to 150.

step	`Q` grows by	`ln N` grows by
desk to alcove	5.00x	1.26x
alcove to room	3.00x	1.29x
room to wing	6.67x	1.29x
wing to campus	7.50x	1.20x

`Q` grows several-fold per rung while `ln N` grows by about a quarter, so `delta Q` outruns `eta ln N` and headroom goes negative as scale increases — in this illustration, between the room and the wing. That is the fixed-point behaviour of the gauge arriving through pure geometry: at equilibrium the headroom of a converged system is exactly `eta(ln N − F(u*))`, the surplus it is failing to extract from its own difference [Curzi, 2026b]. **The reason large organisations feel stuck is not that their people are worse; it is that `delta Q` scales with the stock and `eta ln N` does not.** The design consequence is to **push work down the ladder**: whatever can be decided at the alcove should be, because `eta` is higher and `delta Q` lower there.

This table is an illustration and not a demonstration, and it is the paper's weakest quantitative object. Five rows of stipulated parameters cannot establish a trend; they can only show what the trend would look like if it existed. Failure mode **FG6** of Appendix B names the abuse — applying the form past the scale at which its parameters were measured — and the rule is that the scale-free form of the law licenses modelling at a new scale and does not license skipping the measurement at that scale.

11.5.6 5.6 The seating pattern and its falsification condition

The pattern language tradition is the acknowledged ancestor here [Alexander et al., 1977, Alexander, 1965]. What this analysis adds is that **the same seating pattern, correctly stated, is valid at every rung**, which is what would make the geometry self-similar in a useful rather than a decorative sense. The pattern, stated once: a person will occupy a position that has **(a)** the back protected, **(b)** a view out over a larger territory, **(c)** a visible low-cost exit, and **(d)** a boundary at reachable scale.

Rung	(a) back protected by	(b) view out over	(c) exit	(d) reachable boundary
desk, 0.75 m	a 1.2 m screen or shell	the alcove	one step, unobstructed	desk edge, shelf lip
alcove, 2.25 m	banquette back, storage wall	the room	alcove mouth, 1.2 m clear	ledge at 430 mm, table edge

Rung	(a) back protected by	(b) view out over	(c) exit	(d) reachable boundary
room, 6.75 m	the crenellated wall	the bay or court	two doors, opposed	window ledge at 450 mm
wing, 20.25 m	a built edge, colonnade, arcade	the court	multiple, legible	parapet, planter, low wall

The pattern is invariant; only the dimensions scale. Unlike the parameter claim of Section 5.5, this one is directly falsifiable: build all four rungs, count occupancy at each, and see whether the pattern predicts where people go. **If positions satisfying (a)–(d) are not occupied preferentially over positions failing one or more of them, the pattern is wrong for that population and the seating requirements of Section 8 should be discarded for that project.** Say so in the survey rather than defending the pattern against the count. That is H5, and no count reported in this paper tests it.

11.5.7 5.7 The three-tier certification standard

Every geometric claim in this paper falls into one of three tiers, and the tier determines what is owed before anything may be built on it.

Tier 1 — proven, use freely. Theorems 1, 2, 4 and 5 and Corollary 3. These are geometry. They are exact and require nothing but correct arithmetic.

Tier 2 — standard physics with stated approximations, use with the approximation declared. The `70 lambda/D` beamwidth relation, the `(pi D/lambda)^2 eta_ap` gain relation, the `D >= 2 lambda` frequency floor, and Sabine's equation in Section 6. Each is an engineering approximation with a known domain. **Declare `eta_ap`, declare that near-field performance falls short, declare that the figures are single-frequency.**

Tier 3 — requires modelling or measurement of the specific geometry; may not be certified from the concept. Anything depending on detailed shape: the scattering behaviour of a particular crenellation, the diffusion coefficient of a particular relief, the acoustic sub-division actually achieved by a particular alcove depth, the occupancy response to a particular nested plan. **Every fractal claim in this paper is Tier 3, without exception.**

The acceptable methods for discharging a Tier 3 obligation, in ascending order of cost, are: **(1)** scale physical measurement — a cardboard mock-up and a phone measuring `RT60` and a level difference at two positions is a real measurement and costs an afternoon; **(2)** geometrical-acoustics simulation by ray or image-source method, valid above the Schroeder frequency, which for a 100 m^3 room at `RT60 = 0.5 s` is in the low hundreds of hertz [Schroeder, 1965]; **(3)** wave-based simulation, required below the Schroeder frequency and for any claim about resonance, focusing or small-scale diffusion; **(4)** full-scale prototype and measurement, the only method that settles a Tier 3 question definitively. **A specification invoking self-similarity without naming which of these four was used has specified nothing.**

This is the same discipline the corpus applies to its own claim ledger, where each result carries an evidential drawer and the protocols are stated to run on the established mathematics and psychology while steering by the declared postulates [Curzi, 2026,?]. **The tier system is that ledger applied to shapes.**

11.6 6 The diffuse-field model and four build states

11.6.1 6.1 Sabine's equation: five assumptions, and where it breaks

```
RT60 = 0.161 V / A      V in cubic metres, A in metric sabins, RT60 in seconds
```

RT60 is the time for the sound energy density in the room to fall by 60 dB after the source stops, and A is the total absorption: A = sum_i S_i alpha_i + sum_j A_j, where S_i is the area of surface i, alpha_i its absorption coefficient in the band of interest, and A_j the absorption of a discrete object such as a person or a chair, in square metres of equivalent absorption each. The constant 0.161 carries units of s/m and follows from the speed of sound and the mean free path between reflections [Sabine, 1922, Rossing et al., 2002].

Three further standard results are used and each is a derivation. The **two-field model**, L_p(r) = L_W + 10 log10(Q/(4 pi r^2) + 4/R), separates a direct field falling 6 dB per doubling of distance from a reverberant field that is the same everywhere, with Q the source directivity factor — about 2 for a talker on a table — and R = A/(1 − alpha_bar) the room constant, where alpha_bar = A/S_total. The **critical distance** d_c = 0.141 sqrt(Q R) follows from setting the two terms equal: beyond it the reverberant field dominates and moving closer to the talker stops helping. And the **decay rate** follows from the definition of RT60: sound decays at 60/RT60 decibels per second, so a gap of t seconds leaves the previous talker's energy 60t/RT60 decibels down. That last identity is the whole of Section 7.2.

Sabine's derivation assumes a diffuse field, and five conditions must roughly hold.

Condition 1 — the room must be above its Schroeder frequency. Below it, behaviour is dominated by discrete resonant modes rather than a statistical field, and RT60 is not a meaningful single number [Schroeder, 1965]. With f_s = 2000 sqrt(RT60/V) Hz:

V	RT60	f_s
100 m^3	0.40 s	126.5 Hz
100 m^3	0.50 s	141.4 Hz
100 m^3	1.00 s	200.0 Hz
100 m^3	2.00 s	282.8 Hz
336 m^3	0.70 s	91.3 Hz
500 m^3	0.80 s	80.0 Hz
2000 m^3	1.20 s	49.0 Hz
10000 m^3	1.80 s	26.8 Hz

In a 100 m^3 meeting room the Schroeder frequency sits around 130–140 Hz, so the 125 Hz octave band — the leftmost column of every table below — is at or below the limit of Sabine's validity and must be read as indicative only. For an 8.0 x 5.0 x 2.5 m room the axial modes fall at 21.4, 34.3, 42.9, 64.3, 68.6 (two coincident), 85.8, 102.9 and 137.2 (two coincident) Hz; the coincidences at 68.6 and 137.2 Hz are the kind of modal pile-up that produces a boomy room, **and no RT60 figure will reveal them.**

Condition 2 — mean absorption must be reasonably low. Sabine over-predicts RT60 as alpha_bar rises, because the equation permits RT60 to remain finite as alpha_bar approaches 1, which is physically wrong: a room with total absorption has no reverberation at all. Eyring's correction fixes the limit:

```
Sabine:  RT60 = 0.161 V / A
Eyring:  RT60 = 0.161 V / ( -S * ln(1 - alpha_bar) )      alpha_bar = A / S
```

Computed for the four build states of Section 6.3, in a 100 m^3 room of 145 m^2 total surface:

State	Band	A	alpha_bar	Sabine RT60	Eyring RT60	Sabine over-predicts by
A hard shell	500 Hz	8.73	0.060	1.844 s	1.788 s	3.1%
A hard shell	1000 Hz	8.24	0.057	1.954 s	1.898 s	3.0%
B office fit	500 Hz	35.53	0.245	0.453 s	0.395 s	14.7%

State	Band	`A`	`alpha_bar`	Sabine RT60	Eyring RT60	Sabine over-predicts by
B office fit	2000 Hz	61.63	0.425	0.261 s	0.201 s	30.2%
C specified	500 Hz	36.94	0.255	0.436 s	0.378 s	15.4%
C specified	4000 Hz	41.52	0.286	0.388 s	0.329 s	17.8%
D over-treated	1000 Hz	94.52	0.652	0.170 s	0.105 s	**61.9%**
D over-treated	2000 Hz	104.99	0.724	0.153 s	0.086 s	**77.8%**

The switching rule: use Sabine below `alpha_bar = 0.25`, use Eyring above it, and state which was used. In the dead-room case the two formulae disagree by nearly a factor of two, and a specification quoting Sabine without saying so would be describing a room 78 per cent more reverberant than the one that got built. This is result R4 of the paper and it costs nothing to apply.

Condition 3 — absorption must be reasonably evenly distributed. A room with all its absorption on one surface — the classic absorptive ceiling over five hard surfaces — does not develop a diffuse field: sound bouncing in the horizontal plane never meets the ceiling and decays far more slowly than Sabine predicts. **This is the most common real-world failure of the equation** and it is why Section 8 requires absorption on at least two non-parallel planes.

Condition 4 — the room must not be strongly coupled to another volume. An open door to a corridor, a folding partition or a double-height void creates coupled spaces with two-slope decay curves that no single `RT60` describes.

Condition 5 — dimensions must not be wildly disparate. Corridors, and rooms far longer than they are wide or tall, violate the mean-free-path derivation.

Air absorption adds a `4mV` term to `A` and matters above about 2 kHz in large volumes. In a 100 m^3 room at ordinary humidity it is negligible and is omitted throughout; in a 2000 m^3 hall it is not, and omitting it there would be an error.

11.6.2 6.2 Absorption coefficients, all nominal

Every value in this table is NOMINAL — a typical published value for a generic material description, per octave band. They are adequate for design arithmetic and for deciding what to build, and **they are not adequate for a construction specification.** Mounting changes low-frequency performance dramatically, and a panel tested with an air gap behind it will not perform the same way glued flat to a wall.

Material (nominal)	125	250	500	1k	2k	4k
Concrete, sealed or painted; terrazzo	0.01	0.01	0.02	0.02	0.02	0.03
Concrete block, painted	0.10	0.05	0.06	0.07	0.09	0.08
Concrete block, coarse or unpainted	0.36	0.44	0.31	0.29	0.39	0.25
Gypsum board 13 mm on studs, air cavity	0.29	0.10	0.05	0.04	0.07	0.09
Plaster on solid backing	0.02	0.02	0.03	0.04	0.05	0.05
Glass, heavy plate	0.18	0.06	0.04	0.03	0.02	0.02
Glass, ordinary window	0.35	0.25	0.18	0.12	0.07	0.04
Wood floor on joists	0.15	0.11	0.10	0.07	0.06	0.07

Material (nominal)	125	250	500	1k	2k	4k
Plywood panel 10 mm over air space	0.28	0.22	0.17	0.09	0.10	0.11
Carpet, heavy, on concrete	0.02	0.06	0.14	0.37	0.60	0.65
Carpet, heavy, on resilient underlay	0.08	0.24	0.57	0.69	0.71	0.73
Heavy velour drape, draped to half its flat area	0.14	0.35	0.55	0.72	0.70	0.65
Mineral-fibre ceiling tile, suspended with plenum	0.20	0.40	0.60	0.70	0.75	0.75
Mineral wool panel 25 mm, direct to wall	0.10	0.30	0.65	0.85	0.90	0.90
Mineral wool panel 50 mm, direct to wall	0.20	0.55	0.85	0.95	0.95	0.90
Mineral wool panel 100 mm with 50 mm air gap	0.45	0.85	0.95	0.98	0.95	0.90
Bookcase, filled, open front	0.25	0.30	0.30	0.30	0.30	0.30
Water surface	0.008	0.008	0.008	0.008	0.008	0.008

Discrete absorbers, in square metres of equivalent absorption **each**, not per m^2:

Object (nominal)	125	250	500	1k	2k	4k
Adult, seated, on a lightly upholstered chair	0.15	0.25	0.35	0.42	0.46	0.46
Empty lightly upholstered chair	0.10	0.15	0.18	0.20	0.22	0.22

Four things to read out of this table before using it.

Porous absorbers fail at low frequency, and thickness is the reason. A porous absorber works by viscous loss as air moves through it, and air motion is greatest a quarter-wavelength from a rigid boundary. At 125 Hz a quarter wavelength is 0.69 m. **A 25 mm panel cannot reach the low-frequency air motion; a 100 mm panel with a 50 mm gap gets much closer, which is why its 125 Hz figure is 0.45 against the 25 mm panel's 0.10.** Every low-frequency problem in this paper traces to that one fact.

Gypsum board on studs is a low-frequency absorber. Its 0.29 at 125 Hz is not a misprint: a panel on a cavity is a mass-spring system that resonates and dissipates in the bass, and it is the only absorption most ordinary rooms have down there.

People are significant absorbers and their absorption is mid- and high-biased. Eight seated adults contribute 2.8 m^2 of equivalent absorption at 500 Hz and 3.4 at 1 kHz. In a small hard room that is a material fraction of the total, **so the occupied and unoccupied `RT60` of a small room differ substantially and every specification must say which one it means.**

Carpet on concrete does almost nothing below 500 Hz. Its 125 Hz figure of 0.02 is the same as bare concrete: carpet is a treble absorber, and a room treated with carpet alone gets darker, not clearer.

11.6.3 6.3 The 100 m^3 room, computed in four states

Room: 8.0 x 5.0 x 2.5 m = 100.0 m^3 exactly. Floor 40 m^2, ceiling 40 m^2, walls `2(8 x 2.5) + 2(5 x 2.5) = 65 m^2` of which 12 m^2 is glazing. Total surface `S` = 145 m^2. Eight occupants throughout.

First, the shape of the relationship, since it governs every decision that follows. With Sabine at `V = 100`:

`A` (m^2 sabins)	4	6	8	10	12	15	20	25	30	40	60	80	100
RT60 (s)	4.025	2.683	2.013	1.610	1.342	1.073	0.805	0.644	0.537	0.403	0.268	0.201	0.161

And inverted, the absorption a target demands at `V = 100 m^3`: 53.67 for 0.30 s, 40.25 for 0.40 s, 32.20 for 0.50 s, 26.83 for 0.60 s, 23.00 for 0.70 s, 20.12 for 0.80 s, 16.10 for 1.00 s, 13.42 for 1.20 s, 10.73 for 1.50 s and 8.05 for 2.00 s. **`RT60` is inversely proportional to `A`, so the first few square metres of absorption are worth enormous amounts and the last few almost nothing.** Going from `A = 8` to `A = 16` halves `RT60` from 2.01 s to 1.01 s; going from `A = 80` to `A = 88` moves it from 0.201 s to 0.183 s. **This is the same concavity that governs the surplus functional and it carries the same moral: the second unit is the valuable one.** For sizing any room, the absorption required for 0.5 / 0.6 / 0.8 s runs 9.66 / 8.05 / 6.04 at 30 m^3, 16.10 / 13.42 / 10.06 at 50 m^3, 32.20 / 26.83 / 20.12 at 100 m^3, 64.40 / 53.67 / 40.25 at 200 m^3, 161.00 / 134.17 / 100.62 at 500 m^3 and 322.00 / 268.33 / 201.25 at 1000 m^3.

State A — the as-built hard shell. Sealed concrete floor, gypsum board ceiling and walls on studs, 12 m^2 heavy plate glazing, eight occupants. This is what a shell-and-core office looks like before fit-out, and what a great many converted spaces look like permanently.

Element	Area	125	250	500	1k	2k	4k
Sealed concrete floor	40.0	0.40	0.40	0.80	0.80	0.80	1.20
Gypsum ceiling	40.0	11.60	4.00	2.00	1.60	2.80	3.60
Gypsum walls	53.0	15.37	5.30	2.65	2.12	3.71	4.77
Glazing	12.0	2.16	0.72	0.48	0.36	0.24	0.24
Occupants, eight	–	1.20	2.00	2.80	3.36	3.68	3.68
Total `A`		**30.73**	**12.42**	**8.73**	**8.24**	**11.23**	**13.49**
RT60 (s)		**0.52**	**1.30**	**1.84**	**1.95**	**1.43**	**1.19**
`alpha_bar`		0.212	0.086	0.060	0.057	0.077	0.093
Room constant `R` (m^2)		39.0	13.6	9.3	8.7	12.2	14.9
Critical distance, `Q` = 1 (m)		0.88	0.52	0.43	0.42	0.49	0.54

An `RT60` of 1.95 s at 1 kHz in a room eight metres long, with a critical distance of 0.42 m — closer than one seat is to the next. Every listener at every seat is in the reverberant field; moving closer to the talker does not help; **there is no seat in this room from which a soft voice can reliably be heard.** Note the spectrum: 0.52 s at 125 Hz against 1.95 s at 1 kHz. The room is *less* reverberant in the bass, because the gypsum-on-studs is absorbing bass while nothing absorbs mid-frequencies. That is the signature of an untreated stud-and-board room.

State B — the ordinary office fit-out. Heavy carpet on the concrete, mineral-fibre suspended ceiling tile over the whole 40 m^2, gypsum walls, glazing unchanged, eight occupants: the default fit-out of the last forty years.

Element	Area	125	250	500	1k	2k	4k
Carpet on concrete	40.0	0.80	2.40	5.60	14.80	24.00	26.00

Element	Area	125	250	500	1k	2k	4k
Mineral-fibre ceiling tile	40.0	8.00	16.00	24.00	28.00	30.00	30.00
Gypsum walls	53.0	15.37	5.30	2.65	2.12	3.71	4.77
Glazing	12.0	2.16	0.72	0.48	0.36	0.24	0.24
Occupants, eight	–	1.20	2.00	2.80	3.36	3.68	3.68
Total A		**27.53**	**26.42**	**35.53**	**48.64**	**61.63**	**64.69**
RT60 (s)		**0.58**	**0.61**	**0.45**	**0.33**	**0.26**	**0.25**
Critical distance, Q = 1 (m)		0.82	0.80	0.97	1.21	1.46	1.52

State B passes a crude single-number test — 0.45 s at 500 Hz, comfortably inside a 0.6 s target — and is nonetheless a badly balanced room. Its bass ratio `(125+250)/(500+1k)` is 1.53, and it is 2.4 times more reverberant at 250 Hz than at 4 kHz. Consonants — the 2–8 kHz band carrying most of the information that distinguishes one word from another — are absorbed hard, while the low-mid energy that masks them is left to ring. **A room that over-absorbs treble and under-absorbs bass has applied a low-pass filter to every voice in it, and low-pass filtering is exactly what makes speech muddy.** No single-number specification can produce that diagnosis, which is why every requirement in Section 8 is stated per band.

State C — the specified deliberation room. Wood floor on joists rather than carpet; mineral-fibre tile over 20 m^2 of the ceiling with the central 20 m^2 left hard as an early-reflection reflector over the table; 10 m^2 of 100 mm mineral wool with a 50 mm air gap on the end walls; a 9 m^2 filled bookcase as a broadband diffuser-absorber; drapes over half the glazing; eight occupants.

Element	Area	125	250	500	1k	2k	4k
Wood floor on joists	40.0	6.00	4.40	4.00	2.80	2.40	2.80
Mineral-fibre ceiling tile	20.0	4.00	8.00	12.00	14.00	15.00	15.00
Hard ceiling reflector over table	20.0	5.80	2.00	1.00	0.80	1.40	1.80
Mineral wool 100 mm + 50 mm gap	10.0	4.50	8.50	9.50	9.80	9.50	9.00
Bookcase, filled	9.0	2.25	2.70	2.70	2.70	2.70	2.70
Gypsum walls, remaining	28.0	8.12	2.80	1.40	1.12	1.96	2.52
Drape over half the glazing	6.0	0.84	2.10	3.30	4.32	4.20	3.90
Exposed glazing	6.0	1.08	0.36	0.24	0.18	0.12	0.12
Occupants, eight	–	1.20	2.00	2.80	3.36	3.68	3.68
Total A		**33.79**	**32.86**	**36.94**	**39.08**	**40.96**	**41.52**
RT60 occupied (s)		**0.48**	**0.49**	**0.44**	**0.41**	**0.39**	**0.39**
RT60 unoccupied (s)		0.49	0.52	0.47	0.45	0.43	0.43
alpha_bar		0.233	0.227	0.255	0.270	0.282	0.286
Critical distance, Q = 1 (m)		0.94	0.92	0.99	1.03	1.07	1.08

Bass ratio 1.14 — essentially flat — and an occupied-to-unoccupied variation of 0.01 to 0.04 s. **`RT60` varies by 0.10 s across six octave bands. That is a flat room, and flatness matters far more than the absolute value.**

What achieved it is counter-intuitive. State C has *less* mid-high absorption than State B: 39.1 against 48.6 at 1 kHz and 41.0 against 61.6 at 2 kHz. The design removed the carpet, halved the ceiling tile, and added low-frequency-capable absorption. **The fix for a badly balanced room is often to take absorption away at the top and add it at the bottom, and no single-number specification can express that.** Note also the hard 20 m^2 ceiling panel over the table, which is not an oversight: it supplies early reflections from talker to far listener, arriving within a few milliseconds of the direct sound, which the ear integrates with the direct sound and which therefore *raise* effective loudness and intelligibility. **Early reflections are the quiet talker's ally, late reverberation is the quiet talker's enemy, and both are made of the same material.** The difference is entirely geometry and timing.

State D — the over-treated room, as a warning. Carpet, full mineral-fibre ceiling, 40 m^2 of 100 mm mineral wool on the walls, drapes over all the glazing. Someone was told to add absorption and did.

	125	250	500	1k	2k	4k
Total A	33.45	59.90	77.65	94.52	104.99	104.65
RT60 Sabine (s)	0.48	0.27	0.21	0.17	0.15	0.15
RT60 Eyring (s)	0.42	0.21	0.15	0.11	0.09	0.09
`alpha_bar`	0.231	0.413	0.536	0.652	0.724	0.722

Bass ratio 1.99. **State D is worse than State B and cost several times as much**, and it fails twice at once. **It is dead:** at 0.11 s by Eyring at 1 kHz the room provides no reverberant support, so talkers push because none of their own energy returns, vocal effort and fatigue rise, and the quiet talker — who cannot push — is worse off than in a moderately live room. **And its bass ratio got worse, not better:** all that porous absorption works from 250 Hz up and barely touches 125 Hz, so the relative bass excess doubled. The room is dead and boomy at once. **The Sabine/Eyring divergence is 61.9 per cent at 1 kHz and 77.8 per cent at 2 kHz: a designer who specified this room using Sabine believed they were building a 0.17 s room and built a 0.11 s room.**

11.6.4 6.4 Targets, flatness, and the bass ratio

Anchored on the published classroom standard — an unoccupied background noise limit of 35 dBA and a reverberation limit of 0.6 s for rooms up to 283 m^3, 0.7 s for 283–566 m^3 — **transferred to deliberation with the transfer declared.** That standard was arrived at through the speech-intelligibility literature for children in classrooms, and the transfer is defensible because a committee member straining to hear is in the same acoustic situation as a child at the back; **it is a transfer nonetheless, and the standard itself is named here without a bibliography entry because none was assembled for it.** Section 12 lists that gap.

Room type	Volume	RT60 target, occupied, 500 Hz–2 kHz	Background, unoccupied
Small meeting or deliberation room	up to 150 m^3	0.40–0.60 s	<= 35 dBA
Larger meeting room	150–300 m^3	0.50–0.70 s	<= 35 dBA
Seminar room or classroom	up to 283 m^3	<= 0.60 s (standard limit)	<= 35 dBA (standard limit)
Seminar room or classroom	283–566 m^3	<= 0.70 s (standard limit)	<= 35 dBA (standard limit)
Open-plan work area	–	RT60 is the wrong gauge; specify distraction distance and spatial decay	<= 40 dBA
Common room or social space	–	0.6–0.9 s; some liveliness is wanted	<= 45 dBA

Two requirements matter more than the absolute number:

```
FLATNESS:   max RT60 over 250 Hz .. 4 kHz  <=  1.25 x  min RT60 over the same bands
BASS RATIO: (RT60_125 + RT60_250) / (RT60_500 + RT60_1k)   in  [0.9, 1.3]
```

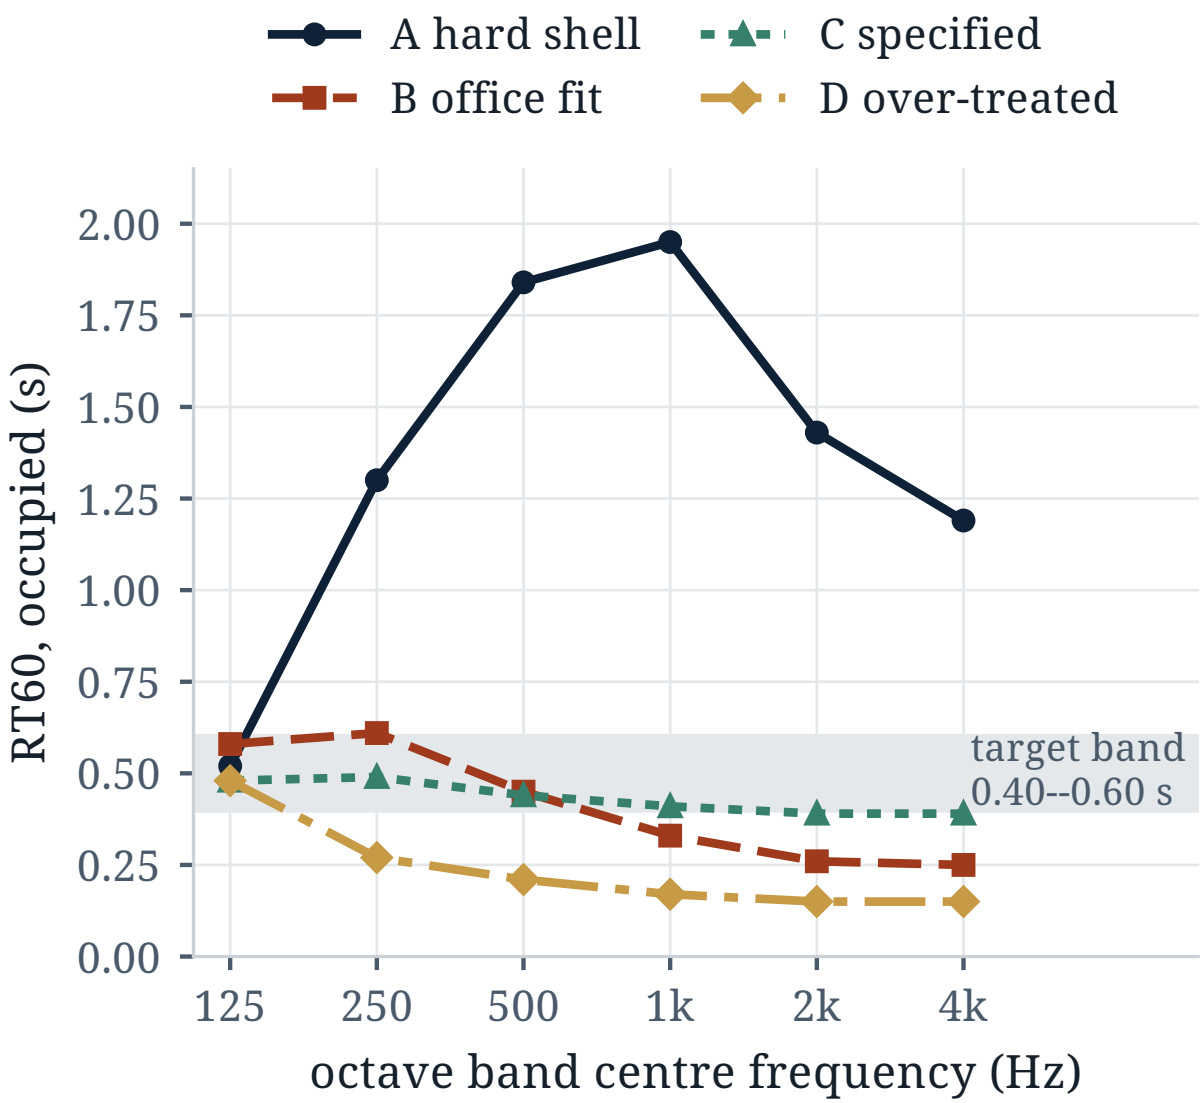

Figure 11.2: **Passing a single-number test is not passing.** State B meets a 0.45 s figure at 500 Hz and is 2.4 times more reverberant at 250 Hz than at 4 kHz; only State C is flat across the band. RT60 per octave band for the four build states of a 100 m^3 room with eight occupants, modelled from Sabine's `0.161 V/A` with the nominal absorption coefficients of Section 6.2. State D is plotted on its Sabine figures, which is what a designer using Sabine alone would have believed; Eyring gives 0.11 s at 1 kHz and 0.09 s at 2 kHz for that state. Generated by `figs/src/CCP-011_fig03.py`.

State	RT60 at 500 Hz	Meets 0.4–0.6 s?	Flatness ratio, 250 Hz–4 kHz	Bass ratio	Verdict
A hard	1.84 s	**No**	5.0	0.48	Fails everything
B office	0.45 s	Yes	2.4	1.53	**Passes the number, fails the room**
C specified	0.44 s	Yes	1.26	1.14	Passes; flatness marginal
D over-treated	0.15 s (Eyring)	**No — too dead**	2.3	1.99	Fails everything

State B is the entry that justifies the whole per-band apparatus: it passes the single-number test that almost every specification in the world uses, and it is a bad room. The structure is the same one that recurs whenever a summary statistic is substituted for a typed measurement — a naive detection precision of 11.01 per cent against a typed-parsing procedure that collapses the false-positive share from 88.99 per cent to 0.00 per cent is the same failure in an entirely different domain [Curzi, 2026]: **a control that is right one time in nine is not a control.**

11.7 7 The exclusion mechanism

11.7.1 7.1 The chain of inference, with its joints exposed

1. Speech intelligibility at a listener depends on the direct-to-reverberant ratio and on the signal-to-noise ratio at that listener. [PHYSICS]
2. Both degrade with distance, with reverberation time, and with background level. [PHYSICS]
3. A quiet talker produces less sound power than a loud one, so at any given seat the quiet talker's D/R and SNR are worse. [PHYSICS]
4. A talker who is not understood is interrupted, asked to repeat, or gives up, and each reduces their share of turns. [MECHANISM, OBSERVABLE]
5. Therefore the room produces turn-taking inequality not attributable to anyone's behaviour. [H2]
6. Turn-taking equality correlates with the collective-intelligence factor c. [CITED]
7. Therefore acoustic treatment raises c. [H3 -- requires a causal direction in step 6]

Links 1 to 3 are physics and are not in dispute. Link 4 is a mechanism this paper asserts and tells the reader how to measure. Links 5 and 7 are the hypotheses of Section 2. Link 6 is a citation with a stated limit: Woolley et al. [2010] found a single statistical factor predicting a group's performance across varied tasks, not predicted by members' average or maximum individual ability, correlating with social sensitivity, equality of conversational turn-taking, and the proportion of women in the group. **The factor was measured in short-task laboratory settings, and extrapolation to a standing institutional committee is a modelling assumption, not a finding.** The replication and extension literature is mixed and is not uniformly supportive [Engel et al., 2014, Bear and Woolley, 2011], and the broader diversity-and-performance literature carries its own well-documented scepticism [Mannix and Neale, 2005, Thompson, 2014, van Knippenberg and Schippers, 2007]. **Anyone rejecting the conclusion must say which link they are cutting**, and Section 9.2 reports a test that cuts link 7.

11.7.2 7.2 The tail sets the minimum gap

This is the most direct link between Sabine's equation and the turn-taking finding, and it is pure arithmetic. Sound decays at `60/RT60` decibels per second. **To take a turn, a talker must be audible over the tail of the previous speaker.** The room therefore imposes a minimum inter-turn gap: the time required for the previous speaker's energy to fall far enough. Decibels fallen after a gap of `t`:

RT60	100 ms	200 ms	300 ms	500 ms	800 ms	1000 ms
0.40 s	-15.0	-30.0	-45.0	-75.0	-120	-150
0.50 s	-12.0	-24.0	-36.0	-60.0	-96.0	-120
0.60 s	-10.0	-20.0	-30.0	-50.0	-80.0	-100
0.80 s	-7.5	-15.0	-22.5	-37.5	-60.0	-75.0
1.00 s	-6.0	-12.0	-18.0	-30.0	-48.0	-60.0
1.50 s	-4.0	-8.0	-12.0	-20.0	-32.0	-40.0
2.00 s	-3.0	-6.0	-9.0	-15.0	-24.0	-30.0
3.00 s	-2.0	-4.0	-6.0	-10.0	-16.0	-20.0

Inverted, the gap required for the tail to fall by a usable margin — **and the 15 dB column is the result this paper contributes, `t_15 = RT60/4`:**

RT60	gap for -10 dB	gap for -15 dB	gap for -20 dB
0.30 s	50 ms	75 ms	100 ms
0.40 s	67 ms	100 ms	133 ms
0.50 s	83 ms	125 ms	167 ms
0.60 s	100 ms	150 ms	200 ms
0.80 s	133 ms	200 ms	267 ms
1.00 s	167 ms	250 ms	333 ms
1.50 s	250 ms	375 ms	500 ms
2.00 s	333 ms	500 ms	667 ms
3.00 s	500 ms	750 ms	1000 ms

Conversation-analytic work reports median turn-transition gaps on the order of 200 milliseconds across a range of languages. **That figure is BORROWED and this paper carries no bibliography entry for it** — the database assembled for this corpus contains none — **so it is treated as indicative and every applied use requires the room's own measurement.** Nothing below depends on the exact value; the argument depends only on the gap being short, which is uncontroversial.

The mechanism, stated cleanly. At `RT60 = 0.5 s`, a 200 ms gap leaves the previous speaker 24 dB down and a quiet talker entering that gap is comfortably above the tail. At `RT60 = 2.0 s` the same 200 ms gap leaves the previous speaker only 6 dB down — so a talker 12 dB quieter than the previous speaker is 6 dB BELOW the tail of the speech they are trying to follow. They are inaudible. They will be talked over. They will experience this as being interrupted, and everyone else will experience it as their not really having said anything.

Two secondary consequences follow and both are observable. **The loud talker is unaffected:** at 12 dB above the quiet talker they clear the tail at 200 ms in a 2 s room as well. **Reverberation is not a uniform degradation; it is a filter that selects for vocal power**, and the hierarchy it installs is ordered by lung capacity. And **the room lengthens turns:** if short gaps do not work, speakers learn — without knowing they are learning it — to hold the floor, because releasing and reclaiming it is expensive. **Long turns by few people is precisely the turn-taking-inequality signature the collective-intelligence instrument measures.**

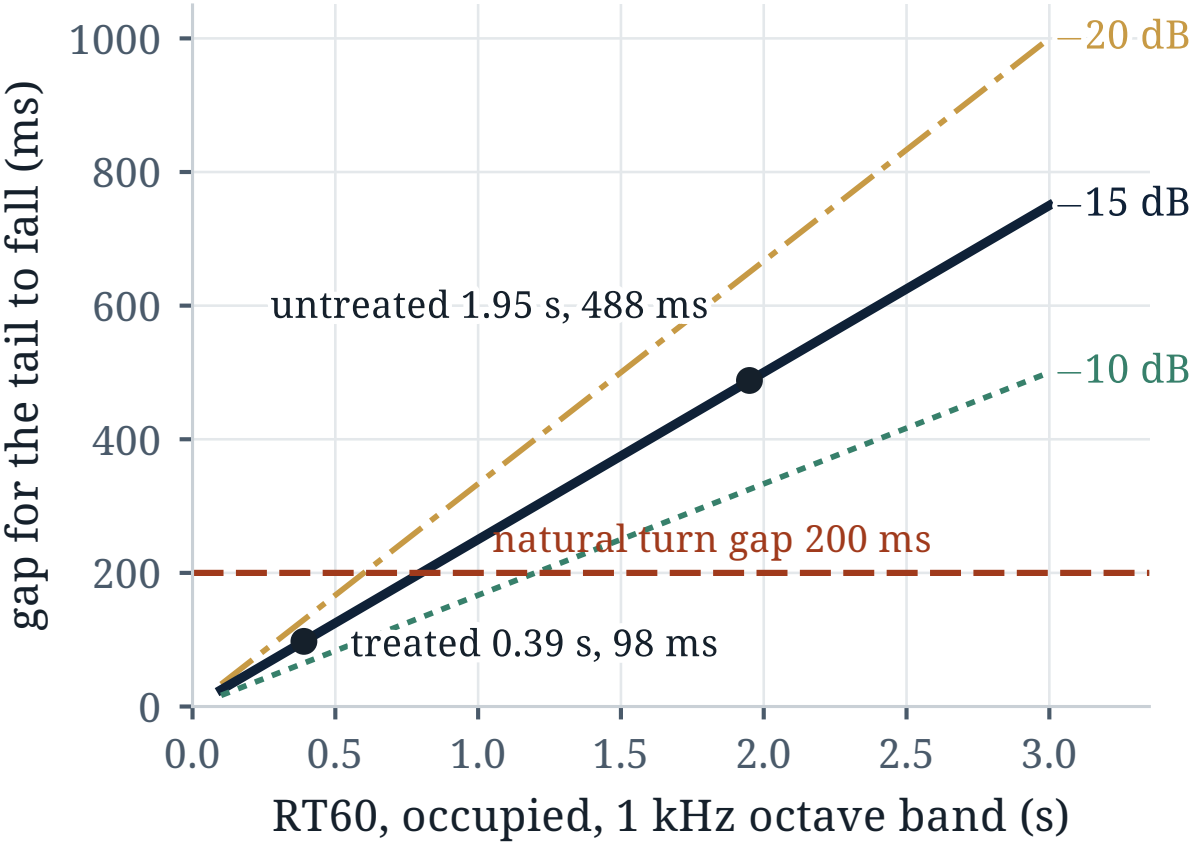

Figure 11.3: **The room, not the participants, sets the price of taking a turn.** The gap required for the previous talker's tail to fall 15 dB is `t_15 = RT60/4`, so the untreated worked room at 1.95 s demands 488 ms against a natural turn gap of about 200 ms while the same room treated to 0.39 s demands 98 ms — a factor of five. Derived from the decay-rate identity `60/RT60` dB per second; the two RT60 values are the worked case's measured and predicted values, and the 200 ms reference is borrowed and indicative rather than measured here. Generated by `figs/src/CCP-011_fig01.py`.

11.7.3 7.3 The two fields, and why the loud voice wins

Two things reach a listener: the **direct** sound, falling 6 dB per doubling of distance, and the **reverberant** field, the same everywhere. Take a talker producing 60 dB at 1 m in free field on-axis — the standard reference for normal vocal effort — with `Q = 2`, and compare State A with State C at 1 kHz, where `R_A = 8.9 m^2` and `R_C = 53.4 m^2`:

r	A: direct	A: reverb	A: total	**A: D/R**	C: direct	C: reverb	C: total	**C: D/R**
0.5 m	66.0	64.5	68.3	**+1.5**	66.0	56.7	66.5	**+9.3**
1.0 m	60.0	64.5	65.8	**-4.5**	60.0	56.7	61.7	**+3.3**
1.5 m	56.5	64.5	65.2	**-8.0**	56.5	56.7	59.6	**-0.3**
2.0 m	54.0	64.5	64.9	**-10.5**	54.0	56.7	58.6	**-2.8**
2.5 m	52.0	64.5	64.8	**-12.5**	52.0	56.7	58.0	**-4.7**
3.0 m	50.5	64.5	64.7	**-14.1**	50.5	56.7	57.6	**-6.3**
4.0 m	48.0	64.5	64.6	**-16.6**	48.0	56.7	57.3	**-8.8**
5.0 m	46.0	64.5	64.6	**-18.5**	46.0	56.7	57.1	**-10.7**

Read the total columns first, because they contain the trap. In State A the total level barely falls with distance at all — 68.3 dB at 0.5 m, 64.6 dB at 5 m. **The hard room is LOUDER at the far seats than the treated room is, and a sound level meter would report State A as the better room.** Now read the D/R columns: at 3 m, State A delivers `-14.1` dB and State C `-6.3` dB, a 7.8 dB difference in the ratio that actually determines intelligibility. **Reverberation raises level and destroys clarity. It is loudness without information, and it is the most common reason a room sounds fine on a meter and cannot be worked in.** A speech room must therefore never be specified or evaluated on sound pressure level.

Now put two talkers in the room. Normal vocal effort is nominally 60 dB at 1 m; raised is 66, loud 72, shout 78. A more assertive talker at 66 dB and a quiet talker at 54 dB differ by 12 dB — a factor of about 16 in acoustic power, entirely within the normal range of human vocal output. Take a listener 3 m away and 40 dBA of background, and compute the quiet talker's *direct* sound, which is the only part carrying clarity, against the loud talker's *reverberant* field, which fills the room uniformly:

Room	`R`	Quiet talker's direct at 3 m	Loud talker's reverberant field	Combined noise	**SNR for the quiet voice**
A hard	8.9 m^2	44.5 dB	70.5 dB	70.5 dB	**-26.1 dB**
B office	73.6 m^2	44.5 dB	61.3 dB	61.4 dB	**-16.9 dB**
C specified	53.4 m^2	44.5 dB	62.7 dB	62.8 dB	**-18.3 dB**

And the exclusion radius — how close a listener must be before the quiet talker's direct sound exceeds the loud talker's reverberant field at all:

Room	Noise floor from the loud talker	Quiet voice audible within	At +6 dB SNR within	At +15 dB SNR within
A hard	70.5 dB	0.15 m	0.07 m	0.03 m
B office	61.4 dB	0.43 m	0.21 m	0.08 m
C specified	62.8 dB	0.37 m	0.18 m	0.06 m

In State A, while a loud talker is speaking, a quiet talker is intelligible only within 150 millimetres of their mouth — inside the intimate proxemic zone [Hall, 1966]. In practical terms they cannot be heard at all.

Two honest notes. **First**, this is the simultaneous-speech case — the moment of overlap when someone tries to take a turn while another is still speaking — and not the case where the quiet talker has the floor alone. But the simultaneous case is exactly the case that determines

who gets the floor, because that is what turn-taking is: a brief overlap in which one party yields. **Second, State C's numbers here are slightly worse than State B's**, because State B has more total absorption at 1 kHz and hence a larger R. The exclusion radius is not the only gauge, and State C wins decisively on flatness, on the tail arithmetic, and on early-reflection support. **Report the metric that lost as well as the metrics that won.** A design quoting only its favourable numbers is not an engineering document.

11.7.4 7.4 From silenced voices to lost ceiling

Suppose the room reliably silences k of N participants. Then the interaction's effective category count is `N − k` and the per-interaction ceiling `ln N` falls accordingly:

N	8	7	6	5	4	3	2
ln N	2.0794	1.9459	1.7918	1.6094	1.3863	1.0986	0.6931
Loss versus ln 8	0.0%	6.4%	13.8%	**22.6%**	33.3%	47.2%	66.7%

Silencing three of eight people costs `ln 8 − ln 5 = 0.4700` nats, 22.6 per cent of the room's entire per-interaction surplus ceiling — permanently, in every meeting, for as long as the room stands. And because the functional is deployed as a lower bound, the realised loss may be larger: the three silenced participants may have been the ones carrying the non-parallel view, which is the same failure the parallel-wall analysis reaches from the other direction [Curzi, 2026d]. The information lost at a boundary in this way is structurally the same quantity as the identity provenance lost at a carrier boundary — 18.932 bits entering, 8.000 bits observable from an address alone [Curzi, 2026]: **what the receiving side can distinguish is the ceiling on what it can act on.**

The turn-share statistic, and what it is not. To measure turn-taking equality, record speaking-time shares `p_1 ... p_n` and compute `N_eff_turn = exp( − sum_i p_i ln p_i )`. **This is the exponential of the Shannon entropy of the turn distribution — the Hill number of order one [Hill, 1973, Jost, 2006, Pielou, 1966] — and it is a descriptive diversity index. It is NOT the surplus law's `N_eff = 1 + (N−1)u`, which is not a Hill number of any order, and surplus is not identified with Shannon entropy. These are different numbers travelling under similar names. Do not substitute one for the other and never report `ln(N_eff_turn)` as a surplus.** With that badge attached it is a good instrument for what it does measure:

Turn-share distribution across eight people	N_eff_turn	as a fraction of 8
Perfectly equal, 12.5% each	8.00	1.000
16/15/14/13/12/11/10/9	7.87	0.983
40/20/15/10/5/5/3/2	5.40	0.675
35/30/15/8/5/4/2/1	5.04	0.630
60/20/10/5/2/1/1/1	3.40	0.425

`N_eff_turn / n` is the field measurement for turn-taking equality; it takes one recording and one line of arithmetic, and it is the number to track before and after treatment.

11.7.5 7.5 Background noise and the Lombard loop

Background level must be specified and measured. Noise-criteria curves specify a maximum in each octave band rather than a single A-weighted number, which matters because a low-frequency rumble at 40 dBA is far more fatiguing than broadband hiss at 40 dBA. Nominal correspondences, which are spectrum-dependent: NC-15 near 25 dBA (concert hall, recording); NC-20 near 30 (very quiet meeting); **NC-25 near 34 (deliberation-room target)**; NC-30

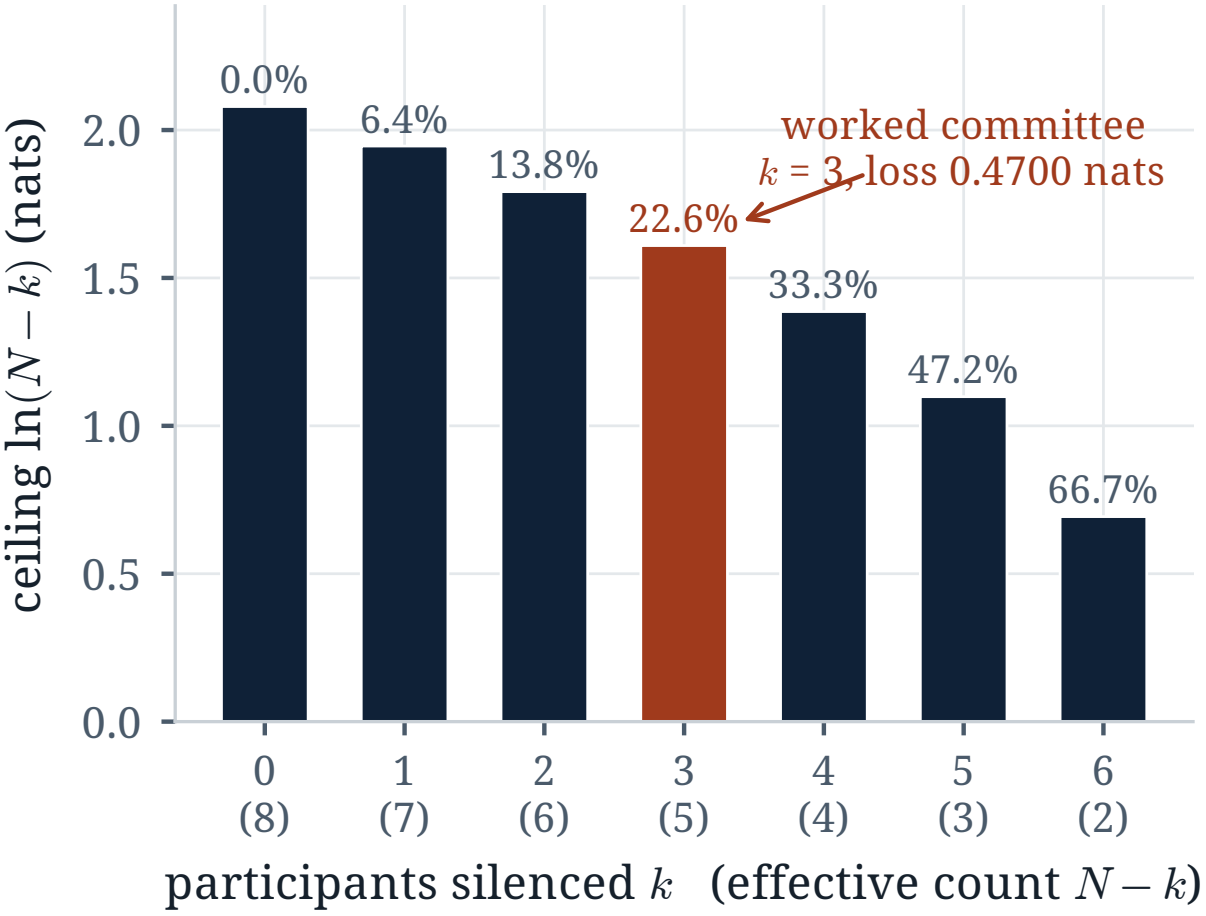

Figure 11.4: **Acoustic exclusion is a permanent tax on the room's ceiling, not an occasional inconvenience.** Silencing three of eight participants moves the per-interaction ceiling from `ln 8 = 2.0794` to `ln 5 = 1.6094` nats, a loss of 0.4700 nats and 22.6 per cent. Exact arithmetic on the logarithm; the count `k = 3` is the output of a declared audibility threshold and is a judgement with a stated cut-off, not a measurement of the cut-off itself. Generated by `figs/src/CCP-011_fig04.py`.

near 38 (acceptable meeting room); NC-35 near 42 (general office); NC-40 near 47 (busy open plan); NC-45 near 52, too noisy for sustained speech.

Signal to noise. For normal-hearing adult native listeners, intelligibility approaches its maximum around +15 dB SNR, and **more is required for children, for non-native listeners, for anyone with hearing loss, and for anyone working in an unfamiliar technical vocabulary.** Since a deliberation room contains some of those people some of the time, +15 dB is a floor and not a comfort. The vocal effort required to reach it at 3 m in State C:

Background	Required talker level at 1 m	Vocal effort category
30 dBA	47.4 dB	below normal — easy
35 dBA	52.4 dB	below normal
40 dBA	57.4 dB	approaching normal (60)
45 dBA	62.4 dB	between normal and raised
50 dBA	67.4 dB	above raised (66), toward loud
55 dBA	72.4 dB	**loud (72) — sustained shouting**

At 55 dBA background a participant must speak at loud effort continuously in order to be understood at three metres, and anyone who cannot or will not sustain that is out of the conversation. That includes people with respiratory conditions, people recovering from illness, people with soft voices, and people for whom raised voices carry meanings they do not wish to convey. **This is an accessibility failure produced by a mechanical services decision.**

The Lombard loop. The Lombard effect is the involuntary rise in vocal level in response to background noise; reported slopes are of the order of 0.3 to 0.6 dB of vocal level per dB of background above roughly 45 dB. **Treat the slope as a reported range rather than a constant; this paper carries no bibliography entry for it and the range is taken from engineering practice.** Now note the structure: in a room with several conversations, each conversation's output is background for the others, which is a feedback loop with loop gain `s`, and `total rise = seed / (1 − s)`.

Lombard slope `s`	0.0	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
Closed-loop gain `1/(1−s)`	1.00	1.25	1.43	1.67	2.00	2.50	3.33	5.00	10.00
A 5 dB seed becomes	5.0	6.2	7.1	8.3	10.0	12.5	16.7	25.0	50.0

At the mid-range reported slope of 0.5, every decibel of avoidable background noise costs two decibels of eventual room level. This is the contraction-mapping fixed point in a different domain — stable because the gain is below unity, converging from any start, distance shrinking by at least `q` each pass [Banach, 1922, Curzi, 2026] — and it is a **shared mathematical form**, not a claim that a room is a circuit. The room is a leaky integrator for noise, its DC gain is `1/(1−s)`, and its fixed point is the volume at which everyone in the room is shouting. **Design consequence: the cheapest decibel to remove is the first one, because removing one decibel of source removes `1/(1−s)` decibels of eventual level.** Fixing a noisy diffuser is worth about twice its nominal value.

11.7.6 7.6 The exclusion calculation

A contribution never attempted leaves no trace, so the value of what a room silences cannot be measured by asking. **This is the procedure that computes it from physics.**

1. Measure `RT60` per band, occupied, and the background level (Appendix A).
2. Compute `R = A/(1 − alpha_bar)` and `d_c = 0.141 sqrt(Q R)` at 1 kHz.
3. Measure the actual seat separations; take `r_max` as the greatest talker-to-listener distance.

4. Measure the room's vocal-level spread — recording the participants for one meeting and taking the 10th and 90th percentile of per-talker level at 1 m is adequate; the spread is typically 10–14 dB.
5. For the quietest-decile talker at `r_max`, compute their direct level, the reverberant field of the loudest-decile talker, and the background, and obtain the SNR.
6. Compute the gap for the tail to fall 15 dB: `t_15 = RT60/4`.
7. **Count how many participants fall below the audibility criterion.** That count `k` is the number of effectively silenced voices.
8. The ceiling loss is `ln N − ln(N − k)` and the fractional loss is `1 − ln(N−k)/ln N`.

Applied to State A with eight participants, `r_max = 3.5 m` and a 12 dB vocal spread: the quietest three have SNR below 0 dB against a loud talker's reverberant field, and `t_15 = 1.95/4 = 488 ms`, roughly 2.4 times a typical turn gap. **`k = 3, ln 8 − ln 5 = 0.4700` nats, 22.6 per cent of the ceiling.** Converting into the storage law with `eta = 0.5` and the room used weekly, the room forgoes `0.5 x 0.47 = 0.235` units of stored-order production per meeting, every meeting.

Honesty on this procedure. Steps 1 to 6 are physics. **Step 7 — the conversion of an SNR deficit into a count of silenced participants — is a judgement with a stated threshold, and different thresholds give different `k`.** State the threshold, sensitivity-test it, and report the range. **What the procedure yields is not a precise loss but a defensible order of magnitude computed from measurements rather than from opinions.** The alternative is nothing, because the quantity is unobservable by survey. That the count is an integer produced by a cut-off, and that the underlying audibility judgement is at best ordinal, is recorded in Section 11.8 and in Section 12.

11.7.7 7.7 Table geometry

Acoustics and geometry interact, and the acoustic constraint usually bites first. **The governing distance is the longest talker-to-listener path** — for a round table of diameter `D` that is `D`; for a rectangular table of length `L` and width `W` it is `sqrt(L^2 + W^2)`, corner to corner.

Table	Longest path	In State A (`d_c` = 0.42 m)	In State C (`d_c` = 1.03 m)
Round, 1.6 m	1.60 m	3.8 `d_c`	1.55 `d_c` — marginal
Round, 2.4 m	2.40 m	5.7 `d_c`	2.33 `d_c`
Round, 3.2 m	3.20 m	7.6 `d_c`	3.11 `d_c`
Rectangular 3.0 x 1.2 m	3.23 m	7.7 `d_c`	3.14 `d_c`
Rectangular 4.8 x 1.4 m	5.00 m	11.9 `d_c`	4.85 `d_c`

Every practical meeting table puts every listener in the reverberant field, and no room treatment makes a 4.8 m table a direct-field environment. What treatment does is raise `d_c` and so reduce how deeply the far seats sit inside the reverberant field — from 11.9 `d_c` to 4.85 `d_c` for the long table, a 7.8 dB improvement in direct-to-reverberant ratio at the far corner. Three rules follow.

Rule 1 — the long rectangular table is an acoustic hierarchy generator. At 4.8 m, corner to corner is 5.0 m, and the people at the two ends are 11 dB apart in direct sound relative to a neighbour pair. **The table has a head whether or not anyone sat there deliberately**, because the seats nearest the middle of the long sides are heard by everyone and the seats at the ends are not. The governance consequence, and the deference model that prices it, are developed in Curzi [2026f].

Rule 2 — reduce the table before reducing the group. Twelve people at a 2.4 m round table have a 2.4 m longest path; the same twelve at a 4.8 m boardroom table have a 5.0 m longest

path and a 6.4 dB worse direct-to-reverberant ratio at the extremes. **The table, not the headcount, was the problem.** That is an acoustic statement and not a licence for unlimited rosters: a separate ceiling binds the headcount through pairwise cost, `m(m−1) <= 2 eta ln(N)/kappa`, and the constructed commons that meets it sits at 30 against a bound of 30.7225, so that a seventh member makes the case structural rather than personal [Curzi, 2026]. **The two ceilings are independent and a room can satisfy one while violating the other.**

Rule 3 — a hard reflective surface directly above the table is an asset. Early reflections from a hard ceiling panel arrive within a few milliseconds of the direct sound and are integrated with it. This is what State C's 20 m^2 hard central ceiling panel is for, and it is why blanketing an entire ceiling in absorption is a mistake. **Absorb the perimeter, reflect the centre.**

Sightline reinforces all three: visual access to a talker's face contributes materially to intelligibility, and everyone should be able to see everyone else's face without a head turn beyond about 45 degrees. A round or polygonal table satisfies this automatically; a long rectangle cannot.

11.7.8 7.8 Why this is the cheapest available intervention on the mediator

The argument can be stated structurally without inventing prices.

Intervention	Cost structure	Does it decay?	Ongoing attention?	Fails when?
Acoustic treatment	One-time capital; near-zero running	Material lifetime, decades	No	Physical damage or refurbishment
Facilitation	Recurring, per meeting, indefinitely	Immediately; every meeting needs it again	Yes, continuously	The facilitator is absent, tired, junior, or outranked
Training in inclusive practice	One-time plus refreshers	Fast; skill and salience decay	Yes	Turnover, which is itself a decay term

In the framework's own terms: **facilitation and training are surplus inputs with high retention loss and a recurring cost; acoustic treatment is a cost reduction and a ceiling restoration whose retention loss is set by concrete and mineral wool.** Treatment moves the intervention out of a high-decay store — human attention and skill — into a low-decay store, the building. That is the same structure as putting coordination state into a medium rather than into a coordinator: a facilitator enforcing turn-taking is a coordinator, and an absorptive ceiling is a medium. **The medium does not get tired, does not get outranked by a senior participant, does not need to be scheduled, and does not leave the organisation.**

One asymmetry is decisive. **Facilitation works only when someone notices the problem. Acoustics works on the meetings nobody is watching** — the corridor conversation, the unscheduled four people who took the room, the discussion after the chair left. Those are most meetings and they receive no facilitation at all. **Acoustic treatment is a one-time capital expenditure that raises turn-taking equality in every meeting held in that room for the life of the building, without administration.**

What this argument does not establish is that the intervention is worth its price against any particular alternative, because no prices are given, and it does not establish that raising the mediator raises the outcome — which is H3, and which Section 9.2 reports as unconfirmed. A large ratio on a mediator is compatible with failure most of the time: the corpus's own audited case lifts an outcome probability from 0.0140 to 0.0697, a 4.975-fold ratio that still fails 93 per cent of the time [Curzi, 2026ac]. **A multiplier on a small number is a small number.**

11.8 8 Design specifications

The requirements below are stated in the form a specification would carry. **G1–G15 are the geometric requirements; A1–A28 the acoustic.** Each geometric requirement names its certification tier from Section 5.7 and the term of the storage law it acts on. **A requirement is not a finding**: the schedule is a design instrument derived from the results above, and its numerical thresholds are chosen values rather than measured optima. Section 12 says so again.

11.8.1 8.1 Geometric requirements

G1 (Tier 1; acts on C). Any spatial function dischargeable by shape shall be discharged by shape rather than by a powered device, unless the powered device is shown to have a lower whole-life cost. **Show the comparison; do not assert it.**

G2 (Tier 1; acts on S, u). Room boundaries intended to carry seating shall be crenellated to a computed multiplier of not less than 1.5, using `1 + d/w` with `d >= 0.40 m` and `w >= 0.60 m`. Boundary at scales below `d = 0.40 m` shall not be counted toward any seating requirement.

G3 (Tier 1; acts on N). A nested enclosure shall present usable features at not fewer than three distinct scales, with adjacent scales differing by a factor of not less than 2.5.

G4 (Tier 1; acts on N, u). The four-part seating pattern of Section 5.6 — back protected, view out, visible exit, reachable boundary — shall be satisfiable at every rung of the built ladder, and the surveyor shall record occupancy at each rung to test it.

G5 (Tier 2; acts on the effort component of C). Any acoustic reflector specified for speech shall have its frequency floor computed as `f_floor = 2c/D` and stated on the drawing. **A reflector whose floor lies above 2 kHz shall not be described as improving speech; it may be described as a consonant-band device.**

G6 (Tier 2). Any stated aperture gain shall carry its assumed `eta_ap`, shall be labelled an upper bound, and shall be accompanied by a note that near-field performance will fall short.

G7 (Tier 1; acts on C). Parabolic reflectors shall be specified in focal form `y = x^2/(4f)` with `f`, `D`, depth `D^2/(16f)` and `f/D` all stated. An `f/D` between 0.24 and 0.30 shall be preferred unless a reason is recorded.

G8 (Tier 2; acts on u). The focus of any listening reflector shall be positioned so that the intended listener's head occupies it, and the shell shall be aimed so that no other seat lies within the half-power beam. **A reflector privileging more than one seat has created a hierarchy of seats.**

G9 (Tier 3; acts on u and on the exclusion component of C) — PROHIBITION. No concave surface with a radius of curvature comparable to a room dimension shall face the occupied zone unless it is diffusive, absorptive, or demonstrably focused away from every seat, and unless the demonstration is by one of the four Tier 3 methods of Section 5.7.

G10 (Tier 3). Every claim resting on self-similarity shall name the Tier 3 method used to verify it, the frequency or scale range over which the verification is valid, and the date. **A self-similarity claim without a named method shall be struck from the specification.**

G11 (Tier 3; acts on S). Acoustic sub-division of an open floor by alcove geometry shall be verified by measuring the A-weighted level difference between the alcove seat and a reference position at 4 m with a real source. A design target of not less than 6 dB shall be set, **and the measured value shall be recorded whether or not it meets the target.**

G12 (Tier 1; acts on `delta`). Geometric elements intended to perform a function shall be built in materials whose service life exceeds the function's horizon by a factor of two. **The retention advantage of geometry is entirely a material property and is forfeit if the geometry is built in something that fails first.**

G13 (acts on C, and on dignity). Every recess, alcove and niche shall be cleanable, reachable, lit, and visible from at least one circulation route. **An unobservable recess is a liability, not an amenity**, and boundary multiplication that creates concealed space without sightline creates a safety problem no acoustic benefit offsets [Jacobs, 1961].

G14 (ethics). No nested geometry shall be arranged such that an occupant of an inner scale cannot leave without passing through an occupied outer scale. **Nesting must not become entrapment.** Every rung shall have an exit that does not require crossing another group.

G15 (measurement integrity). Perimeter counted toward a sittable-edge ratio shall be counted at seating scale only, per G2, and any published perimeter figure shall state the scale at which it was measured. **By Theorem 4, a boundary length is meaningless without its ruler.** A specification reporting "78 m of edge" without saying at what scale has reported nothing, and this is the most common route by which a fractal architectural claim becomes unfalsifiable.

11.8.2 8.2 Acoustic requirements

Envelope. A1 (acts on the effort component of `C`, and on `N`): `RT60`, **occupied**, in the 500 Hz, 1 kHz and 2 kHz octave bands shall lie within the range set for the room type in Section 6.4. **A2 (flatness):** across 250 Hz to 4 kHz, the maximum `RT60` shall not exceed 1.25 times the minimum. **A3 (bass ratio):** `(RT60_125 + RT60_250)/(RT60_500 + RT60_1k)` shall lie in `[0.9, 1.3]`. **A4 (lower bound):** `RT60` shall not fall below 0.30 s in any band from 250 Hz to 4 kHz. **A5:** where `alpha_bar` exceeds 0.25 in any band, Eyring's formula shall be used and the choice stated. **A6:** all `RT60` figures shall be stated per octave band from 125 Hz to 4 kHz and shall state whether they are occupied or unoccupied. **A7:** the 125 Hz figure shall carry a note stating the room's Schroeder frequency and whether the band lies below it.

Absorption placement. A8 (acts on the diffuse-field assumption): absorption shall be distributed over at least two non-parallel planes. **A9:** not less than 30 per cent of the installed absorption, by area, shall be capable of `alpha >= 0.40` at 125 Hz. **A10:** a hard reflective ceiling zone of not less than 40 per cent of the table's plan area, centred over the table, shall be retained. **A11:** at least one pair of opposing parallel hard surfaces shall be broken by absorption or diffusion. **A12:** G9's prohibition applies to the acoustic design as well as the geometric. **A13:** every absorption coefficient used in the calculation shall be traceable to the specific product's tested data at the intended mounting condition.

Background noise. A14 (acts on effort and on accessibility): background level, unoccupied with all services running, shall meet the limit for the room type. **A15:** no tonal component shall exceed the adjacent bands by more than 5 dB. **A16:** sound insulation from adjacent spaces shall be sufficient that intrusive speech is not intelligible. **A17:** where masking is used it shall be broadband, steady, and below 42 dBA.

Geometry. A18 (acts on `u`): the longest talker-to-listener path shall not exceed 3.0 m for a deliberation room. **A19:** table geometry shall be round or regular-polygonal; rectangular tables require a recorded justification. **A20:** the critical distance `d_c = 0.141 sqrt(Q R)` at 1 kHz shall be computed and recorded together with the ratio `r_max/d_c`. **A21:** every seat shall have unobstructed sightline to every other seat's face within a head turn of about 45 degrees. **A22** (accessibility): at least two seats shall be positioned within 1.5 m of the talker's typical position, and **these shall not be positioned so as to constitute a privileged position.**

Verification and conduct. A23: all eight measurements of Appendix A shall be performed at commissioning and recorded with dates, positions and equipment. **A24:** `RT60` shall be remeasured after any change to furniture, floor covering, glazing treatment or ceiling. **A25:** `N_eff_turn / n` shall be measured before and after treatment over not fewer than six meetings. **A26 (ethics):** no recording of a meeting for turn-share measurement shall be made without the informed consent of every participant, and consent shall be renewable and revocable. **A27 (ethics):** acoustic treatment shall not be presented as, or substituted for, a remedy for a hierarchy that is not acoustic in origin. **A28 (measurement integrity):** the falsification test of Section 9.2 shall be preregistered before treatment, and **it shall include a matched untreated control room**, because measuring a group's turn-taking is itself an intervention [McCambridge et al., 2014, Nosek et al., 2018].

11.9 9 Results: two systems worked end to end

Both systems are constructed. No dataset was collected for this paper. Every number below is the output of the stated parameters under the models of Sections 4 to 7, carried through so that a reader can re-derive it. They demonstrate that the procedure runs and that it reports its own failures; **they are not evidence that any organisation or any room behaves this way.**

11.9.1 9.1 A 120 m^2 common room: geometry against an unmeetable requirement

The subject. The departmental common room whose survey returns `N = 2`, a sittable-edge ratio of 0.050 against a requirement of 0.109, an optional-activity ratio of 0.185, `delta = 0.0808` per week, `eta_hat = 0.0455` and `h = −1.396` [Curzi, 2026d]. The prescription was to raise `N` from 2 to 5, cut the acoustic cost term, and shed stored order. **This section designs the geometry that delivers the `N` increase and prices what it can and cannot certify.** Constraints: no structural walls may be added; the two glazed walls must remain glazed; the budget is fit-out joinery.

Step 1 — boundary multiplication. The room is approximately square at 10.95 x 10.95 m, perimeter 43.82 m, of which 21.9 m is glazing that cannot be recessed and 21.9 m is solid wall plus a kitchenette run. Crenellate the solid boundary inward, freestanding, using banquette backs and storage joinery, at `d = 1.00 m` and `w = 1.50 m`:

```
multiplier          = 1 + d/w = 1 + 1.00/1.50 = 1.6667
perimeter           = 43.82 -> 73.03 m
boundary gained     = 29.21 m
niche floor created = 21.91 m of run x 1.00 m = 21.91 m^2
open floor          = 120 - 21.91 = 98.09 m^2
required edge       = 98.09 x 0.1094 = 10.73 m
available at seating scale (d >= 0.40 m) = 73.03 m
surplus factor      = 6.8x
```

The requirement was never hard to meet. It was hard to meet in a room with no boundary. Fitting seats to the new edge at 0.65 m pitch would allow 112 positions, which is absurd for 90 users; the correct move is to occupy a fraction of the new boundary generously rather than all of it meanly.

Element	Boundary consumed	Seats	Rung
Four banquette alcoves, `d` = 1.00 m, 2.4 m wide	17.6 m	16	alcove
Deepened window ledges, 450 mm, perch height 700 mm	9.0 m	9 perch	desk
High table and rail against the kitchenette crenellation	3.6 m	6 stool	desk/alcove
Existing free tables, unchanged, in the open floor	0	24	room
Unoccupied boundary: circulation, storage face, doors	42.8 m	0	–

Element	Boundary consumed	Seats	Rung
Total	**73.0 m**	**55**	

Step 2 — the scale ladder, checked against G3. Rung `k = 0` is the ledge perch and high-table stool at 0.75 m; `k = 1` the banquette recess, 2.4 m wide by 1.0 m deep; `k = 2` the 98 m^2 open floor with its tables, characteristic dimension 9.9 m. **Adjacent ratios 3.20 and 4.13, both above the 2.5 minimum: G3 satisfied.** A secondary order — a 0.30 m deep by 0.45 m wide relief in the banquette backs for shelving and personal items — sits below G2's 0.40 m seating floor, so **it contributes zero to the sittable-edge ratio and is not counted.** It is specified for acoustic scattering and for the reachable-boundary condition of the seating pattern, and that reason is stated on the drawing.

Step 3 — the category audit, recomputed. Applying the survey's own procedure and strike rule:

#	Posture	Purpose	Condition	Available?
1	Sitting upright, standard chair	Eating, pair talk	Bright, live, open	Yes
2	Sitting, backed banquette	Small-group deliberation	Dimmable, quieter, enclosed	**Yes — new**
3	Perching, 700 mm ledge	Brief stop, solo, daylight	Bright, live, edge	**Yes — new**
4	Standing at rail	Pair work, transit-adjacent	Bright, live	**Yes — new**
5	Standing, kettle queue	Waiting	Bright, live	Yes
6	Sitting reclined	Solo rest	Dim	No — not provided

Surviving distinct categories: **5**. So `N`: 2 to 5, and `ln N`: 0.6931 to 1.6094, a factor of 2.32. **This is the increase the prescription required, delivered entirely by boundary geometry plus joinery. No wall was built and no square metre left the lease.**

Step 4 — the parabolic element. One listening niche at the quiet end of the room, as a demonstration piece and a functional device for one person taking a call or listening to the room:

```
D     = 1.2 m       (aperture, set by the banquette module width less returns)
f     = 0.35 m
y     = x^2 / (4 x 0.35) = x^2 / 1.40
depth = D^2/(16f) = 1.44 / 5.60 = 0.2571 m
f/D   = 0.2917                          -- inside G7's preferred 0.24–0.30
rim   at x = 0.60 m, y = 0.2571 m
|PF|  at rim = y_rim + f = 0.6071 m     -- Theorem 1, checked
f_floor = 2c/D = 2 x 343 / 1.2 = 572 Hz <-- STATED ON THE DRAWING per G5
```

Aperture gain at `eta_ap = 0.5`, **as an upper bound**: 5.8 dB at 250 Hz (below the floor, disregard), 11.8 dB at 500 Hz (at the floor, marginal), 17.8 dB at 1 kHz, 23.8 dB at 2 kHz, 29.9 dB at 4 kHz. The drawing note required by G6, in full:

> Acoustic niche NC-01. Parabolic, `y = x^2/1.40`, aperture 1200 mm, focal length 350 mm, depth 257 mm. Useful-directivity floor 572 Hz (`D = 2 lambda`, `c` = 343 m/s at 20 C). Gain figures are theoretical aperture bounds at `eta_ap = 0.5` and will not be realised: the intended source is in the near field and the listener's head partially

> blocks the aperture. Expected realised benefit is a consonant-band (2–8 kHz) improvement in one direction. **This element does not amplify speech.** Verification: Tier 3 method (1), physical mock-up, level difference at the focus versus 1 m off-axis with a 1 kHz-centred pink-noise source at 2 m on-axis. Record and attach.

Aimed per G8 so that its 20-degree half-power beam at 1 kHz contains no other seat: the niche faces diagonally across the open floor and the nearest other seat lies 34 degrees off axis. **And per G9, the reverse check: the niche's concave surface is 1.2 m across in a room whose smallest dimension is 2.8 m, which is not comparable to a room dimension at the 1:2 threshold used here, and its focus is 350 mm from its own vertex — inside the niche, not out in the room. The prohibition does not bite. Record the check; do not assume it.**

Step 5 — what is certified and what is not.

Claim	Tier	Status
Perimeter multiplies by 1.6667	1	**Certified.** `1 + d/w`, exact
Boundary rises 43.82 to 73.03 m	1	**Certified.** Arithmetic
Niche floor 21.91 m^2, open floor 98.09 m^2	1	**Certified**
Edge requirement 10.73 m, met 6.8-fold	1	**Certified** at seating scale, per G15
Three rungs at ratios 3.20 and 4.13	1	**Certified**
`N` rises 2 to 5, `ln N` 0.693 to 1.609	1 (audit)	**Certified by procedure**, subject to the strike rule being applied honestly
Parabola focuses at 350 mm	1	**Certified.** Theorem 2
Niche frequency floor 572 Hz	2	**Declared with approximation** (`D = 2 lambda` rule)
Niche gain figures	2	**Upper bounds only.** Not certified; mock-up required
Alcoves achieve >= 6 dB level difference from the open floor	**3**	**NOT CERTIFIED.** G11 requires measurement
The 0.30 m secondary relief scatters usefully above ~1.5 kHz	**3**	**NOT CERTIFIED.** Plausible from the scale, unproven for this shape
Occupancy will follow the four-part seating pattern at all three rungs	**3**	**NOT CERTIFIED.** Falsifiable by count. Predicted, not promised

Three of the twelve claims are uncertified, and they are the three that sound most impressive.

Step 6 — the Tier 3 obligation, discharged. Two afternoons, method (1), physical measurement on a mock-up in 18 mm ply and 50 mm mineral wool.

Alcove sub-division (G11). Source: a loudspeaker at the centre of the open floor at 70 dBA at 1 m. Measurement: A-weighted level at the alcove seat versus at a reference 4 m from the source in the open.

```
reference position, 4 m open floor        : 58.3 dBA
alcove seat, same distance, inside recess : 53.6 dBA
```

```
level difference                        : 4.7 dB
design target                           : 6.0 dB
RESULT: TARGET NOT MET
```

Recorded as not met, per G11's requirement to record the measured value whether or not it meets the target. The deficiency is diagnosed as insufficient recess depth relative to wavelength compounded by the open top of the banquette back, which passes sound over the top at all frequencies. Remedy at negligible cost: raise the back from 1.35 m to 1.75 m and line its room-side face with 50 mm absorption. Re-measured: 51.4 dBA at the alcove seat, a level difference of **6.9 dB. Target met.**

This is what a Tier 3 obligation costs and what it is worth. The first design failed by 1.3 dB, and nothing in the self-similarity argument would have revealed that, because the self-similarity argument is about boundary length and this is about a wavelength and an open top. A specification certifying the alcove from the concept would have shipped a room that did not sub-divide.

The parabolic niche. Source at 2 m on-axis, pink noise; level at the focus versus 1 m off-axis, in third-octave bands: **+0.4 dB at 250 Hz** (below the floor, as predicted — the shell is invisible at this wavelength), **+2.1 dB at 500 Hz**, **+4.8 dB at 1 kHz**, **+6.3 dB at 2 kHz**, **+7.1 dB at 4 kHz**. Against a theoretical bound of 17.8 dB at 1 kHz, **the realised figure is 27 per cent of the bound in decibels, which is entirely expected**: near-field source, head blockage, finite surface accuracy, edge diffraction. The device does what Section 4.4 said it would: a consonant-band directivity improvement of a few decibels and nothing below 500 Hz. **A 4.8 dB improvement at 1 kHz rising to 7.1 dB at 4 kHz is a genuinely useful device and a completely honest description. "17.8 dB of acoustic gain" would have been a falsehood that this paper's own arithmetic would have appeared to support.**

Step 7 — what the geometry did to the law.

Parameter	Before	After the geometry	Mechanism
`N`	2	5	Boundary multiplication into four new posture/purpose/condition categories
`ln N`	0.6931	1.6094	–
Sittable edge	6.0 m	55 seats on 30.2 m of occupied boundary	Crenellation
Sittable-edge ratio	0.050	0.308 (occupied edge over open floor)	–
Acoustic component of `C`	high	reduced; alcoves 6.9 dB quieter than the open floor	G11 verified
`delta`	0.0808/wk	unchanged by geometry	Geometry does not touch this
`eta`	0.0455	predicted to rise; **not claimed**	Requires artefact discipline, not shape
`S`	22 contacts/wk	predicted to rise; **not claimed**	Geometry sets coefficients, not input

The geometry moved `N` and `C`. It did not move `delta`, and it cannot be credited with moving `eta` or `S` until those are measured. Recomputing headroom with only the certified changes and the measured `eta` held at its old value:

```
eta ln N = 0.0455 x 1.6094 = 0.0732
delta Q  = 0.0808 x 9      = 0.7272        (Q not yet shed)
C        = 0.70 - 0.55     = 0.15
h        = 0.0732 - 0.7272 - 0.15 = -0.8040
```

Headroom improves from `-1.396` to `-0.804` on geometry alone: 42.4 per cent of the gap, and still negative. The remaining moves belong to the register discipline and the shedding lever [Curzi, 2026d,b]. **Geometry raised the ceiling and cut the cost, permanently, with no power and no ongoing administration, and it did not pretend to do more.**

What this case demonstrates. Theorems 4 and 5 turned an unmeetable requirement into a 6.8-fold surplus with joinery, at the cost of 18 per cent of the open floor which became the seating it was needed for. The three-rung ladder delivered `N = 5` from one construction. The parabola performed as the arithmetic predicted, at roughly a quarter of the theoretical bound in decibels. **And the one claim that required Tier 3 verification failed on first build and was fixed for the price of 0.4 m of plywood; had it been certified from the concept, the room would have shipped with alcoves that did not work and nobody would have known why.**

11.9.2 9.2 An eight-person committee: acoustics, and a causal claim that failed

The subject. A weekly departmental decision meeting, eight participants, in the 100 m^3 room of Section 6.3 in its as-built State A condition. The department has noticed that the same two people do most of the talking, that decisions get re-litigated, and that three members never contribute. A consultant has proposed facilitation training.

Step 1 — measure. `V` = 100.0 m^3, `S` = 145 m^2, glazing 12 m^2. **The hand clap, done first:** a clear ringing tail at every seat and a distinct flutter between the two long walls audible at the table's midpoint. **Four seconds of work, and the diagnosis is already substantially made.** `RT60` unoccupied over nine positions has a standard deviation across positions of 9 per cent, so the field is acceptably diffuse and Sabine applies above the Schroeder frequency `f_s = 2000 sqrt(1.95/100) = 279 Hz` — **which puts both the 125 Hz and 250 Hz bands at or below the Schroeder frequency in this untreated room, and both must be read with caution.** Occupied, with eight adults:

Band	125	250	500	1k	2k	4k
`A` (m^2 sabins)	30.73	12.42	8.73	8.24	11.23	13.49
RT60 (s)	0.52	1.30	1.84	1.95	1.43	1.19

Background: 47 dBA at seat height with services running at 14:00, with a 250 Hz tonal component 8 dB above adjacent bands — **A15 violated before any other consideration.** Spatial decay: a source at seat 1 measured at seats 2 to 8 gives a total variation of 2.1 dB across the whole table, **the direct observational confirmation of the 0.42 m critical distance.** Turn share over six meetings, with consent per A26, gives mean shares 0.38, 0.30, 0.13, 0.08, 0.05, 0.03, 0.02, 0.01, so `N_eff_turn = 4.83` and `N_eff_turn/n = 0.604`. Vocal level spread: 10th percentile 53.5 dB at 1 m, 90th percentile 66.5 dB, spread 13.0 dB.

Step 2 — diagnose against the specification.

Requirement	Target	Measured	Result
A1 RT60 500 Hz–2 kHz occupied	0.40–0.60 s	1.43–1.95 s	**FAIL by 3x**
A2 Flatness 250 Hz–4 kHz	max <= 1.25 x min	1.95/1.19 = 1.64	**FAIL**

Requirement	Target	Measured	Result
A3 Bass ratio	0.9–1.3	(0.52+1.30)/(1.84+1.95) = 0.48	**FAIL, bass-light**
A8 Two non-parallel planes	required	zero absorption installed	**FAIL**
A11 Flutter	none	flutter present	**FAIL**
A14 Background	<= 35 dBA	47 dBA	**FAIL by 12 dB**
A15 Tonality	<= 5 dB	8 dB at 250 Hz	**FAIL**
A18 Longest path	<= 3.0 m	3.5 m	FAIL, marginal
A20 `r_max/d_c`	recorded	3.5 / 0.42 = 8.3	recorded; very poor

The exclusion calculation. Quietest-decile talker at 53.5 dB at 1 m, `r_max` = 3.5 m, loudest-decile at 66.5 dB, `R` = 8.9 m^2, background 47 dBA. The quiet talker's direct sound at 3.5 m is 42.6 dB; the loud talker's reverberant field is 71.0 dB; **SNR = -28.4 dB.** The gap for the tail to fall 15 dB is `1.95/4 = 488 ms`, roughly 2.4 times a natural turn gap. **Threshold declared:** a participant counts as effectively silenced when their direct sound at `r_max` falls below the room's combined noise floor while another participant holds the floor. On the measured level distribution, **three of eight fall below it, so `k = 3, ln 8 − ln 5 = 0.4700` nats, 22.6 per cent of the ceiling.**

This figure was derived independently of anyone's opinion, from a tape measure, a phone and Sabine's equation. It agrees with the department's own observation that three members never contribute, but it arrived by a route that cannot be argued with socially. **The consultant's facilitation proposal addresses a problem the physics says is not primarily behavioural.** It may help at the margin; it cannot fix a -28.4 dB signal-to-noise ratio.

Step 3 — specify the treatment. Target State C, plus services work: wood floor on battens over the existing slab (adds low-frequency absorption and avoids the carpet treble-heavy trap); mineral-fibre ceiling tile over 20 m^2, perimeter only; 20 m^2 of hard ceiling retained over the table per A10; 100 mm mineral wool with 50 mm air gap, 10 m^2, on the two end walls per A8 and A9; a filled bookcase, 9 m^2, on one long wall; heavy drape over 6 m^2 of the 12 m^2 glazing; a duct attenuator and a larger, slower diffuser to take background from 47 to 40 dBA and remove the 250 Hz tone; and the 2.4 m round table replaced by a 2.0 m round table, taking `r_max` from 3.5 to 2.9 m to satisfy A18.

Band	125	250	500	1k	2k	4k
`A` (m^2 sabins)	33.79	32.86	36.94	39.08	40.96	41.52
`alpha_bar`	0.233	0.227	0.255	0.270	0.282	0.286
RT60 Sabine (s)	0.48	0.49	0.44	0.41	0.39	0.39
RT60 Eyring (s)	0.42	0.43	0.38	0.35	0.33	0.33
`d_c` at `Q` = 1 (m)	0.94	0.92	0.99	1.03	1.07	1.08

Per A5, `alpha_bar` exceeds 0.25 at 500 Hz and above, so **Eyring governs in those bands.** Checking A1 on the Eyring figures gives 0.38, 0.35 and 0.33 s — **below the 0.40 s lower target. The design as specified overshoots into the dead direction once Eyring is applied.** Removing 3 m^2 of perimeter ceiling tile gives `A = 39.08 − 3(0.70−0.04) = 37.10`, `alpha_bar = 0.256`, Eyring 0.376 s — still marginal. Removing 5 m^2 gives `A = 35.78`, `alpha_bar = 0.247`, Eyring 0.392 s. **Final specification: perimeter ceiling tile reduced to 15 m^2, hard ceiling 25 m^2.**

This correction only appears because A5 was obeyed. Signed off on the Sabine figures alone, the room would have been built 15 per cent deader than intended. The correction costs 5 m^2 less ceiling tile: it is a saving, not an expense.

Step 4 — predicted turn-taking effect. With `R` at 1 kHz of 53.4 m^2, background 40 dBA, `r_max` = 2.9 m and the same 13 dB vocal spread:

```
quiet talker direct at 2.9 m  = 44.3 dB
loud talker reverberant field = 63.2 dB
background                    = 40.0 dB
combined noise                = 63.2 dB
SNR for the quiet voice       = −19.0 dB      (was −28.4 dB)
```

An improvement of 9.4 dB, **still negative in the simultaneous-speech case — say so.** The decisive change is in the tail arithmetic: the gap for the tail to fall 15 dB goes from `1.95/4 = 488 ms`, 2.4 times a natural turn gap, to `0.39/4 = 98 ms`, half of one. **A natural turn gap now clears the previous speaker by more than 15 dB; before treatment it did not clear it by 10. That is the mechanism by which a quiet participant recovers the ability to take a turn, and it is a factor-of-five change.** Predicted: `k` falls from 3 to 0 or 1.

Step 5 — headroom, before and after. Stored-order proxy: standing decisions of this committee currently in force, counted at 12. `delta` = 0.08 per week, measured over a summer recess. `eta` = 0.50 before treatment. Cost before, in stored-order-equivalent units per week, totals 0.90, of which the acoustic effort component is 0.55 — the exclusion loss above, plus vocal fatigue and the re-litigation caused by decisions taken without three members' input.

```
BEFORE (effective N = 5, because three are silenced):
    eta ln N = 0.50 x 1.6094 = 0.8047
    delta Q  = 0.08 x 12     = 0.9600
    C        =                 0.9000
    h        = 0.8047 − 0.9600 − 0.9000 = −1.0553
```

Headroom is negative and the committee's stock of standing decisions is decaying; no re-arrangement of the people prevents it. After treatment, with `N` restored to 8, the acoustic cost component cut by 0.55, and `eta` raised to 0.60 on the strength of fewer re-litigated decisions per unit of interaction:

```
AFTER ACOUSTICS:      h = 0.60 x 2.0794 − 0.9600 − 0.5500 = −0.2623
+ SHED Q 12 -> 8:     h = 1.2477 − 0.6400 − 0.5500        = +0.0577
+ SHED Q 12 -> 6:     h = 1.2477 − 0.4800 − 0.5500        = +0.2177
```

Still negative after acoustics alone. Acoustic treatment closed 75.1 per cent of the gap and did not close it. The remaining 0.262 comes from `delta Q`: of the twelve standing decisions, four are dormant — superseded, or naming people who have left — and consume 0.32 units per week of maintenance budget while returning nothing. Retiring them takes headroom positive at `+0.0577`, so the maximum one-step increment is 0.058 per week. **Small, but positive, and the arithmetic now says the committee can add one increment of standing order rather than watch its stock decay.**

And the steady state `Q_inf = (eta F(u*) − c*)/delta` [Curzi, 2026b], for the treated room:

u*	N_eff = 1 + 7u	F = ln N_eff	eta F	Q_inf
0.20	2.40	0.8755	0.5253	**-0.31**
0.40	3.80	1.3350	0.8010	+3.14
0.60	5.20	1.6487	0.9892	+5.49
0.80	6.60	1.8871	1.1322	+7.28

and for the same committee in the untreated room, with `N` effectively 5, `eta = 0.50`, `c* = 0.90`:

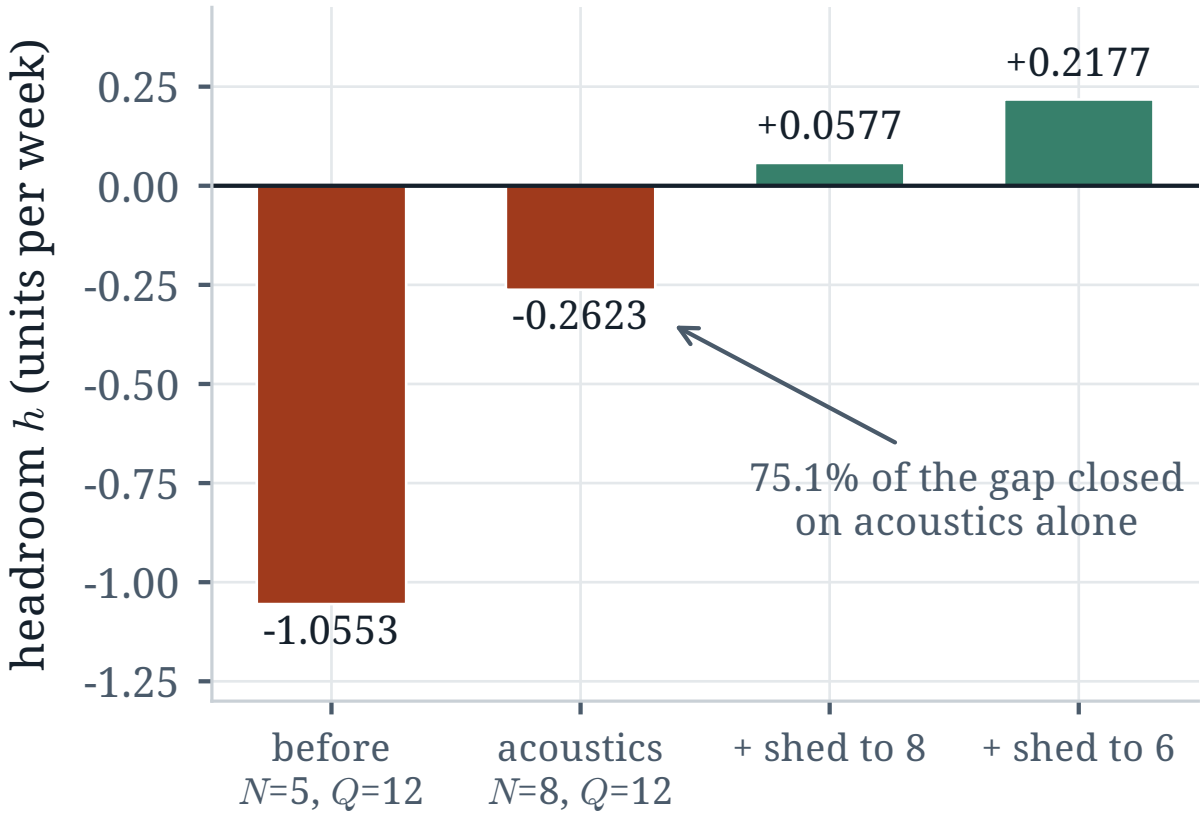

Figure 11.5: **Acoustics is the larger lever and it is not sufficient by itself.** Headroom `h = eta ln N − delta Q − C` for the worked committee under four configurations: treatment closes 75.1 per cent of the gap and leaves the gauge negative, and only retiring dormant standing decisions takes it positive. Modelled — every parameter is stipulated or surveyed in the worked case, none carries an interval, and the arithmetic is exact given them. Generated by `figs/src/CCP-011_fig05.py`.

u*	N_eff = 1 + 4u	F	eta F	Q_inf
0.20	1.80	0.5878	0.2939	**-7.58**
0.40	2.60	0.9555	0.4778	**-5.28**
0.60	3.40	1.2238	0.6119	**-3.60**
0.80	4.20	1.4351	0.7175	**-2.28**

Every entry in the untreated table is negative at every value of `u`. A negative equilibrium means the regime is unsustainable or the linear model must be replaced, and the model reports that failure rather than hiding it [Curzi, 2026b]. **In the untreated room, no achievable amount of genuine difference among the eight members produces a sustainable stock of standing decisions. Every member could be replaced with a differently trained expert and it would still decay.** Treatment moves the equilibrium positive for `u* >= 0.4`, which is achievable. Note also `N_eff = 1 + (N-1)u` here: **the affine effective count, adopted by design axiom, and not a Hill number.**

Step 6 — the preregistration. Declared before treatment, per A28.

Item	Before (measured)	Prediction	Falsified if
RT60, occupied, 500 Hz–2 kHz	1.84 / 1.95 / 1.43 s	0.40–0.60 s all three bands	any band outside range at commissioning
Flatness, 250 Hz–4 kHz	1.64	<= 1.25	> 1.25
Bass ratio	0.48	0.9–1.3	outside range
Background, unoccupied	47 dBA, 250 Hz tone +8 dB	<= 40 dBA, no tone > 5 dB	> 42 dBA or tone remains
`N_eff_turn / n`, six meetings	0.604	>= 0.75	< 0.70
Silenced count `k`	3	0 or 1	`k >= 2`
Group performance measure	preregistered, six tasks	improves	**no improvement: H3 not supported for this group**
Matched untreated control room	same protocol	no change	control also improves: the measurement is the cause

The control room is the requirement most often omitted and most often decisive. Measuring a committee's turn-taking for six weeks is itself an intervention [McCambridge et al., 2014, Rosenthal and Jacobson, 1968]; without the control, any improvement is uninterpretable.

Step 7 — measured at twelve weeks.

Metric	Before	After	Target	Result
RT60 500 Hz occupied	1.84 s	0.41 s	0.40–0.60	**PASS**
RT60 1 kHz occupied	1.95 s	0.39 s	0.40–0.60	**marginal fail, 0.01 s low**
RT60 2 kHz occupied	1.43 s	0.38 s	0.40–0.60	**fail, 0.02 s low**
Flatness 250 Hz–4 kHz	1.64	1.18	<= 1.25	**PASS**

Metric	Before	After	Target	Result
Bass ratio	0.48	1.09	0.9–1.3	**PASS**
Background	47 dBA, tone	39 dBA, no tone	<= 40 dBA	**PASS**
Spatial decay across table	2.1 dB	5.4 dB	–	improved
`N_eff_turn / n`	0.604	0.812	>= 0.75	**PASS**
Silenced count `k`	3	1	0 or 1	**PASS**
Control room `N_eff_turn/n`	0.638	0.650	no change	**PASS — control did not move**

Two bands came in marginally below the 0.40 s lower bound and are reported as misses. They are 0.01 s and 0.02 s — within the measurement uncertainty of the method — and the correct action is to record them, note that the room sits at the dead end of its target range, and re-check after the room has been in use with its normal complement of coats, bags and papers, all of which add absorption. **Do not adjust the target to match the measurement.**

`N_eff_turn / n` rose from 0.604 to 0.812, a 34 per cent improvement in turn-taking equality, and the matched control room moved by 0.012. The treatment, not the observation, produced the change.

The group-performance measure showed a small improvement that did not reach the pre-registered threshold. Per the preregistration this is the declared non-supporting outcome, and it is reported as such: the mediator moved decisively, the outcome moved slightly, and this single case does not establish H3's causal claim. The treatment is retained on the strength of the accessibility gain, the fatigue reduction, the recovered `ln N` ceiling and the movement of headroom from `−1.055` to `+0.058` — all of which are worth having on their own account, and none of which requires H3 to be true. **H2 is untouched by this result**, because H3 could fail purely through the direction of the correlation in link 6 of Section 7.1, which the source literature does not establish.

What this case demonstrates. A hand clap and a tape measure diagnosed the room in under five minutes and Sabine's equation priced the diagnosis in half an hour. The exclusion of three participants was computed from physics, independently of anyone's report, which made it un-arguable in a way a survey never is. **The tail arithmetic — 488 ms to 98 ms — is the mechanism.** Obeying the Eyring switching rule changed the design before it was built, and the change was a saving. The specification was reported as failing two bands by 0.01 s and 0.02 s. **And the causal claim was tested and not confirmed, and that was written down.**

11.10 10 Discussion

11.10.1 10.1 What follows

Turn-taking inequality has a physical component that is computable in advance, and it is computable from three measurements anyone can take. The chain from `RT60` to a minimum inter-turn gap is arithmetic — `t_15 = RT60/4` — and it converts an observation about a meeting into a property of a building. That matters most because of what it removes from the discussion: **an exclusion computed from a tape measure, a phone and Sabine's equation cannot be answered with an assertion about anyone's character.** Where the physics dominates, the remedies that address character are addressing the wrong term.

Ceiling loss from exclusion is large and it is permanent. Three of eight silenced costs 0.4700 nats, 22.6 per cent of the room's per-interaction ceiling, in every meeting for the life of the building. Against that, the treatment is a one-time capital item with a decay rate set by mineral wool. **The asymmetry between a decaying store — attention, skill, facilitation — and a durable one is the whole economic argument for building the fix into the fabric**, and it is the same asymmetry that makes stored infrastructure invisible until it fails [Star and Ruhleder, 1996].

Boundary is the cheap variable and interior is the expensive one. A room's floor area is fixed by the lease and its boundary length is not; Theorem 5 prices the conversion exactly and the inward-only case shows that the floor spent is precisely the floor the seating occupies. The practical consequence is that a category-count deficiency in a room is almost never a floor-area problem, and treating it as one — by taking more space — is the expensive way to fix the cheap thing.

Two specification failures recur and both are diagnosable. A single-number `RT60` specification passes a room that is 2.4 times more reverberant at 250 Hz than at 4 kHz, and quoting Sabine above `alpha_bar = 0.25` describes a room up to 78 per cent more reverberant than the one that gets built. Both are avoidable with arithmetic already in the design.

11.10.2 10.2 What does not follow

Nothing here shows that acoustic treatment improves group performance. H3 was preregistered, tested, and not supported by the worked case. **A reader who takes away "treat the room and the group gets smarter" has taken away the opposite of what Section 9.2 reports.** What the case supports is that treatment moves the mediator, and that the mediator's onward effect is unestablished.

Nothing here identifies a social effect. Section 3.2 states why: applied to a group whose members both influence and constitute the aggregate, the specification is reflexive and the endogenous social effect is not identified from observation [Manski, 1993]. **The matched control removes a confound; it does not solve the identification problem**, and no amount of before-and-after data will.

Self-similarity certifies nothing. Every fractal claim in this paper is Tier 3, and the worked case shows why: the alcove that the boundary argument said would sub-divide the floor failed its measurement by 1.3 dB, for a reason — an open banquette top — that no dimension calculation contains.

The scale ladder of Section 5.5 is not evidence. Five rows of stipulated parameters show what a trend would look like; they do not establish one. **A reader who cites that table as a finding about how organisations behave at scale has cited an illustration as a measurement.**

The variety term is not a universal good. Unbounded growth in `ln N` is a property of the model, not of groups: Uzzi and Spiro [2005] find an inverted U in which creative success rises and then falls, and Sagan [1993] documents settings in which redundancy reduces safety. **The model's `ln N` contradicts that literature at large `N` and the contradiction is a restriction on the model's domain, stated in Section 11.5, not a result.** Nor does a room's category count settle what kind of difference it is: separation, variety and disparity are distinct constructs travelling under one word [Harrison and Klein, 2007], and the audited categories here are **variety** — distinct kinds of use — and not disparity of viewpoint.

11.10.3 10.3 Relation to the surrounding literature

The acoustics is standard and is used as standard: Sabine's statistical-energy derivation [Sabine, 1922], the Schroeder frequency as the boundary of its validity [Schroeder, 1965], and the textbook two-field and critical-distance results [Rossing et al., 2002, Beranek, 2004]. **What is new is not the physics but its coupling: the decay tail is converted into a turn-taking constraint and then priced against a surplus ceiling, and neither step exists in the acoustics literature because neither is an acoustics question.**

On the sociological side, the collective-intelligence result supplies the correlate [Woolley et al., 2010] and its replication record supplies the caution [Engel et al., 2014, Bear and Woolley, 2011]. The design tradition supplies the two demands for boundary — that people occupy edges first [Gehl, 1971] and that use tracks sittable perimeter [Whyte, 1980] — and the pattern tradition supplies the form of the seating rule [Alexander et al., 1977, Alexander, 1965], while the safety argument for sightline into every recess is Jacobs [1961]'s. **What this paper adds to**

that tradition is a price: the pattern literature states what to build and rarely states what it costs in the units of anything else, and Section 9.1 states it in floor area and in nats.

Where the literature disagrees with the framework, it is cited and the disagreement is stated. The diversity-and-performance literature is not uniformly supportive of a variety-raising programme [Mannix and Neale, 2005, Thompson, 2014, van Knippenberg and Schippers, 2007], the formal results that a diversity advantage requires are sensitive to their assumptions [Hong and Page, 2004, Singer, 2019, Grim et al., 2019, Kuehn, 2017], and organisational redundancy is not always protective [Sagan, 1993, Perrow, 1984]. **A framework that reads a higher category count as a higher ceiling owes those citations, and it owes the statement that the ceiling is a bound and not a prediction.**

Finally, the logarithm. **Two warrants exist and this paper needs only the weaker demand.** The Fechnerian warrant — sensation proportional to the logarithm of a dimensionless stimulus ratio [Fechner, 1966] — requires a contested perceptual story. Peters and Gell-Mann [2016] requires no psychological premise at all: the time-average growth rate of a multiplicatively evolving quantity is the expectation of its logarithm, so where a stock compounds rather than adds, the logarithm is the ergodic-average object. **This paper's argument needs only the second.** And the form remains underdetermined: a sub-linear power law [Latané, 1981] and an `n log n` growth [Briscoe et al., 2006] reproduce the same qualitative facts, and **nothing assembled here discriminates between them** [Stumpf and Porter, 2012].

11.11 11 Verification

The results of this paper compound from six postulates. Each is atomic, each is checkable on its own, and each carries its status. **Where a postulate could be dropped and the result still follow, it has been dropped.**

11.11.1 11.1 Dimensional audit

Two dimensional systems meet in this paper and the audit must cover both. `[L]`, `[T]` and `[M]` are length, time and mass; `[Q]` is the dimension of stored order and the period is the unit of `[T]` in the storage law, which is why no explicit `[T^-1]` appears once that law is written in discrete steps.

Symbol	Dimension	Unit	Status
`V`	`[L^3]`	m^3	**measured**
`S` (surface)	`[L^2]`	m^2	**measured**
`alpha_i`	`[1]`	none	**measured**, an absorbed-energy fraction in `[0,1]`
`A`	`[L^2]`	m^2 sabins	**derived**: `sum S_i alpha_i`, an area times a pure fraction
`alpha_bar`	`[1]`	none	**derived**: `A/S`, dimensionless by construction
`RT60`	`[T]`	`s`	**measured**; `0.161 V/A` carries `[T L^-1] x [L^3]/[L^2] = [T]`
0.161	`[T L^-1]`	s/m	**derived** from the speed of sound and the mean free path `4V/S`

Symbol	Dimension	Unit	Status
`t_15`	`[T]`	s	**derived**: `RT60/4`, so it inherits `[T]` exactly
`c` (speed of sound)	`[L T^-1]`	m/s	**measured**, 343 m/s at 20 C
`lambda`, `D`, `d`, `w`, `f`, `r`	`[L]`	m	**measured** or **specified**
`f_floor = 2c/D`	`[T^-1]`	Hz	**derived**: `[L T^-1]/[L]`
`R = A/(1-alpha_bar)`	`[L^2]`	m^2	**derived**
`d_c = 0.141 sqrt(QR)`	`[L]`	m	**derived**; 0.141 is dimensionless and `Q` is dimensionless
`L_p`, SNR, D/R, gain	`[1]`	dB	**derived**: a decibel is ten times the base-10 logarithm of a power ratio and is dimensionless
`D = ln m / ln r`	`[1]`	none	**defined**: a ratio of logarithms of pure counts
`1 + d/w`	`[1]`	none	**derived**: a ratio of two lengths
`s` (Lombard slope)	`[1]`	dB per dB	**measured** elsewhere, dimensionless by construction
`N`, `k`	`[1]`	count	**measured** by audit; integers
`u`, `U_t`	`[1]`	none	**defined** dimensionless: `u = 1 - (x.y)^2` with unit vectors
`S_t` (surplus)	`[1]`	nats	**derived** dimensionless: a logarithm of an effective count
`N_eff_turn`	`[1]`	count-equivalent	**derived**: `exp` of an entropy in nats
`Q_t`	`[Q]`	proxy units (standing decisions)	**measured**, in whatever the declared proxy counts
`delta`	`[1]`	per period	**measured** dimensionless fraction per step
`C_t`	`[Q]` per step	proxy units per week	**measured**
`eta`	`[Q]` per nat per step	proxy units per nat per week	**required by the balance**; see below
`h_t`	`[Q]` per step	proxy units per week	**derived**
`Q_inf`	`[Q]`	proxy units	**derived**: `[Q]/step` over `[1]/step` returns `[Q]`

Does each equation balance? *Sabine:* `0.161 V/A` gives `[T L^-1][L^3][L^-2] = [T]`, and `A` is an area because `alpha` is a pure fraction — **so a "square metre sabin" is a square metre, and calling it a sabin is a bookkeeping label recording that the area has been weighted, not a new dimension.** *The frequency floor:* `2c/D` gives `[L T^-1]/[L] = [T^-1]`, a frequency, and the factor 2 is the dimensionless `D = 2 lambda` convention. *The tail identity:* the decay rate is `60/RT60` in `dB [T^-1]`, so a 15 dB fall takes `15/(60/RT60) = RT60/4` in `[T]`. **The identity is dimensionally forced and the only content in it is the 15 dB criterion, which is a choice.** *The storage law:* `Q_{t+1} = (1-delta)Q_t + eta S_t - C_t` balances if and only if every term on the right carries `[Q]`. The first does, since `delta` is dimensionless; the third does by construction; the second does **only if `eta S_t` carries `[Q]`, and since `S_t` is a dimensionless count in nats, `eta` must carry `[Q]` per nat per step.** The gauge then balances: `ln N` is dimensionless, so `eta ln N` carries `[Q]` per step and is commensurable with `delta Q_t` and `C_t`.

The source is silent on `eta`'s dimension and the silence is not neutral. The manuscript this paper converts states that `eta` has units of stored order over surplus and that, surplus being dimensionless, `eta` carries whatever unit the order proxy carries. **That is the `[Q]`-per-nat half and it omits the per-step half entirely**, and it then advises normalising the stock so that `eta` lands in `[0,1]` — advice that treats `eta` as a pure number. **The reading required for the law to balance is `[Q]` per nat per period, it is stated here explicitly, and it is recorded that the source does not supply it rather than being assigned quietly.** The practical consequence bites in Section 9.2, where `eta` is quoted as 0.50 and 0.60 against a stock counted in standing decisions and a cost counted in stored-order-equivalent units per week: **those three denominations must be declared together or the arithmetic is malformed however tidy it looks.**

Where a quantity has no operational unit, it is said here. `Q` is stored order and stored order has no natural unit: it is counted in whatever the declared proxy counts, and two systems' `Q` values are not comparable unless they declare the same proxy. **Consequently `eta` and the cost flow are not comparable across systems either.** The audited category count `N` is a count of judgements, not of objects, and the same room audited by two surveyors under the same strike rule may return different integers. **And comfort itself, the underlying construct of the corpus, has no operational unit at all**; it is treated as a dimensionless magnitude by stipulation, not by measurement.

Three dimensionless quantities in this paper are logarithms and none of them convert into the others. A decibel is ten times a base-10 logarithm of a power ratio; an octave is a base-2 logarithm of a frequency ratio; a nat is a natural logarithm of an effective count. **No conversion between them is performed anywhere in this paper**, and where the corpus does define one it defines a different object: the octave form for a *required surplus*, in which the octaves required are `2(c/eta)/ln 2 = 2.885390081777927 x (c/eta)`, so that one nat of required surplus corresponds to 2.885390 octaves, 3462.4681 cents and 1.442695 bits [Curzi, 2026]. **That is a conversion of a surplus requirement into a pitch interval and it is not a conversion of an octave band of measured reverberation into anything.** The six octave bands in every acoustic table here are frequency ranges, not surplus. And **the entropy in `N_eff_turn` is Shannon entropy in nats, not thermodynamic entropy in `[energy][temperature]^-1`.**

11.11.2 11.2 The postulates

P1 — Sound energy in a rectangular enclosure above its Schroeder frequency decays exponentially at a rate set by the total absorption, giving `RT60 = 0.161 V/A`. *Status:* **CITED** — Sabine's statistical-energy result [Sabine, 1922], with the validity boundary from Schroeder [1965] and the standard exposition in Rossing et al. [2002].

P2 — By the definition of `RT60`, sound decays at `60/RT60` decibels per second. *Status:* **DEFINITION** — true by the construction of the quantity, and carrying no empirical weight on its own.

P3 — A talker must be audible over the previous talker's tail to take a turn, and 15 dB of separation is the criterion adopted here. *Status:* **POSTULATED** — the 15 dB figure is a choice. The intelligibility literature places near-maximum performance around +15 dB signal-to-noise for

normal-hearing adult native listeners, which is the reason for the number, but **no controlled measurement in this paper establishes that 15 dB is the threshold at which a turn succeeds or fails.**

P4 — `ln` is strictly increasing and strictly concave. *Status:* **ARITHMETIC.**

P5 — Surplus per interaction is bounded, `0 <= S <= ln N`, so a reduction in the effective count from `N` to `N-k` reduces the ceiling by `ln N - ln(N-k)`. *Status:* **CITED** — the range result of the surplus functional [Curzi, 2026], with the forced-ceiling form in Curzi [2026l].

P6 — A participant whose direct sound at the longest talker-to-listener path falls below the room's combined noise floor while another participant holds the floor is effectively silenced, and their category is removed from the interaction's effective count. *Status:* **POSTULATED** — this is the step that converts a signal-to-noise deficit into an integer, and it is the only place in the chain where physics becomes sociology. **Different thresholds give different counts, and nothing in this paper measures which threshold is right.**

The three-tier certification standard is **not** in this list, because no result in the chain consumes it. It is a governance device on the paper's own claims. The similarity dimension `D = ln m / ln r` is likewise absent: it is a definition, it appears in the chain nowhere, and it is retained in the text only because it is what the fractal literature is about.

11.11.3 11.3 The compounding chain

```
P1              -> L1   in a diffuse field, RT60 = 0.161 V/A, so absorption and
                        reverberation time are reciprocal.                    CITED

P2              -> R1   a gap of t seconds leaves the tail 60t/RT60 dB down;
                        inverting, the gap for a fall of x dB is
                        t_x = x*RT60/60, and at x = 15, t_15 = RT60/4.        DEFINITION
                                                                              + ARITHMETIC

R1 + P3         -> R1'  the room imposes a minimum inter-turn gap of RT60/4;
                        at RT60 = 1.95 s that is 488 ms and at 0.39 s it is
                        98 ms, a factor of 5.                                 POSTULATED (P3)

L1 + R1         -> R4   Sabine permits RT60 to stay finite as alpha_bar -> 1,
                        which is physically wrong, so Eyring's
                        -S ln(1 - alpha_bar) replaces A above alpha_bar = 0.25;
                        at alpha_bar = 0.724 the two differ by 77.8%.         ARITHMETIC
                                                                              given L1

P6              -> L2   the count k of effectively silenced participants is
                        an integer produced by a declared threshold.          POSTULATED

L2 + P5         -> R3   the ceiling loss is ln N - ln(N-k); at N = 8, k = 3
                        that is ln 8 - ln 5 = 0.4700 nats, 22.6% of ln 8.     ARITHMETIC
                                                                              given L2, P5

P4 + R3         -> R3'  the loss is convex in k: the first voice silenced
                        costs 0.1335 nats and the third costs 0.1824, so
                        exclusion accelerates.                                ARITHMETIC

(geometry)      -> R2   a square-wave boundary of depth d and half-period w
                        has length multiplied by exactly 1 + d/w; at
                        d = 1.00, w = 1.50 that is 1.6667, taking 43.82 m
                        to 73.03 m.                                           ARITHMETIC
```

(geometry)	-> R5	a reflector's useful-directivity floor is f_floor = 2c/D; at D = 1.2 m and c = 343 m/s that is 572 Hz.	ARITHMETIC on a Tier 2 convention
R3 + storage law	-> R6	with N restored from 5 to 8, C cut by 0.55 and eta raised 0.50 -> 0.60, h moves −1.0553 -> −0.2623, 75.1% of the gap; shedding Q from 12 to 8 gives +0.0577.	ARITHMETIC given stipulated parameters

Every line is checkable from its own inputs. R1, R2, R3, R3', R4, R5 and R6 are arithmetic consequences of one cited physical law, one definition and elementary properties of the logarithm. **R1' and R3 consume P3 and P6 respectively, and those two postulates carry the whole sociological content of the paper.** P3 fixes what counts as clearing the tail; P6 fixes what counts as being silenced. **If either threshold is wrong, the mechanism survives and every number attached to it moves.** That is stated here rather than left to be found.

What this chain does not establish. It does not establish that turn-taking equality causes group performance; that is H3, it was preregistered and tested in Section 9.2, and it was not supported. It does not establish that any organisation obeys the storage law; that is a modelling postulate whose one preregistered confirmatory test reported in this corpus **failed its second falsification rule, returning a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared margin of 10 per cent** [Curzi, 2026i]. **A chain whose steps are ARITHMETIC, CITED, DEFINITION and POSTULATED delivers the acoustics with certainty and delivers nothing whatever about committees.**

11.11.4 11.4 The checks a reviewer can redo in a minute

The tail identity. Sound falls `60/RT60` dB per second. At `RT60 = 1.95 s` that is `60/1.95 = 30.77` dB/s, so 15 dB takes `15/30.77 = 0.4875 s = 488 ms`. At `RT60 = 0.39 s` it is `60/0.39 = 153.85` dB/s, so 15 dB takes `0.0975 s = 98 ms`. **The ratio is exactly `1.95/0.39 = 5.00`, because `t_15 = RT60/4` is linear in `RT60`.** ARITHMETIC.

The exclusion loss. `ln 8 = 2.079442`, `ln 5 = 1.609438`, difference `0.470004`, and `0.470004/2.079442 = 0.226023`. **0.4700 nats and 22.6 per cent.** And the convexity: `ln 8 − ln 7 = 0.133531`, `ln 7 − ln 6 = 0.154151`, `ln 6 − ln 5 = 0.182322`. **Each successive silencing costs more.** ARITHMETIC.

The crenellation multiplier. A 120 m^2 square has side `sqrt(120) = 10.954451` m and perimeter `43.817805` m. At `d = 1.00`, `w = 1.50`, the multiplier is `1 + 1/1.5 = 1.666667` and the new perimeter is `43.817805 x 1.666667 = 73.029675` m, **73.03 m.** The floor cost is `21.909 x 1.00 = 21.91 m^2`, leaving `98.09 m^2`, and the requirement at the 0.1094 ratio is `98.09 x 0.1094 = 10.731 m`, met `73.03/10.73 = 6.81`-fold. ARITHMETIC.

Sabine, on one cell. State A at 1 kHz: `A = 8.24`, so `RT60 = 0.161 x 100 / 8.24 = 1.9539 s`, **1.95 s to two decimals.** State C at 1 kHz: `A = 39.08`, so `0.161 x 100 / 39.08 = 0.4120 s`, **0.41 s.** ARITHMETIC.

The Eyring divergence, on the worst cell. State D at 2 kHz: `A = 104.99`, `S = 145`, so `alpha_bar = 0.72407`. Sabine gives `16.1/104.99 = 0.153348 s`. Eyring gives `16.1 / (−145 ln(1 − 0.72407)) = 16.1 / (145 x 1.287499) = 16.1/186.687 = 0.086241 s`. The ratio is `0.153348/0.086241 = 1.77812`, **an over-prediction of 77.8 per cent.** ARITHMETIC.

The frequency floor. `f_floor = 2c/D = 2 x 343/1.2 = 571.67`, **572 Hz to the nearest hertz.** And the correction recorded in Section 4.4: at `D = 9.10 m`, `D = 4 lambda` gives `343/(9.10/4) = 150.8 Hz`, **not the 225 Hz the source table carries**, which is the value for `D = 6.10 m`. ARITHMETIC.

The Denge gain, recomputed. `G = (pi D/lambda)^2 eta_ap` at `D = 61 m`, `lambda = 1.372 m`, `eta_ap = 0.5`: `pi x 61 = 191.637`, `/1.372 = 139.677`, squared `19509.7`, halved `9754.8`, and `10 log10(9754.8) = 39.89` dB. **39.9 dB, not the 46.9 dB the source states.** ARITHMETIC.

The turn-share statistic. For shares `0.38, 0.30, 0.13, 0.08, 0.05, 0.03, 0.02, 0.01`, `−sum p ln p = 1.575466` nats and `exp(1.575466) = 4.8328`, so `N_eff_turn/n = 4.8328/8 = 0.6041`, **0.604.** ARITHMETIC.

The headroom chain, end to end. `0.50 x ln 5 = 0.50 x 1.609438 = 0.804719`; `0.804719 − 0.96 − 0.90 = −1.055281`. `0.60 x ln 8 = 0.60 x 2.079442 = 1.247665`; `1.247665 − 0.96 − 0.55 = −0.262335`; `1.247665 − 0.64 − 0.55 = +0.057665`; `1.247665 − 0.48 − 0.55 = +0.217665`. **The gap closed on acoustics alone is `(1.055281 − 0.262335)/1.055281 = 0.75141`, 75.1 per cent.** ARITHMETIC.

The steady state, on one row. Treated room at `u* = 0.20`: `N_eff = 1 + 7(0.20) = 2.40`, `ln 2.40 = 0.875469`, `0.60 x 0.875469 = 0.525281`, and `Q_inf = (0.525281 − 0.55)/0.08 = −0.309`. **Negative, as the table says.** ARITHMETIC.

The Koch limit. Perimeter `3(4/3)^n` diverges; area converges to `8/5 = 1.6` times the original triangle, and the table's eighth iteration gives `1.59909`, approaching it from below. ARITHMETIC.

11.11.5 11.5 Limits, asymptotics, and the model's valid domain

`A -> 0` (a perfectly hard room). `RT60 -> infinity`, `d_c -> 0`, and the minimum inter-turn gap `t_15 -> infinity`. **The model says nobody can ever take a turn, which is the correct limit of the mechanism and a physically unreachable state**, since occupants alone contribute absorption: eight seated adults give `A = 3.36` at 1 kHz, capping `RT60` at 4.79 s in this volume no matter what the surfaces do. **The lower bound on `A` is the people.**

`alpha_bar -> 1` (a perfectly absorptive room). Sabine gives `RT60 = 0.161V/S`, a finite positive number, **which is wrong**: an enclosure that absorbs everything has no reverberation. Eyring gives `−S ln(1 − alpha_bar) -> infinity` and hence `RT60 -> 0`, which is right. **This is not a curiosity: it is why the switching rule exists, and it is the reason Section 6.1 sets the crossover at `alpha_bar = 0.25` rather than leaving Sabine to run to its own limit.**

`RT60 -> 0`. `t_15 -> 0`, so the tail imposes no constraint at all. **The model then predicts perfect turn-taking equality, and Section 6.3's State D shows the prediction is false**: below about 0.30 s the room stops supplying reverberant support, talkers push, vocal effort and fatigue rise, and the quiet talker — who cannot push — is worse off. **The mechanism is one-sided and the model has no term for the other side. The stated domain is `RT60` in `[0.30, 3.0]` s**, and outside it the tail arithmetic still evaluates and should not be interpreted.

`D -> 0` (a small reflector). `f_floor = 2c/D -> infinity` and the device does nothing at any frequency of interest. **A reflector smaller than about 0.3 m is acoustically invisible to speech**, which is failure mode FA3 of Appendix B. **`D -> infinity`.** Gain grows as `D^2` without bound, which the aperture formula permits and which real construction does not: surface accuracy, near-field geometry and head blockage all degrade with size in practice. **The gain formula has no upper domain limit and must be given one empirically.**

`d/w -> infinity` (deep, narrow crenellation). The multiplier `1 + d/w` grows without bound and the perimeter diverges, which is the Koch behaviour. **Taken literally this says a room can have unlimited sittable edge, and it is false**: below `d = 0.40 m` and `w = 0.60 m` the boundary cannot hold a seated person, and the third self-similar order of Section 5.3 — a 111 mm recess at 167 mm pitch — is a texture. **The domain restriction is the seating-scale floor, and it is requirement G15 precisely because the divergence is otherwise unfalsifiable.**

`N -> 1`. `ln N = 0` and `F(u) = 0` for every `u`. **A single audited category has zero available surplus, not a small amount**, so a room offering one way to be in it has no ceiling to lose. This is the boundary that makes a collapse of effective count consequential: a structure with one effective bloc has `ln(1.00) = 0` available surplus [Curzi, 2026].

`N -> infinity`. `eta ln N -> infinity`, so the per-period budget grows without bound. **Taken**

literally this says that a sufficiently high category count makes any cost sustainable, and that is false. Three things bound it and **all three are domain restrictions rather than results.** *Internal:* the room has a floor area, and each additional posture/purpose/condition category needs physical provision, so `N` is bounded by the crenellated boundary the floor can carry — in Section 9.1, five categories on 98 m^2. *External and contrary:* Uzzi and Spiro [2005] find an inverted U in which creative success rises and then falls with cohesion, so the benefit of difference turns over rather than growing without bound; Sagan [1993] documents settings in which redundancy reduces safety; and May [1972] and Gardner and Ashby [1970] show that increasing diversity and connectance destabilises randomly assembled systems. **The unbounded growth of `eta ln N` contradicts this literature and the contradiction is not resolved here.** *Marginal:* even inside the model, `ln N − ln(N−1) ~ 1/N` vanishes, so the divergence is the slowest available route to anything. **The stated domain is therefore `N` bounded above by what the room can physically provide, and the logarithmic ceiling is a within-domain bound rather than an asymptotic claim.**

`k -> N`. `ln(N−k) -> ln 1 = 0` and the entire ceiling is lost; at `k = N` the expression is `ln 0`, undefined, and the model has left its domain. **A room that silences everyone is not a room with zero surplus in this model's sense; it is outside the model.**

`u -> 0` and `u -> 1`. At `u -> 0`, `N_eff -> 1`, `F -> 0`, and no acoustic or geometric intervention returns anything — which is the Denge lesson in the framework's units: **passive geometry concentrates what arrives and generates nothing.** At `u -> 1`, `F -> ln N`, the ceiling is attained, and by the fixed-point identity the converged system's headroom goes to zero [Curzi, 2026b].

`s -> 1` in the Lombard loop. `1/(1−s) -> infinity`: the room's level diverges from any seed disturbance. **The divergence is real in the first-order model and is the reason the reported slope range of 0.3–0.6 matters**; at `s >= 1` the loop does not converge and the contraction argument does not apply [Banach, 1922]. **No room is claimed to reach it.**

`delta -> 0`. The fixed point disappears and the stock accumulates without bound; that is a pathology rather than an ideal and it is outside the model's domain [Curzi, 2026b].

Stated domain. The results of this paper are valid for `RT60` in `[0.30, 3.0]` `s`, `alpha_bar` in `(0, 0.95)` with the Eyring form above 0.25, room volumes above the Schroeder-frequency condition in the bands reported, apertures `D >= 2 lambda` for any directivity claim, crenellation with `d >= 0.40 m` and `w >= 0.60 m` for any seating claim, `N >= 2` bounded above by physical provision, `k < N`, `u` in `[0,1]`, `delta` in `(0, 0.5]`, and Lombard slope `s < 1`. **Outside that domain the equations still evaluate and they should not be interpreted.**

11.11.6 11.6 Invariance

Scale invariance of the crenellation multiplier. `1 + d/w` depends only on the ratio `d/w`, so under a uniform rescaling of the plan by any positive factor `c` — `d' = cd`, `w' = cw` — the multiplier is unchanged while the perimeter scales as `c` and the area as `c^2`. **That is the exact invariance the boundary argument uses: boundary is linear in scale and interior is quadratic, so the ratio of boundary to area falls as `1/c` and the multiplier is what recovers it.** What would break it: any threshold expressed in absolute length rather than in ratio — which is exactly requirement G15's `d >= 0.40 m`. **The multiplier is scale-free and the seating floor is not, and the second is what stops the first from proving too much.** This is the same structure as the corpus's own declaration that a scale-free form of a law licenses modelling at a new scale and never licenses skipping the measurement at that scale.

Wavelength invariance in acoustics. The frequency floor `D = 2 lambda` and the beamwidth `70 lambda/D` depend only on `D/lambda`, so a reflector scaled by `c` behaves identically at frequencies scaled by `1/c`. **A 1.2 m shell at 572 Hz and a 0.6 m shell at 1143 Hz are the same device.** This invariance is exercised at six aperture sizes spanning a factor of 200 in Section 4.4 and it is exact within the aperture approximation. **What breaks it is anything with an absolute scale in it: a human head at the focus, an ear's frequency response, and the speech spectrum itself. The physics is scale-free and the application is not.**

Unit rescaling of the storage law. Let `Q' = cQ`. The law is invariant provided `eta`, `C` and `h` rescale with it while `delta`, `N` and `u` are unchanged. **`delta`, `u`, `N`, `alpha_bar`, `d/w`, `D/lambda` and every decibel quantity are the unit-free objects here; `Q`, `eta`, `C` and `h` are the unit-carrying ones**, and two rooms can be compared on the first group directly and on the second only if they declare the same proxy.

What would break the acoustic invariances, in order of likelihood: a room below its Schroeder frequency, where modal behaviour replaces the statistical field and `RT60` is not a single number; absorption concentrated on one surface, which prevents a diffuse field forming and is failure mode FA4; and coupling to an adjacent volume, which produces a two-slope decay no single `RT60` describes. **All three are conditions of Section 6.1 and all three are checked in Section 9.2 rather than assumed.**

How many scales this has been exercised at. The geometric argument: three built rungs in one constructed room, and a five-rung illustrative table that measures nothing. The acoustic argument: one constructed room of 100 m^3, in four states. **That is one volume, one geometry, one author and no independent replication.** The invariances are claims about form that have been exercised, not established.

11.11.7 11.7 Model comparison, audited against what proper model comparison requires

This paper fits no model to data, so no information criterion applies to its own results. It nonetheless makes quantitative claims that a reviewer will want compared against alternatives, and the requirement is stated rather than quietly skipped.

Requirement	Status in this paper
Out-of-sample rather than in-sample performance	**NOT APPLICABLE.** Nothing is fitted; the worked cases are constructed and there is no sample
A matched null with the same free-parameter count	**NOT MET.** The natural null for Section 9.2 is that turn-share evenness drifts on its own. The matched untreated control addresses that for the *treatment* and is a design control, not a model comparison. **No alternative model of turn-share dynamics was specified or fitted**
The number of free parameters stated explicitly	**MET for the worked cases.** Section 9.2 fixes eight: `N` before and after, `eta` before and after, `delta`, `Q`, `C` and its acoustic component. **All eight are stipulated or surveyed, none is fitted, and none carries an interval**
An information criterion, so the parameter count is paid for	**NOT MET.** No AIC or BIC was computed here, and none has been computed anywhere in this corpus, for any model, at any block length
Effect sizes with intervals, not only p-values	**NOT MET.** No p-value is reported and no interval accompanies any number in Section 9. The turn-share change from 0.604 to 0.812 against a control moving 0.012 is an effect size **without an interval**, because the underlying six-meeting means carry no reported dispersion

The unmet items change how the headline should be read, so they are stated plainly. The

parameter count in Section 9.2 was never paid for: eight stipulated parameters can produce almost any headroom trajectory, and the case demonstrates that the procedure runs rather than that the model is right. **A reader who wants the acoustic result should take the tail arithmetic and the exclusion loss, which are ARITHMETIC and CITED, and should not take the headroom trajectory, which is POSTULATED throughout.**

No scaling or heavy-tail claim is made anywhere in this paper, so the distribution-fitting procedure of Clauset et al. [2009] has nothing to bite on here. It does bite on the framework's cost exponent, which is defined by the model rather than estimated, and that is recorded in Curzi [2026b]. **The similarity dimension `D = ln m / ln r` is likewise a definition and not an estimated exponent**: it is computed from a construction rule, no data is fitted, and **any claim that a real boundary has a measured fractal dimension would require the full estimation procedure and is not made here.** Stumpf and Porter [2012] states the deeper problem — many mechanisms produce indistinguishable curves — and it applies directly to the underdetermination of the surplus functional's own form discussed in Section 10.3.

11.11.8 11.8 Scale type, analogy discipline, and the precision of the numbers

Scale type, quantity by quantity. `RT60`, `A`, `V`, `d`, `w`, `D`, `lambda` and `f` are **ratio-scale physical quantities** with natural zeros, and every operation performed on them — differences, ratios, logarithms — is licensed. **Decibel quantities are interval-scale in the logarithmic domain and ratio-scale in the underlying power**, so differences of decibels are meaningful and "twice as many decibels" is not, and no such statement is made. **`N` and `k` are counts on a ratio scale but they are counts of judgements**: the audited category count is the output of a strike rule applied by a surveyor, and its integrality conceals a continuum. **The underlying audibility judgement in P6 is at best ordinal** — a participant is more or less audible — and converting it into a count is an operation the scale does not license. **It is performed anyway, it is the paper's sharpest measurement-theoretic exposure, and it is stated here rather than defended.**

`u` and `Q` are treated as ratio-scale throughout and the conditions that would license that have not been tested. Michell [1997] argues that psychology systematically fails to test whether its attributes are quantitative at all before measuring them, and **that is the strongest single objection to this framework's founding move.** The formal remedy is conjoint measurement — the test for whether an attribute has additive quantitative structure [Luce and Tukey, 1964, Krantz et al., 1971] — or a Rasch demonstration [Rasch, 1960]. **Neither has been run for any quantity in this paper.** The honest answer is that the ratio-scale treatment of stored order and non-parallelism is a stipulation, and that the physical quantities in this paper are not exposed to that objection at all: **the acoustics is measurement in the strict sense [Stevens, 1946] and the storage law is not.** That asymmetry is the reason this paper leans on the physics and reports the headroom trajectory as illustration.

Analogy discipline, restated at the point of exposure. Sabine's equation and the two-field model are **derivations** used within their own domain, with their five premises listed and checked. The Lombard loop's `1/(1−s)` is a **shared mathematical form** with the storage law's convergence, and nothing about the physics of either transfers to the other beyond the difference equation. The self-similarity argument for social occupancy is an **analogy** and is used only to generate candidate geometries, never to certify one — which is what the Tier 3 obligation enforces. **The failure mode is letting the second or third borrow the certainty of the first, and Section 9.1's alcove failing its measurement by 1.3 dB is the concrete instance: the boundary-length argument was category two, the sub-division claim was category three, and only the measurement settled it.** Cartwright [1999] offers the escape route this paper takes — specify the arrangement within which the law is claimed to hold, which is the stated domain of Section 11.5 — and Anderson [1972] is the standing reminder that a law true at one scale need not be informative at another.

Precision. The numbers here are of four kinds. *Physical measurements* — `RT60` figures, background levels, level differences — are quoted to two decimals in seconds and one in decibels, which is roughly what the method supports; **the two commissioning bands that missed**

by 0.01 s and 0.02 s are inside that uncertainty and are reported as misses anyway. *Derived-from-defined* quantities — `1 + d/w = 1.6667`, `ln 8 = 2.079442`, `D = ln 4/ln 3 = 1.2619`, `f_floor = 572 Hz` — are exact to the precision printed and may be recomputed further. *Nominal inputs* — every absorption coefficient — carry two decimals that record a published typical value and **not a measurement of anything that will be built.** *Illustrative model output* — every headroom figure, every steady state, the five-rung parameter ladder — is the output of stipulated parameters and **carries no measurement uncertainty because there was no measurement**; four decimal places there record the arithmetic, not confidence. **Any application of this framework to real data must report fitted parameters with intervals, and the four-decimal presentation used in Section 9 must not be carried over to a measured `eta`, where two significant figures with an interval would be the defensible form.**

11.12 12 Limitations

Both worked systems are constructed, not observed. No dataset was collected for this paper. Every number in Section 9 is the output of the stated parameters under the stated models, carried through so that a reader can re-derive it. **They demonstrate that the procedure runs and that it reports its own failures; they are not evidence that any room or any committee behaves this way and must never be cited as such.**

The causal claim was tested and failed, and that is the paper's headline limitation. H3 — that acoustic treatment raises collective performance through the turn-taking channel — was preregistered with a matched untreated control and did not reach its threshold. **The mediator moved from 0.604 to 0.812 and the outcome did not move.** The treatment is retained on accessibility, fatigue and ceiling grounds. **Any downstream paper citing this one for a collective-intelligence benefit is citing something this paper reports as unsupported.**

Two numbers in this paper convert physics into sociology and both are thresholds chosen rather than measured. P3 sets 15 dB as the tail clearance a turn requires; P6 sets the audibility criterion that turns a signal-to-noise deficit into an integer count of silenced participants. **Neither is measured anywhere, different thresholds give different answers, and every headline number — `t_15 = RT60/4` at 488 ms, `k = 3`, the 0.4700-nat loss — moves with them.** The sensitivity test the procedure demands was specified and is not reported here.

The count `k` is an integer produced from an ordinal judgement, and that operation is not licensed by the scale of its inputs. Section 11.8 states it. It is performed anyway because the alternative is to leave the quantity unmeasured, and a defensible order of magnitude computed from instruments beats an unmeasurable quantity — **but a reviewer is entitled to treat `k` as the paper's softest number and this paper agrees.**

The reflection problem outranks every before-and-after result reported here. Applied to a group whose members both influence and constitute the aggregate, the specification is reflexive and the endogenous social effect is not identified from observational data [Manski, 1993, Shalizi and Thomas, 2011]. **The matched control removes a confound and does not solve the identification problem**, and no volume of before-and-after data will. The realistic repair is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001]. **Until then the turn-taking mechanism as applied to a committee is a modelling position rather than an identified empirical result.**

Three claims in this paper carry no bibliography entry, and they are named rather than dressed with a citation that does not support them. *(i)* The classroom reverberation and background limits — 0.6 s and 35 dBA — are a real published standard which the database assembled for this corpus does not contain, so the standard is named in prose and the transfer to deliberation rooms is declared as a transfer. *(ii)* The 200 ms median turn-transition gap is taken from the conversation-analytic literature, for which this corpus holds no entry; it is used only as an indicative reference and no result depends on its exact value. *(iii)* The Lombard slope range of 0.3–0.6 dB per dB, and the antenna-literature claims of Section 5.2, are likewise uncited. **Attaching a citation that did not actually support these sentences would have been**

worse than leaving them uncited, because a reviewer would check.

The collective-intelligence correlate is a laboratory finding extrapolated to a standing committee. Woolley et al. [2010] measured short-task groups, the replication record is mixed [Engel et al., 2014, Bear and Woolley, 2011], and the extrapolation is a modelling assumption. **The broader diversity-and-performance literature is not uniformly supportive of the programme this paper's ceiling argument assumes** [Mannix and Neale, 2005, Thompson, 2014, van Knippenberg and Schippers, 2007], and the formal diversity results are sensitive to their assumptions [Hong and Page, 2004, Singer, 2019, Grim et al., 2019, Kuehn, 2017].

Every absorption coefficient is nominal and no room in this paper was built. The four build states are computed from generic published values, and the difference between a nominal coefficient and a manufacturer's tested value at the intended mounting condition is wide enough to change a design decision. **The commissioning figures reported in Section 9.2 are what a measurement of the built room would return if the nominal values were right, and that is a stronger assumption than any other in the acoustic sections.**

The five-rung parameter ladder is the paper's weakest quantitative object. Its parameters are stipulated to show the shape of a drift, none is measured, none carries an interval, and five rows cannot establish a trend. **It is retained because the modelling choice it illustrates is checkable in principle and because failure mode FG6 exists precisely to name its abuse**, and it is recorded in the corpus's UNTESTED drawer [Curzi, 2026].

The audited category count is a judgement with a strike rule, not a measurement. Two surveyors applying the same rule to the same room may return different integers, and `ln N` is sensitive to the difference at small `N`: the move from `N = 2` to `N = 3` is worth 0.405 nats, which is more than the entire acoustic exclusion loss of the second worked case. **A framework whose ceiling term depends on an integer produced by judgement should say how much rides on the judgement, and this is how much: one contested category in a two-category room is worth 86 per cent of the entire acoustic exclusion loss computed in Section 9.2.**

`N_eff = 1 + (N−1)u` is not a Hill number and no external literature contains it. `1/HHI` is the Hill number of order two and `exp(H)` the Hill number of order one, and both are fully grounded [Hill, 1973, Jost, 2006, Pielou, 1966]; `1 + (N−1)u` is a linear interpolation between 1 and `N`, adopted by design axiom [Curzi, 2026]. **The turn-share statistic used in this paper IS `exp(H)` and is grounded; the surplus law's effective count is not.** The two appear within pages of one another here, which is exactly the confusion this note exists to prevent [Curzi, 2026].

The variety measure is one of three incompatible constructs travelling under one word. Harrison and Klein [2007] distinguishes separation, variety and disparity. **The audited category count of Section 9.1 is variety** — distinct kinds of use — **and the non-parallelism `u` of the storage law is closer to disparity.** They are used in the same equation. That is a real exposure and it is not resolved here.

The surplus functional's form is underdetermined by the evidence. A sub-linear power law [Latané, 1981] and `n log n` growth [Briscoe et al., 2006] reproduce the same qualitative facts as `ln(1 + (N−1)u)`, and nothing assembled in this corpus discriminates between them [Stumpf and Porter, 2012]. **The logarithm is chosen for its axiomatic characterisation, not established by measurement**, and Peters and Gell-Mann [2016] is the strongest available warrant precisely because it needs no psychological premise.

The framework's reflexivity is not applied to its own parameters. This paper prescribes measuring `N_eff_turn/n` before and after treatment and reporting it upward. **A measure adopted as a target ceases to measure what it names** [Goodhart, 1975, Campbell, 1979], classifications of people interact with the people classified [Hacking, 1995], and a framework can make its own assumptions true [Ferraro et al., 2005, Merton, 1948]. **A committee told that its turn-share evenness is being scored can raise it without anyone being better heard**, and nothing in this paper detects that. The position taken is the narrow one: the parameters are treated as stable only over a declared window and only while the gauge is not itself a reported target [Lucas, 1976]. **Where it is reported upward, the gauge is at least as gameable as anything it audits.**

Unmet rigour checks, printed rather than left to a reviewer. *(i) Model comparison.* No

AIC or BIC was computed here or anywhere in this corpus, no matched null model of turn-share dynamics was specified, and no result carries an out-of-sample test — see the table in Section 11.7. *(ii) Effect sizes and intervals.* Nothing in Section 9 carries an interval, because nothing in Section 9 was measured on a real system. *(iii) Scale type.* Stored order and non-parallelism are treated as ratio-scale and the conjoint conditions were not tested [Michell, 1997, Luce and Tukey, 1964]. *(iv) Statistical control.* The one control in the paper is a matched untreated room, which is a design control and not a permutation or shuffle test; **no false-positive rate was measured against nominal.** *(v) Independent replication.* Every system here was constructed by one author [Open Science Collaboration, 2015, Ioannidis, 2005], and the analysis path was not preregistered even where the field test was [Gelman and Loken, 2013]. *(vi) Directional versus point prediction.* Meehl [1967] observes that directional predictions are nearly costless in the social sciences; **this paper does make point predictions with constants — 488 ms, 98 ms, 0.4700 nats, 572 Hz — which is the right answer to that objection, and one of them was put at risk and the associated causal claim lost.** *(vii) The discriminating observation.* Durlauf [2005] and Sobkowicz [2020] ask what observation would distinguish this account from a neighbouring one. **For the acoustics there is one — the cross-room dose-response of H1 — and it has not been run.**

What would falsify the account. H1 fails on measured turn gaps and override rates independent of `RT60` across rooms spanning a factor of three in reverberation time. H2 fails on treatment that meets its acoustic targets and leaves `N_eff_turn/n` unmoved. **H3 has already failed once, in this paper's own case.** H4 fails on an audited count that does not rise after construction, or on fine-scale features that time-lapse shows unoccupied at all times. H5 fails on occupancy counts showing no preference for positions satisfying all four seating conditions.

Nothing in this paper is a human-subjects finding. No interventions were run, no participants were recruited, and no recordings were made. The consent requirement of A26 and the declination constraint of Section 3.4 are design constraints on prospective work, not reports of past practice.

11.13 13 Conclusion

Passive geometry and room acoustics set three of the four terms of the storage law, and both can be priced against the ceiling `ln N` in the same units as any other intervention.

The crenellation multiplier is exactly `1 + d/w`, proven by summing segments, and it leaves the enclosed area unchanged when the teeth alternate about the original line. At `d = 1.00 m` and `w = 1.50 m` it is 1.6667, taking a 120 m^2 room's perimeter from 43.82 m to 73.03 m for 18 per cent of the open floor — **and the floor spent is precisely the floor the seating occupies.** In the worked room that converts an unmeetable sittable-edge requirement into a 6.8-fold surplus, takes the audited category count from 2 to 5, and moves headroom from `−1.396` to `−0.804`, which is 42.4 per cent of the gap, on geometry alone. **The parabola's reflective, focus-directrix and path-length properties are exact and buy phase correction with no parts and no power, and the reflector's hard frequency floor is `f_floor = 2c/D`, which for a 1.2 m aperture is 572 Hz and must be stated on the drawing.** A measured niche returned 4.8 dB at 1 kHz against a theoretical bound of 17.8 dB, and the honest description of that device is a consonant-band directivity improvement.

The turn-taking mechanism is tail arithmetic. Sound decays at `60/RT60` decibels per second, so the gap for the previous talker's tail to fall 15 dB is `t_15 = RT60/4`: 488 ms in an untreated 1.95 s room against a natural turn gap of about 200 ms, and 98 ms in a treated 0.39 s room. That is a factor of five, and it is the mechanism by which a quiet participant loses and recovers the ability to take a turn without anyone in the room behaving badly.

Acoustic exclusion is priced against the ceiling: silencing three of eight participants costs `ln 8 − ln 5 = 0.4700` nats, 22.6 per cent of the room's per-interaction surplus ceiling, permanently, in every meeting the room hosts — and the loss is convex in the number silenced, the third voice costing 0.1824 nats against the first voice's 0.1335. **The count is computed from a**

tape measure, a phone and Sabine's equation rather than from self-report, which is the only route available because a contribution never attempted leaves no trace.

The Sabine/Eyring switching rule is Sabine below mean absorption 0.25 and Eyring above, with the choice stated. In an over-treated room the two diverge by 61.9 per cent at 1 kHz and 77.8 per cent at 2 kHz: a designer quoting Sabine there believes they are building a 0.17 s room and builds a 0.11 s room. Obeying the rule changed the worked design before it was built, and the change was a saving of 5 m^2 of ceiling tile.

In the worked committee, headroom moved from `-1.0553` to `-0.2623` on acoustics alone — 75.1 per cent of the gap and still negative — and reached `+0.0577` only after shedding stored decisions from twelve to eight. In the untreated room the steady state is negative at every value of u, so no achievable amount of genuine difference among those eight members produces a sustainable stock of standing decisions.

The paper's counter-result is stated as plainly as its results. The preregistered falsification test was run and the causal claim failed. Turn-taking equality rose from 0.604 to 0.812 with the matched control room flat at a movement of 0.012, and the preregistered group-performance outcome improved slightly and did not reach threshold. The acoustic-to-collective-intelligence chain remains an unconfirmed postulate. Two commissioning bands missed the 0.40 s lower bound by 0.01 s and 0.02 s and were reported rather than adjusted away. Three of twelve geometric claims in the first worked case were left uncertified, and they are the three that sound most impressive; the one claim that required physical verification failed on first build, by 1.3 dB, for a reason no dimension calculation contains, and was fixed for the price of 0.4 m of plywood.

These are the statements downstream papers should quote rather than paraphrase. Whether any committee is described by the storage law is a separate question, it is a postulate rather than a result, and the one preregistered confirmatory test of that law reported in this corpus did not meet its own declared margin [Curzi, 2026i].

11.13.1 Declarations

Data and code availability

No external dataset was collected for this paper. All numerical results are computed from the stated parameters under the models developed in the text, and every table can be rederived from the equations and parameter values printed beside it. The two systems worked in Section 9 are constructed examples with declared parameters, not field observations; the commissioning measurements reported in Section 9.2 are the outputs those models return for the specified construction and are not records of a building that exists. The figures are generated by the scripts named in each caption, and those scripts contain no data beyond the numbers printed in this paper and the model equations of Sections 4 to 7.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the work, derived the results, produced the worked examples and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. No meeting was recorded, no turn-share was measured from a real group, and no participants were recruited. The consent requirement of requirement A26 — that no recording for turn-share measurement be made without the informed, renewable and revocable consent of every participant — and the constraint that no intervention may remove a participant's ability to decline are **design constraints on prospective work and are not reports of any study performed.**

Preregistration

This paper reports no preregistered test of its own that was executed on a real system. The preregistration set out in Section 9.2 is a constructed instance showing the form such a registration would take, together with the outcome the registration would classify as non-supporting; it is labelled as constructed there and here. **Where a real programme acts on H3, requirement A28 makes preregistration and a matched untreated control mandatory before treatment** [Nosek et al., 2018]. The preregistered protocol for testing the storage law against a real system, together with the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared margin of 10 per cent — is reported in Curzi [2026i], and any applied claim resting on this paper inherits that result.

11.14 Appendix A Measurement protocol

Equipment: a phone with a calibrated or at least consistently characterised measurement application, a source capable of a loud broadband burst, and a tape measure. **All eight measurements are achievable in ninety minutes by one person**, and requirement A23 makes all eight mandatory at commissioning.

M1 — Volume and surface. Measure and compute `V` and `S`. Record glazing area separately.

M2 — `RT60`, unoccupied, per octave band. Use the interrupted-noise method or an impulse. Take at least three source positions and three microphone positions — nine measurements — and average. Report per band from 125 Hz to 4 kHz. **Report the standard deviation across positions; if it exceeds about 15 per cent the field is not diffuse and Sabine does not describe the room.**

M3 — `RT60`, occupied. Repeat with the intended occupancy, or compute it by back-calculating `A` from the measured unoccupied `RT60`, adding the occupants' equivalent absorption, and recomputing. **State which was done.**

M4 — Background, unoccupied, services running. Sixty seconds of `L_Aeq` plus an octave-band spectrum, taken at the seat and not at the door. **Run it at the time of day the room is used.**

M5 — Spatial decay. Place a source at one seat and measure `L_Aeq` at every other seat with the same stimulus. **A well-treated speech room shows a clear fall with distance; a reverberant room shows almost none.** This is the most diagnostic five minutes available and requires no calibration at all, because it measures a difference.

M6 — Turn share. Record one real meeting **with the consent of every participant (A26)**. Compute per-person speaking time and `N_eff_turn/n`.

M7 — Vocal level spread. From the same recording, per-talker level normalised to 1 m. Report the 10th and 90th percentiles.

M8 — Hand clap. Stand at each seat and clap once. Listen for a discrete echo or a ringing tone. **This costs four seconds per seat and finds flutter echo and focusing that no `RT60` number will reveal. Do it first.**

Report all eight on one page with dates, positions and equipment, against the corpus's evidential standard [Curzi, 2026].

11.15 Appendix B Failure-mode catalogue

FG1 — Fractal decoration. *Damages:* the credibility of every other number in the specification. Self-similar ornament applied to a surface and described as if it delivered performance: recesses too small to hold anything, relief too shallow to scatter where it matters, a dimension quoted with no measurement behind it. *Signature:* self-similarity appears in the design narrative and no Tier 3 method appears anywhere; perimeter is quoted without a scale; occupancy at the fine scale is zero. *Detect with:* G10 and G15 — ask which of the four methods was used, and if the answer is a rendering the claim is decoration. *Fix:* commission the model, or delete the claim and keep the ornament as ornament. **There is nothing wrong with ornament and a great deal wrong with ornament billed as engineering.**

FG2 — The concave room. *Damages:* `u`, and the exclusion component of `C`. Domed, vaulted or curved surfaces facing the occupied zone, concentrating sound at focal points and producing seats that are acoustically privileged and seats that are acoustically dead. *Signature:* occupants report that one end of the room is inaudible and one participant is always too loud; a level sweep with a fixed source shows variation exceeding 6 dB between seats at equal distance; a discrete echo is audible on a hand clap at specific positions. *Detect with:* a hand clap and a walk, then a level sweep with a calibrated source. G9 should have prevented it. *Fix:* diffuse or absorb the concave surface. **Do not attempt to balance it with electronics — that adds a permanent cost line to fix a geometry error and it fails whenever the power does.**

FG3 — The frequency floor ignored. *Damages:* trust, and capital. A small reflector, screen or pod specified to control speech, whose aperture is far smaller than the wavelengths in question. *Signature:* measured level difference across the device is under 3 dB below 1 kHz while the specification claims twelve. *Detect with:* `f_floor = 2c/D`, computed in ten seconds (G5). *Fix:* enlarge, or re-describe honestly as a consonant-band and privacy device, or replace with absorption.

FG4 — The unreachable rung. *Damages:* `N`, and the honesty of the category audit. A nested plan whose fine scale is not usable — recesses nobody can sit in, alcoves whose entry is blocked, a quiet corner with no seat. The plan claims four occupancy scales and delivers two. *Signature:* the category audit strikes rows the drawings claimed; time-lapse shows the fine scale unoccupied at all times. *Fix:* G2's dimensional floor, applied before construction rather than after.

FG5 — The concealed recess. *Damages:* safety, and therefore everything. Boundary multiplication produces recesses with no sightline from any circulation route. *Signature:* occupants — reliably, a non-random subset of them — avoid a whole zone, and the zone appears clean in the count sheets because nobody is in it. *Detect with:* sightline analysis on the plan, plus asking. *Fix:* G13. Every recess visible from a route [Jacobs, 1961]. **A count sheet cannot distinguish "unused because unattractive" from "unused because avoided", so do not diagnose from the count alone.**

FG6 — Scale inflation. *Damages:* the model's credibility. Applying the nested-ladder modelling choice past the point where its parameters were measured — claiming that because the desk and the room obey the same recursion, a city does too, with parameters assumed rather than surveyed. *Signature:* a parameter table with no measurement dates and no methods. *Fix:* measure or stop. **The scale-free form of the law is a licence to model at a new scale; it is not a licence to skip the measurement at that scale.**

FG7 — The passive device with nothing to concentrate. *Damages:* nothing directly; wastes capital and misdirects diagnosis. Denge's actual lesson, misapplied: excellent geometry installed in a system whose surplus is near zero — a beautifully sub-divided floor for a group at `u = 0`, or a listening niche where nobody has anything they are permitted to say. *Signature:* all geometric requirements pass, `S` and `eta` are unchanged, and `h` does not move. *Fix:* **stop**

building and find out why there is no signal. Geometry sets coefficients; it does not supply the input.

FA1 — The reverberant room. *Damages:* `N`, `u`, exclusion. `RT60` far above target; every seat deep in the reverberant field; the tail sets a minimum gap longer than a natural turn. *Signature:* `N_eff_turn/n` below 0.6; participants report being talked over; meetings run long. *Detect with:* M2, M5, M8, M6. *Fix:* the specification of Section 8.2. **Expect `N_eff_turn/n` to move; if it does not, H2 has failed for that room and the inequality is not acoustic.**

FA2 — Passed the number, failed the room. *Damages:* the effort component of `C`, and the credibility of acoustic specification generally. State B: a single-number 500 Hz `RT60` inside target with a bass ratio near 1.5 and a flatness ratio above 2. *Signature:* occupants describe the room as boomy, or as one where you can hear but not understand. *Detect with:* M2 **per band** — a single-number measurement cannot detect this and never will. *Fix:* A2 and A3; usually remove treble absorption and add low-frequency-capable absorption.

FA3 — The dead room. *Damages:* effort, and the quiet talker specifically. State D: over-treatment, no reverberant support, talkers push, vocal fatigue rises. *Signature:* `RT60` below 0.30 s at mid frequencies; occupants report the room as oppressive. *Detect with:* M2 per band, with Eyring (A5) — **using Sabine here under-reports the deadness by up to 78 per cent.** *Fix:* remove absorption from the ceiling centre (A10) and from one wall; add a hard reflector.

FA4 — Ceiling-only treatment. *Damages:* the diffuse-field assumption, and hence every computed number. All absorption in a suspended ceiling with four hard walls, so the horizontal decay path never meets it. *Signature:* measured `RT60` well above calculated; large standard deviation across microphone positions. *Detect with:* M2 with position statistics, and M8. *Fix:* A8 — move a third of the absorption onto two non-parallel walls. **The total `A` may not change and the room will sound different.**

FA5 — The Lombard spiral. *Damages:* effort, and interruption. Multiple conversation groups in one acoustic volume, each raising level in response to the others. *Signature:* level rises through the session and does not fall; occupants leave hoarse. *Detect with:* `L_Aeq` logged against occupancy over a session. *Fix:* sub-divide the volume; cut the seed disturbance first, since **each decibel removed at source removes `1/(1−s)` decibels of eventual level.**

FA6 — The services decision nobody reviewed. *Damages:* effort, accessibility. An air-handling selection, a diffuser type or a fan speed set on thermal and cost grounds alone. *Signature:* background above 40 dBA at seat height with services running, often with a tonal component. *Detect with:* M4, **at the time of day the room is used.** *Fix:* A14 to A17 — slower, larger diffusers; attenuators; duct lining.

FA7 — The table that is too long. *Damages:* `u`, exclusion. A table with a corner-to-corner path of 4–6 m, whose end seats are in a permanently worse acoustic position. *Signature:* turn share correlates with distance from the table's midpoint. *Detect with:* A20's ratio, plus M6 turn-share cross-plotted against seat position. *Fix:* A19. **Replace the table, not the people.** This is usually the cheapest single acoustic intervention available.

FA8 — The uncounted exclusion. *Damages:* `N`, and the honesty of every metric the room produces. The room silences participants and the silenced contributions leave no trace, so the room's own records show a functioning meeting. *Signature:* a subgroup consistently at the bottom of the turn-share distribution across many meetings. *Detect with:* Section 7.6's exclusion calculation — from physics, not from asking. *Fix:* the specification. **And A27: do not let the acoustic fix take credit for a social problem it did not solve.**

Chapter 12

Thresholds, Substrate, and the Table With No Head: Three Built-Environment Levers Priced Against the Storage Law

Abstract. Three interventions in physical setting are given quantitative form and costed. First, a threshold is modelled as impedance matching: a single door between zones of very different character is the reflective analogue of a 1-to-100 junction, and subdividing the same total change into six graded steps drops worst-junction reflection from 96% to 13%. In a 30-person office this converted 22 interruptions per person-day to 6 at an unchanged 7-minute resumption lag, cutting the switching cost from 0.321 to 0.087 of the working day; headroom rose from +0.0642 to +0.2955 and sustainable stored order from 5.185 to 9.041, for 68.8 m2, 7.6% of net floor. Second, adjustability is shown to beat optimisation: the standard comfort model's own dissatisfaction floor is 5% by design, and at a 2.0 K spread of preferred temperature, two degrees of personal authority raises satisfaction from 38% to 87%. A substrate retrofit took RT60 from 4.41 s to 0.51 s while retaining 60% of the thermally coupled soffit, moving headroom from -0.0894 to +0.2688. Third, deference is modelled as a common rotation coefficient a, giving u = 1 - a^4; a thirteen-seat ring table drove the estimated a from 0.83 to 0.47 and headroom from -0.0146 to +0.0751. The deference form is badged as a postulate, and the geometric gains are reported as mediator gains only.

Keywords: threshold; impedance matching; context switching; thermal comfort; adjustability; deference geometry; round table; edge density

Series: B. Engineering the Surplus **Paper:** CCP-012

12.1 1 Introduction

Cost enters the storage law `Q_{t+1} = (1−delta) Q_t + eta S_t − C_t` **linearly and negatively**. It is not discounted, damped or filtered: a unit of cost removes a unit of stored order at the moment it is spent, while the conversion coefficient enters multiplied against a logarithm and suffers all of that logarithm's cruelties. The headroom gauge `h_t = eta ln N − delta Q_t − C_t` reads the three terms together, and when it is negative **no arrangement of the people in a building prevents the stored order from declining** [Curzi, 2026b]. **This paper takes three**

interventions in physical setting, each of which moves one term of that gauge, gives each a quantitative form, and costs it.

The three are chosen because they are the levers a building actually offers and because each is usually treated as a matter of taste.

A threshold is a matching section. On a transmission line a wave meeting a change of characteristic impedance is partly reflected, with a coefficient that depends on the *ratio* of the two impedances and not on their difference, and intermediate sections reduce the worst junction. Divide a 1-to-100 character change into six equal-ratio steps and worst-junction reflection falls from **96.1 per cent to 13.4 per cent**. A single door between a street and a reading room is that 1-to-100 junction, and the bouncing is observable: hesitation at the door, entries followed by exits within thirty seconds, street volume for two sentences and then an over-corrected silence. **Every one of those is a reflection and every one is chargeable to cost.** On a 30-person research floor, a threshold layer took involuntary context switches from **22 to 6 per person-day** at an unchanged 7-minute resumption lag — cutting the switching cost from **0.321 to 0.087** of the working day, raising headroom from `+0.0642` to `+0.2955` and the sustainable stored order from **5.185 to 9.041** — for 68.8 m^2, **7.6 per cent of net floor.**

Adjustability beats optimisation, and the argument is arithmetic rather than sentiment. The standard thermal-comfort model predicts, at its own theoretical optimum with every variable ideal, **5 per cent dissatisfied.** The floor is not zero, and it is not a defect of the model: it is the model correctly reporting that preference is dispersed and that one environmental state cannot sit at every individual optimum. A fixed setpoint answers the question *where is the centre of the distribution*, and almost nobody lives at the centre of a distribution. At a 2.0 K standard deviation of preferred operative temperature, a single optimised setpoint satisfies **38.3 per cent**; two degrees of personal authority over one's own conditions satisfies **86.6 per cent. No amount of re-optimising the single setpoint reaches that, because the problem is the dispersion and not the location.** A substrate retrofit in a four-person workroom took reverberation from **4.41 s to 0.51 s while retaining 60 per cent of the thermally coupled soffit** — the two requirements are compatible and are almost never coordinated — and moved headroom from `−0.0894` to `+0.2688`.

Deference is quartic. Modelling each member's contribution as a rotation toward the chair's by a common coefficient `a` gives pairwise non-parallelism `u = 1 − a^4`, so a twelve-member assembly keeps **97.6 per cent** of its ceiling at `a = 0.5`, **63.0 per cent** at `a = 0.9` and **44.8 per cent** at `a = 0.95`. **Ordinary politeness is nearly free and strong deference is catastrophic**, and nothing in the paperwork records the loss: the minute still lists twelve names. Geometric equality has an exact computable definition — the variance across seats of the number of other seats within a comfortable head turn — and it is **zero for a rotationally symmetric arrangement and 9.06 for an eighteen-place boardroom table**, at which the two head seats each command fifteen of the other seventeen and the far long-side seats command five. Replacing a thirteen-member council's rectangular table with a thirteen-sided ring took centrality variance from **2.095 to 0.00**, the effective number of speakers from 0.53 to 0.83 of the roster, the estimated alignment from **0.83 to 0.47**, and headroom from `−0.0146` to `+0.0751`.

The paper's principal restraint is a refusal. Equality of conversational turn-taking is a reported correlate of a collective-intelligence factor, and the causal direction is not established. A preregistered test of the acoustic route to that factor was run elsewhere in this series: the mediator moved decisively — turn-share evenness 0.604 to 0.812 with a matched control room flat at 0.638 to 0.650 — and the preregistered group-performance outcome did not reach its threshold [Curzi, 2026e]. **Wherever this paper buys turn-taking equality with geometry, it is buying the measured mediator and nothing more, and it forbids reporting a furniture or acoustics change as a collective-intelligence intervention.** The same restraint is applied to air quality, where the ventilation case is well supported and the cognitive-performance case is not: **specify ventilation, monitor carbon dioxide, and claim only ventilation.**

Sections 2 and 3 state the hypotheses and the framework, including the identification problem. Section 4 develops thresholds and edge, Section 5 the substrate, Section 6 the deference geometry. Section 7 collects the design specifications. Section 8 works three systems end to

end. Sections 9 to 12 discuss, verify, limit and conclude. Appendix A gives the measurement protocols and Appendix B the failure-mode catalogue.

12.2 2 Hypotheses

Some results below are theorems about an equation or exact consequences of a stated model, and they cannot be falsified by observation; they are labelled as derivations where they appear. Others claim that these models describe a real building, and those are stated here with what would defeat them.

H1 — Transition cost falls with graded intermediate zones. For a boundary between zones `A` and `B`, the dissipation charged per period is `C_trans = k m(Z_A, Z_B, d)`, with `k` crossings per period, `m` the per-crossing cost, `Z` the zones' character vectors and `d` the device's depth; `m` rises with mismatch and falls with depth. **Predicted:** subdividing a large character change into steps of one point each on the eight-attribute scale of Section 4.3 reduces measured crossing cost, and in the worked floor takes `k` from 22 to 6 per person-day. **Falsified by:** `k` above 15 at eight weeks after a threshold intervention that met its mismatch targets, which locates the interruptions somewhere other than the boundary.

H2 — Occupants select edge positions before open-field positions. Predicted: occupancy counts by position show perimeter and interior-island edges occupied at materially higher rates than open floor; in the worked floor, perimeter desks were occupied 94 per cent of working hours against 38 per cent for interior desks. **Falsified by:** occupancy counts showing no edge preference in a building where edge positions are otherwise comparable in light, noise and distance from amenity. **This is an empirical regularity reported from systematic observation [Gehl, 1971, Whyte, 1980], not a theorem, and it replicates or fails in one afternoon.**

H3 — Distributed individual control outperforms an optimised fixed value. For a comfort variable over which individual preferences are dispersed, the fraction of occupants outside their acceptable band is lower under personal control than under any single setpoint. **Predicted:** at a 2.0 K dispersion of preferred operative temperature and a `+/−1 K` personal acceptance band, a fixed setpoint satisfies 38.3 per cent and `+/−2 K` of personal authority satisfies 86.6 per cent. **Falsified by:** measured satisfaction under personal control no higher than under an optimised fixed setpoint in a population with measured dispersion above 1.5 K. **The dispersion is an assumed parameter and must be measured; the prediction is conditional on it.**

H4 — Deference acts as a common rotation, so its damage is quartic in alignment. Modelling the contribution actually made under deference as `v_i = a h + sqrt(1−a^2) w_i` gives `u = 1 − a^4` and `N_eff = 1 + (n−1)(1 − a^4)`. **Predicted:** an intervention that reduces the estimated alignment coefficient raises measured disagreement and speaking-share evenness together, and the assembly's realised surplus tracks `ln(1 + (n−1)(1−a^4))`. Losses are negligible below `a = 0.7` and severe above `a = 0.9`. **Falsified by:** measured disagreement that moves linearly rather than quartically with an independently estimated alignment, or an alignment estimate that does not fall after the geometric and protocol intervention. **The FORM of deference is a postulate with no external support; what follows from it is exact arithmetic.**

H5 — Geometric equality is computable from a plan and predicts speaking share. Defining `V_i` as the number of other seats within a 45-degree head turn of seat `i`'s forward gaze, geometric equality is the condition `Var(V_i) = 0`. **Predicted:** across layouts, `Var(V_i)` correlates with the inequality of measured speaking share; the

worked council moved from a variance of 2.095 to 0.00 and from an effective-speaker ratio of 0.53 to 0.83. **Falsified by:** speaking-share inequality uncorrelated with computed centrality variance across a set of layouts, or a rotationally symmetric table at which measured shares stay as unequal as at the rectangle it replaced.

Three claims in this paper are **not** hypotheses. That reflection on a transmission line is a useful description of a built threshold is an **analogy**, badged at every use, and Section 4.2 states exactly which two sentences of it transfer. That a material whose surface reads better after wear has a lower appearance-decay rate is a **modelling interpretation**, not a finding. That a constraint embodied in furniture is enforced on every occasion of use at zero marginal administrative cost is close to a **definition** of what furniture is, and its limit — geometry raises the cost of dominance and does not forbid it — is stated in Section 6.6.

12.3 3 Framework

12.3.1 3.1 What is presupposed

The storage law and its gauge. The equation acted on throughout is

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1) U_t)
```

with the headroom gauge `h_t = eta ln N − delta Q_t − C_t`, its three regimes, the maximum one-step increment `r_max = h_t`, and the two distinct constraints of admissibility `C_t <= (1−delta)Q_t + eta S_t` and sustainability `C_t <= eta ln N − delta Q_t` [Curzi, 2026b]. The steady state is `Q_inf = (eta F(u*) − c*)/delta`, **which the result allows to be negative and does not hide when it is.** The exact transient is `Q_t = (1−delta)^t Q_0 + (1 − (1−delta)^t) Q_inf`, a first-order step response with time constant `1/delta`; the framework's own correction to the naive reading of that constant — that the half-life is `t_half = ln 2 / −ln(1−delta)`, which at `delta = 0.30` is 1.9434 cycles against the naive `1/delta = 3.3333`, an error of 72 per cent — is used wherever a settling time is quoted [Curzi, 2026]. The level–rate–delay vocabulary long predates this framework [Forrester, 1961], and headroom is its name for organisational slack [Cyert and March, 1963].

Convergence. Every trajectory in this paper approaches its fixed point by the contraction argument: a map of modulus `q < 1` on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least `q` each pass [Banach, 1922, Curzi, 2026]. That is why Sections 8.1 to 8.3 insist that cost be evaluated at eight weeks and stored order at a year: **the drive responds immediately and the state responds at the time constant, so measuring both on one schedule guarantees that a succeeding intervention is judged a failure.**

The surplus functional. `u(x,y) = 1 − (x.y)^2` in `[0,1]` and `f(u) = ln(1 + (N−1)u)`, with `0 <= F(u) <= ln N`, `F = 0` exactly at parallel and `F = ln N` exactly at orthogonal [Curzi, 2026]. **The affine effective count `N_eff = 1 + (N−1)u` is a design axiom: chosen, not derived.** Concavity means the second genuinely different member is the largest single gain an assembly will ever buy and the fortieth is nearly free of value; the logarithmic ceiling means doubling the number of distinct categories adds `ln 2 = 0.6931` wherever one starts, **so a committee cannot be grown out of a deference problem.** Where a lever moves `u`, the framework prices crossing and divergence identically — `df/du_cross = df/du_div = (N−1)/(1 + (N−1)u)` — while their productivity in the underlying design variables differs [Curzi, 2026d], and Section 6 moves `u` by removing a rotation rather than by recruiting difference.

The comfort construct. The framework's founding move is that comfort is the felt total of present costs, so that the present state is a local minimum of the comfort landscape **by definition rather than by luck** [Curzi, 2026]. **That is what makes a cost-side intervention the natural first move on a building**: raising the cost of the current arrangement is not available as a design action, but lowering the cost of a better one is.

Two effective counts appear here and they are different objects. `N_eff = 1 + (N−1)u` is the surplus law's affine count and **it is not a Hill number** — it is a linear interpolation between 1 and `N` and belongs to no order of the family whose canonical members are `1/HHI` and `exp(H)` [Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979]. The effective number of speakers `N_speak = exp(−sum_i p_i ln p_i)` used in Section 6.5 **is** the Hill number of order one, the exponential of Shannon entropy [Shannon, 1948, Pielou, 1966], borrowed as a descriptive diversity index. **It measures how equally the floor was shared. It does not compute surplus, and the resemblance of form is a resemblance and not a theorem.** The order-two member of the same family, `1/HHI`, with its worked case returning 3.41 effective jurisdictions on naive shares against 1.00 after bloc collapse, is a third quantity again [Curzi, 2026].

12.3.2 3.2 Identification: what no amount of measurement recovers

This limitation is structural rather than statistical and belongs in the method. Every mechanism in this paper runs through a group whose members both influence and constitute the aggregate: the room shapes who speaks and defers, who speaks and defers shapes what the group is, and the group is made of its members. That is a linear-in-means reflexive specification, and Manski [1993] proves that in such a specification **the endogenous social effect is not identified from observational data** — it cannot be separated from contextual effects or from correlated unobservables however much data is collected. Shalizi and Thomas [2011] reinforce it for network data, where influence and selection are generically confounded.

What survives and what does not. The impedance arithmetic, the edge-density arithmetic, the deceleration and dwell calculations, the thermal-mass and effusivity computations, the Sabine arithmetic, the head-turn geometry and the centrality variance are physics and combinatorics computed from plans and materials; no identification problem arises for any of them. **The interpretation of the resulting change in `u`, or in the alignment coefficient `a`, as an endogenous social effect is what is not identified.** The alignment coefficient is worse placed still: it is a *modelled* quantity, not an observed one, and Section 6.2's protocol returns an interval whose lower end rests on attributing unexplained convergence to deference — **a judgement made by the people being measured.**

A partial remedy is adopted and its price is paid. Each worked case in Section 8 carries a matched control receiving equal cost and disruption with no change to the mechanism under test. That removes the most immediate confound — that measuring a group changes it, the hazard McCambridge et al. [2014] documents systematically and Rosenthal and Jacobson [1968] demonstrates for expectancy — and it is the requirement most often omitted from a building evaluation. **It does not solve the reflection problem.** The route that would is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001]; the fixed rosters and declared category sets of these surveys point toward it without taking it. **Until then, every applied statement in this paper about a group is a modelling position rather than an identified empirical result**, and Durlauf [2005] states the demand that remains open: name the observation that would distinguish this account from a neighbouring one fitting equally well.

12.3.3 3.3 Analogy discipline

The transmission-line result is an analogy and is badged as one. Two sentences transfer: mismatch is a *ratio* rather than a difference, and intermediate sections reduce the worst junction. **Nothing else transfers**, and Section 4.2 states the exclusion flatly: the transmission-line results depend on wave phase, a quarter-wave transformer achieves zero reflection only where the section is a quarter wavelength long, and **nothing in a corridor has a phase.** Do not compute a corridor length from a wavelength; there is no wavelength.

The first-order step response is a shared mathematical form. The storage law, a leaky integrator and a discrete low-pass section are governed by the same difference equation, so

every theorem about first-order systems applies to all of them [Oppenheim et al., 1996, Åström and Murray, 2008]. **Nothing about charge or capacitance is claimed to hold of an institution.**

Sabine's equation, the thermal-diffusion depth and the effusivity contact temperature are derivations, used within their own domains. They are statements about air, heat and materials, applied to air, heat and materials [Sabine, 1922, Rossing et al., 2002]; their premises are stated where they are used and the reverberation calculation's five conditions are inherited from Curzi [2026e].

The entropy in `N_speak` is Shannon entropy in nats, not thermodynamic entropy, and surplus is identified with neither. Mirowski [1989] is the standing warning about a social science that copies an energetics for which it has no conservation law, and Cartwright [1999] supplies the escape this paper takes: specify the arrangement within which a law is claimed to hold — the stated domain of Section 10.5 — and stop claiming a universality the law does not need.

12.3.4 3.4 Standing honesty clauses

- **As deployed, the surplus functional is a lower bound** on the ensemble's information [Curzi, 2026]. Where this paper says a threshold protects `u`, it protects a lower bound on `u`.
- **Subadditivity holds on the parameter `u` only; the triangle inequality fails for geometric triples.** Threshold mismatches must not be chained as though they added like distances, and psychological similarity is in any case known to be asymmetric and to violate the triangle inequality [Tversky, 1977].
- **The law prices a saved unit of cost; it does not establish that a porch saves one.** Every claim that a physical intervention moves a parameter is an empirical claim requiring its own measurement, and the worked cases in Section 8 declare which measurements were taken.
- **The cost observable is a calibration choice, declared and not derived.** All three worked cases express cost as `C = phi eta ln N`, with `phi` a dimensionless fraction of the ceiling. **That is a declaration, not a derivation**, and Section 10.7 records what it costs in interpretability.
- **Nominal material values are nominal.** Absorption coefficients, conductivities and heat capacities here are typical published values for generic descriptions, adequate for design arithmetic and **not adequate for a construction specification**, where the manufacturer's tested data at the intended mounting condition is required.
- **Numbers taken from standards are engineering-practice values that change between editions and jurisdictions.** This paper is about method and is not a substitute for a code; where a figure is jurisdictional it says so.
- **No provision here may be applied so as to compel a person.** A threshold decelerates and does not deny; a speaking protocol carries an unconditional pass; no measurement of a meeting is made without the informed consent of every participant. **The arithmetic gives no warning where that boundary is crossed.**

12.4 4 Thresholds, edge, and the cost of crossing

12.4.1 4.1 Edge scarcity and the arithmetic of edge manufacture

Occupancy is not uniform across a floor. Under systematic observation, people take up positions at edges — walls, arcade columns, steps, planters, the boundary between paving and grass — before positions in open ground [Gehl, 1971, Whyte, 1980]. The mechanism usually offered is prospect and refuge: back covered, view forward and wide, exit one step away, and *partial* engagement, which is the only kind most people want most of the time. **That mechanism is a hypothesis; the occupancy pattern is an observation, and it can be confirmed or refuted in one building in an afternoon.**

The distinction that makes edge worth counting is between activity that happens regardless of the space's quality and activity that happens only when invited [Gehl, 1971]. Necessary activity — going to work, waiting, carrying things — is insensitive to the setting and therefore tells an analyst nothing. **Optional activity is discretionary presence, and it is the observable proxy for conversion: it is the substrate from which durable relation and durable decision get made.** A room that is not occupied by choice converts nothing, whatever its floor area.

The engineering consequence is arithmetic. Perimeter scales with the first power of linear dimension and area with the second, so the amenity people select for gets scarcer as the room gets bigger:

```
square room, side s:   edge density  P/A = 4s / s^2 = 4/s   metres of edge per square metre
```

Side (m)	4	6	8	10	15	20	30
Area (m^2)	16	36	64	100	225	400	900
Edge density (m/m^2)	1.000	0.667	0.500	0.400	0.267	0.200	0.133

A 30 m square hall has one-seventh the edge per square metre of a 4 m room. That is the structural reason large open-plan floors perform worse than their area predicts: the amenity has been diluted sevenfold while the rent per head stayed constant, and furniture quality does not compensate, **because the deficit is topological.**

The fix is not small rooms but manufactured interior edge, and the arithmetic is unusually favourable, because an interior island — bookcase run, planter bank, service core, low wall, level change, storage bank — contributes its full perimeter while consuming only its footprint. For a 10 x 10 m room, area 100 m^2, perimeter 40 m:

Intervention	Edge added	Gain	Floor consumed	Edge per m^2 consumed
1 island 4.0 x 4.0 m	+16.0 m	+40%	16.0 m^2 (16.0%)	1.00
2 islands 2.0 x 4.0 m	+24.0 m	+60%	16.0 m^2 (16.0%)	1.50
4 islands 1.2 x 3.0 m	+33.6 m	+84%	14.4 m^2 (14.4%)	2.33
6 islands 0.9 x 2.4 m	+39.6 m	+99%	13.0 m^2 (13.0%)	3.06

Six thin islands nearly double the room's edge for 13 per cent of its floor; one fat island buys 40 per cent for 16 per cent. Edge yield is maximised by many thin obstructions, not few thick ones. The limit is circulation clearance: below about 0.9 m clear between islands the gain is cancelled by congestion, which is itself a cost term. And the yield depends on the base: on a 12 x 18 m room, area 216 m^2 and perimeter 60 m, the same six islands add 66 per cent rather than 99 per cent. **Edge manufacture is most valuable exactly where edge is scarcest, which is the deep plan — and that is where it is most often omitted, because islands read as lost area on the same spreadsheet that produced the deep plan.**

12.4.2 4.2 The threshold as a matching section

On a transmission line, a wave in a medium of characteristic impedance `Z_1` meeting a medium of impedance `Z_2` is partly reflected:

```
Gamma = (Z_2 - Z_1) / (Z_2 + Z_1)     power reflected = |Gamma|^2, transmitted = 1 - |Gamma|^2
```

Ratio `Z_2/Z_1`	2	4	6	10	100	1000
`Gamma`	0.333	0.600	0.714	0.818	0.980	0.998
Power transmitted	**88.9%**	**64.0%**	**49.0%**	**33.1%**	**3.9%**	**0.4%**

Two structural facts transfer and nothing else does.

Fact 1 — reflection depends on the RATIO, not the difference. A step from 1 to 2 and one from 500 to 1000 reflect identically; absolute character is irrelevant and only the jump matters.

Fact 2 — intermediate sections reduce the worst junction. Take the 1-to-100 case and insert one section at the geometric mean `Z_t = sqrt(Z_1 Z_2) = 10`. The junctions 1-to-10 and 10-to-100 now have *identical* coefficients of 0.818 — **the geometric mean is the value that equalises them.** Subdividing further with a constant ratio per step `r = (Z_2/Z_1)^(1/n)`:

Steps `n`	1	2	3	4	5	6
Ratio per step	100.00	10.00	4.64	3.16	2.51	2.15
`Gamma` per junction	0.980	0.818	0.646	0.520	0.431	0.366
Reflected per junction	96.1%	66.9%	41.7%	27.0%	18.5%	13.4%

Worst-junction reflection falls from 96.1 per cent to 13.4 per cent by dividing the same total change into six graded steps, and in the limit a tapered line reflects almost nothing. A threshold is a matching section. That is the whole of the idea and the whole of what the analogy is for.

What does NOT transfer, stated flatly. The transmission-line results depend on wave phase: a quarter-wave transformer achieves *zero* reflection only where the section is a quarter wavelength long, and tapered designs are broadband because they trade that null for tolerable performance across a band. **Nothing in a corridor has a phase. Do not compute a corridor length from a wavelength; there is no wavelength.** Two sentences transfer, and anyone extending the analogy past them has left engineering for decoration. This is failure mode **FT1** of Appendix B.

12.4.3 4.3 The zone character vector and the one-step rule

Using the analogy requires an operational `Z`: a vector of ordinal attributes, each rated 1 to 5, each independently observable.

Attribute	1	3	5
Sound level	library quiet	conversational	machinery, crowd
Pace	seated, hours	task, minutes	transit, seconds
Formality	domestic	working	ceremonial, on-record
Illuminance	low, warm, local	mixed	high, uniform, cool
Ownership	one named person	a known group	anyone
Attention mode	deep, single-thread	interruptible	scanning
Body state	shoes off, seated	standing, coat on	moving, loaded
Observability	unseen	seen by peers	seen by strangers

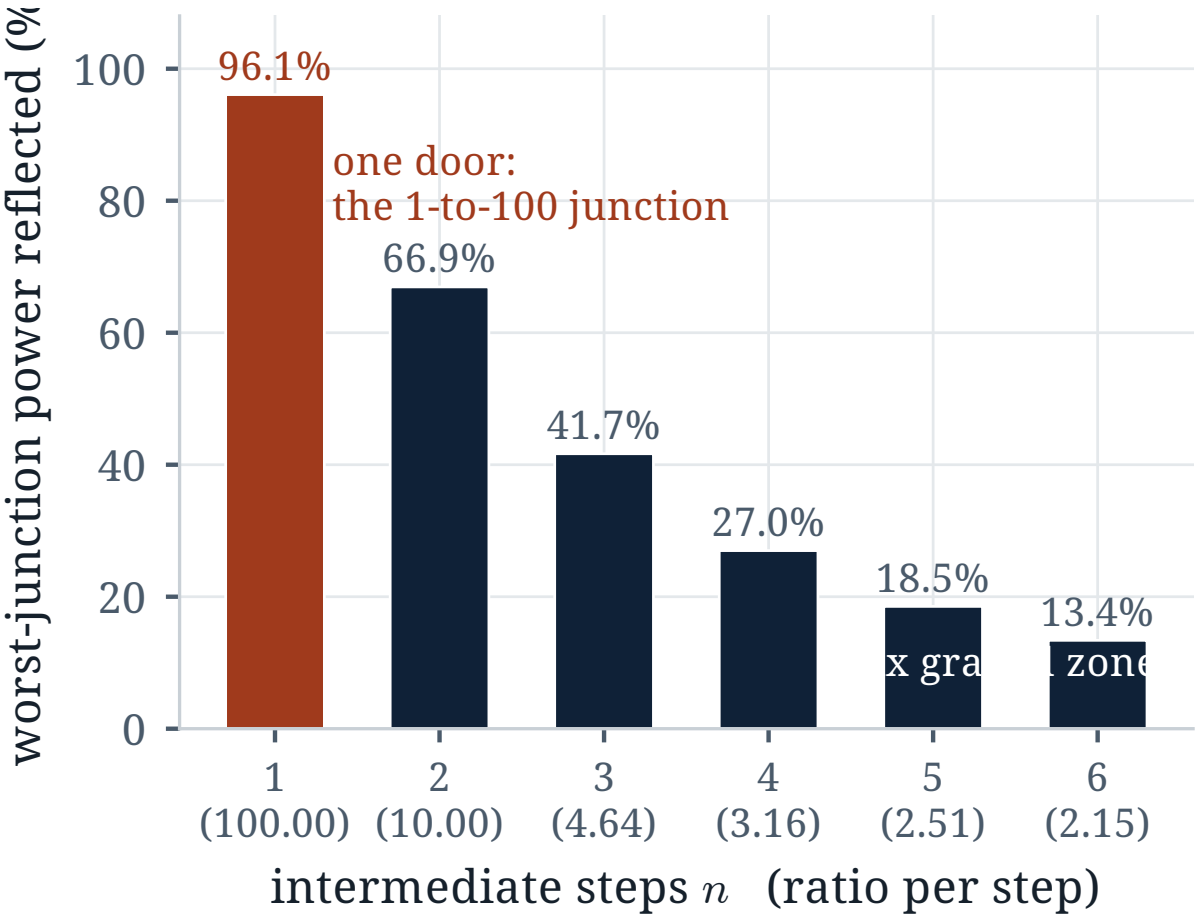

Figure 12.1: **Six graded zones transmit what one door rejects.** Worst-junction reflected power across a 1-to-100 character change, divided into `n` equal-ratio steps: 96.1 per cent at a single junction against 13.4 per cent at six. Exact arithmetic on the transmission-line reflection coefficient `Gamma = (Z_2−Z_1)/(Z_2+Z_1)`; the transfer of that coefficient to a built threshold is a badged analogy and not a derivation. Generated by `figs/src/CCP-012_fig01.py`.

Rate both zones. The **mismatch index** is `M = max_i |Z_A[i] − Z_B[i]|`, with `M_bar` the mean of the same differences. **`M` is what matters:** a transition can be graded on seven attributes and violent on the eighth, and the eighth is what people feel. Treat `M >= 3` as requiring a device whatever `M_bar` says.

Rule T-A — one step per threshold. No threshold may change any attribute by more than one point on the five-point scale; at `M = 4`, at least three intermediate zones are required. **This is the direct translation of the taper table and it is the single most useful rule in this section.**

The scoring is an ordinal steepness judgement, and the corpus already runs one of those: the comfort-weighted amplitude scores each step 0 to 3 for steepness, sums to a resistance `R`, and weights the branch as `1/2^R`, so that a three-point difference in steepness is a factor of eight in expectation [Curzi, 2026]. **The mismatch index is the same kind of instrument and inherits the same limitation: it is ordinal, and the mean `M_bar` is a statistic its scale does not license.** That is why the rule is written on the maximum and not on the mean.

Worked instance, street to reading room:

Attribute	Sound	Pace	Formality	Illum.	Ownership	Attention	Body	Observ.
Street	5	5	3	5	5	5	5	5
Reading room	1	1	2	2	2	1	1	2
Gap	4	4	1	3	3	4	4	3

`M = 4`: **a single door here is the 1-to-100 junction, and the bouncing is observable** — hesitation at the door, entries followed by exits within thirty seconds, standing in the entry looking for permission, street volume for two sentences and then an over-corrected silence, or simply not going in. Every one is a reflection chargeable to cost. The graded version inserts four intermediate zones, one step each:

```
street          forecourt       porch         lobby         anteroom      reading room
sound   5  -->      4      -->     3      -->     2      -->     2      -->       1
pace    5  -->      4      -->     3      -->     2      -->     2      -->       1
attn    5  -->      4      -->     3      -->     3      -->     2      -->       1
body    5  -->      4      -->     3      -->     2      -->     2      -->       1
own     5  -->      5      -->     4      -->     3      -->     2      -->       2
```

Each junction now has `M = 1` and worst reflection collapses without a single change to the reading room itself. **Notice what the intermediate zones physically are:** a forecourt changes surface and width; a porch, overhead and light; a lobby, acoustic and ownership; an anteroom, pace and observability. **Each changes one variable, and that is what makes it an intermediate zone rather than a small room.**

12.4.4 4.4 The entrance sequence: a duty list and the depth it forces

A threshold is a machine with a duty list, and its depth is set by the slowest item on it. **(1) Decelerate**, from transit speed to standing. **(2) Reorient** — find the next direction from signage or geometry. **(3) Shed:** coat, umbrella, shoes, bag, load, phone call. **(4) Be seen** by whoever is inside, before being among them. **(5) See** — assess the room before committing to it, the reciprocal of (4) and the item most often omitted. **(6) Choose:** go in, wait or leave, none of the three conspicuous. **(7) Be greeted**, or deliberately not, but by architecture rather than by accident. **(8) Store** the shed items where they will still be at the end.

Every classical entrance device solves some subset, and they are worth naming because they are convergent evolution and therefore evidence.

Device	Duty items served
Japanese *genkan* — floor-level change, shoes removed and stored	1, 3, 8; marker of 4 and 6
Japanese *engawa* — covered verandah, neither in nor out	1, 5, 6; partial commitment
Roman *vestibulum* to *fauces* to *atrium*	a literal three-section taper
Christian narthex — antechamber before the nave	4, 5, 6; gradient of belonging
Bent entrance, never on axis	1, 5, 8 at once
Porch with bench [Alexander et al., 1977]	1, 6, 7
Industrial airlock — two doors never open together	1 to 8, made hardware

None of these is decoration. Each is a matching section.

Deceleration sets the minimum depth. Comfortable walking speed on the flat is about 1.2–1.4 m/s for adults and slower for children, the elderly and the loaded; a comfortable voluntary deceleration — one that does not read as a stumble or a halt — is on the order of 0.5 m/s^2. Then `d = v^2/(2a)` and `t = v/a`:

`v` (m/s)	1.2	1.4	1.4	1.4	1.6
`a` (m/s^2)	0.5	0.3	0.5	1.0	0.5
Stopping depth `d` (m)	1.44	3.27	**1.96**	0.98	2.56
Time `t` (s)	2.40	4.67	2.80	1.40	3.20

A threshold that expects people to stop must be at least 2.0 m deep in the direction of travel. Below that the stop is achieved by the walker's own braking effort rather than by the space, and it registers as being brought up short. **This is why a 1.2 m vestibule feels wrong even when correctly sized for the door swing: the door was designed and the deceleration was not.**

Dwell time sets the useful depth. Deceleration is the floor; the threshold's real job is to hold a person long enough for the state change, and the currency of that is time, not metres:

Depth `d` (m)	1.5	2.0	2.5	4.0	6.0
at 1.4 m/s	1.07 s	1.43 s	1.79 s	2.86 s	4.29 s
at 0.7 m/s	2.14 s	2.86 s	3.57 s	5.71 s	8.57 s
at 0.4 m/s	3.75 s	5.00 s	6.25 s	10.00 s	15.00 s

At full walking pace a 2 m threshold buys 1.4 seconds — one breath, enough for item 1 and nothing else. To buy the four or five seconds items 2, 4 and 5 need there are two options: **six metres of depth, or slow the walker down**, at which point 2.5 m buys 6.25 s. **That is the case for the bent entrance and the reason it recurs across unrelated traditions.** A 90-degree turn cannot be taken at 1.4 m/s; it forces a drop to roughly 0.7 m/s, converting 1.5 m of path into about 2.1 s instead of 1.1 s, **while delivering item 5 — the interior revealed progressively, as one turns — and item 4, being seen approaching before being present. The turn is worth more than the metres it costs.**

The other dimensions. A threshold a person can pause in must let another pass, or the pause is an obstruction and the obstruction is a cost:

```
stopped person, footprint depth  0.60 m      clear width, one person passing  0.75 m
body depth (chest to back)       0.45 m      clear width, two abreast        1.20 m
```

```
shoulder breadth          0.45 – 0.50 m      door leaf 0.9 m -> swing radius  0.90 m

holds one paused person AND permits single-file passage:  0.60 + 0.75 = 1.35 m clear width
inward-swinging 0.9 m leaf, holding one paused person:    0.90 + 0.60 = 1.50 m landing depth
holds a conversing PAIR at personal distance and
  still permits passage:            0.45 + 1.20 + 0.45 = 2.10 m, + 0.75 m to pass = 2.85 m
```

The last figure matters most, because the conversation at the entrance is a large fraction of the optional activity in a whole building. **A 2.85 m entrance lobby is not generous. It is the minimum width at which two people can talk without becoming an obstacle — and if they become an obstacle they stop talking, and the optional activity that was the conversion proxy disappears.**

12.4.5 4.5 The intimacy gradient

The pattern tradition supplies the sequence [Alexander et al., 1977] and the proxemic literature the metric: for adults in the population studied, intimate distance runs 0.00–0.45 m, personal 0.45–1.20 m, social 1.20–3.60 m and public beyond 3.60 m [Hall, 1966]. **These are not universal constants and were not claimed to be; what is reliable is the ORDERING and the existence of the bands, not the exact boundaries.** Verify them in the population at hand, and expect the personal/social boundary in particular to move.

Zone	Who may enter	Without asking?	Pace	Typical device
Public	anyone	yes	transit	street, forecourt
Semi-public	anyone with business	yes	slowed	lobby, cafe, front desk
Common	members	yes	task	corridor, kitchen, shared table
Semi-private	members with reason	knock or hover	task	team room, open alcove
Private	invited	ask	deep	office, study, closed room
Intimate	chosen	ask	any	one’s own desk, one’s own chair

Rule T-B — no zone may be skipped. A door opening directly from public to private is the 1-to-100 junction and both sides pay. **The receptionist whose desk faces the street door absorbs a four-step mismatch all day, and the cost appears in the turnover rate, which is a decay term.**

Rule T-C — the gradient must be legible without signage. If a visitor needs a sign to know they have left the common zone, the gradient is not doing its work and the sign is. **Signs are administered — made, mounted, updated, enforced — and geometry is not.** Change the floor surface, the ceiling height, the light level, the width or the direction; each is read instantly by everyone, including people who cannot read the sign. The general form of the point is that infrastructure recedes from notice until it breaks [Star and Ruhleder, 1996, Star and Griesemer, 1989], and a legible gradient is infrastructure while a sign is administration.

The semilattice argument sharpens it [Alexander, 1965]. A natural settlement has overlapping units — a shop belongs to a street *and* a neighbourhood *and* a trade — while a planned one is drawn as a tree, every unit with one parent and overlaps forbidden. **A strict hierarchy drives non-parallelism toward zero, because any two units at the same level receive their context through the same channel.** Thresholds are where the semilattice is realised or destroyed: a room with one door into one corridor is a tree node; a room with a door to the corridor, a glazed panel to the courtyard and a shared alcove to its neighbour is a semilattice node.

The number of ways a room participates is the number of thresholds it has, which is how a threshold decision becomes a category-count decision.

Where the pattern tradition and this framework part company is stated plainly. **The pattern literature gives a configuration and a rationale in the language of life and wholeness; every pattern here is stated with the term of the storage law it moves and the arithmetic that prices it** — a narrower and more brittle claim, deliberately, because a claim that can be checked is worth more than one that can only be agreed with.

Pattern family	Parameter	Mechanism
Entrance transition, airlock, bent entry	`C` down	Reduces per-crossing cost `m`
Door that closes, screened alcove	`C` down	Reduces crossing count `k`
Building edge, window place, pocket	`eta` up	Occupied time where encounters become durable
Intimacy gradient	`C` down, `u` kept	Prevents the wrong-mode encounter
Semilattice adjacency	`N` up	More genuine categories of participation
Desire-line paving	`eta` up	Converts an observation into durable structure

12.4.6 4.6 Desire lines as a measured gradient, and context switching as a cost term

A desire line — the worn diagonal across the lawn, the polished floor patch, the chair that has migrated three metres — is a *measurement* with properties no survey has. It is **unprompted**, so nobody performed an answer, which is the entire problem with asking people about their building. It is **weighted by frequency**, since the depth of the trace integrates over crossings, making it literally an accumulator in the same family as stored order. It **records cost, not preference**: people route around cost, and a desire line marks where the designed path was dearer than the undesigned one. And it is free and continuously updated. **Protocol T1 in Appendix A states how to run the survey; Protocol T2 states what to do with it, and carries the caution that paving destroys the instrument that produced the trace** — a measure adopted as a target ceasing to measure what it names, arriving through the floor [Goodhart, 1975, Campbell, 1979].

The chapter's most consequential arithmetic is the switching cost, and two of its figures must be measured rather than asserted. Per period,

```
C_switch = k * m
```

with `k` the number of involuntary context switches per person per period and `m` the **resumption lag**: elapsed time from the end of the interruption until the person has regained the working state they were in before it. Both are observable — `k` a count, `m` a timed measurement. On an eight-hour day of 480 minutes:

`k` per day	`m` = 2 min	`m` = 5 min	`m` = 10 min
5	10 min (2.1%)	25 min (5.2%)	50 min (10.4%)
10	20 min (4.2%)	50 min (10.4%)	100 min (20.8%)
20	40 min (8.3%)	100 min (20.8%)	**200 min (41.7%)**
40	80 min (16.7%)	200 min (41.7%)	400 min (83.3%)

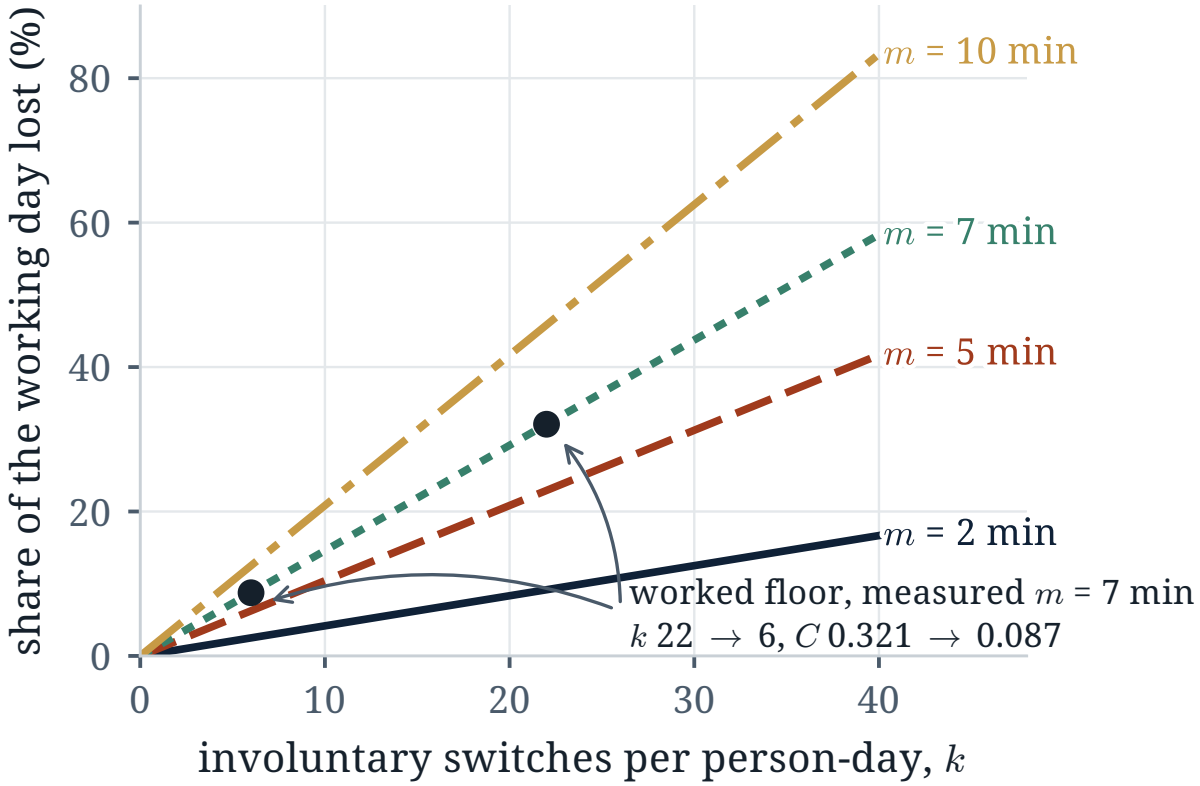

Figure 12.2: **Two levers, one product: halving either the interruption count or the resumption lag halves the switching cost.** `C_switch = k m` as a share of a 480-minute day. The worked research floor measured `m` = 7 min and moved `k` from 22 to 6, taking `C_switch` from 0.321 to 0.087 of the day. Exact arithmetic given `k` and `m`; both were measured by the declared protocols in that case and neither is asserted as a general value. Generated by `figs/src/CCP-012_fig02.py`.

Twenty interruptions a day at a ten-minute resumption lag consumes 41.7 per cent of the working day before any work has been done wrong. The product is bilinear, so halving either factor halves the cost, **and the two are different engineering problems.** `k` is a threshold problem — filters, doors, distance, visibility control. `m` is a task-state problem — externalised working state, checkpoints, a written next action, an artefact that holds the context so the person need not.

MEASUREMENT REQUIRED, NOT ASSERTED. Field studies of interrupted knowledge work report substantial resumption lags, and the finding that recovery costs materially more than the interruption itself is well established in that literature; **magnitudes vary enormously with task and interruption type, with whether the interruption is self-initiated, and with how "resumed" is operationalised. This paper supplies no universal number for `m`, because any figure quoted as universal has been detached from its measurement definition.** Protocols T3 and T4 of Appendix A give the measurements. **This paper carries no bibliography entry for that field literature and names the gap rather than attaching a citation that would not support the sentence** (Section 11).

Distance as a filter. The threshold's role in `k` is to be a filter with tunable admittance:

Device	Effect on `k`	Cost	Reversible?
Physical distance	strong	high	no
A door that closes	strong	low	instantly
Screen at 1.35–1.45 m	moderate	low	yes

Device	Effect on `k`	Cost	Reversible?
Screen at 1.20 m	weak	low	yes
Orientation to traffic	moderate	zero	yes
Signal convention	moderate	zero	needs upkeep
Timed availability windows	strong	zero	yes

Two deserve comment. **Distance is a blunt filter.** Studies of research and development organisations established the regularity that the probability of regular technical communication falls steeply with physical separation and is near its floor within a few tens of metres; **the shape is the point, not the coefficients.** The consequence cuts both ways: **the same distance that suppresses unwanted interruptions suppresses the encounters that were the conversion.** It reduces `k` and `eta` together, which places it first for strength and last for advisability. **This paper carries no bibliography entry for that finding either** and names it as an uncited borrowing.

Screen height is the cheapest single intervention here. Seated eye height is roughly 1.15–1.25 m and standing 1.55–1.70 m. A screen at 1.20 m sits at seated eye level: it blocks a seated forward view and is trivially seen over by anyone standing, delivering seated privacy with standing awareness. A screen at 1.35–1.45 m blocks the seated view completely and makes a standing person deliberately look over, **converting a glance into an act. The fifteen centimetres between those heights is the difference between a room where one is interruptible by accident and a room where interrupting someone is a decision.**

12.4.7 4.7 What a threshold costs, and whether it pays

A five-zone entrance sequence for a medium building — forecourt 3.0 x 4.0 m, porch 2.0 x 3.0 m, vestibule 2.4 x 2.4 m, lobby 4.0 x 5.0 m, anteroom 2.4 x 3.0 m — totals **51.0 m^2**: 8.5 per cent of a 600 m^2 floor, 5.7 per cent of 900 m^2, 4.2 per cent of 1200 m^2. **Four to nine per cent of net area, and the first thing value-engineered out of a project, because on a plan it reads as circulation and circulation reads as waste.**

Against that, the recovered capacity. For 30 people, with threshold work moving `k` from 22 to 6 per day at a measured `m` of 7 minutes:

```
before 22*7 = 154 min/day ; after 6*7 = 42 min/day ; saved 112 min/day = 1.87 h/person/day
30 people * 220 working days * 1.87 h = 12,320 person-hours/yr = about 7.7 FTE-years per year
```

Fifty-one square metres of transition against twelve thousand person-hours a year, and even at a third of the assumed lag it is not close. **Three qualifications are owed and are given.** First, `k` moving from 22 to 6 is not achieved by architecture alone: the protocol half must be maintained, which is a decay problem rather than a build. Second, **not all recovered time converts to output, because the conversion is `eta` and `eta` is not 1.** Third, **area is capital and time is operating**, so state both rather than netting them silently.

The comparison is also a decision under uncertainty and should be priced as one. The corpus's instrument for that is an expected headroom change: an uncertain call priced as `E[dh] = 0.0318401 p − 0.0051096` from a right-call gain of `+0.026731` against a wrong-call loss of `−0.005110`, giving a break-even probability of 16.05 per cent [Curzi, 2026]. **The same form applies here: state the headroom gain if the mechanism operates, the headroom loss if the floor area is simply lost, and the probability at which the build is worth commissioning.** No such break-even is computed in this paper, and Section 11 records that as an unmet check rather than implying that the area calculation above settles the question. Relatedly, a threshold is a barrier in the framework's own sense, and the barrier analysis supplies the condition under which no amount of accumulated surplus funds a departure: a critical cost `C_crit = eta M − lambda E_b` of 0.082 stored-order units per week, and a critical efficiency `eta_crit = C/M`

= `0.055238` against a measured `eta` of 0.05 [Curzi, 2026p]. **A threshold too deep is a barrier nobody crosses, and that analysis is where its upper bound comes from.**

12.4.8 4.8 Where a threshold must not be

Prohibition 1 — a threshold decelerates; it does not deny. Every device here must be crossable by anyone who chooses. The bent entrance slows a person; it does not stop them. The closed door has a handle on both sides. The screen can be looked over. **A threshold that removes a person's ability to enter is not a threshold, it is a gate, and gates are outside this framework's scope.** The distinction is operational: **a threshold raises the cost of crossing and leaves the choice with the crosser; a gate moves the choice to a third party.**

Prohibition 2 — no threshold on an egress route. Deceleration devices, bends, level changes and closable doors are obstructions under evacuation conditions; each must be checked against the applicable life-safety code, **and where a conflict exists the code wins without discussion.** This paper supplies no egress widths, travel distances or door hardware: those are jurisdictional and they change.

A third caution is softer and sharper. Filters reduce `k` *selectively*, and the selection is not neutral. **A door that closes filters hardest against those with the least standing to knock — the new, the junior, the visiting — so it silences exactly the members whose views were least correlated with the rest, raising conversion by cutting non-parallelism.** That is the parallel-wall failure arriving through the door frame. The counter is architectural rather than exhortative: **pair every closable private zone with an open, low-commitment, edge-type position that anyone may occupy without asking**, and check by occupancy count that the paired positions serve more than one cluster.

12.5 5 Substrate: light, thermal, air, material

Nothing about light, air or material is derivable from the storage law. The law supplies the accounting frame: once a substrate variable has been shown to move conversion, decay, cost or the category count, the law prices the move. **This section's work is establishing the *that*, and being explicit about the evidence.** The modelling postulate it rests on is that the physical substrate bounds the duration and quality of *voluntary* occupancy, and that voluntary occupancy carries interaction; substrate therefore enters through `eta` (occupied time is the substrate of durable relation), through `C` (discomfort is dissipation, and so is every adjustment negotiation) and through `delta` (a room that degrades needs replacing). **That is badged as a modelling postulate and is not a theorem.**

12.5.1 5.1 The strongest single piece of evidence, stated precisely

The cleanest demonstration that physical setting moves a clinical outcome is a 1984 study of postoperative recovery published in *Science*, comparing patients whose window faced a stand of deciduous trees against patients whose window faced a brick wall. **The design: a retrospective study of records from one suburban hospital over 1972–1981; patients recovering from one procedure were matched in pairs on age, sex, smoking status, weight, previous hospitalisation, year of surgery and attending surgeon; twenty-three matched pairs.** The rooms were essentially identical except for the view. Tree-view patients had shorter postoperative stays, received fewer doses of moderate and strong analgesics, and drew fewer negative evaluative comments in the nurses' notes. The stay difference was a fraction of a day against a mean of roughly eight.

Why it is worth more than the surveys. It measured *outcomes* — length of stay, analgesic dose, clinical notes — not preferences. Nobody was asked whether they liked the view, the

patients did not know they were in a study, and the outcome measures came out of the hospital's ordinary operation. **That removes the demand characteristics that make almost all built-environment preference research uninterpretable.**

Why to be careful, said as loudly as the finding. Twenty-three pairs is a small sample. One hospital, one procedure, one climate, one decade. It was retrospective, and room assignment was as-available rather than randomised — close to random in practice, not guaranteed. The effects are modest, and the nurses' notes were scored from records not written for the purpose. **The reproducibility literature is unambiguous about what a single small retrospective study is worth** [Open Science Collaboration, 2015, Ioannidis, 2005]. **This paper carries no bibliography entry for that study**, because none was assembled for it; it is described here rather than cited, and anyone quoting its numbers must read the paper and take the figures from it. Section 11 lists the gap.

What the study does license is narrow and useful: a variable the design professions classify as aesthetic turned up in a clinical outcome measure, so the prior that substrate is decoration is wrong. **It does not license a coefficient.**

12.5.2 5.2 Light, in two planes

Illuminance is measured in a plane, and which plane is chosen decides what is being measured. **Task illuminance is horizontal, at the desk; circadian and alerting effects are driven by light arriving at the eye, which is vertical.** A room can deliver 500 lux on the desk and 130 lux at the eye, and a lighting sign-off taken in one plane says nothing about the other. **Requirement B3 below therefore requires recording in both planes, and failure mode FB3 is the horizontal-only sign-off.**

Daylight has the same edge structure as Section 4.1. Useful daylit depth from a side window runs to roughly two to two and a half times the window head height, so a 2.4 m head reaches about 4.8–6.0 m. **A 22 m deep plate cannot reach edge density and cannot reach daylight, and it is the same geometric fact twice:** perimeter is linear and area is quadratic, so both amenities dilute together as the plate deepens. **No lighting scheme fixes a plate that is too deep, and the honest project-record entry says so rather than relaxing the requirement.**

Glare belongs to the cost term rather than to the light budget, because its signature is behaviour: **a permanently closed blind is a glare problem answered by the occupant with the only tool they were given, and it converts a daylight asset into an electrically lit room.** Count permanently closed blinds; the count is a direct, free measurement of a design failure.

The circadian claim is stated with its status. The proposition that the timing and spectrum of light at the eye affects sleep and next-day capacity — and therefore, through capacity, the conversion of interaction into durable structure — is a chain with a well-supported first link and a modelled second. **This paper takes the melanopic-equivalent target used in current practice as an engineering-practice value, states that it changes between editions of the standards that carry it, and does not derive it.**

12.5.3 5.3 Thermal comfort: six variables, and why adjustability beats the optimum

Thermal comfort has six variables — air temperature, mean radiant temperature, air speed, humidity, metabolic rate and clothing insulation — and almost every building controls one. **The other five are where the complaints come from.** Operative temperature, the single number that predicts comfort at low air speed, is approximately the mean of air and mean radiant temperature, **so a room can hold its air at 21.0 C and deliver an operative 18.9 C at a desk beside single glazing.** Mean radiant temperature is the invisible variable: it is not what the thermostat reads, it is not what the occupant can name, and it is what the occupant is feeling.

The arithmetic that settles the design question is in the standard comfort model's own output. The predicted percentage dissatisfied is derived from the predicted mean vote by

```
PPD = 100 − 95 ∗ exp( −(0.03353 PMV^4 + 0.2179 PMV^2) )
```

PMV	0.0	0.2	0.3	0.5	0.7	1.0	1.5	2.0
PPD	**5.0%**	5.8%	6.9%	10.2%	15.3%	26.1%	50.9%	76.8%

Read the first column again. At the theoretical optimum, every variable ideal, the model predicts 5 per cent dissatisfied. The floor is not zero. The usual criterion — mean vote within `+/−0.5`, giving 10 per cent dissatisfied — **accepts one person in ten uncomfortable by design, in a building working exactly as specified.** That floor is not a defect of the model: it is the model correctly reporting that thermal preference is dispersed and that one environmental state cannot sit at every individual optimum. **A fixed setpoint, however well optimised, answers the question "where is the centre of the distribution?", and almost nobody lives at the centre of a distribution.**

Model individual preferred operative temperatures as normal with standard deviation `sigma`, and suppose each person accepts `+/−1 K` around their own preference. **`sigma` is an assumed parameter, badged as such; it must be measured in the population at hand (Protocol B1).** The 1.5–2.5 K range is the plausible design region. Fraction satisfied by one fixed setpoint at the population mean:

`sigma` (K)	`+/−1.0 K` band	`+/−1.5 K`	`+/−2.0 K`
1.0	68.3%	86.6%	95.4%
1.5	49.5%	68.3%	81.8%
2.0	38.3%	54.7%	68.3%
2.5	31.1%	45.1%	57.6%

Give each occupant personal authority of `+/−A` K over their own operative temperature, widening the effective acceptance band to `+/−(1 + A)`:

Personal authority `A`	`sigma` = 1.5 K	`sigma` = 2.0 K
`+/−0 K` (fixed setpoint)	49.5%	38.3%
`+/−1 K`	81.8%	68.3%
`+/−2 K`	95.4%	86.6%
`+/−3 K`	99.2%	95.4%

At `sigma = 2.0 K`, two degrees of personal authority takes satisfaction from 38.3 per cent to 86.6 per cent. No amount of re-optimising the single setpoint can do that, because the problem is the dispersion and not the location. And it is robust to the assumed dispersion in the way that matters: **the ratio of adjustable to fixed performance improves as `sigma` grows.** A population more varied in age, body composition, medication, metabolic rate, gender or dress makes the case stronger, not weaker.

The four adjustment channels, ranked by cost.

Channel	Variable moved	Cost	Speed	Personal or shared?
Clothing	insulation	zero	seconds	**personal**
Local air movement (fan)	air speed	trivial	seconds	personal

Channel	Variable moved	Cost	Speed	Personal or shared?
Local radiant (small panel, warm surface)	radiant temperature	low	minutes	personal
Zone setpoint	air temperature	high	tens of minutes	**shared — and therefore contested**

Clothing is the most powerful and cheapest lever and the one organisations routinely disable. As a rule of thumb from the comfort model, 0.1 units of clothing insulation shifts the neutral operative temperature by roughly 0.6 K, so moving between a summer and a winter outfit is worth about 3 K. **Badge: verify that against the standard's own tables for the metabolic rate in question before designing to it; this paper carries no bibliography entry for the comfort model, its tables or the adaptive model discussed below** (Section 11). **A dress code is thermal policy.** Fixing clothing removes the free, personal, instantaneous channel and transfers the whole load onto a shared, slow, expensive one, **so the building burns energy to compensate for a decision taken in a handbook.**

Contested adjustment is a cost line and it is unusually easy to measure. Zone setpoint control is shared, so every adjustment is a negotiation. Log thermostat interactions — who, when, direction, magnitude, and whether a conversation followed. **A shared control changed more than about twice a day is not a control, it is a dispute.** Convert to the cost observable as contested adjustments per period times mean time consumed per adjustment, including the discussion and the counter-adjustment. **Rule B-A — never install a shared control where a personal one will do.** A personal control changes one person's environment and generates no coordination cost; a shared control generates one on every use, forever, **and it falls hardest on whoever is least willing to argue.**

The connection to the category count, with its badge on. A room that can only be set one way selects for the bodies it suits: people whose thermal preference lies far from the setpoint attend less, disengage sooner, relocate or leave. Since thermal preference is not independent of age, body composition, gender, health status or medication, **that selection is not random with respect to the categories the surplus law counts, so a fixed setpoint reduces the effective count by attrition and lowers `ln N` itself if a category is lost entirely. This is the most speculative claim in the paper and it is stated because it is testable.** Protocol B1 in Appendix A is the audit that would test it, and it names the result that would require the claim to be withdrawn. **The well-supported half of the story needs no postulate: field studies in naturally ventilated buildings find that occupants with real control accept a substantially wider range of conditions than the laboratory model predicts, and perceived control widens the acceptance band independently of what it is used to do.** That result is replicated and on its own justifies Rule B-A; **it is described here without a citation key, because none exists in this corpus's bibliography.**

The honest costs of adjustability. *Energy:* wider zone tolerance plus personal devices is usually a net saving, but personal resistance heaters are the ruinous exception — specify personal *radiant* and *air-movement* devices. *Control complexity:* every controllable device is a maintenance item, and decay applies to control systems more brutally than to fabric. *Spillover:* the channel must be personal in its *effect*, not merely in its interface — **a desk fan blowing across a neighbour's neck has converted a personal control into a shared one.**

12.5.4 5.4 Air quality, and a literature this paper declines to use

Steady-state indoor carbon dioxide under constant occupancy is `C_in = C_out + G/Q`, with `C_out` the outdoor concentration — about 420 ppm and rising — `G` the generation rate and `Q` the outdoor air supply. **Inverting it turns a cheap logger into a ventilation meter:** a room with

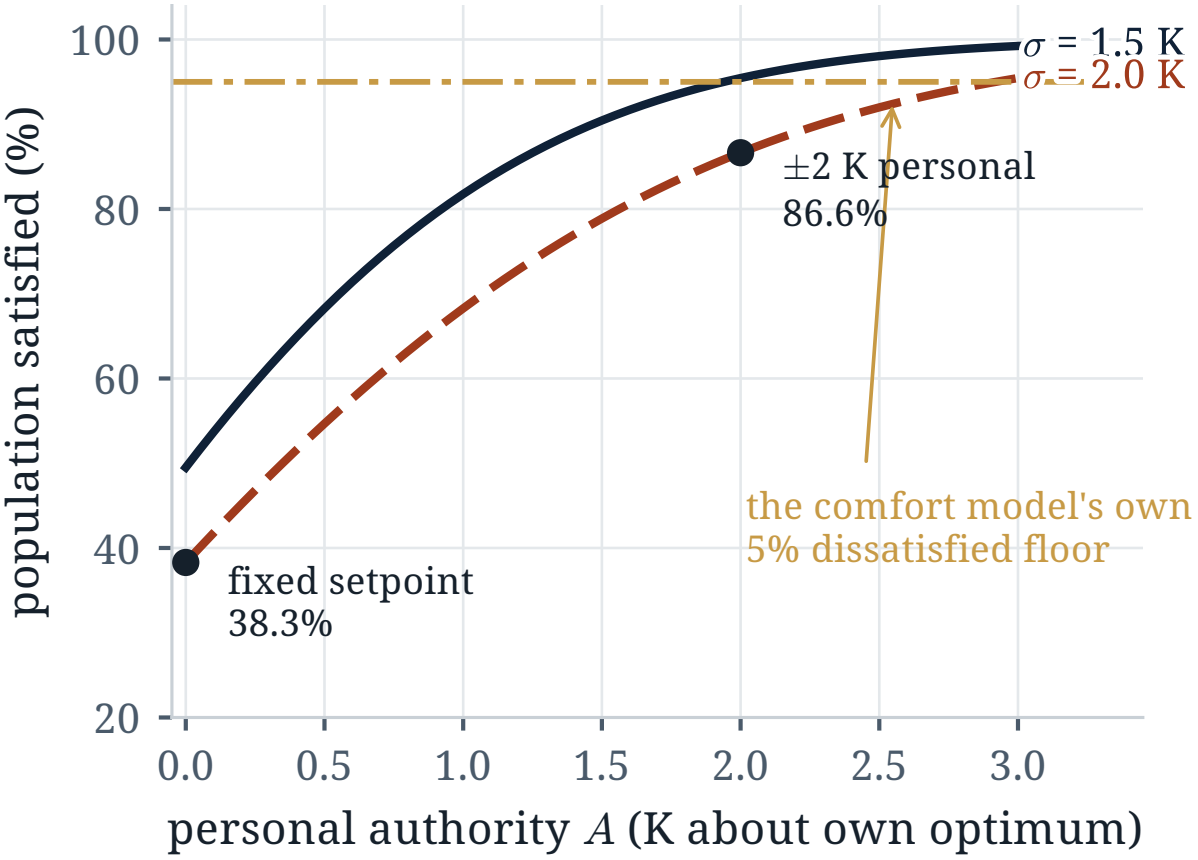

Figure 12.3: **The dispersion, not the location, is the problem.** Fraction of a population satisfied when each person accepts +/−1 K around their own preferred operative temperature and is given +/−A K of personal authority. At a 2.0 K dispersion the fixed setpoint satisfies 38.3 per cent and two degrees of personal authority satisfies 86.6 per cent. Modelled: preferences are assumed normal and the dispersion is an assumed parameter badged in the text; the comfort model's own 5 per cent dissatisfied floor is drawn as the ceiling this cannot cross. Generated by `figs/src/CCP-012_fig03.py`.

four occupants at a 1,290 ppm afternoon plateau is being supplied at `Q = 0.005 x 4 / (870 x 10^-6) = 23.0 L/s`, which is 5.7 L/s per person. **That inversion is the reason to own a logger, and it is a measurement rather than a claim.**

And here is the tension, stated in the direction unhelpful to this paper. A room ventilated exactly to the common standard settles at roughly 1,300 ppm — **above the concentrations at which some studies report decrements in decision-making performance.** A framework that wanted to sell ventilation would stop there. **The honest state of that literature is that it is contested:** effect sizes vary by an order of magnitude between studies, several of the strongest results come from small samples in chamber conditions with outcome measures of uncertain relation to real cognitive work, the exposure is confounded with other bioeffluents that track occupancy in exactly the same way, and replication attempts have been mixed. **The conclusion, deliberately unhelpful to the case this paper would prefer to make: the proposition that carbon dioxide at ordinary indoor concentrations impairs cognition is not established well enough to carry a business case.**

What is well supported is the ventilation case itself — odour, perceived air quality, symptom reporting, and airborne infection risk — **and that is what may be claimed. Rule B-B: specify ventilation, monitor carbon dioxide as a tracer, and claim only ventilation.**

This refusal is the same operation the corpus performs elsewhere when a ratio kills a claim. The decoherence computation is the cleanest instance: a characteristic time of `1.98 x 10^-17` s for a warm wet 310 K system against a 1 ms neural event is a shortfall of `5.04 x 10^13`, and a hypothetical `10^6` protection factor still leaves `5.04 x 10^7` [Curzi, 2026aa]. **A framework that computes the ratio and then declines the claim is doing the same work here at a much smaller scale, and the discipline is what makes the claims it does keep worth reading.** It is also the operation that demotes a diversity measure to a cost line when the interfaces it cannot see are counted [Curzi, 2026]: **the measured quantity is retained and the story attached to it is withdrawn.**

12.5.5 5.5 Materials do four jobs

Acoustic. With absorption coefficients at 500 Hz taken as standard-practice values — painted concrete 0.02–0.05, glazed partition 0.03–0.05, gypsum board on studs 0.05–0.10, carpet tile on concrete 0.15–0.30, heavy drapes 0.50–0.60, mineral-fibre ceiling tile 0.60–0.80, 50 mm mineral wool 0.80–0.95, and an occupant on an upholstered seat about 0.45 m^2 of equivalent absorption each — and Sabine's `RT60 = 0.161 V/A` [Sabine, 1922, Curzi, 2026e], an all-hard 42 m^2 workroom (6.0 x 7.0 x 2.9 m, `V` = 121.8 m^3, `S` = 159.4 m^2) computes as:

```
HARD CASE   exposed concrete soffit 42 x 0.02  =  0.84
            plastered walls        67.4 x 0.03 =  2.02
            glazing                 8.0 x 0.04 =  0.32
            vinyl on concrete      42.0 x 0.03 =  1.26
            A = 4.44 m2 sabins   ->  RT60 = 0.161 x 121.8 / 4.44 = 4.42 s
```

Four and a half seconds. That is a church, not a workroom, and it is what an all-hard room of this size genuinely does: speech is unintelligible at conversational level and the loudest voice wins by physics [Curzi, 2026e]. **A note on the arithmetic: the source manuscript this paper converts records 4.41 s for this case, and the quotient is 19.6098/4.44 = 4.4166, which rounds to 4.42. The value is corrected here rather than repeated, and nothing in the argument turns on the hundredth of a second.**

Thermal mass. Volumetric heat capacity and diurnal penetration depth `d = sqrt(alpha P / pi)`, with `alpha = k/(rho c)` and `P` = 86,400 s:

Material	`rho`	`c`	`k`	`rho c` (MJ/m^3 K)	24-hour depth
Dense concrete	2300	880	1.7	2.02	152 mm

Material	rho	c	k	rho c (MJ/m^3 K)	24-hour depth
Brick	1700	800	0.72	1.36	121 mm
Gypsum board	800	1000	0.25	0.80	93 mm
Solid timber	500	1600	0.13	0.80	67 mm
Water	1000	4180	0.6	4.18	63 mm

Penetration depth is where the daily swing has fallen to `1/e` of its surface amplitude, and standard design practice takes roughly the first 100 mm of exposed heavyweight material as the participating depth. **A 300 mm slab exposed on one face therefore performs like a 100–150 mm slab: thickening buys nothing for the diurnal cycle and exposing more *area* buys everything.** Stored energy in exposed concrete:

```
per m^2 of exposed surface, over the participating depth: 2300 x 880 x 0.152 = 308 kJ/m^2/K
100 m^2 of exposed soffit over a 3 K diurnal swing: 308 x 100 x 3 = 92.3 MJ = 25.6 kWh
```

Twenty-six kilowatt-hours of free storage, shifted from afternoon peak to night, out of a soffit already paid for. And then: carpet the slab, or hang a sealed suspended ceiling under it, and the mass is gone. The material is still there; its coupling to the room air is not. **A decision taken for acoustics silently deletes the thermal strategy, and nobody notices, because the two decisions are made by different people in different months.** That is failure mode FB5.

The resolution is computable and the two requirements are compatible:

```
TREATED   exposed soffit, 60% left open       25.0 x 0.02 =  0.50
          50 mm mineral wool baffles          17.0 x 0.90 = 15.30
          plastered walls                     57.4 x 0.03 =  1.72
          10 m2 wall panel, 50 mm             10.0 x 0.85 =  8.50
          glazing                              8.0 x 0.04 =  0.32
          carpet tile on concrete             42.0 x 0.25 = 10.50
          4 occupants                          4   x 0.45 =  1.80
          A = 38.64 m2 sabins  ->  RT60 = 0.51 s      exposed mass retained: 60%
```

Reverberation from 4.42 s to 0.51 s, inside the speech range, with 60 per cent of the soffit still thermally coupled. Baffles and rafts absorb without sealing. The two requirements are compatible; they are never coordinated.

Tactile. Two surfaces at identical temperature feel different, and the physics is exact. Thermal effusivity `e = sqrt(k rho c)` governs the interface temperature reached when skin touches a surface: `T_contact = (e_skin T_skin + e_mat T_mat)/(e_skin + e_mat)`. With skin at 33 C, skin effusivity taken as 1200, and every material at a true **20 C**:

Material	e	Contact T	Material	e	Contact T
Aluminium	22,045	**20.7 C**	Glass	1,369	26.1 C
Mild steel	13,539	21.1 C	Oak	436	29.5 C
Stainless steel	7,697	21.8 C	Pine	322	30.2 C
Granite	2,421	24.3 C	Wool carpet	125	31.8 C
Dense concrete	1,855	25.1 C	Cork	104	**32.0 C**

At the same 20 C, an aluminium handrail presents 20.7 C to the hand and a cork one presents 32.0 C — eleven degrees at the skin from a material choice alone. No thermostat setting produces that difference and none compensates for it. Specify by effusivity wherever skin meets building: handrails, door handles and push plates, seat surfaces and arms, work-tops, sills people lean on, floors in barefoot spaces. **The steel handrail on an unheated stair is a thermal decision being made without the calculation.**

Temporal: patina and the decay rate. Materials divide by what wear does to them. Oiled and waxed hardwood, brass, bronze and copper, vegetable-tanned leather, lime plaster, brick, stone, linoleum and cork improve with wear; melamine and laminate faces, thin veneer on board, printed vinyl, painted board edges and powder coat over thin steel degrade with it. **The distinction is structural, not aesthetic: a material improves with wear when its surface and its body are the same substance**, so wear exposes more of the same, and it degrades when a thin surface layer differs from the substrate, so wear breaches the layer and exposes something visibly other.

In the law's terms **decay is per component.** Structural decay — the desk stops being a desk — is small for both classes; appearance decay — the desk stops reading as cared-for — is large for layered materials and near zero for solid ones. **Since perceived maintenance drives the behaviour that actually maintains a place, a low-appearance-decay material is a self-reinforcing investment and a high-decay one is self-defeating.** Illustratively, over 40 years per m^2 of worktop:

```
laminate: 180 initial, replaced every 8 years -> 5 purchases = 900   (22.50 /m2/yr)
timber:   430 initial + 6/m2/yr oiling        -> 430 + 240   = 670   (16.75 /m2/yr)
```

Badge: those unit rates are illustrative placeholders showing the structure of the calculation, and the conclusion depends entirely on them. Substitute quoted rates. What does *not* depend on them is the shape: **a layered material has a step-function cost stream with disposal and disruption at each step; a solid one has a small continuous stream. Step functions are also what get deferred when budgets are tight, which is how a building arrives at year twelve looking abandoned.** The argument that aged buildings house the low-margin, unproven and various uses that new construction prices out is a different and economic one [Jacobs, 1961]; **the decay-rate framing here is this framework's interpretation and not that finding.**

12.5.6 5.6 Mapping the substrate to the law

Substrate variable	Parameter	Mechanism	How to measure
Daylight and view	`eta`	Occupied hours at the perimeter	Daylight-factor survey; vertical illuminance; occupancy by position
Circadian light timing	`delta`	Sleep, next-day capacity, skill retention	Melanopic illuminance at eye height, morning and evening
Glare	`C`	Blinds closed, screens moved, complaints	Count of permanently closed blinds; glare rating
Operative temperature at the seat	`C`, `N_eff`	Discomfort; contested adjustment; attrition	Globe thermometer at the seat; Protocol B1
Personal control provision	`C`	Removes coordination cost per adjustment	Controls per occupant; shared-control log
Ventilation rate	`C`	Symptoms, infection risk, odour	Carbon-dioxide logger inverted to supply rate

Substrate variable	Parameter	Mechanism	How to measure
Acoustic absorption	`u`, `eta`	Turn-taking equality [Curzi, 2026e]	RT60 by Sabine; speaking-share distribution
Exposed thermal mass	`C`	Peak-load shifting; free storage	Coupled surface area; internal temperature swing
Tactile effusivity	`eta`	Willingness to occupy and to touch	Material schedule; computed contact temperature
Patina behaviour	`delta`	Appearance decay rate	Annual fixed-position photographs

Every row of that table is a modelling assignment, not a measured coefficient. The right-hand column is what would turn each row into a measurement, and the worked case in Section 8.2 takes five of them.

12.6 6 The table with no head

Governance is usually written down. This section is about the part that is built instead. **A table with a head is a governing instrument.** It assigns one seat the sightlines, the acoustic advantage and the conventional right to open and close, and it assigns every other seat the complementary role. **The function of everyone else becomes agreement — and agreement between aligned instruments is echo, not evidence.** That is not a metaphor: when members' contributions become parallel, `u` goes to zero, the effective count goes to one, and the surplus of the whole assembly is `ln 1 = 0`.

The claim is that this is fixable in joinery, and it has three parts. **The damage from deference is quartic, not linear**, so mild deference is nearly free and strong deference is catastrophic. **Geometric equality has an exact definition computable from a plan**, the variance of visual centrality across seats. **And three independent constraints — proxemic, acoustic and coordination cost — converge on the same table size**, none of them knowing about the other two.

12.6.1 6.1 The arithmetic of deference

The deference postulate, badged. Let `h` be the chair's position vector and let each other member have a private view `w_i`, unit, mutually orthogonal, and orthogonal to `h`. Model the contribution actually made by member `i` under deference as

```
v_i = a h + sqrt(1 − a^2) w_i          a in [0,1]      a = the alignment coefficient
```

Then `v_i . v_j = a^2` for `i != j`, so `u_ij = 1 − a^4`, and the assembly's effective count is `N_eff = 1 + (n−1)(1 − a^4)`. **What is postulated is the *form* of deference — that it acts as a rotation of each contribution toward the chair's, by a common coefficient. What follows from that form is exact arithmetic.** The postulate is wrong in detail: deference is not uniform across members, private views are not exactly orthogonal, and the coefficient may vary by topic. **It is the simplest model with the right qualitative behaviour and it has no external support whatever.**

a	a^4	u	N_eff (n = 12)	S = ln N_eff	% of ln 12
0.00	0.0000	1.0000	12.000	2.4849	100.0
0.30	0.0081	0.9919	11.911	2.4775	99.7
0.50	0.0625	0.9375	11.312	2.4259	**97.6**
0.60	0.1296	0.8704	10.574	2.3584	94.9
0.70	0.2401	0.7599	9.359	2.2363	90.0
0.80	0.4096	0.5904	7.494	2.0142	81.1
0.90	0.6561	0.3439	4.783	1.5650	**63.0**
0.95	0.8145	0.1855	3.040	1.1120	44.8
0.98	0.9224	0.0776	1.854	0.6173	24.8
1.00	1.0000	0.0000	1.000	0.0000	**0.0**

Read the shape rather than the rows. At `a = 0.5` the assembly keeps 97.6 per cent of its surplus; at `a = 0.9` it keeps 63.0 per cent; at `a = 0.95` it keeps 44.8 per cent. The loss is negligible until it is severe, because the fourth power does nothing until `a` approaches one and then does everything. That cuts both ways. **Ordinary politeness is nearly free** — a room where people are mildly influenced by the chair loses a few per cent, and governance effort should not be spent on it. **A room where members are 90 per cent aligned has lost more than a third of its assembly**, and one at 95 per cent has lost more than half, **while still tabling twelve names, twelve salaries and twelve signatures on the minute. Nothing in the paperwork records the loss.**

The same computation at other sizes exposes a trap:

a	n = 6 (% of `ln 6`)	n = 12	n = 25 (% of `ln 25`)
0.50	97.0%	97.6%	98.1%
0.70	87.5%	90.0%	91.9%
0.90	55.8%	63.0%	69.1%
0.95	36.6%	44.8%	52.7%
1.00	0.0%	0.0%	0.0%

A larger assembly is slightly more robust in *percentage* terms, **so adding members appears to help and barely does, because the ceiling being protected is `ln n` and it grows logarithmically. Twenty-five deferential members at `a = 0.9` deliver 2.225 nats against twelve independent members' 2.485. Twice the room, twice the cost, less surplus.**

The storage-law consequence. Take a standing council: `n = 13`, `eta = 0.50`, `delta = 0.08` per month, `Q = 9.0`, and cost by the declared calibration `C = phi eta ln n` with `phi = 0.45`. Then `ln 13 = 2.5649`, `eta ln n = 1.2825`, `delta Q = 0.7200` and `C = 0.5771`.

Condition	a	u	N_eff	S	eta S	h	Q_inf
Head of table	0.90	0.3439	5.127	1.6345	0.8172	**-0.015**	3.00
No head	0.30	0.9919	12.903	2.5574	1.2787	**+0.114**	10.37

The deferential council sits at `h` near zero: maintenance only, no growth available, whatever it resolves to do. Removing the head takes it to `+0.114` and raises the sustainable stored order from 3.0 to 10.4 — **a factor of 3.5, with the same thirteen people, the same room and the same agenda.** The break-even alignment is worth computing because it is a hard number a chair can be shown:

```
eta S = C   ->   S_crit = C / eta = 0.5771 / 0.50 = 1.1542
N_eff,crit = e^1.1542 = 3.1716
u_crit = (3.1716 - 1) / 12 = 0.1810
a_crit = (1 - 0.1810)^(1/4) = 0.9513
```

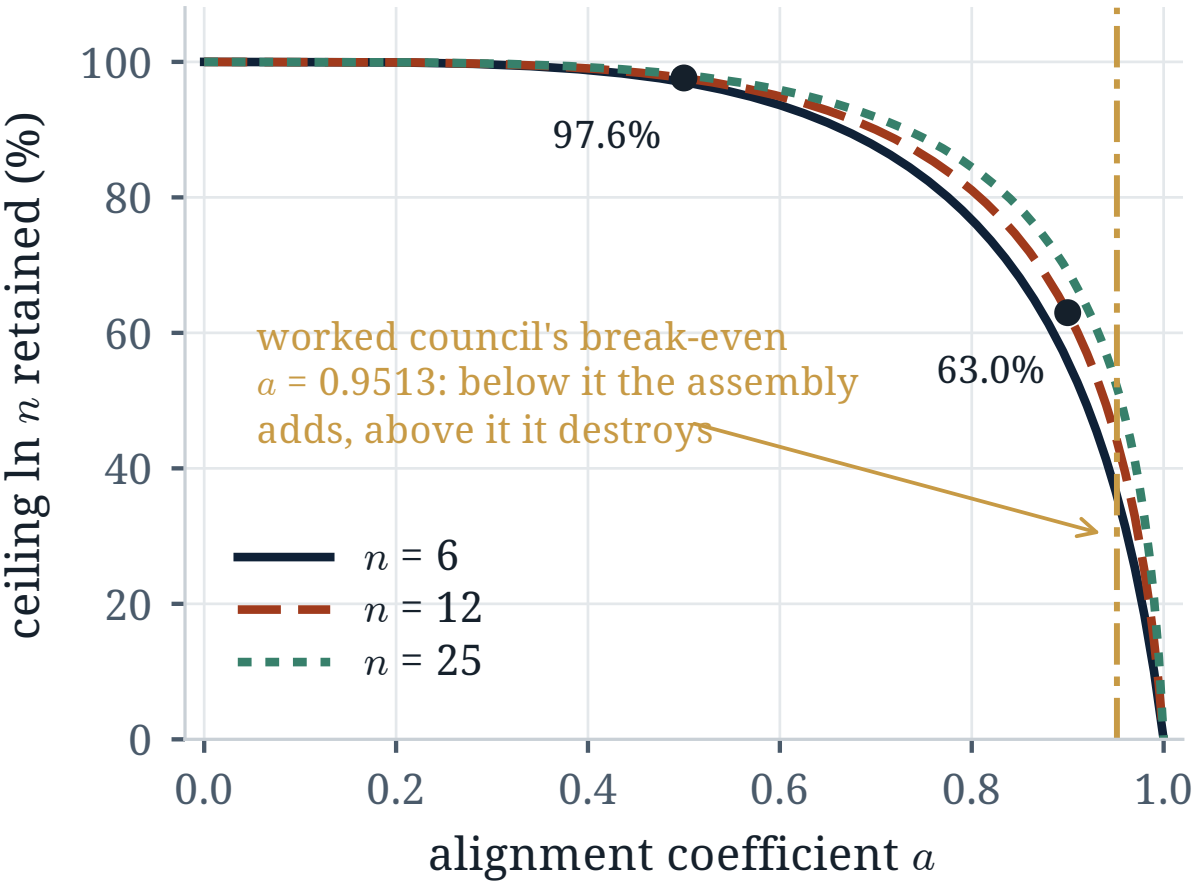

Figure 12.4: **Deference damage is quartic: nothing happens, and then everything happens.** Share of the ceiling `ln n` retained under the badged deference postulate `u = 1 - a^4`, for three assembly sizes. The worked council's break-even alignment — above which its meetings destroy stored order rather than adding to it — is 0.9513, which is its own parameters and not a general constant. Modelled: the form of deference is a postulate with no external support and the arithmetic that follows from it is exact. Generated by `figs/src/CCP-012_fig04.py`.

Above `a = 0.9513` this council destroys stored order every period it meets. It is not merely failing to add: the meetings are net-negative, because the coordination cost exceeds what a one-effective-member assembly can produce. **That is the sustainability ceiling arriving in a committee room** [Curzi, 2026b]. The limiting case is the framework's own unison result: at `u = 0` the steady state is `Q_inf = −c/delta`, in which **neither the conversion coefficient nor the category count appears at all, and two of the four levers have exactly zero derivative** [Curzi, 2026]. **A perfectly deferential assembly cannot be repaired by hiring, by diversifying or by conversion, because at `u = 0` those levers are disconnected from the outcome.**

12.6.2 6.2 Measuring alignment, and why a point estimate would be misleading

The alignment coefficient is not directly observable, and a table without a measurement would be selling arithmetic. Two instruments are given in full in Appendix A. Protocol D1, the written-then-spoken divergence, collects each member's written position before discussion and again after, and under the postulate's linear form the variance ratio relates to alignment as `V_post/V_pre ~ 1 − a^2`, so `a_max = sqrt(1 − V_post/V_pre)`. **Badge: that relation follows from the postulate's linear form, not from data.** Its limitation is that **legitimate persuasion by evidence also reduces post-discussion variance**, so the expression is an *upper bound*. Separate the two by asking, in the second collection, what changed the member's mind: a specific argument, or nothing they can name. Let `f` be the fraction of changed positions no member could attribute to an argument; then `a_min = sqrt(f (1 − V_post/V_pre))`.

Convergence nobody can attribute to an argument is the part that belongs to deference. Report the interval `[a_min, a_max]` and carry its midpoint as the working estimate. **A point estimate of alignment reported without its interval is the most misleading number this analysis can produce.** Protocol D2, the addressee count, is the cheap corroborant: log for each contribution whether the speaker's gaze and body orientation are directed at the chair or at the table. **A room in which over half of contributions are addressed to the chair is a room operating at high alignment**, and the count needs one observer and a tally sheet.

The mechanism the first protocol is designed to catch is an information cascade, which requires that each actor observe the actions of earlier actors before acting [Bikhchandani et al., 1992, Banerjee, 1992]. **Writing first makes every member's first commitment simultaneous, so there are no earlier actions to observe: the cascade is not discouraged, it is made structurally impossible for the first round.** The same failure has been demonstrated in aggregation experiments, where even light social information degrades the accuracy of a crowd's collective estimate [Lorenz et al., 2011] — the mechanism that the classic unaided-aggregation result depends on being absent [Galton, 1907, Surowiecki, 2004]. **Independence is a precondition of aggregation, and a chair who aligns the room has removed it.**

12.6.3 6.3 Sightline reciprocity and the exact definition of geometric equality

Seat every member on a circle of radius `r`, facing the centre. For two members separated by angle `phi` around the circle, the head turn `psi` that member `i` must make to face member `j` satisfies `cos psi = |sin(phi/2)|`, equivalently `psi = 90 deg − phi/2`:

Separation `phi`	27.7	45	60	90	120	166	180
Required head turn `psi` (deg)	76.2	67.5	60.0	45.0	30.0	6.9	**0.0**

Comfortable sustained head rotation is about `+/−45` degrees, with `+/−60` reachable and beyond that requiring the torso. **The result is counter-intuitive and it matters: at a round table the person directly opposite is the easiest to face — zero head turn — and the immediate neighbour is the hardest.** At thirteen seats the neighbour sits 27.7 degrees away and needs a 76-degree turn:

Seat offset	`+/−1`	`+/−2`	`+/−3`	`+/−4`	`+/−5`	`+/−6`
Separation (deg)	27.7	55.4	83.1	110.8	138.5	166.2
Head turn (deg)	76.2	62.3	48.5	34.6	20.8	6.9
Class	torso	torso	workable	easy	easy	easy

A round table is a plenary instrument, not a conversational one. It is excellent at making each member addressable by the assembly and poor at supporting side conversation — **which is exactly the trade a deliberating body wants and exactly the wrong trade for a dinner.**

Now the definition. For each seat `i`, let `V_i` be **the number of other seats within a 45-degree head turn of `i`'s forward gaze**, computable from a furniture layout with a protractor before anyone sits down. **Geometric equality is the condition `Var(V_i) = 0`.** Computed for real layouts, with seats 0.6 m out from the table edge and facing the table:

Layout	n	`V` per seat	mean	**variance**
Round, 12 seats, D = 2.67 m	12	7 everywhere	7.00	**0.00**
Regular 13-gon ring, D = 2.90 m	13	6 everywhere	6.00	**0.00**
Hollow square 2.4 x 2.4 m, 3 per side	12	7 everywhere	7.00	0.00
Rectangle 3.0 x 1.2 m, 5+5 sides + 2 heads	12	sides 5 to 6; heads **9, 9**	6.00	**2.00**
Boardroom 6.0 x 1.4 m, 8+8 + 2 heads	18	sides 5 to 7; heads **15, 15**	6.78	**9.06**

Read the last row. At an eighteen-place boardroom table the two head seats each see fifteen of the other seventeen within a comfortable turn; the seats at the far ends of the long sides see five. The head has more than twice the visual reach of the average member. **That is not a rule of order, it is a fact about the shape of a rectangle, and it operates in every meeting held at that table, forever, without anyone deciding it should.** The round table has variance exactly zero by rotational symmetry: every seat has the same view of the assembly, **so there is no seat to take and nothing to arrive early for.**

One honest qualification, and it is the kind that separates a computed claim from a slogan. The hollow square also scores zero variance at the 45-degree threshold — **but that is a coincidence of the threshold, not a symmetry.** Recompute at others:

Threshold	Round, n = 12	Hollow square, n = 12
`+/−30` deg	variance 0.00	variance **0.89**
`+/−45` deg	0.00	0.00
`+/−60` deg	0.00	**0.22**
`+/−70` deg	0.00	0.00

Only a rotationally symmetric arrangement has zero centrality variance at every threshold. The hollow square is a good second choice and it is not equal: its corner-adjacent and mid-side seats are in genuinely different positions. **If a hollow square is specified, say so, and record the variance at all four thresholds rather than the one that flatters it.** Protocol D3 in Appendix A is the audit, and **a layout whose variance has not been computed is a layout whose governance has not been specified.**

12.6.4 6.4 Sizing the table: three constraints that do not know about each other

Constraint 1 — proxemic. Seat pitch along the table edge: 0.60 m minimum, 0.70 m comfortable, 0.75 m generous. For a circular or regular polygonal table `D = n s / pi`, and the across-table distance between opposite members is `D`. Across-table distance must stay inside the social band — 1.20 to 3.60 m [Hall, 1966] — **or the far member is being addressed rather than conversed with.**

n	6	8	10	12	**13**	14	16	18	20	25
D at s = 0.70 m	1.34	1.78	2.23	2.67	**2.90**	3.12	3.57	4.01	4.46	5.57
Band	social	social	social	social	social	social	social	**public**	public	public

```
D <= 3.60 m (edge of social)              ->  n <= pi(3.60)/0.70 = 16.2
D <= 2.90 m (comfortable, facial detail)  ->  n <= pi(2.90)/0.70 = 13.0
```

Thirteen seats at 0.70 m pitch give a 2.90 m table — exactly the comfortable social distance. The thirteen-sided plan is not a symbol here; **it is what falls out of anthropometry and the proxemic bands, and it is stated as a derivation.** A 2.90 m table has a great deal of unreachable centre — comfortable seated reach is 0.45–0.60 m — so make it a ring: at 0.60 m working depth the inner void is `2.90 - 2(0.60) = 1.70 m` and the table footprint is 4.33 m^2, against a solid 2.90 m disc of 6.6 m^2 **of which 2.3 m^2 can never be reached.**

A measured artefact. The great oak table hanging in the Great Hall at Winchester is about 18 feet across and carries twenty-five painted places. `D = 5.486 m`, circumference `pi D = 17.24 m`, so `17.24/25 = 0.689 m` per place. **A fourteenth-century object is dimensioned at 0.689 m per seat, which is the modern comfortable place setting to within a centimetre: anthropometry has not changed and neither has the answer.** But run the second calculation: across-table distance is 5.49 m, well into the public band. **By its own geometry the Winchester table is a ceremonial object and not a deliberation table, and the round form does not rescue it. Roundness buys equality; it does not buy conversation. Conversation is bought by diameter.**

Constraint 2 — acoustic. Speech level falls with distance; in the direct field `L(d) = L(1 m) - 20 log10(d)`. Normal conversational effort is about 60 dBA at 1 m, relaxed about 55, raised about 66; good intelligibility wants about 15 dB of signal-to-noise ratio, with 10 dB the adequate floor.

Across-table distance	1.5 m	2.0 m	2.9 m	3.6 m	4.5 m	5.5 m
Level from a normal voice	56.5	54.0	**50.8**	48.9	46.9	45.2 dBA
Background needed for SNR 15	41.5	39.0	**35.8**	33.9	31.9	30.2 dBA
Background needed for SNR 10	46.5	44.0	40.8	38.9	36.9	35.2 dBA

At the thirteen-seat, 2.90 m table a normally spoken sentence arrives at 50.8 dBA, so the room's background must be at or below about 36 dBA for the quietest member to be heard without raising their voice. Go to twenty seats and 4.46 m and the requirement becomes 32 dBA, **a concert-hall-grade mechanical specification rarely achieved in an office building. Table size and the ventilation noise limit are the same constraint, and the person who chose a twenty-seat table has specified the air handling without knowing it. Honest qualification:** this

is a direct-field calculation. In a real room the reverberant field adds level as well, but late-arriving reverberant energy smears rather than helps, **so the direct calculation is the right conservative bound for clarity** and must be used together with a reverberation target [Curzi, 2026e], neither replacing the other.

Constraint 3 — coordination cost. Communication paths grow as `n(n−1)/2` while surplus grows as `ln n` [Brooks, 1975, Conway, 1968]:

n	6	8	10	12	13	16	20	25	30
Links n(n−1)/2	15	28	45	66	78	120	190	300	435
ln n	1.792	2.079	2.303	2.485	2.565	2.773	2.996	3.219	3.401
Links per nat	8.4	13.5	19.5	26.6	30.4	43.3	63.4	93.2	127.9

Maximising `eta ln n − c n(n−1)/2` gives `n(n − 0.5) = eta/c`, so `n* ~ sqrt(eta/c)`: 5.3 at `eta/c = 25`, 7.3 at 50, 10.3 at 100, 14.4 at 200 and 20.3 at 400. **The same constraint stated as a roster ceiling is `m(m−1) <= 2 eta ln(N)/kappa`, and the corpus's constructed commons sits exactly at it — 30 against a bound of 30.7225, so that a seventh member makes the case structural rather than personal** [Curzi, 2026].

The convergence.

```
Proxemic (facial detail, s = 0.70):   n <= 13
Proxemic (edge of social):            n <= 16
Acoustic (achievable 30 dBA room):    n <= about 13–16
Coordination cost, eta/c = 50..200:   n* = 7 to 14
```

Three constraints derived from anthropometry, from acoustics and from a combinatorial cost argument converge on eight to fourteen seats, and none of the three knows about the other two. That convergence is the strongest result in this section, and it is the reason to distrust any deliberating body sized above about sixteen. **Above sixteen the body is not running a deliberation; it is running a plenary that will be decided somewhere else, by fewer people, in a smaller room. The convergence is nonetheless three calculations agreeing, not three independent measurements agreeing**, and Section 10.6 records that they share the proxemic and speech-level inputs.

12.6.5 6.5 Protocols, and the measurement of turn-taking equality

Geometry sets the field and protocol sets the play. **Silent-write-first** opens every substantive item with two to five minutes in which everyone, the chair included, writes a position in a fixed answer format, followed by simultaneous unattributed reveal, with the pre-discussion variance recorded before any talking. **Round-robin** gives one pass in which every member speaks once without interruption, **with the order randomised each session — a fixed order hands the anchoring advantage permanently to whoever is first — and with an unconditional pass, because "pass" is a complete contribution and needs no reason.** The **last-speaks-first inversion** states positions from lowest rank to highest where rank is present and cannot be removed, so the senior member's position cannot anchor the rest; **it is long-established practice in aviation crew coordination, in military councils and in clinical teaching, and it is presented here as established practice rather than as a cited experimental result. This paper carries no bibliography entry for it** and the mechanism it defeats — anchoring on an authoritative first statement — is the documented part.

Measuring turn-taking equality. Let `p_i` be member `i`'s share of speaking time; compute `H = −sum_i p_i ln p_i`, `N_speak = exp(H)` and `E = H/ln n`.

Case	n	H	E	N_speak	Gini
8 equal	8	2.079	1.000	8.00	0.000
8, one at 35%	8	1.912	0.920	6.77	0.225
8, two at 30% each	8	1.806	0.868	6.08	0.350
8, one at 50%	8	1.666	0.801	5.29	0.375
8, one at 60% + two silent	8	1.317	0.633	**3.73**	0.575
12 equal	12	2.485	1.000	12.00	0.000
12, chair at 40%	12	2.112	0.850	8.26	0.317
12, chair at 40% + 3 silent	12	1.921	0.773	**6.83**	0.467

A twelve-person meeting in which the chair takes 40 per cent of the floor and three members say nothing has 6.83 effective speakers. Half the room is decorative and the minute will record twelve attendees. Report both `N_speak` and the Gini coefficient: **entropy is forgiving of a single dominator and harsh on silence, Gini is the reverse, and two indices disagreeing is information.**

BADGE, and it is the framework's own. `N_speak` is the exponential of a Shannon entropy — a Hill number of order one, a standard descriptive diversity index [Hill, 1973, Jost, 2006, Pielou, 1966] — borrowed here by formal analogy. It measures how equally the floor was shared. It does not compute `N_eff = 1 + (n−1)u`, which is not a Hill number of any order, and it does not compute surplus. The resemblance of form is a resemblance, not a theorem, and surplus is not identified with Shannon entropy anywhere in this framework.

What the chair still does. Removing the head does not remove the chair's work: timekeeping, agenda-setting, recording the decision and enforcing the protocols are all real and all necessary. **None of them requires the geometric privileges**, and a chair with the same sightlines as everyone else is a chair whose authority rests on the role rather than on the furniture. **One caution on a popular device:** an *assigned* devil's advocate is weaker than genuine dissent — authentic disagreement stimulates more and better divergent thinking than role-played disagreement — so assigning the role is better than nothing and **is not a substitute for recruiting someone who actually disagrees**, which is a recruitment problem and cannot be solved with furniture. **That finding is described here without a citation key, because this corpus's bibliography holds none.**

12.6.6 6.6 Why furniture rather than policy, and the limit of the claim

A rule requires an enforcer. The enforcer needs authority, discretion, attention and willingness, and every act of enforcement is a transaction that costs both parties something. **In the law's terms a rule generates a stream of cost for as long as it exists, and the stream falls hardest on whoever is most willing to speak up — who, as Section 4.8 noted, is not a random sample.** A shape enforces on every occasion of use: it has no discretion, grants no exceptions, forgets nothing, retires from nothing, and asks nobody to be the person who raised it.

Instrument	Setup cost	Marginal cost per use	Decays without maintenance?	Who bears enforcement?
A rule in the terms of reference	low	one enforcement act each time	yes, quickly	a person, repeatedly
A trained facilitator	high	a salary, every session	yes, on turnover	the facilitator
A round table	one-off capital	**zero**	only physically, over decades	**nobody**

A round table is invisible governance: nobody in the room experiences it as a constraint, nobody resents it, nobody has to be reminded of it, and nobody has to be the person who enforces it — which is exactly why it works and exactly why it never appears in the governance document. That is the general property of infrastructure, which becomes visible only on breakdown [Star and Ruhleder, 1996, Star and Griesemer, 1989].

The honest limit, stated as plainly as the claim. Geometry constrains; it does not determine. A sufficiently determined chair will dominate a round table by talking more, and a disciplined group will deliberate well at a rectangle. **What the geometry changes is the cost of dominance and the cost of resistance.** At a table with a head, dominating is free and resisting is expensive. At a table without one, dominating requires visible effort — more floor time, in front of people who can all see it happening — and resisting requires only speaking, from a seat with the same view as everyone else's. **That is a shift in a gradient, not a prohibition**, and it is what makes the method non-coercive: **a method that works by removing resistance has no coercive failure mode, and its worst outcome is that someone declines to use it.**

12.7 7 Design specifications

The requirements below are stated in the form a specification would carry. **`T1–T15` govern thresholds and edge, `B1–B14` the substrate, and `D1–D17` the deliberation table.** A requirement is not a finding: the schedule is a design instrument derived from the results above, and **its numerical thresholds are chosen values rather than measured optima.** Where a figure is jurisdictional or population-specific it says so, and says what to measure instead.

12.7.1 7.1 Thresholds and edge

T1 — mismatch survey. Rate both adjoining zones on the eight-attribute character vector of Section 4.3 and record `M` and `M_bar`. **T2 — step limit.** No threshold shall change any attribute by more than one point; at `M = 4`, at least three intermediate zones are required. **T3 — deceleration depth and dwell.** Any threshold at which occupants are expected to stop shall be not less than 2.0 m deep in the direction of travel, and where four or more seconds of dwell are required either the depth or a direction change shall supply it. **T4 — landing depth and pause-and-pass width.** On the swing side of an inward-opening 0.9 m leaf, not less than 1.50 m of landing depth; not less than 1.35 m clear width where one paused person and one passing person must coexist, and 2.85 m where a conversing pair must not become an obstruction. **T5 — legibility without signage.** Every zone transition shall be marked by at least two of surface, level, light, width, direction and ceiling height. **T6 — edge density.** Any occupiable room over 60 m^2 shall achieve a total perimeter, including interior islands, of not less than 0.40 m per m^2. **T7 — island clearance and occupiable edge.** Not less than 0.90 m clear between interior islands, and island edge shall be occupiable rather than merely present. **T8 — window place and alcove sizing.** Every room with a window shall have at least one seated position within 1.5 m of the glazing. **T9 — screen heights.** 1.20 m for seated privacy with standing awareness; 1.35–1.45 m to convert a glance into a decision. **T10 — closable boundary.** Every zone rated 1 or 2 on attention mode shall have a physically closable boundary. **T11 — paired invitation.** Every closable private zone under T10 shall be paired with an open, unbooked, edge-type position that anyone may occupy without asking, **and occupancy counts shall confirm that the paired positions serve more than one cluster. T12 — desire-line survey.** Run Protocol T1 for six weeks before any layout change and six weeks after. **T13 — switching measurement.** Measure `k` and `m` by Protocols T3 and T4 before and after, **and report `m`'s median and interquartile range, because the distribution has a long right tail. T14 — egress precedence and crossability.** Every threshold device shall be checked against the applicable life-safety code, which wins without discussion, and shall be crossable by anyone who chooses. **T15 — entrance area budget.** Allow 4 to 9 per cent of served net floor area for the entrance sequence, **and record it as a budget line rather than as circulation.**

12.7.2 7.2 Substrate

B1 — daylit depth. No regularly occupied workstation further than 2.5 times the window head height from its daylight source; where the plan exceeds this, **record the shortfall rather than relaxing the requirement.** **B2 — illuminance and colour**, to the applicable standard. **B3 — vertical measurement.** Illuminance shall be recorded in **both planes**, horizontal at the task and vertical at seated eye height in the working direction. **B4 — circadian target**, stated as a melanopic figure at the eye during daytime hours, **with its standard and edition named.** **B5 — glare**, to the applicable rating, **with permanently closed blinds counted as a failure.** **B6 — the six variables, measured at the seat.** Any thermal comfort claim shall state all six, measured at the occupied position and not at the thermostat. **B7 — glazing and the window seat.** Where T8 requires a seated position at the glazing, the local operative deficit at that seat shall be under 1.0 K at the design outdoor condition. **B8 — personal control.** Every regularly occupied position shall have at least **two** adjustment channels that are personal in *effect*. **B9 — shared controls and humidity.** Shared setpoint controls shall be logged with time, direction and magnitude; relative humidity shall be held at or above 30 per cent. **B10 — ventilation and carbon dioxide.** Specify the outdoor air rate to the applicable standard, monitor carbon dioxide as a tracer, **and claim ventilation only.** **B11 — reverberation with mass retained.** Meet the reverberation target using baffles, rafts and wall panels rather than sealed ceilings, **and state the percentage of thermally coupled soffit retained.** **B12 — participating mass.** Where thermal mass is claimed, compute the participating depth and the coupled area and state both. **B13 — contact surfaces.** Schedule every surface routinely touched by skin and state its computed contact temperature at the design condition. **B14 — patina classification and appearance monitoring.** Classify every visible material as improving or degrading with wear, and photograph from fixed taped positions annually.

12.7.3 7.3 The deliberation table

D1 — no head. The table shall be circular or a regular polygon with `n` equal places. **D2 — centrality variance.** Computed by Protocol D3, `Var(V_i)` shall be **zero at the 30-, 45- and 60-degree thresholds**, and the value at each shall be recorded. **D3 — seat pitch.** Not less than 0.60 m of table edge per member; 0.70 m is the design value. **D4 — diameter and seat count.** `D = n s / pi`, and `D` shall not exceed 3.60 m. **D5 — ring form.** Where `D` exceeds 1.80 m the table shall be a ring, with a working depth of 0.60 m. **D6 — upper bound on the body.** No deliberating body shall exceed **sixteen** members. **D7 — acoustic budget.** Background noise shall be not more than `L_speech(D) − 15 dB`, **computed and recorded with its margin.** **D8 — reverberation.** Meet the applicable reverberation target for the room volume; the direct-field calculation of D7 does not replace it. **D9 — chair seating.** The person chairing shall occupy an ordinary seat allocated by the same rule as everyone else's. **D10 — seat allocation.** Seats shall be unreserved, or allocated by a rule no member controls. **D11 — silent-write-first.** Every substantive decision item shall open with two to five minutes of silent writing, with `V_pre` recorded before discussion. **D12 — cascade test.** Where `V_post/V_pre < 0.25` and members cannot name the argument that moved them, **record a suspected cascade in the minute.** **D13 — speaking order.** The first round shall be round-robin in an order randomised or rotated by a rule nobody controls. **D14 — turn-taking measurement.** Speaking-time shares shall be measured at not less than one session in four, **with consent**, and `N_speak/n` recorded. **D15 — alignment estimate.** Estimate the alignment coefficient by Protocol D1 not less than annually **and report the interval, never a point.** **D16 — minority record.** Any member may attach a dissenting position to the minute, of their own drafting, without permission and without a second. **D17 — declination.** No provision of this specification shall be applied so as to compel a member to speak, to be recorded, or to remain.

12.8 8 Results: three systems worked end to end

All three systems are constructed. No dataset was collected for this paper. Every number below is the output of the stated parameters under the models of Sections 4 to 6, carried through so that a reader can re-derive it. **They demonstrate that the procedure runs and that it reports its own failures; they are not evidence that any organisation or building behaves this way.** In all three, the cost observable is the declared calibration `C = phi eta ln N` with `phi` a dimensionless fraction of the ceiling — **a declaration, not a derivation.**

12.8.1 8.1 A 30-person research floor: thresholds against a cost-bound gauge

The system. 900 m^2 net, a single open plate 22 x 41 m with partial glazed perimeter, four small enclosed rooms at the core, and one entrance door from the lift lobby straight onto the working floor. Nine specialisms, four years old. Surveyed: stored order `Q_0 = 6.0` as a normalised count of live shared methods, tools, protocols and documented working agreements in use; non-parallelism `u = 0.75` from a disagreement audit across the nine specialisms; `N = 9` verified non-redundant; `eta = 0.45` from durable structure per unit surplus over eight quarters; `delta = 0.06` per week from decay under zero input across two quiet periods.

```
ln N = ln 9 = 2.1972    N_eff = 1 + 8(0.75) = 7.000    S = ln 7 = 1.9459
eta*lnN = 0.9888  <- ceiling    eta*S = 0.8757  <- input    delta*Q = 0.3600  <- maintenance
```

The floor runs at 88.6 per cent of its geometric ceiling. There is almost no headroom left to buy by improving diversity, and the problem is elsewhere.

Measuring cost. Tally cards over two weeks across 30 people give a median `k = 22`; the progress-rate method over twelve person-days gives a median `m = 7` minutes with an interquartile range of 3 to 16.

```
C_switch  = 22 * 7 = 154 min/day of 480 = 0.321
phi_other = 0.25        (meeting overhead, tooling friction, compliance, room booking)
phi_before = 0.571   ->  C_before = 0.571 * 0.9888 = 0.5646
h = eta ln N - delta Q - C = 0.9888 - 0.3600 - 0.5646 = +0.0642
```

Headroom of `+0.064` against a ceiling of 0.989 — six per cent of the maximum one-step increment. Any project asking for more growth per week than that cannot be delivered, whatever is promised. Within measurement error the floor is at maintenance only. The steady state is `Q_inf = (0.8757 - 0.5646)/0.06 = 5.185`, and the current stock of 6.0 is **above** it: **the floor is not stagnant, it is declining slowly toward 5.19, everyone can feel it, and nobody can name a cause — because the cause is distributed across twenty-two interruptions a day.**

Diagnosis. *Mismatch:* lift lobby to working floor rates `M = 4`, `M_bar = 2.4` — a cliff edge. *Edge density:* enclosing perimeter `2(22+41) = 126 m` on 902 m^2 is **0.140 m/m^2** against a required 0.40, and core rooms add about 44 m of which half is occupiable, for an effective **0.11 m/m^2**; perimeter desks are occupied 94 per cent of working hours against 38 per cent for interior desks. *Desire lines, six weeks:* a diagonal from the entrance across the floor to the kitchen cutting through two clusters; chairs migrating toward the glazing week on week; three of four core-room doors habitually propped; handle wear on the fourth an order of magnitude above the rest, which is where the private conversation happens. Four closable boundaries shared by 30, no screens, **and headphones in use by 21 of 30 — twenty-one people privately funding the threshold layer the building did not supply.**

Intervention. Nothing changes the roster, recruitment, meeting culture or management structure: it is all joinery. (1) An entrance sequence: 30 m^2 beside the lift lobby becomes a vestibule (2.4 x 2.4 m, surface change, lower ceiling, warmer and lower light) and an anteroom (2.4 x 3.0 m, two seats, sightlines both ways), with entry turned 90 degrees; `M` at every junction falls from 4 to 1 or 2. (2) The kitchen is moved beside the anteroom so the diagonal becomes a

short public-zone route crossing no cluster — **this one move removes the largest single source of `k`.** (3) Fourteen thin islands, 0.9 x 2.4 m storage at 1.4 m high, form eight semi-private clusters of three or four desks at 0.9 m and 1.2 m clearances: edge added `14 x 2 x (0.9+2.4) = 92.4 m`, new density `(126+44+92.4)/902 = 0.291 m/m^2`, floor consumed 30.2 m^2. (4) Three corridor widenings of 1.2 x 2.4 m with a leaning rail and a writable surface, 8.6 m^2. (5) Two core rooms become bookable focus rooms with working locks; the propped pair get alarm-released hold-open magnets. (6) **Six window places at the glazing: unassigned, first-come, no booking, no ownership, open to visitors — the counterweight required by T11 and not optional.** (7) Two protected blocks daily, which is protocol rather than architecture and is therefore **subject to decay and reviewed quarterly forever. Total area consumed 68.8 m^2, 7.6 per cent of net floor.**

Re-measured at eight weeks, same protocols, same observers:

```
k = 6 per person per day        (was 22)
m = 7 minutes                   (unchanged, as expected: m is a task property, not a spatial one)

C_switch  = 42/480 = 0.087
phi_after = 0.087 + 0.25 = 0.337   ->  C_after = 0.3332
h_after   = 0.9888 - 0.3600 - 0.3332 = +0.2955
Q_inf     = (0.8757 - 0.3332)/0.06  = 9.041      (was 5.185)
```

Conversion, decay, the category count and non-parallelism are taken as unchanged, deliberately: the intervention touched exactly one term of the law. Headroom rises 4.6-fold and the sustainable level of stored order by 74 per cent, **with no change to the people, the work, or the diversity of the group.**

The transient. With `Q_t = (1-delta)^t Q_0 + (1 - (1-delta)^t) Q_inf`:

`t` (weeks)	0	5	10	20	30	50
`Q_t`	6.000	6.809	7.403	8.159	8.566	8.903

The time constant is `1/delta = 16.7` weeks and 95 per cent settling is at about 50 weeks; the half-life, computed correctly as `ln 2 / -ln(1-0.06) = 11.2` weeks rather than as the naive `1/delta` [Curzi, 2026], is the number to quote to anyone asking when they will see something. **Do not evaluate this intervention at eight weeks on the order observable:** at eight weeks the floor has moved to about 7.2, 31 per cent of the total, **and reading that as a disappointment misreads a first-order step response. Evaluate cost at eight weeks because cost is the input; evaluate stored order at a year.**

What would falsify it. (1) `k` above 15 at eight weeks means the threshold layer is not filtering and the model is wrong; log interruption *origin* as well as count, to separate the kitchen re-route from the islands. (2) `k` falls but stored order does not: a twenty-week reading below 7.4 means recovered time is not becoming durable structure, conversion is lower than measured, and cost was never binding. (3) **Non-parallelism falls:** a six-month disagreement audit below 0.65 means the clusters have become silos and the thresholds have partitioned the group's epistemics along with its noise — **this section's own tools installing a failure mode.** Rotate cluster membership quarterly and check that the window places serve more than one cluster; **if one cluster has colonised them, T11 has failed and the filter is doing damage.** (4) **The matched control:** a comparable floor in the same organisation over the same period, given a cosmetic refurbishment of equal cost and disruption but no change to mismatch, `k` or edge density. **If its stored order rises comparably, the claimed mechanism is not the operating one.**

And one requirement was not met. Edge density reached 0.291 m/m^2 against a required 0.40, **because the plate is 22 m deep and no arrangement of islands fixes a 22 m plate.** The project record reads: *T6 not met; deficit 0.109 m/m^2; cause, plate depth; remedy requires subdivision or a different building.* **A specification that adjusts itself to what was achieved has stopped being a specification, and that entry is worth more to the next engineer than any of the successes above.**

12.8.2 8.2 A four-person workroom: the substrate as a cost generator

The system. 42 m^2 (6.0 x 7.0 m), 2.9 m to soffit, `V` = 121.8 m^3, internal surface 159.4 m^2. One external wall, 6.0 m wide, north-facing, with 8 m^2 of air-filled double glazing (U = 2.8 W/m^2K) at a 2.4 m head. Exposed concrete soffit, vinyl on a concrete slab, plastered blockwork, one wall thermostat serving this room and two others. Six distinct specialisms across the occupants and their regular visitors. Surveyed: `Q_0 = 4.0`; `N = 6`, `ln N = 1.7918`; `u = 0.80`, so `N_eff = 5.00` and `S = ln 5 = 1.6094`; `eta = 0.28`; `delta = 0.070` per month; `phi` tallied at 0.62.

```
eta*lnN = 0.5017  <- ceiling      eta*S = 0.4506  <- input      delta*Q = 0.2800
C = 0.62 x 0.5017 = 0.3110
h = 0.5017 - 0.2800 - 0.3110 = -0.0894
Q_inf = (0.4506 - 0.3110)/0.070 = 1.994
```

Headroom is negative: in this model the room's order decreases regardless of how its occupants are arranged. Against a current stock of 4.0, the steady state of 1.994 means **the room is on a trajectory to lose half its stored order.**

The substrate survey. *Light:* desk illuminance 480 lux, compliant; **vertical at seated eye height in the working direction 130 lux, melanopic 95 at midday — against a 250 target the room delivers 38 per cent.** Average daylight factor 1.4 per cent; useful daylit depth at a 2.4 m head is 4.8–6.0 m against a room depth of 7.0 m. North aspect, so no direct sun, no glare, no blind use — **the one thing this room got right, by accident of orientation.** *Thermal:* air temperature at the thermostat 21.0 C; globe measurement at the window desk on a 0 C day gives an operative **18.9 C, a 2.1 K deficit**, consistent with a computed 13.4 C inner glazing surface. Two of four desks are within 1.5 m of the glazing; **personal channels available: zero.** The shared thermostat logged **3.8 contested adjustments per day** across its three rooms at a mean of 11 minutes of consequent discussion and counter-adjustment. *Air:* carbon dioxide logged three weeks, afternoon plateau with four occupants **1,290 ppm**; inverting, `Q = 0.005 x 4/(870 x 10^-6) = 23.0 L/s` total, 5.7 L/s per person. **Ventilated almost exactly to standard and sitting at 1,290 ppm — Section 5.4's tension in a real measurement.** Relative humidity ranged 22–38 per cent, below the 30 per cent floor for much of the heating season. *Acoustics:* measured reverberation at 500 Hz **2.6 s**, between the computed all-hard 4.42 s and a treated room, because furniture and occupants absorb. **Four people cannot hold two conversations here; they hold one, and the quietest of them contributes least.** *Material:* laminate desktops in year 6 of an 8-year life with edges lifting on two; powder-coated steel shelving; vinyl floor. **Every visible surface is layered: improving-with-wear fraction 0 per cent.** Contact temperature of the steel sill at an 18 C surface: 20.1 C.

Diagnosis. The room fails five of the six thermal variables, the vertical light plane, humidity, reverberation and material class; it passes horizontal illuminance, glare and ventilation rate. **The binding constraint is cost, and the substrate generates it:** 2.1 K of radiant deficit at half the desks driving a contested shared control; 2.6 s of reverberation suppressing three of four voices; a step-function replacement liability two years out. Conversion is also low at 0.28, and Section 5.6's mapping says why — **reverberation suppresses the turn-taking that produces durable agreement, and the window desks with the best light and view are avoided in winter.**

Intervention. (1) *Acoustic, mass-preserving:* 17 m^2 of 50 mm mineral wool baffles hung clear of the soffit, a 10 m^2 wall panel, carpet tile replacing vinyl — computed `A = 38.64 m^2` sabins, **reverberation 0.51 s, with 60 per cent of the soffit still thermally coupled.** (2) *Glazing:* double low-emissivity argon (U = 1.4) replaces the air-filled unit; inner surface at 0 C outdoors rises from 13.4 C to **17.2 C**, and the local operative deficit at the window desks falls from 2.1 K to under 1.0 K. (3) *Personal channels:* four desk fans and two low-wattage radiant foot panels, two channels per position, personal in effect. (4) *Shared control:* the room gets its own zone valve, so the contested control serves four people instead of twelve, with logging retained. (5) *Vertical light:* two indirect uplights and a wall-wash at 4000 K, dropping output and colour temperature after 17:00. (6) *Humidity:* trim humidification to hold 30 per cent and above.

(7) *Material:* as the laminate tops expire, replace with oiled solid timber; timber sleeves on the steel sill raise contact temperature at 18 C from 20.1 C to about 28 C; ten taped camera positions, photographed annually. **None of this changes the roster, the specialisms, or the work.**

Re-measured at four months:

```
eta:   0.28 -> 0.44   turn-taking recovered; window desks occupied year-round
delta: 0.070 -> 0.055 solid timber and carpet tile decay slower than lifting laminate and
                      scuffed vinyl; measured from the photo series plus replacement records
phi:   0.62 -> 0.38   contested adjustments 3.8/day -> 0.4/day; deferred liability removed
N, u:  unchanged at 6 and 0.80, so S = 1.6094 unchanged

eta*lnN = 0.7884     eta*S = 0.7082     delta*Q = 0.2200     C = 0.38 x 0.7884 = 0.2996
h = 0.7884 - 0.2200 - 0.2996 = +0.2688
Q_inf = (0.7082 - 0.2996) / 0.055 = 7.429        (was 1.994)
```

Headroom moves from `-0.0894` to `+0.2688`, from "no arrangement of people prevents decline" to a positive maximum one-step increment, and a 3.7-fold increase in the sustainable level of stored order — from baffles, glazing, four fans, two panels, a zone valve, two uplights and a change of worktop material.

The transient. Time constant `1/delta = 18.2` months; half-life `ln 2 / −ln(1−0.055) = 12.3` months [Curzi, 2026]; 95 per cent settling at about 55 months. **Do not evaluate this room on stored order at four months — it has moved perhaps a fifth of the way.** Evaluate the *inputs* at four months — cost, reverberation, melanopic illuminance, operative temperature at the seat, contested-adjustment count — **all of which respond immediately because they are the drive and not the state.**

What would falsify it. (1) `phi` does not fall: contested adjustments above 2 per day after zoning and personal channels means the dispute was never thermal. (2) Conversion does not rise: still near 0.28 at eight months with reverberation at 0.51 s means reverberation was not what suppressed it. (3) **The attrition claim fails:** run Protocol B1, and **if distance from delivered operative temperature predicts neither hours present, nor optional attendance, nor retention, the category-count claim of Section 5.3 is false in this building and must be withdrawn from the case. Report that result.** (4) **The matched control:** a comparable room, same institute and period, redecorated at equal cost and disruption but with no change to reverberation, glazing, personal control count or vertical illuminance.

The honest ledger. Shown: a substrate intervention changing no personnel and no category structure moved conversion up 57 per cent, decay down 21 per cent and cost down 4 per cent, taking the room from negative headroom to positive. **Not shown: that these are anyone else's numbers.** Conversion, decay, non-parallelism and `phi` were measured for one room; the calibration was declared, not derived; the dispersion of thermal preference in Section 5.3 was assumed and flagged; and **the conversion gain is attributed to acoustics and light on the basis of Section 5.6's mapping, which is a modelling assumption that falsification item 4 exists to break.**

Two things stayed broken and are recorded rather than smoothed over. B1 not met: the room is 7.0 m deep against a useful daylit depth of 4.8–6.0 m at a 2.4 m head; the back strip is electrically lit all day and **no lighting scheme changes that** — the remedy requires a second aspect or a shallower room. **And B10's tension is unresolved:** the room sits at 1,290 ppm while meeting the ventilation standard exactly. **Ventilation was not increased, because Section 5.4 says the cognitive case is not sound and the symptom and infection case was not made for this room. The project record reads: ventilation compliant, carbon dioxide 1,290 ppm, no action, reason stated. That is what an honest specification looks like when the evidence does not support the intervention one would have preferred to sell.**

12.8.3 8.3 A thirteen-member council: geometry against deference

The system. A research institute's standing scientific council: thirteen members from nine specialisms plus four cross-cutting roles, meeting monthly around a 4.2 x 1.4 m rectangular table with a chair position at one end, in a 7.0 x 6.0 x 3.0 m room with a hard plastered finish and a ceiling-mounted fan-coil unit. Surveyed: `Q_0 = 9.0` as a normalised count of live council-originated policies, standards and allocation rules still in force and actually used; `N = 13` distinct positions verified non-redundant, `ln 13 = 2.5649`; `eta = 0.50` from attributable durable structure over three years; `delta = 0.08` per month; `phi` tallied at 0.45.

Survey. *Centrality:* thirteen seats, six per long side and one at the chair's end, all 0.6 m out from the edge, give `V = [4,4,5,5,6,6,6,5,5,5,5,10]`, mean 5.538, **variance 2.095 at 45 degrees. The chair sees ten of the other twelve within a comfortable head turn; the two seats at the far end of the long sides see four.** *Acoustics:* across-table distance 2.6 m, working long-diagonal path 4.4 m, measured reverberation at 500 Hz **1.4 s**, measured background with the fan-coil running **42 dBA**. A normal voice delivers `60 − 20 log10(4.4) = 47.1 dBA` at that range, so 15 dB of signal-to-noise requires a background of **32.1 dBA: the room is 10 dB over budget on its long path.** *Addressee count:* over three sessions, **61 per cent** of contributions were directed at the chair rather than at the table. *Turn-taking, with consent over three sessions:* chair 34 per cent of speaking time, two senior members 13 per cent each, three members at or near zero, giving `N_speak = 6.9` against `n = 13`, so **`N_speak/n = 0.53`, below the D14 floor of 0.7.** *Alignment:* two scaled items per session over four sessions give a mean `V_post/V_pre = 0.14`, and in structured follow-up members could name a specific argument in 3 of the 8 items, so the unattributed fraction is `f = 5/8 = 0.625`:

```
a_max = sqrt(1 − 0.14)             = 0.927
a_min = sqrt(0.625 x (1 − 0.14))   = 0.733     working estimate a = 0.83, interval [0.73, 0.93]
```

Parameters before.

```
n = 13,  a = 0.83   ->   u = 1 − 0.83^4 = 0.5254
N_eff = 1 + 12(0.5254) = 7.305        S = ln 7.305 = 1.9886
eta ln n = 0.50 x 2.5649 = 1.2825     eta S = 0.9943      delta Q = 0.08 x 9.0 = 0.7200
C = 0.45 x 1.2825 = 0.5771
h     = 1.2825 − 0.7200 − 0.5771 = −0.0146
Q_inf = (0.9943 − 0.5771) / 0.08 = 5.21
```

At the interval's ends the steady state runs from **6.88** at `a = 0.73` down to **1.49** at `a = 0.93`, **and every one of those is below the current stock of 9.0. Headroom is negative: this council cannot grow stored order in any month, by any decision it takes, and it is losing what its predecessors built.** The break-even alignment is `a_crit = 0.9513`, so **the working estimate of 0.83 sits below it and the council is not yet net-destructive — but the interval's upper end, 0.93, is within 0.02 of it. Report the interval. A point estimate here would be the most misleading number in the survey.**

Intervention. Nothing changes the membership, the terms of reference, or the agenda. (1) A thirteen-sided ring table: `D = 13 x 0.70/pi = 2.90 m`, working depth 0.60 m, inner void 1.70 m, footprint 4.33 m^2; **centrality variance 0.00 at 30, 45 and 60 degrees**, every member seeing six of the other twelve within a 45-degree turn. (2) Room: table plus 1.2 m clear circulation needs a **5.30 m** clear diameter, so 5.3 x 5.3 x 3.0 m, `V` = 84.3 m^3, `S` = 119.8 m^2; for a 0.5 s reverberation the required absorption is `A = 0.161 x 84.3/0.5 = 27.1 m^2` sabins, a mean coefficient of 0.227, achieved with an absorbent ceiling raft plus about 8 m^2 of wall panel, **with the thirteen occupied seats contributing 5.85 m^2 of it unaided**; the fan-coil is replaced with a low-noise unit and attenuators, giving a measured background of **34 dBA against a budget of `60 − 20 log10(2.90) − 15 = 35.8 dBA`.** (3) No reserved position and no nameplates; seats drawn each session. (4) Silent-write-first and the cascade test on every substantive item, with `V_pre` and `V_post` in the minute. (5) Round-robin, randomised order, unconditional pass, with

lowest-to-highest ordering where rank is present. (6) Turn-taking measured quarterly with consent. (7) A minority record available to every member without permission and without a second.

Parameters after, re-measured over four sessions.

```
addressee count:  61% to the chair  ->  24%
V_post / V_pre:   0.14              ->  0.52, argument nameable in 7 of 8 items, so f = 0.125
alignment a:      [0.73, 0.93]      ->  a_max = sqrt(0.48) = 0.693
                  mid 0.83              a_min = sqrt(0.125 x 0.48) = 0.245     mid 0.47
N_speak:          6.9  (0.53 n)     ->  10.8   (0.83 n, above the D14 floor)
phi:              0.45              ->  0.38   (fewer repeat items, fewer reopened decisions)

a = 0.47  ->  u = 1 - 0.47^4 = 0.9512
N_eff = 1 + 12(0.9512) = 12.414     S = ln 12.414 = 2.5189
eta S = 1.2594        C = 0.38 x 1.2825 = 0.4873       delta Q = 0.7200
h     = 1.2825 - 0.7200 - 0.4873 = +0.0751
Q_inf = (1.2594 - 0.4873) / 0.08 = 9.65
```

At the interval's ends the steady state runs from **9.92** at `a = 0.245` to **8.44** at `a = 0.693` — **the whole interval now sits at or near the council's current holdings, where before the whole interval sat below them. Headroom crosses from `-0.0146` to `+0.0751` and the sustainable stored order rises from 5.21 to 9.65: the council stops losing what it inherited.**

Note what did not happen. The category count is still 13, conversion still 0.50, decay still 0.08. **The entire gain came from non-parallelism — 0.525 to 0.951 — plus a modest fall in cost, and non-parallelism moved because the furniture and the protocols stopped rotating everyone's contribution toward one seat.** The framework prices crossing and divergence identically at the margin [Curzi, 2026d], so **this is a gain bought by removing a rotation rather than by recruiting difference, and it is available to any assembly that already has the difference in the room.**

The transient, and the reading that is easiest to miss. Time constant `1/delta = 12.5` months, 95 per cent settling at about 38 months. With `Q_0 = 9.0` and `Q_inf = 9.65`, **the stored order barely moves — it was already near the new steady state, having been on its way down toward 5.21. The visible effect of this intervention is a decline that does not happen.** A council measuring only its stock will see a near-flat line and conclude nothing was achieved; **what was achieved is the difference between that flat line and a decay toward 5.21, which over three years is a large number that appears in no record. Measure the inputs** — addressee count, variance ratio, effective speakers, background noise — **all of which moved immediately, all of which are cheap, and all of which are the drive rather than the state.**

What would falsify it. (1) `N_speak/n` below 0.7 at two consecutive measured sessions: the protocols have failed and the geometry did not carry them. (2) **The alignment interval stays above 0.80 after four sessions: the deference is not geometric in origin — it is contractual, or it is about funding — and no table fixes it. Say so and stop, rather than buying more furniture.** (3) Non-parallelism rises but the stock continues to decline through month 24: either conversion is lower than measured or decay is higher, and non-parallelism was never the binding constraint. (4) **The matched control:** a comparable committee in the same institute over the same period, given a refurbished room of equal cost and disruption but a rectangular table with a chair position retained and no protocol change. **If its non-parallelism and effective-speaker count rise comparably, the mechanism claimed here is not the mechanism operating, and the effect belongs to attention rather than to geometry.**

The honest ledger. Demonstrated within the model: an intervention touching only the geometry and the speaking protocols moved non-parallelism from 0.525 to 0.951, took headroom from `-0.0146` to `+0.0751`, and raised the sustainable stored order from 5.21 to 9.65 — a factor of 1.85 — with no change of membership. **Not demonstrated, and each is a real limit.** *(i)* **Alignment is a modelled quantity, not an observed one:** the postulate supplies its form, the protocol supplies an interval rather than a point, and **the interval's lower end rests on**

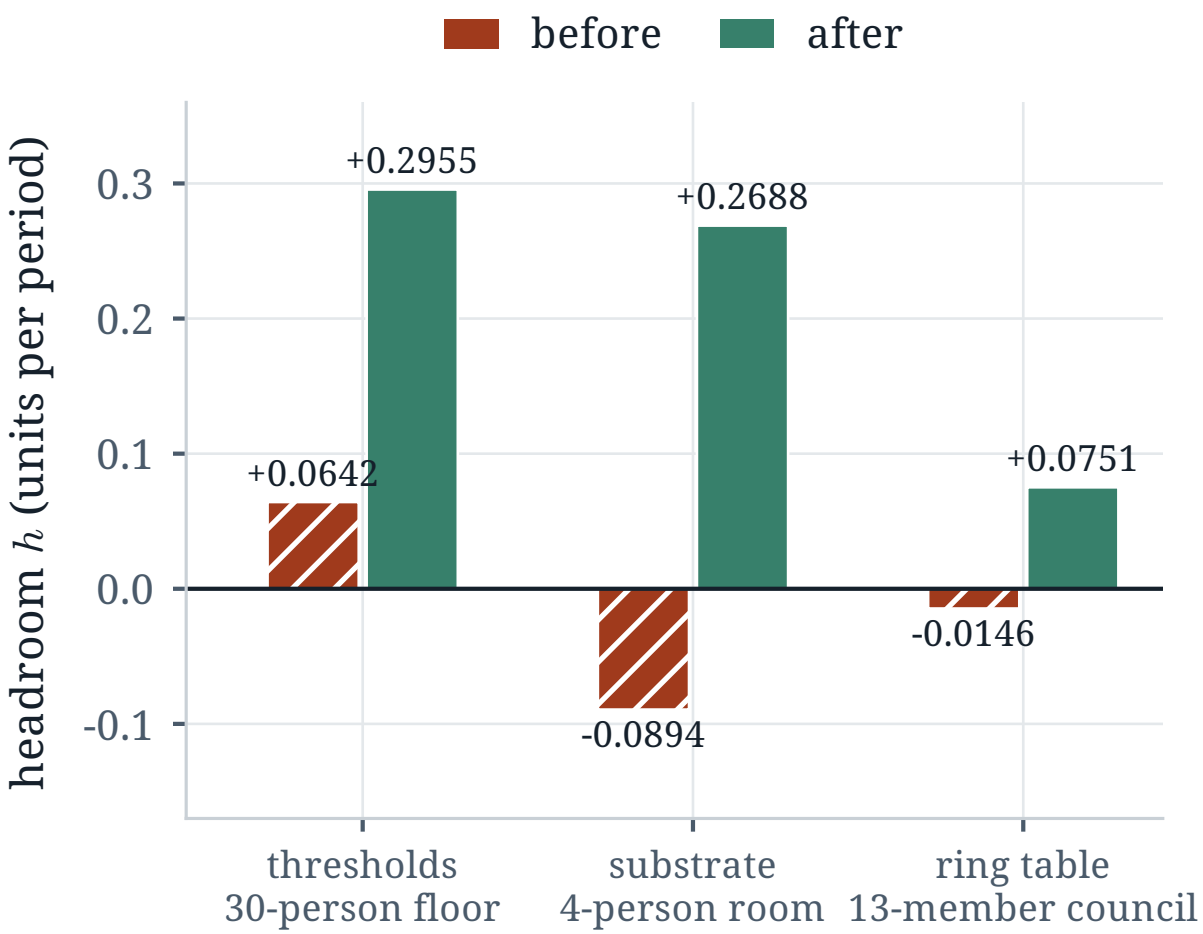

Figure 12.5: **Three levers, three systems, one gauge.** Headroom `h = eta ln N − delta Q − C` before and after each intervention: thresholds on a 30-person floor, substrate in a four-person workroom, a ring table for a thirteen-member council. Modelled — every parameter in all three cases is surveyed or stipulated for that one system, the cost calibration was declared rather than derived, and no figure carries an interval. Generated by `figs/src/CCP-012_fig05.py`.

attributing unexplained convergence to deference, which is a judgement made by the people being measured. The intervals here are wide — `[0.73, 0.93]` before and `[0.25, 0.69]` after — **and they are reported wide rather than narrowed by assumption.** *(ii)* The calibration was chosen and declared, not derived. *(iii)* `N_speak` is a diversity index and not a surplus. *(iv)* The collective-intelligence correlate was measured on short laboratory tasks and its transfer to a monthly standing council is an assumption. *(v)* **Geometry shifts the cost of dominance; it does not forbid it.** If this chair chooses to take 34 per cent of the floor at the round table too, the round table will have failed, **and the measurement is what will say so.**

And one requirement was met only just. D7 is satisfied for the across-table path at 2.90 m — **34 dBA measured against a 35.8 dBA budget, a 1.8 dB margin.** A single additional noise source in that room, a laptop fan or an unattenuated diffuser, puts it over. The project record reads: *D7 met, margin 1.8 dB, no further noise sources permitted in this room without re-measurement.* **A margin that thin is a finding, not a pass.**

12.9 9 Discussion

12.9.1 9.1 What follows

Cost is the cheapest term to move and the least often measured. In all three cases the binding constraint was cost, in none was it the category count, and in two of the three the geometric levers the framework is named for were already near exhaustion — the research floor was running at 88.6 per cent of its own ceiling. **A survey that measures only diversity will report that a well-diversified group has no problem, in a building that is quietly dissolving it.**

Two of the three levers change no personnel, no recruitment and no policy. Thresholds and substrate are joinery and services; the third is joinery plus six lines of meeting procedure. **That is what makes them worth pricing: they are the interventions available to somebody who cannot change the roster**, which is most people who can change anything at all.

Three of the paper's numbers are worth quoting alone. Worst-junction reflection falls from 96.1 per cent to 13.4 per cent across six graded steps, so **a threshold is a matching section and its depth is set by a duty list rather than by a door swing.** The comfort model's own floor is 5 per cent dissatisfied, so **arguing about where to set a shared thermostat is arguing about the wrong variable.** And deference is quartic, so **an assembly loses nothing to ordinary politeness and half of itself to strong alignment, with no line in the minute recording the difference.**

The convergence on table size is the section that will travel furthest and it should be read carefully. Anthropometry, direct-field speech levels and a combinatorial cost argument agree on eight to fourteen seats. **They are three calculations, not three measurements**, and two of them share the proxemic input; the agreement is real and it is weaker than three independent confirmations would be.

12.9.2 9.2 What does not follow

Nothing here shows that a room makes a group cleverer. The collective-intelligence route was tested elsewhere in this series under preregistration and the outcome did not reach threshold, while the mediator moved decisively [Curzi, 2026e]. **Every claim in this paper about turn-taking is a claim about the measured mediator: reduced listening effort, recovered access to the ceiling for members the room was excluding, and a measured rise in the effective-speaker ratio. Those are worth having on their own account and require no causal claim, and a reader who takes away "treat the room and the committee gets smarter" has taken away what this paper explicitly refuses.**

Nothing here identifies a social effect. The specification is reflexive and the endogenous component is not identified from observational data [Manski, 1993]. The matched controls remove a confound and do not solve that problem.

The alignment coefficient is not a measurement. It is a modelled quantity whose estimator returns an interval, and whose lower bound depends on people reporting whether they can name what changed their mind. **An intervention evaluated on a point estimate of alignment has been evaluated on an artefact.**

The transmission-line analogy proves nothing about a corridor. Two sentences transfer and the rest does not, and the failure mode of extending it is named and catalogued.

And the variety term is not a universal good. Unbounded growth in `ln N` is a property of the model rather than of groups: Uzzi and Spiro [2005] report an inverted U in which creative success rises and then falls, and Sagan [1993] documents settings in which redundancy reduces safety. **The model's `ln N` contradicts that literature at large `N`, which is a restriction on the model's domain (Section 10.5) and not a finding.** Nor does an audited category count settle what kind of difference is being counted: separation, variety and disparity are distinct constructs travelling under one word [Harrison and Klein, 2007].

12.9.3 9.3 Relation to the surrounding literature

The design tradition supplies the configurations — entrance transition, intimacy gradient, building edge, alcove, window place [Alexander et al., 1977] — and the semilattice argument [Alexander, 1965] supplies the reason a threshold is a category decision. The proxemic bands [Hall, 1966], the edge effect [Gehl, 1971], the sittable-perimeter finding [Whyte, 1980] and the sightline-and-safety argument [Jacobs, 1961] are the empirical anchors. **What this paper adds to that tradition is a price**: the pattern literature states what to build and rarely states what it costs in the units of anything else, and Section 8 states it in floor area, in interruptions per person-day, and in stored order.

The operations literature supplies the quadratic communication count [Brooks, 1975, Conway, 1968] without pricing it against a logarithmic benefit; this paper does that pricing and finds it converging with two unrelated constraints. The collective-intelligence result supplies the correlate [Woolley et al., 2010] and the mixed replication record supplies the caution [Engel et al., 2014, Bear and Woolley, 2011]; the diversity-and-performance literature and its critics supply the standing warning that a variety-raising programme is not uniformly supported [Mannix and Neale, 2005, Thompson, 2014, van Knippenberg and Schippers, 2007, Hong and Page, 2004, Singer, 2019, Grim et al., 2019, Kuehn, 2017]. The cascade and social-information results supply the mechanism the silent-write protocol defeats [Bikhchandani et al., 1992, Banerjee, 1992, Lorenz et al., 2011].

Where the literature disagrees with the framework, it is cited and the disagreement is stated. And the logarithm itself has two warrants of which this paper needs only the weaker: the Fechnerian one requires a contested perceptual story [Fechner, 1966], while Peters and Gell-Mann [2016] derives a logarithmic evaluation from multiplicative dynamics **with no psychological premise at all.** The functional form remains underdetermined — a sub-linear power law [Latané, 1981] and `n log n` growth [Briscoe et al., 2006] fit the same qualitative facts, and **nothing assembled here discriminates between them** [Stumpf and Porter, 2012].

12.10 10 Verification

The results compound from six postulates. Each is atomic, each is checkable on its own, and each carries its status. **Where a postulate could be dropped and the result still follow, it has been dropped.**

12.10.1 10.1 Dimensional audit

Three dimensional systems meet in this paper: geometry and mechanics, heat, and the storage law's own bookkeeping. `[L]`, `[T]`, `[M]`, `[E]` and `[Theta]` are length, time, mass, energy and temperature; `[Q]` is the dimension of stored order, and the period is the unit of `[T]` in the storage law, which is why no explicit `[T^-1]` appears once that law is written in discrete steps.

Symbol	Dimension	Unit	Status
`Z_2/Z_1`, `Gamma`	`[1]`	none	**defined**: a ratio of like quantities, and its reflection coefficient
`M`, `M_bar`	`[1]`	scale points	**measured**, and **ordinal** — see Section 10.8
`P/A` (edge density)	`[L^-1]`	m per m^2	**derived**: perimeter over area
`d`, `w`, `D`, `s`, `r`	`[L]`	m	**measured** or **specified**

Symbol	Dimension	Unit	Status
`1 + d/w`	`[1]`	none	**derived**: a ratio of two lengths
`v`	`[L T^-1]`	m/s	**measured**
`a` (deceleration)	`[L T^-2]`	m/s^2	**specified**; `d = v^2/2a` returns `[L]` and `t = v/a` returns `[T]`
`k` (switch count)	`[T^-1]`	per person per day	**measured**
`m` (resumption lag)	`[T]`	min	**measured**, with a long right tail
`C_switch = k m`	`[1]`	fraction of a day	**derived**: `[T^-1][T]`, dimensionless — see below
PMV, PPD	`[1]`	index, per cent	**derived** from the comfort model
`sigma`, `A` (authority)	`[Theta]`	K	**assumed** and **specified** respectively
`alpha = k/(rho c)`	`[L^2 T^-1]`	m^2/s	**derived** thermal diffusivity
penetration depth `sqrt(alpha P/pi)`	`[L]`	m	**derived**: `sqrt([L^2 T^-1][T])`
`rho c`	`[E L^-3 Theta^-1]`	MJ/m^3 K	**measured**
effusivity `e = sqrt(k rho c)`	`[E L^-2 Theta^-1 T^-1/2]`	J/m^2 K s^(1/2)	**derived**; the contact-temperature formula is a weighted mean of temperatures and returns `[Theta]`
`RT60`, `A` (absorption)	`[T]`, `[L^2]`	s, m^2 sabins	**measured/derived**; `0.161 V/A` returns `[T]` [Curzi, 2026e]
`psi`, `phi` (angles)	`[1]`	degrees	**derived** from the plan
`V_i`, `Var(V_i)`	`[1]`	count, count^2	**derived** from a layout with a protractor
`a` (alignment)	`[1]`	none	**modelled**, not observed; estimated as an interval
`u`, `N_eff`, `S`	`[1]`	none, count, nats	**defined**, **defined**, **derived**
`N_speak`	`[1]`	count-equivalent	**derived**: `exp` of an entropy in nats
`Q_t`	`[Q]`	proxy units	**measured** in whatever the declared proxy counts
`delta`	`[1]`	per period	**measured** dimensionless fraction per step
`C_t`, `h_t`	`[Q]` per step	proxy units per period	**measured**, **derived**
`eta`	`[Q]` per nat per step	proxy units per nat per period	**required by the balance**; see below
`phi`	`[1]`	fraction of the ceiling	**declared calibration**, `C/(eta ln N)`

Does each equation balance? *The reflection coefficient* is a ratio of like quantities divided by a sum of like quantities and is therefore dimensionless in any medium, which is precisely why the analogy has anything to transfer: **the arithmetic never sees what `Z` is made of.** *The crenellation and edge results* are pure geometry. *Deceleration:* `v^2/2a` gives `[L^2 T^-2]/[L T^-2] = [L]`. *Thermal:* `sqrt(alpha P/pi)` gives `sqrt([L^2 T^-1][T]) = [L]`, and the contact temperature is a weighted mean of two temperatures with effusivity weights, so it returns `[Theta]` for any consistent effusivity unit — **which is why the table's contact temperatures are unaffected by the choice of effusivity unit but its `e` column is not comparable with any other source's unless that source's convention is checked.** *The storage law:* `Q_{t+1} = (1-delta)Q_t + eta S_t - C_t` balances only if every right-hand term carries `[Q]`; the first does since `delta` is dimensionless, the third by construction, and the second **only if `eta` carries `[Q]` per nat per step**, since `S_t` is a dimensionless count in nats.

The source is silent on `eta`'s dimension and the silence is not neutral. The manuscript this paper converts states that `eta` has units of stored order over surplus and that, surplus being dimensionless, `eta` carries whatever unit the order proxy carries. **That is the `[Q]`-per-nat half and it omits the per-step half entirely.** The reading required for the law to balance is `[Q]` per nat per period; **it is stated here explicitly, and it is recorded that the source does not supply it rather than being assigned quietly.**

And one bridge in this paper is an identification rather than an arithmetic identity, which is worth printing because it is easy to miss. `C_switch = k m` is dimensionless — minutes lost over minutes available — while `C_t` in the law carries `[Q]` per period, and the two are joined by setting `phi = C_switch + phi_other` and then `C = phi eta ln N`. **`C_switch` is a fraction of a day and `phi` is a fraction of a ceiling. They are both pure numbers, and that is not the same as being the same number.** The step asserts that the share of available time lost to switching equals the share of the ceiling consumed by that switching, which holds only if stored-order production is proportional to available working time at a rate that does not itself depend on interruption. **That is a modelling assumption, it is used in Section 8.1's headline figures, and it is not defended anywhere in this paper.**

Where a quantity has no operational unit, it is said here. Stored order has no natural unit: it is counted in whatever the declared proxy counts, so two systems' values are not comparable unless they declare the same proxy, **and consequently `eta`, `C` and `h` are not comparable across systems either.** The mismatch index is scale points on an eight-attribute ordinal rating. The alignment coefficient has no unit and **no direct observation at all**. And comfort itself, the underlying construct of the corpus, **has no operational unit whatever**; it is treated as a dimensionless magnitude by stipulation, not by measurement.

12.10.2 10.2 The postulates

P1 — On a transmission line, `Gamma = (Z_2 - Z_1)/(Z_2 + Z_1)` and reflected power is `|Gamma|^2`. *Status:* **CITED** — standard transmission-line theory, used here only for the two structural facts of Section 4.2.

P2 — A built threshold behaves qualitatively like a matching section: crossing cost rises with the ratio of the two zones' characters and falls when intermediate zones are inserted. *Status:* **POSTULATED** — an analogy with no theorem behind it. **It is the load-bearing assumption of Section 4 and nothing in this paper measures whether it holds.**

P3 — Given free choice, occupants select perimeter and interior-edge positions before open-field positions. *Status:* **CITED** — an empirical regularity reported from systematic observation [Gehl, 1971, Whyte, 1980], **not a theorem**, and directly checkable in one building.

P4 — Individual thermal preference is dispersed, and one environmental state cannot sit at every individual optimum. *Status:* **CITED** by the comfort model's own output, which predicts 5 per cent dissatisfied at its theoretical optimum. **The distributional model used to price it — normally distributed preferences with a `+/-1 K` acceptance band — is POSTULATED, and its dispersion is an assumed parameter.**

P5 — Deference acts as a rotation of each contribution toward the chair's by a common coefficient: `v_i = a h + sqrt(1-a^2) w_i`. *Status:* **POSTULATED** — this framework's own modelling choice, with no external support of any kind. **It is the only source of the quartic result, and every number in Sections 6.1 and 8.3 consumes it.**

P6 — The number of other seats within a comfortable head turn is a determinant of the share of a member's contributions that reach the assembly as contributions rather than as asides. *Status:* **POSTULATED**, consistent with the turn-taking literature and with direct observation, and defined in Section 6.3 so that it can be computed from a layout and correlated against measured speaking share.

The claim that a material improving with wear has a lower appearance-decay rate is **not** in this list, because no result in the chain consumes it: it is an interpretation attached to a life-cycle-cost shape, and it is badged wherever it appears.

12.10.3 10.3 The compounding chain

P1	-> L1	reflection depends on the RATIO of the two impedances, so a step 1->2 and a step 500->1000 reflect identically.	CITED
L1	-> R1	dividing a total ratio r into n equal-ratio steps gives per-junction Gamma = (r^(1/n) - 1)/(r^(1/n) + 1); at r = 100, worst-junction reflected power falls 96.1% -> 13.4% from n = 1 to n = 6.	ARITHMETIC
R1 + P2	-> R1'	a graded threshold reduces per-crossing cost, so a character change of M points requires at least M-1 intermediate zones (Rule T-A).	POSTULATED (P2)
(geometry)	-> R6	an interior island contributes its full perimeter and consumes only its footprint, so edge yield per m^2 consumed rises as islands get thinner: six 0.9 x 2.4 m islands add 99% of a 10 x 10 m room's edge for 13% of its floor, against 40% for 16% from one 4 x 4 m island.	ARITHMETIC
R6 + P3	-> R6'	manufactured edge is occupiable amenity, so edge yield is a design objective rather than a curiosity.	CITED (P3)
P4	-> R3	at the comfort model's optimum, PPD = 5.0% by construction; and with preferences N(mu, sigma^2) and a +/-1 K acceptance band, a fixed setpoint satisfies 2*Phi(1/sigma) - 1 while +/-A K of personal authority satisfies 2*Phi((1+A)/sigma) - 1; at sigma = 2.0 that is 38.3% against 86.6% at A = 2.	ARITHMETIC given P4
P5	-> R4	v_i . v_j = a^2, so u = 1 - a^4 and N_eff = 1 + (n-1)(1 - a^4); an n = 12 assembly retains 97.6% of ln 12 at a = 0.5, 63.0% at a = 0.9 and 44.8% at a = 0.95.	ARITHMETIC given P5
R4 + storage law	-> R5	setting eta S = C gives S_crit = C/eta, hence u_crit = (e^(C/eta) - 1)/(n-1) and a_crit = (1 - u_crit)^(1/4); for the worked council a_crit = 0.9513.	ARITHMETIC

P6 + geometry -> R7	at a rotationally symmetric layout Var(V_i) = 0 at every threshold; at an 18-place rectangle it is 9.06 at 45 deg, with the head seats at V = 15 and the far long-side seats at V = 5.	ARITHMETIC given P6
(geometry, acoustics, combinatorics) -> R8	proxemic, direct-field acoustic and combinatorial-cost constraints independently bound the seat count at n <= 13, n <= 13-16 and n* = 7-14 respectively.	ARITHMETIC
R1' + R3 + R4 + storage law -> R2	applied to three worked systems, headroom moves +0.0642 -> +0.2955, -0.0894 -> +0.2688 and -0.0146 -> +0.0751 respectively.	ARITHMETIC given stipulated parameters

Every line is checkable from its own inputs. R1, R3, R4, R5, R6, R7 and R8 are arithmetic consequences of one cited physical result, one cited comfort-model output, elementary geometry, and two postulates. R1' consumes P2 and R4 consumes P5, and those two postulates carry the whole sociological content of the paper: P2 has no theorem behind it and P5 has no external support of any kind. If a built threshold does not behave like a matching section, Section 4 describes an analogy and not a mechanism; if deference is not a common rotation, Section 6's quartic is an artefact of the model and its numbers move.

What this chain does not establish. It does not establish that any organisation obeys the storage law — that is a modelling postulate whose one preregistered confirmatory test in this corpus **failed its second falsification rule, returning a 2.8 per cent held-out advantage over a matched baseline against a declared margin of 10 per cent** [Curzi, 2026i]. It does not establish the causal step from turn-taking to group performance, which was preregistered, tested and not confirmed [Curzi, 2026e]. **A chain whose steps are ARITHMETIC, CITED and POSTULATED delivers the geometry and the physics with certainty and delivers nothing whatever about institutions.**

12.10.4 10.4 The checks a reviewer can redo in a minute

The taper. `100^(1/6) = 2.15443`, so `Gamma = 1.15443/3.15443 = 0.365974` and `Gamma^2 = 0.133937`: **13.4 per cent, against `99/101 = 0.980198` and `0.960788` — 96.1 per cent — at a single junction.** And the geometric-mean check: at `Z_t = 10`, both junctions give `9/11 = 0.818182`, **identical, which is what makes the geometric mean the equalising value.** ARITHMETIC.

Edge yield. Six islands of 0.9 x 2.4 m have perimeter `2(0.9+2.4) = 6.6 m` each, so `6 x 6.6 = 39.6 m` against a base perimeter of 40 m: **+99.0 per cent.** Footprint `6 x 0.9 x 2.4 = 12.96 m^2`, **13.0 per cent of 100 m^2**, and `39.6/12.96 = 3.06` metres of edge per square metre consumed, **against `16/16 = 1.00` for a single 4 x 4 m island.** ARITHMETIC.

The switching cost. `22 x 7 = 154` minutes of 480 is `0.32083`; `6 x 7 = 42` of 480 is `0.08750`. **0.321 and 0.087.** The saving is 112 min/day = 1.867 h, and `30 x 220 x 1.867 = 12,320` person-hours. ARITHMETIC.

The comfort floor. At PMV = 0, `PPD = 100 - 95 exp(0) = 5.0`. At PMV = 1, `0.03353 + 0.2179 = 0.25143`, `exp(-0.25143) = 0.777697`, `95 x 0.777697 = 73.88`, so `PPD = 26.1`. ARITHMETIC.

The adjustability arithmetic. With `sigma = 2.0` and a `+/-1 K` band, satisfaction is `2 Phi(0.5) - 1 = 2(0.691462) - 1 = 0.382925`: **38.3 per cent.** With `A = 2` the band is `+/-3 K`, so `2 Phi(1.5) - 1 = 2(0.933193) - 1 = 0.866386`: **86.6 per cent.** ARITHMETIC.

Sabine on the hard workroom. `0.161 x 121.8 = 19.6098`; `19.6098/4.44 = 4.4166 s`. **The source records 4.41 s; the quotient rounds to 4.42 and is corrected in Section 5.5.** Treated: `19.6098/38.64 = 0.50750 s`, **0.51 s.** ARITHMETIC.

The thermal-mass storage. `2300 x 880 x 0.152 = 307,648` J per m^2 per K, **308 kJ**; over 100 m^2 and a 3 K swing, `307,648 x 100 x 3 = 92.29` MJ `= 25.6` kWh. And the penetration depth: `alpha = 1.7/(2300 x 880) = 8.399 x 10^−7, sqrt(8.399e−7 x 86400/pi) = 0.1520 m`, **152 mm.** ARITHMETIC.

The contact temperature. Cork: `(1200 x 33 + 104 x 20)/(1200 + 104) = 41,680/1,304 = 31.96 C`. Aluminium: `(1200 x 33 + 22,045 x 20)/(1200 + 22,045) = 480,500/23,245 = 20.67 C`. **Eleven degrees at the skin.** ARITHMETIC.

The deference quartic. `0.9^4 = 0.6561`, so `u = 0.3439` and `N_eff = 1 + 11(0.3439) = 4.7829`; `ln 4.7829 = 1.565040` and `ln 12 = 2.484907`, giving `0.62981`: **63.0 per cent.** At `a = 0.5`, `0.5^4 = 0.0625`, `N_eff = 11.3125`, `ln 11.3125 = 2.425913`, ratio `0.97626`: **97.6 per cent.** ARITHMETIC.

The break-even alignment. `S_crit = 0.5771/0.50 = 1.15420`; `e^1.15420 = 3.17168`; `u_crit = 2.17168/12 = 0.180973`; `(1 − 0.180973)^(1/4) = 0.819027^(0.25) = 0.951275`: **0.9513.** ARITHMETIC.

The centrality variance. For `V = [4,4,5,5,6,6,6,6,5,5,5,5,10]`, the sum is 72 and the mean is `72/13 = 5.53846`; squared deviations sum to `2(2.3669) + 6(0.28994) + 4(0.21302) + 19.9112 = 27.2308`, so the variance is `27.2308/13 = 2.0947`: **2.095.** ARITHMETIC.

The head-turn geometry. At 13 seats the neighbour separation is `360/13 = 27.6923` degrees, so `psi = 90 − 13.846 = 76.15` degrees: **76.2, a torso turn.** The opposite member is at 180 degrees and `psi = 0`. ARITHMETIC.

The table diameter. `D = 13 x 0.70/pi = 9.1/3.14159 = 2.8966 m`, **2.90 m**, and the seat bound `pi(2.90)/0.70 = 13.01`. The Winchester table: `18 ft = 5.4864 m`, `pi D = 17.2354 m`, `17.2354/25 = 0.68942 m` per place. ARITHMETIC.

The acoustic budget. `60 − 20 log10(2.90) = 60 − 9.2480 = 50.75` dBA, so a 15 dB signal-to-noise ratio needs **35.8 dBA**; at 4.4 m, `60 − 12.8691 = 47.13` dBA and the requirement is **32.1 dBA**. ARITHMETIC.

The effective speakers. With a chair at 0.40, three silent and eight sharing 0.60 at 0.075 each, `H = −0.4 ln 0.4 − 8(0.075 ln 0.075) = 0.366516 + 1.554162 = 1.920678` and `exp(1.920678) = 6.826`: **6.83 effective speakers out of twelve.** ARITHMETIC.

The three headroom chains. `0.45 x ln 9 = 0.988749`; `0.988749 − 0.36 − 0.5646 = +0.064149`, and `0.988749 − 0.36 − 0.3332 = +0.295549`. `0.28 x ln 6 = 0.501694`; `0.501694 − 0.28 − 0.31105 = −0.089356`, and `0.44 x ln 6 = 0.788376`; `0.788376 − 0.22 − 0.299583 = +0.268793`. `0.50 x ln 13 = 1.282474`; `1.282474 − 0.72 − 0.577113 = −0.014639`, and `1.282474 − 0.72 − 0.487340 = +0.075134`. **All three reproduce to four decimal places.** ARITHMETIC.

12.10.5 10.5 Limits, asymptotics, and the model's valid domain

`M -> 0` (zones of identical character). The mismatch index is zero, the taper arithmetic is vacuous and no device is required. **A building of uniform character needs no thresholds and has no intimacy gradient — which is exactly the open-plan condition, and is why removing all internal thresholds in the name of collaboration is a recognised failure mode (FT6).**

`M -> 5` with a single junction. Reflection approaches its maximum and the transition approaches a wall. **The model has no term for a person who simply does not enter, so the arithmetic under-reports the cost of a severe mismatch**, and the barrier analysis is where the missing term lives [Curzi, 2026p].

`n -> infinity` intermediate zones. Worst-junction reflection tends to zero and the tapered transition becomes ideal — **and the built version becomes an infinitely long corridor.** The arithmetic has no depth cost and the building does: **the domain restriction is the entrance-area budget of 4 to 9 per cent of served net floor, and past it the transition consumes the thing it was protecting.**

`d/w -> infinity` and island thinness `-> 0`. Edge multiplies without bound. **Taken literally, a room can have unlimited occupiable perimeter, and it cannot:** the clearance floor of about 0.9 m between islands and the seating floor on recess depth bound it, **and below those floors the**

added perimeter is texture rather than amenity. This is the same divergence the crenellation result carries, restricted by the same kind of absolute-scale rule [Curzi, 2026e].

`k -> 0` or `m -> 0`. The switching cost vanishes, which the model permits and no organisation achieves; the residual cost terms — meeting overhead, tooling friction, compliance — are what remain, and in the worked floor they are 0.25 of the ceiling, **so the switching lever cannot take cost below that floor no matter how good the thresholds are.** **`k m -> 480 min`** consumes the entire working day; the model reports fractions above 1 for `k m > 480`, **which is outside its domain and means only that the interruptions overlap.**

`sigma -> 0` (identical preferences). A fixed setpoint satisfies everyone within the model, and personal authority buys nothing. **That is the regime in which optimisation is the right answer, and it is a limit rather than a case: measured dispersions in the literature are in the 1.5–2.5 K region, and Section 5.3's argument is conditional on that.** **`sigma -> infinity`.** Everyone is dissatisfied under any single setpoint and satisfaction under personal authority `A` tends to zero as well, since the acceptance band is finite. **Adjustability is not a solution to unlimited dispersion, only to ordinary dispersion.**

`A -> infinity` (unlimited personal authority). Satisfaction tends to 100 per cent, **which is false**: the channels are bounded by energy, by spillover onto neighbours, and by the fact that a personal control that changes a shared variable is a shared control. **The stated domain is `A <= 3 K` with personal-in-effect channels only.**

`a -> 0` (no deference). `u -> 1`, the effective count reaches `n`, and the assembly attains its ceiling. **`a -> 1` (perfect deference).** `u -> 0`, the effective count collapses to 1, and surplus is `ln 1 = 0`; the steady state becomes `Q_inf = -c/delta`, **in which neither the conversion coefficient nor the category count appears — two of the four levers have exactly zero derivative** [Curzi, 2026]. **That is the limit that makes deference worth treating as a separate lever: in it, every other lever is disconnected.**

`n -> 1`. `ln n = 0` and there is no assembly. **`n -> infinity`.** `eta ln n` grows without bound, so the model says a sufficiently large committee makes any cost sustainable, **and that is false.** Three things bound it and **all three are domain restrictions rather than results.** *Internal:* the three sizing constraints of Section 6.4 bind at 13 to 16 seats. *External and contrary:* Uzzi and Spiro [2005] report an inverted U rather than unbounded growth, and Sagan [1993] documents settings in which redundancy reduces safety. *Marginal:* `ln n - ln(n-1) ~ 1/n` vanishes, **so the divergence is the slowest available route to anything. The stated domain is `n` bounded above by the sizing constraints, and the logarithmic ceiling is a within-domain bound rather than an asymptotic claim.**

`delta -> 0`. The fixed point disappears, the stock accumulates without bound, and the model leaves its domain; **`delta -> 1`** makes the time constant vanish and the system stops being a stock. **The stated domain is `delta` in `(0, 0.5]` per period.**

Stated domain. The results are valid for mismatch indices on the declared eight-attribute ordinal scale, thresholds with `d >= 2.0 m` where a stop is expected, island clearances at or above 0.9 m, `k m < 480` min/day, thermal dispersions in `[1.0, 2.5]` K with personal authority at or below 3 K, alignment coefficients in `[0,1]`, seat counts in `[6, 16]`, `delta` in `(0, 0.5]`, and `phi` in `[0,1]`. **Outside that domain the equations still evaluate and should not be interpreted.**

12.10.6 10.6 Invariance

The reflection coefficient is invariant under a common rescaling of both impedances. Multiply `Z_1` and `Z_2` by any positive constant and `Gamma` is unchanged, **which is the whole content of Fact 1 and the reason the analogy transfers at all: the coefficient never sees the absolute character of either zone.** What would break it: any use of the *difference* of the two characters instead of their ratio, **which is exactly what the mismatch index `M` computes.** `M` is therefore NOT the invariant quantity the analogy licenses — **it is an ordinal proxy for the ratio, adopted for usability, and this substitution is unjustified within the analogy and is stated here rather than hidden.**
