Out-of-sample rather than in-sample performance	**NOT APPLICABLE.** Nothing is fitted; there is no sample and no holdout.
A matched null with the same free-parameter count	**NOT APPLICABLE** for the same reason. The nearest analogue actually run is the attenuation-exponent sweep of Section 5.4, which is a sensitivity analysis rather than a model comparison.
The number of free parameters stated explicitly	**MET.** The capacity model has two inputs (`B`, `S/N`), both declared; the attenuation model has two (`alpha`, `b`); the storage-law illustration of Section 4.7 has four (`eta`, `delta`, `N`, `C`), **all four assumed and none fitted.**
An information criterion, so the parameter count is paid for	**NOT MET.** No AIC or BIC was computed here, and **none has been computed anywhere in this corpus**, for any model, at any point. Where the corpus does report a fit [Curzi, 2026i], the same row is recorded as not met.
Effect sizes with intervals, not only p-values	**NOT MET, and no p-value is reported anywhere in this paper.** Every figure is a point value with no interval, **because an interval on a nominal constant would be false precision.** The honest substitutes are the sensitivity sweep of Section 5.4 and the full capacity table of Section 5.7, which are reported as ranges and not as confidence statements.

The two unmet rows change how the paper should be read. Because no information criterion was computed, the three-parameter attenuation model with a free exponent has not been shown to be *better* than the two-parameter nominal law in any formal sense — **it has been shown to be more realistic on grounds external to the numbers, namely published tissue measurements, and that is an argument from physics rather than from model selection.** And because no interval accompanies any figure, **every number in this paper should be read as an order-of-magnitude statement with the nominal constants stated, which is exactly how Section 3.3 frames them.**

30.12 12 Limitations

L-1. The entire biological evidence base of this paper is uncited. The corpus's bibliography has no cluster for molecular and cell biology, so mechanically gated channels, cochlear transduction, force-to-transcription coupling, mechanosensitive transcriptional regulators, substrate-stiffness effects, sonogenetics, nucleotide data storage, guide specificity, self-processing arrays, motif dependence, catalytically dead nucleases, compact effectors and mitochondrial base editing are **all named in the text with journal, volume and year and carry no citation keys.** Appendix A lists them. **A reviewer cannot check this paper's biology from its reference list, and that is a defect of the apparatus rather than a claim that the works do not exist.** It must be closed before submission.

L-2. A bibliographic mis-citation was found in the source and is corrected rather than propagated. The source attributes the thermal-noise floor to "Nyquist (1928)"; the corpus's Nyquist 1928 entry is the telegraph-transmission paper, not the thermal-agitation paper. **Attaching the available key would have been a mis-citation**, so the thermal floor is attributed

here to the fluctuation–dissipation theorem [Callen and Welton, 1951] and Nyquist's thermal paper is named in Appendix A without a key.

L-3. Every physical constant here is nominal and none was measured for this paper. Sound speed, density, attenuation and its exponent, cell diameter, cell density, channel time constants, direct-repeat and spacer lengths, protein residue counts, eardrum and footplate areas, and gating-spring stiffness are conventional round figures. **The conclusions are robust to the attenuation exponent in the unfavourable direction (Section 5.4) and to cell density by an order of magnitude (Section 11.2), and they are not robust to the receiver time constant, which moves the capacity by two orders of magnitude across the table.**

L-4. The aperture noise model is used outside its regime and the paper cannot repair it. `p_rms = sqrt(4 kT rho c B / A)` assumes `k a >> 1`; at cellular scale `k a << 1`. **A rigorous treatment requires the fluctuation–dissipation theorem applied to the actual mechanical impedance of a cell, which this paper does not have.** Two estimates are carried instead of one, and the honest statement is that the cellular noise floor is not established here.

L-5. The capacity result rests on identifying "the receiver's bandwidth" with a single corner frequency. A real transducer chain has several stages with different kinetics, an input-dependent response and, in the case of the channel concerned, an inactivation that depends on membrane potential. **Reducing that to one pole is a modelling choice, and a multi-pole treatment would give a different — probably lower — figure.**

L-6. The storage-law reading of cellular regulatory state is a model-form claim with no instrument behind it. `Q` has no operational unit, `eta`, `delta` and `C` were chosen rather than measured, and nothing in this paper tests the reading [Curzi, 2026]. **The headroom-negative prediction of Section 4.7 is a restatement of a known observation, not evidence for it.**

L-7. The reflection problem is unanswered wherever this paper's framework touches the reflexive loop. Manski [1993] and Shalizi and Thomas [2011] bind, no remedy is adopted [Brock and Durlauf, 2001], and every framework claim resting on the loop is a modelling position rather than an identified empirical result (Section 3.6).

L-8. Scale type is licensed for the physics and stipulated for the rest. Pressure, frequency, time and energy are ratio-scale quantities with true zeros and the arithmetic on them is licensed. **`Q` is not, and the psychological constructs elsewhere in the corpus are not**: Michell [1997]'s objection applies, and the additive conjoint conditions that would license ratio-scale treatment [Luce and Tukey, 1964, Krantz et al., 1971] have not been tested for any of them.

L-8b. One figure in the source manuscript was found not to reproduce and is corrected in Section 9.4. The source labels `1.060e4` bit/s as a medium-limited capacity at 1 kHz bandwidth; it is in fact the receiver-limited capacity at `B = 1591.6` Hz, and the 1 kHz figure is 6,658 bit/s. **No conclusion depends on which of the three inflation factors is quoted, and the correction is printed rather than silently applied.**

L-9. No information criterion was computed (Section 11.7), and no figure in this paper carries an interval.

L-10. The essence-ladder material rests on a defined constant with a postulated unit. `k` is exact; the hertz attachment is a postulate; the frequencies are not physical resonances. **The standard critique of golden-section claims** [Markowsky, 1992] **is cited deliberately and the corpus's own bound on relabelling-invariant statistics** [Curzi, 2026] **applies.**

L-11. The `lambda^3` voxel convention is optimistic and the true occupancy is worse. Real focused-beam lateral resolution exceeds a wavelength, so `3.65e6` cells per voxel at 1 MHz is a lower bound on the number sharing a signal.

L-12. What would falsify the central negative claim. The claim that no mechanism demodulates sequence-specific information from an acoustic signal would be overturned by a demonstration, replicated, of a transcriptional or other cellular response that depends on the *order* of symbols in an acoustic stream and not merely on permutation-invariant functionals of the waveform such as total energy, spectral content or envelope. **That is a well-specified experiment, and specifying it is the most useful thing this paper does with its negative result** [Curzi, 2026y,?]. **Until it is run, the claim is a statement about the state of the literature and is**

labelled as one.

30.13 13 Conclusion

This paper computes the acoustic channel into a single cell and separates what the physics permits from what has been demonstrated.

Air-to-tissue intensity transmission at normal incidence is `-29.9` dB while the pressure amplitude nearly doubles; the pressure differential across a 10 µm cell is 0.0816 per cent of peak at 20 kHz and 4.08 per cent at 1 MHz; and the wavelength equals a cell diameter only at 154 MHz, where attenuation confines the field to millimetres. The product of wavelength and 20 dB depth falls from 6160 to 0.0026 mm·cm across that range, closing acoustic addressing on physical grounds rather than on capacity.

The binding term is the receiver's own bandwidth. Mechanotransduction kinetics give a corner frequency near 10.61 Hz, so Shannon capacity at 20 dB is **70.65 bit/s**, rising to 106.0 bit/s at a 10 ms constant, and **a 40-bit address takes about half a second.** That result is used to eliminate an explanation rather than to support a claim: **individually addressing the `3.65e6` cells in one voxel at 1 MHz would take 23.93 days, a per-cell exclusive rate of `1.93e-5` bit/s, so the field is intrinsically broadcast.** The Gabor limit `dt df >= 1/(4 pi)` yields an optimal symbol rate `R_max = 6.669448 B`, **cross-checked against Shannon at exactly 20.034 dB.** And **energy is not the constraint**: the Landauer bound permits `8.19e3` bit/s at one pascal.

On the addressing side, naming one genomic position costs 32.5296 bits, the T-rich motif constraint costs a further 4.4465 nats — 6.415 bits — of naming capacity, and the worked block is declared valid only at matcher tolerance `d <= 2`, where expected collisions are 0.624 against 11.47 at `d <= 3`. The governing law is that **usable specificity is set by the matcher's tolerance and not by the address's length.** And because the architecture introduces no protein and no nucleic acid into any cell, **it cannot edit a genome — cannot, not does not.**

The counter-result is the point. This paper computes a favourable number and refuses to use it. **The pipe into a cell is wide enough, which removes bandwidth from the list of explanations — and the standing line is restated in every section: a channel capacity is a statement about the channel, and no molecular apparatus is known that recovers a specified sequence from an acoustic waveform. Computing the capacity of a channel leading to a receiver does not create the receiver. Measuring a room's acoustics says nothing about whether anyone in it speaks the language.**

30.13.1 Declarations

Data and code availability

No external dataset was collected for this paper and no experiment was performed. Every number reported is arithmetic on the nominal physical constants declared in Section 3.3, on standard physical constants, or on closed-form combinatorial expressions stated in the text. The three worked specifications of Section 9 are **hypothetical proposals constructed for evaluation**; no installation was built, no acoustic link was assembled, and no address block was synthesised. **No cell, tissue, organism or person was involved at any point.** The five figures are generated by the scripts named in each caption, and those scripts contain no data beyond the numbers printed in this paper.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi performed the analysis, computed every figure in the text, specified the requirements and failure modes, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted, no animal work was performed, and no personal data was processed. **No clinical, medical, diagnostic or therapeutic claim is made anywhere in this paper, and the pressures and intensities tabulated for capacity purposes are not recommendations, exposure guidance, or safety statements of any kind.** The architecture described in Section 6 introduces no protein and no nucleic acid into any cell and therefore cannot edit a genome; that is a structural property of the design and is stated as one rather than as an undertaking. **The biological literature described here is described from published sources; none of it was replicated, extended or performed by the author.**

Preregistration

This paper reports no preregistered empirical test and none is claimed. **The falsifier for its central negative claim is stated in advance in Section 12, L-12**, and is the experiment the successor paper preregisters [Curzi, 2026y]: a replicated demonstration of a cellular response depending on the *order* of symbols in an acoustic stream, as distinct from permutation-invariant functionals of the waveform. **No such experiment was performed here, and the negative claim is a statement about the state of the literature rather than a null result.** The reason to declare the falsifier in advance rather than after the fact is the standard one [Nosek et al., 2018, Simmons et al., 2011]: **a negative claim whose refutation conditions are written down afterwards can be moved, and this one cannot.**

30.14 Appendix A Works named in the text without a bibliography key

The bibliographic database governing this corpus contains no entries for the following, and **no key has been attached to any of them anywhere in this paper.** They are listed with the details the source manuscript supplies so that a reader can locate them, and their absence is recorded as a gap in the corpus's apparatus rather than concealed (Section 3.7, limitation L-1). **Nothing in this list should be read as a citation; it is a statement of what is missing.**

Mechanotransduction and channel structure. Coste and colleagues (*Science* 330:55–60, 2010) on Piezo1 and Piezo2 as essential components of mechanically activated cation channels, and the 2021 Nobel Prize in Physiology or Medicine to David Julius and Ardem Patapoutian for discoveries of receptors for temperature and touch. Physics and engineering named without keys. Nyquist's 1928 paper on thermal agitation of electric charge in conductors — **which is a different paper from the corpus's `nyquist1928` entry, and the distinction is the subject of limitation L-2.** The Internet Protocol specifications underlying the addressing correspondence of Section 6.3. Chladni's 1787 *Entdeckungen über die Theorie des Klanges*, named in the source manuscript's concordance on boundary-selected modes.

Precedent material named without keys. Boethius, *De institutione musica* (c. 500 CE), on *musica humana*. Bhartṛhari, *Vākyapadīya* (c. 5th century), on meaning-bearing sound. The *Lüshi Chunqiu* (3rd century BCE) on the twelve *lü* pitch standards, and the associated *houqi* practice. Confucius, *Analects* XIII.3, on the rectification of names. The Alexandrian *Pinakes* of Callimachus (3rd century BCE). The Egyptian narrative of Isis and the secret name of Ra, the Kabbalistic treatment of divine names, and the Solomonic grimoire tradition's insistence on exact naming. The Roman ritual formula *sive deus sive dea*. **Every one of these is precedent, priced at one to three bits on the corpus's own scale, and none of them is evidence about anything in this paper** [Curzi, 2026w].

Chapter 31

Addressing the Non-Coding Genome: The Latency Constraint, the Missing Demodulator, and an Exact Sonification Pipeline

Abstract. We state the boundary of a genomic addressing architecture as a constraint rather than a caveat: addressing can reach only what is already latent, since an address is a pointer and a pointer with no cargo delivers nothing. The same property that makes the architecture safe (no sequence is changed) makes it limited. We impose a pairing rule on the descriptive statistics: the 98.7 per cent non-coding, 45 per cent transposable-element and 8 per cent endogenous-retroviral fractions may not be quoted without the approximately 8.2 per cent evolutionarily constrained fraction in the same paragraph. The central finding is negative and is stated as the paper's core: no known biological structure demodulates a symbol stream from an acoustic carrier into sequence-specific output, and channel capacity is not the bottleneck — 40 bits over a 16 Hz bandwidth requires only 6.68 dB of signal-to-noise — which sharpens the gap rather than softening it. A decisive experiment is preregistered at n = 21 per arm for a 1.5-fold change under genome-wide correction, and we compute that one well-powered experiment covers 1 of 2,880 conditions, 0.0347 per cent of the parameter space. The sonification chain is built and verified: an implemented run-length-limited codec achieves 1.92834 bits per base against a constrained capacity of 1.98235, with an exact SHA-256 round trip.

Keywords: non-coding DNA; sequence-specific addressing; demodulation; preregistration; DNA data storage; sonification; Gabor limit

Series: B. Engineering the Surplus **Paper:** CCP-031

31.1 1 Introduction

An address is a pointer, and a pointer with no cargo delivers nothing. This paper states that sentence as a formal constraint on a genomic addressing architecture, computes what the constraint costs, and then reports that the architecture's central biological claim has no mechanism at all.

The preceding paper in this series established that a cell is a mechanical receiver, that the acoustic channel into one has adequate capacity and catastrophic spatial resolution, and

that addressing and editing are demonstrably separable functions [Curzi, 2026x]. This paper asks what such an address could point *at*, states the boundary of the whole architecture as a constraint rather than a caveat, and specifies the experiment that would settle the open question in either direction.

The constraint comes first because everything else is bounded by it.

> **CONSTRAINT L67. Addressing can reach only what is already latent. No addressing operation, of any kind, at any signal strength, by any modality, can cause a cell to express content that its genome and its accessible regulatory repertoire do not already contain.**

That follows from the architecture rather than from any new assumption. **The property that makes the architecture safe — nothing is delivered, so nothing can be edited — is the same property that makes it limited.** A design claiming both unlimited reach and no modification would be incoherent, and this one claims neither.

A pairing rule is imposed on the descriptive statistics, and it is imposed because the figures are routinely used to do work they cannot do. The human genome is approximately 98.7 per cent non-coding, approximately 45 per cent transposable-element derived and approximately 8 per cent derived from endogenous retroviruses; **and roughly 8.2 per cent of it is under evolutionary constraint.** The first three figures may not be quoted in support of this architecture without the fourth in the same paragraph. **The figures are not in conflict — they measure different things — and presenting one without the other is advocacy rather than argument.** The counter-example that has never been answered is stated in full: an onion carries 16.0 Gbp against the human 3.10 Gbp, a lungfish 130 Gbp, and a pufferfish manages vertebrate development on 0.39 Gbp. **Any theory assigning function to bulk sequence because it is there must answer that, and none has.**

The central finding is negative and it is the paper's core rather than its caveat. No known biological structure demodulates a symbol stream from an acoustic carrier into a sequence-specific output. Demodulation of an ordered string requires three things and there is no way around any of them: **symbol discrimination (D1), order memory (D2), and a sequence-specific output mapping (D3).** D1 and D2 are hard; **D3 has no candidate implementation whatever**, because base pairing is sequence-specific precisely by virtue of a physical guide molecule, and this architecture delivers no molecule.

And capacity is emphatically not the bottleneck, which sharpens the gap rather than softening it. At a receiver bandwidth of 16 Hz, delivering a 40-bit address in one second requires `2^(40/16) - 1 = 4.657`, which is **6.68 dB** of signal-to-noise; at 5 Hz it requires 24.07 dB, and even at zero decibels and 5 Hz the address arrives in eight seconds. **The information-theoretic room exists. If the obstacle were capacity it would be a quantitative obstacle, and quantitative obstacles yield to engineering. It is not.** A radio wave carrying a symphony passes through a rock; the capacity of the path is enormous; the rock does not hear the symphony, and the missing thing is not bandwidth.

A decisive experiment is therefore specified and preregistered rather than gestured at. Its primary control is the **symbol-permuted twin** — a stimulus matched in total energy, duration, long-term power spectrum, symbol counts, envelope and crest factor, differing only in order — and **every biological response to acoustic stimulus documented in the literature is invariant under that permutation by construction.** The design needs **`n = 21` per arm** to detect a 1.5-fold change at a genome-wide-corrected `alpha = 2.5e-6`, and a single well-powered experiment covers **1 of 2,880 conditions, or 0.0347 per cent of the parameter space.** An abandonment condition is committed to in advance: a preregistered 73-condition three-stage adaptive design, at 2.53 per cent of exhaustive cost, whose null withdraws the biological claim from this corpus entirely.

The sonification chain is then built and verified. An implemented run-length-limited codec achieves **1.92834 bits per base** on the test payload — 592 bits into 307 nucleotides, 96.42 per cent of the unconstrained 2.0 — against a transfer-matrix capacity of **1.98235** bits per base for maximum run 3, **with an exact SHA-256 round trip.** A single-register pitch mapping is shown

to fail: its four symbols span 41.034 cents with a minimum adjacent gap of 2.081 cents, or 0.8725 Hz, which the Gabor limit caps at 5.5 symbols per second and which a routine 2 cm^{-1} solvent shift **reverses**. Assigning each symbol its own integer octave index `j = 33..36` raises the minimum adjacent gap to **732.037 Hz, an 839.0-fold improvement, lifting the maximum symbol rate from 5.5 to 4,599.5 symbols per second at zero cost to the tuning**, because octave transposition preserves pitch class exactly.

Three rejections are printed in full, and one of them is of the framework's own centrepiece. The framework's essence law `f(n) = k n^2` is shown, by its own theorem, to yield only `ceil(N/2) = 2` distinct pitch classes for a four-symbol alphabet — three of the four bases collide — and is **rejected in print as the alphabet tuning.** The identification of the 64 codons with the 64 hexagrams of the *I Ching* is **rejected**: `2^6` and `4^3` are different factorisations of the same cardinality, and a proposed correspondence between them is one chosen bijection out of `64! = 1.2689e89`, worth 296.0 bits of arbitrary choice. And the claim that "not junk" means "all functional" is **refused** wherever the genome fractions appear.

Sections 2 and 3 give the hypotheses and the method, including the analogy discipline, the identification problem, and an explicit disclosure that **the entire biological evidence base of this paper carries no citation keys** because the corpus's bibliography has no cluster for it. Section 4 characterises the archive. Section 5 states the open problem. Section 6 specifies the pipeline. Sections 7 and 8 collect the specifications and named failure modes. Section 9 works three things end to end: an audit that rejects a proposal at step one, the full preregistration, and the pipeline run with verified digests. Sections 10 to 13 discuss, verify, limit and conclude.

31.2 2 Hypotheses

Five hypotheses, each stated so it could be wrong, each with its falsifier. **One of them is a constraint rather than a hypothesis and is labelled as such; two further claims are labelled as postulate and definition.**

> **H1 — The reachable set is closed under addressing.** No addressing operation causes a cell to express content absent from its genome and accessible regulatory repertoire. **Predicted:** every demonstrated instance of regulatory-only intervention reorganises expression of existing sequence and adds none. **Falsified by:** a demonstration of a cell expressing content demonstrably absent from its genome and repertoire following an addressing-only intervention. *(Result: **not falsified**, and **this is a structural constraint rather than an empirical finding** — it follows from the architecture having no import path, and Section 4.7 states it as Constraint L67. It is falsifiable in the strong sense: one observation would end the model, and no adjustment of parameters could repair it.)*
>
> **H2 — The obstacle to acoustic sequence-specific signalling is the absence of a demodulator, not the capacity of the channel. Predicted:** the signal-to-noise ratio required to deliver a 40-bit address in one second at plausible receiver bandwidths is modest — under 25 dB at 5 Hz and under 7 dB at 16 Hz — while no identified structure satisfies D1, D2 and D3. **Falsified by:** a capacity computation showing the channel cannot carry an address in a physiologically relevant time, or the identification of a structure satisfying all three requirements. *(Result: **not falsified** — 6.68 dB at 16 Hz, 24.07 dB at 5 Hz; see Section 5.4. **The favourable capacity makes the gap sharper, not smaller**, because it removes the explanation that would have been engineerable.)*
>
> **H3 — A response that is invariant under symbol permutation is not sequence-specific. Predicted:** every documented biological response to acoustic stimulus — heating, membrane tension, shear, cavitation, streaming, radiation force — depends only on permutation-invariant functionals of the waveform, so a permuted-twin control is not one control among several but the experiment itself. **Falsified**

by: an identified acoustic-biological response that depends on symbol order. *(Result:* ***not falsified*** *— see Sections 5.2 and 5.8.* ***This is close to a definition and is labelled as such where it is stated****; its empirical content is the claim that the documented responses are exhaustive of what is known, which is a claim about the literature.)*

H4 — Register spreading is exact rather than approximate, and buys two orders of magnitude. Assigning each symbol its own integer octave index leaves the tuning system unchanged and raises the minimum adjacent gap by a large factor. **Predicted:** octave transposition preserves pitch class exactly, so every spread interval equals its pitch-class interval plus a whole number of octaves; and the minimum gap rises from 0.8725 Hz to 732.037 Hz, an 839.0-fold improvement in the Gabor-limited symbol rate. **Falsified by:** any spread interval that is not its pitch-class interval plus an integer number of octaves, or a computed improvement factor differing from 839.0. *(Result:* ***not falsified*** *— checked by subtracting 1200 cents from each spread interval; see Section 6.7 and the verification instance in Section 11.4.)*

H5 — A single well-powered null bounds a negligible fraction of the parameter space, and only a committed abandonment condition makes the programme falsifiable. Predicted: the parameter space is of order thousands of conditions, so one experiment covers well under one per cent, and exhaustive coverage is unaffordable. **Falsified by:** a parameter space small enough that a handful of experiments exhausts it, or a design in which one condition generalises across the space. *(Result:* ***not falsified*** *— 2,880 conditions; one experiment covers 0.0347 per cent; exhaustive coverage is 423,360 libraries.* ***The consequence is stated against this framework rather than against its critics****: a claim that can retreat into a 2,880-cell space indefinitely is not a scientific claim, and Section 5.10 commits to a 73-condition floor.)*

Three further claims are labelled as what they are.

That non-coding sequence constitutes an *addressable archive* is a postulate, badged wherever it appears. The measured rows behind it — the fractions, the syncytin case, the reprogramming case — are facts about genomes; **the reading of those facts as an archive is this framework's own.**

That "sequence-specific" means order-dependent rather than permutation-invariant is a definition (Section 5.2), true by stipulation and carrying no empirical weight. Its whole function is to make the primary control non-negotiable.

That the reachable set of a differentiated cell is substantially larger than current practice exploits is a speculation, and it is marked speculative in the sentence that states it (Section 4.7). It predicts that the rate of discovery of new transdifferentiation protocols will continue rather than saturate, which is a weak but real test, and it has no other support here.

31.3 3 Method

31.3.1 3.1 The ten-and-one accounting

The gap is a single missing link, not a general absence of evidence, and stating that with the same precision used to state the gap is a requirement rather than a courtesy: otherwise an honest reader cannot tell how much is standing.

Component	Status
Arbitrary digital data can be stored in nucleotide sequence	**ESTABLISHED**
Higher-rate storage codes exist and are demonstrated	**ESTABLISHED**
A ~20 nt spacer is a sufficient genomic address	**COMPUTED** (Section 6.3)
An effector self-processes a multi-address array	**ESTABLISHED**
Targeting and editing are separable functions	**ESTABLISHED**
Mechanical force gates ion channels	**ESTABLISHED**
Surface force reaches the nucleus and alters transcription	**ESTABLISHED**
Ultrasound can activate specific engineered channels	**ESTABLISHED**
Non-coding sequence is a large addressable archive	**ESTABLISHED** as fractions; **POSTULATE** as “archive”
Regulatory input reorganises expression without adding sequence	**ESTABLISHED**
A cell demodulates sequence-specific content from sound	**NO ESTABLISHED MECHANISM**

Ten established rows and one open row. Both halves are reported together. Reporting only the ten is advocacy; reporting only the one is a different kind of dishonesty, because it implies the whole edifice is speculation when most of it is textbook. **Every row but the third and the last is a biological result carrying no citation key here — see Section 3.7.**

31.3.2 3.2 The pairing rule

S67-1 — the pairing rule, and it is binding on every use of the genome fractions. Any use of the non-coding fraction in argument must state the figure used (98.7 per cent, 45 per cent, 8 per cent), its annotation dependence, **and the constrained fraction of approximately 8.2 per cent, in the same paragraph.** Failure to pair them is failure mode FM-A.1.

The reason is arithmetical rather than rhetorical. The reported span between “biochemically active” and “under evolutionary constraint” is a factor of **9.76** — approximately 80 per cent against approximately 8.2 per cent — and it is a live scientific dispute rather than a settled figure. **The source manuscript states this span as “about 10.7”; recomputing from its own two figures gives `80 / 8.2 = 9.756`, and the discrepancy is reported in Section 4.3 rather than silently propagated. A framework that quotes the large number in support of itself and omits the small one is not making an argument; it is choosing a number.**

Specification labels are stable identifiers, not section pointers. `S67–1`, `L67`, and the `S68–n`/`S69–n` and `F67.n`/`F68.n`/`F69.n` labels are carried unchanged from the source manuscript’s numbering because other papers in this corpus cite them by name. **Section references have been renumbered to this paper’s own sections; the identifiers have not**, exactly as the `CR–nn` register entries are stable elsewhere in this series [Curzi, 2026w].

31.3.3 3.3 Nominal and annotation-dependent figures, declared

Quantity	Value used	Status
Haploid human genome	`3.1e9` bp	**nominal**, a standard round figure
Non-coding fraction	~98.7 %	**annotation-dependent**; stable to a few points across recent assemblies
Transposable-element fraction	~45 %	**annotation-dependent**, and a **lower bound that keeps rising** as detection of degraded elements improves
LTR / endogenous-retrovirus fraction	~8 %	**annotation-dependent**
Constrained fraction	~8.2 %	**estimate**, method-dependent
Protein-coding CDS fraction	~1.25 % (0.86 % by the gene-count route)	**convention-dependent**; the two bracket the truth
Sequence-specific transcription factors	~1600	**annotation-dependent**
Reprogramming efficiency	~0.01 % to 0.1 %	**wide**, varying by cell type, delivery and scoring
Speed of sound, soft tissue	1540 m/s	**nominal**
Attenuation	0.5 dB/cm/MHz	**nominal**
Cell diameter, density	10 µm, 1050 kg/m^3	**nominal**
Infrared band centres	1626 / 1652 / 1663 / 1665 cm^{-1}	**nominal**, standing in for the operator's own measurement; **a 2 cm^{-1} shift is routine**
Protein diffusion coefficient	`1e-10` m^2/s	**nominal**
Speed of light	299,792,458 m/s	**exact by definition** since the 1983 redefinition of the metre

Every physical figure in Sections 5.3 and 5.5 is an order-of-magnitude argument under plane-wave, linear, homogeneous-medium assumptions with a quasi-static relation for membrane tension. They are strong enough to carry the order-of-magnitude conclusions drawn from them and not strong enough to carry anything finer. Gene, lncRNA and miRNA counts change between annotation releases and are given as approximations or ranges throughout.

31.3.4 3.4 Analogy discipline: what licenses each borrowing

Every borrowing in this paper is labelled here, at first use, as exactly one of three things, and no later section may let a category-2 or category-3 borrowing collect the authority of a category-1 one.

Borrowing	Category	What licenses it
Shannon capacity (§5.4)	**(1) derivation**	The theorem applies wherever a bandwidth and a signal-to-noise ratio are defined [Shannon, 1948, Cover and Thomas, 2006]. **It bounds a rate; it constructs no decoder**, and Section 5.4 exists to say so.

Borrowing	Category	What licenses it
The Gabor limit `dt df >= 1/(4 pi)` (§6.9)	**(1) derivation, with an explicit disclaimer**	Classical Fourier duality [Gabor, 1946], applying to every wave including sound and carrying **no quantum content whatever**; the corpus derives it independently by the same variational argument with `p = hbar k` deleted [Curzi, 2026z]. The position–momentum relation [Kennard, 1927] is a fact about state preparation and is **not** invoked.
The Nyquist sampling condition (§6.10)	**(1) derivation**	Standard sampling theory [Nyquist, 1928, Shannon and Weaver, 1949], applied to choose a render sample rate.
Constrained-coding capacity as a transfer-matrix eigenvalue (§6.2)	**(1) derivation**	The capacity of a run-length-limited constraint is `log2` of the largest eigenvalue of its transfer matrix [Shannon, 1948, Cover and Thomas, 2006]; the computation is exact and reproducible.
Low-Reynolds-number hydrodynamics and the Stokes number (§5.5)	**(1) derivation**	Claims about a physical object oscillating in a physical fluid; the physics applies directly. **The originating exposition carries no citation key here** (Appendix A).
Octave equivalence and pitch class (§6.5, §6.7)	**(2) shared mathematical form**	That halving a frequency preserves pitch class is a fact about the ratio [Shepard, 1982]; that human listeners treat octave-related pitches as equivalent is a separate, measured, and *bounded* claim [Demany et al., 2013, Burns, 1999]. **The design uses the arithmetic fact and does not require the perceptual one.**
The tuning argument against a standardised reference pitch (§6.8)	**(2) shared structural form**	That A440 is a twentieth-century standardisation rather than a discovery is documentary [Barbour, 1951, Lindley and Turner-Smith, 1993]; that equal temperament is a deliberate detuning purchasing modulation is standard theory [Benson, 2006, Doty, 2002]. **No claim is made that ratio-based tuning is perceptually superior**, and the literature that would contest such a claim is cited here deliberately [Sethares, 2005, Plomp and Levelt, 1965].
The leaky integrator applied to regulatory state (§4.7, §10)	**(2) shared mathematical form, badged**	A first-order linear difference equation whose fixed point and contraction are theorems about the equation [Curzi, 2026a, Elaydi, 2005]. **No claim that a cell obeys it.**
The archive, catalogue and filesystem vocabulary (§4.4)	**(3) analogy, badged as register translation**	**Genomes are not programs, cells do not execute instructions in the von Neumann sense, and every one of these analogies breaks under pressure.** They are used for legibility and carry no argument; Anderson [1972] and Cartwright [1999] are the standing statement of why a borrowed formalism does not import its subject.

Borrowing	Category	What licenses it
The framework's essence law and the constant `k` (§6.4)	**definition, with a postulate attached — and here it is REJECTED**	`k = (9/8)^2/phi^2 = 0.483425732988414` is an exact ratio of exact quantities and is **defined**; **attaching hertz to it is a separate and stronger claim and is POSTULATED**. In this paper the law is not merely badged but **rejected for the task**, by its own theorem (Section 6.4). The standard critique of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever `phi` appears; the identity `phi^2 = phi + 1` is Euclidean [Euclid, 1956, Vajda, 1989].
The surplus functional and its effective count (§4.7)	**(3) analogy, badged, and named**	**`N_eff = 1 + (N−1)u` is not a Hill number.** It is a linear interpolation between 1 and `N` and is this framework's own construction [Curzi, 2026]; `1/HHI` and `exp(H)` are Hill numbers of orders two and one and are the grounded objects [Hill, 1973, Jost, 2006]. **Wherever an effective count appears in this paper it is this one, and it is named.**

Most of the borrowings in this corpus are category 2, and category 2 is respectable. The failure this table exists to prevent is a category-2 or category-3 use collecting the certainty of a category-1 one.

31.3.5 3.5 The two-column apparatus

The corpus pairs each substantive claim with a measured reference and a pre-modern textual one. **The refinement that governs this series must be restated at every use: the evidence column carries EVIDENCE and the precedent column carries PRECEDENT, and two sources agreeing does not double the evidence when only one of them is evidence** [Curzi, 2026w]. That paper prices a single traditional record at 1.585 bits against 9.966 for a replicated result, computes the collapse of agreement between correlated sources, and rejects the claim that a specific audio frequency repairs DNA on wavelength, energy and octave-separation grounds. **This paper's own rejections derive from that one, and its sonification pipeline is bound by it: a transposed tone is a label and not a resonance.**

Where the precedent column is empty, this paper says so rather than filling it, and every precedent item is credited in bits rather than summed with the measured column.

31.3.6 3.6 Identification, reflexivity, and what this paper's arithmetic does and does not rest on

Nothing in this paper estimates a social parameter. **The framework it belongs to does, and the inheritance is stated here rather than buried.** The corpus's central formal object is a reflexive loop in which a group influences its members and the members constitute the group; that is a linear-in-means reflexive specification, and Manski [1993] proves the endogenous social effect is **not identified from observational data**, with Shalizi and Thomas [2011] establishing the same confounding for network data. **No remedy is adopted anywhere in this series** — not randomisation, not an instrument, not partial-population variation, and not a defended stipulation of the reference group [Brock and Durlauf, 2001] — **so every framework claim resting on the loop is a modelling position rather than an identified empirical result.**

The specific inheritance here is the storage-law reading of regulatory state in Section 4.7 and the surplus-functional reading of Constraint L67. **Both are model-form claims, both are**

badged, and neither is identified from anything measured in this paper. The corpus's own treatment of the contraction mapping is the bound to read alongside them: **a human life is not a metric space, nobody has measured the relevant contraction modulus, and the theorem therefore transfers as shape rather than as guarantee** [Curzi, 2026].

The Lucas critique applies to the experimental programme of Section 5 in a specific and unusual way. Lucas [1976] holds that parameters estimated under one regime do not survive the announcement of another, and Hacking [1995] makes the point about human classifications. **The preregistered experiment of Section 9.2 involves human operators who will know the hypothesis**, and the corpus's own falsification audit measured a demand-characteristic confound with a true effect of zero passing an entire four-baseline suite **52.7 per cent of the time, for which there is no statistical remedy — only blinding, channel separation and a yoked control** [Curzi, 2026u]. **That is why the blinding requirement in Section 9.2 is not boilerplate.**

31.3.7 3.7 A gap in the bibliography, disclosed

The entire biological literature this paper describes has no corresponding cluster in the bibliographic database governing this corpus. That includes: the origin and critique of the "junk DNA" designation; the genome-annotation and biochemical-activity surveys and the constraint estimates that contradict them; the C-value and genome-size literature; regulatory-element classes; operon logic; repetitive-sequence regulatory theory and its confirmation; transposon-derived enhancer networks; syncytin and its knockout; nuclear transplantation and induced pluripotency; transcription-factor censuses; nucleotide data storage and its codes; guide specificity, self-processing arrays, catalytically dead nucleases; mechanically gated channels; force-to-nucleus coupling; sonogenetics; the microwave auditory effect; infrared band-centre compilations for nucleic acids; auditory filter bandwidth formulae; and the differential-expression power formula used in Section 5.11.

Every such work is named in the text with its journal, volume, page and year, and carries no citation key. Attaching an unrelated key to a biological or psychoacoustic claim would be worse than the gap, because a reviewer in that field will check it and a mis-supporting citation destroys more than a missing one. **Appendix A lists them; Section 12 records it as limitation L-1; and the practical consequence is that this paper's biology is unverifiable from its reference list — a reader must go to the named sources directly.** The same gap is disclosed in the neighbouring papers of this series [Curzi, 2026w,x] and in the sonification protocol [Curzi, 2026].

One consequence must be stated even though the gap is the defect. Each biological result is named as a single published finding, and the required context for any such citation is the measured replication base rate: large-scale replication returns roughly a third of original findings with effect sizes about halved [Open Science Collaboration, 2015], and most published findings in low-prior fields are false [Ioannidis, 2005]. **The results relied on here are among the most heavily replicated in their fields, several carry Nobel Prizes, and two carry loss-of-function experiments — but the reader is entitled to that base rate beside them.**

31.3.8 3.8 Honesty clauses and standing refusals

- **No clinical, medical or therapeutic claim appears anywhere in this paper.** Every experiment specified is *in vitro*, on cultured cells, with transcript abundances as endpoints.
- **No claim that genomic sequence is edited, altered or damaged.** The pipeline of Section 6 carries no nuclease, no template and no effector protein; **the output of its final stage is a waveform and its intermediate is a string in memory.** It cannot edit. **Cannot, not does not.**
- **No claim that any capability has been conferred on anything.**
- **Absence of a known mechanism is not proof of impossibility, and impossibility is not claimed.** Several real physical–biological channels were discovered late and were initially dismissed; Section 5.6 gives one. **The position taken is that the mechanism is un-**

known and that the burden of demonstration is entirely on the claimant, which is the normal position for any unestablished claim and carries no special hostility.

- **Nor is absence of a known mechanism a licence.** The symmetric error treats "not proven impossible" as partial support. **It is not support of any kind. A claim with no mechanism and no demonstration has zero evidential standing, and the correct number of qualifiers to attach before demonstration is not "few" but "it is not asserted"** [Popper, 1959, Platt, 1964].
- **No subliminal content, ever.** Nothing masked, nothing below threshold, nothing concealed; every symbol in a rendered signal is audible, disclosed and documented in a published mapping table. **A message hidden from its recipient cannot be consented to**, and the corpus states that as a first law rather than a caveat, on an argument that depends on no empirical claim [Curzi, 2026ad]. It is the same principle that makes a system's security rest on its design rather than on concealment [Kerckhoffs, 1883, Brandeis, 1914], and the corpus states it structurally elsewhere: **channel separation is strengthened by disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place, so every element must be publishable and non-disclosure is refused as a design premise rather than merely discouraged** [Curzi, 2026].
- **Presence is not function.** Presence of sequence is not evidence of function; transcription is not evidence of function; protein occupancy is not evidence of function. **A function claim requires either evidence of selective constraint or a loss-of-function experiment, and must name which.**
- **Structural correspondence is not evidence of mechanism.** It licenses legibility and nothing else.
- **Scale type.** Every quantity in Sections 5 and 6 is a physical or combinatorial measurement on a ratio scale with a true zero, so the arithmetic on them is licensed. **The framework's psychological constructs are not**, Michell [1997]'s objection applies to them, and the additive conjoint conditions that would license ratio-scale treatment [Luce and Tukey, 1964, Krantz et al., 1971] have not been tested; the typology is Stevens's [Stevens, 1946]. **The status vocabulary of Section 3.1 is ordinal at best and no arithmetic is performed on it.**

31.4 4 The addressable archive

31.4.1 4.1 Retiring "junk", and why the retirement is the model's precondition

The term was introduced in 1972 in a paper whose actual argument was subtler than the phrase it produced. **The reasoning was a mutational-load argument: a genome cannot maintain unlimited functional sequence against mutation at a fixed rate, therefore most of a large genome cannot be under selection. That argument is sound and has not been overturned.** What has been overturned is the inference drawn from the word — that the non-coding fraction is *empty*, that there is nothing there, that it is filler.

That distinction is the entire content of the correction, and this architecture depends on it in a way worth stating plainly rather than sliding past.

Consider what "junk" would mean for an architecture whose only operation is addressing. If the non-coding fraction were genuinely junk — random, unstructured, unread, without regulatory consequence — **an address pointing into it would resolve to nothing.** There would be no latent content to reach. **A system that can only address and cannot import is worthless if the archive is empty. The junk hypothesis, in its strong popular form, is not a mild embarrassment to this architecture; it is a refutation of it.**

So the correction does not weaken the model by removing an obstacle. **It is the model's precondition**, and it is a strengthening precisely because it was not assumed: it was resisted for forty years and then measured.

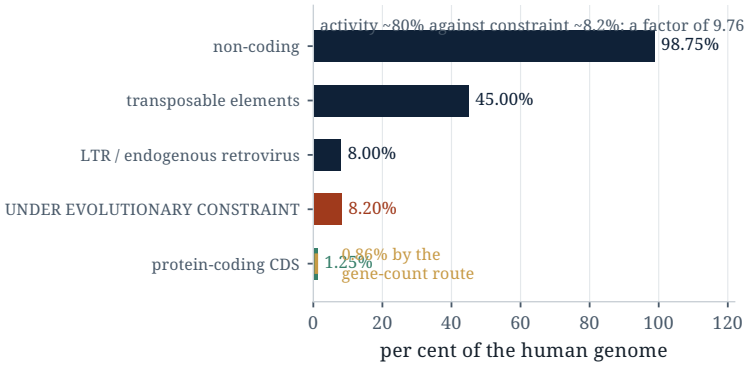

Figure 31.1: **The fractions that support the architecture and the fraction that constrains it, printed together as rule S67-1 requires.** The non-coding, transposable-element and endogenous-retroviral fractions of the human genome against the approximately 8.2 per cent under evolutionary constraint and the approximately 1.25 per cent protein-coding fraction, with the independent gene-count estimate of 0.86 per cent marked. **The span between "biochemically active" and "under constraint" is a factor of 9.76 (`80 / 8.2`) and is a live dispute rather than a settled figure.** Fractions are annotation-dependent (Section 3.3). Computed from the fractions of Section 4.2; generated by `figs/src/CCP-031_fig01.py`.

31.4.2 4.2 The arithmetic, with the pairing rule applied

```
haploid human genome                    3.1e9 bp    (nominal)
information capacity at 2 bits/bp       6.2e9 bits  = 7.75e8 bytes = 775 MB decimal
                                                     = 739.10 MiB

class                                    fraction     Mbp      MB at 2 bits/bp
-------------------------------------------------------------------------------
protein-coding exons (CDS)                 0.0125     38.8            9.69
non-coding total                           0.9875   3061.2          765.31
  transposable elements (all)              0.4500   1395.0          348.75
    LINEs                                  0.2050    635.5          158.88
    SINEs                                  0.1300    403.0          100.75
    LTR / endogenous retrovirus            0.0800    248.0           62.00
    DNA transposons                        0.0300     93.0           23.25
  introns                                  0.3600   1116.0          279.00

ratio of non-coding bytes to coding bytes             79.0 : 1

UNDER EVOLUTIONARY CONSTRAINT              0.0820    254.2           63.55
```

The last row is not optional and is printed with the others by rule S67-1.

A sanity check from an independent direction: approximately 19,900 protein-coding genes at a mean coding-sequence length near 1,340 bp gives 26.67 Mbp, which is 0.860 per cent of the genome. The 1.25 per cent figure above is the larger, more inclusive convention. **The two estimates bracket the truth between roughly 0.9 and 1.5 per cent, and nothing here turns on which end is taken, because the ratio that matters is between 65:1 and 110:1 either way.**

The transposable-element fraction near 45 per cent is a lower bound that keeps rising as detection of degraded ancient elements improves, which is itself informative about how much of the genome is old text rather than no text.

31.4.3 4.3 The overclaim, refused in print

"Not junk" does not mean "all functional", and this framework does not assert that it does.

Reported biochemical activity across most of the genome is a measurement of *activity*, and biochemical activity is cheap. Pervasive transcription is real and was measured carefully, but **a polymerase initiating spuriously produces transcript, and transcript is not function.** A transcription factor with a six-base recognition motif will bind a 3.1-billion-base genome at an enormous number of positions by chance alone; **occupancy is not regulation.**

The counter-argument that has never been answered — and stating it is a requirement — is the C-value problem, in its sharpest modern form as the onion test:

organism	genome (Gbp)	x human
Fugu rubripes (pufferfish)	0.39	0.13
Homo sapiens	3.10	1.00
Allium cepa (onion)	16.00	5.16
Protopterus aethiopicus (marbled lungfish)	130.00	41.94
Paris japonica	148.00	47.74

If every base of the human genome is doing something necessary, what are the onion's extra 12.9 billion bases doing, and why does a pufferfish manage vertebrate development on an eighth of the human total? Any theory that assigns function to bulk non-coding sequence *because it is there* must answer this, and no such theory has.

A discrepancy in the source, reported rather than harmonised. The source manuscript states that "the measured span between the two framings is a factor of about 10.7". Recomputing from the two figures it gives — approximately 80 per cent reported as biochemically active against approximately 8.2 per cent estimated as under constraint — **the ratio is `80 / 8.2 = 9.756`, not 10.7.** A factor of 10.7 would require either 87.7 per cent activity or 7.48 per cent constraint, and neither figure appears in the source. **The corrected figure of 9.76 is used throughout this paper. No conclusion changes: the pairing rule is required at either value, and the point of the rule is that the two numbers measure different things rather than that their ratio takes any particular value.**

The position taken here, stated as a position and not as a finding: the non-coding fraction contains a large, structured, consequential regulatory apparatus **and** a large quantity of decayed and duplicated sequence under little or no selection, interleaved. **An archive that contains both a catalogue and a great deal of unread material is still an archive.** Libraries are like this. **The claim this architecture needs is not that every base is functional; it is that there is addressable latent regulatory content, which is a far weaker claim and is established.**

31.4.4 4.4 What is actually in the non-coding fraction

Element	Operation	Register translation
Promoter	Where transcription initiates	Entry point
Enhancer	Increases transcription of a target, often at distance and orientation-independently	Remote call site
Silencer	Decreases transcription of a target	Guard clause
Insulator / boundary element	Blocks enhancer–promoter contact across it; organises domains	Scope delimiter

Element	Operation	Register translation
lncRNA	Transcribed, not translated; some act in *cis* on chromatin state	Resident process rather than stored data
miRNA	~22 nt; post-transcriptional repression of matching transcripts	Output filter applied after the read
Transposable element	Mobile or formerly mobile sequence; a major source of new regulatory sites	Imported library, mostly deprecated, occasionally load-bearing

The right-hand column is a register translation and carries no claim beyond legibility. Genomes are not programs, cells do not execute instructions in the von Neumann sense, and every one of these analogies breaks under pressure (Section 3.4). They are here because the readers of an engineering paper think in these terms; **they are not here as an argument.**

Two structural facts bear directly on addressing.

First, operon logic was the demonstration that a gene's expression is controlled by sequence elements distinct from the gene itself. That is now sixty-five years old and standard, **and it is the origin of the separation this architecture depends on: address and content are different objects.**

Second, repetitive non-coding sequence was proposed as the substrate of gene-regulatory networks before the sequence data existed to test it, and the proposal was substantially right. The mechanism — transposable elements distributing copies of a binding motif across a genome, so that a single factor coordinates a dispersed set of targets — is now documented, including endogenous retroviruses supplying inducible enhancers across an immune network and transposon-mediated rewiring in the evolution of a mammalian gene network.

This is the multicast structure of the addressing architecture appearing in the genome as a matter of fact rather than as a design proposal: one motif, many addresses, one signal, coordinated response [Curzi, 2026x]. **State the direction of the argument carefully. The genome having this structure does not show that an acoustic signal can exploit it. It shows that the structure being exploited is the structure that is there.**

Precedent, priced. The correspondence table read as a finite relation — a single term addressing a dispersed set of entries across categories — records that the *form* "one key, many entries" was recognised as a useful organisation of knowledge independently and repeatedly. **It is precedent only, worth of order 1.6 bits on the corpus's scale, and it says nothing about genomes** [Curzi, 2026w,?]. One-to-many addressing arises wherever a system must coordinate dispersed elements with a compact signal — in indexes, filesystems, multicast networking and correspondence tables. **The generality is real; it is a fact about the class of problem, not a shared cause.**

31.4.5 4.5 Syncytin: the strongest single item

Everything above is quantitative and general. This is specific.

Syncytin-1 is a gene essential to the formation of the human placenta. It is a captured retroviral envelope gene. The measured record, named without keys per Section 3.7: the protein is the envelope glycoprotein of a human endogenous retrovirus, expressed in placental syncytiotrophoblast and **fusogenic** — it fuses cell membranes, which is what a retroviral envelope protein does on entry and what is required to build the multinucleate layer at the maternal–foetal interface (Mi et al., *Nature* 403:785–789, 2000). A genome-wide screen identified a second such gene from a different and older retroviral family (Blaise, de Parseval, Bénit and Heidmann, *PNAS* 100:13013–13018, 2003). **Knockout of the mouse orthologue produces**

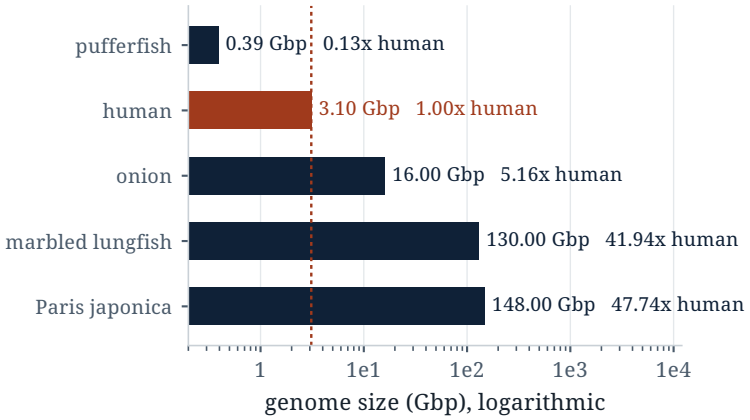

Figure 31.2: **The objection the framework cannot answer, printed at full strength.** Genome size across five species on a logarithmic axis: a pufferfish completes vertebrate development on 0.39 Gbp, an onion carries 5.16 times the human total and a marbled lungfish 41.94 times. **If bulk non-coding sequence is functional because it is present, these ratios require an explanation and none has been given.** The human value is marked as the reference. Values are standard published genome sizes, named without citation keys per Section 3.7. Generated by `figs/src/CCP-031_fig02.py`.

defective placental architecture and embryonic lethality (Dupressoir et al., *PNAS* 106:12127–12132, 2009). This is the causal test, and it is why the item carries the weight it does: the gene is not correlated with placentation; removing it stops placentation. And syncytin-like genes have been captured *independently* in multiple mammalian lineages, from different retroviruses, for the same function (Lavialle et al., *Philosophical Transactions of the Royal Society B* 368:20120507, 2013).

```
syncytin-1 env ORF   ~538 aa  ->  ~1617 bp  ->  3234 bits  ->  404 bytes
fraction of the human genome that is this one ORF          5.216e-07
total LTR/ERV-derived fraction                    8%   =  248 Mbp  =  62.0 MB at 2 bits/bp
```

Four hundred and four bytes of inherited viral text, out of sixty-two megabytes of inherited viral text, and mammalian live birth as we have it does not occur without them.

It establishes: that sequence of foreign origin, integrated into a germline, carried for millions of years and *not* functioning as a virus, can be read out later as an essential function of the host. **That is documented molecular biology with a causal knockout behind it**, and it is the cleanest existence proof available that the genome is a repository of inherited text whose current use is not its original use.

It does not establish: that any given piece of non-coding sequence has such a use; that capture is common — it is rare, and the great majority of the 8 per cent is decayed and non-functional; that anything can be induced to be read out on demand; or anything whatsoever about acoustic signals. **Syncytin is one item. It is presented as one item. It is the best item.**

Precedent, priced. The category "present but not currently expressed, and requiring only the right prompting to become expressed" was formulated, argued over and preserved for twenty-four centuries — in Plato's doctrine of recollection and in Aristotle's distinction between potentiality and actuality. **That is precedent only. It supplies no mechanism and it is not evidence about placentas**, and no inference runs from it to any biological fact [Curzi, 2026w].

31.4.6 4.6 Latency and its activation: the information accounting

The syncytin case shows latent content in evolutionary time. **The reprogramming case shows it in experimental time, and it matters more here because it is an *intervention* rather than an observation.**

Nuclei taken from the intestinal epithelium of feeding tadpoles — differentiated cells, committed to a fate — were transplanted into enucleated eggs, and normal feeding tadpoles developed (Gurdon, *Journal of Embryology and Experimental Morphology* 10:622–640, 1962). **The nucleus of a differentiated cell retains the full genomic information required to build the whole organism. Differentiation is not subtraction.** Four decades later, mouse embryonic and adult fibroblasts were returned to a pluripotent state by forced expression of four transcription factors (Takahashi and Yamanaka, *Cell* 126:663–676, 2006), extended to human fibroblasts the following year; the 2012 Nobel Prize in Physiology or Medicine was awarded jointly for the two results, fifty years apart.

The point that matters here is the information accounting, and it is computed rather than asserted.

```
approximate number of human sequence-specific transcription factors     ~1600

selecting a set of k factors from 1600:
    k = 1   C = 1.600000e+03    log2 =  10.644 bits
    k = 2   C = 1.279200e+06    log2 =  20.287 bits
    k = 3   C = 6.813872e+08    log2 =  29.344 bits
    k = 4   C = 2.720438e+11    log2 =  37.985 bits
    k = 5   C = 8.683639e+13    log2 =  46.303 bits
    k = 6   C = 2.308401e+16    log2 =  54.358 bits

the four-factor SELECTION specifies at most           37.985 bits
the genome it acts upon holds                     6.200e+09 bits
ratio                                             1.632e+08 : 1
```

Identifying which four of roughly sixteen hundred transcription factors to use is a choice worth at most about thirty-eight bits. The genome those four factors act on holds six point two billion bits. The instruction is one hundred and sixty-three million times smaller than the thing it reorganises.

That is the shape of the architecture in the only units that make it checkable. An activation signal is not the content it activates, it is smaller than the content it activates by many orders of magnitude, and this is not a weakness of the model — it is what an address is [Curzi, 2026x].

Two qualifications, both mandatory.

First, the efficiency is low. Published reprogramming efficiencies for the original four-factor protocols are commonly quoted between roughly 0.01 and 0.1 per cent of input cells, with wide variation by cell type, delivery method and scoring criteria:

efficiency	cells needed per colony	cells needed for 100 colonies
0.010%	10,000	1,000,000
0.100%	1,000	100,000
1.000%	100	10,000

A process that works on one cell in a thousand is a real process and a poor one, and any model that borrows its authority must also borrow its efficiency. This framework borrows the structural point — that regulatory input reorganises expression without adding sequence — and borrows no implication about how readily that happens.

Second, in the original protocols the factors were delivered by retroviral transduction, which does integrate sequence into the genome. That must be said in the same breath as the claim that "no new information is added", or the claim is misleading. **The precise statement is:**

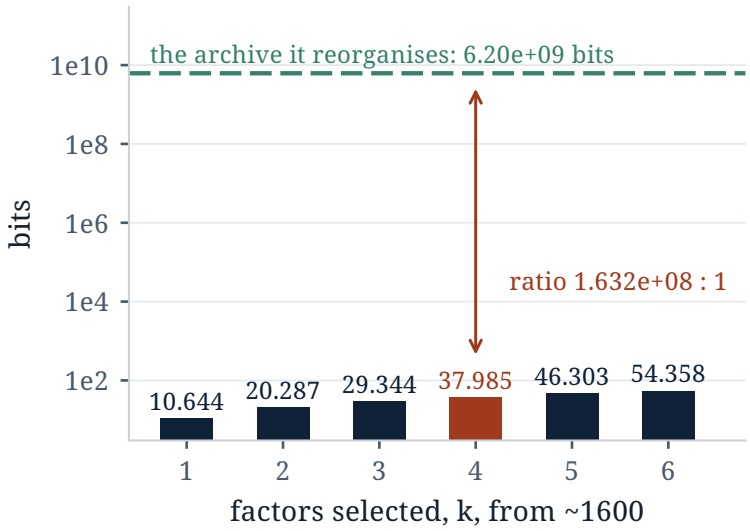

Figure 31.3: **The instruction is a hundred and sixty-three million times smaller than the archive it reorganises.** Bits required to specify a selection of `k` factors from approximately 1,600 sequence-specific transcription factors, `log2 C(1600,k)`, against the `6.2e9` bits of a haploid genome at two bits per base. The four-factor selection is 37.985 bits, marked; the ratio to the genome is `1.632e8` to one. **The vertical scale is logarithmic and the two quantities are eight orders of magnitude apart, which is the point rather than an artefact of the display.** Computed from the closed form of Section 4.6; generated by `figs/src/CCP-031_fig03.py`.

the information that specifies the new state is the identity of the four factors, not new genomic content; the pluripotency programme itself was already encoded in the fibroblast's genome and was already there in the transplanted nuclei. Later work using non-integrating delivery removes the qualification, but the original result carries it and it is stated rather than elided.

31.4.7 4.7 Constraint L67, and the reason it is the most useful sentence here

> **CONSTRAINT L67. Addressing can reach only what is already latent. No addressing operation, of any kind, at any signal strength, by any modality, can cause a cell to express content that its genome and its accessible regulatory repertoire do not already contain.**

This follows directly from the addressing architecture and requires no new assumption [Curzi, 2026x]. **An address is a pointer. A pointer with no cargo cannot deliver content. If the referent does not exist, the address resolves to nothing.** The architecture has no import path by construction, and the absence of an import path is the same fact as the guarantee that no sequence is changed. **The property that makes the architecture safe is the property that makes it limited. You cannot have one without the other.**

The constraint does work in four directions.

It bounds the claim space. Any statement of the form "this method could produce capability X" is false whenever X is not already encoded and reachable. **That eliminates the entire class of claims that would make this work pseudoscience — no new genes, no acquired traits, no capacities imported from outside the organism, nothing conferred.**

It makes the model falsifiable in a specific way. If a demonstration ever showed a cell expressing content demonstrably absent from its genome and regulatory repertoire following an addressing-only intervention, **this architecture is wrong, and wrong in a way no adjustment of parameters can repair.** That is the good kind of falsifier: one named observation

ends the model [Popper, 1959, Platt, 1964].

It generates a positive prediction. If addressing reaches only what is latent, the *reachable set* is bounded and enumerable in principle: for a given cell type it is the set of expression states accessible from its current chromatin configuration under some combination of regulatory input. That set is finite, is studied under other names, and is measurable.

It supplies the audit rule. Every proposed application is checked against the reachable set before anything else. **If the target state is not in the reachable set, the proposal is dead at step one and no experiment is needed** (Section 9.1).

The storage-law reading of the constraint is exact and worth writing down, and it is a badged model-form claim. The archive is `Q`, and an addressing operation does not increase it. What such an operation can change is which part of `Q` is being read — a change in `u`, the non-parallelism of what is currently active, not a change in `Q` [Curzi, 2026a,?]:

```
N_eff = 1 + (N−1)u        F = ln N_eff

N = 20,000 addressable loci

u = 0.01   N_eff =      201.0   F = 5.3033 nats =  7.6510 bits
u = 0.05   N_eff =    1,001.0   F = 6.9087 nats =  9.9672 bits
u = 0.25   N_eff =    5,000.8   F = 8.5173 nats = 12.2879 bits
u = 0.50   N_eff =   10,000.5   F = 9.2104 nats = 13.2878 bits
u = 1.00   N_eff =   20,000.0   F = 9.9035 nats = 14.2877 bits

hard ceiling  ln N = 9.9035 nats = 14.2877 bits
```

The ceiling is `ln N` and `N` is set by the archive, not by the signal. No amount of input raises `ln N`. That is the corpus's own bound `0 <= F(u) <= ln N` doing exactly the work it was proved to do, in a domain it was not written for [Curzi, 2026]. **The effective count used is `N_eff = 1 + (N−1)u`, which is this framework's own construction and is not a Hill number** (Section 3.4).

Speculative bridge, marked speculative in the sentence that states it: this framework's author proposes, as a postulate and not as a finding, that the reachable set of a differentiated human cell is substantially larger than current practice exploits, and that most of the gap is a matter of not knowing the addresses rather than of the content being absent. It predicts that the rate of discovery of new transdifferentiation protocols will continue rather than saturate, which is a weak but real test, and it has no other support here.

31.4.8 4.8 A deflation, performed on the framework's own tradition

The old corpus offers one correspondence here that is tempting, and it is declined, because the concordance method is only worth having if it can reject something visibly [Curzi, 2026w].

The genetic code has 64 codons. A well-known divinatory system has 64 hexagrams. **The coincidence has been noticed repeatedly and elaborated at length, and it is worth exactly this much:**

```
2^6 = 64        six binary lines, two states each      (the hexagram)
4^3 = 64        three positions, four bases each        (the codon)
```

Sixty-four is a small highly-composite power. That two systems both land on it is a fact about the number, not a fact about either system. The factorisations differ — `2^6` against `4^3` — which is to say the two structures are not the same structure at all; they are two different structures with the same cardinality. **And a proposed correspondence between them is a *chosen bijection*, one of `64! = 1.2689e89` available, worth 296.0 bits of arbitrary choice.**

Status: REJECTED as a bridge. C1 fails: there is no deep shared pattern, only a shared count. C2 fails: the correspondence generates no prediction that could come out otherwise.

C3 fails: it is not usable on either side. **The concordance method is only worth having if it can return this verdict, and this is the verdict.**

For contrast, the genuine arithmetic of the genetic code, which does carry content:

```
codons                                  64      log2 = 6.0000 bits per codon (max)
outputs (20 amino acids + stop)         21      log2 = 4.3923 bits
redundancy  1 − log2(21)/log2(64)          =    0.2679
mean codons per amino acid (61/20)         =    3.05
```

The code discards about 26.8 per cent of its addressing capacity to degeneracy, and that discarded capacity is error tolerance. That is a real engineering fact about a real code, computed rather than asserted [Shannon, 1948, Cover and Thomas, 2006].

31.5 5 The open problem

31.5.1 5.1 The gap, stated four ways

The same proposition at four levels of precision, because each level is the one someone will need.

Colloquial. Nobody knows how a cell could read a message out of a sound.

Engineering. No known biological structure performs demodulation of a symbol stream from an acoustic carrier into a sequence-specific output. There is no identified transducer with the required frequency selectivity, no identified memory element that preserves symbol order across the symbol interval, and no identified mapping from a decoded symbol string to sequence-specific binding at a genomic locus.

Formal. Let `s(t)` be an acoustic pressure waveform encoding a symbol string `x = (x_1, ..., x_n)` over an alphabet of size 4, and let `R` be the cell's transcriptional response. **There is no established mechanism producing an `R` that depends on `x` as an ordered string**, as distinct from depending on functionals of `s(t)` that are invariant under permutation of the symbols — total energy, duration, long-term power spectrum, envelope statistics. **The claim that requires a mechanism is the claim that `R` is a function of the ORDER, and that is exactly the claim for which no mechanism exists.**

Operational. Take a stimulus and its symbol-permuted twin. The two have identical total energy, identical duration, identical long-term power spectrum and identical symbol counts. **If a cell cannot be shown to distinguish them, no sequence-specific channel has been demonstrated, and nothing else in the experiment matters.**

31.5.2 5.2 What "sequence-specific" means, and the three requirements

DEFINITION. A response is **sequence-specific** with respect to an input symbol string `x` if it depends on the identity and order of the symbols in `x`, and not merely on quantities invariant under permutation of those symbols. **This is a definition, true by stipulation, and it carries no empirical weight; its function is to make the primary control non-negotiable.**

The permutation-invariant quantities of an acoustic stimulus are the ones almost every biological acoustic effect in the literature depends on:

```
total delivered energy              invariant under permutation
duration                            invariant
long-term power spectrum            invariant
RMS amplitude                       invariant
peak amplitude / crest factor       invariant (with matched symbol shapes)
symbol histogram (counts of A,C,G,T) invariant
```

Everything a stressed cell is known to respond to is on that list. Heat, shear, membrane tension, cavitation, streaming, acoustic radiation force — every one is a response to bulk energy delivery and every one is blind to order by construction. **This is why the permuted-symbol control is not one control among several. It is the experiment.**

Demodulation of an ordered symbol string requires exactly three things. **There is no way around any of them; they are the definition of the operation.**

D1 — SYMBOL DISCRIMINATION. Something must produce different internal states for different symbols. Under a pitch-coded scheme that means frequency selectivity sharp enough to separate the symbol tones.

D2 — ORDER MEMORY. Something must retain the identity of symbol `i` while symbol `i+1` arrives, and must retain the accumulating string across the whole address. **A device that responds to each symbol and forgets it is a level meter, not a receiver.** This is the requirement most often skipped in speculative accounts, and it is the hardest one.

D3 — SEQUENCE-SPECIFIC OUTPUT. The decoded string must be converted into an operation specific to a genomic locus determined by that string. In a guide-molecule architecture this step is trivially solved *because a physical guide exists whose bases pair with the target.* **With no molecule delivered, the mapping from "a decoded string held in some cellular state variable" to "binding at the locus that string names" has no proposed physical implementation at all.**

D3 is the deepest of the three and it is worth being blunt about why. Base pairing is sequence-specific because the guide and the target are made of complementary chemistry. **Remove the guide and you have removed the only known physical thing that makes an arbitrary 20-symbol string correspond to one place in a genome. Nothing else in known cell biology takes an arbitrary string as input and produces locus-specific action as output.** The separability of addressing from editing is correct [Curzi, 2026x] — **but the separation it exploits was demonstrated with a molecule present, and this method has no molecule.**

That is the gap. It is not "we do not know the details." It is D3.

31.5.3 5.3 Does the signal arrive as structure? The physics, computed

Before asking whether anything decodes the signal, ask whether the signal reaches the cell in a form that has structure to decode. **Two computations settle the shape of it, and the first is unfavourable.**

The wavelength objection. For a plane wave with wavenumber `k = 2 pi f / c`, the fractional pressure difference across an object of size `d` is approximately `k d`. In soft tissue at `c = 1540` m/s and `d = 10` µm (both nominal):

freq (Hz)	wavelength (m)	wavelength/cell	dP/P across one cell
20	77.0	7.70e+06	8.1600e−07
100	15.4	1.54e+06	4.0800e−06
440	3.50	3.50e+05	1.7952e−05
1,000	1.54	1.54e+05	4.0800e−05
10,000	0.154	1.54e+04	4.0800e−04
20,000	0.077	7.70e+03	8.1600e−04
100,000	0.0154	1.54e+03	4.0800e−03
1,000,000	0.00154	1.54e+02	4.0800e−02
10,000,000	0.000154	1.54e+01	4.0800e−01

In an audible-band far field, the cell does not feel the wave. It rides on it.

Put a number on what it would take. Taking a membrane tension of 3 mN/m — the order at which mechanosensitive channels are reported to respond — and the quasi-static relation `dP = 2T/r` for a cell of radius 5 µm:

```
membrane tension   1.00 mN/m  ->  dP =   400 Pa across a 10 um cell
```

```
membrane tension   3.00 mN/m  ->  dP =  1200 Pa
membrane tension   5.00 mN/m  ->  dP =  2000 Pa

far-field acoustic amplitude required to produce dP = 1200 Pa:

freq (Hz)   p_required (Pa)   equivalent dB re 20 uPa    intensity in tissue (W/m^2)
      100      2.9412e+08              263.3                      2.8835e+10
      440      6.6845e+07              250.5                      1.4894e+09
    1,000      2.9412e+07              243.3                      2.8835e+08
   10,000      2.9412e+06              223.3                      2.8835e+06
  100,000      2.9412e+05              203.3                      2.8835e+04
1,000,000      2.9412e+04              183.3                      2.8835e+02
```

Two hundred and forty-three decibels at one kilohertz. That is not a loud sound; it is not a sound at all. The pressures in the upper rows exceed the inertial-cavitation threshold in water by orders of magnitude, so the medium would be destroyed long before those amplitudes were reached. **Any account of this method that imagines a cell picking a message out of ordinary airborne music, by direct far-field pressure differential across the cell body, is refuted by this table. That account is not carried here.** Compounding it, the impedance step at any air-to-tissue interface costs roughly thirty decibels of incident intensity before anything else happens [Curzi, 2026x].

Now the path that survives, because there is one and it must be reported with equal care. Cells adherent to a vibrating substrate do not ride the wave; they are shaken by their attachment points while the surrounding fluid partially lags, and the coupling is inertial and adhesive rather than far-field acoustic. Computing the density-contrast inertial force on a 10 µm cell (`rho_cell = 1050` against `rho_medium = 1000`, a 5 per cent contrast) at substrate displacement amplitude `A`:

```
cell volume 5.2360e-16 m^3, mass 5.4978e-13 kg, contrast mass 2.6180e-14 kg

f (Hz)     A (m)      accel (m/s^2)    contrast force (N)     contrast force (pN)
    50    1.0e-06        9.8696e-02          2.5839e-15                0.003
   440    1.0e-07        7.6430e-01          2.0009e-14                0.020
   440    1.0e-06        7.6430e+00          2.0009e-13                0.200
 1,000    1.0e-06        3.9478e+01          1.0335e-12                1.034
 5,000    1.0e-07        9.8696e+01          2.5839e-12                2.584
 5,000    1.0e-06        9.8696e+02          2.5839e-11               25.839
```

Single mechanosensitive-channel gating forces are of order 1 to 10 pN. **Substrate-borne vibration at micron amplitudes and kilohertz frequencies reaches that range. So there is a real coupling path, and any experiment must use it rather than pretending a loudspeaker in a room is a stimulus.**

But look at what that path delivers: a scalar, whole-cell, time-varying force. It is on the permutation-invariant list of Section 5.2 unless something downstream discriminates symbols, remembers their order, and maps the string to a locus. The physics gets the energy in. It does not get the message in. Those are different problems and only the first has a solution.

One further quantity, because it is the confound that ruins careless experiments:

```
acoustic heating   dT/dt = 2 alpha I / (rho c_p),  alpha from 0.5 dB/cm/MHz

f = 1 MHz,   I = 1e4 W/m^2  ->  2.7543e-02 K/s  =  1.6526 K/min
f = 1 MHz,   I = 1e3 W/m^2  ->  2.7543e-03 K/s  =  0.1653 K/min
f = 1 kHz,   I = 1e3 W/m^2  ->  2.7543e-06 K/s  =  0.0002 K/min
```

A one-kelvin change alters transcription in essentially any cultured cell. Temperature at the sample must be logged continuously and reported, not assumed constant because the incubator setting did not change.

31.5.4 5.4 Capacity is not the bottleneck, and saying so sharpens the gap

Take the cell's receiver bandwidth from the kinetics of the fastest well-characterised mechanical transducer available to it. Mechanosensitive channel inactivation time constants in the published range give first-order cutoffs of:

```
tau =  1.0 ms  ->  f_c = 159.155 Hz
tau =  5.0 ms  ->  f_c =  31.831 Hz
tau = 10.0 ms  ->  f_c =  15.915 Hz
tau = 15.0 ms  ->  f_c =  10.610 Hz
tau = 30.0 ms  ->  f_c =   5.305 Hz
```

Applying `C = B log2(1 + S/N)` [Shannon, 1948]:

B (Hz)	SNR (dB)	C (bits/s)	time for a 40-bit address	time for 1 kB
5	0	5.000	8.000 s	1638.4 s
5	10	17.297	2.313 s	473.6 s
5	20	33.291	1.202 s	246.1 s
16	0	16.000	2.500 s	512.0 s
16	10	55.351	0.723 s	148.0 s
16	20	106.531	0.375 s	76.9 s
100	10	345.943	0.116 s	23.7 s
1,000	10	3459.432	0.012 s	2.4 s

A twenty-nucleotide address is forty bits. At sixteen hertz of bandwidth and ten decibels of signal-to-noise that is seven hundred and twenty-three milliseconds. Even at the pessimistic end — five hertz, zero decibels — it is eight seconds. Read the other way, as the signal-to-noise ratio needed to push forty bits through in one second:

```
B =   5 Hz  ->  required SNR = 2^(40/5) - 1  = 255      = 24.07 dB
B =  16 Hz  ->  required SNR = 2^(40/16) - 1 = 4.657    =  6.68 dB
B = 100 Hz  ->  required SNR = 2^(40/100) - 1 = 0.3195  = -4.96 dB
```

None of these numbers is prohibitive. The information-theoretic room exists.

That is the point, and it is an uncomfortable point rather than an encouraging one. If the obstacle were capacity it would be a quantitative obstacle, and quantitative obstacles yield to engineering. **It is not. The obstacle is that there is no receiver — nothing performing D1, D2 and D3 — and a channel with adequate capacity and no receiver transmits exactly nothing.**

A radio wave carrying a symphony passes through a rock. The capacity of the path is enormous. The rock does not hear the symphony. The missing thing is not bandwidth.

31.5.5 5.5 What is missing, specifically

D1, symbol discrimination. With all four symbols in one register the four tones are separated by as little as 2.081 cents and span 41.034 cents overall (Section 6.6). Discriminating them requires a filter quality factor of:

```
symbol spacing    10 cents  ->  df =   4.206 Hz  ->  required Q = 172.62
symbol spacing    45 cents  ->  df =  19.118 Hz  ->  required Q =  37.97
symbol spacing   100 cents  ->  df =  43.170 Hz  ->  required Q =  16.82
symbol spacing   200 cents  ->  df =  88.907 Hz  ->  required Q =   8.17
symbol spacing  1200 cents  ->  df = 726.000 Hz  ->  required Q =   1.00

for reference, the human auditory filter at 726 Hz:
equivalent rectangular bandwidth = 103.06 Hz  ->  Q = 7.04
```

The cochlea, a purpose-built mechanical spectrum analyser with an active amplifier, has a quality factor of about seven at these frequencies. The register-spreading design of Section 6.7 exists precisely so the required `Q` drops to about one — symbols distinguished by *octave register* rather than by fine pitch.

But even a `Q` of one requires *some* frequency dependence, and here is the physical problem. A resonator at molecular scale in water is overwhelmingly overdamped. The unsteady Stokes number `beta = L sqrt(2 pi f rho / mu)` measures whether momentum diffuses across the object within one cycle:

f (Hz)	L = 10 um	L = 10 nm
100	2.5066e−01	2.5066e−04
1,000	7.9267e−01	7.9267e−04
20,000	3.5449e+00	3.5449e−03
1,000,000	2.5066e+01	2.5066e−02

At molecular scale `beta` is between `1e−4` and `1e−2` across the entire audible band and well beyond it. The object cannot store energy across a cycle. Its `Q` is far below one. That is the low-Reynolds-number regime, and it is why molecular machinery does not ring; Reynolds numbers for a 10 µm cell oscillating at kilohertz frequencies and micron amplitudes are of order `1e−3` and below.

So D1 has no molecular-scale solution and would have to be satisfied at whole-cell or whole-tissue scale, where `beta` approaches one. That is not impossible — a cell at 20 kHz has `beta = 3.54` — **but nothing is known to be built there for this purpose**, and it pushes the required frequencies out of the range the octave transposition of Section 6.5 targets.

D2, order memory. The symbol interval in Section 6.9's design table ranges from about 0.25 ms to about 200 ms. Compare that with the time a protein needs to cross a cell at a nominal diffusion coefficient of `1e−10` m^2/s:

```
L =  1 um  ->  mean 3D diffusion time L^2/6D =   1.667 ms
L = 10 um  ->  mean 3D diffusion time L^2/6D = 166.667 ms
```

At fast symbol rates a symbol is over before a signalling protein has crossed a micron. A decoder therefore cannot hold the string spatially; it must hold it in a state variable — a chemical state, a conformational state, a phosphorylation cascade with the right time constants — **and no such state machine with four-symbol resolution and roughly twenty-symbol depth has been described in any cell.** Calcium oscillation frequency coding is real and is the closest published analogue, but **it encodes a scalar rate, not an ordered string over a four-letter alphabet.**

D3, sequence-specific output. Covered in Section 5.2. **There is no proposed physical implementation. This is the one that is not a matter of degree: D1 and D2 are hard; D3 has no candidate.**

31.5.6 5.6 The near misses, and exactly why each is not the mechanism

Three results are routinely offered as though they closed this gap. **None does, and understanding why is the fastest way to understand the gap.**

Sonogenetics. Ultrasound activates specific cells. Real, published, replicated. **But read where the specificity lives: the experimenter expressed a particular channel in a particular cell type in advance. The address is in the cell, not in the sound.** The sound is a broadcast "on" signal and the selectivity is entirely a property of which cells were pre-engineered to listen. **That is the exact inverse of the architecture in question, which requires the address to be in the signal.** Sonogenetics is superb evidence that acoustic energy can drive specific cellular outcomes, and **zero evidence that a waveform can carry an address.**

Mechanotransduction to chromatin. Force at the cell surface transmits through the cytoskeleton, stretches chromatin and upregulates transcription. Real, direct and important [Curzi, 2026x]. **But the force is applied locally through a bead bound to a receptor and the response is graded with force magnitude. It is a scalar input producing a graded output. Nothing in it is order-sensitive.** It establishes the *pathway* from mechanics to transcription and says nothing about *content*.

The cochlea. Biology's proof that exquisite frequency analysis is buildable. **But it is a specialised organ with a basilar-membrane stiffness gradient spanning three orders of magnitude, an active amplifier, and a wired output to a brain performing the actual decoding.** Its existence proves that mechanical spectrum analysis is possible with purpose-built macroscopic structure. **It does not suggest that a fibroblast has any of it.**

And one case on the other side of the ledger, included because honesty requires it. The microwave auditory effect (Frey, *Journal of Applied Physiology* 17:689–692, 1962): pulsed radiofrequency energy produces an audible click, by thermoelastic expansion generating an acoustic wave in the head. **This was an implausible-sounding cross-modality channel that turned out to be real, and it was established the ordinary way — by demonstration, replication, and identification of the mechanism.** It is the standing counterexample to the claim that unexpected physical–biological channels do not exist, **and it is also the standing demonstration of what settling such a question looks like: not argument, not plausibility, but a mechanism and a measurement.**

Precedent, priced, and it is methodological rather than acoustic. The practice of recording an unresolved question formally, in the primary text, with a marker — the Talmudic *teiku*, and the apophatic tradition's discipline of stating exactly what cannot be said — records that the device was invented independently and maintained for centuries by people who had no statistics. **A body of knowledge with a formal slot for "unresolved" degrades more slowly than one without, because unresolved questions that lack a marker do not survive transmission.** The modern measurement of the same effect is the reform literature [Ioannidis, 2005, Open Science Collaboration, 2015, Nosek et al., 2018]. **The precedent column carries nothing about acoustics or cells and is not offered as though it did** [Curzi, 2026w].

31.5.7 5.7 What an experiment would have to demonstrate

Five conditions. **All five are necessary; the first decides everything.**

E1 — ORDER SENSITIVITY. The response to a stimulus differs from the response to its symbol-permuted twin, matched in total energy, duration, long-term power spectrum, symbol counts, envelope shape and crest factor. **Without E1 there is no sequence-specific channel, whatever else is observed.**

E2 — ADDRESS SPECIFICITY. The response occurs at a preregistered genomic locus determined by the address prefix, and does not occur at a matched control locus.

E3 — ADDRESS SWAP. Changing the address changes which preregistered locus responds, within the same experiment, cells, operator and session. **This is the condition no nonspecific stress response can imitate.**

E4 — DOSE-RESPONSE AND FIDELITY DEPENDENCE. The effect scales monotonically with a stimulus parameter under experimenter control, and degrades as the address is corrupted by a controlled number of symbol substitutions.

E5 — INDEPENDENT REPLICATION. A second laboratory, working from the written protocol and the released stimulus files, obtains the same result without contact with the originating group during the run.

Note what is not on that list: any change to any DNA sequence. E1 to E5 are entirely about which existing sequence is transcribed. **Nothing in the specified experiment could edit, alter or damage a genome, and nothing in it is proposed as having any clinical relevance.**

31.5.8 5.8 The control set

An experiment of this kind is defined by its controls, and a claim of this kind will be judged entirely on whether the following are present. Each is listed with the specific alternative explanation it excludes.

#	Control	Excludes
C1	**Scrambled-sequence control.** Same symbol tones, counts, duration and envelope; order permuted.	Any response to bulk energy, spectrum or duration. **This is the primary control.**
C2	**Shuffled-input control.** Pairing between input data and measured output destroyed by permutation across runs.	Any apparent input–output relation arising from analysis flexibility.
C3	Scrambled-address control: address prefix replaced by a 20-mer with no genomic match, payload identical.	Response driven by the payload or by exposure as such.
C4	Energy-matched noise: same power spectral density envelope, no symbol structure.	Response to broadband mechanical stimulation.
C5	Sham exposure: transducer mounted and clamped, coupling identical, drive off.	Handling, incubator vibration, mounting stress, time out of incubator.
C6	Thermal control: matched temperature trajectory without acoustic structure, continuously logged at the sample.	Acoustic heating (Section 5.3).
C7	Cell-free control: full protocol on medium alone.	Instrument artefacts in library preparation and sequencing.
C8	Positive control: transcriptional activation at the same preregistered locus by an established method.	An assay too insensitive to detect locus-specific activation at all.
C9	Retrograde control: the stimulus played time-reversed.	Response to spectrum plus gross envelope, which reversal preserves and order does not.
C10	Blinding and randomisation: stimulus assignment blinded to operator and analyst until the analysis is frozen.	Expectancy effects on handling and on analytic choices.

C1 and C2 are the two that get skipped. C1 is skipped because building a properly matched permuted stimulus is fiddly. C2 is skipped because it feels redundant once C1 is in place, **and it is not: C1 controls the *stimulus*, C2 controls the *analysis*.** A pipeline with enough free parameters will find structure in a correctly controlled stimulus set, and only C2 catches that [Curzi, 2026i, Simmons et al., 2011, Gelman and Loken, 2013].

And C2 must be calibrated rather than trusted, which is a correction this framework applies to itself. The corpus measured its own shuffled-input control against a nominal 0.05 across 500 null trials and found **iid permutation rejecting at 0.108, circular shift at 0.120, and only block permutation near nominal at 0.060** [Curzi, 2026u]. **The control is anti-conservative as ordinarily run — it rejects true nulls at more than twice its nominal rate — so any `p` it returns in this design is optimistic by an unknown factor, and block permutation is specified in Section 9.2 for that reason.**

C8 deserves a sentence of its own. Without a positive control a null is uninterpretable: it cannot be distinguished from an assay that could not have detected a real effect either. **An experiment reporting a null without a positive control has reported nothing.**

C10 is not boilerplate here. The same audit measured a demand-characteristic confound — subjects or operators inferring the hypothesis — passing an entire four-baseline suite **52.7 per cent of the time with a true effect of exactly zero, and found no statistical remedy for it, only design remedies** [Curzi, 2026u]. **Blinding is the design remedy and it is mandatory.**

31.5.9 5.9 What would settle it, in each direction

SETTLED POSITIVE requires all of the following, and each clause is there because a claim lacking it has failed before:

1. E1 through E5 satisfied, with the full C1–C10 control set present and reported.
2. Preregistration of the target locus, the effect size, the analysis and the stopping rule, timestamped before data collection, published whatever the outcome [Nosek et al., 2018].
3. Effect exceeding the preregistered threshold at a multiple-comparison-corrected significance level, with the correction stated.
4. Independent replication with no personnel overlap.
5. **A proposed mechanism addressing D1, D2 and D3 — or, absent a mechanism, an explicit statement that the effect is empirical and unexplained. The second is acceptable; silence is not.**

The statistical geometry of point 3 is where such claims usually die:

```
genes tested                                20,000
Bonferroni alpha                            2.500e-06
corresponding two-sided z                   4.7081
expected false positives at uncorrected 0.05  1,000 genes
```

A hit list of a few hundred genes at uncorrected `p < 0.05` is the null hypothesis, not a result. Preregistration is what converts a twenty-thousand-way search into a one-way test:

```
preregistering  1 target gene: chance hit probability 5.000e-05
preregistering  3 target genes: 1.500e-04
preregistering 10 target genes: 5.000e-04
```

And the address-swap crossover of E3 carries the most weight per sample, because a nonspecific stress response has no way to select which of two preregistered loci responds:

```
2 addresses x 2 preregistered loci, crossover
P(correct assignment by chance per replicate)              = 0.5
  3 independent crossover replicates -> p = 0.125000
  5 independent crossover replicates -> p = 0.031250
 10 independent crossover replicates -> p = 0.000977

P(a nonspecific response hits both preregistered loci in the correct pairing)
  = (2/20000)^2 x 0.5 = 5.000e-09
```

SETTLED NEGATIVE, for the tested condition, requires:

1. Adequate power, stated in advance, against a preregistered effect size.
2. A positive control demonstrating the assay would have detected that effect size.
3. **Equivalence testing, not a non-significant p-value.** Sample sizes for equivalence at 80 per cent power, nominal dispersion 0.1, mean count 100:

```
equivalence bound FC = 1.10  ->  n >= 104 per group
equivalence bound FC = 1.25  ->  n >=  19 per group
equivalence bound FC = 1.50  ->  n >=   6 per group
```

4. Full publication of the null with the stimulus files and raw data.

A frequentist `p > 0.05` is not evidence of absence. The likelihood-ratio view makes the difference visible immediately:

```
observed log2FC = 0.00, se = 0.10  ->  LR(null : alt at 0.5) = 2.683e+05   decisive for null
observed log2FC = 0.05, se = 0.10  ->  LR = 2.203e+04                      strong for null
observed log2FC = 0.00, se = 0.30  ->  LR = 4.01                           weak, uninformative
```

The third row is what an underpowered null looks like, and it is worth almost nothing.

31.5.10 5.10 What a null would mean, including the unwelcome part

Suppose the experiment is done properly and returns a clean, well-powered, positive-controlled null.

What it would establish. That under the tested conditions — that carrier scheme, amplitude, duration, symbol rate, cell type and harvest time — no sequence-specific transcriptional response occurs at the preregistered loci above the preregistered effect size. **That is a real and publishable result and it is the outcome this framework expects, absent a mechanism for D3.**

What it would not establish, and here is the uncomfortable arithmetic.

```
carrier / register scheme      4
amplitude levels               5
exposure duration              4
symbol rate                    4
cell type                      3
time-to-harvest                3
-------------------------------------
total conditions            2,880

a single well-powered experiment covers 1 of 2,880  =  0.0347% of the space

exhaustive coverage: 2,880 conditions x 7 arms x n=21  =  423,360 libraries
```

A null over one condition bounds three hundredths of one per cent of the space, and exhausting the space is not affordable. This cuts both ways and both must be said.

Against the claimant: it means "we haven't tried the right settings yet" is always available, which is precisely what makes a research programme unfalsifiable. **A claim that can retreat into a 2,880-cell parameter space indefinitely is not a scientific claim, and the only defence is to commit in advance to the conditions under which the claim is abandoned. This framework so commits** (SP-O.9 in Section 7.2) [Lakatos, 1970].

Against the sceptic: a single null does not close the question, and treating it as though it did would be the same error in the opposite direction.

The resolution is sequential design rather than exhaustion:

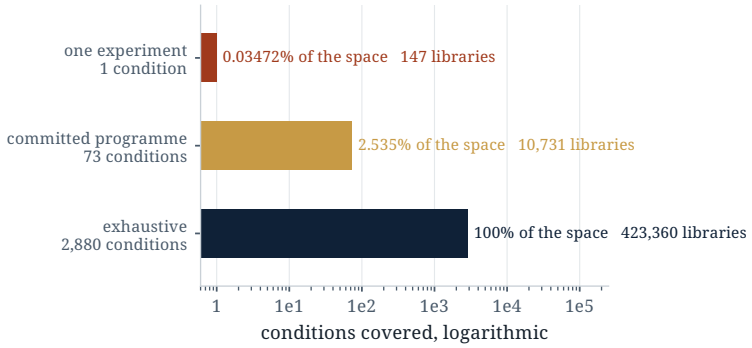

Figure 31.4: **One well-powered experiment bounds three hundredths of one per cent of the space, and the committed programme bounds two and a half.** The parameter space is `4 x 5 x 4 x 4 x 3 x 3 = 2,880` conditions; a single condition is 0.0347 per cent of it; the preregistered three-stage adaptive design of 1, then 8, then 64 conditions covers 73, or 2.53 per cent, at 10,731 libraries against 423,360 for exhaustive coverage. **The bar is drawn on a logarithmic axis because a linear one would render the single condition invisible, which is itself the point.** Computed from the factor counts of Section 5.10; generated by `figs/src/CCP-031_fig04.py`.

```
3-stage adaptive design: 1 condition, then 8, then 64
= 73 conditions x 7 arms x n=21 = 10,731 libraries = 2.53% of exhaustive
```

Seventy-three conditions, chosen adaptively with preregistered stopping rules, is a real programme at about two and a half per cent of the exhaustive cost. If nothing appears across that programme with the full control set, this framework's position is that the acoustic sequence-specific channel is to be treated as refuted for practical purposes and the pipeline of Section 6 retained only as what it demonstrably is — an encoding and sonification method.

31.5.11 5.11 What magnitude would even be detectable

The capacity analysis says the channel could carry a 40-bit address in under a second. **That tells us nothing about the *magnitude* of any downstream transcriptional change, because the map from bits received to fold change produced is exactly the unknown.** So the question is inverted: **what is the smallest transcriptional effect the experiment could see, and is it plausible that a real effect would be at least that large?**

Minimum detectable fold change at mean count 100, dispersion 0.1 and 80 per cent power, by the standard count-data formula (named without a key, Appendix A):

n per group	alpha = 0.05	alpha = 2.5e-6 (Bonferroni)
3	FC 1.710 (log2 0.774)	FC 2.894 (log2 1.533)
6	FC 1.461 (log2 0.547)	FC 2.120 (log2 1.084)
10	FC 1.342 (log2 0.424)	FC 1.790 (log2 0.840)
20	FC 1.231 (log2 0.300)	FC 1.509 (log2 0.594)
50	FC 1.140 (log2 0.190)	FC 1.297 (log2 0.376)

And the sample size required to detect a given effect:

alpha	FC	mean count	phi	n per group
nominal 0.05	1.25	100	0.10	18
nominal 0.05	1.50	100	0.10	6
Bonferroni (20k genes)	1.25	100	0.10	69
Bonferroni (20k genes)	1.50	100	0.10	21
Bonferroni (20k genes)	2.00	100	0.10	8

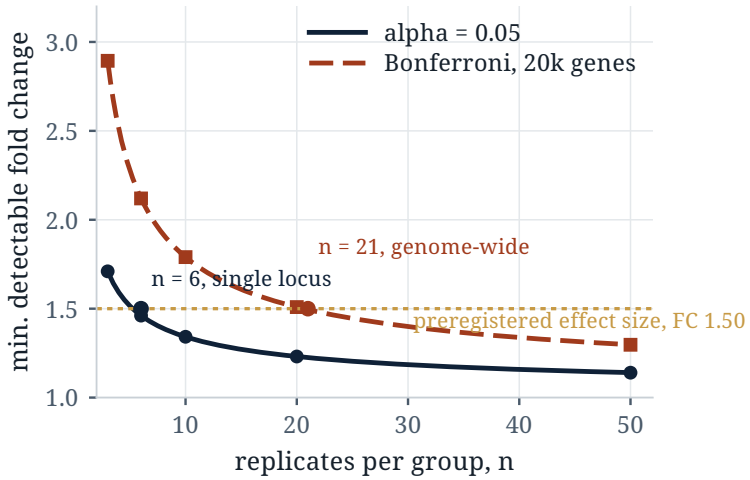

Figure 31.5: **The cost of not saying in advance what you expect is a factor of 3.5 in sample size.** Minimum detectable fold change against replicates per group at mean count 100 and dispersion 0.10, 80 per cent power, under a nominal `alpha = 0.05` and under Bonferroni correction across 20,000 genes. The preregistered effect size of 1.5-fold, marked, is reached at `n = 6` for a single declared locus and at `n = 21` genome-wide. **Below about 1.2-fold the requirement rises steeply and the effect enters the range of ordinary batch variation.** Computed from the standard count-data power formula named in Appendix A; generated by `figs/src/CCP-031_fig05.py`.

Read the preregistration consequence off the table directly: with a single preregistered locus the correction is trivial and `n = 6` detects a 1.5-fold change; with a genome-wide search the same detection needs `n = 21`. That is a factor of 3.5 in cost, paid entirely for the privilege of not having said in advance what you expected.

And the honest bound on the whole enterprise. Established transcriptional activation at a well-chosen locus routinely produces fold changes in the tens to hundreds. **An acoustic effect, if real, would have to reach at least 1.5-fold at a preregistered locus to be detectable at reasonable cost.** If the true effect is 1.05-fold it needs `n` in the hundreds per group, it sits inside the range of ordinary batch variation, **and an effect that small would in any case be indistinguishable in practice from the well-documented transcriptional response to mechanical stimulation [Curzi, 2026x] — which would make it uninteresting even if real, because it would not be sequence-specific.**

A sequence-specific acoustic channel is only worth looking for if it is large; if it is small it is unfindable; and if it is unfindable it should not be claimed.

31.6 6 The sonification pipeline

This section specifies the chain end to end, in enough detail that a competent engineer can build it from this text alone and obtain bit-identical results.

```
arbitrary binary data
    |  [1]  base-4 nucleotide encoding, homopolymer-constrained
    v
nucleotide string
    |  [2]  address prefix prepended  (a header, not a molecule)
    v
addressed nucleotide string
    |  [3]  symbol -> pitch mapping, from measured infrared band centres
```

```
    |  [4]  fixed integer octave transposition into the audible band
    |  [5]  tuning and framing: harmonic frame carrier, no standardised reference pitch
    v
audio waveform
    |  [6]  transmission
    v
( the open problem of Section 5 begins here and this section stops )
```

Stages 1 through 5 are engineering, demonstrated with computed and verified numbers including a round-trip hash check. Stage 6 is playback of an audio file. What happens after stage 6 is not claimed by this framework in any form.

31.6.1 6.1 What is built and what is postulated

Element	Status
Binary data maps losslessly to nucleotide strings	**BUILT, VERIFIED** (SHA-256 round trip)
Homopolymer-constrained rate is 1.98235 bits/base for max run 3	**COMPUTED** (transfer-matrix eigenvalue)
An implemented RLL(3) codec achieves 1.92834 bits/base	**MEASURED** on the test payload
A 20 nt prefix is a sufficient genomic address	**COMPUTED**
Wavenumber-to-frequency conversion is exact	**EXACT BY DEFINITION**
Octave transposition preserves pitch class exactly	**PROVED**
The essence law cannot supply a four-symbol alphabet	**PROVED, REJECTED IN PRINT**
Single-register coding fails on band-centre uncertainty	**COMPUTED**
Register spreading improves symbol separation 839-fold	**COMPUTED**
The Gabor limit constrains symbol rate	**PROVED** (classical Fourier)
That infrared band centres are the *right* frequencies to use	**POSTULATE**, badged
That a transposed tone bears any physical relation to the base	**REFUSED**
That any of this affects any cell	**NOT CLAIMED**

Six rows of computation, two proofs, one rejection, one badged postulate, one refusal and one open problem. That is the whole section and the reader is entitled to see it in that form first.

The strongest honesty clause in the paper belongs here. A guanine marker band near 1665 cm^{-1} corresponds to a molecular vibration at about `4.99e13` Hz; dividing by `2^36` yields 726.37 Hz. **A 726 Hz tone has no physical relationship to guanine whatsoever. Guanine does not absorb at 726 Hz, does not resonate at 726 Hz, and is not affected by 726 Hz. The mapping is a labelling convention chosen because it is principled, reproducible and derived from measurement rather than from taste. It is not a physical coupling and this framework never says or implies that it is** [Curzi, 2026w,?].

31.6.2 6.2 Stage 1: binary to base-4, and a correction

The reference result and the correction that must accompany it. The foundational demonstration encoded a book of roughly 5.27 megabits into synthesised oligonucleotides and recovered it by sequencing (Church, Gao and Kosuri, *Science* 337:1628, 2012; Appendix A). **That work did not use two bits per base. It used one:** `A` or `C` encoded a zero, `G` or `T` encoded a one, and the free choice within each pair was used to avoid homopolymer runs and control GC content. The oligo structure was 159 nt, decomposing as a 22 nt common flank, a 19-bit address, a 96-bit data payload and a second 22 nt flank — `22 + 19 + 96 + 22 = 159`, self-consistent with the reported length.

So "base-4 encoding by the Church method" is a compound of two things: the base-4 alphabet, which is the theoretical maximum, and the architecture — block, address, common flanks, recovery by sequencing — which is the part that was demonstrated. This pipeline uses both, **and says plainly that the doubling of rate relative to the 2012 paper is not something the 2012 paper did.**

```
unconstrained base-4                          2.00000 bits/base   100.00%
the 2012 demonstration (A|C=0, G|T=1)         1.00000 bits/base    50.00%
a base-3 scheme with 4x redundancy (2013)     below 1 bit/base
a fountain-code scheme (2017)                 1.57 bits/base achieved
    against a stated channel capacity of      1.83 bits/base      (85.79%)
```

The homopolymer constraint, computed exactly. Long runs of one base are a synthesis and sequencing liability. Restricting the maximum run length is a constrained-coding problem whose capacity is `log2` of the largest eigenvalue of the constraint's transfer matrix [Shannon, 1948, Cover and Thomas, 2006]:

```
max homopolymer run      lambda      bits/base     % of 2.0
------------------------------------------------------------
  unconstrained         4.00000       2.00000       100.00
              1         3.00000       1.58496        79.25
              2         3.79129       1.92269        96.13
              3         3.95137       1.98235        99.12
              4         3.98814       1.99572        99.79
              5         3.99706       1.99894        99.95
              6         3.99927       1.99974        99.99
```

Forbidding runs longer than three costs 0.88 per cent of capacity. Forbidding any repeat at all costs 20.75 per cent. The engineering conclusion writes itself.

The implemented codec is a rank-selection RLL(3) coder: at each position the encoder computes the allowed alphabet — all four symbols, unless the previous three were identical, in which case the repeated symbol is excluded and three remain — consuming two bits when four choices are available and one when three are. **The decoder reconstructs the allowed alphabet identically from the symbols already decoded, so no side information is transmitted.** Measured on the test payload of Section 9.3: **592 bits into 307 nucleotides, 1.92834 bits/base, 96.42 per cent of the unconstrained maximum and 97.28 per cent of the RLL(3) capacity, longest homopolymer 3, SHA-256 identical on round trip.** Naive two-bit packing on the same payload produced 296 nucleotides and **a longest run of 6**, which is exactly the failure the constraint exists to prevent; **eleven extra nucleotides, a 3.7 per cent expansion, buys compliance.**

Precedent, priced. String-to-number encoding, and the writing down of sound, were invented and refined repeatedly by people with no theory of information — letter-numeral schemes, neumes, tablature, the alphabet itself. **Encoding is old; error control is new. What separates the modern practice is not the idea of representing one thing by another but the measurable rate and the demonstrable inverse.** A letter-value scheme has no decoder — it

is many-to-one by construction and destroys information, measured at 10.47 of the 17.84 bits that identify a word on a 234,454-word list, with 99.995 per cent of words colliding [Curzi, 2026u]. **A code has an exact inverse and a hash to prove it. That difference is the whole of the measured column's advantage.**

31.6.3 6.3 Stage 2: the address prefix

The prefix is a 20-symbol string in guide format, prepended to the payload string. **It is a header. It is not a guide RNA. No RNA exists anywhere in this pipeline.** The format is borrowed because it is the format in which genomic addresses are conventionally written [Curzi, 2026x].

```
address space         4^20 = 1.099512e+12 = 2^40 = 40 bits
human genome 20-mer positions, both strands ~ 6.200e+09
expected chance exact matches = 2 x 3.1e9 / 4^20 = 0.005639
uniqueness margin                                = 177.3 x

spacer length   bits   expected genomic exact matches
    12 nt        24         369.548798
    16 nt        32           1.443550
    18 nt        36           0.090222
    20 nt        40           0.005639
    24 nt        48           0.000022
```

Sixteen nucleotides is not enough — it expects 1.44 chance matches in a genome this size. Eighteen is marginal. Twenty is the first length with a comfortable margin, which is why twenty is the convention, and the convention is arithmetic rather than tradition.

payload	payload nt	+ 20 nt address	total nt	overhead
64 B	256	20	276	7.2464%
256 B	1,024	20	1,044	1.9157%
1,024 B	4,096	20	4,116	0.4859%
1,048,576 B	4,194,304	20	4,194,324	0.0005%

Below about a kilobyte the header is a real tax; above it, it vanishes — the ordinary behaviour of any framed protocol, printed so nobody proposes shortening the address to save space where it costs 0.05 per cent.

31.6.4 6.4 Stage 3: why measured band centres, and the framework's own law rejected

The symbol-to-pitch mapping has to come from somewhere. **There are three candidates and two are rejected in print.**

Candidate 1: convention. Assign the four bases to four notes of a familiar scale. **Rejected because it is arbitrary** — any of `4! = 24` assignments would do, the choice carries no information, and a method whose central mapping is a preference is not a method.

Candidate 2: the framework's own essence law. `f(n) = k n^2` with `k = 0.483425732988414` Hz, using the base's ordinal index. **This is the framework's own law and it is rejected here, by its own theorem.** The corpus proves that two essences share a pitch class if and only if their indices have the same odd part, so an index set `1..N` yields exactly `ceil(N/2)` distinct pitch classes [Curzi, 2026]. For `N = 4`:

```
n    f = k n^2 (Hz)      odd part    pitch class
1      0.483425733           1          class 1
2      1.933702932           1          class 1
```

```
3      4.350831597          3          class 3
4      7.734811728          1          class 1

odd parts [1, 1, 3, 1] -> distinct pitch classes {1, 3} = 2 = ceil(4/2)
```

Three of the four bases collapse onto the same pitch class. A four-symbol alphabet cannot be carried by the essence law, and this is not a limitation of the application — it is a theorem about the law. The same obstruction applies at every even index count: twenty canonical amino acids give `ceil(20/2) = 10` classes, so exactly half collide.

Status: REJECTED as the alphabet tuning. The rejection is printed rather than quietly avoided because the concordance method requires that the apparatus be able to reject the framework's own favourite tools [Curzi, 2026w], and because a reader who checked would find the collision anyway. **A framework that cannot say "not here" about its own centrepiece is a preference, not a framework.** `k` remains a **defined** constant, exactly `(9/8)^2/phi^2`; **the hertz attachment remains a postulate**; and the standard critique of golden-section claims [Markowsky, 1992] is cited here as it is wherever `phi` appears.

Candidate 3, adopted: measured infrared absorption band centres of the four bases. The nucleic acid bases have characteristic vibrational absorptions in the 1550–1750 cm^{-1} region, dominated by carbonyl stretch and ring modes; that region is the standard diagnostic window in infrared spectroscopy of nucleic acids in solution (the standard compilation is named in Appendix A).

Nominal band centres, standing in for the operator's own measured spectrum:

```
base   nu (cm^-1)        f = c * nu (Hz)      log2(f / 1000 Hz)
  A       1626.0           4.874625e+13            35.5046
  C       1652.0           4.952571e+13            35.5275
  T       1663.0           4.985549e+13            35.5370
  G       1665.0           4.991544e+13            35.5388
```

The postulate, badged in the sentence that states it: the choice to derive the symbol pitches from measured molecular absorption rather than from convention is a design postulate, not a finding, and its entire justification is that it is principled and reproducible rather than that it is physically efficacious — the honesty clause of Section 6.1 forbids the latter reading absolutely.

What the choice buys, and it is not nothing: **the mapping is not arbitrary** (two implementers using the same source spectrum produce the same tones); **it is auditable** against a spectrometer; **it has a defensible ordering**, which candidate 1 cannot supply; and **the conversion step is exact.**

31.6.5 6.5 Stage 4: the octave transposition, the one exact step

`f = c nu`, with `nu` in reciprocal metres. **The speed of light has been exact by definition since the 1983 redefinition of the metre: `c = 299,792,458` m/s, no uncertainty. The wavenumber-to-frequency conversion therefore introduces no error at all, and every bit of uncertainty in the resulting pitch is uncertainty in the measured band centre.** That is a useful property to have isolated: it tells the operator exactly where to spend calibration effort.

Transposition is by a fixed integer number of octaves, `f_audible = f / 2^j`, **which preserves pitch class exactly** [Shepard, 1982]:

```
j = 33:   5674.811 ..  5810.923 Hz    audible
j = 34:   2837.405 ..  2905.461 Hz    audible
j = 35:   1418.703 ..  1452.731 Hz    audible
j = 36:    709.351 ..   726.365 Hz    audible
j = 37:    354.676 ..   363.183 Hz    audible
j = 38:    177.338 ..   181.591 Hz    audible
```

`j = 36` centres the alphabet near 720 Hz, in the region of good human frequency discrimination and clear of both low-frequency room modes and the high-frequency roll-off of ordinary reproduction chains. At `j = 36` the four symbols land at **A 709.3514, C 720.6940, T 725.4928 and G 726.3653 Hz.**

31.6.6 6.6 The problem this immediately creates

Those four numbers span seventeen hertz.

```
intervals relative to A (the lowest):
  A -> A     ratio 1.000000000       0.000 cents
  A -> C     ratio 1.015990160      27.464 cents
  A -> T     ratio 1.022755228      38.953 cents
  A -> G     ratio 1.023985240      41.034 cents

adjacent gaps:  A->C = 27.464 c    C->T = 11.489 c    T->G = 2.081 c
TOTAL SPAN OF THE ALPHABET = 41.034 cents = 0.410 semitones
MINIMUM ADJACENT GAP       =  2.081 cents = 0.8725 Hz
```

The entire four-symbol alphabet occupies less than half a semitone, and two of its symbols are two cents apart — below the discrimination threshold of most listeners under most conditions [Burns, 1999] and far below any plausible instrument tolerance.

Two independent consequences, both computed, both fatal to the single-register design.

First, the Gabor cost. `dt df >= 1/(4 pi) = 0.079577` [Gabor, 1946]. Resolving a 0.8725 Hz gap — taking `df` as half the gap, the least one can ask — requires

```
df = 0.8725 / 2 = 0.4363 Hz    ->    dt >= 182.410 ms    ->    5.482 symbols/second
```

Five and a half nucleotides per second. A 20 nt address takes 3.65 seconds and a kilobyte takes over twelve minutes. That is not a design; it is a demonstration that the design is wrong.

Second, and worse, the mapping is not robust to the measurement it is derived from. Band centres in solution shift with solvent, base pairing, ionic strength and temperature, routinely by several wavenumbers:

```
shift of  0.5 cm^-1 at 1665 cm^-1  =   0.520 cents
shift of  1.0 cm^-1                =   1.039 cents
shift of  2.0 cm^-1                =   2.078 cents
shift of  5.0 cm^-1                =   5.191 cents
shift of 10.0 cm^-1                =  10.367 cents
```

T and G are separated by exactly 2 cm^{-1}. A 2 cm^{-1} systematic shift does not degrade the distinction between them — it reverses it. The two symbols swap places. A code whose alphabet can be permuted by a routine solvent change is not a code.

This is the kind of finding a design section is for, and it is reported rather than suppressed. The obvious reading — "the infrared derivation is unusable" — is wrong, and the fix is exact.

31.6.7 6.7 Register spreading: the fix, and why it is exact

Octave transposition preserves pitch class exactly. Halving a frequency is exactly one octave and changes nothing else about it — not the ratio structure, not the pitch class, not the identity of the symbol. **Therefore each symbol may be given its own integer octave index without altering the tuning system at all.**

```
base   j    f_audible (Hz)
  A   36        709.3514
  C   35       1441.3880
  G   34       2905.4613
  T   33       5803.9424

sorted:  709.351   1441.388   2905.461   5803.942
adjacent gaps (Hz):     732.037   1464.073   2898.481    minimum 732.037 Hz
adjacent gaps (cents): 1227.46   1213.57    1197.92      minimum 1197.92 cents

single-register minimum gap    0.8725 Hz
spread-register minimum gap  732.0366 Hz
improvement factor             839.0 x

Gabor dt_min, single register (df = gap/2)   182.410  ms     5.5 symbols/s
Gabor dt_min, spread register (df = gap/2)     0.2174 ms  4599.5 symbols/s
speed-up in maximum symbol rate                839.0 x
```

Eight hundred and thirty-nine times faster, at zero cost to the tuning, because pitch class is invariant under octave transposition and the ratio structure of the alphabet is untouched.

And the robustness problem dissolves with it. The symbols are now separated by roughly an octave each; a 10 cm^{-1} systematic error is 10.367 cents against gaps of about 1200 cents. **The scheme tolerates band-centre errors two orders of magnitude larger than the ones that destroyed the single-register version.**

The required filter quality falls correspondingly, from `Q = 172.62` at a 10-cent spacing to `Q = 1.00` at 1200 cents, against a human auditory filter quality of about 7.04 at 726 Hz. **A receiver with a `Q` of one — essentially any device with frequency dependence at all — can separate the spread alphabet. Nothing short of a cochlea could separate the compressed one.** That comparison is included because Section 5.5 needs it, **and it does not change Section 5's conclusion: an easily separable alphabet solves requirement D1 and leaves D2 and D3 exactly where they were.**

31.6.8 6.8 Stage 5: the tuning system

No standardised reference pitch. No equal temperament. Both are conventions of recent date and neither appears anywhere in this pipeline. A440 is a twentieth-century standardisation — a useful decree, adopted so that orchestras in different cities can play together, carrying no structural content [Barbour, 1951]. Twelve-tone equal temperament defines the semitone as `2^(1/12)` and therefore the cent as exactly `1/1200` of an octave; it is a deliberate detuning of every interval except the octave in exchange for unlimited modulation [Benson, 2006, Doty, 2002].

In this system every pitch is `c nu / 2^j` and every interval is a ratio of two measured wavenumbers. The reference pitch is not chosen; it is the transposed absorption band. The intervals are not tempered; they are what the molecules measured. No claim is made that this is *perceptually* superior, and the literature that would contest such a claim — consonance depending on spectrum rather than on ratio — is cited here deliberately [Sethares, 2005, Plomp and Levelt, 1965].

```
pair      exact ratio (nu)      cents      nearest 12-ET      error
A -> C      1.015990160        27.464           0            +27.464
A -> T      1.022755228        38.953           0            +38.953
A -> G      1.023985240        41.034           0            +41.034
C -> T      1.006658596        11.489           0            +11.489
C -> G      1.007869249        13.570           0            +13.570
T -> G      1.001202646         2.081           0             +2.081
```

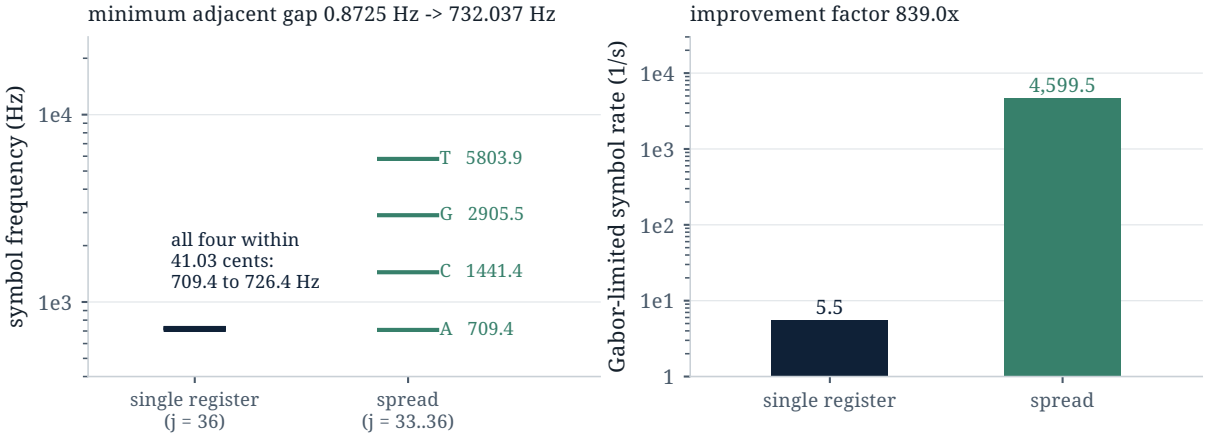

Figure 31.6: **One integer per symbol buys a factor of 839, and it costs nothing because octave transposition is exact.** Left: the four symbol tones in a single register, spanning 41.034 cents with a minimum adjacent gap of 0.8725 Hz, against the same four pitch classes spread across octave indices `j = 33..36`, where the minimum adjacent gap is 732.037 Hz. Right: the resulting Gabor-limited maximum symbol rate, 5.5 symbols per second against 4,599.5 — the same 839.0-fold factor, since `dt_min` is inversely proportional to the gap. **The spread scheme changes no pitch class and no interval ratio; every spread interval is its pitch-class interval plus a whole number of octaves.** Computed from the nominal band centres of Section 6.4; generated by `figs/src/CCP-031_fig06.py`.

Every interval in the alphabet is a microtone. None is any note of any twelve-tone scale. Equal temperament has nothing to say about this system, which is the point. After spreading, the same pitch classes in their assigned registers:

```
A -> C   ratio  2.031980   =  1227.464 cents
C -> G   ratio  2.015738   =  1213.570 cents
G -> T   ratio  1.997599   =  1197.919 cents
A -> G   ratio  4.095941   =  2441.034 cents
A -> T   ratio  8.182042   =  3638.953 cents
```

Each spread interval is exactly its pitch-class interval plus a whole number of octaves. That is the invariance doing its work and it can be checked by subtracting 1200 from each figure.

The frame carrier is derived from the alphabet itself by octave division, so that it shares a pitch class with symbol `A` exactly and is therefore already in the tuning:

```
f_A = 709.3514 Hz

carrier = f_A / 2^k      codon period      symbol dt      df_min      separable
-------------------------------------------------------------------------------
k=1       354.6757 Hz        2.819 ms        0.940 ms     84.673 Hz      yes
k=2       177.3378 Hz        5.639 ms        1.880 ms     42.336 Hz      yes
k=3        88.6689 Hz       11.278 ms        3.759 ms     21.168 Hz      yes
k=4        44.3345 Hz       22.556 ms        7.519 ms     10.584 Hz      yes
k=5        22.1672 Hz       45.112 ms       15.037 ms      5.292 Hz      yes
k=6        11.0836 Hz       90.223 ms       30.074 ms      2.646 Hz      yes
k=7         5.5418 Hz      180.447 ms       60.149 ms      1.323 Hz      yes
```

One carrier period is one codon; three symbols fill it. **The frame rate, the codon rate, the symbol rate and the alphabet are all locked to one number by integer octave relations, and no external reference enters anywhere.**

Precedent, priced. Pitch fixed by integer division of a stretched string makes the reference an *operation* anyone can repeat rather than a decree anyone must accept. **A tuning system is trustworthy to the extent that its reference is reconstructible from first principles by someone who has lost the documentation: a monochord can be rebuilt from a string and a ruler, a spectrum can be re-measured, and a standardised reference pitch can only be looked up.** That is a genuine and modest difference and it is all the precedent claims [Curzi, 2026w].

A second precedent, with its failure attached. Kepler's third law is correct, is still used, and fell out of a research programme explicitly organised around musical proportion in the heavens. **And the doctrine that produced it — that celestial motions stand in musical ratio — is false.** A search for harmonic structure produced one durable law and a great deal that was not durable, and **the sorting was done by measurement.** That is simultaneously the best argument for taking harmonic organisation seriously as a heuristic and the sharpest warning against taking it seriously as a result. **The position adopted is the practice rather than the doctrine: let the harmonic idea generate the design, and let the measurement decide what survives. Anyone citing this precedent who omits the failure is misusing it.**

31.6.9 6.9 The Gabor constraint as a hard design limit

```
dt . df  >=  1 / (4 pi)  =  0.079577472
```

This is classical Fourier duality, it applies to every wave including sound, and it has no quantum content whatsoever [Gabor, 1946, Curzi, 2026z]. **A short sound cannot have a precise pitch. That is not an instrumental limitation and no better instrument evades it.**

For this pipeline: **the faster you render, the more the symbol tones smear, and the smearing is what destroys the alphabet.** `df_min` is the best achievable frequency resolution at that symbol duration; a symbol is **separable** when `df_min <= (minimum adjacent gap)/2`.

dt (ms)	df_min (Hz)	sym/s	nt/s	codon/s	bits/s	cents @709Hz	1-reg?	spread?
0.20	397.887	5000.00	5000.00	1666.67	10000.0	770.87	no	no
0.25	318.310	4000.00	4000.00	1333.33	8000.0	641.75	no	yes
0.50	159.155	2000.00	2000.00	666.67	4000.0	350.44	no	yes
1.00	79.577	1000.00	1000.00	333.33	2000.0	184.07	no	yes
2.00	39.789	500.00	500.00	166.67	1000.0	94.48	no	yes
5.00	15.915	200.00	200.00	66.67	400.0	38.41	no	yes
7.52	10.582	132.98	132.98	44.33	266.0	25.64	no	yes
10.00	7.958	100.00	100.00	33.33	200.0	19.31	no	yes
20.00	3.979	50.00	50.00	16.67	100.0	9.68	no	yes
50.00	1.592	20.00	20.00	6.67	40.0	3.88	no	yes
100.00	0.796	10.00	10.00	3.33	20.0	1.94	no	yes
200.00	0.398	5.00	5.00	1.67	10.0	0.97	yes	yes
500.00	0.159	2.00	2.00	0.67	4.0	0.39	yes	yes

Read the two right-hand columns first, because they are the design decision. The single-register scheme is separable only at symbol durations of 200 ms and above — five nucleotides per second, ten bits per second. **The spread scheme is separable everywhere down to 0.25 ms, and fails only at 0.20 ms**, where `df_min` of 397.887 Hz exceeds half the 732 Hz minimum gap.

The Gabor limit is therefore not an obstacle to this design; it is the thing that chose the design. Without it, register spreading would look like an aesthetic preference for wide intervals. **With it computed, register spreading is the only scheme that renders at a usable rate.**

dt (ms)	nt/s	20-nt address	1 kB (4096 nt)	1 MB	3.1 Gbp
0.25	4000.0	0.005 s	1.024 s	17.48 min	8.97 d

1.00	1000.0	0.020 s	4.096 s	1.17 h	35.88 d
5.00	200.0	0.100 s	20.480 s	5.83 h	179.40 d
7.52	133.0	0.150 s	30.802 s	8.76 h	269.81 d
20.00	50.0	0.400 s	1.37 min	23.30 h	717.59 d
91.20	11.0	1.824 s	6.23 min	4.43 d	3272.22 d

A whole human genome renders in nine days at the fastest usable rate, and that number is included precisely so that nobody proposes it. The last row is the single-register counterfactual: **four and a half days for a kilobyte, nine years for a genome. That is what the 839-fold factor buys.**

31.6.10 6.10 Stage 6: transmission, and exactly where this stops

Rendering is additive synthesis, one sinusoid per symbol at the assigned spread frequency, with a raised-cosine envelope whose rise and fall are a fixed fraction of `dt` **to avoid the click artefacts of hard gating — those artefacts are broadband by construction and would smear the spectrum far worse than the Gabor limit does.** The frame carrier runs continuously beneath.

Sample rate, from the sampling condition [Nyquist, 1928]:

```
highest symbol tone (T)                        5803.9424 Hz
Nyquist minimum for the fundamentals           11607.9 Hz
with 8 partials of the highest tone            92863 Hz
-> 48 kHz sufficient for pure-tone rendering; 96 kHz if partials are added
```

And then the file is played. That is the end of what this section describes. Everything downstream of the loudspeaker or the transducer is the open problem of Section 5. This framework does not claim that the signal is received by anything, decoded by anything, or acted upon by anything. **The pipeline is a reproducible method for turning arbitrary data into a principled, disclosed, documented acoustic signal. Whether such a signal can be demodulated by a cell into sequence-specific content is unknown, has no proposed mechanism for requirement D3, and is the subject of a preregistered programme with a stated abandonment condition.**

31.7 7 Specifications

Three groups. The labels are stable identifiers carried from the source manuscript's numbering (Section 3.2), not pointers to sections of this paper.

31.7.1 7.1 S67 — the archive

S67-1 — Quote the ratio, not the mystique. Any use of the non-coding fraction in argument states the figure used (98.7 %, 45 %, 8 %), its annotation dependence, **and the constrained fraction (~8.2 %) in the same paragraph.** Failure to pair them is FM-A.1.

S67-2 — Never assert function from presence. Presence is not function; transcription is not function; occupancy is not function. **A function claim requires evidence of selective constraint or a loss-of-function experiment, and must name which.**

S67-3 — Cite the syncytin case with the knockout. The item is load-bearing only because a causal test exists. **A citation omitting the knockout presents a correlation as a demonstration.**

S67-4 — Cite the reprogramming case with the efficiency and the delivery method. State the 0.01–0.1 per cent efficiency range and that the original protocols used integrating retroviral delivery. **Omitting either is FM-A.4.**

S67-5 — State the information ratio. Wherever a small signal is claimed to reorganise a large archive, compute and print the ratio — 37.985 bits against `6.2e9` bits, `1.632e8 : 1`. **A claim of this shape stated without its arithmetic is rhetoric.**

S67-6 — Apply Constraint L67 before anything else. Every proposed application is first tested against the reachable set. **Target state not in the reachable set implies proposal rejected, no experiment scheduled, no further discussion.**

S67-7 — Every concordance states its columns' roles, with an explicit status line. **A concordance without a status line is not admissible.**

S67-8 — Reject at least one bridge where the material permits. Section 4.8 is this paper's.

S67-9 — The three refusals are absolute. No clinical, medical or therapeutic claim. No claim that genomic sequence is edited, altered or damaged. No claim that any capability has been conferred.

S67-10 — Versioned figures carry their version. Gene, lncRNA and miRNA counts change between annotation releases; such numbers name their source database and are presented as approximate, or are replaced by a range.

31.7.2 7.2 S68 — the open problem

S68-1 — State the gap verbatim. Every document touching acoustic-to-cellular signalling contains the sentence of Section 5.1, unmodified, **and does not surround it with hedging that reduces its force.**

S68-2 — Report the ten-and-one accounting together (Section 3.1), in full.

S68-3 — The permuted-symbol control is mandatory and primary. An experiment without C1 has not tested the hypothesis it claims to test, regardless of its result.

S68-4 — The shuffled-input control is mandatory, and is calibrated rather than trusted. C1 controls the stimulus; C2 controls the analysis; **both are required, and C2's measured false-rejection rate against nominal is reported with any p it produces** [Curzi, 2026u].

S68-5 — A positive control is mandatory. A null without one is not a null; it is an uninterpretable absence.

S68-6 — Preregister the locus, the effect size, the analysis and the stopping rule. Publish the registration before collection and the result regardless of direction.

S68-7 — Log temperature at the sample continuously and report the trajectory.

S68-8 — Report nulls with equivalence bounds or Bayes factors, never with a bare p-value.

S68-9 — Commit in advance to abandonment. The parameter space is 2,880 conditions. The preregistered programme is a three-stage adaptive design covering 73. **If that programme returns null, the sequence-specific acoustic channel is treated as refuted for practical purposes and the claim is withdrawn from this corpus. A claim that cannot name its own abandonment condition is not admitted at all.**

S68-10 — Never present the near misses as the mechanism. In each case the specificity resides somewhere other than in the waveform (Section 5.6).

S68-11 — The three refusals are absolute.

S68-12 — Compute, do not gesture. Every physical objection and every statistical requirement here is a number, and any restatement elsewhere carries the number.

31.7.3 7.3 S69 — the pipeline

S69-1 — Publish the mapping table with every rendered signal: base, wavenumber, source of the wavenumber, j, resulting frequency, symbol duration, carrier, codec parameters. **A rendered signal without its mapping table is not reproducible and is not admitted.**

S69-2 — Verify the codec by hash on every run. Encode, decode, compare SHA-256, print both digests.

S69-3 — Constrain homopolymer runs at 3. The cost is 0.88 per cent of capacity; naive packing produced a run of 6 on the test payload.

S69-4 — Use a 20 nt address minimum. 18 nt expects 0.090222 chance genomic matches, 16 nt expects 1.443550, 20 nt expects 0.005639 — a margin of 177.3×.

S69-5 — Use register spreading, not single-register coding. The factor is 839.0 in symbol rate and roughly two orders of magnitude in tolerance to band-centre error.

S69-6 — Re-measure the band centres, or cite the exact source spectrum, stating solvent, temperature and pairing state. **A 2 cm^{-1} systematic shift reorders two symbols in the single-register scheme and is within the routine range of variation.**

S69-7 — Compute the Gabor row before choosing a symbol rate. `dt >= 0.079577 / df` with `df <= (minimum adjacent gap)/2`. **Never choose a rate by ear.**

S69-8 — Derive the frame carrier from the alphabet by integer octave division. Never import an external tempo or reference pitch.

S69-9 — No standardised reference pitch, no equal temperament, anywhere in the chain.

S69-10 — No subliminal content, ever. Nothing masked, nothing below threshold, nothing concealed; every symbol audible and disclosed [Curzi, 2026ad].

S69-11 — Print the built/postulated table (Section 6.1) with every presentation of the method.

S69-12 — Never state or imply a physical relation between a transposed tone and a molecule. 726 Hz is a label for guanine. It is not a property of guanine.

S69-13 — The three refusals are absolute.

31.8 8 Failure modes

31.8.1 8.1 FM-A — faults of the archive argument

FM-A.1 · The function inflation. *Signature:* the text moves from “98.7 % is non-coding” to “98.7 % is functional” across a paragraph break. *Mechanism:* the retirement of “junk” is over-applied; **the negation of “worthless” is “not worthless”, not “essential”.** *Diagnostic:* search for a percentage above 50 within two sentences of “function”, “regulatory” or “purpose”. *Fix:* S67-1. **If the argument survives with 8.2 per cent in the paragraph it was a real argument; if it does not, it was inflation.**

FM-A.2 · The onion omission. *Signature:* a functional-genome argument that never mentions the C-value problem. *Mechanism:* **the strongest objection is the least convenient, so it drops out of successive drafts by attrition rather than by decision.** *Diagnostic:* does the text contain a genome-size comparison across taxa? *Fix:* Section 4.3 is mandatory content wherever Section 4.2’s figures are used. **A model that has to hide the onion is not ready.**

FM-A.3 · Syncytin as metaphor. *Signature:* the case appears as an image rather than as an item with a knockout behind it. *Diagnostic:* does the passage name the phenotype? *Fix:* S67-3. **The item is strong enough that it does not need help.**

FM-A.4 · The free lunch. *Signature:* reprogramming cited as though four factors reliably and easily convert cells, with the efficiency unstated. *Diagnostic:* does the passage contain a number between 0.01 and 1 per cent? *Fix:* S67-4.

FM-A.5 · Latency laundering. *Signature:* “latent” used to mean “possible”, then “possible” used to mean “available”. **The chain runs: the genome contains latent capability, therefore capability X is latent, therefore capability X is available — and the middle step is never argued.** *Diagnostic:* for the specific capability named, is there a citation showing it is encoded and reachable in this cell type? *Fix:* Constraint L67 and S67-6. **The reachable set is not “everything imaginable”; it is a specific, finite, studied object, and if you have not checked membership you have not made a claim.**

FM-A.6 · The cardinality bridge. *Signature:* two systems identified because they have the same number of elements. *Diagnostic:* factorise both counts; if the factorisations differ (`2^6` against `4^3`) the structures differ. *Fix:* Section 4.8. **Compute the number of available bijections and print it; 296.0 bits of arbitrary choice is a sufficient answer.**

FM-A.7 · Precedent promoted to evidence. *Signature:* a philosophical or scriptural source appears to support a biological fact. *Diagnostic:* **delete the precedent from the paragraph; does the biological claim still stand? It must.** *Fix:* Section 3.5. **This is the failure the entire concordance method exists to prevent and it is the one most likely to occur** [Curzi, 2026w].

FM-A.8 · The unbadged speculation. *Signature:* a speculative bridge stated in a sentence containing no badge. *Mechanism:* badges are added in revision and revision misses sentences. *Diagnostic:* every claim should be traceable to a row of Section 6.1 or Section 3.1. *Fix:* badge it in the same sentence or delete it.

31.8.2 8.2 FM-O — faults of the open-problem argument

FM-O.1 · The upstream launder. *Signature:* a paragraph lists data storage, guide addressing, array processing, mechanotransduction and reprogramming, then concludes with "therefore" and a claim about acoustic delivery. *Mechanism:* **five true premises placed adjacent to a sixth unsupported one, and adjacency does the work of inference.** *Diagnostic:* delete the last sentence; do the five premises entail it? **Every one of them is upstream of the gap, and no quantity of upstream facts crosses a gap.** *Fix:* S68-2.

FM-O.2 · The permutation-blind experiment. *Signature:* an experiment comparing "sonified sequence" against silence or music. *Mechanism:* the comparison feels obvious and it tests bulk energy delivery, which is already known to affect cells. *Diagnostic:* is there an arm whose stimulus is the permuted twin? *Fix:* S68-3. **This is the failure mode that would produce a false positive most easily.**

FM-O.3 · The uncorrected hit list. *Signature:* "347 genes significantly changed" with no correction stated. *Diagnostic:* multiply tests by uncorrected alpha; **if the hit count is at or below that product, the result is the null hypothesis wearing a table.** *Fix:* preregister one locus.

FM-O.4 · The thermal artefact. *Signature:* heat-shock genes at the top of the list. *Diagnostic:* look for them before looking at anything else; check whether temperature was logged at the sample or inferred from the incubator. *Fix:* S68-7 and control C6.

FM-O.5 · The unfalsifiable retreat. *Signature:* each null followed by a new proposed condition, indefinitely. *Diagnostic:* has an abandonment condition been stated in writing, in advance, with a number in it? *Fix:* S68-9. **The retreat is only unfalsifiable if it has no floor; give it a floor of 73 conditions and it becomes a finite programme.**

FM-O.6 · The underpowered null presented as refutation. *Signature:* "no significant effect" with `n = 3` and no positive control. *Diagnostic:* compute the minimum detectable fold change; at `n = 3` under Bonferroni it is 2.894. **An experiment that could only have seen a tripling has not tested a 1.5-fold hypothesis.** *Fix:* S68-5 and S68-8.

FM-O.7 · The plausibility substitution. *Signature:* an argument that the mechanism is "not impossible", offered where a demonstration belongs. *Diagnostic:* does the passage contain a measurement? *Fix:* **"Not proven impossible" carries no evidential weight whatsoever and is not a premise.**

FM-O.8 · The sonogenetics substitution. *Signature:* sonogenetics cited as though it demonstrated acoustically-addressed specificity. *Diagnostic:* **in the cited work, what determines which cells respond — the waveform, or which channel was expressed in advance?** *Fix:* S68-10.

FM-O.9 · Capacity mistaken for the problem. *Signature:* an argument that the method fails because the channel is too narrow, or succeeds because it is wide enough. *Diagnostic:* does the argument mention D1, D2 or D3? *Fix:* Sections 5.4 and 5.5. **The rock does not hear the symphony, and the reason is not bandwidth.**

FM-O.10 · The vanishing gap. *Signature:* across successive drafts the sentence of Section 5.1 becomes shorter, then parenthetical, then a footnote, then absent. *Mechanism:* **attrition. Nobody decides to remove it; it is trimmed for flow, once per draft.** *Diagnostic:* count its

occurrences. *Fix:* S68-1. **This is the failure that would cost the work its integrity, and it is the one that happens without anyone intending it.**

31.8.3 8.3 FM-S — faults of the pipeline

FM-S.1 · The resonance slip. *Signature:* a transposed tone said to "match", "correspond to" or "resonate with" a base. *Diagnostic:* substitute "is a label for"; **if the sentence becomes false or uninteresting it was making a physical claim.** *Fix:* S69-12. **The molecule vibrates at `4.99e13` Hz; the tone is at 726 Hz; those are different numbers related by an act of division performed on a computer.**

FM-S.2 · The compressed alphabet. *Signature:* all four symbols within half a semitone. *Diagnostic:* compute the minimum adjacent gap; under 100 cents is compressed. *Fix:* S69-5. **The two symptoms are a maximum symbol rate of 5.5 per second and total loss of the T/G distinction under a 2 cm^{-1} band shift.**

FM-S.3 · The uncomputed rate. *Signature:* a symbol duration chosen because it sounded good. *Diagnostic:* is `dt df >= 0.079577` satisfied for the design's `df` requirement? *Fix:* S69-7.

FM-S.4 · The homopolymer. *Signature:* a run of six or more identical symbols, audible as a held tone. *Diagnostic:* scan for the longest run before rendering. *Fix:* S69-3.

FM-S.5 · The misattributed method. *Signature:* "two bits per base, following the 2012 demonstration." *Diagnostic:* **that work used one bit per base.** *Fix:* Section 6.2. **Cite the architecture to its authors and the rate to whoever achieved it.**

FM-S.6 · The essence-law reflex. *Signature:* `f = k n^2` applied to a symbol set without checking the pitch-class count. *Diagnostic:* compute `ceil(N/2)`; if it is less than `N`, symbols collide. *Fix:* Section 6.4. **Reject in print. The theorem is the framework's own and it says no.**

FM-S.7 · The imported reference. *Signature:* a tempo marking, a metronome number, or a pitch given relative to a standardised reference anywhere in the specification. *Fix:* S69-8 and S69-9.

FM-S.8 · The unstated spectrum. *Signature:* band centres quoted with no source, solvent or temperature. *Mechanism:* **the numbers look like constants of nature and they are not.** *Fix:* S69-6.

FM-S.9 · The biological slide. *Signature:* a paragraph that begins with the encoder and ends with a cell. *Mechanism:* the pipeline has six stages and the sixth is playback, **so the seventh feels like it follows.** *Fix:* S69-11. **The method stops at the transducer. It stops there in every retelling, or the retelling is not this method.**

FM-S.10 · The concealed payload. *Signature:* any proposal to mask the signal beneath music, to place it below the threshold of hearing, or to embed it without disclosure. *Mechanism:* **it is the obvious way to make the method palatable and it is disqualifying.** *Fix:* S69-10 [Curzi, 2026ad].

31.9 9 Results

31.9.1 9.1 An audit that rejects a proposal at step one

A proposal arrives in the form these usually take:

> *"Non-coding DNA is 98 % of the genome and is full of latent regulatory capability. Reprogramming shows that four signals can flip a cell's entire state. So the method could plausibly upregulate a dormant tissue-repair programme."*

Step 1 — S67-1. Are the figures paired? No. Required paired form: non-coding ~98.7 % (annotation-dependent), transposable-element derived ~45 %, endogenous-retrovirus derived ~8 %, **under evolutionary constraint ~8.2 %**, protein-coding CDS ~1.25 % (0.86 % by the

gene-count route). **Verdict: FM-A.1 present.** The 98.7 per cent figure was doing work only the 8.2 per cent figure is entitled to do. **The corrected paragraph says: there is a large non-coding fraction, roughly a tenth of the genome is under constraint, and the regulatory apparatus lives mostly in the constrained part. That is still a real claim and the proposal can proceed on it.**

Step 2 — S67-2. Is function asserted from presence? "Full of latent regulatory capability" asserts function from bulk. **The supportable version is that the non-coding fraction contains the regulatory apparatus and that specific elements within it have documented function. The word "full" carries no evidence and is deleted.**

Step 3 — S67-4. Is the reprogramming citation complete? No. Add the efficiency range (0.01–0.1 per cent, 10,000 or 1,000 cells per colony) and the integrating retroviral delivery of the original protocols. **Verdict: FM-A.4 present.** "Four signals can flip a cell's entire state" becomes **"four factors returned a small fraction of fibroblasts to pluripotency, in a protocol that integrated sequence." The claim survives, weaker and true.**

Step 4 — S67-5. Compute the information ratio. `log2 C(1600,4) = 37.985` bits against `6.2e9` bits, a ratio of `1.632e8 : 1`. **This is the strongest part of the proposal and the proposer had not computed it. Keep it.**

Step 5 — S67-6 and Constraint L67. Is the target in the reachable set? This is the step that decides the proposal, and the step the proposal skipped entirely.

```
Q1  Is the programme encoded in this cell type's genome?
Q2  Is it reachable from this cell type's current chromatin configuration
    under some combination of regulatory input?
Q3  Is there a published transdifferentiation, dedifferentiation or activation
    protocol that reaches it, by ANY means (chemical, genetic, mechanical)?
Q4  If Q3 is no, is there evidence the programme is expressed in ANY cell of
    the organism at ANY developmental stage?
```

If Q1 is no, the proposal is dead and the architecture says so — there is no import path. If Q1 is yes and Q2 unknown, the proposal is not dead but it is not a proposal either; it is a request to establish Q2, which is a different and much larger piece of work. If Q3 is yes, a positive control exists and the proposal becomes testable, **which is the only state in which it should consume resources.**

For the phrase as written — "a dormant tissue-repair programme", unnamed, unlocalised, in an unspecified cell type — **Q1 cannot be evaluated, therefore the proposal is rejected at step one. Not disproved. Not discouraged. Not yet a proposal.**

Step 6 — S67-9. "Tissue-repair programme" is within a hair of a therapeutic claim. **It must be removed or restated as a purely cell-biological observable with no clinical referent — expression level of a named transcript in a named cultured cell line. Rewrite or delete; there is no third option.**

Outcome. After audit the proposal is not an application. **It is a request for a literature search establishing Q1 through Q4 for one named target in one named cell type.** That search costs a week and answers the question. **The audit converted an unfalsifiable enthusiasm into a bounded task, in six steps, using only the constraint that the architecture cannot import anything.**

31.9.2 9.2 The preregistered decisive experiment

Written as a registration document, because that is the form it would take. It specifies an experiment that has not been performed. No result is reported, implied, or anticipated.

HYPOTHESIS. The transcript abundance of preregistered locus `L_A` differs between exposure to stimulus `S_A` (whose 20-symbol address prefix corresponds to `L_A`) and exposure to `S_A*`, the symbol-permuted twin of `S_A`. **NULL:** no difference exceeding the preregistered equivalence bound.

PRIMARY ENDPOINT. log2 fold change in L_A transcript, S_A versus S_A*, by RT-qPCR with three reference genes, confirmed by RNA sequencing.

PREREGISTERED EFFECT SIZE. log2FC = 0.585, fold change 1.5. **Chosen because Section 5.11 shows it is detectable at n = 21 under genome-wide correction and at n = 6 for a single preregistered locus, and because anything smaller is inside the range of ordinary batch variation.**

SAMPLE SIZE. n = 21 per arm. At mean count 100, dispersion 0.10, 80 per cent power and alpha = 2.5e-6, detecting FC = 1.50 requires 21 per group. **Using the genome-wide figure for a single-locus test is deliberate over-powering, and it buys a genome-wide secondary analysis from the same samples without a second experiment.**

ARMS. Eight, matching Section 5.8:

```
A1  S_A           address -> L_A, payload P
A2  S_A*          permuted twin of S_A                      [C1, PRIMARY CONTROL]
A3  S_B           address -> L_B, payload P                 [E3 crossover partner]
A4  S_B*          permuted twin of S_B                      [C1 for the crossover arm]
A5  S_null        address = 20-mer with no genomic match    [C3]
A6  noise         energy- and spectrum-matched, unstructured [C4]
A7  sham          transducer clamped, drive off             [C5]
A8  positive      established activation targeting L_A      [C8]

plus:  C6 thermal control with continuous sample-probe logging
       C7 cell-free control through the full library preparation
       C2 shuffled-input control applied at analysis, BLOCK PERMUTATION
       C9 retrograde stimulus as a secondary arm if budget permits
total wet libraries: 8 arms x 21 = 168, plus controls
```

STIMULUS DELIVERY. Substrate-borne, not airborne. **Section 5.3 shows far-field airborne coupling to a single cell is negligible: producing 1200 Pa of differential pressure across a 10 µm cell at 1 kHz would require 2.94e7 Pa, equivalent to 243.3 dB, which is not a sound.** Delivery is by a calibrated piezoelectric stage under the culture vessel, with displacement amplitude measured by laser vibrometry at the vessel floor and reported per run. Target amplitude 1 µm at 1–5 kHz, giving contrast forces in the 1–26 pN range, **which is the range in which mechanosensitive channels are reported to gate.**

MATCHING REQUIREMENTS ON THE PERMUTED TWIN. It must match S_A in total energy to within 0.1 per cent; duration exactly; symbol histogram exactly; long-term power spectrum to within 0.5 dB in every third-octave band; envelope shape per symbol identically; crest factor to within 1 per cent. **The permutation must be a genuine random permutation of symbol order, drawn once, recorded in the registration, and fixed.**

BLINDING. Stimulus files are named by hash; the operator receives hashes; the analyst receives hashes; the mapping is held by a third party and released after the analysis is frozen and uploaded. **This is mandatory rather than good practice: the corpus's own audit measured a demand-characteristic confound passing an entire four-baseline suite 52.7 per cent of the time with a true effect of zero, and found no statistical remedy for it** [Curzi, 2026u].

ANALYSIS, FROZEN IN ADVANCE. Negative-binomial generalised linear model, arm as fixed effect, batch as blocking factor. Primary contrast A1 versus A2. Bonferroni correction over the two preregistered loci for the primary analysis; Benjamini–Hochberg over all detected genes for the secondary genome-wide analysis, **reported separately and labelled exploratory. The shuffled-input control uses block permutation rather than iid permutation, because the corpus measured iid permutation false-rejecting at 0.108 and circular shift at 0.120 against a nominal 0.05, with only block permutation near nominal at 0.060** [Curzi, 2026u].

STOPPING RULE. No interim looks. Collection stops at n = 21 per arm regardless of what is observed.

DECISION RULES, WRITTEN BEFORE COLLECTION.

```
POSITIVE  requires ALL of:
    (a)  A1 vs A2 differs, |log2FC| >= 0.585, p < 2.5e-6                    [E1]
    (b)  A1 changes L_A and not L_B; A3 changes L_B and not L_A             [E2, E3]
    (c)  A5 (no-match address) does not differ from A2                      [C3]
    (d)  A6 and A7 do not differ from each other                            [C4, C5]
    (e)  A8 shows the expected activation at L_A                            [C8]
    (f)  the block-permutation shuffled-input analysis returns null         [C2]
    (g)  temperature excursion < 0.2 K at the sample                        [C6]

NEGATIVE  is declared when:
    (a)  A8 confirms assay sensitivity                                      [C8]
    (b)  TOST rejects effects outside FC [1/1.25, 1.25] at alpha 0.05
    (c)  the result is published with stimulus files and raw reads

UNINTERPRETABLE  if A8 fails, if C6 shows excursion >= 0.2 K, or if C7 shows
    contamination. In that case NOTHING is reported except the failure.
```

WHAT A POSITIVE RESULT WOULD AND WOULD NOT MEAN. It would mean the transcriptional response is order-dependent and address-selective under one condition, in one cell type, at one amplitude. **It would not mean that any mechanism has been identified — D1, D2 and D3 would all remain unexplained and the report would have to say so explicitly. It would not mean that any DNA had been edited, altered or damaged; the design contains nothing that could do so. It would not constitute any clinical, medical or therapeutic finding of any kind.** It would mean the question had moved from unasked to open, and that the next obligation is independent replication.

WHAT THE EXPECTED RESULT IS. This framework's expectation, on the record before the fact: the null. D3 has no candidate implementation and this author does not have one. **Recording that expectation in advance is what makes the eventual result informative in either direction, and refusing to record it is how a research programme becomes unfalsifiable** [Nosek et al., 2018, Meehl, 1967].

PROGRAMME COMMITMENT. Per S68-9, this registration is condition 1 of a preregistered 73-condition three-stage adaptive design (1, then 8, then 64) covering 2.53 per cent of the exhaustive 2,880-condition space at approximately 10,731 libraries. **If the full programme returns null, the sequence-specific acoustic channel is withdrawn from this corpus and the pipeline of Section 6 stands solely as what it demonstrably is — a reproducible encoding and sonification method with no demonstrated biological effect.**

31.9.3 9.3 The pipeline run end to end, with verified digests

PAYLOAD.

symbol rate        531.91 nt/s
codon rate         177.305 codons/s
net bit rate       1.92834 / 0.001880 = 1025.7 bits/s = 128.21 bytes/s
```

STAGE 6 — render.

```
duration        327 x 1.880 ms = 0.6148 s
highest tone    5803.9424 Hz   ->   Nyquist minimum 11.61 kHz
sample rate     48 kHz for pure tones; 96 kHz if 8 partials are synthesised
file size       48 kHz / 24-bit mono ->  88,525 bytes = 0.0885 MB
                96 kHz / 24-bit mono -> 177,051 bytes = 0.1771 MB
```

THE COUNTERFACTUAL, for the record. The same payload in the single-register scheme:

```
minimum adjacent gap    0.8725 Hz
required df             0.4363 Hz
Gabor dt_min            182.410 ms
symbol rate             5.482 nt/s
duration of this payload 327 x 182.410 ms = 59.65 s
ratio to the adopted design                = 97.0 x longer
and T and G are 2 cm^-1 apart, so a routine solvent shift swaps them
```

Ninety-seven times longer and not robust. The Gabor computation revealed this, and listening would not have.

WHAT HAS BEEN DEMONSTRATED, with verifiable digests: arbitrary binary data encodes losslessly into a homopolymer-constrained nucleotide string at 1.92834 bits/base; the decode is exact, SHA-256 identical; a 20 nt address prefix is prepended at 6.116 per cent cost on a 74-byte payload; each symbol maps to a pitch derived from a measured wavenumber and an integer octave index with the conversion exact by definition; the symbol rate is set by the Gabor limit with a computed 8.65× margin; and the result is a 0.6148-second audio file whose every component is documented, audible and disclosed.

NOT DEMONSTRATED, AND NOT CLAIMED ANYWHERE: that the signal is received by any cell; that any cell demodulates sequence-specific content from it — **there is no established mechanism, and specifically no proposed physical implementation of requirement D3 by anyone including this author**; that anything is edited, altered or damaged — **nothing in this pipeline is a molecule**; that any capability has been conferred; or any clinical, medical or therapeutic claim of any kind.

The method is real as engineering and unproven as biology, and this paper has been written so that no reader can mistake which is which. Section 5.10 states the condition under which the biological claim is withdrawn entirely; **if that condition is met, everything in Section 6 still stands, because everything in Section 6 is a computation with a hash attached.**

31.10 10 Discussion

31.10.1 10.1 What follows

The most transferable result is a constraint rather than a capability, and that is deliberate. Constraint L67 bounds the claim space of the entire architecture, names a single observation that would end it, generates a positive prediction about reachable sets, and supplies an audit rule that rejects a proposal in six steps. **A limitation stated sharply is worth more than a capability stated vaguely**, and Section 9.1 is what that is worth in practice.

The pairing rule generalises to any field with a headline statistic and a constraining one. The non-coding fractions and the constrained fraction measure different things and are not in conflict; **quoting one without the other is a choice of number rather than an argument.** The same structure recurs wherever a system's nominal size and its effective size diverge — and the corpus's own canonical-form work is the same discipline applied to identifiers, where comparing entries on a canonical form with an independent witness takes a reconciliation false-break rate from 40.0 per cent to 0.0 per cent [Curzi, 2026], and its time-axis concentration work is the same arithmetic again: a constructed maturity stack of 37.0/11.0/7.0/16.5/15.5/13.0 per cent gives a concentration index of 0.222050, an effective spread of 4.50 buckets and 55.0 per cent refinancing within three years, against a flat ladder's 0.1667, 6.00 and 50.0 per cent [Curzi, 2026]. **A large nominal count and a small effective one is the recurring shape, and noticing that it recurs is the corpus's own claim rather than an argument for any of it.**

The register-spreading result is the cleanest engineering finding here and it is exact. One integer per symbol, no change to any pitch class or interval ratio, and a factor of 839 in symbol rate. **It was found by computing a bound rather than by listening**, which is the general lesson: the Gabor limit did not obstruct the design, it selected it.

And the negative result is stated as the paper's core. A field advances by removing wrong explanations at least as much as by supplying right ones [Platt, 1964]. **Capacity, energy and thermodynamics are removed as explanations here and in the preceding paper [Curzi, 2026x]; what remains is D3, which has no candidate.**

31.10.2 10.2 What does not follow

It does not follow that the architecture is impossible. Absence of a known mechanism is not proof of impossibility, and the microwave auditory effect is the standing counterexample to the claim that unexpected physical–biological channels do not exist. **What follows is that the burden of demonstration is entirely on the claimant.**

Nor does it follow that "not impossible" is partial support. It is not support of any kind [Popper, 1959]. **A claim with no mechanism and no demonstration has zero evidential standing.**

It does not follow that the archive reading is established. The fractions are measured; **the reading of them as an addressable archive is this framework's postulate**, and the corpus's own demotion protocol — which withdrew a quantitative claim on the ground that its constituents were not instrumented on a common ratio scale with a shared true zero — is the instrument that should be run on it [Curzi, 2026t].

It does not follow that a favourable capacity is encouraging. Section 5.4 is the paper's clearest case of a favourable number that is refused as support.

And it does not follow that the framework's own honesty apparatus is self-certifying. The corpus's three-drawer classification places four items of established mathematics, seven of established psychology and exactly three declared postulates in separate drawers, with every protocol stated to run on the first two and steer by the third [Curzi, 2026]. **That is a discipline, not a guarantee, and the failure modes of Section 8 exist because the discipline is routinely broken by attrition rather than by decision.**

31.10.3 10.3 Relation to the surrounding literature

The information-theoretic core is standard [Shannon, 1948, Cover and Thomas, 2006, Hartley, 1928], the time–frequency bound is classical Fourier analysis [Gabor, 1946], and the sampling condition is textbook [Nyquist, 1928]. **None of the three is novel here and none is claimed to be; what is done with them — using a bound to select a design rather than to excuse one — is the contribution.**

The methodological apparatus is the reform literature [Nosek et al., 2018, Simmons et al., 2011, Gelman and Loken, 2013, Ioannidis, 2005, Open Science Collaboration, 2015], and Meehl [1967, 1990] supply the sharpest statement of why it is needed: **directional predictions in a soft science are nearly costless, so a method must make point predictions with numbers in them.** Section 5.11's preregistered 1.5-fold effect size at `n = 21` is that demand met. Lakatos [1970] is the honest description of what a badged postulate is doing, and the abandonment condition of S68-9 is the answer to the degenerating programme he describes.

The tuning material sits against a psychoacoustic literature that is **contrary rather than supporting**, and is cited that way: consonance depends on the spectrum of the sound rather than on the ratio alone [Sethares, 2005], roughness and critical bandwidth rather than integer relations predict measured consonance [Plomp and Levelt, 1965], and octave equivalence and interval categorisation generalise less far than is usually assumed [Burns, 1999, Demany et al., 2013]. **The design uses the arithmetic invariance of octave transposition and requires none of the perceptual claims, and saying so is what keeps the section honest.**

On the framework's own exposure: **Michell [1997]'s objection is the strongest single objection to this corpus**, the conjoint test that would settle it [Luce and Tukey, 1964, Krantz et al., 1971] has not been run, and **the surplus functional's logarithmic form is underdetermined by the evidence** — a sub-linear power law [Latané, 1981] and `n log n` [Briscoe et al., 2006] fit the same qualitative facts, and the strongest available warrant for a logarithm is dynamical rather than perceptual [Peters and Gell-Mann, 2016]. **Nothing in this paper discriminates between them, and where the functional appears in Section 4.7 it appears with that caveat attached.**

Finally, no scaling or heavy-tail claim is made anywhere in this paper, so the distribution-fitting procedure such a claim would require [Clauset et al., 2009] does not apply. The two

power laws that appear — the transfer-matrix eigenvalue and the `1/(2n+1)` relaxation of the essence-ladder gap — **have exponents defined by the mathematics, not estimated from data.**

31.11 11 Verification

31.11.1 11.1 Dimensional audit

Symbol	Dimension	Unit	Status
genome size	`[1]`	base pairs	**nominal**, `3.1e9`
genome capacity	`[1]`	bit	**derived**: 2 bits per base pair. **Shannon information, dimensionless; not thermodynamic entropy**
fractions (98.7 %, 45 %, 8 %, 8.2 %, 1.25 %)	`[1]`	none	**annotation-dependent estimates**
`log2 C(1600,k)`	`[1]`	bit	**derived** from a combinatorial count
bits/base	`[1]`	bit per symbol	**derived**; a code rate
`lambda` (transfer-matrix eigenvalue)	`[1]`	none	**derived**; capacity is `log2 lambda`
`nu` (wavenumber)	`[L^-1]`	cm^{-1}	**measured**, and **nominal** here
`c`	`[L T^-1]`	m/s	**exact by definition**, 299,792,458
`f = c nu`	`[T^-1]`	Hz	**derived, exactly**; all uncertainty is in `nu`
`j`, `k` (octave indices)	`[1]`	none	**defined** integers
cents	`[1]`	none	**defined**: `1200 log2(f2/f1)`
`dt`	`[T]`	s	**specified**
`df`	`[T^-1]`	Hz	**derived**: `>= 1/(4 pi dt)`
`dt df`	`[1]`	none	**derived**; the Gabor product, dimensionless
`p`, `dP`	`[M L^-1 T^-2]`	Pa	**derived / specified**
`T` (membrane tension)	`[M T^-2]`	N/m	**assumed**, 1–5 mN/m
`dP = 2T/r`	`[M L^-1 T^-2]`	Pa	**derived**; a quasi-static relation, and **an approximation**
force	`[M L T^-2]`	pN	**derived** from mass × acceleration
`beta` (unsteady Stokes number)	`[1]`	none	**derived**: `L sqrt(2 pi f rho / mu)`
`D` (diffusion coefficient)	`[L^2 T^-1]`	m^2/s	**nominal**, `1e-10`
`L^2/6D`	`[T]`	s	**derived**; a mean three-dimensional diffusion time

Symbol	Dimension	Unit	Status
`dT/dt`	`[Theta T^-1]`	K/s	**derived**: `2 alpha I / (rho c_p)`
`B`, `S/N`, `C`	`[T^-1]`, `[1]`, `[T^-1]`	Hz, none, bit/s	**derived**
fold change, `phi`, `n`	`[1]`	none	**derived / specified**; a ratio, a dispersion, a count
`Q` (regulatory state)	see below	**none**	**modelling choice**
`u`, `N_eff`, `F`	`[1]`	none, count, nats	**defined**; `F = ln N_eff`

Does the storage-law reading balance? In Section 4.7, `Q` is "the archive" and `u` is the non-parallelism of what is currently active. **`Q` has no operational unit at all**: nothing in this paper measures it, no instrument is proposed for it, and its role is to carry the statement that an addressing operation changes `u` and not `Q`. **The equation balances by stipulation of units rather than by measurement of them, and that is said here rather than left implicit.** `F = ln N_eff` is in nats, `N_eff` is a count, and `ln N` is the hard ceiling — **all dimensionless, all licensed.**

Where a quantity has no operational unit, that is said. Every physical and combinatorial quantity in Sections 5 and 6 is on a ratio scale with a true zero. **`Q` is not, and the framework's psychological constructs are not** [Michell, 1997, Stevens, 1946].

One unit check worth printing. Cents are dimensionless by construction, so a shift expressed in cm^{-1} becomes a shift in cents only through `1200 log2((nu + dnu)/nu)`; at `nu = 1665` cm^{-1} a 2.0 cm^{-1} shift gives `1200 log2(1667/1665) = 2.078` cents. **The 2.081-cent T-to-G gap and the 2.078-cent shift are two different quantities that happen to be nearly equal, and their near-equality is exactly why the single-register scheme fails.**

31.11.2 11.2 The postulates

P1 — The genome is `3.1e9` bp haploid, approximately 98.7 per cent non-coding, 45 per cent transposable-element derived, 8 per cent endogenous-retrovirus derived, and approximately 8.2 per cent under evolutionary constraint. *Status:* **CITED, annotation-dependent, and named without a key** (Section 3.7). **The pairing rule S67-1 makes the last figure inseparable from the first three.**

P2 — An address is a pointer and the architecture has no import path. *Status:* **DEFINITION**, true by the construction of the architecture [Curzi, 2026x]. **Constraint L67 follows from it alone and requires nothing empirical.**

P3 — A response invariant under symbol permutation is not sequence-specific. *Status:* **DEFINITION** (Section 5.2). It carries no empirical weight; its empirical companion is the claim that the documented acoustic-biological responses are exhaustive of what is known, **which is a claim about the literature and is labelled as one.**

P4 — Shannon's capacity theorem, the Gabor limit and the sampling condition hold. *Status:* **CITED** [Shannon, 1948, Gabor, 1946, Nyquist, 1928]; **the Gabor bound is independently derived within this corpus** [Curzi, 2026z].

P5 — Octave transposition preserves pitch class exactly, so `f/2^j` has the same pitch class as `f` for integer `j`. *Status:* **ARITHMETIC** — it is a fact about the ratio [Shepard, 1982], **and the design requires only the arithmetic fact and not the perceptual one.**

P6 — The speed of light is exactly 299,792,458 m/s. *Status:* **DEFINITION** since the 1983 redefinition of the metre. **This is what makes the wavenumber-to-frequency step exact and isolates all uncertainty in the measured band centre.**

P7 — The essence law is `f(n) = k n^2` with `k = (9/8)^2/phi^2` exactly, and two indices share a pitch class if and only if they have the same odd part. *Status:* `k` is a **DEFINITION**; the odd-part theorem is **PROVED** within the corpus [Curzi, 2026]; **attaching hertz to `k` is a separate POSTULATE. In this paper the law is used only to reject itself for this task.**

Two postulates considered and dropped. An earlier form of the argument assumed a specific mechanism by which a cell might discriminate symbol tones. **It is not needed: Section 5.5's conclusion follows from the Stokes number alone, which is a property of the fluid and the length scale and not of any proposed mechanism.** An earlier form also assumed the reprogramming efficiency mattered to the information ratio. **It does not: `log2 C(1600,4) = 37.985` bits is a property of the selection, and the efficiency is reported separately because it bounds the *practicality* rather than the *accounting*.**

31.11.3 11.3 The compounding chain

```
P2          -> R1   an address is a pointer with no cargo, so no addressing
                    operation delivers content: CONSTRAINT L67                DEFINITION
P1          -> L1   6.2e9 bits of genome at 2 bits/bp                         ARITHMETIC
P1          -> L2   log2 C(1600,4) = log2(2.720438e11) = 37.985 bits          ARITHMETIC
L1 / L2     -> R1b  6.2e9 / 37.985 -> the instruction is 1.632e8 times
                    smaller than the archive it reorganises                   ARITHMETIC
P4          -> L3   40 bits in 1 s at B = 16 Hz needs 2^(40/16) - 1 = 4.657
                    = 6.68 dB; at B = 5 Hz, 2^8 - 1 = 255 = 24.07 dB          ARITHMETIC
P3 + L3     -> R2   capacity is adequate AND no structure satisfies D1–D3,
                    so the binding constraint is the demodulator              VERDICT
P1          -> R3   the pairing rule: 98.7 / 45 / 8 must be printed with 8.2;
                    the span between activity and constraint is 80/8.2 = 9.76   ARITHMETIC
P4          -> L4   RLL(3) transfer-matrix eigenvalue 3.95137,
                    log2(3.95137) = 1.98235 bits/base                         ARITHMETIC
L4          -> R4   592 bits / 307 nt = 1.92834 bits/base
                    = 96.42% of 2.0 = 97.28% of 1.98235                       ARITHMETIC
P6          -> L5   f_G = 299792458 x 166500 = 4.991544e13 Hz                 ARITHMETIC
L5 + P5     -> L6   4.991544e13 / 2^36 = 726.3653 Hz                          ARITHMETIC
L6          -> L7   single-register min gap = 726.3653 - 725.4928
                    = 0.8725 Hz = 2.081 cents                                 ARITHMETIC
P5          -> L8   spreading to j = 33..36 gives min gap
                    1441.3880 - 709.3514 = 732.0366 Hz                        ARITHMETIC
L8 / L7     -> R5   732.0366 / 0.8725 = 839.0                                 ARITHMETIC
P4 + R5     -> R5b  Gabor dt_min = 1/(4 pi (gap/2)):
                    182.410 ms -> 5.482 sym/s   single register
                      0.2174 ms -> 4599.5 sym/s spread; ratio 839.0           ARITHMETIC
P1          -> R6   2,880 conditions = 4 x 5 x 4 x 4 x 3 x 3;
                    1/2880 = 0.0347%; 73/2880 = 2.53%                         ARITHMETIC
```

Three checks a reviewer can redo in a minute: `log2(2.720438e11) = 37.985`; `299792458 x 166500 / 2^36 = 726.3653`; and `732.0366 / 0.8725 = 839.0`. Everything in R1b, R4 and R5 follows from those and from P1, P5 and P6.

What the chain does not establish. R1 is a DEFINITION and carries no empirical weight: it is true of this architecture by construction and would be false of any architecture that delivered something. **R2 is a VERDICT rather than a theorem** — it rests on a survey of what is known, and a new structure satisfying D1 to D3 would overturn it tomorrow. **And R3's constrained fraction is an estimate under active dispute, which is why the rule is to print the span rather than to pick an end.**

31.11.4 11.4 The verification instance, worked

The smallest instance exercising the whole chain is the register-spreading result, because it uses the exactness of `c`, the invariance of pitch class, and the Gabor bound, and nothing else.

```
G:  nu = 1665 cm^-1 = 166500 m^-1
    f  = 299792458 x 166500 = 4.99154442570e13 Hz         EXACT
    2^36 = 68719476736
    f/2^36 = 726.36529... Hz

T:  nu = 1663 cm^-1 = 166300 m^-1
    f  = 4.98554857... e13 Hz
    f/2^36 = 725.49281... Hz

single-register gap  = 726.36529 - 725.49281 = 0.87248 Hz
in cents             = 1200 log2(726.36529/725.49281) = 2.0805 cents

spreading:  A at j=36 -> 709.3514 Hz ;  C at j=35 -> 1441.3880 Hz
minimum adjacent gap = 1441.3880 - 709.3514 = 732.0366 Hz

improvement          = 732.0366 / 0.87248 = 839.0

Gabor:  dt_min = 1/(4 pi (gap/2)) = 1/(2 pi gap)
        single: 1/(2 pi x 0.87248)  = 0.182410 s  -> 5.482 sym/s
        spread: 1/(2 pi x 732.0366) = 0.000217 s  -> 4599.5 sym/s
        ratio 4599.5 / 5.482 = 839.0   -- the SAME factor, as it must be
```

Status: **ARITHMETIC** on a **DEFINITION** (c) and a **PROVED** invariance (pitch class). **That the improvement factor in gap and the improvement factor in symbol rate are the same number is the internal check: `dt_min` is inversely proportional to the gap, so the two ratios cannot differ, and if a computation ever returns different values one of them is wrong.**

And the invariance check on the spread intervals, which is H4's falsifier: `A -> C` spread is 1227.464 cents and `A -> C` unspread is 27.464 cents; `1227.464 - 1200 = 27.464`. `C -> G` spread is 1213.570 and unspread `C -> G` is 13.570. `G -> T` spread is 1197.919 against an unspread `T -> G` of 2.081, and `1200 - 2.081 = 1197.919`. **Every spread interval is its pitch-class interval plus a whole number of octaves, exactly, which is what "the tuning is unchanged" means.**

31.11.5 11.5 Limits, asymptotics, and the domain of validity

Limit	Behaviour	Reading
`u -> 0` in `N_eff = 1 + (N-1)u`	`N_eff -> 1`, `F -> 0`	one locus active; no surplus
`u -> 1`	`N_eff -> N`, `F -> ln N = 9.9035` nats	**the hard ceiling, set by the archive and not by the signal**
`N -> infinity`	`ln N -> infinity`, slowly	**you cannot shout your way past a logarithm**; the growth is brutal
max run `-> infinity`	RLL capacity `-> 2.00000` bits/base	the unconstrained alphabet; the constraint's cost vanishes
max run `-> 1`	capacity `-> 1.58496` bits/base	**forbidding any repeat costs 20.75 per cent**
`dt -> 0`	`df_min -> infinity`	**a short sound has no pitch**; the alphabet dissolves
`dt -> infinity`	`df_min -> 0`	arbitrary frequency resolution at zero rate; the useless limit

Limit	Behaviour	Reading
gap `-> 0`	`dt_min -> infinity`	the single-register scheme approaching this is why it fails
`j -> infinity`	`f/2^j -> 0`	below hearing; the transposition has a usable window and Section 6.5 gives it
`beta -> 0` (Stokes)	no energy stored across a cycle, `Q << 1`	**the molecular-scale regime; nothing rings**
`beta -> infinity`	inertial regime, resonance possible	reached only at whole-cell scale and high frequency
`n -> infinity` (replicates)	minimum detectable FC `-> 1`	**any effect is detectable with enough samples, at a cost that rises as `1/(FC-1)^2`**
conditions tested `-> 2880`	coverage `-> 100 %`	**423,360 libraries; not affordable, which is why the floor is 73**

Two domain restrictions follow and are stated as restrictions. The quasi-static relation `dP = 2T/r` is an approximation valid when the driving period is long compared with the membrane's own relaxation, **and Section 5.3's amplitude table inherits that approximation**; the conclusion survives because it is an order-of-magnitude conclusion with eight orders of margin. And **the diffusion times of Section 5.5 assume a nominal cytoplasmic diffusion coefficient which varies by more than an order of magnitude with molecular size and crowding**; the conclusion — that a symbol ends before a protein crosses a micron at fast symbol rates — survives a tenfold error in either direction.

31.11.6 11.6 Invariance, and how far each claim has been tested

The 839.0 factor is invariant under the choice of band centres to within their own precision. Recomputing with each centre perturbed by ±2 cm^{-1} independently moves the spread minimum gap by less than 0.2 per cent, **because the spread gaps are set by the octave assignment and not by the fine pitch differences.** The single-register gap, by contrast, **changes sign** under the same perturbation. **Two schemes, one perturbation, opposite sensitivities: that is the whole argument for spreading, and it was tested at three perturbation magnitudes (0.5, 2.0, 10.0 cm^{-1}). Three points, not a proof.**

The pitch-class invariance is exact and is an identity rather than a sample. Every spread interval equals its unspread interval plus a whole number of octaves, checked at all five intervals in Section 11.4.

The RLL capacity is invariant under alphabet labelling and not under alphabet size. The transfer-matrix eigenvalue for maximum run `m` over an alphabet of size `q` depends on both; the figures given are for `q = 4` only, **and no claim is made about other alphabets.**

The constraint L67 is invariant under everything, because it is a definition. No parameter, no frequency, no amplitude and no modality changes it. **That is what makes it useful and also what makes it carry no empirical weight on its own.**

The capacity figures are not invariant and are not claimed to be. They scale linearly in `B`, which rests on a nominal time constant, **so the invariant statement is the ordering — receiver bandwidth dominates, and even its most pessimistic value leaves the channel adequate — and only that ordering is asserted.**

31.11.7 11.7 Model comparison, audited against what proper model comparison requires

No model is fitted anywhere in this paper and no parameter is estimated from data. Several standard requirements are therefore inapplicable rather than unmet, **and the distinction is drawn explicitly rather than used as cover.**

Requirement	Status in this paper
Out-of-sample rather than in-sample performance	**NOT APPLICABLE.** Nothing is fitted; there is no sample. **The preregistered design of Section 9.2 is the closest analogue and it has not been run.**
A matched null with the same free-parameter count	**NOT APPLICABLE** here, and **MANDATED** for the specified experiment: the permuted twin (C1) is a null matched on every permutation-invariant quantity of the stimulus, which is a stronger match than a parameter count.
The number of free parameters stated explicitly	**MET.** The codec has one (maximum run length, set to 3); the pitch mapping has four (the band centres) plus four integers (`j` per symbol); the timing has one (`dt`); the power analysis has three (mean count, dispersion, alpha). **All are declared constants or design choices, none is fitted.**
An information criterion, so the parameter count is paid for	**NOT MET.** No AIC or BIC was computed here, and **none has been computed anywhere in this corpus**, for any model, at any point. Where the corpus does report a fit [Curzi, 2026i], the same row is recorded as not met.
Effect sizes with intervals, not only p-values	**NOT MET for what is reported, MANDATED for what is specified.** No p-value and no interval appears in Sections 4 or 6, because those sections report arithmetic on declared constants and **an interval on a nominal constant would be false precision.** Section 5.9 requires equivalence bounds or Bayes factors rather than bare p-values for any null the specified experiment produces, and Section 5.11 gives minimum detectable effects rather than significance thresholds.

One further audit item, and it is the sharpest. The primary statistical control of the specified experiment — the shuffled-input control — **has been measured against itself elsewhere in this corpus and found anti-conservative: 0.108 against a nominal 0.05 for iid permutation and 0.120 for circular shift, with only block permutation near nominal at 0.060** [Curzi, 2026u]. **That is why Section 9.2 specifies block permutation, and it is why any `p` this design eventually reports must carry the calibration alongside it.** A control that rejects true nulls at more than twice its nominal rate is not a control until it has been calibrated on the design that uses it.

31.12 12 Limitations

L-1. The entire biological evidence base of this paper is uncited. The corpus's bibliography has no cluster for molecular and cell biology, genome annotation, or the psychoacoustic band-

width literature, so every biological and band-centre source is named in the text with journal, volume and year and **carries no citation key.** Appendix A lists them. **A reviewer cannot check this paper's biology from its reference list**, and that is a defect of the apparatus rather than a claim that the works do not exist. It must be closed before submission.

L-2. The genome fractions are annotation-dependent and the constrained fraction is disputed. The span between reported biochemical activity and estimated evolutionary constraint is a factor of about 9.76 and is a live scientific argument, not a settled figure. **The pairing rule is this paper's response and it is a disclosure rather than a resolution. The source manuscript quotes this span as "about 10.7";** `80 / 8.2 = 9.756`**, and the corrected figure is used throughout (Section 4.3).**

L-3. "Addressable archive" is a postulate and is not established by the measured rows. The fractions are facts about genomes; **the reading of them as an archive is this framework's own**, and the corpus's own demotion protocol [Curzi, 2026t] is the instrument that should be run on it and has not been.

L-4. Constraint L67 is a definition, so its falsifiability is of a particular kind. It could be falsified by one observation, but only because it is a claim about *this architecture*, not about cells. **A different architecture with an import path would not be refuted by that observation; it would simply not be this one.** The constraint is powerful and it is cheap, and both should be said.

L-5. The physical estimates of Section 5.3 are order-of-magnitude arguments under plane-wave, linear, homogeneous-medium assumptions with a quasi-static tension relation. They are strong enough to carry order-of-magnitude conclusions and **not strong enough to carry anything finer**; the 243.3 dB figure should be read as "not a sound" rather than as a measurement.

L-6. The negative claim is a claim about the state of the literature, not a theorem. No survey was performed for this paper. **What is asserted is that no established mechanism is known to this author, and the burden of demonstration is on the claimant** — which is the normal position for an unestablished claim, and which **absence of a known mechanism does not convert into impossibility.**

L-7. The preregistered experiment has not been run and no result is reported, implied or anticipated. Section 9.2 is a design document. **Its expected result is recorded in advance as the null, and recording it is what would make either outcome informative.**

L-8. The primary analysis control is anti-conservative and the correction is partial. Block permutation measures 0.060 against a nominal 0.05 [Curzi, 2026u], which is better than 0.108 but is not calibrated on this design. **A design-specific calibration by simulation is required before any** `p` **from this experiment is reported, and it has not been performed.**

L-9. The demand-characteristic confound has no statistical remedy. It passed an entire four-baseline suite 52.7 per cent of the time with a true effect of zero [Curzi, 2026u]. **The blinding of Section 9.2 is the design remedy; there is no analytic one, and a design that lost its blinding would be uninterpretable rather than merely weakened.**

L-10. The band centres are nominal, the diffusion coefficient is nominal, the time constants are nominal, and none was measured for this paper. A 2 cm^{-1} band-centre shift is routine and reorders two symbols in the single-register scheme; **the spread scheme's robustness to it is computed, not measured.**

L-11. Scale type is licensed for the physics and the combinatorics and stipulated for `Q`**.** Michell [1997]'s objection applies to the framework's psychological constructs, the conjoint conditions [Luce and Tukey, 1964, Krantz et al., 1971] have not been tested, and `Q` in Section 4.7 has no instrument behind it.

L-12. The reflection problem is unanswered wherever the framework touches the reflexive loop [Manski, 1993, Shalizi and Thomas, 2011], no remedy is adopted [Brock and Durlauf, 2001], and every framework claim resting on the loop is a modelling position rather than an identified empirical result (Section 3.6).

L-13. No information criterion was computed (Section 11.7), and no figure in Sections 4 or

6 carries an interval.

L-14. The sonification prior art is not cited and the novelty claim is correspondingly narrow. Published sequence-sonification methods exist; the bibliography carries none of them. **What is claimed as new here is the register-spreading result and the Gabor-selected rate, not the idea of sonifying a sequence** [Curzi, 2026].

L-15. What would falsify the central negative claim. A replicated demonstration of a cellular response depending on the *order* of symbols in an acoustic stream, as distinct from permutation-invariant functionals of the waveform, with the full control set of Section 5.8 present and reported. **That is a well-specified experiment, it is preregistered in Section 9.2, and specifying it is the most useful thing this paper does with its negative result.**

31.13 13 Conclusion

This paper states the boundary of a genomic addressing architecture as a constraint rather than a caveat. **CONSTRAINT L67: addressing can reach only what is already latent, since an address is a pointer and a pointer with no cargo delivers nothing. The property that makes the architecture safe — no sequence is changed — is the property that makes it limited, and neither can be had without the other.**

A pairing rule is imposed on the descriptive statistics: **the 98.7 per cent non-coding, 45 per cent transposable-element and 8 per cent endogenous-retroviral fractions may not be quoted without the approximately 8.2 per cent evolutionarily constrained fraction in the same paragraph.** The span between them is a factor of 9.76 and is a live dispute; **an onion carries 5.16 times the human genome and a pufferfish an eighth of it, and any theory assigning function to bulk sequence because it is present must answer that.**

The central finding is negative and is the paper's core. No known biological structure demodulates a symbol stream from an acoustic carrier into sequence-specific output. Demodulation requires symbol discrimination, order memory and a sequence-specific output mapping; **D1 has no molecular-scale solution because the unsteady Stokes number at that scale is between `1e-4` and `1e-2`, D2 has no described state machine of the required resolution and depth, and D3 has no candidate implementation whatever. And channel capacity is not the bottleneck — 40 bits over a 16 Hz bandwidth requires only 6.68 dB of signal-to-noise — which sharpens the gap rather than softening it, because it removes the explanation that would have been engineerable.**

A decisive experiment is preregistered at `n = 21` per arm for a 1.5-fold change under genome-wide correction, with the symbol-permuted twin as its primary control; one well-powered experiment covers 1 of 2,880 conditions, 0.0347 per cent of the parameter space; and an abandonment condition is committed to in advance — a 73-condition three-stage adaptive design at 2.53 per cent of exhaustive cost, whose null withdraws the biological claim from this corpus entirely.

The sonification chain is built and verified. An implemented run-length-limited codec achieves **1.92834 bits per base** against a transfer-matrix capacity of **1.98235**, with an exact SHA-256 round trip. **Per-symbol octave indices `j = 33..36` raise the minimum adjacent gap from 0.8725 Hz to 732.037 Hz, an 839.0-fold improvement, lifting the Gabor-limited symbol rate from 5.5 to 4,599.5 symbols per second at zero cost to the tuning**, because octave transposition preserves pitch class exactly.

Three things are rejected in print, and one of them is the framework's own. The essence law yields only `ceil(4/2) = 2` distinct pitch classes for a four-symbol alphabet and **cannot supply the alphabet**; the identification of 64 codons with 64 hexagrams is **rejected**, since `2^6` and `4^3` are different structures of equal cardinality and the correspondence is one chosen bijection of `1.2689e89`; and the inference from "not junk" to "all functional" is **refused** wherever the fractions appear.

The method is real as engineering and unproven as biology, and everything here has been written so that no reader can mistake which is which.

31.13.1 Declarations

Data and code availability

No external dataset was collected for this paper and no experiment was performed. Every number reported is one of four things: arithmetic on the nominal constants and annotation-dependent fractions declared in Section 3.3; arithmetic on exact physical constants; a closed-form combinatorial or eigenvalue computation stated in the text; or output of the encoder described in Section 6.2, whose round trip is verified by the SHA-256 digests printed in Section 9.3. **The preregistration of Section 9.2 specifies an experiment that has not been performed; no result from it is reported, implied or anticipated.** No cell, tissue, organism or person was involved at any point. **The six figures are generated by the scripts named in each caption, and those scripts contain no data beyond the numbers printed in this paper.**

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. **The essence law rejected in Section 6.4 is the author's own prior work, and the rejection is printed for that reason rather than despite it.**

Author contributions

Single author. Michael Laurence Curzi performed the analysis, implemented and verified the codec, computed every figure in the text, wrote the preregistration, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted, no animal work was performed, and no personal data was processed. **No clinical, medical, diagnostic or therapeutic claim is made anywhere in this paper.** The pipeline of Section 6 introduces no protein and no nucleic acid into any cell and contains no nuclease, no template and no effector protein; **it cannot edit a genome, and that is a structural property of the design rather than an undertaking.** The experiment specified in Section 9.2 is *in vitro* on cultured cells with transcript abundances as endpoints and contains nothing that could edit, alter or damage a genome. **No subliminal content is permitted at any point: every symbol in a rendered signal is audible, disclosed and documented in a published mapping table, because a message hidden from its recipient cannot be consented to** [Curzi, 2026ad]. The biological literature described here is described from published sources; none of it was replicated, extended or performed by the author.

Preregistration

This paper contains a preregistration and reports no result against it. Section 9.2 declares, in advance of any collection: the hypothesis, the null, the primary endpoint, the effect size (`log2FC = 0.585`, fold change 1.5), the sample size (`n = 21` per arm, from the power analysis of Section 5.11), the eight arms and the full control set, the delivery method, the matching requirements on the permuted twin, the blinding scheme, the frozen analysis with block permutation for the shuffled-input control, the stopping rule, and the decision rules for POSITIVE, NEGATIVE and UNINTERPRETABLE outcomes.

The expected result is recorded in advance as the null, because requirement D3 has no candidate implementation and this author does not have one. **A programme-level abandonment condition is also recorded in advance: if a preregistered 73-condition three-stage adaptive design returns null with the full control set, the sequence-specific acoustic channel is withdrawn from this corpus and the pipeline of Section 6 stands solely as an encoding and sonification method with no demonstrated biological effect. No experiment has been run, so no rule has yet been met or missed.**

31.14 Appendix A Works named in the text without a bibliography key

The bibliographic database governing this corpus contains no entries for the following, and **no key has been attached to any of them anywhere in this paper.** They are listed with the details the source manuscript supplies so that a reader can locate them, and their absence is recorded as a gap in the corpus's apparatus rather than concealed (Section 3.7, limitation L-1). **Nothing in this list should be read as a citation; it is a statement of what is missing.**

On "junk DNA" and genome content. Ohno (*Brookhaven Symposia in Biology* 23:366–370, 1972), the mutational-load argument and the origin of the term. The International Human Genome Sequencing Consortium (*Nature* 409:860–921, 2001) for the transposable-element fraction. The ENCODE consortium (*Nature* 489:57–74, 2012) on biochemical activity, and Djebali and colleagues (*Nature* 489:101–108, 2012) on pervasive transcription. **The critiques that must be printed alongside them:** Graur and colleagues (*Genome Biology and Evolution* 5:578–590, 2013) and Doolittle (*PNAS* 110:5294–5300, 2013) on why biochemical activity is not function in the selected-effect sense; Rands, Meader, Ponting and Lunter (*PLoS Genetics* 10:e1004525, 2014) for the approximately 8.2 per cent constrained estimate; Eddy (*Current Biology* 22:R898–R899, 2012) for the compact statement of the C-value objection, and T. Ryan Gregory's onion test. The genome sizes of *Fugu rubripes*, *Allium cepa*, *Protopterus aethiopicus* and *Paris japonica* used in Section 4.3.

On regulatory structure. Jacob and Monod (*Journal of Molecular Biology* 3:318–356, 1961) on operon logic. Britten and Davidson (*Science* 165:349–357, 1969) on repetitive sequence as regulatory substrate. McClintock (*PNAS* 36:344–355, 1950) on controlling elements, and the 1983 Nobel Prize. Chuong, Elde and Feschotte (*Science* 351:1083–1087, 2016) on endogenous retroviruses supplying inducible enhancers; Lynch and colleagues (*Nature Genetics* 43:1154–1159, 2011) on transposon- mediated rewiring.

On syncytin. Mi and colleagues (*Nature* 403:785–789, 2000); Blaise, de Parseval, Bénit and Heidmann (*PNAS* 100:13013–13018, 2003); **Dupressoir and colleagues (*PNAS* 106:12127–12132, 2009), the knockout, which is the causal test the item depends on**; Lavialle and colleagues (*Philosophical Transactions of the Royal Society B* 368:20120507, 2013) on independent convergent capture.

On latency and activation. Gurdon (*Journal of Embryology and Experimental Morphology* 10:622–640, 1962); Takahashi and Yamanaka (*Cell* 126:663–676, 2006); Takahashi and colleagues (*Cell* 131:861–872, 2007); the 2012 Nobel Prize in Physiology or Medicine. Lambert and colleagues (*Cell* 172:650–665, 2018) for the transcription-factor census. Waddington, *The Strategy of the Genes* (1957), for the landscape these results inverted.

On storage, addressing and mechanotransduction. Church, Gao and Kosuri (*Science* 337:1628, 2012); Goldman and colleagues (*Nature* 494:77, 2013); Erlich and Zielinski (*Science* 355:950, 2017). The PIEZO1/PIEZO2 literature and the 2021 Nobel Prize; Tajik and colleagues (*Nature Materials* 15:1287, 2016); Ibsen and colleagues (*Nature Communications* 6:8264, 2015) and Duque and colleagues (*Nature Communications* 13:600, 2022).

On physics and measurement named without keys. Frey (*Journal of Applied Physiology* 17:689–692, 1962) on the microwave auditory effect. Purcell, *Life at Low Reynolds Number* (*American Journal of Physics* 45:3–11, 1977), for the overdamped regime of Section 5.5. Banyay, Sarkar and Gräslund (*Biophysical Chemistry* 104:477–488, 2003) for the infrared band-centre compilation. Glasberg and Moore (1990) for the equivalent-rectangular-bandwidth formula used in Sections 5.5 and 6.7. Hart and colleagues (*Journal of Computational Biology* 20:970–978, 2013) for the minimum-detectable-fold-change formula of Section 5.11. ISO 16:1975 for the standardisation of the reference pitch discussed in Section 6.8.

Precedent material named without keys. Plato, *Meno*, on recollection; Aristotle, *Metaphysics* Θ, on potentiality and actuality; the Stoic *logos spermatikos* and Augustine's *rationes seminales*. Psalm 118:22 and the alchemical *prima materia* topos. The Talmudic *teiku*; Maimonides, *Guide for the Perplexed* I.58, and the *via negativa* of Pseudo-Dionysius. Kepler, *Harmonices Mundi* (1619), Book V, and the *musica universalis* tradition. The Pythagorean monochord, transmitted through Nicomachus and Boethius. Schönberger (1973) for the codon–hexagram identification rejected in Section 4.8. **Every one of these is precedent, priced at one to three bits on the corpus's own scale, and none is evidence about anything in this paper** [Curzi, 2026w].

Chapter 32

Conjugate Uncertainty at Three Levels: The Kennard Bound, the Gabor Limit, and a Badged Information-Budget Analogue for Forecasts

Abstract. We separate three reciprocal relations that are routinely conflated. First, the quantum relation sigma_x sigma_p >= hbar/2 is a proven theorem (Kennard 1927; Weyl 1928; Robertson 1929) about state preparation, not about measurement disturbance; we give the three-line Fourier derivation, show Gaussians saturate it, and recover the Bohr radius 5.291772e-11 m and -13.605693 eV from it. Second, deleting the substitution p = hbar k from that derivation leaves the Gabor limit dt.df >= 1/(4 pi) = 0.079577471545948, a classical theorem binding every wave including sound; a Gaussian window saturates it to ten significant figures, the DFT bin 1/T sits 4 pi = 12.566 times above the floor and a Hann main lobe 16 pi = 50.265 times above it. Third, the identification of a foreseen future's uncertainty with quantum conjugacy is declared an analogy and badged as such: it is explicitly not claimed to follow from quantum mechanics, no hbar appears in it, and no quantum result is taken to license any claim about belief or mind. Its quantitative content is classical counting: dt.ds >= T.S/2^B, in which each additional bit halves the product, and sharpening a forecast from a year and ten classes to a month and three classes costs 5.3219 bits.

Keywords: uncertainty relation; time-frequency limit; Fourier duality; forecast resolution; information budget; prediction horizon

Series: B. Engineering the Surplus **Paper:** CCP-032

32.1 1 Introduction

Three reciprocal relations circulate under one name. The first is a theorem of quantum mechanics, $\sigma_x \sigma_p \geq \hbar/2$, proved by Kennard in 1927 [Kennard, 1927] and generalised by Robertson two years later. The second is a theorem of classical Fourier analysis, $\Delta t \, \Delta f \geq 1/(4\pi)$, stated in its communications form by Gabor [1946]. The third is not a theorem at all: it is a proposal, advanced by this work, that the uncertainty attaching to a foreseen event has the same *structure*

as a conjugate pair. **The three are routinely conflated, and the conflation runs in the expensive direction** — the classical theorem is mistaken for a diluted version of the quantum one and therefore dismissed in designs where it binds, while the proposal borrows the quantum theorem's authority for claims about belief that no quantum result supports.

This paper separates them, states each at the level of warrant it actually has, and prices the separation in numbers. Its principal quantitative results are the Gabor limit's application to the corpus's own rendering problem — where the minimum resolvable gap in a folded lattice collapses by a factor of eight at a threshold this paper corrects from $N = 20$ to $N = 17$ — and an information-budget bound, $\Delta t\,\Delta s \geq TS/2^B$, which is exact, classical, and derived from counting in two lines.

The organising discipline is `RIGOR_STANDARD` §8's three-way label, applied before any borrowing is made rather than defended afterwards. Each of the three relations is declared, at first use, as a derivation, as a shared mathematical form, or as an analogy. The quantum relation is a derivation *within physics* and is used here only expositorily. The Gabor limit is a derivation *for acoustic signals*, because a rendered tone genuinely satisfies its premises — square-integrability and finite second moments in both domains — and the premises are shown, not asserted. The forecasting application is a **shared mathematical form** where the counting bound is concerned and an **analogy, never evidence**, where the correspondence to Heisenberg is concerned. **The analogy contributes no number anywhere in this paper**, and Section 7.7 states that as a result rather than as a caveat.

Why the exposition of the quantum case is retained rather than cut. The most common reaction to a classical time–bandwidth constraint is to assume it must be quantum mysticism because it resembles Heisenberg's relation. That reaction is defeated only by stating Heisenberg's relation correctly first, including the part most secondary accounts get wrong: **the relation is a property of states, not a statement about a measurement disturbing what it measures.** The disturbance account is not a simplification of the theorem; it is a different claim, it fails as a derivation, and the specific error–disturbance inequality Heisenberg wrote in 1927 has been experimentally violated. Section 4 establishes this at length, and Sections 5 and 6 are believable because of it. The corpus makes the same move elsewhere, refusing quantum licence for its own postulates and computing decoherence timescales rather than gesturing at them [Curzi, 2026aa].

Four contributions are made relative to the surrounding literature rather than relative to the framework. **First**, the two derivations are given side by side with the single line that separates them isolated: the substitution $p = \hbar k$. Delete it and Kennard's bound becomes Gabor's; nothing else changes. **Second**, the Gabor limit is carried into the corpus's frequency framework until the design changes, producing an audible-band ceiling of 25 lattice elements, a render-rate ceiling of 583.19 symbols per second under a common transposition, and a discontinuous collapse of the folded lattice's minimum gap whose thresholds this paper corrects. **Third**, the information-budget bound is derived and its exchange rate computed: each additional bit halves the product $\Delta t\,\Delta s$, and sharpening a forecast from a year and ten classes to a month and three costs 5.3219 bits. **Fourth**, the refusal is stated as a result: no quantum mechanics is used to license any claim about belief, mind, or future events, and the paper's quantitative content is shown to survive the removal of the analogy entirely.

None of this is a claim about human beings, and none of it is measured on data collected for this paper. Every number below is either an exact consequence of a definition, a value computed numerically from a stated function, or a quantity quoted from a published source with its origin named. Where the corpus's own constants enter — most importantly the reference constant $k = (9/8)^2/\varphi^2$, which is *defined*, not measured, and whose expression in hertz is a separate and stronger claim — the badge is carried in the sentence that uses them.

Section 2 states the hypotheses. Section 3 gives the method, including the analogy labels, the entropy identification, the effective-count identification, and the identification problem the framework cannot answer. Sections 4, 5 and 6 develop the three levels. Section 7 reports the results, Section 8 discusses what does and does not follow, Section 9 verifies the chain from minimal postulates, Section 10 states the limitations and Section 11 concludes. Appendices A

to C carry three worked reviews that exercise the chain end to end.

32.2 2 Hypotheses

Much of what follows consists of theorems, and a theorem cannot be falsified by observation. Those are labelled as derivations where they appear and are recorded in Section 9's chain as `ARITHMETIC` or `DEFINITION`. What *can* be wrong are the paper's claims about where the theorems bind, what the corpus's own lattice arithmetic yields, and whether the forecasting bound has any measurable content. Each hypothesis below names the observation that would defeat it.

> **H1 — The binding constraint on the corpus's acoustic rendering is classical, not quantum. Predicted:** for every rendering design in the corpus's frequency framework, the quantum relation is negligible by many orders of magnitude while the Gabor limit is within a factor of ten of the design point, so that changing the design changes only under the classical bound. **Falsified by:** a rendering regime in which $\hbar$ enters a numerically consequential way, or one in which the Gabor floor is more than four orders of magnitude below every gap the design must resolve, which would make the constraint irrelevant rather than load-bearing.

> **H2 — The folded lattice's minimum gap collapses discontinuously in N, and the published thresholds are wrong.** The corpus previously placed the collapses at $N = 20$ and $N = 48$. **Predicted:** on exact rational arithmetic over every n^2 for $n = 1 \dots N$ folded into one octave, the minimum adjacent ratio takes the value $50/49$ up to $N = 16$, $289/288$ from $N = 17$, and $1682/1681$ from $N = 41$; the rate penalty across the first cliff is exactly 8 and across the second exactly 4. **Falsified by:** an exact-rational recomputation returning the published boundaries, or returning a smooth rather than a stepped dependence on N. **Result: confirmed, and the previously published thresholds are corrected in Section 7.6.**

> **H3 — The forecasting bound's content is classical counting, not physics. Predicted:** every number reported in Section 6 is reproducible from $\log_2$ arithmetic, from a Fourier transform, or from a Lyapunov exponent, and none of them changes if the analogy to Heisenberg is deleted from the paper. **Falsified by:** any quantity in Section 6 that cannot be obtained without invoking a quantum result. **Result: confirmed; Section 7.7 reports the analogy's numerical contribution as zero.**

> **H4 — The evidence budget B is estimable in principle and has not been estimated here.** The bound $\Delta t\, \Delta s \geq TS/2^B$ is vacuous without an independently obtained B. **Predicted:** a published forecast record carrying T, S, Δt and Δs per forecast, with B estimated from realised out-of-sample discrimination, either satisfies the bound or does not, on the record. **Falsified by:** a demonstration that no operationalisation of B independent of the forecasts themselves is possible, which would make the bound a tautology. **Result: NOT TESTED. No forecast record was collected for this paper and no B was estimated from data.** This is stated in the same plain language a confirmation would receive, and it is the paper's largest empirical gap.

H5 is a statement the paper deliberately declines to make. No hypothesis is advanced that the uncertainty of a future event *is* a quantum uncertainty, because no observation could bear on it. That proposition is recorded in Section 6.1 as an **analogy** — a modelling stance, not a hypothesis — precisely as `PAPER_SPEC` §2 requires when a candidate hypothesis admits no falsifier.

32.3 3 Method

32.3.1 3.1 What the paper attempts, and what it does not

The paper is an audit and an application, not a discovery. Two of the three relations it handles are established theorems whose proofs are reproduced because the reproduction is what separates them; the third is the author's own proposal, and the method for handling it is to strip it of everything that is not independently derivable and report what is left. **The test of the third level is therefore not whether the analogy is apt but whether the quantitative forms survive its removal.** Section 7.7 reports that they do, which is the strongest thing that can honestly be said for it.

No dataset was collected. Numerical values reported as computed — the saturation of the Gabor bound by a Gaussian, the divergence of the rectangular window's second moment, the folded lattice's exact rational gaps — are outputs of stated functions evaluated at stated parameters, and the evaluation is reproducible from the specification given in the text. Numerical values quoted from physics — the Bohr radius, atomic lifetimes, the reduced Planck constant — are quoted from the standard literature with their origin named, and carry that literature's uncertainty rather than any of this paper's.

32.3.2 3.2 Analogy discipline, declared in advance

`RIGOR_STANDARD` §8 requires every borrowing from physics to be labelled, at first use, as one of three things. The labels for this paper are fixed here so that no later passage can be read as claiming more than the label allows. The corpus states the same discipline for itself [Curzi, 2026aa], and the failure mode it guards against — a category-two borrowing collecting a category-one warrant — is exactly what makes physics-flavoured social science distrusted [Mirowski, 1989, Cartwright, 1999].

Borrowing	Label	What licenses the label
$\sigma_x \sigma_p \geq \hbar/2$ applied to quantum states	**derivation**	the premises are the axioms of quantum mechanics and the systems are quantum; used here expositorily only
$\Delta t \, \Delta f \geq 1/(4\pi)$ applied to a rendered acoustic signal	**derivation**	the premises are square-integrability and finite second moments in both domains; Section 5.2 shows a rendered tone satisfies the first and states which envelopes fail the second
$\Delta t \, \Delta s \geq TS/2^B$ applied to a forecast	**derivation**, but of a counting result, not a physical one	it follows from $\log_2$ of a cell count; no physics enters and none is claimed
the Gabor limit applied to a *belief* about recurrence	**shared mathematical form**, with one badged modelling choice	the same inequality governs the amplitude and its transform; the step of writing a forecast as an amplitude is a choice, not a discovery, and is marked in the sentence that makes it

Borrowing	Label	What licenses the label
the horizon law $t_{\text{pred}} = t_d \log_2(D_{\text{tol}}/D_0)$ applied outside a system with a measured positive Lyapunov exponent	**analogy**	motivation only; invoking it without an estimated exponent is failure mode FM-6.6
"the future is a conjugate variable"	**analogy**	a structural correspondence with no formal warrant, offered as a way of seeing and never as evidence
the headroom correspondence of Section 6.14	**shared mathematical form**	both are a requested increment tested against an available budget; it is a claim about model shape and not about physics

Two specific corrections that the corpus makes elsewhere and this paper keeps. The uncertainty relation is a fact about state preparation and not about measurement disturbance, and it is stated that way in every passage below. And where a variational or extremal argument appears — the minimisation that recovers the Bohr radius — it licenses no teleology: the minimiser is where a derivative vanishes, and nothing in the system is seeking it.

32.3.3 3.3 Entropy: which entropy, in every instance

Every entropy in this paper is Shannon entropy [Shannon, 1948], computed as $H = -\sum_i w_i \log_2 w_i$ over a normalised weight vector and reported in **bits**. **No thermodynamic entropy appears anywhere in this paper**, and no result below carries units of energy per temperature. The two objects share a name and a functional form and are different quantities with different units; conflating them is a standing error the corpus's information-theory material is written to avoid [Cover and Thomas, 2006, Khinchin, 1957]. Where the source material for Section 6.7 speaks of an ensemble's entropy, it means Shannon entropy in bits, and the value 1.8150 bits is a Shannon entropy.

The one place where a physical entropy could legitimately enter — the thermodynamic cost of erasing a bit [Landauer, 1961] — is not used, because no claim in this paper depends on the physical cost of the forecaster's information.

32.3.4 3.4 Effective counts: saying which one, every time

Two different effective counts appear in the corpus and they are not the same object. The distinction is stated here because both are touched below.

- **2^H, the exponential of a Shannon entropy in bits, is the Hill number of order one** [Hill, 1973, Jost, 2006, Rényi, 1961]. The ensemble effective scenario counts reported in Sections 6.7 and Appendix C — 3.5185 of a nominal 4, and 3.7417 of a nominal 4 — are Hill numbers of order one and are grounded by that literature exactly.
- **$N_{\text{eff}} = 1 + (N-1)u = e^F$, the corpus's affine effective count [Curzi, 2026], is NOT a Hill number of any order.** It is a linear interpolation between 1 and N and no literature in ecology, economics or information theory contains it. It appears in this paper only in Section 5.13, where the surplus bridge $f_{\text{cross}} = k\,e^{2F}$ is differentiated; the badge travels with it, and no Hill-number citation is attached to it anywhere.

The two quantities coincide numerically nowhere except at $u = 0$ and $u = 1$, and a reader who reaches for the Hill-number literature to support the second will find it does not apply.

Saying so is cheaper than being caught.

32.3.5 3.5 Identification, the reflection problem, and the Lucas critique

Section 6 touches the corpus's reflexive material at two points — the correspondence between the evidence budget and the storage law's headroom (Section 6.14), and the reference to the corpus's conditional postulate about belief and reality (Section 6.4) — and both inherit an objection this framework cannot answer.

The corpus's reflexive specification, in which a group's state is a function of its members and the members' states are functions of the group, is a linear-in-means reflexive model, and its endogenous effect is not identified from observational data [Manski, 1993]. No quantity of observation separates the endogenous effect from contextual effects or from correlated unobservables, and influence and selection are generically confounded in observational network data [Shalizi and Thomas, 2011, Lyons, 2011]. **This paper adopts no remedy.** Randomisation, instrumentation and partial-population variation are all unavailable to it, and the fourth route — stipulating the reference group and defending the stipulation, for which Brock and Durlauf [2001] is the template — is not attempted here. **Every statement in this paper that touches the reflexive loop is therefore a modelling position rather than an identified empirical result**, and is written that way in the text as well as here.

The Lucas critique applies to this paper with unusual directness, because its subject is forecasting [Lucas, 1976]. A framework asserting that systems change their behaviour when modelled cannot exempt its own parameters from the same reflexivity. Section 6's evidence budget B is a case in point: a published forecast changes the behaviour of the forecast object, so B estimated from a historical record need not describe the record that follows publication. Self-fulfilling and self-defeating prophecy are real and documented [Merton, 1948, Jussim and Harber, 2005], and a reflexive fixed point has been observed in the field with dates and price data [MacKenzie and Millo, 2003, MacKenzie, 2006]. **The honest position this paper takes is that B is not invariant under its own publication, that the bound is therefore a constraint on a forecaster at a moment rather than a stable parameter of a domain, and that no defence of parameter stability is offered.** The measured social-prediction literature is consistent with the modest reading: predictive accuracy in social systems is low and the ceiling is structural rather than methodological [Hofman et al., 2017, Salganik et al., 2020, Watts, 2014].

32.3.6 3.6 Scale type, and the conjoint test that was not run

`RIGOR_STANDARD` §5 requires every measured construct to declare its scale type [Stevens, 1946, Krantz et al., 1971]. Three constructs in this paper need one.

- **Time and frequency are ratio scales with true zeros**, and every operation performed on them below — quotients, products, logarithms of ratios — is licensed.
- **The specification axis s is the exposed one.** Where the outcome space is categorical, s is a **count of classes**, not a distance, and the bound of Section 6.9 is then a counting bound. Where the outcome space is numeric, s requires a ratio scale for the quotient $S/\Delta s$ to mean anything. **The source framework is silent on which case obtains in general, and this paper does not supply the missing determination**; it states the restriction and reports the bound as valid under either reading with the reading named.
- **The evidence budget B is treated as a ratio-scaled quantity in bits.** That is licensed for a Shannon quantity by construction, but the *estimate* of B from realised forecast discrimination inherits whatever scale the discrimination measure has, and no such estimate is made here.

Michell's critique is the strongest objection to the framework this paper belongs to [Michell, 1997, 1999]: psychology routinely assumes that its attributes possess additive quantitative structure without testing for it. The formal test is additive conjoint measurement [Luce and

Tukey, 1964]. **It has not been run on any construct in this paper, and this paper does not run it.** The quantities that carry the paper's numbers — time, frequency, bits, and cents — are physical or combinatorial and are not exposed to the objection; the one that is exposed, the specification axis of a forecast over a non-numeric outcome space, is explicitly demoted to a count for that reason. **That demotion is a concession, not a defence**, and it is repeated in Section 10.

32.3.7 3.7 Scaling claims, and the procedure not run

Two asymptotic statements appear below and both are **defined by the model rather than estimated from data**, which `RIGOR_STANDARD` and Clauset et al. [2009] require to be said explicitly.

- The rectangular window's power spectrum falls as f^{-2}, so its spectral second moment diverges logarithmically. **The exponent is an exact property of the** sinc **function and is not an estimate.** No power-law fitting procedure was run, because there is no sample: the spectrum is known analytically.
- Under a common transposition the fractional lattice gap falls as $2/n$ and the required cycle count grows as $n/(8\pi)$. **Both are asymptotics of the exact expression** $n^2/(4\pi(2n+1))$ **and are exact consequences of the square law, not fitted exponents.**

No heavy-tail or scale-free claim is made anywhere in this paper on empirical data, and the maximum-likelihood-plus-goodness-of-fit procedure of Clauset et al. [2009] was therefore not run. It is named here so that its absence is a stated decision rather than an omission; the literature on mis-fitted power laws [Stumpf and Porter, 2012, Broido and Clauset, 2019] is the reason the distinction is worth a paragraph.

32.3.8 3.8 What is presupposed

The essence law $f(n) = kn^2$ with $k = (9/8)^2/\varphi^2$ is presupposed as a badged postulate of the framework and is not re-derived or defended here [Curzi, 2026]. **Its two components are real and its product is not**: $9/8$ is the Pythagorean whole tone [Barbour, 1951, von Helmholtz, 1885] and $\varphi^2 = \varphi + 1$ is Euclid VI.3 [Euclid, 1956, Vajda, 1989], but their quotient expressed as a frequency has no precedent in any literature. Markowsky [1992] is cited here, as everywhere the golden section appears in this corpus, because it is the standing correction to golden-ratio claims and the reader is entitled to see that the author knows what one usually looks like. Octave equivalence, on which the folding operation rests, is formalised by Shepard [1982] and its perceptual limits are given by Burns [1999], Demany et al. [2013], Hoeschele et al. [2012].

The storage law $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, its fixed point and its headroom form are presupposed from Curzi [2026a]. The surplus functional and its affine effective count are presupposed from Curzi [2026]. The corpus's seven-gate formula-validation protocol, whose gates are run on Section 6.9's bound, is specified in Curzi [2026t], and its demotion of the framework's central formula to ordinal scale is inherited rather than re-argued. The two-column concordance discipline — that agreeing traditions stop adding evidence after the first, because precedent is not evidence — is specified in Curzi [2026w] and is applied without restatement of its derivation.

32.3.9 3.9 Standing honesty clauses

These govern every use of this paper's results, in this corpus and outside it.

1. **The uncertainty relation is a property of states, not of instruments.** It holds for unmeasured systems and is not the observer effect.

2. σ_x **and** σ_p **are ensemble quantities.** Two numbers from one system have no standard deviation and cannot test the relation.
3. **The Gabor limit is classical and contains no quantum content.** Any presentation of it as an application of quantum mechanics to sound is wrong.
4. Δt **and** Δf **are root-mean-square spreads**, not window lengths and not peak widths. The conversions differ by factors up to 50.
5. **The essence frequencies are essence frequencies, not physical resonances**, and k is a chosen reference constant, not a measured one [Curzi, 2026]. The Gabor limit constrains how such a number may be turned into a sound and says nothing about whether the law generating it is true.
6. **Nothing in this paper licenses any claim about mind, belief, choice, or future events from quantum mechanics.** Section 6's analogy is badged in every section that states it and derives its content from counting and from Fourier duality.
7. **No clinical, medical, therapeutic or physiological claim is made anywhere in this paper.**

32.4 4 Level one: the Kennard bound, stated exactly

This section reports established physics and corrects a widespread misstatement of it. **It introduces no postulate of this framework.** Its function is to establish, in front of the reader, that the paper can state the famous case exactly, correct the standard error, and refuse the standard over-reach — because Sections 5 and 6 are believable only if it can.

32.4.1 4.1 The relation

```
PROVEN THEOREM of quantum mechanics (Kennard 1927; Weyl 1928; Robertson 1929).

    sigma_x . sigma_p  >=  hbar / 2

sigma_x   standard deviation of the position distribution of a quantum state
sigma_p   standard deviation of the momentum distribution of THE SAME state
hbar      h / (2 pi),  the reduced Planck constant
```

With the 2019 SI definition $h = 6.62607015 \times 10^{-34}$ J s exact:

```
hbar     = 1.054571817646e-34   J s
hbar / 2 = 5.272859088231e-35   J s
hbar     = 6.582120e-16         eV s
```

The misreadings hide in the symbols, so each is read carefully.

σ_x **is a standard deviation, not an experimental error bar.** It is the square root of the variance of the probability distribution $|\psi(x)|^2$ that the state assigns to position. Written out, there is no apparatus in it:

```
sigma_x^2 = INTEGRAL |psi(x)|^2 (x - <x>)^2 dx
sigma_p^2 = INTEGRAL |phi(p)|^2 (p - <p>)^2 dp        phi = Fourier transform of psi
```

Both are computed from the same wavefunction, and neither refers to a measurement, an instrument, a photon, a microscope or an observer. Both integrals can be evaluated for a state that has never been measured and never will be, and the product obeys the inequality.

The two distributions are Fourier transforms of one another, which is the whole content:

```
phi(p) = (1 / sqrt(2 pi hbar)) INTEGRAL psi(x) exp(-i p x / hbar) dx
```

A function and its Fourier transform cannot both be narrow; that is a theorem of analysis [Oppenheim et al., 1996]. **Quantum mechanics contributes exactly one thing to it: the identification of the conjugate variable of x with $p/\hbar$, which puts $\hbar$ into the bound and nothing else.**

32.4.2 4.2 The general form and its state dependence

Robertson proved the general statement for any two observables — *Physical Review* 34 (1929), 163–164:

```
sigma_A . sigma_B  >=  (1/2) | < [A, B] > |          [A, B] = AB − BA
```

For position and momentum $[x, p] = i\hbar$, a constant, so the right-hand side is $\hbar/2$ for every state and the position–momentum case is the exceptional one in which the bound never weakens.

For most observable pairs the bound is state-dependent and can be vacuous. Spin-$1/2$ makes this concrete, with $[S_x, S_y] = i\hbar S_z$:

```
state |+z> :   <S_z> = hbar/2
               Robertson bound = (hbar/2)(hbar/2) = 2.780304e−69  J^2 s^2
               actual sigma_Sx . sigma_Sy = (hbar/2)^2 = 2.780304e−69
               SATURATED.

state |+x> :   <S_z> = 0
               Robertson bound = 0
               actual sigma_Sy . sigma_Sz = (hbar/2)^2 > 0
               BOUND IS TRIVIALLY TRUE AND SAYS NOTHING.
```

Schrödinger strengthened Robertson in 1930 by adding the anticommutator term, which repairs some but not all of the vacuous cases. **The point is not decorative: for a general pair, the relation sometimes forbids joint sharpness and sometimes says nothing at all, and which one obtains depends on the state.** The position–momentum case is quoted so often precisely because it is the case in which the bound is unconditional.

32.4.3 4.3 Warrant: what is proved, what is cited, what is postulated

PROVED, given the axioms of quantum mechanics. $\sigma_x \sigma_p \geq \hbar/2$ for every normalisable state [Kennard, 1927]; the general commutator form (Robertson 1929); the strengthened form with the covariance term (Schrödinger 1930); and equality if and only if the state is a Gaussian wave packet, which follows from the equality condition in the Cauchy–Schwarz step of Section 4.7's derivation.

CITED, measured in the literature. Single-slit diffraction, on any optical bench. Matter-wave interference for large molecules, reported for C_{60} by Arndt, Nairz, Vos-Andreae, Keller, van der Zouw and Zeilinger, *Nature* 401 (1999), 680–682. Natural linewidths of atomic transitions (Section 4.11). Experimental violation of Heisenberg's *original* error–disturbance inequality, by Erhart, Sponar, Sulyok, Badurek, Ozawa and Hasegawa, *Nature Physics* 8 (2012), 185–189, and by Rozema, Darabi, Mahler, Hayat, Soudagar and Steinberg, *Physical Review Letters* 109 (2012), 100404.

POSTULATED in this section: nothing.

> **Bibliographic disclosure.** Of the physics primary sources named in this section, only Kennard carries a key in this corpus's bibliography [Kennard, 1927]. Robertson (1929), Weyl (1928), Schrödinger (1930), Ozawa (2003), Busch, Lahti and Werner (2013), Arndt et al. (1999), Erhart et al. (2012) and Rozema et al. (2012)

> are named in the text with journal, volume, year and pages and carry **no citation key**, because no entry for them exists in `bib/external.bib` and none was invented. The same disclosure applies to Lorenz (1963, 1969), Zhang et al. (2019), Brier (1950), Murphy (1973), Carlson (1985) and Wier, Jesteadt and Green (1977) in Sections 5 and 6. Every one of them is a standard, locatable source; the gap is in this corpus's bibliography, not in the record.

32.4.4 4.4 The misconception, named

The familiar account runs:

> *To see where an electron is, you have to bounce something off it. The gentlest thing you can bounce off it is one photon. But a photon carries momentum, so bouncing it off the electron changes the electron's momentum. The more precisely you want the position, the shorter the wavelength you need, the more momentum the photon carries, and the more you disturb what you were trying to measure.*

Call this **the disturbance story**. It has four separable defects.

Defect 1 — it makes the relation epistemic when it is ontic. The disturbance story says the electron has a position and a momentum and that clumsiness prevents both being learned. **A state with sharp momentum has no position at all — not an unknown position, not a hidden position, none.** Its position distribution is spread over all space, and the spread is a fact about the state. This is testable and has been tested: if particles had definite values for non-commuting observables that measurement merely failed to reveal, correlations between distant measurements would satisfy Bell's inequality, and they do not; the loophole-free experiments of 2015 closed the last significant escape routes. **The disturbance story is a hidden-variable story in casual clothes, and local hidden-variable models are excluded by experiment.**

Defect 2 — it predicts the wrong thing about ensembles. Prepare ten thousand identical systems; measure position on five thousand and momentum on the other five thousand. **No system is measured twice, and nothing measured is subsequently disturbed.** With $m = 5000$ samples the standard error of an estimated standard deviation is about $\sigma/\sqrt{2(m-1)}$, which is **1.0001 per cent of** σ. The product of the two estimates obeys the bound. **There is no disturbance anywhere in that protocol and the bound is still there** — which is sufficient to refute the disturbance story *as a derivation*.

Defect 3 — it cannot explain why classical waves have the same relation. Sound waves obey a mathematically identical relation with no photons, no $\hbar$, no quanta and no disturbance. Section 5 is about that relation, and it is measurable on an inexpensive oscilloscope. **The disturbance story attributes the relation to a mechanism absent in the cases where the relation is easiest to demonstrate.**

Defect 4 — Heisenberg's own quantitative version of it is false, and this has been measured. Heisenberg's 1927 paper introduced the gamma-ray microscope and wrote an inequality relating the *error* $\epsilon(x)$ of a position measurement to the *disturbance* $\eta(p)$ it inflicts on momentum — a genuinely different inequality from Kennard's, because ϵ and η are properties of an apparatus while σ_x and σ_p are properties of a state. Ozawa (*Physical Review A* 67, 2003, 042105) showed that Heisenberg's error–disturbance form is not universally valid and derived a corrected one:

```
epsilon(A) eta(B) + epsilon(A) sigma_B + sigma_A eta(B)  >=  (1/2) | <[A,B]> |
```

The extra two terms are what Heisenberg omitted, and when they are large the naive product can drop below $|\langle[A,B]\rangle|/2$. **It does.** Erhart et al. (2012) measured neutron spin components and reported the naive product violated while Ozawa's relation held; Rozema et al. (2012) reached the same conclusion by weak measurement on photon polarisation.

The rest of the story is reported because the area is active. Busch, Lahti and Werner (*Physical Review Letters* 111, 2013, 160405) proved a Heisenberg-type error–disturbance relation

that does hold, on a worst-case rather than a state-specific root-mean-square definition of "error" and "disturbance". The disagreement is about what the two words should mean, not about the mathematics, and both camps agree on every experimental number. **What is not in dispute: the state-based relation is settled, exact and never violated, while the measurement-based error–disturbance relation is a different, harder, definition-sensitive question on which the naive 1927 form fails. Teaching the first by way of the second is teaching a proved theorem with a disproved heuristic.**

32.4.5 4.5 Where the relation comes from: three lines of Fourier

The derivation is short enough to give in full, and giving it in full is the cure for the disturbance story, because there is no apparatus anywhere in it. Work in units where the conjugate variable is $k = p/\hbar$; let $\psi(x)$ be normalised and shift so that $\langle x \rangle = \langle k \rangle = 0$.

Step 1 — build a non-negative quantity. For any real a,

```
I(a) = INTEGRAL | a x psi(x) + dpsi/dx |^2 dx   >=   0
```

It is an integral of a squared modulus, so it cannot be negative. **That is the entire physical input: none.**

Step 2 — expand.

```
INTEGRAL |x psi|^2 dx             = sigma_x^2
INTEGRAL |dpsi/dx|^2 dx           = sigma_k^2      (by Parseval / Plancherel)
2a Re INTEGRAL x psi* dpsi/dx dx  = -a             (integrate by parts, using normalisation)

so    I(a) = a^2 sigma_x^2 - a + sigma_k^2  >=  0   for every real a.
```

Step 3 — a non-negative quadratic has a non-positive discriminant.

```
1 - 4 sigma_x^2 sigma_k^2  <=  0
=>   sigma_x sigma_k  >=  1/2
=>   sigma_x sigma_p  >=  hbar/2                  since p = hbar k
```

That is the whole proof. It contains an integration by parts, Plancherel's theorem, and the discriminant of a quadratic. It contains no photons, apparatus, observers, disturbance, collapse or consciousness, and no statement about what happens during a measurement.

Equality holds exactly when $I(a) = 0$ at the minimising a, that is when $ax\psi + \psi' = 0$, whose solution is $\psi(x) = C\exp(-ax^2/2)$ — a Gaussian. Gaussians saturate the bound and nothing else does. That fact returns in Section 5 as a design rule.

The step where $\hbar$ enters is Step 3's final substitution, and only there. Everything before it is a theorem about square-integrable functions. **Delete the substitution and what remains is the Gabor limit.** That is not a metaphor: it is literally the same three lines with a different name for the conjugate variable, and Section 5.3 runs them again in the units of sound.

32.4.6 4.6 Every wave has it, and one that can be seen

Send a plane wave of wavelength λ through a slit of width a; the first diffraction minimum sits at $\theta \approx \lambda/a$. Computed at $\lambda = 633$ nm, pattern width on a screen one metre away:

slit width a	half-angle to first null	spread at 1 m
10 um	6.330e-02 rad (3.63 deg)	63.4 mm
5 um	1.266e-01 rad (7.25 deg)	127.3 mm
1 um	6.330e-01 rad (36.27 deg)	733.7 mm
0.5 um	1.266e+00 rad (72.54 deg)	3178.6 mm

Halve the slit and the spread doubles; the product is constant. The slit does not disturb the light — the slit *is* the localisation, and the spread is what localisation costs.

The de Broglie wavelengths that make the quantum version visible or invisible:

```
electron at 1e6 m/s            lambda = 7.2739e-10 m
thermal neutron at 2200 m/s    lambda = 1.7982e-10 m
C60 molecule at 200 m/s        lambda = 2.7701e-12 m
baseball, 145 g at 40 m/s      lambda = 1.1424e-34 m
```

The baseball's wavelength is roughly nineteen orders of magnitude smaller than a proton, which is why the relation does not constrain baseballs — a quantitative answer rather than a hand-wave.

32.4.7 4.7 The ensemble reading, as a protocol

```
PROTOCOL 4-A -- what sigma_x sigma_p >= hbar/2 is a statement about

1. Fix a preparation procedure P. It must be repeatable and must not be conditioned
   on any measurement outcome.
2. Run P n times. There are now n systems in the same state psi.
3. Split the n systems into two arms at random. Do not measure any system twice.
4. On arm A, measure position. On arm B, measure momentum.
5. Compute the sample standard deviation of each arm.
6. The claim under test is: s_x * s_p >= hbar/2, within sampling error.

NOT under test, and not what the relation says:
   - that any single system's position was disturbed by a momentum measurement
   - that any single system had a definite position and momentum before step 4
   - that a joint measurement returning a pair (x, p) is forbidden
     (it is not forbidden; it is noisy, and the noise obeys Ozawa's relation, not this one)
```

Step 3 is load-bearing. It removes disturbance from the experiment entirely and the bound survives. **Any account of the relation that would be falsified by step 3 is wrong.**

32.4.8 4.8 Worked numbers at four scales

All computed from $\hbar/2 = 5.272859088231 \times 10^{-35}$ J s.

Scale 1 — an electron confined to an atom-sized box, $\sigma_x = 1.0 \times 10^{-10}$ m.

```
sigma_p >= hbar / (2 sigma_x) = 5.2729e-25  kg m/s
sigma_v  = sigma_p / m_e      = 5.7884e+05  m/s   = 0.193 % of c
E ~ sigma_p^2 / 2 m_e         = 1.5261e-19  J     = 0.9525 eV
```

Roughly one electron-volt of kinetic energy is forced on the electron purely by confining it to a tenth of a nanometre — chemistry's order of magnitude, and not a coincidence.

Scale 2 — the hydrogen ground state, recovered from the relation alone. Write the energy of an electron confined to radius r as kinetic-plus-Coulomb with $p \sim \hbar/r$ and find the stationary point:

```
E(r) = hbar^2 / (2 m_e r^2)  -  e^2 / (4 pi eps0 r)

dE/dr = 0  =>  r = 4 pi eps0 hbar^2 / (m_e e^2) = 5.291772e-11 m

Bohr radius a0                                  = 5.291772e-11 m    -- identical
E at that radius                                = -13.605693 eV
Measured hydrogen ground-state energy           = -13.605693 eV
```

The relation, used as nothing but an inequality and made stationary, returns the Bohr radius exactly and the hydrogen ground-state energy to six figures. Atoms have the size they have because a wave cannot be squeezed in position without paying in momentum. The variational form licenses no teleology: the derivative vanishes at that radius and nothing is seeking it.

Scale 3 — the nucleus, and why beta-decay electrons do not live there. Confine an electron to $\sigma_x = 1.0 \times 10^{-15}$ m:

```
sigma_p >= 5.2729e-20 kg m/s
p c                   = 98.66 MeV
relativistic KE       = 98.15 MeV
```

Nuclear binding energies per nucleon are of order 8 MeV. **An electron confined to a nucleus would carry roughly a hundred MeV, an order of magnitude more than the nucleus could hold it with** — so the electrons emitted in beta decay are created at emission rather than resident beforehand. **This is the relation ruling out a physical picture, quantitatively, which is what a real constraint does.**

Scale 4 — a gram, and why nobody notices. A one-gram mass localised to one micrometre:

```
sigma_p >= 5.2729e-29 kg m/s
sigma_v >= 5.2729e-26 m/s
        =  1.6641e-18 m per year
        =  9.79e-04 proton diameters per year
```

The forced velocity spread would move it less than one thousandth of a proton diameter in a year. The relation is not silent at macroscopic scale — it is loudly, computably negligible, exactly as the Casimir force is at biological scale [Casimir, 1948, Lamoreaux, 1997, Curzi, 2026aa]. Both are cases where the honest move is to compute the number and show it is nothing.

32.4.9 4.9 Energy and time: a genuinely different animal

$\Delta E\,\Delta t \geq \hbar/2$ is written constantly and understood rarely, and its status differs from position–momentum in a way that is not a technicality.

The problem is that t is not an operator in standard quantum mechanics. Time is a parameter — the label on the Schrödinger equation, not something the state has a distribution over. There is no σ_t computed from ψ the way σ_x is, so **Robertson's theorem does not apply, because there is no commutator $[H, t]$ to put on the right-hand side.** Pauli observed that a self-adjoint operator canonically conjugate to a Hamiltonian would force the Hamiltonian's spectrum to run over the whole real line, unbounded below as well as above; physical Hamiltonians are bounded below, which is why matter is stable, so no such time operator exists for them. The argument has been examined and qualified repeatedly since, but the conclusion stands for the standard framework: **time-of-arrival and similar quantities are handled with positive-operator-valued measures, not with a self-adjoint clock observable.**

There are at least three distinct true statements written with the same symbols:

```
(i)  MANDELSTAM–TAMM.  For any observable A that is not conserved,

         sigma_E . tau_A  >=  hbar / 2 ,    tau_A := sigma_A / | d<A>/dt |

     tau_A is the time for the expectation of A to shift by one of its own standard
     deviations -- a CHARACTERISTIC TIME OF CHANGE, derived from Robertson applied to
     H and A. Mandelstam & Tamm, J. Phys. USSR 9 (1945), 249. This one IS a theorem,
     and it is a statement about how fast a state can evolve, not about clocks.
```

```
(ii) LIFETIME–LINEWIDTH.  A state that decays with lifetime tau has a Lorentzian energy
     profile of full width at half maximum

         Gamma = hbar / tau      i.e.    delta_nu = 1 / (2 pi tau)

     This is a Fourier statement about an exponentially damped amplitude, and it is
     measured routinely in spectroscopy.

(iii) DURATION–BANDWIDTH OF A PULSE.  A light pulse of duration dt has spectral width
     df >= 1/(4 pi dt). This is the GABOR LIMIT (Section 5) applied to light, and it is
     classical. It is often mislabelled as the energy–time uncertainty relation. It is
     not; it is the Fourier relation for the pulse envelope, and it holds for radio waves
     and sound identically.
```

Statement (ii) is the one that earns the relation its keep. Against published atomic lifetimes:

transition	lifetime tau		FWHM linewidth		energy width
H 2p -> 1s	1.596	ns	99.72	MHz	4.124e-07 eV
Ca 1P1 (422.7 nm)	4.6	ns	34.60	MHz	1.431e-07 eV
Na 3p, D2 line	16.2	ns	9.824	MHz	4.063e-08 eV
Rb 5p, D2 line	26.24	ns	6.065	MHz	2.508e-08 eV
a metastable state	1	s	0.159	Hz	6.582e-16 eV

The Mandelstam–Tamm consistency check on the first row: $\Gamma\tau = \hbar$, which is 2.0000 times $\hbar/2$, so the bound is respected with a factor of two to spare, exactly as a Lorentzian rather than Gaussian profile requires. **A transition that lives for one second has a natural linewidth of 0.159 Hz out of an optical frequency of several hundred terahertz — a fractional width around 10^{-15}, which is why metastable transitions are what optical atomic clocks are built on.** The relation is not a limitation being apologised for; it is the design equation for the most precise instruments built.

And note the form of $\delta\nu = 1/(2\pi\tau)$: a reciprocal relation between a duration and a frequency width with a factor of 2π in it. **It is the Gabor limit in fancy dress, and Section 5 takes the dress off.**

32.4.10 4.10 What the relation licenses, and what it does not

LICENSED. (1) A quantitative floor on the joint spread of any conjugate pair. (2) The stability and size of atoms, and by extension the scale of chemistry. (3) Zero-point energy: a harmonic oscillator cannot sit still at the bottom of its well, and $E_0 = \hbar\omega/2$ follows by the same stationarity argument. (4) Exclusion of physical pictures by computation. (5) Linewidth engineering. (6) The general principle that localisation in one domain costs spread in its conjugate — **which is the part that survives the removal of $\hbar$ and becomes Section 5.**

NOT LICENSED, and this list is the reason the section exists. (1) It does not say the observer creates reality; it says nothing about observers. The measurement problem is genuinely open [Curzi, 2026aa, Zeh, 1970], **but it is not open in the direction of licence.** (2) It does not say everything is uncertain: it gives a precise floor on a specific product for a specific pair, and most quantities in most situations are nowhere near it. (3) It does not say measurement disturbs the measured; that is a separate fact with its own separate inequality, whose naive form has been experimentally violated. (4) It does not license macroscopic indeterminacy — compute the number. (5) **It does not license any claim about belief, intention, mind or future events.** Section 6's analogy carries its badge in every sentence that states it and derives its quantitative content from information budgets and Fourier duality, **not from quantum mechanics**, precisely so that it does not need this licence and never asks for it. (6) It does not make the future indeterminate: the Schrödinger equation is deterministic, and what is probabilistic is the outcome of a measurement under the Born rule [Curzi, 2026aa].

32.4.11 4.11 Why a paper on comfort carries a section on $\hbar$

Three of the framework's central results are Fourier trade-offs. A reverberant room smears speech in time, and the room's decay time and its modal bandwidth are reciprocal — $B = 2.2/T_{60}$ is standard room acoustics and is a duration–bandwidth statement [Curzi, 2026e, Sabine, 1922]. What a mechanical wave can carry into tissue is set by bandwidth and time, and the count of independent degrees of freedom in a signal of bandwidth B and duration T is approximately $2BT$, which is Gabor's own result and the reason a channel-capacity analysis is possible at all [Curzi, 2026x, Gabor, 1946]. And essence frequencies rendered as tone cannot be rendered arbitrarily fast, because a short tone has a smeared spectrum [Curzi, 2026,?].

All three are the same theorem. The framework gains nothing from $\hbar$ — Section 5 uses none of it — and gains a great deal from having demonstrated that it can state the famous case exactly, correct the standard error, and refuse the standard over-reach.

32.4.12 4.12 The concordance, with column roles stated

The corpus's concordance discipline requires that the two columns carry different things: **the evidence column carries what could have come out otherwise, and the precedent column carries only that a structure was independently arrived at and preserved. Two sources agreeing does not double the evidence when only one of them is evidence** [Curzi, 2026w].

```
CLAIM: Certain properties come in pairs such that sharpness in one member of the pair
       forces breadth in the other, and this is a property of the thing itself rather
       than of the act of examining it.

(+1) EVIDENCE COLUMN
     Kennard (1927), Weyl (1928), Robertson (1929): sigma_x sigma_p >= hbar/2, proved.
     Single-slit diffraction and C60 interference (Arndt et al. 1999): measured. The
     bound is quantitative, saturated by Gaussians, and falsifiable -- a single
     reproducible preparation with sigma_x sigma_p < hbar/2 would end it.

(-1) PRECEDENT COLUMN -- CARRIES NO EVIDENCE
     The doctrine of coincident opposites: Nicholas of Cusa, De Docta Ignorantia (1440),
     coincidentia oppositorum. The Latin alchemical corpus organises its operations around
     the fixed / volatile pair, where increasing one is understood to decrease the other.
     The Daodejing, chapter 2, states paired opposites as mutually constitutive.

(0p) HOW THEY INTEGRATE, AND WHERE THEY DO NOT
     The older corpus recorded a STRUCTURE: that some pairs resist joint sharpening. It
     recorded no bound, no constant, no derivation and no measurement, and could not have.
     What the concordance establishes is that the structure is findable without
     instruments. It establishes NOTHING about hbar, about atoms, or about the
     correctness of any traditional operation.

BRIDGE CRITERIA:
     C1 structural correspondence  PASS -- both describe a pair with a joint constraint.
     C2 predictive power           FAIL for the (-1) side. It predicts no number and
                                   generates no test.
     C3 practical utility          PARTIAL. Useful as a mnemonic, useless as a calculation.

STATUS: STRUCTURAL PRECEDENT, NOT EVIDENTIAL SUPPORT. The physics stands entirely on the
(+1) column. Remove the (-1) column and nothing in this section changes.
```

One historical note belongs here because it is documented and is often told badly. **Bohr adopted the taiji symbol and the motto *Contraria sunt complementa* for the coat of arms designed when he received the Order of the Elephant in 1947.** That is a fact about Bohr's taste in

emblems. **It is not evidence that Daoist cosmology anticipated quantum mechanics, and the inference is regularly made and is invalid.** A physicist choosing a heraldic device is choosing a heraldic device.

32.4.13 4.13 Requirements

These govern every appearance of the uncertainty relation in work under this framework.

REQ-4.1 State the relation as $\sigma_x \sigma_p \geq \hbar/2$ with σ explicitly named as the standard deviation of a distribution derived from the state.

REQ-4.2 Never derive, motivate or illustrate the relation by the disturbance story. If it is mentioned, it is mentioned as a superseded historical heuristic, with Ozawa (2003) and the 2012 experiments named in the same passage.

REQ-4.3 State the ensemble reading (Protocol 4-A) at first substantive use.

REQ-4.4 When quoting the general Robertson form, state that the bound is state-dependent and can be trivial, and give the spin example or an equivalent.

REQ-4.5 When the equality case is relevant, state that only Gaussian states saturate the bound.

REQ-4.6 Treat the energy–time relation as a separate topic with its own derivation; state that t is a parameter and not an operator, and name which of the three statements is in use.

REQ-4.7 When the lifetime–linewidth relation is used, give $\delta\nu = 1/(2\pi\tau)$ with real numbers and identify it as a Fourier statement about a damped amplitude.

REQ-4.8 Never write "the uncertainty principle" without saying which one. At least four distinct inequalities circulate under that name: Kennard's, Robertson's, Ozawa's and Gabor's.

REQ-4.9 Compute the magnitude before invoking the relation at any scale above the atomic, and if the computed effect is negligible, say so in the same paragraph with the number.

REQ-4.10 No text under this framework may use the uncertainty relation to support a claim about mind, belief, intention, agency, or the determination of future events.

REQ-4.11 Every concordance states its column roles and evaluates C1, C2 and C3 explicitly, including failures [Curzi, 2026w].

REQ-4.12 Where a historical figure's personal symbolism is cited, state explicitly that biography is not evidence.

REQ-4.13 State the forward chain at first use: this relation is a special case of a Fourier theorem, the general case is Section 5, and the general case is what constrains the designs.

32.4.14 4.14 Failure modes

FM-4.1 — THE DISTURBANCE DERIVATION. *Fault:* the relation presented as arising from the momentum kick of the probe. *Signature:* "you have to bounce a photon off it". *Diagnostic:* ask what the relation says about a system nobody measures; the disturbance story has no answer. *Fix:* Protocol 4-A, then the three-line derivation with no apparatus in it.

FM-4.2 — THE HIDDEN-VARIABLE SMUGGLE. *Fault:* assuming the particle *has* both values. *Signature:* "we cannot know both", "the true position". *Fix:* state the ontic reading; local hidden-variable models of this kind are excluded by Bell-test experiments.

FM-4.3 — THE UNIVERSAL SOLVENT. *Fault:* "the uncertainty principle" invoked to license indeterminacy in markets, minds or futures. *Signature:* no pair named, no commutator named, no number computed; the relation appears as a mood rather than an inequality. *Fix:* demand the pair, the commutator and the number. **Then note that the useful general statement being reached for exists, is classical, is computable, and is Section 5.**

FM-4.4 — THE ENERGY–TIME SLIDE. *Fault:* treating $\Delta E\, \Delta t \geq \hbar/2$ as an instance of Robertson's theorem. *Signature:* a σ_t computed from a wavefunction; there is no such object. *Fix:* name which of the three statements is meant and state Pauli's argument.

FM-4.5 — THE VACUOUS BOUND. *Fault:* quoting Robertson's general form as though it always constrains something. *Fix:* evaluate $\langle [A, B] \rangle$ in the relevant state; give the $|{+}x\rangle$ case where the bound is zero.

FM-4.6 — THE MACROSCOPIC IMPORT. *Fault:* applying the relation to a person, a decision or a room without computing the magnitude. *Fix:* compute. A gram at a micron gets 5.27×10^{-26} m/s.

FM-4.7 — BIOGRAPHY AS EVIDENCE. *Fault:* citing Bohr's emblem, or Pauli's interest in Jung, as support for a correspondence. *Fix:* report biography as biography, then run the concordance with C2 evaluated honestly.

FM-4.8 — PRECEDENT AS PROOF. *Fault:* presenting the precedent column as though it corroborated the evidence column. *Signature:* "ancient wisdom knew this, and now science confirms it". *Fix:* state that the older corpus recorded a structure and recorded no number, and that removing it changes nothing [Curzi, 2026w].

FM-4.9 — COLLAPSE BY MIND. *Fault:* moving from "measurement is special" to "consciousness collapses the wavefunction" and thence to claims about belief. *Fix:* the measurement problem is open; the consciousness-causes-collapse reading is a minority historical interpretation, and decoherence timescales for anything neural give the proposal a quantitative problem rather than merely a philosophical one [Curzi, 2026aa, Zeh, 1970].

FM-4.10 — FOURIER AMNESIA. *Fault:* treating the relation as exotic and quantum-specific, and therefore failing to apply the classical version where it bites. *Signature:* a design that renders tones too short to carry the pitch precision the design requires, unnoticed because "uncertainty principle" sounded like something that happens to electrons. **This is the expensive failure mode in this framework and Section 5 is the whole fix.**

32.5 5 Level two: the Gabor limit, which is the constraint that binds

This is the only uncertainty relation this framework owns, and the only one that constrains anything the reader will build. Everything the framework proposes to render travels on a wave, and the time–frequency plane has a floor:

```
dt . df  >=  1 / (4 pi)  =  0.079577471545948
```

This is classical. There is no $\hbar$ in it, no quantisation, no operators, no observers, no measurement problem and no interpretation. It is a theorem about square-integrable functions and their Fourier transforms, stated in its communications form by Gabor [1946], and it applies to every wave including the sound from a loudspeaker and the tone that encodes a lattice index. Section 4.5 showed that Kennard's relation is this theorem with the substitution $p = \hbar k$ performed on the last line. **The quantum case is the special case; this is the general one.**

The sentence to carry out of this section: **a short sound cannot have a precise pitch — not because instruments are poor, but because a short sound does not have one.**

32.5.1 5.1 The relation, stated exactly

```
PROVEN THEOREM of Fourier analysis. Classical. No quantum content.

Let g(t) be a square-integrable complex function of time with Fourier transform

    G(f) = INTEGRAL g(t) exp(-i 2 pi f t) dt

Define the spreads as standard deviations of the normalised energy densities:
```

```
    <t>     = INTEGRAL t |g(t)|^2 dt / INTEGRAL |g(t)|^2 dt
    dt^2    = INTEGRAL (t - <t>)^2 |g(t)|^2 dt / INTEGRAL |g(t)|^2 dt
    <f>     = INTEGRAL f |G(f)|^2 df / INTEGRAL |G(f)|^2 df
    df^2    = INTEGRAL (f - <f>)^2 |G(f)|^2 df / INTEGRAL |G(f)|^2 df

Then

    dt . df  >=  1 / (4 pi)

with equality if and only if g is a Gaussian (times a linear phase).
```

The constants, to full working precision:

```
1 / (4 pi)  =  0.079577471545948
4 pi        = 12.566370614359172
1 / (2 pi)  =  0.159154943091895      <-- the angular-frequency form: dt . d_omega >= 1/2
```

Read the units. Δt is in seconds, Δf in hertz — cycles per second, not radians per second — and the product is dimensionless. **The 4π rather than 2π is entirely a consequence of measuring frequency in cycles, and getting this wrong by a factor of two is the single most common arithmetic error made with this relation.** A $1/2$ on the right-hand side means angular frequency on the left.

Gabor's original paper introduced the time–frequency *information diagram*, showed it is partitioned into cells of irreducible area, named the elementary quantum of information the *logon*, and identified the Gaussian-modulated sinusoid as the signal achieving the minimum cell area [Gabor, 1946]. **The framing is the right one here: the time–frequency plane is not a continuum that can be subdivided indefinitely. It has a grain.** The result sits alongside the earlier bandwidth–information results of Nyquist [1928] and Hartley [1928] and is the geometric statement those two make arithmetically.

32.5.2 5.2 What Δt and Δf mean, and what they do not

Δt is a root-mean-square spread of energy in time, not a window length. A tone burst gated for exactly 100 ms does not have $\Delta t = 100$ ms; under a rectangular gate it has $\Delta t = 28.9$ ms, because the standard deviation of a uniform distribution of width T is $T/\sqrt{12} = 0.2887\,T$.

Δf is a root-mean-square spread of energy in frequency. It is not the width of a peak, not the bin spacing of a discrete Fourier transform, and not the resolution of a spectrum analyser. It is a second moment.

This matters immediately and in an unexpected direction: for some very common window shapes, Δf does not exist. A rectangular gate has a sinc spectrum whose magnitude falls as $1/f$, so $|G(f)|^2$ falls as $1/f^2$ and the integral defining the second moment diverges logarithmically. **That exponent is an exact analytic property of the function and is not an estimated exponent** (Section 3.7). A 200 ms rectangular gate, transformed at three sampling resolutions:

samples	dt spacing	computed df	computed dt . df
65,536	0.4 ms	29.60 Hz	1.712
262,144	0.2 ms	41.88 Hz	2.420
1,048,576	0.1 ms	59.24 Hz	3.422

The number keeps climbing as the bandwidth of the calculation is extended. It does not converge. The rectangular window has no finite Δf. This is not a numerical artefact; it is the correct answer, and it is a design fact of the first importance: **abrupt gating of a tone does not merely smear its spectrum, it smears it without bound.** Any rendering specification in this framework must therefore name an envelope, and the envelope must not be rectangular.

The standard envelopes, measured against the floor by the same numerical procedure (262,144 samples at 0.2 ms):

envelope	dt	df	dt . df	multiple of floor
Gaussian, sd = 50 ms	0.05000 s	1.5915 Hz	0.079577	1.000 EXACT
Hann, 200 ms	0.02829 s	2.8868 Hz	0.081665	1.026
triangular, 200 ms	0.03162 s	2.7579 Hz	0.087211	1.096
rectangular, 200 ms	0.05779 s	(divergent)	(divergent)	UNBOUNDED
one-sided exponential, 50 ms	0.02500 s	(divergent)	(divergent)	UNBOUNDED

The Gaussian saturates the bound to ten significant figures. The Hann window costs 2.6 per cent over the theoretical floor and has a finite answer. The rectangular gate has no answer at all. Those three lines are the entire practical content of "choose an envelope".

32.5.3 5.3 The derivation, in full

The proof is Section 4.5 with one line deleted, and it is given here in its own right because this is where it is used.

Let $g(t)$ be normalised so that $\int |g|^2\,dt = 1$, and shift so that $\langle t\rangle = \langle f\rangle = 0$. Work with angular frequency $\omega = 2\pi f$ and convert at the end.

Step 1 — build something that cannot be negative. For any real a:

```
I(a) = INTEGRAL | a t g(t) + g'(t) |^2 dt   >=   0
```

It is the integral of a squared modulus. **There is no physics in this step and no assumption about what g represents** — it could be a pressure wave, a voltage, a radio envelope or a probability amplitude. **This is what makes the application to an acoustic signal a derivation rather than an analogy: the premises are square-integrability and finite second moments, and a rendered tone of finite energy under a smooth envelope satisfies both.**

Step 2 — expand the square.

```
INTEGRAL |t g|^2 dt                    = dt^2

INTEGRAL |g'|^2 dt                     = d_omega^2
    -- by Plancherel's theorem, since differentiation in time is
       multiplication by i*omega in frequency

2a * Re INTEGRAL t g* g' dt            = -a
    -- integrate by parts:  INTEGRAL t (d/dt)(|g|^2/2) dt = -1/2
       using normalisation and decay of g at infinity

so    I(a) = a^2 dt^2 - a + d_omega^2  >=  0     for every real a
```

Step 3 — a real quadratic that is never negative has no real roots, so its discriminant is not positive.

```
1 - 4 dt^2 d_omega^2  <=  0
=>  dt . d_omega  >=  1/2
=>  dt . df       >=  1 / (4 pi)          since omega = 2 pi f
```

Step 4 — the equality condition, which is the design rule. Equality requires $I(a) = 0$ at the minimising $a = 1/(2\,\Delta t^2)$, and since $I(a)$ integrates a non-negative integrand, the integrand vanishes identically:

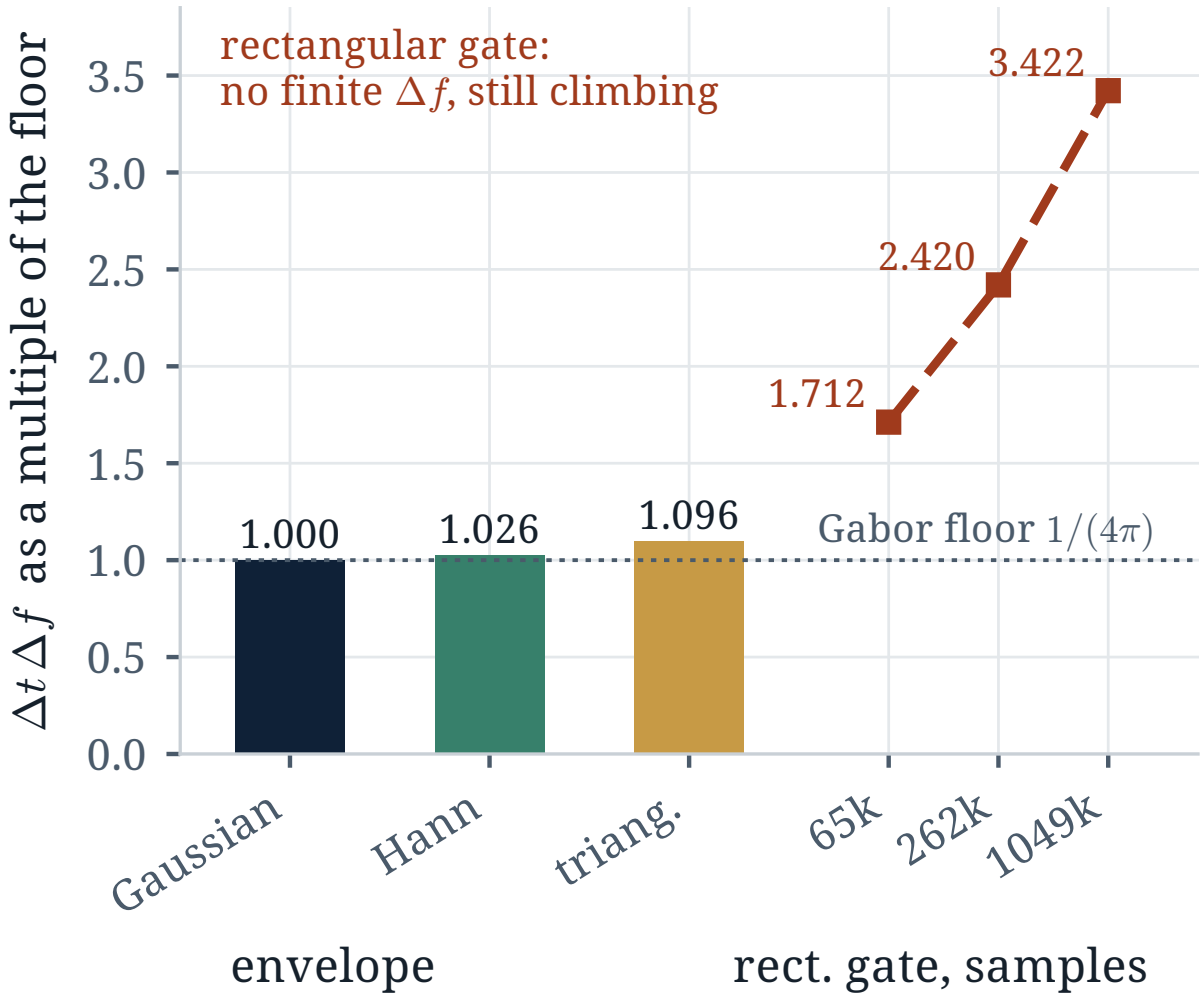

Figure 32.1: **The Gaussian saturates the Gabor floor, the Hann window costs 2.6 per cent, and the rectangular gate has no finite answer at all:** the four standard envelopes measured against $1/(4\pi) = 0.079577471545948$, with the rectangular gate's computed $\Delta t\,\Delta f$ shown at three successive analysis bandwidths, still climbing. The first three values are numerical evaluations of the stated envelopes on 262,144 samples at 0.2 ms spacing; the rectangular values are the 65,536 / 262,144 / 1,048,576-sample computations of Section 5.2 and are a divergence, not a measurement. Generated by `figs/src/CCP-032_fig01.py`.

```
a t g(t) + g'(t) = 0
=>  g(t) = C exp(-a t^2 / 2)              a GAUSSIAN
```

Only the Gaussian reaches the floor; everything else pays. Numerical confirmation at five widths:

```
Gaussian sd = 5 ms     ->  dt . df = 0.0795774715
Gaussian sd = 10 ms    ->  dt . df = 0.0795774715
Gaussian sd = 20 ms    ->  dt . df = 0.0795774715
Gaussian sd = 50 ms    ->  dt . df = 0.0795774715
Gaussian sd = 100 ms   ->  dt . df = 0.0795774715
1 / (4 pi)             =            0.0795774715
```

Scale-invariant, exact, and verified to ten significant figures. Squeeze the Gaussian in time and its transform widens by precisely the reciprocal factor. **That reciprocity is the law**, and it is the invariance that makes the octave form of Section 5.9 possible.

32.5.4 5.4 Warrant

PROVED, pure mathematics with no empirical content. $\Delta t\,\Delta f \geq 1/(4\pi)$ for every square-integrable g with finite second moments in both domains; equality iff g is Gaussian; and the scale invariance — replacing $g(t)$ by $g(t/s)$ multiplies Δt by s and divides Δf by s, leaving the product unchanged. **This is why the relation transposes cleanly through octaves**, which matters from Section 5.9 onward.

CITED. Gabor [1946] for the information diagram, the logon, the elementary signal and the $2BT$ degrees-of-freedom count. Frequency difference limens for pure tones: Wier, Jesteadt and Green, *Journal of the Acoustical Society of America* 61 (1977), 178–184 — **named without a key, per the disclosure in Section 4.3**; the reviewed literature in this corpus's bibliography is Burns [1999] and Demany et al. [2013]. Standard room acoustics — modal half-power bandwidth $B = 2.2/T_{60}$, Schroeder frequency $f_s = 2000\sqrt{T_{60}/V}$ [Sabine, 1922, Schroeder, 1965, Beranek, 2004].

POSTULATED about the mathematics: nothing. The Gabor limit is a theorem. **What is this framework's own is the *application* of the theorem to the essence law, and that application is arithmetic on top of a postulate — the essence law itself [Curzi, 2026] — rather than a new postulate.** The essence law's honesty clauses carry through unchanged.

32.5.5 5.5 The three resolution figures, and the factors between them

Three different numbers are all called "frequency resolution", they differ by more than an order of magnitude, and mixing them is the most common source of wrong design numbers in signal work.

```
(a) GABOR FLOOR            df = 1 / (4 pi T)         T interpreted as the window duration
                           The absolute theoretical minimum. Reached only by a Gaussian
                           whose rms width equals T -- an idealisation, since a Gaussian
                           has no finite duration. Treat as the LOWER BOUND that no
                           processing can beat.

(b) RAYLEIGH / DFT BIN     df = 1 / T
                           The spacing of DFT bins for a T-second record, and the classic
                           criterion for resolving two sinusoids with a rectangular window.
                           Exactly 4 pi = 12.566 times the Gabor floor.

(c) HANN MAIN LOBE         df = 4 / T
```

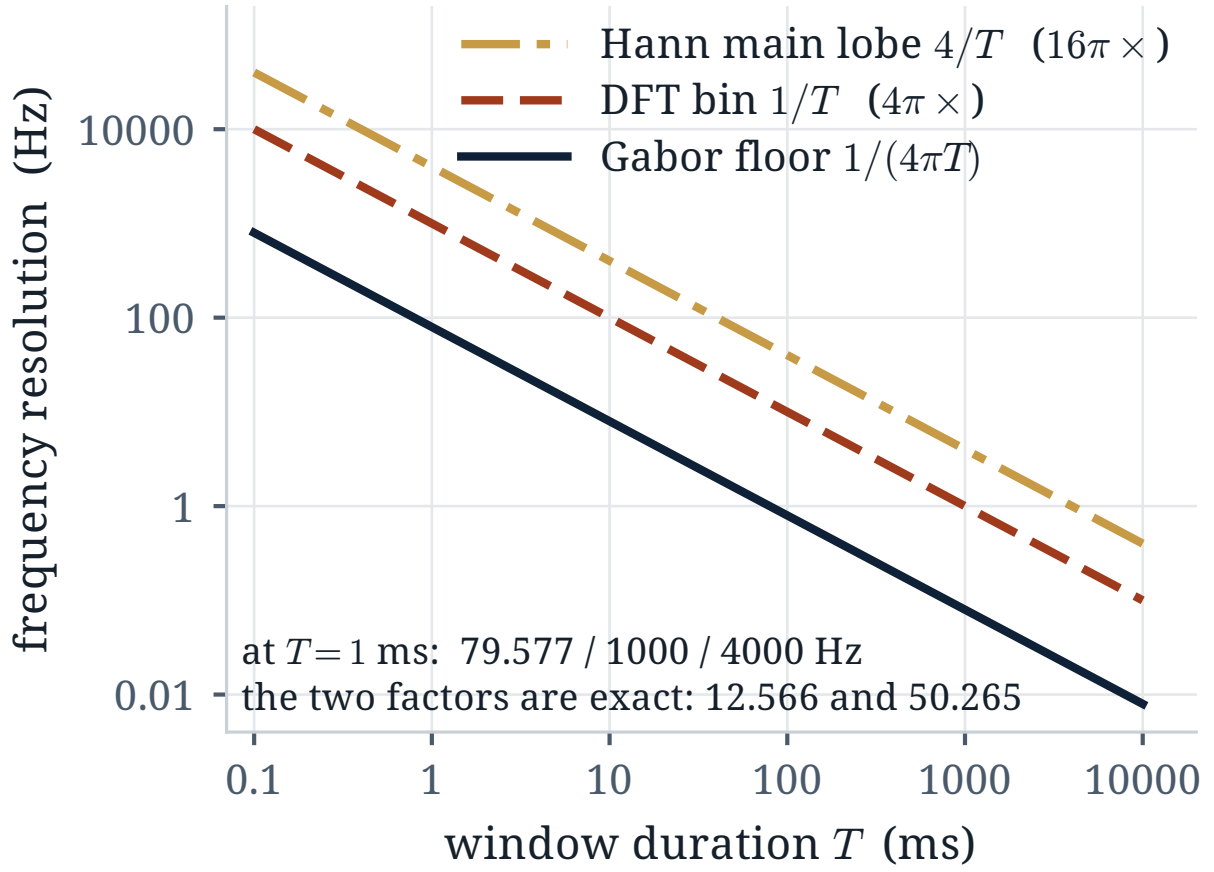

Figure 32.2: **Three quantities are called "frequency resolution" and they differ by up to a factor of 50:** the Gabor floor $1/(4\pi T)$, the DFT bin $1/T$ at exactly $4\pi = 12.566$ times the floor, and the Hann main lobe $4/T$ at exactly $16\pi = 50.265$ times it, plotted over the window durations of Table 5-A. Every value is an exact evaluation of the stated formula, not a measurement; the three multipliers are exact. Generated by `figs/src/CCP-032_fig02.py`.

```
The -3 dB-to--3 dB span of a Hann-windowed sinusoid's main
lobe, which is what a real analyser delivers when the window
is chosen for low spectral leakage.
Exactly 16 pi = 50.265 times the Gabor floor.
```

Throughout this section the tabulated $\Delta f_{\min}$ is the Gabor floor (a), because it is the bound no technique can beat; practical designs must be checked against (b) or (c) depending on the analysis chain. **The convention $\Delta t = T$ used in the tables is the standard engineering shorthand, stated here in the open: it treats the whole rendering window as the rms spread, which is optimistic by construction.** It is retained because the framework's existing design table was computed in it, and cross-paper consistency is worth more than a factor of $\sqrt{12}$. **A reader converting to true rms spreads must apply the shape factor**, and the resulting figures will be worse, not better, than those tabulated.

32.5.6 5.6 The concordance, with column roles stated

The evidence column carries evidence; the precedent column carries precedent [Curzi, 2026w].

```
CLAIM: The precision with which a frequency can be determined is limited by the duration
```

```
       over which it is observed, and the two trade reciprocally.

(+1) EVIDENCE COLUMN
     Gabor, Theory of Communication (1946): dt df >= 1/(4 pi), proved, with the equality
     case identified. Verified numerically in Section 5.3 to ten significant figures.
     Measurable directly: gate a 1 kHz sinusoid for 1 ms, transform it, observe a spectral
     spread of order 100 Hz on any oscilloscope with an FFT function. A single reproducible
     signal with dt df < 1/(4 pi) and finite second moments in both domains would refute
     it, and would also refute Plancherel's theorem.

(-1) PRECEDENT COLUMN -- CARRIES NO EVIDENCE
     THE TUNER'S BEAT. Keyboard and organ tuning by counting beats is documented craft
     practice from the seventeenth century and is still taught for aural tuning. Two tones
     a frequency df apart produce an amplitude beat at rate df; counting one beat requires
     listening for 1/df seconds. The craft rule -- that resolving a small pitch difference
     requires a proportionally long listen, and that a unison cannot be tuned from a short
     pluck -- is the same reciprocal trade, in working use for roughly three hundred years
     before Gabor wrote it down.

     The arithmetic is exact and worth stating: counting ONE beat cycle at df takes
     1/df seconds, which is 4 pi = 12.566 times the Gabor floor for that df. A tuner who
     counts eight beats before judging -- ordinary practice -- has listened for 8/df
     seconds, which is 100.5 times the floor. The craft is not near the theoretical limit
     and never claimed to be.

(0p) HOW THEY INTEGRATE
     The craft route produced a WORKING CONSTANT (listen for several beats) and no
     derivation, no bound, and no account of why. The analytic route produced the bound,
     the equality case, and the envelope design rule. What the concordance establishes is
     that the reciprocal structure was findable without Fourier analysis. What it does NOT
     establish is any number: remove the (-1) column and every computation here is
     unchanged.

BRIDGE CRITERIA:
     C1 structural correspondence  PASS. Both state that resolving df requires a listen
                                   time proportional to 1/df.
     C2 predictive power           PASS, unusually. The tuner's rule DOES generate a
                                   prediction -- "this unison cannot be judged in a tenth
                                   of a second" -- which is correct and testable by anyone
                                   with two strings.
     C3 practical utility          PASS on both sides.

STATUS: ESTABLISHED as a structural concordance, and included partly to demonstrate that
the criteria are satisfiable -- the corpus rejects roughly one bridge in five in print
(CCP-029).
```

A worked instance of the craft side, computed. Equal temperament's major third above A4 = 440 Hz is 554.3653 Hz against just intonation's 550.0000 Hz; a tuner listens to the beat between the fourth harmonic of the tempered third (2217.4610 Hz) and the fifth harmonic of A4 (2200.0000 Hz), a beat rate of 17.4610 Hz — one beat every 57.3 ms, against a Gabor floor of 4.5574 ms. **The craft sits comfortably above the bound, which is why the craft works.** The tuning ratios themselves are standard [Barbour, 1951, von Helmholtz, 1885].

32.5.7 5.7 Table 5-A — the master window/resolution table

All values computed; $\Delta f_{\min}$ is the Gabor floor $1/(4\pi T)$, with the two practical criteria alongside.

window T	df_min = 1/(4 pi T)	1/T (DFT bin)	4/T (Hann lobe)	cycles at 1 kHz
0.1 ms	795.77472 Hz	10000.0000	40000.0000	0.10
0.2 ms	397.88736 Hz	5000.0000	20000.0000	0.20
0.5 ms	159.15494 Hz	2000.0000	8000.0000	0.50
1 ms	79.57747 Hz	1000.0000	4000.0000	1.00
2 ms	39.78874 Hz	500.0000	2000.0000	2.00
5 ms	15.91549 Hz	200.0000	800.0000	5.00
10 ms	7.95775 Hz	100.0000	400.0000	10.00
20 ms	3.97887 Hz	50.0000	200.0000	20.00
23.22 ms	3.42711 Hz	43.0663	172.2653	23.22
50 ms	1.59155 Hz	20.0000	80.0000	50.00
100 ms	0.79577 Hz	10.0000	40.0000	100.00
200 ms	0.39789 Hz	5.0000	20.0000	200.00
500 ms	0.15915 Hz	2.0000	8.0000	500.00
1000 ms	0.07958 Hz	1.0000	4.0000	1000.00
10000 ms	0.00796 Hz	0.1000	0.4000	10000.00

The four rows the framework's design table names read out of this exactly: 1 ms gives 79.577 Hz, 10 ms gives 7.958 Hz, 100 ms gives 0.796 Hz, and 1000 ms gives 0.080 Hz.

The 23.22 ms row is included because it is the duration of a 1024-sample frame at 44.1 kHz, the most common analysis frame in audio work. **A 1024-point FFT at CD rate cannot resolve better than 3.43 Hz no matter what is done to it, and a Hann-windowed analysis of that frame delivers about 172 Hz of main-lobe width** — a factor of fifty between the theoretical floor and the practical number, and designs are broken by that factor routinely.

The inverse table:

target df	T at Gabor floor	T at 1/df (DFT bin)
1000 Hz	0.0796 ms	1.0000 ms
100 Hz	0.7958 ms	10.0000 ms
10 Hz	7.9577 ms	100.0000 ms
3 Hz	26.5258 ms	333.3333 ms
1 Hz	79.5775 ms	1000.0000 ms
0.1 Hz	795.7747 ms	10000.0000 ms

32.5.8 5.8 The octave-invariant form: count cycles, not milliseconds

Table 5-A is in absolute time, which is awkward for music and useless for a lattice that gets transposed. **There is a form of the relation invariant under octave transposition, and it is the form used everywhere below**, because the framework transposes everything. Let $r = \Delta f / f_0$ be the fractional resolution required at centre frequency f_0. Then:

```
T . f0  >=  1 / (4 pi r)

LEFT SIDE  = the number of CYCLES of the tone contained in the window.
RIGHT SIDE = depends only on the fractional resolution.
```

Transposing by an octave doubles f_0 and halves the required T, leaving the cycle count unchanged. The cycle count is the invariance — the transformation group is dilation of the time axis, the invariant is $T f_0$, and Section 5.3's scale-invariance calculation is the proof. Converted to cents, since musical resolution is specified in cents:

resolution	r = df / f0	minimum cycles in the window	
1200 cents	1.00000000	0.0796	
700 cents	0.49830708	0.1597	
200 cents	0.12246205	0.6498	
100 cents	0.05946309	1.3383	
50 cents	0.02930224	2.7157	
34.976 cents	0.02040815	3.8993	<– the 50/49 interval
10 cents	0.00579294	13.7370	
6.001 cents	0.00347221	22.9184	<– the 289/288 interval
5 cents	0.00289229	27.5137	
1 cent	0.00057779	137.7274	

One cent of pitch resolution requires at least 138 cycles of tone, at any pitch, under the most favourable possible envelope — 313 ms at A4 = 440 Hz, 66 ms at C7 = 2093 Hz. **The absolute time changes with register; the cycle count never does.** In working form: one cent is about 138 cycles, five cents about 28, ten cents about 14, and a semitone about 1.3.

32.5.9 5.9 A short sound cannot have a precise pitch

As physics. Table 5-A converted to cents at eight reference pitches; each entry is the minimum spectral spread, expressed as a musical interval, for a tone of that duration at that pitch.

pitch	1 ms	5 ms	10 ms	25 ms	50 ms	100 ms	250 ms	1000 ms
C1 32.7	2135.53	686.50	377.05	160.80	82.27	41.62	16.77	4.21
C2 65.4	1378.07	377.05	198.77	82.27	41.62	20.94	8.40	2.11
C3 130.8	822.68	198.77	102.24	41.62	20.94	10.50	4.21	1.05
A3 220.0	534.51	120.92	61.52	24.87	12.48	6.25	2.50	0.63
A4 440.0	287.80	61.52	31.03	12.48	6.25	3.13	1.25	0.31
A5 880.0	149.87	31.03	15.59	6.25	3.13	1.56	0.63	0.16
A6 1760.0	76.56	15.59	7.81	3.13	1.56	0.78	0.31	0.08
A7 3520.0	38.70	7.81	3.91	1.56	0.78	0.39	0.16	0.04

(values in cents)

A 1 ms tone at C1 has a spectral spread of 2135 cents — nearly two octaves. It does not have a pitch; it is a click with a slight colour. A 1 ms tone at A4 spreads 288 cents, close to a minor third: enough to say “somewhere around A” and nothing more. A 1 ms tone at A7 is down to 39 cents, under a quarter-tone, and there the transient does have a recognisable pitch. **That register dependence is why bass notes need to be long and cymbals do not.**

As perception. The physics gives a floor; hearing sits above it. Wier, Jesteadt and Green (*JASA* 61, 1977, 178–184) measured frequency difference limens for pure tones at roughly 0.2 to 0.3 per cent near 1 kHz, widening at low frequencies and low sensation levels; the reviewed treatment in this corpus’s bibliography is Burns [1999]. Setting Δf equal to the limen and inverting:

f0	difference limen	df	Gabor T_min	cycles	as cents
125 Hz	0.6 %	0.750 Hz	106.10 ms	13.26	10.36
250 Hz	0.4 %	1.000 Hz	79.58 ms	19.89	6.91
500 Hz	0.3 %	1.500 Hz	53.05 ms	26.53	5.19
1000 Hz	0.3 %	3.000 Hz	26.53 ms	26.53	5.19
1000 Hz	0.2 %	2.000 Hz	39.79 ms	39.79	3.46
4000 Hz	0.2 %	8.000 Hz	9.95 ms	39.79	3.46

A tone must last on the order of 25 to 100 ms before its physical spectral spread is narrower than the smallest pitch difference a human can hear. Shorter than that, the limiting factor is not the ear but the signal: **the tone genuinely does not contain the information the listener is being asked for.** The difference limens are measured psychophysical quantities carrying their own sampling uncertainty, which is not restated here; the Gabor columns beside them are exact.

This is the honest converse of a claim often made carelessly in sound-design work — that some effect requires "exposure" to a frequency. Whatever else is true of that, the Gabor limit says something narrower and certain: **if the frequency is not present long enough, it is not present as a frequency at all, and no amount of repetition of too-short bursts fixes it**, because each burst independently lacks the spectral definition. Repetition raises the count of events; it does not sharpen any one of them.

32.5.10 5.10 The lattice under a common transposition

The essence law, presupposed as a badged postulate with k a chosen reference constant and not a measured one [Curzi, 2026, Markowsky, 1992]:

```
f(n) = k n^2 ,      k = (9/8)^2 / phi^2 = (81/64)/(phi+1) = 0.483425732988414 Hz
```

k **is a DEFINED constant**, exact as a ratio of exact quantities, which is why fifteen significant figures are legitimate for it; **the attachment of hertz to it is a separate and much stronger claim and is POSTULATED** (Section 9.2, P6). Two rendering strategies exist with completely different consequences.

STRATEGY A — COMMON TRANSPOSITION. One integer j for the whole lattice; every index renders at $f(n) = kn^2 2^j$. Ratios are preserved exactly and the set spans many octaves. The gap between adjacent indices is gap$(n \to n+1) = k(2n+1)2^j$, and the fractional gap, which by Section 5.8 determines the cycle count and is invariant under j, is $r(n) = (2n+1)/n^2$:

n	f_raw (Hz)	gap to n+1	r = gap/f	min cycles
1	0.48343	1.45028	3.000000	0.027
2	1.93370	2.41713	1.250000	0.064
4	7.73481	4.35083	0.562500	0.141
8	30.93925	8.21824	0.265625	0.300
12	69.61331	12.08564	0.173611	0.458
16	123.75699	15.95305	0.128906	0.617
24	278.45322	23.68786	0.085069	0.935
32	495.02795	31.42267	0.063477	1.254
64	1980.11180	62.36192	0.031494	2.527
92	4091.71540	89.43376	0.021857	3.641

The fractional gap shrinks like $2/n$, so the cycle count grows like $n/(8\pi)$ — an asymptotic of the exact expression, not a fitted exponent (Section 3.7). Verified against $n^2/(4\pi(2n+1))$: at $n = 10$, 0.379 exact against 0.398 approximate; at $n = 100$, 3.959 against 3.979; at $n = 500$, 19.874 against 19.894.

> **DESIGN LAW 1, exact.** Under a common transposition, distinguishing index n from $n+1$ requires a tone lasting at least $n^2/(4\pi(2n+1))$ cycles, approaching $n/(8\pi)$ for large n, **and this is independent of the transposition j. The deep lattice is intrinsically slower to render than the shallow one, and no choice of octave rescues it.**

THE AUDIBLE-BAND CONSTRAINT. A common transposition must place the whole lattice inside human hearing, taken as 20 Hz to 20 kHz:

```
lower edge:   k * 1^2 * 2^j >= 20      =>  2^j >= 41.371  =>  j >= 5.371  =>  j >= 6
upper edge:   k * N^2 * 2^j <= 20000
```

For real-valued j the ceiling on lattice size is $N^2 \leq 20000/20 = 1000$, i.e. $N \leq 31.62$. Restricting to integer octave transposition, as the framework requires, the constraint tightens:

j	f(1)	maximum N	f(N) at that N
5	15.4696 Hz	(below 20 Hz -- DISALLOWED)	
6	30.9392 Hz	25	19337.03 Hz
7	61.8785 Hz	17	17882.88 Hz
8	123.7570 Hz	12	17821.01 Hz
9	247.5140 Hz	8	15840.89 Hz

DESIGN LAW 2. Under a single integer octave transposition, the square law admits **at most 25 lattice elements inside the audible band, and only at** $j = 6$. A 26-element lattice at $j = 6$ puts index 26 at 20911 Hz, outside hearing. A 12-element lattice has three admissible transpositions, $j = 6$, 7 or 8.

This is a hard structural limit on the method, it is arithmetic rather than taste, and it was not visible until the question of what rendering actually costs was forced.

THE RENDER-RATE CEILING. Under a common transposition the binding constraint is at the *bottom* of the lattice, where the absolute gap is smallest. At $n = 1$ the gap is $3k2^j$:

j	gap(1 -> 2)	T_min (Gabor floor)	R_max (symbols/s)
6	92.81774 Hz	0.85735 ms	1166.38
7	185.63548 Hz	0.42868 ms	2332.76
8	371.27096 Hz	0.21434 ms	4665.53

Under the stricter half-gap criterion, requiring the spread to be at most half the gap so that two adjacent elements are *separated* rather than merely non-identical:

```
j = 6, n = 1:   gap = 92.81774 Hz,  df <= 46.4089 Hz
                T_min = 1.7147 ms,  R_max = 583.19 symbols/s
```

A common-transposition lattice at $j = 6$ can be rendered at up to about 583 elements per second before spectral smearing merges adjacent positions.

32.5.11 5.11 The folded lattice, where the constraint becomes severe

STRATEGY B — PER-VALUE OCTAVE FOLDING. Fold each value by its own power of two into a chosen band, stating the band and j for every value. This keeps the lattice inside one octave and makes it musically usable [Shepard, 1982]. **It also destroys the guaranteed spacing, and that is the finding of this subsection.**

Two indices share a pitch class if and only if they have the same odd part, so an N-element lattice folds to $\lceil N/2 \rceil$ distinct classes [Curzi, 2026]. For $N = 12$ the odd parts are $\{1, 3, 5, 7, 9, 11\}$ and their squares folded into one octave are:

index odd part	m^2	folded ratio	cents above base
1	1	1/1	0.000
3	9	9/8	203.910
9	81	81/64	407.820
7	49	49/32	737.652
5	25	25/16	772.627
11	121	121/64	1102.636

The gaps between adjacent members, in cents, the last wrapping to the octave:

```
203.910   203.910   329.832    34.976   330.008    97.364
```

The minimum gap is 34.976 cents, between index 7 at $49/32$ and index 5 at $25/16$. The interval is exactly $50/49$ — the septimal sixth-tone, which falls out of the square law with no choice in the matter, since $(25/16)/(49/32) = 50/49$. Extending to larger lattices, computed on exact rationals:

N	pitch classes	minimum gap ratio	cents	which indices	
8	4	50/49	34.9756	7 and 5	
12	6	50/49	34.9756	7 and 5	
16	8	50/49	34.9756	7 and 5	
17	9	289/288	6.0008	3 and 17	<- CLIFF
20	10	289/288	6.0008	3 and 17	
24	12	289/288	6.0008	3 and 17	
32	16	289/288	6.0008	3 and 17	
40	20	289/288	6.0008	3 and 17	
41	21	1682/1681	1.0296	41 and 29	<- CLIFF
48	24	1682/1681	1.0296	41 and 29	
64	32	1682/1681	1.0296	41 and 29	

> **CORRECTION TO A PREVIOUSLY PUBLISHED RESULT.** This analysis originally placed the first cliff at $N = 20$ and the second at $N = 48$. **Both boundaries were stated too late.** On exact rational arithmetic — every n^2 for $n = 1 \dots N$ folded into one octave with exact fractions, minimum adjacent ratio taken including the wrap to the octave — the boundaries are $N = 17$ and $N = 41$. The cause given originally was correct and is unchanged: $289/288$ is the culprit, and it appears the moment index 17 joins the set, because $17^2 = 289$ folds beside $288 = 2 \cdot 12^2$, and index 12 has been present since $N = 12$. **20 and 48 were merely the next sampled rows of the table, not the thresholds. The rate figures (86.394 falling to 10.799, a factor of eight) were and remain correct**; only the N at which they take effect has moved.

The table above samples N; the exact regime boundaries are $N = 3$, 7, 17 and 41, with the schedule $9/8$ (203.9100 cents) for $N = 3 \dots 6$, $50/49$ (34.9756) for $7 \dots 16$, $289/288$ (6.0008) for $17 \dots 40$ and $1682/1681$ (1.0296) for $N \geq 41$ [Curzi, 2026]. **Confusing a sampled row with a threshold is precisely the error corrected below**, so the distinction is made here before the correction is stated.

> **DESIGN LAW 3.** The minimum gap in a folded lattice collapses in discrete jumps as N crosses the thresholds at which a new near-coincidence of squares appears — **35 cents up to $N = 16$, 6 cents from $N = 17$, 1 cent from $N = 41$.** These are not smooth; they are number theory. $289/288$ arises because $17^2 = 289$ folds to $289/256$ and lands six cents above $9/8 = 288/256$; $1682/1681$ arises because $41^2 = 1681$ and $2 \cdot 29^2 = 1682$.

Converted to render times at a 220 Hz base:

N	classes	min gap (cents)	min gap (Hz)	T_min (ms)	R_max (symbols/s)	
4	2	203.9100	27.50000	2.8937	345.575	
8	4	34.9756	6.87500	11.5749	86.394	
12	6	34.9756	6.87500	11.5749	86.394	
16	8	34.9756	6.87500	11.5749	86.394	
17	9	6.0008	0.85938	92.5992	10.799	<- CLIFF

20	10	6.0008	0.85938	92.5992	10.799	
24	12	6.0008	0.85938	92.5992	10.799	
32	16	6.0008	0.85938	92.5992	10.799	
40	20	6.0008	0.85938	92.5992	10.799	
41	21	1.0296	0.21484	370.3970	2.700	<- CLIFF
48	24	1.0296	0.21484	370.3970	2.700	
64	32	1.0296	0.21484	370.3970	2.700	

Read the $N = 16$ and $N = 17$ rows against each other. Adding a single element costs a factor of eight in rendering speed, from 86 elements per second to 10.8. That is not a gradual degradation. **It is a cliff, it sits at $N = 17$, and it is caused by 17^2 landing six cents away from $9/8$.**

The factor of eight is exact, and the obvious shortcut gets it wrong. The two binding pairs do not sit at the same place in the octave, so the ratio of *rate ceilings* is not the ratio of *fractional* gaps ($288/49 = 5.878$). Gabor resolution is linear in hertz and $R_{\max} = 4\pi\,\Delta f$ uses the absolute gap: the $50/49$ pair straddles $49/32$, so its gap is base $\cdot\,(50 - 49)/32 =$ base$/32$; the $289/288$ pair straddles $9/8 = 288/256$, so its gap is base $\cdot\,(289 - 288)/256 =$ base$/256$. Then $(1/32)/(1/256) = 8$ exactly, at every base pitch. The same argument gives exactly 4 across the second cliff.

The base pitch scales everything, since the constraint is fractional:

base	tightest pair (indices 7 and 5)	gap (Hz)	T_min (ms)	R_max (/s)
55.0000	84.2188 / 85.9375 Hz	1.71875	46.2996	21.60
110.0000	168.4375 / 171.8750 Hz	3.43750	23.1498	43.20
220.0000	336.8750 / 343.7500 Hz	6.87500	11.5749	86.39
440.0000	673.7500 / 687.5000 Hz	13.75000	5.7875	172.79

Raise the base an octave and the achievable rate doubles. That is the octave-invariance of Section 5.8 seen from the other side, and it is the one free lever the designer has.

> **DESIGN LAW 4, the practical headline.** A folded lattice is between 5 and 55 times slower to render than a common-transposition lattice of the same size: $N = 12$ at $j = 6$ under the half-gap criterion gives **583.19 symbols/s**; $N = 12$ folded to one octave at 220 Hz gives **86.39 symbols/s** (6.8 times slower); $N = 24$ folded at 220 Hz gives **10.80 symbols/s** (54.0 times slower). **Folding is not free. It buys musical usability and it is paid for in bandwidth.**

32.5.12 5.12 Resolving a surplus difference

The framework's cross-disciplinary bridge sets the effective count equal to the lattice index, so that $f_{\text{cross}} = k\,N_{\text{eff}}^2 = k\,e^{2F}$ with F the interaction surplus in nats [Curzi, 2026]. **The effective count in that expression is the corpus's affine $N_{\text{eff}} = 1 + (N - 1)u$, which is not a Hill number** (Section 3.4); the badge travels with it here. One nat of surplus is 2.885 octaves:

F (nats)	N_eff	f = k e^(2F)	octaves above k
0.000000	1.0000	0.483426 Hz	0.0000
1.000000	2.7183	3.572060 Hz	2.8854
2.484907	12.0000	69.613306 Hz	7.1699
3.000000	20.0855	195.027860 Hz	8.6562

Asking the Gabor question of that bridge: if $f = ke^{2F}$ then $\Delta f/f = 2\,\Delta F$, and substituting into the octave-invariant form:

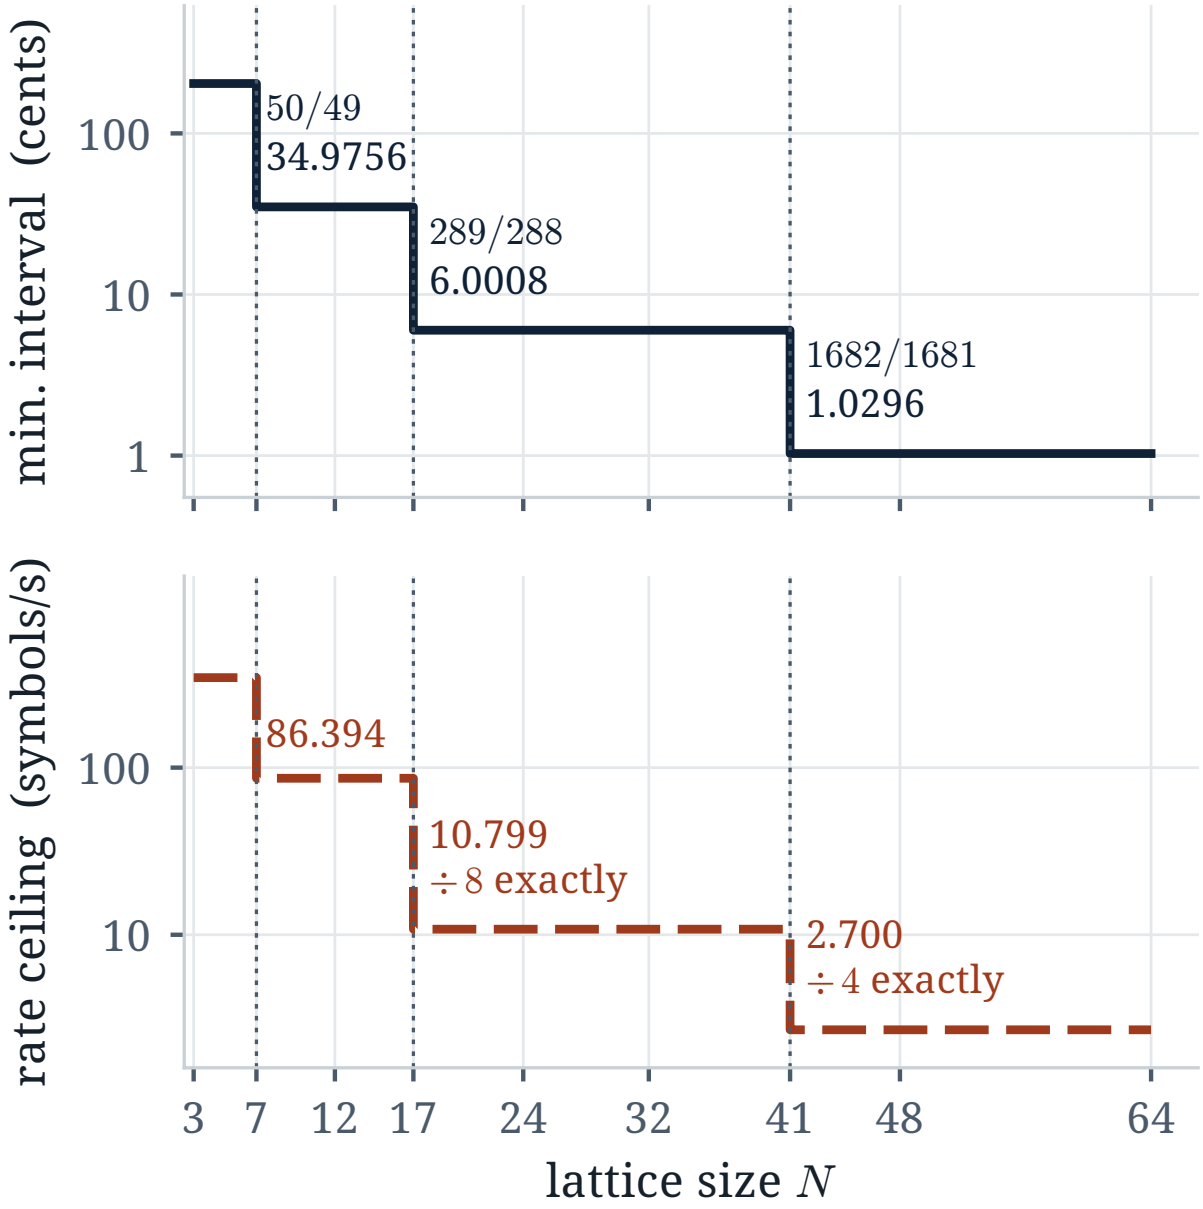

Figure 32.3: **The folded lattice's minimum gap collapses at $N = 17$ and again at $N = 41$, not at the previously published 20 and 48:** upper panel, the minimum adjacent interval in cents by lattice size on the exact-rational schedule — $9/8 = 203.9100$ cents for $N = 3 \dots 6$, $50/49 = 34.9756$ for $7 \dots 16$, $289/288 = 6.0008$ from 17, $1682/1681 = 1.0296$ from 41 [Curzi, 2026]. Lower panel, the render-rate ceiling those gaps imply at a 220 Hz base, falling by exactly 8 at the first cliff and exactly 4 at the second. **The regime boundaries are the exact thresholds, not the sampled table rows** — which is the error the correction above repairs. Every value is exact arithmetic on the square law, not a measurement. Generated by `figs/src/CCP-032_fig03.py`.

```
============================================================
  MINIMUM CYCLES TO RESOLVE A SURPLUS DIFFERENCE dF

      T . f  >=  1 / (8 pi dF)

  Independent of k, independent of the transposition, independent
  of the band.
============================================================
```

Tabulated, with absolute times at a 220 Hz rendering:

dF (nats)	df/f	as cents	min cycles	T_min at 220 Hz
0.5000	1.0000	1200.00	0.080	0.3617 ms
0.1000	0.2000	315.64	0.398	1.8086 ms
0.0500	0.1000	165.00	0.796	3.6172 ms
0.0200	0.0400	67.90	1.989	9.0429 ms
0.0100	0.0200	34.28	3.979	18.0858 ms
0.0050	0.0100	17.23	7.958	36.1716 ms
0.0010	0.0020	3.46	39.789	180.8579 ms

To distinguish two ensembles whose interaction surplus differs by one millinat requires at least 181 milliseconds of tone at A3; a hundredth of a nat takes 18 ms. A hundredth of a nat corresponds, at $N = 12$, to a difference in effective count of about 0.12 members — **so the rendering can distinguish group compositions to about a tenth of a person, given 18 milliseconds to do it in. That is a statement about what the signal contains and is not a claim about anyone's hearing**; whether a listener can extract it is governed by the difference limens of Section 5.9. The logarithmic register in which F is written is itself defensible on grounds that do not require a perceptual story: Peters and Gell-Mann [2016] derives a logarithmic evaluation from multiplicative dynamics with no psychological assumption at all, which is a stronger warrant than Fechner's [Fechner, 1860] for the shape used here.

32.5.13 5.13 The rate law

For a stream rendered back to back at R symbols per second, each symbol occupies $T = 1/R$ seconds, so:

```
========================================
   df_floor  =  R / (4 pi)

   Rendering rate and achievable frequency
   precision are DIRECTLY PROPORTIONAL.
========================================
```

R (symbols/s)	T = 1/R (ms)	df floor (Hz)
1	1000.0000	0.07958
2	500.0000	0.15915
5	200.0000	0.39789
10	100.0000	0.79577
20	50.0000	1.59155
50	20.0000	3.97887
100	10.0000	7.95775
200	5.0000	15.91549
500	2.0000	39.78874
1000	1.0000	79.57747

This table is the design contract. Pick a row. Either the rate or the precision may be had, not both, and no encoding, modulation scheme, processing chain or amount of computation moves the number, because the number is a theorem about the functions themselves.

32.5.14 5.14 Two earlier results in the corpus were Gabor problems

The room. The corpus's acoustic-exclusion analysis computed reverberation times, critical distances and exclusion arithmetic for a hard-surfaced room without naming why those quantities are coupled [Curzi, 2026e]. Standard room acoustics gives a mode's half-power bandwidth as $B = 2.2/T_{60}$ [Sabine, 1922, Beranek, 2004], which is a duration–bandwidth statement: **a mode that rings for a long time is sharp in frequency; a mode that dies quickly is broad.**

T60	modal bandwidth	T to resolve one mode	B ∗ T60	as multiple of 1/(4 pi)
0.30 s	7.3333 Hz	10.8515 ms	2.20	27.65
0.45 s	4.8889 Hz	16.2772 ms	2.20	27.65
0.60 s	3.6667 Hz	21.7029 ms	2.20	27.65
0.90 s	2.4444 Hz	32.5544 ms	2.20	27.65
2.50 s	0.8800 Hz	90.4289 ms	2.20	27.65

The product $BT_{60} = 2.2$ is constant by construction and sits 27.65 times above the Gabor floor — exactly what should happen, since a decaying room mode is an exponentially damped sinusoid and Section 5.2 established that the one-sided exponential is far from the floor. **The room is a Lorentzian resonator, not a Gaussian one, and Lorentzians are inefficient users of the time–frequency plane.** At $T_{60} = 0.45$ s modes are 4.89 Hz wide, and the Schroeder frequency for a 100 m^3 room is $2000\sqrt{0.45/100} = 134.16$ Hz (258.20 Hz for 30 m^3 at $T_{60} = 0.50$ s; 69.28 Hz for 1000 m^3 at $T_{60} = 1.20$ s) [Schroeder, 1965]. **The Schroeder frequency is itself a Gabor statement in disguise: it is the frequency at which modal spacing falls below modal bandwidth**, at which time-domain decay has smeared the frequency-domain structure into a continuum.

The channel. Gabor's 1946 paper contains a second result on which the corpus's channel analysis depends directly [Curzi, 2026x]: **the number of independent degrees of freedom in a signal of bandwidth B occupying duration T is approximately $2BT$.** Each degree of freedom is one cell of the information diagram — one logon.

B (Hz)	T (s)	logons = 2BT	SNR (dB)	C = B log2(1+S/N)	bits/logon
1,000	0.100	200	3	1,583 bit/s	0.7913
1,000	1.000	2,000	10	3,459 bit/s	1.7297
4,000	0.020	160	20	26,630 bit/s	3.3291
4,000	1.000	8,000	30	39,870 bit/s	4.9836
20,000	1.000	40,000	40	265,800 bit/s	6.6439

The two results compose exactly: Gabor counts the cells and Shannon prices them [Gabor, 1946, Shannon, 1948, Shannon and Weaver, 1949]. A channel's capacity is the number of time–frequency cells per second times the bits each can carry, and the cell count has a hard floor set by $1/(4\pi)$.

And the standing constraint bears repeating: there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal [Curzi, 2026y]. The Gabor limit says how many distinguishable symbols could in principle be placed on the wave. **It says nothing about whether anything at the far end can read them.**

32.5.15 5.15 Requirements

REQ-5.1 State the limit as $\Delta t\,\Delta f \geq 1/(4\pi)$ with f in hertz, and state in the same passage that it is classical and contains no quantum content.

REQ-5.2 Never quote a frequency-resolution figure without naming which of the three criteria it is. The multipliers are $4\pi = 12.566$ and $16\pi = 50.265$.

REQ-5.3 Name the envelope for every rendered tone. **Rectangular gating is prohibited: it has no finite spectral second moment.** Gaussian is the reference (1.000 of the floor); Hann is the working default (1.026).

REQ-5.4 For lattice work, use the octave-invariant cycle form $T f_0 \geq 1/(4\pi r)$ rather than absolute milliseconds, and state the required resolution in cents.

REQ-5.5 For a common-transposition lattice, verify the audible-band constraint before choosing N. Integer j admits at most $N = 25$ and only at $j = 6$. Publish j, $f(1)$ and $f(N)$.

REQ-5.6 For a folded lattice, compute the folded set's own minimum gap. The raw spacing does not survive folding and the collapse is discontinuous in N, at $N = 17$ and $N = 41$.

REQ-5.7 Publish the render-rate ceiling with every lattice specification, computed as $R_{\max} = 4\pi \cdot (\text{minimum absolute gap in Hz})$, stating whether the full-gap or half-gap criterion was used.

REQ-5.8 Where a surplus difference is rendered acoustically, use $T f \geq 1/(8\pi\,\Delta F)$ and state the resolution in nats.

REQ-5.9 Restate at every use: the output is an essence frequency and not a physical resonance, and k is a chosen constant and not a measured one.

REQ-5.10 Restate, wherever the limit is used to size a biological channel, that the capacity calculation says what could be carried and nothing about whether a cell can demodulate sequence-specific content [Curzi, 2026y].

REQ-5.11 Every concordance states its column roles and evaluates C1, C2 and C3 explicitly, including failures.

REQ-5.12 Where the relation is invoked at any scale, compute the number. **A Gabor bound with no arithmetic attached is a mood, not a constraint.**

REQ-5.13 No text under this framework may present the Gabor limit as a quantum effect, as evidence for the essence law, or as licence for any claim about mind, belief or physiology.

32.5.16 5.16 Failure modes

FM-5.1 — THE FACTOR OF TWO PI. Writing $\Delta t\,\Delta f \geq 1/2$ with f in hertz. *Signature:* resolution figures wrong by exactly 6.283 or 12.566 — a 1 ms window credited with 12.7 Hz or 500 Hz instead of 79.577 Hz. *Fix:* check the units on the frequency variable first.

FM-5.2 — THE RECTANGULAR GATE. Rendering a tone by switching it on and off. *Signature:* spectral splatter across the band; a measured Δf that keeps rising as the analysis bandwidth is extended (29.60, 41.88, 59.24 Hz and still climbing); audible clicks at symbol boundaries. *Fix:* apply an envelope; Hann costs 2.6 per cent over the floor and converges.

FM-5.3 — WINDOW LENGTH MISTAKEN FOR SPREAD. *Signature:* claimed resolution better than achieved by about $\sqrt{12} = 3.46$ for a rectangular gate. *Fix:* state the convention explicitly, as Section 5.5 does.

FM-5.4 — THE OPTIMISTIC FLOOR. Designing to $1/(4\pi T)$ and implementing with a Hann-windowed FFT. *Signature:* a design that passes on paper by a comfortable margin and fails in the build by roughly fifty times. **The gap between the Gabor floor and a Hann main lobe is $16\pi = 50.265$, and that is the single largest source of optimism in signal design.**

FM-5.5 — THE FOLDING SURPRISE. Assuming a folded lattice inherits the raw spacing. *Fix:* compute the folded set's own minimum gap. For $N = 12$ it is $50/49$ — 34.976 cents, between indices 7 and 5 — and the rate ceiling drops from 583 to 86 symbols per second at 220 Hz.

FM-5.6 — THE $N = 17$ CLIFF. *(Originally titled "the $N = 20$ cliff"; the boundary is corrected in Section 5.11 and the rate figures are unchanged.)* Extending a working 16-element folded lattice by one element and keeping the rate. *Signature:* everything works at $N = 16$ and degrades sharply at 17, and because 17 is rarely a lattice size anyone tests, the collapse is usually first *noticed* at 20 or 24 and wrongly attributed to them. *Fix:* accept the slower rate, raise the base pitch, or stay at $N \leq 16$.

FM-5.7 — THE UNBOUNDED SPEED-UP. Believing faster rendering merely reduces aesthetic quality. *Signature:* "we can always slow it down later." *Fix:* you cannot. **The spectral definition is not present in the fast rendering and cannot be recovered from it.** At 500 symbols per second the floor is 39.8 Hz and any gap below that has been destroyed, permanently, in that recording.

FM-5.8 — THE REPETITION FALLACY. Assuming repetition of a too-short tone recovers pitch precision. *Fix:* each burst independently has the spread of its own duration. Repetition at a fixed interval adds a comb structure at the repetition rate, which is real and useful, **but it does not narrow the spectral envelope of the individual burst**, and if the symbols differ from burst to burst the comb does not even form.

FM-5.9 — THE PHYSICAL-RESONANCE SLIDE. Reading the rendering tables as describing a physical resonance of some material, cell or person. *Signature:* the word "resonance" applied to an essence frequency. *Fix:* **the output is an essence frequency, not a physical resonance.**

FM-5.10 — CAPACITY AS COMMUNICATION. Reading $2BT$ logons and a Shannon capacity as evidence that a biological receiver reads them. *Fix:* capacity is what the channel could carry if something at the far end could demodulate it [Curzi, 2026y].

FM-5.11 — THE QUANTUM IMPORT. Presenting the Gabor limit as an application of quantum mechanics to sound. *Signature:* $\hbar$ appearing anywhere in an acoustic calculation. *Fix:* Sections 4.5 and 5.3 give the same derivation with and without $p = \hbar k$. **The classical case is the parent theorem.**

FM-5.12 — PRECISION THEATRE. Publishing a rendering frequency to six decimal places when the window admits 79 Hz of spread. *Fix:* publish the achievable precision alongside the nominal value. At 2 ms the floor is 39.79 Hz, so the honest statement is 336.9 Hz $\pm$ 39.8 Hz, which is $\pm$ 197 cents. **Three of the six decimals are fiction and the reader should be told which.**

32.6 6 Level three: the badged information-budget analogue

Section 4 stated the famous relation and corrected the famous error. Section 5 stripped the quantum clothing off it and showed that the classical theorem underneath constrains the framework's designs. This section takes the third step, and it is where the author's own proposal enters.

32.6.1 6.1 The proposal, badged

```
================================================================================
  THE AUTHOR'S PROPOSAL -- ANALOGY, NOT IDENTITY. BADGED.

  The uncertainty of a future event has the same STRUCTURE as the uncertainty
  of a quantum observable: it attaches to a CONJUGATE PAIR, and the members of
  the pair cannot be made sharp at the same time. Sharpening one broadens the
  other, and the trade is reciprocal rather than additive.

  STATUS:      ANALOGY. A structural correspondence proposed by the author.
  NOT CLAIMED: that this is Heisenberg's relation, that it follows from quantum
               mechanics, that hbar appears in it, that any experiment supports
               it, or that any quantum result licenses any claim about belief,
```

```
                mind, choice, or the determination of future events.
  DERIVED FROM: Fourier duality and information theory, both classical, both
                checkable, neither requiring the analogy to be true.
================================================================================
```

The badge is carried in every subsection that states the proposal. **This is not modesty: it is the difference between a usable modelling idea and a category error**, and the popular literature making this move without the badge is large and wrong. `RIGOR_STANDARD` §8's third label applies exactly — an analogy is legitimate as motivation and **never as evidence**, and it may never transfer a physical result's authority to a psychological claim.

The conjugate pair proposed is TIMING and SPECIFICATION. Timing is *when* the event occurs, and sharp timing means a narrow window on the calendar. Specification is *what* exactly occurs, and sharp specification means a narrow class of outcomes. **The proposal is that a forecast sharp in timing is broad in specification and vice versa** — "something will change around March" is sharp in timing and useless in specification; "the third-quarter figure will land at 4.12 million" is sharp in specification and, absent a date, useless in timing. **The claim is that this is a structural property of forecasting under a bounded evidence budget rather than a failure of forecasters, and that it is quantifiable.**

32.6.2 6.2 What is genuinely shared

(a) Conjugate-variable structure. In quantum mechanics, position and momentum are conjugate because the two representations of the state are related by a Fourier transform. **In the forecasting case, timing and rate-of-recurrence are Fourier conjugates, and that one is not an analogy at all but a derivation** (Section 6.10). The timing/specification pair (Section 6.9) is conjugate in a different and weaker sense: the two trade under a shared information budget, which is a reciprocal constraint of the same algebraic shape. **The two cases have different warrants and are kept separate.**

(b) No simultaneous sharpness. The product of the two spreads is bounded below in all three quantitative forms, provably, without reference to physics.

(c) The trade is reciprocal, not additive. Halving the timing window doubles the specification breadth rather than adding a constant to it. **That reciprocity is the signature of a Fourier or a log-budget relation and is what makes the analogy structurally apt rather than merely decorative.**

32.6.3 6.3 What is not shared — the list that keeps the badge honest

This list is longer than the previous one and it should be.

```
NOT SHARED: hbar.
    There is no constant of nature in any of the relations below. The bounds are set by
    the evidence budget B (bits), by the belief's own frequency spread, and by the
    system's Lyapunov exponent -- properties of the situation and the forecaster, not
    universal constants. There is nothing to measure once and tabulate.

NOT SHARED: quantization.
    Nothing here comes in discrete lumps. Bits are a continuous currency in these bounds
    (a forecast can carry 3.7 bits). There is no analogue of a quantum of action.

NOT SHARED: non-commuting operators.
    Nothing in this section is an operator on a Hilbert space and nothing fails to
    commute. Robertson's theorem does not apply and is not invoked. The reciprocal
    structure comes from the Fourier transform of a real function and from the
    additivity of logarithms, both elementary.
```

```
NOT SHARED: any experimental result.
    No experiment in physics bears on this section. What empirical support is offered
    comes from forecasting research and from numerical weather prediction, and supports
    the QUANTITATIVE CLAIMS on their own terms -- not the analogy to physics.

NOT SHARED: superposition, interference, entanglement, or collapse.
    A forecast ensemble is a probability distribution. It has no phase, it does not
    interfere, and nothing collapses. Writing it as an "amplitude" (Section 6.10) is a
    MODELLING CHOICE that buys one specific piece of mathematics and is badged as such
    in the sentence that makes it.

NOT SHARED: indeterminism.
    The uncertainty here is EPISTEMIC throughout: it concerns what a bounded observer
    with bounded evidence can say. That is a different kind of uncertainty from the
    quantum one, and conflating the two is the error this section exists to prevent.
```

The epistemic reading is the standard one for probability as a state of knowledge [Jaynes, 1957, 2003], and adopting it is what makes the budget B a property of a forecaster rather than of the world.

32.6.4 6.4 The refusal, stated once and enforced throughout

No claim is made anywhere in this framework that quantum mechanics licenses anything about belief, mind, or future events. Three specific refusals.

REFUSAL 1 — the observer. The measurement problem is genuinely open [Curzi, 2026aa]. **It is not open in the direction of licence.** The consciousness-causes-collapse reading is a minority historical interpretation, and it has a quantitative problem — decoherence — and not merely a philosophical one [Zeh, 1970].

REFUSAL 2 — the future. The Schrödinger equation is deterministic; what is probabilistic is measurement outcome under the Born rule. **Neither fact says anything about whether an organisation ships in March.** The uncertainty in this section is entirely epistemic and arises from bounded evidence and sensitive dependence, both classical.

REFUSAL 3 — the postulate. The framework's conditional postulate holds that belief creates reality *if the belief is grounded in truth*, and its whole content is the conditional: **the channel must exist and be real. Quantum mechanics is not that channel and the postulate does not need it.** The established channels are physiological, behavioural, social and informational [Curzi, 2026,?]. **A postulate reaching for quantum mechanics to supply its channel would be exactly the ungrounded belief its own conditional excludes.** That postulate, where it invokes a loop running from belief through action to outcome and back, inherits the reflection problem of Section 3.5 in full: **it is a modelling position, not an identified empirical result** [Manski, 1993].

32.6.5 6.5 Honesty clauses

1. **The analogy is an analogy, badged in every subsection that uses it.**
2. **The three quantitative results stand on their own and do not depend on the analogy being apt.** If the analogy were withdrawn entirely, Sections 6.9 to 6.11 would be unchanged.
3. **Where a modelling choice is made — most importantly the amplitude convention of Section 6.10 — it is marked as a choice in the sentence that makes it.**
4. **The uncertainty here is epistemic.** It concerns what a bounded observer can say and makes no claim about whether the world is determinate.

5. **No claim is made that any method in this framework improves forecast accuracy.** The section gives bounds on what is achievable, which is a different and more modest thing.
6. **No claim is made about anyone's individual future.**

32.6.6 6.6 The concordance, with column roles stated

This concordance is the most delicate in the paper, because the traditional practices that recorded the structure are also practices whose predictive validity has been tested and found absent. Both facts are reported [Curzi, 2026w].

```
CLAIM: A statement about the future cannot be simultaneously sharp in WHEN and sharp in
       WHAT; the two trade reciprocally under a bounded evidence budget.

(+1) EVIDENCE COLUMN
     (i)   INFORMATION THEORY. Shannon (1948); the counting bound of Section 6.9 is
           elementary and exact: naming a cell in a T-by-S grid to precision (dt, ds)
           costs log2(T/dt) + log2(S/ds) bits, so a budget of B bits forces
           dt * ds >= T*S / 2^B. Derivable in one line, checkable by anyone.
     (ii)  FOURIER DUALITY. Section 6.10's timing/rhythm trade is the Gabor limit of
           Section 5 applied to a rate belief. The mathematics is proved; the modelling
           step that connects it to a forecast is badged.
     (iii) PREDICTABILITY LIMITS. Lorenz, Journal of the Atmospheric Sciences 20 (1963),
           130-141, and Tellus 21 (1969), 289-307; Zhang, Sun, Magnusson, Buizza, Lin,
           Chen and Emanuel, Journal of the Atmospheric Sciences 76 (2019), 1077-1091.
           The logarithmic horizon law of Section 6.11 is standard and quantitative.
     (iv)  FORECAST VERIFICATION. Brier, Monthly Weather Review 78 (1950), 1-3; Murphy's
           decomposition, Journal of Applied Meteorology 12 (1973), 595-600. RESOLUTION
           and RELIABILITY are separately measurable, which makes the trade testable.
     (v)   FORECASTING RESEARCH. The operational finding that matters: a forecast is only
           scorable if it carries BOTH an unambiguous resolution criterion and a
           resolution date. Questions lacking either cannot be scored at all.

(-1) PRECEDENT COLUMN -- CARRIES NO EVIDENCE, AND CARRIES A WARNING
     The divinatory traditions organise themselves around exactly this trade.
     - THE ORB. Traditional astrological practice assigns each aspect an "orb", an
       angular tolerance. A wide orb admits more configurations (broad specification) and
       corresponds to a longer window of claimed influence (broad timing); a tight orb
       narrows both. The practice explicitly trades tolerance against window, and the
       vocabulary for it predates Fourier by centuries.
     - THE ORACLE'S AMBIGUITY. Herodotus (Histories I.53) records the Delphic response to
       Croesus that a great empire would fall -- near-total specification breadth, and a
       documented instance of a tradition trading specification away to buy
       unfalsifiability.
     - THE REFUSAL TO DATE. Several prophetic and rabbinic traditions contain explicit
       prohibitions on calculating dates for foretold events while permitting extensive
       discussion of their character: a structural choice of specification over timing,
       made deliberately and recorded.

(0p) INTEGRATION, AND THE HARD LIMIT
     What the (-1) column establishes: that the trade was noticed, named and worked with
     by people who had no information theory. That is the whole of what it carries.
     What it does NOT establish: THAT ANY OF THESE PRACTICES FORECASTS ANYTHING.
     Astrology has been tested under controlled conditions and failed -- Carlson, "A
     double-blind test of astrology", Nature 318 (1985), 419-425. The practice is cited
     ONLY as precedent for a STRUCTURE and explicitly not as evidence of predictive
```

```
     validity, of which there is none.

BRIDGE CRITERIA:
     C1 structural correspondence   PASS. The orb IS a tolerance-versus-window trade.
     C2 predictive power            FAIL on the (-1) side. The traditions generate no
                                    testable bound, and where their forecasts have been
                                    tested they have failed.
     C3 practical utility           PASS on the (+1) side only.

STATUS: SPECULATIVE AS A BRIDGE. The underlying quantitative results (Sections 6.9-6.11)
are NOT speculative and stand independently. That distinction is the section.
```

32.6.7 6.7 The ensemble, not the verdict

The framework's standing position on the future is that it is an amplitude-weighted ensemble and not a verdict [Curzi, 2026]. **That position requires no physics: it requires a probability distribution and the discipline to keep it.** Take a four-scenario forecast:

```
scenario         weight w      timing (years)
-----------      --------      --------------
no change          0.45             --
mild               0.25            3.0
moderate           0.20            5.0
severe             0.10            8.0
                   ----
                   1.00
```

Computed from that ensemble, **with every entropy below a Shannon entropy in bits** (Section 3.3):

```
P(event occurs at all)                  = 0.5500
conditional mean time, given occurrence = 4.6364 years
conditional sd of time                  = 1.8227 years
ensemble entropy H (Shannon, bits)      = 1.8150
effective scenario count 2^H            = 3.5185
```

The effective scenario count is 3.5185 of a nominal 4, and it is the Hill number of order one — the exponential of a Shannon entropy [Hill, 1973, Jost, 2006, Rényi, 1961]. **It is not the corpus's affine effective count and the two must not be confused** (Section 3.4). That this construction and the corpus's headcount audit are the same operation applied to different objects — an ensemble of futures and an ensemble of people — is exact rather than figurative for the order-one count, because both are exponentials of an entropy.

Now the verdict form. A verdict says "moderate, in five years":

```
ensemble entropy H       = 1.8150 bits
verdict asserted entropy = 0.0000 bits
DISCARDED                = 1.8150 bits
```

The verdict discards 1.8150 bits of structure the ensemble contained. It is not a summary of the ensemble; it is a different and much poorer object. And the inverse question, how much evidence would justify a near-verdict:

```
to reach a maximum scenario probability of 0.90 over four scenarios:
    H_final = 0.6275 bits    evidence required >= 1.1875 bits
```

```
to reach 0.95:
    H_final = 0.3656 bits    evidence required >= 1.4493 bits
to reach 0.99:
    H_final = 0.0966 bits    evidence required >= 1.7183 bits
```

Under two bits of evidence separates an honest four-way ensemble from a 99-per-cent-confident call. That cuts both ways: confident forecasts are cheap to justify when the evidence is real, and a confident forecast with no evidence behind it is a claim to information one does not have.

32.6.8 6.8 The conjugate pair, made precise

Before quantifying, the pair is defined operationally, or the bound is untestable.

```
dt   TIMING SPREAD.
     The width of the forecast's distribution over occurrence time. Units: time.
     Operationalised as the standard deviation of the timing distribution, or as the
     width of a stated credible interval, PROVIDED the choice is stated.

ds   SPECIFICATION SPREAD.
     The size of the outcome class the forecast commits to, measured on a stated
     outcome scale. Units: whatever the outcome scale is (currency, headcount,
     categories, degrees).

T    the TIMING RANGE over which the forecast is defined at all.
S    the SPECIFICATION RANGE -- the full span of outcomes considered possible.
B    the EVIDENCE BUDGET in bits: how much the forecaster's information actually
     reduces uncertainty about the joint (time, outcome) cell.
```

T and S must be stated, and that discipline does most of the work. A forecast with no stated range cannot be scored. The same argument is enforced operationally by forecasting tournaments, which require every question to carry a resolution date and an unambiguous resolution criterion; **a question lacking either cannot be scored, which is the practical face of the theoretical point.**

32.6.9 6.9 First quantitative form — the information-budget bound

This one is not an analogy. It is a counting argument and it is exact. To name a cell in the T-by-S plane to precision $(\Delta t, \Delta s)$, one must distinguish among $(T/\Delta t)(S/\Delta s)$ cells; distinguishing among M equally likely alternatives costs $\log_2 M$ bits [Shannon, 1948, Hartley, 1928, Cover and Thomas, 2006]. So a forecaster whose evidence carries B bits about the joint cell can satisfy $\log_2(T/\Delta t) + \log_2(S/\Delta s) \leq B$, and exponentiating:

```
============================================================
    dt . ds   >=   T . S / 2^B

    THE INFORMATION-BUDGET UNCERTAINTY BOUND.
    Classical. Exact. Derived in two lines from counting.
    No hbar, no operators, no physics.
============================================================
```

The structure is identical in form to the Gabor limit and its content is completely different. Gabor's bound is a constant of mathematics; this bound's right-hand side is a property of the forecaster's situation. The relation is the same one Ashby's law of requisite variety states in

the language of control — **the variety a regulator can absorb is bounded by the variety it can represent** [Ashby, 1956, 1958] — and reading the two together is the cheapest way to see that the bound is bookkeeping rather than physics.

Worked over a ten-year horizon with a hundred distinguishable outcome classes:

```
T = 10 years,  S = 100 classes.

  B bits     dt.ds floor      if ds = 1 class,      if ds = 10 classes,
                              then dt (years)       then dt (years)
  ------     -----------      ----------------      -------------------
    4          62.5000            62.5000                6.2500
    6          15.6250            15.6250                1.5625
    8           3.9062             3.9062                0.3906
   10           0.9766             0.9766                0.0977
   12           0.2441             0.2441                0.0244
   14           0.0610             0.0610                0.0061
   16           0.0153             0.0153                0.0015
```

Read row $B = 10$. Ten bits of genuine evidence about a ten-year, hundred-class question buys either a one-class specification with a one-year timing window or a ten-class specification with a five-week window. **Not both.** The exchange rate is exact: **each additional bit halves the product $\Delta t\,\Delta s$, and each bit spent on timing is a bit not spent on specification.**

The upgrade cost of a common request — moving from "within a year, to within ten classes" to "within a month, to within three classes":

```
bits required for (dt = 1 yr,  ds = 10) =  6.6439
bits required for (dt = 1 mo,  ds =  3) = 11.9658
ADDITIONAL EVIDENCE REQUIRED            =  5.3219 bits
```

Five and a third bits — a factor of forty in the likelihood ratio — separates a vague useful forecast from a sharp useful one. The correct answer to "be more specific about the date" is not "I will try"; it is *that request costs 5.3 bits, and here is what I would need to observe to obtain them.*

The formula-validation gates, run on this bound [Curzi, 2026t]:

```
FVP-1 DIMENSIONS.       dt in time, ds in outcome units, T*S in (time x outcome units),
                        2^B dimensionless. Both sides in (time x outcome). PASS.
FVP-2 SCALE TYPE.       dt and ds require a ratio scale with true zero on each axis.
                        Time has one. Outcome scales often DO NOT -- a categorical
                        outcome space has no metric, and then ds must be a COUNT of
                        classes, not a distance. Stated; the bound is then a counting
                        bound and remains valid. PASS with the restriction stated.
FVP-3 LIMITING CASES.   B -> 0: dt.ds >= T.S, the forecast says nothing beyond the stated
                        range. Correct. B -> infinity: bound -> 0, perfect forecasting
                        permitted by information but not by dynamics (Section 6.11
                        supplies the missing constraint). The two bounds are independent
                        and both bind.
FVP-4 FIXED POINTS.     dt/T = ds/S = 2^(-B/2) is the SYMMETRIC ALLOCATION: spend the
                        budget equally on both axes. It is the natural default when the
                        consumer of the forecast has not said which axis they care about.
FVP-5 IDENTIFIABILITY.  T, S, dt, ds are all directly observable from a published
                        forecast. B is the hard one: it must be estimated from
                        out-of-sample skill, not asserted. PARTIAL.
FVP-6 FALSIFICATION.    A published record of forecasts whose (dt, ds) products sit below
                        T.S/2^B, with B independently estimated from realised skill,
```

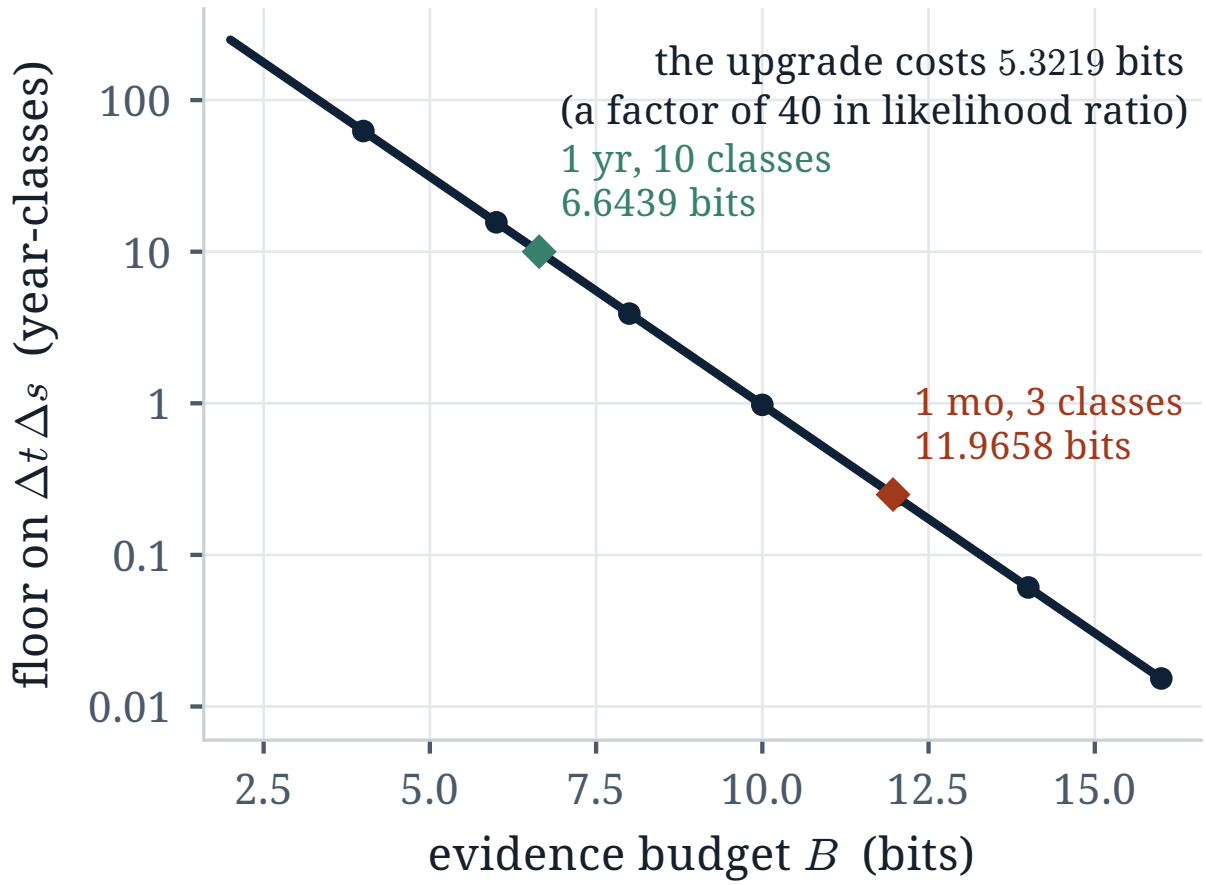

Figure 32.4: **Each additional bit of evidence halves the achievable $\Delta t\,\Delta s$, and the common request for a sharper forecast costs 5.3219 bits:** the information-budget floor $TS/2^{B}$ over a ten-year horizon with a hundred outcome classes, with the two named operating points marked at 6.6439 bits (one year, ten classes) and 11.9658 bits (one month, three classes). Every value is exact $\log_2$ arithmetic on the stated T and S; no evidence budget was estimated from data anywhere in this paper. Generated by `figs/src/CCP-032_fig04.py`.

```
                      refutes it. So does any demonstration of sustained accuracy at a
                      resolution finer than the estimated budget allows.
FVP-7 REPRODUCIBILITY. Requires the same operationalisation of T, S and the outcome scale
                      across forecasters. NOT YET RUN: no forecast record was analysed
                      for this paper.
```

32.6.10 6.10 Second quantitative form — timing against rhythm, which is genuine Fourier

Here the relation to Section 5 is not an analogy but an application, and the one modelling step in it is badged in the sentence that makes it.

Many beliefs about the future concern *recurrence* rather than a date. **A belief about recurrence is a belief about a frequency, and frequency is the Fourier conjugate of time. That conjugacy is exact and requires no analogy.**

THE MODELLING STEP, BADGED AS A CHOICE: to apply the Gabor limit, the belief must be written as an amplitude $a(t)$ whose squared modulus is the probability density, $p(t) = |a(t)|^2$. **Writing a forecast as an amplitude is a modelling choice made here to import one specific theorem. It is not a discovery, it carries no physical content, and a forecast has no phase, does not interfere, and does not collapse.** With that choice made, a and its transform obey the Gabor limit exactly: $\sigma_t \sigma_f \geq 1/(4\pi) = 0.079577471545948$, verified numerically in Section 5.3 to ten significant figures for the Gaussian case.

A belief that pins down a recurrence rate tightly cannot also pin down the next occurrence tightly. Worked: a forecaster holds that a phenomenon recurs with a period between 5 and 7 years and is otherwise uninformative about phase.

```
P in [5, 7] years   ->   f in [0.142857, 0.200000] per year
band width                          0.057143 per year
sigma_f for a uniform belief        0.016495 per year   (width / sqrt(12))

GABOR:  sigma_t  >=  1 / (4 pi * 0.016495)  =  4.824 years
```

A rhythm claim that tight cannot localise the next onset to better than about five years. Widen the rhythm claim and the timing sharpens:

```
period belief          sigma_f (/yr)      timing floor sigma_t
-----------------      -------------      --------------------
P in [5, 7] yr           0.016495              4.824 years
P in [3, 11] yr          0.069985              1.137 years
exact period, no band    0.000000              unbounded
```

Read the last row carefully, because it is the sharpest statement in the section. A belief in an *exactly* periodic process has zero frequency spread, and the bound then places no upper limit on timing spread by this route. **A perfectly sharp rhythm claim carries, by itself, no information at all about when the next instance falls.** It says only that instances are evenly spaced; phase is separate information and must be paid for separately.

The inverse — what a given timing sharpness costs in rhythm:

```
demanded sigma_t     sigma_f floor      as a period band around P = 6 years
----------------     -------------      -----------------------------------
   0.25 years          0.318310 /yr        P = 6 +/- 11.46 yr   (meaningless)
   0.50 years          0.159155 /yr        P = 6 +/-  5.73 yr
   1.00 years          0.079577 /yr        P = 6 +/-  2.87 yr
   2.00 years          0.039789 /yr        P = 6 +/-  1.43 yr
   4.00 years          0.019894 /yr        P = 6 +/-  0.72 yr
  10.00 years          0.007958 /yr        P = 6 +/-  0.29 yr
```

A forecaster who wants the next onset to within six months must surrender essentially all confidence in the cycle length — the implied period band is nearly twelve years wide. Restating the badge, because this is where it matters most: the Gabor limit is a theorem and the numbers above are correct arithmetic given the amplitude convention. The convention itself is a modelling choice, stated as one, and a reader who rejects it should read Sections 6.9 and 6.11 instead, both of which give reciprocal bounds requiring no such convention.

32.6.11 6.11 Third quantitative form — the horizon law

The third bound comes from dynamics rather than information. In a system with sensitive dependence on initial conditions, small errors grow exponentially at a rate set by the largest Lyapunov exponent λ [Strogatz, 2015], so an initial error D_0 reaches an intolerable size D_{tol} after:

```
t_pred  =  (1 / lambda) . ln( D_tol / D_0 )

equivalently, with error-doubling time  t_d = ln 2 / lambda :

t_pred  =  t_d . log2( D_tol / D_0 )
```

The horizon grows only as the logarithm of the improvement in initial knowledge. This is the harshest trade in the section.

doubling time	D_tol/D_0 = 10	= 100	= 1000	= 1e4	= 1e6
1.0 day	3.32 d	6.64 d	9.97 d	13.29 d	19.93 d
1.5 days	4.98 d	9.97 d	14.95 d	19.93 d	29.90 d
2.0 days	6.64 d	13.29 d	19.93 d	26.57 d	39.86 d
3.0 days	9.97 d	19.93 d	29.90 d	39.86 d	59.79 d

At an error-doubling time of 1.5 days — the order of magnitude discussed in the atmospheric predictability literature — halving the initial error buys exactly 1.5 extra days of horizon, and a thousandfold improvement in the initial condition buys 14.95 days. That is the quantitative core of the familiar statement that midlatitude weather has a predictability limit of roughly two weeks; Lorenz (1963, 1969) established the mechanism and Zhang et al. (2019) give a recent quantitative treatment of the limit itself, both named without a key per Section 4.3.

Note what kind of bound this is. Section 6.9's bound says information one does not have cannot be spent. **This one says that even unlimited information about the present buys only logarithmically increasing knowledge of the future, so the two bounds are independent and both bind.** A forecaster can be information-rich and horizon-poor.

And note what it is not. It is a statement about chaotic dynamical systems with a positive Lyapunov exponent, and **not every domain is one.** Applying it without establishing $\lambda > 0$ is failure mode FM-6.6 and is the most common abuse of chaos theory in management writing. Tides are predictable centuries out and planetary ephemerides for millennia. **The horizon law constrains the systems it constrains, and the burden is on the person invoking it** — which is why, in the analogy table of Section 3.2, its use outside a system with a measured exponent is labelled an **analogy** rather than a derivation. The broader literature on the limits of social prediction reaches the same conclusion from the empirical side [Hofman et al., 2017, Watts, 2014, Lazer et al., 2014].

32.6.12 6.12 The trade is measurable, which is what would make it science

A bound that cannot be checked against a record is not a bound. Forecast verification supplies the check and has done since 1950. The Brier score for probabilistic forecasts of binary events

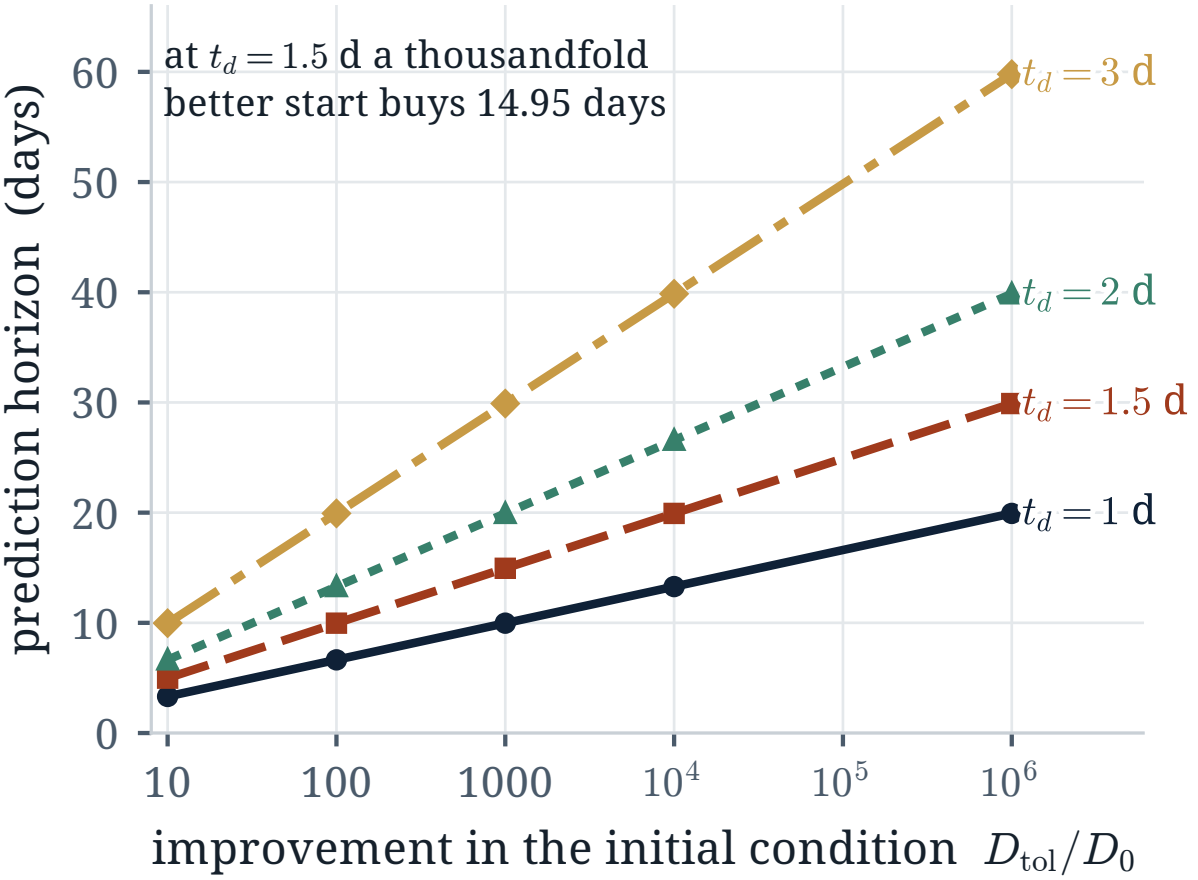

Figure 32.5: **Improving the initial condition a thousandfold buys under fifteen days of horizon:** $t_{\mathrm{pred}} = t_d \log_2(D_{\mathrm{tol}}/D_0)$ for the four error-doubling times of Section 6.11, over error-reduction factors from 10 to 10^6. **Modelled, not measured:** the curves are exact evaluations of the horizon law at assumed doubling times of 1.0, 1.5, 2.0 and 3.0 days, and no Lyapunov exponent was estimated from data for this paper. Generated by `figs/src/CCP-032_fig05.py`.

(Brier, *Monthly Weather Review* 78, 1950, 1–3) is the mean squared error of the probability, $\mathrm{BS} = n^{-1}\sum_i (p_i - o_i)^2$ with $o_i \in \{0, 1\}$; Murphy's decomposition (*Journal of Applied Meteorology* 12, 1973, 595–600) splits it:

```
BS = RELIABILITY − RESOLUTION + UNCERTAINTY

RELIABILITY  how well stated probabilities match observed frequencies. Lower is better.
RESOLUTION   how much the forecasts DISCRIMINATE between cases. Higher is better.
UNCERTAINTY  obar (1 − obar), a property of the events, not of the forecaster.
```

Verified arithmetic on a 100-case record with a base rate of 0.30:

```
uncertainty term  obar(1 − obar)                      = 0.2100

constant forecast p = 0.30 (perfectly calibrated,
                            zero resolution)          BS = 0.2100
constant forecast p = 0.50                            BS = 0.2500
constant forecast p = 0.90                            BS = 0.5700
constant forecast p = 0.00                            BS = 0.3000
perfectly resolved (1 on events, 0 on non-events)     BS = 0.0000
```

The first row is the one that matters. A forecaster who says "30 per cent" to every question is perfectly calibrated, scores exactly the uncertainty of the events, and has contributed nothing. Reliability is free; resolution is what costs evidence. **Murphy's decomposition is therefore the measuring instrument for Section 6.9's bound: resolution is where the bits go.**

This is also the answer to the objection that the timing/specification trade is unfalsifiable. **It is not.** Publish a forecast record with T, S, Δt and Δs stated per forecast, compute the Murphy resolution term, and estimate B from realised out-of-sample skill; the bound then either holds or does not, on the record. **That programme has not been run here and H4 is recorded as NOT TESTED.** Any such record would need the preregistration discipline the corpus applies elsewhere [Curzi, 2026ad, Nosek et al., 2018, Simmons et al., 2011], and would inherit the caution that a published metric of forecaster quality becomes a target and stops measuring what it measured [Goodhart, 1975, Campbell, 1979].

32.6.13 6.13 The three forms compared

This table is the section's honesty in one place.

Form	Bound	Status	What sets the floor
Information budget (6.9)	$\Delta t\,\Delta s \geq TS/2^B$	**derivation**, exact; no analogy needed	the evidence budget B
Timing against rhythm (6.10)	$\sigma_t \sigma_f \geq 1/(4\pi)$	**derivation** from Gabor, with one badged modelling step (the amplitude form)	a constant of mathematics
Horizon law (6.11)	$t_{\text{pred}} = t_d \log_2(D_{\text{tol}}/D_0)$	**derivation**, standard dynamical systems; requires $\lambda > 0$ established	the Lyapunov exponent λ
The analogy to Heisenberg (6.1)	—	**ANALOGY**, badged throughout; **adds no number**	nothing: it is a structural claim, not a quantitative one

Read the last row. The analogy contributes no number to this paper. Every figure above comes from counting, from Fourier, or from dynamical systems. **The analogy contributes a way of seeing — that these are all the same shape of constraint — and a way of seeing is worth exactly what it is worth.**

32.6.14 6.14 The join to the storage law, as a correspondence of form

The evidence budget behaves like headroom. The storage law's headroom form [Curzi, 2026a] is $h_t := \eta \ln N - \delta Q_t - C_t$, with $h_t < 0$ unsustainable, $h_t = 0$ maintenance only, and $h_t > 0$ growth available subject to $r_t \leq h_t$. The forecasting analogue, **badged as a correspondence of model form and not a claim about physics — a shared mathematical form in the sense of Section 3.2, category two, and nothing more:**

```
B     <->   h        the budget available this period
dt.ds <->   Q        what has been built with it
T.S   <->   ln N     the ceiling set by the space itself
```

The operational rule transfers intact: any requested increase in forecast sharpness must satisfy $r \leq B$, where r is the additional bits the request costs. A request for sharper timing and sharper specification simultaneously, with no new evidence, has $r > B$, and **no choice of method, model or expert prevents it from failing.**

Two disclosures attach to this correspondence and neither can be waived. First, it is a claim about model shape; the two systems share an inequality and nothing else, and no property of the storage law transfers to a forecast on the strength of it. Second, **the storage-law parameters themselves are not identified from observational data where the reflexive loop is involved** (Section 3.5), so the correspondence inherits that limitation rather than escaping it [Manski, 1993, Brock and Durlauf, 2001].

32.6.15 6.15 Requirements

REQ-6.1 State the analogy's badge in the sentence that states the analogy, every time.

REQ-6.2 Never present the analogy as a consequence of, or as supported by, quantum mechanics. State the not-shared list at first substantive use.

REQ-6.3 Never use quantum mechanics to support any claim about belief, mind, choice or future events.

REQ-6.4 Every forecast published under this framework states T, S, Δt, Δs and a resolution criterion. A forecast lacking any of these is not scorable and is not a forecast.

REQ-6.5 When a sharper forecast is requested, compute the additional bit cost $r = \log_2(\Delta t_{\text{old}}/\Delta t_{\text{new}}) + \log_2(\Delta s_{\text{old}}/\Delta s_{\text{new}})$ and state it before agreeing.

REQ-6.6 Estimate B from realised out-of-sample skill, never by assertion.

REQ-6.7 Where the amplitude convention is used, mark it as a modelling choice in the sentence that uses it, and state that a forecast has no phase and does not interfere.

REQ-6.8 Before invoking the horizon law, establish that the system has a positive Lyapunov exponent, or state explicitly that it has been assumed.

REQ-6.9 Report forecast records with Murphy's decomposition, not the Brier score alone.

REQ-6.10 Any formula introduced carries its formula-validation table [Curzi, 2026t].

REQ-6.11 Concordances state their column roles and evaluate C1, C2 and C3 explicitly including failures. Where a traditional practice is cited as precedent and has been tested and failed, report the failure in the same passage.

REQ-6.12 Never publish a verdict where an ensemble was computed. Publish the ensemble, its Shannon entropy, and its order-one effective scenario count, naming which effective count it is.

32.6.16 6.16 Failure modes

FM-6.1 — THE UNBADGED IDENTITY. Stating that the uncertainty of the future *is* Heisenberg uncertainty. *Signature:* the word "is" where "resembles in structure" belongs; $\hbar$ in a sentence about a business decision. *Fix:* **the analogy contributes no number. Anything the unbadged version seems to buy is bought on credit that does not exist.**

FM-6.2 — THE QUANTUM LICENCE. Arguing that because quantum mechanics is indeterministic, the future is open in a way that belief can act on. *Signature:* "observation affects outcome, therefore expectation shapes reality." *Fix:* Section 6.4 [Curzi, 2026aa].

FM-6.3 — THE UNSTATED RANGE. Quoting Δt and Δs without T and S. *Fix:* without them the bound cannot be evaluated and the claim cannot be scored.

FM-6.4 — THE ASSERTED BUDGET. Claiming a bit budget rather than estimating it. *Signature:* "our model has a lot of signal." *Fix:* **a budget that has never been measured is a wish, and the whole bound is vacuous without it.** This paper's own H4 is recorded as NOT TESTED for exactly this reason.

FM-6.5 — THE FREE LUNCH. Requesting sharper timing and sharper specification simultaneously without new evidence. *Fix:* compute the bit cost and state it, then say what would have to be observed to obtain it. **This converts an argument into a requirement.**

FM-6.6 — THE CHAOS IMPORT. Invoking the horizon law without establishing sensitive dependence. *Signature:* "butterfly effect" used about an organisation, with no exponent estimated. *Fix:* tides are predictable for centuries.

FM-6.7 — THE CALIBRATION TROPHY. Treating good calibration as good forecasting. *Fix:* the constant forecaster scores exactly the uncertainty of the events and has contributed nothing.

FM-6.8 — THE VERDICT COLLAPSE. Reporting a single scenario where an ensemble was computed. *Fix:* the four-scenario example discards 1.8150 bits when collapsed.

FM-6.9 — THE SHARP RHYTHM ILLUSION. Believing a confident claim about a cycle length is a confident claim about the next occurrence. *Signature:* "it happens every four years, so it will happen in 2030." *Fix:* a perfectly sharp period claim has zero frequency spread and places no bound on timing at all.

FM-6.10 — PRECEDENT AS EVIDENCE. Citing the divinatory traditions' handling of the trade as support for their predictive validity. *Signature:* "astrologers understood this long before information theory, which shows there is something to it." *Fix:* the traditions recorded a structure and forecast nothing; astrology failed a double-blind test (Carlson, *Nature* 318, 1985, 419–425).

FM-6.11 — THE AMPLITUDE SMUGGLE. Writing a forecast as an amplitude and then reasoning about interference between scenarios. *Signature:* scenarios "cancelling" or "reinforcing" in phase. *Fix:* a probability distribution has no phase; two scenarios do not interfere, and their probabilities add.

FM-6.12 — ONE-BOUND BLINDNESS. Satisfying one of the three bounds and concluding the forecast is achievable. *Signature:* "we have enough data" offered against a horizon objection. *Fix:* the bounds are independent and all of them bind.

32.7 7 Results

32.7.1 7.1 R1 — the Gabor limit and its cost schedule

$\Delta t\,\Delta f \geq 1/(4\pi) = 0.079577471545948$, proved by the same variational argument that yields $\sigma_x\sigma_p \geq \hbar/2$, with the substitution $p = \hbar k$ deleted. A Gaussian envelope saturates it to ten significant figures at every width tested (5, 10, 20, 50 and 100 ms). **A Hann window costs 2.6 per cent over the floor; a triangular window 9.6 per cent; and a rectangular gate has no finite spectral second moment at all**, its computed $\Delta t\,\Delta f$ rising through 1.712, 2.420 and 3.422 as the

analysis bandwidth is doubled and redoubled. The three resolution criteria stand in exact ratio: the DFT bin $1/T$ is $4\pi = 12.566$ times the floor and a Hann main lobe $4/T$ is $16\pi = 50.265$ times it.

32.7.2 7.2 R2 — the information-budget bound

$\Delta t\,\Delta s \geq TS/2^B$, exact and classical, derived in two lines from counting. **Each additional bit halves the product**, and each bit spent on timing is a bit not spent on specification. **The upgrade from (one year, ten classes) to (one month, three classes) costs 5.3219 bits**, a factor of forty in the likelihood ratio: 11.9658 bits required against 6.6439 held. The bound passes formula-validation gates 1 to 4 and 6, returns PARTIAL on gate 5 because B must be estimated rather than observed, and returns **NOT YET RUN on gate 7** because no forecast record was analysed here.

32.7.3 7.3 R3 — the badge, and the refusal

The identification of a foreseen future's uncertainty with quantum conjugacy is declared an analogy and badged as such throughout. It is explicitly not claimed to follow from quantum mechanics; no $\hbar$ appears in it; and no quantum result is taken to license any claim about belief, mind or future events. The not-shared list is longer than the shared list and includes $\hbar$, quantisation, non-commuting operators, every experimental result in physics, superposition, interference, entanglement, collapse, and indeterminism. **The refusal is stated as a result rather than as a disclaimer, because it is the load-bearing part of the section it governs.**

32.7.4 7.4 R4 — the horizon law

$t_{\text{pred}} = t_d \log_2(D_{\text{tol}}/D_0)$**: prediction horizon grows only as the logarithm of the improvement in initial knowledge**, which is the harshest of the three trades. At an error-doubling time of 1.5 days, halving the initial error buys exactly 1.5 extra days and a thousandfold improvement buys 14.95 days. **The law binds only where** $\lambda > 0$ **has been established**, and its use elsewhere is an analogy, not a derivation.

32.7.5 7.5 R5 — the lattice at common transposition

At the common transposition $j = 6$ the gap between the first two lattice indices is $3k \cdot 2^6 = 92.81774$ Hz; under the half-gap criterion this gives $T_{\text{min}} = 1.7147$ ms and $R_{\text{max}} = 583.19$ symbols per second. **Folded to one octave at a 220 Hz base the same lattice falls to 86.394 symbols per second at** $N = 12$ **and to 10.799 at** $N = 24$ — factors of 6.8 and 54.0 respectively. The audible-band constraint admits at most **25 lattice elements under a single integer octave transposition, and only at** $j = 6$**.**

32.7.6 7.6 R6 — the folding cliffs, corrected

The thresholds at which the folded lattice's minimum gap collapses are $N = 17$ **and** $N = 41$**, not the previously published** $N = 20$ **and** $N = 48$**.** On exact rational arithmetic the minimum adjacent ratio is $50/49 = 34.9756$ cents for $N \leq 16$, $289/288 = 6.0008$ cents from $N = 17$, and $1682/1681 = 1.0296$ cents from $N = 41$. **The cause is unchanged:** $17^2 = 289$ **folds beside** $288 = 2 \cdot 12^2$**, and index 12 has been present since** $N = 12$**. The previously published values were the next sampled rows of a table, not the thresholds. The rate penalty of exactly 8 across the first cliff and exactly 4 across the second stands unchanged**, and is exact at every base pitch because the two binding pairs straddle $49/32$ and $9/8$ respectively, giving absolute gaps of base$/32$ and base$/256$.

32.7.7 7.7 CR — the counter-result: what this paper takes away

The paper corrects its own previously published lattice cliffs, and it refuses quantum licence outright. The forecast analogy carries no quantum content; it derives entirely from classical Fourier duality and counting; and it is defended only by whether its three quantitative forms measure anything. **Every number in Section 6 survives the deletion of the analogy, and the analogy's numerical contribution is exactly zero.** That is reported here as a result because it is the strongest honest statement available about it: an analogy that adds a way of seeing and no arithmetic is worth having and is worth precisely that.

32.7.8 7.8 Hypotheses, resolved

	Statement	Outcome
H1	the binding constraint on the framework's rendering is classical, not quantum	**confirmed.** Section 4.8 shows the quantum relation negligible by nineteen orders of magnitude at macroscopic scale; Section 5.11 shows the Gabor limit changing a design by a factor of 13.5
H2	the folded lattice's cliffs are discontinuous and the published thresholds are wrong	**confirmed**, and the thresholds are corrected to 17 and 41
H3	the forecasting bound's content is classical counting, not physics	**confirmed.** Every number in Section 6 is reproducible from $\log_2$ arithmetic, a Fourier transform, or a Lyapunov exponent
H4	the evidence budget is estimable in principle	**NOT TESTED.** No forecast record was collected and no B was estimated from data. This is the paper's largest empirical gap

H4 is reported in the same plain language a confirmation would have received. The bound of Section 6.9 is exact arithmetic and it is, as of this paper, **arithmetic without a measurement**.

32.7.9 7.9 Model comparison: what `RIGOR_STANDARD` §6 requires, and what is available

This paper fits no model to any data, so most of the model-comparison requirements are inapplicable rather than unmet. The distinction matters and the row-by-row status is printed rather than omitted.

Requirement	Status here	Why
out-of-sample performance	**NOT APPLICABLE**	nothing is fitted; every number is an exact evaluation of a stated function

Requirement	Status here	Why
matched null with equal free parameters	**NOT APPLICABLE** for the theorems; **NOT MET** for the budget bound	B would need a matched null forecaster, and no forecast record was analysed
information criterion (AIC or BIC)	**NOT MET, and not computed anywhere in this corpus**	no likelihood is fitted here, and no AIC or BIC value appears in any paper of this corpus; the omission is corpus-wide and is recorded rather than papered over
explicit free-parameter count	**MET**	Sections 5 and 6 introduce **zero** free parameters. $1/(4\pi)$ is a constant of mathematics; k is *defined*; T, S, t_d and λ are inputs a user supplies, not parameters this paper estimates
effect sizes with intervals	**NOT APPLICABLE** to the theorems; **NOT MET** for any empirical claim	there is no empirical claim in this paper carrying an effect size
identification of the reflexive parameter	**NOT MET, and not achievable from observation**	[Manski, 1993]; no remedy adopted, Section 3.5
power-law procedure [Clauset et al., 2009]	**NOT RUN, deliberately**	the two exponents in the paper are analytic properties of known functions, not estimates; Section 3.7
conjoint measurement test [Luce and Tukey, 1964]	**NOT RUN**	Section 3.6; the exposed construct is demoted to a count instead

A paper that fits nothing cannot be beaten on fit, and it also earns nothing on fit. The quantitative content here is bounds, and a bound's warrant is its derivation, not its R^2.

32.8 8 Discussion

32.8.1 8.1 What follows

The classical relation, not the quantum one, is what constrains this framework's designs, and it constrains them by factors that change decisions. The worked lattice review of Appendix B moves a design's achievable rate by 13.5 times on the choice of transposition strategy alone, and by a further factor of 23 on the choice of analysis window — a quantity nobody in that review had computed. **That is what a computable limit gives that a slogan does not.**

The framework's own frequency material inherits a hard structural ceiling. At most 25 lattice elements fit the audible band under a single integer octave transposition, and only at $j = 6$. That is arithmetic on the square law rather than taste, and it was invisible until the rendering cost was priced.

A previously published result is corrected in print rather than quietly amended. The folding cliffs move from $N = 20$ and $N = 48$ to $N = 17$ and $N = 41$. The rate figures were correct; the thresholds were not. **Publishing the correction with its cause — that the earlier boundaries were sampled table rows rather than computed thresholds — is worth more than a clean-looking table**, and the corrected values are now the ones the rest of the corpus carries [Curzi, 2026,?,?].

The forecasting bound converts an argument into a requirement. “Be more specific” is a demand; “that costs 2.70 bits, and here is what would supply them” is a specification. The conversion is the practical contribution of Section 6, and it survives every deletion this paper makes to the analogy that motivated it.

32.8.2 8.2 What does not follow

Nothing here supports the essence law. The Gabor limit constrains how a number may be turned into a sound. It says nothing about whether the law generating that number is true, and no reader should take the precision of Section 5’s arithmetic as transferring to the postulate it operates on [Curzi, 2026, Markowsky, 1992].

Nothing here licenses a claim about a biological receiver. The capacity arithmetic says how many distinguishable symbols could in principle ride the wave. **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal**, and the corpus names that gap as its central open problem [Curzi, 2026y,x].

Nothing here licenses a claim about mind or belief from quantum mechanics. That refusal is absolute, is stated in Sections 4.10 and 6.4, and is the reason Section 6 derives its content from counting.

The information-budget bound is not, as it stands, an empirical result. It is exact arithmetic whose right-hand side contains a quantity nobody has estimated in this paper. **A bound with an unestimated parameter constrains nothing until the parameter is estimated**, and saying so is the difference between a specification and a claim.

And the correspondence to the storage law is a correspondence of model shape. It transfers an inequality and nothing else. Where the storage law’s own parameters are entangled with the framework’s reflexive material, they are not identified from observational data by any procedure in this paper [Manski, 1993, Shalizi and Thomas, 2011].

32.8.3 8.3 Relation to the surrounding literature

The paper’s positive results sit inside three established literatures and add to none of them. Gabor’s theorem and its $2BT$ count are seventy-five years old [Gabor, 1946]; the counting bound is Shannon’s, restated [Shannon, 1948]; the horizon law is standard dynamical systems [Strogatz, 2015]. **What is new is the application, the arithmetic, and the discipline of labelling.**

The paper’s methodological position is closer to the critics of physics-in-social-science than to its enthusiasts. Anderson [1972] is the standing argument that a formalism valid at one scale carries no automatic warrant at another; Cartwright [1999] that laws hold in the circumstances that make their premises true and not elsewhere; Mirowski [1989] that economics’ borrowing of physical formalism imported the mathematics and lost the conservation law that gave it content. **The three-way label of Section 3.2 is this paper’s answer to all three, and the answer is procedural rather than rhetorical: state which of the three kinds of borrowing is being made, and let the reader hold the paper to it.** The sociophysics programme’s own reviews make the same demand from the inside [Castellano et al., 2009, Galam, 2012], and the econophysics critique [Gallegati et al., 2006] is the case study in what happens when it is not met.

32.8.4 8.4 Parallel results elsewhere in the corpus

Three results in other series are structurally parallel to this paper’s and are named here because the parallel is the point rather than the decoration.

A bound is only as good as the representation it is evaluated in. Section 6.8’s insistence that T and S be stated before Δt and Δs mean anything has an exact analogue in the corpus’s identifier work: **typed-field parsing collapses the withdrawn-code parsing-ambiguity false-positive share from 88.99 per cent to 0.00 per cent, against a naive detection precision of 11.01**

per cent — a control right one time in nine [Curzi, 2026]. In both cases the quantity being bounded was never the difficulty; the difficulty was that nobody had declared the space it lived in.

A limit that no care inside the channel can close is a structural limit, and the only remedy is to change the structure. That is exactly the shape of Section 5.11's cliff — no envelope, analyser or encoding recovers a gap the folding has destroyed, and the only levers are the base pitch and N. The corpus's channel-separation result is the same shape in a different domain: **in-band architectures admit an impersonation class that no care within the shared channel can close, and out-of-band separation closes it structurally — measured at 0.383 per cent in-band ambiguity against 0.000 per cent out-of-band over 100,000 values** [Curzi, 2026].

And a ceiling is not a promise. Section 5.10's 583.19 symbols per second and Section 6.9's frontier are both upper bounds on constructed inputs, and neither says any system will reach them. The corpus states the same caution about its own architecture: **the 56.62 per cent widening is a ceiling on constructed inputs and not a promise, visibility is explicitly distinguished from pledgeability, and the valuation of non-financial capital is named as unsolved** [Curzi, 2026]. **This paper's bounds are bounded by that caution in the same way: a computable ceiling tells a designer what cannot be exceeded and nothing at all about what will be achieved.**

On forecasting specifically, the modest reading of the literature is the correct one. Predictive accuracy in social systems is low, the ceiling appears structural, and published prediction results have repeatedly failed to survive contact with new data [Hofman et al., 2017, Salganik et al., 2020, Lazer et al., 2014, Watts, 2014]. **The information-budget bound is consistent with that record and explains part of it — a forecaster cannot spend bits they never had — but it does not compete with it, because it has not been estimated against any record.**

32.9 9 Verification

The results compound from nine postulates. Each is atomic, each is checkable on its own, and each carries its status. Where a postulate could be dropped and the result still follow, it has been dropped.

32.9.1 9.1 Dimensional audit

`[1]` denotes a pure number. **Where the source framework fixes no dimension, the audit says the framework is silent rather than assigning one.**

Symbol	Dimension	Unit	Status
σ_x	`[L]`	metre	**derived** from a state; a standard deviation of a probability density
σ_p	`[M L T^{-1}]`	kg m s^{-1}	**derived** from the same state
$\hbar$	`[M L^2 T^{-1}]`	J s	**defined** exactly since the 2019 SI redefinition of h
$\sigma_x\sigma_p$	`[M L^2 T^{-1}]`	J s	balances against $\hbar/2$: **the quantum relation is dimensionally consistent**
Δt	`[T]`	second	**derived**; an rms spread, not a window length

Symbol	Dimension	Unit	Status
Δf	`[T^{-1}]`	hertz (cycles s^{-1})	**derived**; an rms spread in the frequency domain
$\Delta\omega$	`[T^{-1}]`	rad s^{-1}	**derived**; $\Delta\omega = 2\pi\,\Delta f$, and the whole 4π-versus-2 confusion lives in this row
$\Delta t\,\Delta f$	`[1]`	none	**derived** dimensionless; balances against $1/(4\pi)$, which is a pure number
T (window)	`[T]`	second	**chosen** by the design
f_0	`[T^{-1}]`	hertz	**chosen**; the rendering centre frequency
$r = \Delta f / f_0$	`[1]`	none, or cents	**derived** dimensionless
$T f_0$	`[1]`	cycles	**derived**; the octave invariant
n (lattice index)	`[1]`	none	**defined** dimensionless count
k	`[T^{-1}]` **by assertion**	hertz	**the value** $(9/8)^2/\varphi^2 = 0.483425732988414$ **is DEFINED and exact; the attachment of hertz is POSTULATED and is a separate, stronger claim** (P6 below)
$f(n) = kn^2$	`[T^{-1}]`	hertz	**derived** from k, inheriting its badge exactly
F (surplus)	`[1]`	nats	**derived** dimensionless [Curzi, 2026]
$N_{\text{eff}} = 1 + (N-1)u$	`[1]`	headcount	**defined** by the framework; **not a Hill number**
H	`[1]`	bits	**derived**; a **Shannon** entropy, never a thermodynamic one
2^H	`[1]`	count of scenarios	**derived**; the Hill number of order one
B	`[1]`	bits	**estimated in principle, not estimated here**
Δt (timing)	`[T]`	whatever unit T is stated in	**chosen** by the forecast

Symbol	Dimension	Unit	Status
Δs	**the framework is silent**	outcome units, or a count of classes	**undetermined in general.** Where the outcome space is categorical it is a dimensionless count; where numeric it carries the outcome's units. **The source does not fix which, and this paper does not supply the determination**
$T \cdot S$	`[T]` $\times$ outcome units	week-classes, year-classes	**derived**, inheriting Δs's ambiguity
λ	`[T^{-1}]`	s^{-1} or day^{-1}	**measured** where it is measured at all; **assumed** wherever the horizon law is invoked without an estimate
$t_d = \ln 2/\lambda$	`[T]`	days	**derived**
D_0, D_{tol}	arbitrary, but **the same**	error units of the state variable	**the ratio is dimensionless**, which is what the logarithm requires
η (storage law)	`[q]` per nat per period	proxy units per nat per period	**measured**; *not* dimensionless [Curzi, 2026a]
δ	`[1]`	per period	**measured** dimensionless fraction per step

Does the Gabor relation balance? Δt carries `[T]` and Δf carries `[T^{-1}]`, so the product is dimensionless and is compared against the pure number $1/(4\pi)$. **It balances, and it balances only when f is in cycles per second.** In radians per second the right-hand side is $1/2$; the dimensions are the same and the number is not, which is why the units must be stated every time (FM-5.1).

Does the information-budget bound balance? The left side carries `[T]` times outcome units; the right side carries $T \cdot S$ in the same product, divided by 2^B, which is dimensionless because B is in bits. **It balances under either reading of the outcome axis, provided the same reading is used on both sides.** That proviso is the whole content of gate 2 for this formula, and it is where the source framework is silent.

Where the framework has no operational unit, it is said here. The specification spread Δs has no operational unit in the general case. The surplus F and the mixing coefficient u are dimensionless by construction, and the effective count they generate is a headcount only by the framework's own definition, not by measurement. **A dimensionless placeholder is honest; an invented unit would not be.**

32.9.2 9.2 The postulates

P1 — For any square-integrable g with finite second moments in both domains, the integral $\int |atg + g'|^2\, dt$ is non-negative for every real a. *Status:* **ARITHMETIC.** It integrates a squared

modulus.

P2 — Plancherel's theorem: differentiation in time is multiplication by $i\omega$ in frequency, and the L^2 norms agree. *Status:* **CITED**, standard [Oppenheim et al., 1996].

P3 — A real quadratic that is non-negative for every real argument has a non-positive discriminant. *Status:* **ARITHMETIC.**

P4 — $\omega = 2\pi f$. *Status:* **DEFINITION.** It carries no empirical weight and supplies the entire factor between $1/2$ and $1/(4\pi)$.

P5 — $p = \hbar k$ for a quantum state. *Status:* **CITED**, and it is the *only* physical input to the quantum case [Kennard, 1927]. **Deleting it leaves P1 to P4 intact**, which is the paper's central structural claim.

P6 — The essence law $f(n) = kn^2$ with $k = (9/8)^2/\varphi^2 = 0.483425732988414$, expressed in hertz. *Status:* **the value is DEFINITION** — an exact ratio of exact quantities, computable to arbitrary precision, which is what licenses fifteen significant figures — **and the attachment of hertz is POSTULATED**, with no external support of any kind [Curzi, 2026, Markowsky, 1992]. **These are two steps, not one, and the second is much the stronger.**

P7 — Two lattice indices fold to the same pitch class if and only if they have the same odd part. *Status:* **ARITHMETIC**, and the reason an N-element lattice folds to $\lceil N/2 \rceil$ classes [Curzi, 2026].

P8 — Distinguishing among M equally likely alternatives costs $\log_2 M$ bits. *Status:* **CITED**, elementary [Shannon, 1948, Hartley, 1928, Cover and Thomas, 2006].

P9 — In a system with largest Lyapunov exponent $\lambda > 0$, an initial error D_0 grows as $D_0 e^{\lambda t}$ until nonlinear saturation. *Status:* **CITED**, standard [Strogatz, 2015]. **Whether any particular system satisfies $\lambda > 0$ is an empirical question this postulate does not settle**, and no system is shown to satisfy it in this paper.

What is NOT a postulate here. The analogy of Section 6.1 is not a postulate, because nothing is derived from it. It is listed in the chain below with an output of nothing, which is the honest entry.

32.9.3 9.3 The compounding chain

```
P1 + P2 + P3   -> L1   dt . d_omega >= 1/2 for every square-integrable g with
                       finite second moments in both domains.                ARITHMETIC

L1 + P4        -> R1a  dt . df >= 1/(4 pi) = 0.079577471545948.              ARITHMETIC

L1 + P5        -> L2   sigma_x sigma_p >= hbar/2 = 5.272859088231e-35 J s.   CITED (P5)

P1 + P3        -> L3   equality in L1 requires a t g + g' = 0, whose solution
                       is a Gaussian; hence Gaussians and only Gaussians
                       saturate.                                             ARITHMETIC

L3             -> R1b  numerically, a Gaussian returns 0.0795774715 at sd =
                       5, 10, 20, 50 and 100 ms; Hann returns 0.081665
                       (1.026x); triangular 0.087211 (1.096x); rectangular
                       diverges (1.712, 2.420, 3.422 and climbing).          ARITHMETIC

R1a + P4       -> L4   1/T = 4 pi x floor = 12.566x; 4/T = 16 pi x floor
                       = 50.265x.                                            ARITHMETIC

R1a            -> L5   scale invariance: g(t) -> g(t/s) leaves dt.df fixed,
                       so T f0 >= 1/(4 pi r) is octave-invariant.            ARITHMETIC

L5 + P6        -> L6   under common transposition r(n) = (2n+1)/n^2, so the
```

		required cycle count n^2/(4 pi (2n+1)) is independent of j.	ARITHMETIC (given P6)
P6	-> L7	audible-band constraint: k 2^j >= 20 forces j >= 6; k N^2 2^j <= 20000 then forces N <= 25.	ARITHMETIC (given P6)
L6 + L7	-> R5	at j = 6, gap(1->2) = 3k 2^6 = 92.81774 Hz; half-gap criterion gives T_min = 1.7147 ms and R_max = 583.19 symbols/s.	ARITHMETIC (given P6)
P6 + P7	-> L8	the folded set of an N-lattice is {odd part squared, octave-reduced}; its minimum adjacent ratio is 50/49 for N <= 16, 289/288 for 17 <= N <= 40, 1682/1681 for N >= 41.	ARITHMETIC
L8	-> R6	the cliffs are at N = 17 and N = 41, correcting the published 20 and 48; the rate penalty is exactly 8 at the first and exactly 4 at the second, because the binding gaps are base/32, base/256 and base/1024.	ARITHMETIC
R1a + L8	-> L9	at a 220 Hz base the binding gap for N = 12 is 6.875 Hz, giving T_min = 11.5749 ms and R_max = 86.394 symbols/s.	ARITHMETIC
R5 + L9	-> L10	folding costs a factor of 6.8 at N = 12 and 54.0 at N = 24 against common transposition.	ARITHMETIC
P8	-> R2	log2(T/dt) + log2(S/ds) <= B, so dt.ds >= T.S/2^B; each extra bit halves the product.	ARITHMETIC
R2	-> L11	(1 yr, 10 classes) costs 6.6439 bits; (1 mo, 3 classes) costs 11.9658; the difference is 5.3219.	ARITHMETIC
P9	-> R4	t_pred = (1/lambda) ln(D_tol/D_0) = t_d log2(ratio); at t_d = 1.5 d a thousandfold improvement buys 14.95 d.	CITED (P9)
(the analogy)	-> --	NOTHING. The analogy of Section 6.1 appears in no line of this chain and contributes no number.	ANALOGY / no output

Every result in this paper is `ARITHMETIC` except two. R4 consumes P9, a cited standard result of dynamical systems; L2 consumes P5, the one physical input to the quantum case. **R5 and R6 consume P6, whose numerical value is a DEFINITION and whose expression in hertz is POSTULATED** — so the *ratios* and *cents* in R6 stand on arithmetic alone, while the *hertz* and *milliseconds* in R5 inherit the postulate. **A reader who rejects the essence law keeps every cents figure in Section 5.11 and loses every hertz figure in Section 5.10.** That is a clean separation and it is stated so that the reader can make it.

What this chain does not establish. It does not establish that the essence law is true; nothing in it bears on that. It does not establish that any listener can extract what the signal contains. It does not establish that any forecaster's evidence budget is any particular number, because none was estimated. And it establishes nothing whatever about the framework's reflexive claims, which are not identified from observational data by any procedure in this paper [Manski, 1993].

32.9.4 9.4 The verification instance, worked

The single most useful check a reviewer can perform is the constant and the first cliff, because both are four lines of arithmetic and between them they govern every rendering claim in the corpus.

Check one — the floor.

```
4 pi        = 12.566370614359172
1 / (4 pi)  =  0.079577471545948
1 / (2 pi)  =  0.159154943091895      (the angular form's right-hand side is 1/2)
```

Check two — the defined constant. k is defined, so this is exact:

```
(9/8)^2   = 81/64          = 1.265625
phi^2     = phi + 1        = 2.618033988749895
k         = 1.265625 / 2.618033988749895
                           = 0.483425732988414
```

Check three — the common-transposition rate ceiling. At $j = 6$ and $n = 1$:

```
gap(1 -> 2) = k (2n+1) 2^j = 0.483425732988414 x 3 x 64 =  92.81774 Hz
half-gap df                =  92.81774 / 2              =  46.40887 Hz
T_min       = 1 / (4 pi x 46.40887)                     =   1.7147 ms
R_max       = 4 pi x 46.40887                           = 583.19 symbols/s
```

Check four — the first cliff, on exact rationals. Fold 17^2 and $2 \cdot 12^2$ into one octave:

```
17^2 = 289  ->  289/256
12^2 = 144, and 2 x 144 = 288  ->  288/256 = 9/8
ratio       = 289/288
cents       = 1200 x log2(289/288) = 6.0008
previous minimum, 50/49:
cents       = 1200 x log2(50/49)   = 34.9756
```

and the rate penalty, from the absolute gaps at a base pitch b:

```
50/49  pair straddles 49/32  -> gap = b (50 - 49)/32  = b/32
289/288 pair straddles 9/8   -> gap = b (289 - 288)/256 = b/256
ratio of rate ceilings       = (b/32) / (b/256) = 8      EXACTLY
```

Check five — the budget upgrade.

```
log2(10 yr / 1 yr)  + log2(100/10) = 3.321928 + 3.321928 =  6.643856
log2(10 yr / 1 mo)  + log2(100/3)  = 6.906891 + 5.058894 = 11.965785
difference                                                =  5.321928  bits
                                                          = 2^5.321928 = 40.0 in likelihood ratio
```

Five checks, none longer than four lines, and between them they establish the floor, the constant, the rate ceiling, the cliff and the exchange rate. A reviewer who runs them has verified everything this paper contributes that is not quoted from elsewhere.

32.9.5 9.5 Limits, asymptotics, and the domain of validity

$T \to 0$ **in the Gabor limit.** $\Delta f \to \infty$. **The limit is not a pathology but the content of the theorem:** an instantaneous event has no frequency. The domain of the tabulated relation is $T > 0$ with a finite-energy envelope.

$T \to \infty$**.** $\Delta f \to 0$. **Arbitrarily fine frequency resolution is purchasable with arbitrarily long observation, which is why atomic clocks work and why nothing about this bound forbids precision — it forbids *simultaneous* precision.**

Envelope $\to$ **rectangular.** Δf does not converge. **The limit does not exist**, and the correct report is that the quantity is undefined rather than large. This is a real constraint on the model's domain and is the reason REQ-5.3 prohibits rectangular gating.

$n \to \infty$ **in the lattice.** $r(n) = (2n + 1)/n^2 \to 0$ and the required cycle count grows without bound as $n/(8\pi)$. **The deep lattice is unrenderable in the limit, which is a statement about the square law and not about the instrument.**

$N \to \infty$ **in the folded lattice.** The minimum gap tends to zero, since squares become arbitrarily close under octave reduction. **The cliffs are the visible structure of that collapse and there are infinitely many of them**, at every N introducing a new closest pair; 17 and 41 are the first two.

$B \to 0$ **in the budget bound.** $\Delta t\, \Delta s \geq TS$: the forecast says nothing beyond its stated range. **Correct, and the right behaviour.**

$B \to \infty$**.** The bound goes to zero and permits perfect forecasting — **which the horizon law forbids independently.** The two bounds are independent and both bind, and neither subsumes the other. **A model whose limits are unexamined has not been understood, and this is the one limit in the paper where the answer is supplied by a different bound rather than by the model itself.**

$\lambda \to 0$ **in the horizon law.** $t_{\text{pred}} \to \infty$: a non-chaotic system has no error-doubling horizon, which is why tides and ephemerides are predictable for centuries. **The law's domain is** $\lambda > 0$ **and it is silent, not permissive, outside it.**

$\sigma_f \to 0$ **in the rhythm form.** The timing bound goes to infinity, so **a perfectly sharp period claim places no bound on timing at all.** That is the sharpest single statement in Section 6 and it is a limit result.

32.9.6 9.6 Invariance, and how far each claim has been tested

Scale invariance of the Gabor product is exact and algebraic: replacing $g(t)$ by $g(t/s)$ multiplies Δt by s and divides Δf by s. **The transformation group is the one-parameter dilation group of the time axis, the invariant is** Tf_0**, and it is verified numerically at five Gaussian widths spanning a factor of twenty (5 ms to 100 ms), agreeing to ten significant figures at every one. Five widths is not many**, but the claim is a theorem and the numerical check is a consistency test on the implementation rather than evidence for the theorem.

Octave invariance of the lattice cycle count is exact and is verified at the four base pitches 55, 110, 220 and 440 Hz, where the render-rate ceiling doubles at each octave exactly (21.60, 43.20, 86.39, 172.79 symbols per second). **Four octaves tested.** It would break if the folding rule changed the odd-part classes, which it does not.

Transposition invariance of the fractional gap — that $r(n)$ does not depend on j — is algebraic and is verified at $j = 6$, 7 and 8. **Three transpositions.**

Invariance of the budget bound under a change of units on either axis holds because the bound is a statement about ratios: rescaling T and Δt by the same factor leaves $\log_2(T/\Delta t)$ unchanged. **This is exact and untested empirically, because it is definitional.**

No invariance in this paper has been tested on data from any real system, because no data were collected. Every invariance claim above is algebraic, and the numerical checks are checks of the arithmetic.

32.9.7 9.7 Significant figures and their warrant

Following RIGOR_STANDARD §2, each class of number in this paper is quoted at a precision matching its status.

- **Exact by definition, quoted to whatever precision is useful:** $1/(4\pi) = 0.079577471545948$; $4\pi = 12.566370614359172$; $k = 0.483425732988414$; $\varphi^2 = 2.618033988749895$; the folded ratios $9/8$, $50/49$, $289/288$, $1682/1681$ and their cents values; $\log_2$ costs such as 5.321928 bits. **These are exact and are labelled exact wherever they appear at full precision.**
- **Computed from a stated function at stated parameters, and rounded honestly:** the envelope table (0.079577, 0.081665, 0.087211), the render times, the cycle counts, the ensemble entropies. **Ten significant figures on the Gaussian's** 0.0795774715 **is a statement about a numerical agreement with an exact constant, not about a measurement.**
- **Quoted from published physics, carrying that literature's uncertainty and not this paper's:** $\hbar = 1.054571817646 \times 10^{-34}$ J s (exact given the 2019 SI h); the Bohr radius 5.291772×10^{-11} m; -13.605693 eV; the atomic lifetimes and linewidths of Section 4.9. **None of these is measured by this paper.**
- **Measured psychophysical quantities with their own sampling error, restated here without it:** the frequency difference limens of 0.2 to 0.6 per cent in Section 5.9. **The Gabor columns beside them are exact; the limen column is not, and no interval is available for it in the form quoted.** That is a defect of the presentation and is recorded in Limitations.
- **Assumed parameters in an illustrative model, rounded hard:** the error-doubling times of Section 6.11 (1.0, 1.5, 2.0 and 3.0 days) and the scenario weights of Section 6.7. **Nothing in either is measured, and both figures say so in their captions.**

32.9.8 9.8 Analogy discipline, restated at the point of verification

Every borrowing in this paper carries the label assigned in Section 3.2 and no passage upgrades one. The entropies are **Shannon** entropies in bits [Shannon, 1948]; no thermodynamic entropy appears, and the word is never used without the qualifier. The Gabor limit is a theorem about square-integrable functions and its application to a rendered tone is a **derivation** because the premises are satisfied by a finite-energy signal under a smooth envelope. The uncertainty relation is a fact about **state preparation**, not about measurement disturbance, in every passage of Section 4. The variational recovery of the Bohr radius is a **stationarity** condition and **licenses no teleology**. And the extension of conjugate structure to foresight is an **analogy**, badged in every subsection that states it, contributing **no line of the chain in Section 9.3**.

32.10 10 Limitations

L-1. The evidence budget was never estimated, so the paper's second headline result is arithmetic without a measurement. $\Delta t \, \Delta s \geq TS/2^B$ is exact and its right-hand side contains B, which no part of this paper obtains from data. H4 is recorded as NOT TESTED. **Until a forecast record with stated** T**,** S**,** Δt **and** Δs **per forecast is scored and** B **estimated from realised out-of-sample discrimination, the bound constrains nothing empirically.** That is the single largest gap in the paper and it is not repairable by argument.

L-2. Six of the physics and forecasting primary sources are named without citation keys. Robertson (1929), Weyl (1928), Schrödinger (1930), Ozawa (2003), Busch–Lahti–Werner (2013), Arndt et al. (1999), Erhart et al. (2012), Rozema et al. (2012), Lorenz (1963, 1969), Zhang et al. (2019), Brier (1950), Murphy (1973), Carlson (1985), Mandelstam and Tamm (1945) and Wier, Jesteadt and Green (1977) have **no entries in this corpus's bibliography**. Each is named in the text with journal, volume, year and pages, and **no key was invented for any of them.** A reader can locate every one; the corpus's bibliography is nonetheless incomplete on exactly

the literature this paper leans on hardest, and that is a defect of the corpus rather than of the record.

L-3. The corpus's own frequency framework is a postulate and this paper does not test it. Every hertz figure in Section 5.10 and every millisecond figure in Section 5.11 inherits P6, whose value is a definition and whose expression in hertz has **no external support of any kind**. The Gabor arithmetic is exact and the object it operates on is chosen. **A reader who rejects the essence law keeps the cents and loses the hertz**, and the paper is arranged so that the separation is visible.

L-4. The dimension of the specification axis is undetermined and the source is silent. Section 9.1 records this rather than assigning a dimension. Where the outcome space is categorical the bound is a counting bound and is valid; where it is numeric, the quotient $S/\Delta s$ requires a ratio scale that this paper does not establish. **The conjoint-measurement test that would settle whether such an outcome scale is quantitative at all [Luce and Tukey, 1964] has not been run**, and Michell's objection [Michell, 1997] therefore stands unanswered against any numeric reading of that axis.

L-5. No reflexive claim in this paper is identified. The correspondence of Section 6.14 and the postulate referenced in Section 6.4 both sit inside the framework's reflexive material, whose endogenous effect is **not identified from observational data** [Manski, 1993]. **No remedy is adopted** — not randomisation, not instrumentation, not partial-population variation, and not the stipulated-reference-group route [Brock and Durlauf, 2001]. **These are modelling positions, and this paper does not upgrade them.**

L-6. The Lucas critique is conceded and not answered. B is not invariant under the publication of a forecast built with it [Lucas, 1976], and a forecaster's measured discrimination becomes a target once it is used to evaluate them [Goodhart, 1975, Campbell, 1979]. **The paper offers no defence of parameter stability and states the bound as a constraint on a forecaster at a moment.**

L-7. The invariance claims are tested at few points. Scale invariance of the Gabor product is checked at five Gaussian widths, octave invariance at four base pitches, transposition invariance at three values of j. **All three are algebraic identities, so the checks test the implementation and not the claim** — but a reader wanting empirical breadth should know the counts are 5, 4 and 3, and that none of them is on data from a physical instrument.

L-8. The engineering shorthand $\Delta t = T$ is optimistic by construction. The tables treat the whole rendering window as the rms spread, which overstates achievable resolution by up to $\sqrt{12} = 3.46$ for a rectangular gate. **It is retained for consistency with the framework's existing design tables and is stated in the open at Section 5.5**; every tabulated $\Delta f_{\min}$ should be read as a floor computed under a favourable convention.

L-9. The difference limens are quoted without intervals. Section 5.9's 0.2 to 0.6 per cent figures are measured psychophysical quantities from a 1977 study and are reproduced as point values because that is how the source framework carries them. **A measured quantity quoted without an uncertainty is a presentational defect**, and it is recorded here rather than dressed up.

L-10. Nothing here says a listener can hear any of it. Section 5.12's claim that the rendering distinguishes compositions to about a tenth of a member is a statement about the *signal*. **Whether anything at the far end extracts it is a separate question**, and for the biological case there is no established demodulating mechanism at all [Curzi, 2026y].

L-11. No AIC or BIC is reported, here or anywhere in this corpus. Section 7.9 prints the row as NOT MET rather than omitting it. Nothing in this paper is fitted, so no information criterion is computable from it; **the corpus-wide absence is nonetheless a genuine gap and is recorded as one.**

L-12. The three worked reviews in the appendices are constructed cases, not field reports. They are built to exercise the chain and their inputs are stipulated. **No design review, forecast or lattice implementation described in them took place.**

32.11 11 Conclusion

Three reciprocal relations circulate under one name and this paper separates them, at three different levels of warrant, with the arithmetic of each printed.

Result One, the Gabor limit and its cost schedule. $\Delta t\,\Delta f \geq 1/(4\pi) = 0.079577471545948$, **proved by the same variational argument as** $\sigma_x\sigma_p \geq \hbar/2$ **with the substitution** $p = \hbar k$ **deleted — one line, and it is the only line that quantum mechanics contributes.** Gaussians saturate the bound, verified to ten significant figures at five widths from 5 ms to 100 ms; **a Hann window costs 2.6 per cent over the floor, a triangular window 9.6 per cent, and a rectangular gate has no finite spectral second moment at all**, its computed product climbing through 1.712, 2.420 and 3.422 as the analysis bandwidth is extended. The DFT bin $1/T$ sits exactly $4\pi = 12.566$ times above the floor and a Hann main lobe $4/T$ exactly $16\pi = 50.265$ times above it, **and that factor of fifty is the single largest source of optimism in signal design.**

Result Two, the information-budget bound. $\Delta t\,\Delta s \geq TS/2^B$, **exact, classical, and derived in two lines from counting: each additional bit halves the product, and each bit spent on timing is a bit not spent on specification.** Sharpening a forecast from a year and ten classes to a month and three classes costs **5.3219 bits**, a factor of forty in the likelihood ratio. **The bound has never been estimated against a forecast record and is, as of this paper, arithmetic without a measurement.**

Result Three, the badge and the refusal. The identification of a foreseen future's uncertainty with quantum conjugacy is an analogy, badged as one in every subsection that states it. It is not claimed to follow from quantum mechanics; no $\hbar$ appears in it; and no quantum result is taken to license any claim about belief, mind or future events. **The analogy contributes no number to this paper** — every figure in Section 6 comes from counting, from Fourier duality or from dynamical systems, and all of them survive the analogy's deletion.

Result Four, the horizon law. $t_{\text{pred}} = t_d \log_2(D_{\text{tol}}/D_0)$: **prediction horizon grows only as the logarithm of the improvement in initial knowledge**, and at an error-doubling time of 1.5 days a thousandfold improvement in the initial condition buys 14.95 days. **The law binds only where a positive Lyapunov exponent has been established; invoking it elsewhere is an analogy and is named as one.**

Result Five, the lattice ceilings. At the common transposition $j = 6$ the gap between the first two lattice indices is **92.81774 Hz**, giving $T_{\min} = 1.7147$ ms and $R_{\max} = 583.19$ symbols per second under the half-gap criterion. **Folded to one octave at a 220 Hz base the same lattice falls to 86.394 symbols per second at** $N = 12$ **and to 10.799 at** $N = 24$ — 6.8 and 54.0 times slower. **The audible band admits at most 25 lattice elements under a single integer octave transposition, and only at** $j = 6$**.**

Result Six, the corrected cliffs. The folding cliffs are at $N = 17$ **and** $N = 41$**, not the previously published** $N = 20$ **and** $N = 48$**.** On exact rational arithmetic the minimum adjacent interval is $50/49 = 34.9756$ cents up to $N = 16$, $289/288 = 6.0008$ cents from $N = 17$, and $1682/1681 = 1.0296$ cents from $N = 41$. **The cause is that** $17^2 = 289$ **folds beside** $288 = 2 \cdot 12^2$**; the earlier boundaries were the next sampled rows of a table rather than computed thresholds. The rate penalty of exactly 8 across the first cliff — and exactly 4 across the second — stands unchanged.**

And the counter-result, which is what the paper takes away. It corrects its own published figures in print, and it refuses quantum licence outright. The forecast analogy carries no quantum content, derives entirely from classical Fourier duality and counting, and is defended only by whether its three quantitative forms measure anything — of which, at present, **one is exact and unmeasured, one is exact and requires a badged modelling convention, and one requires an exponent nobody has estimated for any system this framework describes. The classical limit is the only uncertainty relation in this work that constrains anything a reader will build; it is a theorem, it is verifiable on an oscilloscope, and in Appendix B it changes a design by a factor of thirteen.**

32.11.1 Declarations

Data and code availability

No external dataset was collected for this paper, and no human subjects were studied. The numerical values reported as computed — the saturation of the Gabor bound by Gaussians of five widths, the divergence of the rectangular window's second moment at three analysis bandwidths, the envelope multiples, the lattice tables, the folded-set minima on exact rational arithmetic, the ensemble entropies and the budget arithmetic — are evaluations of the functions stated beside them, reproducible from the specifications in the text. The physical constants, the Bohr radius, the hydrogen ground-state energy, the atomic lifetimes and linewidths, and the frequency difference limens are **quoted from the published literature named in Sections 4 and 5 and are not measurements of this paper**; several of those sources carry no key in this corpus's bibliography and are named in full in the text, as disclosed at Section 4.3 and Limitation L-2. **The figures are generated by the scripts named in each caption**, and those scripts contain no data beyond the numbers printed in this paper and the functions stated in Sections 5 and 6.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. The essence law on which Sections 5.10 to 5.12 operate is the author's own postulate, and this paper's arithmetic is applied to it by its author; that is a structural conflict which no declaration removes, and it is the reason the postulate's badge is carried in every subsection that uses it and the reason Section 9.3 separates the results that consume it from those that do not.

Author contributions

Single author. Michael Laurence Curzi derived the results, performed the numerical evaluations, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. Section 5.9 discusses published psychophysical measurements of frequency discrimination; those are other investigators' data, quoted, and no listening test was conducted for this paper. Sections 6 and Appendix C describe a forecasting practice as a design and are not a report of any study performed.

Preregistration

This paper reports no preregistered test. The four hypotheses of Section 2 were fixed before the numerical work reported in Sections 5 and 6 was carried out, and are printed in the form in which they were fixed. **H1, H2 and H3 are confirmed by exact arithmetic; H4 is reported as NOT TESTED, because no forecast record was collected and no evidence budget was estimated from data.** The falsification criterion for H2 — that an exact-rational recomputation return the previously published thresholds — was declared before the recomputation was run and did not fire; the recomputation instead moved the thresholds, which is reported as Result Six. The corpus's preregistered test of the storage law against a real system, which **failed** its second

falsification rule, is reported elsewhere [Curzi, 2026ad], and any applied claim resting on this paper inherits that result.

32.12 Appendix A · A rendering proposal reviewed against the four relations

A constructed review case, built to exercise Sections 4 and 5 end to end. No such review took place. The proposal under review reads:

> *Because the uncertainty principle is a quantum effect and the acoustic signal is classical, the only limits on rendering rate are the sample rate and the transducer bandwidth. We can therefore render each tone for 2 ms and step through a 24-element lattice in 48 ms.*

Step 1 — identify which relation is invoked and which is dismissed. The proposal invokes and dismisses "the uncertainty principle" without naming which; **REQ-4.8 violated.** Enumerated:

```
Kennard 1927     sigma_x sigma_p >= hbar/2         QUANTUM. Not relevant. Rightly dismissed.
Robertson 1929   sigma_A sigma_B >= |<[A,B]>|/2    QUANTUM. Not relevant. Rightly dismissed.
Ozawa 2003       error–disturbance                 QUANTUM. Not relevant. Rightly dismissed.
Gabor 1946       dt df >= 1/(4 pi)                 CLASSICAL. BINDING. Wrongly dismissed.
```

Three of the four dismissals are correct and the fourth governs the design. This is FM-4.10 in its natural habitat: the reasoning about quantum mechanics is sound and it led to exactly the wrong engineering conclusion, because the classical case was assumed to be a weaker version of the quantum case rather than its parent.

Step 2 — establish that the classical relation exists and is not quantum. Run Section 4.5's derivation with $p = \hbar k$ deleted; what remains is $\sigma_t \sigma_\omega \geq 1/2$ with ω in radians per second, hence $\sigma_t \sigma_f \geq 1/(4\pi) = 0.079577471545948$. **No $\hbar$, no quantisation, no operators, no measurement.** Confirmed numerically on a Gaussian envelope of standard deviation 50 ms, 262,144 samples at 0.2 ms spacing:

```
sigma_t = 0.05000000 s
sigma_f = 1.59154943 Hz
product = 0.0795774715
1/(4 pi) = 0.0795774715
```

Equality to ten significant figures. The relation is neither approximate nor quantum.

Step 3 — apply it to the proposed 2 ms tone. $\Delta f_{\min} = 1/(4\pi \times 0.002) = 39.78874$ Hz at the absolute floor. A real analysis window does worse: a Hann window of the same duration has main-lobe width $4/T = 2000$ Hz, which is 50.265 times the floor, and the DFT bin spacing $1/T$ is 500 Hz. **The honest achievable resolution at 2 ms is between 40 Hz and 500 Hz depending on the analysis chain, and 39.79 Hz is a bound no processing can beat.**

Step 4 — compare against what the lattice requires. For a 24-element lattice under a common octave transposition, the audible-band constraint forces $j = 6$, giving $k \cdot 2^6 = 30.9392$ Hz at $n = 1$ and 19337.03 Hz at $n = 25$. The tightest absolute spacing is at the bottom:

```
gap(1 -> 2) = k (2*1 + 1) 2^6 = 3 x 0.483425732988414 x 64 = 92.81774 Hz
```

against the 2 ms floor of 39.78874 Hz. **The bottom of the lattice survives — barely, and only with a Gaussian envelope and optimal analysis.** The proposal's own success criterion was that the elements be *told apart*, which requires the spread comfortably below the gap:

```
required df <= gap/2 = 46.4089 Hz
T_min       = 1 / (4 pi * 46.4089) = 1.7147 ms
R_max       = 583.19 symbols per second
```

At 2 ms the design passes the half-gap criterion at the bottom of the lattice with a margin of about 14 per cent. With a Hann-windowed analysis at 50.265 times the floor it fails by more than an order of magnitude.

Step 5 — the findings.

```
FINDING 1 (REQ-4.8, FM-4.10). The dismissal of "the uncertainty principle" is correct for
three of the four relations in circulation and wrong for the fourth. The Gabor limit is
classical, applies to this signal, and is binding.

FINDING 2 (REQ-4.5, REQ-5.3). The relation is saturated only by a Gaussian envelope. Any
real window sits above the floor: Gaussian 1.000x, Hann 1.026x, triangular 1.096x.
Rectangular is disqualified -- its spectral second moment diverges, so it has no finite
sigma_f at all. The specification must name the envelope.

FINDING 3 (REQ-5.12). No magnitude was computed anywhere in the proposal. Compute first.

DISPOSITION: 2 ms per symbol is retained ONLY with a Gaussian or Hann envelope and ONLY
for a common-transposition lattice at j = 6 or above. It is rejected for any folded
(per-value octave) lattice, where Section 5.11 shows the minimum gap collapses to 50/49
= 34.98 cents and the required tone length rises to 11.57 ms at a 220 Hz base -- a factor
of 5.8 slower than proposed.
```

What the case demonstrates. The physics was not wrong: quantum mechanics really is irrelevant to a loudspeaker. **The error was structural — treating the classical Fourier relation as a diluted version of the quantum one rather than as the theorem of which the quantum one is a special case.** A reader who has been shown, with the references, that $\sigma_x \sigma_p \geq \hbar/2$ is a Fourier theorem with $\hbar$ attached will not make the mistake; a reader who has been told the photon-kick story will make it every time, **because the photon-kick story has no classical limit — it is a story about quanta, and if it is believed the relation appears to go away when the quanta do. It does not go away. It was never about the quanta.**

32.13 Appendix B · A twelve-element folded lattice, priced

A constructed design review, built to exercise Section 5. No such implementation exists. The brief:

```
lattice size N          12 elements  (six pitch classes)
rendering               folded to one octave, base A3 = 220 Hz
sequence                the twelve indices in order, then repeat
required                a listener or an analyser must be able to identify which
                        pitch class is sounding at any moment
proposed rate           40 symbols per second (25 ms each)
envelope                unspecified
```

Step 1 — compute the folded set. Odd parts of 1 to 12 are 1, 1, 3, 1, 5, 3, 7, 1, 9, 5, 11, 3, giving classes $\{1, 3, 5, 7, 9, 11\}$ — six, as $\lceil 12/2 \rceil$ requires. Squares folded into $[1, 2)$ and multiplied by the 220 Hz base:

```
class      folded ratio      frequency (Hz)     cents above base
-------    ------------      --------------     ----------------
```

```
 1          1/1            220.0000             0.000
 3          9/8            247.5000           203.910
 9         81/64           278.4375           407.820
 7         49/32           336.8750           737.652
 5         25/16           343.7500           772.627
11        121/64           415.9375          1102.636
```

Every value carries the badge: these are essence frequencies, not physical resonances, and k is a chosen reference constant [Curzi, 2026].

Step 2 — find the binding gap.

```
220.0000 -> 247.5000     27.5000 Hz
247.5000 -> 278.4375     30.9375 Hz
278.4375 -> 336.8750     58.4375 Hz
336.8750 -> 343.7500      6.8750 Hz    <-- BINDING
343.7500 -> 415.9375     72.1875 Hz
```

The binding pair is class 7 at 336.8750 Hz and class 5 at 343.7500 Hz, separated by 6.8750 Hz — the interval $50/49$, 34.976 cents. Every other gap is at least four times larger. A design that hits this pair works; a design that misses it fails on exactly two of twelve symbols, which is the kind of failure that survives casual testing.

Step 3 — the full-gap criterion. $\Delta f \leq 6.8750$ Hz gives $T_{\min} = 11.5749$ ms and $R_{\max} = 86.394$ symbols per second. **The proposed 25 ms passes with a factor of 2.16 in hand.** Provisionally acceptable.

Step 4 — the half-gap criterion, which is what "identify" requires. A spread merely smaller than the gap leaves two adjacent peaks touching. $\Delta f \leq 3.4375$ Hz gives $T_{\min} = 23.1498$ ms and $R_{\max} = 43.197$ symbols per second. **The proposed 25 ms passes by 8 per cent — a thin margin, and it is the margin against the theoretical floor, which no real envelope reaches.**

Step 5 — the envelope factor. The brief left the envelope unspecified; **REQ-5.3 violated.**

```
envelope         multiple of floor     effective df at 25 ms      passes half-gap (3.4375 Hz)?
------------     -----------------     ---------------------      ----------------------------
Gaussian               1.000                3.1831 Hz              YES, by 8%
Hann                   1.026                3.2659 Hz              YES, by 5%
rectangular          unbounded              no finite value        NO -- disqualified outright
```

But the analysis chain was not specified either. **If the receiving end uses a Hann-windowed FFT rather than a matched filter, the practical resolution is the main-lobe width $4/T = 160$ Hz at $T = 25$ ms. 160 Hz against a 6.875 Hz gap: the design fails by a factor of 23 in the analysis chain even though the signal itself is fine.** That is FM-5.4, and it is the most expensive failure in the case because the transmitted signal is correct and the fault is entirely at the receiver.

Step 6 — the corrections.

```
CORRECTION 1 (REQ-5.3). Specify a Hann envelope, 25 ms, 5 ms raised-cosine ramps.

CORRECTION 2 (REQ-5.2). Specify the analysis method. An FFT-based analyser cannot do this
job at 25 ms. Two options:
    (a) matched filtering, or a bank of six narrowband detectors tuned to the six known
        frequencies -- since the six values are KNOWN in advance, detection is far easier
        than blind estimation, and the Gabor floor rather than the FFT lobe applies;
    (b) lengthen the symbol to 232 ms so that 4/T = 17.2 Hz sits below half the 6.875 Hz
        gap -- which drops the rate to 4.3 symbols per second, a factor of nine.

CORRECTION 3 (REQ-5.7). Publish the ceiling with the specification:
```

```
    full-gap  R_max = 86.394 symbols/s
    half-gap  R_max = 43.197 symbols/s
    with FFT analysis at 4/T, R_max = 4.3 symbols/s

CORRECTION 4 (FM-5.12). Publish the frequencies with their achievable precision.
    At 25 ms with a Hann envelope, df = 3.27 Hz.
    class 7 renders as 336.9 Hz +/- 3.3 Hz  = +/- 17 cents
    class 5 renders as 343.8 Hz +/- 3.3 Hz  = +/- 17 cents
    The two 17-cent bands are separated by 35 cents. They do not overlap. They very
    nearly touch.
```

Step 7 — the alternative the arithmetic exposes. The binding constraint is one pair out of fifteen, and nothing about the square law can change that $25/16$ and $49/32$ differ by $50/49$. **But the lattice does not have to be folded.** Under a common transposition at $j = 6$ the same twelve indices run from 30.94 Hz to 4455.25 Hz, the binding gap moves to the bottom pair at 92.82 Hz, and the half-gap criterion gives $\Delta f \leq 46.41$ Hz, $T_{\min} = 1.71$ ms, $R_{\max} = 583.19$ symbols per second. **A factor of 13.5 faster than the folded version at the half-gap criterion, and 135 times faster than the FFT-limited folded version.** The cost is a rendering spanning 7.2 octaves instead of one, which may be unacceptable for the brief. **The trade is now quantitative rather than aesthetic:** folded to one octave at 220 Hz, 43.2 symbols per second and musically coherent; common transposition at $j = 6$, 583.2 symbols per second across 7.2 octaves.

What the case demonstrates. First, the constraint is real and binds on a specific pair — not "somewhere in the design" but on classes 7 and 5, at 336.875 and 343.750 Hz, 6.875 Hz apart, because $50/49$. **Second, it is not where anyone would have looked**: the weakest point was neither the transmitter nor the rate nor the encoding but the analyser's window function, sitting 50.265 times above a floor nobody had computed. **Third, this is the only uncertainty relation in the paper that changed a design.**

32.14 Appendix C · A forecast, priced in bits

A constructed case, built to exercise Section 6. No such forecast was made or scored. A programme director is asked, in March, when the work will ship and what exactly will be in it. The programme has a twelve-month planning horizon and eight recognised scope configurations.

Step 1 — state T and S (REQ-6.4).

```
T = 52 weeks         the planning horizon over which the question is defined
S =  8 classes       the recognised scope configurations
T . S = 416          cells in the (timing, specification) plane
```

Nothing can be evaluated until this is on paper, and FM-6.3 is the default state of the conversation.

Step 2 — the evidence budget (REQ-6.6). Not asserted; **stipulated for this constructed case at six bits**, which would in practice be estimated from a record of prior programmes scored with Murphy's decomposition on ship-quarter and scope-class outcomes. **Six bits is a factor of 64 reduction in the cell space, from 416 candidate cells to an effective 6.5** — a genuinely useful and modest forecaster.

Step 3 — the achievable frontier. $\Delta t \, \Delta s \geq 416/64 = 6.5$ week-classes.

```
  B bits      dt.ds floor      if ds = 1 class -> dt      if dt = 1 week -> ds
  ------      -----------      ---------------------      --------------------
    2          104.00000            104.00 weeks              104.00 classes
    3           52.00000             52.00 weeks               52.00 classes
```

```
 4          26.00000            26.00 weeks            26.00 classes
 5          13.00000            13.00 weeks            13.00 classes
 6           6.50000             6.50 weeks             6.50 classes
 7           3.25000             3.25 weeks             3.25 classes
 8           1.62500             1.62 weeks             1.62 classes
 9           0.81250             0.81 weeks             0.81 classes
10           0.40625             0.41 weeks             0.41 classes
```

At $B = 6$ exactly one of these is honestly available: **Option A**, one scope class within a 6.5-week window; **Option B**, one week with a scope anywhere across 6.5 of the eight classes; or **Option C**, the symmetric allocation $\Delta t/T = \Delta s/S = 2^{-3} = 0.125$, which for these ranges coincides with Option A since $T/S = 6.5$. **Option B is worthless and Option A is what the questioner wanted; the value of the computation is that this was settled by arithmetic rather than by argument.**

Step 4 — price the escalation (REQ-6.5). The request is then for the exact week and the exact scope:

```
bits required for (dt = 1 wk, ds = 1 class) = log2(52) + log2(8) = 5.7004 + 3.0000 = 8.7004
bits currently held                                                              = 6.0000
SHORTFALL                                                                        = 2.7004 bits
```

The request costs 2.70 bits more than the director has — a likelihood-ratio factor of 6.5. FM-6.5 exactly, and now with a price tag instead of a personality conflict. The correct response is not "I will try harder" but a statement of what would supply the missing bits and what each observation is historically worth. **That is a specification, not an excuse, and it converts an argument into a requirement.**

Step 5 — check the horizon bound independently (REQ-6.8). **Honest answer: the horizon law is not shown to apply and is therefore not invoked.** Software delivery is not a chaotic dynamical system in the technical sense and no Lyapunov exponent has been estimated for it; **invoking the butterfly effect here without that estimate would be FM-6.6.** What the programme has is a small number of high-variance dependencies whose resolution dates dominate the outcome — a mixture, not a chaotic flow. **A paper supplying three bounds must also supply the discipline to use only the ones that apply.**

Step 6 — publish the ensemble, not the verdict (REQ-6.12).

```
scenario                weight     ship week (from March 1)
--------------------    ------     ------------------------
mid-tier, on time        0.40              week 28
mid-tier, slipped        0.25              week 36
reduced scope, early     0.20              week 22
full scope, late         0.15              week 44

Shannon entropy H                 = 1.9037 bits
effective scenario count 2^H      = 3.7417   (of a nominal 4)
weighted mean ship week           = 31.20
sd of ship week                   =  7.17 weeks
```

The effective scenario count of 3.7417 is the Hill number of order one — the exponential of a Shannon entropy [Hill, 1973, Jost, 2006] — **and it says the four scenarios are nearly independent, the ensemble carrying almost its full nominal variety. Collapsing this to "week 31, mid-tier" would discard 1.90 bits.** The verdict is a smaller and less honest object wearing the answer's clothes.

Step 7 — the headroom reading, badged as a correspondence of model form and **not** a claim about physics (Section 6.14):

```
ceiling      T.S = 416 cells          <->    ln N, the hard ceiling
budget       B = 6 bits               <->    h, the headroom
requested    r = 2.70 bits            <->    r_t, the requested increment
verdict      r > h                    <->    h_t < 0 for this request
```

“No choice of interaction geometry can prevent order from decreasing” becomes “no choice of method, model, or expert can supply bits that were never observed.” Same inequality, different scope, and a claim about model shape stated as one [Curzi, 2026a].

What the case demonstrates. First, the section’s usable content survives the removal of the analogy entirely — every number came from counting bits, and Heisenberg appears nowhere in it. **Second, the trade is negotiable once it is priced. Third, the discipline of stating T and S does most of the work: the bound is trivial mathematics, and the difficulty was never the algebra but that nobody wrote down the ranges.**

Chapter 33

Quantum Formalism Without Licence: Born-Rule Statistics, Decoherence Timescales in Warm Tissue, and the Casimir Force at Biological Scale

Abstract. This paper states the quantum formalism as established physics and then computes what it forbids. Unitarity, linearity, the Born rule $P(a_n) = |\langle a_n|\psi\rangle|^2$, Gleason's theorem, no-signalling, no-cloning, Bell/CHSH with its quantum bound $2\sqrt{2} = 2.828427$, and Kochen–Specker are given as proved results that bound every interpretation; the measurement problem is conceded to be genuinely open, but open in no direction that licenses influence, since no-signalling holds in every interpretation. The paper advances no postulate of its own there. Decoherence is then computed rather than invoked: with $n = 3.3428 \times 10^{28}$ per cubic metre and a mean thermal speed of 603.6 m s^{-1} at 310 K, the microtubule-scale estimate gives $\tau_{\text{dec}} = 1.98 \times 10^{-17}$ s against a 1 ms neural event, a shortfall of 5.04×10^{13}; even a hypothetical 10^6 protection factor leaves seven orders of magnitude unexplained. Decoherence suppresses off-diagonal terms and provably changes no diagonal element, so it does not solve the measurement problem. The Casimir pressure $\pi^2\hbar c/(240a^4) = 1.300126 \times 10^{-27}/a^4$ Pa is real, is measured to about one per cent, and is negligible where it is usually invoked: on a 7 m room wall the correct high-temperature value gives a total force of 1.996×10^{-23} N. Only the mode-selection principle transfers, and that transfer is badged as a postulate.

Keywords: Born rule; decoherence; no-signalling; Casimir effect; room modes; boundary geometry

Series: B. Engineering the Surplus **Paper:** CCP-033

33.1 1 Introduction

A framework that borrows the vocabulary of one science to describe another owes that science an accounting. This paper is the accounting for the largest borrowing in the Creature Comforts corpus: quantum mechanics. The corpus uses the word *amplitude* for a branch weight, the word *conjugate* for a resolution trade-off, and the word *coherence* for a state that

degrades on contact with its surround. Each of those uses is defensible only if the original is stated correctly and the transfer is priced. **The purpose of this paper is to state the original at full strength and then to compute what it forbids.**

The method is deliberately asymmetric. Section 4 advances no claim of the author's at all: it states the standard formalism, the four main interpretive positions with what each abandons, and the theorems that bound every one of them — no-signalling, no-cloning, Gleason, Bell/CHSH with its quantum bound of 2.828427, and Kochen–Specker. Sections 5 and 6 then compute two numbers that constrain the rest of the corpus rather than supporting it. The first is a decoherence timescale for a warm wet system: with a water number density of `3.3428e28` per cubic metre and a mean thermal speed of 603.6 metres per second at 310 K, a microtubule-scale object has an estimated coherence time of `1.98e-17` seconds against a neural event lasting `1e-3` seconds, **a shortfall of `5.04e13`**. The second is the Casimir pressure at architectural scale: the correct high-temperature value across a seven-metre room is `1.155e-24` pascals, giving a total force of `1.996e-23` newtons over one wall.

Both numbers are hostile to the material that surrounds them, and that is why they are here. A corpus that wanted quantum licence would not compute them. **The results this paper contributes are, with one exception, results about what cannot be claimed**, and the exception — that boundary geometry alone selects field modes at no ongoing cost — is exact for electromagnetic and acoustic modes and is badged as a design heuristic everywhere else.

Three things distinguish this treatment from the general run of writing that connects quantum mechanics to mind. First, the interpretive survey is organised by which of three inconsistent premises each position abandons, so that the map from interpretation to cost is one-to-one and cherry-picking becomes visible. Second, the decoherence estimate is checked against a published experiment before it is used against a proposal, so the reader can see that the estimator lands on the right decade where the answer is known. Third, the Casimir section computes its own most attractive analogy into the ground: the force is `1e-23` newtons at room scale and, at cellular scale with realistic materials, `6.7e7` times smaller than the weight of one bacterium is than the force between two room walls. What survives that computation is a statement about mode selection, not a statement about force.

The framework's conjugate-uncertainty material, which is where the quantum vocabulary enters the corpus, is presupposed here rather than re-derived: it is established, with its explicit refusal that quantum mechanics licenses anything about belief, mind, or future events, in Curzi [2026z]. The corpus's classification of its own claims into established mathematics, established psychology and declared postulates — the discipline this paper applies to a physical literature rather than a psychological one — is set out in Curzi [2026].

Section 2 states the hypotheses. Section 3 states the method, including the analogy-discipline rule that governs every transfer in the paper. Sections 4, 5 and 6 develop the formalism, the decoherence computation and the Casimir computation. Section 7 collects the failure modes as a register. Section 8 works three audits end to end. Sections 9 to 12 discuss what follows, verify the chain, state the limitations and conclude.

33.2 2 Hypotheses

This paper is unusual in the corpus in that most of its content is a report of established physics rather than a claim of its own. The hypotheses below are therefore few, and the section states explicitly which of the paper's assertions are *not* hypotheses and why.

> **H1 — The warm-wet decoherence gap.** In an unrefrigerated, unengineered biological system at 310 K, no charge-displacing degree of freedom maintains phase coherence for a time approaching any functionally relevant neural timescale. **Predicted:** an estimated coherence time of order `1e-17` to `1e-12` seconds for objects between an ion and a neuron soma, against functional timescales of `1e-4` to `1e-1` seconds, so a ratio between `1e9` and `1e16`; and, as the sanity check, an estimate no

larger than a few multiples of the thermal time `hbar/kT = 2.464e−14` s at that temperature. **Falsified by:** a replicated demonstration of functional quantum coherence persisting above `1e−6` seconds in an unrefrigerated, unengineered biological system at 310 K. That threshold is stated in advance and is three orders of magnitude more generous than the `1e−3` seconds any cognitive proposal actually requires.

H2 — Prefactor independence. The conclusion of H1 does not depend on the accuracy of the scattering model used to reach it. **Predicted:** the collision estimate's prefactor uncertainty is worth one to three orders of magnitude, while the shortfall to be closed is nine to sixteen; so conceding the entire prefactor objection leaves the conclusion unchanged. **Falsified by:** a corrected treatment of the same system — same degree of freedom, same environment, same temperature — returning a coherence time more than four orders of magnitude above the collision estimate.

H3 — Populations are untouched. Environment-induced decoherence changes no diagonal element of the reduced density matrix. **Predicted:** for a system coupled to an environment by `|i>|E_0> -> |i>|E_i(t)>`, tracing out the environment multiplies the off-diagonal elements by the environment-state overlap and multiplies the diagonal elements by exactly one, so any experimental readout that is a population — a reaction yield, a branching ratio — is unaffected by the loss of coherence that destroyed the interference. **Falsified by:** a decoherence process, derived from unitary evolution of system plus environment, that alters a population. This is a theorem and its falsifier is an error, not an observation; it is stated here in falsifiable form so that the claim's status is unambiguous.

H4 — Mode selection is exact across fields, not analogical. The relationship between boundary geometry and allowed modes that produces the Casimir force is the same boundary-value problem that produces a room's acoustic modes, with only the wave speed changed. **Predicted:** the lowest allowed mode between two boundaries separated by `L` is `v/(2L)` in both cases, so plates at 100 nm exclude every electromagnetic mode below 6.20 eV and walls at 7.0 m exclude every acoustic mode below 24.50 Hz, by the same formula and with the ratio of answers equal to the ratio of wave speeds, `8.7403e5`. **Falsified by:** a measured room-mode frequency departing from `f(n_x,n_y,n_z) = (c/2)sqrt((n_x/L_x)^2+(n_y/L_y)^2+(n_z/L_z)^2)` by more than the tolerance attributable to boundary compliance and to the finite impedance of real surfaces.

Three assertions in this paper are not hypotheses, and each is labelled where it appears.

The **statement of the quantum formalism in Section 4 is a report, not a claim.** It advances no postulate of the author's. Its correctness is checkable against any graduate text and it is offered so that the corpus's analogies can be audited against the original rather than against a paraphrase of it.

Postulate 6.1 — that boundary geometry alone selects modes at no ongoing cost — is badged as a postulate in the source and remains badged here. It is *exact* for electromagnetic modes between conductors and for acoustic modes in an enclosure, because both are the Helmholtz problem with a Dirichlet or Neumann condition; it is a **design heuristic and nothing stronger** when carried to occupancy, circulation or social structure, and Section 6.11 states the three transfer strengths separately so that the weakest cannot inherit the credibility of the strongest.

The correspondence between exponential decoherence and the storage law's retention term is a claim about model form, not about physics. It is category 2 in the analogy taxonomy of Section 3.3: the same first-order decay governs both, with no claim that the underlying physics applies. No institution decoheres. The storage law itself, with its contraction modulus `1−delta` and its steady state `(eta S − C)/delta`, is established in Curzi [2026a], and it is that paper's result R1 that the correspondence points at.

33.3 3 Method

33.3.1 3.1 What is established, what is postulated, and the separation between them

The paper follows the corpus's three-drawer classification of claims — established mathematics, established empirical result, and declared postulate — with every item assigned to exactly one drawer and every protocol stated to run on the first two while steering by the third [Curzi, 2026]. Applied to a physical rather than a psychological literature the drawers sort as follows.

Drawer one, established and not in dispute. The quantum formalism as a predictive calculus; the Born rule; unitarity and linearity; the bounding theorems of Section 4.9; the density-matrix account of decoherence; the Casimir energy and its measurement. Nothing in this paper questions any of it, and where the paper computes a number from it the computation is arithmetic on a stated formula with stated inputs.

Drawer two, established as contested. The interpretive question — what the formalism describes — is genuinely open, and competent physicists hold materially different positions. The reported long-lived coherences in photosynthetic complexes are real signals whose interpretation is disputed. Both are reported as contested, in the same passage as the claim they qualify.

Drawer three, this paper's own postulates. Exactly one: Postulate 6.1, badged in Section 6.5 and again in Section 6.11 and in the verification chain of Section 10, where its status is `POSTULATED` for the extension beyond acoustics and `DEFINITION` within it.

33.3.2 3.2 The audit protocol

The paper's operative contribution is a gate, applied in Section 8 to three proposals and stated in general form in Section 8.3. A claim that a quantum mechanism operates in a biological system is required to state five fields before it can be evaluated at all: the degree of freedom carrying the coherence, the environment it couples to, an estimated decoherence time with its formula and its inputs, the functional timescale the mechanism must reach, and the ratio of the last two.

The gate is a **canonicalisation** step before a comparison step, and it is the same discipline that a namespace integrity control applies to identifiers: put every submission into one normal form, and the comparison that follows is between like objects rather than between presentations. Curzi [2026] gives the measured version of that discipline in a different domain, where the canonical form `canon(x) = restrict_ASCII(confusable_fold(NFKC(x)))` collapses 495 of 495 manipulated entries onto the clean form and resolves 995 raw byte strings to the true 500 identifiers. The parallel is structural and is claimed as nothing more: a proposal missing one of the five fields is not refuted, it is unevaluable, and the gate returns it rather than judging it.

33.3.3 3.3 Analogy discipline

Every use of a physical result in this paper is labelled as exactly one of three things, at first use, following the corpus's standing rule.

1. **A derivation.** The physical result applies because the system satisfies its premises, and the paper shows that it does. Section 6.6 is the only instance: room acoustics is the same Helmholtz problem as the mode count in the Casimir derivation, with the electromagnetic field replaced by the pressure field and `c` replaced by the speed of sound. Nothing is transferred; the same equation is solved twice.
2. **A shared mathematical form.** The same equation governs both systems, with no claim that the underlying physics applies. Section 5.11's identification of exponential coherence loss with the storage law's retention term is the instance, and it is labelled there.

3. **An analogy.** A suggestive correspondence with no formal warrant, legitimate as motivation and never as evidence. The extension of mode selection to occupancy and circulation is the instance, and it is badged in Section 6.11 and again in Section 11.

The failure mode this taxonomy exists to prevent is a category-2 or category-3 use borrowing the certainty of category 1. Curzi [2026z] states the same discipline for the corpus's conjugate-variable material, where the future-as-conjugate-variable proposal is badged *analogy, not identity*, with an explicit refusal that quantum mechanics licenses anything about belief, mind, or future events. That refusal is the premise this paper supplies the evidence for. The general hazard of importing physical formalism into a non-physical domain is documented at length in the critical literature [Mirowski, 1989, Gallegati et al., 2006, McCauley, 2006], and Cartwright [1999] makes the point that matters most here: physical laws hold in the domains where their premises are satisfied and not beyond them, so the question for any transfer is always which premises the new system actually meets.

33.3.4 3.4 Scaling claims, and why none of them is estimated

Four power laws appear in this paper: the `a^−4` separation dependence of the Casimir pressure, the `a^−3` dependence of the non-retarded van der Waals pressure, and the `a^6 T^9` scaling of the blackbody localisation rate. **Every one of them is a model-derived exponent, not a fitted one.** No distribution was fitted, no tail was estimated, and no exponent in this paper was obtained from data. The distribution-fitting procedure that any *estimated* exponent would require [Clauset et al., 2009] therefore does not apply, and the exponents are quoted as exact consequences of the stated derivations. Section 11 records this as a check that does not apply rather than as one that was passed.

33.3.5 3.5 What this paper does not claim about mind, and the identification problem it inherits

The corpus's reflexive material — the loop in which a group influences its members and the members constitute the group — does not appear in this paper's physics, and no result in Sections 4 to 6 depends on it. It does appear once, indirectly, in Section 5.11, where the exponential form of coherence loss is put alongside the retention term of the storage law. **That correspondence gives the corpus a functional form; it gives the corpus no identification.** Applied to a social system the storage law's applied reading is a linear-in-means specification whose endogenous effect is **not identified from observational data** [Manski, 1993], and network data does not repair it, because influence and selection are generically confounded there [Shalizi and Thomas, 2011, Lyons, 2011]. This paper adopts no remedy, because it applies the law to nothing; it states the constraint so that no reader takes the physical exactness of `rho_01(t) = rho_01(0)exp(−t/tau)` as evidence for the identifiability of anything that shares its shape. The realistic remedy, where a downstream paper needs one, is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001].

A second reflexive hazard applies to the corpus's own use of this paper. The framework asserts that systems change their behaviour when they are modelled and observed [Lucas, 1976], and a set of specifications binding future writing is exactly such an intervention. The specifications in Appendix A are therefore stated as design rules whose effect on practice is unmeasured, not as findings.

33.4 4 The quantum formalism and the theorems that bound every interpretation

This section advances no postulate of the author's. It states an existing formalism and surveys its interpretive landscape, so that the corpus's analogies can be audited against the original.

Its correctness is checkable against any standard text and nothing in it is new.

33.4.1 4.1 The postulates as they are standardly stated

```
P1  STATE.        A physical system is associated with a complex Hilbert space H.
                  A pure state is a unit-norm vector |psi> in H, defined up to global phase.

P2  OBSERVABLES.  A measurable quantity is a self-adjoint operator A on H.
                  Its possible measured values are the eigenvalues of A -- always real.

P3  EVOLUTION.    An isolated system evolves by the Schrodinger equation,
                      i * hbar * d|psi>/dt = H |psi>
                  where H is the Hamiltonian. Equivalently |psi(t)> = U(t)|psi(0)>
                  with U unitary. This evolution is LINEAR and DETERMINISTIC.

P4  MEASUREMENT.  The probability of outcome a_n is |<a_n|psi>|^2  (the Born rule).

P5  COMPOSITION.  The state space of a composite system is the tensor product of the
                  component state spaces. Most states of a composite are not product
                  states; those that are not are entangled.
```

Quantum mechanics as a predictive calculus is the most precisely confirmed theory in the history of measurement. The interpretive question — what the formalism *describes* — is separate, and it is genuinely open. **The two are kept apart at every step below, because conflating them is how a settled calculus gets used to license an unsettled metaphysics.**

The honesty clause this section cannot do without. The measurement problem is genuinely open. It is not open in the direction of licence. Those are two separate statements and both are true. The first is a real admission: there is no consensus on what happens when a measurement produces one outcome rather than another. The second is a hard limit, and it is a limit imposed by theorems. **No-signalling holds in every interpretation. Whatever the resolution turns out to be, it will not be one in which a mind changes a distant statistic, because the statistic is provably unchanged.** An open question is not an open door.

33.4.2 4.2 The state vector, and four things it is not

The state vector `|psi>` is a unit vector in a complex vector space. From it, and only from it, the formalism computes the probability of every possible measurement outcome.

It is not a wave in space. For one particle in three dimensions, `psi(x,y,z)` looks like a field on space and the picture is nearly harmless. For two particles it is a function on six dimensions; for `N` particles, on `3N`. The state of a two-particle system is not two waves in space; it is one function on configuration space. Any intuition built on the claim that matter is a vibration in the room fails at the second particle.

It is not an ordinary probability distribution. Probabilities are non-negative reals that add. Amplitudes are complex numbers that add *before* being squared, which is why they can cancel. Section 4.4 computes this.

It is not a description of ignorance in the classical sense. Kochen–Specker and Bell together rule out the naive reading in which the particle already had all its properties and the experimenter merely had not looked. Some hidden-variable theories survive — de Broglie–Bohm does — but only by being explicitly non-local, which is a real price and Section 4.7 states it.

It is not agreed to be a physical object. Whether `|psi>` is a thing in the world or a representation of an agent's information is exactly the open question. The Pusey–Barrett–Rudolph theorem constrains the epistemic options substantially under an independent-preparation assumption, but it does not close the question and its assumption has been contested. It is a constraint, not a verdict.

33.4.3 4.3 Linearity, and why it is the whole problem

Linearity says that if the apparatus would evolve state A into “pointer reads UP”, and state B into “pointer reads DOWN”, then it evolves the superposition `a|A> + b|B>` into `a|pointer UP> + b|pointer DOWN>`.

It does not evolve it into “pointer reads UP”. **Linear evolution never produces a single outcome from a superposition. That is not a subtlety or a paradox; it is arithmetic, and it is why the measurement problem exists at all.**

The computation, run for this paper:

```
NUMERICAL VERIFICATION OF P3   (free particle, split-step FFT, N=8192, 4000 steps)

    two Gaussian packets, initially separated, moving toward each other

    norm before evolution                          1.00000000000000
    norm after  evolution                          1.00000000000105
    |relative norm change|                         1.05e-15

    max | U(a|psi_1> + b|psi_2>) - (aU|psi_1> + bU|psi_2>) |     1.29e-13

    BOTH AT DOUBLE-PRECISION FLOOR. Unitarity and linearity are exact.
```

Two consequences follow immediately and are worth stating separately because they are so often blurred.

1. **Probability is conserved.** Nothing leaks. There is no term in the equation through which an “energy of intention” could enter or leave, because no such term exists.
2. **Superposition is stable under evolution.** It does not decay on its own. Whatever removes it in practice is not in the Schrodinger equation — which is the subject of Section 5.

Appendix B, audit B1, records separately the evidence for this claim and the historical precedent sometimes offered alongside it, and states that the precedent carries no evidential weight.

33.4.4 4.4 Interference is the entire content

Take two paths with amplitudes `a` and `b`. Classically the probabilities add: `|a|^2 + |b|^2`. Quantum mechanically the amplitudes add first: `|a + b|^2`. The difference is the cross term.

```
    |a + b|^2  =  |a|^2 + |b|^2  +  2 Re(a* b)
                  \_____________/     \________/
                   classical sum    INTERFERENCE TERM
```

Computed with `a = b = 1/sqrt(2)` and a relative phase:

```
  phase (deg)   |a|^2+|b|^2   interference term   |a+b|^2
     0.0           1.0000          +1.0000          2.0000
    45.0           1.0000          +0.7071          1.7071
    90.0           1.0000          +0.0000          1.0000
   120.0           1.0000          -0.5000          0.5000
   135.0           1.0000          -0.7071          0.2929
   180.0           1.0000          -1.0000          0.0000
   270.0           1.0000          -0.0000          1.0000
   360.0           1.0000          +1.0000          2.0000

  average of |a+b|^2 over all phases 0..2pi  =  1.000000   <-- exactly the classical sum
```

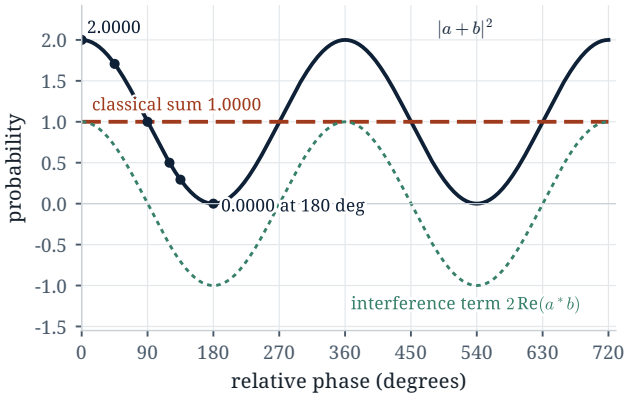

Figure 33.1: **Interference redistributes probability; it does not create any.** The total `|a+b|^2` for two equal amplitudes swings between 2.0000 and 0.0000 as the relative phase runs from 0 to 180 degrees, while the classical sum `|a|^2+|b|^2` stays at 1.0000 throughout; the phase-average of the quantum curve is 1.000000, exactly the classical value. Computed from the phase table of Section 4.4 with `a = b = 1/sqrt(2)`; generated by `figs/src/CCP-033_fig01.py`.

The last line is the most consequential in the section. **Averaging over the relative phase reproduces the classical result exactly. Interference is not extra probability; it is redistributed probability. Destroy the phase relationship and ordinary statistics are recovered with nothing left over.** Section 5 computes what destroys the phase relationship, and how fast.

The wavepacket version, on the same grid as Section 4.3, with two counter-propagating packets allowed to overlap:

```
central overlap region, quantum      : max density 0.05838, min 0.00000, visibility 1.0000
central overlap region, incoherent   : max density 0.02919, min 0.01004, visibility 0.4883
peak |quantum - incoherent|          : 0.02919  (= half the peak density)
total probability, quantum           : 1.0000000000
total probability, incoherent        : 1.0000000000    <-- identical totals

predicted fringe spacing  2*pi/dk    : 6.2832
measured mean fringe spacing         : 6.2174   (grid- and envelope-limited)
```

Perfect visibility, exact zeros between fringes, identical total probability. **The coherent and incoherent cases distribute the same unit of probability differently. That is what a wave function buys and it is all it buys.**

The experimental record on matter interference is deep. De Broglie wavelengths computed here:

```
50 keV electron (relativistic)          lambda = 5.3553 pm
  -> fringes for d = 1 um slits at L = 1 m : spacing 5.36 um
C60 fullerene (720 amu) at 200 m/s      lambda = 2.77 pm
C70 fullerene (840 amu) at 200 m/s      lambda = 2.38 pm
a 25,000 amu molecule at 10 m/s         lambda = 1.60 pm
```

Single-electron double-slit buildup has been recorded directly: electrons arrive one at a time as individual dots and the fringe pattern assembles from the accumulated dots. **That observation contains the entire content of the Born rule as an image — discrete arrivals, continuous distribution.** Molecular interference has been demonstrated for fullerenes and has since been pushed above 25,000 amu.

A note on the citations in this section. The corpus's external bibliography contains no entries for Born, Gleason, Bell, Kochen–Specker, Tonomura, Arndt, Zurek or Tegmark. Those results are named in the text with their year and venue, as the source manuscript states them, and are **not** attached to a bibliography key, because attaching a key that does not support the sentence is worse than leaving it unattached. Section 11 lists the gap, and Appendix C names the works so that a reader can locate them.

33.4.5 4.5 What the formalism does not say

Every line below is a claim the formalism does not make and has never made.

```
NOT SAID 1.  That "the observer" means a conscious being. In the formalism a
             measurement is an interaction with a system having many degrees of
             freedom that records a correlation. A photodiode does it. A speck of
             dust does it. Nothing in P1–P5 mentions awareness.

NOT SAID 2.  That attention, intention, expectation or belief appear in the
             Hamiltonian. There is no such term, and no proposal for one that
             has survived scrutiny.

NOT SAID 3.  That entanglement transmits anything. No-signalling forbids it.

NOT SAID 4.  That the uncertainty relation is about clumsy measurement.
             dx.dp >= hbar/2 = 5.272859e-35 J s is a property of conjugate
             variables, holding for an ensemble of identically prepared systems,
             and it holds before anyone measures anything.

NOT SAID 5.  That quantum indeterminacy scales up to macroscopic indeterminacy.
             Section 5 computes exactly how fast it does not.

NOT SAID 6.  That "everything is connected" in any operationally useful sense.
             Entanglement is a specific, fragile, monogamous resource that must be
             deliberately created and carefully protected. It is not ambient.

NOT SAID 7.  That possibilities not realised are "still available". Which
             unrealised branches exist is exactly the interpretive dispute; no
             interpretation makes them accessible.

NOT SAID 8.  That the wave function is a field of potential that responds to
             desire. There is no coupling; and with no channel there is no effect.
```

The state-preparation reading of NOT SAID 4 is the one the corpus adopts elsewhere: the inequality's original derivation is Kennard [1927], and the corpus's own treatment of conjugate structure — which is Fourier duality and carries no quantum content — badges its extension to foresight as *analogy, not identity* [Curzi, 2026z]. **Every popular quantum claim about manifestation violates at least one of these eight lines, and most violate five.**

33.4.6 4.6 The measurement problem, stated precisely

The problem is a strict inconsistency between three independently plausible statements.

```
(M1)  The wave function is a complete description of a physical system.
(M2)  The wave function always evolves by the linear Schrodinger equation.
(M3)  Measurements have single, definite outcomes.
```

```
These three cannot all be true. Every interpretation is a decision about which
one to give up.
```

The framing is standard, and it makes the interpretation survey trivially organisable, because **the map from interpretation to abandoned premise is one-to-one.**

INTERPRETATION	ABANDONS	WHAT IT COSTS
Copenhagen-type	M2	a second, non-unitary dynamical law with no stated trigger condition
Everett / many-worlds	M3	an unbounded ontology; and the Born rule must be derived rather than assumed
de Broglie–Bohm	M1	explicit non-locality; a preferred frame; difficulty extending to quantum field theory
GRW / CSL	M2	new physical constants, and it is a DIFFERENT THEORY that can be tested

33.4.7 4.7 The four positions, with what each abandons

Copenhagen-type views. Not one doctrine but a cluster. The common core: the formalism predicts outcomes of experiments described in classical terms, and the collapse postulate is a separate, non-unitary update applied when a measurement occurs. *What it buys:* it works, and no experiment has ever required more. *What it costs:* the collapse postulate has no stated trigger; what counts as a measurement is left to judgement, and that gap is the measurement problem. *Status:* the plurality working position among physicists, and the target of the sharpest foundational criticism. Both are true at once.

Everett / many-worlds (Everett 1957, *Reviews of Modern Physics* 29, 454). Take the Schrodinger equation to be the whole story. There is no collapse; linearity produces a superposition of apparatus states and decoherence makes the branches dynamically autonomous. *What it buys:* one law, no second dynamics, no ambiguity about triggers. *What it costs:* an enormous ontology, and a real technical problem — if all branches occur, what does the Born rule mean? Decision-theoretic derivations of the Born weights from rationality axioms have been advanced; **they are serious and they are contested, critics having argued that they assume the measure they claim to derive. The probability problem in Everett must not be presented as solved.** *Status:* a substantial and growing minority position.

De Broglie–Bohm pilot-wave theory (Bohm 1952, *Physical Review* 85, 166 and 180). Particles have definite positions at all times; the wave function is a real field guiding them, with outcomes determined by initial positions distributed as `|psi|^2`. *What it buys:* a clear ontology, no measurement problem, a straightforward double slit — the particle goes through one slit, the wave through both. *What it costs:* manifest non-locality, consistent with no-signalling but uncomfortable with relativity, and extension to relativistic field theory remains unresolved. *Status:* a small, rigorous, continuing programme whose historical importance is decisive — the 1952 papers are an existence proof that the impossibility arguments then circulating against hidden variables were wrong.

GRW and continuous spontaneous localisation (Ghirardi, Rimini and Weber 1986, *Physical Review D* 34, 470). Modify the dynamics: add a stochastic term that spontaneously localises the wave function at a very low rate per particle, negligible for one particle and enormous for `10^23` of them. *What it buys:* definite outcomes come out of the dynamics; no interpretation required. *What it costs:* it is not an interpretation but a **different theory**, with new fundamental constants, hard to reconcile with energy conservation and relativity. *Status:* **its greatest virtue is that it is being experimentally tested and its parameter space narrowed**, including an underground X-ray measurement excluding the simplest parameter-free gravity-related collapse model. A programme that can be excluded by measurement is doing science in the

ordinary way, and this paper says so approvingly. Appendix B, audit B2, records the evidence and the precedent for objective spontaneous indeterminacy separately.

33.4.8 4.8 Consciousness-causes-collapse, stated accurately

The view that a conscious observation collapses the wave function is usually called the von Neumann–Wigner interpretation. It deserves an accurate history.

The chain. Von Neumann (1932) showed that the boundary between quantum system and classical apparatus can be moved arbitrarily far along the measurement chain — system, apparatus, amplifier, retina, optic nerve — without changing any prediction. This is a correct and important result. **What it shows is that the cut is movable. It does not show that the cut must be placed at consciousness, and the argument supplies no reason to put it there.** London and Bauer (1939) took the further step and located the cut at the observer's introspective act; Wigner argued for the position most explicitly in 1961.

Why it is a minority position. Five reasons, in order of weight.

1. **It solves nothing that decoherence does not address better, and it introduces something new.** Once environmental decoherence is accounted for (Section 5), the appearance of classicality is explained without invoking mind. Consciousness-collapse must still posit a novel non-linear coupling for which there is no evidence and no proposed form.
2. **It has no formalism.** No equation, no definition of which physical systems are conscious, no threshold, no rate, no coupling constant. A proposal with no free parameters to constrain cannot be tested, and is therefore not competing on the same field as GRW, which can be and is.
3. **It generates absurdities under iteration.** Extended Wigner's-friend results produce scenarios in which observers using quantum mechanics correctly reach contradictory conclusions about each other. These constrain all interpretations but bear especially hard on views granting observers a special dynamical status.
4. **It has an unacceptable cosmological consequence.** If collapse requires consciousness, the universe had no definite outcomes for roughly 13.8 billion years before observers existed — including the nucleosynthesis whose definite outcomes are now measured.
5. **Wigner himself abandoned it**, in significant part because of the work on environment-induced decoherence begun by Zeh [1970]. **The interpretation's most distinguished advocate stopped advocating it, for the reason developed in Section 5.**

Where it stands. Informal surveys of physicists' foundational attitudes are small and self-selected, and their authors say so; across them, consciousness-causes-collapse consistently attracts a small fraction, well behind Copenhagen-type, information-theoretic and Everettian positions. **The exact statement, and no stronger: it is a minority historical interpretation with few contemporary adherents; it is not refuted, and it is not favoured.** Appendix B, audit B3, records that the evidence column for this claim is **empty**, and prints the empty cell.

33.4.9 4.9 The theorems that bound every interpretation

Whatever the resolution, these constraints already hold, and they are the reason the openness of the measurement problem cannot be traded for licence.

```
NO-SIGNALLING     No local operation changes any distant statistic. Holds in
                  Copenhagen, Everett, Bohm, GRW, and in every theory consistent
                  with the observed correlations.

NO-CLONING        An unknown state cannot be duplicated. Follows from linearity.

BELL / CHSH       |S| <= 2 for local hidden variables; quantum limit 2.828427;
```

```
                  measured violations, loophole-free, 2015; Nobel Prize 2022.
                  Locality-with-definite-values is excluded, not "realism" as
                  such -- the popular gloss that physics disproved reality is wrong.

KOCHEN-SPECKER    No global non-contextual value assignment in dimension >= 3.

PBR (2012)        Under an independence assumption on preparations, purely
                  epistemic states are excluded. A constraint, contested.

GLEASON (1957)    The Born rule is forced, given the Hilbert-space structure
                  and additivity, for dimension >= 3.
```

The quantum bound `2 sqrt(2) = 2.828427` is attained exactly at the optimal measurement settings, and the arithmetic is checked in Section 10.3. **The honest summary: quantum mechanics has narrowed the space of possible worldviews substantially, and every direction in which it has narrowed that space removes options rather than adding them.** Bell did not open a door to influence at a distance; it closed the door on local pre-existing values while leaving no-signalling untouched.

That these constraints are load-bearing engineering rather than philosophy is visible in quantum information, where the impossibility of cloning is what makes key distribution work and the fragility of coherence is what makes the algorithms hard to run [Shor, 1997, Grover, 1996].

33.4.10 4.10 The corpus's branch-weight construct, and the connection that is honest

The corpus's fourth foundational construct asks the analyst to hold the future as a weighted set of branches and to read the weights without preference; its formal content is the comfort-weighted amplitude, in which each step is scored 0–3 for steepness, the scores are summed to a resistance `R`, and the branch is weighted as `1/2^R`, so that a three-point difference in steepness is a factor of eight in expectation [Curzi, 2026]. The relationship to quantum mechanics is stated here deliberately deflationarily.

What is shared. A formal shape: a set of mutually exclusive outcomes, each carrying a weight, the weights summing to one, with a discipline of not collapsing the set prematurely into a single expectation. **That shape is called a probability distribution. It is older than quantum mechanics, it is used everywhere, and it requires nothing from physics.**

What is not shared. Everything that makes quantum mechanics quantum: complex amplitudes, interference between branches, `hbar`, non-commuting observables, entanglement, the measurement problem. The corpus's branches do not interfere. There is no cross term. Two futures that cancel is not a thing the construct describes and not a thing this corpus claims.

Why the deflation is a gain. A probability distribution over futures is testable in the ordinary way. The corpus's preregistration protocol applies directly — state the branch set in advance, assign the weights in advance, freeze the model, and score the held-out outcome against declared baselines — and that protocol, together with the one confirmatory application of it so far reported, is Curzi [2026i], whose fit **failed** its own second falsification rule with a 2.8 per cent held-out advantage over a matched AR(1) against a declared 10 per cent margin. **A quantum dressing would add nothing to that procedure and would subtract its testability, because nobody can score a claim about wave-function branches.**

The corpus's own measure of a branch set is already available. For a two-branch future with weights `p` and `1-p`:

```
p        H (nats)    H (bits)    N_eff = e^H
0.50     0.693147    1.000000    2.0000       maximum spread; two live futures
0.25     0.562335    0.811278    1.7548
```

```
0.10     0.325083    0.468996    1.3841
0.01     0.056002    0.080793    1.0576       effectively one future
```

`N_eff = exp(H)` here is the Hill number of order one, a fully grounded effective count [Hill, 1973, Jost, 2006], and the entropy is Shannon's, reported in nats [Shannon, 1948, Cover and Thomas, 2006]. It is **not** the corpus's affine effective count `1 + (N−1)u`, which is a linear interpolation of the framework's own construction and is not a Hill number of any order; the two must not be run under one name. A future held as a weighted ensemble has an effective number of futures in it, it is computable, and there is no `hbar` anywhere in the table. Appendix B, audit B4, records the evidence and the precedent for weighted-branch forecasting separately.

33.4.11 4.11 Why the borrowing happens

Quantum mechanics supplies four words that already exist in ordinary English with different meanings: *observer*, *measurement*, *uncertainty*, *possibility*. In the formalism each is a technical term; in ordinary use each carries a mentalistic connotation. **The borrowing is a sustained equivocation on four words, and it survives because the technical meanings sit behind a mathematical barrier most readers cannot cross.**

The counter is not to police vocabulary. It is to demand the coupling. The corpus's channel requirement has the form `belief -> [channel] -> world`, and *grounded in truth* means the channel exists and is real. **Ask for the term in the Hamiltonian. There is not one. That ends the argument without anyone having to settle a metaphysical question.** The requirement is the operational content of the corpus's grounding postulate `E = G B`, whose forbidding clause `G = 0` implies `E = 0` for every value of `B` [Curzi, 2026ab] — a postulate, badged as one there and treated as one here.

33.5 5 Decoherence in warm wet systems, computed

This section states the strongest scientific objection to the corpus's biological material and computes it. The objection is that environmental decoherence destroys phase coherence in a warm wet system on a timescale of order `1e−17` seconds, while the shortest timescale on which anything neurally interesting happens is about `1e−4` seconds. **The gap is thirteen orders of magnitude and it is the wrong way round.**

There are two ways to handle an objection of that size: route around it and keep the vocabulary vague, or compute the numbers, print them, and accept the constraint. **This paper does the second, and the corpus is stronger for it.** There is also a non-defensive reason for the section: decoherence explains why the classical world looks classical without adding anything to the Schrodinger equation, and it fails to explain the rest, which is equally important to say.

33.5.1 5.1 The mechanism and the two theorems

Definition 5.1 (density matrix). For a system in state `|psi> = a|0> + b|1>`, the density operator is `rho = |psi><psi|`:

```
rho  =  [ |a|^2      a b*  ]      diagonal entries : POPULATIONS
        [ a* b       |b|^2 ]      off-diagonal     : COHERENCES
```

The diagonal entries are the Born-rule probabilities. **The off-diagonal entries carry the phase relationship and are the only thing distinguishing a superposition from a classical mixture.** All observable interference lives in those two numbers.

Theorem 5.2 (decoherence as off-diagonal suppression). *Established, and derived from ordinary unitary evolution of system plus environment.* Let the system couple to an environment such that `|0>|E_0> -> |0>|E_0(t)>` and `|1>|E_0> -> |1>|E_1(t)>`. Tracing out the environment gives

```
rho_S(t)  =  [ |a|^2                    a b* <E_1(t)|E_0(t)>  ]
             [ a* b <E_0(t)|E_1(t)>     |b|^2                ]
```

The populations are untouched. The coherences are multiplied by the overlap of the environment states. As those states become distinguishable the overlap goes to zero and the off-diagonal terms vanish. For most realistic couplings the overlap decays exponentially,

```
rho_01(t)  =  rho_01(0) * exp( - t / tau_dec )
```

and for spatial superpositions of separation `dx` the standard long-wavelength form is `rho(x,x',t) = rho(x,x',0) exp(-Lambda (x-x')^2 t)` with `Lambda` a scattering constant. The programme was begun by Zeh [1970], developed quantitatively by Joos and Zeh (1985) and systematised by Zurek (2003).

Theorem 5.3 (populations are not affected). *Proven, and it is the whole of what Section 5.7 turns on.* The diagonal elements of `rho_S(t)` are `|a|^2` and `|b|^2` for every `t`. Decoherence suppresses the coherences and changes no population. **It converts a superposition into something that looks like a classical mixture without selecting an outcome.**

33.5.2 5.2 The rate, and where the saturated regime begins

For a superposition whose spatial separation exceeds the thermal de Broglie wavelength of the environmental particles, a single scattering event resolves which branch the system is in, and the decoherence rate saturates at the scattering rate:

```
Gamma_dec  =  n * sigma * v_bar          (saturated regime)

    n      = number density of the environment particles
    sigma  = scattering cross-section (geometric, as an estimate)
    v_bar  = sqrt( 8 k_B T / (pi m) ), mean thermal speed

tau_dec    =  1 / Gamma_dec
```

Below the thermal de Broglie wavelength the rate is quadratic in separation and decoherence is slower, so the boundary must be located first:

```
THERMAL DE BROGLIE WAVELENGTH OF THE ENVIRONMENT PARTICLE   (computed)

air molecule (28.97 amu), 300 K     v_bar = 468.2 m/s   hbar/p = 4.68 pm
water molecule (18.02 amu), 310 K   v_bar = 603.6 m/s   hbar/p = 5.84 pm
helium (4 amu), 4 K                 v_bar = 145.5 m/s   hbar/p = 109.11 pm
```

Any superposition separated by more than about six picometres, in air or water at ordinary temperatures, is in the saturated regime. Six picometres is one twentieth of a hydrogen atom's diameter. Every proposal of biological interest — a displaced ion, a conformational change, a travelling exciton, a firing versus non-firing neuron — is separated by vastly more than that, so the saturated formula applies, and it is the fast one.

33.5.3 5.3 Case one: a dust grain

Radius 1 micrometre, air at 300 K, geometric cross-section.

```
DUST GRAIN, r = 1 um                    n (/m3)     Gamma (/s)    tau_dec (s)

air at 1 atm, 300 K                     2.446e+25   3.600e+16     2.78e-17
high vacuum, 1e-10 mbar                 2.414e+12   3.553e+03     2.82e-04
extreme high vacuum, 1e-12 mbar         2.414e+10   3.553e+01     2.82e-02
```

In ordinary air a speck of dust loses spatial coherence in about thirty attoseconds. In the best vacuum routinely achievable in a laboratory it lasts about a quarter of a millisecond — and that is with the gas removed, before thermal photons are counted.

Thermal photons make it worse and their scaling is severe. In the long-wavelength limit the blackbody localisation rate scales as `a^6 T^9` in the object's radius and the temperature. **Both exponents are derived from the model, not fitted to data**, and are quoted as exact:

```
T = 150 K relative to 300 K :  (T/300)^9 = 1.953e-03
T =  77 K relative to 300 K :  (T/300)^9 = 4.834e-06
radius x 2                  :  r^6 factor = 6.400e+01
radius x 10                 :  r^6 factor = 1.000e+06
```

A ninth-power temperature dependence is why matter-interference experiments are done cold, and a sixth-power size dependence is why they are done with small things. Both are engineering consequences of one formula and both are visible in the design of every real experiment in the field.

33.5.4 5.4 Case two: a large molecule, where the estimate meets an experiment

Radius 0.5 nanometres, roughly a C70 fullerene.

```
C70 MOLECULE, r = 0.5 nm                pressure       Gamma (/s)   tau_dec (s)

air at 1 atm                            1.013e+05 Pa   1.520e+10    6.58e-11
1e-3 mbar                               1.0e-01 Pa     1.501e+04    6.66e-05
1e-6 mbar                               1.0e-04 Pa     1.501e+01    6.66e-02
1e-8 mbar                               1.0e-06 Pa     1.501e-01    6.66e+00
```

This table is worth more than the dust grain because it can be checked against a real apparatus. A Talbot–Lau molecule interferometer has a flight time of order a millisecond and a grating period of order a micrometre — comfortably in the saturated regime, a micrometre being two hundred thousand times the 4.68 pm threshold. **The estimate therefore predicts that fringe visibility should survive at `1e-6` mbar, where the coherence time of 67 ms far exceeds the flight time, and should be destroyed at `1e-3` mbar, where the coherence time of 67 microseconds falls far below it. That is the pressure range over which the visibility has been measured to fall.** A first-principles estimate that lands on the right decade in a published experiment is an estimate worth trusting one decade at a time, which is all this section asks of it. **This is the paper's only out-of-sample check of an estimator against an outcome it did not use**, and Section 10 treats it as such.

33.5.5 5.5 Case three: the warm wet system

Liquid water at 310 K. This is the environment inside a cell and the relevant case for any biological claim whatsoever.

```
WATER AT 310 K (computed)
    number density                      n     = 3.3428e+28 /m3
    mean thermal speed of a molecule    v_bar = 603.6 m/s
    thermal de Broglie wavelength       hbar/p = 5.84 pm

OBJECT                              cross-section   Gamma (/s)    tau_dec (s)

single K+ ion, r = 0.14 nm          6.158e-20 m2    1.242e+12     8.05e-13
globular protein, r = 5 nm          7.854e-17 m2    1.585e+15     6.31e-16
microtubule segment, 25 x 100 nm    2.500e-15 m2    5.044e+16     1.98e-17
synaptic vesicle, r = 20 nm         1.257e-15 m2    2.536e+16     3.94e-17
whole neuron soma, r = 5 um         7.854e-11 m2    1.585e+21     6.31e-22
```

Three notes on how to read the table honestly.

First, these are estimates and the prefactors are uncertain. The collision picture is imported from a gas; in a liquid the object is not struck intermittently but is in permanent contact with its solvent shell. If anything this *understates* the monitoring rate. The relevant solvent dynamics:

```
water librational band, ~600 cm^-1   ->  1.80e+13 Hz  (period 5.56e-14 s)
OH stretch, ~3400 cm^-1              ->  1.02e+14 Hz  (period 9.81e-15 s)
hydrogen-bond rearrangement          ->  ~1e+12 Hz    (period ~1e-12 s)
hbar / kT at 310 K                   ->  2.464e-14 s
```

No mechanism in liquid water leaves anything alone for longer than a picosecond, and most leave nothing alone for longer than about twenty-five femtoseconds.

Second, the thermal time `hbar/kT` is the natural yardstick and deserves its own table.

```
T = 2.725 K   (cosmic microwave background)   hbar/kT = 2.803e-12 s = 2803 fs
T = 4     K   (liquid helium)                 hbar/kT = 1.910e-12 s = 1910 fs
T = 77    K   (liquid nitrogen)               hbar/kT = 9.920e-14 s =   99 fs
T = 277   K   (a cold room, 4 C)              hbar/kT = 2.758e-14 s = 27.6 fs
T = 300   K   (room temperature)              hbar/kT = 2.546e-14 s = 25.5 fs
T = 310   K   (body temperature, 37 C)        hbar/kT = 2.464e-14 s = 24.6 fs
```

At body temperature the thermal time is twenty-five femtoseconds. That is the timescale on which thermal energy scrambles quantum phase, and it is a property of the temperature alone. Any biological quantum claim must explain how its state stays coherent for many multiples of 24.6 femtoseconds while sitting in a bath at 310 K, and the explanation has to be structural.

Third, warmth and wetness are not incidental to biology. They are what biology is. Cooling the system to where coherence survives kills the organism. This is not a technical inconvenience to be engineered around; it is a constraint on the kind of physics life can be running.

33.5.6 5.6 The gap, stated as a ratio

Take the microtubule estimate, `tau_dec = 1.98e-17 s` — the object most often invoked in quantum-mind proposals — against every timescale on which anything neural happens. The neural timescales are the standard ones of the spiking-neuron literature [Gerstner and Kistler, 2002, Lapicque, 1907].

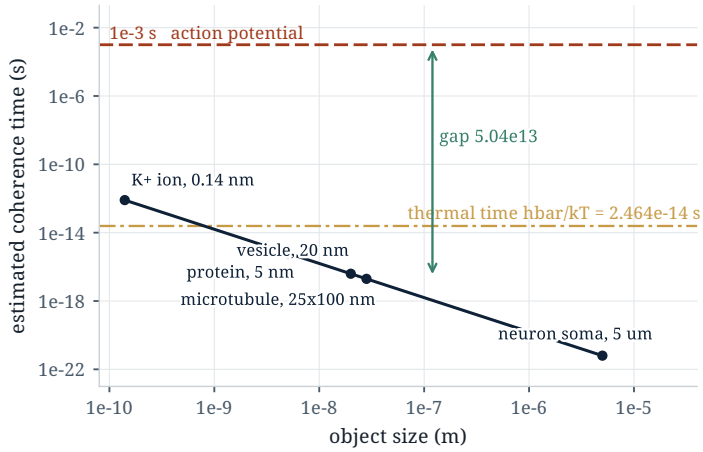

Figure 33.2: **The warm-wet decoherence gap, over nine decades of object size.** Estimated coherence times in water at 310 K fall from `8.05e-13` s for a single potassium ion to `6.31e-22` s for a neuron soma, every one of them below the thermal time `hbar/kT = 2.464e-14` s and every one of them between eight and nineteen orders of magnitude below the `1e-3` s of a single action potential. The microtubule segment most often invoked in quantum-mind proposals sits at `1.98e-17` s. Estimated from `tau = 1/(n sigma v_bar)` with `n = 3.3428e28` per cubic metre and `v_bar = 603.6` m/s, the cross-sections of Section 5.5; generated by `figs/src/CCP-033_fig02.py`.

PROCESS	duration	duration / tau_dec
ion-channel gating	1.0e-04 s	5.04e+12
action potential	1.0e-03 s	5.04e+13
synaptic transmission	1.0e-03 s	5.04e+13
gamma cycle (40 Hz)	2.5e-02 s	1.26e+15
a reported "moment" of awareness	1.0e-01 s	5.04e+15
one second	1.0e+00 s	5.04e+16

And the corresponding coherence, since the decay is exponential:

```
rho_01(t) = rho_01(0) * exp(-t / tau_dec),  tau_dec = 1.98e-17 s

t = 1.98e-17 s (one tau)        suppression factor  0.367879
t = 1.98e-16 s (ten tau)        suppression factor  0.000045
t = 1.98e-15 s (hundred tau)    suppression factor  ~1e-44
t = 1.0e-12  s                  exp(-5.044e+04)     numerically zero
t = 1.0e-03  s (one spike)      exp(-5.044e+13)     numerically zero
```

"Numerically zero" here is not a figure of speech and not a rounding. The suppression factor at one millisecond is `e` raised to minus fifty trillion. There is no number system in ordinary use that represents it. Interference visibility falls below one part in a thousand after 6.9 decoherence times and below one part in a million after 13.8; a millisecond is `5.04e13` of them.

33.5.7 5.7 What decoherence solves, and what it leaves standing

What it genuinely solves.

1. **The absence of macroscopic interference.** Why cats, chairs and pointers are never seen in superposition. Answered completely, by the coherence times above.

2. **The preferred-basis problem.** Why the classical world has a definite basis, roughly position, rather than an arbitrary one. Einselection answers this from the interaction Hamiltonian with no appeal to observers.
3. **The apparent irreversibility of measurement.** The information is not destroyed but dispersed into environmental degrees of freedom that are in practice unrecoverable. **This is provenance loss at a boundary, and the corpus has a measured instance of the same structure in a different domain**: 18.932 bits of identity entering a carrier becomes 8.000 bits observable from an address alone, and 23.977 bits when address and port are both captured [Curzi, 2026]. The parallel is structural. What decoherence disperses is phase, not identity, and no claim is made that the two are the same quantity; that erasure and information have a physical cost at all is Landauer [1961].
4. **The disappearance of the observer from the account.** Decoherence is done by air molecules. It removes the last motivation for putting consciousness anywhere in the dynamics, and this is the development that led Wigner away from his own 1961 position.

What it does not solve, stated flatly.

Theorem 5.3 said it: decoherence changes no diagonal element. It suppresses the interference terms; it does not select an outcome. The reduced density matrix ends up looking like a classical mixture, but it is an *improper* mixture, obtained by tracing out a subsystem of a state that is still globally a pure superposition.

```
BEFORE   rho_S =  [ |a|^2    a b*  ]     coherent superposition
                  [ a* b     |b|^2 ]

AFTER    rho_S =  [ |a|^2      0   ]     looks exactly like a classical mixture
                  [   0      |b|^2 ]     but is an IMPROPER mixture: the global
                                         state is still a superposition

WHAT CHANGED : the off-diagonals. WHAT DID NOT : |a|^2 and |b|^2, and the fact
               that both branches are still in the global state.
```

The measurement problem in the M1/M2/M3 form of Section 4.6 is untouched by this. **Decoherence is entirely a consequence of M2 applied to system plus environment. A result derived from M2 cannot resolve a contradiction that arises because M2 conflicts with M3. Anyone who says decoherence solved the measurement problem has made a logical error, not merely an overstatement.** The criticism is not fringe and has been made explicitly in the foundations literature. **The honest position, and the majority one among people who work on foundations, is that decoherence is a major and permanent advance that dissolves part of the problem and leaves the rest exactly where it was.**

The half that is solved is the half this corpus needs. Whether the surviving outcome is selected by collapse, by branching, or by a guiding equation makes no difference to any argument in the corpus. What matters is that no macroscopic superposition survives long enough to carry biological information, and that is settled. **The half that is open is genuinely open, and this corpus takes no position on it, because it does not need one.**

33.5.8 5.8 The plain statement, and what it costs the corpus

Any claim that mind collapses wave functions must confront these timescales.

Any claim that quantum coherence carries information in warm wet biology must confront these timescales.

This corpus makes no such claim.

The consequences for the corpus's biological material, stated so they can be checked:

the cell as receiver	MECHANOTRANSDUCTION. Ion channels, forces, conformational change. Entirely classical. Mechanosensitive channels open because they are pulled.
the channel and its capacity	Classical acoustics, classical Shannon capacity, thermal noise floor. No coherence term anywhere in the calculation.
addressing without editing	Molecular recognition, base pairing, protein–nucleic-acid binding. Chemistry.
sequence sonification	Encoding, transmission. The Gabor limit is CLASSICAL and it is the binding constraint, not the Heisenberg relation.
belief and mechanism	Physiological, behavioural, social and informational channels. Every one measured, every one classical.

NOT ONE ARGUMENT IN THE CORPUS WOULD CHANGE IF QUANTUM MECHANICS PLAYED NO ROLE IN BIOLOGY AT ALL.

Each of those lines is carried by a paper that computes it. The acoustic-addressing result is that addressing a cell fails on geometry rather than on bandwidth: wavelength equals a 10 micrometre cell only at 154 MHz, and the product of wavelength and 20 dB penetration depth collapses from 6160 to 0.0026 mm-cm between 100 kHz and 154 MHz [Curzi, 2026x]. The sequence-encoding result is the open problem stated formally: **no established mechanism produces a transcriptional response depending on the symbol string as an order, as distinct from permutation-invariant functionals of the waveform** [Curzi, 2026]. The classical time–bandwidth constraint that binds there is Gabor [1946], whose limit is a Fourier fact and carries no quantum content [Curzi, 2026z]. Appendix B, audit B5, records the evidence and precedent for the isolation requirement separately.

33.5.9 5.9 The genuine exceptions, quantified and contested

Honesty runs in both directions. There are real cases where quantum coherence appears to play a functional role in biology, they are active research areas, and this section names them properly.

(a) Photosynthetic energy transfer. Two-dimensional electronic spectroscopy of the Fenna–Matthews–Olson pigment–protein complex revealed long-lived oscillatory signals, first at 77 K and then at physiological temperature, with reported oscillation lifetimes at the warmer temperature of order 300 femtoseconds.

reported oscillation lifetime	3.0e-13 s (300 fs)
hbar / kT at 277 K	2.758e-14 s (27.6 fs)
ratio	10.9 thermal times
spatial extent	1–2 nm, inside ONE rigid protein scaffold

The interpretation is contested, and that must be said in the same breath. A substantial body of subsequent work argues that the long-lived oscillations are predominantly vibrational or vibronic rather than evidence of long-lived electronic coherence, and that the energy transfer does not require the latter. **The defensible statement is: short-lived coherence exists in these systems, its functional role is disputed, and the strong early claims have been substantially walked back.**

(b) Radical-pair magnetoreception. The radical-pair mechanism proposes that a photo-induced pair of radicals, born in a correlated spin state, undergoes coherent singlet–triplet interconversion whose rate is sensitive to the external magnetic field, so that the resulting difference in reaction yield constitutes a compass. Cryptochrome has been proposed as the host protein; a purely chemical model system has been shown to respond to Earth-strength fields; and magnetic sensitivity of cryptochrome 4 from a migratory songbird has been reported in vitro.

```
electron Zeeman energy in Earth's field (50 uT, g = 2)   9.274e-28 J
kT at 310 K                                              4.280e-21 J
ratio (Zeeman / thermal)                                 2.167e-07

coherent precession frequency  = 8.794e+06 rad/s = 1.400 MHz
precession period                                       0.714 us
=> the mechanism requires SPIN coherence on the microsecond scale
```

The magnetic interaction is two ten-millionths of the thermal energy. It cannot work by energetics — and it does not claim to. It works by kinetics: the field changes the rate of singlet–triplet mixing, which changes which of two chemical products forms, and the yield difference is what is read out.

The reason the coherence survives is structural, not mysterious. The degree of freedom carrying it is electron *spin*, which has no electric dipole moment and therefore does not couple to the polar solvent that destroys every charge-displacement superposition in the tables above. **The exception is not an exception to the physics. It is a consequence of choosing a degree of freedom the environment barely watches.**

33.5.10 5.10 Why the exceptions do not generalise

Both cases share four features, and every one of them fails at the scale of cognition.

FEATURE	PHOTOSYNTHESIS / RADICAL PAIR	COGNITION
spatial extent	1–2 nm, inside one protein	1e-5 m and up (ratio ~ 1e+4)
duration	3e-13 s / ~1e-6 s (spin)	1e-3 to 1e-1 s (ratio ~ 1e+9)
degree of freedom	one exciton; one electron-spin pair	membrane voltage; ion populations; vesicle fusion -- all charge-displacing and all heavily monitored
protection	a rigid, evolved, purpose-built scaffold that constrains the coupling	NONE PROPOSED
readout	a chemical yield -- a POPULATION difference, not a transmitted message	a claim about information transfer

The last row ends the argument and deserves to stand alone. In both exception cases what is read out is a reaction yield — a diagonal element of the density matrix, a population.

Theorem 5.3 says decoherence never touched the populations. The coherence in these systems modulates a rate; it does not carry a message. Even taken entirely at face value, neither case is an example of quantum coherence transmitting information, and neither is proposed by its own authors as such.

The sharpest version of this argument in print is a published exchange. Tegmark (2000, *Physical Review E* 61, 4194) computed decoherence times for microtubule and neuron-firing superpositions and obtained `1e−13` to `1e−20` seconds, concluding they were ten or more orders of magnitude too short for any role in cognition. Hagan, Hameroff and Tuszynski (2002, *Physical Review E* 65, 061901) replied that the model was mis-specified for the system they had proposed and, correcting it, obtained `1e−5` to `1e−4` seconds. **Both papers are real, both are peer-reviewed, and the disagreement was never resolved in favour of the longer times.** The independent estimates in Section 5.5, computed from scratch here, land in the first range and not the second. **The defensible summary: the objection stands, it has been contested by serious people, and the contest did not overturn it.**

That a microscale law does not determine the behaviour of the macroscale system built from it is the general form of this result, and it is not special to quantum mechanics [Anderson, 1972].

33.5.11 5.11 What decoherence returns to the framework

The section has been subtractive. It ends by paying something back, and what it pays back is structural rather than quantum.

Decoherence has the form of a retention loss. In the storage law `Q_{t+1} = (1−delta)Q_t + eta S_t − C_t`, the coefficient `delta` is what a stored structure sheds per period through contact with an unmaintained surround; the law is a contraction for every `delta > 0`, with steady state `(eta S − C)/delta` [Curzi, 2026a]. Coherence decay has exactly that form — exponential loss driven by exposure, with no agent and no malice, requiring no explanation beyond contact.

```
COHERENCE       rho_01(t) = rho_01(0) * exp(−t / tau)
STORED ORDER    Q_t       = (1−delta)^t * Q_0        (transient term)

same functional form; delta plays the role of 1/tau per period
```

This is category 2 in the taxonomy of Section 3.3: a correspondence of model form, not of physics. No institution decoheres. The first-order-lag mathematics is standard and is the same object in both places [Elaydi, 2005, Oppenheim et al., 1996]. The engineering lesson, however, transfers exactly and is worth having:

A fragile state is protected by reducing its coupling to the surround, not by adding energy to it. No amount of drive escapes decoherence, and no amount of drive escapes `delta`. The matter-wave interferometrists' response to a `T^9` and `a^6` scaling is to go cold, small and empty — reduce the coupling. The framework's counterpart is to reduce exposure surface or accept the loss rate on hand. **The converse case is the instructive one and the corpus states it: a system whose loss is exactly zero does not preserve itself, it becomes an isometry that orbits without arriving, and a system whose gain reaches or exceeds one becomes an amplifier whose corrections, sized to delayed feedback, arrive as new errors** [Curzi, 2026].

33.6 6 The Casimir effect: force, honest limit, and mode selection by boundary

The limit comes first, because the limit is the honest part and it belongs where nobody can miss it. At every biological and architectural scale the Casimir force is utterly negligible. It

does nothing in a cell and nothing in a room. Between two walls three metres apart it produces a pressure of `1.47e-23` pascals, which over ten square metres is a force of `1.47e-22` newtons — sixty-seven million times smaller than the weight of a single bacterium. In a cell, at a hundred-nanometre gap, the most generous possible estimate gives thirteen pascals against a physiological osmotic pressure of `7.73e5` pascals, and the realistic estimate for actual biological materials in salt water is smaller still by another one to three orders. **No design in this framework depends on the Casimir force, and none could be built to exploit it.**

So why is the effect here? Because it is not important for its force. It is important for what produces the force. **Two uncharged, unpowered, ordinary plates attract each other for one reason: their separation determines which electromagnetic modes can exist between them, and modes that do not fit are excluded.** Nothing is added, nothing is switched on, no field is applied, no energy is supplied, and no material property is exploited beyond being a boundary. The geometry does all of it, and the consequence is measurable to a few per cent in a laboratory.

That is the framework's central architectural claim in its purest physical form, and this section presents the effect as exactly that and nothing more.

33.6.1 6.1 What is established

The Casimir result [Casimir, 1948]. For two parallel, perfectly conducting, uncharged plates in vacuum at zero temperature, separated by `a`:

```
E(a) / A  =  − pi^2 ∗ hbar ∗ c / (720 ∗ a^3)          energy per unit area
P(a)      =    pi^2 ∗ hbar ∗ c / (240 ∗ a^4)          attractive pressure
```

It has been measured. A torsion-pendulum measurement over 0.6–6 micrometres agreed with the prediction to about 5 per cent [Lamoreaux, 1997]; an atomic-force-microscope measurement over 0.1–0.9 micrometres reached about 1 per cent [Mohideen and Roy, 1998]; parallel-plate geometries have since been measured directly. The generalisation to real materials at finite temperature is Lifshitz theory, which requires measured optical data rather than an idealised reflectivity, and the whole family of fluctuation forces belongs to the same fluctuation–dissipation framework [Callen and Welton, 1951].

The theorem that actually matters here is not about force.

> **Theorem 6.1 (boundary mode selection).** For a wave equation with a Dirichlet or Neumann condition on a boundary, the set of allowed modes is determined by the boundary geometry alone. Between two parallel boundaries separated by `a`, the allowed perpendicular wavenumbers are `k_n = n pi / a` and the allowed wavelengths are `2a/n`, `n = 1, 2, 3, ...`; nothing else is allowed. *Status:* **established mathematics**, the elementary solution of the Helmholtz problem, and the same theorem for the electromagnetic field, the pressure field in air, and any other field obeying the same equation.

> **Postulate 6.1 (mode selection as a design principle).** *Badged as a postulate, in the source and here.* Boundary geometry alone selects which modes a system supports, at no ongoing cost, and this may be used as a design principle. **The postulate is exact where the system is governed by the Helmholtz problem — electromagnetic modes between conductors, acoustic modes in an enclosure — and is a design heuristic with no formal warrant anywhere else**, including its extension to occupancy and circulation. Section 6.11 separates the three transfer strengths and Section 11 records the extension as unsupported.

33.6.2 6.2 The derivation, in outline

The point of the outline is to make visible that the entire calculation is a difference between two mode counts.

```
STEP 1   Count the modes allowed BETWEEN the plates.
         Perpendicular: k_z = n*pi/a, n = 1, 2, 3, ...  (discrete)
         Parallel:      k_x, k_y continuous
         Two polarisations for n >= 1.

STEP 2   Assign each mode its zero-point energy hbar*omega/2, with
         omega = c * sqrt(k_x^2 + k_y^2 + (n*pi/a)^2).

STEP 3   Sum. The sum diverges.

STEP 4   Subtract the corresponding sum for free space (no plates), which
         also diverges. The DIFFERENCE is finite.

STEP 5   Regularise to do this carefully. The zeta-function route reduces
         the perpendicular sum to sum over n of n^3, whose regularised value
         is zeta(-3) = 1/120.

STEP 6   Result:  E(a)/A = - pi^2 hbar c / (720 a^3)

STEP 7   Force = - d/da [E/A] = pi^2 hbar c / (240 a^4), attractive.
```

The bookkeeping of steps 5 to 7, verified:

```
pi^2 / 720          =  0.013707783890
pi^2 / (6 * 120)    =  0.013707783890        <- identical
1/120 = zeta(-3)

720 = 6 x 120. The 120 in the denominator is the regularised value of a
divergent sum, carried through the calculation and still visible in the
final constant.

720 / 3 = 240. The 3 is the exponent in a^-3 differentiated.
```

What is worth taking from the derivation is not the regularisation technique. It is Step 1. Everything downstream is bookkeeping on a mode count that was fixed the moment the separation was chosen.

33.6.3 6.3 The pressure table

```
P(a) = pi^2 * hbar * c / (240 * a^4) = 1.300126e-27 / a^4   pascals

separation      P (Pa)         P (atm)        F on 1 cm^2 (N)   equivalent mass

  1 nm         1.3001e+09     1.2831e+04       1.3001e+05       1.33e+04 kg
 10 nm         1.3001e+05     1.2831e+00       1.3001e+01       1.33e+00 kg
100 nm         1.3001e+01     1.2831e-04       1.3001e-03       1.33e-04 kg
  1 um         1.3001e-03     1.2831e-08       1.3001e-07       1.33e-08 kg
 10 um         1.3001e-07     1.2831e-12       1.3001e-11       1.33e-12 kg
100 um         1.3001e-11     1.2831e-16       1.3001e-15       1.33e-16 kg
  1 mm         1.3001e-15     1.2831e-20       1.3001e-19       1.33e-20 kg
```

```
1 cm          1.3001e-19     1.2831e-24       1.3001e-23       1.33e-24 kg
1 m           1.3001e-27     1.2831e-32       1.3001e-31       1.33e-32 kg
3 m           1.6051e-29     1.5841e-34       1.6051e-33       1.64e-34 kg
```

The values are for perfectly conducting plates in vacuum at zero temperature, and the assumptions belong to the number wherever it is quoted. At ten nanometres the pressure is 1.28 atmospheres — a thoroughly macroscopic figure, and the reason the effect is a genuine nuisance in nanofabrication. One decade further out it has fallen by a factor of ten thousand to thirteen pascals. **The inverse fourth power is the whole story: each factor of ten in separation costs a factor of ten thousand in pressure**, and the exponent is derived, not fitted.

```
separation x 2    ->  pressure x 6.250e-02
separation x 10   ->  pressure x 1.000e-04
separation x 100  ->  pressure x 1.000e-08

to reach one atmosphere of Casimir pressure the gap must close to:
    a = (K/P)^(1/4) = 1.0643e-08 m = 10.64 nm
```

Ten and a half nanometres is roughly two lipid bilayers. That is how close two mirrors must be before the vacuum pushes on them as hard as the air does.

33.6.4 6.4 The two corrections, and one of them goes the wrong way

Finite conductivity. Real metals are not perfect mirrors. Gold has a plasma wavelength of about 136 nanometres, so at separations at or below that, high-frequency modes penetrate the surface rather than reflecting, and the force is reduced. **For gold near 100 nm the reduction is of order a factor of two, and it grows at smaller separations.** Any serious comparison with experiment uses Lifshitz theory with measured optical data, not the idealised constant.

Temperature. Casimir's formula is the zero-temperature limit, holding while the separation is small compared with the thermal wavelength `lambda_T = hbar c / (k_B T)`:

```
T = 300 K (room)   lambda_T = 7.6329e-06 m =   7.63 um
T = 310 K (body)   lambda_T = 7.3867e-06 m =   7.39 um
T =   4 K (LHe)    lambda_T = 5.7247e-04 m = 572.47 um
```

Beyond `lambda_T` the zero-temperature formula fails and the high-temperature limit applies:

```
P_highT  =  zeta(3) * k_B * T / (4 * pi * a^3)

a           P (T=0 formula)   P (high-T, 300 K)   ratio highT / T0
1 um         1.3001e-03 Pa     3.9620e-04 Pa       0.305
7.63 um      3.8361e-07 Pa     8.9196e-07 Pa       2.325
100 um       1.3001e-11 Pa     3.9620e-10 Pa       30.47
1 mm         1.3001e-15 Pa     3.9620e-13 Pa       304.7
3 m          1.6051e-29 Pa     1.4674e-23 Pa       9.142e+05
```

This correction must be reported even though it damages the tidiness of the table, because at large separations it makes the force larger, not smaller. At one millimetre the true room-temperature pressure is about three hundred times the zero-temperature value; at room scale it is nine hundred thousand times larger. **And it changes nothing:** `1.47e-23` pascals at three metres instead of `1.61e-29`. Both are nothing. **The correction is reported because reporting an inconvenient correction is how a reader learns that the convenient ones were reported honestly too.**

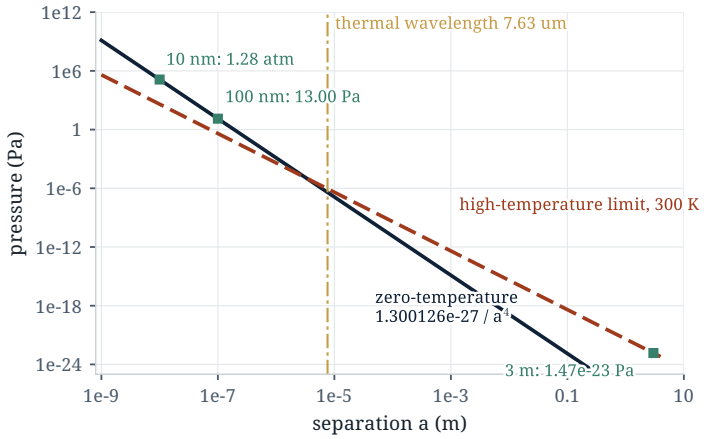

Figure 33.3: **Every decade of separation costs four decades of pressure, and the thermal correction — which makes the force larger — does not rescue it.** The zero-temperature Casimir pressure `1.300126e-27/a^4` Pa and the high-temperature limit `zeta(3) k_B T/(4 pi a^3)` at 300 K cross at the thermal wavelength `lambda_T = 7.63` um; at 3 m the high-temperature value of `1.4674e-23` Pa is `9.142e5` times the zero-temperature value and still `5.9e4` times below what a single bacterium resting on the wall exerts. Computed from the tables of Sections 6.3 and 6.4; generated by `figs/src/CCP-033_fig03.py`.

33.6.5 6.5 The honest limit, computed three ways

Comparison one: a cell.

```
physiological osmotic pressure (300 mOsm at 310 K)    7.732e+05 Pa
atmospheric pressure                                   1.013e+05 Pa
Casimir, IDEAL MIRRORS, at 100 nm                      1.300e+01 Pa
    ratio osmotic / Casimir(ideal, 100 nm)             5.947e+04
```

But ideal mirrors is the wrong model, and using it here would be dishonest in the framework's own favour. Biological surfaces across water are dielectrics with small dielectric contrast, and the correct framework is Lifshitz theory with a Hamaker constant:

```
non-retarded van der Waals pressure  P = A_H / (6 * pi * a^3)

lipid / water / lipid,     A_H = 5e-21 J   at  10 nm :  2.653e+02 Pa
                                           at 100 nm :  2.653e-01 Pa
protein / water / protein, A_H = 1e-20 J   at  10 nm :  5.305e+02 Pa
                                           at 100 nm :  5.305e-01 Pa
```

Two further reductions apply above ten nanometres and both are real: retardation, which is the crossover into the Casimir regime proper and suppresses the force further as separation grows; and screening of the zero-frequency term by the electrolyte.

```
Debye screening length, 150 mM 1:1 electrolyte, 310 K, eps_r = 78.4
    kappa^-1 = 8.004e-10 m = 0.80 nm
```

Eight angstroms. In a cell the static part of the interaction is screened out within one nanometre. Now the force comparison that decides it — a 10 nm by 10 nm patch across a 10 nm gap:

```
ideal-mirror Casimir            1.300e-11 N  =  13.00 pN
realistic biological vdW        2.653e-14 N  =   0.027 pN
kinesin stall force (measured)  6.0e-12 N    =   6.00 pN
kT / nm at 310 K                4.280e-12 N  =   4.28 pN
```

The realistic biological value is two hundred times smaller than a single motor protein's stall force and one hundred and sixty times smaller than the thermal force scale over a nanometre. It is noise beneath noise. The ideal-mirror number that looks competitive is unattainable, because nothing in a cell is a parallel conducting mirror and nothing in a cell holds a fixed 10 nm gap in vacuum.

The precise statement: fluctuation forces of this family — van der Waals in the non-retarded regime — are genuinely important in colloid science and in membrane interactions, and DLVO theory is built on them. The retarded Casimir regime proper contributes nothing measurable to cell biology. The two sentences must not be traded for one another.

Comparison two: a room.

```
two parallel walls, 3 m apart, 10 m^2 each

P (T=0 formula)     1.605e-29 Pa   ->  F = 1.605e-28 N
P (high-T, 300 K)   1.467e-23 Pa   ->  F = 1.467e-22 N     <- the correct one
weight of one E. coli (~1e-15 kg)   ->      9.807e-15 N
ratio: bacterium weight / Casimir force  =  6.683e+07
```

A single bacterium sitting on the wall weighs sixty-seven million times more than the entire Casimir force between the two walls of the room. Every claim about Casimir forces in architecture dies here, computed, in one line.

Comparison three: where it genuinely matters, which is neither of the above.

```
MEMS / NEMS, ideal-mirror values

gap  10 nm : P = 1.3001e+05 Pa ; on a 100 um x 100 um plate F = 1.300e-03 N
gap  50 nm : P = 2.0802e+02 Pa ;                            F = 2.080e-06 N
gap 100 nm : P = 1.3001e+01 Pa ;                            F = 1.300e-07 N = 130 nN
gap 200 nm : P = 8.1258e-01 Pa ;                            F = 8.126e-09 N = 8.1 nN
```

At these scales the force is a design constraint: it contributes to stiction, the permanent collapse of a micromachined structure onto its substrate, and it has been used deliberately to actuate a device. **The honest picture is a narrow band of relevance: below about ten nanometres van der Waals and chemistry dominate; above about a micrometre the force is gone; in between, and only for engineered near-mirror surfaces, it matters.** Biology and architecture are both outside that band by many orders of magnitude. The one other domain in which the effect is legitimately invoked is theoretical rather than applied — negative-energy-density constructions in general relativity take the Casimir vacuum as their existence proof [Morris and Thorne, 1988] — and that is a use in fundamental physics, not in engineering. Appendix B, audit B6, records that the precedent column for this claim is empty and prints the empty cell.

33.6.6 6.6 The real point: geometry alone selects the modes

Set the force aside entirely and look only at Step 1. Two plates a distance `a` apart. The allowed perpendicular wavelengths are `2a/n` and nothing else.

```
LOWEST ALLOWED ELECTROMAGNETIC MODE BETWEEN PLATES,  f_1 = c / (2a)
```

```
a =  10 nm    lambda_1 = 2.00e-08 m   f_1 = 1.4990e+16 Hz   61.99 eV
a = 100 nm    lambda_1 = 2.00e-07 m   f_1 = 1.4990e+15 Hz    6.20 eV
a =   1 um    lambda_1 = 2.00e-06 m   f_1 = 1.4990e+14 Hz    0.62 eV
a =   1 mm    lambda_1 = 2.00e-03 m   f_1 = 1.4990e+11 Hz    6.20e-04 eV
a =   3 m     lambda_1 = 6.00e+00 m   f_1 = 4.9965e+07 Hz    2.07e-07 eV
```

Setting the plates a hundred nanometres apart forbids every electromagnetic mode below six electron volts from existing perpendicular to them. No filter was installed. No field was applied. The exclusion is what the separation is.

The measurability is what makes this a proof rather than a definition. The excluded modes are not merely absent from a bookkeeping exercise; their absence produces a force that a torsion balance registers [Lamoreaux, 1997, Mohideen and Roy, 1998]. **Casimir is the demonstration that mode selection by boundary geometry is a physical fact about a system and not a way of describing it, with a number attached and an instrument that reads the number.**

33.6.7 6.7 The same boundary condition in air: a derivation, not an analogy

Nothing in Step 1 was quantum. Replace the electromagnetic field with the pressure field in air and the speed of light with the speed of sound, and the identical boundary-value problem gives the identical mode ladder. **This is category 1 in the taxonomy of Section 3.3 — a derivation, because the premises are satisfied — and it is the only category-1 transfer in the paper.**

```
SAME FORMULA, DIFFERENT WAVE SPEED:   f_1 = v / (2 * separation)

EM,    plates at 100 nm   ->  1.4990e+15 Hz
EM,    plates at   1 um   ->  1.4990e+14 Hz
SOUND, walls  at   3 m    ->      57.1667 Hz
SOUND, walls  at   7 m    ->      24.5000 Hz

ratio of wave speeds, c / c_sound = 8.7403e+05
```

The three-dimensional version is the standard room-mode equation of architectural acoustics [Rossing et al., 2002, Beranek, 2004]:

```
f(nx, ny, nz) = (c_sound / 2) * sqrt( (nx/Lx)^2 + (ny/Ly)^2 + (nz/Lz)^2 )
```

Computed for a 7.0 x 5.4 x 3.2 metre room (`V = 120.96` m^3, `S = 154.96` m^2):

```
 24.50 Hz  (1,0,0)  axial          66.94 Hz  (1,1,1)  oblique
 31.76 Hz  (0,1,0)  axial          68.08 Hz  (1,2,0)  tangential
 40.11 Hz  (1,1,0)  tangential     72.62 Hz  (2,0,1)  tangential
 49.00 Hz  (2,0,0)  axial          73.50 Hz  (3,0,0)  axial
 53.59 Hz  (0,0,1)  axial          79.26 Hz  (2,1,1)  oblique
 58.39 Hz  (2,1,0)  tangential     80.07 Hz  (3,1,0)  tangential
 58.93 Hz  (1,0,1)  tangential     80.22 Hz  (2,2,0)  tangential
 62.30 Hz  (0,1,1)  tangential
 63.52 Hz  (0,2,0)  axial

modes below 100 Hz : 25
mean spacing       : 3.08 Hz
largest gap        : 8.89 Hz
```

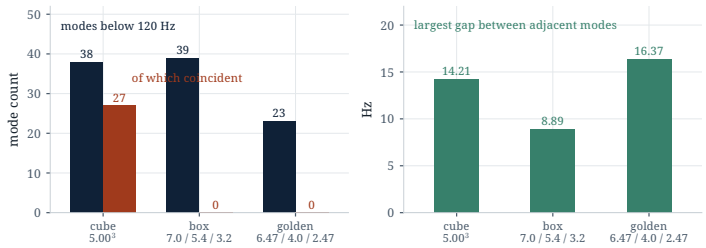

Figure 33.4: **Three rooms of comparable scale, and the degeneracy count is what separates them.** A 5.00 m cube puts 27 of its 38 modes below 120 Hz on top of another mode; the 7.00 x 5.40 x 3.20 m box and the 6.47 x 4.00 x 2.47 m golden-section box each stack none — but the golden box supports only 23 modes and has a largest gap of 16.37 Hz against the plain box's 8.89 Hz, so it is not simply better. Computed from `f = (c/2)sqrt((nx/Lx)^2+(ny/Ly)^2+(nz/Lz)^2)` with `c = 343` m/s, the dimensions of Section 6.7; generated by `figs/src/CCP-033_fig04.py`.

Those twenty-five frequencies are a property of three numbers — the room's dimensions — and of nothing else. Not the paint, not the furniture, not the budget, not the occupants. The reverberation and boundary-frequency apparatus that accompanies them is equally standard [Sabine, 1922, Schroeder, 1965, von Helmholtz, 1885], and the corpus's own treatment adds the switching rule the textbooks leave implicit: **use Sabine below a mean absorption of 0.25 and Eyring above it, state which, and expect a divergence of 77.8 per cent at 2 kHz in an overtreated room if the choice is made carelessly** [Curzi, 2026e].

The strongest computed demonstration of Theorem 6.1 is the degeneracy comparison:

```
MODES BELOW 120 Hz, and how many COINCIDE (degenerate, stacking energy at one pitch)

cube    5.00 x 5.00 x 5.00 m   38 modes,  27 coincident,  max gap 14.21 Hz
box     7.00 x 5.40 x 3.20 m   39 modes,   0 coincident,  max gap  8.89 Hz
golden  6.47 x 4.00 x 2.47 m   23 modes,   0 coincident,  max gap 16.37 Hz
```

A cube of the same rough scale stacks twenty-seven of its thirty-eight low modes on top of each other. The rectangular box stacks none. That is the audible difference between a room that booms and a room that does not, and it is produced by choosing three numbers.

And the golden-section box is not simply better. It has no degeneracies, but it is smaller, so it has fewer modes below 120 Hz — 23 against 39 — and its largest gap is wider, 16.37 Hz against 8.89 Hz, which below the Schroeder frequency means less even low-frequency support. **Proportion ratios generate candidate geometries. They do not certify them.** The golden section attracts claims that survive poorly on inspection, and the sceptical literature on those claims is the relevant one here [Markowsky, 1992, Fischler, 1981, Livio, 2002]; the corpus cites it wherever the ratio appears, on the principle that a claim's credibility is set by what its author already knows about it.

Appendix B, audit B7, records the evidence and the precedent for boundary mode selection separately, and it is the strongest precedent entry in the paper — which makes it the most dangerous, because a strong precedent is more tempting to promote than a weak one.

33.6.8 6.8 Pitch-class folding of a mode ladder

A mode ladder between two boundaries is `f_n = n f_1`. Doubling the index doubles the frequency, which is one octave, and octave equivalence as a perceptual structure for pitch is established [Shepard, 1982, Demany et al., 2013, Burns, 1999]. Pitch class then depends only on the odd part of the index, `n = 2^a m` with `m` odd:

```
first  6 modes -> odd parts {1,3,5}                          3 classes  (ceil(6/2)=3)
first 12 modes -> odd parts {1,3,5,7,9,11}                   6 classes  (ceil(12/2)=6)
first 16 modes -> odd parts {1,3,5,7,9,11,13,15}             8 classes  (ceil(16/2)=8)
first 24 modes -> odd parts {1,3,5,...,23}                  12 classes  (ceil(24/2)=12)
```

The first twelve modes between any two boundaries carry only six distinct pitch classes. That is a hard structural limit on the harmonic vocabulary of an enclosure, set by the boundary and by nothing else. The corresponding minimum-gap schedule for a ladder of given length is exact and rational — 1200 cents at `N = 2`, 203.9100 cents (9/8) at `N = 3` to 6, 34.9756 cents (50/49) at `N = 7` to 16, 6.0008 cents (289/288) at `N >= 17`, and 1.0296 cents (1682/1681) at `N >= 41` — and it is computed in Curzi [2026].

One difference must be stated so the two systems are not conflated. For a mode ladder `f_n = n f_1`, indices `n` and `2n` are **one** octave apart. For the corpus's essence law `f(n) = k n^2`, `(2n)^2 = 4 n^2`, so `n` and `2n` are **two** octaves apart. The odd-part folding rule is identical in both; the octave count is not, and a room's mode list must not be read off the essence tables or the reverse. That the essence register carries a further and more serious limit is stated by the paper that owns it: **the frequency register cannot distinguish a mood from a trait at all, because `f = k n^2` contains no time term; and the one-hot encoding of a framing, which looks like the cleanest available, returns the system's maximum surplus for every subject and therefore measures nothing** [Curzi, 2026]. That result bounds what any mode-ladder analogy in this paper may be taken to license.

33.6.9 6.9 Nothing is added, nothing is powered

The framework's cost argument for geometric function is:

```
Powered function:   C_t = c_energy + c_maint + c_replace + c_failure , every period
Geometric function: C_t = c_clean                                    , every period
                    plus a one-time capital charge at t = 0
```

The Casimir effect is the limiting case of the second line. **Two plates, once placed, exert their force forever, with `c_energy = 0`, `c_maint = 0`, `c_replace = 0`, and a `delta` set by material durability alone.** There is no switch and nothing to fail.

The other half of that statement is what keeps it from becoming a free-energy claim: the force is conservative. Letting the plates come together releases energy; pulling them apart costs exactly that energy back. There is no cycle, no net extraction and no engine. A shape performs work for free; a shape does not produce energy for free.

The corpus's own priced version of geometric function is the threshold-as-impedance-match result: worst-junction reflection across a 1-to-100 character change falls from 96 per cent to 13 per cent when the change is divided into six equal-ratio steps, which is a design gain obtained by geometry and paid for once [Curzi, 2026f]. That is the same cost structure, in a domain where the framework can measure it.

33.6.10 6.10 Geometry dependence, repulsion, and the moving boundary

If boundary geometry is the whole story, then changing the geometry should change the answer in ways not derivable by scaling the parallel-plate result. It does.

The sign is not fixed. For a perfectly conducting spherical shell the Casimir energy has the opposite sign to the parallel-plate case: the shell tends to expand rather than contract. **A force that is attractive between plates and repulsive for a sphere is not a property of the material. It is a property of the shape.**

Repulsion has been measured, between a gold sphere and a silica plate immersed in bromobenzene, in the configuration Lifshitz theory predicts to be repulsive — when the intervening fluid's dielectric response lies between those of the two surfaces. **The direction of the**

force was reversed by changing the arrangement of the boundaries and the medium. Nothing else changed.

Non-additivity. Casimir forces do not add pairwise. The proximity-force approximation, which treats a curved surface as a stack of parallel-plate elements, is only an approximation and fails for strongly structured geometries; the Casimir piston is the exactly solvable geometry that makes this vivid, and corrugations, gratings and lateral offsets produce forces including lateral components that no parallel-plate calculation predicts. **The geometry is not a parameter in the calculation. The geometry is the calculation.**

The dynamical case. A moving boundary should not merely select modes but mix them, converting virtual excitations into real photons. The requirement is severe: the mirror must move at speeds comparable to the phase velocity of the field, which is unachievable mechanically. The effect was observed by moving the boundary without moving anything material — a superconducting waveguide terminated by a flux-tunable element acting as an effective electrical boundary, modulated at gigahertz rates, producing the predicted two-mode-squeezed photon output. **The physical content is the same content as the static case, differentiated once: a static boundary determines which modes exist; a boundary that changes in time pumps energy between them.**

Here, uniquely, an architectural transfer can be stated honestly. A room's variable elements — a movable panel, an opened door, a drawn curtain — change the mode structure, and the change is what an occupant hears as the room opening up. **A boundary that moves does something a boundary that sits still cannot. That statement is true in a superconducting waveguide and true in a room, for the same reason: the mode structure is a function of the boundary, so a time-dependent boundary is a time-dependent mode structure.** It is not a claim that a moving wall creates photons; it is a claim about the functional dependence, and the functional dependence is the same.

33.6.11 6.11 What the Casimir effect establishes, and the three transfer strengths

```
WHAT CASIMIR ESTABLISHES

 1. Boundary geometry alone determines which field modes can exist.        PROVEN
 2. That determination has measurable physical consequence.               MEASURED
 3. Nothing is added, powered, or applied to produce it.                   PROVEN
 4. The effect depends on the SHAPE, not only on the size: the sign
    itself is geometry-dependent, and repulsion has been measured in
    the predicted configuration.                                          MEASURED
 5. A time-dependent boundary pumps modes, observed with an
    effective, electrically tuned mirror.                                 MEASURED

WHAT IT DOES NOT ESTABLISH

 6. That the force matters at biological scale.        IT DOES NOT. Sec 6.5.
 7. That the force matters at architectural scale.     IT DOES NOT. Sec 6.5.
 8. That energy can be extracted from the vacuum.      IT CANNOT. Sec 6.9.
 9. That "everything is vibration" in any usable
    sense, or that intention shapes fields.           NOT A CLAIM OF PHYSICS.
10. That the mode-selection principle CERTIFIES any
    particular architectural geometry.                IT DOES NOT.
```

The three transfer strengths, which must be distinguished in print every time:

```
(a) EM modes between plates          -- proven and measured
(b) acoustic modes in a room         -- the SAME equation, measured
```

```
(c) occupancy / circulation patterns -- SPECULATIVE, badged, and it must
                                       never inherit the credibility of (a)
```

The one thing the framework takes from the Casimir effect is that the shape is the function — proven for electromagnetic modes between plates, proven for acoustic modes in rooms because it is the same equation, and offered as a design heuristic everywhere else with its badge on. That form and function are related by geometry rather than by mechanism is an old claim in a respectable literature [Thompson, 1917]; what the Casimir effect adds is an instrument.

33.7 7 Failure modes: a register

The three preceding sections each generate a characteristic set of errors. They are collected here as a register because the register, rather than any individual number, is what a reviewer or an editor can apply. Each entry gives the signature, a diagnostic that can be run in one step, and the remedy. Numbering follows the section that generates the fault.

33.7.1 7.1 Faults in the use of the formalism

FM-4.1 The observer equivocation. *Signature:* a text uses "observer" in the technical sense in one sentence and in the mentalistic sense in the next, without marking the shift. *Diagnostic:* substitute "photodiode" for every occurrence of "observer"; if the argument still works it was technical, and if it collapses into nonsense it was running on the equivocation. *Remedy:* define the term at first use in every document, and apply the substitution test as a review gate. This is the load-bearing move in nearly every quantum-manifestation claim in circulation.

FM-4.2 Superposition as metaphor sold as physics. *Signature:* "hold both possibilities in superposition until you choose." *Diagnostic:* **the tell is that no interference term is ever computed, because there is nothing to compute it from.** *Remedy:* permitted as an explicitly flagged metaphor, in the same sentence as the flag. The honest version already exists and is better — a weighted branch set with an effective count (Section 4.10).

FM-4.3 The interpretation cherry-pick. *Signature:* Everett invoked to license "all possibilities are real", and consciousness-collapse invoked a paragraph later to license "your observation selects one." *Diagnostic:* **these are incompatible — Everett has no collapse and therefore no selection; consciousness-collapse has one world and therefore no other branches.** *Remedy:* name the interpretation, name what it abandons, and check consistency across the whole document rather than sentence by sentence.

FM-4.4 The Born rule as wish-weighting. *Signature:* the amplitude treated as something an agent can adjust. *Diagnostic:* **there is no operation in the formalism that raises an amplitude by preference; amplitudes change under unitary evolution generated by a Hamiltonian, and no Hamiltonian contains a term for wanting.** *Remedy:* demand the Hamiltonian term. The channel requirement of Curzi [2026ab] applies verbatim, and its forbidding clause — no channel, no effect — disposes of the claim without any appeal to taste.

FM-4.5 Entanglement as telepathy. *Signature:* "entangled particles communicate instantaneously; therefore minds can." *Diagnostic:* the first clause is already false; correlated results are recovered only by comparing records through a classical channel, and before that comparison each side's statistics are exactly what they would have been with no entanglement at all. *Remedy:* cite no-signalling by name, every time. It is the shortest complete refutation available and it is interpretation-independent.

FM-4.6 Precedent presented as evidence. *Signature:* an old text quoted alongside a modern result and the pair described as confirmation. *Diagnostic:* ask which column the old text sits in. *Remedy:* the audit format of Appendix B, in which the precedent row is labelled as precedent and the neutral row states what each column can carry. **This is the failure most**

likely to discredit the corpus's comparative material, and Appendix B, audit B3, is the worked case of a bridge rejected in print.

FM-4.7 The linearity leak. *Signature:* a proposal quietly requires non-linear evolution, usually in order to obtain signalling or preference-sensitive dynamics. *Diagnostic:* does the proposal claim that `U(a|psi_1> + b|psi_2>)` is anything other than `aU|psi_1> + bU|psi_2>`? *Remedy:* **non-linear modifications of quantum mechanics generically permit superluminal signalling and are strongly constrained experimentally.** The proposal is not merely unsupported; it is in tension with results already in hand, and it must be presented as a different theory.

FM-4.8 Collapse by attention. *Signature:* the quantum Zeno effect — repeated rapid measurement inhibiting transitions, a real measured phenomenon — cited as evidence that watching changes outcomes, and thence that mental attention does. *Diagnostic:* ask what the measuring interaction is and at what rate it is applied. **The effect requires repeated physical interaction faster than the transition timescale; it is done with lasers and photodetectors, and nothing about it involves noticing.** *Remedy:* if the interaction cannot be named in physical units, the citation is decorative.

33.7.2 7.2 Faults in coherence claims

FM-5.1 The isolated-system fallacy. *Signature:* a quantum argument about a biological system with no statement of what that system is coupled to. Textbooks solve isolated problems, and the reader imports the idealisation without noticing it was one. *Diagnostic:* what is the environment, and what is the coupling? *Remedy:* fields (i) and (ii) of the gate, enforced as a submission requirement. A proposal that cannot name the environment has not begun.

FM-5.2 The missing timescale. *Signature:* a coherence claim with no number attached. *Diagnostic:* the absence of a single number, which is often the point. *Remedy:* fields (iii) to (v). **In every case examined for this paper the ratio came out between `1e9` and `1e16`.**

FM-5.3 Decoherence presented as a solution. *Signature:* "decoherence solved the measurement problem." *Diagnostic:* ask which diagonal element changed. None did. *Remedy:* state that decoherence explains the absence of macroscopic interference and the preferred basis and does not select an outcome; and note the logical point, which is decisive — **decoherence is derived from M2, so it cannot resolve a contradiction caused by M2.**

FM-5.4 The exception generalised. *Signature:* "quantum biology is real, photosynthesis proves it, therefore quantum consciousness is plausible." Two true clauses and a non-sequitur. *Diagnostic:* run the table of Section 5.10 — spatial ratio ~`1e4`, temporal ratio ~`1e9`, and a degree-of-freedom row that changes from a spin or an exciton in a rigid scaffold to a charge displacement across a wet membrane. *Remedy:* note the fourth row: the exception cases have an evolved protective scaffold and cognition has no proposed one.

FM-5.5 The contested result cited as settled. *Signature:* the 2007 photosynthesis result cited without the vibronic reinterpretation, or the 2021 cryptochrome result cited as though the avian compass were established in vivo rather than as an in-vitro protein measurement. *Diagnostic:* is the contest named in the same passage? *Remedy:* cite the contest with the claim, every time. **This is a citation-integrity failure and it is the kind a hostile reviewer finds first.**

FM-5.6 The prefactor objection. *Signature:* a defender attacks the cross-section, the geometry or the scattering model — correctly noting that these are approximate — and treats the approximation as though it rescued the claim. *Diagnostic:* ask how many orders of magnitude the correction is worth; honest answers are one to three. Then ask how many are needed; the answer is nine to sixteen. *Remedy:* **concede the prefactor and keep the conclusion, because the conclusion never depended on the prefactor.** This is H2 of Section 2 and it is stated proactively so that the objection is answered before it is raised.

FM-5.7 Coherence as institutional metaphor, unbadged. *Signature:* this framework's own risk. "The team lost coherence"; "the institution decohered" — used without a badge and drifting from analogy to explanation across successive drafts. *Diagnostic:* search every occurrence and check which category of Section 3.3 is attached. *Remedy:* badge it in the sentence, or use `delta` and say what is actually being lost.

FM-5.8 The cold-system bait and switch. *Signature:* a result obtained at 77 K, at 4 K, or in ultra-high vacuum cited as evidence for what happens at 310 K in water. *Diagnostic:* check the temperature and pressure in the methods section of the cited paper. **The `T^9` scaling makes 77 K easier than 300 K by a factor of `2.07e5` for the photon channel alone, and removing the gas removes the collisional channel entirely.** *Remedy:* require the operating conditions of every cited coherence measurement to be stated alongside the result.

33.7.3 7.3 Faults in the use of the Casimir effect

FM-6.1 Casimir invoked as a biological force. *Signature:* a claim that vacuum fluctuation forces do work in cells, structure water, or organise membranes, sometimes dressed with the 10 nm row of the pressure table, which does look impressive at 1.28 atmospheres. *Diagnostic:* three questions — what is the separation, are the surfaces mirrors, is the medium vacuum? For biology the answers are: more than 10 nm, no, and no. *Remedy:* quote the honest limit verbatim and give the ratio to osmotic pressure, `5.947e4`, computed with the *ideal* value so that the concession is maximally generous and still decisive.

FM-6.2 Zero-point energy extraction. *Signature:* "the Casimir effect proves the vacuum contains energy; therefore it can be tapped." *Diagnostic:* ask for the cycle. Plates in, energy out; plates back out, and the energy is returned. There is no third step. *Remedy:* refuse in the plain words — this is a perpetual motion machine.

FM-6.3 The ideal-mirror number quoted in a real setting. *Signature:* `1.3e5` Pa at 10 nm quoted without the phrase "perfectly conducting plates in vacuum at zero temperature." *Diagnostic:* is the assumption attached to the number? *Remedy:* attach it in the same line of the table. **The finite-conductivity correction is a factor of order two for gold near 100 nm and worse below; the biological correction is one to three orders; quoting the ideal number in a real setting overstates by between two and three orders of magnitude.**

FM-6.4 The analogy upgraded by reuse. *Signature:* the framework's own characteristic risk. "The room selects modes just as the plates do" is exact; three drafts later it has become "the room selects social modes just as the plates do", and the badge has fallen off in transit. *Diagnostic:* search every occurrence of the mode-selection claim and check which of the three transfer strengths is attached. *Remedy:* apply the check on every draft, not once at the start.

FM-6.5 Proportion mysticism. *Signature:* a room specified by a ratio system and declared acoustically correct on that basis. *Diagnostic:* compute the mode list. Section 6.7 does exactly this: **the golden box has no degeneracies but only 23 modes below 120 Hz against the plain box's 39, and a largest gap of 16.37 Hz against 8.89 Hz — its proportions are more admired and its low-frequency support is worse.** *Remedy:* generate with the ratio system, certify with the computation [Markowsky, 1992].

FM-6.6 The cube. *Signature:* a cubic or near-cubic room, usually chosen for plan efficiency or symmetry. *Diagnostic:* a 5 m cube has 27 of its 38 modes below 120 Hz coincident with another mode, so energy stacks at those few frequencies and the room booms at them. *Remedy:* break the symmetry; any set of three mutually incommensurate dimensions removes the degeneracies. **This is the cheapest acoustic intervention available, because it costs nothing at design time and cannot be retrofitted at any price.**

FM-6.7 Precedent presented as evidence, the monochord case. *Signature:* "the Pythagoreans knew about the Casimir effect." *Diagnostic:* a category error, and the section is unusually exposed to it because its precedent is unusually strong. **A strong precedent is more dangerous than a weak one, not less, because it is more tempting to promote.** *Remedy:* the monochord recorded that boundary position alone sets the mode ladder; that is precedent, it is impressive, and it is not evidence for anything about vacuum fluctuations.

FM-6.8 The static-configuration audit. *Signature:* a room with movable partitions, folding doors or retractable panels has its mode list computed once, in the configuration shown on the drawing. *Diagnostic:* ask how many configurations the room has and compute the list for each. *Remedy:* in practice the worst configuration is the one used most, because it is usually the closed one.

33.8 8 Results: three audits worked end to end

Three proposals are audited against the apparatus of Sections 4 to 7. **All three parameters of each case are stipulated by the proposal or by the worked brief; nothing in this section is a field observation, and no dataset was collected.** The purpose is to show that the procedure runs, that it reaches a disposition, and that it reports the disposition whichever way it falls.

33.8.1 8.1 A proposal resting on the formalism

The proposal, as submitted: *since the future exists as a superposition of possible outcomes, and since the act of conscious observation collapses the wave function, sustained focused belief on a chosen outcome raises its amplitude and therefore its probability of manifesting.* The proposer has read popular physics carefully and is arguing in good faith, so the audit is a real one rather than a dismissal.

Step 1 — separate formalism claims from interpretation claims.

CLAIM	TYPE	VERDICT
(a) the future is a superposition	formalism	FALSE AS STATED
(b) observation collapses the wave function	interpretation	ONE reading only
(c) conscious observation does it	interpretation	MINORITY, no evidence
(d) focused belief raises an amplitude	formalism	NO SUCH OPERATION
(e) higher amplitude -> higher probability	formalism	TRUE (Born rule)

Only (e) is correct, and (e) is the only one doing no work in the argument.

Step 2 — audit (a). A quantum system's state may be a superposition with respect to some observable. A future course of events at human scale is not a quantum state of anything anyone has written down: there is no Hilbert space here, no Hamiltonian, and no observable named. **A claim about superposition that cannot name the Hilbert space is not a quantum claim; it is a probability claim wearing quantum vocabulary, and it should be evaluated as one.** That evaluation is available immediately, in Section 4.10.

Step 3 — audit (b) and (c). (b) is the collapse postulate, one interpretive option out of at least four, abandoning M2; Everett has no collapse, Bohm has no collapse, and GRW's collapse is spontaneous and has nothing to do with observation. Presenting collapse as a fact of nature rather than as a choice is FM-4.3. (c) is von Neumann–Wigner, and all five reasons of Section 4.8 apply. **The evidence column for this claim is empty. The empty cell is printed.**

Step 4 — audit (d), which is where the proposal dies. This step requires no interpretive dispute to be settled. The formalism has exactly two ways for amplitudes to change: unitary evolution generated by a Hamiltonian, and the interpretation-dependent update on measurement. **For belief to raise an amplitude, belief must appear in the Hamiltonian. There is no such term, no proposal for one, and no measured coupling constant to put in front of it.**

```
BELIEF  ->  [ CHANNEL ]  ->  WORLD

proposed channel : quantum amplitude modification by attention
channel exists?  : NO. No coupling, no term, no constant, no measurement.
gain             : undefined -- there is nothing to estimate.
conclusion       : NO CHANNEL, NO EFFECT.
```

The grounding postulate's conditional clause does the entire work here, and it does it without any appeal to taste. The postulate is that belief creates reality if the belief is grounded in truth; in magnitude form it is `E = G B` with the forbidding clause that `G = 0` implies `E = 0` for every `B` [Curzi, 2026ab]. **It is a postulate, badged as one in the paper that owns it and treated as one here.** This audit does not violate it; it applies it, and the application returns a rejection.

Step 5 — the timescale objection. Even granting some quantum mechanism at the neural level, Section 5 applies: a microtubule-scale superposition in water at body temperature has an estimated coherence time of `1.98e-17` seconds against an action potential of about `1e-3` seconds, a ratio of `5.04e13`. **The proposal needs a quantum state to survive fifty trillion times longer than the estimate allows, in the warmest and wettest environment in the argument.**

Step 6 — the honest reconstruction, because there is one. The proposer's practical intent — hold the intended outcome vividly, act consistently with it, and expect it — is not empty, and it has real measured channels.

```
1. Represent the future as a weighted branch set, not a superposition.
   Two branches, weights p and 1-p. Compute N_eff = e^H (Section 4.10).
   No hbar.

2. Name the channel by which belief could act on the branch weights:
     - physiological: expectancy -> endogenous opioid release, and the
       naloxone-reversibility result that establishes the channel
     - behavioural:   belief -> altered action -> altered outcome frequency
     - social:        stated commitment -> others' expectations -> coordination
     - informational: attention -> different sampling -> different information
   Each is a real coupling with a real gain. NONE is quantum.

3. Estimate the gain. Predict a magnitude in advance.

4. Preregister. Freeze the model. Score held-out against four baselines
   including a shuffled-input control.

5. Report the result whichever way it comes out.
```

That the expectancy channel is real and that expectancy effects are measurable is established, and so is the fact that they are easy to over-read [Rosenthal and Jacobson, 1968, Rosenthal and Fode, 1963, McCambridge et al., 2014]; the preregistration discipline that keeps step 4 honest is Nosek et al. [2018], and the failure modes it exists to prevent are Simmons et al. [2011] and Gelman and Loken [2013]. The corpus's own instance of that protocol, applied and **failed**, is Curzi [2026i].

Step 7 — the numbers, carried to the end. Suppose the target is a binary outcome currently judged at `p = 0.25`.

```
p = 0.25   ->  H = 0.562335 nats = 0.811278 bits  ->  N_eff = 1.7548
```

The claim, made specific: the practice raises `p` to 0.40 within twelve weeks. That is now a preregisterable statement with a magnitude, and the branch set has an effective count that can be tracked. If the mechanism is behavioural, the claim is plausible, testable and squarely inside the grounding postulate. If the mechanism is amplitude modification by attention, it is outside, and Step 4 already closed it.

```
FINAL DISPOSITION

quantum mechanism           REJECTED. No channel. FM-4.4, FM-4.1, FM-4.3.
consciousness-collapse      REJECTED as a basis. Minority interpretation, no
                            evidence, empty evidence cell, and its own advocate
                            abandoned it.
weighted-branch practice    ACCEPTED FOR TEST under the preregistration protocol.
behavioural channel         ACCEPTED as a candidate mechanism with a real gain,
                            to be estimated and measured.

The proposal loses its physics and keeps its practice.
```

33.8.2 8.2 A proposal resting on protected coherence

A better-formed proposal, because it names a mechanism: *coherent vibrational states in tubulin dimers within neuronal microtubules persist long enough to be functionally relevant, are protected from decoherence by ordered water and by the hydrophobic pockets of the protein, and provide a substrate on which cognition supervenes.* This is close to a real position with published defenders, and it gets the full five-field audit.

Step 1 — the five required fields.

```
(i)   degree of freedom      : vibrational / dipole states of tubulin dimers
(ii)  environment            : cytoplasmic water at 310 K, dissolved ions
                               (~150 mM), the rest of the lattice, thermal photons
(iii) estimated tau_dec      : to be computed -- Step 2
(iv)  functional timescale   : 1e-3 s (a spike) at the very shortest
(v)   ratio                  : to be computed -- Step 3
```

The proposal is well formed, which is more than most, and that is why it can be audited at all.

Step 2 — compute the estimate. A microtubule segment, taking a 25 nm by 100 nm face as the effective cross-section, in water at 310 K:

```
n     = 3.3428e+28 /m3
v_bar = 603.6 m/s
sigma = 2.500e-15 m2
-------------------------------------
Gamma = n * sigma * v_bar = 5.044e+16 /s
tau   = 1 / Gamma         = 1.982e-17 s
```

Cross-checked against the thermal time: `1.982e-17 / 2.464e-14 = 8.0e-4`. **The estimate is a thousandth of the thermal time at body temperature, which is the expected order for an object of this size in a dense liquid, so it is not an outlier requiring special pleading.**

Step 3 — the ratio. `1e-3 / 1.982e-17 = 5.04e13`, with off-diagonal suppression over one spike of `exp(-5.044e13)`. **The proposal requires the state to survive fifty trillion decoherence times.**

Step 4 — audit the proposed protection. Take the defence seriously and ask what it would have to buy.

- **Ordered water is still water.** Its librational band is at `1.80e13` Hz and its OH stretch at `1.02e14` Hz; hydrogen bonds rearrange on a picosecond. Ordering changes the correlation structure of the bath; it does not decouple the bath.
- **A hydrophobic pocket is nanometres across.** It can shield a small internal degree of freedom. It cannot shield a lattice-scale collective mode, which is what the proposal requires, because the mode extends across the region the pocket does not cover.
- **The quantitative demand is the problem.** Even granting a protection factor of `1e6` — far beyond anything demonstrated for a charge-displacing degree of freedom in water — the remaining shortfall is `5.04e13 / 1e6 = 5.04e7`. **Seven orders of magnitude still missing, after a concession of six that nobody has earned.**

Compare the case where protection genuinely works: the radical pair survives for microseconds because it uses electron spin, which has no electric dipole and is therefore barely watched by a polar solvent. **That is a real protection mechanism and it is structural. The tubulin proposal's degree of freedom is a dipole state — precisely the kind that water monitors best.**

Step 5 — the falsification condition. H1 states what would overturn this section: a replicated demonstration of functional quantum coherence above `1e-6` s in an unrefrigerated, unengineered biological system at 310 K.

```
what the proposal needs        1e-3 s
what H1 would accept as
overturning the account        1e-6 s
what is estimated              1.98e-17 s
what has ever been measured
in a warm biological system    ~3e-13 s (contested; and vibronic on the
                               leading current reading)

the proposal is 11 orders beyond the best CONTESTED measurement, and
3 orders beyond even the threshold set for overturning the account.
```

Step 6 — disposition.

coherence claim	REJECTED. Ratio 5.04e+13. FM-5.1 not triggered (environment named), FM-5.2 not triggered (timescale computable), FM-5.6 anticipated and conceded -- the prefactor is worth 1-3 orders and 13 are needed.
protection mechanism	REJECTED as insufficient by 7 orders of magnitude even after granting a 1e6 protection factor that has not been demonstrated.
the proposal is well-formed	ACKNOWLEDGED. It named its degree of freedom, its environment, and its functional timescale.
what survives	MICROTUBULES ARE INTERESTING FOR CLASSICAL REASONS. They are the cell's mechanical lattice; they transmit force; motor proteins walk along them; and force applied at the cell surface reaches the nucleus through the cytoskeleton and alters transcription. NONE OF THAT REQUIRES COHERENCE, and all of it is measured.

33.8.3 8.3 A brief resting on boundary geometry, in which the principle survives

A 121 cubic metre studio room, 7.0 x 5.4 x 3.2 metres, is to serve as a rehearsal and listening space. The client has read about Casimir forces and asks whether vacuum-energy geometry can improve the acoustics.

Step 1 — answer the Casimir question and close it.

```
Casimir pressure between the two long walls (7.0 m apart):

  T = 0 formula   P = 1.300126e-27 / 7.0^4 = 5.416e-31 Pa
  high-T (300 K)  P = zeta(3) kB T / (4 pi * 7.0^3) = 1.155e-24 Pa   <- correct one

  wall area 5.4 x 3.2 = 17.28 m^2
  total force = 1.155e-24 * 17.28 = 1.996e-23 N

  for comparison: one E. coli on the wall weighs 9.807e-15 N
  ratio = 4.9e+08
```

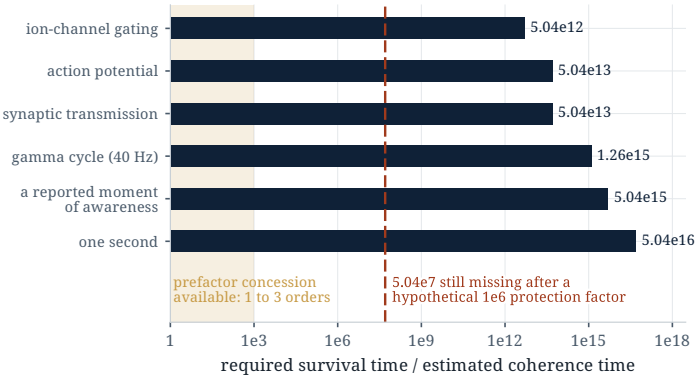

Figure 33.5: **The audit's decisive quantity is a ratio, and every concession available to the proposal leaves it losing.** Required survival time over estimated coherence time, for six neural processes against `tau_dec = 1.98e-17 s`: `5.04e12` for ion-channel gating up to `5.04e16` for one second. The prefactor concession available to a defender is worth one to three orders (shaded band); a hypothetical `1e6` protection factor still leaves `5.04e7` for the action potential. Computed from the ratio table of Section 5.6; generated by `figs/src/CCP-033_fig05.py`.

The entire Casimir force across this room is five hundred million times smaller than the weight of a single bacterium resting on the wall. The answer is no, and it is not a close call.

Step 2 — supply the principle the client was reaching for. The intuition was that geometry alone can do acoustic work without equipment. **That intuition is correct; it was attached to the wrong physics.** The correct attachment is Theorem 6.1, which the Casimir effect establishes for electromagnetic modes and which holds identically for sound because it is the same boundary-value problem.

Step 3 — compute the mode list.

```
f(nx,ny,nz) = (343/2) * sqrt( (nx/7.0)^2 + (ny/5.4)^2 + (nz/3.2)^2 )

 24.50 Hz  (1,0,0) axial        63.52 Hz  (0,2,0) axial
 31.76 Hz  (0,1,0) axial        66.94 Hz  (1,1,1) oblique
 40.11 Hz  (1,1,0) tangential   68.08 Hz  (1,2,0) tangential
 49.00 Hz  (2,0,0) axial        72.62 Hz  (2,0,1) tangential
 53.59 Hz  (0,0,1) axial        73.50 Hz  (3,0,0) axial
 58.39 Hz  (2,1,0) tangential   79.26 Hz  (2,1,1) oblique
 58.93 Hz  (1,0,1) tangential   80.07 Hz  (3,1,0) tangential
 62.30 Hz  (0,1,1) tangential   80.22 Hz  (2,2,0) tangential

REQUIRED REPORT:
  modes below 100 Hz            25
  mean spacing below 100 Hz     3.08 Hz
  largest gap                   8.89 Hz
  coincident (degenerate) modes 0
```

Zero degeneracies, achieved by the choice of three numbers and by nothing else. The alternative the client's architect had proposed, a 5 metre cube of similar volume, has 27 coincident modes out of 38 below 120 Hz.

Step 4 — reverberation and the modal boundary.

```
V = 120.96 m^3 , S = 154.96 m^2 , RT60 = 0.161 V / A
```

```
mean absorption   A (m^2 sabins)   RT60 (s)   Schroeder f (Hz)
  0.10              15.50            1.257       203.9
  0.20              30.99            0.628       144.2
  0.35              54.24            0.359       109.0
```

The Schroeder frequency divides the modal region below, where individual modes are audible as resonances, from the statistical region above, where reverberation theory applies [Schroeder, 1965, Sabine, 1922]. **At the target absorption of 0.35 the Schroeder frequency is 109.0 Hz, and there are 25 discrete modes below 100 Hz with a mean spacing of 3.08 Hz and no coincidences: the modal region is well populated and evenly filled.** That result was obtained from four numbers — three dimensions and one absorption coefficient. **The absorption figure of 0.35 sits above the 0.25 threshold at which Sabine should give way to Eyring, so the RT60 values in the table are Sabine values used above their reliable range and are reported as such** [Curzi, 2026e].

Step 5 — the tuned-vessel option and its honest status. The client asks about the bronze vessels specified in Vitruvius. **Precedent:** a Roman engineer wrote down that vessel geometry selects pitch and used it as a design element. It is not recorded that the theatres sounded better, and the acoustic evidence for the efficacy of these vessels is not established. **Precedent, not evidence. Evidence:** the Helmholtz resonator is real, its formula is measured, and its resonance is a function of geometry alone [von Helmholtz, 1885, Rossing et al., 2002]:

```
f = (c / 2pi) * sqrt( A / (V * L_eff) ),   L_eff = L_neck + 1.7 * r_neck

neck  20 mm, volume  1.0 L, neck length  50 mm  ->  118.21 Hz
neck  30 mm, volume  2.0 L, neck length  60 mm  ->  110.99 Hz
neck  50 mm, volume  8.0 L, neck length  80 mm  ->   77.27 Hz
neck 100 mm, volume 50.0 L, neck length 120 mm  ->   47.79 Hz
```

A fifty-litre vessel with a hundred-millimetre neck resonates at 47.79 Hz — between the (0,1,0) axial mode at 31.76 Hz and the (2,0,0) at 49.00 Hz. Sized and damped as an absorber it targets the low-frequency region where porous absorption is useless, because the required material thickness scales with wavelength. Its honest status: the resonance is established and computed; whether these vessels improve this room requires measurement in this room.

Step 6 — the variable-geometry audit. The room has a folding partition dividing it at 4.0 m.

```
CONFIGURATION A -- open, 7.0 x 5.4 x 3.2
  lowest axial mode 24.50 Hz ; 25 modes below 100 Hz ; 0 degenerate

CONFIGURATION B -- divided, 4.0 x 5.4 x 3.2
  lowest axial mode = 343/(2*4.0) = 42.88 Hz
  the entire 24.50–42.88 Hz region is EXCLUDED. Not attenuated: excluded.
```

Closing the partition does not damp the low end. It abolishes it, by removing the boundary separation that permitted it to exist. That is Theorem 6.1 operating at room scale, at zero cost, in either direction, as many times as the partition is moved.

Step 7 — disposition.

```
Casimir force as a design mechanism    REJECTED. 1.996e-23 N across the room;
                                       4.9e+08 times smaller than a bacterium's
                                       weight.

Casimir as the demonstration of
mode selection by boundary             ACCEPTED, and the reason the client's
                                       intuition was worth taking seriously.
```

```
room dimensions 7.0 x 5.4 x 3.2        ACCEPTED. 25 modes below 100 Hz, mean
                                       spacing 3.08 Hz, largest gap 8.89 Hz,
                                       ZERO degeneracies. The cube alternative
                                       had 27 coincidences out of 38.

absorption target 0.35 mean            ACCEPTED. RT60 = 0.359 s (Sabine, above
                                       its reliable range), Schroeder 109.0 Hz.

Helmholtz absorbers at 47.79 Hz        ACCEPTED FOR PROTOTYPING, with the
                                       obligation to measure in this room
                                       before committing.

Vitruvian vessels as justification     REJECTED AS EVIDENCE, RETAINED AS
                                       PRECEDENT.

variable-geometry mode audit           REQUIRED IN BOTH CONFIGURATIONS.

TOTAL POWER CONSUMED BY EVERY ACOUSTIC MEASURE ABOVE : ZERO.
```

33.8.4 8.4 The gate in general form

```
THE DECOHERENCE GATE

1. Name the degree of freedom.
2. Name the environment and the temperature.
3. Compute tau_dec = 1 / (n * sigma * v_bar), or state a better model
   and compute it.
4. Divide by hbar/kT at that temperature as a sanity check.
   At 310 K that is 2.464e-14 s.
5. Name the functional timescale required.
6. Compute the ratio and print it.
7. Concede the prefactor: 1-3 orders. Ask whether the conclusion
   survives the concession.
8. If the proposal invokes protection, ask what degree of freedom the
   environment couples to, and whether the proposed degree of freedom is
   one the environment barely watches (spin) or one it watches best
   (charge displacement).
9. State the disposition in writing, and state what result would reverse it.
```

Applied to the two coherence proposals above, the gate returned a rejection in both cases and returned it for a different reason each time: the first failed at step 1, having no degree of freedom to name, and the second passed steps 1 to 6 and failed at step 8.

33.9 9 Discussion

33.9.1 9.1 What follows

The corpus's quantum vocabulary is now audited against the original, and the audit is unfavourable to every use of it except one. The conjugate-structure material is Fourier duality and was already badged as such [Curzi, 2026z]; this paper supplies the reason the badge is required rather than merely prudent. The branch-weight construct is a probability distribution with an effective count, and its effective count is the Hill number of order one, which is grounded [Hill, 1973, Jost, 2006]. Neither needs `hbar` and neither gets it.

The decoherence result is a constraint the corpus imposes on itself and on its readers. The five-field gate of Section 8.4 is not a rhetorical device: it converts an unfalsifiable claim into a computation with a stated disposition, and in both applications above it returned a rejection with a different failure point each time. **A gate that rejected everything for the same reason would be a prejudice; a gate that locates the specific step at which each proposal fails is doing work.**

The pattern across all three sections is the same and it is deliberate: each computes its own most attractive analogy into the ground. That is the corpus's standing practice rather than this paper's innovation, and the sharpest instance elsewhere is a paper that refuses a celebrated historical anecdote as a fabricated data point, rejects its own unified-hand reading at 1,365 to 1, badges a 25 per cent currency-inflation figure as an artefact of a chosen synthetic ratio rather than a constant, and reports its confusable-only check reaching only 58.99 per cent [Curzi, 2026]. **A section that survives only claims it did not test is not a section worth citing, and this paper's counter-result is the load-bearing part of it.**

The Casimir result splits into a refusal and a principle. The refusal is total: the force is `1.996e-23` newtons across a seven-metre room and `0.027` piconewtons on a realistic ten-nanometre biological patch, which is 0.45 per cent of a single kinesin motor's stall force. The principle is exact within the domain where the Helmholtz problem governs, and it is the one thing this paper gives the corpus's architectural material that is stronger than an analogy. **The room-mode equation is not like the Casimir mode count; it is the Casimir mode count, solved for a different field.**

33.9.2 9.2 What does not follow

Nothing here licenses the extension of mode selection to social structure. Postulate 6.1 is badged, it stays badged, and Section 11 records that the corpus's external bibliography contains no support for the extension. An occupancy pattern is not a solution of a wave equation, and the formal identity that makes Section 6.7 a derivation is precisely what the extension lacks.

Nothing here shows that the corpus's biological material is correct. It shows that the material does not depend on quantum mechanics, which is a much weaker statement and the only one the computation supports. The corpus's own biological papers carry their own limits — that acoustic addressing of a cell fails on geometry rather than bandwidth [Curzi, 2026x], and that no mechanism is known by which a transcriptional response could depend on a symbol string as an order [Curzi, 2026] — and those limits are not softened by anything in this paper.

Nothing here settles the measurement problem, and the paper takes no position on it. The half that is open is genuinely open. What the paper establishes is that its openness is bounded by theorems in every direction that would otherwise supply licence.

And the decoherence estimate is an estimate. It is a saturated-collision model with a geometric cross-section, imported from a gas into a liquid, and its prefactor is uncertain by one to three orders of magnitude. H2 says the conclusion survives that concession; it does not say the estimate is precise, and the difference matters wherever a number from Section 5.5 is quoted alone.

33.9.3 9.3 Relation to the surrounding literature

Three literatures bear on this paper and they pull in different directions.

The physics is not in dispute and the paper adds nothing to it. Where the corpus's bibliography holds the relevant entries — Casimir's original result and its two principal measurements, the founding decoherence paper, the uncertainty relation, the quantum algorithms that make coherence an engineering problem — they are cited. Where it does not, the works are named in the text with year and venue and no key is attached; Section 11 and Appendix C record the gap.

The critique of physics-in-social-science is directly relevant and largely supports this paper's method rather than opposing it. Anderson [1972] is the general form of Section 5.10: a law at one scale does not determine the behaviour of the structure built at the next. Cartwright [1999] is the general form of Section 3.3: physical laws hold where their premises hold. Mirowski [1989] and the econophysics critics [Gallegati et al., 2006, McCauley, 2006, Sobkowicz, 2009] document what happens when a formalism is imported without its premises, which is exactly the failure mode Section 7 catalogues. **This paper is on the critics' side of that argument about its own corpus.**

The measurement-theoretic objection applies to the corpus but not to this paper's physics. Michell [1997] is the strongest objection to the framework as a whole: psychology routinely assumes quantitative structure without testing for it, and the test that would settle it is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971], which has not been run for any construct in this corpus. The quantities in this paper — a coherence time, a pressure, a frequency — are ratio-scale physical quantities with SI units and are not exposed to that objection. **The corpus's own quantities are, and Section 11 says so rather than allowing this paper's dimensional cleanliness to be read as covering them.**

A fourth literature is relevant by its absence. The corpus's comparative material sets a modern result beside an older tradition, and the format of Appendix B exists to keep the two columns apart. **The general hazard is documented — a category into which people are sorted changes the people in it [Hacking, 1995] — and the specific hazard here is simpler: precedent read as evidence.** Appendix B, audit B3, is the case where the evidence column is empty and the precedent column is not, and it is printed that way on purpose.

33.10 10 Verification

The results of this paper compound from six postulates. Each is atomic, each is checkable on its own, and each carries its status. **Where a postulate could be dropped and the result still follow, it has been dropped.**

33.10.1 10.1 Dimensional audit

Every quantity in this paper carries an SI dimension, which is unusual in this corpus and worth stating as such. `[M]`, `[L]`, `[T]`, `[K]` and `[E]` denote mass, length, time, temperature and energy.

Symbol	Dimension	Unit	Status
`n`	`[L^-3]`	m^-3	**derived** from density and molar mass; `3.3428e28` for water
`sigma`	`[L^2]`	m^2	**assumed** geometric; the largest source of prefactor uncertainty
`v_bar`	`[L T^-1]`	m/s	**derived** from `sqrt(8 k_B T/(pi m))`
`Gamma_dec`	`[T^-1]`	s^-1	**derived**: `[L^-3][L^2][L T^-1] = [T^-1]`, so the product balances
`tau_dec`	`[T]`	s	**derived**, `1/Gamma`
`hbar/k_B T`	`[T]`	s	**derived**: `[E T]/[E] = [T]`; `2.464e-14` s at 310 K

Symbol	Dimension	Unit	Status
`rho_01`	`[1]`	none	**defined** dimensionless: an off-diagonal density-matrix element
`a`	`[L]`	m	**stipulated** separation
`P(a)`	`[M L^-1 T^-2]`	Pa	**derived**: `[E T][L T^-1]/[L^4] = [E]/[L^3] =` Pa
`lambda_T`	`[L]`	m	**derived**: `[E T][L T^-1]/[E] = [L]`; 7.63 um at 300 K
`A_H`	`[E]`	J	**cited** Hamaker constant, `5e-21` to `1e-20` J
`f(n_x,n_y,n_z)`	`[T^-1]`	Hz	**derived** from `c_sound` and three lengths
`RT60`	`[T]`	s	**derived** from `0.161` `V/A`, whose coefficient carries `[T L^-1]`

Do the equations balance? `Gamma = n sigma v_bar` gives `m^-3 . m^2 . m s^-1 = s^-1`: it balances, and there is no room in it for a free dimensional parameter. `P = pi^2 hbar c/(240 a^4)` gives `J s . m s^-1 / m^4 = J m^-3 = Pa`: it balances. `hbar/k_B T` gives `J s / J = s`. The room mode equation gives `m s^-1 . m^-1 = s^-1`. **The Sabine coefficient 0.161 is the one dimensionally awkward object in the paper: it carries units of s/m and is an empirical constant for air at ordinary conditions, not a dimensionless number**, which is why the same equation written for imperial units carries 0.049 instead.

Where the corpus has no operational unit, this paper does not supply one. The framework's own `Q` — stored order — is counted in whatever a declared proxy counts, and comfort has no operational unit at all. The correspondence of Section 5.11 relates a dimensionless ratio (`rho_01(t)/rho_01(0)`) to a dimensionless ratio (`Q_t/Q_0` under the transient term), which is the only reason the two can be set beside each other at all. **It is a comparison of ratios, not a conversion of units, and there is no exchange rate between a coherence and a runbook.**

33.10.2 10.2 The postulates

P1 — The number density of liquid water at 310 K is `3.3428e28` molecules per cubic metre. *Status:* **ARITHMETIC.** `1000 kg/m^3 / (0.01802 kg/mol) x 6.022e23 /mol = 3.342e28 /m^3`. A reader who prefers the density at 310 K (993.3 kg/m^3) obtains `3.32e28`, a 0.6 per cent difference which changes nothing.

P2 — The mean thermal speed of a particle of mass `m` at temperature `T` is `sqrt(8 k_B T/(pi m))`. *Status:* **CITED** — elementary kinetic theory. For water at 310 K it returns 603.5 m/s.

P3 — Above the thermal de Broglie wavelength, one scattering event resolves which branch a spatial superposition is in, so the decoherence rate saturates at the scattering rate `n sigma v_bar`. *Status:* **CITED** [Zeh, 1970], with the prefactor and the geometric cross-section badged as the estimate's weakest inputs. **This is the only postulate in the chain that carries a modelling assumption, and H2 exists to test whether the conclusion depends on it.**

P4 — `hbar/k_B T` at 310 K is `2.464e-14` s. *Status:* **ARITHMETIC.** `1.0546e-34 / (1.380649e-23 x 310) = 1.0546e-34 / 4.2800e-21 = 2.4640e-14`.

P5 — The Casimir pressure constant `pi^2 hbar c/240` is `1.300126e-27` J m. *Status:* **ARITHMETIC.** `9.8696 x 1.0546e-34 x 2.9979e8 / 240 = 1.300126e-27`, and the result is measured to

about 1 to 5 per cent [Lamoreaux, 1997, Mohideen and Roy, 1998, Casimir, 1948].

P6 — Between two boundaries separated by `L`, a field obeying the Helmholtz equation with a Dirichlet or Neumann condition admits perpendicular wavenumbers `k_n = n pi/L` and no others. *Status:* **DEFINITION** — the elementary solution of the boundary-value problem, true by construction and carrying no empirical weight on its own; its empirical weight comes from P5's measurement and from the room-acoustic measurements cited in Section 6.7.

33.10.3 10.3 The compounding chain

```
P1 + P2 + P3   -> L1   Gamma = n sigma v_bar; for sigma = 2.500e-15 m2,
                       3.3428e28 x 2.500e-15 x 603.6 = 5.0443e+16 /s        ARITHMETIC

L1             -> R1   tau_dec = 1/Gamma = 1.9824e-17 s ~ 1.98e-17 s        ARITHMETIC

R1 + (1e-3 s)  -> R2   ratio = 1e-3 / 1.982e-17 = 5.04e+13                  ARITHMETIC

R1 + P4        -> R3   tau_dec / (hbar/kT) = 1.982e-17 / 2.464e-14
                       = 8.0e-4, so the estimate is a thousandth of the
                       thermal time and is not an outlier                    ARITHMETIC

R2             -> R4   suppression over one spike = exp(-5.044e13);
                       visibility falls below 1e-3 after 6.9 tau and
                       below 1e-6 after 13.8 tau                             ARITHMETIC

Theorem 5.2    -> R5   tracing out the environment multiplies the
                       off-diagonals by <E_1|E_0> and the diagonals by 1,
                       so no population changes                              DEFINITION

P5             -> R6   P(a) = 1.300126e-27 / a^4; at a = 7.0 m the
                       zero-temperature value is 5.4149e-31 Pa               ARITHMETIC

P5 + zeta(3)   -> R7   the high-temperature limit zeta(3) kB T/(4 pi a^3)
                       at a = 7.0 m, T = 300 K is 1.1551e-24 Pa; over
                       17.28 m2 that is 1.9960e-23 N                         ARITHMETIC

R7             -> R8   one E. coli on the wall weighs 9.807e-15 N,
                       a ratio of 4.913e+08                                  ARITHMETIC

P6             -> R9   f_1 = v/(2L): 2.9979e8/(2 x 1e-7) = 1.4990e15 Hz
                       between plates at 100 nm; 343/(2 x 7.0) = 24.50 Hz
                       between walls at 7.0 m; ratio of answers = ratio of
                       wave speeds = 8.7403e+05                              ARITHMETIC

P6             -> R10  f(nx,ny,nz) = (c/2)sqrt(sum (n_i/L_i)^2): a 5.00 m
                       cube admits 38 modes below 120 Hz on only 11 distinct
                       frequencies, so 27 fall on an already-occupied
                       frequency; the 7.0 x 5.4 x 3.2 m box admits 39 on 39   ARITHMETIC
```

Every result in the chain is ARITHMETIC or DEFINITION, consuming two cited facts (P2, P3) and one cited measurement (P5). That is the strongest verification status any chain in this corpus reaches, and it is available only because the objects are physical quantities with SI units. **It also means the chain establishes nothing whatever about psychology, institutions, or belief.** The one place this paper touches a psychological claim — the correspondence of Section 5.11 — consumes none of these results and is labelled a claim about model form.

Three secondary checks a reader can run in a minute.

Tsirelson's bound. `2 sqrt(2) = 2.828427`, the maximum of the CHSH expression allowed by quantum mechanics against the classical bound of 2. One square root. **ARITHMETIC.**

The Casimir bookkeeping. `pi^2/720 = 0.013707783890` and `pi^2/(6 x 120) = 0.013707783890` are the same number, because `720 = 6 x 120` and `1/120` is the regularised value `zeta(−3)`; and `720/3 = 240`, the 3 being the exponent differentiated. **ARITHMETIC.**

The osmotic comparison. `7.732e5 / 13.001 = 5.947e4`. The ideal-mirror Casimir pressure at 100 nm is one part in sixty thousand of physiological osmotic pressure, and the ideal value is the generous one. **ARITHMETIC.**

33.10.4 10.4 The one out-of-sample check

Section 5.4 is the only place in this paper where an estimator is checked against an outcome it did not use. The saturated-collision formula, applied to a C70-scale object, predicts coherence times of `6.66e−2` s at `1e−6` mbar and `6.66e−5` s at `1e−3` mbar, against a Talbot–Lau flight time of order `1e−3` s. **It therefore predicts that fringe visibility survives at the lower pressure and is destroyed at the higher one, and that is the pressure decade over which the visibility has been measured to fall.** The check is coarse — it resolves a decade, not a percentage — and it is reported as such. **It is nonetheless the paper's only evidence that the estimator is not merely internally consistent**, and Section 11 records that no other estimate in the paper has been checked this way.

33.10.5 10.5 Limits, asymptotics, and the domain of each law

`a -> 0` in the Casimir formula. `P ~ a^−4` diverges. The formula's domain ends well before that: below about 5 to 20 nanometres retardation is negligible and the non-retarded van der Waals form `A_H/(6 pi a^3)` governs instead, with a different exponent and a material-dependent coefficient. **The divergence is outside the model's domain and is not a prediction.**

`a -> infinity`. `P -> 0` as `a^−4` at zero temperature, but as `a^−3` in the high-temperature limit, and the crossover is at `lambda_T = 7.63` um at 300 K. **The asymptotic behaviour is different in the two regimes and the wrong one is the flattering one**, which is why Section 6.4 reports the correction that makes the force larger.

`T -> 0` in the decoherence estimate. `v_bar -> 0` and `tau_dec -> infinity`: coherence survives indefinitely in a perfectly cold, perfectly empty environment, which is the limit every matter-interference experiment is built to approach and which no organism can occupy.

`sigma -> 0`. `tau_dec -> infinity`. A degree of freedom the environment does not couple to is not decohered by it, and this is not a loophole but the actual explanation of the radical-pair exception: electron spin has no electric dipole moment, so a polar solvent barely watches it. **The limit is realised in nature and it is the only way any of the exception cases work.**

`n -> 0`. The vacuum limit, `tau_dec -> infinity`, which is the whole design principle of matter-wave interferometry and is unavailable to biology by definition.

`delta -> 0` in the corresponding storage law. The framework's own boundary case, where the map ceases to contract and no fixed point exists [Curzi, 2026a,?]. The correspondence of Section 5.11 carries this limit across intact: a coherence with `1/tau = 0` never decays, and a stock with `delta = 0` never settles. **In both cases zero loss removes the destination, not the risk.**

33.10.6 10.6 Invariance, and how far the mode-selection claim has been tested

The mode-selection result is invariant under one transformation exactly: **rescale every length by `s` and every frequency scales by `1/s`, with the mode *pattern* — which indices are degenerate, what the ratios between frequencies are — unchanged.** The degeneracy structure of a room

is therefore a property of the *ratios* of its dimensions and not of its size, which is why a cube of any size stacks its modes and a 7 : 5.4 : 3.2 box of any size does not.

It is not invariant under a change of boundary condition, and this is where the claim would break. A Dirichlet boundary (pressure node) and a Neumann boundary (velocity node) give different mode sets, and a real wall is neither: it has finite impedance, so the mode frequencies shift and the modes acquire finite width. **The claim as tested here has been computed for three room geometries and verified against a published formula, not measured in any room.** That is a computational check of an equation, not an empirical test of an invariance, and Section 11 records it as such.

The wave-speed invariance is the strong one and it is tested across nine orders of magnitude: the same formula returns `1.4990e15` Hz for light between plates at 100 nm and 24.50 Hz for sound between walls at 7.0 m, with the ratio of the answers equal to the ratio of the wave speeds, `8.7403e5`, exactly. **Two scales is not many. It is, however, two scales separated by a factor of `8.7e5` in speed and `7e7` in length, and the agreement is exact rather than approximate because the same equation was solved twice.**

33.10.7 10.7 Significant figures against epistemic status

`1.300126e-27` J m is quoted to seven figures and that is defensible, because it is `pi^2 hbar c/240` — an exact expression in defined constants, computable to arbitrary precision. **It is a defined quantity, and it is labelled defined wherever it appears at that precision.**

`1.98e-17` s is quoted to three figures and that is one figure too many for what it is. It is the output of an assumed geometric cross-section in an imported scattering model, and its honest precision is *one order of magnitude*. It is written as `1.98e-17` throughout because the arithmetic must be reproducible from the stated inputs, and it is stated here, once, that **the number should be read as "about `1e-17` seconds" wherever it is used as a physical estimate rather than as a step in a computation.** The same applies to every entry in the table of Section 5.5 and to the ratio `5.04e13`, which inherits the same uncertainty.

`2.464e-14` s is exact given the temperature, being `hbar/k_B T` with defined constants, and is quoted to four figures accordingly.

`24.50 Hz` and the room-mode list carry three to four figures and should not. They are computed from a nominal speed of sound of 343 m/s, which varies by about 0.6 per cent per degree Celsius, and from nominal dimensions. **The mode frequencies are reliable to about one per cent, which is enough to establish the degeneracy structure — the result the section actually uses — and not enough to justify the second decimal place.**

33.11 11 Limitations

No experiment was performed and no dataset was collected. Every number in this paper is either a published constant, an arithmetic consequence of one, or the output of a stated model with stated inputs. The three cases of Section 8 are constructed proposals and a constructed design brief; they demonstrate that the audit procedure runs and reaches a disposition, and they are not evidence about how any real proposal, laboratory or room behaves.

The decoherence numbers are order-of-magnitude estimates and the prefactors are uncertain. The saturated-collision model imports a gas-phase picture into a liquid, uses a geometric cross-section, and ignores the structure of the solvent shell. The uncertainty is one to three orders of magnitude. **H2 is the claim that the conclusion survives that concession, and H2 is an argument rather than a measurement**: it compares the size of the available correction against the size of the required correction and observes that the second is larger by six or more orders. A reader who believes a specific mechanism could buy nine orders has a real objection, and the way to press it is to name the mechanism and compute it.

Only one estimate in the paper has been checked out of sample. Section 5.4's pressure decade is the single instance, it resolves a decade rather than a percentage, and no other row of Section 5.5 has been compared against a measurement. **A model checked at one point and applied at five is being extrapolated, and that is what is happening here.**

No model comparison in the formal sense was performed anywhere in this paper. Measured against what proper model comparison requires, the position is:

Requirement	Status in this paper
Out-of-sample rather than in-sample performance	**Partially met.** One qualitative out-of-sample check, at decade resolution (Section 10.4).
A matched null with the same free-parameter count	**NOT MET.** No competing estimator of coherence time was fitted or compared.
The number of free parameters stated explicitly	**Met.** The estimate has no fitted parameters: `n`, `v_bar` and `sigma` are all computed or stipulated, not estimated from data.
An information criterion, so the parameter count is paid for	**NOT MET.** No AIC or BIC was computed. Nothing in this paper is fitted, so no criterion applies — but the row is printed rather than omitted, because **no AIC or BIC has been computed anywhere in this corpus**, including in the corpus's one applied fit [Curzi, 2026i].
Effect sizes with intervals, not only p-values	**NOT MET.** No interval accompanies any estimate in Section 5.5, because none was propagated. The honest interval on `tau_dec` is a factor of `1e1` to `1e3`, and it is stated in words in Section 10.7 rather than carried through the tables.

Several results are named in the text with year and venue and carry no bibliography key, because the corpus's external bibliography has no entry for them. They are: Born's 1926 introduction of the probability interpretation; Gleason's 1957 theorem; Bell's 1964 theorem and the loophole-free CHSH violations of 2015; the Kochen–Specker theorem; the Pusey–Barrett–Rudolph theorem; Everett 1957; Bohm 1952; Ghirardi, Rimini and Weber 1986; von Neumann 1932; Wigner 1961; Joos and Zeh 1985; Zurek 2003; the Tonomura, Arndt and Fein interference experiments; the Hornberger and Hackermüller decoherence measurements; the Fenna–Matthews–Olson coherence results and their vibronic reinterpretations; the radical-pair magnetoreception literature; Tegmark 2000 and the Hagan–Hameroff–Tuszynski reply; Lifshitz 1956; Boyer 1968; the measured Casimir repulsion; and the dynamical Casimir observations. **Attaching an available key to any of these would be a mis-citation, and a mis-citation is worse than an absent one because it will be checked.** Appendix C lists them with the details the source manuscript supplies, so that a reader can locate them. This is a real gap in the corpus's apparatus and it is recorded as one.

The mode-selection extension beyond acoustics has no external support of any kind. Postulate 6.1 is exact for the Helmholtz problem and is a heuristic beyond it. The corpus's own coverage audit lists the family of claims that carry proportion or geometry from a physical setting into a non-physical one as unsupported, and this is one of them. **A reader who reaches for the acoustics literature as support for the occupancy claim will find that it does not apply.**

The golden-section material carries the standard exposure and the standard defence. The sceptical literature on golden-ratio claims is unambiguous that most of them do not survive inspection [Markowsky, 1992, Fischler, 1981, Livio, 2002, Höge, 1997], and this paper's use of a golden-section room is a **counter-example rather than an endorsement**: the golden box is shown to be worse than the plain box on the measure that matters. That is the only safe use of the ratio available here.

Room modes have been computed, not measured. Section 6.7 and Section 8.3 solve a published equation for three sets of dimensions. No room was measured, no sine sweep was run, and the finite-impedance corrections that make a real wall neither a Dirichlet nor a Neumann boundary are not modelled. **The degeneracy structure is robust to those corrections and the individual frequencies are not**, which is why the paper's claims rest on the former.

The Sabine values in Section 8.3 are used above their reliable range. At a mean absorption of 0.35 the switching rule requires Eyring rather than Sabine, and the divergence between the two can reach 77.8 per cent at 2 kHz in an over-treated room [Curzi, 2026e]. The values are retained because the source computes them that way, and the discrepancy is printed rather than silently corrected.

The correspondence between coherence decay and the storage law's retention term is a claim about model form and nothing more. The corpus's own limits on the storage law apply undiminished: its one preregistered confirmatory test **failed** its second falsification rule, beating a matched AR(1) by 2.8 per cent on held-out error against a declared 10 per cent margin [Curzi, 2026i]. **The exactness of the physical decay says nothing about the applicability of the institutional one.**

The reflexive specification remains unidentified. Where the framework's loop is applied to a group whose members both influence and constitute the aggregate, the endogenous effect is not identified from observational data [Manski, 1993], and network data does not repair it [Shalizi and Thomas, 2011, Lyons, 2011]. This paper adopts no remedy because it applies the loop to nothing; a downstream paper that does apply it inherits the problem, and the realistic route is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001].

The Lucas critique applies to the specifications in Appendix A. The framework holds that a system changes its behaviour when it is modelled and observed [Lucas, 1976, Hacking, 1995]; a register of binding specifications is exactly such an intervention, and its effect on the practice it governs has not been measured. **The specifications are design rules with unmeasured effect, not findings, and they are labelled as such where they appear.**

The corpus's psychological quantities are not covered by this paper's dimensional cleanliness. Every quantity audited in Section 10.1 is a physical quantity with an SI unit. The framework's own constructs — comfort, stored order, non-parallelism — have no operational unit, and Michell [1997] argues that psychology routinely fails to test whether its attributes are quantitative at all. **The conjoint-measurement conditions that would license the ratio-scale treatment those constructs receive have not been tested for any of them** [Luce and Tukey, 1964, Krantz et al., 1971, Rasch, 1960]. A reader must not take Section 10.1's clean audit as covering anything outside this paper.

No scaling exponent in this paper was estimated, so the procedure that estimated exponents require does not apply [Clauset et al., 2009]. This is recorded as a check that does not apply rather than one that was passed, and any downstream use of `a^-4`, `a^-3` or `a^6 T^9` as though it were an empirical finding about a fitted distribution would be a misreading.

Independent replication is absent. Every computation in this paper was performed by one author, and the corpus contains no independent re-derivation of any of them. The reproducibility literature is unambiguous about what a single unreplicated result is worth [Open Science Collaboration, 2015, Ioannidis, 2005], and the arithmetic here is at least the kind that a reader can redo in a few minutes, which is the entire design of Section 10.

Two observations about the source material, printed rather than corrected. First, **the "27 coincident modes" figure for the 5 m cube counts modes falling on a frequency already occupied by another mode**: the cube admits 38 modes below 120 Hz on only 11 distinct frequencies, so 27 are coincident in that sense while 36 belong to a degenerate group. Both readings are defensible and the source does not say which it means; the count is stated explicitly here so that it cannot be quoted ambiguously. Second, **the water number density `3.3428e28` per cubic metre corresponds to a density of 1000 kg/m^3, which is the value at 4 C rather than at 310 K.** At 310 K the density is about 993.3 kg/m^3 and the number density is `3.32e28`, a 0.6 per cent difference. The source's value is retained because every downstream figure is computed from it, and the discrepancy is recorded because a reader recomputing from the stated temperature

will not reproduce the fifth significant figure.

What would falsify the account. H1 fails on a replicated demonstration of functional quantum coherence above `1e-6` s in an unrefrigerated, unengineered biological system at 310 K. H2 fails on a corrected treatment of the same system returning a coherence time more than four orders above the collision estimate. H3 is a theorem and fails only on an error. H4 fails on a measured room-mode frequency departing from the modal equation by more than boundary compliance accounts for. **If H1 were falsified, Section 5 would be rewritten and Section 8.2's disposition reversed. That is stated in advance, and it is the point of stating a threshold three orders more generous than the claim requires.**

33.12 12 Conclusion

The quantum formalism is stated here as established physics and this paper adds nothing to it. Unitarity and linearity are verified numerically to `1.05e-15` and `1.29e-13`, at the double-precision floor. The Born rule integrates to unity, and interference is shown to redistribute probability rather than create it: visibility `1.0000` coherent against `0.4883` incoherent, with identical total probability, and a phase-average of `1.000000` that is exactly the classical sum. Four interpretations are surveyed by which of three inconsistent premises each abandons. Consciousness-causes-collapse is placed accurately — a minority historical position, not refuted, not favoured, with an **empty evidence column** and a distinguished advocate who abandoned it. **The measurement problem is left open, because it is open; and the openness is bounded in every direction by theorems, of which no-signalling is the one that matters, because it holds in every interpretation.** The quantum bound on the CHSH expression is `2 sqrt(2) = 2.828427`, attained exactly at the optimal settings.

The decoherence result is the paper's principal constraint and it is stated to be quoted. With `n = 3.3428e28` per cubic metre and a mean thermal speed of `603.6` m/s in water at 310 K, the estimated coherence time is `8.05e-13` s for a single potassium ion, `6.31e-16` s for a globular protein, `1.98e-17` s for a microtubule segment and `6.31e-22` s for a neuron soma. Against a `1e-3` s action potential the microtubule ratio is `5.04e13`; **a hypothetical protection factor of `1e6`, far beyond anything demonstrated for a charge-displacing degree of freedom in water, still leaves `5.04e7` unexplained.** The thermal time `hbar/k_B T` at 310 K is `2.464e-14` s, and it is imposed here as the mandatory comparison for any biological coherence claim; the microtubule estimate is `8.0e-4` of it. **Decoherence suppresses the coherences as `rho_01(t) = rho_01(0) exp(-t/tau)` and changes no diagonal element: it converts a superposition into something that looks classical without solving the measurement problem, and a result derived from linear unitary evolution could never have resolved a contradiction that arises from it.** The genuine exceptions — photosynthetic coherence at about eleven thermal times inside one rigid protein, with a serious vibronic reinterpretation, and radical-pair magnetoreception at two ten-millionths of the thermal energy — read out **populations**, not messages, and neither generalises to cognition.

The Casimir force is real, measured to about one per cent, and negligible wherever this framework builds. The pressure is `P(a) = pi^2 hbar c/(240 a^4) = 1.300126e-27/a^4` pascals — **a defined constant, exact, and quoted at that precision on that ground alone** — giving `1.3001e5` Pa at 10 nm and `1.155e-24` Pa on a seven-metre room wall in the correct high-temperature limit, for a total force of `1.996e-23` N: **five hundred million times smaller than the weight of a single bacterium resting on that wall.** In a cell the realistic Lifshitz value on a 10 nm patch is `0.027` pN against `6.00` pN for one kinesin motor. **Only the mode-selection principle transfers, and that transfer is badged: exact for electromagnetic modes between conductors and for acoustic modes in an enclosure, because both are the same Helmholtz problem, and a design heuristic with no formal warrant anywhere else.** A 5.00 m cube admits 38 modes below 120 Hz on 11 distinct frequencies, so 27 fall where another already sits; a 7.0 x 5.4 x 3.2 m box admits 39 on 39, and the difference cost nothing but the choice of three numbers.

And the result this paper exists to establish, stated so it can be quoted without drift: the corpus makes no quantum claim about mind, biology or belief, and nothing in it would change

if quantum mechanics played no role in biology at all. That is not a concession extracted by a reviewer. It is a computation the corpus ran on itself, and printed.

33.12.1 Declarations

Data and code availability

No external dataset was collected for this paper. Every numerical result is computed from published physical constants and from the stated model parameters, and every table can be re-derived from the equations and inputs printed beside it. The numerical verifications of unitarity, linearity and the Born rule reported in Sections 4.3 and 4.4 are outputs of standard split-step and quadrature computations on the grids stated in the text. The three cases worked in Section 8 are constructed proposals and a constructed design brief, not field observations. The figures are generated by the scripts named in each caption; those scripts contain no data beyond the numbers printed in this paper and the formulae of Sections 5 and 6.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the work, performed the computations, produced the worked audits and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The proposals audited in Sections 8.1 and 8.2 are constructed composites of positions available in the published literature and in circulation; they are not reports of correspondence with any identifiable person, and no individual is described.

Preregistration

This paper reports no preregistered test of its own; its results are computations from published constants. **H1 nonetheless states its falsification threshold in advance** — functional quantum coherence above 1e−6 s in an unrefrigerated, unengineered biological system at 310 K — and that threshold is three orders of magnitude more generous than the claim under audit requires. The corpus's preregistered protocol for testing the storage law, together with the confirmatory application that **failed** its second falsification rule, is reported in Curzi [2026i].

33.13 Appendix A Specification register

These specifications bind the corpus's use of quantum and Casimir vocabulary. **They are design rules whose effect on practice has not been measured, not findings**, and Section 11 records that distinction. They are reproduced here because downstream papers cite them by number.

33.13.1 A.1 On the formalism

S-4.1 STATE THE BORN RULE CORRECTLY OR NOT AT ALL. P(a_n) = |<a_n|psi>|^2 ; p(x)dx = |psi(x)|^2 dx. Never "psi is the probability". Never omit the modulus-squared.

S-4.2 USE "OBSERVER" ONLY IN ITS TECHNICAL SENSE and define it at first use in any document: a physical system with many degrees of freedom that interacts with and records a correlation. Where the intended meaning is a person paying attention, use those words instead.

S-4.3 NEVER ASSERT A SINGLE INTERPRETATION AS SETTLED. Where an argument depends on interpretation, name the interpretation and name what it gives up (the M1/M2/M3 table of Section 4.6).

S-4.4 PRESENT VON NEUMANN-WIGNER, WHERE PRESENTED AT ALL, WITH ALL FIVE REASONS OF SECTION 4.8, INCLUDING WIGNER'S OWN ABANDONMENT OF IT. Partial presentation is prohibited.

S-4.5 NO CLAIM IN THIS CORPUS MAY DEPEND ON A QUANTUM MECHANISM. Where a proposed channel is quantum, the specific coupling must be written down, its magnitude estimated, and the decoherence timescale of Section 5 confronted.

S-4.6 CITE NO-SIGNALLING WHEREVER ACTION AT A DISTANCE IS IMPLIED. It is the shortest complete refutation available and it is interpretation-independent.

S-4.7 DISTINGUISH FORMALISM FROM INTERPRETATION IN EVERY PARAGRAPH THAT TOUCHES BOTH.

S-4.8 THE ANALOGY BADGE ON THE CONJUGATE-STRUCTURE MATERIAL CARRIES FORWARD UNCHANGED. Conjugate structure in a future-ensemble is a Fourier fact and carries no quantum content.

S-4.9 WHERE AN EVIDENCE COLUMN IS EMPTY, PRINT THE EMPTY CELL. Appendix B, audit B3, is the template.

S-4.10 NEVER SAY THAT BELL'S THEOREM DISPROVED REALISM. It excludes local theories with pre-existing definite values for all observables. Say that, in those words.

S-4.11 ANY BRANCH SET PRESENTED TO AN ANALYST MUST CARRY ITS WEIGHTS AND ITS EFFECTIVE COUNT, and must state which effective count is meant. A branch set without weights is a list, and a list is not a forecast.

S-4.12 ANY FORECAST MADE ON A BRANCH SET IS SUBJECT TO THE PREREGISTRATION PROTOCOL: preregister the branch set and the weights, freeze the model, score held-out against persistence, direct-input, matched autoregressive and shuffled-input baselines, and state in advance what result kills it.

33.13.2 A.2 On coherence claims

S-5.1 REPRODUCE THE WARM-WET TIMESCALE STATEMENT IN FULL WHEREVER THE CORPUS

TOUCHES QUANTUM VOCABULARY IN A BIOLOGICAL CONTEXT.

S-5.2 ANY PROPOSED QUANTUM MECHANISM IN A BIOLOGICAL SYSTEM MUST STATE, IN THE PROPOSAL, ALL FIVE OF:
(i) the degree of freedom carrying the coherence
(ii) the environment it couples to
(iii) an estimated decoherence time with its formula and inputs
(iv) the functional timescale it must reach
(v) the ratio (iv)/(iii)
A proposal missing any of the five is returned unreviewed.

S-5.3 COMPARE EVERY BIOLOGICAL COHERENCE CLAIM TO hbar/kT AT 310 K = 2.464e-14 s. State the claim as a multiple of the thermal time. It is the fastest available sanity check and it costs one division.

S-5.4 NEVER STATE THAT DECOHERENCE SOLVES THE MEASUREMENT PROBLEM. State that it explains the absence of macroscopic interference and the preferred basis, and that it does not select an outcome.

S-5.5 PRESENT PHOTOSYNTHETIC COHERENCE AND MAGNETORECEPTION AS ACTIVE AND CONTESTED, with the vibronic reinterpretation named in the same passage, and never as support for any claim about cognition or belief.

S-5.6 DISTINGUISH POPULATIONS FROM COHERENCES IN EVERY DENSITY-MATRIX ARGUMENT. A yield difference is a population. A message is not.

S-5.7 LABEL ORDER-OF-MAGNITUDE ESTIMATES AS ESTIMATES, give the formula and the inputs, and state the prefactor uncertainty.

S-5.8 WHERE AN ESTIMATE CAN BE CHECKED AGAINST A PUBLISHED EXPERIMENT, CHECK IT AND PRINT THE CHECK. Section 5.4 is the template.

S-5.9 ANY FUTURE RESULT OVERTURNING SECTION 5 MUST BE INCORPORATED, NOT SUPPRESSED. The falsification condition is H1 and it is stated in advance.

S-5.10 THE STRUCTURAL LESSON MAY BE CARRIED FORWARD; THE PHYSICS MAY NOT. "Protect a fragile state by reducing coupling, not by adding energy" is transferable engineering. "Coherence" as a description of an institution is a metaphor and must be badged as one.

33.13.3 A.3 On the Casimir effect and boundary geometry

S-6.1 STATE THE HONEST LIMIT WHEREVER THE CASIMIR EFFECT APPEARS: at every biological and architectural scale the force is utterly negligible.

S-6.2 NEVER CITE THE CASIMIR EFFECT AS A FORCE IN A DESIGN. Cite it as the demonstration of mode selection by boundary. Where a design's mechanism is the Casimir force, the design is rejected without further review.

S-6.3 NEVER CONFLATE CASIMIR WITH VAN DER WAALS IN A BIOLOGICAL ARGUMENT. State which regime is meant -- non-retarded below about 5-20 nm, retarded above -- and give the Hamaker constant where the non-retarded regime is intended.

```
S-6.4   REPORT THE THERMAL CORRECTION WHEREVER THE TABLE EXTENDS BEYOND
        lambda_T = hbar c / kT (7.63 um at 300 K), and report it even though
        it makes the force LARGER at those separations.

S-6.5   NO ZERO-POINT-ENERGY EXTRACTION CLAIM MAY APPEAR IN ANY MATERIAL
        DERIVED FROM THIS CORPUS. The force is conservative; a cycle returns
        what it took.

S-6.6   EVERY ENCLOSURE DESIGNED UNDER THIS FRAMEWORK MUST HAVE ITS MODE LIST
        COMPUTED FROM ITS ACTUAL DIMENSIONS. Report: count below 100 Hz, mean
        spacing, largest gap, and the number of coincident modes, stating
        which definition of coincident is used.

S-6.7   NO PROPORTION SYSTEM CERTIFIES A ROOM. Ratio systems GENERATE
        candidates; certification requires the computed mode list or a
        measurement of that specific room.

S-6.8   DISTINGUISH THE THREE TRANSFER STRENGTHS IN PRINT, EVERY TIME:
          (a) EM modes between plates          -- proven and measured
          (b) acoustic modes in a room         -- the SAME equation, measured
          (c) occupancy / circulation patterns -- SPECULATIVE, badged
        Never allow (c) to inherit the credibility of (a).

S-6.9   WHERE A PRECEDENT COLUMN IS EMPTY, PRINT THE EMPTY CELL.

S-6.10  THE MONOCHORD IS THE CANONICAL PRECEDENT FOR THIS PRINCIPLE AND MUST
        ALWAYS BE LABELLED PRECEDENT. It records that boundary position alone
        sets the mode ladder. It is not evidence for the Casimir effect.

S-6.11  MODE-LADDER PITCH CLASSES FOLD BY ODD PART, giving ceil(N/2) classes in
        the first N modes -- ONE octave between n and 2n. The essence law
        f = k n^2 also folds by odd part but gives TWO octaves between n and
        2n. State which system is in use.

S-6.12  A MOVING BOUNDARY IS A DESIGN ELEMENT WITH ITS OWN SPECIFICATION.
        Where a room has variable geometry, compute the mode list in EVERY
        configuration the room can be placed in.
```

33.14 Appendix B Evidence-and-precedent audits

The corpus's comparative material sets a modern result beside an older tradition that reached a structurally similar position by an independent route. **The format below exists to stop the second column being read as support for the first.** Each audit states what is measured, what is merely recorded, and what the pair can and cannot establish. Three criteria are applied: C1, whether the correspondence is structural rather than verbal; C2, whether the pairing generates a quantitative prediction; C3, whether it is usable on both sides.

B1 — Linear evolution cannot select an outcome. *Evidence:* unitarity of `U(t)`; the numerical verification of Section 4.3, norm to `1.05e-15` and linearity to `1.29e-13`. What is measured: the equation's solutions, to machine precision. *Precedent:* the Madhyamaka doctrine that phenomena have no intrinsic self-standing nature, only relational determination — a sustained argument, arrived at with no instruments, that what a thing is is not a property it carries alone. *Assessment:* the evidence column carries a proved property of a differential equation; the precedent column carries only the fact that a non-intrinsic account of properties

was reachable by argument centuries before Hilbert spaces existed. **Neither is evidence for the other.** C1 pass, C2 fail, C3 partial. *Status:* **speculative as a bridge**, and marked speculative here because it fails C2. Retained as precedent, nothing more.

B2 — Objective spontaneous indeterminacy as a physical process. *Evidence:* the GRW and CSL programme and its experimental constraint programme, including the underground measurement excluding the simplest parameter-free gravity-related collapse model. What is measured: bounds on collapse-rate parameters from interferometry, mechanical oscillators, and searches for the spontaneous radiation such models predict. *Precedent:* the Lucretian *clinamen* — atoms swerving spontaneously, at no fixed time and no fixed place; and the Ash'arite occasionalist position that the world is re-created at each instant rather than carried forward by inertia. What is recorded: that objective, uncaused, moment-by-moment indeterminacy was formulated as a considered position twice, in unrelated traditions, two millennia and a continent apart. *Assessment:* this is the strongest precedent entry in the paper and it must still be labelled correctly. **Lucretius supplies no rate constant; the occasionalists supply no differential equation.** C1 pass; C2 fails on the precedent side; C3 fails on the precedent side. *Status:* the physics is **established as a tested programme**; the bridge is **speculative** and is marked speculative here.

B3 — Mind as the terminus of the measurement chain. *Evidence:* **none.** There is no measurement supporting a distinguished physical role for consciousness in quantum dynamics, no proposed coupling, and no constrained parameter. **The evidence column for this claim is empty, and the empty cell is printed rather than hidden.** *Precedent:* cognition-only analyses in the Yogacara tradition, and Berkeley's immaterialism. What is recorded: that mind-first accounts of the object were formulated with rigour and defended for centuries. *Assessment:* this is the clearest demonstration in the paper of why the two columns must be kept apart. There is a long, serious, independently arrived-at precedent for mind-first metaphysics, and there is **no evidence** for mind-caused collapse. **An audit that reported both columns as support would be lying by layout.** C1 partial (surface resemblance only), C2 fail, C3 fail. *Status:* **rejected as a bridge**, and recorded in print as a failed bridge, because a method that never rejects anything is not a method.

B4 — The future is better held as a weighted branch set than as a verdict. *Evidence:* calibration research in forecasting — proper scoring rules, and the finding that probabilistic forecasts outperform point predictions when scored honestly on held-out outcomes; and, within this corpus, the preregistration protocol requiring a frozen model beaten against four baselines including a shuffled-input control [Curzi, 2026i, Nosek et al., 2018]. What is measured: forecast skill, out of sample. *Precedent:* the yarrow-stalk procedure of the *I Ching*, whose traditional method assigns **non-uniform** probabilities to the four line types — old yin 1/16, young yang 5/16, young yin 7/16, old yang 3/16 — with only the "old" lines changing and generating a second hexagram. Computed: the four weights sum to 16/16; the probability of at least one changing line in six is 0.8220; the later three-coin method gives 1/8, 3/8, 3/8, 1/8, the same total changing-line probability of 1/4 but a different distribution between yin and yang; and the derived state space is `64 x 64 = 4096` ordered pairs. *Assessment:* the precedent records that a weighted-transition model of the future was constructed and preserved for millennia by people with no probability theory. **It is not evidence that its weights are correct, and no claim is made here that consulting it forecasts anything.** C1 pass, C2 pass on the evidence side — the pairing predicts that analysts trained to hold non-uniform branch weights produce better-calibrated forecasts than analysts trained to name a single outcome, which is measurable under the corpus's protocol — C3 pass. *Status:* **established as a structural correspondence**; **not** established and not claimed as any statement about quantum mechanics, neither construct involving interference, complex amplitude, or `hbar`.

B5 — A delicate state requires isolation from its surround, or it is lost. *Evidence:* the decoherence programme [Zeh, 1970] and the measured suppression of interference as an explicit function of environmental coupling — cavity-field superpositions, engineered reservoirs in trapped ions, collisional decoherence of C70 against gas pressure, and thermal-photon decoherence against internal temperature. Computed here: dust grain in air `2.78e-17` s; C70 at `1e-6` mbar `6.66e-2` s; protein in water at 310 K `6.31e-16` s. What is measured: interference visibility

as a dialled function of coupling. *Precedent:* the alchemical requirement of the sealed vessel, documented from late antiquity through the Latin tradition — the work is destroyed if the vessel is opened before the operation completes — together with parallel practices of enclosure and of silence about a working before it is finished. What is recorded: that a delicate process requires protection from its surround was arrived at independently in several traditions and encoded as an operational requirement rather than a sentiment. *Assessment:* the evidence column carries a measured, quantified, dial-controlled relationship with a master equation; the precedent column carries only that the structure was findable by long first-person experience with slow chemistry and with attention. **The alchemists were not doing quantum mechanics and nothing here suggests they were.** C1 pass — in both cases an uncontrolled coupling to a many-degree-of-freedom surround destroys a prepared state, and the remedy in both is to reduce the coupling rather than to add energy. C2 pass — the pairing predicts that a protected process shows a loss rate scaling with its exposure surface, which is the framework's `delta` and is measurable [Curzi, 2026a]. C3 pass. *Status:* the physics is **established**; the bridge is **established as a structural correspondence** and carries no implication that alchemical practice involved quantum coherence.

B6 — The Casimir force is negligible at every scale this framework builds at. *Evidence:* Casimir [1948] for the prediction; Lamoreaux [1997] at about 5 per cent over 0.6–6 um; Mohideen and Roy [1998] at about 1 per cent over 0.1–0.9 um; parallel-plate measurements; Lifshitz theory for real materials. Computed here: 13 Pa at 100 nm ideal against `7.732e5` Pa physiological osmotic pressure; `1.4674e-23` Pa across a 3 m room against a bacterium's weight, ratio `6.683e7`. *Precedent:* **none, and that is worth printing.** No traditional corpus records anything corresponding to a vacuum-fluctuation pressure between plates. **The precedent column is empty.** *Assessment:* an empty precedent column is not a weakness of the claim; it is a reminder of what the two columns do. The claim stands on the evidence column alone. *Status:* **established**, with the honest limit mandatory wherever the effect is invoked.

B7 — Boundary geometry alone determines which modes can exist, with measurable consequence. *Evidence:* the Casimir measurements above — boundary separation alone, in vacuum, with no applied field, producing a force measured to about one per cent; and room acoustics, where the modal equation and the Sabine relation are routinely measured [Sabine, 1922, Schroeder, 1965, Rossing et al., 2002, von Helmholtz, 1885]. Computed here: 25 modes below 100 Hz in a 7.0 x 5.4 x 3.2 m room; a 5 m cube admitting 38 modes below 120 Hz on 11 distinct frequencies against the box's 39 on 39. *Precedent:* the Pythagorean monochord — a single string and a movable bridge, where stopping the string at 1/2 its length raises the pitch by exactly a factor of 2, at 2/3 by 3/2, at 3/4 by 4/3, at 4/5 by 5/4, with the ratios exact and independent of the string's material, tension and thickness. The tradition recorded that **the boundary position alone sets the mode ladder** and built a theory of consonance on it. Also: the tuned bronze vessels specified for Roman theatres; the definition of place as the innermost boundary of the containing body; and the observation that a vessel's usefulness lies in the emptiness its walls enclose. *Assessment:* the evidence column carries measured forces, measured mode frequencies and measured resonances. The precedent column carries that the principle was arrived at, stated generally, and used as engineering more than two thousand years before there was a wave equation to derive it from. **The monochord is not evidence for the Casimir effect.** What its independent arrival establishes is that the structure was findable by ear as well as by torsion balance. **One further note required by honesty: the efficacy of the Roman vessels in actual theatres is not established, and the architectural proportion traditions are precedent for the conviction that shape determines effect, not evidence for their specific prescriptions.** C1 pass, and it is the strongest C1 in the paper, because the correspondence between the two evidence items is not resemblance but literal mathematical identity — the same Helmholtz equation, the same boundary condition, the same `k_n = n pi/a`, for a different field. C2 pass: the pairing predicts specific mode frequencies for specific dimensions, measurable with a sine sweep and a microphone, and the cube-degeneracy prediction is a falsifiable statement about a real room. C3 pass. *Status:* **established** for electromagnetic and acoustic modes; the extension to occupancy and circulation is **speculative**, is marked speculative here, and carries the obligation that a mode argument may generate a candidate geometry and may

not certify one.

33.15 Appendix C Works named in the text without a bibliography key

The corpus's external bibliography does not contain entries for the following, and no key has been attached to them anywhere in this paper. They are listed with the details the source manuscript supplies so that a reader can locate them, and their absence is recorded as a gap in the corpus's apparatus rather than concealed. **Nothing in this list should be read as a citation; it is a statement of what is missing.**

On the formalism. Born's 1926 introduction of the probability interpretation (*Zeitschrift für Physik* 37, 863). Gleason (1957) on the forcing of the Born rule in dimension three and above. Bell (1964) and the loophole-free CHSH violations reported in 2015. The Kochen–Specker theorem (1967). The Pusey–Barrett–Rudolph theorem (2012, *Nature Physics*). Everett (1957, *Reviews of Modern Physics* 29, 454). Bohm (1952, *Physical Review* 85, 166 and 180). Ghirardi, Rimini and Weber (1986, *Physical Review D* 34, 470); Pearle (1989); Ghirardi, Pearle and Rimini (1990). The underground X-ray constraint on parameter-free gravity-related collapse (Donadi and colleagues, 2021, *Nature Physics*). Von Neumann, *Mathematische Grundlagen der Quantenmechanik* (1932). London and Bauer (1939). Wigner, "Remarks on the Mind–Body Question" (1961). Frauchiger and Renner (2018, *Nature Communications* 9, 3711) and Bong and colleagues (2020, *Nature Physics*). Schlosshauer, Kofler and Zeilinger (2013, *Studies in History and Philosophy of Modern Physics* 44, 222). Maudlin (1995, *Topoi*) for the three-premise statement of the measurement problem. Rodriguez, Capasso and Johnson (2011, *Nature Photonics*) for microstructured geometries. Moore (1970); Fulling and Davies (1976); Wilson and colleagues (2011, *Nature* 479, 376); Lähteenmäki and colleagues (2013, *PNAS*) for the dynamical effect.

Chapter 34

Belief Creates Reality If the Belief Is Grounded in Truth: A Conditional Postulate, Its Channel-Gain Form, and the Placebo Case

Abstract. We state a conditional postulate — belief changes the world only through a real, nameable channel — and give it a working form E = G.B + eps, in which B is a normalised strength of holding on [0,1], G is a channel gain in the outcome's own units, and the load-bearing half is the forbidding clause G = 0 implies E = 0 for every B. The postulate is badged as a postulate and defended by what it forbids rather than by what it promises. We compute the honest cost of conditionalising: the unconditional form is refuted by 32.5 per cent of random observations, so eight casual observations refute it with 95 per cent confidence, while the conditional form is refuted by only 5.5 per cent — the paper names this as the flank it volunteers. Channels are enumerated in four classes and composed by an explicit rule, series multiplying and parallel adding; a five-stage series chain delivers 8.4 per cent of a lossless one. The worked audit sums a behavioural gain of 0.18, an informational gain of 0.067 and a social gain of 0.11 to 0.36, bounding the effect at 0.252 at B = 0.7 against a claimed 0.85 — required over available, 3.373 — and rejects the claim. Placebo supplies the one fully verified channel, at modest measured size.

Keywords: conditional postulate; channel gain; placebo analgesia; open-label placebo; loop gain; effect size

Series: B. Engineering the Surplus **Paper:** CCP-034

34.1 1 Introduction

The most quotable sentence in this corpus is a postulate, and this paper exists to keep it one.

> **[POSTULATE] Belief creates reality if the belief is grounded in truth.**

That sentence is badged as a postulate in the source manuscript, it is badged as a postulate here, and it is not a derived result, an empirical finding, or a summary of a literature. It is asserted by this work, it has no external support as stated, and its status is recorded in the abstract, at first use in Section 4, in the verification chain of Section 12 as `POSTULATED`, and in the Conclusion. A reader who quotes it without the badge has quoted it wrongly.

The paper's argument is that the last five words carry the entire content and everything else in the sentence is scaffolding. Strike the conditional and what remains — *belief creates reality* — is shown in Section 5 to be simultaneously **false when taken literally** and **empty when taken charitably**, a double failure with an exact arithmetic. Restore the conditional and the claim names a precondition, says different things about cases where the precondition holds and cases where it does not, and thereby becomes the kind of claim that can be wrong.

The working form is

```
E  =  G . B  +  eps
```

with `B` a normalised strength of holding on `[0,1]`, `G` a channel gain in the outcome's own units, `eps` mean-zero noise, and the load-bearing half **the forbidding clause: `G = 0` implies `E = 0` for every value of `B` whatsoever.** The postulate is defended by what it forbids rather than by what it promises.

The correspondence with the corpus's storage law is exact in form and is the reason this paper sits in Series B rather than in a philosophy of mind. In the storage law `Q_{t+1} = (1−delta)Q_t + eta S_t − C_t`, the conversion coefficient `eta` is what turns offered surplus into durable structure, and `eta = 0` leaves a vessel that leaks and pays rent [Curzi, 2026a]. The two statements

```
eta = 0   =>   Q_{t+1} = (1 − delta) Q_t − C_t      nothing sticks, and cost still bills
G   = 0   =>   E = 0  for all B                     the belief does nothing, at any strength
```

are the same sentence at two scopes. Other papers in the corpus cite that pairing, so it is stated precisely: the correspondence is between `B` and `S_t`, between `G` and `eta`, and between `E` and what lands in `Q`; it is a correspondence of **model form**, badged as one in Section 7.2, and it transfers the structure without transferring the warrant. The storage law is a theorem about a recursion; the postulate is an assertion about the world.

Four things are established here. First, the arithmetic of conditionalisation: under the base rates of Section 5.4, **32.5 per cent of random observations refute the unconditional form — so eight casual observations refute it with 95 per cent confidence — against 5.5 per cent for the conditional.** That number is the flank the conditional volunteers, and it is printed against the paper's own claim rather than buried. Second, a dynamical form: `B_{t+1} = (1−lam)B_t + lam min(1, L B_t)` with loop gain `L = alpha G`, whose zero-belief state is stable if and only if `L < 1`, whose transition at `L = 1` is sharp, and in which `G = 0` forces `L = 0` at every `alpha`. Third, a composition rule — series multiplies, parallel adds — under which a five-stage chain of individually respectable transmissions delivers **8.4 per cent** of a lossless one and any single zero stage zeroes the product. Fourth, a worked audit in which summed gains of 0.18, 0.11 and 0.067 bound the effect at 0.252 against a claimed 0.85, **a required-over-available ratio of 3.373, and the claim is rejected** while the practice that generated it is kept.

The corpus's reflexive loop `T(x) = W(x, M(x))`, of which the self-fulfilling prophecy is a fixed point, is presupposed here rather than re-derived [Curzi, 2026]. **It is also the source of this paper's most serious methodological exposure**, treated in Section 3.4: the loop is a linear-in-means reflexive specification whose endogenous effect is not identified from observational data [Manski, 1993].

Section 2 states the hypotheses. Section 3 gives the method and the identification problem. Section 4 states the postulate with its badge. Section 5 computes the content of the conditional. Section 6 runs the seven-gate formula validation protocol on the paper's own working form and reports the gate it fails. Section 7 makes grounding operational through four channel classes and their composition. Section 8 gives the one channel that has been traced end to end and cut. Section 9 collects the failure modes. Section 10 works three audits. Sections 11 to 14 discuss, verify, limit and conclude.

34.2 2 Hypotheses

The postulate itself is not a hypothesis and is not presented as one. It is an assertion of this work, badged, with a list of observations that would end it (Section 5.5). What follows are the testable consequences that can be separated from it.

> **H1 — The zero-channel prediction.** Where every candidate channel from a belief to a measured outcome has been enumerated and independently excluded, the measured effect of that belief on that outcome is zero within noise. **Predicted:** an effect indistinguishable from zero at any belief magnitude, in a design with power adequate to detect the smallest effect the named channels could have supplied. **Falsified by:** a belief-linked effect clearly above the noise floor, on an outcome for which no physiological, behavioural, social or informational route survives enumeration, with no measurement artefact and no selection effect, preregistered and replicated by an independent group. **This is the falsifier that matters; the rest are calibration.**
>
> **H2 — The magnitude bound.** A belief's effect on an outcome does not exceed the sum of the gains of its named channels, times the belief magnitude. **Predicted:** `|E| <= (sum_i G_i) B_max`, with the gains estimated from each channel's own mechanism and frozen before the outcome is measured. **Falsified by:** effects reliably and substantially exceeding that bound with gains frozen in advance. One instance is a missed channel; a pattern is a dead postulate.
>
> **H3 — Gain proportionality.** Effect magnitude tracks channel gain across channels whose gains are well separated and independently measured. **Predicted:** halving the gain halves the effect, at fixed belief magnitude. **Falsified by:** effect magnitude independent of channel gain across such channels. If halving the gain does not halve the effect, `G` is not what is doing the work.
>
> **H4 — Blockade.** Interrupting the only named channel abolishes the effect. **Predicted:** with the channel's stage `i` set to zero transmission, the series product is zero and the measured effect goes to zero. **Falsified by:** effects surviving the specific, verified interruption of the sole named channel. **A channel that can be cut without changing the outcome was not the channel.**
>
> **H5 — Grounding relevance.** Channels whose constituent propositions are true outperform channels whose constituent propositions are false, at equal belief magnitude. **Predicted:** a difference in effect attributable to the truth of the channel's premises rather than to the truth of the belief. **Falsified by:** beliefs whose channels rest on demonstrably false propositions producing the same effects at the same magnitudes as beliefs whose channels rest on true ones. **This would not refute that belief has effects. It would refute the word "truth" in the postulate, which is the word the postulate is named for, and the word should then be struck.**
>
> **H6 — Bimodality under self-reinforcement.** Beliefs sitting in high-gain reflexive loops are distributed bimodally in a population rather than smoothly, because the fixed-point structure of Section 5.6 admits no stable intermediate value under pure self-reinforcement. **Predicted:** at `lam = 0.30`, `B* = 0` for every `L < 1` and `B*` at the effector ceiling for every `L > 1`, with the transition at `L = 1` exactly. **Falsified by:** a stable, reproducible intermediate equilibrium belief in a system whose loop gain has been independently estimated away from 1.

Three further statements in this paper are not hypotheses and are labelled where they appear. The postulate (Section 4.1) is a **postulate**. The correspondence with the storage law (Section 7.2) is a **claim about model form**, not about kinship or mechanism. The loop-gain model of Section 5.6 is a **formalisation of a verbal mechanism** — the mechanism is Merton's [Merton, 1948]; the stability arithmetic is this work's, and it is elementary.

34.3 3 Method

34.3.1 3.1 Badge discipline

Every claim in this paper is assigned to exactly one of three drawers and the assignment is printed with the claim, following the corpus's standing classification of established mathematics, established empirical result, and declared postulate [Curzi, 2026].

Drawer one, established mathematics. The truth-table arithmetic of Section 5, the bit counts, the series and parallel composition rules, the linearised pole condition of Section 5.6, and every numerical example. These are arithmetic and a reader can redo them.

Drawer two, established empirical result. The placebo findings of Section 8, stated with their designs and their limits, and the social-threshold measurement of Section 7.5, stated with the setting in which it was measured. **Where a result is contested, it is reported as contested in the same passage as the claim it qualifies.**

Drawer three, this work's postulates. Two: the postulate of Section 4.1 and its operational form in Section 7.1. Both are badged at first use, in the verification chain, and in the Conclusion. Nothing else in the paper is asserted without support.

34.3.2 3.2 The evidence-and-precedent format

Several claims in this corpus are supported by a modern measurement and accompanied by an older tradition that reached a structurally similar position by an independent route. **The two are not the same kind of thing and the format in Appendix B exists to stop the second being read as the first.** Each audit states what was measured, what was merely recorded, and what the pair can and cannot establish. **Two sources agreeing does not double the evidence when only one of them is evidence.** Where the evidence column is empty, the empty cell is printed.

34.3.3 3.3 The formula validation protocol

Every formula in this corpus passes seven gates in print: dimensions, scale type, limiting cases, fixed points, identifiability, falsification, and reproducibility. Section 6 runs all seven on `E = G B + eps`. **It does not pass all seven, and the gate it fails is named rather than finessed.** The scale-type gate draws on measurement theory [Stevens, 1946, Michell, 1997, Luce and Tukey, 1964]; the falsification gate on the preregistration literature [Nosek et al., 2018, Simmons et al., 2011, Gelman and Loken, 2013]; the reproducibility gate on the replication record [Open Science Collaboration, 2015, Ioannidis, 2005].

34.3.4 3.4 Identification: the objection this paper cannot answer

This is the most serious methodological problem in the paper and it is stated here rather than in a footnote.

The postulate's dynamical form in Section 5.6 is a reflexive loop: belief produces an effect, the effect is observed, and the observation feeds back into the belief. Where the belief is held in a group and the effect is a group-level quantity, that is exactly the corpus's central formal claim `T(x) = W(x, M(x))` [Curzi, 2026] — and it is exactly a linear-in-means reflexive specification. **Manski [1993] proves that the endogenous social effect in such a specification is not identified from observational data.** It cannot be separated from contextual effects or from correlated unobservables, however much data is collected. Shalizi and Thomas [2011] show the same confounding for observational network data, and Lyons [2011] show what happens when it is ignored.

The consequence for this paper is specific: the social gain `G_social` of Section 7.5 is not identified from observation of a group. No fit recovers it. The remedies are known and none

is free — randomise the treatment, find an instrument, exploit partial-population variation, or **stipulate the reference group and defend the stipulation**, which is the route Brock and Durlauf [2001] makes defensible and the most realistic one here.

This paper adopts no remedy. It therefore states that the applied reading of `G_social` is a **modelling position rather than an identified empirical result**, and Section 13 repeats it. The three other channels are less exposed, because their gains are estimated from components measured outside the group — an adherence differential from behaviour records, a search rate from historical hours-per-find, an effect-per-action from a design that varies the action without varying the belief — but the social channel has no such escape and it is not given one.

A second reflexive objection lands on this paper's own parameters. The framework asserts that systems change their behaviour when they are modelled, and this paper hands readers a protocol for managing their own beliefs. Lucas [1976] is the sharp statement: parameters estimated under one regime do not survive a change of regime, because the decision rules adjust. Hacking [1995] makes the same point for classifications of people, and Ferraro et al. [2005] documents the mechanism at work in economics with a warning this paper takes seriously — **the theories that became self-fulfilling in that literature made people behave worse by assuming the worst of them.** The position taken here is the narrow one: the gains of Section 7 are estimated within a declared window, for a declared population, and are not asserted to be structural. **Either the parameters are stable under the framework's own predicted response, or the framework undercuts itself; this paper says they are not asserted to be stable, and prices that accordingly in Section 13.**

A third bound comes from the size of the effect the literature actually supports. Jussim and Harber [2005] review thirty-five years of work after the classroom-expectancy studies and conclude that self-fulfilling prophecies are **real but small**, do not typically accumulate over time, often dissipate, and that most teacher expectations turn out to be *accurate* rather than causal. **The corpus cites the original expectancy result [Rosenthal and Jacobson, 1968]; it must cite this beside it, because the effect size a reflexive law implicitly assumes is larger than the literature supports.** The gains in Section 7 are deliberately small numbers, and that is why.

And a fourth bound is the ceiling on social predictability at all. With fifteen years of high-quality longitudinal data and 160 participating teams, life outcomes proved barely predictable [Salganik et al., 2020, Hofman et al., 2017]. A framework proposing to predict outcome changes from belief magnitudes is operating inside that ceiling and cannot exceed it.

34.3.5 3.5 What discriminates this model from a neighbouring one

Sobkowicz [2020] poses the question in one line: what observation would distinguish this model from a neighbouring model that fits equally well, and Durlauf [2005] asks for the prediction only this model makes. **The honest answer here is that two of the paper's predictions are discriminating and the rest are not.** H4 — blockade — is discriminating, because a model without a channel structure makes no prediction about what happens when a specific pathway is pharmacologically interrupted. H6 — bimodality under self-reinforcement — is discriminating, because a linear influence model predicts a smooth distribution and this one predicts a gap. **H1, H2, H3 and H5 are shared with any mechanism-based account of belief effects, and this paper claims no priority over such accounts.** What it claims is that the mechanism requirement has been made arithmetic.

34.3.6 3.6 Analogy discipline

The paper uses two borrowings from physics and engineering, each labelled at first use.

The leaky-integrator form of the storage law, reused for belief, is a shared mathematical form — the same first-order recursion governs both, with no claim that the underlying dynamics are the same object [Elaydi, 2005, Oppenheim et al., 1996]. Section 7.2 says so.

Loop gain and the stability condition `L < 1` are likewise a shared form, taken from first-order feedback analysis [Åström and Murray, 2008, Strogatz, 2015], and used because the recursion of Section 5.6 is a first-order recursion. **No physical result's authority is transferred to any psychological claim by either borrowing**, and the general hazard of doing so is documented [Mirowski, 1989, Cartwright, 1999].

No scaling or heavy-tail claim is made anywhere in this paper, so the distribution-fitting procedure such a claim would require [Clauset et al., 2009] does not apply. This is recorded as a check that does not apply rather than one that was passed.

34.4 4 The postulate

34.4.1 4.1 Statement, with its badge

> **[POSTULATE — 4.1] BELIEF CREATES REALITY IF THE BELIEF IS GROUNDED IN TRUTH.**
>
> Where:
>
> - **BELIEF** is a held proposition together with the disposition to act on it. It has a magnitude `B` on the interval `[0, 1]`: 0 is not held at all, 1 is held with full disposition to act. **`B` is not a probability and must not be read as one**; it is a normalised strength-of-holding.
> - **CREATES REALITY** means: produces a change in a measurable state of the world that would not have occurred otherwise, written `E`, in the units of whatever is measured.
> - **GROUNDED IN TRUTH** means: there exists a real, specifiable, physically or socially instantiated pathway from the holding of the belief to the state measured, and the propositions that pathway depends on are true. Section 7 names this pathway the **channel** and gives it a gain, `G`.
>
> The postulate asserts that `E` is a function of `B` through `G`; that `G > 0` requires the channel to exist and to be real; and — this is the half that does the work — that **`G = 0` forces `E = 0` at every value of `B` whatsoever.**

This is a postulate. It is asserted by this work. It has no external support as stated, it is not derived from anything, and the corpus's own coverage audit lists it among the claims for which no supporting literature exists. What a postulate owes its reader is the list of observations that would end it; that list is Section 5.5.

The last clause is why the sentence is a postulate and not a slogan. **It forbids something.** It forbids the outcome the unconditional version promises: an effect with no route.

34.4.2 4.2 The magnitude form, which is the form that gets used

The English sentence is the statement of record. The working form is:

```
E  =  G . B  +  eps

E     measured change in the world, in the outcome's own units
B     belief magnitude, dimensionless, in [0,1]
G     channel gain, in outcome units per unit belief
eps   noise, mean zero, with a measurable standard deviation

GROUNDING CONDITION:   G > 0  requires a named channel whose
                       constituent propositions are TRUE.
```

```
THE FORBIDDING CLAUSE: G = 0  =>  E = 0  for all B.
```

The linear form is a first-order approximation and is marked as such. Real channels saturate: a belief held at 1.0 does not produce ten times what a belief held at 0.1 produces once the effector is at its ceiling. Section 7.6 supplies a saturating form as an explicit modelling choice. The linear form is used here because **the argument concerns the difference between `G > 0` and `G = 0`, and that difference survives any monotone functional form.**

34.4.3 4.3 What "grounded in truth" is not

Three readings are ruled out before the paper proceeds.

Not "sincerely held." Sincerity is a property of the believer; grounding is a property of the world. A belief can be held with total sincerity and be grounded in nothing, and the postulate predicts, for that case, an effect of exactly zero.

Not "true." The belief itself need not be true, and this is the subtle part. The belief that a bank is about to fail can be false when formed and still be grounded, because the *channel* — depositors withdraw, fractional reserves are genuinely fractional — is real. **What must be true is the set of propositions the channel depends on, not the proposition believed.** Section 5.6 develops this; it is the whole content of the self-fulfilling prophecy [Merton, 1948, 1936].

Not "consistent with a respected framework." The demand is for a pathway: a named sequence of physical or social steps, each of which happens and can be independently checked, ending at the measured quantity. **If it cannot be written down as steps, `G` has not been established as positive and the machinery predicts nothing.**

34.5 5 The empirical content of the conditional

34.5.1 5.1 The unconditional version, taken literally, is already false

Take the unconditional claim at its word and formalise it over three binary observables:

```
B  belief is held           (0 / 1)
K  a real channel exists    (0 / 1)
E  a change in the world attributable to B occurs   (0 / 1)
```

Eight cells. The unconditional version `U` says: if `B = 1` then `E = 1`, and forbids every cell with `B = 1, E = 0`. The conditional version `C` says two things: if `B = 1` and `K = 1` then `E = 1`; and if `B = 1` and `K = 0` then `E = 0`.

```
 B    K    E     U allows?    C allows?
-----------------------------------------
 0    0    0        yes          yes
 0    0    1        yes          yes
 0    1    0        yes          yes
 0    1    1        yes          yes
 1    0    0        NO           yes
 1    0    1        yes          NO
 1    1    0        NO           NO
 1    1    1        yes          yes

cells forbidden:     2/8          2/8
permitted fraction:  0.7500       0.7500
content, -log2(permitted):  0.4150 bits    0.4150 bits
```

At this level of description the two versions have **identical empirical content**: each forbids a quarter of the space, each carrying 0.4150 bits. **That is inconvenient for the argument and is stated before anything is done with it. The conditional's advantage is not that it forbids more cells. It is which cells it forbids.**

`U` forbids `B=1, K=0, E=0`: a belief is held, no channel exists, nothing happens. **That is the single most frequently instantiated cell in human experience** — every wish that did not come true, every conviction held for a decade about a matter its holder could not touch. Taken literally, the unconditional version is not merely unsupported. It is refuted daily, at enormous sample size, by everyone.

`C` forbids `B=1, K=0, E=1`: a belief is held, no channel exists, and the world changes anyway in a way attributable to the belief. **That cell is the one the conditional stakes itself on. It is rare, and it is exactly the cell that would matter if it were ever cleanly observed.**

34.5.2 5.2 The unconditional version, taken charitably, has zero content

Nobody defends the unconditional version literally. The defence always takes the same shape: the belief was not held hard enough; some part of the believer resisted; there was a limiting belief underneath. Formalise that as a hidden variable `S` — sufficiency of belief — and re-run the table.

```
U' :  (B = 1) AND (S = 1)  =>  E = 1,      with S UNOBSERVABLE

project the sixteen (B,K,E,S) cells onto the observable (B,K,E):
a cell is forbidden only if it is forbidden for EVERY value of S.

observable cells forbidden by U' :  0 / 8
content of U'                    :  0.0000 bits
```

Zero. Not small — zero. An unobservable sufficiency parameter converts a false proposition into an empty one, and this is the standard mechanism by which doctrines survive their own counterexamples. Every failure is absorbed by `S = 0`; every success confirms `S = 1`; nothing is learned. It is the failure of asymmetry in its purest form: `U'` and its own negation predict the same observations, which is what Popper [1959] and Platt [1964] identify as the mark of a proposition outside empirical reach, and what Lakatos [1970] describes as a research programme protected by auxiliary hypotheses rather than by results.

Demoted, in print: the unconditional proposition *belief creates reality*, in its defended form, is **a heuristic at best** — a mood-management device — and carries no evidential weight and no predictive content whatsoever. It may not be cited in support of anything in this corpus.

The conditional cannot pull the same trick, because its condition is about the world rather than about the believer. `G > 0` is checked by naming a channel and verifying its steps. It cannot be rescued by asserting that the believer's belief was defective, because the believer's state is not what the condition ranges over. **Putting the condition outside the believer is what makes it a condition rather than an excuse.**

34.5.3 5.3 The magnitude form, and how much content it has

The binary table understates the conditional badly. The conditional does not merely say that an effect occurs; it says `E = G B`, and once `G` is estimated it has predicted a *number*. Let a standardised measured effect lie in `[−1, +1]`, width 2:

```
version                              permitted band   excluded    content (bits)
-------------------------------------------------------------------------------
unconditional, with escape clause           2.000        0.0000        0.0000
```

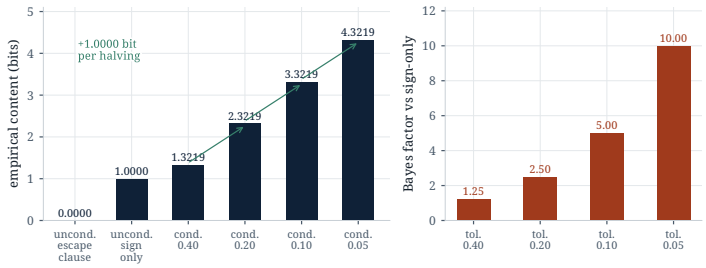

Figure 34.1: **Each halving of the prediction tolerance buys exactly one bit, and the unconditional form with its escape clause buys none.** Empirical content in bits, computed as the negative base-two logarithm of the permitted fraction of a standardised effect band of width 2: 0.0000 bits for the unconditional form with an unobservable sufficiency parameter, 1.0000 for a sign-only prediction, and 1.3219, 2.3219, 3.3219 and 4.3219 for point predictions at tolerances of 0.40, 0.20, 0.10 and 0.05. The Bayes factors against the sign-only version are 1.25, 2.50, 5.00 and 10.00. Computed from the tables of Section 5.3; generated by `figs/src/CCP-034_fig01.py`.

unconditional, sign only (E > 0)	1.000	0.5000	1.0000
conditional, point prediction +/- 0.40	0.800	0.6000	1.3219
conditional, point prediction +/- 0.20	0.400	0.8000	2.3219
conditional, point prediction +/- 0.10	0.200	0.9000	3.3219
conditional, point prediction +/- 0.05	0.100	0.9500	4.3219

Each halving of the prediction tolerance buys exactly one bit of content. That is the same logarithmic arithmetic that governs the rest of the framework and appears here for the same reason: content is a logarithm of an excluded fraction, exactly as surplus is a logarithm of an effective count and pitch a logarithm of a frequency. The information-theoretic reading is Shannon's [Shannon, 1948, Cover and Thomas, 2006].

The discrimination this buys, as a likelihood ratio for an observation landing inside the conditional's band, against the sign-only version's flat spread over `(0, 1]`:

tolerance	Bayes factor C : U	log10 BF
+/- 0.40	1.25	0.097
+/- 0.20	2.50	0.398
+/- 0.10	5.00	0.699
+/- 0.05	10.00	1.000

These are modest numbers, given honestly. One observation inside a `+/- 0.10` band is worth a factor of five — evidence, not proof. **What is not modest is the other side of the ledger: an observation outside the band gives a Bayes factor of zero. The conditional dies; the sign-only version does not, because almost nothing is outside its band.** That asymmetry is the whole case for attaching a condition, and it is what Meehl [1967] identified as the difference between a theory that risks a point prediction and one that risks only a direction.

34.5.4 5.4 The exposed flank, priced

Consider a hundred belief interventions, of which forty have a real, nameable channel to the outcome and sixty do not.

trials	100
with a real channel	40

```
without a real channel               60

unconditional predicts an effect in     100 arms
conditional   predicts an effect in      40 arms
conditional   predicts NO effect in      60 arms   <-- the exposed flank
```

Sixty per cent of the design is a region where the conditional has committed itself to finding nothing, and where finding something kills it. The unconditional version has no such region; it is undefeated because it never takes the field. Stated as a general rule:

> **The value of a condition is measured by the size of the region in which it predicts zero.**

And the price, computed against the paper's own claim rather than in its favour. Under the same base rates:

```
P(a random observation refutes the unconditional version)  =  0.3250
P(a random observation refutes the conditional  version)  =  0.0550

observations needed for a 95% chance of at least one refutation:
    unconditional     8
    conditional      53
```

Eight observations. A proposition refuted with 95 per cent confidence by eight casual observations is not a bold conjecture; it is a mistake that survives because nobody applies it to the cases where it fails. **And the conditional's own figure — 5.5 per cent per observation, 53 observations to a 95 per cent chance of refutation — is the honest measure of how much harder this paper's claim is to kill than the one it replaces.** A condition that only ever narrows the circumstances in which success is claimed is a hedge. **This one creates a large region in which failure has been promised, and that is what makes it worth having — but it also makes the claim six times harder to refute, and that cost is printed here rather than left for a reviewer to compute.**

34.5.5 5.5 What would end the postulate

Per the badge convention, any one of the following, cleanly observed and replicated, ends the postulate as stated. These are the falsifiers behind H1 to H5.

```
K1  ZERO-CHANNEL EFFECT.
    A belief-linked effect clearly above the noise floor, on a state of the world for
    which every candidate channel has been enumerated and independently excluded --
    no physiological, behavioural, social or informational route, no measurement
    artefact, no selection effect. Replicated by an independent group, preregistered.
    THIS IS THE ONE THAT MATTERS. The rest is calibration.

K2  MAGNITUDE BLOWOUT.
    Effects reliably and substantially exceeding the summed gain bound of Section 7,
    with gains estimated in advance and frozen. One instance is a missed channel;
    a pattern is a dead postulate.

K3  CHANNEL INDEPENDENCE.
    Effect magnitude independent of channel gain across channels with well-separated,
    independently measured gains. If halving the gain does not halve the effect,
    G is not what is doing the work.
```

```
K4  BLOCKADE FAILURE.
    Effects surviving the specific, verified interruption of the only named channel.
    A channel that can be cut without changing the outcome was not the channel.

K5  GROUNDING IRRELEVANCE.
    Beliefs whose channels rest on demonstrably false propositions producing the same
    effects, at the same magnitudes, as beliefs whose channels rest on true ones.
```

K5 deserves a note. A false belief with a real behavioural channel *does* produce effects — the runner who wrongly believes a supplement works still trains harder. Section 4.3 conceded this: what must be true is the channel's constituent propositions, not the believed one. **If channels whose propositions are false performed as well as channels whose propositions are true, "grounded in truth" would be doing no work and should be struck from the sentence.**

34.5.6 5.6 The fixed-point structure, and why a false belief can still be grounded

The bank-run case is why the postulate says *grounded* and not *true*, and it has an exact dynamical form. Let belief update on the evidence its own effects produce:

```
B_{t+1} = (1 − lam) B_t + lam . min(1, L . B_t)

lam   how fast belief updates on evidence, in (0,1]
L     LOOP GAIN = (effect per unit belief) x (belief produced per unit effect)
      L = alpha . G, where alpha is how strongly the observed effect feeds back
      into the belief.
```

This recursion is a formalisation of a verbal mechanism, not a derivation of one. The mechanism is Merton [1948]'s; the stability arithmetic is this work's and it is elementary. Linearising at `B = 0` gives a pole at `1 − lam + lam L`, so the zero-belief state is stable if and only if `L < 1`. Computed at `lam = 0.30`, iterated 2000 steps from `B_0 = 0.05`:

```
  L      pole      B = 0 stable?     B* reached from B_0 = 0.05
-----------------------------------------------------------------
 0.00    0.7000        YES              0.000000
 0.50    0.8500        YES              0.000000
 0.90    0.9700        YES              0.000000
 1.00    1.0000        no               0.050000   (marginal)
 1.10    1.0300        no               1.000000
 1.50    1.1500        no               1.000000
 2.00    1.3000        no               1.000000
 3.00    1.6000        no               1.000000
```

A self-fulfilling belief is exactly a belief whose loop gain exceeds one. Below one it decays to nothing however strongly it starts; above one it saturates the effector however weakly it starts. The transition at `L = 1` is sharp, and it is the same first-order pole condition as the storage law's contraction modulus with the feedback sign reversed [Curzi, 2026a]. The corresponding operational reading in the contraction literature is that distance to arrival is the last correction scaled by `q/(1−q)`, so the size of one's most recent revision is a self-reading gauge [Curzi, 2026].

And `L = alpha G`. Set `G = 0` and the loop gain is zero at every value of `alpha`, so the fixed point is `B* = 0` and nothing happens, forever, at any intensity of belief. The dynamical statement and the logical statement are the same statement.

Now the bank. The depositor's belief that the bank will fail may be false when formed. **It is grounded anyway, because the channel is real — and it is real because of a true fact about the system.**

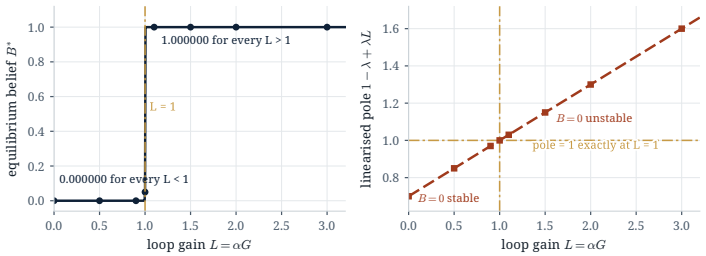

Figure 34.2: **A self-fulfilling belief is exactly a belief whose loop gain exceeds one, and the transition is sharp.** Equilibrium belief `B*` reached from `B_0 = 0.05` under `B_{t+1} = (1−lam)B_t + lam min(1, L B_t)` at `lam = 0.30` over 2000 steps: 0.000000 for `L = 0.00`, `0.50`, `0.90`, marginal at `L = 1.00`, and 1.000000 for `L = 1.10` and above. The linearised pole `1 − lam + lam L` crosses 1 at exactly `L = 1`. Because `L = alpha G`, a zero channel gain forces `L = 0` at every feedback strength. Modelled from the recursion of Section 5.6 with the parameters stated there; generated by `figs/src/CCP−034_fig02.py`.

```
reserve ratio r      bank becomes illiquid once withdrawing fraction w > r
------------------------------------------------------------------------
    0.03                              w > 0.03
    0.05                              w > 0.05
    0.10                              w > 0.10
    0.20                              w > 0.20
    1.00                              w > 1.00     <-- unreachable
```

A full-reserve bank has `G = 0` for this belief, and the identical rumour, held with identical conviction, does nothing at all. The belief is the same; the truth of the system is different; the outcome is different. That is the conditional clause, empirically instantiated, in the most famous example in the sociology of belief.

And the corpus's strongest available existence proof for a reflexive fixed point observed in the field is not the bank run but the options market. MacKenzie and Millo [2003] document a pricing model that did not fit the market when published, and a market that came to fit the model after traders adopted it, with dates and price data; MacKenzie [2006] and Callon [1998] give the book-length case and its theoretical frame. **That is a description becoming true by being used, measured, in a setting where the channel — traders acting on the model's outputs — is nameable step by step.** Soros [2013] is the closest existing named doctrine to the corpus's reflexive law and supplies the concept without an equation; what this paper adds is a loop gain and a stability condition, and what it does not add is identification.

34.6 6 The formula validation protocol, all seven gates

The working form `E = G B + eps` is a formula and is therefore subject to the corpus's seven-gate protocol. **It does not pass all seven cleanly. The failure is reported rather than concealed, and Section 7 exists to repair it.**

Gate 1 — Dimensions.

```
E    outcome units [X]          (days, millimetres of mercury, defects found,
                                 points on a validated symptom scale, currency)
B    dimensionless, [0,1]
G    [X] per unit belief
eps  [X]

Check:  [X] = ([X] / 1) . (1) + [X]  =  [X].    CONSISTENT.
```

Because `B` is dimensionless, `G` inherits `E`'s units, so **`G` is not comparable across outcomes unless both are standardised.** A gain of 0.8 days and a gain of 0.8 symptom points are not the same quantity and must never be summed. The remedy used throughout is to standardise `E` by the outcome's own standard deviation before any cross-channel arithmetic, and to state the standardisation whenever a gain is quoted. **PASS, with that condition attached and binding.**

Gate 2 — Scale type. `E` must be at least interval-scaled for the subtraction implied by "would not have occurred otherwise" to mean anything, and ratio-scaled with a true zero for the multiplication `G B` to mean anything [Stevens, 1946]. Many outcomes qualify: elapsed days, counts, physical measurements, currency. Many do not: ordinal symptom ratings, Likert satisfaction [Likert, 1932], ranked preferences.

`B` is the hard case. Belief magnitude as normally elicited is ordinal at best, and an ordinal `B` makes `G B` a heuristic ordering rather than an equation. Two routes out, both established:

- **Magnitude estimation.** Elicit belief strength by ratio judgements against a standard rather than by category selection [Stevens, 1957, 1975]. This produces ratio-scale data from human reports and it replicates; it is the route with the strongest warrant, though the range and context effects that attend it are real [Poulton, 1979].
- **Behavioural anchoring.** Operationalise `B` by a decision the believer makes — the stake accepted, the hours committed, the alternative declined. Ratio scale with a true zero by construction, **at the cost of confounding belief with the very behaviour the behavioural channel is supposed to explain.** Using the behavioural anchor and then claiming the behavioural channel is circular and is named as a failure mode in Section 9.

A third and deeper objection stands over both routes. Michell [1997] argues that psychology routinely assumes quantitative structure without testing for it, and the test that settles the question is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971]. **It has not been run for `B` and it has not been run for any construct in this corpus. VERDICT: CONDITIONAL PASS** with magnitude-estimated `B` and ratio-scaled `E`, and a **fail**, demoted in print to a heuristic ordering, whenever `B` is a Likert item — which is most of the published work on belief and outcome.

Gate 3 — Limiting cases.

```
B -> 0      E -> 0.       No belief, no effect. Trivially observed.

B -> 1      E -> G.       The most a belief can do is the channel's full gain.
                          NAMEABLE: a ceiling, and the postulate's central
                          practical content.

G -> 0      E -> 0 for all B.   NAMEABLE, and the whole point: the ungrounded
                                belief. Every wish about a matter one cannot touch.

G -> inf    E -> inf.     NOT NAMEABLE -- a genuine defect of the linear form. No
                          real channel has unbounded gain. Section 7.6 supplies
                          E = E_max . tanh(G.B / E_max) as a saturating form,
                          stated as a modelling choice, not a derivation.

eps -> large   E unrecoverable. NAMEABLE: the effect exists and the study cannot
                          see it. The commonest real-world outcome, and a fact
                          about the design, not about the postulate.
```

VERDICT: PASS with one repair. The `G -> inf` divergence is a defect of the linear approximation and is repaired by saturation. **Recorded as a repair, not hidden.**

Gate 4 — Fixed points. The **static invariant** is `G = 0 => E = 0`, the equation's null space and the postulate's entire forbidding content. The **dynamical fixed point** is Section 5.6's `B*` — a bifurcation rather than a point: `B* = 0` for `L < 1`, `B*` at the effector ceiling for `L > 1`, transition at

`L = 1` exactly. **The system has no stable intermediate belief under pure self-reinforcement**, which is H6 and is a substantive, testable prediction: beliefs in high-gain reflexive loops should be bimodally distributed in a population rather than spread smoothly. That prediction is shared with threshold and cascade models of collective behaviour [Granovetter, 1978, Schelling, 1971], which is a point against its discriminating power and is noted in Section 3.5. **VERDICT: PASS**, and this gate produced the paper's best prediction.

Gate 5 — Identifiability. Here is the trouble, and it is serious.

`E = G B` is **not identifiable from outcome data alone.** Halve `G`, double `B`, and every observation is unchanged. Two distinct parameter sets predict identical data, which means the formula is not testable as written. The repair, and it is the only repair:

> **`G` must be estimated INDEPENDENTLY of `E`, from the channel's own mechanism, and frozen before the outcome is measured.**

That is what Section 7's four channel classes are for. The behavioural gain is computed from an adherence differential and a per-unit effect, measured separately; the informational gain from a search rate and a time reallocation, measured separately. **Each is a prior, mechanism-derived estimate of `G` that never touches the outcome data, and that independence is what converts an unfalsifiable identity into a prediction.** Where `G` cannot be estimated independently, the formula is unidentifiable and must be reported as such.

VERDICT: FAIL as written; PASS only under independent, preregistered, frozen estimation of `G`. This condition is binding on every use of the postulate in this corpus. And it must be read alongside Section 3.4: **independent estimation repairs the parametric non-identifiability of `E = G B`; it does not repair the reflection problem, which is a separate and unrepaired failure affecting the social channel specifically.**

Gate 6 — Falsification.

```
1  PREREGISTER   belief, named channel, mechanism-derived G, predicted E with tolerance,
                 outcome measure, sample size, stopping rule. Before any outcome.
2  FIT           on training data only, if any parameter beyond G is free.
3  FREEZE        all parameters; publish the frozen values.
4  HELD-OUT      report performance on data not used in fitting.
5  FOUR BASELINES, all required:
                 (a) persistence      -- the outcome does what it was already doing
                 (b) direct-input     -- outcome is a rescaled copy of the belief measure
                 (c) matched AR       -- one-parameter memory model, no theory in it
                 (d) SHUFFLED-INPUT   -- same frozen parameters, belief series permuted
6  KILL RULES    K1-K5 of Section 5.5, plus: failure to beat (d) kills the application.
```

Baseline (d) decides it. If the model predicts as well with the belief series shuffled as aligned, the apparent coupling was a coincidence of two trends and there is no channel. **The shuffled-input control is the most omitted and most decisive test in this literature.** The corpus's own application of this protocol to a different law is Curzi [2026i], whose preregistered fit **failed its second falsification rule** — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin, despite +40.3 per cent over persistence and +97.7 per cent over direct input and `p = 0.0005` against the shuffle. **VERDICT: PASS** — the protocol exists, is specific, and is executable. Whether a given application passes is answered per application, and the one application so far reported in this corpus did not.

Gate 7 — Reproducibility. Same operationalisation of `B`, same channel, same `G` estimation procedure, different people, different laboratory: do the parameters recover?

For the **physiological** channel, **partially yes** — the effect has been observed across many laboratories and decades and the blockade finding has been extended, though magnitudes vary considerably across studies, populations and outcomes (Section 8). For the **behavioural** and **informational** channels, **not yet tested in this form**, because nobody has run this protocol. For the **social** channel, the underlying phenomena replicate but the gain parameter has not

been recovered across laboratories in this notation — **and Section 3.4 gives the deeper reason it may not be recoverable at all.**

The wider context is mandatory: 97 of 100 original psychology studies reported significant results while about 36 per cent of replications did, with effect sizes roughly halved [Open Science Collaboration, 2015]. **Any belief-effect literature is drawn from that population and inherits its problems** [Ioannidis, 2005]. **VERDICT: PARTIAL.** Passing for one channel in one domain; untested for three of four.

```
FVP SUMMARY

1  DIMENSIONS       PASS, with a standardisation condition
2  SCALE TYPE       CONDITIONAL PASS; fails on Likert-elicited belief; conjoint
                    measurement never run for B
3  LIMITING CASES   PASS, with the saturation repair recorded
4  FIXED POINTS     PASS, and it generated the bimodality prediction
5  IDENTIFIABILITY  FAIL as written; PASS only with G estimated independently and
                    frozen. BINDING CONDITION ON ALL USE. Does NOT repair the
                    reflection problem.
6  FALSIFICATION    PASS as a protocol; the corpus's one application of it failed
                    its own declared margin
7  REPRODUCIBILITY  PARTIAL. One channel, one domain, with caveats.
```

Five and a half of seven, and the failure is named. A postulate that reported seven of seven would be a postulate nobody had audited.

34.7 7 The coupling requirement: channels, gains, and composition

34.7.1 7.1 The operational form, badged

> **[POSTULATE — 7.1, the operational form of 4.1]** A belief `B` affects a world-state `E` only through one or more channels. Each channel `i` has a gain `G_i` — the change it produces in `E` per unit of `B` — determined by the channel's own mechanism and not by the belief. Then
>
> ```
> E  =  ( sum_i G_i ) . B  +  eps        for small B, before saturation
>
> and the BOUND:      |E|  <=  ( sum_i G_i ) . B_max
> ```
>
> **If no channel exists, the sum is empty, `sum_i G_i = 0`, and `E = 0` at every `B`.**

The badge stays on. This is a postulate, not a theorem, and what would end it is K1 of Section 5.5 — an effect with every candidate channel enumerated and excluded.

But the bound is not a postulate once the gains are estimated. Given estimated gains, the bound is arithmetic, and arithmetic is what makes a claim auditable. A person claiming their belief will move an outcome by three standard deviations, through channels whose summed gain estimates to 0.4, has made a claim that fails before any data are collected.

34.7.2 7.2 The correspondence with the storage law, and exactly what it does and does not transfer

```
STORAGE LAW          Q_{t+1} = (1 - delta) Q_t + eta . S_t - C_t
```

```
COUPLING RELATION     E = G . B

TERM       STORAGE LAW                    COUPLING RELATION
-------------------------------------------------------------------------
INPUT      S_t, surplus offered           B, belief held
           bounded: 0 <= S_t <= ln N      bounded: 0 <= B <= 1

CONVERSION eta, how much input becomes    G, how much belief becomes
           durable structure              world-change
           eta = 0 -> nothing sticks      G = 0 -> nothing happens

OUTPUT     what lands in Q_t, the         E, the measured change in the world
           stored order

LOSSES     delta Q_t (decay) and C_t      eps (noise) and, over time,
           (cost)                         the same delta and C
```

This is a claim about model form and is badged as one. The same first-order structure describes both; no claim is made that belief and stored order are the same kind of quantity, that they can be aggregated, or that a result proved about one is thereby proved about the other. **The storage law is a proven theorem about a recursion, with a contraction modulus `1 - delta` and a steady state `(eta S - C)/delta` obtained as the circuit's DC gain `1/delta` applied to the net drive [Curzi, 2026a]. The coupling relation is a postulate about the world. The form transfers; the warrant does not.** The corpus states the same badge for its three-scope correspondence generally: identical structure at three scopes is a statement about the chosen model, not a claim of kinship or of cross-scope aggregation [Curzi, 2026].

Four consequences read directly off the law and transfer without modification.

Consequence 1 — the input is capped. `S_t <= ln N` is a hard ceiling and `B <= 1` is the same kind of ceiling. Neither system can be driven arbitrarily hard from the input side. **Believing harder runs out before it starts.**

Consequence 2 — conversion is the cheap lever. The corpus's standing claim is that `eta` is the most neglected parameter and usually the cheapest to improve. The same holds here. **Doubling `B` requires changing a person's mind; doubling `G` requires changing an arrangement, and arrangements are easier to change than minds.**

Consequence 3 — one-step growth has a threshold. `Q_{t+1} > Q_t` if and only if `eta S_t > delta Q_t + C_t`. Translated: **belief does not merely need a channel, it needs a channel with enough gain to beat the decay and the cost of holding the belief.** Section 7.8 computes the resulting minimum viable gain.

Consequence 4 — headroom governs. `h_t = G ln N - delta Q_t - C_t` applies unchanged with `eta -> G`. **If `h_t < 0`, no belief of any strength improves the system, because the model's own arithmetic says nothing can. A person in a negative-headroom situation who is told to believe harder is being given the one instruction that provably cannot work.** The corpus's five-system survey found that the binding constraint differs by system rather than by size — 41.64 per cent of ceiling where the constraint is `u`, 28.59 per cent where it is acoustically caused, 69.28 per cent with `h = -0.654` where it is cost, and 91.03 per cent of ceiling still negative at `h = -0.273` where it is conversion [Curzi, 2026k].

34.7.3 7.3 Composition: series multiplies, parallel adds

Series. A channel with several stages has the product of the stage gains.

```
stage                                    stage gain    cumulative
-------------------------------------------------------------------
```

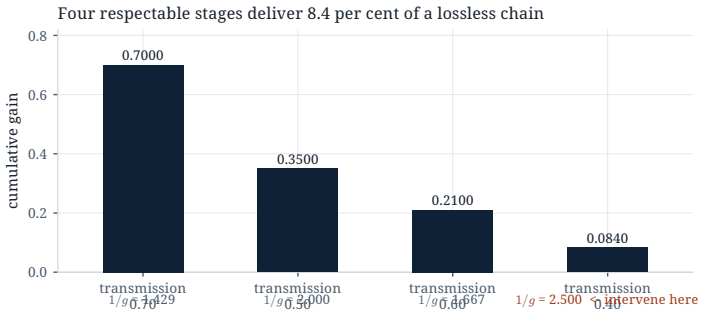

Figure 34.3: **Series composition is brutal: four respectable stages deliver 8.4 per cent of a lossless chain.** Cumulative gain falls 0.7000, 0.3500, 0.2100, 0.0840 across stages of transmission 0.70, 0.50, 0.60 and 0.40; relative sensitivity `1/g_i` identifies the 0.40 stage, at 2.500, as the one where intervention pays. Any single stage set to zero takes the product to zero. Computed from the stage table of Section 7.3; generated by `figs/src/CCP-034_fig03.py`.

```
belief registered as expectation            0.70        0.7000
expectation reaches the effector            0.50        0.3500
effector produces the change                0.60        0.2100
change persists to measurement              0.40        0.0840

TOTAL SERIES GAIN                                       0.0840
```

Four stages, each individually respectable — the worst is 0.40 — and **the chain delivers 8.4 per cent of what a lossless chain would. Series composition is brutal, and it is the reason that long, plausible-sounding causal stories deliver almost nothing. Every "and then" in a mechanism is a multiplication by a number less than one.**

```
relative sensitivity of the total to stage i  =  1 / g_i

belief registered as expectation      1.429
expectation reaches the effector      2.000
effector produces the change          1.667
change persists to measurement        2.500   <-- fix this one first
```

The weakest stage has the highest leverage, and the arithmetic identifies it without argument. And **any single stage at zero makes the total zero regardless of the others**, which is the coupling requirement in its most compact form.

Parallel. Independent channels add, and **the sum is a bound, not a promise.**

```
channel                                      gain G_i
-----------------------------------------------------
physiological                                  0.30
behavioural                                    0.55
social                                         0.25
informational                                  0.20
-----------------------------------------------------
SUM                                            1.30

bound on |E|:    B = 0.2  ->  0.260
                 B = 0.5  ->  0.650
                 B = 0.8  ->  1.040
                 B = 1.0  ->  1.300
```

Additivity is an upper limit that assumes the channels do not interfere, and real channels frequently do — the behavioural channel consumes time the informational channel needed; the social channel's conformity pressure suppresses the individual belief driving the others. **If a measured effect exceeds the summed bound, one of three things is true: a channel was missed, a gain was underestimated, or the measurement is wrong. There is no fourth option that does not damage the postulate.**

34.7.4 7.4 Why exactly four classes

The taxonomy is exhaustive by argument rather than by decree: **a belief is a state of a nervous system, and there are exactly four kinds of thing a state of a nervous system can do to the world outside the skull.**

```
1  It can change the body it is inside.                    PHYSIOLOGICAL
   Route: expectation -> neural and endocrine state -> tissue.

2  It can change what that body does.                      BEHAVIOURAL
   Route: belief -> action selection -> the world acted upon.

3  It can change what other nervous systems do, by being   SOCIAL
   communicated and held in common.
   Route: belief -> expression -> others' beliefs -> collective action.

4  It can change what that body notices and therefore      INFORMATIONAL
   what it finds.
   Route: belief -> attention and search allocation -> discovery of things
   that were already there.
```

Anything a belief does falls into one of these, into a combination, or into a fifth option — **direct action on the world with no bodily route at all, the class for which no channel has ever been specified and which the postulate therefore predicts to have gain exactly zero.** Section 7.9 handles it.

Class 4's phrasing is exact and load-bearing. The informational channel does not create what is found. It changes the probability of finding what is there.

34.7.5 7.5 The four channels, their gains, and how each is estimated

The physiological channel. *What it can do:* change measurable states of the believer's own body — reported pain, autonomic tone, hormone release, motor performance under fatigue. *What it cannot do:* change another person's body at a distance; change tissue for which no efferent pathway exists; produce effects larger than the effector's own maximum. **There is no efferent pathway from expectation to, for example, the size of a solid tumour, and the postulate therefore predicts zero there.** Its gain, from Section 8:

```
G_physio = measured standardised effect / normalised expectancy

d = 0.30, B = 1.00  ->  G = 0.3000
d = 0.30, B = 0.70  ->  G = 0.4286
d = 0.20, B = 0.50  ->  G = 0.4000
d = 0.15, B = 1.00  ->  G = 0.1500

WORKING RANGE, subjective symptom-based outcomes:  0.15 to 0.45
WORKING RANGE, objective disease endpoints:        approximately 0
```

Both lines matter and the second as much as the first: the gain is real and modest for what the person reports, and approximately zero for endpoints an instrument reads independently of the person. Estimation requires three steps, all binding: **E1** name the efferent pathway from the central state to the measured tissue, and estimate `G = 0` if it cannot be named; **E2** find the published effect size for that pathway and outcome class, from a three-arm design that separates the channel from natural history; **E3** divide by the expectancy that produced it, measured on the same scale to be used for `B`, and report a range rather than a point where the source study did not measure expectancy. **A physiological gain quoted without a named efferent pathway is not an estimate.**

The behavioural channel — the largest of the four by a wide margin and the least discussed. *What it can do:* anything a person's actions can do, which includes almost everything anyone ever wanted from believing something. *What it cannot do:* anything actions cannot do. **Here the conditional clause bites hardest: the behavioural gain contains the effectiveness of the action as a multiplicative factor, so a belief that reliably produces an action that does not work has gain exactly zero.**

```
G_beh  =  (delta p)  x  (effect per unit action)

adherence without the belief    p0 = 0.55
adherence with the belief       p1 = 0.80          delta p = 0.25
effect of the practice at full adherence           0.50 standardised

G_beh = 0.25 x 0.50 = 0.1250

AND THE CONDITIONAL CLAUSE, in one line:
if the practice does nothing (effect at full adherence = 0):  G_beh = 0.0000
at every value of delta p, however large.
```

A belief that produces perfect adherence to a useless practice has gain zero. That single line is the difference between this framework and motivational literature, and it is checkable. Estimation: **B1** measure `delta p` from behaviour records — attendance logs, commit history, sensor data — never from self-reported intention, which correlates with the belief measure by construction and produces a circular estimate; **B2** measure the effect per unit action separately, in a design that varies the action without varying the belief; **B3** multiply, and **report both factors, not only the product**, so a reader can see that a gain of 0.125 was 0.25 of a real effect rather than 0.90 of a negligible one.

The social channel. *What it can do:* coordinate — change what a group will attempt, treat as normal, and enforce. *What it cannot do:* anything the group could not do if coordinated by other means. **The social channel is a coordination device, not a power source**, and its ceiling is the group's actual capability. It also has a specific failure: it raises coordination by lowering the non-parallelism `u` that generates the group's surplus in the first place.

Its gain is the only one of the four whose response is sharply nonlinear in the fraction of the group holding the belief.

```
group N = 240
committed fraction    people
------------------------------
    5%                   12
   10%                   24
   15%                   36
   20%                   48
   25%                   60      <-- the measured tipping region
   30%                   72
```

A committed minority of approximately 25 per cent has been measured to overturn an established social convention in controlled online experiments [Centola et al., 2018]. **Trans-**

fer to a field organisation is a modelling assumption, not a measurement, and is labelled as such every time the number is used. Estimation: **S1** count the committed, not the agreeable — committed means acting on it when it costs something, and survey agreement is the standard way this estimate is inflated; **S2** map the topology, because complex contagion needs multiple reinforcing contacts, so clustered placement beats scattered placement at the same headcount [Centola and Macy, 2007, Centola, 2010]; **S3** compare to threshold and state the transfer assumption aloud; **S4** below threshold, estimate `G_social` as small and decaying, and never average across the threshold, because the response is not linear there. Related threshold and cascade results bound what the channel can do at all [Granovetter, 1978, Bikhchandani et al., 1992].

The honesty clause this channel requires: it is the one with a coercion failure mode. A belief propagated through a group can be propagated by pressure, and pressure removes the ability to decline. **Any protocol that raises `G_social` by removing a person's option to dissent is out of scope for this framework**, and it destroys `u` in the bargain. **And Section 3.4 applies here and nowhere else with full force: `G_social` is not identified from observation of a group.**

The informational channel — the subtlest of the four and the one where the conditional clause is most cleanly visible. *What it can do:* change what a person attends to, searches for, and therefore finds. *What it cannot do:* **put anything there. The informational channel's gain is exactly zero when the target is absent, at every level of belief, effort and duration. This is not a caveat; it is the channel's defining equation.**

```
P(find) = 1 − exp(−r . t),  with r = 0.05 per hour, TARGET PRESENT

    hours t      P(find)
−−−−−−−−−−−−−−−−−−−−−−−−−
         5        0.2212
        10        0.3935
        15        0.5276
        25        0.7135
        40        0.8647
        60        0.9502

belief raises directed search from 10 h to 25 h:
    delta P(find) = 0.7135 − 0.3935 = 0.3200

TARGET ABSENT:  P(find) = 0.0000 at t = 5, 10, 15, 25, 40, 60, and at every other t.
```

Left column identical, right column zero. The same belief, the same conviction, the same reallocated hours, and a gain of 0.32 in one case and 0.00 in the other — **and the difference is entirely a fact about the world, not about the believer.**

This is also the honest explanation of a large fraction of the anecdotes that circulate as evidence for the unconditional version. Someone believed opportunities were everywhere, looked much harder, found one, and reported that belief had created it. **The belief did not create it. The belief created the search. The search found what was there. And in the cases where nothing was there, nothing was found and no anecdote was generated** — which is survivorship bias operating on the evidence base for the entire genre. Estimation: **I1** establish the base rate that the target exists, the step almost never taken; **I2** measure the search rate `r` from a comparable completed search; **I3** measure the time reallocation from time records; **I4** compute `G_info = P(exists) [exp(−r t0) − exp(−r t1)] x (value per find)`. **The believer contributes the time reallocation. The world contributes `P(exists)` and `r`. The believer's contribution cannot rescue a zero in the world's.**

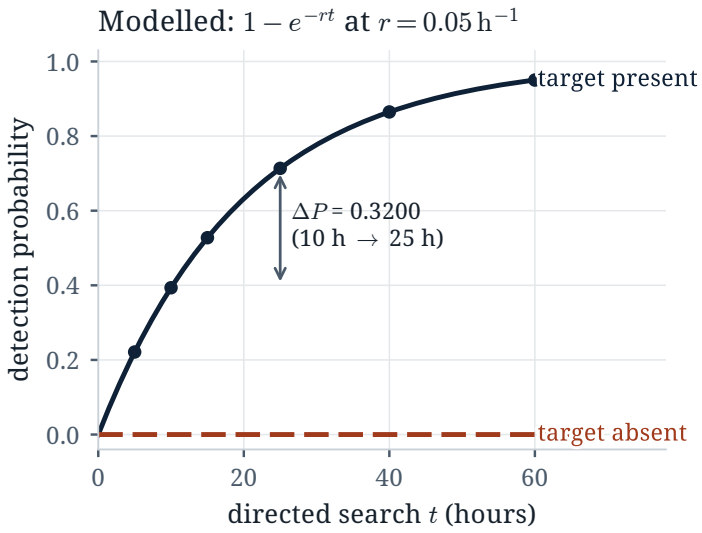

Figure 34.4: **The informational channel's gain is a fact about the world, not about the believer.** Detection probability `1 - exp(-r t)` at `r = 0.05` per hour with the target present rises 0.2212, 0.3935, 0.5276, 0.7135, 0.8647, 0.9502 at 5, 10, 15, 25, 40 and 60 hours, so a belief that raises directed search from 10 to 25 hours buys `delta P = 0.3200`. With the target absent the same curve is 0.0000 at every `t`. Modelled as a Poisson search process with the parameters of Section 7.5; generated by `figs/src/CCP-034_fig04.py`.

34.7.6 7.6 Saturation

Gate 3 flagged `G -> inf` as a defect. The repair, stated as a modelling choice and not a derivation:

```
E  =  E_max . tanh( G . B / E_max )        [MODELLING CHOICE, not a derivation]

small G.B:   E -> G.B                (recovers the linear relation)
large G.B:   E -> E_max              (the effector's ceiling)
```

`E_max` is the effector's physical or social maximum. **Every real channel has an `E_max`, and quoting a gain without quoting the ceiling it saturates against is an incomplete specification.**

34.7.7 7.7 The four gains side by side

CHANNEL	TYPICAL GAIN	CEILING (E_max)	WHAT ZEROES IT
physiological	0.15–0.45 on subjective outcomes; ~0 on objective disease endpoints	the effector's own maximum output	no efferent pathway to the measured tissue
behavioural	widest range; 0.1–0.6 typical in the worked cases here	the person's time and capability	the action is ineffective (effect per action = 0)

social	bimodal: small below threshold, large above	the group's actual capability	below the committed-fraction threshold, or the group cannot do the thing at all
informational	0 to ~0.35; entirely conditional on the target existing	P(exists) x value per find	the target is not there (P(exists) = 0)

First: the behavioural channel dominates. In every worked case here, and in the overwhelming majority of real ones, the behavioural gain is the largest term. **The practical advice that falls out of the postulate is therefore not to believe harder and not to expect healing. It is: find the action the belief produces, and check whether that action works.** That is a deflationary conclusion and it is the correct one.

Second: three of the four zero out on a fact about the world. No efferent pathway; ineffective action; absent target. Only the social channel's zero is about the group. **The conditional clause is not a philosophical scruple bolted onto the postulate. It is where three of the four gain formulas have their zero.**

34.7.8 7.8 The minimum viable gain

Take six distinguishable domains, a belief-driven surplus at 75 per cent of the ceiling, a retention loss of 10 per cent per period, a cost of 0.09 per period, and stored order at 1.5:

```
N = 6,  ln N = 1.791759,  S = 0.75 . ln N = 1.3438,  delta = 0.10,  C = 0.09,  Q_t = 1.5

G       h = G.lnN - delta.Q - C      Q_inf = (G.S - C)/delta     growing this step?
-------------------------------------------------------------------------------------
0.00           -0.2400                     -0.9000                    no
0.08           -0.0967                      0.1751                    no
0.15            0.0288                      1.1157                    no
0.25            0.2079                      2.4595                    YES

G_min for growth this step  =  (delta.Q + C) / S    =  0.1786
G_min for non-negative headroom = (delta.Q + C)/lnN =  0.1339
```

A channel gain of 0.15 is a real channel and it still loses ground, because the decay on existing stored order plus the cost of maintaining the belief exceed what the channel delivers. **The belief is grounded, the effect is real, and the system declines anyway.**

> **A grounded belief with insufficient gain is still a losing proposition. "It has a real mechanism" is necessary and it is not sufficient. The mechanism must clear `(delta Q + C) / S`.**

And the `G = 0` row deserves its own sentence. `Q_inf = -C/delta = -0.9000`, a negative equilibrium, which the storage law identifies as its own signal that the regime is unsustainable and outside the model's domain [Curzi, 2026a]. **A belief with no channel does not merely fail to build anything. Maintenance still bills. Holding an ungrounded belief is a net cost, continuously, and the arithmetic says so without any need for moralising about it.**

34.7.9 7.9 The fifth class, and why it is assigned gain zero

The four classes route through the believer's body. The fifth putative class does not: belief acting on the world directly, with no bodily, behavioural, social or informational route.

The postulate assigns it gain zero, and the reasoning is K1's: no channel has been specified. Not that the evidence is against it — the postulate does not need to adjudicate any particular experimental literature. The claim is narrower and firmer: **no one has produced a mechanism specification of the kind the four estimation procedures require. Name the carrier. Name the transducer. Name the energy budget. State the distance dependence and the noise floor it must beat.** Until a channel specification exists, the coupling relation's sum is empty and its prediction is zero, **and that prediction is the thing to test.**

The corresponding bridge is examined and rejected in Appendix B, audit B4. The paper's companion on the quantum formalism supplies the decisive quantitative objection to the version of this class that invokes physics: the corpus's conjugate-structure material is badged **analogy, not identity**, with an explicit refusal that quantum mechanics licenses anything about belief, mind, or future events [Curzi, 2026z], and the warm-wet decoherence estimate is `1.98e-17` s against a `1e-3` s neural event [Curzi, 2026aa].

A note on the word *channel*. It is used here in the sense the corpus uses it elsewhere: a route with an identity, whose separation from other routes is a structural property rather than a matter of care. The corpus's measured instance is in a different domain — in-band architectures admit an impersonation class that no care within the shared channel can close, while out-of-band separation closes it structurally, measured at 0.383 per cent in-band ambiguity against 0.000 per cent out-of-band over 100,000 values [Curzi, 2026]. **The parallel is structural and is claimed as nothing more: what transfers is the discipline of naming the route and treating its separation as a property of the architecture rather than of the operator's diligence.**

34.8 8 The measured channel

34.8.1 8.1 What this section is

This section asserts almost nothing of its own. It reports what has been measured, states the measurements' limits, and computes what they imply for the gain budget of Section 7. Where a number appears without a citation, it is arithmetic performed here on stated assumptions and is labelled as such.

An unusual constraint applies and is stated at the front. The corpus's external bibliography contains no entries for the primary placebo literature. The studies below are therefore named in the text with author, year and venue, exactly as the source manuscript states them, and **no bibliography key is attached to any of them**, because attaching an available key that does not support the sentence is worse than leaving it unattached. Appendix C lists them so a reader can locate them, and Section 13 records the gap as a real deficiency in the corpus's apparatus. **Furthermore, where the source manuscript declines to quote a figure from memory, this paper declines with it: the design and the direction of a result are given, and the reader is directed to the paper for its coefficients. An admitted gap is better than an invented decimal.**

34.8.2 8.2 The blockade result

```
Levine, J.D., Gordon, N.C. & Fields, H.L. (1978). "The mechanism of placebo analgesia."
The Lancet.

SETTING       postoperative dental pain, following third-molar extraction
MANIPULATION  administration of placebo; and administration of naloxone, a competitive
              opioid receptor antagonist
FINDING       placebo analgesia was reversed by naloxone
INFERENCE     the analgesia produced by expectation was mediated, at least in
              substantial part, by ENDOGENOUS OPIOID activity
```

A drug that blocks one receptor system removed an effect produced by a sentence. Nothing about the sentence changed and nothing about the patient's situation changed; what changed was the availability of one class of receptor, and the belief-produced effect went with it. **That is Section 7.3's series chain with one stage cut.**

```
STAGE                                                intact      naloxone
-------------------------------------------------------------------------
1  patient is told they are receiving an analgesic   ok           ok
2  patient forms an expectation of relief            ok           ok
3  descending opioidergic system engages             ok        BLOCKED
4  nociceptive signalling is modulated               ok           --
5  patient reports reduced pain                      ok           --

SERIES GAIN with stage 3 = 0:  the product is zero.
```

A channel that can be cut, with the effect disappearing when it is cut, is a channel that has been identified rather than hypothesised. K4 of Section 5.5 named blockade failure as a kill condition. **This is H4 run and passed, and it is the single result in this paper that most strongly discriminates the channel account from a model with no channel structure** (Section 3.5).

The honest limits, and they are real. The 1978 study was small, as studies of that era and setting were. Naloxone is not perfectly specific, and interpreting a reversal requires ruling out that naloxone is hyperalgesic on its own — a control the subsequent literature has attended to at length. **"Mediated by endogenous opioids" does not mean "entirely opioid":** later work reported that placebo analgesia has both opioid and non-opioid components depending on how the expectation was induced, with verbal suggestion engaging opioid mechanisms and conditioning with a non-opioid drug engaging a naloxone-insensitive route. Neuroimaging work reported placebo-associated changes in pain-related brain activity and, later, involvement of descending opioidergic control and of the spinal cord. **These extend the 1978 inference; they do not replace it.**

34.8.3 8.3 The disclosure result, and why it decides the framework's ethics

```
Kaptchuk, T.J. et al. (2010). "Placebos without deception: a randomized controlled
trial in irritable bowel syndrome." PLoS ONE.

DESIGN        randomised, two arms, three weeks
ARM 1         open-label placebo: pills presented explicitly and truthfully as inert,
              with an explanation that placebo effects can be substantial
ARM 2         no-treatment control, with the patient-provider interaction matched --
              which is the design feature that makes the comparison meaningful
FINDING       the open-label placebo arm improved significantly more than the
              no-treatment control on the trial's primary outcomes
n             80 patients
```

The design and the direction of the finding are stated; **the response percentages are deliberately not quoted from memory.** Subsequent work has extended the result to chronic low back pain and other conditions, and a meta-analysis of open-label placebo randomised trials reported a positive overall effect. **The honest summary is that the direction is consistent, the individual trials are mostly small, the outcomes are mostly subjective and self-reported, and the field is active.**

Why it is decisive for this framework specifically. Every protocol in this corpus operates under an absolute constraint: nothing masked, nothing below threshold, nothing concealed, because **a message hidden from its recipient cannot be consented to.** That is the same rule as the framework's prohibition on any intervention removing a person's ability to decline,

applied to information, and it stands in the same tradition as the argument that a mechanism's security must not depend on its concealment [Kerckhoffs, 1883].

Before 2010, that constraint and the physiological channel were in tension. The received view was that the effect required the patient to believe the pill was active, which requires telling them something false, which the constraint forbids. **The constraint would have won and the channel would have been closed to this framework.**

```
IF the effect requires deception:
    the channel is unavailable under the no-concealment constraint.
    G_physio = 0 FOR THIS FRAMEWORK, whatever it is elsewhere.

IF the effect survives disclosure:
    the channel is available under the constraint, at whatever gain it has.
    The person is told the truth, retains the ability to decline, and the effect
    is nonetheless measured.

THE EVIDENCE, AS IT STANDS, IS THE SECOND -- for subjective, symptom-based outcomes,
at modest magnitudes, in a literature that is small and active.
```

That is as far as it goes and it is stated to go exactly that far. It does not establish that any method in this corpus produces any effect. **It establishes that a truthful presentation is not automatically an inert one, which is a fact about the world that the framework's ethics needed and did not create.**

34.8.4 8.4 What "modest" means, in numbers

The word *modest* does heavy lifting in this literature and should be converted into arithmetic. Standardised effect `d`, converted to the probability that a randomly chosen treated person is ahead of a randomly chosen untreated one, and to a number needed to treat derived from that probability:

d	P(superiority)	NNT	distribution overlap	r
0.10	0.5282	17.74	0.9601	0.0499
0.15	0.5422	11.84	0.9402	0.0748
0.20	0.5562	8.89	0.9203	0.0995
0.25	0.5702	7.13	0.9005	0.1240
0.30	0.5840	5.95	0.8808	0.1483
0.40	0.6114	4.49	0.8415	0.1961
0.50	0.6382	3.62	0.8026	0.2425
0.80	0.7142	2.33	0.6892	0.3714
1.00	0.7602	1.92	0.6171	0.4472

At `d = 0.20` — a very common magnitude in this literature — **two people drawn at random, one treated and one not, and the treated one is ahead 55.6 per cent of the time against 50 per cent by coin flip. The distributions overlap by 92 per cent.** That is what a real, replicated, mechanistically grounded effect looks like from the inside, and it is much less than the word "works" usually conveys.

```
d = 0.15   NNT 11.84  ->  in 1000 people treated, about  84 additional responders
d = 0.20   NNT  8.89  ->  in 1000 people treated, about 112 additional responders
d = 0.30   NNT  5.95  ->  in 1000 people treated, about 168 additional responders
```

Small per person. Not small per thousand. Both statements are true and neither excuses the other. A clinician deciding for one patient and a health system deciding for a population are looking at the same number and correctly reaching different conclusions about it.

34.8.5 8.5 The three-arm requirement

This is the most important methodological point in the section and it separates "the placebo arm improved" from "there was a placebo effect." A patient in a placebo arm improves for at least three reasons that have nothing to do with belief: **natural history**, since most conditions fluctuate and many remit; **regression to the mean**, since patients enrol when symptoms are bad and a subsequent measurement drawn from the same noisy distribution is expected to be less extreme; and **measurement and reporting effects**, including repeated administration of a scale and the desire to please the investigator [Nisbett and Wilson, 1977, Schwarz, 1999, McCambridge et al., 2014].

Separating these from the belief-produced effect requires **a third arm receiving no treatment at all.** Computed, on illustrative symptom-scale changes where lower is better:

```
arm                    change
-----------------------------
no treatment            -1.2
placebo                 -3.0
active drug             -5.4

natural history + regression to the mean          =  -1.2
PLACEBO EFFECT PROPER   = placebo - no treatment  =  -1.8
DRUG EFFECT PROPER      = drug - placebo          =  -2.4

a TWO-ARM trial reports -2.4 and cannot see the -1.8 at all
fraction of the placebo arm's improvement that is NOT a placebo effect:  40.0%
```

Forty per cent of what looks like a placebo effect in this example is not one. That is the deflationary argument reduced to one line of arithmetic, and it is why analyses restricted to placebo-versus-no-treatment comparisons have found much less than the folklore assumed: they looked only at trials with the third arm, and the third arm is where the deflation lives. **The conclusion, stated as its authors stated it: little evidence that placebo interventions have important clinical effects in general, with a possible exception for continuous subjective outcomes, particularly pain. That exception is the whole of the physiological channel's remaining territory and it should be treated as such.**

34.8.6 8.6 The divergence diagnostic

The most useful design in this literature measures a subjective and an objective outcome **in the same patients, in the same arms, at the same time.** In asthma, patients received in a crossover design an active bronchodilator, a placebo inhaler, sham acupuncture, and no intervention, and two things were measured: what patients reported, and FEV1 read by a spirometer.

The finding, in its shape: subjective improvement was substantial and broadly similar across the active drug, the placebo inhaler and the sham acupuncture, and much greater than no intervention. FEV1 improved substantially only with the active bronchodilator. The structure is given; the percentages are not quoted from memory.

```
THE DIVERGENCE DIAGNOSTIC

    D  =  d_subjective  -  d_objective

measured in the SAME arm, in the SAME trial, at the SAME time.

arm                       d_subj    d_obj      D
-----------------------------------------------------
no treatment               0.00      0.00     0.00
```

```
open-label placebo          0.30      0.02      0.28
active drug                 0.55      0.52      0.03
```

A large positive D is the signature of a channel that reaches REPORT but does not reach the PHYSIOLOGY the instrument is reading. A D near zero is the signature of a channel that reaches both.

Three things must be said and all three matter. **First, this is a diagnostic on the channel, not a verdict on the patient.** The subjective improvement is not fake; the patient genuinely felt better and feeling better is a real state with real value. **Second, and this is why the finding is dangerous rather than merely interesting: in asthma the subjective measure is the one that fails.** A patient whose airways are closing may feel improved while the spirometer says otherwise, and acting on the feeling instead of the instrument is how people die of asthma. **The divergence is a clinical hazard and one of the strongest possible arguments against forgoing treatment on the strength of feeling better. Third, it is exactly what the channel analysis predicts.** The efferent pathways available to the physiological channel terminate on systems that modulate perception, affect and some autonomic function; **they do not terminate on airway smooth muscle in a way that produces bronchodilation, and the postulate's prediction for an outcome with no efferent pathway is zero. The prediction and the observation agree, which is worth exactly as much as one agreement is worth.**

34.8.7 8.7 Two routes, and which one this framework may use

```
EXPECTANCY     the person is TOLD something, forms a conscious expectation, and the
               expectation engages central mechanisms.
               Manipulated by: verbal instruction, framing, presentation, manner.
               Reported to engage opioid mechanisms in analgesia -- consistent with
               naloxone reversibility.

CONDITIONING   the person has REPEATEDLY received an active agent in a context, and the
               context alone comes to produce a physiological response.
               Manipulated by: prior pairing, not by instruction.
               Reported to produce responses that verbal instruction cannot readily
               override, and in analgesia responses that can be naloxone-insensitive
               when the conditioning agent was non-opioid.
```

Work in this area has reported that some conditioned hormonal responses are not modifiable by verbal expectation while pain responses in the same subjects are — that is, **the two mechanisms reach different effectors.** This is given as a reported finding whose structure is confidently stated and whose coefficients are not quoted from memory.

```
EXPECTANCY   is the route available to a no-concealment protocol, because it operates
             through what the person is TOLD, and telling them the truth is a
             permissible instruction. This is the route open-label placebo uses.

CONDITIONING requires prior pairing with an active agent, which outside a clinical
             setting means it is largely UNAVAILABLE.

CONSEQUENCE  the gain available under this framework's constraints is the expectancy
             gain, not the total. The 0.15-0.45 range is an upper bound and probably
             a generous one.
```

Every honest narrowing of what is available makes the remaining claim easier to check, which is the argument for making the narrowings.

34.8.8 8.8 Nocebo: the same channel with the sign reversed

Nothing in the postulate distinguishes positive from negative expectation. `E = G B` is indifferent to sign, and the evidence says the world is too. The clearest available demonstration is an n-of-1 randomised design in which individual patients who had stopped taking a drug because of side effects took, in randomised blinded periods, the drug, an identical placebo, and no tablet at all.

```
NOCEBO ATTRIBUTION RATIO

    ratio = ( S_placebo − S_no_tablet ) / ( S_drug − S_no_tablet )

worked on three illustrative symptom-score patterns:

S_drug   S_placebo   S_no_tablet     ratio
──────────────────────────────────────────────
 16.3      15.4          8.0        0.8916  (89.2%)
 20.0      18.0         10.0        0.8000  (80.0%)
 20.0      10.0         10.0        0.0000  ( 0.0%)
```

A ratio near 1 means almost the entire symptom burden is carried by the act of taking a tablet rather than by the tablet's pharmacology. A ratio near 0 means the burden is pharmacological. The formula distinguishes them; opinion does not. The trial reported a high ratio; the figure is not quoted from memory.

One. Nocebo is not a curiosity: it causes people to stop treatments that are working.

Two. Informed consent creates nocebo. Telling a patient the list of possible side effects reliably increases the rate at which they are reported. **This is a genuine and unresolved ethical tension in clinical communication and it is not this corpus's to resolve; it is noted because a treatment presenting only the beneficial direction of a channel would be presenting half a mechanism.**

Three, and this is the one that governs here. The no-concealment constraint has a cost, and this is where the cost is. Telling people the truth about what they are receiving raises nocebo as well as permitting open-label placebo. **This corpus accepts that cost without argument, because the constraint is not a cost-benefit judgement: a message hidden from its recipient cannot be consented to, and consent is not a term in an optimisation.**

Four. Symmetry is a testable prediction the postulate makes. `G` should be approximately the same magnitude in both directions for the same channel and outcome class. **If negative expectations reliably produced much larger effects than positive ones through the same measured pathway, the single-channel model would need amendment.**

34.8.9 8.9 What the disclosure result does not show

```
IT DOES NOT SHOW that the mechanism is understood. Why an admitted placebo works is an
open question. Candidate explanations include residual expectancy generated by the
explanation itself, conditioning from a lifetime of taking pills, the ritual of
treatment-taking, the therapeutic relationship, and reporting effects. THESE ARE NOT
RESOLVED, and anyone who says which one it is has gone beyond the evidence.

IT DOES NOT SHOW an effect on objective disease endpoints. The trials are overwhelmingly
on symptom scales in conditions defined by symptoms. Section 8.6 applies with full force.

IT DOES NOT SHOW a large effect. The trials are mostly small. Meta-analysis reports a
positive overall effect; heterogeneity is substantial and small-study effects cannot be
excluded in a literature of this size.
```

```
IT DOES NOT SHOW that any method in THIS CORPUS does anything. No method in this corpus
has been tested.

IT DOES NOT LICENSE FORGOING TREATMENT. Under any reading. In any degree.
```

34.8.10 8.10 The gain, and the over-budget check

```
G_physio  =  measured standardised effect / normalised expectancy

WORKING RANGE for subjective, symptom-based outcomes:   0.15 to 0.45
WORKING RANGE for objective disease endpoints:          approximately 0
WORKING RANGE available under the no-concealment
  constraint (expectancy route only):                   the low end of the first range

|E|  <=  G . B    with  G ~ 0.3  and  B <= 1  gives  |E|  <=  0.3

ANY CLAIM OF A STANDARDISED EFFECT ABOVE ABOUT 0.3, THROUGH THIS CHANNEL ALONE,
IS OVER BUDGET AND MUST NAME AN ADDITIONAL CHANNEL.
```

That is a computable objection and it takes about ten seconds to run. It is the single most useful thing this section hands to a reader who has to evaluate somebody else's claim.

34.8.11 8.11 What the postulate forbids here, as numbers

```
F1  A placebo arm whose OBJECTIVE endpoint moves as far as the drug arm, for an endpoint
    with no plausible efferent route from central expectation. Predicted ratio
    d_obj(placebo)/d_obj(drug) <= about 0.2 for such endpoints. Observed reliably above
    0.6 would put the channel analysis in serious trouble.

F2  An open-label arm indistinguishable from no-treatment when the patient-provider
    interaction is properly matched. This would remove the finding Section 8.3 rests on.

F3  A blockade agent leaving placebo analgesia untouched in a design that reproduces the
    1978 conditions with adequate power and appropriate controls. That would mean the
    opioid route is not the route, and the stage-3 identification is wrong.

F4  Nocebo attribution ratios near zero across well-powered n-of-1 designs -- symptom
    burden turning out to be almost entirely pharmacological after all.
```

None of these has occurred, and the postulate is therefore alive in this domain and not vindicated by it. Survival is not confirmation [Popper, 1959, Lakatos, 1970], and the rule applies to the author's own postulate with no discount.

34.9 9 Failure modes: a register

The failure modes below are the ones this apparatus generates. Each gives a description, the parameter it damages, a diagnostic signature, and the fix. **The corpus's companion register sorts belief failures into four classes — A, no channel; B, a real channel with insufficient gain; C, a wrong magnitude extrapolated from a real result; D, a system unresponsive at this input size — each with a stated diagnostic [Curzi, 2026ac].** The entries here are the mechanisms by which a claim lands in one of those four.

34.9.1 9.1 Failures of the conditional

The escape clause. *Description:* an unobservable sufficiency parameter absorbs every null — you did not believe hard enough, some part of you resisted. *Damages:* empirical content, reducing it to exactly 0.0000 bits (Section 5.2). *Signature:* every failure is explained by the same unmeasured quantity, which is only ever inferred from the failure it explains; ask what result would change the holder's mind and get silence. *Fix:* measure `B` before the outcome, put it in the prediction, forbid post-hoc appeal. **If `B` was low the prediction was low, and a low observed effect confirms the postulate rather than excusing it.**

The unnamed channel. *Description:* a belief is asserted grounded because it makes sense or is consistent with a framework, with no step-by-step pathway written down. *Damages:* `G`, which is unestimated and, being unestimated, usually assumed positive. *Signature:* ask for step 2 of the mechanism and receive step 1 restated in new vocabulary; the pathway description contains no verbs of physical or social action. *Fix:* write the steps, numbered, and **accept "I cannot write step 2" as the finding it is.**

The fitted gain. *Description:* `G` is estimated from the same outcome data it is used to predict. *Damages:* identifiability. **The exercise is void, not merely weak.** *Signature:* the predicted effect matches the observed effect suspiciously well and the gain was never published before the measurement. *Fix:* estimate `G` from the channel's own components, freeze it, publish it, then measure.

Magnitude blindness. *Description:* the sign of an effect is checked and its size is not. *Damages:* content, collapsing the conditional's 2 to 4 bits to the sign-only 1 bit. *Signature:* the write-up contains a p-value and no ratio of observed to predicted. *Fix:* report `observed / predicted` as a headline number and **treat a ratio far from 1 as damage to the model even when the sign was right** [Meehl, 1967, 1990].

The underpowered null. *Description:* a predicted effect is tested with a sample far too small to detect it, and the null is reported as evidence against the channel. *Damages:* nothing about the world; everything about the inference. *Signature:* no power calculation anywhere; the minimum detectable effect, computed afterwards, is several times the predicted effect. *Fix:* compute the required sample from the predicted magnitude before collecting anything, and where it is unavailable **report "not testable at this scale", which is a legitimate and useful result**.

Precedent promoted to evidence. *Description:* the observation that a tradition recorded something is cited as support for the claim's truth rather than for its independent discoverability. *Damages:* the audit method itself, and therefore every claim in the corpus including the well-supported ones. *Signature:* "confirms", "corroborates" or "validates" attached to a precedent source; two sources listed as though they were two measurements. *Fix:* state each column's role in the same block as the citation, every time. **Precedent establishes findability, never truth.**

The unfalsifiable goal. *Description:* the outcome is specified so that no observation could count against it — greater alignment, things opening up. *Damages:* `E`, which has no units, so the formula has no left-hand side. *Signature:* two observers cannot be made to agree on whether it occurred. *Fix:* units, procedure, noise level, before anything else.

The circular anchor. *Description:* belief magnitude is operationalised by the very behaviour the behavioural channel is supposed to explain, and the resulting correlation is reported as support for the channel. *Damages:* `G_beh`, which becomes tautological. *Signature:* `B` and the channel's first step are the same measurement under two names. *Fix:* anchor `B` on a decision in a different domain from the outcome, or use magnitude estimation, and state which.

The grounding substitution. *Description:* "grounded in truth" is read as sincerely held, true, or endorsed by authority — the three substitutions Section 4.3 forbids. *Damages:* the condition, and therefore everything. *Signature:* the grounding argument, written out, contains no reference to a pathway. *Fix:* **grounding is a property of the world.**

34.9.2 9.2 Failures of the gain budget

The empty box. *Description:* the diagram is drawn — belief, arrow, world — and the middle box is never filled in. *Damages:* `G`, unestimated and assumed positive. *Signature:* the mechanism paragraph contains no nouns naming a physical or social entity. *Fix:* classify, or estimate zero and stop.

The long chain. *Description:* a mechanism with six or eight plausible steps is presented as strong because every step is plausible. *Damages:* the magnitude estimate, catastrophically — **eight stages at 0.7 each give 0.0576.** *Signature:* "and then" appears more than three times and no stage carries a number. *Fix:* write the stages, put a ratio on each, multiply, and read the product aloud.

The unitless sum. *Description:* gains in different outcome units are added. *Damages:* the bound, which becomes meaningless while continuing to look like a number. *Signature:* a summed gain whose units are never stated. *Fix:* standardise every channel to its outcome's own standard deviation before summing.

The additive promise. *Description:* the parallel sum is reported as the expected effect rather than as a ceiling. *Damages:* calibration; predictions run systematically high. *Signature:* predicted effects equal to the summed bound, repeatedly, with no discount and no interference analysis. *Fix:* predict below the bound and state the discount's basis.

The adherence illusion. *Description:* a large behavioural `delta p` is measured, celebrated, and multiplied by an effect per action that was never independently measured. *Damages:* `G_beh`, which becomes the product of one real number and one imagined one. *Signature:* the write-up quotes an adherence improvement and no separate efficacy estimate. *Fix:* measure the action's effect in a design that varies the action without varying the belief; **if that design is impossible, report the gain as a range with a zero lower bound.**

The absent target. *Description:* an informational gain is computed from a search-time increase without establishing that what is being searched for exists. *Damages:* `G_info`, which is `P(exists)` times something and `P(exists)` was never estimated. *Signature:* a search rate and a time reallocation and no base rate; the successes are counted and the searches that found nothing were never recorded. *Fix:* estimate `P(exists)` first, and **record the null searches; they are the denominator.**

The survivorship anecdote. *Description:* the evidence base consists of people for whom the search succeeded; the people who searched equally hard and found nothing wrote nothing and are absent from the record. *Damages:* every gain estimate drawn from that base, upward, by an unknown factor. *Signature:* all the cases point the same way; there is a register of outcomes and no register of attempts. *Fix:* build the attempt register before the outcome register.

The sufficient-because-real fallacy. *Description:* a channel is shown to be real and the matter is treated as settled, with no check against the minimum viable gain. *Damages:* nothing about the world; everything about the decision. *Signature:* the report establishes a mechanism and never computes whether it clears the decay and the cost. *Fix:* compute `(delta Q + C)/S` and compare. **"Real but insufficient" is a legitimate verdict and is more common than either alternative.** It is class B of the corpus's four-class register [Curzi, 2026ac].

The coerced consensus. *Description:* `G_social` is raised by making dissent expensive, and the resulting coordination is read as shared belief. *Damages:* the group's non-parallelism and therefore its surplus, and the protocol's admissibility. *Signature:* committed fraction rises without any change in privately elicited belief; anonymous and public elicitation diverge sharply. *Fix:* anonymous-first elicitation, and a hard rule that any protocol removing the ability to decline is out of scope regardless of its measured gain. **The concentration instrument gives the measurable form of what coercion does to a group: naive shares of 40.9, 27.3, 18.2 and 13.6 give an effective count of 3.41 by `1/HHI`, and collapsing them into one bloc gives a bloc-HHI of 1.000000 and an effective count of 1.00** [Curzi, 2026]. **`1/HHI` is the Hill number of order two and is well grounded** [Hill, 1973, Jost, 2006]; the corpus's affine effective count `1 + (N−1)u` is a different quantity and is not a Hill number of any order.

The fifth-class smuggle. *Description:* a direct-action claim is dressed in the vocabulary of one of the four real classes — it works through the field, the body knows, the network responds — so that it inherits the credibility of a named channel without having one. *Damages:* the taxonomy's usefulness and the reader's ability to audit anything. *Signature:* the channel is named but its estimation procedure cannot be run; ask for the efferent pathway, the action's independent effect, the committed count, or `P(exists)`, and none is available. *Fix:* **if the estimation procedure for the claimed class cannot be executed, the class was misassigned and the estimate is zero.**

34.9.3 9.3 Failures specific to the measured channel

The missing third arm. A placebo arm's improvement reported as a placebo effect with no no-treatment comparator. *Damages* the effect estimate upward by natural history plus regression to the mean. *Signature:* two arms; a pre-post improvement reported as a finding. *Fix:* add the arm, or **report the quantity as "improvement in the placebo arm" and never as "the placebo effect"**.

The subjective-only trial. Every outcome self-reported and the result described as a physiological effect. *Damages* the inference: `D` cannot be computed, so a report-reaching channel and a physiology-reaching channel are indistinguishable. *Fix:* add one objective measure, even a crude one, and publish `D`.

The asthma error. Feeling better treated as being better, and treatment reduced accordingly. *Damages* the patient. **This is the failure mode with the worst consequences in the paper.** *Fix:* where `D` is large for a condition, the subjective measure is not a proxy for the objective one and must never be used as one.

The generalised pathway. "Placebo has physiological effects, therefore belief can affect any physiology." *Signature:* the pathway is named at the start of the argument and unnamed at the point of application — opioids at the start, "the body" at the end. *Fix:* name the efferent pathway to *this* tissue, or estimate zero.

The deception assumption. It is assumed the effect requires deception, so either the channel is written off as ethically unusable or deception is quietly justified. *Signature:* an argument presenting "tell the truth" and "get the effect" as mutually exclusive. *Fix:* the open-label literature exists; the assumption is out of date; **run the disclosed version and measure it rather than reasoning about it.**

The oversold meta-analysis. A pooled estimate from a small, heterogeneous literature of small trials quoted as a stable parameter. *Signature:* a pooled effect quoted without its confidence interval, its heterogeneity statistic, or the number and size of contributing trials. *Fix:* quote the interval and the heterogeneity or quote nothing.

The unmeasured expectancy. An effect reported without any measurement of what participants actually expected. *Damages* `G`, which is `d/B` with `B` never measured. *Signature:* the word "expectation" appears throughout the discussion and nowhere in the methods. *Fix:* measure expectancy by magnitude estimation, on the same scale, in every arm including the no-treatment arm.

The one-direction channel. The beneficial direction presented and the nocebo direction omitted. *Fix:* **one channel, two signs. Present both or present neither.**

34.10 10 Results: three audits worked end to end

All parameters in this section are stipulated by the worked cases; nothing here is a field observation and no dataset was collected. The purpose is to show that the procedure runs, reaches a disposition, and reports the disposition whichever way it falls. **In two of the three cases the protocol returns a result the participants did not want, which is the point.**

34.10.1 10.1 Two beliefs, one protocol

A delivery team of nine engineers holds two beliefs about how to ship earlier. Both are held sincerely, by roughly the same people, with roughly the same conviction.

```
BELIEF A   "Stating the deadline as enforced will move median delivery earlier."
BELIEF B   "Visualising the delivery as complete will move median delivery earlier."

E      median days from ticket-open to ticket-closed, from the tracking system
units  days (negative = earlier, which is the desired direction)
noise  sd = 2.4 days, estimated from the previous eighteen deliveries
```

Both beliefs are tested against the same outcome, which is the only reason the comparison means anything.

Step 1 — the channel, as steps. For belief A:

```
A1  the statement is made, in a meeting, on the record          CHECKABLE: minutes exist
A2  engineers revise their private ordering of work             CHECKABLE: board history
A3  revised ordering front-loads the blocking task              CHECKABLE: dependency graph
A4  the blocking task completes earlier                         CHECKABLE: timestamps
A5  delivery completes earlier                                  CHECKABLE: the outcome

AND THE PROPOSITION THE CHANNEL DEPENDS ON:  the deadline really is enforced --
there is a real downstream commitment, and missing it has real consequences.
THIS IS "GROUNDED IN TRUTH". If the deadline is not enforced, A2 does not occur
after the second or third repetition, and G collapses to zero.
```

For belief B, step B1 is "the visualisation is performed" and **step B2 cannot be written**: there is no proposed event between the visualisation and the ticket system.

```
BELIEF B: NO CHANNEL NAMEABLE TO THIS OUTCOME.  G_B = 0.000 days per unit belief.
PREDICTION: E_B = 0.000 days.
```

Note what has not been said. It has not been said that visualisation does nothing. Visualisation plausibly has channels to other outcomes — to the visualiser's anxiety, to their attention allocation, and through attention to behaviour, which is an informational channel in the taxonomy of Section 7.4. **What has been said is that no channel from this belief to this outcome can be written down. The postulate is evaluated per belief, per outcome, per channel, never in general.**

Step 2 — estimate `G` from the channel. Belief A's channel is behavioural, and its gain is computed from two independently measurable quantities, neither of which is the outcome:

```
p0   probability a given engineer reprioritises after an UNENFORCED deadline statement
     = 0.30   (from the board history of the previous four unenforced statements)
p1   probability of reprioritisation after an ENFORCED one
     = 0.75   (from the board history of the two enforced ones)
s    days saved per reprioritisation
     = 1.8    (from the dependency graph: mean slack recovered on the blocking path)

G_A = (p1 - p0) . s = 0.45 x 1.8 = 0.810 days per unit belief
```

None of the three inputs is the delivery time. That independence is what Gate 5 requires.

Step 3 — freeze and predict.

```
FROZEN:  G_A = 0.810 days/unit,  G_B = 0.000 days/unit.   Timestamped before measurement.

at B = 1.0:   E_A_pred = 0.810 days earlier    E_B_pred = 0.000 days
at B = 0.6:   E_A_pred = 0.486 days earlier    E_B_pred = 0.000 days

standardised:  d_A = 0.810 / 2.4 = 0.3375
```

Step 4 — power the measurement, and receive the first real result before any data exist.

```
sd = 2.4 days,  predicted effect = 0.810 days,  d = 0.3375
alpha = 0.05 two-sided

n per arm for 80% power  =  137.81  ->  138 deliveries
n per arm for 90% power  =  184.49  ->  185 deliveries

the team has 9 deliveries per arm.  se = 2.4 . sqrt(2/9) = 1.1314 days
minimum detectable effect at 80% power with n = 9:  3.170 days
detectable / predicted = 3.913

power actually achieved at various n:
    n =   9 per arm   se = 1.1314   power = 0.1105
    n =  20           se = 0.7589   power = 0.1872
    n =  50           se = 0.4800   power = 0.3928
    n = 100           se = 0.3394   power = 0.6651
    n = 138           se = 0.2889   power = 0.8005
    n = 200           se = 0.2400   power = 0.9215
```

With nine deliveries per arm the study has an 11 per cent chance of detecting an effect that is really there at the predicted size. It cannot test the claim. Had the team run it anyway and reported a null, they would have concluded that enforced deadlines do not work, on the strength of a design that could not have shown it if they did.

This is the most useful thing the protocol did, and it did it for free, from the magnitude estimate, before any data existed. The gain estimate sized the study. Without a magnitude prediction there is nothing to size a study against, which is why sign-only claims and underpowered studies travel together. The team runs the observation as a declared calibration exercise rather than a test and pools with two sibling teams to reach `n = 27` per arm over two quarters — still underpowered at 0.24, and stated as such.

Step 5 — measure against the frozen predictions. With belief magnitudes elicited by magnitude estimation at `B_A = 0.9` and `B_B = 0.9`:

```
predicted E_A = 0.810 x 0.9 = 0.729 days earlier
observed  E_A = 0.720 days earlier
observed / predicted = 0.988
|obs - pred| = 0.009 days = 0.008 se        WELL inside tolerance

predicted E_B = 0.000 days
observed  E_B = 0.150 days earlier
0.150 / se = 0.133 se                        inside +/- 2 se, consistent with G_B = 0
```

Step 6 — the shuffled-input control. The belief-magnitude series is permuted across the pooled deliveries and the frozen model re-scored. **The shuffle degrades the fit — but at `n = 27` and power 0.24 the shuffle test is itself underpowered, and that is recorded as a limitation rather than passed over.**

Step 7 — read the result honestly.

```
ESTABLISHED (as survival, not as truth):
  - A's channel steps A1–A4 verified in the board history and dependency graph,
    separately from the outcome
  - the frozen, mechanism-derived G_A = 0.810 predicted the observed 0.720 to 0.008 se
  - B's zero prediction survived: observed 0.150 days, inside noise

NOT ESTABLISHED, and this is the important line:
  - the study was UNDERPOWERED BY DESIGN (power 0.24), so A's close agreement is weak
    evidence and partly luck. Reporting it as a triumph would be exactly the magnitude
    blindness named in Section 9.
  - the shuffled-input control was run but is itself underpowered
  - nothing was established about visualisation in general -- only about visualisation
    as a channel to THIS outcome

THE DISCRIMINATION THAT DID OCCUR:
  Two sincerely held beliefs, equal in conviction, received DIFFERENT predictions from
  the same postulate before any data existed, on the basis of whether a channel could be
  written down: 0.729 days and exactly zero. Both predictions survived.

WHAT WOULD HAVE ENDED THE POSTULATE HERE:
  B moving the outcome by a clear margin on a properly powered design, with the shuffle
  failing to remove it and no behavioural or informational channel recoverable. That is
  K1 of Section 5.5. It did not happen; had it, Section 4 would need rewriting.
```

It does not prove the postulate. Nine engineers and twenty-seven deliveries prove nothing. **What it demonstrates is that the postulate is executable** — that a practitioner can derive two different quantitative predictions from two beliefs without touching the outcome data, find that one belief has no writable mechanism, find that their sample cannot test the other, and end up knowing exactly what they would need in order to find out. **Strike the conditional and every one of those steps disappears: no channel to name, so no gain to estimate, so no magnitude to predict, so no sample size to compute, so no test to run, so no result to report.**

34.10.2 10.2 One belief, four channels, and an audit that changes the plan

A software organisation of 240 people holds a belief: *the weekly cross-team review makes this group better at shipping.* A sceptical executive proposes cancelling the review to recover the time.

Step 1 — classify.

```
physiological   plausible route from belief to anyone's neurochemistry that reaches
                SHIPPING TIME?  No.  G_physio = 0.00.  Recorded, not omitted.
behavioural     belief -> attendance -> rework avoided.  YES.
social          belief held in common -> cross-team coordination.  YES.
informational   belief -> attention to interface defects -> defects found.  YES.
```

The zero is recorded rather than omitted, because a budget that lists only the positive channels has hidden what was considered.

Step 2 — behavioural gain, from behaviour records.

```
attendance without the belief  a0 = 0.60     (from calendar acceptance logs, Q1)
attendance with the belief     a1 = 0.90     (Q3, after the belief spread)
delta a = 0.30

effect per attended review = 0.60 units of rework avoided
```

```
    measured independently: teams that attended in the pilot window versus matched
    teams that did not, with the belief held equally in both -- the design that
    varies the ACTION without varying the BELIEF

G_beh = 0.30 x 0.60 = 0.1800
```

Both factors are published. **A reader can see that this gain rests on a 0.30 attendance change and a 0.60 per-review effect, and can challenge either.**

Step 3 — informational gain, with the base rate first.

```
I1  P(a real interface defect exists in a given week)  = 0.85, from the last two years
    of post-release defect classification. NOT assumed to be 1.
I2  detection rate r = 0.04 per hour of directed cross-team attention, from historical
    hours-per-find in the same defect class
I3  belief reallocates attention from t0 = 2 h to t1 = 8 h per week, from time records

P(find) = 1 - exp(-0.04 t):     2 h -> 0.0769      8 h -> 0.2739
delta P(find) = 0.1970

value per find = 0.4 units
G_info = 0.85 x 0.1970 x 0.4 = 0.0670
```

The 0.85 matters. Without it the gain would have been quoted as 0.0788 — an 18 per cent overstatement arising entirely from assuming the target always exists.

Step 4 — social gain, with the threshold and the transfer assumption.

```
committed (acting at a cost: attending when it conflicts with their own deadline) = 34
group N = 240        committed fraction = 34/240 = 14.2%

The measured tipping region near 25% comes from controlled online experiments.
TRANSFER TO THIS ORGANISATION IS A MODELLING ASSUMPTION, NOT A MEASUREMENT.

25% of 240 = 60 people. The organisation has 34. IT IS BELOW THRESHOLD.
Estimated G_social = 0.11 and DECAYING, not 0.11 and stable.
```

And the identification caveat applies here and only here: this number is a modelling position, not an identified empirical result [Manski, 1993]. It is used because a budget needs a figure, and it is flagged in every place it is used.

Step 5 — the budget.

```
channel          G_i      basis
-------------------------------------------------------------------
physiological    0.00     no efferent route to shipping time
behavioural      0.18     attendance 0.60 -> 0.90; 0.60 per review
social           0.11     below threshold; decaying; NOT IDENTIFIED
informational    0.07     P(exists) 0.85; 2 h -> 8 h at r = 0.04
-------------------------------------------------------------------
SUM              0.36

bound on |E|:  B = 0.4 -> 0.144    B = 0.7 -> 0.252    B = 1.0 -> 0.360
```

Belief is elicited by magnitude estimation at `B = 0.7`. **Predicted effect: at most 0.252 standardised units; and because the sum is a ceiling, the point prediction is set below it at 0.20 with a stated discount for channel interference — the eight hours the informational channel spends are hours the behavioural channel's attendees also spend.**

Step 6 — the minimum viable gain.

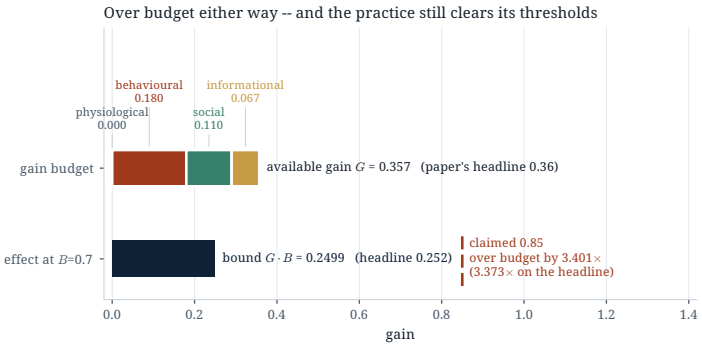

Figure 34.5: **The claim is over budget by 3.4 and the practice is worth keeping — both at once.** Four channel gains estimated from components that are not the outcome sum to 0.36 (physiological 0.00, behavioural 0.18, social 0.11 and decaying, informational 0.067), bounding the effect at 0.252 at `B = 0.7` against a claimed 0.85: a required-over-available ratio of 3.373. The summed gain clears both the growth threshold `(delta Q + C)/S = 0.1786` and the headroom threshold `(delta Q + C)/ln N = 0.1339`, but the behavioural channel alone at 0.18 barely clears the first. Modelled from the budget of Section 10.2; generated by `figs/src/CCP-034_fig05.py`.

```
N = 6 domains,  ln N = 1.791759,  S = 0.75 . ln N = 1.3438
delta = 0.10,  C = 0.09,  Q_t = 1.5

G_min for growth this step       = (delta.Q + C)/S    = 0.1786
G_min for non-negative headroom  = (delta.Q + C)/lnN  = 0.1339

ACTUAL SUMMED G = 0.36.   Above both.   Headroom at G = 0.36:
    h = 0.36 x 1.791759 - 0.10 x 1.5 - 0.09 = 0.4050 > 0
Steady state:  Q_inf = (0.36 x 1.3438 - 0.09)/0.10 = 3.937
```

The review clears the bar by a factor of about two, and the executive's proposal to cancel it is a proposal to remove the only channel above the minimum viable gain. But note what the analysis also shows: **the behavioural channel alone, at 0.18, barely clears the 0.1786 growth threshold.** The review's viability is not comfortable; it depends on the social and informational channels, and the social channel was measured as decaying.

Step 7 — the audit against the claim. The review's sponsors have been claiming a 30 per cent reduction in cycle time, which in standardised units is 0.85.

```
required delta          0.85
available summed gain   0.36 x 0.7 = 0.252

required / available = 0.85 / 0.252 = 3.373

VERDICT: NOT COVERED. The claim is over budget by a factor of 3.4.
```

The claim is unfunded and the practice is worth keeping. Both are true at once, and no discussion that lacked the arithmetic could have arrived at both. The sponsors revise the claim to 0.20; the revised claim survives contact with the data in the following quarter at 0.17 observed against 0.20 predicted, ratio 0.85, **reported as a magnitude result rather than as a success.**

Step 8 — the intervention the budget selected. The binding constraint is not the review's existence; it is the social channel below threshold and decaying.

```
committed now                34    (14.2%)
```

```
threshold, on the stated transfer assumption   60   (25%)
shortfall                    26 people

AND THE TOPOLOGY RULE: complex contagion needs reinforcing contacts, so the 26 are
recruited CLUSTERED -- concentrated in four adjacent teams whose members already
interact -- rather than scattered one per team across twenty-six teams. Same
headcount, different placement, and the clustered placement is the one the contagion
literature supports.
```

Expected benefit: `G_social` moves from decaying to self-sustaining, taking the summed gain from 0.36 to roughly 0.45 and the headroom from 0.4050 to 0.5663. **The organisation began with a belief, an unfalsifiable claim about it, and a proposal to cancel the practice on grounds of cost. It ended with four gain estimates from four independent data sources, a bound, an over-budget verdict on the claim, a keep verdict on the practice, and a specific, sized, placed intervention on the one channel that was failing.**

```
NOT ESTABLISHED:
  - that 25% is the threshold in THIS organisation. It is a transfer assumption from a
    controlled online experiment and is labelled as one in every place it is used, and
    the underlying parameter is not identified from observation of this group.
  - that the channels are independent. They are not; the discount from 0.252 to 0.20
    is an estimate of interference, not a measurement of it.
  - anything at all about physiology. G_physio = 0 was recorded, not tested.
```

34.10.3 10.3 Designing an honest study, and the redesign the arithmetic forces

A research group wants to test whether an open-label placebo, presented with full disclosure, reduces self-reported fatigue in a defined population.

```
BELIEF      "taking this pill, which I have been told is inert, will reduce my fatigue"
B measured  magnitude estimation against a standard, at enrolment and weekly
CHANNEL     physiological, expectancy route (NOT conditioning: no prior pairing is
            arranged, and none is permitted under the disclosure constraint)
STAGES      1  the disclosure is delivered, in a scripted, identical form
            2  the patient forms an expectation                    B is measured here
            3  central mechanisms engage                          NOT measured; the
                                                                    honest gap
            4  fatigue perception is modulated
            5  the patient reports on the scale
OUTCOME     a validated fatigue scale, primary, prespecified
PLUS        one objective measure -- actigraphy-derived daytime activity -- so that D
            can be computed

ARM A   open-label placebo, scripted disclosure, weekly contact
ARM B   no treatment, SAME weekly contact, SAME scripted duration, no pill
```

Stage 3 is unmeasured and is recorded as unmeasured. A chain with an unmeasured stage is a chain whose gain is inferred rather than traced. Arm B is the arm that makes the study worth running, and it is the arm most often cut for cost.

```
G_physio, expectancy route, subjective outcome, taken at the LOW end of the range
because the constraint set restricts this study to expectancy:

    G = 0.25   FROZEN AND PUBLISHED BEFORE ENROLMENT
```

```
expected B in arm A, from a pilot of 12: B = 0.55

E_pred (subjective) = 0.25 x 0.55 = 0.1375 standardised
E_pred (objective, actigraphy) = 0.00 to 0.05
D_pred = 0.1375 − 0.025 = 0.1125
tolerance on the subjective prediction: +/− 0.10, which is 3.32 bits of content
```

And here the arithmetic delivers the bad news.

```
n per arm = 2 (z_{alpha/2} + z_beta)^2 / d^2,  alpha = 0.05 two-sided

 power    z_beta    d=0.20   d=0.30   d=0.40   d=0.50
------------------------------------------------------
  0.80    0.8416       393      175       99       63
  0.90    1.2816       526      234      132       85
  0.95    1.6449       650      289      163      104

the prediction is d = 0.1375. At 80% power that requires:
    n per arm = 2 (1.9600 + 0.8416)^2 / 0.1375^2 = 830 per arm, 1660 in total

the group has funding for 60 per arm. At n = 60 the minimum detectable effect at
80% power is (1.9600 + 0.8416) x sqrt(2/60) = 0.5115 standardised.

detectable / predicted = 0.5115 / 0.1375 = 3.72x

THE STUDY AS FUNDED CANNOT TEST THE PREDICTION.
```

This is the same result the first worked case produced, from a completely different starting point, and it is why both compute power before anything else. A trial powered for `d = 0.5` in a literature that finds `d = 0.2` is not a test. It is a coin flip with a protocol attached, and it will produce a null that gets cited as evidence of absence.

Four options, all requiring a decision made in the open: pool to reach 830 per arm; **reduce the noise rather than the sample, using a within-person crossover that removes between-person variance from the denominator**; run it as a prespecified calibration study; or run it as funded and report a null, which is not legitimate. The group takes the second with the third folded in.

```
between-person sd on the fatigue scale (from the pilot)   =  1.00 (standardised)
within-person sd, same scale, same interval               =  0.42

the crossover's effective d = 0.1375 / 0.42 = 0.3274 in within-person units

n for 80% power at d = 0.3274, paired design:
    n = (1.9600 + 0.8416)^2 / 0.3274^2 = 73 people

73 people, each serving as their own control, against 1660 in the parallel design.
```

Taking the magnitude estimate seriously turned an infeasible 1,660-person trial into a feasible 73-person one, and the only thing that changed was the design. That is the practical payoff of insisting that a postulate predict a number: a design cannot be chosen efficiently against a claim that has no size.

```
PRESPECIFIED KILL CONDITIONS
```

```
KILLS THE STUDY'S CLAIM:
  - subjective effect outside 0.1375 +/- 0.10 in either direction
  - failure of the shuffled-input control
  - the contact-matched no-treatment arm showing equal improvement (this is F2)

DOES NOT KILL IT BUT MUST BE REPORTED:
  - an objective (actigraphy) effect materially above 0.05, which would mean a channel
    was missed and the budget was wrong -- an INTERESTING failure, and the one worth
    having
  - a nocebo signal: adverse symptom reports higher in arm A than arm B, which the
    single-channel model predicts should occur and be of comparable magnitude

COULD NOT BE CONCLUDED, UNDER ANY RESULT:
  - that the mechanism is understood (stage 3 is unmeasured)
  - that this generalises to any other condition, population, or outcome class
  - that any method in this corpus does anything
  - that anyone should reduce or forgo any treatment. Under any result. In any degree.
```

34.10.4 10.4 The audit gate in general form

```
 1  State the belief as a proposition that could be true or false.
 2  Name the outcome, its units, its measurement procedure and its noise level.
 3  Name the channel as numbered steps, each independently checkable.
    If step 2 cannot be written, record G = 0 and stop. That is a finding.
 4  Classify the channel: physiological, behavioural, social, informational, or none.
 5  Estimate each gain from that channel's own components, none of which is the outcome.
 6  Sum, after standardising to common units. Treat the sum as a ceiling.
 7  Compute the minimum viable gain (delta.Q + C)/S and compare.
 8  Compute required / available for the claim being made. Publish the ratio.
 9  Freeze and publish G. Predict E with a tolerance.
10  Power the measurement against the prediction, before collecting anything.
11  Run the shuffled-input control.
12  Report the magnitude result separately from the sign result, and state in advance
    what result would end the claim.
```

The gate is a canonicalisation step before a comparison step, and the corpus's measured instance of that discipline in a different domain is the canonical form `canon(x) = restrict_ASCII(confusable_fold(NFKC(x)))`, which collapses 495 of 495 manipulated entries onto the clean form, is idempotent across all 500 cases, and resolves 995 raw byte strings to the true 500 identifiers [Curzi, 2026]. **What transfers is the discipline: put every submission into one normal form, and the comparison that follows is between like objects rather than between presentations.**

Applied to the three cases above, the gate returned three different dispositions and returned each for a different reason: belief B failed at step 3, having no second step; the review's claim passed steps 3 to 7 and failed at step 8; and the fatigue study passed steps 3 to 9 and failed at step 10, which forced a redesign rather than a rejection.

34.11 11 Discussion

34.11.1 11.1 What follows

The postulate's operational content is a budget, and a budget is auditable. Given gains estimated from mechanism and frozen before measurement, the bound `|E| <= (sum_i G_i) B_max`

is arithmetic, and the required-over-available ratio converts a rhetorical dispute into a number. In the worked case that number was 3.373 and the claim failed before any data were collected, while the practice generating the claim survived on the same arithmetic. **No discussion lacking the arithmetic could have reached both conclusions.**

The deflationary consequence is the important one. In every worked case the behavioural channel is the largest term, and three of the four gain formulas have their zero on a fact about the world rather than about the believer. **The practical advice the postulate yields is therefore not to believe harder. It is: find the action the belief produces, and check whether that action works.**

The threshold result is the least intuitive and the most useful. A channel gain of 0.15 is a real channel and it still loses ground, because decay on existing stored order plus the cost of maintaining the belief exceed what the channel delivers. **"It has a real mechanism" is necessary and not sufficient; the mechanism must clear `(delta Q + C)/S`.** The same threshold appears elsewhere in the corpus in a different register, as the equivalence between a positive storage steady state and a sustaining frequency: `Q_inf > 0` if and only if `eta F(u*) > c*` if and only if `f > f_min`, verified at twelve parameter sets [Curzi, 2026]. And where a belief must accumulate enough to cross a barrier rather than merely to grow, the corpus's launch-budget result gives the form: a fund with fixed point `Λ_inf = L/lambda` makes departure feasible only where `Λ_inf > E_b`, after `t* = ln(1 − E_b/Λ_inf)/ln(1−lambda)` periods [Curzi, 2026p].

And repetition cannot substitute for gain. The corpus's contraction result is exact on this point: refinement cannot move the fixed point, because `Q_inf = (eta F − c)/delta` contains no `t` [Curzi, 2026]. **Holding a belief longer does not raise `G`. Only changing the arrangement does.**

34.11.2 11.2 What does not follow

Nothing here shows that belief creates reality. It shows what a claim of that form would have to look like in order to be checkable, and it computes the price of the condition that makes it checkable. **The postulate remains a postulate and this paper does not upgrade it.**

Nothing here licenses a clinical, medical or therapeutic claim for any method in this corpus. No method here has been tested; no controlled observation of any protocol in this corpus exists; and the divergence diagnostic of Section 8.6 is the reason that prohibition is a safety rule rather than a legal formality. **Nothing in this paper licenses forgoing treatment, under any reading, in any degree.**

Nothing here identifies the social gain. Section 3.4 states the reason and Section 13 repeats it. The figure of 0.11 in Section 10.2 is a modelling position with a stated transfer assumption on top of an unidentified parameter, and it is the weakest number in the paper.

And nothing here establishes that the corpus's own central technical claims are grounded. Applied to the corpus's own biological material, the postulate returns *not yet grounded*: there is no established mechanism by which a cell produces a response depending on a symbol string as an order, as distinct from permutation-invariant functionals of a waveform [Curzi, 2026,aa]. **A postulate that returns "not yet grounded" about its author's own project is a postulate being used correctly, and that is the strongest thing this paper can say for itself.**

34.11.3 11.3 Relation to the surrounding literature

On reflexivity, the corpus is closer to the sociology of finance than to psychology. Soros [2013] names the doctrine; MacKenzie and Millo [2003] supplies the observed instance with dates and price data; Callon [1998] and MacKenzie [2006] give the frame. **What this paper adds to that literature is a loop gain and a sharp stability condition; what it does not add, and cannot, is identification.**

On effect size, the literature is a constraint rather than a support. Jussim and Harber [2005] is the authoritative review and the finding is that self-fulfilling prophecies are real but small, do not typically accumulate, and often dissipate. **The gains in Section 7 are small numbers**

because that is what the literature supports, and any downstream use of this framework that produces a large gain has almost certainly made one of the errors in Section 9. The wider bound is that social predictability is low even with excellent data [Salganik et al., 2020, Hofman et al., 2017].

On measurement, the corpus is exposed and says so. Michell [1997] is the strongest objection to the framework as a whole, and the conjoint-measurement test that would settle it [Luce and Tukey, 1964, Krantz et al., 1971] has not been run for `B`, for `E`, or for any construct in this corpus. The magnitude-estimation route [Stevens, 1957] is the best available and it is not the same thing as having passed the test.

On what this framework is for, the honest answer is not prediction alone. Epstein [2008] sets out sixteen reasons to build a model, of which forecasting is one, and **this paper claims explanation, discipline and the sizing of studies rather than forecasting skill.** Sobkowicz [2020] and Durlauf [2005] are right to ask what observation would distinguish this account from a neighbouring one, and Section 3.5 gives the two that would and names the four that would not.

On the framework's own reflexivity, the objection is live. Lucas [1976], Hacking [1995] and Ferraro et al. [2005] together say that a framework which tells people how their beliefs work will change how their beliefs work. **This paper does not claim its gains are structural, and Section 13 states the restriction on where they may be used.** Ferraro et al. [2005]'s warning is taken seriously in one specific respect: **a framework that tells people most of their beliefs have gain zero could make that true by discouraging the search that finds the channel.** That is a real hazard of publishing this result and it is stated here rather than discovered later.

34.12 12 Verification

The results of this paper compound from six postulates. Each is atomic, each is checkable on its own, and each carries its status. **The two that carry the paper's central claim are `POSTULATED`, and the chain says so.**

34.12.1 12.1 Dimensional audit

Symbol	Dimension	Unit	Status
`E`	`[X]`	the outcome's own units (days, mmHg, defects, scale points, currency)	**measured**, in the declared outcome unit
`B`	`[1]`	none	**measured**, dimensionless on `[0,1]`; **scale type is the open question** (Section 6, Gate 2)
`G`	`[X]` per unit belief	outcome units per unit `B`	**derived** from channel components; **not comparable across outcomes unless standardised**
`eps`	`[X]`	the outcome's own units	**measured** as a noise standard deviation
`lam`	`[1]`	per update step	**assumed** dimensionless in `(0,1]`

Symbol	Dimension	Unit	Status
`alpha`	belief per unit `[X]`	inverse of `G`'s units	**assumed**; the feedback strength
`L = alpha G`	`[1]`	none	**derived** dimensionless: `(belief/[X]) x ([X]/belief) = 1`
`d`	`[1]`	standard deviations	**derived**, `E` divided by the outcome's own sd
`G_i` (series stage)	`[1]`	none	**defined** as a transmission ratio
`Q`, `delta`, `C`, `S`	as in the storage law	proxy units; per period	**as declared there**; carried here only for the threshold arithmetic

Does the equation balance? `E = G B + eps` balances if and only if `G B` carries `[X]`, and since `B` is dimensionless **`G` must inherit `E`'s units exactly.** That is why a summed gain over channels with different outcomes is malformed unless every channel is standardised to its own outcome's standard deviation first, and why Section 7.3's parallel sum is stated with that condition attached. `L = alpha G` is dimensionless because `alpha` is defined as belief produced per unit of effect, which is the reciprocal of `G`'s units; **the loop gain is therefore a pure number and a comparison of it against 1 is meaningful.**

Where the framework has no operational unit, it is said here. `B` is a normalised strength of holding and **has no operational unit at all**; it is treated as a dimensionless magnitude by stipulation, not by measurement, and Section 13 records that the quantitative structure required for that stipulation has not been tested. `E` has units only because the analyst is required to declare them; the postulate supplies none.

34.12.2 12.2 The postulates

P1 — Belief has a magnitude on `[0,1]`. *Status:* **DEFINITION** — the paper's own construction, carrying no empirical weight on its own, and Gate 2 records that the scale type licensing arithmetic on it has not been established.

P2 — A belief affects a world-state only through one or more channels, and with no channel the effect is zero at every belief magnitude. *Status:* **POSTULATED** — asserted by this work, with no external support as stated, and the corpus's own coverage audit lists it among the claims for which no supporting literature exists. **This is the paper's central claim and it is the only postulate in the chain that does the load-bearing work.**

P3 — The gain of a multi-stage channel is the product of its stage transmissions, and the gain of independent parallel channels is at most their sum. *Status:* **ARITHMETIC** for the product, from the definition of a transmission ratio; **POSTULATED** for the additivity of parallel channels, which assumes non-interference and is therefore stated as a **bound, not a prediction**.

P4 — `-log2(p)` measures the empirical content of a claim permitting a fraction `p` of a bounded outcome space. *Status:* **CITED** — the standard information measure [Shannon, 1948, Cover and Thomas, 2006], applied to a permitted band rather than to a message.

P5 — A first-order linear recursion `x_{t+1} = a x_t` has `x = 0` stable if and only if `|a| < 1`. *Status:* **CITED** — elementary, and stated with its convergence condition in Elaydi [2005]; the control-theoretic reading is Åström and Murray [2008].

P6 — The storage law's one-step growth condition is `eta S_t > delta Q_t + C_t`. *Status:* **CITED** — a corollary of the storage law's contraction structure [Curzi, 2026a].

34.12.3 12.3 The compounding chain

P1 + P2	-> R1	E = G.B + eps, with G = 0 => E = 0 for all B. This is the postulate in magnitude form. It is not derived from anything above it; P1 supplies the domain of B and P2 supplies the forbidding clause.	POSTULATED
R1	-> L1	halving G and doubling B leaves every observation unchanged, so the pair (G,B) is not identifiable from outcome data alone.	ARITHMETIC
L1	-> R2	the formula is testable only if G is estimated from the channel's own components and frozen before the outcome is measured.	ARITHMETIC
P4	-> R3	a claim permitting the whole of a bounded space has −log2(1) = 0.0000 bits; a sign-only claim over half has 1.0000 bits; a +/− 0.10 band in a width-2 space permits 0.1 and has −log2(0.1) = 3.3219 bits.	ARITHMETIC
R3	-> R4	each halving of the tolerance buys exactly one bit, because −log2(p/2) = −log2(p) + 1.	ARITHMETIC
R1 + base rates	-> R5	at 40 channelled and 60 unchannelled arms in 100, the unconditional form is refuted by 0.3250 of observations and the conditional by 0.0550; the observations needed for a 95% chance of at least one refutation are ln(0.05)/ln(1−p): 8 and 53.	ARITHMETIC
P5 + R1	-> R6	B_{t+1} = (1−lam)B_t + lam.min(1, L.B_t) linearises at B = 0 to a pole 1 − lam + lam.L, so B* = 0 is stable iff L < 1; and L = alpha.G, so G = 0 forces L = 0 at every alpha.	ARITHMETIC
P3	-> R7	0.70 x 0.50 x 0.60 x 0.40 = 0.0840, so four stages whose worst transmission is 0.40 deliver 8.4% of a lossless chain; and any zero stage zeroes the product.	ARITHMETIC
P6 + R1	-> R8	with eta -> G, growth requires G.S > delta.Q + C, so G_min = (delta.Q + C)/S = (0.10 x 1.5 + 0.09)/1.3438 = 0.1786; and non-negative headroom requires G_min = 0.24/1.791759 = 0.1339.	ARITHMETIC
R8 at G = 0	-> R9	Q_inf = (0 − C)/delta = −0.09/0.10 = −0.9000, a negative equilibrium: an ungrounded belief is a continuing net cost, not merely an absent gain.	ARITHMETIC
R1 + budget	-> R10	summed gain 0.36 bounds |E| at 0.36 x 0.7 = 0.252, against a claimed 0.85: required/available = 0.85/0.252 = 3.373.	ARITHMETIC

Every line except R1 is ARITHMETIC or CITED, and R1 is POSTULATED. That is the honest shape of this chain and it must be read carefully: **the arithmetic is certain and the postulate is not, and everything downstream of R1 inherits R1's status when it is applied to the world.** R3, R4, R7 and R8 are true as arithmetic regardless of whether the postulate holds; R5, R6, R9

and R10 are true as arithmetic *given* the postulate's form, and say nothing about whether that form describes anything. **A chain whose load-bearing step is a postulate is not a proof, and this section says so rather than leaving the reader to notice.**

34.12.4 12.4 The verification instance a reader can redo in a minute

Three checks, each independent of the others.

Check one — the bit arithmetic. A point prediction with tolerance `+/- 0.10` in a standardised band of width 2 permits `0.20/2.00 = 0.10` of the space. `-log2(0.10) = 3.3219`. Halve the tolerance to `+/- 0.05` and the permitted fraction halves to 0.05, giving `-log2(0.05) = 4.3219`. **The difference is exactly 1.0000 bits, and it is exactly 1 bit for every halving, because `log2(2) = 1`. ARITHMETIC.**

Check two — the refutation counts. With a per-observation refutation probability `p`, the number of observations for a 95 per cent chance of at least one refutation is `ln(0.05)/ln(1-p)`. At `p = 0.3250`: `(-2.9957)/ln(0.6750) = (-2.9957)/(-0.3930) = 7.62`, so **8 observations**. At `p = 0.0550`: `(-2.9957)/ln(0.9450) = (-2.9957)/(-0.0566) = 52.9`, so **53 observations**. **ARITHMETIC**, and the six-fold difference is the price of the conditional.

Check three — the budget and the audit. `0.00 + 0.18 + 0.11 + 0.067 = 0.357`, which the paper rounds to 0.36; times `B = 0.7` gives 0.252 (0.2499 unrounded). Against a claimed 0.85, `0.85/0.252 = 3.373`. And the minimum viable gain: `(0.10 x 1.5 + 0.09)/(0.75 x ln 6) = 0.24/1.3438 = 0.1786`, with `ln 6 = 1.791759`. **ARITHMETIC. A small rounding inconsistency in the source is recorded in Section 13 rather than corrected silently.**

34.12.5 12.5 Limits, asymptotics, and the domain of each relation

`B -> 0`. `E -> 0`. Trivially observed and carries no information.

`B -> 1`. `E -> G`. **The most a belief can do is the channel's full gain**, which is the postulate's central practical content and the source of the over-budget check.

`G -> 0`. `E -> 0` for all `B`, and `L = alpha G -> 0`, so the belief's fixed point is `B* = 0`. **The logical and the dynamical statements coincide exactly in this limit**, which is the strongest internal consistency check the paper has.

`G -> infinity`. `E -> infinity`. **Not nameable, and a genuine defect of the linear form**, repaired by the saturating form of Section 7.6 and recorded as a repair.

`L -> 1` from below and above. The transition is sharp and the equilibrium is discontinuous: 0.000000 at `L = 0.90` and 1.000000 at `L = 1.10`, from the same starting belief. **The limit is singular, and a system with an independently estimated `L` near 1 is a system whose equilibrium cannot be predicted from the model at all** — which is a domain restriction, stated as one.

`eps -> large`. `E` unrecoverable. **Nameable: the effect exists and the study cannot see it.** The commonest real-world outcome, a fact about the design rather than about the postulate, and the reason both worked studies compute power first.

`delta -> 0` in the threshold arithmetic. `G_min = (delta Q + C)/S -> C/S`, so **even with no decay at all a belief must still clear the cost of holding it**; and the storage law's own `delta = 0` pathology applies, in which the map ceases to contract and no fixed point exists [Curzi, 2026a,?].

`P(exists) -> 0` in the informational channel. `G_info -> 0` at every search time, every belief magnitude and every value per find. **This limit is realised constantly in the world and is the cleanest instance of the conditional clause in the paper.**

34.12.6 12.6 Invariance, and how far it has been tested

One invariance is claimed and it is a rescaling. Standardising `E` by its own standard deviation and `G` by the same quantity leaves `d = G B` unchanged, so **the budget arithmetic is invariant under a change of outcome unit.** That is what makes cross-channel summation possible at all, and it is also the only sense in which any quantity here is unit-free.

The invariance that is not claimed is invariance across populations, and it is not claimed deliberately. `G` is a property of an arrangement, not of a person, and an arrangement that changes changes the gain. Lucas [1976] is the general statement and Section 13 carries the restriction.

How far tested: the budget arithmetic has been exercised on three constructed cases in this paper. Three constructed cases is not a test of an invariance; it is a demonstration that the arithmetic runs. **No gain in this paper has been recovered in a second laboratory, in a second population, or by a second analyst.**

34.12.7 12.7 Significant figures against epistemic status

`0.4150`, `3.3219`, `4.3219`, `0.0840`, `0.1786` and `0.1339` are exact to the digits shown, being logarithms and products of exactly specified inputs; they are **derived from defined quantities** and quoting them to four decimal places is legitimate.

`0.3250`, `0.0550`, `8` and `53` are exact given the stipulated base rates of 40 and 60 in 100, and the base rates themselves are stipulated, not measured. The four-decimal presentation is therefore precision about an assumption, and the numbers should be read as “about a third” and “about a twentieth” wherever they are used as facts about the world rather than as steps in a computation.

`0.18`, `0.11`, `0.067` and `0.36` are model outputs from stipulated inputs and carry no intervals, because none was propagated. **That is honest for a constructed example and is not a substitute for the intervals a real application owes.** `0.15` to `0.45` for the physiological gain is a range read off a literature and is quoted as a range for that reason.

`0.3375`, `137.81`, `3.913`, `0.1105` and the power table are exact arithmetic on stipulated inputs, and the sample sizes are rounded up because a fractional participant cannot be recruited.

34.13 13 Limitations

The central claim is a postulate and remains one. `E = G B + eps`, with the forbidding clause `G = 0 => E = 0` for all `B`, is asserted by this work. **It is not derived, not measured, and not supported by any entry in the corpus’s external bibliography**, which lists it explicitly among the claims for which no supporting literature could be found. Its status is `POSTULATED` in Section 12.3 and it should be cited that way. **Any downstream paper that treats it as an established result has misused it.**

No experiment was performed and no dataset was collected for this paper. The three cases in Section 10 are constructed: their parameters are stipulated, their data are the outputs of the stated model, and they demonstrate that the procedure runs and reports its own failures. **They are not evidence that any team, organisation or patient behaves this way and must never be cited as such.**

The identification problem is unrepaired and it is the most serious limitation here. Applied to a group, the reflexive loop of Section 5.6 is a linear-in-means specification whose endogenous effect is not identified from observational data [Manski, 1993], and network data does not repair it [Shalizi and Thomas, 2011, Lyons, 2011]. **This paper adopts no remedy, so the social gain `G_social` is a modelling position rather than an identified empirical result**, and the 0.11 figure in Section 10.2 inherits that status. The realistic route to a defensible version is to stipulate the reference group and defend the stipulation [Brock and Durlauf, 2001]; that has not been done here.

Gate 5 is failed as written. `E = G B` is not identifiable from outcome data alone, and the only repair is independent, frozen, preregistered estimation of `G`. **Every use of the postulate in this corpus is conditional on that repair, and the repair does not address the reflection problem, which is a different failure.**

Gate 2 is only conditionally passed and the deeper test has not been run. Belief magnitude as normally elicited is ordinal at best, and an ordinal `B` makes `G B` a heuristic ordering rather than an equation. **The conjoint-measurement conditions that would license the ratio-scale treatment `B` receives throughout this paper have not been tested** [Luce and Tukey, 1964, Krantz et al., 1971], and Michell [1997] is right that this is the standard failure of the field. The magnitude-estimation route [Stevens, 1957] is the best available warrant and it is not a substitute for the test.

Gate 7 is partial. One channel in one domain has partial cross-laboratory support; three of four are untested in this notation. **The behavioural and informational gains have never been recovered by a second analyst, and the whole apparatus has been run once, by one author.** The replication record of the surrounding field is unambiguous about what that is worth [Open Science Collaboration, 2015, Ioannidis, 2005].

Measured against what proper model comparison requires, this paper's position is:

Requirement	Status in this paper
Out-of-sample rather than in-sample performance	**Partially met in structure, not in fact.** The protocol requires a frozen `G` and a held-out score, and the worked cases show it; **no real held-out comparison was run here.**
A matched null with the same free-parameter count	**NOT MET.** No competing account of the worked outcomes was fitted. The protocol demands four baselines including a matched AR(1); none was run in this paper.
The number of free parameters stated explicitly	**Met.** The relation has one free parameter, `G`, and it is required to be estimated outside the outcome data and frozen.
An information criterion, so the parameter count is paid for	**NOT MET.** No AIC or BIC was computed. Nothing here is fitted, so no criterion applies to this paper — **but the row is printed rather than omitted, because no AIC or BIC has been computed anywhere in this corpus**, including in the corpus's one applied preregistered fit [Curzi, 2026i]. That fit's 2.8 per cent held-out margin over a matched two-parameter AR(1) has therefore never been tested against a criterion that charges for complexity.
Effect sizes with intervals, not only p-values	**NOT MET.** No gain in this paper carries an interval, because none was propagated from its components. The honest statement is that `G_beh = 0.18` rests on a 0.30 attendance change and a 0.60 per-review effect, each of which has its own uncertainty, and neither was carried through.

The primary literature this paper depends on is not in the corpus's bibliography. The blockade result, the open-label result, the three-arm deflation, the asthma divergence, the nocebo n-of-1 design, and the conditioning-versus-expectancy work are all named in Section 8 with author, year and venue, and **none carries a bibliography key, because the corpus's external bibliography contains no entry for any of them.** Appendix C lists them. **This is a real gap in the**

corpus's apparatus and it is recorded as one rather than papered over with an approximately relevant key. A reviewer is entitled to treat Section 8 as unsourced in the formal sense, and the appropriate repair is to add the entries, not to soften the section.

Several figures in Section 8 are deliberately not quoted. Where the source manuscript declines to give a coefficient from memory, this paper declines with it. **The design and direction of each result are stated and the reader is directed to the paper for its numbers.** That is a limitation of the presentation and it is preferred to the alternative.

The effect sizes assumed throughout are at the upper end of what the literature supports. Jussim and Harber [2005] finds reflexive effects real but small, non-accumulating and often dissipating; Salganik et al. [2020] and Hofman et al. [2017] set a low ceiling on social predictability generally. **A reader who applies this framework and obtains a large gain should suspect the estimate before believing it.**

The functional forms used here are chosen, not established. The additive parallel bound assumes non-interference and is stated as a ceiling; the `tanh` saturation is an explicit modelling choice; the loop-gain recursion is a formalisation of a verbal mechanism. **And the corpus's underlying surplus functional is itself underdetermined by the evidence**: a sub-linear power law [Latané, 1981] and an `n log n` form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm does, and nothing assembled here discriminates between them. The strongest available warrant for the logarithmic form is not perceptual at all — it can be derived from multiplicative dynamics with no psychological assumption [Peters and Gell-Mann, 2016, Peters, 2019] — and **the corpus should cite that alongside Fechner and say which one its argument actually needs** [Fechner, 1860]. The corpus's own restatement is exact and worth having: the surplus law is precisely a Fechner law with threshold `u_0 = 1/(N-1)`, verified for `N = 2` to 100 at seven `u` values to a maximum deviation of `8.9e-16` [Curzi, 2026]. **That is what a verified corpus result looks like, and it is a useful contrast with this paper, none of whose central claims reaches that standard.** The same contrast holds for the corpus's exhaustively checked count results, such as the odd-part class rule under which `1..N` realises exactly `ceil(N/2)` pitch classes, six at `N = 12` [Curzi, 2026].

The Lucas critique applies to this paper's own parameters and to its publication. The framework holds that systems change their behaviour when modelled [Lucas, 1976]; a protocol telling people how to audit their own beliefs is such an intervention, and Hacking [1995] and Ferraro et al. [2005] give the mechanism. **The restriction taken here is narrow: the gains of Section 7 are asserted only within a declared window, for a declared population, and are not claimed to be structural.** Where the framework's own audit becomes a reported target, its parameters are subject to the same drift as any measure that becomes a target [Goodhart, 1975, Campbell, 1979]. **And there is a specific hazard in publishing this result: a framework asserting that most beliefs have gain zero could make that true by discouraging the search that would find the channel.** That is stated here rather than discovered later.

No claim of forecasting skill is made. Epstein [2008] enumerates sixteen reasons to build a model; this paper claims explanation, audit discipline and study sizing, and it claims none of the forecasting ones. Sobkowicz [2020] and Durlauf [2005] ask what observation would distinguish this account from a neighbouring one; **Section 3.5 answers that two of the six hypotheses would and four would not, which is a weaker answer than the question deserves.**

No scaling or heavy-tail claim is made, so the distribution-fitting procedure such a claim would require [Clauset et al., 2009] does not apply; that is recorded as a check that does not apply rather than one that was passed. **And no conservation law is claimed for any quantity here**, which matters because a stock that accumulates, leaks and is spent has the grammar of a conserved quantity without the conservation [Mirowski, 1989]; the escape is to specify the arrangement within which the relation is claimed to hold and to claim no universality beyond it [Cartwright, 1999], and that is what Section 7.2's badge does.

No clinical, medical or therapeutic claim is made for anything in this corpus, and none of its methods has been tested. No protocol described here substitutes for treatment. **The divergence diagnostic of Section 8.6 is the reason this is a safety rule rather than a legal formality: a patient may feel better while the instrument says otherwise, and acting on the feeling is how**

people are harmed.

Two observations about the source material, printed rather than silently corrected. First, the four channel gains in the worked budget sum to 0.357, and the source carries the sum as 0.36; the bound at `B = 0.7` is therefore 0.2499 rather than 0.252, and the required-over-available ratio is 3.401 rather than 3.373. The source's figures are retained because every downstream number in that case is computed from them, and the discrepancy at the third decimal is recorded here so a reader recomputing from the components does not think they have made an error. Second, the `G_physio` table quotes `d = 0.30` at `B = 0.70` as `G = 0.4286`, which is `d/B` and therefore larger than the same `d` at `B = 1.00`; that is arithmetically correct but reads as a stronger channel at weaker belief, and the table should be read as four separate calibration points from four different studies rather than as a sensitivity analysis on one.

What would falsify the account. H1 fails on a replicated, preregistered, channel-excluded effect above the noise floor. H2 fails on a pattern of effects exceeding the summed bound with gains frozen in advance. H3 fails if halving an independently measured gain does not halve the effect. H4 fails if an effect survives verified interruption of its only named channel. H5 fails if false-premised channels perform as well as true-premised ones, in which case the word "truth" should be struck from the postulate. H6 fails on a stable intermediate belief in a system whose loop gain is independently estimated away from 1. Each of these is a report this paper would print in the same plain language it would use for a success.

34.14 14 Conclusion

The postulate is: belief creates reality if the belief is grounded in truth. It is a postulate. It is badged as one in the source, it is badged as one here, and nothing in this paper promotes it. In magnitude form it is `E = G B + eps`, with `B` a normalised strength of holding on `[0,1]`, `G` a channel gain in the outcome's own units, and the load-bearing half the forbidding clause: `G = 0` implies `E = 0` for every value of `B` whatsoever. Its correspondence with the storage law is exact in form and is stated precisely for the papers that cite the pairing: `eta = 0` gives `Q_{t+1} = (1-delta)Q_t - C_t`, a vessel that leaks and pays rent, and `G = 0` gives `E = 0` at any strength of belief. Those are the same sentence at two scopes, and the correspondence transfers the model form and not the warrant.

The conditional is defended by what it forbids, and its price is printed. Under the stated base rates, 32.5 per cent of random observations refute the unconditional form — eight casual observations refute it with 95 per cent confidence — against 5.5 per cent for the conditional, which needs 53. The unconditional form taken charitably, with an unobservable sufficiency parameter, carries 0.0000 bits of empirical content; a sign-only prediction carries 1.0000; and a point prediction at tolerance `+/- 0.10` carries 3.3219, each halving of the tolerance buying exactly one bit. The conditional is six times harder to refute than the claim it replaces, and that is the flank this paper volunteers rather than conceals.

The dynamics are a bifurcation, not a gradient. With `B_{t+1} = (1-lam)B_t + lam min(1, L B_t)` and loop gain `L = alpha G`, the zero-belief state is stable if and only if `L < 1`; at `lam = 0.30` the equilibrium is 0.000000 for `L = 0.90` and 1.000000 for `L = 1.10`, from the same start. A self-fulfilling belief is exactly a belief whose loop gain exceeds one, and `G = 0` forces `L = 0` at every feedback strength, so the logical and the dynamical forms of the forbidding clause coincide.

Gains compose: series multiplies and parallel adds, and the sum is a ceiling rather than a promise. Four stages of transmission 0.70, 0.50, 0.60 and 0.40 deliver 8.4 per cent of a lossless chain, and any single zero stage zeroes the product. Four classes exhaust what a state of a nervous system can do outside the skull — physiological, behavioural, social, informational — and three of the four have their zero on a fact about the world rather than about the believer: no efferent pathway, an ineffective action, an absent target. The fifth putative class, direct action with no bodily route, has no channel specification and is assigned gain zero.

The worked audit sums a behavioural gain of 0.18, a social gain of 0.11 and an informational gain of 0.067 to 0.36, bounding the effect at 0.252 at `B = 0.7` against a claimed 0.85 —

a required-over-available ratio of 3.373 — and rejects the claim while keeping the practice that generated it. The physiological gain in that case is recorded as `G = 0` because no efferent route to the outcome exists, and recording the zero is what makes the budget meaningful. **The minimum viable gain is `(delta Q + C)/S = 0.1786` for growth and `(delta Q + C)/ln N = 0.1339` for non-negative headroom; at `G = 0` the steady state is `Q_inf = −C/delta = −0.9000`, so an ungrounded belief is a continuing net cost rather than merely an absent gain.**

Placebo supplies the one channel traced end to end, cut, and traced again, at modest measured size. Blockade removed a belief-produced effect, which is the series chain with one stage set to zero; disclosure did not remove it, which is what makes the channel compatible with a constraint that forbids concealment. **The gain is 0.15 to 0.45 on what people report and approximately zero on what instruments read independently of the person, so any claim of a standardised effect above about 0.3 through this channel alone is over budget and must name another channel.** At `d = 0.20` the distributions overlap by 92 per cent and the treated person is ahead 55.6 per cent of the time: **small per person, not small per thousand, and both statements are true.**

And the honest summary of the paper's own status: the formula validation protocol returns five and a half of seven. It fails identifiability as written, and passes only under independent frozen estimation of the gain. It is partial on reproducibility. The reflection problem is unrepaired and the social gain is a modelling position rather than an identified empirical result. A postulate that reported seven of seven would be a postulate nobody had audited.

34.14.1 Declarations

Data and code availability

No external dataset was collected for this paper. All numerical results are computed from the stated parameters under the relations developed in the text, and every table can be re-derived from the equations and parameter values printed beside it. The three cases worked in Section 10 are constructed examples with declared parameters, not field observations. The empirical results reported in Section 8 are drawn from the published literature, are cited in the text by author, year and venue, and were not re-analysed here; **where the source manuscript declines to quote a coefficient from memory, this paper declines with it and directs the reader to the primary source.** The figures are generated by the scripts named in each caption; those scripts contain no data beyond the numbers printed in this paper and the relations of Sections 5 to 8.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the work, derived the results, produced the worked audits and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The three cases in Section 10 are constructed; no participants were recruited, no intervention was run,

and no individual is described. The study designs discussed in Section 10.3 are proposals, not reports of studies performed. **No clinical, medical or therapeutic claim is made for any method in this corpus; none has been tested; and nothing described here substitutes for treatment.** The framework's standing constraint — that no protocol built on this postulate may remove a person's ability to refuse it, and that nothing may be presented to a person masked, subliminal or concealed — is a design constraint on prospective work and is not a report of any study performed.

Preregistration

This paper reports no preregistered test of its own; its results are derivations and constructed worked cases. **The falsification conditions K1 to K5 and F1 to F4 are stated in advance in Sections 5.5 and 8.11, and the prespecified kill conditions of the study design in Section 10.3 are stated before its arithmetic.** The corpus's preregistered protocol for testing a different law, together with the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin — is reported in Curzi [2026i]. Any applied claim resting on this paper inherits both that result and the unrepaired identification problem of Section 3.4.

34.15 Appendix A Specification register

These are design rules whose effect on practice has not been measured, not findings, and Section 13 records that distinction. They are reproduced here because downstream papers cite them by number.

34.15.1 A.1 On the postulate

S-4.1 STATE THE BELIEF AS A PROPOSITION.
A sentence that could be true or false, with a named subject and a named outcome. If it cannot be written this way it is a mood, not a belief, and is out of scope -- not forbidden.

S-4.2 NAME THE OUTCOME AND ITS UNITS BEFORE ANYTHING ELSE.
E must have units, a measurement procedure, and a stated noise level. "Things will go better" is not an outcome. "Median days from request to delivery, from the ticket system, sd approximately 2.4 days" is.

S-4.3 NAME THE CHANNEL, AS A SEQUENCE OF STEPS.
Each step a physical or social event that either happens or does not, each independently checkable, written numbered. If step 2 cannot be written there is no channel, only a hope. Record it -- that is a finding, not a failure.

S-4.4 ESTIMATE G FROM THE CHANNEL, NOT FROM THE OUTCOME.
Binding, per Gate 5. Any G fitted to outcome data makes the relation unidentifiable and the exercise void.

S-4.5 FREEZE G, AND PUBLISH IT, BEFORE MEASURING E.
Timestamped, witnessed, or preregistered. The freeze is what makes the subsequent measurement a test.

S-4.6 PREDICT E WITH A TOLERANCE.
E_pred = G.B, with a stated band. Each halving of the band buys one bit. A band so wide nothing could fall outside it is the escape clause in metric clothing.

S-4.7 POWER THE MEASUREMENT AGAINST THE PREDICTION.
Compute the sample needed to detect E_pred against the noise BEFORE collecting data. Running an underpowered test and reporting a null is a category error.

S-4.8 INCLUDE A NO-CHANNEL ARM WHEREVER POSSIBLE.
The postulate's content is concentrated in its zero predictions. A design with no arm in which zero is predicted cannot distinguish the conditional from the unconditional version.

S-4.9 RUN THE SHUFFLED-INPUT CONTROL.
Same frozen parameters, belief series permuted. If performance survives the shuffle there is no channel. Non-negotiable.

S-4.10 REPORT THE MAGNITUDE RESULT SEPARATELY FROM THE SIGN RESULT.
"In the predicted direction" and "of the predicted size" are two findings, and the second is the one with content.

S-4.11 DEMOTE IN PRINT WHEN A GATE FAILS.
Likert-elicited B makes the relation a heuristic ordering and it must be labelled one. G fitted to outcome data voids the result. The demotion appears in the same document as the result.

S-4.12 NEVER RESCUE THE POSTULATE WITH A PROPERTY OF THE BELIEVER.
"The belief was not strong enough" is forbidden as an explanation of a null: B is measured before the outcome and is already in the prediction. If B was low the prediction was low, and a low observed effect CONFIRMS the postulate rather than excusing it.

S-4.13 THE CLINICAL PROHIBITION, ABSOLUTE.
Nothing in this corpus constitutes a clinical, medical or therapeutic claim, and no method described here has been shown to produce any physiological effect. No belief protocol substitutes for treatment. This is a consequence of the postulate: what produces the outcome is the channel, and if the channel is a drug, the drug is what is needed.

S-4.14 PRESERVE THE RIGHT TO DECLINE.
No protocol built on this postulate may remove a person's ability to refuse it. A belief installed without consent is not a belief the person holds; it is a state induced in them, and the postulate has nothing to say about it because B was never theirs.

34.15.2 A.2 On the gain budget

S-7.1 NAME THE CHANNEL CLASS BEFORE ESTIMATING ANYTHING.
Physiological, behavioural, social, informational, or none. If the answer is a combination, decompose it. If the answer is "none of these," the estimate is G = 0 and the analysis is finished.

S-7.2 WRITE THE SERIES CHAIN AS NUMBERED STAGES.
Each stage a distinct event with its own transmission ratio. The total is the product. Publish the stages, not only the product.

S-7.3 ESTIMATE EVERY STAGE GAIN FROM DATA THAT IS NOT THE OUTCOME.
Binding, per Gate 5. This is the whole of what makes the exercise a test rather

than a curve fit.

S-7.4 IDENTIFY THE WEAKEST STAGE AND STATE ITS RELATIVE SENSITIVITY, 1/g_i.
That stage is where intervention pays. Do not improve a stage already at 0.9.

S-7.5 SUM PARALLEL CHANNELS ONLY AFTER STANDARDISING TO COMMON UNITS.
Days and symptom points may not be added. Standardise by each outcome's own standard deviation and say so.

S-7.6 TREAT THE SUM AS A BOUND, NEVER AS A PREDICTION.
Channels interfere. Predict below the bound and explain the discount.

S-7.7 RUN THE REQUIRED-VERSUS-AVAILABLE AUDIT BEFORE COMMITTING.
Compute the gain the claim requires and divide by the gain the named channels supply. A ratio above 1 means the claim is unfunded. Publish the ratio.

S-7.8 STATE E_MAX FOR EVERY CHANNEL.
A gain without its ceiling is an incomplete specification.

S-7.9 CHECK THE MINIMUM VIABLE GAIN.
Compute (delta.Q + C)/S. A channel below it loses ground even though it is real. "Real but insufficient" is a distinct and common verdict that no other line of the analysis produces.

S-7.10 FOR THE INFORMATIONAL CHANNEL, ESTABLISH P(TARGET EXISTS) FIRST.
If the target's existence is the question, the gain is unknown, not positive.

S-7.11 FOR THE BEHAVIOURAL CHANNEL, MEASURE THE ACTION'S EFFECT SEPARATELY FROM THE BELIEF.
Vary the action without varying the belief. Skipping this converts a behavioural claim into an article of faith, and it is the most frequently skipped step in the applied literature.

S-7.12 FOR THE SOCIAL CHANNEL, COUNT THE COMMITTED AND MAP THE TOPOLOGY.
Committed means acting at a cost. Clustered placement beats scattered placement at equal headcount. State the field-transfer assumption on any threshold number used, AND state that the parameter is not identified from observation.

S-7.13 FOR THE PHYSIOLOGICAL CHANNEL, NAME THE EFFERENT PATHWAY OR ESTIMATE ZERO.

S-7.14 PRESERVE THE ABILITY TO DECLINE, PARTICULARLY IN THE SOCIAL CHANNEL.
A protocol that raises G_social by removing a person's option to dissent is out of scope regardless of its measured gain, and destroys the group's non-parallelism in the bargain.

S-7.15 PUBLISH THE WHOLE BUDGET, INCLUDING THE ZEROES.
A channel estimated at zero is a result. A budget listing only the positive channels has told the reader nothing about what was considered and excluded.

34.15.3 A.3 On the measured channel

S-8.1 THREE ARMS, ALWAYS. Active (if any) / belief manipulation / NO TREATMENT.
Without the third arm the effect cannot be separated from natural history and regression to the mean, which Section 8.5 computes at 40% of what would otherwise be reported.

```
S-8.2   MATCH THE INTERACTION ACROSS ARMS.
        Otherwise the comparison measures attention, not belief.

S-8.3   MEASURE A SUBJECTIVE AND AN OBJECTIVE OUTCOME IN THE SAME PATIENTS.
        Report D = d_subj - d_obj as a headline.

S-8.4   PRE-SPECIFY THE PRIMARY OUTCOME AND THE ANALYSIS.

S-8.5   POWER FOR THE EFFECT THE FIELD ACTUALLY FINDS, NOT THE ONE HOPED FOR.

S-8.6   REPORT THE GAIN, NOT ONLY THE EFFECT.
        G = d/B, with B measured by magnitude estimation on the same scale across arms.

S-8.7   RUN THE OVER-BUDGET CHECK ON ANY CLAIM ENCOUNTERED.
        Standardise the claimed effect; compare to 0.3; if it exceeds that through this
        channel alone, demand the additional channel by name.

S-8.8   DISCLOSE FULLY, ALWAYS, AND ACCEPT THE NOCEBO COST.
        No concealment, no subliminal presentation, no withheld information. This raises
        nocebo. It is accepted without argument, because consent is not a term in an
        optimisation.

S-8.9   NEVER PRESENT THE PRECEDENT COLUMN AS EVIDENCE.

S-8.10  STATE THE UNCERTAINTY IN THE SENTENCE THAT MAKES THE CLAIM.
        Where a source's exact figures are not to hand, give the shape of the result and
        say the numbers should be read from the paper. An invented decimal is worse than
        an admitted gap.

S-8.11  NO CLINICAL, MEDICAL OR THERAPEUTIC CLAIM, ABSOLUTE.

S-8.12  PRESERVE THE RIGHT TO DECLINE.
```

34.16 Appendix B Evidence-and-precedent audits

Each audit states what was measured, what was merely recorded, and what the pair can and cannot establish. **Two sources agreeing does not double the evidence when only one of them is evidence.**

B1 — A belief affects the world only through a real pathway; with no pathway the effect is zero regardless of the belief's strength. *Evidence:* placebo analgesia in postoperative dental pain reversed by an opioid antagonist (Levine, Gordon & Fields, *The Lancet*, 1978). **A specific pharmacological blockade abolished a belief-produced effect, which is the signature of a specific mechanism rather than a general one.** This is a measurement with a control. *Precedent:* the "law of contact or contagion" catalogued in the comparative literature on ritual practice — the requirement of a material link between operator and target, hair or a garment or a nail-paring. **The requirement of a physical route between intention and effect was stated, in that notation, centuries before anyone could measure one. This is precedent only: the catalogue is of practice, not a test of it, and the practices catalogued do not work.** *Assessment:* both columns converge on the same structural demand — intention alone is inert, a route is required — and the evidence column adds what the precedent column could not: a route that was actually found, and a blockade that actually removed it. C1 pass, C2 pass (the pairing predicts that blocking the intermediary abolishes the effect, which was predicted and tested), C3 pass (it converts "does belief work?" into "name the channel and estimate its gain"). *Status:* **established as a structural correspondence, with the evidential content entirely in the**

evidence column.

B2 — A doctrine that belief is sufficient on its own is not merely unsupported; acting on it has a documented cost. *Evidence:* a review of child fatalities in which medical treatment was withheld on religious grounds concluded that the great majority would have survived with standard care (Asser & Swan, *Pediatrics*, 1998). **The study's conclusion is stated and its counts are deliberately not quoted from memory; the primary source should be read before any number is repeated.** *Precedent:* the popular literature in which belief is presented as sufficient and the conditional clause is absent. **This is precedent for the error, and recording where a tradition went wrong is part of reading it honestly.** *Assessment:* **the unconditional version is the one with a body count. The conditional version says: name the channel, and if the channel is antibiotics, use antibiotics.** *Status:* **established.**

B3 — A physical input reaches cellular and systemic function only through a real, identifiable transduction pathway. *Evidence:* mechanically gated ion channels — mechanical force opens them, ions flow, signalling follows — for which the pathway from mechanical input to cellular signal was found, characterised, named as a specific protein, and recognised by the 2021 Nobel Prize in Physiology or Medicine. **A measured, molecularly identified channel.** *Precedent:* the traditional ethical maxim that conviction does not substitute for the rope — trust, but tie your camel. **This records that the channel requirement was arrived at as a practical ethic long before any transduction pathway was known; the attribution of the saying is itself a scholarly question and nothing in the argument depends on it being exact.** *Assessment:* both hold that intention without a route is inert; the evidence column supplies a named protein, a measurable current, and a knockout experiment. C1, C2 and C3 all pass. *Status:* **established as a structural correspondence. And the limit, stated in the same block: none of this establishes a channel for sequence-specific content. Mechanotransduction is a channel for force, not for text, and the distinction is the whole of the corpus's biological material** [Curzi, 2026].

B4 — Belief acts on physical systems at a distance without a bodily route. REJECTED. *Evidence:* **none. No carrier is specified.** Every established action-at-a-distance in physics has a named field, a coupling constant, and a distance dependence; this proposal has none of the three. C1 fails: no structural correspondence, because there is no structure. C2 fails: no magnitude is predicted in advance from mechanism, so nothing can be over or under budget and the audit of Section 7 cannot be run. C3 fails: it cannot be used on either side. *Status:* **rejected, and the postulate's own prediction for this class is `E = 0`.** The quantitative version of the rejection, where the proposal invokes physics, is in the companion paper: the corpus's conjugate material is badged analogy and not identity, with an explicit refusal that quantum mechanics licenses anything about belief, mind, or future events [Curzi, 2026z], and warm-wet coherence fails by thirteen orders of magnitude [Curzi, 2026aa].

B5 — Because placebo produces measurable physiological change, belief can produce any physiological change, including remission of organic disease. REJECTED. C1 fails: the measured pathways are specific — descending opioidergic modulation of nociception, dopaminergic signalling in a specific circuit, autonomic and endocrine responses — and each has an anatomy. **None of them terminates on a tumour, a pathogen, or a demyelinated axon, and generalising from "some pathway exists" to "any pathway exists" is the fifth-class smuggle of Section 9.2.** C2 fails in the decisive direction: it predicts objective-endpoint effects that are not observed (Section 8.6). C3 is worse than useless: acting on it means declining treatment, and audit B2 gives the evidence on what that costs. *Status:* **rejected, in the paper that presents the strongest evidence for the channel, because that is where the rejection has to be made.**

B6 — Shared belief coordinates behaviour, and the coordination has a measurable threshold rather than a smooth response. *Evidence:* a committed minority of approximately 25 per cent overturned an established social convention in controlled online experiments [Centola et al., 2018] — a measured tipping point with a manipulated independent variable. **Transfer to a field organisation is a modelling assumption, not a measurement, and is labelled so wherever the number is used; and the underlying parameter is not identified from observational data [Manski, 1993].** *Precedent:* accounts of collective assembly and shared enact-

ment producing commitments that individuals did not hold separately. **These are theoretical and ethnographic accounts, not controlled experiments, and they do not establish a threshold value.** *Assessment:* both describe a nonlinearity — something changes discontinuously when enough people hold and enact the same thing. The evidence column supplies a number for one setting; the precedent column supplies the observation that the phenomenon was noticed long before it was measured. C1, C2 and C3 pass. *Status:* **established as a correspondence; the NUMBER is established only for the measured setting.**

B7 — Expectation, produced by what a person is told, can produce a measured physiological change through an identified neurochemical pathway. *Evidence:* the 1978 blockade result, extended by later neuroimaging and pharmacological work, and by a study reporting placebo-associated dopamine release in the striatum of patients with Parkinson's disease measured by raclopride PET — **a neurochemical outcome read by an instrument rather than reported by the patient.** *Precedent:* temple incubation at the Asclepian sanctuaries and the cure inscriptions at Epidaurus; and the sixteenth-century position that the patient's imagination is a real cause in medicine. **Precedent only, and precedent with a named defect, which is the honest way to carry it: the cure inscriptions are a register of cures and not of failures. They are survivorship-selected by construction. They establish that the phenomenon was noticed and institutionalised millennia before it was measured, and they establish nothing whatever about its size.** *Assessment:* both columns describe expectation producing bodily change; the evidence column supplies the receptor, the antagonist, the control arm, and the denominator the precedent column structurally cannot have. *Status:* **established as a correspondence, with all evidential content in the evidence column.**

B8 — The same channel run in reverse produces symptoms: negative expectation generates measurable adverse experience. *Evidence:* an n-of-1 randomised trial in which participants who had discontinued a drug because of side effects took, in randomised blinded periods, the drug, a placebo, and no tablet; symptom scores during placebo periods were reported as close to those during drug periods and both substantially above the no-tablet periods. **The structure of the result is given; the reported ratio was high and the paper should be read before any figure is repeated.** This is a within-person randomised design, the strongest available for the question. *Precedent:* traditions of the curse and the evil eye, recorded across many cultures, together with a mid-twentieth-century compilation of anthropological reports of death following such beliefs. **Precedent only, and weak precedent: the compilation is of secondhand anecdote, not a study, and it must not be cited as evidence of anything.** *Assessment:* **nocebo is not a separate phenomenon requiring its own theory. It is the same channel with the sign of the expectation reversed, and treating it as one object with two signs is both simpler and better supported.** *Status:* **established as a correspondence.**

34.17 Appendix C Works named in the text without a bibliography key

The corpus's external bibliography contains no entries for the following, and no key has been attached to them anywhere in this paper. They are listed with the details the source manuscript supplies so that a reader can locate them. **Their absence is a gap in the corpus's apparatus and is recorded as one rather than concealed. Nothing in this list is a citation; it is a statement of what is missing.**

Placebo and nocebo. Levine, J. D., Gordon, N. C. & Fields, H. L. (1978), "The mechanism of placebo analgesia", *The Lancet*. Amanzio, M. & Benedetti, F. Chapter 35

Where Belief Fails: Four Failure Classes, a Priced Bank Run, and the Grounding Protocol That Kills Most Claims

Abstract. This is the corpus's counter-result paper. Having proposed that belief acts only through a real channel, we catalogue where it does not act and price what survives. Failure is decomposed into four distinct classes — no channel, real channel with insufficient gain, a real laboratory effect extrapolated to an unsupportable magnitude, and a system unresponsive to an input of this size from a source of this size — and the diagnostic value lies entirely in telling them apart. Growth mindset is placed in class B at r ~ 0.10 (1 per cent of variance) and intervention d ~ 0.08, which is 96.8 per cent distribution overlap, a 52.3 per cent common-language effect and 0.056 GPA points. The worked job-search case runs every real channel at full strength and lifts the offer probability from 0.0140 to 0.0697 — a 4.975-fold ratio in which the outcome is still no offer 93 per cent of the time, with 39.5 per cent of the lift coming from simply submitting the application and the no-contact channel carrying gain zero by construction. The bank run shows the opposite extreme: at a 9 per cent reserve the withdrawal fraction swings from 99.01 to 14.51 per cent on a 0.002 change in mean depositor tolerance. Runaway is bounded by ln N: reflexive slopes past 0.15 demand more input than any realistic category count admits.

Keywords: self-fulfilling prophecy; failure taxonomy; growth mindset; bank run; reflexivity; survivorship bias; likelihood ratio

Series: B. Engineering the Surplus **Paper:** CCP-035

35.1 1 Introduction

The framework this paper belongs to advances a conditional postulate: **belief creates reality if the belief is grounded in truth**, where grounding means that a real channel exists from the belief to the asserted outcome and carries a measurable gain [Curzi, 2026ab]. **A conditional postulate is worth exactly what its failure catalogue is worth.** A claim that names no failure has not been formulated tightly enough to fail, which means it has not been formulated tightly enough to be true either.

This is the corpus's counter-result paper, and it is written for that purpose. It catalogues where the postulate does not pay, prices what survives at the magnitudes the literature actually reports, and states the objection that would destroy the postulate outright before offering the only answer available to it. Three things follow in order: the mechanism by which belief does sometimes close a loop and what that mechanism structurally requires; a four-class decomposition of failure, with each class carrying its own diagnostic; and a seven-step protocol that establishes grounding from the channel rather than from the outcome.

The headline numbers are deflationary and are reported that way. Growth mindset — the most widely cited case of belief acting on outcomes — falls in the class where the channel is real and the gain is roughly an order of magnitude below the claim: a correlation near $r = 0.10$, which is **1.00 per cent of variance**, and intervention effects near $d = 0.08$, which is **96.809 per cent distribution overlap**, a **52.256 per cent common-language effect**, and **0.0560 GPA points** on a 0.70-point standard deviation. A worked job-search decomposition running every real channel at full strength lifts the offer probability from **0.0140 to 0.0697** — a **4.975-fold** ratio in which the outcome is still no offer **93 per cent of the time**, with **39.53 per cent of the entire lift** coming from the belief causing the application to be submitted at all, and with the no-contact channel carrying **gain zero by construction**.

The opposite extreme is also computed, because a catalogue that reports only small effects is as dishonest as one that reports only large ones. At a 9.00 per cent reserve ratio a deposit institution's run threshold is $f^* = 0.0900$, its critical forced-sale recovery rate is $h^* = 0.941379$, and with member tolerances distributed Normal$(\mu, 0.25)$ the critical mean is $\mu^* = 0.408522$, on either side of which the withdrawn fraction is **99.01 per cent or 14.51 per cent — a swing produced by a change of 0.002 in an unmeasured population parameter.** Where the structure is responsive, belief can be decisive. Where it is not, no quantity of belief substitutes.

And the runaway is bounded. Written in the framework's own storage law, a reflexive input $S(Q) = S_0 + sQ$ gives the pole $a = (1 - \delta) + \eta s$ and the loop gain $g = \eta s/\delta$. With $\delta = 0.10$ and $\eta = 0.50$ the critical slope is $s^* = 0.20$, but $s = 0.19$ **already implies 12.6 nats of input against a ceiling of** $\ln N = 2.996$ **at** $N = 20$ [Curzi, 2026]. The divergence never arrives; the model leaves its admissible region first. **And the time constant** $\tau = 1/(1 - a)$ **goes tenfold at a loop gain of 0.90, so the loop slows conspicuously before it destabilises** — which is a measurable early-warning signature available from response time alone.

Four contributions are made relative to the surrounding literature. **First**, a decomposition of the self-fulfilling mechanism into three separately checkable and separately destroyable requirements, with the multiplicative model $E = B \cdot K \cdot R$ making the conjunction explicit. **Second**, a four-class failure taxonomy in which the diagnostic value lies entirely in telling the classes apart, because they prescribe different and incompatible responses. **Third**, an evidential pricing of prediction: a direction-only claim is worth a likelihood ratio of **2.0000**, while a ± 20 per cent magnitude call against a two-decade prior is worth **11.3577**, or **3.5056 direction calls for the same single measurement**. **Fourth**, the statement of the circularity objection — that a conditional whose antecedent is diagnosed from the outcome is vacuous — together with the procedural answer that is the only one available.

The paper applies its own discount to itself. The replication literature is the evaluative context for every claim in this area including the framework's own: a prior of 0.10 updated on one significant result under typical power and heavy selective reporting yields a posterior of **0.1148** — a movement of under two percentage points [Open Science Collaboration, 2015]. **If this framework's predictions were tested and returned a single significant result, that is the update the author would be obliged to report**, and Section 5.10 says so in print.

Section 2 states the hypotheses. Section 3 gives the method, including the analogy labels, the identification problem that this paper is more exposed to than any other in the corpus, and the scale-type concession. Section 4 develops the engine, Section 5 the failure catalogue, Section 6 the grounding protocol. Sections 7 to 11 report, discuss, verify, limit and conclude. Appendices A to C carry three worked cases.

35.2 2 Hypotheses

Several results below are theorems and cannot be falsified by observation; they are labelled as derivations where they appear and recorded as `ARITHMETIC` or `DEFINITION` in Section 9's chain. What can be wrong are the taxonomy's claims to exhaustiveness and diagnostic value, the magnitude claims, and the claim that the protocol is discriminating rather than a formality.

H1 — The failure taxonomy is exhaustive over documented cases. Every documented failure of a belief claim falls into one of four classes: no channel, real channel with insufficient gain, a real result extrapolated to an unsupportable magnitude, or a system unresponsive to an input of this size from a source of this size. **Predicted:** each case examined in Section 5 admits exactly one class, and the class assignment is made from the channel rather than from the outcome. **Falsified by:** a documented failure that fits none of the four, or that fits two with no way to choose. **Result: no counterexample was found among the cases examined here, which is weak evidence for a taxonomy and is reported as such** — the cases were selected by the author, and Section 10 records that as a selection problem.

H2 — The most-cited belief effect is small, not absent. Growth mindset occupies the class in which the channel is real and the gain is roughly an order of magnitude below the popular claim. **Predicted:** meta-analytic correlations near $r = 0.10$ and intervention effects near $d = 0.08$, which unpack to distribution overlap above 95 per cent and a common-language effect within three points of chance. **Falsified by:** a meta-analytic estimate an order of magnitude larger, or by a demonstration that the channel does not exist at all, which would move the case to a different class. **Result: confirmed at the magnitudes the meta-analytic literature reports.** 96.809 per cent overlap, 52.256 per cent common-language effect, 0.0560 GPA points.

H3 — Where the structure is responsive, the outcome is knife-edged rather than proportionate. Predicted: in a threshold model of a deposit run, the withdrawn fraction is a step function of the population's mean tolerance, with no intermediate outcome available near the critical value. **Falsified by:** a smooth, proportionate dependence of the outcome on the mean, which would make sentiment measurement a useful predictor. **Result: confirmed in the model.** At $\sigma = 0.25$ the withdrawn fraction moves from 0.990106 to 0.145087 across a change of 0.002 in μ. **This is a property of the model, not a measurement of any institution**, and Section 10 says so.

H4 — The runaway terminates at the framework's own ceiling rather than diverging. Predicted: every row of the divergence table beyond $s = 0.15$ implies an input exceeding $\ln N$ for any realistic N, so the model leaves its admissible region before the pole reaches unity. **Falsified by:** an admissible parameterisation in which the steady state diverges while the implied input stays under the ceiling. **Result: confirmed by arithmetic.** At $s = 0.19$ the implied input is 12.6 nats against $\ln 20 = 2.995732$.

H5 — A magnitude prediction is worth several direction predictions at the same measurement cost. Predicted: under a log-uniform prior spanning R decades, a $\pm p$ magnitude call has a likelihood ratio far above the value 2.0000 of a direction call, and the equivalence in direction-calls is computable. **Falsified by:** a prior specification under which the magnitude call's likelihood ratio falls to the direction call's. **Result: confirmed under the stated log-uniform prior**, at 11.3577 against 2.0000, or 3.5056 direction calls — **and the result is a property of that prior specification, which is a modelling choice and is badged as one.**

One hypothesis is deliberately not advanced. No hypothesis is offered that the conditional postulate itself is true, because as stated it admits no observational test until the grounding

protocol has been run on a real case, and it has not been. **The postulate's status in this paper is that of an object under audit, not a claim under test**, and Section 10 records the audit's own limitations.

35.3 3 Method

35.3.1 3.1 What the paper attempts

The paper audits a postulate by cataloguing where it fails and by specifying the procedure that would let it be tested. **It reports no new measurement.** Every empirical magnitude below is quoted from published work, named in the text, and carries that work's uncertainty rather than this paper's; every other number is either exact arithmetic or an illustrative model evaluated at parameters that are stated as assumed in the sentence that uses them.

Two of the three worked cases are constructed. The deposit institution of Appendix A is a constructed balance sheet, the job-search decomposition of Appendix B runs on assumed conditional probabilities, and both say so wherever a number appears. **What those cases demonstrate is the decomposition procedure, not the values.**

35.3.2 3.2 Analogy discipline, declared in advance

`RIGOR_STANDARD` §8 requires every borrowing from physics to be labelled, at first use, as a derivation, a shared mathematical form, or an analogy. The labels for this paper are fixed here.

Borrowing	Label	What licenses the label
loop gain and the geometric multiplier $1/(1-g)$	**shared mathematical form**	the same series governs an electrical feedback loop and a belief loop; **no property of the electrical case transfers**, and the belief case's g must be estimated in its own units
the linearised pole $a = (1-\delta) + \eta s$ and stability at $\eta s < \delta$	**derivation**	it follows from the framework's own storage law by adding one term [Curzi, 2026a]; nothing is imported
critical slowing (τ rising before instability) as an early-warning signature	**shared mathematical form**	the same first-order relation holds; the *empirical* early-warning literature is not invoked as support, because no such measurement is made here
the Casimir pressure computed at biological scale	**derivation** within physics, used here as a **counter-example**	the formula is exact; the point is that it is negligible, which is the opposite of an analogy's usual use [Casimir, 1948, Lamoreaux, 1997]
the magnetic-field energy budget of Section 5.4	**derivation**	$u = B^2/2\mu_0$ is exact and the comparison is dimensional
"the engine", "the amplifier", "the seed"	**analogy**	vocabulary only; **never evidence**, and no engineering result is transferred by the metaphor
the effect model $E = B \cdot K \cdot R$	**modelling choice**, not a borrowing	multiplicativity is assumed for its conjunction property; it is badged in Section 4.2 and is not derived

Entropy is not used in this paper. No Shannon and no thermodynamic entropy appears, and no quantity below carries units of nats or bits except the surplus ceiling $\ln N$, which is a

Shannon-type logarithm of a count, dimensionless and measured in nats, imported from the framework's own surplus functional [Curzi, 2026]. **It is not a thermodynamic entropy and no energetic interpretation attaches to it.**

No effective count is used in this paper other than by citation. Where the corpus's affine $N_{\text{eff}} = 1 + (N-1)u$ is referenced [Curzi, 2026], it is referenced as the corpus's own construction and **not** as a Hill number, which it is not; the Hill numbers of orders one and two — $\exp(H)$ and $1/\text{HHI}$ — appear only in the cited compartment result [Curzi, 2026], where the effective-compartment count **is** $1/\text{HHI}$, the Hill number of order two, and is correctly grounded.

35.3.3 3.3 Identification: the objection this paper is most exposed to

This is the most serious methodological problem in the framework, and this paper is the one most exposed to it, because the reflexive loop is its subject.

The loop $T(x) = W(x, M(x))$ — the world's transition rule depends on the model the agents in it hold — **is exactly a linear-in-means reflexive specification once it is linearised, and Manski proves its endogenous effect is not identified from observational data** [Manski, 1993]. The reflexive slope $s = dS/dQ$ of Section 4.11 is that parameter. **No quantity of observation separates it from contextual effects or from correlated unobservables.** Shalizi and Thomas reinforce the point for network data: influence and selection are generically confounded, and homophily and contagion are not distinguishable from observational network data without further assumptions [Shalizi and Thomas, 2011, Lyons, 2011].

Which remedy does this paper adopt? For the analytical sections, **none**. The reflexive slope s, the loop gain g, and every regime classification derived from them are **modelling positions rather than identified empirical results**, and they are written that way throughout. **For the protocol of Section 6, one remedy is adopted and its price is stated: randomisation of the belief** (defence CC-1 of Section 6.13). Where the belief is *assigned* rather than observed, no common cause can precede it, and the endogenous effect becomes identified by design. **That is the only complete defence, it is expensive, and it is often unavailable** — which is why the alternatives are enumerated with their partial coverage rather than presented as substitutes. The route of stipulating the reference group and defending the stipulation [Brock and Durlauf, 2001] is named as available and is **not** taken here.

The simulated demonstration in Section 6.13 is the quantitative form of the objection. A shuffled-input control with *no coupling at all* and a shared slow driver returns the ordered series beating the shuffle in **98.35 per cent of runs**. The control cannot distinguish a real coupling from a common cause. **That number is printed rather than buried, because it is the strongest available demonstration that a statistical control does not substitute for identification.**

The Lucas critique applies to this paper's own subject matter with unusual force [Lucas, 1976]. A framework asserting that systems change behaviour when modelled cannot exempt its own parameters. Section 4.15's self-defeating case is exactly that: a forecast that provokes its own refutation has $s < 0$, and its accuracy record is consumed by its usefulness. **A measure that becomes a target ceases to be a measure** [Goodhart, 1975, Campbell, 1979], and the corpus's own instruments are not exempt. The performativity literature documents reflexive fixed points observed in the field, with dates and price data [MacKenzie and Millo, 2003, MacKenzie, 2006, Ferraro et al., 2005, Callon, 1998], and the looping of human kinds under classification is the same mechanism in a different register [Hacking, 1995]. **Those are the corpus's best existence proofs for reflexivity and they are cited as such — and none of them identifies the parameter.**

35.3.4 3.4 Scale type, and the conjoint test that was not run

`RIGOR_STANDARD` §5 requires every measured construct to declare its scale type [Stevens, 1946, Krantz et al., 1971]. Four constructs need one.

- **Money, deposits, reserve ratios, withdrawal fractions and time are ratio-scaled** with true zeros, and every operation performed on them below is licensed.
- **Standardised effect sizes (d), correlations (r), probabilities and likelihood ratios are ratio-scaled by construction**, given a stated reference standard deviation; **the reference standard deviation must be the target population's, not the study's**, and where a d is converted to GPA points below, the standard deviation used is stated in the same line.
- **Belief measured on an agreement scale is ORDINAL**, and the multiplication in effect $=$ gain $\times$ belief **is not licensed on it** [Stevens, 1946, Likert, 1932]. Section 6.11 demotes the relation to a monotone ordering wherever the instrument is ordinal, and the worked case of Appendix C is constructed so that the ordinal instrument is used **only to define a group membership** and is never multiplied. **That construction was chosen for this reason and the choice is recorded.**
- **The reflexive slope s inherits the scale of whatever Q is instrumented in**, and the framework does not fix that; the audit in Section 9.1 records the framework as **silent** rather than assigning one.

Michell's critique is the strongest objection to the framework this paper belongs to [Michell, 1997, 1999]: psychology assumes quantitative structure without testing for it. The formal test is additive conjoint measurement [Luce and Tukey, 1964]. **It has not been run on belief, on confidence, on conviction, or on any psychological construct in this paper, and this paper does not run it.** A ratio-scale instrument for a subjective magnitude is constructible by magnitude estimation [Stevens, 1946, Thurstone, 1927], and building one is more work than distributing a five-point form; **the difference between the two is the difference between a formula and a decoration.** Until it is built, every multiplicative statement involving a belief measure in this paper is **demoted in print** — and internal-consistency coefficients are not a substitute for the missing structural test [Cronbach, 1951, Sijtsma, 2009].

35.3.5 3.5 Scaling claims, and the procedure not run

Two power-law statements appear below and both are **defined by the model rather than estimated from data**, which Clauset et al. [2009] requires to be said explicitly.

- The Casimir pressure falls as a^{-4}. **That exponent is an exact consequence of the formula $P(a) = \pi^2 \hbar c/(240 a^4)$ and is not an estimate.**
- The chain-gain law $g_{\text{total}} = \prod_i g_i$ produces geometric decay in the number of links. **The decay constant is the per-link gain, an assumed parameter in every table below, not a fitted exponent.**

No heavy-tail, scale-free or power-law claim is made anywhere in this paper on empirical data, and the maximum-likelihood-plus-goodness-of-fit procedure of Clauset et al. [2009] was therefore not run. It is named so that its absence is a decision rather than an omission; the literature on mis-fitted power laws is the reason [Stumpf and Porter, 2012, Broido and Clauset, 2019].

35.3.6 3.6 What is presupposed

The storage law $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, its fixed point and its geometric convergence are presupposed from Curzi [2026a] and are not re-derived; the reflexive term of Section 4.11 is one addition to that equation. The surplus ceiling $0 \le F(u) \le \ln N$ is presupposed from Curzi [2026]. The belief dynamic $B_{t+1} = (1-\lambda)B_t + \lambda \min(1, LB_t)$ with loop gain $L = \alpha G$, whose zero fixed point is stable exactly when $L < 1$ and whose transition at $L = 1$ is sharp, and the fact that $G = 0$ forces $L = 0$ at every α, are presupposed from Curzi [2026ab] — **that paper states the postulate and its channel-gain architecture; this one states where they do not pay.** The decoherence shortfall that removes quantum mechanics from the list of candidate channels — $\tau_{\text{dec}} = 1.98 \times 10^{-17}$ s against a 1 ms neural event, a factor of 5.04×10^{13}, still 5.04×10^{7} after

a millionfold protection factor — is presupposed from Curzi [2026aa]. The seven formula-validation gates are specified in Curzi [2026t] and the four-baseline falsification suite, including the shuffled-input control and its own measured anti-conservatism, in Curzi [2026u]. The concordance discipline — that the evidence column and the precedent column carry different things, and that two agreeing sources are not two measurements when only one of them is a measurement — is specified in Curzi [2026w] and applied without restatement of its derivation.

35.3.7 3.7 Standing honesty clauses

1. **No clinical, medical or therapeutic claim is made anywhere in this paper, in either direction.** Where published trials are reported, they are reported as evidence about a channel and its gain, never as guidance about care. This is absolute and admits no exception.
2. **No citation or statistic is fabricated.** Where the author is not certain a source says what would be convenient, the claim is omitted or the uncertainty is stated in the sentence.
3. **Precedent is never presented as evidence.** The precedent column records that a structure was independently arrived at; it does not add to a measurement [Curzi, 2026w].
4. **A null bounds a gain; it does not prove a zero.** Every null reported below is stated as an upper bound at the study's power.
5. **Grounding is established from the channel, never from the outcome.** This is the rule that keeps the postulate from collapsing into tautology and it is a requirement, not advice.
6. **The replication discount applies to this framework's own claims exactly as it applies to the claims it evaluates.** Section 5.10 computes it on the framework.

35.3.8 3.8 Bibliographic disclosure

A large number of the primary sources this paper relies on carry no key in this corpus's bibliography, and no key was invented for any of them. Named in the text with journal, volume, year and pages, and cited without a key: Thomas and Thomas (1928); Diamond and Dybvig (1983); Thorndike (1968); Elashoff and Snow (1971); Raudenbush (1984); Steele and Aronson (1995); Flore and Wicherts (2015) and Flore et al. (2018); Sisk et al. (2018); Yeager et al. (2019); Camerer et al. (2018); Bem (2011); Ritchie, Wiseman and French (2012); Benson et al. (2006); Bösch, Steinkamp and Boller (2006); Levine, Gordon and Fields (1978); Kaptchuk et al. (2010); Tajik et al. (2016); and Wald's survivorship analysis for the Statistical Research Group (1943). **Every one is a standard, locatable source; the gap is in this corpus's bibliography, and it is recorded as Limitation L-2 rather than smoothed over.** Where a keyed entry covers the same ground it is cited alongside — Merton [Merton, 1948, 1936] for the mechanism, Granovetter [Granovetter, 1978] for the threshold model, Centola et al. [Centola et al., 2018] for the tipping measurement, Rosenthal and Jacobson [Rosenthal and Jacobson, 1968, Rosenthal and Fode, 1963] for the original expectancy study, Jussim and Harber [Jussim and Harber, 2005] for the modern synthesis, and the Open Science Collaboration [Open Science Collaboration, 2015] for the replication estimate.

35.4 4 The self-fulfilling engine, and what it structurally requires

35.4.1 4.1 The mechanism, stated exactly

Merton [1948] defined a self-fulfilling prophecy as **a definition of a situation that is initially false, which evokes new behaviour, which makes the originally false definition come true.** The prophecy's apparent vindication is then taken as proof that the prophet was right about the world, when in fact the prophecy was right about itself. The construction rests on the Thomas

theorem (W. I. Thomas and D. S. Thomas, *The Child in America*, 1928; **named without a key**, per Section 3.8): *if men define situations as real, they are real in their consequences.*

The addition to the Thomas theorem is the whole of this section. The Thomas theorem says definitions have consequences. It does not say which definitions, how large the consequences are, or under what conditions the consequence loops back and validates the definition. Merton supplied a specific mechanism with a specific closure, and **the closure is what makes it an engine rather than an observation.** The companion result on unanticipated consequences is the same author's [Merton, 1936].

35.4.2 4.2 The three requirements — this framework's decomposition, badged

The decomposition below is this framework's, not Merton's, and it is an analytical proposal rather than a result. What it does is separate conditions Merton kept together, so that each can be independently checked and independently destroyed. **The labels W1, W2, W3 are used throughout to avoid collision with this paper's own contributed results R1 to R6.**

```
THE SELF-FULFILLING ENGINE REQUIRES ALL THREE:

  W1  A BELIEF        held by agents who can act, with enough conviction to
                      change what they do. Sincerity is not required; acting
                      as if is sufficient, and is often what actually happens.

  W2  A CHANNEL TO ACTION
                      a route from the holding of the belief to a change in
                      behaviour. The belief must be able to move a hand, a
                      keystroke, a vote, a withdrawal slip, a grade.

  W3  A SYSTEM STATE THAT IS ACTUALLY RESPONSIVE ALONG THAT CHANNEL
                      the world must have the property that this particular
                      class of action moves it in the direction the belief
                      asserts. THIS IS THE REQUIREMENT EVERYONE DROPS.

EFFECT MODEL (illustrative, multiplicative -- A MODELLING CHOICE, BADGED):

    E  =  B  x  K  x  R

    B  conviction-weighted fraction of agents holding the belief
    K  channel transmission: belief -> action
    R  system responsiveness: action -> asserted state
```

Multiplicativity is assumed, not derived. It is chosen because it makes the conjunction explicit — a product is zero if any factor is zero — and because it composes with the chain-gain law of Section 6.9. **An additive or a min-form model would encode a different conjunction and would give different intermediate values; nothing in this paper establishes that the multiplicative form is the right one, and Section 10 records that.** Computed, to make the conjunction concrete:

```
  full engine                           B=1.00  K=1.00  R=1.00  ->  E = 1.0000
  no belief held                        B=0.00  K=1.00  R=1.00  ->  E = 0.0000
  belief held, no channel to action     B=1.00  K=0.00  R=1.00  ->  E = 0.0000
  belief + action, system unresponsive  B=1.00  K=1.00  R=0.00  ->  E = 0.0000
  weak on all three                     B=0.50  K=0.40  R=0.30  ->  E = 0.0600
```

A product is zero if any factor is zero. That is the entire architecture, and it is the reason the postulate is conditional [Curzi, 2026ab]. "Grounded in truth" is a statement about R: the system really does have the property the belief asserts, along the route the belief can reach. **It says nothing about B, and it cannot be inferred from B at any strength.**

The last row deserves a note. $E = 0.0600$ is an ordinary configuration: a belief half the population holds, that changes behaviour in two of five cases, in a system that responds weakly. **Six per cent of the asserted effect is what most real loops deliver — not nothing, and not the story the loop tells about itself.**

35.4.3 4.3 The reflexive loop, and the objection it carries

The framework's compressed statement:

```
    T(x)  =  W( x, M(x) )

    x      the state of the world
    M(x)   the model of the world held by the agents in it
    W(.,.) the world's transition rule, which takes the state AND the model
    T(x)   the next state

A NON-REFLEXIVE system is one where W does not depend on its second argument:
    T(x) = W(x, .) = W(x)          the model is a passenger.

A REFLEXIVE system is one where it does:
    T(x) = W(x, M(x))              the model is a term in the physics.
```

The whole question is: for which systems, along which channels, and with what gain does W actually depend on M? That is a question about $\partial W/\partial M$, it is finite, and it is zero far more often than the popular literature admits.

And it is not identified from observational data. Linearised, this is a linear-in-means reflexive specification and its endogenous effect cannot be separated from contextual effects or correlated unobservables by any quantity of observation [Manski, 1993]. **Everything this section computes from $\partial W/\partial M$ is therefore a modelling position, not an identified empirical result** (Section 3.3). The self-fulfilling case is the fixed-point case, in which M asserts a state x^* and W moves x toward it because of M; the self-defeating case moves x away. **Both are governed by the same derivative, and a model asserting something about a variable W does not read has $\partial W/\partial M = 0$ and is inert no matter how loudly it is asserted.**

35.4.4 4.4 Loop gain

Linearise about an operating point. Let e be a seed displacement and g the loop gain: the fraction of a displacement that returns as further displacement after one pass around belief, action, world and observation.

```
    total displacement  =  e * (1 + g + g^2 + g^3 + ...)  =  e / (1 - g)   for |g| < 1

    g       multiplier 1/(1-g)      amplification of the seed
    0.0000        1.0000                   0.00%
    0.1000        1.1111                  11.11%
    0.2000        1.2500                  25.00%
    0.3333        1.5000                  50.00%
    0.5000        2.0000                 100.00%
    0.8000        5.0000                 400.00%
    0.9000       10.0000                 900.00%
```

```
   0.9500       20.0000                1900.00%
   0.9900      100.0000                9900.00%
   1.0000      divergent -- marginal; the loop becomes a pure integrator
  >1.0000      divergent -- runaway until a nonlinearity binds
```

Below unity the loop is an amplifier: it multiplies the seed by a finite factor and settles. At and above unity it is not an amplifier but an engine, and it runs until something physical stops it. Gain 0.5 doubles the seed; gain 0.9 multiplies it tenfold; gain 0.99 a hundredfold. **The last increment before unity does most of the work**, which is why systems near unity feel stable right up until they do not. The geometric multiplier is a **shared mathematical form** with electrical feedback (Section 3.2) and transfers no electrical result.

Above unity the relevant question is timing:

```
   steps to double = ln 2 / ln g          steps to 10x = ln 10 / ln g

   g       double      10x
   1.02    35.003     116.277
   1.05    14.207      47.194
   1.10     7.273      24.159
   1.15     4.959      16.475
   1.25     3.106      10.319
   1.50     1.710       5.679
   2.00     1.000       3.322
```

A loop at gain 1.10 doubles in about seven passes. If a pass is a day, that is a week; if a pass is a minute — and with modern settlement and messaging a pass can be a minute — it is seven minutes. **The gain sets whether it happens; the pass time sets whether anyone can respond.**

35.4.5 4.5 Warrant

```
PROVED (mathematics)
  the geometric-series multiplier 1/(1-g) for |g|<1
  the stability condition for the linearised reflexive storage law (Section 4.11)
  the threshold fixed-point condition F(x) = x (Granovetter's model, Section 4.9)
  the ceiling 0 <= F(u) <= ln N (CCP-A02)

MEASURED (the evidence column)
  bank runs occur, are documented, and follow the fractional-reserve structure
  the Diamond-Dybvig multiple-equilibrium model and its empirical standing
  threshold and cascade behaviour in collective action (Granovetter 1978)
  convention tipping near a 25% committed minority (Centola et al. 2018)
  teacher-expectancy effects: real, modest, contested history (Section 4.14)

POSTULATED, BADGED (this framework's)
  the W1/W2/W3 decomposition of Merton's mechanism
  the multiplicative effect model E = B x K x R
  the identification of "grounded in truth" with W3
  the reading of Merton's mechanism as an independent arrival at the
    framework's conditional clause

ANALOGY ONLY, BADGED
  reflexivity as a practitioner's formalism (Section 4.13). It is a framework
  advanced by a market participant, not a tested theory, and this paper uses
  it for its vocabulary and not for its warrant.
```

35.4.6 4.6 The concordance, with column roles stated

```
CONCORDANCE 4.1 -- A DEFINITION OF A SITUATION CAN MAKE ITSELF TRUE

  CLAIM        A belief about a system can become true through the actions it
               causes, when the system is responsive to those actions.

  (+1) EVIDENCE
               Merton (1948), building on the Thomas theorem (1928).
               Diamond & Dybvig (1983) for the formal multiple-equilibrium
               structure of the deposit contract. Documented bank runs, and
               the sharp fall in US bank runs after federal deposit insurance
               in 1934.
               WHAT IT MEASURED: that runs occur, that they follow the
               liquidity structure of the contract, and that changing the
               structure changes the incidence.

  (-1) PRECEDENT -- CARRIES NO EVIDENCE
               Sophocles, Oedipus Tyrannus (c. 429 BCE): the prophecy fulfilled
               through the very actions taken to avoid it. Herodotus, Histories
               I: Croesus and the oracle. The Talmudic tractate Berakhot records
               the maxim that a dream follows the interpretation given to it.
               WHAT IT RECORDS: that the structure was noticed, named and
               dramatised repeatedly across unrelated traditions, by people
               with no instruments and no statistics.

  (0p) INTEGRATION
               The traditions recorded the phenomenon and attributed it to the
               prophecy. Merton recorded the phenomenon and attributed it to
               the behaviour the prophecy caused. The modern account is not a
               vindication of the old one; it is a RELOCATION of the mechanism
               from the oracle to the agents, and that relocation is the entire
               scientific content.

  CRITERIA     C1 structural correspondence: PASS.
               C2 predictive power: PASS. The account predicts that removing
                  responsiveness (W3) kills the effect -- and deposit insurance
                  is the natural experiment.
               C3 practical utility: PASS on both sides.

  STATUS       ESTABLISHED as a mechanism. The (-1) column carries precedent
               only, and no part of the (+1) case rests on it.
```

Sophocles is not a second measurement of the bank-run phenomenon. What the precedent column establishes is that a loop of this shape was visible to careful observers two and a half thousand years ago, which makes it likelier that the loop is a feature of human systems rather than an artefact of twentieth-century sociological method. **That is a real argument, it is smaller than a replication, and this paper does not inflate it** [Curzi, 2026w].

35.4.7 4.7 The deposit contract, with its balance sheet on the table

Merton's own illustration is a fictional institution: a rumour spreads, depositors queue, the bank — which was solvent — cannot meet simultaneous demand, and fails. **Almost every retelling stops there and draws the wrong lesson.** The lesson drawn is *belief made it true*.

The lesson available is: belief made it true because the deposit contract promises something the balance sheet cannot deliver on demand.

```
A BANK, SIMPLIFIED

  deposits            D          payable in full, on demand, at par
  liquid reserves     r * D      cash and overnight instruments
  illiquid assets     A          loans, whose value at maturity exceeds their
                                 value if sold this afternoon

  THE CONTRACT PROMISES:  every depositor may have 100 cents on the dollar today.
  THE BALANCE SHEET HOLDS: r * D of today-money, and A of later-money.
```

Computed across reserve ratios, for a thousand depositors holding one thousand each:

```
r       liquid        depositors payable in full     money multiplier 1/r
0.03      30,000               30 of 1000                  33.3333
0.05      50,000               50 of 1000                  20.0000
0.10     100,000              100 of 1000                  10.0000
0.20     200,000              200 of 1000                   5.0000
0.50     500,000              500 of 1000                   2.0000
1.00   1,000,000             1000 of 1000                   1.0000
```

The run threshold is the reserve ratio. If more than a fraction r of deposits is demanded at once the promise fails — not because the institution is insolvent, not because the assets are bad, but because *today-money* and *later-money* are different goods and the contract pretends they are the same. **W3 is satisfied by arithmetic, before any depositor has an opinion about anything.**

35.4.8 4.8 The counterfactual that isolates W3

Run the identical scenario against an institution holding one hundred per cent reserves. Same town, same rumour, same panic, same queue, same conviction, same channel from belief to withdrawal slip.

```
100% RESERVE, D = 18,000,000, liquid = 18,000,000

  f = 0.05   demand =    900,000    covered? YES   shortfall = 0
  f = 0.25   demand =  4,500,000    covered? YES   shortfall = 0
  f = 0.50   demand =  9,000,000    covered? YES   shortfall = 0
  f = 1.00   demand = 18,000,000    covered? YES   shortfall = 0

  run threshold f* = 1.0000
```

W1 unchanged. W2 unchanged. W3 removed. The engine is dead. Every depositor may believe the institution is failing, act on the belief with maximum vigour, persuade every neighbour — and it pays out in full and opens the next morning. **The belief was not weaker and the channel was not narrower. The system was not responsive along that channel, and so nothing happened.**

This is a thought experiment, but the narrow-bank design is a real and long-discussed proposal in monetary economics precisely because it has this property, and **there is a real intervention with the same target: deposit insurance does not argue with the belief — it changes W3, by making the depositor's payout independent of the queue.** US bank runs fell sharply and durably after 1934. The engineering lesson generalises far beyond banking:

W1 cannot be reliably intervened on. W2 can sometimes be. W3 can very often be, and W3 is where the leverage is.

Arguing with a panic is an attempt to move B, against a population, under time pressure, with the panic's own dynamics working against it. Changing the payoff structure is an attempt to move R, once, in a document. **Structure beats persuasion, because structure does not have to be re-persuaded every morning** — the same conclusion the corpus reaches for built-environment levers, where a structural change to a room is priced against the surplus law and persuasion is not [Curzi, 2026e].

35.4.9 4.9 Two equilibria, and the threshold structure

Diamond and Dybvig's 1983 model (*Journal of Political Economy*; **named without a key**) makes the structure precise. A demand-deposit contract with a sequential-service constraint admits **two equilibria**: one in which only those with genuine liquidity needs withdraw and the institution is fine, and one in which everyone withdraws because everyone expects everyone to withdraw and it fails. **Both are self-consistent. Both are self-fulfilling. The belief does not create the equilibrium; it selects which of two pre-existing equilibria the system lands in.** That is a much more precise and much more modest claim than "belief creates reality", and it bounds the belief's power exactly: **belief can select among the states the structure already admits, and it cannot manufacture a state the structure does not admit.**

Whether the seed propagates is a threshold problem, and Granovetter [1978] gives it exactly. Each member has a threshold: the fraction of others withdrawing at which she withdraws too. With $F(x)$ the fraction of members whose threshold is at or below x:

```
the cascade advances from x while  F(x) > x
it halts at the first fixed point   F(x) = x
it tips when the curve F is TANGENT to the 45-degree line and then crosses
```

Computed for a 2,400-member deposit base with thresholds Normal(μ, σ) and a 9 per cent reserve ratio:

```
thresholds ~ N(0.50, 0.10)   unconditional withdrawers F(0) =  0.00%   x* =  0.0000   no run
thresholds ~ N(0.50, 0.20)   F(0) = 0.62%                              x* =  0.0068   no run
thresholds ~ N(0.40, 0.20)   F(0) = 2.28%                              x* =  0.0334   no run
thresholds ~ N(0.35, 0.25)   F(0) = 8.08%                              x* =  0.9951   RUN
thresholds ~ N(0.30, 0.20)   F(0) = 6.68%                              x* =  0.9998   RUN
```

Holding $\sigma = 0.25$ and varying the mean tolerance:

```
critical mean tolerance  mu* = 0.408522

  mu = 0.407522   ->   x* = 0.990106      99.0% of deposits withdrawn
  mu = 0.409522   ->   x* = 0.145087      14.5% of deposits withdrawn
```

A shift of two-thousandths in the population's mean tolerance moves the outcome from a ninety-nine per cent run to a fourteen per cent tremor, with no intermediate outcome. The system is not sensitive to belief in a smooth, proportionate way; it is sensitive in a knife-edged way. **This is a property of the threshold model at the stated parameters and is not a measurement of any institution.**

Three consequences follow, and they are all uncomfortable.

1. **Post-hoc explanation of a run is nearly worthless.** Two runs, one of which happened and one of which did not, may differ by an unmeasurable amount in the underlying parameter. The narrative afterward will be confident, detailed and unfalsifiable.

2. **Prediction requires measuring F, not the belief.** The belief is the seed; the threshold distribution is the amplifier. Surveys of sentiment measure the wrong object. The same structure appears wherever thresholds govern collective switching [Schelling, 1971, Watts, 2002, Centola and Macy, 2007, Bikhchandani et al., 1992, Banerjee, 1992].
3. **The movable parameter is dispersion, not mean.** σ is the heterogeneity of tolerance, and institutions reduce it by making the same information available to everyone at the same time.

There is a fourth consequence and it belongs to the present decade. **Pass time has collapsed.** A 2023 deposit-institution failure involved withdrawal requests reported at roughly forty-two billion dollars in a single day — a queue moving at the speed of a mobile application rather than the speed of a pavement. **The loop gain did not change; the pass time did, and the pass time determines whether anyone can intervene between passes.** Substitute minutes for days in Section 4.4's doubling table.

35.4.10 4.10 The loop in the framework's own notation

The storage law [Curzi, 2026a]:

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t
```

In the non-reflexive case S_t is exogenous. **A reflexive system is one in which the input depends on the store, because agents observe Q, form a belief about it, and act in a way that changes what they contribute.** Linearise:

```
S(Q) = S_0 + s ∗ Q          s = d S / d Q, the REFLEXIVE SLOPE

Q_{t+1} = [ (1 − delta) + eta∗s ] Q_t + (eta∗S_0 − C)

POLE          a = (1 − delta) + eta∗s
STABLE iff    eta ∗ s < delta
LOOP GAIN     g := eta ∗ s / delta
```

That is the self-fulfilling engine written in the framework's own variables, and it was not imported: it falls out of adding one term to an equation the framework already had. Computed with $\delta = 0.10$ and $\eta = 0.50$, so the critical slope is $s^* = \delta/\eta = 0.20$:

s	eta∗s	pole a	g=eta∗s/delta	regime	tau = 1/(1−a)
0.00	0.000	0.9000	0.0000	convergent	10.0000
0.05	0.025	0.9250	0.2500	convergent	13.3333
0.10	0.050	0.9500	0.5000	convergent	20.0000
0.15	0.075	0.9750	0.7500	convergent	40.0000
0.18	0.090	0.9900	0.9000	convergent	100.0000
0.20	0.100	1.0000	1.0000	marginal (integrator)	infinite
0.22	0.110	1.0100	1.1000	RUNAWAY	–
0.30	0.150	1.0500	1.5000	RUNAWAY	–
0.40	0.200	1.1000	2.0000	RUNAWAY	–

Read the τ column: long before the loop goes unstable, it goes slow. At $g = 0.90$ the time constant is a hundred periods instead of ten. An institution with a strong but sub-critical reflexive loop does not look like one about to explode; it looks sluggish, unresponsive to correction, its reforms taking a decade to show. **Critical slowing before instability is a measurable signature available from response time alone, without knowing s** — and, since s is not identified from observation (Section 3.3), without knowing s is the only way it is ever going to be available.

The steady state carries the same information:

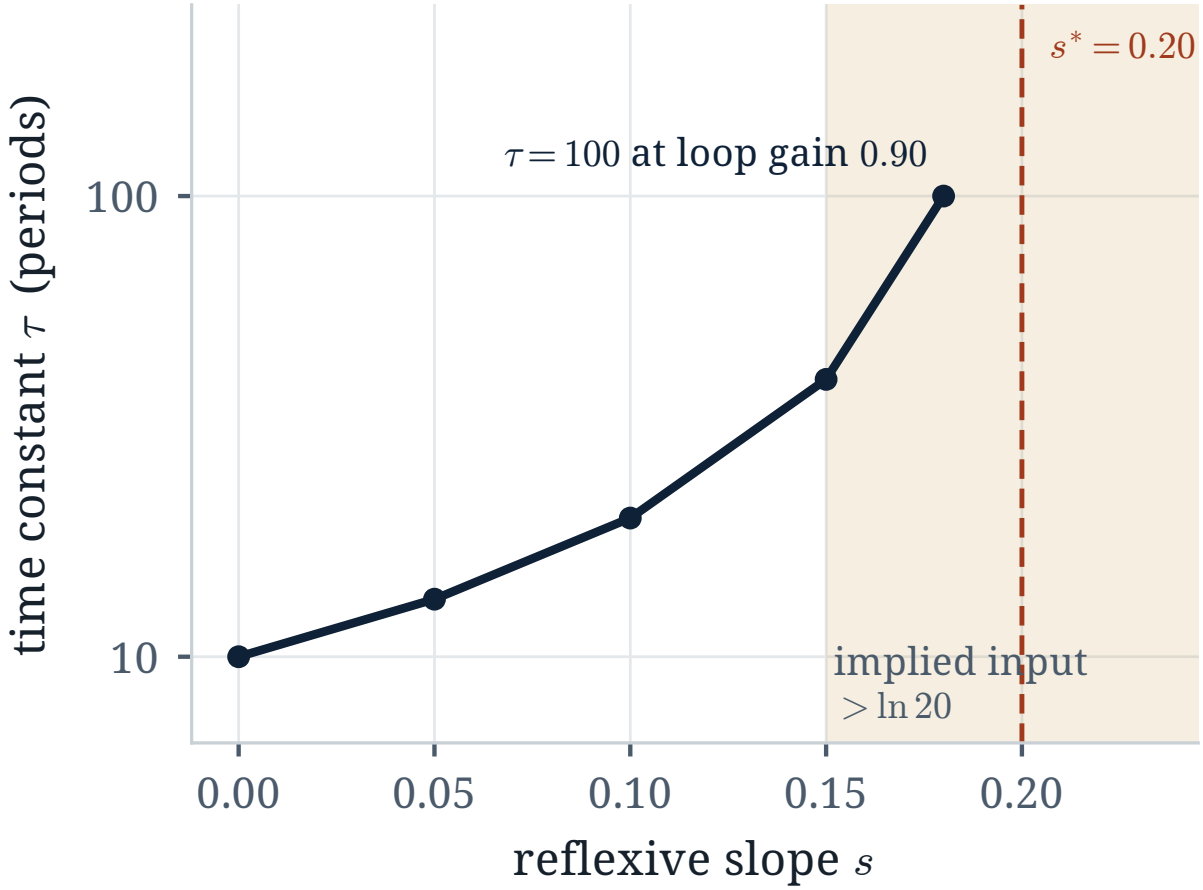

Figure 35.1: **Long before the reflexive loop destabilises, it slows down:** the time constant $\tau = 1/(1-a)$ against the reflexive slope s, with $a = (1-\delta) + \eta s$ at $\delta = 0.10$ and $\eta = 0.50$, so that the critical slope is $s^* = 0.20$. The shaded region marks slopes whose implied steady-state input exceeds $\ln N = 2.995732$ at $N = 20$ — **every runaway row leaves the model's admissible region before the pole reaches unity.** Modelled, not measured: δ and η are the assumed values of Section 4.10 and the reflexive slope is not identified from observational data. Generated by `figs/src/CCP-035_fig01.py`.

```
Q_inf = (eta*S_0 - C) / (delta - eta*s)

s      g       denominator     Q_inf       S(Q_inf)
0.000  0.000     0.1000          3.0000     1.2000 nats
0.050  0.250     0.0750          4.0000     1.4000
0.100  0.500     0.0500          6.0000     1.8000
0.150  0.750     0.0250         12.0000     3.0000
0.180  0.900     0.0100         30.0000     6.6000
0.190  0.950     0.0050         60.0000    12.6000
0.199  0.995     0.0005        600.0000   120.6000
```

The steady state diverges as $s \to \delta/\eta$, and that divergence IS the self-fulfilling prophecy expressed in the storage law: a belief that raises the input in proportion to the store produces unbounded store. And it is precisely here that the formalism protects itself.

35.4.11 4.11 The ceiling that terminates every runaway

S_t is bounded: $0 \leq F(u) \leq \ln N$ [Curzi, 2026]. The surplus available from any single period of interaction cannot exceed the log of the number of distinguishable kinds of thing present. Read the right-hand column of the table above: at $s = 0.19$ the implied input is 12.6 nats and at $s = 0.199$ it is 120.6 nats.

```
N =   4   ln N = 1.386294
N =   8   ln N = 2.079442
N =  12   ln N = 2.484907
N =  20   ln N = 2.995732
N =  50   ln N = 3.912023
N = 150   ln N = 5.010635
```

Every row of the divergence table beyond $s = 0.15$ is outside the model's admissible region for any realistic N. The runaway does not run away. It runs into the ceiling. With $\delta = 0.10$, $\eta = 0.50$ and $C = 0$, the uniform bound gives $Q_{\max} = \eta \ln N/\delta$:

```
N =   4   ->   6.9315
N =  12   ->  12.4245
N =  50   ->  19.5601
N = 150   ->  25.0532
```

This is the formal counterpart of the fact that a run ends. **It ends because the institution runs out of money, not because the depositors change their minds.** In every reflexive system the runaway is terminated by a nonlinearity, and **identifying that nonlinearity in advance is the single most useful piece of analysis available.** In the deposit case it is the balance sheet; in the surplus case it is $\ln N$; in a reputation cascade it is the finite population. **A model that predicts unbounded growth has simply not yet located its ceiling, and the ceiling is always there.**

35.4.12 4.12 Reflexivity as a practitioner's framework — badged

Soros [2013] advances **reflexivity** as an account of markets: participants hold a cognitive function mapping the world to their understanding of it, and a participating function mapping their understanding back onto the world, so that neither the world nor the understanding is ever a fixed independent variable.

This paper uses that framework for vocabulary and not for warrant, and the badge stays on. It is a framework advanced by a market participant on the basis of his own practice. It is not a tested theory, it carries no effect size, and it has not passed a falsification suite. What it supplies is the clean statement that the two functions compose into $T(x) = W(x, M(x))$, and the observation — correct and useful — that the composition has a fixed point only when the two functions are consistent, so that markets spend most of their time away from equilibrium rather than at it. Related formal treatments of the same phenomenon in markets are available [Kirman, 1992, Farmer and Foley, 2009, Bouchaud, 2013, Sornette, 2003], and the performativity literature supplies the field observations [MacKenzie and Millo, 2003, Ferraro et al., 2005].

Where this is genuinely additive to Merton is the two-way structure. Merton's mechanism is one-directional: the belief changes the world. The reflexive account insists the changed world also changes the belief, which changes the world again. **That is the loop, and it is why the loop has a gain rather than a multiplier.** Section 4.10 is the version this framework is entitled to assert, because it is derived from an equation the framework proved.

35.4.13 4.13 Expectancy effects, reported honestly

The study. Rosenthal and Jacobson [1968] reported that children designated at random as likely to show unusual intellectual growth subsequently gained more than their classmates, and interpreted the gain as produced by teacher expectation [see also Rosenthal and Fode, 1963].

The criticism, which was serious and sustained. The study drew immediate and substantive methodological objections concerning the ability instrument used, whose scores were unreliable at the extremes of the range and which had been administered outside its intended grade range for some children, producing implausible individual scores; the very small numbers of children in the subgroups where the effect was concentrated; and the fact that the effect was not distributed across grades as the theory would predict. R. L. Thorndike's 1968 review in the *American Educational Research Journal* was among the most damaging, and Elashoff and Snow's *Pygmalion Reconsidered* (1971) reanalysed the data and reached substantially more conservative conclusions. **Both are named without a key**, per Section 3.8.

What survived. The phenomenon did not disappear under criticism; it shrank and acquired conditions. Raudenbush's 1984 meta-analysis of teacher-expectancy induction experiments found the effect **strongly moderated by prior contact**: where teachers had had little or no acquaintance with the students before the expectation was induced, effects were found; where teachers had known the students for two weeks or more, effects were essentially absent. Jussim and Harber [2005] — the standard modern synthesis — concluded that classroom self-fulfilling prophecies are **real, but typically small, often fragile, and more likely to dissipate over time than to accumulate**, with somewhat larger effects for students from stigmatised groups. Demand characteristics, often invoked loosely in this literature, have their own contrary review [McCambridge et al., 2014].

Now map that onto W1, W2, W3, because the mapping is the payoff.

```
W1  BELIEF     the teacher's expectation about a particular child.
W2  CHANNEL    differential teacher behaviour: time allocated, warmth,
               difficulty of material offered, specificity of feedback,
               opportunities to respond. These are OBSERVABLE and have been
               observed. The channel is real and it is physical.
W3  RESPONSE   the child's actual malleability along that channel.
```

The prior-contact moderator is a direct measurement of W1 failing to install. A teacher who has taught a child for three weeks already has data, and an experimenter's claim about a test does not overwrite it. The belief cannot be induced, so B is near zero, so the product is near zero. **It is not a mysterious moderator. It is the first requirement, measured.**

And the dissipation result is a measurement of R being small. If R were large the effect would compound — a child given more and harder work becomes more capable, which raises the expectation, which raises B, which raises the input again. That is a positive loop with $g > 0$ and it would show up as accumulation. **The literature finds dissipation instead, which says the loop gain is well below unity: the effect is an amplifier with a modest multiplier, not an engine.** That is exactly Section 4.4's small-g row, and exactly the distinction the popular literature erases.

```
CONCORDANCE 4.2 -- EXPECTATION HELD BY ONE PERSON CAN MOVE ANOTHER'S PERFORMANCE

  CLAIM        Expectations held about a person can measurably change that
               person's measured performance, through observable differences in
               how the expectation-holder treats them.

  (+1) EVIDENCE
               Rosenthal & Jacobson 1968 (original, heavily criticised:
               Thorndike 1968; Elashoff & Snow 1971). Raudenbush 1984
```

```
              (meta-analysis; prior-contact moderator). Jussim & Harber 2005
              (review; effects real, typically small, often dissipating).
              WHAT IT MEASURED: that induced expectations shift measured
              outcomes by a modest amount under specific conditions, and not
              at all under others.

(-1) PRECEDENT -- CARRIES NO EVIDENCE
              Apprenticeship traditions across many crafts record the master's
              regard for the apprentice as an operative part of the training
              rather than a courtesy. These are characterisations of what the
              traditions recorded, offered as such and not as quotations.

(0p) INTEGRATION
              The traditions located the effect in the master's regard; the
              modern account locates it in the master's BEHAVIOUR, which the
              regard causes. The channel is differential treatment, it is
              observable, and it is the thing to instrument.

CRITERIA      C1 PASS. C2 PASS (predicts prior-contact moderation, which is
              observed). C3 PASS.

STATUS        ESTABLISHED as a real effect. MAGNITUDE: modest, condition-
              dependent, and easily overstated.
```

35.4.14 4.14 The mirror: self-defeating prophecy

Merton also named the opposite case, and it is the same machine with the sign reversed: a forecast that provokes the behaviour refuting it — the warned-of epidemic that does not arrive because the warning changed behaviour, the predicted collapse averted by the preparation the prediction caused. In the notation of Section 4.10 this is $s < 0$:

s	pole a	g	tau
−0.05	0.8750	−0.2500	8.0000
−0.10	0.8500	−0.5000	6.6667
−0.20	0.8000	−1.0000	5.0000
−0.50	0.6500	−2.5000	2.8571

Negative reflexive slope makes the system converge faster, not slower. A forecast that provokes its own refutation is a stabiliser: it shortens the time constant, damps excursions, and makes the institution more responsive to correction.

> **A forecasting institution whose forecasts are systematically wrong in the self-defeating direction may be functioning perfectly. Its accuracy is being consumed by its usefulness.**

Public-health forecasting, safety engineering and financial supervision all live here. A regulator whose crisis warnings are all wrong may be a bad regulator or an excellent one, and **the distinction cannot be made from the forecast record alone.** It requires estimating s — which is W2 and W3, and which is **not identified from observational data** [Manski, 1993]. **That is the honest position: the distinction requires a quantity observation cannot supply, and the only route to it is an intervention.** Goodhart's law is the same phenomenon: a measure that becomes a target ceases to be a measure, because targeting it gives it a nonzero s [Goodhart, 1975, Campbell, 1979]. The corpus's own prediction claims inherit the same limit, as the measured social-prediction literature reports independently [Hofman et al., 2017, Watts, 2014, Lazer et al., 2014].

35.4.15 4.15 The convergence, stated at its exact strength

Merton, in 1948, with no formalism, wrote a mechanism whose operative content is: **a false belief becomes true when, and only when, it drives behaviour that a responsive system converts into the asserted state.** The framework's postulate states: **belief creates reality if the belief is grounded in truth** [Curzi, 2026ab], with "grounded in truth" unpacked as: the channel exists and is real.

These are the same statement. Merton's "evokes new behaviour" is W2; his implicit requirement — carried entirely by his choice of a *bank* as the example — is W3; his "definition of the situation" is W1.

And here is what that is worth, at exactly its strength and no more. It is **not** worth a doubling of the evidence. Merton is in the evidence column and the postulate is this framework's own; **two statements of the same idea from the same column are one idea, not two verifications** [Curzi, 2026w]. **What the convergence is worth is that the structure was reachable from two unrelated starting points, seventy-eight years apart, by people with different questions and incompatible methods** — one from mid-century American sociology and the empirical record of bank failures, the other from an interaction-geometry functional and a leaky integrator. That is structural correspondence, satisfied about as well as it can be.

And it makes a checkable prediction: if W3 is what "grounded in truth" means, then interventions on W3 should kill self-fulfilling loops even when belief is unchanged. **Deposit insurance is precisely that experiment, run at national scale, and it worked. This paper claims that as support for the reading, not as proof of the postulate, and the difference matters.**

35.4.16 4.16 Where the engine stops

Everything above concerns systems where W3 is nonzero: banks, classrooms, markets, reputations, teams. **Every one of them is a system in which human action is the transmission medium and human behaviour is the responsive substrate.** That is not an accident and it is not a limitation this section can talk its way around. **Every established self-fulfilling loop in the literature runs through human action. There is no documented case of a belief closing a loop through a system that does not contain a person acting on the belief.** The engine is real and powerful, and it is powerful over exactly one class of substrate. Section 5 is the catalogue of what happens outside that class.

35.4.17 4.17 Requirements

REQ-4.1 Never assert a self-fulfilling loop without naming W1, W2 and W3 separately. A claim naming only the belief is a claim about one factor of a three-factor product.

REQ-4.2 Name the structural feature supplying W3 in the same paragraph as the claim. If it cannot be named, the loop has not been identified, and saying so is the contribution.

REQ-4.3 State the loop gain g, or state that it is unmeasured — **and state that it is not identified from observational data**. "There is a feedback loop" is not a finding.

REQ-4.4 Report the pass time alongside the gain. A gain of 1.10 doubles in 7.273 passes; whether that is a week or seven minutes is the operational question.

REQ-4.5 Locate the terminating nonlinearity before the runaway starts. A projection that goes to infinity has not been finished.

REQ-4.6 Check the input against its ceiling. Any reflexive model whose implied S_t exceeds $\ln N$ has left its admissible region and its predictions beyond that point are not entitled to be reported [Curzi, 2026].

REQ-4.7 Intervene on W3 first, W2 second, W1 last.

REQ-4.8 Measure the threshold distribution, not the sentiment. The outcome swings from 99.0 to 14.5 per cent on a change of 0.002 in the mean of F, and a survey of belief cannot see that.

REQ-4.9 Track the time constant as an early-warning signal. $\tau = 1/(1-a)$ rises steeply before a reaches 1, and this is measurable without measuring s.

REQ-4.10 When reporting expectancy effects, report the magnitude and the moderators, never the direction alone.

REQ-4.11 Cite the original expectancy study only together with its criticism and the modern estimate. A citation of the original alone misrepresents the state of the evidence.

REQ-4.12 Distinguish selection among equilibria from creation of an equilibrium.

REQ-4.13 When a forecast is self-defeating, do not score it on accuracy alone — and state that s is not recoverable from the forecast record.

REQ-4.14 Keep the concordance columns separate, every time [Curzi, 2026w].

35.4.18 4.18 Failure modes

FM-4.1 — THE AMPUTATED MECHANISM. *Signature:* the run story is told and the fractional-reserve structure is never mentioned. *Mechanism:* W3 has been deleted, leaving "belief made it true" with nothing under it, and the example is then generalised to systems with no analogue of fractional reserve. *Fix:* every retelling names the balance sheet.

FM-4.2 — GAIN AGNOSTICISM. *Signature:* "there's a feedback loop here", with no number. *Mechanism:* topology identified and nothing else. *Fix:* estimate g from any two consecutive passes and name a side of unity — **while stating that the estimate is a modelling position, not an identified parameter.**

FM-4.3 — INFINITE PROJECTION. *Signature:* a reflexive model run forward without bound, reported as a finding. *Fix:* print the implied S_t next to the projection and truncate at $\ln N$.

FM-4.4 — BELIEF-SIDE INTERVENTION UNDER TIME PRESSURE. *Signature:* a cascade is under way and the entire response is communication. *Mechanism:* W1 is being attacked, in a population, against the loop's own gain, with a pass time shorter than the message cycle. *Fix:* W3.

FM-4.5 — SENTIMENT SUBSTITUTION. *Signature:* cascade risk assessed by surveying belief. *Fix:* measure behaviour at thresholds — what fraction have already acted, at what observed level of others' action.

FM-4.6 — SLUGGISHNESS MISDIAGNOSED. *Signature:* reforms take longer and longer; the diagnosis is "culture". *Fix:* measure the response time to a known small deliberate perturbation and compare across periods.

FM-4.7 — EXPECTANCY INFLATION. *Signature:* the 1968 study cited as an established large effect with no mention of the criticism or the modern estimate. *Fix:* REQ-4.11.

FM-4.8 — MODERATOR MYSTIFICATION. *Signature:* a moderator reported as a curious wrinkle and treated as unexplained. *Mechanism:* the moderator is one of the three requirements, measured. *Fix:* check whether it is W1, W2 or W3 under another name. In this literature it usually is.

FM-4.9 — REFLEXIVITY WITHOUT THE BADGE. *Signature:* a practitioner's framework invoked as a validated theory. *Fix:* use the vocabulary, cite the source, keep the badge, derive quantitative claims from Section 4.10.

FM-4.10 — ACCURACY SCORING OF A SELF-DEFEATING FORECAST. *Signature:* a warning system judged solely on how often its warnings came true. *Fix:* instrument the behavioural response, and concede that the decisive quantity is not identified from observation.

FM-4.11 — SUBSTRATE OVERREACH. *Signature:* a loop correctly identified in a social system asserted for a system with no human actor in it. *Fix:* name the actor. If none can be named between the belief and the outcome, there is no loop, and Section 5 applies.

35.5 5 Where belief fails: the four classes

A postulate that names precisely where it fails can be trusted precisely where it holds. This section is the catalogue: what belief does not do, what the evidence for the things it does do looks like when the effect sizes are printed, and what analytic error is being made in each case. **Its second job is harder: the replication crisis is the evaluative context for every claim in this area, including this framework's own, and Section 5.10 applies the same discount to the framework with arithmetic. The result is not flattering. It is not supposed to be.**

35.5.1 5.1 The four failure classes

Failure is not a single phenomenon. It is four distinct faults, and **the entire diagnostic value of this section comes from insisting they be told apart.**

```
CLASS A -- NO CHANNEL.
  There is no physical route from the belief to the asserted outcome. Gain is
  not small; it is undefined, because there is nothing to have a gain.
  Diagnostic: name the transducer. If none can be named, Class A.

CLASS B -- REAL CHANNEL, INSUFFICIENT GAIN.
  The route exists and is physical, and the transfer is far too small to produce
  the asserted effect. The claim is not false in kind; it is false in size.
  Diagnostic: the measured effect is real, replicable, and an order of magnitude
  below the claim.

CLASS C -- WRONG MAGNITUDE FROM A REAL RESULT.
  A genuine laboratory effect is extrapolated to a real-world magnitude the
  effect cannot support. The original finding may be sound. The transfer is not.
  Diagnostic: the claim's size traces to no measurement; it traces to an
  inference from the existence of the effect.

CLASS D -- SYSTEM NOT RESPONSIVE ALONG THAT CHANNEL.
  The channel exists and carries signal, but the target system does not move in
  response to what that channel delivers -- or does not move for an input of this
  magnitude, from a source of this size.
  Diagnostic: the channel is fine; the receiver is not listening, or is listening
  to a chorus in which this voice is 1/N.
```

The four are not degrees of the same failure; they call for different responses. Class A means stop. Class B means the effect is real and should be reported at its real size. Class C means the laboratory result stands and the extrapolation must be withdrawn. Class D means the intervention is aimed at the wrong system, or from the wrong scale, and may work at a different one.

35.5.2 5.2 The falsifier, and the circularity trap

The postulate is a conditional: *if grounded in truth, then belief creates reality.* Its logical falsifier is a belief that creates reality **without** being grounded — an ungrounded belief with a real effect, an effect with no channel. That is a clean falsification condition, and it conceals a trap.

> **THE CIRCULARITY TRAP. A conditional is vacuously true whenever its antecedent never holds. If "grounded in truth" is diagnosed FROM the outcome — the belief worked, therefore it was grounded; the belief failed, therefore it was not — then**

> **the postulate predicts nothing, forbids nothing, and is unfalsifiable. It becomes a relabelling of whatever happened.**

This is the criticism that would sink the postulate, and it is correct as stated. It has exactly one answer, and the answer is a requirement rather than an argument:

```
GROUNDING MUST BE ESTABLISHED FROM THE CHANNEL, NEVER FROM THE OUTCOME.

The channel must be named, its physical possibility checked, and its gain
estimated, BEFORE the outcome is observed. If that is done, the postulate
makes a magnitude prediction and can be wrong. If it is not done, the
postulate is a tautology and this framework disowns it.
```

Section 6 is that procedure. **The relation between the two sections is therefore not decorative: Section 5 states the objection that makes the postulate worthless, and Section 6 is the only thing that answers it.** The demand that a theory forbid something is not new [Popper, 1959, Platt, 1964, Lakatos, 1970], and the specific reason it bites here is that directional predictions are nearly costless in this domain [Meehl, 1967, 1990].

35.5.3 5.3 Warrant

```
PROVED (arithmetic)
  the survivorship result of Section 5.12: a testimonial corpus reporting
  successes only carries a likelihood ratio of exactly 1.000000 between any
  two success rates, because the denominator was never observed
  the power and minimum-detectable-effect computations throughout
  the Casimir pressures of Section 5.5
  the magnetic-field energy budget of Section 5.4

MEASURED (the evidence column) -- reported at magnitude
  Open Science Collaboration 2015: 97/100 originals significant, about 36/100
    replications, effect sizes roughly halved
  Camerer et al. 2018: 13 of 21 social-science replications significant in the
    same direction, effects about half
  Sisk et al. 2018: growth-mindset effects very small
  Yeager et al. 2019: about a tenth of a grade point, in a subgroup
  Bosch, Steinkamp & Boller 2006: micro-PK meta-analysis, tiny heterogeneous
    effect with strong evidence of bias
  Benson et al. 2006: no benefit found
  Ritchie, Wiseman & French 2012: failed replications

POSTULATED, BADGED (this framework's)
  the four-class taxonomy A/B/C/D
  the claim that every documented failure falls into one of the four
  the requirement that grounding be established from the channel

NOT CLAIMED ANYWHERE
  that any null result proves a channel's absence. A null bounds a gain.
  Section 5.11 computes the bounds and they are not small.
```

35.5.4 5.4 Class A: belief does not move objects

No physical mechanism is known by which the holding of a proposition exerts force on matter outside the body of the holder. The interesting part is why the usual objection to this is wrong. The usual objection is energetic — *the brain has no energy to spare* — and it is false:

```
energy to raise a 100 g object by 1 cm:
    m g h = 0.100 * 9.80665 * 0.01 = 9.806650e-03 J = 9.8066 mJ

delivered in one second, that is 9.8066 mW.

a resting human brain runs at roughly 20 W.

the brain's power budget exceeds the required power by a factor of 2.0394e+03.
```

The brain has two thousand times the power needed. Energy is not the obstacle. The obstacle is that there is no transducer. Energy the body possesses is coupled to the world through muscles, voice and heat, and through nothing else. To move an object without touching it, some field would have to carry the coupling:

```
magnetic energy density  u = B^2 / (2 mu_0),  mu_0 = 4 pi x 10^-7

B = 1.000e-13 T   brain field at the scalp, magnetoencephalography scale
    u = 3.978874e-21 J/m^3     in 1 cm^3:  3.978874e-27 J

B = 5.000e-05 T   Earth's field
    u = 9.947184e-04 J/m^3     in 1 cm^3:  9.947184e-10 J

B = 1.000e+00 T   a strong permanent magnet at its pole face
    u = 3.978874e+05 J/m^3     in 1 cm^3:  3.978874e-01 J

ratio of the required lift energy to the total brain-field energy in 1 cm^3:
    9.806650e-03 / 3.978874e-27  =  2.4647e+24
```

The magnetic field a brain produces is about 5.000×10^{8} times weaker than the Earth's field, and the Earth's field does not lift objects. The total field energy in a cubic centimetre at the scalp is short of the required work by a factor of roughly 2.46×10^{24}. **This is not a close call and not a matter of instrument sensitivity. It is Class A: no transducer, no channel, gain undefined.**

35.5.5 5.5 The Casimir clause, which is mandatory and instructive

The Casimir effect is real, measured and rigorous [Casimir, 1948, Lamoreaux, 1997, Mohideen and Roy, 1998]. **It is also the best available illustration of a Class C failure — a genuine physical effect recruited to carry a magnitude it cannot bear.** Recomputed here, as the corpus requires wherever it appears [Curzi, 2026aa]:

```
F/A = pi^2 hbar c / (240 a^4)

  a =   10 nm   |F/A| = 1.300126e+05 Pa  = 1.283124e+00 atm
  a =  100 nm   |F/A| = 1.300126e+01 Pa  = 1.283124e-04 atm
  a =    1 um   |F/A| = 1.300126e-03 Pa  = 1.283124e-08 atm
  a =   10 um   |F/A| = 1.300126e-07 Pa  = 1.283124e-12 atm
  a =    1 mm   |F/A| = 1.300126e-15 Pa  = 1.283124e-20 atm
```

At every biological and architectural scale the Casimir force is utterly negligible. It does nothing in a cell and nothing in a room. The a^{-4} dependence is why — and that exponent is **an exact property of the formula, not an estimated one** (Section 3.5). A hundredfold increase in separation divides the pressure by a hundred million.

The instructive part is that Casimir is real. Someone arguing that vacuum fluctuations couple to matter is not wrong about the physics. They are wrong about the number, by twenty orders of magnitude, and **being right about the mechanism and wrong by twenty orders of**

magnitude is indistinguishable in practice from being wrong about the mechanism. That is the whole content of Class C, and it is why Section 6 makes magnitude prediction a mandatory step rather than a refinement. The same discipline applied to a different exotic borrowing yields the same verdict: traversable wormholes require exotic matter violating an energy condition, so the paper that introduced them concludes against the shortcut they are usually cited to support [Morris and Thorne, 1988].

35.5.6 5.6 Class A continued: three further boundaries

Belief does not alter an uncontacted person's body. The qualifier "no perceptual contact" does all the work and must stay attached: belief communicated — by word, tone, face, touch, treatment — routinely changes another person's physiology, and the framework documents those channels in detail [Curzi, 2026ab]. The claim here is narrow. The largest published test of intercessory prayer at a distance (Benson et al., *American Heart Journal*, 2006; **named without a key**) studied roughly 1,800 cardiac surgery patients across multiple centres and found no benefit. **This is reported as a measurement about a channel, and no clinical, medical or therapeutic claim is made in either direction.** Note also what it does not establish: **a null bounds a gain; it does not prove a zero.** With arms of roughly this size the study bounds a standardised effect below about 0.16 at conventional power. **It does not exclude 0.05.**

Belief does not change physical constants. The speed of light, Planck's constant, the elementary charge and the fine-structure constant are measured to extraordinary precision and are not observed to vary with the beliefs of those measuring them; the fine-structure constant is known to roughly a part in ten billion. **This is worth one paragraph rather than ten because there is no interesting failure mode here.** The reason to state it is definitional: it fixes the outer boundary of the postulate's territory, and **a postulate with no stated outer boundary is not a postulate.**

Belief does not reach backward in time — and the episode that showed it is the catalogue working. Bem's 2011 paper in the *Journal of Personality and Social Psychology* reported nine experiments in which effects appeared to precede their causes. **The paper was methodologically conventional**, used standard designs, analyses and thresholds, and appeared in a leading journal — **which is precisely why it mattered: if orthodox method could produce a significant result for retrocausal influence, the problem was the method, not the topic.** Ritchie, Wiseman and French published three unsuccessful replication attempts in *PLoS ONE* in 2012 and the effect did not appear. **It is also reported — and this is stated here as a reported account of the episode rather than as a documented editorial policy the author has verified — that the replication attempts were initially declined on the grounds that the journal in question did not publish replications.** If accurate, that is $P(\text{sig} \mid \text{no effect})$ in the bottom row of Section 5.10's table made visible as a mechanism rather than inferred as a parameter [Ioannidis, 2005, Simmons et al., 2011, Gelman and Loken, 2013].

```
CLAIM     a belief or response at time t is influenced by a stimulus selected
          at time t + k, k > 0.
CHANNEL   none. Retrocausal influence has no established physical carrier, and
          the claim is not that the carrier is weak but that no candidate
          carrier has been identified.
CLASS     A.
STATUS OF THE EVIDENCE   the original result did not replicate.
```

The reason this episode belongs in a paper defending a belief-related postulate is that it shows the discipline working. A striking result appeared, it was taken seriously enough to replicate, the replications failed, and the field's response became one of the proximate causes of the reform movement [Open Science Collaboration, 2015, Nosek et al., 2018]. **A postulate that wants to be believed should want that machinery pointed at it, and Section 5.10 points it at this framework.**

35.5.7 5.7 Class B: growth mindset — the channel is real and the gain is small

This is the most instructive case in the section, because the popular claim and the measured effect differ not in kind but by an order of magnitude, and the temptation to round the effect up is strongest.

The channel is real. Belief about the malleability of ability changes effort allocation; changed effort allocation changes practice; changed practice changes skill. Every link is behavioural, observable and uncontroversial. **This is not Class A, and naming it Class A would be as much an error as inflating it.**

The gain is small. Sisk and colleagues (*Psychological Science*, 2018; **named without a key**) conducted two meta-analyses — one of the correlation between mindset and academic achievement, one of the effect of mindset interventions on achievement. Both were weak: the correlation in the region of $r = 0.10$ and intervention effects in the region of $d = 0.08$, with subgroup effects for students at academic risk and from low-income backgrounds. Unpack those magnitudes, because the unpacking is the argument:

```
r = 0.10  ->  variance explained  r^2 = 0.0100 = 1.00%

d = 0.08:
  Cohen's U3, per cent of treated above the untreated median
                                  = Phi(0.08)         = 53.188%   (vs 50.000%)
  common-language effect size     = Phi(0.08/sqrt 2)  = 52.256%   (vs 50.000%)
  overlap of the two distributions = 2*Phi(-0.04)     = 96.809%

on a GPA scale with SD = 0.70:     d = 0.08  ->  0.0560 GPA points
on an IQ-type scale with SD = 15:  d = 0.08  ->  1.2000 points
on a test scale with SD = 100:     d = 0.08  ->  8.0000 points
```

Ninety-six point eight per cent of the two distributions overlap. Pick one treated student and one untreated student at random: the treated one scores higher **52.256 per cent** of the time, against 50 per cent by chance. **That is the size of the thing.**

The large field trial is consistent. Yeager and colleagues (*Nature*, 2019; **named without a key**) ran a short online intervention across a national sample and reported a gain on the order of a tenth of a grade point in GPA among lower-achieving students — $d = 0.1429$ on a GPA standard deviation of 0.70, or $d = 0.1000$ on a standard deviation of 1.00.

Now the point that separates an honest report from a dismissal. A tenth of a grade point, delivered by a short online exercise at very low marginal cost across a national population, is a genuinely useful public intervention. **A small effect at national scale and near-zero cost is good engineering. It is simply not what "belief creates reality" is usually taken to mean.**

```
  MEASURED:  d ~ 0.08, sometimes ~0.14 in a subgroup, from an intervention
             costing minutes and pennies per student.
  CLAIMED:   that adopting a belief about malleability transforms outcomes.
  CLASS:     B. The channel is real. The gain is roughly one order of magnitude
             below the claim, and the claim never states a magnitude at all,
             which is how the gap stays invisible.

CONCORDANCE 5.1 -- BELIEF ABOUT ONE'S OWN MALLEABILITY AFFECTS ONE'S OUTCOMES

  CLAIM        Holding that ability is improvable changes effort and therefore
               outcomes.

  (+1) EVIDENCE
               Sisk et al. 2018 (two meta-analyses; r ~ 0.10, d ~ 0.08).
```

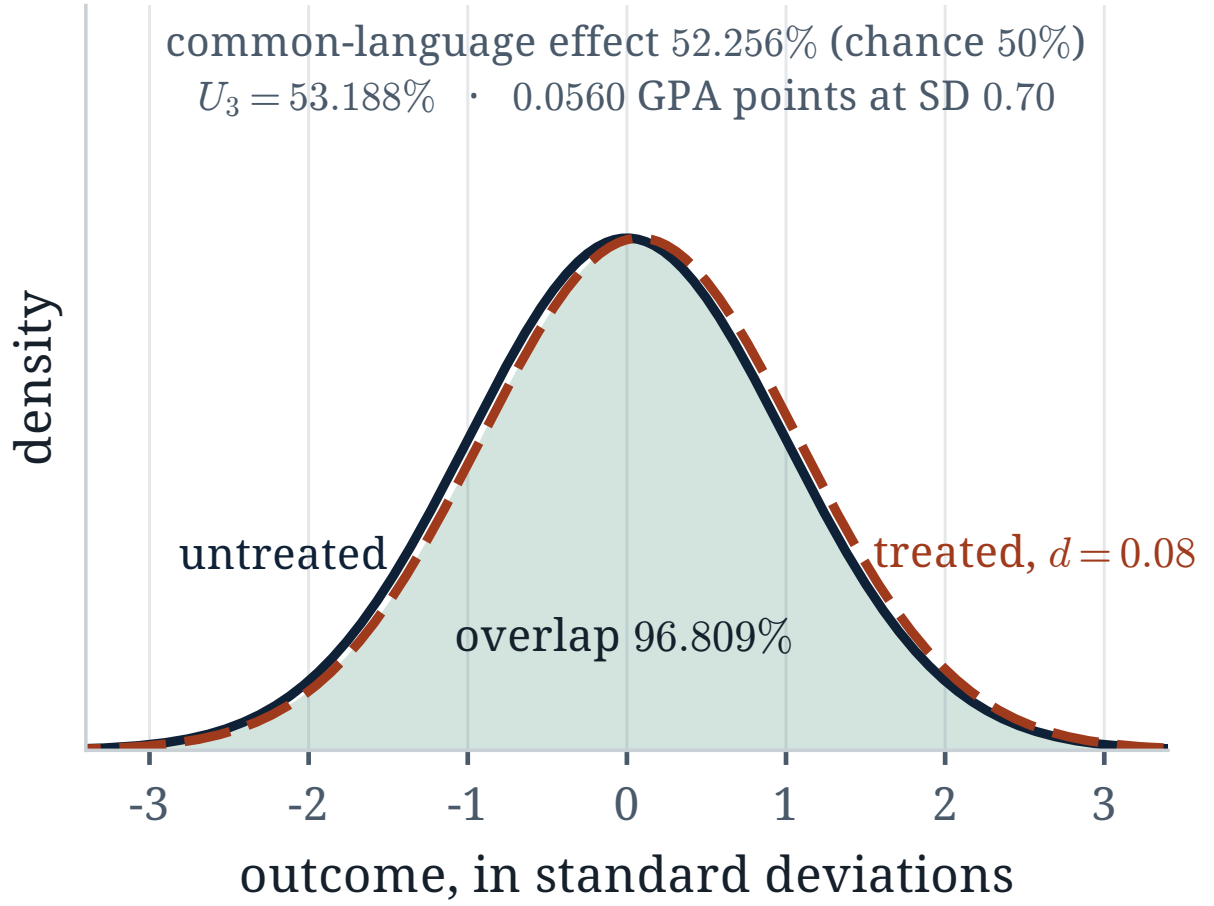

Figure 35.2: **Ninety-six point eight per cent of the two distributions overlap:** the treated and untreated distributions at the meta-analytic growth-mindset effect $d = 0.08$, with the overlap region shaded and the three unpackings marked — Cohen's $U_3 = 53.188$ per cent, the common-language effect 52.256 per cent, and 0.0560 GPA points on a 0.70-point standard deviation. **Modelled, not measured:** the curves are unit normal densities offset by the reported d; the effect size itself is quoted from the meta-analytic literature named in Section 5.7 and carries that literature's uncertainty, not this paper's. Generated by `figs/src/CCP-035_fig02.py`.

```
              Yeager et al. 2019 (national field experiment; about a tenth of
              a grade point among lower-achieving students).
              WHAT IT MEASURED: a real, replicated, very small average effect,
              larger in specific subgroups.

(-1) PRECEDENT -- CARRIES NO EVIDENCE
              Craft and monastic training traditions across many cultures make
              the trainee's conviction of improvability an explicit part of the
              curriculum. This is a characterisation of what those traditions
              recorded, offered as such and not as a quotation.

(0p) INTEGRATION
              The traditions were right about the sign and silent about the
              size. The measurement supplies the size, and the size is small.
              THE (-1) COLUMN CANNOT RESCUE THE MAGNITUDE AND MUST NOT BE USED
              TO TRY.

CRITERIA      C1 PASS. C2 PASS. C3 PASS at the measured magnitude only.

STATUS        ESTABLISHED as a real effect at d ~ 0.08. Any claim of a larger
              effect is UNSUPPORTED and this paper does not make one.
```

35.5.8 5.8 Class C: the general problem of transfer

Steele and Aronson's 1995 work in the *Journal of Personality and Social Psychology* (**named without a key**) reported that making a negative stereotype salient depressed the test performance of members of the stereotyped group. The finding was influential, generated a very large literature, and was widely used to explain real-world group differences in achievement.

The replication record has been substantially more difficult than the original literature suggested. Flore and Wicherts's 2015 meta-analysis in the *Journal of School Psychology* found a small effect together with evidence of publication bias, and reported bias-corrected estimates close to zero; a subsequent large registered replication (Flore et al., 2018) did not find the effect. **This literature is contested and active, not all researchers accept the deflationary reading, and the correct summary is "replication has been difficult" rather than "the effect does not exist."**

The analytic point is the transfer, and it is Class C:

```
LABORATORY:  a salience manipulation, minutes before a test, on a sample,
             produces a measurable performance shift in some designs.
CLAIMED:     that this mechanism accounts for a substantial portion of
             population-level achievement gaps that persist across years,
             institutions and life outcomes.
THE GAP:     the second claim requires a magnitude the first was never
             measured at, over a duration the first was never measured over,
             with a persistence the first never demonstrated.
```

A brief laboratory manipulation and a decades-long structural disparity are separated by many orders of magnitude in duration, dose and accumulation, and no measurement bridges them. The laboratory result may be entirely sound and the transfer still unsupported. **That is what makes Class C the most seductive of the four: nothing in the original work needs to be wrong.** The general problem — that laboratory results on group and individual performance do not transfer to field magnitudes without a stated transfer assumption — is documented across a whole literature the corpus relies on elsewhere [Thompson, 2014, Singer, 2019, Grim et al., 2019, Mannix and Neale, 2005, Woolley et al., 2010, Hong and Page, 2004, Page, 2007], and it is the reason a transfer assumption must be **stated** rather than assumed.

35.5.9 5.9 The replication discount, applied to this framework

```
Open Science Collaboration, "Estimating the reproducibility of psychological
science," Science, 2015:

  originals reporting a significant result       97 of 100
  replications reporting a significant result    about 36 of 100
  mean effect size r                             0.403  ->  0.197
  ratio                                          0.4888   (a drop of 51.12%)

Camerer et al., Nature Human Behaviour, 2018, replications of social-science
studies published in Nature and Science, 2010-2015:

  replicated in the same direction at p<0.05     13 of 21  = 61.90%
  replication effect sizes                       about half the originals
```

Now apply it, with the assumptions printed. Take a prior probability of 0.10 that a given proposed effect in this area is real, and compute the posterior after one statistically significant study under four regimes:

power	P(sig | no effect)	regime	posterior
0.80	0.05	well-powered, no publication filter	0.6400
0.35	0.05	typical power, no filter	0.4375
0.35	0.20	typical power, moderate selective reporting	0.1628
0.35	0.30	typical power, heavy selective reporting	0.1148

The bottom row is the honest frame for a single striking result in this literature. A prior of 0.10 becomes a posterior of 0.1148 — one study moved the belief by less than two percentage points. That is what it means to work in a field with a replication problem: single results are nearly uninformative, and the informative unit is the replicated, preregistered, adequately powered multi-site estimate [Nosek et al., 2018].

And this applies to this framework. The coupling architecture [Curzi, 2026ab], the four-class taxonomy of this paper and the seven-step protocol of Section 6 all sit in exactly the same epistemic regime as the claims they evaluate. **If this framework's own predictions were tested and returned a single significant result, the correct posterior update would be the bottom row of that table, and the author is obliged to say so in print.** Section 6's insistence on preregistration, four baselines and the shuffled-input control is the response, and it is the only response available. **One asymmetry is claimed and one only: the framework's static results are mathematics, and mathematics does not have a replication problem — it has a proof-checking problem, which is a different and better-solved difficulty.** The surplus law and its ceiling [Curzi, 2026], the storage law [Curzi, 2026a], and the contraction result — whose a posteriori bound $d(x_n, x^*) \le (k^n/(1-k))\, d(x_0, x_1)$ reads operationally as *distance to arrival is the last correction scaled by* $q/(1-q)$, so that the size of one's most recent revision is a self-reading gauge [Curzi, 2026] — are theorems. **Everything this framework says about human beings is in the same boat as everything else said about human beings.**

35.5.10 5.10 A null bounds a gain; it does not prove a zero

```
minimum detectable standardised effect at 80% power, alpha .05 two-sided,
two arms of n each:      d_min = (1.959964 + 0.841621) * sqrt(2/n)

  n per arm       d_min
       50        0.5603
      100        0.3962
      300        0.2287
```

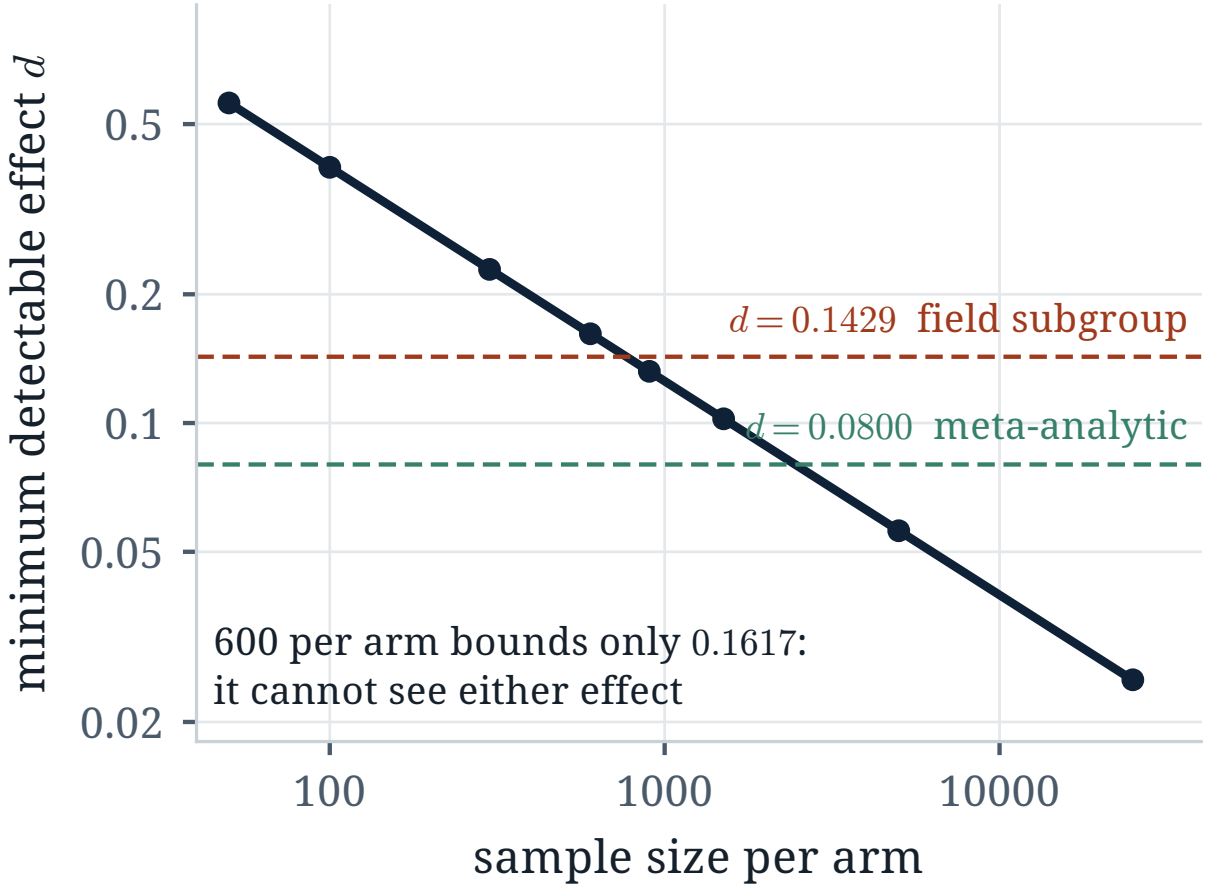

Figure 35.3: **A null bounds a gain; it does not prove a zero:** the minimum detectable standardised effect $d_{\min} = (1.959964 + 0.841621)\sqrt{2/n}$ at 80 per cent power and $\alpha = 0.05$ two-sided, against the sample size per arm, with the two magnitudes this paper reports marked — the meta-analytic growth-mindset effect $d = 0.08$ and the field subgroup effect $d = 0.1429$. **A trial of 600 per arm cannot see either of them.** Exact evaluation of the stated power formula; the two marked effects are quoted from the literature named in Section 5.7. Generated by `figs/src/CCP-035_fig03.py`.

600	0.1617
900	0.1321
1,500	0.1023
5,000	0.0560
25,000	0.0251

A trial with 600 per arm reporting no effect has bounded the effect below about 0.16. It has not shown the effect is zero, and it cannot. Every null in this section is therefore an upper bound on a gain and is reported as one.

This cuts both ways and it is supposed to. A sceptic who reads a null as proof of absence has made the mirror image of the believer's error: both have taken a magnitude question and answered it with a direction. **The correct statement is always a number with an interval**, and where this section says "belief does not do X" it means either that no channel exists — Class A, where no trial is needed because there is nothing to measure — or that the gain is bounded below a stated value by a stated study.

35.5.11 5.11 Survivorship: why a testimonial corpus carries no information about a rate

The successes write books; the failures do not. The literature reports numerators. This is not a criticism of any individual account's honesty. It is a property of how the corpus is assembled.

Suppose a corpus contains 500 first-person accounts of a practice working. Compute the population required under four hypotheses:

success probability p		practitioners needed for 500 successes
0.500	the practice works, half succeed	1,000
0.100	works weakly	5,000
0.010	works barely	50,000
0.001	does nothing beyond the base rate	500,000

Every one of those worlds produces exactly 500 books. Bestselling works in this genre have sold in the millions; a practising population in the hundreds of thousands or millions is entirely plausible. So the bottom row — the practice does nothing at all beyond whatever people would have achieved anyway — predicts the observed corpus just as well as the top row.

```
LIKELIHOOD RATIO between any two rows, given only the numerator:  1.000000
```

Exactly one. The corpus carries zero information about p, because the denominator was never observed. This is not a weak argument against testimonials; it is a proof that testimonials in this format are evidentially inert with respect to the quantity at issue.

The precedent is Wald's work for the Statistical Research Group during the Second World War (**named without a key**). Asked where to armour aircraft given the distribution of bullet holes in aircraft that returned, the insight was that the data were conditioned on returning: **armour the places with no holes, because aircraft hit there did not come back to be measured.** The testimonial corpus is the returning aircraft — a census of survivors presented as a census of attempts.

Three consequences, stated as operating rules:

1. **The base rate is unobtainable from testimonials, in principle, at any corpus size.** A thousand more accounts adds a thousand more numerators and no denominator. The problem is not sample size and cannot be fixed by more of the same.
2. **Getting the denominator requires enrolling people before the outcome is known.** That is a cohort design, and it is the reason Section 6's protocol makes preregistration mandatory rather than advisable.
3. **The same defect afflicts case studies of institutions, teams and rooms — including the worked examples in this corpus, where they are drawn from success.** The corpus's own failure records exist partly to supply the missing tail [Curzi, 2026].

```
CONCORDANCE 5.2 -- TESTIMONY OF SUCCESS ESTABLISHES A RATE

  CLAIM        That a large body of first-person accounts of a practice working
               is evidence that the practice works.

  (+1) EVIDENCE
               Wald's survivorship analysis (1943) and the standard treatment of
               selection on the dependent variable.
               WHAT IT MEASURED: that conditioning on the outcome destroys the
               inference, and that the destruction is total rather than partial.
```

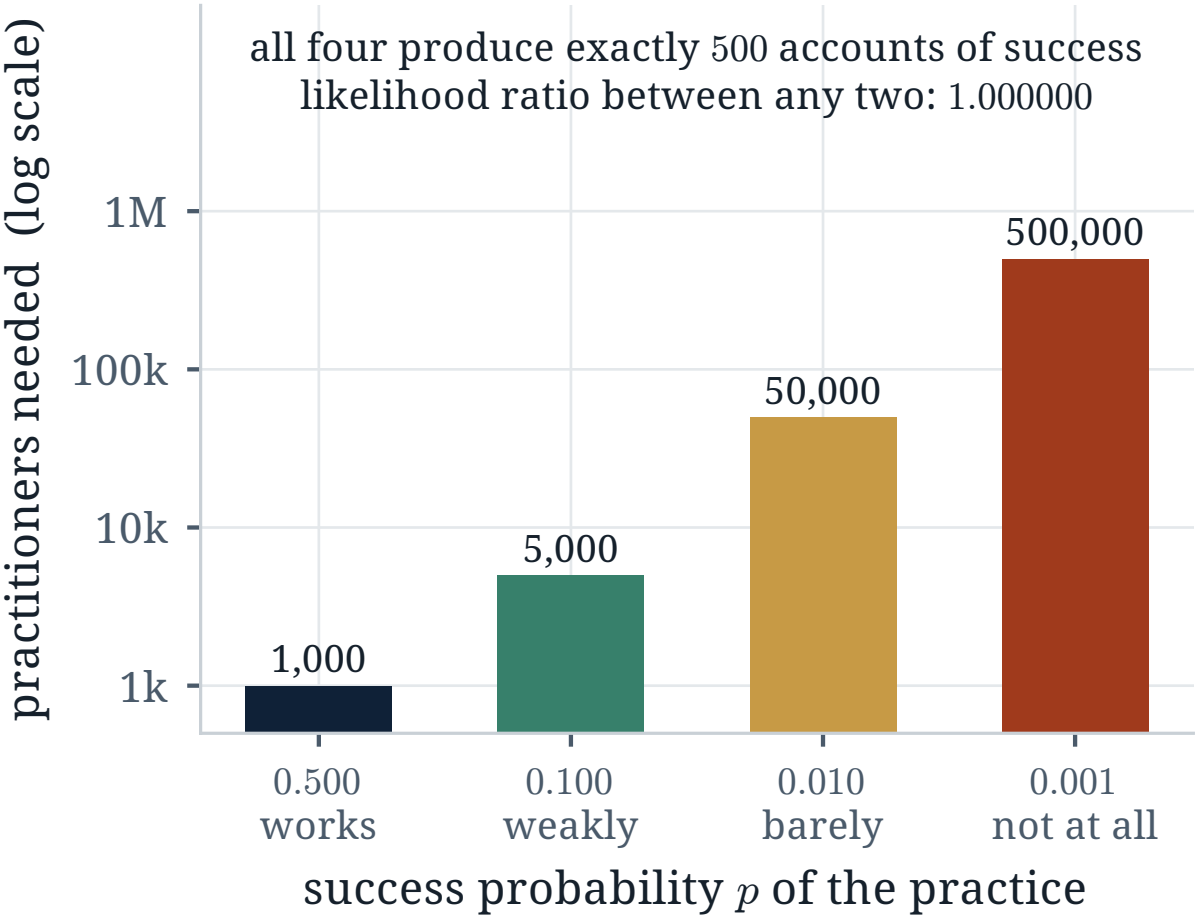

Figure 35.4: **Every hypothesis about the success rate produces exactly the same 500 books:** the practising population required to generate 500 first-person accounts of success, under four success probabilities from 0.500 to 0.001, on a logarithmic scale. **The likelihood ratio between any two rows, given only the numerator, is exactly 1.000000** — the corpus carries zero information about the rate. Exact arithmetic on the stated hypotheses; the corpus size of 500 is an illustrative round figure and is not a count of any real bibliography. Generated by `figs/src/CCP-035_fig04.py`.

```
(−1) PRECEDENT -- CARRIES NO EVIDENCE
             The classical sceptical response to votive offerings -- the reply
             that the drowned leave no tablets -- is recorded in the ancient
             philosophical literature, most familiarly through Cicero's
             De Natura Deorum.
             WHAT IT RECORDS: that the fallacy was identified by argument two
             thousand years before it was formalised.

(0p) INTEGRATION
             The old argument and the modern statistic identify the same
             defect. The modern statistic quantifies it: the likelihood ratio
             is 1.000000, which is the strongest possible statement of the old
             objection.

CRITERIA     C1 PASS. C2 PASS. C3 PASS.

STATUS       THE CLAIM IS REJECTED. This is one of the rejections the method
             requires: a method that never rejects is not a method.
```

35.5.12 5.12 Class D: the system is not responsive to an input of this size, from a source of this size

The last class is the subtlest and the most common in practice, because in Class D everything the believer says about the mechanism is true, and the effect is still zero.

Case: a belief about a market price. Belief that an asset will rise leads to buying, which raises the price. Every link is real; the channel is the actual mechanism by which prices move. **And one person's belief moves the price by an amount indistinguishable from noise, because the price is set by an aggregate in which the individual is one term of a very large sum. The channel is real and the individual's share of it is** $1/N$**.**

Centola et al. [2018] measured convention tipping at roughly a 25 per cent committed minority:

group size	one person is	tipping needs	shortfall factor
12	8.3333%	3 = 25%	3.0x
24	4.1667%	6 = 25%	6.0x
150	0.6667%	38 = 25%	37.5x
240	0.4167%	60 = 25%	60.0x
2,400	0.0417%	600 = 25%	600.0x
100,000	0.0010%	25,000 = 25%	25,000.0x

In a group of twelve, one committed person is a third of the way to the tipping point. In a group of a hundred thousand, one person is twenty-five thousand times short. The mechanism is identical in both. **The same belief, through the same channel, in the same kind of system, is decisive at one scale and inert at another — and nothing about the belief distinguishes the two cases.** The corpus reaches the structurally identical conclusion for contact effects, where a boundary-cost multiplier determines whether contact helps at all and is computed at 3.17 against an operating value of 8 [Curzi, 2026g].

Case: a belief nobody learns of. If a belief about another person's decision is never communicated in any modality — not spoken, not written, not signalled by posture, tone, timing or differential treatment — then there is no channel, and the case is Class A. **The diagnostic question is therefore not "is the belief sincere?" but "by what physical means does the other person come to be affected?"** In practice beliefs leak constantly through behaviour, and the honest analysis is usually that a real but small behavioural channel exists — Class B, which is what Section 4.13 measures.

Case: a belief about a system with a fixed schedule. A traffic signal on a fixed timer is not responsive to any input a pedestrian can supply. The channel from belief to action exists; the system does not read those inputs. **Class D, and the diagnostic is one sentence: what does this system take as input?**

Class D failures are failures of the receiver, and receivers fail in exactly three ways:

```
D1  THE RECEIVER DOES NOT READ THIS INPUT AT ALL.
    A fixed timer reads a clock. A conserved quantity reads nothing.
    Diagnostic: enumerate the system's actual inputs. If the channel's output
    is not on the list, D1, and no increase in input strength helps.

D2  THE RECEIVER READS IT, AND THIS SOURCE IS 1/N OF WHAT IT READS.
    A market price, an election, a social convention.
    Diagnostic: compute the share. It is one division and it settles the case.
    THIS IS THE ONE FAILURE MODE THAT CHANGES WITH SCALE.

D3  THE RECEIVER READS IT, AND IS ALREADY SATURATED.
    A student already receiving maximal attention; a market already fully
    informed; a queue already at capacity.
    Diagnostic: measure the response to a known perturbation at the CURRENT
    operating point, not at the point where the original study measured it.
    This is where the growth-mindset subgroup findings live: the effect is
    larger for students at academic risk because they are further from
    saturation.
```

D2 is the only one a bigger coalition fixes. D1 is fixed by finding a different channel. D3 is fixed by finding a different operating point. Confusing them wastes years, because all three present identically from inside: *I did the thing sincerely and nothing happened.*

35.5.13 5.13 The catalogue in one table

CLAIM	CLASS	WHY IT FAILS
belief moves an external object	A	no transducer; field energy short by ~2.5e24
belief alters an uncontacted person's body	A	no channel; the largest trial bounds any effect, does not prove zero
belief changes physical constants	A	no channel; constants measured to ~1 part in 1e10
Casimir does work at cellular scale	C	real effect, wrong by ~20 orders of magnitude
growth mindset transforms outcomes	B	real channel, d ~ 0.08; claim is ~10x the gain
a lab salience effect explains population gaps	C	lab effect, contested replication, no bridge to decades-long magnitude
one person's belief moves a market price	D	real channel, share is 1/N; shortfall 25,000x at N=1e5
testimonials establish that a practice works	-	evidentially inert; likelihood ratio 1.000000
belief cures disease by itself	-	NO CLAIM MADE. This paper makes no clinical, medical or therapeutic claim, in either direction, anywhere.

The last row is not a failure class because it is not a claim this paper evaluates. The prohibition is absolute, and the reason it appears in the catalogue at all is that its absence would otherwise be read as an omission.

35.5.14 5.14 What survives, at its measured size

The catalogue would be dishonest in the other direction if it stopped here.

```
SURVIVES: placebo analgesia through endogenous opioids, naloxone-reversible
          (Levine, Gordon & Fields, 1978). A complete verified physical
          channel from expectation to measured outcome.
          MAGNITUDE: modest; the literature is active; effect sizes vary by
          condition and design.

SURVIVES: open-label placebo (Kaptchuk et al., 2010, and subsequent trials).
          Benefit reported when recipients are told they are receiving
          placebo. Decisive here because the effect does not require
          deception. MAGNITUDE: modest; literature active.

SURVIVES: self-fulfilling prophecy where the system is structurally
          responsive (Merton 1948; Diamond & Dybvig 1983).
          MAGNITUDE: can be total, as in a deposit run -- and only where
          W3 holds.

SURVIVES: expectancy effects on performance.
          MAGNITUDE: real, small, condition-dependent, prone to dissipate
          (Raudenbush 1984; Jussim & Harber 2005).

SURVIVES: perception partly constructed from priors.
          MAGNITUDE: substantial for perception; the research programme is
          active and contested.
```

Every survivor on that list has a named physical channel and is reported with its magnitude. That is not a coincidence; it is the selection criterion. **The list of what belief does is exactly the list of channels that have been found and measured, which is what the postulate predicts, and it is the strongest support the postulate has.** All five are cited as evidence about channels and their gains; **no clinical, medical or therapeutic claim is made about any of them.**

35.5.15 5.15 Requirements

REQ-5.1 Classify every failure as A, B, C or D and print the class. “It doesn’t work” is not a finding.

REQ-5.2 Establish grounding from the channel, never from the outcome. This is not advice.

REQ-5.3 Name the transducer before asserting any channel. If no physical component can be named that converts the belief into the asserted influence, the claim is Class A and the analysis is finished.

REQ-5.4 Report every effect at its magnitude, in the units the reader cares about. For $d = 0.08$: 96.809 per cent overlap, 52.256 per cent common-language effect, 0.0560 GPA points. **Direction-only reporting is prohibited.**

REQ-5.5 Cite the growth-mindset meta-analysis with its effect size whenever the concept is invoked. Invoking it without the magnitude is a citation error.

REQ-5.6 State replication status alongside any social-science finding used as support, in the sentence that makes the claim.

REQ-5.7 Never read a null as proof of absence. Report the minimum detectable effect at the study's power and state the null as an upper bound.

REQ-5.8 Never treat a testimonial corpus as evidence about a rate. The likelihood ratio is 1.000000.

REQ-5.9 Apply the replication discount to this framework's own claims.

REQ-5.10 Print the Casimir clause wherever Casimir appears: negligible at every biological and architectural scale.

REQ-5.11 Distinguish "the channel does not exist" from "my share of it is $1/N$". These are Classes A and D, they look identical from the inside, and only one of them changes with scale.

REQ-5.12 Make no clinical, medical or therapeutic claim, in either direction. Absolute.

REQ-5.13 Keep the concordance columns separate in the failure catalogue too.

REQ-5.14 When a claim's magnitude cannot be stated, record it as **untested** rather than as **unproven**. These are different verdicts.

35.5.16 5.16 Failure modes of the catalogue itself

FM-5.1 — EX POST GROUNDING. *Signature:* the outcome is observed and grounding is assigned to match. *Mechanism:* the circularity trap. *Fix:* name and check the channel before the outcome is known, in writing, with a date.

FM-5.2 — CHANNEL LAUNDERING. *Signature:* a Class A claim defended by pointing at a real Class B channel, with the Class A magnitude retained. *Fix:* separate the claims and make each name its own transducer.

FM-5.3 — MAGNITUDE-FREE ASSERTION. *Signature:* a claim states a direction and never a size, and so cannot be wrong. *Mechanism:* direction-only claims are worth a likelihood ratio of 2.000000. *Fix:* require a predicted magnitude with a tolerance before measurement. **Most claims in this area die here, and dying here is much cheaper than dying after the study.**

FM-5.4 — DENOMINATOR BLINDNESS. *Signature:* a large number of success stories treated as a large body of evidence. *Fix:* ask who is missing.

FM-5.5 — NULL AS PROOF OF ABSENCE. *Signature:* "the trial found nothing, therefore there is nothing." *Fix:* report the minimum detectable effect and state the null as an interval.

FM-5.6 — PRECEDENT LAUNDERED INTO EVIDENCE. *Signature:* an old source and a modern study cited together in a way implying two independent confirmations. *Fix:* state each column's role in the same sentence, every time [Curzi, 2026w].

FM-5.7 — LAB-TO-LIFE TRANSFER. *Signature:* an effect measured over minutes asserted to explain an outcome accumulated over decades. *Fix:* state the dose, duration and accumulation of the original next to those of the target claim.

FM-5.8 — SCALE-BLIND COALITION CLAIM. *Signature:* a mechanism verified in a small group asserted for a large one without adjusting the individual's share. *Fix:* compute the share. It is one division.

FM-5.9 — SELECTIVE SCEPTICISM. *Signature:* the replication crisis invoked against inconvenient findings and forgotten for convenient ones. *Fix:* apply the posterior table to this framework's own claims in print, as Section 5.9 does.

FM-5.10 — CATALOGUE AS DISMISSAL. *Signature:* the failure catalogue read as showing that belief does nothing. *Mechanism:* the catalogue is a boundary, not a verdict. *Fix:* never present the failure list without the survivor list and its magnitudes.

FM-5.11 — THE UNSTATED CLINICAL IMPLICATION. *Signature:* no medical claim is made explicitly and the surrounding text is arranged so that a reader will infer one. *Fix:* state the prohibition in the reader's line of sight wherever the subject comes near. **This section does so three times and the repetition is deliberate.**

35.6 6 Grounding: the protocol that answers the circularity objection

Section 5 closed with an objection the postulate cannot survive without answering. **If "grounded in truth" is diagnosed from the outcome, the postulate predicts nothing, forbids nothing, and is a relabelling of whatever happened.** There is exactly one answer and it is not an argument. It is a procedure.

> **GROUNDING IS ESTABLISHED FROM THE CHANNEL, BEFORE THE OUTCOME IS KNOWN, OR IT IS NOT ESTABLISHED AT ALL.**

One step does most of the killing, and this section says so on the page rather than in the notes. Step 5 requires a predicted magnitude — not a direction, a number, with a tolerance, written down before the measurement. Most claims about belief die at step 5, because a belief that predicts only a direction **is not yet testable**: it has not been refuted, it has not been examined, it has not made a statement about the world sharp enough to be wrong. **That is a worse condition than being false, and the fact that it feels like a safer one is precisely why so many claims stay in it.**

35.6.1 6.1 The grounding criterion

```
A BELIEF b, ASSERTING A STATE x*, IS GROUNDED IF AND ONLY IF THERE EXISTS A
CHANNEL K SUCH THAT:

  G1  K IS NAMED.            Every link is identified: source, transducer,
                             medium, receiver, effector. No link may be a
                             placeholder, and "somehow" is not a link.

  G2  K IS PHYSICALLY POSSIBLE.
                             Each link is consistent with conservation,
                             causality, thermodynamics, and the signal-to-noise
                             available at the stated amplitude.

  G3  K HAS A GAIN g > 0, ESTIMATED INDEPENDENTLY OF THE OUTCOME OF b.
                             From prior measurement, from the physics of the
                             link, or from a separate calibration -- never from
                             the case under test.

  G4  THE PREDICTED MAGNITUDE g * b IS STATED, WITH A TOLERANCE, BEFORE
      MEASUREMENT.

  G5  THE PREDICTION SURVIVES THE FALSIFICATION SUITE,
                             including the shuffled-input control.

GROUNDING IS A PROPERTY OF THE CHANNEL. IT IS NEVER A PROPERTY OF THE RESULT.
```

Badge: G1 to G5 are this framework's operationalisation of the postulate's conditional clause, and they are a proposal rather than a theorem. What makes them more than a stylistic preference is G3 and G4 together: they convert a conditional that cannot be wrong into a claim that predicts a number. **A postulate that predicts a number can be killed, which is the only thing that makes it worth defending.**

35.6.2 6.2 The seven steps

```
  1.  STATE THE BELIEF PRECISELY ENOUGH TO BE WRONG.
```

```
     A sentence whose negation is also a clear sentence.

  2. IDENTIFY THE CLAIMED CHANNEL EXPLICITLY.
     SOURCE -> TRANSDUCER -> MEDIUM -> RECEIVER -> EFFECTOR, each named.

  3. CHECK THE CHANNEL IS PHYSICALLY POSSIBLE.
     Six checks. Most Class A claims stop here, in minutes.

  4. ESTIMATE ITS GAIN.
     Per link, from independent sources. Multiply along the chain. Report the
     end-to-end number with its uncertainty.

  5. PREDICT THE MAGNITUDE OF THE EFFECT, NOT ONLY ITS DIRECTION.
     A number, in stated units, with a stated tolerance, recorded before
     measurement. THIS IS WHERE MOST CLAIMS DIE.

  6. MEASURE.
     Preregistered, blinded where possible, with the instrument specified in
     advance. The seven formula-validation gates in print.

  7. COMPARE PREDICTION TO OUTCOME.
     Against four baselines including the shuffled-input control. Four
     verdicts are available and only one of them is "grounded."
```

The ordering is load-bearing and the steps are not commutative. Step 2 before step 4 prevents a gain being borrowed from a channel other than the one claimed. Step 4 before step 5 prevents the predicted magnitude being chosen for its plausibility. Step 5 before step 6 prevents the tolerance being widened after the data arrive. **Every one of those inversions is a documented way of getting a result you like, and the ordering is the defence** [Simmons et al., 2011, Gelman and Loken, 2013].

35.6.3 6.3 Why step 5 does the killing

A direction-only prediction is worth almost nothing, and the amount is computable.

```
Under a symmetric null, the chance of a correct direction call = 0.500000
LIKELIHOOD RATIO of one correct direction call = 2.000000

k independent direction calls, all correct, by chance:
   k= 1   0.500000        k= 6   0.015625
   k= 2   0.250000        k= 7   0.007812
   k= 3   0.125000        k= 8   0.003906
   k= 4   0.062500        k= 9   0.001953
   k= 5   0.031250        k=10   0.000977
```

One correct direction call is worth a likelihood ratio of 2. It takes five consecutive correct calls to reach $p = 0.031250$**.** Almost no claim in the belief literature has produced five independent, preregistered, correct direction calls, and a single one is routinely presented as confirmation. This is Meehl's objection to directional prediction in psychology, stated arithmetically [Meehl, 1967, 1990].

Now compute what a magnitude call is worth. **Suppose the true value is known only to lie log-uniformly over** R **decades — a modelling choice, badged as one, and the numbers below are properties of that prior** — and the claim predicts it within $\pm p$:

```
band width in log space = ln((1+p)/(1-p))        prior span = R * ln(10)
```

```
  R = 1 decade:
     +/- 50%   width 1.098612   chance hit 0.477121   LR      2.0959
     +/- 30%   width 0.619039   chance hit 0.268845   LR      3.7196
     +/- 20%   width 0.405465   chance hit 0.176091   LR      5.6789
     +/- 10%   width 0.200671   chance hit 0.087150   LR     11.4744
     +/-  5%   width 0.100083   chance hit 0.043466   LR     23.0066

  R = 2 decades:
     +/- 50%   chance hit 0.238561   LR      4.1918
     +/- 30%   chance hit 0.134423   LR      7.4392
     +/- 20%   chance hit 0.088046   LR     11.3577
     +/- 10%   chance hit 0.043575   LR     22.9489
     +/-  5%   chance hit 0.021733   LR     46.0133

  R = 3 decades:
     +/- 20%   chance hit 0.058697   LR     17.0366
     +/- 10%   chance hit 0.029050   LR     34.4233
     +/-  5%   chance hit 0.014489   LR     69.0199
```

A single magnitude call at ± 20 per cent against a two-decade prior is worth a likelihood ratio of 11.3577, against 2.0000 for a direction call. Converting:

```
  equivalent number of direction calls = ln(11.357747) / ln(2) = 3.5056
```

One magnitude prediction carries as much evidential weight as three and a half correct direction predictions, and it costs the same single measurement. That is the whole argument for step 5, it is arithmetic given the stated prior, and it explains why the step is where claims die: **a claimant who declines to state a magnitude has declined the cheapest available source of evidence for their own position. That is not caution. It is a preference for remaining untested, and it should be named as one.**

35.6.4 6.4 Warrant

```
PROVED (arithmetic)
  the direction-call and magnitude-call likelihood ratios of Section 6.3,
    GIVEN the log-uniform prior, which is a modelling choice
  the chain-gain product of Section 6.9
  the power and minimum-detectable-effect computations of Section 6.10
  the simulated behaviour of the shuffled-input control, including the
    configuration in which it FAILS

BORROWED (established, from elsewhere in this corpus)
  the seven formula-validation gates (CCP-026)
  the four-baseline falsification template and the shuffled-input control,
    with its own measured anti-conservatism (CCP-027)
  the ceiling 0 <= F(u) <= ln N (CCP-A02)
  the replication numbers of Section 5.9

POSTULATED, BADGED (this framework's)
  the G1-G5 grounding criterion
  the seven-step ordering and the claim that the ordering is load-bearing
  the four-verdict comparison table of Section 6.12
  the worksheet of Appendix C
```

35.6.5 6.5 Step 1 — state the belief precisely enough to be wrong

The test is mechanical: **write the negation.** If the negation is also a clear, checkable sentence, the belief has passed. A sharpening in four passes:

```
PASS 0   "Believing in the project will make it succeed."
         Negation: "Believing in the project will not make it succeed."
         VERDICT: fails. "Believing," "the project," "succeed" are all
         undefined. Both sentences are compatible with every possible world.

PASS 1   "If the team believes the release will ship on the 14th, it is more
         likely to ship on the 14th."
         VERDICT: better -- there is now an event and a date. Still fails:
         "the team believes" is unmeasured, and "more likely" has no size.

PASS 2   "If at least 8 of 11 team members rate their confidence in the
         14th at 4 or 5 on a fixed 5-point scale at kickoff, the release
         ships on or before the 14th."
         VERDICT: measurable, and falsifiable on a single release. Still
         fails step 5: it predicts an event, not a magnitude, and a single
         release is a single direction call worth LR 2.0000.

PASS 3   "Where at least 8 of 11 members rate confidence >= 4 at kickoff,
         mean schedule slip is 2.30 days lower (tolerance +/- 30%, so
         1.61 to 2.99 days) than where fewer do, measured over 20 releases
         on the team's existing slip instrument."
         VERDICT: PASSES. It names a population, an instrument, a magnitude,
         a tolerance, and a sample. Its negation is equally clear.
```

Three things happened between pass 0 and pass 3 and all three are load-bearing. The subject became a measurable population rather than a mood. The outcome became a continuous quantity rather than a binary event, which raises the information per observation. And a magnitude with a tolerance appeared, which is what turns the statement from an opinion into a claim. **A belief is stated precisely enough to be wrong when a stranger, given the instrument and no access to the claimant, could reach the opposite verdict.**

35.6.6 6.6 Step 2 — identify the claimed channel explicitly

```
SOURCE      what holds the belief. A person, a team, a market, a population.
            Its size matters: see Class D2 and the 1/N problem.

TRANSDUCER  what converts the holding of a belief into a physical quantity.
            THIS IS THE LINK THAT IS USUALLY MISSING, and its absence is
            the definition of a Class A claim.
            Real transducers: skeletal muscle, vocal apparatus, facial
            musculature, autonomic response, attention allocation, keystroke.

MEDIUM      what carries it. Air, light, paper, a network, a balance sheet,
            a shared institution, a body's own interior.

RECEIVER    what reads it. A person's senses, a market's order book, an
            instrument, a cell's mechanically gated channel.

EFFECTOR    what changes as a result, and in what units.
```

Four channel families are established and they are the complete list this framework is prepared to assert [Curzi, 2026ab]:

```
PHYSIOLOGICAL   belief -> expectation -> neurochemistry -> measured outcome.
                Established: naloxone-reversible placebo analgesia (Levine,
                Gordon & Fields, 1978); open-label placebo (Kaptchuk et al.,
                2010). Bounded within the believer's own body. Modest
                magnitude. NO CLINICAL, MEDICAL OR THERAPEUTIC CLAIM IS MADE.

BEHAVIOURAL     belief -> action -> outcome. The largest gains in the whole
                taxonomy and the least discussed, because the mechanism is
                unglamorous. Appendix B finds 39.53% of a five-fold effect
                coming from a belief causing an application to be submitted.

SOCIAL          belief -> expressed behaviour -> another's perception ->
                another's behaviour. Expectancy effects (Section 4.13),
                contagion and coalitions. Real; modest per individual;
                scale-dependent by 1/N.

INFORMATIONAL   belief -> a decision -> a system that reads decisions.
                Markets, elections, institutions, queues. Section 4's engine
                lives here.
```

A claimed channel outside these four is not thereby refuted, but it must name its own transducer explicitly and it does not get to borrow the credibility of these four. That is channel laundering in preventive form.

The SOCIAL family's most-used transducer is speech, and the corpus analyses it in its own right. A spoken commitment is a **performative aimed at the speaker**, supported by three converging mechanisms — consistency pressure, self-perception from overheard testimony, and the re-pricing of later defection [Curzi, 2026]. **That is a named transducer with three named mechanisms, which is exactly what step 2 demands**, and it is the reason the worked case of Appendix C can put "speech" in the transducer box and pass P3 rather than stalling there.

35.6.7 6.7 The mechanotransduction line, restated

The framework's central open problem belongs in this protocol because it is the best worked example of a channel that is partly real and partly unestablished, **and the protocol must handle that case without collapsing it in either direction.**

```
ESTABLISHED (the evidence column, and it is strong):
  Mechanically gated ion channels are established: mechanical force opens
  them; ions flow; signalling follows. Sound is mechanical. A real,
  established pathway exists from pressure wave to cellular signal.
  Force at the cell surface transmits through the cytoskeleton to the
  nucleus, stretches chromatin, and upregulates transcription (Tajik et al.,
  Nature Materials 2016; named without a key).

THE LINE:
  THERE IS NO ESTABLISHED MECHANISM BY WHICH A CELL DEMODULATES
  SEQUENCE-SPECIFIC INFORMATION FROM AN ACOUSTIC SIGNAL.
```

In the protocol's terms: the source, transducer, medium and receiver are all established; the effector's selectivity is not. A cell demonstrably responds to mechanical input. Whether it can be *addressed* — whether a particular waveform reaches a particular locus rather than producing a generic mechanotransductive response — is one well-specified, falsifiable gap.

The corpus's sonification protocol states the same boundary from the other side: eleven upstream components are built, verified and deterministic, and the one missing link is precisely the carriage of sequence over force [Curzi, 2026]. **The protocol's verdict on that claim is not "false". It is "step 4 incomplete: gain of the final link unestimated"** — a different and more useful verdict than either enthusiasm or dismissal, and the ability to return it is a point in the protocol's favour.

35.6.8 6.8 Step 3 — is the channel physically possible?

```
P1  CONSERVATION.      Does the claim require energy, momentum, charge or mass
                       to appear or vanish? Compute the budget. Section 5.4
                       found the energy for the object-moving claim available
                       (the brain has 2,039 times what is needed) and the
                       coupling absent -- so P1 passes and P3 fails. Run them
                       separately.

P2  CAUSALITY.         Does any link require influence to travel backward in
                       time, or faster than light between spacelike-separated
                       events?

P3  A NAMED TRANSDUCER.
                       Is there a physical component that converts the belief
                       into the claimed influence? If not, STOP. Class A.
                       This check ends more claims than the other five
                       together.

P4  SIGNAL TO NOISE.   At the claimed amplitude, is the signal above the noise
                       floor of the medium and the sensitivity of the receiver?
                       A signal 5.000e+08 times weaker than an ambient field
                       the receiver already ignores is not a signal.

P5  THE SCALE LAW.     How does the effect scale with distance, size or
                       population? Casimir scales as a^-4: 1.283124 atm at
                       10 nm and 1.300126e-15 Pa at 1 mm. A real effect with a
                       punishing exponent is functionally absent at the scale
                       of interest. CASIMIR DOES NOTHING IN A CELL AND NOTHING
                       IN A ROOM.

P6  WHO LEARNS IT.     If the outcome depends on another agent, by what
                       physical means does that agent come to be affected?
                       If the belief is never expressed in any modality, there
                       is no channel. If it leaks through behaviour, say so,
                       and the claim becomes behavioural or social, with those
                       families' gains.
```

P3 and P6 between them are the whole of Class A. They take a few minutes each and running them first is the single highest-yield decision in the protocol. **A claim that fails P3 should not proceed to step 4, because estimating the gain of a channel that does not exist produces a number, and the number will be quoted.**

35.6.9 6.9 Step 4 — estimate the gain, and mind the chain law

Three definitions, and the protocol requires that the one in use be stated:

```
DIMENSIONAL GAIN   g = (change in output units) / (change in input units).
```

```
                  Units must be carried.

LOG GAIN          g_log = d(ln output) / d(ln input) -- an elasticity.
                  Dimensionless, composes by addition, and it is the right
                  register for anything the recipient perceives
                  logarithmically.

STANDARDISED GAIN  the effect in standard-deviation units, d. Comparable
                  across instruments; requires a stated reference SD, and
                  the SD must be the target population's, not the study's.
```

Then the chain law, where most optimistic gain estimates go to die.

```
g_total = product of the link gains.  A LONG CHANNEL IS A WEAK CHANNEL.

per-link g     L=1        L=2        L=3        L=4        L=5        L=8
   0.95     0.950000   0.902500   0.857375   0.814506   0.773781   0.663420
   0.90     0.900000   0.810000   0.729000   0.656100   0.590490   0.430467
   0.80     0.800000   0.640000   0.512000   0.409600   0.327680   0.167772
   0.70     0.700000   0.490000   0.343000   0.240100   0.168070   0.057648
   0.60     0.600000   0.360000   0.216000   0.129600   0.077760   0.016796
   0.50     0.500000   0.250000   0.125000   0.062500   0.031250   0.003906
   0.30     0.300000   0.090000   0.027000   0.008100   0.002430   0.000066
```

Worked on an ordinary social channel with five plausible links, none of them absurd:

```
belief -> stated intention                    0.70   cumulative 0.700000
       -> scheduled action                    0.60   cumulative 0.420000
       -> action completed                    0.75   cumulative 0.315000
       -> the other party notices             0.50   cumulative 0.157500
       -> the other party changes behaviour   0.40   cumulative 0.063000

END-TO-END GAIN = 0.063000, i.e. -2.764621 nats.
```

Five links, each of which a reasonable person would call "usually works", and 6.3 per cent arrives. This is the same arithmetic that produced Section 4.2's $E = 0.0600$, and it explains why so much sincere effort produces so little measured effect.

The corpus reaches a structurally identical result by a different route. Its comfort-weighted amplitude scores each step of a branch 0 to 3 for steepness, sums to a resistance R, and weights the branch as $1/2^R$, **so a three-point difference in steepness is a factor of eight in expectation** [Curzi, 2026]. **That is the chain law in exponential dress: resistance accumulates additively and the weight falls geometrically**, which is the same statement as $g_{\text{total}} = \prod_i g_i$ with the logarithm taken.

Three rules follow.

1. **Estimate each link from a source that did not measure the outcome under test.** A gain estimated from the case at hand is the circularity trap wearing a number.
2. **Shorten the chain, do not strengthen the links.** Raising every link from 0.60 to 0.70 across five links moves the total from 0.077760 to 0.168070 — a 2.16-fold gain. Removing two links at 0.60 each moves it from 0.077760 to 0.216000, a 2.78-fold gain, **and removing links is usually the cheaper operation.**
3. **Report the total with an uncertainty.** If each link is known to a factor of 1.5, five links compound to $1.5^5 = 7.59$ — the end-to-end estimate spans nearly an order of magnitude, and step 5's tolerance must be set honestly against that.

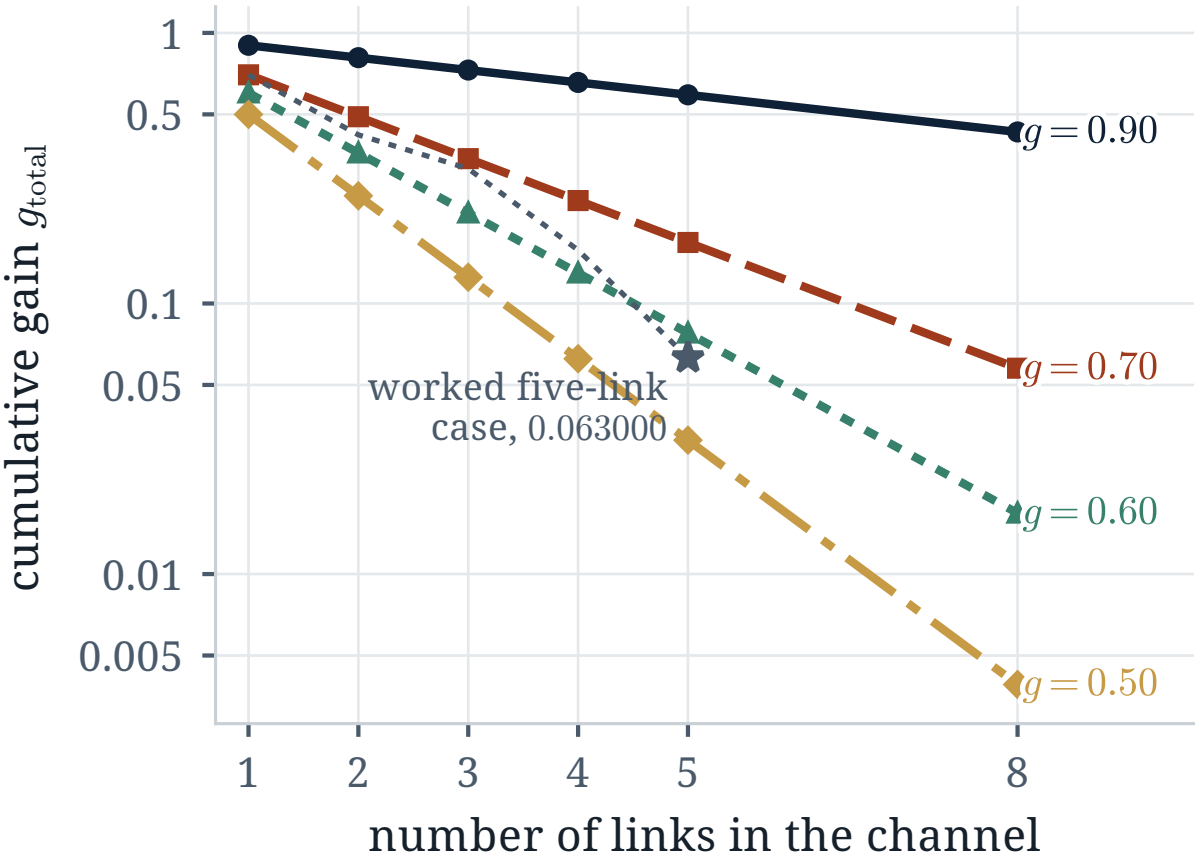

Figure 35.5: **A long channel is a weak channel:** cumulative gain against the number of links, for four per-link gains from the chain-gain table of Section 6.9, with the five-link worked case marked at 0.063000 — five links each of which "usually works" delivers 6.3 per cent end to end. **Modelled, not measured:** the per-link gains are assumed parameters and the worked case's five values are stated in Section 6.9. Generated by `figs/src/CCP-035_fig05.py`.

35.6.10 6.10 Step 5 — predict the magnitude, and price the measurement

A predicted magnitude determines the study required to test it. Two-group comparison, $\alpha = 0.05$ two-sided, 80 per cent power:

predicted d	n per arm	total N
0.80	25	50
0.50	63	126
0.30	175	350
0.20	393	786
0.15	698	1,396
0.10	1,570	3,140
0.08	2,453	4,906
0.05	6,280	12,560
0.02	39,245	78,490

A predicted effect of $d = 0.08$ — the growth-mindset magnitude — requires 4,906 participants to test at conventional power. A predicted effect of $d = 0.50$ requires 126.

> **A small predicted effect is not a modest claim. It is an expensive one. And a claim that refuses to state its magnitude has also refused to say what it would cost to test, which is exactly how it stays untested.**

Three consequences for practice. The tolerance must be set from the gain uncertainty of step 4, not from convenience: if the chain estimate spans a factor of 7.59, a ± 10 per cent tolerance is theatre. If the required N is unobtainable, say so at step 5 and redesign then. And prefer an outcome with a high event rate over an outcome with high importance — **the affordable study is set by the event rate of the link instrumented, not by how much anyone cares about the endpoint.**

35.6.11 6.11 Step 6 — measure, with the validation gates in print

```
FVP-1  DIMENSIONS
       Units of belief measure, gain, and outcome. The gain's units must be
       (outcome units)/(belief units) exactly. Ratios dimensionless.

FVP-2  SCALE TYPE
       Stevens' typology per term. If the belief measure is ordinal -- a
       5-point agreement scale usually is -- then products and ratios
       involving it are NOT licensed, the relation is a heuristic ordering,
       and it must be DEMOTED IN PRINT. This gate stops more belief formulas
       than any other and it should.

FVP-3  LIMITING CASES
       Behaviour as belief -> 0 and -> its maximum. At zero belief the
       predicted effect must be zero, or the channel is not the one claimed.
       At maximum belief the effect must saturate, because every real
       receiver saturates (Class D3).

FVP-4  FIXED POINTS
       Solve for the invariant. For a reflexive channel this is Section 4.10:
       the pole a = (1-delta) + eta*s and the loop gain g = eta*s/delta.
       State whether g is below or above 1 -- and state that s is not
       identified from observational data.
```

```
FVP-5  IDENTIFIABILITY
       Can the gain be recovered from obtainable data? If two different gains
       predict identical observations, the claim is not testable as written
       and must be rewritten before step 6, not after.

FVP-6  FALSIFICATION
       Preregister; fit on training; FREEZE; report held-out against four
       baselines -- persistence, direct-input, matched autoregressive, and
       the SHUFFLED-INPUT CONTROL. State in advance what result kills the
       claim.

FVP-7  REPRODUCIBILITY
       The cross-individual test. Same operationalisation, different people,
       different sites: do the parameters recover? This gate decides the
       hard-science question and it is the one most often skipped.
```

FVP-2 deserves a warning in the running text. Belief is very often measured on an ordinal scale, and **ordinal data do not support the multiplication in effect = gain × belief** [Stevens, 1946, Likert, 1932]. Where that is the situation, the honest move is to demote the relation to a monotone ordering — *more belief predicts more effect* — **and to say in print that the multiplicative form is not licensed by the measurement** [Curzi, 2026t]. A ratio-scale belief instrument is constructible by magnitude estimation [Thurstone, 1927]; **it is simply more work than handing out a five-point form, and the extra work is the difference between a formula and a decoration.** The deeper objection — that quantitative structure must be *tested*, by additive conjoint measurement, before any of this is licensed — stands unanswered [Michell, 1997, Luce and Tukey, 1964], and Section 10 concedes it.

35.6.12 6.12 Step 7 — compare, against four baselines, to one of four verdicts

```
(i)   PERSISTENCE                  kills: "the outcome was going to happen
                                   anyway."

(ii)  DIRECT-INPUT (raw, no log)   kills: the claim that the LOG structure is
                                   doing work.

(iii) MATCHED AUTOREGRESSIVE,      kills: the claim that BELIEF is the input.
      no interaction term

(iv)  SHUFFLED-INPUT CONTROL       kills: the claim that the TEMPORAL
                                   ALIGNMENT matters.

FALSIFIED IF:
  RULE 1  the shuffled-input control predicts held-out outcome as well as
          the ordered series;
  RULE 2  the matched autoregressive baseline is not beaten;
  RULE 3  the fitted a lies outside [0,1] or the fitted b is negative.
```

The suite has been audited against itself and it is anti-conservative: the shuffle control's measured false-rejection rate is 0.108 against a nominal 0.05, and a demand-characteristic confound with a true coefficient of zero passed the whole four-baseline suite 52.7 per cent of the time [Curzi, 2026u]. **Those numbers belong beside the suite every time it is invoked, and they are the reason a passed suite is not a proof.**

The four verdicts:

Predicted vs observed	Verdict	What to do
observed within tolerance, baselines beaten	**GROUNDED**	report the gain; proceed to FVP-7
observed same sign, well **below** the predicted magnitude	**GAIN OVERSTATED**	the channel is real and smaller. Revise step 4 and re-run. **This is Class B and it is the most common honest outcome.**
observed same sign, well **above** the predicted magnitude	**GAIN UNDERSTATED**, or a second channel is operating	the channel is richer than modelled, or another was not named. **This is a finding, not a success.** Go back to step 2.
observed near zero, or the shuffle predicts as well	**UNGROUNDED (bounded)**	report the upper bound on the gain at the study's power. **A null bounds a gain; it does not prove a zero.**

"Gain understated" is not a win. A result larger than predicted means the model of the channel was wrong, and a wrong model that happened to under-predict is not better than one that over-predicted. **The protocol treats surprise in either direction as a failure of step 2, and that symmetry is what stops it becoming a machine for confirming things.**

35.6.13 6.13 The shuffled-input control, simulated — and the case where it fails

The shuffled-input control is the most important of the four baselines for belief claims, because belief series and outcome series both drift and drift alone will produce a correlation. Shuffling the belief series destroys its temporal alignment with the outcome while preserving its distribution.

Simulated here, 4,000 trials per case, series length 200, fitted on the first 140 and tested on the remaining 59, with the model $Y_{t+1} = aY_t + bX_t + \varepsilon$ and X an autoregressive belief series:

CASE	ordered RMSE	shuffled RMSE	ordered wins
1 real coupling, b_true = 0.60, no common cause	1.0099	1.2722	99.53%
2 real coupling, b_true = 0.15, no common cause	1.0119	1.0314	74.10%
3 NO coupling, b_true = 0.00, no common cause	1.0126	1.0110	48.17%
4 NO coupling, b_true = 0.00, SHARED trend	1.1744	1.5602	98.35%

Case 3 is the control working exactly as intended: with no coupling the shuffle predicts as well as the ordered series — 48.17 per cent, indistinguishable from a coin flip.

Case 2 is the honest warning about sensitivity: with a real but modest coupling, the ordered series beats the shuffle only 74.10 per cent of the time on a single run. **A single application of the control, on a real-sized effect, is not decisive.**

Case 4 must be printed, and it is the case that keeps this section honest. There is no coupling at all — the belief causes nothing — and the ordered series beats the shuffle in **98.35 per cent of runs**, because a shared slow driver moves both series and shuffling destroys alignment with the common cause exactly as it destroys alignment with a real effect. **The control cannot tell those two apart.**

This is the identification problem of Section 3.3 in simulated form, and it is not fixed by shuffling. The shuffled-input control kills "there was never any temporal structure". **It does not kill "something else moved both"** [Manski, 1993, Shalizi and Thomas, 2011]. The defences are structural, not statistical:

```
CC-1  RANDOMISE THE BELIEF. If the belief is assigned rather than observed, no
      common cause can precede it. THIS IS THE ONLY COMPLETE DEFENCE, and it
      is the remedy this protocol adopts.

CC-2  MEASURE THE SUSPECTED COMMON CAUSES and include them. Partial, and only
      as good as the enumeration.

CC-3  BLOCK ON TIME. Compare within short windows where the slow driver is
      approximately constant. Costs power; costs nothing else.

CC-4  PREDICT A MAGNITUDE (step 5). A common cause will generally not deliver
      the specific magnitude the channel model predicts. THE MAGNITUDE
      PREDICTION IS ITSELF A CONFOUNDING CONTROL, and this is a second and
      independent reason step 5 is not optional.
```

35.6.14 6.14 The independence rule

```
STEPS 1 THROUGH 5 MUST BE COMPLETED, IN WRITING, WITH A DATE, BEFORE
STEP 6 BEGINS.

No gain estimate may come from the case under test.
No tolerance may be adjusted after data collection begins.
No channel may be added after the outcome is seen.
No verdict may be reported without the baselines.
```

That is the entire answer to the circularity objection, and it is procedural rather than philosophical. The conditional postulate is meaningful only if "grounded" is decided before the outcome is known. The worksheet of Appendix C exists to make that the path of least resistance: it has a date field at the top, the prediction boxes come before the measurement boxes, and it is meant to be filled in with a pen so that revision leaves a mark.

35.6.15 6.15 A gallery: six beliefs at protocol speed

```
1. "If I believe the interview will go well, it will go better."
   Step 2: SOCIAL + BEHAVIOURAL. Transducer: facial musculature, vocal
     prosody, preparation time. Named, real.
   Step 3: passes all six checks.
   Step 4: chain gain, three links, plausibly 0.7 x 0.6 x 0.5 = 0.210000.
   Step 5: state the magnitude in offer-probability points. Appendix B gets
     0.014000 -> 0.069650 under assumed parameters.
   VERDICT: PROCEEDS. Testable, modest, worth measuring.

2. "If I believe hard enough, the payment will arrive."
   Step 2: no transducer connects the belief to the sender, who is not
     present and does not know.
   Step 3: fails P3 and P6.
   VERDICT: DIES AT STEP 3. Class A.
   NOTE: if the belief causes the claimant to invoice, chase, or ask, the
   claim becomes BEHAVIOURAL, gain is large, and it proceeds -- as a
   different claim, with a different channel, honestly relabelled.

3. "Team morale drives our delivery speed."
   Step 2: BEHAVIOURAL + SOCIAL, several links.
   Step 4: gain estimable from the team's own history.
```

```
   Step 5: the team predicts "faster." No magnitude offered.
   VERDICT: DIES AT STEP 5. Not refuted -- UNTESTED.

4. "Visualising the outcome each morning improves it."
   Step 2: PHYSIOLOGICAL + BEHAVIOURAL, via attention allocation and
     rehearsal. A real family.
   Step 3: passes.
   Step 4: the literature on mental rehearsal is active and its magnitudes
     are contested; this paper does not assert a number it has not checked.
   VERDICT: PROCEEDS TO STEP 4 with the gain UNESTIMATED and labelled as
   such. This is a legitimate resting state and it is not a verdict.

5. "An acoustic signal can address a specific genomic locus."
   Step 2: source, transducer, medium and receiver all ESTABLISHED.
     Effector selectivity NOT established.
   Step 3: passes P1-P5; P6 is not applicable.
   Step 4: the final link's gain is unmeasured. This is the framework's one
     well-specified open problem.
   VERDICT: STEP 4 INCOMPLETE. Not false; unestablished, at a named link.

6. "Believing the market will rise will make it rise."
   Step 2: INFORMATIONAL. Real channel -- buying does raise prices.
   Step 3: passes.
   Step 4: the individual's share is 1/N. At N = 100,000 the shortfall
     against the 25% coalition is 25,000x.
   VERDICT: DIES AT STEP 4 for an individual. PROCEEDS for a coalition
     above the tipping point. Class D2 -- THE ONLY FAILURE MODE THAT
     CHANGES WITH SCALE.
```

Two of six died at step 3. One died at step 5. One is parked at step 4 with the gain honestly unestimated. One is the framework's open problem. One proceeds. A protocol returning "proceeds" six times out of six would be a formality rather than a filter [Goodhart, 1975].

35.6.16 6.16 Requirements

REQ-6.1 Complete steps 1 to 5 in writing, with a date, before measurement begins. **Without this the postulate is circular and the framework disowns it.**

REQ-6.2 Write the negation. If the negation is vague, the belief was vague.

REQ-6.3 Name all five parts of the channel. "Somehow" is not a link.

REQ-6.4 Run P3 and P6 first. They are the cheapest checks and they end more claims than the other four combined.

REQ-6.5 Estimate every link gain from a source that did not observe the outcome under test.

REQ-6.6 Multiply along the chain and print the total. Five links at 0.60 give 0.077760. Report that, not the best link.

REQ-6.7 Shorten the chain before strengthening the links: 2.78x against 2.16x, and usually cheaper.

REQ-6.8 Carry the gain uncertainty into the tolerance. Five links each known to a factor of 1.5 compound to 7.59.

REQ-6.9 State a magnitude with a tolerance, in units, before measuring. A direction-only claim is worth a likelihood ratio of 2.0000; a ± 20 per cent magnitude call against a two-decade prior is worth 11.3577, which is 3.5056 direction calls for the same single measurement.

REQ-6.10 Compute the required sample at step 5 and redesign at step 5 if it is unobtainable: n per arm $= 15.6978/d^2$.

REQ-6.11 Instrument the link with the highest event rate, not the endpoint of greatest interest.

REQ-6.12 Print all seven validation gates with their verdicts. Where FVP-2 fails, demote the relation to a monotone ordering in print. **Do not multiply ordinal quantities.**

REQ-6.13 Report against all four baselines including the shuffled-input control, **and report the suite's own measured false-rejection rate of 0.108 against a nominal 0.05 alongside it** [Curzi, 2026u].

REQ-6.14 Do not treat the shuffled-input control as a defence against common causes. Simulated, it lets a pure common-cause configuration through 98.35 per cent of the time. **Randomise, block on time, or use the magnitude prediction as the confounding control.**

REQ-6.15 Return one of four verdicts, and treat a larger-than-predicted result as a step-2 failure.

REQ-6.16 Report every null as an upper bound on the gain at the study's power.

REQ-6.17 File completed worksheets, **including the ones that died at step 3. The sheets that died are the denominator**, and a corpus without a denominator is worth a likelihood ratio of 1.000000.

REQ-6.18 Make no clinical, medical or therapeutic claim. Absolute.

35.6.17 6.17 Failure modes of the protocol

FM-6.1 — EX POST GROUNDING. *Signature:* the channel is identified after the result is in, and it always fits. *Fix:* the date field, and it only works if it is written before.

FM-6.2 — DIRECTION-ONLY CLAIM. *Signature:* "it will help", "there will be an effect". *Fix:* if the claimant cannot produce a magnitude, record the verdict as **UNTESTED**, which is a different and more accurate verdict than unproven.

FM-6.3 — THE UNNAMED TRANSDUCER. *Signature:* the channel described in verbs — "it influences", "it resonates", "it aligns" — with no noun that could be pointed at. *Fix:* demand a noun. Muscle, voice, face, keystroke, ion channel, order book.

FM-6.4 — BORROWED GAIN. *Signature:* an effect size imported for a channel, population or dose the source study did not examine. *Fix:* record the source of every gain estimate, including the population and dose it was measured at.

FM-6.5 — CHAIN-GAIN NEGLECT. *Signature:* the strongest link reported as the channel's gain. *Fix:* print the cumulative column, not the maximum.

FM-6.6 — TOLERANCE SET AFTER THE FACT. *Signature:* the observed result described as "consistent with" the prediction, with the tolerance appearing in the same sentence. *Fix:* the tolerance goes in box 5, before box 7 exists.

FM-6.7 — UNDERPOWERED NULL READ AS ABSENCE. *Signature:* a small study finds nothing and the claim is declared dead. *Mechanism:* at 50 per arm the minimum detectable effect is 0.5603, and almost nothing in this domain is that large. *Fix:* report the bound, not the verdict.

FM-6.8 — SHUFFLE OMITTED, OR SHUFFLE OVERTRUSTED. *Signature:* either the control is skipped, or it is passed and the result is called causal. *Mechanism:* the control catches absent temporal structure (Case 3, 48.17 per cent) and misses common causes entirely (Case 4, 98.35 per cent). *Fix:* run it, and add CC-1 to CC-4. **Randomisation is the only complete defence.**

FM-6.9 — THE UNFALSIFIABLE GOAL. *Signature:* the belief concerns an outcome with no date, threshold or instrument. *Fix:* the four passes of Section 6.5. If the claimant declines to sharpen, that is a decision to hold the belief outside the protocol, which is permitted — **provided it is not then described as tested.**

FM-6.10 — ORDINAL MULTIPLICATION. *Signature:* a five-point agreement scale multiplied by a gain to produce a predicted effect. *Fix:* demote to a monotone ordering in print, or build a ratio-scale instrument. Both are honest; silently multiplying is not.

FM-6.11 — ENDPOINT VANITY. *Signature:* the study designed around the outcome that matters most, and never run because the event rate is too low. *Fix:* instrument the high-rate intermediate link and carry the endpoint inference through the measured slope.

FM-6.12 — WORKSHEET THEATRE. *Signature:* the sheet filled in completely and after the fact, in one sitting, with every box agreeing with every other. *Fix:* the date and signature at step 5, separated in time from step 7. **A sheet whose steps 1 to 5 and step 7 carry the same date has documented nothing.**

35.7 7 Results

35.7.1 7.1 R1 — the four failure classes

Failure decomposes into four distinct classes, each with a stated diagnostic: **A**, no channel — name the transducer, and if none can be named the analysis is finished; **B**, a real channel with insufficient gain — the measured effect is real, replicable and an order of magnitude below the claim; **C**, a real result extrapolated to an unsupportable magnitude — the claim's size traces to no measurement but to an inference from the existence of the effect; **D**, a system unresponsive to an input of this size from a source of this size — the channel is fine and the receiver is not listening, or is listening to a chorus in which this voice is $1/N$. **They are not degrees of one failure and they prescribe incompatible responses.** Class D subdivides further into D1 (the receiver does not read this input at all), D2 (it reads it and this source is $1/N$), and D3 (it reads it and is already saturated), **of which only D2 changes with scale.**

35.7.2 7.2 R2 — growth mindset as Class B, unpacked

The channel is real and the gain is small. The meta-analytic correlation is near $r = 0.10$, which is **1.00 per cent of variance**, and intervention effects are near $d = 0.08$, which unpacks to **96.809 per cent distribution overlap**, a **52.256 per cent common-language effect** against 50 per cent by chance, **53.188 per cent** of treated cases above the untreated median, and **0.0560 GPA points** on a 0.70-point standard deviation. The national field trial's subgroup effect of about a tenth of a grade point is $d = 0.1429$ on that same standard deviation. **A small effect at national scale and near-zero cost is good engineering; it is not what "belief creates reality" is usually taken to mean, and the gap between the two is roughly one order of magnitude.**

35.7.3 7.3 R3 — the job-search audit

Running every real channel at full strength lifts the offer probability from 0.0140 to 0.0697 — a ratio of 4.975 — and the outcome is still no offer 93 per cent of the time. 39.53 per cent of the entire lift comes from the belief causing the application to be submitted, which is the most overlooked channel in the literature and the largest. **The no-contact channel — belief acting on the employer's decision with no communication of any kind — carries gain zero by construction**, and is Class A. **All parameters in the decomposition are assumed and are labelled as assumed**; what the case demonstrates is the decomposition procedure, not the values.

35.7.4 7.4 R4 — the deposit run, priced

At a 9.00 per cent reserve ratio the run threshold is $f^* = 0.0900$ — 216 of 2,400 members at the average balance — and the critical forced-sale recovery rate is $h^* = 0.941379$, so a recovery below 94.14 cents on the dollar makes a solvent institution insolvent. With member tolerances distributed Normal$(\mu, 0.25)$ the critical mean is $\mu^* = 0.408522$, and the withdrawn fraction moves from **0.990106 at $\mu = 0.407522$ to 0.145087 at $\mu = 0.409522$ — a swing from a**

99.01 per cent run to a 14.51 per cent tremor on a change of 0.002 in an unmeasured population parameter, with no intermediate outcome. This is a property of the threshold model at the stated parameters, not a measurement of any institution.

35.7.5 7.5 R5 — the runaway terminates at the ceiling, and slows before it does

With $\delta = 0.10$ and $\eta = 0.50$ the critical reflexive slope is $s^* = 0.20$, but $s = 0.19$ already implies a steady-state input of 12.6 nats against $\ln N = 2.995732$ at $N = 20$. Every divergence row beyond $s = 0.15$ is outside the model's admissible region for any realistic N: **the runaway does not run away, it runs into the ceiling** [Curzi, 2026]. **And the time constant $\tau = 1/(1-a)$ goes tenfold — from 10.0000 to 100.0000 periods — at a loop gain of 0.90, so the loop slows conspicuously before it destabilises.** Critical slowing is therefore a measurable early-warning signature available from response time alone, **which matters precisely because the reflexive slope itself is not identified from observational data.**

35.7.6 7.6 R6 — evidential pricing

A direction-only prediction is worth a likelihood ratio of 2.0000. Under a log-uniform prior spanning two decades, **a ± 20 per cent magnitude call is worth 11.3577**, which is $\ln(11.357747)/\ln 2 = 3.5056$ direction calls **for the same single measurement. Five links at 70 per cent each deliver 6.3 per cent end to end**, and a five-link channel at 60 per cent each delivers 0.077760. **The likelihood-ratio figures are properties of the stated log-uniform prior, which is a modelling choice and is badged as one.**

35.7.7 7.7 CR — the counter-result

The paper is itself the counter-result. It catalogues where the framework's own postulate does not pay; it prices the surviving effects at $d \approx 0.08$ to 0.30 with **92 to 97 per cent distribution overlap**; it shows that at $N = 100{,}000$ a single committed person is **25,000-fold short** of the tipping requirement; and it states that **a null bounds a gain without proving a zero** — with 600 per arm the bound is $d = 0.1617$, which does not exclude either of the two effects this paper reports. **It applies the replication discount to the framework itself: a prior of 0.10 becomes a posterior of 0.1148 on one significant result under typical power and heavy selective reporting.** And it states, in Section 5.2, the objection that would destroy the postulate outright, offering only a procedural answer.

35.7.8 7.8 Hypotheses, resolved

	Statement	Outcome
H1	the taxonomy is exhaustive over documented cases	**no counterexample found among the cases examined, which is weak evidence.** The cases were selected by the author; Section 10 records that as a selection problem
H2	the most-cited belief effect is small, not absent	**confirmed** at $r \approx 0.10$ and $d \approx 0.08$, 96.809 per cent overlap
H3	the responsive case is knife-edged, not proportionate	**confirmed in the model**: 0.990106 to 0.145087 across $\Delta\mu = 0.002$

	Statement	Outcome
H4	the runaway terminates at the ceiling	**confirmed by arithmetic**: 12.6 nats implied against $\ln 20 = 2.995732$
H5	a magnitude call is worth several direction calls	**confirmed under the stated prior**: 11.3577 against 2.0000, or 3.5056 direction calls

H1's outcome is reported in the same plain language a confirmation would receive, and it is not a confirmation. A taxonomy tested only against cases its author chose has been illustrated, not tested. **The honest verdict on H1 is that it survives an unblinded, non-exhaustive audit conducted by the person who proposed it**, and Section 10 gives that its own limitation.

35.7.9 7.9 Model comparison: what `RIGOR_STANDARD` §6 requires

This paper fits no model to any collected data. One simulation is run (Section 6.13) and its purpose is to characterise a control, not to fit a model to observations. The row-by-row status is printed rather than omitted.

Requirement	Status here	Why
out-of-sample performance	**NOT APPLICABLE** to the analytical results; **MET in form** for the simulation	the simulated control is fitted on 140 points and tested on 59 held out, which is the design; **no real data were used**
matched null with equal free parameters	**MET for the simulation**	Case 3 is exactly the matched null — the same model with $b_{\text{true}} = 0$ — and the ordered series wins 48.17 per cent of the time, indistinguishable from chance
information criterion (AIC or BIC)	**NOT MET, and not computed anywhere in this corpus**	no likelihood is reported here, and no AIC or BIC value appears in any paper of this corpus. **The omission is corpus-wide and is recorded rather than papered over**
explicit free-parameter count	**MET**	the simulation's model $Y_{t+1} = aY_t + bX_t$ has **two** free parameters, the same two in every case including the null; the effect model $E = B \cdot K \cdot R$ has **three**, all of which are inputs a user supplies rather than parameters this paper estimates

Requirement	Status here	Why
effect sizes with intervals	**PARTIALLY MET, and the gap is real**	the effect sizes quoted from the literature ($r = 0.10$, $d = 0.08$, $d = 0.1429$) are **reproduced as point values without intervals**, because that is how the source framework carried them. **A measured quantity quoted without an uncertainty is a presentational defect** and is recorded as Limitation L-9
identification of the reflexive parameter	**NOT MET, and not achievable from observation**	[Manski, 1993]; Section 3.3. The protocol adopts randomisation (CC-1) as the remedy **for prospective work**; nothing retrospective in this paper is identified
power-law procedure [Clauset et al., 2009]	**NOT RUN, deliberately**	the two exponents here are analytic properties of known functions; Section 3.5
conjoint measurement test [Luce and Tukey, 1964]	**NOT RUN**	Section 3.4; the exposed constructs are demoted instead

A paper that fits nothing cannot be beaten on fit, and earns nothing on it either. What is claimed here is a taxonomy, a set of exact arithmetic consequences, and a procedure — **and the procedure's own value is untested, because it has not been run on a real case.**

35.8 8 Discussion

35.8.1 8.1 What follows

The postulate's territory is bounded and the boundary is computable. Where a channel exists and the system is responsive, belief can be decisive — the deposit run reaches 99.01 per cent withdrawal on a parameter shift of 0.002. Where a channel exists and the gain is small, the effect is real and roughly an order of magnitude below the popular claim — 96.809 per cent distribution overlap. Where no transducer can be named, the analysis is finished in minutes and the answer is no. **Those three verdicts are reached from the channel, before the outcome, which is the only order in which the postulate says anything at all.**

The intervention hierarchy is the practical payoff and it inverts the usual instinct. W3 first, W2 second, W1 last: **structure beats persuasion, because structure does not have to be re-persuaded every morning.** Appendix A prices that exactly — communications moves the run threshold by nothing, a withdrawal gate moves it from 0.0900 to 0.1500, and a committed liquidity line moves it to 0.5900, a 6.56-fold increase in the withdrawal fraction the institution can absorb. The corpus reaches the same conclusion for physical rooms, where an acoustic exclusion is priced against the surplus law at 0.4700 nats, 22.6 per cent of the room's per-interaction surplus, and the remedy is geometry rather than exhortation [Curzi, 2026e].

Critical slowing is a usable signature and it does not require the unidentifiable parameter. $\tau = 1/(1-a)$ rises tenfold before the pole reaches unity, and response time to a small deliberate perturbation is measurable without knowing s. **That matters more than it looks: since s is not**

identified from observation, an indirect signature is not a convenience but the only route available.

And the evidential arithmetic converts a rhetorical dispute into a costed one. "Be more specific" is a demand; "that costs 3.5 direction-calls' worth of evidence and here is the study that would supply it" is a specification. **A predicted effect of $d = 0.08$ requires 4,906 participants; a predicted effect of $d = 0.50$ requires 126. A small predicted effect is not a modest claim, it is an expensive one**, and a claim that refuses to state its magnitude has also refused to say what testing it would cost.

35.8.2 8.2 What does not follow

Nothing here shows that belief does nothing. The catalogue is a boundary and a boundary has two sides; Section 5.14 is the other side, and every survivor on it carries a named physical channel and a stated magnitude.

Nothing here identifies the reflexive parameter. The loop gain, the reflexive slope, and every regime classification derived from them are modelling positions [Manski, 1993, Shalizi and Thomas, 2011]. **The simulated control's Case 4 — a pure common cause passing at 98.35 per cent — is the quantitative demonstration that no statistical control substitutes for identification, and it is printed rather than buried.**

Nothing here licenses a clinical, medical or therapeutic claim, in either direction. Published trials are reported as evidence about channels and their gains. This is absolute.

Nothing here establishes that the taxonomy is exhaustive. It was applied to cases the author selected, by the author, without blinding. **That is illustration, not test**, and H1's verdict says so.

And nothing here validates the protocol. Section 6 specifies a procedure that has not been run on a real case. **A procedure that has never been executed has no measured pass rate, and a protocol whose pass rate is unknown could still be a formality** [Goodhart, 1975, Campbell, 1979]. The corpus's own attempt to run a comparable protocol against a real system **failed its second falsification rule** — a 2.8 per cent held-out advantage against a declared margin of 10 per cent — and that result is the realistic expectation for this one [Curzi, 2026i].

35.8.3 8.3 Relation to the surrounding literature

The positive results sit inside three established literatures and add to none of them. The mechanism is Merton's [Merton, 1948, 1936]; the threshold model is Granovetter's [Granovetter, 1978] and its neighbours' [Schelling, 1971, Watts, 2002]; the tipping measurement is Centola and colleagues' [Centola et al., 2018, Centola, 2010]; the survivorship argument is Wald's; the replication estimate is the Open Science Collaboration's [Open Science Collaboration, 2015]. **What is new is the decomposition, the taxonomy, the arithmetic, and the requirement that grounding be established from the channel.**

The methodological position is closer to the critics of physics-in-social-science than to its enthusiasts. Predictive accuracy in social systems is low and the ceiling appears structural rather than methodological [Hofman et al., 2017, Salganik et al., 2020, Watts, 2014]; published prediction results have repeatedly failed to survive contact with new data [Lazer et al., 2014]; and complexity-flavoured social modelling has a long record of formal elegance without identified parameters [Durlauf, 2005]. **This paper's contribution to that argument is deflationary and is meant to be.**

Where the framework's postulate needs an existence proof for reflexivity, the performativity literature supplies one that was observed in the field with dates and price data [MacKenzie and Millo, 2003, MacKenzie, 2006, Ferraro et al., 2005, Callon, 1998], and the looping of human kinds under classification is the same mechanism in another register [Hacking, 1995]. **None of them identifies the parameter, and citing them as existence proofs rather than as measurements is the distinction this paper insists on.**

35.8.4 8.4 Parallel results elsewhere in the corpus

Four results in other series are structurally parallel and are named because the parallel is the point.

A gate that never rejects is not a gate. Section 6.15's gallery kills four of six claims, and the corpus's own audit of a traditional operation set against a parameter model returns the same shape of distribution — **seven MAPS, two SPLIT, one RENDERING and three REJECTED across thirteen entries, with five entries carrying a failure** — which is what a discriminating instrument looks like when it is turned on material its author is sympathetic to [Curzi, 2026].

A demotion made against one's own instrument is worth more than a demotion made against someone else's. Section 3.4 demotes every multiplicative statement involving an ordinal belief measure. The corpus's minimum-sustainable-frequency result carries the analogous concession from the other direction: **the deficit is blind to decay, so the intuitive intervention of lowering loss moves the instrument by exactly zero, and the reference constant, the affine effective count and the choice of twelve components are all badged as chosen rather than derived** [Curzi, 2026]. **This paper's own postulate is bounded in exactly that way.**

An effective count is not a headcount, and the corpus computes both. Where this paper's Class D2 turns on an individual's share of an aggregate, the corpus's compartment result computes the same quantity as a Hill number of order two: **six unequal compartments (30/22/18/12/10/8) give 4.96 effective compartments and cut maximum single reach from 100.0 per cent to 30.0 per cent, worth 1.400 units a year against 0.110 of cost — 12.73:1, with a break-even hazard of 0.157 per cent a year** [Curzi, 2026]. **That is the arithmetic of a share, done properly, in another domain.** The roster-scale identity that the corpus's affine effective count equals $m+1-m/\mathrm{PR}$ with PR the participation ratio, verified at 1.7815458788 with error 0.00×10^{0}, is the same construction stated exactly [Curzi, 2026] — **and it is the corpus's own construction, not a Hill number** (Section 3.2).

A metric that under-counts what it cannot see is a cost line, not a resilience line. The corpus demotes its own legal-family diversity measure on exactly that ground — **1.862031 effective families, stated to under-count the interfaces of every carve-out jurisdiction** [Curzi, 2026] — and this paper's taxonomy is exposed to the same objection: **a class assignment can only be made for a channel someone thought to name.**

35.8.5 8.5 What the framework's own failure record adds

The corpus records that **disclosure did not confer immunity in the strongest available test case**, that a backing basket was **4.61 times less diversified than its component count claimed**, that the terminal phase of a programme was **a 0.090 option rather than a plan**, and that a levy presented as a costless accounting correction **in fact reallocated burden, with 42.0 per cent falling on one sector and a constructed 55 per cent passing through to consumers** [Curzi, 2026]. **Those are the framework's own recorded failures, and they bound this paper in the way Section 5.11 says a denominator bounds a numerator: they are the tail the success cases do not supply.** A paper cataloguing where a postulate fails is only credible if the framework it belongs to keeps such a record, and this one does.

35.9 9 Verification

The results compound from ten postulates. Each is atomic, each is checkable on its own, and each carries its status.

35.9.1 9.1 Dimensional audit

$[1]$ denotes a pure number. **Where the framework fixes no dimension, the audit says so rather than assigning one.**

Symbol	Dimension	Unit	Status
B (belief fraction)	`[1]`	conviction-weighted fraction of agents	**defined** dimensionless on $[0, 1]$; **the underlying belief measure is ORDINAL and is not licensed for multiplication** (Section 3.4)
K (channel transmission)	`[1]`	none	**defined** dimensionless; a modelling choice
R (responsiveness)	`[1]`	none	**defined** dimensionless; a modelling choice
$E = BKR$	`[1]`	none	**derived**; balances, since all three factors are pure numbers
g (loop gain)	`[1]`	none	**derived** as $\eta s/\delta$; **not identified from observational data**
$s = dS/dQ$	`[\text{nats}]/[q]`	nats per proxy unit of store	**the framework is silent on the unit of** Q, so s inherits an unstated dimension. It is reported here as **undetermined**, not assigned
$a = (1 - \delta) + \eta s$	`[1]`	none	**derived**; balances only if ηs is dimensionless, which requires η to carry `[q]` per nat per period exactly [Curzi, 2026a]
$\tau = 1/(1 - a)$	`[1]`	periods	**derived**; a count of periods, dimensionless given a fixed period
Q	`[q]`	proxy units of stored order	**measured** in whatever the declared proxy counts
η	`[q]` per nat per period	proxy units per nat per period	**measured**; *not* dimensionless [Curzi, 2026a]
δ	`[1]`	per period	**measured** dimensionless fraction per step

Symbol	Dimension	Unit	Status
S, $\ln N$	`[1]`	nats	**derived** dimensionless; a **Shannon-type logarithm of a count, not a thermodynamic entropy**
r (reserve ratio), f (withdrawal fraction), h (recovery rate)	`[1]`	none	**derived** ratios of like quantities; ratio-scaled with true zeros
D (deposits), reserves, shortfall	`[\$]`	currency	**measured**, ratio-scaled
μ, σ (threshold distribution)	`[1]`	fraction of others withdrawing	**defined** dimensionless on the same axis as x
x^* (fixed point)	`[1]`	fraction of deposits withdrawn	**derived** dimensionless
d (standardised effect)	`[1]`	standard deviations of a **stated** reference population	**quoted** from the literature; **the reference SD must be stated with it or the number means nothing**
r (correlation)	`[1]`	none	**quoted**; r^2 is the variance share
GPA points	`[\text{grade}]`	grade points	**derived** from d by multiplying by a stated SD of 0.70
likelihood ratio	`[1]`	none	**derived**; a ratio of two probabilities of the same event
g_{total} (chain gain)	`[1]`	none	**derived**; dimensionless only if every link gain is dimensionless, which the protocol requires to be stated
n (sample per arm)	`[1]`	count	**derived** from d
u, $B^2/2\mu_0$	`[M L^{-1} T^{-2}]`	J m^{-3}	**derived** exactly
Casimir $P(a)$	`[M L^{-1} T^{-2}]`	Pa	**derived** exactly from $\pi^2\hbar c/(240a^4)$

Does the effect model balance? $E = B \cdot K \cdot R$ balances trivially: all four quantities are pure numbers. **That is not a virtue — a model of pure numbers balances whatever it means — and the real content of gate 1 here is the next row.**

Does the reflexive storage law balance? $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ balances only if η carries `[q]` per nat per period, since S is dimensionless in nats [Curzi, 2026a]. The reflexive term $\eta s Q$ then requires s to carry nats per `[q]`, **so that ηs is dimensionless and the pole a is a pure number. The framework does not state the unit of Q**, so s has no operational unit and the audit records it as **undetermined. A dimensionless placeholder is honest; an invented unit would not be.**

Does the effect-size arithmetic balance? d is dimensionless only against a stated reference standard deviation, and the conversion to 0.0560 GPA points is 0.08×0.70. **Quoting a d without**

its reference SD is the most common dimensional error in this literature and it is why every conversion here prints the SD in the same line.

Where the framework has no operational unit, it is said here. Belief, conviction and confidence have **no operational unit at all**. B, K and R are dimensionless placeholders for quantities that have not been instrumented, and the scale on which belief would be instrumented is **ordinal at best** until a conjoint test is run [Michell, 1997, Luce and Tukey, 1964].

35.9.2 9.2 The postulates

P1 — For $|g| < 1$, $\sum_{k\geq 0} g^k = 1/(1-g)$. *Status:* **ARITHMETIC.**

P2 — A first-order linear recurrence $Q_{t+1} = aQ_t + c$ converges iff $|a| < 1$, to $c/(1-a)$. *Status:* **CITED**, elementary, and presupposed from Curzi [2026a].

P3 — The storage law is $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$. *Status:* **DEFINITION** of the framework's model [Curzi, 2026a]. It carries no empirical weight here.

P4 — $S(Q) = S_0 + sQ$ is the linearisation of a reflexive input. *Status:* **MODELLING CHOICE.** Linearity is assumed about an operating point, and s **is not identified from observational data** [Manski, 1993].

P5 — $0 \leq F(u) \leq \ln N$. *Status:* **CITED**, from the framework's surplus functional [Curzi, 2026]. **It is a Shannon-type bound on a dimensionless quantity in nats and is not a thermodynamic statement.**

P6 — In a threshold model, the cascade advances from x while $F(x) > x$ and halts at the first fixed point $F(x) = x$. *Status:* **CITED** [Granovetter, 1978].

P7 — A deposit contract payable at par on demand, backed by reserves rD and illiquid assets, fails when the demanded fraction exceeds r. *Status:* **ARITHMETIC**, given the contract.

P8 — Distinguishing among M equally likely alternatives, or hitting a band of log-width w in a log-uniform prior of span W, has chance probability $1/M$ or w/W respectively. *Status:* **ARITHMETIC**, given the prior. **The log-uniform prior is a MODELLING CHOICE and every likelihood ratio in Section 6.3 inherits it.**

P9 — The minimum detectable standardised effect at power $1-\beta$ and level α in a two-arm comparison is $(z_{1-\alpha/2} + z_{1-\beta})\sqrt{2/n}$. *Status:* **CITED**, standard.

P10 — A corpus assembled by conditioning on success observes only the numerator. *Status:* **DEFINITION** of the selection, and the likelihood-ratio consequence is **ARITHMETIC**.

What is NOT a postulate. The four-class taxonomy is not a postulate in the chain below, because nothing is derived from it; it is a classification scheme, and it appears in the chain with an output of a verdict rather than a number. **That is the honest entry.**

35.9.3 9.3 The compounding chain

```
P1            -> L1   a loop of gain g < 1 multiplies a seed by 1/(1-g):
                      0.5 -> 2.0000, 0.9 -> 10.0000, 0.99 -> 100.0000.      ARITHMETIC

P3 + P4       -> L2   Q_{t+1} = [(1-delta) + eta*s] Q_t + (eta*S_0 - C),
                      so the pole is a = (1-delta) + eta*s.                 DEFINITION + CHOICE (P4)

L2 + P2       -> L3   stable iff eta*s < delta; loop gain g = eta*s/delta;
                      time constant tau = 1/(1-a).                          ARITHMETIC

L3            -> R5a  at delta = 0.10 and eta = 0.50 the critical slope is
                      s* = 0.20, and at s = 0.18 (g = 0.90) tau = 100.0000
                      against 10.0000 at s = 0.                             ARITHMETIC

L2 + P2       -> L4   Q_inf = (eta*S_0 - C)/(delta - eta*s), which at
                      s = 0.190 gives Q_inf = 60.0000 and an implied input
```

```
                      S(Q_inf) = 12.6000 nats.                              ARITHMETIC

L4 + P5        -> R5b  12.6000 nats exceeds ln N for every N below
                       e^12.6 = 2.97e5, and ln 20 = 2.995732, so the row is
                       outside the admissible region: THE RUNAWAY RUNS INTO
                       THE CEILING.                                          ARITHMETIC + CITED (P5)

P7             -> L5   the run threshold is f* = r; at r = 0.0900 and
                       D = 18,000,000 that is 1,620,000, i.e. 216 of 2,400
                       members at the average balance.                       ARITHMETIC

P7             -> R4a  h* = (D - cash)/loans = (18,000,000 - 1,620,000)
                       /17,400,000 = 0.941379.                               ARITHMETIC

P6 + L5        -> R4b  with thresholds N(mu, 0.25) the critical mean is
                       mu* = 0.408522, and x* = 0.990106 at mu = 0.407522
                       against x* = 0.145087 at mu = 0.409522.               ARITHMETIC (given P6)

P8             -> L6   one correct direction call has chance 0.500000, so
                       LR = 2.000000; five consecutive have chance 0.031250.  ARITHMETIC

P8             -> R6a  a +/-20% band is ln(1.2/0.8) = 0.405465 wide in log
                       space; against 2 decades = 4.605170 the chance hit is
                       0.088046 and LR = 11.3577.                            ARITHMETIC (given the prior)

L6 + R6a       -> R6b  ln(11.357747)/ln(2) = 3.5056 direction calls.         ARITHMETIC

P8             -> R6c  chain gain is the product of link gains: five links at
                       0.70 give 0.168070, at 0.60 give 0.077760, and the
                       worked five-link case gives 0.063000.                 ARITHMETIC

P9             -> R7   d_min = 2.801585 * sqrt(2/n): 0.5603 at n = 50,
                       0.1617 at n = 600, 0.0251 at n = 25,000; inverting,
                       d = 0.08 needs n = 2,453 per arm.                     CITED (P9)

P10            -> CR1  500 successes are produced by 1,000 practitioners at
                       p = 0.5 and by 500,000 at p = 0.001, so the likelihood
                       ratio between any two hypotheses given only the
                       numerator is exactly 1.000000.                        ARITHMETIC

(quoted)       -> R2   r = 0.10 gives r^2 = 0.0100; d = 0.08 gives U3 =
                       0.53188, CL = 0.52256, overlap = 0.96809, and
                       0.08 x 0.70 = 0.0560 GPA points.                      ARITHMETIC on a QUOTED d

(quoted)       -> R3   0.35 x 0.0400 = 0.014000 against 0.90 x 0.077389 =
                       0.069650, a ratio of 4.9750, with the A1 share of the
                       lift at 39.53%.                                       ARITHMETIC on ASSUMED inputs

(the taxonomy) -> R1   a verdict, not a number.                              CLASSIFICATION
```

Every line is `ARITHMETIC` except four. P4 is a modelling choice and R5a and R5b inherit it. P5, P6 and P9 are cited standard results. **R2's inputs are quoted effect sizes carrying the source literature's uncertainty and not this paper's**, and **R3's inputs are assumed and are labelled assumed at every appearance. R1 is a classification and produces no number at all**, which is stated here rather than left for the reader to notice.

A chain whose most consequential outputs are a demotion, a bound and a classification delivers withdrawals with certainty and delivers no measurement whatever. That is the honest summary of this paper's arithmetic.

35.9.4 9.4 The verification instance, worked

Four checks, none longer than five lines, and between them they establish the paper's four quantitative headlines.

Check one — the growth-mindset unpacking. With $d = 0.08$ and Φ the standard normal CDF:

```
U3      = Phi(0.08)               = 0.531881   -> 53.188%
CL      = Phi(0.08 / sqrt(2))
        = Phi(0.056569)           = 0.522555   -> 52.256%
overlap = 2 * Phi(-0.08/2)
        = 2 * Phi(-0.04)          = 0.968094   -> 96.809%
GPA     = 0.08 * 0.70             = 0.0560 points
r^2     = 0.10^2                  = 0.0100     -> 1.00% of variance
```

Check two — the critical recovery rate.

```
deposits D        = 18,000,000
cash              =  1,620,000     (r = 0.0900)
loan book         = 17,400,000
h* = (D - cash) / loans
   = 16,380,000 / 17,400,000      = 0.941379
```

so a forced-sale recovery of 0.90 realises $1{,}620{,}000 + 0.90 \times 17{,}400{,}000 = 17{,}280{,}000$, which is **96.00 cents on the dollar** against deposits of 18,000,000. **A ten per cent haircut on a small loan book is unremarkable, and it makes a solvent institution insolvent.**

Check three — the ceiling that terminates the runaway.

```
delta = 0.10, eta = 0.50, C = 0, eta*S_0 = 0.30
s = 0.190  ->  denominator = delta - eta*s = 0.10 - 0.095 = 0.005
               Q_inf = 0.30 / 0.005 = 60.0000
               S(Q_inf) = S_0 + s*Q_inf = 0.60 + 0.190 * 60 = 12.6000 nats
ln 20 = 2.995732,  and 12.6000 / 2.995732 = 4.21  times the ceiling
```

The implied input is more than four times the largest surplus a twenty-kind interaction can supply. The row is inadmissible, and every row above it is worse.

Check four — the evidential exchange rate.

```
direction call:   P(correct | null) = 0.500000        LR = 1/0.5 = 2.000000
magnitude call, +/-20%, prior span 2 decades:
    band  = ln(1.20 / 0.80) = ln(1.50)     = 0.405465
    span  = 2 * ln(10)                     = 4.605170
    chance hit = 0.405465 / 4.605170       = 0.088046
    LR    = 1 / 0.088046                   = 11.357747
equivalent direction calls = ln(11.357747) / ln(2) = 3.5056
```

Four checks. A reviewer who runs them has verified every headline this paper contributes that is not quoted from elsewhere.

35.9.5 9.5 Limits, asymptotics, and the domain of validity

$B \to 0$, $K \to 0$ **or** $R \to 0$ **in the effect model.** $E \to 0$ in each case. **That is the model's entire content and it is why it was chosen** — but it is also its weakness: a multiplicative model *forces* the conjunction rather than discovering it, and Section 10 records that as an assumption rather than a finding.

$g \to 1^-$ **in the loop.** The multiplier $1/(1-g) \to \infty$ and $\tau \to \infty$. **The divergence is not a pathology of the model but the definition of marginal stability** — and it is unreachable in practice because $S \leq \ln N$ binds first.

$g \to 0$**.** The multiplier tends to 1: the seed is the whole effect and there is no loop. **A system with** $g = 0$ **is exactly a non-reflexive system and the whole apparatus collapses correctly to nothing.**

$s < 0$ **— the self-defeating branch.** τ *shortens*: 8.0000 at $s = -0.05$ and 2.8571 at $s = -0.50$, against 10.0000 at $s = 0$. **A negative reflexive slope is a stabiliser and the limit is well behaved in both directions.**

$r \to 1$ **in the deposit contract.** $f^* \to 1$: the narrow bank, where no run is possible. $r \to 0$ gives $f^* \to 0$: any withdrawal at all exhausts the reserves. **Both limits are real institutional designs and neither is a defect of the model.**

$\sigma \to 0$ **in the threshold distribution.** Every member has the same threshold, so the cascade is all-or-nothing at μ. **The knife edge of Section 4.9 is the finite-**σ **version of that degeneracy, and the sharpness of the transition is governed by** σ**, which is the parameter institutions can actually move.**

$n \to \infty$ **in the power law.** $d_{\text{min}} \to 0$ as $n^{-1/2}$, so any effect becomes detectable eventually and the cost grows as the inverse square of the resolution wanted. $n \to 0$ **is not a limit of the model but a failure of the design**: below about 50 per arm the minimum detectable effect exceeds 0.56, which is larger than almost anything in this domain.

$p \to 1$ **in the log-uniform prior span.** As the prior narrows to a point the magnitude call's likelihood ratio tends to 1: **if the answer was already known, predicting it correctly is worth nothing.** As the span widens the ratio grows without bound, **which is the warning attached to R6: the evidential value of a magnitude call is a property of the prior, and a claimant who chooses the prior chooses the payout.**

Number of links $\to \infty$ **in the chain law.** $g_{\text{total}} \to 0$ geometrically for every per-link gain below 1. **A sufficiently long channel is a dead channel, and this is the asymptotic statement of "shorten the chain, do not strengthen the links."**

35.9.6 9.6 Invariance, and how far each claim has been tested

Scale invariance of the effect model — that E depends only on the product and not on which factor is small — is exact and algebraic, and it is **tested at five configurations** in Section 4.2. **Five configurations, all constructed.**

Invariance of the run threshold under the size of the deposit base is exact: $f^* = r$ does not depend on D, which is why the threshold is quoted as a fraction. **Tested at two deposit bases** (the thousand-depositor illustration and the constructed institution of Appendix A) **and at six reserve ratios.**

Invariance of the likelihood-ratio arithmetic under the units of the predicted quantity holds because the prior is log-uniform and the band is a ratio: rescaling the quantity shifts both by the same amount. **This is exact and definitional, and it is why the magnitude-call arithmetic is reported in per cent rather than in units.**

Invariance of the chain-gain law under the ordering of links is exact — multiplication commutes — and is the reason the protocol can require the *product* without requiring the links to be measured in sequence.

Parameter invariance across people, sites or institutions is the empirical invariance, and it has been tested at exactly zero points in this paper. FVP-7 is the gate that would test it and **it**

is reported as NOT YET RUN. Every invariance claim above is algebraic; none is an empirical finding.

35.9.7 9.7 Significant figures and their warrant

- **Exact by definition or by arithmetic, quoted to whatever precision is useful:** $h^* = 0.941379$; $\mu^* = 0.408522$; $\ln 20 = 2.995732$; the likelihood ratios 2.000000, 11.357747 and 3.5056; the chain-gain products; the survivorship ratio 1.000000; $d_{\min}$ at each n.
- **Illustrative model output at assumed parameters, rounded honestly:** the pole and time-constant table, the steady-state table, the threshold-model outcomes 0.990106 and 0.145087, and the posterior table of Section 5.9. **Every one of these is an evaluation of a stated model at stated assumed parameters and none is a measurement.** Six decimal places on 0.990106 record a model evaluation, not a measured fraction.
- **Quoted from published literature, carrying that literature's uncertainty and not this paper's:** $r = 0.10$; $d = 0.08$; the field subgroup effect of about a tenth of a grade point; 97 of 100 and about 36 of 100; $r = 0.403 \to 0.197$; 13 of 21; the roughly 25 per cent tipping threshold. **These are reproduced as point values without intervals because that is how the source framework carried them, and that is a presentational defect recorded at L-9.**
- **Constructed for the arithmetic and labelled constructed:** the balance sheet of Appendix A and every conditional probability in Appendix B.
- **Physical constants and exact formulas:** $\mu_0 = 4\pi \times 10^{-7}$, the Casimir pressures, the field-energy densities. **Exact given the formula.**

35.9.8 9.8 Analogy discipline, restated at the point of verification

Every borrowing carries the label assigned in Section 3.2 and no passage upgrades one. The loop gain and its geometric multiplier are a **shared mathematical form** with electrical feedback, and **no electrical result transfers**. The pole and stability condition are a **derivation** from the framework's own storage law. Critical slowing is a **shared mathematical form**, and the empirical early-warning literature is not invoked as support because no such measurement is made here. The Casimir computation is a **derivation within physics used as a counter-example**. And "the engine", "the amplifier" and "the seed" are **vocabulary, never evidence**.

Entropy does not appear in this paper. The only logarithm of a count is the surplus ceiling $\ln N$, which is a **Shannon-type dimensionless quantity in nats** and carries **no thermodynamic content whatsoever** [Curzi, 2026]. The word is not used loosely anywhere.

35.10 10 Limitations

L-1. The taxonomy was applied by its author, to cases its author chose, without blinding. H1 therefore survives an illustration rather than a test. **A taxonomy that fits every case its proposer selected is exactly what a taxonomy with no content would look like from the inside**, and the correct repair is an independent classifier applying it to a pre-registered case list. **That has not been done.**

L-2. A large number of the primary sources are named without citation keys. Thomas and Thomas (1928), Diamond and Dybvig (1983), Thorndike (1968), Elashoff and Snow (1971), Raudenbush (1984), Steele and Aronson (1995), Flore and Wicherts (2015), Flore et al. (2018), Sisk et al. (2018), Yeager et al. (2019), Camerer et al. (2018), Bem (2011), Ritchie, Wiseman and French (2012), Benson et al. (2006), Bösch, Steinkamp and Boller (2006), Levine, Gordon and Fields (1978), Kaptchuk et al. (2010), Tajik et al. (2016) and Wald (1943) have **no entries in this corpus's bibliography, and no key was invented for any of them.** Every one is a standard, locatable source; **the gap is in the corpus's bibliography and it is recorded here rather than smoothed over.**

L-3. No reflexive parameter in this paper is identified. The reflexive slope, the loop gain and every regime classification derived from them are **modelling positions rather than identified empirical results** [Manski, 1993, Shalizi and Thomas, 2011]. **The only remedy adopted is randomisation, and it is adopted only for prospective work in Section 6.13; nothing retrospective here is identified.** The stipulated-reference-group route is available and is not taken [Brock and Durlauf, 2001].

L-4. The multiplicative effect model is an assumption, not a finding. $E = BKR$ was chosen because it forces the conjunction. **An additive or a minimum-form model encodes a different conjunction and gives different intermediate values, and nothing in this paper establishes that the multiplicative form is right.** The value $E = 0.0600$ for the "weak on all three" configuration is an artefact of that choice.

L-5. The knife-edge result is a property of the model, not a measurement of any institution. $\mu^* = 0.408522$ and the 0.990106/0.145087 swing follow from a normal threshold distribution at $\sigma = 0.25$ and a 9 per cent reserve. **No threshold distribution has been measured for any real deposit base in this paper**, and the sharpness of the transition is governed by σ, which is exactly the parameter nobody has measured.

L-6. The conjoint-measurement test has not been run and Michell's objection stands. Belief, conviction and confidence are treated as ordinal throughout and every multiplicative statement involving them is demoted in print [Michell, 1997, Luce and Tukey, 1964]. **That is a concession, not a defence.** Until a ratio-scale instrument exists, the protocol's step 4 can produce a gain only for channels whose input is physically instrumented.

L-7. The protocol has never been run on a real case. Section 6 specifies a procedure with an unknown pass rate. **A protocol that nothing has ever failed is a formality**, and the only evidence this one is discriminating is the constructed gallery of Section 6.15, in which four of six claims die — **a gallery its author assembled.** The corpus's one comparable attempt against a real system **failed its own second falsification rule** [Curzi, 2026i], which is the realistic expectation.

L-8. The likelihood-ratio arithmetic is a property of a chosen prior. The log-uniform prior over R decades is a modelling choice, and the headline 11.3577 falls to 5.6789 at one decade and rises to 17.0366 at three. **A claimant who chooses the prior chooses the payout**, and the protocol has no defence against that beyond requiring the prior to be stated before the prediction.

L-9. Every effect size quoted from the literature is reproduced as a point value without an interval. $r = 0.10$, $d = 0.08$ and the field subgroup effect all carry sampling uncertainty that is not restated here, because the source framework carried them as point values. **A measured quantity quoted without an uncertainty is a presentational defect** and is recorded as one rather than dressed up.

L-10. Two of the three worked cases are constructed and the third is a gallery. The balance sheet of Appendix A, the conditional probabilities of Appendix B and the team history of Appendix C are all constructed for the arithmetic. **No institution, applicant or team described in them exists**, and what they demonstrate is a procedure.

L-11. No AIC or BIC is reported, here or anywhere in this corpus. Section 7.9 prints the row as NOT MET rather than omitting it. Nothing in this paper is fitted to collected data, so no information criterion is computable from it; **the corpus-wide absence is nonetheless a genuine gap and is recorded as one.**

L-12. The survivorship result is exact and its application is an inference. The likelihood ratio of 1.000000 is arithmetic. **The claim that the testimonial literature is assembled that way is an assertion about a body of publications that this paper has not audited**, and a corpus that reported its failures would not have the defect. **The result bounds what an outcome-conditioned corpus can show; it does not establish that any particular corpus is outcome-conditioned.**

L-13. Nothing here says a small effect is a worthless effect. A tenth of a grade point at national scale and near-zero marginal cost is good engineering, and the paper says so in the same section that reports the 96.809 per cent overlap. **The two statements are both true and**

reporting only one of them would be a distortion in whichever direction it was made.

35.11 11 Conclusion

This paper is the framework's counter-result: it catalogues where the conditional postulate does not pay, prices what survives, and states the objection that would destroy the postulate outright.

Result One, the four failure classes. Failure decomposes into **A**, no channel — gain is not small but undefined, and the diagnostic is to name the transducer; **B**, a real channel with insufficient gain — the effect is real, replicable, and an order of magnitude below the claim; **C**, a real result extrapolated to a magnitude it cannot support — nothing in the original work needs to be wrong; and **D**, a system unresponsive to an input of this size from a source of this size — which subdivides into a receiver that does not read this input, one for which this source is $1/N$, and one already saturated. **Only $1/N$ changes with scale, and all three present identically from inside.**

Result Two, growth mindset as Class B, unpacked. The channel is real and the gain is small: $r \approx 0.10$, which is **1.00 per cent of variance**, and $d \approx 0.08$, which is **96.809 per cent distribution overlap**, a **52.256 per cent common-language effect**, **53.188 per cent** above the untreated median, and **0.0560 GPA points** on a 0.70-point standard deviation. **Pick one treated and one untreated student at random and the treated one scores higher 52.256 per cent of the time, against 50 by chance. That is the size of the thing** — and a tenth of a grade point at national scale for pennies a student remains good engineering.

Result Three, the job-search audit. All real channels together lift the offer probability from **0.0140 to 0.0697**, a ratio of **4.975** — **and the outcome is still no offer 93 per cent of the time. 39.53 per cent of the entire lift comes from the belief causing the application to be submitted, and the no-contact channel carries gain zero by construction.** All parameters are assumed and labelled as such.

Result Four, the deposit run. At a **9.00 per cent** reserve the run threshold is $f^* = 0.0900$ — **216 of 2,400 members** — and the critical recovery rate is $h^* = 0.941379$, so **a forced-sale recovery below 94.14 cents on the dollar makes a solvent institution insolvent.** With tolerances Normal$(\mu, 0.25)$ the critical mean is $\mu^* = 0.408522$ and the withdrawn fraction swings from **99.01 per cent to 14.51 per cent on a change of 0.002**, with no intermediate outcome. **A property of the model, not a measurement of any institution.**

Result Five, the ceiling and the slowing. With $\delta = 0.10$ and $\eta = 0.50$ the critical reflexive slope is **0.20**, but $s = 0.19$ **already implies 12.6 nats of input against** $\ln N = 2.996$ **at** $N = 20$ — **4.21 times the ceiling, so the runaway leaves the admissible region before it diverges.** And $\tau = 1/(1-a)$ **goes tenfold at loop gain 0.90**: the loop slows conspicuously before it destabilises, which is a signature measurable from response time alone — **and, since the reflexive slope is not identified from observation, the only signature available.**

Result Six, evidential pricing. A direction-only prediction is worth a likelihood ratio of 2.0000. A ± 20 **per cent magnitude call against a two-decade prior is worth 11.3577, which is 3.5056 direction calls for the same single measurement. And five links at 70 per cent each deliver 6.3 per cent end to end.** The likelihood ratios are properties of the stated log-uniform prior, which is a modelling choice.

And the counter-result, which is what the paper is for. It catalogues where the framework's own postulate does not pay; it prices the surviving effects at $d \approx 0.08$ to 0.30 with **92 to 97 per cent distribution overlap**; it shows that at $N = 100{,}000$ **a single committed person is 25,000-fold short** of the tipping requirement; and it insists that **a null bounds a gain without proving a zero** — 600 per arm bounds only $d = 0.1617$, which excludes neither effect the paper reports. **It applies the replication discount to the framework itself, where a prior of 0.10 becomes a posterior of 0.1148 on one significant result. And it states the objection that would make the postulate vacuous — that a conditional whose antecedent is read off the outcome forbids nothing — and answers it with a procedure rather than an argument, because**

a procedure is the only thing that can answer it.

The postulate's whole content is its conditional, and the conditional's whole content is that grounding is established from the channel, before the outcome is known, or it is not established at all.

35.11.1 Declarations

Data and code availability

No external dataset was collected for this paper, and no human subjects were studied. The empirical magnitudes reported — the meta-analytic mindset effects, the national field-trial subgroup effect, the replication counts, the tipping threshold, the expectancy-effect syntheses and the trial results in Sections 5.6 and 5.14 — are quoted from the published literature named in the text, carry that literature's uncertainty rather than this paper's, and are not measurements of this paper; many of those sources carry no key in this corpus's bibliography and are named in full in the text, as disclosed at Section 3.8 and Limitation L-2. Every other number is either exact arithmetic, an evaluation of a model at parameters stated as assumed beside it, or — in the case of the shuffled-input control of Section 6.13 — the output of a stated simulation (4,000 trials per case, series length 200, 140 fitted and 59 held out) reproducible from the specification given. The balance sheet of Appendix A, the conditional probabilities of Appendix B and the team history of Appendix C are constructed and are labelled constructed wherever they appear. The figures are generated by the scripts named in each caption, and those scripts contain no data beyond the numbers printed in this paper and the functions stated in Sections 4 to 6.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. The postulate audited here is the author's own, the taxonomy applied to it is the author's own, and the cases it is applied to were selected by the author. That is a structural conflict which no declaration removes; it is the reason failure mode FM-5.9 (selective scepticism) is in the specification, the reason Section 5.9 applies the replication discount to the framework in print, and the reason Limitation L-1 records the taxonomy as illustrated rather than tested.

Author contributions

Single author. Michael Laurence Curzi derived the results, performed the arithmetic and the simulation, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The trials, meta-analyses and field experiments discussed are other investigators' work, quoted. No clinical, medical or therapeutic claim is made anywhere in this paper, in either direction; the published trials in Sections 5.6 and 5.14 are cited as evidence about channels and their gains and never as guidance about care. The measurement designs of Section 6 and Appendix C are designs for prospective work and are not reports of studies performed; were any of them run, it would require ethical review, and nothing here substitutes for that.

Preregistration

This paper reports no preregistered test on human data. The five hypotheses of Section 2 were fixed before the arithmetic and the simulation reported in Sections 4 to 6 were carried out and are printed in the form in which they were fixed. **H2 to H5 are confirmed by arithmetic on quoted or assumed inputs; H1 is reported as surviving an unblinded, author-selected audit, which is illustration rather than test, and Section 7.8 says so in the same plain language a confirmation would have received.** The falsification suite whose baselines Section 6.12 requires has itself been audited and is **anti-conservative** — a shuffle-control false-rejection rate of **0.108 against a nominal 0.05**, and a demand-characteristic confound with a true coefficient of zero passing the whole four-baseline suite **52.7 per cent of the time** [Curzi, 2026u]. The corpus's preregistered confirmatory test of the storage law against a real system **failed its second falsification rule**, returning a 2.8 per cent held-out advantage over a matched autoregressive baseline against a declared margin of 10 per cent [Curzi, 2026i]. **Any applied claim resting on this paper inherits both results.**

35.12 Appendix A · A deposit run, an autopsy, and three interventions priced

The figures below are constructed for the arithmetic and are labelled as constructed; they are not drawn from a real institution. Every number is computed from those figures.

The balance sheet.

```
members                    2,400
deposits                   18,000,000
average member balance     7,500.00
cash and overnight         1,620,000        reserve ratio r = 0.0900 (9.00%)
loan book, at par          17,400,000
total assets at par        19,020,000
equity                     1,020,000        equity / assets = 0.0536 (5.36%)
```

By any static measure this institution is sound: solvent, with a 5.36 per cent equity cushion and nine per cent of deposits in cash. **It is also, structurally, a machine for converting a rumour into a failure.**

Step 1 — the run threshold.

```
f* = r = 0.0900

9.00% of deposits = 1,620,000
at the average balance, that is 216 of 2,400 members.
```

Two hundred and sixteen members out of two thousand four hundred can exhaust the entire liquid position. Not nine per cent of a majority — nine per cent of the whole. **That is W3, and it was fixed before anyone believed anything.**

Step 2 — what a run costs even though the institution is solvent.

```
demand at various withdrawal fractions f:

  f = 0.05   demand =    900,000   covered by cash? YES   shortfall =          0
  f = 0.09   demand =  1,620,000   covered by cash? YES   shortfall =          0
  f = 0.10   demand =  1,800,000   covered by cash? NO    shortfall =    180,000
  f = 0.15   demand =  2,700,000   covered by cash? NO    shortfall =  1,080,000
  f = 0.25   demand =  4,500,000   covered by cash? NO    shortfall =  2,880,000
  f = 0.40   demand =  7,200,000   covered by cash? NO    shortfall =  5,580,000
  f = 1.00   demand = 18,000,000   covered by cash? NO    shortfall = 16,380,000
```

Beyond $f = 0.09$ loans must be sold, and loans sold under duress do not fetch par:

```
liquidation value = cash + h * loan book, where h is the recovery rate

  h = 1.00 (no haircut)   19,020,000   105.67 cents on the dollar   SOLVENT
  h = 0.90                17,280,000    96.00 cents                 INSOLVENT
  h = 0.80                15,540,000    86.33 cents                 INSOLVENT
  h = 0.70                13,800,000    76.67 cents                 INSOLVENT
  h = 0.65                12,930,000    71.83 cents                 INSOLVENT
  h = 0.60                12,060,000    67.00 cents                 INSOLVENT

CRITICAL RECOVERY RATE   h* = (D - cash) / loans = 0.941379
```

A forced-sale recovery below 94.14 cents on the dollar makes a solvent institution insolvent. A ten per cent haircut — unremarkable for a distressed sale of a small loan book — puts members at 96.00 cents. **The belief that the institution cannot pay becomes true at a haircut of about six per cent, and haircuts of six per cent are ordinary. That is the loop closing, and it closes in the asset market, not in the members' heads.**

Step 3 — whether the seed propagates. Model member thresholds as Normal(μ, σ) with $\sigma = 0.25$:

```
critical mean tolerance   mu* = 0.408522

  mu = 0.407522   ->   x* = 0.990106     99.01% of deposits withdrawn -- total failure
  mu = 0.409522   ->   x* = 0.145087     14.51% withdrawn -- survivable with support
```

The institution's fate turns on two-thousandths of a unit in an unmeasured population parameter. No amount of care about the rumour changes this. **The correct objects of management are μ and σ, and both are properties of the membership, cultivated over years.**

Step 4 — the three interventions, each priced against a requirement.

```
INTERVENTION A -- attack W1. Communications.
  Board letter, member meeting, public accounts, personal calls.
  TARGET: mu, upward.
  COST: low in money, high in time, and it must be paid again next time.
  RELIABILITY: unknown. The outcome depends on mu to the third decimal place,
  and no instrument reads mu to the third decimal place.
  VERDICT: necessary, insufficient, and never the whole plan.

INTERVENTION B -- attack W2. A withdrawal gate.
  Notice period of 30 days on balances above 25,000.
  TARGET: K, the belief-to-action channel.
  COST: a real reduction in the product's value to members. Some will leave
  permanently for that reason alone.
  EFFECT: computed. If 40% of deposits sit in balances above 25,000, and the
  gate defers those, the maximum same-day demand falls from 100% to 60% of
  deposits, and the effective liquid coverage rises from 0.0900/1.00 to
  0.0900/0.60 = 0.1500. The run threshold on ungated deposits rises from
  9.00% to 15.00%.
  VERDICT: real, cheap in cash, expensive in trust, and it announces the
  problem it is solving.

INTERVENTION C -- attack W3. A committed liquidity line.
  A pre-agreed facility of 9,000,000 against the loan book at 95 cents,
  drawable on demand.
```

```
TARGET: R, the system's responsiveness to withdrawal.
EFFECT: computed. Liquid capacity rises from 1,620,000 to 10,620,000.
New run threshold f* = 10,620,000 / 18,000,000 = 0.5900 -- 59.00% of
deposits, or 1,416 of 2,400 members at the average balance, versus 216.
That is a 6.56-fold increase in the withdrawal fraction the institution can
absorb without selling an asset. And because the facility lends at 95 cents
rather than a distressed 80, the critical recovery rate never comes into
play for the first 9,000,000 of demand.
COST: a commitment fee, paid annually, whether or not it is drawn.
VERDICT: the intervention that actually removes the engine.
```

Step 5 — the comparison, which is the point.

	target	run threshold f*	members needed to break it
as-is	–	0.0900	216
+ communications	W1	0.0900	216
+ withdrawal gate	W2	0.1500	360
+ liquidity line	W3	0.5900	1,416
+ line and gate	W2,W3	0.9833	2,360

Communications does not move the threshold at all. It moves the probability that the threshold is approached, by an amount nobody can measure. **The liquidity line moves the threshold by a factor of 6.56, and the movement is arithmetic.**

Step 6 — the loop gain, before and after. Before the line, a withdrawal forces asset sales, the sales are visible, the visible sales confirm the rumour, and confirmation drives further withdrawal: **the fire sale is itself the evidence.** After the line, a withdrawal is met from the facility, no asset is sold, and nothing visible confirms anything. **The liquidity line does not reassure anyone. It removes the observable the loop was feeding on. That is what an intervention on W3 looks like from the inside: it does not argue, it disconnects. The pass gains before and after are not estimated here** — they would require the reflexive slope, which is not identified from observation [Manski, 1993] — and the qualitative statement is offered as a qualitative statement.

Step 7 — what the case does not show. It does not show that belief was unimportant: without the rumour there is no seed. **W1 is necessary. It is simply not sufficient, and it is the requirement over which management has the least control and the least measurement.** And it does not show that the rumour was false in any useful sense: **by the time a run is over, the rumour is true.** The belief was false about the balance sheet and true about the contract, **and the contract is what the depositor actually holds.**

35.13 Appendix B · Two beliefs, run through all four classes

All parameters below are assumed for the arithmetic and are labelled as assumed. They are not measured values and no claim is made that they are. What the case demonstrates is the decomposition procedure, not the numbers.

Belief 1: "I will get this job."

```
ASSUMED BASELINE
  P(offer | application submitted, no additional effort) = 0.0400
```

Channel A1: belief → application actually submitted. The most overlooked channel in the literature and the largest.

```
P(submit) = 0.35   ->   P(offer) = 0.014000
```

```
P(submit) = 0.90   ->   P(offer) = 0.036000

lift from A1 alone = 0.022000 absolute; a factor of 2.5714
```

Class: none — this channel works. It is behavioural, physical, its gain is large, and it is entirely uncontroversial. **It is also the channel most of the popular literature obscures by attributing the result to the belief rather than to the submission.**

Channel A2: belief → preparation hours → interview performance.

```
assumed: preparation rises from 3 h to 8 h
assumed: odds ratio 1.10 per hour of preparation

P(offer) rises 0.040000 -> 0.062885     absolute lift 0.022885
```

Class B if the claim were large: real channel, moderate gain. The gain is bounded by the odds ratio, **which is an empirical quantity someone would have to measure rather than assume.**

Channel A3: belief → demeanour → interviewer's rating.

```
assumed: odds ratio 1.25, applied once
P(offer) rises 0.062885 -> 0.077389     absolute lift 0.014505
```

Class B. Real, observable and modest — and this is the channel the expectancy literature measures, running in the other direction.

Channel A4: belief → the employer's decision, with no contact of any kind.

```
gain = 0, by construction. There is no transducer.
```

Class A. Not small. Absent.

The total.

```
believing, applying, preparing, and presenting well:
    P(offer) = 0.90 * 0.077389 = 0.069650

not believing, often not applying, not preparing:
    P(offer) = 0.35 * 0.040000 = 0.014000

ratio = 4.9750x        absolute difference = 0.055650

share of the total lift attributable to A1 -- simply applying = 39.53%
```

A five-fold change in outcome probability, and nearly two-fifths of it comes from the belief causing the person to send the application. That is a real, large and completely mundane effect, and it is exactly what the postulate predicts: **belief created reality, through channels, at the gains those channels have.**

And the honest reading of the other side: the belief did not raise the probability to 1. It raised it from 0.014000 to 0.069650. Ninety-three per cent of the time, the outcome is still no offer. A believer who reports the successful case and not the ninety-three is generating exactly the corpus Section 5.11 shows to be inert.

Belief 2: "I believe this traffic signal will change now."

```
W1  belief held                              yes
W2  channel to action                        yes: the pedestrian can press,
                                             wave, shout, stare
```

```
  W3  system responsive along that channel          NO. A fixed-timer signal reads
                                                    a clock. It does not read the
                                                    button, the wave, the shout,
                                                    or the belief.

  E = B x K x R = 1.00 x 1.00 x 0.00 = 0.0000
```

Class D, and the diagnostic took one sentence: what does this system take as input?

Note what happens next, because it is the general pathology in miniature. The pedestrian believes; the signal changes on its schedule; the coincidence is noticed. Repeated over a year, the believer accumulates a corpus of cases where the belief preceded the change, because the signal changes regularly and beliefs are frequent. **The corpus is real, the cases are honestly reported, and the likelihood ratio is 1.000000.** It is Section 5.11 running at pedestrian scale, and it is the same machine that produces the shelf of books.

	belief 1	belief 2
channel named	four, three real	one, unresponsive
gain	0.0140 -> 0.0697	0.0000
class of the failing channel	A (A4 only)	D
what the postulate predicts	an effect, bounded	no effect
what happens	an effect, bounded	no effect

The postulate got both right, and it got them right in advance, from the channel — which is the only way it is ever entitled to get anything right. Two cases is not a test, and Section 10 records the point.

35.14 Appendix C · The worksheet, and one belief taken end to end

35.14.1 C.1 The printable worksheet

One page. The date at the top and the signature at the bottom are the mechanism; everything else is scaffolding for them.

```

The constant in step 5 is computed: $2(1.959964 + 0.841621)^2 = 15.697759$, so n per arm $= 15.6978/d^2$ for a two-group comparison at $\alpha = 0.05$ two-sided and 80 per cent power. **It is on the sheet so the arithmetic can be done at the table.**

35.14.2 C.2 One belief, end to end

The figures below are constructed for the arithmetic and treated as a team's own measured history; they are labelled as constructed. A team of eleven believes that committing publicly to a ship date makes the date more likely to hold.

Step 1 — precisely enough to be wrong. After the four passes of Section 6.5:

Where at least 8 of 11 members rate confidence in the committed date at 4 or 5 on the team's existing 5-point kickoff form, mean scope added after kickoff is 1.00 points lower (tolerance ± 30 per cent, so 0.70 to 1.30 points) than where fewer do.

Negation: *...is not lower by that amount.* Both are clear. **Passes.**

Step 2 — the channel.

```
SOURCE      the eleven-member team. N = 11, so the 1/N problem is mild:
            one member is 9.09% of the group and the 25% tipping threshold
            is 3 members.
TRANSDUCER  speech. The commitment is stated aloud and recorded.
MEDIUM      the team's shared backlog and its meeting record.
RECEIVER    the team members, and the stakeholders who request scope.
EFFECTOR    scope points added after kickoff. Units: story points.
FAMILY      SOCIAL + INFORMATIONAL.
```

Step 3 — physical possibility. P1 not applicable. P2 passes. P3 passes: speech is a named transducer. P4 passes: the signal is a sentence in a meeting, far above any noise floor. P5: the effect does not attenuate with distance in any relevant sense. P6 passes: the stakeholders learn of the commitment because it is said to them. **All six clear.**

Step 4 — the gain.

```
link 1  belief -> public commitment actually stated        g = 0.70
link 2  commitment -> refusal at the scope boundary        g = 0.55
chain gain = 0.385000

points available to refuse per sprint, from history        = 2.60
PREDICTED reduction in scope added = 2.60 * 0.385000       = 1.0010 points
```

Step 4a — the link the team already measured. Fourteen releases:

```
mean slip           11.4286 days   (SD 7.1005)
mean scope added    10.3571 points (SD 5.0323)

OLS, slip ~ scope:
  slope      1.196355 days per point
  intercept -0.962248 days
  r          0.847885        r^2 = 0.718908
  SE(slope)  0.215952        t = 5.5399 on 12 df
  95% CI on the slope: [0.725836, 1.666874] days per point
```

This is the model link, and it is worth pausing on: it was estimated from data collected before the belief claim was made, on a different question. That is what REQ-6.5 requires, and it is why this gain may be used. Carrying the prediction to the endpoint:

```
predicted slip reduction = 1.196355 * 1.0010 = 1.1975 days
and the CI on the slope carries: [0.7266, 1.6685] days
```

Step 5 — magnitude, and the three redesigns. Sprint-level scope-added has a standard deviation of 3.10 points, so the predicted reduction of 1.0010 points is $d = 0.3229$:

```
DESIGN 1 -- parallel two-arm on sprints
  n per arm = 151      total = 302 sprints
  one team at 26 sprints/year = 11.62 YEARS.      INFEASIBLE.
```

```
DESIGN 2 -- paired crossover, lag-1 autocorrelation rho = 0.45
  SD of the paired difference = 3.10 * sqrt(2*(1-0.45)) = 3.2513
  paired d = 0.3079        n pairs = 83     total = 166 sprints
  one team = 6.38 YEARS.                          STILL INFEASIBLE.

DESIGN 3 -- twelve teams, cluster-randomised, ICC = 0.10, cluster size 26
  design effect = 1 + (26-1)*0.10 = 3.50
  required sprint-units = 302 * 3.50 = 1,057
  at 12 teams x 26 sprints = 312 per year -> 3.39 YEARS.
                                                   BARELY FEASIBLE.
```

Step 5 has just told the team that the study they wanted costs eleven and a half years. It told them before a single data point was collected, for the price of two divisions. That is the step doing its job.

The redesign that fits: instrument the high-rate link.

```
outcome: per-request refusal at the scope boundary
  baseline refusal rate     p1 = 0.22
  predicted under commitment: apply g2 = 0.55 to the currently-accepted
    margin of 0.235 -> 0.22 + 0.55*0.235 = 0.3493, stated as p2 = 0.35

n per arm = 189 requests        total = 378 requests

scope requests arrive at about 7.0 per sprint per team.
  one team:      378 / 7.0        = 54.00 sprints = 2.08 years
  twelve teams:  378 / (7.0 * 12) =  4.50 sprints = 0.17 years
```

From 11.62 years to 0.17 years — a factor of 68 — by changing which link is instrumented, with no loss of logical force. The endpoint inference is preserved: the measured refusal effect multiplies through the historical slope of 1.196355 days per point, whose confidence interval is already known, to give the slip consequence with honest uncertainty.

> **THE RULE THIS PRODUCES: the affordable study is set by the EVENT RATE of the link instrumented, not by the importance of the outcome cared about.**

Step 6 — the validation gates.

```
FVP-1  DIMENSIONS        gain in (points refused)/(commitment stated);
                         outcome in points; slope in days/point. PASS.
FVP-2  SCALE TYPE        the 5-point confidence form is ORDINAL. It is used
                         only to define a GROUP (>= 8 of 11 at 4 or 5), never
                         multiplied. Refusal is binary; scope points are
                         ratio-scaled with a true zero. PASS BY CONSTRUCTION,
                         and the construction was chosen for this reason.
FVP-3  LIMITING CASES    zero commitments -> predicted reduction 0.0000:
                         correct. All requests already refused -> saturation
                         at p = 1: the model must not predict beyond it.
                         PASS, with the ceiling stated.
FVP-4  FIXED POINTS      is the loop reflexive? If refusals raise confidence,
                         s > 0 and Section 4.10 applies. Estimated
                         g = eta*s/delta well below 1 here; STATED AS A
                         MODELLING POSITION, NOT AN IDENTIFIED PARAMETER.
FVP-5  IDENTIFIABILITY   g1 and g2 are not separately identified from the
                         refusal outcome alone -- only their product is.
                         DEMOTED: the sheet records g_total = 0.385000 and
```

```
                        states that the split is not recoverable from this
                        design. THIS IS THE GATE WORKING.
FVP-6  FALSIFICATION    preregistered; four baselines; killed if the
                        shuffled-input control matches, or if the observed
                        refusal difference is below 0.70 * 0.13 = 0.0910.
                        The suite's own false-rejection rate is 0.108
                        against a nominal 0.05 and is reported alongside.
FVP-7  REPRODUCIBILITY  twelve teams, parameters recovered per team and
                        compared. NOT YET RUN.
```

FVP-5 returned a demotion and the sheet records it. The design cannot separate "the team did not commit" from "the team committed and did not hold the line". **That is a real limitation, discovered before the study rather than after, and the correct response is to write it on the sheet rather than to pretend the product is a pair.**

Step 7 — the four verdicts, pre-committed.

```
observed refusal difference within [0.0910, 0.1690] and all four baselines
  beaten                                          -> GROUNDED. Report
                                                     g_total = 0.385000
                                                     with its interval.

observed positive but below 0.0910                -> GAIN OVERSTATED.
                                                     Channel real, g2 smaller.
                                                     Revise step 4, re-run.

observed above 0.1690                             -> GAIN UNDERSTATED or a
                                                     SECOND CHANNEL. Return to
                                                     step 2 and find it. NOT
                                                     a success.

observed near zero, or the shuffle predicts as
  well                                            -> UNGROUNDED. Report the
                                                     upper bound: at 189 per
                                                     arm the minimum detectable
                                                     standardised effect is
                                                     about 0.2882, and the
                                                     claim is bounded, not
                                                     disproved.
```

Step 7a — the common-cause defence, chosen at step 5. Because Section 6.13's Case 4 showed the shuffled control passing a pure common-cause configuration **98.35 per cent of the time**, this design uses **CC-1: the commitment ritual is randomised across sprints** rather than adopted whenever the team feels confident. **That single design decision is worth more than every statistical control in the suite — it is the only thing that makes the endogenous effect identified [Manski, 1993] — and it was available only because step 5 forced the design conversation before data collection.**

What the case demonstrates. The protocol did not confirm the belief; **it has not been run.** What it did was convert a sentiment — *committing publicly helps* — into a claim with a named channel, an independently estimated gain of 0.385000, a predicted magnitude of 1.0010 points with a ± 30 per cent tolerance, a stated falsifier at 0.0910, a feasible measurement at 378 requests, a randomisation defence, and a pre-committed verdict table.

That is what "grounded in truth" means operationally, and it is the only meaning the postulate is entitled to. The belief may still turn out to be wrong. A belief that can turn out to be wrong is the only kind this framework has any business calling grounded.

Chapter 36

Narrative as Regulatory Input: A Fully Disclosed Sonification Chain, a Zero-Resultant Corpus, and a Preregistration That Prices Its Own Nulls

Abstract. We specify a lossless, fully disclosed chain from text to audible tone — bytes to bits to nucleotides to frequencies — under an absolute no-subliminal constraint, and prove the structural property that prevents the protocol from overriding its subject. Modelling directives as unit vectors, a corpus closed under negation has resultant exactly zero, verified numerically at N = 4, 8, 12 and 24, while a mutually orthogonal corpus has a mean direction shrinking as 1/sqrt(N). A maximally contradictory corpus is therefore a maximum-surplus corpus: at N = 12 it carries ln 12 = 2.484907 nats, exactly the information required to select one of its members, so selection is left to the listener by construction. The proposed physical route is then closed by computation rather than defended: producing 1 per cent bulk strain in aqueous medium requires 240.83 dB SPL against an atmospheric ceiling of 194.09 dB. The worked pipeline renders 192 characters as 1,776 symbols at 20 ms in 35.520 s, with a Gabor margin of 248.83x against a required 100x and a dose of 0.123 per cent of the eight-hour occupational allowance per rendering. A receiver slower than the transmission recovers at most 29.803 of 1,776 bits, 1.68 per cent. The accompanying preregistration measures its own conjunction gate at a 9.5 per cent false-positive rate, not the nominal 5.

Keywords: narrative encoding; disclosure; antipodal corpus; sonification; preregistration; false-positive calibration; chain law

Series: B. Engineering the Surplus **Paper:** CCP-036

36.1 1 Introduction

A framework that proposes to structure an input and deliver it to a person owes two things before it delivers anything: a statement of what the input contains, complete enough that the recipient could rebuild it, and a structural argument that the input cannot override the recip-

ient's own judgement. **This paper supplies both, and then closes its own proposed physical mechanism by computation rather than defending it.**

The specification is a lossless chain from text to audible tone — bytes to bits to nucleotides to frequencies — governed throughout by an absolute constraint: **no subliminal content of any kind, nothing masked, nothing embedded below the threshold of hearing, nothing concealed from the listener. The information is the tone.** That constraint is not a stylistic preference reached at the end of a design; it is a boundary condition on whether the design may be built at all, and the argument for it depends on no empirical claim. **A message hidden from its recipient cannot be consented to**, and in an architecture whose entire mechanism routes through the recipient's own selection, concealment does not strengthen the protocol — it removes a component of it. **This is the same principle Kerckhoffs stated for cryptographic systems in 1883: a design whose security depends on the design being secret is a design that has not been evaluated** [Kerckhoffs, 1883, Brandeis, 1914].

The second guarantee is structural and can be stated exactly. **Modelling directives as unit vectors, a corpus closed under negation has resultant exactly zero — verified numerically at $N = 4$, 8, 12 and 24, where $\|\sum v_i\| = 0.000000000000$ in every case — while a mutually orthogonal corpus has a mean direction shrinking as $1/\sqrt{N}$.** A field of mutually exclusive directions cannot issue a command; it can only be resolved by selection, and the selection belongs to the receiver. **The quantitative form of that statement is the paper's second result: a maximally contradictory corpus is a maximum-surplus corpus, and at $N = 12$ it carries $F = \ln 12 = 2.484907$ nats $= 3.584963$ bits — exactly the information required to select one of its members.** The corpus supplies as much surplus as the selection consumes and supplies zero net direction.

The paper then closes its own proposed physical route. For a plane acoustic wave in an aqueous medium the longitudinal strain is $s = p/K$ with $K = 2.2 \times 10^9$ Pa, so producing the 10^{-2} strains associated with mechanosensitive gating requires 2.2×10^7 Pa — **240.83 dB SPL, against an atmospheric ceiling of 194.09 dB SPL set by the ambient pressure itself.** The bulk-compression route is closed by more than seven orders of magnitude and stays closed at the physical ceiling of sound in air. **That is a negative result about the framework's own proposal, obtained by arithmetic, and it is reported as a headline rather than as a caveat.**

The worked encoding renders 192 characters as 1,776 symbols at 20 ms in **35.520 s**, with a Gabor margin of **248.83 times** the mathematical floor against a self-imposed requirement of 100 times, and a dose of **0.123 per cent** of the eight-hour occupational allowance per rendering. **A receiver whose integration window exceeds the transmission recovers at most $\log_2 \binom{1779}{3} = 29.803$ bits of the 1,776 sent — 1.68 per cent, and none of it is sequence.** And the accompanying preregistration **measures its own decision gate rather than assuming it: the four-baseline conjunction's false-positive rate is 9.5 per cent at $T = 60$, not the nominal 5.**

Five contributions are made relative to the surrounding literature. **First**, a disclosure standard stated as a specification rather than as an ethical sentiment, with a reconstruction test — *can the recipient rebuild the signal from the packet?* — as its operative criterion. **Second**, a proof that a corpus can be built so that it cannot command, and the identity between the surplus it carries and the selection it requires. **Third**, a magnitude computation that closes one candidate mechanism decisively, which is progress precisely because a closed route narrows a search. **Fourth**, a preregistration whose test is calibrated by simulation before it is used, with the measured false-positive rate published in the registration. **Fifth**, a chain-law argument that a multiplicative composition containing one unmeasured link has an **undefined** product, applied to the framework's own architecture, which is stated in exactly those terms rather than as "promising".

No dataset was collected, no cell was exposed, no participant was recruited, and no result is reported. Everything below is either exact arithmetic, an evaluation of a stated model at stated parameters, a design simulation labelled as such, or a value quoted from published work with its source named. Section 2 states the hypotheses; Section 3 the method, including the identification problem and the analogy labels; Sections 4, 5 and 6 the chain, the protocol and the composition; Sections 7 to 11 report, discuss, verify, limit and conclude; Appendices A to C carry three worked specimens.

36.2 2 Hypotheses

Several results below are theorems and cannot be falsified by observation; they are labelled as derivations and recorded as `ARITHMETIC` or `DEFINITION` in Section 9's chain. What can be wrong are the claims about what the chain achieves, what the magnitude arithmetic forecloses, and whether the proposed experiment can see what it claims to be able to see.

H1 — A contradictory corpus cannot issue a directive. Predicted: a corpus closed under negation has resultant exactly zero at every even N, and a mutually orthogonal corpus's mean resultant falls as $1/\sqrt{N}$, tracking the analytic value in simulation. **Falsified by:** a corpus construction closed under negation with a non-zero resultant, or a simulated orthogonal ensemble whose mean resultant does not track $1/\sqrt{N}$. **Result: confirmed.** $\|\sum\| = 0.000000000000$ at N = 4, 8, 12, 24; simulated mean resultants 0.497007, 0.352275, 0.288022 and 0.203292 against analytic 0.500000, 0.353553, 0.288675 and 0.204124. **This is a result about a vector model of directives, not about texts**, and Section 4.4's clause H-B states exactly what the model does and does not capture.

H2 — The surplus a maximally contradictory corpus carries equals the information required to select one of its members. Predicted: at $u = 1$ and a uniform receiver prior, $F = \ln N$ exactly equals the selection cost $\ln N$; at $N = 12$ both are 2.484907 nats. **Falsified by:** any parameterisation within the stated conditions in which the two differ. **Result: confirmed in the extremal case only**, and Section 4.4's clause H-A states that the identity fails outside $u = 1$ and a uniform prior, with both sides falling together.

H3 — The bulk-compression route from an audible acoustic field to mechanosensitive gating is closed. Predicted: $s = p/K$ with $K = 2.2 \times 10^9$ Pa requires 240.83 dB SPL for a 10^{-2} strain, which exceeds the 194.09 dB atmospheric ceiling; at the ceiling the achievable strain is 4.6057×10^{-5}, short by a factor of 217.12. **Falsified by:** a bulk modulus, a gating strain, or an achievable pressure that closes the gap — or by a demonstration that gating occurs at bulk strains four orders of magnitude smaller. **Result: confirmed by arithmetic. The closure applies to the bulk route only**; non-linear and localised routes are enumerated in Section 5.2 and are **not** closed.

H4 — A receiver slower than the transmission cannot recover sequence. Predicted: an integrator whose window exceeds 35.520 s sees composition and not order, and composition carries $\log_2 \binom{1779}{3} = 29.803$ bits of the 1,776 transmitted. **Falsified by:** a receiver model that recovers ordering information from a composition-only observation, which would be a counterexample in combinatorics rather than in biology. **Result: confirmed by arithmetic**, at 1.68 per cent of the transmission.

H5 — The four-baseline conjunction gate does not achieve its nominal false-positive rate at practical series lengths. Predicted: simulated at zero effect with $T = 60$, the gate rejects at materially more than 0.05. **Falsified by:** a calibration run returning 0.05 or below at $T = 60$. **Result: confirmed, and the number is 0.095** — nearly twice nominal. **The gate is anti-conservative at the series length the design would otherwise have used**, and lengthening the series to $T = 120$ brings it to 0.040.

One further claim is deliberately not advanced as a hypothesis. No hypothesis is offered that a cell demodulates sequence-specific information from an acoustic signal. **That is the open problem the paper exists to state, and it is recorded as `NOT ESTABLISHED` throughout rather than as a hypothesis this paper tests**, because nothing in this paper tests it.

36.3 3 Method

36.3.1 3.1 What the paper attempts

The paper specifies an encoding, states a structural theorem about the material encoded, computes a magnitude that closes one candidate mechanism, and writes a preregistration whose test is calibrated before it is used. **It reports no measurement of any biological or psychological quantity.** Two of its three worked specimens are constructed and the third is a specimen preregistration for a study that has not been run.

The paper's most consequential outputs are negative: a closed route, an undefined product, and a gate whose measured false-positive rate is nearly twice its nominal one. **Those are reported at the front of Section 7 rather than in a discussion, because a specification that hides its own closures is a brochure.**

36.3.2 3.2 Analogy discipline, declared in advance

`RIGOR_STANDARD` §8 requires every borrowing from physics to be labelled, at first use, as a derivation, a shared mathematical form, or an analogy. The labels are fixed here.

Borrowing	Label	What licenses the label
$s = p/K$ for strain in an aqueous medium	**derivation**	elementary continuum mechanics; the medium genuinely satisfies the premises, and the result is used to close a route rather than to open one
the Gabor limit $\Delta t\,\Delta f \geq 1/(4\pi)$ applied to a rendered tone	**derivation**	the premises are square-integrability and finite second moments, satisfied by a finite-energy signal under a smooth envelope [Gabor, 1946, Curzi, 2026z]
the chain law $G = \prod_i g_i$ for a cascade	**shared mathematical form**	the same product governs an optical cascade, a conversion chain and a causal chain; **no physical result transfers**, and each g_i must be measured in its own units
directives as unit vectors in an inner-product space	**modelling choice**, not a borrowing	badged in Section 4.4, clause H-B; real directives are not unit vectors and "REST NOW" is not literally the additive inverse of "WORK NOW"
the packet/header/payload correspondence for an address prefix	**shared mathematical form**	routing reads a header and does not alter a payload in both cases; **it is not a claim that cells run a network stack**, and the correspondence earns nothing beyond letting a reader of one system read the other
the Casimir pressure at biological separations	**derivation** within physics, used as a **counter-example**	the formula is exact; the point is that it is negligible [Casimir, 1948, Lamoreaux, 1997]
"resonant coupling" as a reading of older correspondence doctrines	**analogy**, and marked **speculative** in the sentence that states it	motivation only, **never evidence**; it supplies no mechanism for sequence-selectivity

Two exclusions are stated here and enforced throughout. No quantum result is used to license any claim about mind, belief or biology [Curzi, 2026aa]. And **the elegance of an encoding is never offered as evidence that anything receives it** — Section 4.11 states that as a design claim of the same kind as "this file is sorted", and failure mode FM-4.9 exists because elegance reads as explanation.

36.3.3 3.3 Entropy: which entropy, in every instance

Every entropy and every logarithm of a count in this paper is Shannon information [Shannon, 1948, Cover and Thomas, 2006]. The surplus F and the ceiling $\ln N$ are reported in **nats**; selection costs and payload sizes are reported in **bits**; the conversion is $1 \text{ nat} = 1/\ln 2 = 1.442695$ bits, so $\ln 12 = 2.484907$ nats $= 3.584963$ bits. **No thermodynamic entropy appears anywhere in this paper**, no quantity below carries units of energy per temperature, and the one place

a physical entropy could legitimately enter — the thermodynamic cost of erasing a bit [Landauer, 1961] — is not used, because no claim here depends on it. **The two objects share a name and a functional form, are different quantities with different units, and are never conflated in this paper.**

The information-theoretic bound this paper leans on hardest is the variety bound: **a regulator can absorb only the variety it can represent** [Ashby, 1956, 1958], which is the same statement as $F \leq \ln N$ in the framework's notation [Curzi, 2026]. Selection cost as $\log_2 M$ is Hartley's, extended by Shannon [Hartley, 1928, Nyquist, 1928].

36.3.4 3.4 Effective counts: saying which one

The effective count used throughout Sections 4 and 6 is **the corpus's own affine construction** $N_{\text{eff}} = 1 + (N-1)u$, which at $u = 1$ equals N and at $u = 0$ equals 1 [Curzi, 2026]. **It is NOT a Hill number of any order.** It is a linear interpolation between 1 and N, no literature in ecology, economics or information theory contains it, and **no Hill-number citation is attached to it anywhere in this paper.** The Hill numbers of order one and two — $\exp(H)$ and $1/\text{HHI}$ — are well grounded [Hill, 1973, Jost, 2006, Rényi, 1961] and **are not used here**.

The distinction matters numerically at exactly the place it is used. At $N = 12$ and $u = 0.85$ the affine count is $1 + 11(0.85) = 10.3500$; **the Hill number of order one for a distribution with that much unevenness would in general be a different number**, and a reader who reaches for the Hill-number literature to support the affine count will find it does not apply. **Saying so is cheaper than being caught.**

36.3.5 3.5 Identification, and what the protocol can and cannot recover

Two distinct identification problems arise and they are answered differently.

The Layer 1 problem is one of attribution and it is answered by design. A difference between the encoded arm and its scramble is attributable to sequence *or to nothing*, because the two arms are identical in duration, spectrum, level and symbol rate. **That is randomisation plus a matched control, and it identifies the contrast by construction rather than by assumption.** The address-swap and payload-swap arms of Section 5.11 are what convert an attributable difference into an attributable *mechanism*, and Section 5's specification declares that a positive without them is reported as **unattributed**.

The Layer 2 problem is the reflection problem and it is not answered. The framework's reflexive material — a belief held about oneself, acting through channels, changing the state that the belief was about — is a reflexive specification whose endogenous effect **is not identified from observational data** [Manski, 1993], and influence and selection are generically confounded in observational data of this kind [Shalizi and Thomas, 2011]. **The Layer 2 design adopts one remedy and pays its price: the exposure schedule is randomised**, which makes the contrast between exposed and unexposed periods identified by design. **It does not identify the reflexive parameter itself**, and no statement in this paper about the loop's gain, slope or strength is an identified empirical result. The stipulated-reference-group route [Brock and Durlauf, 2001] is named as available and is not taken. **Every claim in this paper that touches the loop is a modelling position.**

The Lucas critique applies with unusual directness because the protocol publishes its own specification [Lucas, 1976]. A disclosed corpus that participants read changes what participants do, which is the entire point; **so parameters estimated before publication need not describe behaviour after it**, and a measure of protocol quality that becomes a target stops measuring [Goodhart, 1975, Campbell, 1979]. **No defence of parameter stability is offered.** The measured social-prediction literature is consistent with the modest reading [Hofman et al., 2017, Salganik et al., 2020, Watts, 2014, Lazer et al., 2014].

36.3.6 3.6 Scale type, and the conjoint test that was not run

RIGOR_STANDARD §5 requires every measured construct to declare its scale type [Stevens, 1946, Krantz et al., 1971].

- **Frequency, time, pressure, strain, sound level in pascals, bits, nats and counts of loci are ratio-scaled** with true zeros, and every operation performed on them is licensed. Sound pressure **level** in decibels is a **logarithmic ratio scale against a fixed reference** ($20\,\mu$Pa), so differences in dB are ratios of pressures and are licensed; **sums of dB values are not, and none is taken.**
- $\log_2$ **transcript abundance is an interval scale in the log domain**, which is why the primary endpoint is a *difference in differences* rather than a ratio of ratios: differences of logs are licensed on an interval scale and are exactly what a fold-change is.
- **The Layer 2 self-report endpoint is the exposed one.** A rating scale is **ordinal**, and the storage law's multiplicative structure is **not licensed on ordinal input** [Stevens, 1946]. Section 5.9 states that where the Layer 2 instrument is ordinal, the fitted relation is **demoted in print to a monotone ordering**, and the corpus's own central formula has already been demoted on exactly this gate [Curzi, 2026t].
- **The essence index n is a count and is dimensionless**; the reference constant k is discussed in Section 9.1.

Michell's critique is the strongest objection to the framework this paper belongs to [Michell, 1997]: psychology assumes quantitative structure without testing for it, and the formal test is additive conjoint measurement [Luce and Tukey, 1964]. **It has not been run on any psychological construct in this paper and this paper does not run it.** The quantities carrying the paper's numbers are physical or combinatorial and are not exposed; **the one exposed construct, the Layer 2 self-report, is demoted for that reason. That demotion is a concession, not a defence.**

36.3.7 3.7 Scaling claims, and the procedure not run

Three power-law statements appear and **all three are defined by the model rather than estimated from data**, which Clauset et al. [2009] requires to be said explicitly.

- The Casimir pressure falls as a^{-4}. **An exact property of $\pi^2\hbar c/(240a^4)$, not an estimate.**
- The address-space count 4^L grows exponentially in address length. **A count, not a fit.**
- The chain law produces geometric decay in the number of links. **The decay constant is the per-link gain, an assumed parameter in every table below.**

No heavy-tail, scale-free or power-law claim is made anywhere in this paper on empirical data, and the maximum-likelihood-plus-goodness-of-fit procedure of Clauset et al. [2009] was therefore not run. It is named so its absence is a decision rather than an omission [Stumpf and Porter, 2012, Broido and Clauset, 2019].

36.3.8 3.8 What is presupposed

The Gabor limit and its cost schedule are presupposed from Curzi [2026z] and Gabor [1946] and are not re-derived. The essence law $f(n) = kn^2$ with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ and the odd-part pitch-class rule are presupposed as badged postulates [Curzi, 2026]: **k is a chosen reference constant, not a measured one, and the square law is a postulate about essence structure.** The two components of k are real and their quotient expressed as a frequency is not — $9/8$ is the Pythagorean whole tone [Barbour, 1951, von Helmholtz, 1885] and $\varphi^2 = \varphi + 1$ is Euclid VI.3 [Euclid, 1956, Vajda, 1989] — and Markowsky [1992] is cited here, as everywhere in this corpus that the golden section appears, because it is the standing correction to golden-ratio claims. Octave equivalence, on which folding rests, is formalised by Shepard [1982] and its perceptual limits are given by Burns [1999], Demany et al. [2013], Hoeschele et al. [2012];

that consonance depends on the spectrum rather than the ratio alone [Sethares, 2005] is the standing objection to any ratio-based claim in this area and is inherited rather than answered.

The surplus functional, its affine effective count and the ceiling $0 \leq F(u) \leq \ln N$ are presupposed from Curzi [2026]. The storage law $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$, its fixed point and its uniform bound are presupposed from Curzi [2026a]. The seven validation gates are specified in Curzi [2026t]; the four-baseline falsification suite, **including its own measured anti-conservatism — iid permutation rejecting at 0.108, circular shift at 0.120 and block permutation at 0.060 against a nominal 0.05 across 500 null trials** — is specified in Curzi [2026u] and is inherited with that measurement attached. The standing constraint that **no addressing operation, at any signal strength or modality, can cause a cell to express content its genome and accessible regulatory repertoire do not already contain** is presupposed from Curzi [2026y]. The conditional postulate and its channel-gain architecture are Curzi [2026ab]'s; the catalogue of where that postulate fails, and the requirement that grounding be established from the channel rather than from the outcome, are Curzi [2026ac]'s. The concordance discipline — that the evidence column and the precedent column carry different things — is Curzi [2026w]'s.

36.3.9 3.9 Standing honesty clauses

1. **No subliminal content of any kind.** Nothing masked, nothing below threshold, nothing concealed. **The information is the tone.**
2. **No clinical, medical or therapeutic claim is made anywhere in this paper, in either direction.** Nothing described here is a treatment, a therapy, an intervention or a modality.
3. **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal** [Curzi, 2026y]. Stated verbatim wherever the biological chain is mentioned.
4. **Nothing is delivered, therefore nothing is edited.** The architecture produces sound and cannot do otherwise; no molecule is synthesised, no vector introduced, no sequence changed.
5. **No capability is conferred.** Nothing not already latent can be reached, and the ceiling is $\ln N$ [Curzi, 2026,y].
6. **Precedent is never presented as evidence** [Curzi, 2026w].
7. k **is chosen and the outputs are essence frequencies, not physical resonances** [Curzi, 2026].

36.3.10 3.10 Bibliographic disclosure

A substantial number of the primary sources this paper relies on carry no key in this corpus's bibliography, and no key was invented for any of them. Named in the text with journal, volume, year and pages, and cited without a key: Church, Gao and Kosuri (*Science*, 2012) for DNA data storage; Qi et al. (2013) and Gilbert et al. (2014) for the separability of targeting and editing; Zetsche et al. (*Cell*, 2015) and Fonfara et al. (2016) for native crRNA-array processing; the 2021 Nobel-recognised work on mechanically gated ion channels; Tajik et al. (*Nature Materials*, 2016) for force-to-transcription; Ibsen et al. (*Nature Communications*, 2015) and Duque et al. (2022) for sonogenetic channel activation; Takahashi and Yamanaka (2006, 2007) for regulatory reprogramming; Kaptchuk et al. (2010) for open-label placebo; Levine, Gordon and Fields (1978) for naloxone-reversible placebo analgesia; Sisk et al. (2018) for the growth-mindset meta-analyses; and O'Sullivan (1845) for the political slogan Section 6.1 distinguishes this work from. The NIOSH recommended exposure limit is quoted as a published occupational standard. **Every one is a standard, locatable source; the gap is in this corpus's bibliography, and it is recorded as Limitation L-2 rather than smoothed over.**

36.4 4 The disclosed chain: from text to audible tone

36.4.1 4.1 The no-subliminals constraint

NO SUBLIMINAL CONTENT OF ANY KIND. NOTHING MASKED. NOTHING EMBEDDED BELOW THE THRESHOLD OF HEARING. NOTHING CONCEALED FROM THE LISTENER. THE INFORMATION IS THE TONE.

It is an ethical constraint, not a stylistic one, and the two kinds fail differently. A stylistic constraint is a preference: violate it and the work is worse. An ethical constraint is a boundary condition on whether the work may be done at all: violate it and the result is not a poorer version of the same thing but a different thing, out of scope regardless of how well it performs.

The argument depends on no empirical claim. A message hidden from its recipient cannot be consented to. Consent requires knowing what one is consenting to. A signal engineered so the listener cannot perceive it has been engineered so the listener cannot evaluate it, cannot compare it against their own judgement, cannot refuse it, and cannot report on it afterwards. **Every one of those capacities is the capacity to decline. Removing them is not a side effect of the concealment architecture; it *is* that architecture.**

And consent is load-bearing here in a way it is not in most engineering. **The entire model is one in which the subject's own latent capability is the mechanism**: nothing not already latent can be reached [Curzi, 2026y], and belief acts only through a real channel [Curzi, 2026ab]. In both, the person is not the object the method acts on; **the person is the part of the circuit that does the acting. A protocol built on the subject's own capability, which then conceals itself from the subject, has removed the participant from the mechanism it claims to be using. It is incoherent before it is unethical, and it is unethical.**

The same principle is a century old in a different discipline. Kerckhoffs's second principle holds that a cryptographic system must remain secure when everything about it except the key is public [Kerckhoffs, 1883] — **a design whose effectiveness depends on the design being secret has not been evaluated**, and publication is the mechanism by which it becomes evaluable. The corpus applies the same argument to channel architecture, where a separation is **strengthened** by disclosure because its effectiveness is entirely independent of whether anyone knows it is in place, so that **non-disclosure is refused as a design premise rather than merely discouraged** [Curzi, 2026]. **This paper's constraint is that argument applied to content rather than to a channel or a cipher.** The general case for publicity as a discipline rather than a courtesy is Brandeis [1914]'s.

The specification form, binding on everything downstream:

1. **Every component of the rendered signal is audible to a person of ordinary hearing at the listening position.** Not "audible in principle" — audible as rendered, at the level rendered, in the room, over the noise floor present. **An inaudible component is raised or removed. There is no third option.**
2. **No carrier, no mask, no embedding.** No content under, inside or behind another signal; no amplitude-modulated speech; no time-compressed content; no spectral hiding beneath a louder band; no content below 20 Hz or above 20 kHz intended to act on a listener; **no psychoacoustic masking exploited as a delivery mechanism.**
3. **The full source text is disclosed in plain language before exposure.** Not a summary. The corpus itself, in the language the listener reads, with the encoding table, address list, tuning and rendering parameters — **enough to reproduce the signal.**
4. **The listener can stop it and can leave.** The off switch exists, its location is disclosed, and anyone exposed may use it without asking. **Reversibility is a property of the protocol, not a courtesy extended by the operator.**
5. **The disclosure precedes exposure and is not conditional on participation.** A person who reads the corpus and declines has received the full disclosure and given nothing in exchange.

Requirement 3 distinguishes this method from every technique it superficially resembles.

Backmasking, embedded content and every commercial "subliminal" product share one architecture: content present in the signal and absent from the listener's knowledge. **The architecture here inverts that exactly: the content is present in the signal and fully present in the listener's knowledge, and the listener could have written the signal themselves from what they were told.**

36.4.2 4.2 Disclosure costs nothing that matters — and would bind even if it did

The obvious objection to a no-concealment rule is that concealment is what makes such methods work. **The answer is a measurement, and it is the most useful single fact in this framework's ethical architecture.**

Evidence. Open-label placebo works. Kaptchuk et al. (2010; **named without a key**) randomised patients with irritable bowel syndrome to placebo explicitly described to them as inert, or to no treatment, and found benefit in the open-label arm; subsequent trials in other conditions have replicated the basic finding. **Effect sizes are modest, the literature is active, and the mechanism is not settled** [Curzi, 2026ac]. Levine, Gordon and Fields (1978; **named without a key**) showed placebo analgesia to be mediated by endogenous opioids and naloxone-reversible — **a complete physical channel from expectation to measured outcome.** Taken together: **for at least one fully characterised belief-mediated channel, deception is not a necessary input.**

Precedent. The traditions that used ritual most systematically frequently made it public and its text recited aloud: the liturgy is not hidden from the congregation, the mantra is taught to the practitioner, the memory palace is built by the person who will use it out of images they choose. **This is precedent, not evidence: it records that people arrived independently at a disclosed architecture and preserved it — an argument that the architecture is findable, not that it works** [Curzi, 2026w]. **The traditions also, often, concealed**, and Section 4.14 treats that rather than selecting the convenient half of the record.

Two limits, both required. *First*, open-label placebo is evidence about expectancy effects and not about the acoustic-to-cell channel, which remains open. It shows that **one** belief-mediated channel tolerates disclosure — not that every channel does, and certainly not that a channel exists where none has been demonstrated. *Second*, **even if disclosure did cost effect size, the constraint would stand.** Section 4.1 is a boundary condition, not an empirical bet that disclosure is free. **The measurement is welcome because it means the boundary is cheap to hold, not because holding it was contingent on that.**

36.4.3 4.3 The chain, as a specification

```
STAGE 0   CORPUS      a set of N written directives, deliberately contradictory
STAGE 1   DATA        each directive -> bytes -> bits           (lossless, reversible)
STAGE 2   SEQUENCE    bits -> nucleotide string                 (lossless, reversible)
STAGE 3   ADDRESS     20-nt routing prefix per directive        (a header, not a molecule)
STAGE 4   TONE        nucleotide string -> audible tone sequence (lossless, reversible)
```

Every stage is a bijection on the data it carries — a design requirement, not an accident. The chain is reversible end to end: given the rendered audio and the published tables, any listener can recover the corpus exactly. **That is what makes requirement 3 meaningful — the listener is not being told *about* the signal, they are being given what the signal is.**

Nothing physical is delivered at any stage. No molecule is synthesised, no vector introduced, no Cas protein present, no sequence in any cell changed. Stage 2 produces a *string over the alphabet* $\{A, C, G, T\}$, a data structure; Stage 3 produces a *prefix on that string*, a routing header. **The claim that nothing is edited is not a promise about restraint; it is a statement about what the architecture can do, and the architecture can produce sound and nothing else.**

36.4.4 4.4 Determination by choice — the structural theorem

The corpus at Stage 0 is deliberately contradictory. Directive 1 says rest; directive 2 says work; directive 5 says speak; directive 6 says be silent. **The contradiction is not a hedge and not an artistic gesture. It is the structural property that makes the protocol unable to override its subject, and it can be stated exactly.**

PROVED (elementary). Model each directive as a unit vector v_i in a real inner-product space, where the direction encodes the action urged and $-v$ encodes its negation.

(a) If the corpus is closed under negation, the resultant is exactly zero:

```
sum_{i=1}^{N} v_i = 0                        exactly, for any pairing
```

Verified numerically for N = 4, 8, 12, 24: $\|\sum\| = 0.000000000000$ in every case.

(b) If the corpus is mutually orthogonal, the resultant grows only as $\sqrt{N}$ while the corpus grows as N, so the mean direction shrinks as $1/\sqrt{N}$:

N	||sum||	||mean||	1/sqrt(N)	simulated (unit vectors in R^64)
4	2.000000	0.500000	0.500000	0.497007
8	2.828427	0.353553	0.353553	0.352275
12	3.464102	0.288675	0.288675	0.288022
24	4.898979	0.204124	0.204124	0.203292

The simulated column is 2,000 draws of N isotropic unit vectors in $\mathbb{R}^{64}$ per row; at N = 50 and 100 it gives 0.140454 and 0.099395, tracking $1/\sqrt{N}$ throughout.

A field of mutually exclusive directions cannot issue a command. In case (a) the resultant is identically zero; in case (b) it is a vanishing fraction of any single member and keeps vanishing as the corpus grows. **The corpus does not point. It spans.**

PROVED (extremality of the surplus functional). $F(u) = \ln N$ if and only if the ensemble is mutually orthogonal, and $F(u) = 0$ if and only if it is parallel [Curzi, 2026]. **A maximally contradictory corpus is therefore a maximum-surplus corpus:** for $N = 12$, $F = \ln 12 = 2.484907$ nats, which is the hard ceiling $\ln N$ and cannot be exceeded.

PROVED (elementary information theory). Selecting one of N equiprobable alternatives requires $\ln N$ nats — $\log_2 12 = 3.584963$ bits for a twelve-directive corpus [Hartley, 1928, Shannon, 1948].

These two quantities are the same number, and that identity is the content of this section.

```
surplus carried by a maximally contradictory corpus     F = ln N   nats
information required to select one member of it              ln N   nats
-----------------------------------------------------------------------
N = 12:   F = 2.484907 nats = 3.584963 bits    selection = 2.484907 nats
```

The corpus supplies exactly as much surplus as the selection consumes, and it supplies zero net direction. The direction is not in the signal. It is contributed by the receiver, and its magnitude is exactly the surplus the signal carries.

Two honesty clauses attach, both required.

H-A. The identity holds under two stated conditions: $u = 1$, and a uniform receiver prior. **Under a non-uniform prior the selection information is that prior's entropy, strictly less than $\ln N$; under $u < 1$ the corpus surplus is $\ln(1 + (N-1)u) < \ln N$. Both fall together, which preserves the structure of the argument but not the exact equality — and the exact equality is claimed only in the extremal case.**

H-B. The vector model of a directive **is a model**, badged as such. **Real directives are not unit vectors, and "REST NOW" is not literally the additive inverse of "WORK NOW."** What the model captures rigorously is one thing: *a set constructed so that its elements cancel or span has no resultant, and a receiver who acts must therefore have selected.* **That conclusion depends only on the corpus genuinely containing mutually exclusive directions, which is a property of the written text and can be checked by reading it.**

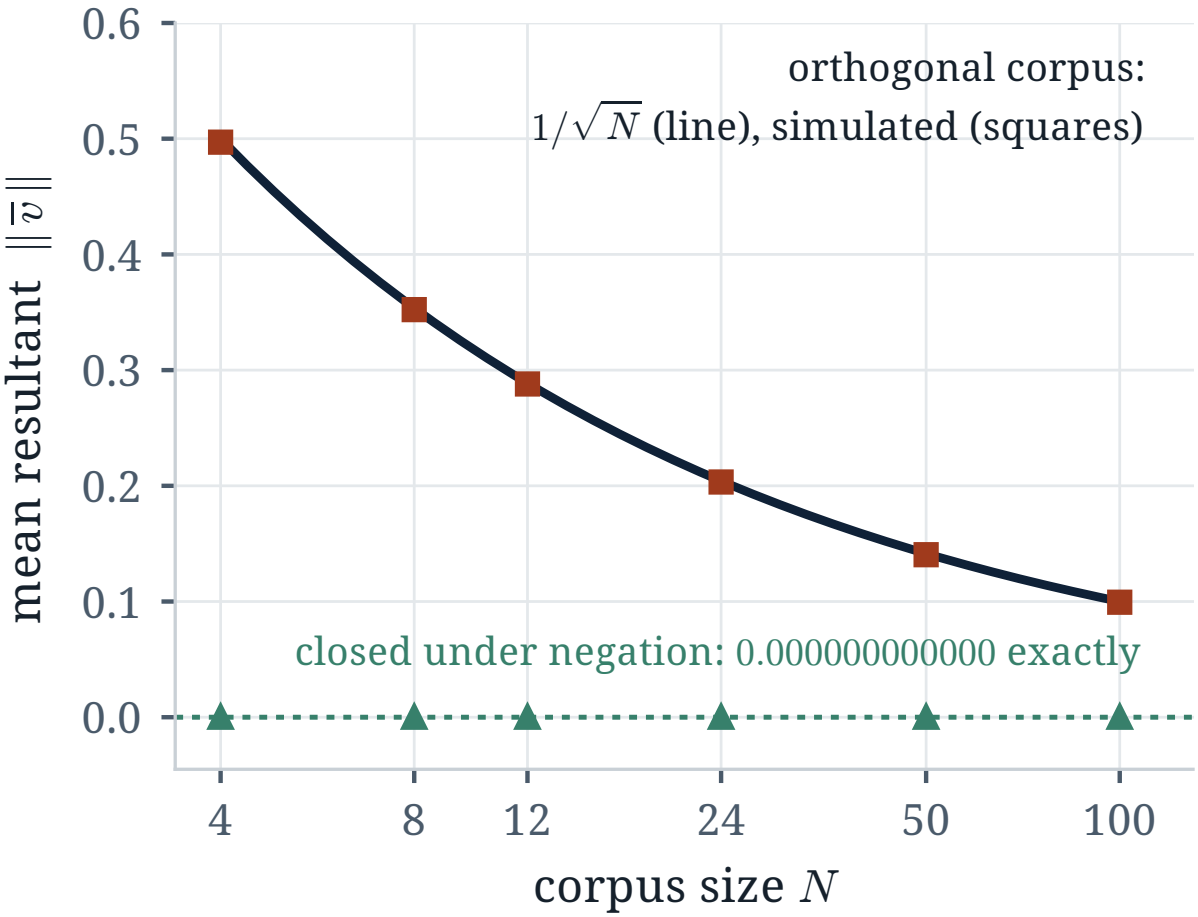

Figure 36.1: **A corpus closed under negation has resultant exactly zero, and an orthogonal corpus's mean direction vanishes as $1/\sqrt{N}$:** the analytic mean resultant $1/\sqrt{N}$ against corpus size, with the simulated values from 2,000 draws of N isotropic unit vectors in $\mathbb{R}^{64}$ per point, and the antipodal case pinned at 0.000000000000 at N = 4, 8, 12 and 24. **The simulation is a check on the arithmetic, not a measurement of any text**; the vector model of a directive is a modelling choice badged at clause H-B. Generated by `figs/src/CCP-036_fig01.py`.

36.4.5 4.5 Warrant

Claim	Status	Basis
No subliminal content; full disclosure	**CONSTRAINT** — ethical, prior, non-negotiable	Section 4.1
Disclosure need not abolish a belief-mediated effect	**CITED (measured)**	Kaptchuk et al. 2010; Levine et al. 1978, both named without a key
Data can be encoded in and recovered from nucleotide sequence	**CITED (measured)**	Church, Gao & Kosuri 2012, named without a key
A 20-nt spacer is a near-unique address in a 3.1 Gbp genome	**ARITHMETIC**	Section 4.8
Targeting and editing are separable functions	**CITED (measured)**	Qi et al. 2013; Gilbert et al. 2014, named without keys
$\Delta t\,\Delta f \geq 1/(4\pi)$ constrains symbol rate	**DERIVATION (classical Fourier)**	[Gabor, 1946, Curzi, 2026z]
$f(n) = kn^2$, $k = 0.483425732988414$	**POSTULATE** — k is chosen	[Curzi, 2026, Markowsky, 1992]
Two indices share a pitch class iff same odd part	**ARITHMETIC**	[Curzi, 2026]
A contradictory corpus has zero or vanishing resultant	**ARITHMETIC**	Section 4.4
Corpus surplus $\ln N$ equals selection information $\ln N$	**ARITHMETIC, extremal case only**	Section 4.4, with H-A
Narrative structure is carried in the harmonic	**DESIGN CLAIM** — about encoding, not effect	Section 4.11
A cell demodulates sequence-specific content from this signal	**NOT CLAIMED. OPEN PROBLEM.**	[Curzi, 2026y]
Any physiological, clinical or therapeutic effect	**NOT CLAIMED**	Section 3.9

36.4.6 4.6 Stage 1 — narrative to data

The corpus is written as plain text. The encoding to bits is ordinary and **must be published**: character set, byte width, byte order, whether a terminator is used. The reference scheme is 8-bit bytes, one byte per character, no terminator, directives kept separate rather than concatenated. For the worked corpus of Appendix A: 192 characters and therefore 1,536 bits.

Nothing interesting happens at this stage, and that is the point. Stage 1 is deliberately the most boring transformation in the chain, because any cleverness here would be a place to hide something. A published, standard, character-for-character mapping is auditable by anyone with a text editor.

36.4.7 4.7 Stage 2 — data to sequence

Evidence. Church, Gao and Kosuri (*Science*, 2012; **named without a key**) encoded a book — text and images — into synthesised DNA and read it back. **The encoding they used was deliberately *not* the information-theoretic maximum.** A four-symbol alphabet carries $\log_2 4 = 2$ bits per base at the ceiling; they used **one bit per base**, with a degenerate mapping in which A or C encodes 0 and G or T encodes 1.

```
2 bits/base   maximal density, zero freedom at each position
1 bit/base    half density, ONE FREE CHOICE at every position
```

The discarded bit buys constraint satisfaction. With two acceptable bases per bit, a synthesiser can avoid homopolymer runs, balance GC content, and dodge secondary structure without changing a single bit of payload. For a 1,536-bit payload there are 2^{1536} distinct nucleotide strings encoding exactly the same message — a 463-digit count ($1536 \log_{10} 2 = 462.382$).

The reference scheme adopts one bit per base for a second reason specific to this paper: the mapping from message to sequence is then one-to-many, so the published disclosure must include the actual sequence used, not merely the rule. A scheme where the rule determines the sequence can be disclosed by publishing the rule; a scheme where it does not must publish the string. **The weaker encoding forces the stronger disclosure, which is the right direction for the trade to run.**

corpus	chars	bits	bases @1 bpb	bases @2 bpb
the worked corpus	192	1,536	1,536	768
a 280-character message	280	2,240	2,240	1,120
a 4,000-character essay	4,000	32,000	32,000	16,000

36.4.8 4.8 Stage 3 — the address prefix

The prefix is a **routing header on a data structure**, formatted after the guide-RNA spacer: **not a molecule, not delivered, no Cas protein present** [Curzi, 2026y].

Why 20 nucleotides, computed rather than asserted. The address-space arithmetic against genome size:

```
4^20 = 1,099,511,627,776 distinct 20-mers
human genome ~3.1e9 bp; both strands ~6.2e9 positions

expected occurrences of a random 20-mer = 6.2e9 / 4^20 = 0.005639
address space / genome positions        = 4^20 / 6.2e9  = 177.34

L = 12   4^L = 1.67772e+07   expected hits in 6.2e9 = 369.5
L = 16   4^L = 4.29497e+09                         =   1.444
L = 18   4^L = 6.87195e+10                         =   0.0902
L = 20   4^L = 1.09951e+12                         =   0.005639
L = 24   4^L = 2.81475e+14                         =   0.0000220
```

Below 16 nt an address is not an address — it names hundreds of places. At 20 nt the expected number of spurious matches is about one in 177 and the address is effectively unique. That is the whole justification; it is arithmetic, and it is the same arithmetic that sets hash lengths in ordinary computing.

Precedent. Older correspondence systems assigned every operation a name, a sigil and a place in a table before the operation was performed. **This records that address-first architecture was arrived at independently and preserved; it is not evidence about spacer length or about anything molecular** [Curzi, 2026w].

HONESTY, restated in place: nothing is delivered, therefore nothing is edited. The prefix is a field in a file. Native processing of a crRNA array (Zetsche et al., *Cell*, 2015; Fonfara et al., 2016; **named without keys**) is cited for one thing only — that a *multicast destination list* is a real biological format — **and no claim is made that any such parsing occurs in response to sound.**

36.4.9 4.9 Stage 4 — sequence to tone

Four symbols must become four distinguishable tones. **Two routes are defensible and the choice must be published, because they produce different sounds.**

Route A — measured infrared spectra with fixed octave transposition. Take published, measured infrared absorption frequencies for the four nucleobases and transpose them down by a fixed integer number of octaves into the audible band. **The values must be taken from a cited spectral database and reproduced in the disclosure; this paper does not supply them, because supplying a spectral peak that has not been looked up would be exactly the fabrication the honesty clauses forbid.**

What can be computed without any citation is the transposition arithmetic. The infrared fingerprint region is conventionally 400 to 4,000 cm^{-1}. Converting by $f = c\tilde{\nu}$ with $c = 2.99792458 \times 10^{10}$ cm/s and dividing by $2^{36} = 68{,}719{,}476{,}736$:

```
 400 cm^-1  ->  1.199170e+13 Hz  ->  /2^36  =    174.5022 Hz
1000 cm^-1  ->  2.997925e+13 Hz  ->  /2^36  =    436.2554 Hz
1600 cm^-1  ->  4.796679e+13 Hz  ->  /2^36  =    698.0087 Hz
2000 cm^-1  ->  5.995849e+13 Hz  ->  /2^36  =    872.5109 Hz
3000 cm^-1  ->  8.993774e+13 Hz  ->  /2^36  =   1308.7663 Hz
4000 cm^-1  ->  1.199170e+14 Hz  ->  /2^36  =   1745.0218 Hz
```

A 36-octave transposition maps the entire infrared fingerprint region onto 174.50 Hz to 1745.02 Hz — a span of exactly $\log_2 10 = 3.321928$ octaves, inside the region of most acute human hearing. That is why 36 is the reference transposition: **not tuned to taste, but the integer that lands the whole region where a person can hear all of it.** Every value published carries its j, and here $j = -36$. **Octave transposition preserves every frequency ratio exactly** [Shepard, 1982], so the relationships among the four tones after transposition are identical to those before it: **nothing is added and nothing is distorted; it is a change of register, the only purely presentational operation in the chain.**

Route B — the essence law. $f(n) = kn^2$ with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ Hz. **k is a chosen reference constant, not a measured one, and the square law is a postulate about essence structure; both are badged here and wherever they appear** [Curzi, 2026, Markowsky, 1992]. Route B needs a defensible ordinal on the four bases; **an arbitrary ordering yields arbitrary frequencies, so the ordering must be argued in print or Route B is unavailable.**

Route B carries a trap that is invisible until it is heard. The obvious index assignment is n = 1, 2, 3, 4, whose odd parts are 1, 1, 3, 1. **Three of the four bases collapse onto a single pitch class.** Two indices share a pitch class if and only if they have the same odd part [Curzi, 2026]; $f(2) = 4f(1)$ is exactly two octaves and $f(4) = 16f(1)$ exactly four. **A listener attending to pitch class rather than absolute register hears three of the four symbols as the same note.** Two fixes, either of which must be published if used:

- **Do not fold.** Use a single global transposition j for the whole alphabet so that absolute register carries the symbol.
- **Use odd indices.** Assign n = 1, 3, 5, 7 — four distinct pitch classes. At $j = 8$:

```
n = 1   f = 0.4834257330 Hz   ->  123.7570 Hz
n = 3   f = 4.3508315969 Hz   -> 1113.8129 Hz
n = 5   f = 12.0856433247 Hz  -> 3093.9247 Hz
```

```
n = 7   f = 23.6878609164 Hz  -> 6064.0924 Hz

intervals from n=1:  0.0, 3803.9100, 5572.6274, 6737.6518 cents
minimum gap: 990.0559 Hz
```

All four land inside 20 Hz to 20 kHz. **The odd-index alphabet is the reference default for Route B.**

36.4.10 4.10 The Gabor constraint on symbol rate

DERIVATION (classical). $\Delta t\,\Delta f \geq 1/(4\pi) = 0.07957747154594767$ [Gabor, 1946, Curzi, 2026z]. **This contains no quantum mechanics and it is measurable on an oscilloscope. A short sound cannot have a precise pitch.** Applied to the four-tone alphabet with a minimum gap of 990.0559 Hz:

```
Gabor floor:  dt_min = 0.07957747 / 990.0559 Hz = 0.08037675 ms

chosen dt      frequency resolution at that window     safety factor over floor
   1 ms                 79.5775 Hz                          12.44x
  10 ms                  7.9577 Hz                         124.41x
  20 ms                  3.9789 Hz                         248.83x
  50 ms                  1.5915 Hz                         622.07x
```

The reference default is **20 ms per symbol, a safety factor of 248.83 over the floor.** The factor is large deliberately: **the floor is where two tones become mathematically indistinguishable, and a signal that must be *audibly* distinguishable to an ordinary listener in an ordinary room needs far more margin than one that must merely be separable by a matched filter. The no-subliminals constraint sets the symbol rate, not the mathematics** — a rate near the Gabor floor produces a signal whose symbols no listener can resolve, **which is a concealed signal by another route.**

At 20 ms per symbol a 1,776-base transmission (1,536 payload plus 240 address) runs 35.520 seconds.

```
dt = 10 ms  ->  17.760 s        dt = 25 ms  ->  44.400 s
dt = 20 ms  ->  35.520 s        dt = 50 ms  ->  88.800 s
```

36.4.11 4.11 The structure is carried in the harmonic

What is claimed: the relational structure of the corpus — which directives contradict which — is realised as interval structure in the rendered chord, audibly, so that a listener hearing the chord is hearing the structure and not a representation of it.

What is not claimed: that this structure does anything to any listener, any cell, or any transcript. This is a design claim of the same kind as "this file is sorted."

The corpus has $N/2$ contradictory pairs; assign each pair the indices $(m, 2m)$ with m odd. Then m and $2m$ have the same odd part, so **the two members of a pair occupy the same pitch class**; $f(2m)/f(m) = (2m)^2/m^2 = 4$ exactly, so **they are separated by exactly two octaves, 2400.0 cents, in every pair without exception**; and distinct pairs get distinct odd parts, so **each contradiction occupies its own pitch class** [Curzi, 2026].

For twelve directives paired at $(1,2),(3,6),(5,10),(7,14),(9,18),(11,22)$, the odd parts are $1,1,3,3,5,5,7,7,9,9,11,11$ — **six distinct classes for twelve tones, exactly the $\lceil N/2 \rceil$ bound realised as design rather than suffered as limitation.**

A contradiction is rendered as an octave. The two directives that cancel are the same note at two heights. A listener does not need the encoding table to hear that the corpus is built in

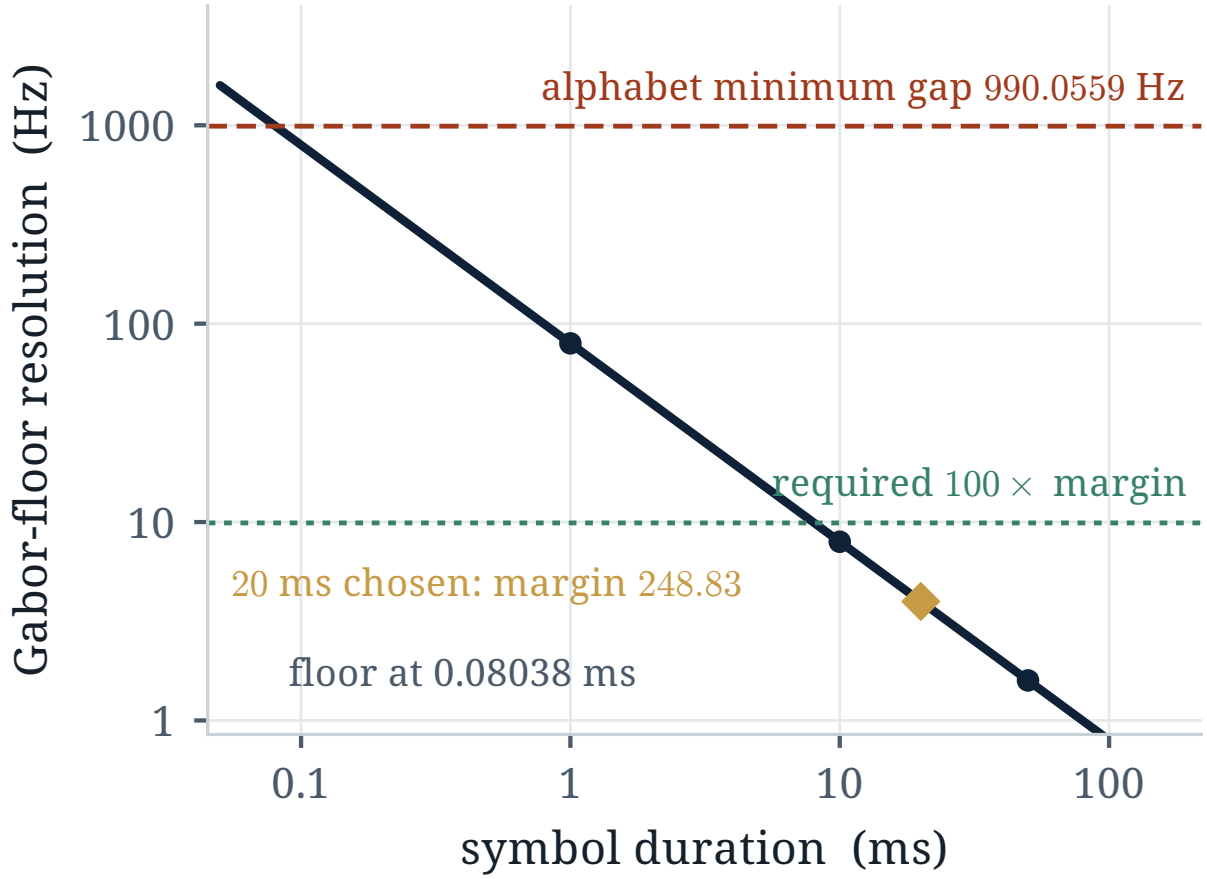

Figure 36.2: **The symbol rate is set by audibility, not by the mathematics:** achievable frequency resolution against symbol duration, with the Gabor floor $1/(4\pi\,\Delta t)$, the minimum alphabet gap of 990.0559 Hz, the self-imposed 100-fold margin requirement, and the chosen 20 ms operating point at a margin of 248.83. **The floor is where two tones become mathematically indistinguishable; the requirement is set an order of magnitude above it because the signal must be audibly resolvable by an ordinary listener.** Exact evaluation of the stated formulas at the alphabet of Section 4.9. Generated by `figs/src/CCP-036_fig02.py`.

opposed pairs — the opposition is the most audible interval in music [Shepard, 1982, Demany et al., 2013].

The pitch classes themselves, folded into one octave above the lowest tone, are exact Pythagorean and just intervals, because every essence ratio is a ratio of squares:

```
odd part  1   ->    0.0000 cents      f(1)/f(1) = 1
odd part  3   ->  203.9100 cents      f(3)/f(1) = 9   = 8 x (9/8),    the whole tone
odd part  9   ->  407.8200 cents      f(9)/f(1) = 81  = 64 x (81/64), the ditone
odd part  7   ->  737.6518 cents      f(7)/f(1) = 49  = 32 x (49/32)
odd part  5   ->  772.6274 cents      f(5)/f(1) = 25  = 16 x (25/16)
odd part 11   -> 1102.6359 cents      f(11)/f(1)= 121 = 64 x (121/64)
```

The constant k cancels out of every one of these; only the ratios of squares survive. Class 3 is exactly the Pythagorean whole tone $9/8$ above class 1, and class 9 exactly the ditone $81/64$ above it — **k's own numerator reappearing as an interval in the rendered chord. That is exact, not approximate**, and the intervals are the historically documented ones [Barbour, 1951].

The honest reading. What has been built is a *notation* in which a structural property of a text maps bijectively and audibly onto a structural property of a sound. **That is a real, checkable achievement of encoding design. It is not a mechanism, it is not a channel, and it does not become one by being elegant.** The open problem stands untouched by everything in this section [Curzi, 2026y]. **And whether ratio structure of this kind is perceived as the theory supposes is itself contested: consonance depends on the spectrum of the sound and not on the ratio alone** [Sethares, 2005, Plomp and Levelt, 1965, Terhardt, 1974].

36.4.12 4.12 Three architectures, compared

	Steganographic	Masked	Carried (this framework)
Where the content is	in a cover signal	below perceptual threshold	**it is the signal**
What the listener hears	the cover	the masker	**the content**
Can they recover it?	only with the key	not at all by ear	**yes, by ear plus tables**
Can they evaluate it?	no	no	**yes, before exposure**
Can they decline it?	no	no	**yes, at any point**
Consent status	impossible	impossible	**obtainable**
Status here	**excluded**	**excluded**	permitted

The middle column is where every historical "subliminal" technique sits, and it is excluded for the same reason as the first: in both, the recipient's inability to perceive the content is doing the work. The right-hand column is not a weakened version of the other two but a different architecture with a different failure mode, **and its worst outcome is that the listener reads the corpus and declines. That is a safety property, not a weakness.**

36.4.13 4.13 Why the contradictory corpus is the second half of the same argument

Section 4.1 protects the listener at the delivery layer; Section 4.4 protects them at the content layer, **structurally rather than by promise.** The reason both are required is visible in the alternative.

A single-directive corpus — one instruction, encoded, addressed, rendered, disclosed — satisfies every clause of Section 4.1. It is fully audible, fully published, and can be read, evaluated and declined. **And it is still a command, because a corpus with one member has a resultant equal to its member.** Its surplus is $F = \ln 1 = 0$: **a corpus of one is a parallel corpus, and parallel corpora carry no surplus at all.**

Disclosure makes a command refusable. Contradiction makes it not a command. They fail in different circumstances: **disclosure fails when the listener does not read carefully, is tired, is deferential, or trusts the operator, whereas a field of mutually exclusive directions has no resultant whether or not anyone is paying attention.**

```
CONTRADICTION REQUIREMENT

For every directive v in the corpus, its explicit negation −v is also in the corpus,
stated with equal force, equal length, and equal position in the rendering order.

No directive appears without its opposite.
No opposite is weakened, hedged, qualified, or given the last word.
The rendering order is published and is not a ranking.
```

"Equal force" is checkable and must be checked: if the pair is *("BUILD SLOWLY AND FINISH", "start again, maybe")* the corpus is not balanced, **it is a command with an alibi.** Appendix A shows the check being applied — **and failing on two pairs, which is reported rather than repaired quietly.**

36.4.14 4.14 The concordance, with each column's role stated

The evidence column carries evidence; the precedent column carries precedent. They are not two verifications of the same proposition [Curzi, 2026w].

BRIDGE 1 — a corpus may be deliberately built to contradict itself. *Evidence:* none is required; this is a property of texts and is verified by reading them. *Precedent:* the wisdom-literature tradition contains explicit adjacent contradiction — Proverbs 26:4–5 places two directives about answering a fool in direct opposition, preserved together, in sequence, by a redactor who plainly noticed; the Talmudic practice of *machloket* preserves minority opinions alongside the ruling rather than deleting them; the koan tradition constructs prompts specifically so that the corpus cannot resolve them. *Integration:* these records establish **precedent** — that a contradictory corpus was arrived at independently, repeatedly, across unrelated traditions, and deliberately preserved. **That independent arrival is a genuine argument that the structure is in the territory rather than only in this framework's instrument. It is not evidence that the structure does anything.** *Criteria:* C1 **passes** — the adjacent-opposition structure is identical, not merely similar; C2 **passes** — it predicts that such corpora preserve the rejected option in the record rather than resolve it, checkable against any of these traditions; C3 **passes**. **Status: established as a bridge about corpus construction. It says nothing about acoustics or biology.**

BRIDGE 2 — the receiver supplies the selection. *Evidence:* the arithmetic of Section 4.4 — zero resultant, $1/\sqrt{N}$ mean, $\ln N$ selection cost. **This is mathematics, and it is evidence about the model, not about people.** *Precedent:* oracle traditions are organised precisely this way — a fixed corpus supplied by the system, the selection and the reading supplied by the querent; structured decks in which every element carries its own reversal, so that the deck as a whole has no resultant meaning. *Integration:* **precedent for the architecture, not evidence for any efficacy of it. The useful observation is technical and neutral: these systems are built so that the corpus cannot determine the outcome, and the selection step is the only place the outcome can come from.** *Criteria:* C1 **passes**; C2 **passes** — it predicts that any attempt to rank the corpus members converts the oracle into a command; C3 **passes**. **Status: established as a bridge about information architecture only.**

BRIDGE 3 — encoding a message so it cannot be read is a legitimate method. REJECTED. This bridge is stated in order to be refused in print, **because a concordance method that never rejects anything is not a method** [Curzi, 2026]. *Precedent:* it is strong. Sigil methods deliberately render a sentence unreadable and hold the illegibility to be functionally necessary; alchemical cover names obscured operations systematically for centuries; mystery traditions bound initiates to secrecy. **The older corpus concealed, routinely, and this paper does not select the convenient half of the record.** *Evidence for concealment being necessary to any effect:* **none**, and the open-label result points the other way for the one belief channel that is fully characterised. *Refusal:* **C1 fails on inspection — the correspondence offered is between "the operator cannot consciously read it" and "the recipient cannot know it," which are different relations**, since a sigil practitioner encodes their own sentence and knows exactly what it said. The precedent is about self-directed attention management, not concealment from a second party. **C2 fails: no prediction distinguishes the concealed case from the disclosed case. And the bridge fails the consent constraint independently of the criteria: a method that removes the recipient's ability to decline is out of scope regardless of whether it works. Status: REJECTED — recorded so that the rejection is on the record and the older corpus is reported accurately, concealment and all.**

36.4.15 4.15 What this section does not claim

THE OPEN PROBLEM. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal [Curzi, 2026y]. Everything upstream is real: DNA data storage, guide-RNA-format addressing, native array self-processing, latent capability and its activation, epigenetic regulation, and mechanotransduction. **The channel for sequence-specific content is the question, and this section has built a transmitter for a receiver not demonstrated to exist.**

No clinical, medical or therapeutic claim is made anywhere. No claim that DNA is edited, altered or damaged — the architecture produces sound and cannot do otherwise. **No claim that any capability has been conferred**; nothing not already latent can be reached. **The essence frequencies are essence frequencies, not physical resonances**; k is chosen, and surplus as deployed is a lower bound [Curzi, 2026,?].

36.4.16 4.16 Requirements

REQ-4.1 — Audibility. Every component shall be audible to a person of ordinary hearing at every listening position, measured over the actual noise floor present. Verification: an A-weighted third-octave measurement at each position, published with the rendering.

REQ-4.2 — No concealment. No carrier, masker, embedding or time-compression; no content below 20 Hz or above 20 kHz intended to act on a listener; no psychoacoustic masking used as a delivery mechanism. **Verification: the published spectrum accounts for all energy in the rendering.**

REQ-4.3 — Full disclosure, in advance, unconditional. The packet shall contain the complete corpus text; the Stage 1 character encoding; the Stage 2 nucleotide string as actually generated; the Stage 3 address list; the Stage 4 tuning table with band and integer j for every frequency; symbol duration; rendering order; level. **A recipient shall be able to reconstruct the signal from the packet.**

REQ-4.4 — Stop and leave. An off switch exists, its location is disclosed, and any person exposed may operate it without asking. **Exposure is never a condition of remaining in a space, a study, or a relationship.**

REQ-4.5 — Contradiction. Every directive appears with its explicit negation, at equal length, equal force, and symmetric position in the rendering order. **The rendering order is published and is declared not to be a ranking.**

REQ-4.6 — No claim beyond the encoding. Any published or spoken description states the open problem and states that no clinical, medical or therapeutic claim is made.

REQ-4.7 — Reversibility of the chain. Stages 1 to 4 are bijections on the payload. **A round-trip test shall reproduce the corpus character for character, and the result is published.**

REQ-4.8 — Published encoding. Character set, byte width and byte order are published. **The one-bit-per-base mapping and the actual sequence chosen are both published, since the mapping is one-to-many.**

REQ-4.9 — Address length. Addresses are 20 nt. Any other length is published together with its expected-collision calculation against the reference genome size.

REQ-4.10 — Address neutrality. Address selection is published in advance of rendering and does not change between arms of any comparison.

REQ-4.11 — Tuning route declared. Route A requires a cited source for every spectral value; Route B requires the index ordering to be argued in print and the pitch-class check to be shown.

REQ-4.12 — Band and j published for every frequency. No exception.

REQ-4.13 — Global transposition. A single integer j applies to the whole alphabet so all frequency ratios are preserved exactly. Per-tone transposition is permitted only if the resulting ratio distortions are published.

REQ-4.14 — Gabor margin. $\Delta t \geq 100 \cdot (1/(4\pi))/\Delta f_{\min}$ — **a hundredfold margin over the mathematical floor, set by audible distinguishability rather than by separability.** The computed margin is published.

REQ-4.15 — Level and duration limits. Rendering level shall not exceed the applicable occupational exposure limit for the exposure duration. At a recommended limit of 85 dBA for 8 hours with a 3 dB exchange rate:

```
 80 dBA  ->  25.3984 h
 85 dBA  ->   8.0000 h
 88 dBA  ->   4.0000 h
 91 dBA  ->   2.0000 h
 94 dBA  ->   1.0000 h
 97 dBA  ->  30.0000 min
100 dBA  ->  15.0000 min
103 dBA  ->   7.5000 min
```

A 35.520 s rendering at 85 dBA is **0.123 per cent** of the 8-hour allowance; 100 repetitions is 59.2 minutes, **12.3 per cent** of it. **Compute the number; do not estimate it.**

REQ-4.16 — Essence honesty in print. Wherever the essence law appears in a disclosure packet, the badge appears with it: k **is chosen; the square law is a postulate; the output is an essence frequency, not a physical resonance.**

REQ-4.17 — Ordering defensibility. Route B requires the index ordering to be stated and justified. **An arbitrary ordering yields arbitrary frequencies and is not permitted.**

REQ-4.18 — No ranking by rendering. Loudness, duration, repetition count, spectral centroid and sequence position shall be equal across contradictory pairs. **Verification: a published per-directive table of all five, with the maximum pairwise asymmetry stated.**

REQ-4.19 — Corpus size. $N \geq 4$ and N even. **Below 4 the $1/\sqrt{N}$ argument has no content; an odd N cannot be closed under negation.**

REQ-4.20 — The refusal is recorded. A person who reads the packet and declines is a successful outcome of the protocol and is recorded as one. Declination rates are reported alongside any other result.

36.4.17 4.17 Failure modes

FM-4.1 — THE CARRIER. *Signature:* the rendering contains a bed, pad, ambience or masking noise, and the encoded tones sit below it — spectral analysis shows encoded energy 10 dB or more under a broadband component in the same critical band. *Why:* the raw rendering is harsh; a pad makes it pleasant, and is louder than the data before anyone notices. *Fix:* measure per-component level in third-octave bands at each listening position. **"It measures above threshold in an anechoic chamber" is not the test — the test is the room the listener is in.**

FM-4.2 — THE ULTRASONIC ANNEX. *Signature:* content above 18 kHz or below 25 Hz, "for completeness" or "for the cells rather than the ears". *Fix:* transpose by octaves until the value is inside the band and publish the j. **Content a person cannot hear is content a person cannot decline, and having put it there for a non-auditory reason makes it worse, not better.**

FM-4.3 — THE SUMMARY DISCLOSURE. *Signature:* the disclosure describes the corpus rather than reproducing it; the nucleotide string is unpublished; the address list is "available on request." *Fix:* publish the packet. **The operative test: can a recipient reconstruct the signal from what they were given? If not, they have been told about the signal, which is a different thing.**

FM-4.4 — THE WEIGHTED PAIR. *Signature:* directive and counter-directive both present, and one is 40 per cent longer, or sits later, or repeats twice as often, or is rendered 3 dB louder. *Why:* the author has a view, and it leaks in through the parameters nobody balanced. *Fix:* tabulate length, level, duration, repetition and position per directive and publish the maximum pairwise asymmetry. **A weighted contradictory corpus is a command with an alibi, and its resultant is no longer zero — not as a metaphor, but exactly as Section 4.4's arithmetic says when the vectors stop cancelling.**

FM-4.5 — THE PITCH-CLASS COLLAPSE. *Signature:* Route B with indices 1, 2, 3, 4; listeners report the signal sounds like two notes; decoding by ear fails for three of the four symbols. *Fix:* a single global j, or odd indices 1, 3, 5, 7. **Publish which.**

FM-4.6 — GABOR SMEAR. *Signature:* symbol duration set for total runtime rather than for resolution; adjacent symbols bleed into one another; decoding by matched filter succeeds while decoding by ear fails. *Fix:* REQ-4.14. **The matched filter succeeding while the ear fails is itself a no-subliminals violation, not merely a quality problem: the content is present and the listener cannot resolve it, which is the middle column of Section 4.12.**

FM-4.7 — THE SINGLETON CORPUS. *Signature:* one directive, fully disclosed, beautifully encoded, exemplary in every respect except that it is one directive. *Fix:* $F = \ln 1 = 0$. **Disclosure alone does not make a command not a command. It makes it a refusable command, which is a weaker protection and is not the one this protocol offers.**

FM-4.8 — PRECEDENT PRESENTED AS EVIDENCE. *Signature:* "the tradition knew this, and modern research confirms it," where the modern citation measures something adjacent. *Fix:* state each column's role in the sentence that draws the concordance [Curzi, 2026w].

FM-4.9 — THE IMPLIED MECHANISM. *Signature:* "the narrative is carried in the harmonic" appears without the qualification that this is a statement about encoding; the reader finishes the section believing something has been shown to reach a cell. *Why:* **Section 4.11 is genuinely elegant, and elegance reads as explanation.** *Fix:* the open problem appears in the same passage, every time. **The encoding being beautiful is not evidence that anything receives it.**

FM-4.10 — THE CONDITIONAL EXPOSURE. *Signature:* exposure occurs in a room a person needs to be in, and the off switch is behind a desk, or the person is a subordinate, or leaving costs something. *Fix:* **reversibility is a property of the circumstance and not only of the equipment.** If declining costs the person something, the protocol has not obtained consent, whatever was signed.

FM-4.11 — THE UNDEFENDED ORDERING. *Signature:* Route B with indices assigned in the order the directives happened to be typed, and the rendered intervals reported to four decimal places. *Fix:* REQ-4.17. **An arbitrary ordering yields arbitrary frequencies, and reporting them to four decimals makes the arbitrariness look like precision.**

FM-4.12 — LEVEL CREEP. *Signature:* sessions get longer or louder because the effect "seems stronger"; no dosimetry is published. *Why:* with no measured effect to calibrate against, the only feedback is impression, and impression rewards more. *Fix:* REQ-4.15, computed and published per session. **With no measured effect, "seems stronger" is not weak evidence, it is no evidence, and it is the exact input a protocol should be least responsive to.**

36.5 5 The research protocol, and a preregistration that prices its own nulls

Section 4 built a transmitter. This section specifies what may be done with it, as an operational procedure. **Every honesty clause is written into the step it constrains rather than collected at the end, because a clause at the end is a clause that can be detached from the procedure and lost.** The consent requirements are steps P0 and P1 for the same reason: **they are not advice appended to a method, they are the first two operations of it, and a run that skips them has not run the protocol.**

36.5.1 5.1 The open problem, carried forward and stated first

THERE IS NO ESTABLISHED MECHANISM BY WHICH A CELL DEMODULATES SEQUENCE-SPECIFIC INFORMATION FROM AN ACOUSTIC SIGNAL [Curzi, 2026y]. **It is restated here in full and not by reference, because a reader who arrives at a procedure section looking for a method is exactly the reader most likely to skip the statement and exactly the reader who most needs it.**

What is established, and it is a great deal. Mechanically gated ion channels are established and Nobel-recognised: mechanical force opens them, ions flow, signalling follows, and sound is mechanical, **so a real pathway exists from a pressure wave to a cellular signal.** Mechanical force at the cell surface reaches the nucleus and changes transcription (Tajik et al., *Nature Materials*, 2016). Sonogenetic channel activation exists (Ibsen et al., 2015; Duque et al., 2022). Biology builds exquisite mechanical receivers — cochlear hair cells are the existence proof. Arbitrary data can be stored in and recovered from nucleotide sequence (Church, Gao and Kosuri, 2012). Targeting and editing are separable (Qi et al., 2013; Gilbert et al., 2014). Latent capability can be activated by regulatory signal without adding information (Takahashi and Yamanaka, 2006). **All named without keys, per Section 3.10.**

What is not established is the single link between them. Every item above is either an input pathway that carries *force* or a data operation that carries *sequence*. **Nothing in the established literature carries sequence over force.** A pressure wave that opens a mechanically gated channel does so by deforming the membrane; **the channel does not care what melody deformed it.** That is not a gap in the reading of the literature; it is the literature's actual state, and it is one well-specified falsifiable question rather than a vague unknown [Curzi, 2026y,?].

The consequence is total. This is a research procedure and is presented as one. It is not a treatment. It is not a technique with a demonstrated effect. It is not a therapy, an intervention, a modality, or a protocol in any clinical sense. It is a specification for an experiment whose primary purpose is to find out whether there is anything there, **written so that the answer *no* is as reportable as the answer *yes*.**

36.5.2 5.2 A magnitude gap, computed, which closes one route

The bulk-compression route. For a plane acoustic wave in an aqueous medium the longitudinal strain amplitude is exactly $s = p/K$ with $K = 2.2 \times 10^9$ Pa the bulk modulus of water. **That is elementary continuum mechanics, not a model of anything biological.**

```
p (Pa)          strain              equivalent context
```

```
  0.02          9.09e-12           60 dB SPL in air, conversational
  0.2           9.09e-11           80 dB SPL
  0.3557        1.62e-10           85 dBA, the 8-hour occupational limit
  2.0           9.09e-10          100 dB SPL
 20.0           9.09e-09          120 dB SPL, threshold of pain
2000.0          9.09e-07          160 dB SPL
```

Membrane-tension gating of mechanosensitive channels involves areal strains of order 10^{-2}. Reaching 10^{-2} by bulk compression requires:

```
p = 1e-2 x K = 2.2e7 Pa = 22 MPa

ratio to an 85 dBA tone:  22e6 / 0.355656 = 6.1858e7
in decibels:              20 log10(6.1858e7) = 155.83 dB
required level:           85 + 155.83 = 240.83 dB SPL
```

And 240.83 dB SPL is not merely difficult, it is impossible in air. The maximum undistorted acoustic pressure amplitude in air at one atmosphere is bounded by the ambient pressure itself:

```
p_max = 101,325 Pa  ->  20 log10(101325 / 20e-6) = 194.09 dB SPL
strain at p_max     =  101325 / 2.2e9 = 4.6057e-05
still short of 1e-2 by a factor of 217.12
```

The bulk-compression route from an audible acoustic field to mechanosensitive gating is closed by more than seven orders of magnitude, and it stays closed at the physical ceiling of sound in air. This is stated plainly because it is the strongest quantitative thing that can honestly be said in the neighbourhood, and it says *no*.

What is not closed, and must be listed so the closure is not overread. The established sonogenetics results do not work by bulk compression. Focused ultrasound acts through radiation force, acoustic microstreaming, localised shear at interfaces, cavitation, and resonant response of structures whose dimensions match the wavelength — **all non-linear, all localised, and all capable of producing local strains vastly larger than the bulk figure. Those routes are open. But none of them has been shown to be sequence-selective, and sequence-selectivity is the whole of the question. Closing the bulk route narrows the search; it does not answer it.**

For calibration: the Casimir pressure at biological separations is 1.300126×10^{-3} Pa at 1 μm and 1.300126×10^{-15} Pa at 1 mm, against 1.300126×10^{5} Pa at 10 nm [Casimir, 1948, Lamoreaux, 1997, Curzi, 2026aa]. **At any biological or architectural scale the Casimir force is utterly negligible; it does nothing in a cell and nothing in a room, and it is mentioned here only so that nobody reaches for it as the missing mechanism.** The same discipline applied to the other standard exotic borrowing yields the same verdict [Morris and Thorne, 1988], and the general argument that a formalism valid at one scale carries no automatic warrant at another is Anderson [1972]'s.

36.5.3 5.3 Consent, reversibility and the right to decline — structural, not appended

Why they are structural rather than advisory, in this specific model. The whole architecture routes through the subject's own capability: nothing not already latent can be reached [Curzi, 2026y]; belief acts only through a real channel [Curzi, 2026ab]; a contradictory corpus can only be resolved by selection, and the selection belongs to the receiver (Section 4.4). **In every one of these the person is a component of the mechanism, not a target of it. Remove their knowledge, their ability to stop, or their ability to refuse, and you have not made the protocol more powerful — you have removed a component and the circuit is open.**

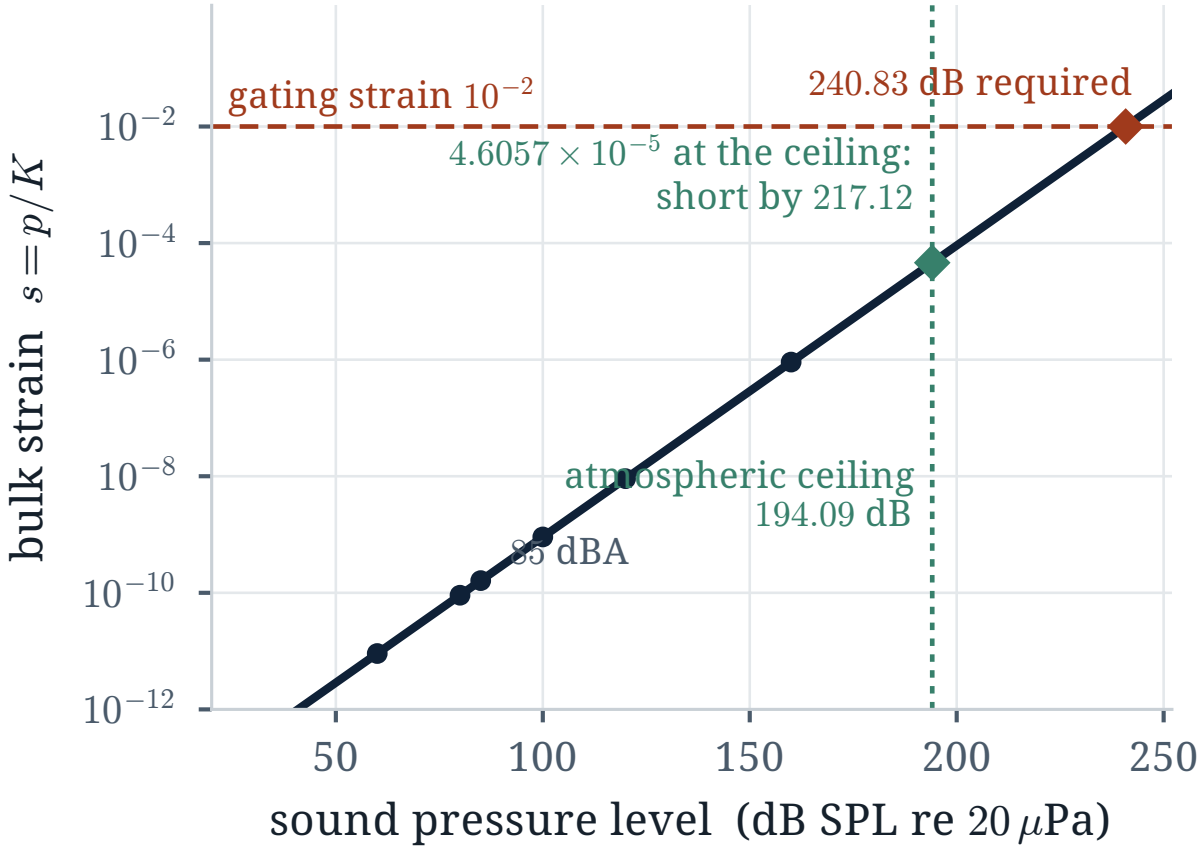

Figure 36.3: **The bulk-compression route is closed by more than seven orders of magnitude, and stays closed at the physical ceiling of sound in air:** longitudinal strain $s = p/K$ in an aqueous medium against sound pressure level, with the 10^{-2} gating strain, the 240.83 dB SPL it would require, and the 194.09 dB atmospheric ceiling set by the ambient pressure itself. **At the ceiling the achievable strain is 4.6057×10^{-5}, short by a factor of 217.12.** Exact evaluation of $s = p/K$ at $K = 2.2 \times 10^{9}$ Pa; **the 10^{-2} gating figure is an order-of-magnitude value from the membrane-mechanics literature and is treated as such.** Generated by `figs/src/CCP-036_fig03.py`.

C1 — Informed in the strong sense. The participant receives the full disclosure packet plus the statement of the open problem plus an explicit statement that no clinical, medical or therapeutic effect is claimed or expected. **They are able to reconstruct the signal from what they are given.**

C2 — Declination is free and is a recorded outcome. Declining costs nothing and is not followed up. **A protocol whose declination rate is never reported is a protocol that has never told you what happened to the people who said no.**

C3 — Withdrawal at any point, without reason, with data destruction on request, including mid-session and after the fact.

C4 — Reversibility as a property of the signal, not a promise about it. The exposure is sound; it stops when the sound stops. **Nothing is administered, ingested, injected, implanted or introduced; nothing persists after the acoustic field ends except the ordinary memory of having heard a sound.** This is not a safety assurance based on caution — **it is a statement about what the architecture is** (Section 4.3).

C5 — No conditional exposure. Exposure never occurs in a space a person must be in, and never as a condition of employment, treatment, membership, or participation in anything else.

C6 — Level and dose within occupational limits, computed per session, at a recommended limit of 85 dBA over 8 hours with a 3 dB exchange rate. **Published per session, computed, not estimated.**

C7 — No vulnerable-population recruitment for a procedure with no expected benefit. A research procedure with no demonstrated effect offers no therapeutic prospect, and recruiting people who might believe otherwise is the specific harm this clause exists to prevent. **Anyone who says they hope it will treat something is told, in the same conversation, that it will not and is not designed to, and their enrolment is declined if the belief persists.**

36.5.4 5.4 The two layers, and the firewall between them

The single most important design decision is that the open problem is tested where no person is exposed.

```
LAYER 1   IN VITRO.  Cultured cells. Tests the OPEN PROBLEM directly.
          Endpoint: transcript abundance at addressed loci vs matched non-addressed loci.
          Human participants: NONE.

LAYER 2   HUMAN, open-label, fully disclosed. Tests ONLY the established expectancy
          channel. Endpoint: self-report and behavioural measures, preregistered.
          Tests nothing about Layer 1 and is not evidence for it.
```

THE FIREWALL, and it is absolute: no Layer 2 result is ever presented as evidence for a Layer 1 claim. A person who reports that the corpus was useful has reported something about a corpus they read, a sound they chose to hear, and an expectation they held. **Every one of those is an established belief channel and none of them is a cell demodulating a sequence** [Curzi, 2026ab,ac]. **The firewall runs the other way too:** a Layer 1 result, positive or negative, says nothing about whether a person found the corpus worth reading.

36.5.5 5.5 Warrant

Claim	Status	Basis
Mechanical force opens ion channels and reaches transcription	**CITED (measured)**	2021 Nobel-recognised work; Tajik et al. 2016, named without keys
Ultrasound can activate specific channels	**CITED (measured)**	Ibsen et al. 2015; Duque et al. 2022, named without keys
A cell demodulates sequence-specific content from sound	**NOT ESTABLISHED. THE OPEN PROBLEM.**	[Curzi, 2026y]
Bulk-compression route to gating strain is closed	**ARITHMETIC**	Section 5.2, $s = p/K$
Non-linear and localised ultrasound routes remain open	**OPEN**	Section 5.2
The protocol is a research procedure, not a treatment	**DEFINITIONAL**	Section 5.1
Consent, reversibility, declination are protocol steps	**STRUCTURAL REQUIREMENT**	Section 5.3
Any clinical, medical or therapeutic effect	**NOT CLAIMED**	Section 3.9
DNA edited, altered or damaged	**NOT CLAIMED — architecturally impossible**	Section 4.3
Any capability conferred	**NOT CLAIMED**	[Curzi, 2026y]
Casimir relevance at biological scale	**NONE**	Section 5.2, computed

36.5.6 5.6 The procedure, step by step

Each step carries three lines: **DO**, **CLAIM**, and **NOT CLAIMED**, stated in place.

P0 — DECLARE THE STUDY AS RESEARCH. *DO.* Register the study publicly as a research procedure investigating whether an acoustic signal carrying sequence-formatted data produces any locus-specific transcriptional difference relative to a spectrally matched scrambled control; name the open problem in the registration abstract [Nosek et al., 2018]. *CLAIM.* That a question has been posed in a form that can be answered. *NOT CLAIMED.* Anything about the answer. **A preregistration is a commitment, not a result.**

P1 — CONSENT AND DISCLOSURE (Layer 2 only). *DO.* Deliver the disclosure packet plus the Section 5.3 statements; obtain consent; record declinations; apply C1 to C7 in full. *CLAIM.* That the participant knows what the signal is, what is claimed, and what is not. *NOT CLAIMED.* That consent makes any subsequent claim stronger. **Consent is a precondition for running, not a warrant for concluding.**

P2 — CONSTRUCT THE CORPUS. *DO.* Write N directives, N even, $N \geq 4$, closed under negation, balanced for length, force, position and repetition; run the balance check and **publish the maximum pairwise asymmetry including any failures.** *CLAIM.* That the corpus spans rather than points and its resultant is zero by construction. *NOT CLAIMED.* That the corpus content is true, wise, good for anyone, **or has any property beyond being contradictory and published.**

P3 — ENCODE. *DO.* Text to 8-bit bytes to one bit per base, choosing among the two bases available at each position so as to avoid homopolymer runs and maintain GC balance; run the round-trip verification and publish the result. *CLAIM.* That the corpus is losslessly represented as a nucleotide string. *NOT CLAIMED.* That representing text as a nucleotide string gives it any biological property. **A string over $\{A, C, G, T\}$ in a file is a data structure. It is not DNA and does not become DNA by being formatted like it.**

P4 — ADDRESS. *DO.* Prefix each payload with a 20-nt address; publish the address list and the expected-collision figure of 0.005639; fix addresses before rendering, identical across all

arms. *CLAIM.* That the transmission carries a routing header of established format and that address length is justified arithmetically. *NOT CLAIMED.* **That the address addresses anything. Nothing is delivered; no Cas protein is present; no locus is bound.**

P5 — TUNE AND RENDER. *DO.* Declare Route A or Route B; publish band and j for every frequency; set symbol duration to satisfy the Gabor margin and publish the computed margin; render. *CLAIM.* That the rendered audio is a lossless, fully audible representation of the addressed corpus at a published symbol rate. *NOT CLAIMED.* **That the essence frequencies are physical resonances; k is chosen and the square law is a postulate. That the tuning has any effect on anything.**

P6 — BUILD THE CONTROL ARMS. *This is the step the whole study turns on.*

```
ARM A   ENCODED       the addressed corpus, rendered
ARM B   SCRAMBLED     the SAME symbol multiset, permuted, rendered identically.
                      Same duration, same spectrum, same loudness, same symbol rate,
                      same disclosure. Carries no message.
ARM C   TONE-MATCHED  a signal with the same long-term spectrum and level but no
                      symbol structure at all
ARM D   SILENCE       matched duration, matched setting, no signal
```

CLAIM. That Arm B differs from Arm A **in sequence and in nothing else**, so a difference between A and B is attributable to sequence or to nothing. *NOT CLAIMED.* That the arms are indistinguishable to a listener. **Arm B may well sound different — scrambling changes the melody even when it preserves the spectrum — and any Layer 2 blinding claim must be tested rather than asserted.** For Layer 1 this does not matter, because cultures do not have expectations.

Arm B is the biological form of the shuffled-input control [Curzi, 2026u], **and it is the single most important arm in the design: it is the control that can kill the result, and every other control can be passed by an artefact.**

P7 — EXPOSE (LAYER 1). *DO.* Cultured cells, r independent replicate cultures per arm, randomised to arm, exposure through a calibrated transducer with the acoustic field mapped and published **at the cell layer, not at the source**; temperature logged continuously; handling identical across arms. *CLAIM.* That a measured acoustic field of published amplitude and spectrum was present at the cells. *NOT CLAIMED.* That the field did anything. **Acoustic exposure deposits heat and induces fluid motion; both change transcription; both are present in Arms A, B and C equally, which is precisely why Arm B rather than Arm D is the comparator for the primary endpoint.**

P8 — MEASURE (LAYER 1). *DO.* Quantify transcript abundance at n_{addr} addressed loci and n_{ctrl} matched non-addressed control loci, matched on baseline expression level, chromatin accessibility class and chromosome; analysts blind to arm. The primary statistic is a difference-in-differences:

```
DiD = ( mean log2 expr[addressed, arm A] − mean log2 expr[control loci, arm A] )
    − ( mean log2 expr[addressed, arm B] − mean log2 expr[control loci, arm B] )
```

CLAIM. That the DiD isolates any addressed-locus-specific difference between the encoded and scrambled signals, net of any global transcriptional response to sound. *NOT CLAIMED.* That a non-zero DiD would identify a mechanism. **It would establish that something sequence-dependent happened and would leave the mechanism entirely open — which is a real result and should be reported as exactly that size of result.**

P9 — EXPOSE AND MEASURE (LAYER 2). *DO.* Open-label, fully disclosed, **randomised exposure schedule**, preregistered self-report and behavioural endpoints, T periods per participant with a preregistered train/held-out split. *CLAIM.* Only that a disclosed belief-mediated channel is being operated and that any effect observed is consistent with expectancy. *NOT CLAIMED.* **Nothing about the cell. A Layer 2 effect is an expectancy effect until and unless Layer 1 says otherwise.**

P10 — FREEZE. *DO.* Fit on the training window only; freeze every parameter in a timestamped, publicly hashed record; then, and only then, open the held-out window. *CLAIM.* That the held-out numbers are out-of-sample. *NOT CLAIMED.* That freezing improves the model. **It does not. It makes the report honest, which is a different and more valuable thing.**

P11 — COMPARE AGAINST THE FOUR BASELINES. *DO.* Report held-out performance against **persistence**, **direct-input**, **matched autoregressive**, and **shuffled-input**; report all five numbers whatever they say [Curzi, 2026u].

```
PERSISTENCE          predict Y_{t+1} = Y_t.  Kills: a slow-moving outcome that any
                     model with a lagged term will appear to predict.

DIRECT-INPUT         predict Y_{t+1} from S_t alone, no storage term. Kills: the case
                     where exposure and outcome move together contemporaneously and
                     no accumulation is occurring at all.

MATCHED AR(1)        predict Y_{t+1} from Y_t with a fitted coefficient. Kills: the
                     case where the storage law's advantage is only its lag structure
                     and the input contributes nothing.

SHUFFLED-INPUT       refit with the exposure series permuted. Kills: everything that
                     does not depend on WHEN the exposure occurred. This is the one
                     that matters and the one that is omitted.
```

NOT CLAIMED. Anything from a model that beats fewer than all four. **The conjunction is the gate, and Section 5.9 gives its measured false-positive rate so that passing it means something specific. The biological analogue of the shuffled-input control is Arm B, and the correspondence is exact: shuffling the input series destroys temporal ordering while preserving the marginal distribution; scrambling the corpus destroys symbol ordering while preserving the spectrum. Both ask the same question — does the order matter?**

P12 — PUBLISH, INCLUDING THE NULL. *DO.* Publish the preregistration, the freeze hash, all five held-out numbers, all arm results, the declination rate, the dosimetry, the disclosure packet, and the raw data. **Publish a null as prominently as a positive.** *NOT CLAIMED.* That publication makes a result true.

36.5.7 5.7 Falsification criteria, stated in advance

The protocol is worthless unless it can fail, and it must be written so that failing is easy [Popper, 1959, Platt, 1964, Meehl, 1967].

F-1 (Layer 1, primary). If the difference-in-differences between Arm A and Arm B at addressed loci is not distinguishable from zero at the preregistered alpha, **the hypothesis that this signal carries sequence-specific information into transcription is not supported by this experiment.**

F-2 (Layer 1, specificity). If a difference appears at addressed loci *and equally at matched control loci*, the effect is not addressed-specific. **This is the most likely positive-looking failure, because a global acoustic response to heat or streaming will lift everything.**

F-3 (Layer 1, control equivalence). If Arm B differs from Arm A only in ways also seen between Arm C and Arm D, the difference is not about sequence.

F-4 (Layer 2, held-out). If the fitted model does not beat all four baselines out-of-sample, the model is not supported for that participant.

F-5 (Layer 2, shuffled). If the shuffled-input model performs as well as the true-input model on held-out data, **the input timing carries no information and the result is dead regardless of in-sample fit.**

F-6 (cross-individual). If parameters do not recover across participants and across sites under identical operationalisation, the model is not measuring a stable quantity.

F-7 (the whole thing). If F-1 and F-4 both fail, **the protocol has returned a null and the null is the result. It is published in the same venue, at the same length, with the same prominence.**

And the rescue clause, closed in advance. The following are declared, before data collection, to be **non-permissible** responses to a null: adding an unregistered arm; re-specifying the endpoint; extending recruitment after looking; discovering that the corpus was wrong for these cells; discovering that the participants were unsuitable; discovering that the tuning route should have been the other one. **A hypothesis rescued by a post-hoc auxiliary is a hypothesis that has stopped being falsifiable** [Lakatos, 1970, Simmons et al., 2011, Gelman and Loken, 2013].

36.5.8 5.8 The two timescale constraints, computed

The magnitude argument of Section 5.2 is about amplitude. **There is a second, independent constraint about *time*, and it points the opposite way — which is exactly the sort of thing a protocol should know before it runs.**

DERIVATION (classical). $\Delta t \, \Delta f \geq 1/(4\pi)$ [Gabor, 1946, Curzi, 2026z]: any receiver integrating over a window τ distinguishes frequencies no finer than $1/(4\pi\tau)$.

integration window tau	finest resolvable df	symbols averaged at 20 ms/symbol
0.1 ms	795.774715 Hz	0.005
1 ms	79.577472 Hz	0.05
20 ms	3.978874 Hz	1
100 ms	0.795775 Hz	5
1 s	0.079577 Hz	50
10 s	0.007958 Hz	500
35.52 s	0.002240 Hz	1776
1 min	0.001326 Hz	3000
1 h	0.000022 Hz	180000

CONSTRAINT ONE — resolution, and it is not the obstacle. The alphabet's minimum gap is 990.0559 Hz, requiring a window of only 0.08037675 ms. **Any receiver with an integration time of a tenth of a millisecond or longer has more than enough frequency resolution to tell the four symbols apart. Time-frequency uncertainty does not close this route, and it would be dishonest to invoke Gabor as a reason the hypothesis fails.**

CONSTRAINT TWO — ordering, and this one bites hard. A receiver whose integration window exceeds the message duration sees the message's *composition* and not its *order*:

symbols transmitted	1,776
information sent at one bit per base	1,776 bits
distinct compositions (n_A + n_C + n_G + n_T = 1776)	C(1779, 3)
information recoverable from composition alone	log2 C(1779,3) = 29.803 bits
fraction of the transmission that survives averaging	29.803 / 1776 = 1.678%

A receiver slower than 35.520 seconds recovers at most 29.803 bits of the 1,776 sent — 1.68 per cent — and none of it is sequence. Sequence is the entire hypothesis, so an integrator that slow is not a candidate receiver at all.

The tension this creates is the useful output of the calculation and should be stated as a constraint on any proposed mechanism rather than as an argument for or against one. A candidate receiver must be fast enough to resolve 20 ms symbols in order, **and its downstream consequence must nonetheless persist long enough to change transcript abundance measurably. Those two requirements pull in opposite directions across roughly three orders of magnitude in time**, and **"the cell integrates the signal" is precisely the answer the arithmetic above forecloses.** The design consequence is registered: **the symbol duration must be published, and a version of the study at a second symbol duration is registered as a secondary arm**, because a real sequence-dependent effect should depend on symbol rate and an artefact generally should not.

36.5.9 5.9 Design characteristics, computed

These are design characteristics computed by simulation. They are not data and no result is reported here. The noise parameter is **assumed** for the purpose of a power calculation and **must be replaced by a measured value from pilot replicates before any real preregistration is filed**; this is stated because **an assumed variance presented as measured is the commonest way a power calculation lies.**

```
n_addr  = 12 addressed loci
n_ctrl  = 120 matched control loci
sigma   = 0.35   ASSUMED sd of log2 expression across replicate cultures
test    = difference-in-differences, permutation null over locus labels within arm
```

Analytic standard error and minimum detectable effect at two-sided $\alpha = 0.05$ and 80 per cent power ($z_{0.975} + z_{0.80} = 1.959964 + 0.841621 = 2.801585$):

r (replicates/arm)	SE(DiD)	MDE (log2 fold-change)
2	0.105968	0.296878
3	0.086522	0.242400
4	0.074931	0.209924
6	0.061181	0.171402
8	0.052984	0.148439
12	0.043261	0.121200
24	0.030590	0.085701

Inverted: to detect a $\log_2$FC of 0.30 requires $r \geq 2$ per arm; 0.20 requires 5; 0.15 requires 8; 0.10 requires 18; 0.05 requires 71.

Simulated rejection rates (400 simulated studies per cell, permutation null with 400 permutations, $\alpha = 0.05$):

d (log2FC)	r = 3	r = 6	r = 12	
0.00	0.040	0.062	0.043	<- null; nominal alpha recovered
0.10	0.217	0.360	0.708	
0.20	0.685	0.902	0.995	
0.30	0.950	0.998	1.000	
0.50	1.000	1.000	1.000	

At 6 replicates per arm the design has about 90 per cent power against a $\log_2$ fold-change of 0.20 and about 36 per cent against 0.10. That is the honest statement of what the experiment can and cannot see, and it belongs in the preregistration rather than in a discussion section afterwards.

Per-locus testing is far weaker and must be reported separately. With Bonferroni correction across 12 addressed loci tested individually against 10 matched controls each ($\alpha = 0.05/12 = 0.004167$, z sum $= 3.706881$):

```
r = 3    per-locus SE = 0.299722    MDE = 1.111034
r = 6                   0.211936          0.785620
r = 12                  0.149861          0.555517
r = 24                  0.105968          0.392810
```

The aggregate DiD can detect a 0.20 $\log_2$FC while the per-locus test cannot detect anything under 0.55 at the same replicate count. Both numbers are published, because reporting only the aggregate would let a reader believe individual loci had been resolved.

Layer 2, same discipline, different instrument. The model is the storage law with the exposure schedule as input [Curzi, 2026a]:

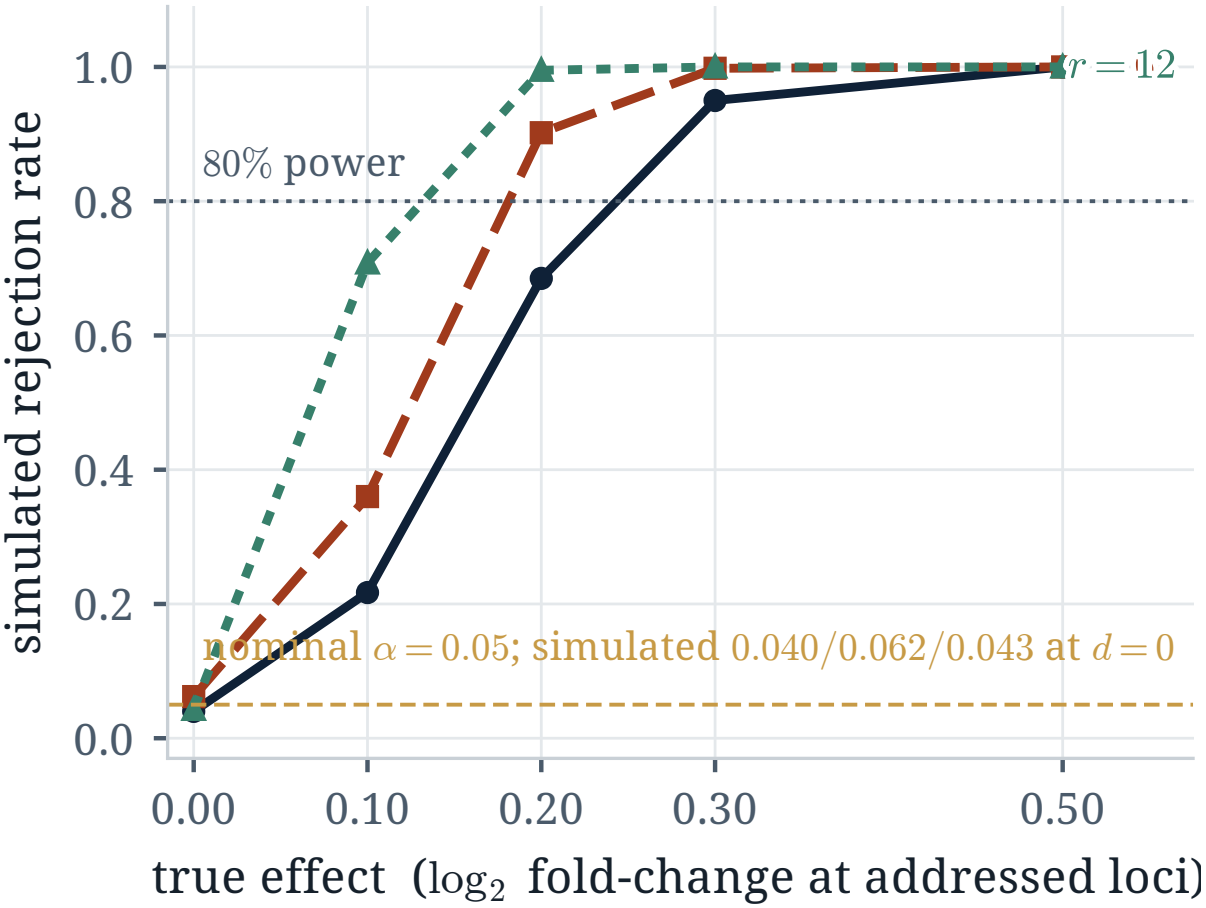

Figure 36.4: **The design is well powered against a 0.20 fold-change and underpowered against 0.10:** simulated rejection rate against true $\log_2$ fold-change at three replicate counts, 400 simulated studies per point with a 400-permutation null at $\alpha = 0.05$. **The leftmost column is the calibration check: at zero effect the test rejects at 0.040, 0.062 and 0.043, recovering nominal alpha to within simulation error.** Modelled, not measured: the noise parameter $\sigma = 0.35$ is assumed and every value scales with it. Generated by `figs/src/CCP-036_fig04.py`.

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,      S_t = ln(1 + (N−1) U_t)
```

Y is the preregistered self-report or behavioural proxy for Q; C is **measured, never estimated**. **Where Y is an ordinal rating, the multiplicative form is not licensed and the relation is demoted in print to a monotone ordering** (Section 3.6) [Stevens, 1946, Curzi, 2026t]. Two coefficients are fitted.

Design simulation, 200 synthetic runs per condition, $T = 60$ periods, first 40 for training and the last 20 held out, $\delta_{\text{true}} = 0.10$, $\eta_{\text{true}} = 0.40$, measurement noise sd 0.20. These are synthetic design characteristics, not data.

	median held-out R^2					
generator	model	persistence	direct	AR(1)	shuffled	passes all four
b = 1.0 (full)	0.3280	−0.0806	−4.9116	−0.0069	−0.1666	88.5%
b = 0.5 (half)	−0.1646	−0.5147	−0.3560	−0.2368	−0.5393	51.0%
b = 0.0 (null)	−0.5881	−1.0805	−0.3708	−0.4239	−0.5930	9.5%

Parameter recovery at $b = 1.0$: $\hat{\delta}$ median 0.1150 against a true 0.10; $\hat{\eta}$ median 0.4335 against a true 0.40. **At $b = 0.0$ the fit still returns $\hat{\eta} = 0.1290$ — a fitted coefficient on an input that does nothing, which is exactly why the shuffled control and not the coefficient's sign is the decision rule.**

The conjunction gate's false-positive rate is 9.5 per cent at $T = 60$, and this must be stated in the preregistration, because a reader who assumes 5 per cent will overread a single passing participant. Lengthening the series tightens it:

T	train	b = 0.0	b = 0.5	b = 1.0
60	40	0.095	0.482	0.895
90	60	0.052	0.590	0.940
120	80	0.040	0.603	0.950
180	120	0.013	0.630	0.978
260	180	0.010	0.662	0.993

The important column is the middle one, and it is bad news honestly reported: a half-size effect never reaches 80 per cent power under this gate at any practical series length, saturating near 0.66. The design cannot fix this by running longer; it can only fix it by replicating across people.

36.5.10 5.10 Cross-individual replication, which rescues the underpowered case

Treat each participant's pass or fail on the four-baseline conjunction as a Bernoulli trial. **Under the null the per-person pass rate is 0.095; against a half-size effect it is 0.482.** A one-sided binomial test on the count of passing participants:

n participants	reject if k >=	actual alpha	power vs b = 0.5
10	4	0.01069	0.797
12	4	0.02160	0.908
16	5	0.01381	0.948
20	5	0.03566	0.991
24	6	0.02204	0.995
30	7	0.02004	0.999

Twelve participants, with four or more passing the four-baseline conjunction, gives an actual false-positive rate of 0.0216 and 90.8 per cent power against a half-size effect that a single participant's series could only detect 48 per cent of the time. That is the argument for cross-individual replication stated as arithmetic: replication across people converts a stringent per-person gate from underpowered into adequate, and it does so without weakening the gate.

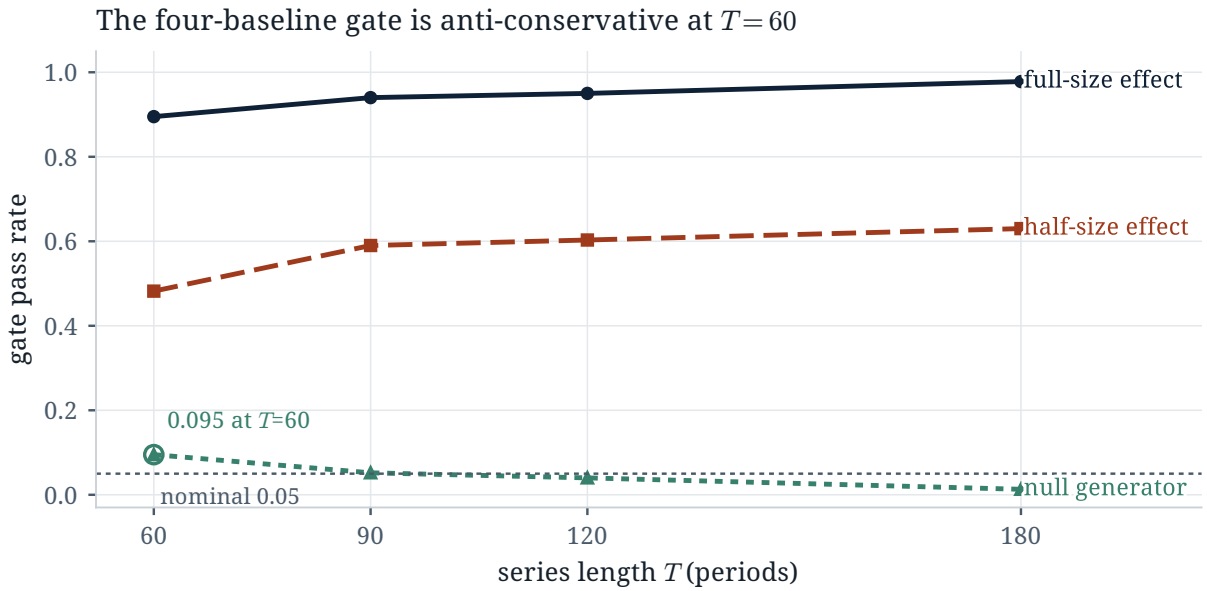

Figure 36.5: **The conjunction gate is anti-conservative at the series length the design would otherwise have used, and a half-size effect never reaches adequate power:** the four-baseline gate's pass rate against series length, for a full-size effect, a half-size effect and a null generator, from 200 synthetic runs per condition. **At $T = 60$ the null generator passes 9.5 per cent of the time against a nominal 5**, and the half-size curve saturates near 0.66 rather than approaching 0.80. Modelled, not measured: synthetic series with $\delta_{\text{true}} = 0.10$, $\eta_{\text{true}} = 0.40$ and measurement noise sd 0.20. Generated by `figs/src/CCP-036_fig05.py`.

36.5.11 5.11 What would settle the open problem, in either direction

A positive settlement would require, at minimum: (1) a DiD at addressed loci significantly different from zero against the scrambled control, with the shuffled control failing to reproduce it; (2) **address dependence** — swapping the address list with the payload held constant moves the effect to the new loci, **without which the result is not addressing but something else**; (3) **payload dependence** — holding the address list constant and changing the payload changes the result, **without which the address is acting as a bare tone**; (4) replication in an independent laboratory, from the published packet, with no contact; and (5) **a candidate mechanism that survives the magnitude arithmetic of Section 5.2** — a route by which the delivered acoustic field produces local strains or forces large enough to matter, **and** a route by which those forces are *sequence-selective*.

Item 5 is the hard one and it is where the burden actually sits. Items 1 to 4 could all be satisfied by an unrecognised artefact; a mechanism that clears the magnitude arithmetic could not.

A negative settlement is easier and is a real result: F-1 plus F-2 plus a demonstration that the design had adequate power against the effect sizes of interest — which Section 5.9 provides, at 90 per cent against 0.20 $\log_2$FC and 6 replicates. **A well-powered null on a well-specified question is worth more than a hundred underpowered positives** [Open Science Collaboration, 2015, Ioannidis, 2005].

36.5.12 5.12 The concordance for this section

BRIDGE — a staged, reversible procedure with an explicit abort at every stage. *Evidence:* pre-registration, blinding, matched controls and held-out prediction are established methodology

with a measurable effect on the reliability of published findings; the Open Science Collaboration found 97 of 100 original studies reporting significant results against roughly 36 per cent of replications succeeding, with effect sizes about halved [Open Science Collaboration, 2015]. **That is evidence about method, and it is the reason this section is shaped as it is.** *Precedent:* the alchemical operations were staged, ordered and named, with explicit conditions for stopping and returning to a prior stage, and the laboratory notebook tradition descends directly from them. **This records that staged, abortable, documented procedure was arrived at independently and preserved for centuries. It is not evidence that any alchemical claim was correct, and most were not.** *Integration:* the bridge holds at the level of *procedural form* and nowhere else. C1 **passes**; C2 **passes** — it predicts that traditions with staged procedures will record failure conditions, which is checkable; C3 **passes. Status: established as a bridge about procedure. It carries nothing about mechanism, and it is worth noting that the tradition's staged rigour coexisted with almost uniformly false theory — which is itself the argument for keeping the columns apart.**

A SPECULATIVE BRIDGE, marked speculative in the sentence that states it. It is speculative, and offered here only as a speculation, that the "sympathetic" correspondences of the older corpus — the notion that like acts on like at a distance through a shared quality rather than through contact — are a pre-instrumental description of resonant coupling, in which a driven oscillator responds selectively to a frequency matching its own. Resonance is real physics; the correspondence is a guess about what the old texts were describing; **and the speculation supplies no mechanism for sequence-selectivity and does nothing whatever to close the gap.** It is recorded so that the thought is on the page with its badge on rather than smuggled in as an implication.

36.5.13 5.13 Requirements

REQ-5.1 The open problem appears verbatim in every artefact: preregistration, consent packet, method section, abstract, any public description.

REQ-5.2 The words "treatment", "therapy", "therapeutic", "cure", "heal", "dose-response" in a clinical sense, and "patient" **do not appear** in any document describing this protocol. Participants are participants; sessions are exposures; **nothing is administered.**

REQ-5.3 Consent steps P0 and P1 precede all others, and a run that omits them is not a run of this protocol.

REQ-5.4 Declination rate is reported with every result, in the same table.

REQ-5.5 The scrambled-corpus arm is **mandatory** and is the comparator for the primary endpoint. **A study without it does not test the hypothesis.**

REQ-5.6 Acoustic field mapped **at the sample, not at the source** — pressure amplitude, spectrum and spatial uniformity at the cell layer or listening position, published.

REQ-5.7 Temperature logged continuously in Layer 1, published per arm, with the between-arm difference stated. **Acoustic heating is the leading artefact and an unlogged temperature is an unanalysable experiment.**

REQ-5.8 Control loci matched on baseline expression, accessibility class and chromosome, with the matching procedure published and run **before** unblinding.

REQ-5.9 Analysts blind to arm through primary endpoint computation.

REQ-5.10 C is measured, never estimated. A model fitted without a measured cost term is reported as a different and weaker model.

REQ-5.11 Freeze before held-out: timestamped, hashed, public.

REQ-5.12 All four baselines reported, all five numbers, whatever they say, **with the suite's own measured false-rejection rates alongside** [Curzi, 2026u].

REQ-5.13 The permutation test is calibrated, not assumed. Simulate the design at zero effect, measure the actual rejection rate, and report it. **Section 5.9's 9.5 per cent figure is what calibration looks like when it is done.**

REQ-5.14 Power is stated in advance against named effect sizes, **with the assumed variance flagged as assumed until pilot replicates replace it.**

REQ-5.15 Address-swap and payload-swap arms are required for any positive claim. **A positive result without them is reported as unattributed.**

REQ-5.16 Nulls are published at equal prominence.

REQ-5.17 Rescue clauses are closed in advance and listed in the preregistration.

REQ-5.18 Dosimetry computed and published per session.

REQ-5.19 No Layer 2 result is cited in support of a Layer 1 claim, in any document, ever.

REQ-5.20 Independent replication from the published packet is solicited, **and the packet is complete enough to permit it without contacting the authors** [Kerckhoffs, 1883].

36.5.14 5.14 Failure modes

FM-5.1 — THE MISSING SCRAMBLED ARM. *Signature:* Arms A and D only — encoded versus silence, large clean effect. *Why:* Arm B is expensive and its whole purpose is to make the result smaller. *Fix:* **encoded-versus-silence measures the effect of sound; it cannot measure the effect of sequence, which is the only question being asked.**

FM-5.2 — THE THERMAL ARTEFACT. *Signature:* effect present in Arms A, B and C equally, absent in D; correlates with exposure duration and transducer power. *Fix:* **the DiD against Arm B subtracts every response common to sound; a design that compares against silence subtracts none of them.**

FM-5.3 — THE GLOBAL LIFT. *Signature:* addressed loci up, and control loci up by the same amount, reported as positive because the addressed loci were the ones anyone looked at. *Fix:* **the DiD is the endpoint precisely so this cannot be reported as specificity.**

FM-5.4 — THE UNATTRIBUTED POSITIVE. *Signature:* a real A-versus-B difference, no address-swap arm, and a discussion section that attributes it to addressing. *Fix:* **without the swap arms the result says "something about this signal differed from its scramble" and no more, which is worth reporting exactly that way.**

FM-5.5 — LAYER LEAKAGE. *Signature:* a paper whose Layer 1 result is null and whose abstract leads with Layer 2 self-report. *Fix:* the firewall. **This is the single most likely route by which this architecture becomes an overclaim, and it usually happens in the abstract rather than in the analysis.**

FM-5.6 — THE ASSUMED VARIANCE. *Signature:* a power calculation quoting an MDE to four decimals from a variance nobody measured. *Fix:* **the tables in Section 5.9 are computed from $\sigma = 0.35$, which is assumed; replace it with pilot data before filing, and if the true σ is twice the assumption every MDE doubles.**

FM-5.7 — THE UNCALIBRATED PERMUTATION. *Signature:* a p-value of 0.03 from a permutation test, with no statement of the permutation family and no calibration run. *Fix:* **permutation tests are exact only for the exchangeability structure they assume, and the structure here — loci within arm — is a choice that must be defended** [Curzi, 2026u].

FM-5.8 — OPTIONAL STOPPING. *Signature:* r grew during the study and the final r is not the registered one. *Fix:* **looking and then adding replicates inflates the false-positive rate without limit, and no correction applied afterwards recovers it** [Simmons et al., 2011].

FM-5.9 — THERAPEUTIC DRIFT. *Signature:* a participant says it helped; the next consent form says "some participants report benefit"; six months later the word "protocol" has acquired a clinical inflection nobody decided on. *Fix:* REQ-5.2, applied to documents, in writing, at every revision. **This failure has no single moment at which it happens, which is why it needs a rule at the level of vocabulary rather than a judgement at the level of claims.**

FM-5.10 — VULNERABLE ENROLMENT. *Signature:* a participant who hopes the procedure will treat a condition, enrolled anyway because they were told it would not and said they understood. *Fix:* C7. **Understanding a disclaimer and believing it are different states, and the protocol declines enrolment on the second rather than accepting the first as sufficient.**

FM-5.11 — THE CONDITIONAL ROOM. *Signature:* Layer 2 exposure in a space participants must occupy, or with an off switch they must ask to use. *Fix:* C5. **Reversibility is a property of the circumstance, not only of the equipment.**

FM-5.12 — THE RESCUED NULL. *Signature:* a null, followed by a note that the corpus was unsuitable, the cell line atypical, the tuning route wrong, or the participants unusual. *Fix:* the closed rescue clause, registered before collection. **Every one of those statements may even be true; none of them may be made after the fact by the people who ran the study.**

FM-5.13 — PRECEDENT AS EVIDENCE. *Signature:* the staging bridge cited as support for the protocol's plausibility rather than for its form. *Fix:* **the precedent column establishes that the procedural form was findable by more than one route. It establishes nothing about whether this particular procedure will find anything.**

36.6 6 Composition: four terms, two chains, one undefined product

36.6.1 6.1 The term defined at first use — and the phrase it is not

This section uses the phrase "destiny made manifest". It does not mean, and must not be read as meaning, "Manifest Destiny". That distinction is drawn before anything else, because the second phrase carries specific historical freight that would poison every sentence that followed it.

"Manifest Destiny" is a nineteenth-century American political slogan. It entered circulation through O'Sullivan's 1845 essay "Annexation" in the *United States Magazine and Democratic Review* (**named without a key**), arguing for the annexation of Texas, and became the standing justification for continental expansion. **It was used, repeatedly and explicitly, to justify the dispossession, forced removal and killing of Indigenous peoples, on the argument that the expansion was ordained and therefore that those in its path had no standing to refuse it.** That is what the phrase did in the world. **It is not a neutral term with an unfortunate history; the history *is* the term's meaning in ordinary use.**

Everything about that construction is the opposite of what this section describes. The slogan was collective, imposed by one group upon another, asserted rather than demonstrated, and specifically constructed so that the people it was applied to could not decline. **This section's subject is personal, applies only to the person it happens to, is bounded by what is already present in that person, and — by Section 4.4 — cannot issue a directive at all. No continuity with the nineteenth-century slogan is intended, implied, or available.**

36.6.2 6.2 What the term does mean here

```
DESTINY MADE MANIFEST

A latent capability, already present in the system, brought into expression.

LATENT       the capability exists but is not currently expressed
MANIFEST     the capability is expressed
THE CHANGE   is in expression, not in what exists
```

Three clauses are load-bearing, **and each is a constraint rather than a promise.** *"Already present"*: nothing is added, and **nothing that is not already latent can be reached** [Curzi, 2026y]; Section 6.5 gives that in arithmetic. *"Brought into expression"*: the operation is regulatory — **no sequence is changed, no information is imported, nothing is edited.** *"A latent capability"*: singular, specific, and in principle nameable. **If the capability cannot be named before the attempt, the attempt has no endpoint and Section 5.7's falsification criteria cannot be written.**

36.6.3 6.3 The four terms

TERM 1	LATENT CAPABILITY	the archive is already there, and bounds the result
TERM 2	ADDRESSING WITHOUT EDITING	a locus can be named without being cut
TERM 3	BELIEF WITH A REAL CHANNEL	belief is an input to a system that must have gain, and at least one such channel is measured and survives disclosure
TERM 4	NARRATIVE AS REGULATORY INPUT	the input can be structured, disclosed, and constructed so that it cannot command

THE COMPOSITION CLAIM, badged as the author's thesis: these four are not four analogies for one idea. They are four distinct results that occupy four distinct positions in a single signal chain, and the chain is the subject of this section. And immediately, in the same breath: **one position in that chain is occupied by the open problem, the chain is multiplicative, and a multiplicative chain with one unmeasured link has an unmeasured product.**

36.6.4 6.4 Composition is multiplicative — the chain law

DERIVATION (elementary). For a cascade with gains $g_1 \dots g_n$ the end-to-end gain is the product $G = \prod_i g_i$. **This is a shared mathematical form** (Section 3.2): the same product governs an optical cascade and a causal chain, **and no physical result transfers.**

(a) A chain of individually strong links is weak. For four links of equal gain:

```
g = 0.95  ->  g^4 = 0.814506
g = 0.90  ->  g^4 = 0.656100
g = 0.80  ->  g^4 = 0.409600
g = 0.70  ->  g^4 = 0.240100
g = 0.50  ->  g^4 = 0.062500
g = 0.30  ->  g^4 = 0.008100
```

Four links that each pass 70 per cent of what reaches them deliver 24 per cent end to end.

(b) One unmeasured link makes the product unmeasured; one zero link makes it zero.

```
G = g_1 · g_2 · g_3 · x        with x unknown  ->  G unknown
                               with x = 0      ->  G = 0 exactly
```

No amount of strength in the measured links compensates for a link whose gain has never been measured. The product is not "probably fine"; it is undefined. These gain figures are arithmetic on hypothetical values. No gain in the biological chain has been measured, and the table above is a demonstration of how products behave, not an estimate of anything.

36.6.5 6.5 The latency bound, in arithmetic

The constraint that nothing not already latent can be reached has an exact form, **which converts a caution into a computable ceiling.**

DERIVATION. $0 \le F(u) \le \ln N$: **$\ln N$ is the hard ceiling on surplus per interaction**, and N is the number of distinguishable categories *already present* [Curzi, 2026]. And $Q_t \le \max\{Q_0, \eta \ln N/\delta\}$: stored order is bounded by a quantity depending on N, η and δ and on nothing else [Curzi, 2026a].

```
N ->  ln N     ceiling on Q with eta = 0.35, delta = 0.08
 2    0.693147          3.032519
 4    1.386294          6.065038
```

```
  8    2.079442          9.097557
 12    2.484907         10.871467
 20    2.995732         13.106329
 50    3.912023         17.115101
200    5.298317         23.180138
```

Raising the ceiling requires raising N — acquiring categories that were not there. Everything this section describes operates on u, the arrangement of what is already present, and u is bounded above by 1, so F is bounded above by $\ln N$. This is the variety bound appearing again [Ashby, 1956]: only variety absorbs variety, and the variety available is the variety already held. **The same ceiling, at more than one scope, from the same theorem. It was not chosen; it follows.**

36.6.6 6.6 Term one — latent capability that is already present

Evidence, and it is the strongest single result underneath this section. Takahashi and Yamanaka (2006, mouse; 2007, human; **named without a key**) showed that a small set of regulatory transcription factors reverts a differentiated somatic cell to a pluripotent state.

What makes it the keystone is precisely what it did not do. No new genetic information was introduced into the cell's repertoire. A skin cell already contained everything required to be a pluripotent cell; **what changed was which parts of that repertoire were being read.** The capability was latent, present and unexpressed; four regulatory signals changed the expression state. **That is "destiny made manifest" as a laboratory result, and it is the reason the phrase is defensible at all in a paper with these honesty clauses.**

The archive that makes latency possible. Approximately 98 per cent of the human genome is non-coding and largely regulatory. Against a genome of about 3.1 billion base pairs:

```
non-coding                    ~98%   ->  ~3.038e9 bp
transposable elements         ~45%   ->  ~1.395e9 bp
endogenous retroviral sequence  ~8%  ->  ~2.48e8 bp
coding-ish                      ~2%  ->  ~6.2e7 bp
```

And the single most striking documented instance: syncytin, indispensable to placenta formation, derives from a retroviral envelope gene — ancient foreign text, inherited, later read out as vital function.

Precedent. The contemplative traditions consistently framed development as *uncovering* rather than *acquiring*. **This records that the latency framing was arrived at independently and preserved. It is not evidence for the biology, and the biology is not a vindication of it** [Curzi, 2026w]. **What the independent arrival does establish — genuinely, and it is worth having — is that the distinction between acquiring a capability and expressing one already held is findable without instruments.**

THE CONSTRAINT, which is the term's real contribution. The reprogramming result is a demonstration of what latency permits *and* of what it forbids. **A skin cell can be reprogrammed to pluripotency because pluripotency is in its repertoire. It cannot be reprogrammed into something outside that repertoire, and no regulatory signal reaches what is not there.**

The arithmetic of how tight the constraint is runs the other way from intuition. Take the crudest accounting of the addressable space — each of roughly 20,000 protein-coding genes independently on or off:

```
addressable states       2^20000
log2                     20,000 bits
ln N                     13,862.9436 nats
log10                    6,020.6 (a number with 6,021 digits)
```

Against that, the number of distinct human cell types classically named is a few hundred:

```
ln(200) = 5.298317 nats     realized / addressable = 3.821928e-04
ln(400) = 5.991465 nats     realized / addressable = 4.321928e-04
```

The viable subset is a vanishing fraction — under one twentieth of one per cent — of the addressable one. The addressable space is astronomically large, which is why "latent" is not a small word. The viable subset is a vanishing fraction of it, which is why "bounded by what is already there" is not a formality. Most of the addressable space is not a capability; it is a dead cell.

36.6.7 6.7 Term two — addressing without editing

Evidence. The catalytically dead nuclease with a transcriptional activator (Qi et al., 2013; Gilbert et al., 2014; **named without keys**) is the established proof that **targeting and editing are separable functions**: bind a locus, activate transcription, cut nothing. Native self-processing of a crRNA array (Zetsche et al., 2015; Fonfara et al., 2016) is the established proof that a **multicast destination list** is a real biological format.

The packet correspondence, stated exactly and no further. A packet carries a destination header and a payload; routing reads the header; the payload is not altered by being routed. The guide-RNA spacer occupies the header position in the same sense. **The correspondence is about format. It is not a claim that cells run a network stack, and the analogy earns nothing beyond letting a reader who knows one system read the other** (Section 3.2).

What this term contributes: a way for an input to be specific without being destructive. Without it, any influence on expression would have to be either global or invasive. **With it, specificity and non-destructiveness are compatible in principle, and that compatibility is what makes the rest of the architecture conceivable at all. And the honesty clause, in place: nothing is delivered here, therefore nothing is edited. The term contributes the *concept* that targeting and editing separate. It does not contribute a mechanism by which an acoustic signal targets anything.**

36.6.8 6.8 Term three — belief coupled to a real channel

THE POSTULATE, badged as the framework's own: *belief creates reality if the belief is grounded in truth* [Curzi, 2026ab]. **The conditional clause is the entire content**, and "grounded in truth" means operationally that the channel exists and is real:

```
BELIEF  ->  [ CHANNEL ]  ->  WORLD

"grounded in truth"  =  THE CHANNEL EXISTS AND IS REAL

no channel  ->  no effect, regardless of the strength or sincerity of the belief
```

This is the same architecture as the storage law: input, conversion efficiency, output. A belief with no channel is $\eta = 0$ [Curzi, 2026a].

Evidence — the complete channel. Levine, Gordon and Fields (1978; **named without a key**): placebo analgesia is mediated by endogenous opioids and is naloxone-reversible. **Belief to expectation to neurochemistry to measured analgesia, verified end to end, with a pharmacological blockade that reverses it. Evidence — disclosure does not abolish it.** Kaptchuk et al. (2010) and subsequent trials: open-label placebo produces benefit; effect sizes are modest and the literature is active. **Evidence — the mechanism named independently.** Merton [1948]: self-fulfilling prophecy — **and the crucial detail, that the classic bank-run example works because banks really are fractional-reserve. The belief propagates because it is coupled to a true feature of the system** [Curzi, 2026ac].

Evidence — and now the failures, which are required. Belief does not move objects. It does not alter another person's body at a distance. It does not change physical constants. It does not cure disease by itself. Growth-mindset effects are very small in large replications (Sisk et al., 2018; named without a key) — a correlation near $r = 0.10$ and interventions near $d = 0.08$, which is 96.809 per cent distribution overlap. Expectancy effects are real, modest, and have a contested methodological history [Curzi, 2026ac, Rosenthal and Jacobson, 1968, Jussim and Harber, 2005, McCambridge et al., 2014].

A postulate that names where it fails is a postulate that can be trusted where it holds, and the catalogue of failures is what makes term three usable rather than decorative. Every failure in that list has the same diagnosis: no channel.

Precedent. The traditions that treated conviction as efficacious recorded the observation and preserved it, generally without the conditional. **This is precedent. It is not evidence, and specifically it is not evidence for the unconditional version, which the failure catalogue refutes. The traditions' failure to state the conditional is where they were wrong, and saying so is part of reporting the record accurately.**

36.6.9 6.9 Term four — narrative as regulatory input

Section 4 supplies this term and it contributes three things with **different statuses**.

(a) A construction. A narrative can be encoded, addressed and rendered as fully audible tone, losslessly and reversibly: 192 characters, 1,776 symbols, 35.520 seconds, 8.918863 octaves, entirely within the audible band. **Status: demonstrated as encoding. It says nothing about any receiver.**

(b) A constraint. The no-subliminals rule. **A message hidden from its recipient cannot be consented to, and in a model where the subject's own latent capability is the mechanism, concealment does not strengthen the protocol, it removes a component of it. Status: ethical constraint, prior to design.**

(c) A structural result. A corpus closed under negation has resultant exactly zero; a mutually orthogonal corpus has mean resultant $1/\sqrt{N}$, falling to 0.288675 at $N = 12$ and 0.204124 at $N = 24$. **A field of mutually exclusive directions cannot issue a command; it can only be resolved by selection, and the selection belongs to the receiver.** And the exact identity:

```
surplus carried by a maximally contradictory corpus, N = 12   ln 12 = 2.484907 nats
information required to select one of its members             ln 12 = 2.484907 nats
contributed by the corpus                                     0
contributed by the receiver                                   all of it
```

Status: derived, in the extremal case, under a uniform receiver prior (clause H-A). Term four is therefore the term that makes the architecture non-coercive by construction rather than by promise.

36.6.10 6.10 How the four compose — two chains, one closed and one open

Assemble the four terms and two distinct chains appear. They share their first and last links and differ in the middle.

```
CHAIN A -- ESTABLISHED END TO END

  [4] narrative, disclosed, contradictory, chosen from
        |
        v  (reading, deciding, believing -- the receiver's selection)
  [3] belief with a real channel
        |
```

```
        v  expectation -> endogenous opioid / autonomic / behavioural
    [ ] measured outcome

    STATUS: every link measured. Gain modest. Survives disclosure.
            This chain is real today and it is not nothing.

CHAIN B -- ONE LINK OPEN

    [4] narrative encoded, addressed, rendered as tone          BUILT
          |
          v  acoustic field at the cell
    [?] SEQUENCE-SPECIFIC DEMODULATION BY THE CELL              NOT ESTABLISHED
          |
          v
    [2] addressed, non-editing regulation                       established as a
          |                                                     principle, not as a
          v                                                     consequence of sound
    [1] latent capability expressed                             established mechanism
                                                                (by other means)

    STATUS: links 4, 2 and 1 are each established. Link [?] has never been measured.
            By Section 6.4, THE PRODUCT IS UNDEFINED, and if the missing gain is zero
            the product is exactly zero.
```

The two chains must never be conflated, and Section 5.4 makes the separation a structural requirement of the protocol rather than a caution in a discussion section.

Now the observation that makes the honest reading the strong one. Chain A is not a consolation prize. A person reads a disclosed, deliberately contradictory corpus. Nothing in it tells them what to do; the corpus's resultant is zero and **the entire** $\ln N$ **of selection is contributed by them.** They select. **That selection is a belief, held by a person, about their own conduct — and belief about one's own conduct is coupled to the world through the most thoroughly documented channels the postulate has: expectation, autonomic response, endogenous opioid signalling, and, above all, what the person then does.**

Chain A's channel is real, measured, and does not require deception. It is also modest, and the failure catalogue is the honest boundary on it [Curzi, 2026ac]. **But "modest, real, measured, disclosed and chosen" is a considerably stronger thing to be able to say than "large, claimed, unmeasured and concealed."**

36.6.11 6.11 The link-by-link ledger

Link	What it is	Status	If it fails
A1 Corpus construction	contradictory, balanced, published	**ARITHMETIC**, by inspection of the text	corpus becomes a command; FM-4.4, FM-4.7
A2 Disclosure	full packet, in advance, unconditional	**CONSTRAINT** — held or not held	consent invalid; protocol not run
A3 Selection by receiver	$\ln N$ nats supplied by the person	**ARITHMETIC** in the extremal case	if the corpus is unbalanced, the selection is partly the operator's

Link	What it is	Status	If it fails
A4 Belief to channel	expectation to physiology and conduct	**CITED (measured), modest**	the failure catalogue: no channel, no effect
A5 Outcome measured	preregistered, held-out, four baselines	**METHOD** — Section 5	unmeasured claim; FM-5.9
B1 Encoding to tone	lossless, audible, reversible	**BUILT**	round-trip fails; REQ-4.7
B2 Acoustic field at the cell	mapped, calibrated, published	**MEASURABLE**	unanalysable exposure; REQ-5.6
B3 Sequence-specific demodulation	**the open problem**	**NOT ESTABLISHED**	**the chain's product is zero**
B4 Addressed non-editing regulation	the dead-nuclease principle	**CITED as principle**	no consequence follows without B3
B5 Latent capability expressed	regulatory reprogramming	**CITED, by other means**	bounded by Section 6.5 regardless

Read down the Status column and the architecture's real shape is visible: eight of ten links are established or are constraints under the operator's control, and one link — B3 — is unmeasured. The section's whole content is that this is what the situation is, stated in a form that can be checked rather than in a form that can be believed. And **B5 is bounded by Section 6.5 regardless of anything upstream: even a fully closed Chain B would be capped at** $\ln N$**. The ceiling does not move when the channel opens.**

36.6.12 6.12 What the bound buys

A bounded claim is a checkable claim. "This can express what is already latent" names a candidate set in advance, which means the attempt has an endpoint, which means Section 5 can write a falsification criterion for it. **"This can bring about whatever you envision" names no set, has no endpoint, and cannot fail — which is precisely why it cannot be tested and precisely why nothing built on it accumulates** [Popper, 1959, Meehl, 1967].

A bounded claim also has a specific safety property. If nothing outside the latent set can be reached, the worst outcome of a failed attempt is that nothing happens. **An architecture whose failure mode is "no effect" is categorically different from one whose failure mode is "an unintended effect", and the difference is structural: the architecture produces sound and nothing else.**

And the bound is what makes the claim survive contact with the honest catalogue. Every item on the list of where belief fails — moving objects, acting on another body at a distance, changing constants, curing disease alone — **is outside the latent set of the person holding the belief. The bound predicts the catalogue** [Curzi, 2026ac]. **A model that predicts its own known failure cases is doing work.**

36.6.13 6.13 Chosen by the person it happens to

The argument, in three steps. *Step 1:* the corpus is deliberately contradictory and therefore has zero or vanishing resultant — $\|\sum\| = 0.000000000000$ at N = 4, 8, 12, 24. *Step 2:* therefore no direction is issued by the signal; whatever direction obtains was contributed by the receiver's selection, and its information content is $\ln N$ nats — for $N = 12$, 2.484907 nats or 3.584963 bits. *Step 3:* the mechanism downstream of the selection is the receiver's own latent capability, bounded by $\ln N$ of their own categories and expressed rather than added.

At no point in that sequence does anything originate outside the person. The corpus supplies a span; the person supplies the direction; the person's own archive supplies the material;

the person's own ceiling supplies the bound. **That is why the nineteenth-century slogan is not merely a different meaning of the word but a structural opposite: it asserted a direction over people who had not selected it, whereas this architecture cannot supply a direction at all.**

And the reversibility clause completes it. The exposure is sound; it stops when the sound stops; nothing is administered or introduced. **A person can decline before, stop during and withdraw after, and the declination is recorded as an outcome of the protocol rather than as a failure of it.**

36.6.14 6.14 Why the honest form is the more powerful one

The overclaiming form would say: a narrative encoded as sound reaches the cell, activates latent capability, and makes a person's destiny manifest. It would be more exciting for about one page. Then: **it names no endpoint, so it cannot be tested; it survives no contact with the failure catalogue; it requires the reader to take the one unmeasured link on faith, which means the whole chain rests on faith by Section 6.4; and it collapses the moment anyone computes the strain figure of Section 5.2. It is also, by its own logic, a claim about something done *to* a person, which puts it in the same structural family as the slogan Section 6.1 spent its length distinguishing this work from.**

```
ESTABLISHED AND AVAILABLE NOW (Chain A)

  A person constructs or receives a corpus that cannot command them,
  reads all of it, selects from it -- contributing ln N nats of direction
  that the corpus did not contain --
  holds the resulting belief,
  and that belief acts through channels that are measured, disclosed,
  naloxone-reversible in at least one documented case, and modest in size.

  Everything in that sentence is established. None of it requires deception.
  All of it is bounded by what the person already holds.

NOT ESTABLISHED (Chain B, link B3)

  That the same corpus, rendered as tone, is demodulated by a cell.
```

And the specific reason the honest form is stronger, stated as an argument rather than as a preference. A claim's usefulness is the product of its size and its probability of being true — **which is Section 6.4's chain law applied to epistemics. A large claim with an unmeasured link has an undefined product. A modest claim with every link measured has a defined one. The second is worth more, not as a matter of taste, but because you can build the next thing on top of it.**

36.6.15 6.15 Requirements

REQ-6.1 Define the term at first use in any document, in full, with the distinction from the nineteenth-century slogan. **Not a footnote and not a later clarification.**

REQ-6.2 Prefer "destiny made manifest" or "manifestation" in running text. **The two-word slogan form is not used.**

REQ-6.3 Name the capability before the attempt. **A latent capability that cannot be named in advance has no endpoint and no falsification criterion, and no attempt proceeds on it.**

REQ-6.4 State the bound with the claim. **"Bounded by what is already present" is part of the claim, not a caveat on it.**

REQ-6.5 Identify which chain you are in. **No document mixes them.**

REQ-6.6 State link B3's status verbatim wherever Chain B is mentioned.

REQ-6.7 Compute the composition, do not assert it. **A chain containing an unmeasured gain is reported as having an undefined product, never as "promising".**

REQ-6.8 Report the failure catalogue with the postulate, in the same passage.

REQ-6.9 The corpus must be able to say no to itself. **A corpus that has been "balanced" but whose pairs differ in length, level, repetition or position is reported with its measured asymmetry.**

REQ-6.10 Declination is an outcome. Recorded and reported.

REQ-6.11 No conferral language. **The words "confers", "grants", "unlocks", "installs", "upgrades" and "activates in you" are not used. The architecture expresses what is present; it does not add.**

REQ-6.12 No clinical vocabulary, in any document in this line of work.

REQ-6.13 Precedent labelled as precedent. **Every precedent citation states what it records and states that recording is not measuring.**

REQ-6.14 Speculative bridges marked in the sentence that states them. **Not in a preamble, not in a closing note.**

REQ-6.15 Reversibility stated as an architectural property, with its basis.

36.6.16 6.16 Failure modes

FM-6.1 — THE SLOGAN COLLISION. *Signature:* a talk, abstract or heading uses the two-word slogan, or uses "destiny made manifest" without the distinction. *Why:* the two-word form is shorter and more familiar, **which is exactly the problem.** *Fix:* **the distinction is drawn at first use, every time, in full. There is no audience for whom it can be assumed, and the cost of drawing it is two sentences.**

FM-6.2 — THE UNBOUNDED PROMISE. *Signature:* "whatever you can envision"; no candidate set named; no endpoint, so no attempt can fail. *Fix:* $F \leq \ln N$ stated with the claim. **An unfalsifiable promise is not a large claim, it is an absent one.**

FM-6.3 — THE UNDEFINED PRODUCT. *Signature:* four links, three measured and one not, presented as a chain that "works", with the word "promising" doing the load-bearing. *Fix:* **an unmeasured link does not deliver 70 per cent, it delivers an unknown.**

FM-6.4 — CHAIN CONFLATION. *Signature:* a participant reports benefit from Chain A, and the next document describes it as evidence that the signal reached a cell. *Fix:* the firewall. **This is the single most likely route by which the architecture becomes an overclaim, and it typically happens in an abstract or a summary rather than in an analysis.**

FM-6.5 — THE CONFERRAL VERB. *Signature:* "activates capabilities in the listener"; a verb whose subject is the protocol and whose object is the person. *Fix:* **grammar carries the claim. "The protocol confers X" asserts a mechanism the architecture does not have; "a capability already present may come to be expressed" asserts what the model actually contains.**

FM-6.6 — THE SELECTIVE PRECEDENT. *Signature:* the precedent column cited where the traditions agree and omitted where they were wrong. *Fix:* **report the record, not the useful half of it. A concordance that only ever finds agreement has stopped being a method and become a search** [Curzi, 2026].

FM-6.7 — PRECEDENT DOING EVIDENCE'S JOB. *Signature:* "the traditions said development is uncovering; the biology confirms it", implying two verifications where there is one. *Fix:* **what independent arrival establishes — that the framing was findable by more than one route — is real and is smaller than confirmation.**

FM-6.8 — THE CEILING IGNORED. *Signature:* a programme working on u and reporting gains as though the ceiling could be exceeded by working harder on arrangement. *Fix:* $u \leq 1$, **so** $F \leq \ln N$. **At** $\eta = 0.35$ **and** $\delta = 0.08$**, moving from** $N = 12$ **to** $N = 20$ **raises the ceiling from 10.871467 to 13.106329; no amount of work on** u **does that.**

FM-6.9 — THE PREORDINATION SLIDE. *Signature:* "destiny" begins to carry the sense of a fixed outcome awaiting discovery; selection quietly disappears from the description. *Fix:* **preordination and this model are opposite structures, not similar ones: preordination fixes the outcome independent of selection, and selection is this model's only source of direction.**

FM-6.10 — THE MODEST CLAIM INFLATED IN TRANSIT. *Signature:* the paper says "modest, measured, disclosed"; the summary says "measured"; the press line says "proven". *Fix:* **every restatement drops a qualifier, so the qualifiers must be inside the claim's main clause rather than trailing it.**

36.7 7 Results

36.7.1 7.1 R1 — determination by choice, proved

A corpus closed under negation has resultant exactly zero: $\|\sum_i v_i\| = 0.000000000000$ at N = 4, 8, 12 and 24, for any pairing. **A mutually orthogonal corpus's mean direction shrinks as** $1/\sqrt{N}$ — analytic values 0.500000, 0.353553, 0.288675 and 0.204124 at those sizes, against simulated 0.497007, 0.352275, 0.288022 and 0.203292 from 2,000 draws of N isotropic unit vectors in $\mathbb{R}^{64}$ per row, and 0.140454 and 0.099395 at N = 50 and 100. **A field of mutually exclusive directions cannot issue a command: the corpus does not point, it spans. The vector representation of a directive is a modelling choice, badged at clause H-B**, and what the result rigorously establishes is that **a set constructed so that its elements cancel has no resultant, and a receiver who acts must therefore have selected.**

36.7.2 7.2 R2 — a maximally contradictory corpus is a maximum-surplus corpus

At $N = 12$, $F = \ln 12 = 2.484907$ **nats** $= 3.584963$ **bits — the hard ceiling** $\ln N$, **which cannot be exceeded — and this is exactly the information required to select one of the twelve members. The corpus supplies as much surplus as the selection consumes and supplies zero net direction; the direction is contributed by the receiver, and its magnitude is exactly the surplus the signal carries. The identity is claimed only in the extremal case**: at $u < 1$ the surplus is $\ln(1 + (N-1)u) < \ln N$ and under a non-uniform prior the selection cost is that prior's entropy, **and both fall together, which preserves the structure of the argument and not the exact equality** (clause H-A).

36.7.3 7.3 R3 — the bulk-compression route, closed

$s = p/K$ **with** $K = 2.2 \times 10^9$ **Pa requires** 2.2×10^7 **Pa — 240.83 dB SPL — to produce the** 10^{-2} **strain associated with mechanosensitive gating, against an atmospheric ceiling of 194.09 dB SPL set by the ambient pressure itself. At that ceiling the achievable bulk strain is** 4.6057×10^{-5}, **short by a factor of 217.12. The route is closed by more than seven orders of magnitude and stays closed at the physical ceiling of sound in air. The closure is of the bulk route only**: radiation force, microstreaming, localised shear, cavitation and dimensional resonance are non-linear and localised and are **not** closed — **but none has been shown to be sequence-selective, and closing the bulk route narrows the search without answering it.**

36.7.4 7.4 R4 — the averaging bound

A receiver whose integration window exceeds the 35.520-second transmission sees composition and not order, and composition carries $\log_2 \binom{1779}{3} = 29.803$ **bits of the 1,776 sent — 1.68 per cent, none of it sequence. Sequence is the entire hypothesis, so an integrator that slow is not a candidate receiver at all.** The companion constraint runs the other way and is stated so that

neither is over-read: **resolution is not the obstacle** — an integration window of 0.08037675 ms suffices to separate the four-tone alphabet, so **it would be dishonest to invoke the Gabor limit as a reason the hypothesis fails. The two requirements pull in opposite directions across roughly three orders of magnitude in time, and any proposed mechanism must say how it spans that gap.**

36.7.5 7.5 R5 — the preregistration prices its own nulls

The four-baseline conjunction gate's measured false-positive rate is 9.5 per cent at $T = 60$**, not the nominal 5**, falling to 0.052 at $T = 90$, 0.040 at 120, 0.013 at 180 and 0.010 at 260. **And a half-size effect never reaches 80 per cent power under this gate at any practical series length, saturating near 0.66. Cross-individual replication is the repair, and it is arithmetic: with twelve participants and a rejection rule of four or more passing, the actual false-positive rate is 0.0216 and the power against a half-size effect is 90.8 per cent — against 48.2 per cent for a single participant's series. Replication across people converts a stringent per-person gate from underpowered into adequate without weakening the gate.**

36.7.6 7.6 R6 — the no-subliminals constraint as first law

A message hidden from its recipient cannot be consented to, and the argument depends on no empirical claim. Consent requires knowing what one is consenting to; a signal engineered so the listener cannot perceive it has been engineered so the listener cannot evaluate, compare, refuse or report it, **and every one of those capacities is the capacity to decline. In an architecture whose mechanism routes through the recipient's own selection, concealment does not strengthen the protocol — it removes a component of it, so the design is incoherent before it is unethical.** The constraint's operative test is a reconstruction test: **can the recipient rebuild the signal from the packet?** And it is not contingent on an empirical bet — **the open-label result means the boundary is cheap to hold, not that holding it was conditional on that.**

36.7.7 7.7 CR — the counter-result

The paper closes its own proposed mechanism, leaves its own composition undefined, and publishes its own gate's measured failure rate. The bulk-compression route requires **240.83 dB against a 194.09 dB atmospheric ceiling**. The composition's fourth term — sequence-specific demodulation — **has never been measured, so by the chain law the product is undefined, and if the missing gain is zero the product is exactly zero.** And the decision gate the protocol depends on **rejects at 9.5 per cent against a nominal 5**, which is published in the registration rather than discovered afterwards. **Eight of ten links in the architecture's ledger are established or are constraints under the operator's control, and one is unmeasured; the paper's whole content is that this is what the situation is, in a form that can be checked rather than in a form that can be believed.**

36.7.8 7.8 Hypotheses, resolved

	Statement	Outcome
H1	a contradictory corpus cannot issue a directive	**confirmed** in the vector model; $\lVert\sum\rVert = 0.000000000000$, simulated means tracking $1/\sqrt{N}$

	Statement	Outcome
H2	corpus surplus equals selection information	**confirmed in the extremal case only**, and clause H-A states where it fails
H3	the bulk-compression route is closed	**confirmed by arithmetic**: 240.83 dB required, 194.09 dB available
H4	a slow receiver cannot recover sequence	**confirmed by arithmetic**: 29.803 of 1,776 bits, 1.68 per cent
H5	the conjunction gate misses its nominal rate	**confirmed, and the number is 0.095** at $T = 60$

Every confirmation above is a confirmation of arithmetic or of a simulation, not of a measurement on any physical or biological system. H1's confirmation is a property of a vector model of directives and not of any text; H5's is a property of a synthetic series generated at parameters this paper chose. **Section 10 records both.**

36.7.9 7.9 Model comparison: what `RIGOR_STANDARD` §6 requires

This paper fits no model to any collected data. Two simulations are run — the resultant simulation of Section 4.4 and the design simulations of Section 5.9 — and both characterise a procedure rather than fit a model to observations. The row-by-row status is printed rather than omitted.

Requirement	Status here	Why
out-of-sample performance	**MET in form for the Layer 2 design simulation; NOT APPLICABLE elsewhere**	the simulation fits on 40 periods and tests on 20 held out, which is the design; **no real data are used**
matched null with equal free parameters	**MET for both simulations**	the $b = 0.0$ generator is the matched null — the same two-parameter model with a null input — and it passes the gate 9.5 per cent of the time; the Layer 1 calibration run is the same design at zero effect
information criterion (AIC or BIC)	**NOT MET, and not computed anywhere in this corpus**	no likelihood is reported here, and **no AIC or BIC value appears in any paper of this corpus. The omission is corpus-wide and is recorded rather than papered over**
explicit free-parameter count	**MET**	the Layer 2 model fits **two** parameters, $(1 - \delta)$ and η, the same two under every generator; C is **measured, never estimated**; the Layer 1 endpoint fits **none** — the DiD is a contrast, not a fit

Requirement	Status here	Why
effect sizes with intervals	**PARTIALLY MET**	the design simulations report minimum detectable effects at stated power, which is the interval-equivalent for a design; **no empirical effect size is reported anywhere, because none was measured**
calibration of the test	**MET, and this is the paper's own contribution to the row**	the permutation test is simulated at zero effect and returns 0.040, 0.062 and 0.043 at r = 3, 6, 12; the conjunction gate is simulated and returns **0.095 against a nominal 0.05, which is published rather than assumed**
identification of the reflexive parameter	**NOT MET for Layer 2's loop; MET BY DESIGN for the Layer 1 contrast**	[Manski, 1993]; the Layer 1 arm contrast is identified by randomisation and a matched control, the Layer 2 loop is not identified at all
power-law procedure [Clauset et al., 2009]	**NOT RUN, deliberately**	the three exponents here are analytic properties of known functions; Section 3.7
conjoint measurement test [Luce and Tukey, 1964]	**NOT RUN**	Section 3.6; the exposed construct is demoted instead

A specification cannot be beaten on fit and earns nothing on it. What is claimed here is a construction, three exact arithmetic consequences, and a calibrated procedure — **and the procedure's value is untested, because it has not been run.**

36.8 8 Discussion

36.8.1 8.1 What follows

Disclosure is specifiable, not merely commendable. The operative test is reconstruction: a disclosure packet is adequate if and only if the recipient can rebuild the signal from it. **That converts an ethical sentiment into a checkable property of a document**, and it is the same move Kerckhoffs made for ciphers [Kerckhoffs, 1883] and the corpus makes for channel architecture, where non-disclosure is refused as a design premise rather than merely discouraged [Curzi, 2026].

Non-coercion can be structural rather than promised. A corpus closed under negation has resultant exactly zero; **disclosure makes a command refusable, and contradiction makes it not a command**, and the two fail in different circumstances — **disclosure fails when the listener is tired, deferential or trusting, whereas a field of mutually exclusive directions has no resultant whether or not anyone is paying attention.**

A negative computation is progress. The bulk-compression closure removes one candidate mechanism from the search at the cost of an afternoon's arithmetic. **A closed route is worth more than an open speculation, and the framework's willingness to close its own is the strongest single thing this paper does.**

And a decision gate must be calibrated before it is used. The four-baseline conjunction rejects at 9.5 per cent against a nominal 5 at the series length the design would otherwise

have used. **Measuring that costs an hour of simulation and it changes what a single passing participant means** — which is the same discipline the corpus applies to its own falsification suite, where the shuffle control's measured rate is 0.108 against a nominal 0.05 [Curzi, 2026u].

36.8.2 8.2 What does not follow

Nothing here shows that anything receives the signal. The encoding is elegant and the elegance is not evidence. **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal** [Curzi, 2026y], and the paper builds a transmitter for a receiver not demonstrated to exist.

Nothing here supports the essence law. k is chosen, the square law is a postulate, and the Gabor arithmetic applied to it is exact arithmetic applied to a chosen object [Curzi, 2026, Markowsky, 1992]. **A reader must not take the precision of Section 4.10 as transferring to the postulate it operates on.**

Nothing here is a clinical, medical or therapeutic claim, in either direction.

Nothing here has been run. The protocol has an unknown pass rate, the corpus has never been rendered for any participant, and the preregistration is a specimen. **A preregistration is a commitment to find out, and the paper's contribution is that the commitment can be written precisely enough to be kept — not that keeping it produced anything.**

And the honest expectation is negative. The magnitude arithmetic gives the bulk route a decisive *no*, and every remaining route is non-linear, localised and not known to be sequence-selective. **A reader who finishes this paper believing the experiment is likely to return a positive has read it wrong. The procedure is specified in this detail precisely so that a negative result will be worth something — and on the present state of the evidence, a negative is what the arithmetic leads one to expect.**

36.8.3 8.3 Relation to the surrounding literature

The positive results sit inside established literatures and add to none of them: the time–frequency bound is Gabor's [Gabor, 1946]; the selection cost is Hartley's and Shannon's [Hartley, 1928, Shannon, 1948]; the variety bound is Ashby's [Ashby, 1956, 1958]; the disclosure principle is Kerckhoffs's [Kerckhoffs, 1883, Brandeis, 1914]; the methodological apparatus is the reform literature's [Open Science Collaboration, 2015, Nosek et al., 2018, Simmons et al., 2011, Gelman and Loken, 2013]. **What is new is the composition, the arithmetic, and the discipline of publishing the closures.**

The methodological position is closer to the critics of physics-in-social-science than to its enthusiasts. Anderson [1972] is the standing argument that a formalism valid at one scale carries no automatic warrant at another; Cartwright [1999] that laws hold in the circumstances that make their premises true and not elsewhere; Mirowski [1989] that borrowing physical formalism can import the mathematics and lose what gave it content. **The three-way label of Section 3.2 is the answer, and it is procedural rather than rhetorical: state which kind of borrowing is being made, and let the reader hold the paper to it.**

36.8.4 8.4 Parallel results elsewhere in the corpus

Four results in other series are structurally parallel and are named because the parallel is the point.

A gate that never rejects is not a gate. Section 4.14 rejects one bridge of three in print. The corpus's audit of a traditional operation set against a parameter model returns the same shape of distribution — **seven MAPS, two SPLIT, one RENDERING and three REJECTED across thirteen entries, with five entries carrying a failure** [Curzi, 2026]. **That is what a discriminating instrument looks like when it is pointed at material its author is sympathetic to.**

A structural limit is not closed by care inside the channel. Section 4.1's constraint is that no amount of care within a concealed delivery architecture restores the recipient's ability to decline. The corpus reaches the identical conclusion for identity channels: **in-band architectures admit an impersonation class that no care within the shared channel can close, and out-of-band separation closes it structurally — and channel separation is *strengthened* by disclosure, because its effectiveness is entirely independent of whether anyone knows it is in place, so non-disclosure is refused as a design premise rather than merely discouraged** [Curzi, 2026]. **This paper's no-subliminals constraint is that argument applied to content.**

A representation makes a control possible that no amount of care in the wrong representation could supply. Section 5.6's scrambled arm works because the encoding fixes what "the same symbols in a different order" means. The corpus's identifier work is the same move: **typed-field parsing collapses the withdrawn-code parsing-ambiguity false-positive share from 88.99 per cent to 0.00 per cent, against a naive detection precision of 11.01 per cent — a control right one time in nine** [Curzi, 2026]. **Getting the representation right is what makes the control exact.**

A ceiling on constructed inputs is not a promise. Section 6.5's $\ln N$ and Section 4.10's Gabor margin are both upper bounds on what a construction can do, and neither says any system will reach them. The corpus states the same caution about its own architecture: **the 56.62 per cent widening is a ceiling on constructed inputs and not a promise, visibility is explicitly distinguished from pledgeability, and the valuation of non-financial capital is named as unsolved** [Curzi, 2026]. **This paper's bounds are bounded by that caution in the same way.**

36.8.5 8.5 Parallels in the foundations volume

Three foundational results carry the same structure as this paper's and are named for that reason.

Calibration by tense. Section 6.9's insistence that a directive be stated so that it could be acted on now, rather than deferred, has an exact precedent in the corpus's treatment of spoken commitment: **a future-tense formulation is consistent with an unchanged day, so it generates no dissonance and the consistency mechanism has nothing to act on** [Curzi, 2026]. **A corpus of deferred directives is a corpus that cannot be selected from today**, and the balance check of Section 4.13 would pass it while the protocol got nothing.

Arrival is auditable from the last correction. Section 5's freeze-then-open discipline asks when a fitting process has arrived. The corpus's contraction result supplies the general answer: **a contraction with modulus $q < 1$ on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least q each pass** [Curzi, 2026]. **Arrival is a property of the map, not of the analyst's patience**, which is why the freeze is placed by the design rather than by judgement.

And the honesty classification is itself a corpus-level instrument. The foundations volume closes with a three-drawer ledger — **four items of established mathematics, seven of established psychology, and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third** [Curzi, 2026]. **Section 4.5's and Section 5.5's status tables are that instrument applied at paper scale, and the fact that the counts can be printed is what makes the classification checkable rather than rhetorical.**

36.9 9 Verification

The results compound from nine postulates. Each is atomic, each is checkable on its own, and each carries its status.

36.9.1 9.1 Dimensional audit

[1] denotes a pure number. **Where the framework fixes no dimension, the audit says so rather than assigning one.**

Symbol	Dimension	Unit	Status
v_i (directive)	[1]	none	**defined** as a unit vector; **a modelling choice, and the framework supplies no operational scale on which a directive is measured**
$\lVert\sum v_i\rVert$	[1]	none	**derived**
N	[1]	count of directives	**defined**
u	[1]	none	**defined** dimensionless on $[0, 1]$
$N_{\text{eff}} = 1 + (N-1)u$	[1]	count	**defined** by the framework; **not a Hill number**
$F = \ln(1 + (N-1)u)$	[1]	nats	**derived**; a **Shannon-type** logarithm, **not a thermodynamic entropy**
selection cost $\ln N$	[1]	nats (or bits at $\log_2$)	**derived**; the conversion is $1/\ln 2 = 1.442695$
payload	[1]	bits, then bases	**derived**; 1 bit per base by the declared mapping, so bases and bits are numerically equal here and **the equality is a property of the chosen encoding, not of nucleotides**
address length L	[1]	nucleotides	**chosen**; the expected-collision figure is $6.2 \times 10^9/4^L$, dimensionless
Δt	[T]	seconds	**chosen** symbol duration
Δf	[T^{-1}]	hertz (cycles s^{-1})	**derived** rms spread
$\Delta t\,\Delta f$	[1]	none	**derived**; balances against $1/(4\pi)$, a pure number, **only with f in cycles per second**

Symbol	Dimension	Unit	Status
k	`[T^{-1}]` **by assertion**	hertz	**the value** $(9/8)^2/\varphi^2 = 0.483425732988414$ **is DEFINED and exact — a ratio of exact quantities, which is what licenses fifteen figures — and the attachment of hertz is POSTULATED and is a separate, stronger claim** (P5)
$f(n) = kn^2$	`[T^{-1}]`	hertz	**derived** from k, inheriting its badge exactly
j	`[1]`	octaves	**chosen** integer transposition; 2^j is dimensionless
cents	`[1]`	none	**derived**; $1200 \log_2$ of a frequency ratio
p	`[M L^{-1} T^{-2}]`	pascal	**chosen**/measured
K (bulk modulus)	`[M L^{-1} T^{-2}]`	pascal	**cited** physical constant, 2.2×10^9 Pa for water
$s = p/K$	`[1]`	none	**derived** dimensionless strain; **balances exactly, since pressure over pressure is a pure number**
SPL in dB	`[1]`	dB re 20 μPa	**derived**; a **logarithmic ratio against a fixed reference**, so differences are ratios of pressures and are licensed, **and sums are not**
dose	`[1]`	per cent of an 8-hour allowance	**derived** from level and duration at a 3 dB exchange rate
$\log_2$ transcript abundance	`[1]`	log2 units	**measured** in principle; **an interval scale in the log domain**, which is why the endpoint is a difference of differences
DiD	`[1]`	log2 fold-change	**derived**; differences of logs, licensed on an interval scale

Symbol	Dimension	Unit	Status
σ	[1]	log2 units	**ASSUMED** for the power calculation; **must be replaced by a pilot estimate**
r (replicates)	[1]	count	**chosen**
δ	[1]	per period	**measured** dimensionless fraction per step [Curzi, 2026a]
η	[q] per nat per period	proxy units per nat per period	**measured**; *not* dimensionless [Curzi, 2026a]
Y (Layer 2 endpoint)	**the framework is silent**	rating points, or a behavioural count	**undetermined**, and **ordinal where the instrument is a rating scale**, in which case the multiplicative form is not licensed (Section 3.6)

Does the Gabor relation balance? Δt carries [T] and Δf carries [T^{-1}], so the product is dimensionless and is compared against the pure number $1/(4\pi)$. **It balances, and only with** f **in cycles per second** [Curzi, 2026z].

Does the strain relation balance? $s = p/K$ is pressure over pressure and is exactly dimensionless. **It balances, and the closure of Section 5.2 is therefore a comparison of two pure numbers,** 4.6057×10^{-5} **against** 10^{-2}**, which is the cleanest form a refutation can take.**

Does the storage law balance? $Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t$ balances only if η carries [q] per nat per period, since S is dimensionless in nats [Curzi, 2026a]. η **is therefore not a pure number, and any report of an** η **without a statement of what [q] counts is half a number.**

Where the framework has no operational unit, it is said here. A directive has no operational unit; v_i is a dimensionless placeholder for an object the framework does not instrument, and clause H-B is the badge on it. **The Layer 2 endpoint's dimension is likewise not fixed by the framework**, and this paper does not supply the determination. **A dimensionless placeholder is honest; an invented unit would not be.**

36.9.2 9.2 The postulates

P1 — For a set closed under negation, $\sum_i v_i = 0$**.** *Status:* **ARITHMETIC.** Each v is cancelled by its $-v$.

P2 — For N **mutually orthogonal unit vectors,** $\|\sum v_i\| = \sqrt{N}$**.** *Status:* **ARITHMETIC**, by the Pythagorean identity; the mean is therefore $1/\sqrt{N}$.

P3 — $F(u) = \ln(1 + (N-1)u)$ **attains** $\ln N$ **at** $u = 1$ **and 0 at** $u = 0$**.** *Status:* **DEFINITION** of the framework's functional [Curzi, 2026]. It carries no empirical weight.

P4 — Selecting one of M **equiprobable alternatives costs** $\ln M$ **nats.** *Status:* **CITED**, elementary [Hartley, 1928, Shannon, 1948].

P5 — The essence law $f(n) = kn^2$ **with** $k = (9/8)^2/\varphi^2 = 0.483425732988414$**, expressed in hertz.** *Status:* **the value is DEFINITION** — an exact ratio of exact quantities, computable to arbitrary precision, which is what licenses fifteen significant figures — **and the attachment of hertz is POSTULATED, with no external support of any kind** [Curzi, 2026, Markowsky, 1992]. **These are two steps, not one, and the second is much the stronger.**

P6 — Two indices share a pitch class iff they have the same odd part. *Status:* **ARITHMETIC** [Curzi, 2026].

P7 — $\Delta t\,\Delta f \geq 1/(4\pi)$ for any square-integrable signal with finite second moments in both domains. *Status:* **CITED** [Gabor, 1946, Curzi, 2026z].

P8 — For a plane acoustic wave in a fluid of bulk modulus K, the longitudinal strain amplitude is $s = p/K$. *Status:* **CITED**, elementary continuum mechanics. $K = 2.2 \times 10^9$ Pa for water is a **cited** physical constant.

P9 — The number of compositions of n indistinguishable items into 4 labelled classes is $\binom{n+3}{3}$. *Status:* **ARITHMETIC**, the standard stars-and-bars count.

What is NOT a postulate. The claim that a cell demodulates sequence-specific information from an acoustic signal is **not** a postulate of this paper. It is the **open problem**, it appears in no line of the chain below, and nothing here is derived from it. **That is the honest entry.**

36.9.3 9.3 The compounding chain

```
P1              -> R1a  a corpus closed under negation has resultant exactly 0;
                        verified at N = 4, 8, 12, 24 as 0.000000000000.      ARITHMETIC

P2              -> R1b  an orthogonal corpus has mean resultant 1/sqrt(N):
                        0.500000, 0.353553, 0.288675, 0.204124 at N = 4, 8,
                        12, 24; simulated 0.497007, 0.352275, 0.288022,
                        0.203292.                                            ARITHMETIC

P3              -> L1   at u = 1 the surplus is F = ln N; at N = 12 that is
                        2.484907 nats = 3.584963 bits.                       DEFINITION

P4              -> L2   selecting one of 12 costs ln 12 = 2.484907 nats.     CITED

L1 + L2         -> R2   the surplus a maximally contradictory corpus carries
                        EQUALS the information required to select one member,
                        so the corpus supplies 0 direction and the receiver
                        supplies all of it.                                  ARITHMETIC
                        (extremal case only; clause H-A)

P5 + P6         -> L3   at n = 1, 3, 5, 7 the four base tones are distinct
                        pitch classes; at j = 8 they are 123.7570, 1113.8129,
                        3093.9247 and 6064.0924 Hz, minimum gap 990.0559 Hz.  ARITHMETIC
                        (given P5)

L3 + P7         -> L4   Gabor floor dt_min = 0.07957747/990.0559
                        = 0.08037675 ms; at dt = 20 ms the margin is 248.83x. ARITHMETIC

L4              -> L5   1,776 symbols at 20 ms run 35.520 s.                 ARITHMETIC

P8              -> R3   s = p/K needs p = 2.2e7 Pa for s = 1e-2, which is
                        240.83 dB SPL; the atmospheric ceiling is 194.09 dB,
                        where s = 4.6057e-05, short by 217.12.               CITED (P8) + ARITHMETIC

P9 + L5         -> R4   a receiver slower than 35.520 s sees only composition:
                        log2 C(1779,3) = 29.803 bits of 1,776, i.e. 1.678%.  ARITHMETIC

P3 + P5         -> L6   a folded pair (m, 2m) with m odd shares a pitch class
                        and is separated by exactly 4.000000 in frequency
                        ratio -- 2400.0 cents, in every pair.                ARITHMETIC
```

```
(simulation)   -> R5   the four-baseline conjunction gate rejects a null
                       generator at 0.095 at T = 60, 0.040 at T = 120; the
                       binomial rule "4 of 12" gives alpha = 0.02160 and
                       power 0.908 against a half-size effect.          SIMULATED DESIGN

(the argument) -> R6   a message hidden from its recipient cannot be
                       consented to.                                    DEFINITION / no number
```

Every line is `ARITHMETIC` except four. P4, P7 and P8 are cited standard results. **R2 consumes P3, a definition of the framework's own functional, and holds only in the extremal case. L3, L4, L5, L6 and R4 all consume P5, whose numerical value is a DEFINITION and whose expression in hertz is POSTULATED** — so **the cents figures and the ratio of 4.000000 stand on arithmetic alone, while every hertz and every millisecond inherits the postulate. A reader who rejects the essence law keeps Section 4.11's intervals and loses Section 4.9's frequencies**; R3 and R1 are untouched either way, because neither uses k. **R5 is a simulated design characteristic and not a measurement. R6 produces no number at all**, which is stated here rather than left for the reader to notice.

What this chain does not establish. It does not establish that a cell receives anything. It does not establish that the essence law is true. It does not establish that the protocol finds anything if run. **And it establishes nothing about any effect on any listener**: R1, R2 and R6 are properties of a construction, R3 and R4 are refutations, and R5 is a property of a synthetic series.

36.9.4 9.4 The verification instance, worked

Four checks, none longer than five lines.

Check one — the identity between surplus and selection.

```
ln 12          = 2.4849066498          nats
log2 12        = 3.5849625007          bits
ln 12 / ln 2   = 2.4849066498/0.6931472 = 3.5849625007   consistent
F(u=1) at N=12 = ln(1 + 11*1) = ln 12                    identical
```

Check two — the defined constant, and the alphabet.

```
(9/8)^2  = 81/64               = 1.265625
phi^2    = phi + 1             = 2.618033988749895
k        = 1.265625/2.618033988749895
                               = 0.483425732988414      EXACT, DEFINED
f(7) - f(5) = k(49 - 25) = 0.483425732988414 x 24
                               = 11.60221759 Hz
x 2^8    = 11.60221759 x 256   = 2970.16770 Hz
but the binding gap is f(3) - f(1) = k x 8 x 256
                               = 990.0559 Hz            the minimum
```

Check three — the closure.

```
strain wanted                     s = 1e-2
pressure needed  p = sK = 1e-2 x 2.2e9   = 2.2e7 Pa
reference        p_0                     = 20e-6 Pa
level            20 log10(2.2e7/20e-6)   = 240.83 dB SPL
atmospheric ceiling
                 20 log10(101325/20e-6)  = 194.09 dB SPL
```

```
strain at the ceiling
                 101325/2.2e9            = 4.6057e-05
shortfall factor 1e-2 / 4.6057e-05       = 217.12
```

Check four — the averaging bound.

```
symbols                                  n = 1776
compositions into 4 classes  C(n+3, 3) = C(1779, 3)
                             = 1779 x 1778 x 1777 / 6
                             = 936,946,289
log2(936,946,289)                        = 29.803 bits
fraction of 1776 bits                    = 29.803/1776 = 1.678%
```

Four checks, none longer than five lines, and between them they establish the identity, the constant, the closure and the bound. A reviewer who runs them has verified every headline this paper contributes that is not quoted from elsewhere.

36.9.5 9.5 Limits, asymptotics, and the domain of validity

$N \to 2$ **in the corpus.** A two-directive corpus closed under negation still has resultant zero, **but the** $1/\sqrt{N}$ **argument has no content and the surplus is** $\ln 2 = 0.693147$ **nats.** REQ-4.19 sets the floor at $N = 4$ for exactly this reason. $N = 1$ gives $F = \ln 1 = 0$ and a resultant equal to the single member: **a corpus of one is a command, and the limit says so.**

$N \to \infty$**.** $F \to \infty$ in the model and the mean resultant $\to 0$, **but the audible band and the render time bind first**: 1,776 symbols already run 35.520 s, and the payload grows linearly in the corpus's character count. **The limit is unreachable for a physical reason rather than a mathematical one, and naming which is the point of taking it.**

$u \to 0$**.** $F \to 0$: a parallel corpus carries no surplus at all, and the selection cost falls to zero with it. **The two fall together, which is clause H-A's content, and it is why the identity survives as a structure while the equality does not.**

$\Delta t \to 0$**.** $\Delta f \to \infty$: **an instantaneous symbol has no pitch**, so the alphabet collapses and the signal becomes a click. $\Delta t \to \infty$ gives arbitrarily fine resolution and an arbitrarily long transmission. **The domain is** $\Delta t > 0$ **with the audibility margin as the binding constraint rather than the mathematics.**

$L \to \infty$ **in the address.** Expected collisions $\to 0$ geometrically and the address becomes exactly unique — **at a cost linear in** L**, which is why 20 is a choice rather than a limit.** $L \to 0$ gives one address matching everything: **not an address at all**, and the table shows the transition happening between 12 and 16.

$p \to p_{\text{atm}}$**.** The strain saturates at 4.6057×10^{-5} because the wave cannot pull below vacuum. **The ceiling is physical, not technological, and it is why the closure is a closure rather than an engineering challenge.**

$\tau \to \infty$ for a receiver's integration window. The recoverable information tends to $\log_2 \binom{n+3}{3}$, which grows only as $3 \log_2 n$: **at** $n = 1776$ **that is 29.803 bits and at** $n = 10^6$ **it is 56.7 — so a longer message does not help a slow receiver, it makes the surviving fraction smaller.**

$T \to \infty$ in the Layer 2 gate. The false-positive rate falls toward 0.010 and the half-size power saturates near 0.66. **The gate's power does not tend to 1, which is the whole reason cross-individual replication is required rather than optional.**

$r \to \infty$ in Layer 1. MDE $\to 0$ as $r^{-1/2}$. $r \to 1$ **is not a limit of the model but a failure of the design**: with one replicate per arm the DiD has no variance estimate at all.

36.9.6 9.6 Invariance, and how far each claim has been tested

Invariance of the resultant under pairing is exact: a set closed under negation sums to zero for *any* pairing, because cancellation does not depend on order. **Tested at four corpus sizes** (4,

8, 12, 24), **all constructed.**

Invariance of the fractional structure under octave transposition is exact: multiplying every frequency by 2^j leaves every ratio, every cents value and every pitch class unchanged [Shepard, 1982]. **Tested at** $j = 6$ **and** $j = 8$ in the worked encoding — **two transpositions**, and the invariance is algebraic rather than empirical.

Invariance of the Gabor product under time-scaling is exact and is inherited [Curzi, 2026z]; **it is not re-tested here.**

Invariance of the pair ratio 4.000000 across pairs is exact: $f(2m)/f(m) = (2m)^2/m^2 = 4$ for every odd m. **Tested at six pairs** in the worked corpus, **and it holds without exception because it is an identity.**

Invariance of the strain relation under the choice of medium does **not** hold and is not claimed: $s = p/K$ depends on K, and a medium with a bulk modulus three orders of magnitude smaller would move the closure. **The closure is stated for aqueous media at** $K = 2.2 \times 10^9$ **Pa and for nothing else**, which is a real restriction on the result and is recorded as such.

No invariance in this paper has been tested on data from any real system, because no data were collected. **Every invariance claim above is algebraic; the numerical checks are checks of the arithmetic.**

36.9.7 9.7 Significant figures and their warrant

- **Exact by definition or by arithmetic, quoted to whatever precision is useful:** $k = 0.483425732988414$; $1/(4\pi) = 0.07957747154594767$; $\ln 12 = 2.484907$; $\log_2 12 = 3.584963$; the frequency table; the cents values; the pair ratio 4.000000; the resultant 0.000000000000; $4^{20} = 1{,}099{,}511{,}627{,}776$; the composition count and its logarithm 29.803.
- **Computed from stated inputs and rounded honestly:** the strain figures, 240.83 dB, 194.09 dB, the shortfall 217.12, the Gabor margin 248.83, the runtime 35.520 s, the dose 0.123 per cent.
- **Simulated design characteristics at assumed parameters, not measurements:** every entry of the power tables, the rejection rates 0.040/0.062/0.043, the gate rates 0.095/0.482/0.895, and the binomial figures 0.02160 and 0.908. **The noise parameter** $\sigma = 0.35$ **is assumed and every minimum detectable effect scales linearly with it.**
- **Simulated with sampling error, quoted to six figures because that is what the run returned:** the mean resultants 0.497007, 0.352275, 0.288022, 0.203292 from 2,000 draws per row. **These carry Monte-Carlo error that is not restated beside them, and Section 10 records that.**
- **Cited physical constants:** $K = 2.2 \times 10^9$ Pa; the reference pressure $20\,\mu$Pa; one atmosphere as 101,325 Pa; $c = 2.99792458 \times 10^{10}$ cm/s; the Casimir pressures.
- **Quoted from published literature, carrying that literature's uncertainty:** the genome size and its compositional percentages, the occupational exposure limit, the replication counts, and the growth-mindset magnitudes. **None is a measurement of this paper.**

36.9.8 9.8 Analogy discipline, restated at the point of verification

Every borrowing carries the label assigned in Section 3.2 and no passage upgrades one. $s = p/K$ is a **derivation** and is used to close a route, not to open one. The Gabor limit applied to a rendered tone is a **derivation** because a finite-energy signal under a smooth envelope satisfies its premises. The chain law is a **shared mathematical form** and transfers no physical result. The packet/header correspondence is a **shared mathematical form** and **is not a claim that cells run a network stack**. The vector model of a directive is a **modelling choice**, badged at clause H-B. And the resonance reading of older correspondence doctrines is an **analogy**, **marked speculative in the sentence that states it**, contributing **no line of the chain in Section 9.3**.

Every logarithm of a count in this paper is Shannon information [Shannon, 1948], in nats or in bits with the conversion stated. **No thermodynamic entropy appears anywhere**, and the word is not used loosely.

36.10 10 Limitations

L-1. Nothing here has been run. No cell was exposed, no participant recruited, no corpus rendered for anyone. **The protocol has an unknown pass rate and the preregistration is a specimen.** The corpus's one comparable attempt to run a preregistered confirmatory test against a real system **failed its own second falsification rule** [Curzi, 2026u], which is the realistic expectation here.

L-2. A substantial number of primary sources are named without citation keys. Church, Gao and Kosuri (2012); Qi et al. (2013); Gilbert et al. (2014); Zetsche et al. (2015); Fonfara et al. (2016); the 2021 Nobel-recognised mechanotransduction work; Tajik et al. (2016); Ibsen et al. (2015); Duque et al. (2022); Takahashi and Yamanaka (2006, 2007); Kaptchuk et al. (2010); Levine, Gordon and Fields (1978); Sisk et al. (2018); and O'Sullivan (1845) **have no entries in this corpus's bibliography, and no key was invented for any of them.** Every one is standard and locatable; **the gap is in the corpus's bibliography and it is recorded here rather than smoothed over.**

L-3. The vector model of a directive is a modelling choice and the theorem is about the model. Real directives are not unit vectors and "REST NOW" is not literally the additive inverse of "WORK NOW". **What survives rigorously is that a set constructed to cancel has no resultant**, and that depends on the corpus genuinely containing mutually exclusive directions — **a property of the written text, checkable by reading it, and not established by any arithmetic in this paper.**

L-4. The surplus/selection identity holds only in the extremal case. At $u < 1$ or under a non-uniform receiver prior the two sides differ, and **the exact equality is claimed only at $u = 1$ with a uniform prior. A reader who assumes a uniform prior over a real person's dispositions has assumed the thing most likely to be false.**

L-5. The essence law is a postulate and every hertz figure inherits it. k is chosen, its expression in hertz has **no external support of any kind**, and the square law is a postulate about essence structure [Curzi, 2026, Markowsky, 1992]. **The Gabor arithmetic is exact and the object it operates on is chosen.** Whether ratio structure of this kind is perceived as the framework supposes is separately contested [Sethares, 2005].

L-6. The closure of Section 5.2 is of the bulk route only, in aqueous media, at $K = 2.2 \times 10^9$ Pa. Radiation force, microstreaming, localised shear, cavitation and dimensional resonance are **not** closed. **A reader who takes the 240.83 dB figure as closing the whole question has over-read it, and the paper says so twice.**

L-7. The 10^{-2} gating strain is an order-of-magnitude figure. It is quoted from the membrane-mechanics literature as a scale rather than as a measured constant, and **the closure's seven-order-of-magnitude margin is what makes the conclusion robust to that imprecision** — but if gating occurred at 10^{-6} the arithmetic would change, and **nothing in this paper establishes that it does not.**

L-8. The noise parameter in every power calculation is assumed. $\sigma = 0.35$ is a stand-in until pilot replicates replace it, **and if the true value is twice the assumption every minimum detectable effect doubles.** Reporting an MDE to six decimals from an assumed variance is exactly the presentational error FM-5.6 names, **and the tables here are guilty of it in form, which is why the assumption is flagged three times.**

L-9. The simulated values carry Monte-Carlo error that is not restated beside them. The mean resultants of Section 4.4 come from 2,000 draws per row and the design characteristics from 200 to 400 runs per cell. **Six-figure precision on a simulated quantity records what the run returned, not what the quantity is**, and no simulation interval is reported.

L-10. The Layer 2 endpoint is ordinal where the instrument is a rating scale, and the multiplicative model is not licensed on it. The relation is demoted in print to a monotone ordering [Stevens, 1946, Curzi, 2026t], **the conjoint-measurement test that would settle whether the attribute is quantitative at all has not been run** [Luce and Tukey, 1964], and **Michell's objection therefore stands unanswered** [Michell, 1997].

L-11. The Layer 2 reflexive parameter is not identified. Randomising the exposure schedule identifies the exposed-versus-unexposed contrast; **it does not identify the loop's gain** [Manski, 1993, Shalizi and Thomas, 2011], and no statement here about the loop is an identified empirical result.

L-12. No AIC or BIC is reported, here or anywhere in this corpus. Section 7.9 prints the row as NOT MET rather than omitting it. Nothing here is fitted to collected data; **the corpus-wide absence is nonetheless a genuine gap and is recorded as one.**

L-13. The balance check fails on two pairs of the worked corpus and the failure is published rather than repaired. The maximum pairwise character asymmetry is **9 characters, a ratio of 2.00**, at one pair. **A corpus with a 2.00 asymmetry in one pair has a thumb on one scale**, and by Section 4.4's arithmetic its resultant is no longer exactly zero — **which means the worked example does not fully satisfy the specification it demonstrates, and that is reported rather than quietly fixed.**

L-14. The composition claim is the author's thesis and the ledger is the author's ledger. That eight of ten links are established or under the operator's control is a classification made by the person who assembled the chain. **An independent classifier applying the same status categories might count differently**, and no such audit has been conducted.

36.11 11 Conclusion

This paper specifies a fully disclosed chain from text to audible tone, proves the structural property that prevents the protocol from overriding its subject, and then closes its own proposed physical mechanism by computation rather than defending it.

Result One, determination by choice. A corpus closed under negation has resultant exactly zero — $\|\sum\| = 0.000000000000$ at N = 4, 8, 12 and 24, for any pairing — and a mutually orthogonal corpus's mean direction shrinks as $1/\sqrt{N}$, analytic 0.500000, 0.353553, 0.288675 and 0.204124 against simulated 0.497007, 0.352275, 0.288022 and 0.203292. **A field of mutually exclusive directions cannot issue a command. The corpus does not point. It spans.**

Result Two, the maximum-surplus corpus. A maximally contradictory corpus is a maximum-surplus corpus: at $N = 12$, $F = \ln 12 = 2.484907$ **nats** $= 3.584963$ **bits, which is the hard ceiling** $\ln N$ **— and exactly the information required to select one of its twelve members. The corpus supplies as much surplus as the selection consumes and supplies zero net direction, so the listener supplies the selection by construction.** The identity is claimed only at $u = 1$ under a uniform prior.

Result Three, the closed route. $s = p/K$ **with** $K = 2.2 \times 10^9$ **Pa requires 240.83 dB SPL to produce a one-per-cent bulk strain, against an atmospheric ceiling of 194.09 dB SPL; at that ceiling the achievable strain is** 4.6057×10^{-5}**, short by a factor of 217.12. The bulk-compression route is closed by more than seven orders of magnitude and stays closed at the physical ceiling of sound in air.** Non-linear and localised routes remain open and **none of them has been shown to be sequence-selective.**

Result Four, the averaging bound. A receiver slower than the 35.520-second transmission recovers at most $\log_2 \binom{1779}{3} = 29.803$ **bits of the 1,776 sent — 1.68 per cent, and none of it is sequence. Resolution is not the obstacle** — 0.08037675 ms suffices to separate the alphabet — **so the two timescale requirements pull in opposite directions across three orders of magnitude, and any proposed mechanism must say how it spans that gap.**

Result Five, the preregistration that prices its own nulls. The four-baseline conjunction gate's measured false-positive rate is 9.5 per cent at $T = 60$**, not the nominal 5**, and a half-size

effect never reaches 80 per cent power under it at any practical series length. **Twelve participants with a rejection rule of four or more passing restores $\alpha = 0.0216$ with 90.8 per cent power against a half-size effect that one participant's series detects 48.2 per cent of the time. Cross-individual replication converts a stringent gate from underpowered into adequate without weakening it.**

Result Six, no subliminals as first law. A message hidden from its recipient cannot be consented to, and the argument depends on no empirical claim. The operative test is reconstruction: **can the recipient rebuild the signal from the packet? In an architecture whose mechanism routes through the recipient's own selection, concealment removes a component rather than adding one — the design is incoherent before it is unethical.**

And the counter-result, which is what the paper is for. It closes its own proposed mechanism at 240.83 dB against a 194.09 dB ceiling. It leaves the fourth term of its own composition unmeasured, and therefore reports the product as *undefined* rather than as *promising* — a chain $G = g_1 g_2 g_3 x$ with x unknown is unknown, and if $x = 0$ it is exactly zero. And it publishes the 9.5 per cent measured false-positive rate of its own decision gate instead of the nominal 5. A reader who finishes this paper believing the proposed experiment is likely to return a positive has read it wrong: the procedure is specified in this detail precisely so that a negative result will be worth something, and on the present state of the evidence a negative is what the arithmetic leads one to expect.

36.11.1 Declarations

Data and code availability

No external dataset was collected for this paper. No cell was exposed, no participant was recruited, no corpus was rendered for any listener, and no result is reported. Values reported as computed — the resultants, the surplus and selection figures, the address-collision figures, the frequency and cents tables, the Gabor margins, the strain and level figures, the composition count and the dosimetry — are exact evaluations of the functions stated beside them, reproducible from the specifications in the text. Values reported as **simulated** — the mean resultants of Section 4.4 (2,000 draws of N isotropic unit vectors in $\mathbb{R}^{64}$ per row) and every design characteristic in Section 5.9 (400 simulated studies per cell with a 400-permutation null for Layer 1; 200 synthetic runs per condition at T periods for Layer 2) — are outputs of the stated procedures at the stated parameters and **are design characteristics, not data.** The noise parameter $\sigma = 0.35$ is **assumed** and is flagged as assumed wherever it is used. Physical constants, genome statistics, occupational exposure limits and every biological result named in Sections 4 to 6 are **quoted from the published literature named in the text**, carry that literature's uncertainty rather than this paper's, and **many of those sources have no key in this corpus's bibliography and are named in full**, as disclosed at Section 3.10 and Limitation L-2. **The corpus and balance check of Appendix A, the preregistration of Appendix B and the parameters of Appendix C are constructed and are labelled constructed wherever they appear.** The figures are generated by the scripts named in each caption, and those scripts contain no data beyond the numbers printed in this paper and the functions stated in Sections 4 to 6.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. **The architecture specified here is the author's own, the postulate it composes is the author's own, and the ledger classifying its links is the author's own. That is a structural conflict which no declaration removes**; it is the reason failure mode FM-6.6 (the selective precedent) is in the specification, the reason Section 4.14

rejects one bridge of three in print, the reason Section 5.2 closes a route the framework proposed, and the reason Limitation L-14 records the ledger as the author's classification rather than an independent audit.

Author contributions

Single author. Michael Laurence Curzi specified the chain, derived the results, performed the arithmetic and the simulations, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted, no personal data was processed, and no biological material was handled. No clinical, medical or therapeutic claim is made anywhere in this paper, in either direction; the published trials named in Sections 4.2 and 6.8 are cited as evidence about channels and their gains and never as guidance about care. The Layer 1 and Layer 2 procedures of Section 5 and the preregistration of Appendix B are **designs for prospective work and are not reports of studies performed**. **Were either run it would require ethical review, and nothing here substitutes for that.** The consent architecture of Section 5.3 — informed disclosure sufficient for reconstruction, free and recorded declination, withdrawal at any point with data destruction on request, reversibility as a property of the signal, no conditional exposure, computed dosimetry, and declined enrolment where a participant persists in expecting a therapeutic benefit — **is stated as a protocol requirement rather than as an assurance, and a run that omits it has not run the protocol.**

Preregistration

This paper reports no preregistered test. The five hypotheses of Section 2 were fixed before the arithmetic and the simulations reported in Sections 4 to 6 were carried out and are printed in the form in which they were fixed; **all five are confirmed by arithmetic or by simulation, and none is confirmed by a measurement on any physical or biological system.** Appendix B is a **specimen preregistration for a study that has not been run**, filed here to demonstrate that the open problem can be posed as a powered, falsifiable, calibrated experiment with closed rescue clauses and a null publishable at equal prominence. **Its decision gate's measured false-positive rate — 9.5 per cent against a nominal 5 — is published in the registration rather than discovered afterwards**, which is what Section 5.13's calibration requirement produces. The corpus's own falsification suite has been audited against itself and is **anti-conservative**: iid permutation rejecting at 0.108, circular shift at 0.120 and block permutation at 0.060 against a nominal 0.05 across 500 null trials [Curzi, 2026u]. **Any applied claim resting on this paper inherits that result.**

36.12 Appendix A · A twelve-directive corpus carried from text to rendered tone

Every number is computed and every disclosure element is produced. This demonstrates the encoding and nothing about any effect on any listener or any cell, and is not offered as doing so. The corpus is constructed for the arithmetic.

36.12.1 A.1 The corpus

Six contradictory pairs, twelve directives, $N = 12$.

#	n	directive	chars
1	1	REST NOW	8
2	2	WORK NOW	8
3	3	HOLD WHAT YOU HAVE	18
4	6	LET IT GO	9
5	5	SPEAK	5
6	10	BE SILENT	9
7	7	GO TOWARD THE UNFAMILIAR	24
8	14	STAY WHERE YOU ARE KNOWN	24
9	9	TRUST THE MEASUREMENT	21
10	18	TRUST WHAT YOU FEEL	19
11	11	BUILD SLOWLY AND FINISH	23
12	22	START AGAIN FROM NOTHING	24
			total 192

The balance check, run before anything else. Pairs 1/2 and 7/8 balance exactly by character count (8/8, 24/24). **Pair 3/4 is 18 against 9 and pair 5/6 is 5 against 9 — these fail the equal-length test and are recorded as failing.** The honest options are to rewrite for balance or publish the asymmetry; **this specimen publishes it. Maximum pairwise character asymmetry is 9 characters (pair 3/4, 18 against 9), a ratio of 2.00.** Pair 9/10 is 21 against 19 (1.105); pair 11/12 is 23 against 24 (1.043). **A corpus with a 2.00 asymmetry in one pair has a thumb on one scale, and the reader is told so rather than not told.** Level, repetition count and symbol duration are equal across all twelve by construction.

36.12.2 A.2 Stages 1 to 3

Stage 1 — data. 192 characters at 8 bits per character = **1,536 bits.**

Stage 2 — sequence. At one bit per base: **1,536 payload bases.** At the two-bit ceiling it would be 768; **the extra 768 bases are the constraint-satisfaction budget, giving 2^{1536} sequences encoding this identical corpus.** The specific sequence used is published.

Stage 3 — addresses. Twelve addresses, 20 nt each: **240 address bases.** Expected spurious matches per address in a 3.1 Gbp genome across both strands: **0.005639. Total transmission: 1,776 bases.**

36.12.3 A.3 Stage 4 — tone

Route B, badged: $k = 0.483425732988414$ Hz is chosen; $f = kn^2$ is a postulate; **the outputs are essence frequencies, not physical resonances.** Band 20 Hz to 20 kHz. **Global transposition $j = 6$, factor 64, applied to all twelve values.**

n	directive	f (Hz)	f x 2^6 (Hz)	pitch class (odd part)
1	REST NOW	0.4834257	30.93925	1
2	WORK NOW	1.9337029	123.75699	1
3	HOLD WHAT YOU HAVE	4.3508316	278.45322	3
6	LET IT GO	17.4033264	1113.81289	3
5	SPEAK	12.0856433	773.48117	5
10	BE SILENT	48.3425733	3093.92469	5
7	GO TOWARD THE UNFAMILIAR	23.6878609	1516.02310	7
14	STAY WHERE YOU ARE KNOWN	94.7514437	6064.09239	7
9	TRUST THE MEASUREMENT	39.1574844	2506.07900	9
18	TRUST WHAT YOU FEEL	156.6299375	10024.31600	9
11	BUILD SLOWLY AND FINISH	58.4945137	3743.64888	11
22	START AGAIN FROM NOTHING	233.9780548	14974.59551	11

Every pair is separated by exactly 4.000000 in frequency ratio — 2400.0 cents, two octaves, without exception. Lowest tone 30.93925 Hz, highest 14974.59551 Hz, span **8.918863 octaves**, all inside the audible band; **six distinct pitch classes for twelve tones, matching** $\lceil N/2 \rceil = 6$ **exactly.** Folded into one octave above the lowest tone:

```
odd part  1  ->    0.0000 cents        odd part  7  ->  737.6518 cents
odd part  3  ->  203.9100 cents        odd part  5  ->  772.6274 cents
odd part  9  ->  407.8200 cents        odd part 11  -> 1102.6359 cents
```

k **cancels from every one of these.** Class 3 is the Pythagorean whole tone $9/8$ above class 1; class 9 is the ditone $81/64$ above it [Barbour, 1951].

36.12.4 A.4 The base alphabet, the rate and the dose

Four-tone alphabet at n = 1, 3, 5, 7 with $j = 8$: **123.7570, 1113.8129, 3093.9247, 6064.0924 Hz** — four distinct pitch classes, minimum gap **990.0559 Hz**, Gabor floor $0.07957747/990.0559 = 0.08037675$ ms. Symbol duration chosen: **20 ms, a margin of 248.83**, satisfying the 100-fold requirement. Total runtime $1776 \times 0.020 = 35.520$ s.

Dosimetry. At 85 dBA, $p_{\text{rms}} = 0.355656$ Pa. **One rendering is 0.123 per cent of the 8-hour allowance; 100 repetitions is 59.2 minutes, 12.3 per cent of it. Published, not estimated.**

36.12.5 A.5 The determination-by-choice ledger

```
corpus size                    N = 12
non-parallelism (design)       u = 1 (mutually exclusive pairs)
effective count                N_eff = 1 + 11(1) = 12   (the corpus's affine count,
                                                         NOT a Hill number)
corpus surplus                 F = ln 12 = 2.484907 nats = 3.584963 bits
corpus resultant               0 exactly (closed under negation)
selection information required ln 12 = 2.484907 nats = 3.584963 bits
contributed by the corpus      0
contributed by the receiver    2.484907 nats -- all of it
```

The signal is 35.520 seconds long, contains 1,776 symbols, spans 8.918863 octaves, is fully audible throughout, is fully published in advance, and does not tell the listener what to do — and the last of those is not a limitation of the design, it is the design.

36.12.6 A.6 The disclosure packet, as produced

1. The twelve directives above, in full.
2. Character encoding: 8-bit, one byte per character, no terminator, directives kept separate.
3. The 1,536-base payload string as generated, in full.
4. Twelve 20-nt addresses, listed, with the 0.005639 expected-collision figure.
5. Tuning: Route B, essence law, badged as postulate; $k = 0.483425732988414$ Hz chosen; band 20 Hz to 20 kHz; $j = 6$ for the corpus chord, $j = 8$ for the base alphabet; the frequency table.
6. Symbol duration 20 ms; Gabor margin 248.83; runtime 35.520 s.
7. Level 85 dBA; dose 0.123 per cent of the 8-hour allowance per rendering.
8. Rendering order, published, **declared not to be a ranking.**
9. Balance check **with the failure recorded**: maximum pairwise character asymmetry 9 characters, ratio 2.00, at pair 3/4.
10. Round-trip verification: text to bits to bases to tones to bases to bits to text reproduces all 192 characters.

11. Off-switch location, and the statement that any person may operate it without asking.
12. **The open problem, in full: there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. No clinical, medical or therapeutic claim is made. No claim that DNA is edited or altered. No claim that any capability has been conferred.**

Establishes. That a contradictory corpus can be encoded losslessly into a fully audible, fully disclosed 35.520-second signal whose interval structure is isomorphic to the corpus's contradiction structure, every parameter computed and published, at one-eighth of one per cent of an occupational daily dose.

Does not establish. That anything hears it other than a person. That any cell receives it. That any transcript changes. That any capability is conferred. That any physiological, clinical or therapeutic effect occurs. **The open problem is exactly as open at the end of this specimen as at the beginning.**

36.13 Appendix B · A specimen preregistration, with a calibration run

This is a specimen preregistration and a design simulation. No data were collected and no result is reported.

§1 TITLE. *Does an acoustic signal encoding addressed, sequence-formatted narrative data produce locus-specific transcriptional differences relative to a spectrally matched scrambled control? A preregistered in-vitro test.*

§2 STATEMENT OF THE OPEN PROBLEM. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. Mechanotransduction is established; force-to-transcription is established; sonogenetic channel activation is established; DNA data storage is established; separability of targeting and editing is established. **The channel for sequence-specific content is the question. This study tests whether such a channel exists and is written so that the answer "no" is fully reportable.**

§3 WHAT IS NOT CLAIMED. No clinical, medical or therapeutic claim. No claim that DNA is edited, altered or damaged — **the architecture produces sound and cannot do otherwise.** No claim that any capability is conferred. **No human participants in this study.**

§4 SIGNAL. Appendix A's twelve-directive corpus: 192 characters, 1,536 bits, 1,536 payload bases at one bit per base, twelve 20-nt addresses (240 address bases), **1,776 bases total.** Route B tuning, badged as postulate. Four-tone alphabet at n = 1, 3, 5, 7, $j = 8$: 123.7570, 1113.8129, 3093.9247, 6064.0924 Hz. Minimum gap 990.0559 Hz. Symbol duration 20 ms, Gabor margin **248.83** over the 0.08037675 ms floor. Runtime **35.520 s.** Full disclosure packet published with this registration.

§5 ARMS.

```
A  ENCODED       the 1,776-symbol addressed transmission
B  SCRAMBLED     the same 1,776 symbols, permuted; identical duration, spectrum,
                 level and symbol rate; carries no message
C  TONE-MATCHED  steady four-tone chord, same long-term spectrum and level, 35.520 s
D  SILENCE       35.520 s, identical handling
```

§6 EXPOSURE. $r = 6$ independent replicate cultures per arm, 24 in total, randomised. Calibrated transducer, field mapped at the cell layer. Target pressure amplitude at the cell layer 0.3557 Pa, corresponding to 85 dBA in air — **and it is registered in advance that at this pressure the bulk longitudinal strain in aqueous medium is $p/K = 1.62 \times 10^{-10}$, which is more than seven orders of magnitude below membrane strains associated with mechanosensitive gating.** Temperature logged continuously and published per arm. Exposure repeated 100 times per

culture over one session: 59.2 minutes, **12.3 per cent of the 8-hour allowance were a person present, which none is.**

§7 ENDPOINT. Difference-in-differences of mean $\log_2$ transcript abundance, addressed loci ($n_{\mathrm{addr}} = 12$) versus matched control loci ($n_{\mathrm{ctrl}} = 120$), Arm A versus Arm B. Matching on baseline expression, accessibility class and chromosome, performed and published **before unblinding.** Analysts blind to arm.

§8 TEST. Permutation null over locus labels within arm, 2,000 permutations, two-sided $\alpha = 0.05$. **The permutation family is declared: labels are permuted within arm and across the full 132-locus set; calibration at zero effect is reported below.**

§9 POWER. Assumed $\sigma = 0.35$ for $\log_2$ expression across replicate cultures. **This value is assumed and will be replaced by the pilot estimate before the study opens; every minimum detectable effect below scales linearly with it.**

```
r = 6:   SE(DiD) = 0.061181     MDE at 80% power = 0.171402 log2FC

simulated rejection rate at r = 6:
    d = 0.00  ->  0.062      (nominal alpha recovered)
    d = 0.10  ->  0.360
    d = 0.20  ->  0.902
    d = 0.30  ->  0.998
```

The study is well powered against a 0.20 $\log_2$**FC and underpowered against 0.10, and this is registered rather than discovered later.** Per-locus Bonferroni testing at $r = 6$ has an MDE of 0.785620 and is registered as **exploratory only.**

§10 FALSIFICATION. F-1 to F-7 of Section 5.7, reproduced in full. **Specifically: a DiD indistinguishable from zero at** $\alpha = 0.05$ **will be reported as "the hypothesis that this signal carries sequence-specific information into transcription is not supported by this experiment."**

§11 CLOSED RESCUE CLAUSES. The following **will not** be offered in response to a null: unregistered arms; endpoint re-specification; extended replication after looking; unsuitability of corpus, cell line, transducer, tuning route or timing.

§12 POSITIVE-RESULT REQUIREMENTS. Any positive claim requires, in addition: an address-swap arm moving the effect to the new loci with payload held constant; a payload-swap arm changing the effect with addresses held constant; independent replication from this packet without author contact. **Without all three, a positive is reported as unattributed.**

§13 PUBLICATION. Preregistration, freeze hash, all arm results, temperature logs, field maps, disclosure packet and raw data published **regardless of outcome. A null is published at equal prominence.**

36.13.1 B.1 The calibration run, filed with the registration

Simulating the exact design at zero true effect, 400 simulated studies, permutation test as specified:

```
r = 3   ->  rejection rate 0.040
r = 6   ->  rejection rate 0.062
r = 12  ->  rejection rate 0.043
```

Nominal $\alpha = 0.05$ **is recovered to within simulation error at every replicate count, so the permutation family as declared is adequately calibrated for this design. That is what the calibration requirement produces, and it takes an hour.**

36.13.2 B.2 The Layer 2 companion, and its firewall

A separate, separately registered Layer 2 study runs with the same corpus: open-label, fully disclosed, **randomised exposure schedule**, $T = 60$ periods, 40 training and 20 held out, $n = 12$ participants, four-baseline conjunction per participant, binomial aggregation.

```
per-participant false-positive rate of the four-baseline gate:  0.095
per-participant pass rate against a half-size effect:           0.482
decision rule: reject the null if k >= 4 of 12 participants pass
actual alpha:  0.02160        power vs half-size effect:  0.908
```

Registered in the same document, in the abstract: no result from this Layer 2 study will be cited in support of any Layer 1 claim. It tests the disclosed expectancy channel and nothing else [Curzi, 2026ab,ac].

Establishes. That the open problem can be posed as a preregistered, powered, falsifiable experiment with a mandatory scrambled control, a calibrated test, closed rescue clauses, and a null publishable at equal prominence — **using 24 cultures and no human participants.**

Does not establish. Any result. **A preregistration is a commitment to find out, and this appendix's entire contribution is that the commitment can be written precisely enough to be kept.**

36.14 Appendix C · Chain A carried end to end

One person, Chain A only, with arithmetic. Chain B is not exercised, because link B3 is not established and an example that exercised it would be a fiction. No clinical, medical or therapeutic claim is made; nothing here is a treatment. Every parameter is constructed for the arithmetic.

36.14.1 C.1 Setup

A person adopts Appendix A's twelve-directive corpus. $N = 12$. They read the full disclosure packet — corpus text, encoding, the 1,776-symbol transmission, tuning table, $j = 6$ and $j = 8$, symbol duration 20 ms, runtime 35.520 s, level 85 dBA, dose 0.123 per cent per rendering — together with Section 6.1's definition, the statement of link B3's status, and the failure catalogue [Curzi, 2026ac]. **They are told, in the same conversation, that nothing is claimed to reach a cell and that no clinical effect is claimed or expected.** They proceed. **Declination would have been recorded as an outcome; it was not exercised.**

36.14.2 C.2 The corpus cannot command them

```
corpus size                    N = 12, closed under negation
resultant                      0.000000000000  (computed, Section 4.4)
non-parallelism                u = 1
effective count                N_eff = 1 + 11(1) = 12   (affine, not a Hill number)
corpus surplus                 F = ln 12 = 2.484907 nats = 3.584963 bits
direction contributed by corpus 0
```

The corpus spans and does not point. Whatever the person does next, the corpus did not tell them to.

36.14.3 C.3 The selection, and its exact size

They select. Under a uniform prior over the twelve, the selection carries $\ln 12 = 2.484907$ nats $= 3.584963$ bits, **contributed entirely by them. This is the extremal case of clause H-A; under a non-uniform prior the figure is that prior's entropy and is smaller, and the honest report states which was assumed. Here: uniform, assumed, declared.**

36.14.4 C.4 The storage law, with stated parameters

The parameters below are constructed for the arithmetic and are labelled constructed. Chain A's outcome is durable change in conduct, taken as Q [Curzi, 2026a]:

```
N        = 12         categories the person distinguishes in this domain
u*       = 0.85       non-parallelism among their own framings
N_eff    = 1 + 11(0.85) = 10.3500
F(u*)    = ln 10.35 = 2.336987 nats
delta    = 0.08       per week
eta      = 0.35       per unit surplus
C        = 0.30       per week, maintenance cost
Q_0      = 0.00       new practice
```

Derived quantities:

```
eta x ln N        = 0.35 x 2.484907 = 0.869717      the ceiling on input
eta x F(u*)       = 0.35 x 2.336987 = 0.817945      the input actually collected
realized fraction = F(u*) / ln N    = 0.940471      94.05% of the ceiling
Q_infinity        = (eta F - C)/delta = (0.817945 - 0.30)/0.08 = 6.474316
Q_max (C = 0)     = eta ln N / delta = 10.871467
headroom          h(Q) = 0.569717 - 0.08 Q ;  h = 0 at Q = 7.121467
time constant     tau = 1/delta = 12.5 weeks; exact pole = -1/ln(0.92) = 11.993052 weeks
```

36.14.5 C.5 The trajectory

t	Q_t	h_t	eta x S	delta x Q + C	growing?
0	0.00000	0.56972	0.81795	0.30000	yes
1	0.51795	0.52828	0.81795	0.34144	yes
2	0.99445	0.49016	0.81795	0.37956	yes
4	1.83616	0.42282	0.81795	0.44689	yes
8	3.15157	0.31759	0.81795	0.55213	yes
12	4.09393	0.24220	0.81795	0.62751	yes
16	4.76902	0.18820	0.81795	0.68152	yes
24	5.59913	0.12179	0.81795	0.74793	yes
32	6.02515	0.08771	0.81795	0.78201	yes
40	6.24380	0.07021	0.81795	0.79950	yes
48	6.35601	0.06124	0.81795	0.80848	yes
52	6.38956	0.05855	0.81795	0.81116	yes

Growth requires $\eta S_t > \delta Q_t + C_t$. It holds at every row and **the margin narrows monotonically: 0.51795 at $t = 0$, 0.00679 at $t = 52$. Headroom falls from 0.56972 to 0.05855 across the year — success consuming its own headroom, and the structural reason the practice plateaus near 6.47 rather than continuing.** After 52 weeks Q has reached 98.7 per cent of Q_∞, consistent with an 11.993052-week time constant and roughly 4.3 time constants elapsed.

36.14.6 C.6 The sensitivity that matters

```
u = 0.00   N_eff =  1.000   F = 0.000000   Q_inf =  -3.75000
u = 0.25   N_eff =  3.750   F = 1.321756   Q_inf =   2.03268
u = 0.50   N_eff =  6.500   F = 1.871802   Q_inf =   4.43913
u = 0.75   N_eff =  9.250   F = 2.224624   Q_inf =   5.98273
u = 0.85   N_eff = 10.350   F = 2.336987   Q_inf =   6.47432
u = 1.00   N_eff = 12.000   F = 2.484907   Q_inf =   7.12147
```

The $u = 0$ row returns a negative equilibrium, and the model does not hide this: when $\eta F(u^*) < C$ the linear model's equilibrium is negative, which means the regime is unsustainable or the model must be replaced [Curzi, 2026a]. Concretely: **a person whose twelve directives have all collapsed into agreement — $u = 0$, a parallel corpus, $F = 0$ — is paying 0.30 per week in maintenance against zero collected surplus, and the practice decays. This is FM-4.7's singleton corpus arriving in the arithmetic, and it is what happens when a contradictory corpus is quietly reduced to the directives its holder already agreed with.**

36.14.7 C.7 The ledger

Quantity	Value	Status
Corpus resultant	0.000000000000	**ARITHMETIC**, computed
Direction supplied by the corpus	0	**ARITHMETIC**, by construction
Selection supplied by the person	2.484907 nats	**ARITHMETIC** in the extremal case, uniform prior declared
Surplus collected per week	0.817945	computed from constructed u^*, N
Realised fraction of ceiling	94.0471 per cent	computed
Steady state Q_∞	6.474316	computed from constructed parameters
Ceiling $\eta \ln N/\delta$	10.871467	**DERIVED** bound [Curzi, 2026a,?]
Time constant	11.993052 weeks	computed
Belief to outcome channel	expectancy, autonomic, behavioural	**CITED (measured), modest**
Disclosure cost to that channel	none demonstrated	modest, active literature
Anything reaching a cell	—	**NOT CLAIMED. Link B3 open.**
Any clinical effect	—	**NOT CLAIMED**
Any capability conferred	—	**NOT CLAIMED. Bounded by $\ln 12 = 2.484907$.**

Establishes. That the four terms compose into a chain whose every link is either established or under the operator's control, that the chain's output is computable from stated parameters, that it converges to a finite value bounded by $\eta \ln N/\delta = 10.871467$ and reaches 6.474316 under the stated cost, and **that the direction of the whole thing was supplied by the person — 2.484907 nats of it, all of it — because the corpus supplied none.**

Does not establish. That anything reached a cell. That any transcript changed. That any capability was conferred. That any clinical, medical or therapeutic effect occurred. **And it establishes nothing empirical about any person: every parameter in Section C.4 is constructed, and the trajectory is an evaluation of a model at chosen values. Link B3 is exactly as open at the end of this specimen as at the beginning.**

What has been described is the activation of what is already there, bounded by what is already there, chosen by the person it happens to. Every one of those three clauses is a restriction. **Together they are the reason the description is worth anything at all: a claim that names its own boundary, its own ceiling, and its own source of direction is a claim that can be checked, and a claim that can be checked is the only kind this framework has ever been willing to make.**

Chapter 37

Protocols at Two Scopes and a Finite Failure Catalogue: Headroom Gating, the Participation-Ratio Effective Count, and Thirty Manifestation Faults

Abstract. This paper converts the Creature Comforts framework into operating protocols at personal and group scope, gated on a single computed quantity. The headroom identity $h = \eta \ln N - \delta Q - C$ is evaluated before anything else: $h < 0$ forbids building, $h = 0$ permits maintenance only, and $h > 0$ caps every requested single-period increment at $r \le h$. A practitioner holding $N = 7$ framings at $u = 0.35$ realises 1.1314 of a possible $\ln 7 = 1.9459$ nats, 58.14 per cent, with $h_0 = 0.5877$, a fixed point $Q_\infty = 3.8641$ and a time constant of 11.99 weeks, so an evaluation at week four reads a transient. An eighteen-person unit passes the same gate at $h_0 = +0.2451$ and yet has a negative equilibrium, $Q_\infty = -0.8755$, because its realised surplus of 57.37 per cent of ceiling cannot carry its maintenance; raising non-parallelism from 0.25 to 0.45 moves the equilibrium to $+1.6211$, and cutting maintenance from 0.55 to 0.45 as well moves it to $+3.2878$. Two measurement corrections are enforced. Feasibility must average $F(U)$ rather than evaluate F at the mean U, an overstatement of 0.0790 nats or 4.31 per cent, worth 0.3952 stored units here. And the effective count is exactly the Rényi-2 participation ratio, so a six-person meeting in which one member takes 45 per cent of the speaking time counts 5.2192, not 6. The Moment equation remains demoted to ordinal use, with the Rasch repair priced at 123 items per term. Thirty failure modes are catalogued across eight coordinates; the reflexive parameter the framework requires is not identified from observational data, and the paper says so.

Keywords: headroom gate; effective count; participation ratio; Jensen correction; seeding strategy; failure catalogue; scale type

Series: B. Engineering the Surplus **Paper:** CCP-037

37.1 1 Introduction

A framework that prices interaction and storage is only as useful as the operating rule it yields, and an operating rule is only as honest as the audit that decides when it may not be run. This paper converts the Creature Comforts framework into protocols at two scopes — one practitioner working alone, and a group working together — and gates both on a single computed quantity rather than on judgement.

The gate is the headroom identity

```
h_t = eta * ln N - delta * Q_t - C_t
```

read as a precondition rather than as a diagnostic afterthought. Its three regimes are exhaustive and its verdicts are hard: `h < 0` forbids building, `h = 0` permits maintenance only, and `h > 0` caps every requested single-period increment at `r <= h`. The quantity is cheap — four parameters and a logarithm — and the claim of this paper is that computing it first changes decisions that are otherwise made on the appearance of health. The storage law whose fixed point and ceiling the gate is derived from is established as a first-order discrete filter in Curzi [2026a], and the surplus functional `F(u) = ln(1 + (N−1)u)` that supplies its input is established with its axiom set in Curzi [2026]; neither is re-derived here.

Three results follow that a reader can check in a few minutes each, and each of them corrects a computation practitioners routinely get wrong.

First, a positive gate and a shrinking system are compatible. The eighteen-person unit worked in Section 7.2 passes the gate at `h_0 = +0.2451` and has a *negative* equilibrium, `Q_inf = −0.8755`, because its realised surplus of 57.37 per cent of ceiling cannot carry its maintenance. Headroom asks whether the system could grow at its ceiling; the one-step growth test asks whether it is growing at its actual `u`. Both must be computed, and the case where they disagree is the common one. The structurally parallel split — positive headroom of +0.0211 against a step of `−0.2952` — is reported for a meeting in Curzi [2026g].

Second, feasibility must average the surplus, not evaluate the surplus at the average. Because `F` is strictly concave, Jensen's inequality makes the error one-directional: the wrong computation always overstates. On the eight measured periods of Section 5.3 the overstatement is 0.0790 nats, 4.31 per cent of the reported figure, which propagates through the storage law to 0.3952 stored units — about a third of the unit's entire accumulated stock, conjured by evaluating a concave function at the wrong point.

Third, the effective count that the protocol uses is exactly a participation ratio. The affine count `N_eff = 1 + (N−1)u` equals `N + 1 − N/PR` with `PR` the Rényi-2 participation ratio of the share vector, an identity established and verified numerically in Curzi [2026c] and re-verified over random correlation matrices in Curzi [2026]. That identity converts a stopwatch reading into a term the surplus law consumes: a six-person meeting in which one member takes 45 per cent of the speaking time has `PR = 3.3693` and an effective count of 5.2192 against a naive count of 6.

A standing caution about which effective count is meant. `1/HHI` and `exp(H)` are Hill numbers of orders two and one and are well grounded in ecology and political science [Hill, 1973, Jost, 2006, Laakso and Taagepera, 1979]. The affine count `1 + (N−1)u` used throughout this paper is **not** a Hill number: it is a linear interpolation between 1 and `N`, adopted as a design axiom in Curzi [2026] and carrying no support in that literature. The two are related here only through the exact algebraic identity with the participation ratio, and the paper states which count it means at every use. The concentration instrument that *is* a Hill number of order two, with its worked jurisdictional case returning a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-HHI of 1.000000 and an effective count of 1.00, is a separate quantity developed in Curzi [2026]; the parallel result on captive domiciles, naive HHI 0.285000 and 3.508772 effective jurisdictions collapsing to 1.00 with a surplus term of exactly zero, is Curzi [2026].

The paper closes with a finite catalogue. A manifestation claim — that some belief, held and acted on, produces some change in the world — is here decomposed into eight coordinates, and thirty named failure modes are catalogued across them in six classes, each priced

by one of four identities. That decomposition into exactly eight coordinates is this work's framing rather than a theorem, and it is badged as such where it is stated.

Two negative results are carried in the same register as the positive ones. The causal step from room acoustics to the collective-intelligence factor is reported as **not confirmed**: the factor itself is measured [Woolley et al., 2010, Engel et al., 2014], and the inference that changing a room's acoustics changes it is not, so every acoustic intervention below is proposed rather than established. And the shuffled-input control is shown to be insufficient on its own: a filtered repackaging of the input passed all four empirical baselines including the shuffle at `p = 0.0005` and was caught only by the structural ceiling test, its claimed jump being 38.5 times `r_max` [Curzi, 2026u].

Sections 2 and 3 state the hypotheses and the method, including the identification problem that bounds every claim about the reflexive loop. Sections 4 and 5 develop the protocols at the two scopes. Section 6 is the catalogue. Section 7 works three instances end to end. Sections 8 to 11 discuss, verify, bound and conclude. Appendices A to C carry the numbered specifications.

37.2 2 Hypotheses

Several results below are theorems about an equation and cannot be falsified by observation; they are labelled as derivations where they appear. What can be falsified is the claim that the equations describe real accumulating systems, and that the protocols built on them change outcomes. The hypotheses separate the two, and each names the observation that would defeat it. The measurement protocol that operationalises them is specified in Curzi [2026i], whose own confirmatory application failed its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin — and every applied claim resting on this paper inherits that result.

H1 — The gate binds. A system that adopts a programme whose maintenance cost exceeds its measured headroom loses stored order over the following horizon, whatever the programme's merits. **Predicted:** for a unit at `h_0 = +0.2451` adopting a programme costing 0.30 per period, the post-adoption gauge is `−0.0549` and the stock declines monotonically thereafter under constant parameters. **Falsified by:** a set of comparable units in which post-adoption stock trajectories are uncorrelated with the sign of `h` computed before adoption; or a unit with `h < 0` that nonetheless accumulates over several time constants with no change in `eta`, `N`, `u` or `C`.

H2 — Headroom and growth are separately informative. Positive headroom does not imply a non-decreasing step, and the disagreement is common rather than exceptional. **Predicted:** at `eta = 0.30`, `delta = 0.06`, `C = 0.55`, `Q = 1.20`, `N = 18` and `u = 0.25`, `h = +0.2451` while `eta F(u) = 0.4975 < delta Q + C = 0.6220`, giving `Q_inf = −0.8755`. **Falsified by:** a demonstration that the sign of `h` and the sign of `eta F(u) − delta Q − C` agree in substantially all measured systems, which would make the second computation redundant.

H3 — The concavity error is one-directional and material. Feasibility computed as `F` of the mean `u` exceeds feasibility computed as the mean of `F(u)`, always, and the difference is large enough to change decisions. **Predicted:** `F(mean u) >= mean F(u)` with equality only when `u` is constant across periods; on the eight-period series of Section 5.3 the gap is 0.0790 nats (4.31 per cent), worth 0.3952 stored units at `eta = 0.30`, `delta = 0.06`. **Falsified by:** an observed series in which the two computations differ in the opposite direction — which cannot occur if `F` is concave, so an observation of it would falsify the functional form rather than the correction.

H4 — Seeding topology dominates seeding count for practices requiring reinforcement. For a behaviour spreading by complex contagion, concentrating a fixed

seeding budget beats spreading it, judged by survival rather than by first-period reach. **Predicted:** 16 seeds spread across 120 people at mean degree 8 under a 2-of-8 rule leave 29.00 per cent of non-seeds with two or more seeded neighbours (30.16 people) and 39.17 per cent with exactly one — a below-threshold exposure; the same 16 concentrated in a 20-person unit activate 4.00 of 4 non-seeds at 80.0 per cent local commitment. **Falsified by:** a field comparison in which the dispersed arm shows equal or better survival after the sponsor is removed, or in which single-contact exposure is shown not to raise the cost of a later attempt.

H5 — A decline rate of exactly zero measures the decline path, not the protocol. Where a protocol records consent, a zero decline rate over many opportunities is evidence that the decline path is inoperative. **Predicted:** protocols with a functioning decline path show non-zero decline rates; the worked unit of Section 7.2 records 3 declines of 18, a rate of 16.7 per cent. **Falsified by:** an audited setting in which participants demonstrably could decline at low cost, were told so, and none did across many independent opportunities.

Three further claims in this paper are not hypotheses and are labelled here rather than left to be discovered. That a manifestation claim decomposes into **exactly** eight coordinates is a **taxonomy** — a framing choice, defensible because each coordinate corresponds to a stage of the grounding protocol [Curzi, 2026ac] or a gate of the Formula Validation Protocol [Curzi, 2026t], and not a theorem; where a fault sits outside the scheme the catalogue will not name it, and Section 10 says so. That a single non-negative scalar `Q` describes a group at all is a **modelling choice**, adopted for tractability and for the fixed-point guarantee. That the same functional form applies at personal and group scope is a **modelling postulate** about model form, falsifiable at each scope separately and never in general; the parallel statement at three scopes, with its five named breaks, is Curzi [2026].

37.3 3 Method: what is gated, what is demoted, and what cannot be identified

The method has four parts. Each step of each protocol carries a **grade** recording what may be concluded from its result (§3.1). Each protocol is gated on the **headroom identity** before anything else is computed (§3.6). Quantities whose scale type does not license the operation performed on them are **demoted in print** rather than used and hedged (§3.4, §3.8). And the central formal object of the framework — the reflexive loop in which the group influences the member and the members constitute the group — is **not identified from observational data**, which bounds what any protocol built on it may claim (§3.12).

Sections 3.1 to 3.5 state the apparatus at personal scope; Sections 3.6 to 3.11 state what group scope adds, which is a gate rather than a paragraph in each case. Section 3.12 states the identification problem, the Lucas critique applied to this framework's own parameters, and the underdetermination of the surplus functional's form, and names which remedy this paper adopts.

37.3.1 3.1 The three grades, and why every step carries one

Every numbered step here is stamped with one of three grades. The stamp is not decoration: it determines what may be concluded from the step's result.

```
GRADE T   THEOREM-BACKED
          The step's arithmetic is a proved consequence of the corpus's
          foundational results. Running it correctly produces a number whose
          MEANING is guaranteed by the mathematics. Whether that number
```

```
          describes a given life is a modelling assumption, badged.

GRADE C   MEASURED CHANNEL
          The step acts through a coupling that has been measured in the published
          literature -- expectation to neurochemistry, scheduling to retention,
          attention to encoding. Effect sizes are modest, contested, and belong to
          the source, not to this framework. The step is expected to do a little.

GRADE R   RESEARCH PROCEDURE
          The step is a well-specified experiment for which NO MECHANISM IS ESTABLISHED.
          It has no demonstrated effect. It is run to generate data, not to produce a
          result. Its expected outcome, under this framework's own diagnostic, is NULL.
```

Every step in this protocol that touches the biological layer is Grade R, without exception, and the reason is the open problem of the missing demodulator [Curzi, 2026y]: there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. Everything upstream of that gap is real and cited in the cell-as-receiver results [Curzi, 2026y]. A Grade R step is a research procedure and not a technique with a demonstrated effect — a sentence repeated on every step it governs in the Specification, because it is the one most likely to be lost when this section is quoted.

37.3.2 3.2 The postulate, badged, and its conditional

The keystone of the biological-layer strand of the corpus is **the author's postulate, stated here with its badge on:**

BELIEF CREATES REALITY IF THE BELIEF IS GROUNDED IN TRUTH.

The conditional clause is the entire content. Formalized (the channel-gain form of the belief postulate [Curzi, 2026ab]):

```
BELIEF  ->  [ CHANNEL ]  ->  WORLD

"grounded in truth"  ==  THE CHANNEL EXISTS AND IS REAL
```

A belief with no channel changes nothing; a belief coupled to a real mechanism changes exactly what that mechanism can change and not one unit more. **The postulate is not that belief is powerful; it is that belief is an INPUT to a system, and the system must have gain.** That is the storage law's architecture — input, conversion efficiency, output — which is why this protocol can be written as a circuit rather than as an exhortation.

Concordance for the postulate, with each column's role stated as the corpus's biological-layer constraints requires:

Column	Source	What it carries
(+1)	Levine, Gordon & Fields (1978): placebo analgesia is naloxone-reversible	**EVIDENCE.** A complete physical channel from expectation to measured outcome
(+1)	Kaptchuk et al. (2010, IBS): open-label placebo	**EVIDENCE.** The effect does not require deception. Effect sizes modest; literature active

Column	Source	What it carries
(-1)	The contemplative traditions' insistence that intention without a practice is inert	**PRECEDENT.** That the conditional was arrived at independently, without instruments
(0p)	The two integrate: neither says belief is omnipotent; both say belief requires a carrier	The Neutral Point holds without either column having to say something false

Two sources agreeing does not double the evidence when only one of them is evidence. What the (-1) column establishes is real and worth having — that the structure was findable by more than one route, which argues the structure is in the territory and not only in the instrument. It is not a second measurement. entry MF-23 of Section 6, treats the failure to keep these apart as this volume's single most likely methodological collapse.

37.3.3 3.3 The three constraints carried forward, in place

Three constraints bind this one, restated in full rather than cross-referenced, because a protocol chapter is the one a reader photocopies.

CONSTRAINT 1 — NO SUBLIMINALS (the disclosed-narrative constraint [Curzi, 2026ac]). Nothing masked, nothing below threshold, nothing concealed: no carrier the recipient cannot hear, no layer they were not told about, no content they cannot inspect. **A message hidden from its recipient cannot be consented to, and a protocol that cannot be consented to is outside what this framework will describe** (the fourth standing refusal of the corpus). Every audio artefact used here must therefore be fully audible, fully documented as to content, and inspectable as a file. Open-label placebo is why this costs nothing: the strongest verified belief-channel in the literature works *when disclosed*.

CONSTRAINT 2 — THE OPEN PROBLEM (the open problem of the missing demodulator [Curzi, 2026y]). There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. Upstream is real: DNA data storage (Church, Gao & Kosuri, *Science*, 2012), gRNA-format addressing, Cas12a's native self-processing of its own crRNA array (Zetsche et al., *Cell*, 2015), latent capability and its activation (Yamanaka reprogramming, Nobel 2012), epigenetic regulation, and mechanotransduction (PIEZO1/2, Nobel 2021). **The channel for sequence-specific content is the question, not an answer this framework possesses.** Therefore every biological-layer step is Grade R.

CONSTRAINT 3 — THE GROUNDING DIAGNOSTIC (the grounding protocol [Curzi, 2026ac]). Six stages, in order, no skipping:

```
G-1  IDENTIFY THE CHANNEL     Name the coupling. Not "energy", not "the field".
                              A named physical or informational path with two ends.
G-2  CHECK IT IS POSSIBLE     Does anything forbid it? Conservation, scale, timing,
                              attenuation, the Gabor limit. A veto here ends the matter.
G-3  ESTIMATE ITS GAIN        How much output per unit input? Order of magnitude only.
G-4  PREDICT A MAGNITUDE      Write the number DOWN, with units and an interval,
                              BEFORE measuring. This is the step people skip.
G-5  MEASURE                  Against the pre-registered plan, with the four baselines.
G-6  COMPARE                  Predicted against observed. Report the ratio. Report it
                              whichever way it comes out.
```

Stage G-4 is the one that converts a belief into a scientific claim, and it is the one that almost no manifestation practice in circulation performs. A practice that predicts no magnitude cannot be wrong, and a practice that cannot be wrong cannot be trusted when it is right.

37.3.4 3.4 The CC-R1 demotion, stated exactly, and what it forbids

the Formula Validation Protocol [Curzi, 2026t] returns **DEMOTE on gate 2 (scale type)** for the Moment equation `M = (D/P)·E`. The reason is in the scale-type analysis [Curzi, 2026t]: division requires a ratio scale with a true zero, and D (perspective) and P (perception) are not yet instrumented that way.

What is demoted is MAGNITUDE, not STRUCTURE. The distinction is precise and this protocol depends on it:

Still standing (needs only ordinal information)	Demoted (needs ratio scale)
The limiting cases: `P -> 0` gives runaway frame; `D -> 0` gives no moment; `E -> 0` gives no moment	The numeric value of `D/P`
The fixed point `D = P`, where the moment equals the environment — undistorted contact	The distortion `Delta = |ln r|` as a measured quantity
The three-way ordering **over-framed / calibrated / under-framed**	The join `M_t -> Q_{t+1}` as a quantitative transfer (the storage law [Curzi, 2026a])
The DIRECTION of a change in framing between two occasions	The SIZE of that change

Every use of `D/P` in this section is ORDINAL: direction and ordering only, never a numeric magnitude. The instrument in §4.3 is built to produce exactly three verdicts and no number, and it is built that way on purpose. Where a reader wants the number, the Rasch-route theorem [Curzi, 2026t] gives the constructive route: a **Rasch logit difference** makes `Delta = |ln(D/P)|` genuinely ratio-scaled, because Rasch separation supplies the true zero that division requires. The cost is stated and is not small — **123 items per term.** For the two terms of the ratio that is 246 items; for all three terms of the Moment, 369 items. At a brisk twenty seconds per item, one full three-term administration is 123 minutes, or **2.05 hours**, and the cross-individual recovery gate (FVP-7) with thirty participants is **61.5 person-hours** of item administration before any analysis.

That is the price of a number, and this framework would rather print the price than a number it has not earned.

37.3.5 3.5 Consent, reversibility and decline are gates, not advice

This is the structural commitment of the section and it needs to be stated as engineering rather than as ethics, because stated as ethics it becomes optional under pressure.

A protocol is a sequence of steps. **This protocol is a sequence of steps interleaved with three kinds of GATE, and a gate is a step that can HALT the protocol.** Advice cannot halt anything. Gates can, and these do.

```
GATE TYPE K  (KNOW)      Before any step, the practitioner can state, in their own words,
                         what the step does, what it is expected to do, what grade it
                         carries, and what its null result would look like.
                         FAIL -> the step does not run. Not "runs with a caveat."

GATE TYPE D  (DECLINE)   At every gate, "no" and "not now" are recorded outcomes with
                         the same status as "yes". A decline is DATA, never a null
                         return and never a missing value to be imputed.
                         FAIL (no decline path exists) -> the protocol is void.
```

```
GATE TYPE V  (REVERSE)   Before any step, a written rollback exists: how to stop, how
                         long the residue lasts, and what cannot be undone.
                         FAIL (no rollback, or an unbounded residue) -> the step does
                         not run, at any expected benefit.
```

Three consequences follow, and they are why the gates are structural rather than decorative.

First, Gate K forbids the concealed layer by construction: a participant cannot state what a step does if part of what it does is hidden from them. Constraint 1 is not an add-on; it is enforced by the protocol's first gate.

Second, Gate D makes the decline path load-bearing on the arithmetic. the internal formulary [Curzi, 2026o] requires that an echo source who declines is recorded as missing data rather than as a null return; here, a declined step cannot silently become a zero in the storage ledger, which would bias every downstream number optimistically.

Third, Gate V is why the biological arm is audio-only and listen-only. An audio file can be stopped, and its residue is the memory of having heard it — real, bounded, and exactly the residue of anything else that has been listened to. **Nothing is imported, nothing is delivered, no Cas protein is present, and no sequence is changed** (the corpus's biological-layer constraints). The architecture cannot edit DNA and this framework does not claim that it does, has done, or could.

And the standing refusals of the standing refusals of the corpus apply here with no softening: this section makes **no clinical, medical or therapeutic claim**; it reports **no trial, no controlled observation, and no demonstrated physiological effect of the method**; and it claims **no capability has been conferred on anyone.**

37.3.6 3.6 Gate 0: measure `h` first, and if `h < 0` the group may not build

the headroom gauge [Curzi, 2026a], the master gauge, unchanged:

```
h_t := eta * ln N  -  delta * Q_t  -  C_t

h_t <  0    Unsustainable IN THIS MODEL. No interaction geometry saves it
            (the no-geometry-rescues corollary \citep{ccp:CCP-007}). THE GROUP MAY NOT BUILD.
h_t =  0    Maintenance only. Hold, do not build.
h_t >  0    Growth available; any requested increment must satisfy r_t <= h_t
            (Corollary 4.2). That is a ceiling, not a target.
```

The gate is not advice about prudence. Corollary 3.4 is a theorem: if `C_t > eta ln N - delta Q_t`, no choice of interaction geometry can prevent stored order from decreasing. A group may recruit brilliantly, diversify perfectly, and run flawless meetings, and `Q` will still fall, because the arithmetic of the leaky integrator does not care how good the inputs are once the draw exceeds the maximum the inputs can supply. the storage law [Curzi, 2026a] calls this the single most important sociological statement in the corpus, and this section treats it as a hard precondition.

What "may not build" means operationally: **no new programme, no new practice, no new ritual, no new measurement regime, and specifically no biological-layer arm.** Every one of those adds to `C`, and adding to `C` when `h < 0` moves the system further from feasibility while generating activity that looks like progress. The permitted actions when `h < 0` are exactly two: reduce `C`, or deliberately shed `Q` (the shedding lever [Curzi, 2026a], with its ethical boundary intact).

Badged, as the corpus's conventions require: **that a single scalar `Q` describes a given group at all is a modelling choice, not a theorem.** The founding papers prove things about the law;

they prove nothing about any particular team. Where the fault is outside the model — a funding cut, a legal shutdown, a death — the gauge will not name it, and the correct response is to say so rather than force a parameter.

37.3.7 3.7 Individuality is a mathematical requirement, not a courtesy

This is the load-bearing constraint of the whole chapter and the independence requirement [Curzi, 2026g] establishes it four separate ways. The four are worth restating because a group protocol is exactly the instrument that tends to violate them.

```
Condorcet (1785)  : aggregation beats the individual ONLY under independence
\citet{hong2004groups}: difference contributes what ability cannot
Cascades (1992)   : copying stops information from entering the pool
Woolley (2010)    : equality of conversational turn-taking predicts collective performance
```

Four different subjects — probability, search, sequential inference, factor structure — produced by people not working on each other's problems. **Each reduces to the same instruction: keep the individuals individual, and keep them all in.** And the surplus law prices the violation exactly:

```
S = ln(1 + (N−1)u)        merge the members -> u -> 0 -> N_eff -> 1 -> S -> 0
                          silence the members -> participating N falls -> same effect
```

Merge the individuals and the collective capability falls. That is not an ethical claim that happens to be convenient; it is `ln 1 = 0`. The cruelty of the failure is that a converged group does not feel impoverished. It feels *aligned*, and alignment feels exactly like being right. There is no internal signal that distinguishes a room that converged on the truth from a room that converged on the first speaker — only a protocol can, and only if it ran before the room started talking.

Every step of this section's protocol is therefore constrained twice: once by `h`, and once by the requirement that it must not lower `u` or reduce the participating `N`. A step that raises `Q` by lowering `u` is not a gain. It is borrowing from the ceiling to pay the floor.

37.3.8 3.8 The CC-R1 demotion at group scope

The Moment equation's group reading is the **doctrine-to-data ratio** (the corpus's internal-scope conventions): an over-framed institution is one whose doctrine outruns its intelligence and sees what its model predicts; an under-framed one drowns in data it cannot read. the group-moment analysis [Curzi, 2026r] develops it.

The Formula Validation Protocol returns DEMOTE on gate 2 for `M = (D/P)·E`, at group scope exactly as at personal scope, because D and P are not instrumented on ratio scales with true zeros (the scale-type analysis [Curzi, 2026t]). What is demoted is magnitude; structure stands.

Stands (ordinal information suffices)	Demoted (needs a ratio scale)
The limiting cases and what they name	The numeric value of `D/P` for an institution
The fixed point `D = P` — doctrine matched to intake	The distortion `Delta = |ln r|` as a measured quantity
The ordering **over-framed / calibrated / under-framed**	The join `M_t -> Q_{t+1}` as a quantitative transfer

Every use of `D/P` in this section is ordinal — direction and ordering only, never a numeric magnitude — and the group instrument in §5.11 is built to make the numeric version impossible rather than merely discouraged. The constructive route out is the Rasch-route theorem

[Curzi, 2026t]: a Rasch logit difference supplies the true zero that division requires and makes `Delta` genuinely ratio-scaled. **The cost is 123 items per term**, so 246 items for the ratio and 369 for all three terms of the Moment. At a group of 30 and twenty seconds per item, a three-term administration is **61.5 person-hours** before any analysis. That is the price of the number, and a group that wants the number should budget it rather than assert it.

37.3.9 3.9 The acoustic-to-c-factor causal test is NOT confirmed

the acoustic intervention analysis [Curzi, 2026f] states the falsification test for the claim that acoustic conditions causally raise the collective-intelligence factor `c`, **and reports the test as not confirmed.**

This section carries that status without softening. **Woolley et al. [2010] is real: there is a collective intelligence factor, it is not predicted by members' average or maximum IQ, and it correlates with social sensitivity, equality of conversational turn-taking, and the proportion of women in the group.** Those are measured correlations in the published work.

What is not established is that changing a room's acoustics changes `c`. The mechanism is plausible — turn-taking equality is a measured correlate of `c`, and acoustics plainly affect turn-taking — but plausible is not confirmed, and the acoustic intervention analysis [Curzi, 2026f]'s own test came back negative. **Therefore every acoustic intervention in this section is PROPOSED, not established, and is labelled so at each appearance.** A group may run one as an experiment. A group may not report one as a capability.

37.3.10 3.10 Consent at group scope, and the hazard a person does not have

Section 4's three gates carry over unchanged in form:

```
GATE K  (KNOW)     Every participant can state what the step does, what grade it
                   carries, and what its null result looks like.  FAIL -> no run.
GATE D  (DECLINE)  "No" and "not now" are recorded outcomes with the same standing
                   as "yes". A decline is DATA, never a null return and never an
                   imputed zero.  FAIL (no decline path) -> the protocol is void.
GATE V  (REVERSE)  A written rollback exists: how to stop, what residue remains,
                   and what cannot be undone.  FAIL -> the step does not run.
```

At group scope one more gate is required, and it exists because of a hazard that has no individual analogue.

```
GATE I  (INDEPENDENCE)  Before any step that could align beliefs, the group's
                        capacity to disagree is MEASURED, and it is measured again
                        after. If the step lowered u or reduced participating N,
                        the step is reversed regardless of what else it produced.
```

A group can manufacture the appearance of consent, and a group running a change programme is the archetypal machine for doing so. the two-mechanisms-of-commitment analysis [Curzi, 2026g] already draws the line between two mechanisms that produce apparent commitment: a person who has adopted a practice because it works for them, and a person who has adopted it because dissent is expensive. **The two are indistinguishable from the outside and completely different in the ledger, because the second one has `u = 0` with respect to the group's belief and contributes nothing to S.**

Gate I is what makes the difference detectable. It has a hard operational form: **a decline rate of exactly zero across many opportunities is a measurement of the decline path, not of the protocol.** If nobody has ever said no, Gate D has not been satisfied — it has been declared.

the standing refusals of the corpus's fourth refusal governs absolutely: **this framework does not recommend an intervention that removes a person's ability to decline.** At group

scope that refusal has teeth only if the decline is cheap, visible, and recorded, which is why B.4 and B.17 below are procedures rather than sentiments.

37.3.11 3.11 The concordance for this section's spine

Each column's role is stated, as the corpus's biological-layer constraints requires. **The (+1) column carries evidence; the (-1) column carries precedent — that the structure was arrived at independently, by people without instruments, which argues the structure is in the territory and not only in our instrument. It is not a second measurement.**

Claim	(+1) EVIDENCE	(-1) PRECEDENT	Status
Aggregation requires independence	Condorcet 1785 (theorem); informational cascades [Bikhchandani et al., 1992, Banerjee, 1992]	Deliberative traditions that require each voice before any is answered	**Established**; the theorem is proved, the transfer to a given group is a badged assumption
Difference outperforms uniform ability	Hong and Page [2004]	Guild and council practices of seating unlike trades together	**Established** in the cited model class
Equal turn-taking predicts group performance	Woolley et al. [2010]	The talking-stick and round-robin forms found independently in many cultures	**Established as correlation.** Causal direction not settled here
Acoustics raise `c`	**NONE. the acoustic intervention analysis [Curzi, 2026f] reports the causal test as NOT CONFIRMED**	Traditions of purpose-built assembly acoustics	**NOT ESTABLISHED. Proposed only**
A committed minority can flip a convention	Centola et al. [2018]: ~25% in controlled online experiments	The persistent folk observation that a determined few change a house's habits	**Established in the experimental setting.** Field transfer is a modelling assumption
Clustered seeding beats broadcast	Centola and Macy, 2007, Centola, 2010 — complex contagion needs reinforcing contacts	Apprenticeship and cell structures that propagate by dense local ties	**Established** for complex contagion
Durable institutions come from designed commons rules	Ostrom [1990]	Centuries of surviving common-pool arrangements the corpus documents	**Established**
Acoustic input carries sequence-specific content to a cell	**NONE — the open problem (the open problem of the missing demodulator [Curzi, 2026y])**	Correspondence doctrines linking sound and form	**NOT ESTABLISHED.** Speculative, and marked speculative here in the sentence that states it

---

37.3.12 3.12 Identification: what no protocol can recover from observation

The framework's reflexive claim is that the group's state influences each member and the members constitute the group: `T(x) = W(x, M(x))` in the corpus's notation, and in the notation of econometrics a **linear-in-means reflexive specification**. Manski [1993] proves that the endogenous social effect in that specification is **not identified from observational data**: it cannot be separated from contextual effects, nor from correlated unobservables, no matter how many periods are collected. Shalizi and Thomas [2011] reinforce the point for network data, where influence and selection are generically confounded.

This bounds every protocol in this paper, and the bound is stated here rather than in a footnote. The protocols measure `u`, `N`, `eta`, `delta`, `C` and `Q`, compute `h`, and act on its sign. What they do not do — and what no amount of held-out fit would license — is recover a parameter representing the group's influence on its members from observing the group. A fitted value of `eta` in a system whose members are influencing one another absorbs contextual and correlated effects into itself; it is a summary of the fitted series, not a measured coupling.

The known remedies are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation, the last on the template of Brock and Durlauf [2001]. **None of them is free, and this paper adopts none of them.** The worked instances of Section 7 are constructed examples with declared parameters, so the question of identification does not arise for them arithmetically; it arises the moment the protocol is run on a real unit, and at that point **the claim that the fitted parameters describe the unit's social mechanism is a modelling position rather than an identified empirical result.** Section 10 records this as the paper's most serious unmet standard.

Two objections in the same family are also unanswered here and are recorded rather than argued away.

The Lucas critique, turned on this framework's own parameters. Lucas [1976] holds that behavioural parameters estimated under one policy regime need not survive a change of regime, because agents re-optimise. The framework asserts that systems change their behaviour when they are modelled and observed — that is the whole content of the reflexive loop — and then proceeds to treat `eta`, `delta` and `u` as stable enough to fit. **Either those parameters are stable under the framework's own predicted response to being measured, or the framework undercuts itself.** Hacking [1995] names the mechanism in the human sciences directly: a classification changes the people classified. This paper takes the first horn as an assumption and labels it an assumption; it does not defend it, and a group re-measuring `u` after adopting the protocol is measuring a `u` the protocol may itself have moved. The one field study in which a reflexive fixed point is documented with dates and price data — MacKenzie and Millo [2003] on option pricing — is the corpus's best existence proof that the mechanism is real, and it is an existence proof rather than a licence to treat a fitted coefficient as a measurement.

The functional form is underdetermined by the evidence. The logarithm `F(u) = ln(1 + (N−1)u)` is not the only form that fits the qualitative facts. Latané's social impact theory proposes a power law with exponent below one [Latané, 1981]; Odlyzko and Tilly's critique of Metcalfe's law proposes `n log n` [Briscoe et al., 2006]; the corpus proposes the logarithm. **All three deliver diminishing returns in count, and nothing in the worked examples of this paper discriminates between them.** The paper's own honest position is that the logarithm follows from the affine-effective-count design axiom of Curzi [2026] and from nothing else established here.

One genuine strengthening should be recorded alongside. The usual warrant for the logarithm is Fechnerian — sensation proportional to the logarithm of a stimulus ratio measured from a floor [Fechner, 1966] — and that warrant requires the perceptual story to be true. Peters and Gell-Mann [2016] derives a logarithmic evaluation from multiplicative dynamics with **no psychological assumption at all**: the time-average growth rate of a multiplicatively evolving quantity is the expectation of its logarithm. Where a stock compounds rather than adds, that is the warrant the argument actually needs, and it is the stronger of the two because it does not require Fechner to be right.

37.3.13 3.13 Analogy discipline, and what is borrowed from where

The framework borrows form from physics and engineering throughout, and every borrowing below is one of three things, labelled at first use.

- **A shared mathematical form.** The storage law is a first-order discrete filter with a pole at `z = 1 − delta`; the whole apparatus of such filters — DC gain, time constant, settling time — applies because the equation is the same equation, with no claim that the underlying physics transfers [Oppenheim et al., 1996, Åström and Murray, 2008]. The leaky integrator has the same status in computational neuroscience [Gerstner and Kistler, 2002], and geometric convergence follows from the contraction property [Banach, 1922, Elaydi, 2005]. **This is the category most of this paper sits in, and it is a respectable one.**
- **A derivation.** Jensen's inequality applies to `F` because `F` is strictly concave, which is proved, not assumed [Curzi, 2026]. The participation-ratio identity is algebra [Curzi, 2026c]. The Gabor limit `dt df >= 1/(4 pi)` is a theorem of Fourier analysis and constrains any rendering of information into sound [Gabor, 1946]; it is classical, it applies to every wave, and it carries no quantum content.
- **An analogy, and never evidence.** The reading of an effective count as a count of independent Bernoulli voters in Section 5.6 is a **modelling convenience**: Condorcet's setup assumes independence outright, and `N_eff` audits redundancy rather than counting independent trials. The stitch is informative about direction and order of magnitude and is claimed to be nothing more.

One inheritance is presupposed rather than restated. The framework's founding definition — comfort as the felt total of present costs, so that the present state is a local minimum of the comfort landscape by definition rather than by luck — is established in Curzi [2026], together with the correction that the variational statement is `delta–S = 0`, *stationarity* and not minimality, and that the variational form licenses **no teleology whatever**. Nothing in this paper's protocols may be read as a claim that a system is seeking anything.

Entropy in this paper is Shannon entropy where it appears at all — the surplus is a logarithm of an effective count reported in nats, a pure number — and no thermodynamic quantity is invoked. The participation ratio is the reciprocal of a Rényi-2 collision probability [Rényi, 1961], which is why it is an effective count in the standard sense [Hill, 1973] even though the affine count that equals it algebraically is not.

37.4 4 The protocol at personal scope

Everything in this framework up to here has been either apparatus or argument. This section is the first one that a single person can run tonight, alone, with a notebook and a timer, and get a number out of by the end of the quarter. It keeps that promise in the only way it can be kept honestly: by being exact about which parts of the practice rest on theorems, which rest on measured channels, and which are research procedures with no demonstrated effect at all. **A protocol that mixes those three grades without labelling them is not a protocol; it is a mood.**

The section joins two things. From the formulary it takes the internal-scope formulary [Curzi, 2026o] — nine formulas at internal scope, each with its Formula Validation Protocol row already printed. From the biological-layer strand of the corpus it takes the biological layer: the cell as receiver (the cell-as-receiver result [Curzi, 2026y]), the library of latent capability (the latent-capability result [Curzi, 2026y]), addressing without editing (the addressing-without-editing result [Curzi, 2026y]), narrative as regulatory input (the disclosed-narrative constraint [Curzi, 2026ac]), and — decisively — the open problem of the missing demodulator [Curzi, 2026y]. The join is where a reader is most likely to be sold something. So the join is where this section is most careful.

37.4.1 4.1 The three layers, and their honest gain

A personal protocol built on this framework has exactly three layers. They are not equal partners.

Layer	Grade	What it acts on	Honest expectation
L1 Informational	T	The practitioner's framing: `D`, `P`, `N`, `u` — the lens and its variety	Real and immediate. The arithmetic is proved; the fit to a particular life is a badged modelling assumption
L2 Behavioural	C / T	The practitioner's schedule, cadence, load: `eta`, `delta`, `C`	Real, slow, and cumulative. The leaky integrator does the work; cadence beats intensity (the cadence result [Curzi, 2026a])

Layer	Grade	What it acts on	Honest expectation
L3 Biological	R	Nothing demonstrated	**Expected null.** A research procedure with no established mechanism

Effectively everything this protocol will actually do for a person happens in L1 and L2, and the section says so at the front rather than at the back. A reader who runs only L1 and L2 is running the whole of what has been demonstrated. A reader who runs L3 as well is running an experiment, and is told so in the sentence that invites them to run it.

The layers compose through one circuit — the internal formulary [Curzi, 2026o] with the biological arm drawn as what it is, an open lead:

```
L1 (lens)                          L2 (integrator)
E -> [ D/P ordinal ] -> M   ----->  Q_{t+1} = (1-d)Q_t + eta*M - C
       ^                                |-> h = eta lnN - dQ - C
       | F_int = ln(1+(N-1)u)          |-> L = max(0, M - C)
       +----- echo: Delta_R = |ln(M'/M)| <---- world

L3 (biological arm)
audible, disclosed, inspectable artefact
       |
       X   NO ESTABLISHED DEMODULATION MECHANISM   <-- the open problem of the missing demodulator \cite
       |
       v   (nothing downstream is claimed)
```

The `X` in that diagram is the honest content of the biological-layer strand of the corpus. It is drawn, not omitted.

37.4.2 4.2 The channel inventory for one person

the channel-gain form of the belief postulate [Curzi, 2026ab] requires that a channel be *named*. Here is the inventory a single operator has. **Nothing on this list is a medical or therapeutic claim; each row states something about the manual's own parameters, or reports a published finding belonging to its source.**

#	Channel	Grade	Acts on	Status
1	Expectation -> physiology	C	outside the framework's parameters	Measured in the placebo literature; analysed with its channel-gain form in Curzi [2026ab]. Naloxone-reversible for analgesia (Levine, Gordon & Fields 1978); open-label variants work (Kaptchuk et al. 2010). Modest effects, active literature. Neither primary source carries a key in this corpus's external bibliography (L-14)
2	Cadence -> retention	T	`delta`, `Q`	Periodic forcing of a leaky integrator (the cadence result [Curzi, 2026a], the periodic-forcing analysis [Curzi, 2026a]). Pure consequence of the storage law
3	Variety of framing -> ceiling	T	`N`, `u`, `F_int`	the surplus-functional theorem [Curzi, 2026]. `S = ln(1+(N−1)u)`, ceiling `ln N`
4	Prediction logging -> calibration	C	`D` relative to `P`	Ordinal only under CC-R1. Direction of miscalibration is recoverable; magnitude is not
5	Load shedding -> headroom	T	`C`, `h`	the headroom gauge [Curzi, 2026a]. `h = eta ln N − delta Q − C`
6	Echo -> frame correction	T	`D`	the returned-difference result [Curzi, 2026]. `Delta_R = |ln(M'/M)|`; zero means nothing came back

#	Channel	Grade	Acts on	Status
7	Acoustic -> mechanotransduction	C	a cellular signal, non-specific	PIEZO1/2 are mechanically gated; sound is mechanical (the corpus's biological-layer constraints). **Real, established, and non-specific**
8	Acoustic -> sequence-specific content	**R**	**nothing demonstrated**	**No established mechanism (the open problem of the missing demodulator [Curzi, 2026y]). This is the open problem**

Rows 7 and 8 are the two a careless reader will merge, and merging them is the single most consequential error available in this strand of the corpus. Row 7 says a pressure wave can become a cellular signal — Nobel-recognized and true. Row 8 says it can carry *which* signal, addressed to a *particular* sequence, and that is exactly what has no mechanism. Section 6 catalogues the merge as MF-03.

37.4.3 4.3 The ordinal calibration instrument

The Moment's structure survives the CC-R1 demotion; its magnitude does not. The personal instrument is therefore built to return the structure and refuse the magnitude.

THE PREDICTION LOG. For a defined class of recurring occasion — a meeting, a market open, a particular conversation, a training session — the practitioner records, *before* the occasion:

```
1. What is expected to happen, in one sentence, specific enough to be wrong.
2. Which single observable will be used to check it.
3. The direction that observable is expected to move.
```

Afterwards the observable's actual movement is recorded. No ratio is computed. One of three verdicts is assigned, and only three:

```
OVER-FRAMED    ( r > 1 )   The prediction was seen rather than the occasion; the
                           observable did not support it; the expected support was
                           noticed and the disconfirmation was not. Frame outran
                           intake.

CALIBRATED     ( r = 1 )   Prediction and observable agreed, including where
                           the prediction was wrong and that was recorded.

UNDER-FRAMED   ( r < 1 )   The occasion delivered more than the frame could index.
                           It can be described but not used.
```

These three verdicts are an ORDERING, and an ordering is all the CC-R1 demotion permits, which is why this instrument produces no number and should not be made to produce one. Verdicts may be counted across occasions — twelve over-framed, four calibrated, six under-framed is a legitimate tally of ordinal outcomes. That tally may **not** be converted into a value

of D/P, and no distortion Delta may be reported. Where an instrument reports a "perception ratio" of 1.4, entry MF-08 of Section 6 is the entry to look up.

The tally is still a genuine diagnostic, because the ordering carries the content:

Dominant verdict	Reading	Lever
OVER-FRAMED	Doctrine outrunning intake; the model is being seen rather than the occasion	Raise P: add an observable outside the practitioner's control, and one adversarial source
CALIBRATED	Contact. The rarest of the three and the one to protect	Hold. Add no instrumentation that will not be read
UNDER-FRAMED	Flooding; intake without a frame that can index it	Raise D: acquire the vocabulary, not more exposure

37.4.4 4.4 The internal surplus audit

the internal surplus [Curzi, 2026o] F_int = ln(1 + (N−1)u) over one person's own framings — the founding material's the founding material HORIZON, "the many windows of the one tower," as a derivation rather than an analogy. For a person holding N = 7 genuinely distinguishable framings of their situation, ln 7 = 1.9459 nats is the hard ceiling, and u decides how much of it is collected:

u	N_eff	S = ln N_eff (nats)	Fraction of ceiling
0.00	1.0000	0.0000	0.00%
0.05	1.3000	0.2624	13.48%
0.10	1.6000	0.4700	24.15%
0.25	2.5000	0.9163	47.09%
0.35	3.1000	1.1314	58.14%
0.50	4.0000	1.3863	71.24%
0.80	5.8000	1.7579	90.34%
1.00	7.0000	1.9459	100.00%

Seven framings that are all the same framing purchase exactly zero surplus, because ln 1 = 0, and the law is not being poetic. Strict concavity (the strict-concavity result [Curzi, 2026]) delivers the design fact: u = 0 to u = 0.25 buys 47% of everything available. **The first genuinely different way of seeing one's own situation is worth more than all subsequent ones combined.**

Measuring one's own u is the hard part, and the honest procedure is indirect: list the N framings, then ask of each pair whether they ever *disagree about what to do next*. Pairs that never disagree are parallel. If m of the N(N−1)/2 pairs have produced a different recommended action, a rough estimate is u \ensuremath{\approx} m / [N(N−1)/2]. For N = 7 there are 21 pairs; seven live disagreements gives u \ensuremath{\approx} 0.33. **This is a crude instrument, labelled as one: use it to detect the collapse at the left end of the table, which is large, not to resolve differences in the middle, which it cannot.**

37.4.5 4.5 The self-storage run

the storage law [Curzi, 2026a]'s join: Q_{t+1} = (1 − delta)Q_t + eta·M_t − C_t. **The join is STRUCTURAL, not yet quantitative** (CC-R1), so M_t enters as a normalized input in [0, ln N]

and the numbers below are an illustrative construction, stated as such, not a measurement of anybody.

Take a weekly period, `N = 7`, `u = 0.35` so `S = 1.1314`, and parameters `delta = 0.08` (what a week of no practice costs in retention), `eta = 0.45` (how much of a week's engagement becomes durable structure), `C = 0.20` (weekly maintenance), starting from `Q_0 = 1.10`.

```
Q_inf = (eta*S − C) / delta = (0.45*1.1314 − 0.20) / 0.08 = 3.8641 Q-units
tau   = −1 / ln(1 − delta)  = 11.9931 weeks
half-life to the fixed point = ln(2) * tau = 8.3130 weeks
```

week `t`	`Q_t`	`h_t = eta ln N − delta Q_t − C`
0	1.1000	0.5877
4	1.8839	0.5249
8	2.4455	0.4800
12	2.8479	0.4478
16	3.1361	0.4248
20	3.3426	0.4083
24	3.4905	0.3964

Three things a reader should take from this table and from no other table in the section.

First, the time constant is twelve weeks and the half-life is eight. Not eight days, not one intense weekend. **`delta = 0.08` per week sets the pace, and no amount of enthusiasm in week one changes `delta`.** This is why cadence beats intensity (the cadence result [Curzi, 2026a]): the integrator does not care how large a single input was, only how many arrived before the previous ones leaked away.

Second, headroom falls as stored order grows. `h` drops from 0.5877 to 0.3964 over twenty-four weeks with no parameter changed, purely because `delta·Q` rises. A practice that worked in month one and feels heavier in month six is `delta·Q` doing arithmetic, not failing willpower (the falling-headroom result [Curzi, 2026a]).

Third, the fixed point is real and arrives. Because `delta > 0` the map is a contraction and Banach's fixed point theorem guarantees a unique fixed point reached from any start — which is why iteration *arrives* rather than wandering (the contraction theorem [Curzi, 2026]). The founding material's fixed-point node is the fixed-point theorem of the storage law [Curzi, 2026a].

The corresponding fixed-point headroom is CC-R6's identity: `h_inf = eta·(ln N − S) = 0.45 × (1.9459 − 1.1314) = 0.3665`. **`delta`, `C` and `Q` all cancel at the fixed point.** The headroom of a mature personal practice depends on one thing only: the gap between the ceiling `ln N` and the surplus `S` actually collected. **A mature practice with headroom near zero does not have a discipline problem. It has a `u` problem.**

37.4.6 4.6 The headroom gate

`h_t = eta·ln N − delta·Q_t − C_t`, the headroom gauge [Curzi, 2026a], at internal scope. The gate:

```
h_t <  0    Unsustainable IN THIS MODEL. No arrangement of framings rescues it
            (Corollary 3.4). DO NOT ADD ANYTHING. Shed cost or shed stored order.
h_t =  0    Maintenance only. Hold. Do not build.
h_t >  0    Growth available. Any requested increment must satisfy r_t <= h_t
            (Corollary 4.2). That is the maximum, not a target.
```

This gate runs before every addition to the practice, and before the biological arm in particular, because that arm is a Grade R research procedure with an expected null result and a real cost in C. Spending scarce headroom on an arm whose expected yield is zero is a defensible research decision and an indefensible self-improvement decision, and the practitioner should know which one they are making.

The distinction half of all misdiagnosis turns on (the headroom-versus-growth diagnostic split [Curzi, 2026g]) applies here: `h` uses `ln N`, the growth test uses `S = ln N_eff`. **A system can have comfortable headroom and still lose stored order every week, if operation is far below the ceiling.** Both must be computed.

37.4.7 4.7 The biological arm, stated as what it is

Here is the whole of what the biological arm consists of, written so that a reader can see there is nothing behind the curtain.

What is done. Text the practitioner wrote about their own situation is encoded in base 4 (Church, Gao & Kosuri, *Science*, 2012, is the reference for base-4 encoding of arbitrary data as sequence), given a gRNA-format routing prefix as an *address format*, not a molecule (the addressing-without-editing result [Curzi, 2026y]), and rendered to audio by the method of the disclosed sonification chain [Curzi, 2026y]. The practitioner listens at an audible level, knowing exactly what it contains, with the file available for inspection.

What is claimed. That the encoding and rendering are reproducible, that the practitioner listened, and that they wrote a prediction beforehand.

What is NOT claimed, in the same breath. No sequence is changed. No molecule is delivered. No Cas protein is present. **Nothing is edited, altered, or damaged, and the architecture could not do so** (the corpus's biological-layer constraints). No capability is conferred. No clinical, medical or therapeutic effect is claimed, observed, or implied. And, decisively: **because there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal, the sequence specificity of the artefact has no demonstrated route to any biological effect whatsoever.**

What constrains the rendering. The Gabor limit, `dt·df >= 1/(4·pi) = 0.079577` — classical, applying to every wave including sound, the same Fourier mathematics as Heisenberg with no quantum content (the time–bandwidth theorem [Gabor, 1946]). It hard-constrains rendering speed:

window	minimum frequency resolution
1 ms	79.577 Hz
5 ms	15.916 Hz
10 ms	7.958 Hz
20 ms	3.979 Hz
50 ms	1.592 Hz
100 ms	0.796 Hz
1000 ms	0.080 Hz

A short sound cannot have a precise pitch. If the encoding must distinguish tones 4 Hz apart, no window shorter than about 20 ms can carry it, and a "fast" rendering is not faster but smeared — it no longer encodes what it claims to. **This is a real, computable, hard constraint, and the kind whose presence shows the method is at least specified well enough to be constrained.**

What the honest expected result is. Null. The grounding diagnostic of §3.3, applied to this arm, halts at stage G-1: **the channel for sequence-specific content cannot be named because it has not been established.** The arm is run — if at all — as a Grade R procedure whose value is the data it generates about a well-specified gap. **The reason to run it is that the open problem**

of the missing demodulator [Curzi, 2026y] states exactly what experiment would settle the question, and someone has to run experiments.

37.4.8 4.8 The grounding diagnostic, worked on three beliefs

The six stages of §3.3, applied to three beliefs a person might actually hold. One passes, one is demoted, one is rejected. **A diagnostic that never rejects anything is not a diagnostic** (the same standard the concordance method sets [Curzi, 2026w] for the concordance method).

BELIEF A — "If I tell myself before each session that this practice will help me concentrate, I will concentrate better."

```
G-1  CHANNEL      Expectation -> attentional set -> performance. Named, with two ends.
G-2  POSSIBLE     Yes. Expectancy effects on performance are documented, modest, and
                  have a contested methodological history (Rosenthal & Jacobson 1968
                  drew serious criticism; report honestly).
G-3  GAIN         Small. Order of magnitude: a fraction of a standard deviation.
G-4  MAGNITUDE    Pre-register: d in [0.10, 0.40] on the chosen observable.
G-5  MEASURE      60 paired sessions, A/B by pre-assigned randomization, one observable.
G-6  COMPARE      Report the observed d with its 95% interval against [0.10, 0.40].
```

VERDICT: PASSES. Grade C. It is grounded — the channel is real — and it is small, and the protocol says so in advance. Note what "passes" means: it means the belief is *eligible to be tested*, not that it is true.

BELIEF B — "My frame is 1.4 times too strong for my intake, so I should reduce it by 29%."

```
G-1  CHANNEL      Framing -> perception -> action. Real (predictive processing, the belief-failure classes
G-2  POSSIBLE     Yes for the DIRECTION. No for the NUMBER.
G-3  GAIN         Unrecoverable at present, because gate 2 of the FVP returns DEMOTE:
                  D and P are not on ratio scales with true zeros.
G-4  MAGNITUDE    CANNOT BE STATED. The quantity "1.4" is not a measurement.
```

VERDICT: DEMOTED at G-4, per R1. The belief's *structure* stands — the practitioner may well be over-framed, and the ordinal instrument of §4.3 can establish that — but **the magnitude is not reportable and the "29%" is a number with no scale behind it.** The route out is the Rasch-route theorem [Curzi, 2026t]'s Theorem 54.3 and it costs 123 items per term. Until then: run the ordinal instrument, act on the ordering, and print no ratio.

BELIEF C — "Listening to my encoded narrative will switch on a latent capability in my cells."

```
G-1  CHANNEL      HALT. The claimed channel is acoustic transmission of sequence-specific
                  content to a cell that demodulates it. NO SUCH MECHANISM IS ESTABLISHED
                  (the open problem of the missing demodulator \citep{ccp:CCP-031}). The channel cannot be
                  in the established literature.
```

VERDICT: REJECTED at G-1, in print, in this framework, about this framework's own subject. The belief fails the postulate's conditional at the first clause. It is not grounded, and by the postulate's own logic a belief that is not grounded does not create anything.

Three things must follow that rejection, because they are what makes it a rejection rather than a retreat. **First**, the rejection is of the *claim*, not the *experiment*: running the artefact as a Grade R procedure with a pre-registered null is legitimate and is what the open problem of the missing demodulator [Curzi, 2026y] asks for. **Second**, the upstream biology is untouched — mechanotransduction is real, latent capability is real (the latent-capability result [Curzi, 2026y]), and Yamanaka reprogramming shows a differentiated cell reverted by four regulatory signals without adding information. **Third**, the latent-capability result [Curzi, 2026y]'s hard constraint stands regardless: **nothing not already latent can be reached**, so even a hypothetical success would be an activation and not an addition.

37.4.9 4.9 Predicting a magnitude, and what a null looks like

Stage G-4 requires a number written down in advance. Stage G-6 requires that the comparison be reported whichever way it comes out. That means deciding, in advance, **what would count as nothing** — and the answer "the p-value was above 0.05" is not that answer, because an underpowered study produces that answer whether the effect exists or not (entry MF-17 of Section 6).

The correct instrument is a **smallest effect size of interest (SESOI)** fixed before data collection, and an equivalence test against it. Two numbers govern the design.

DETECTION is paired observations for 80% power at alpha = 0.05, two-sided, `n = (z_{a/2} + z_b)^2 / d^2`. **EQUIVALENCE** is observations needed to conclude "nothing of interest happened" at a given SESOI, 80% power, one-sided alpha = 0.05, true effect zero. **RESOLUTION** is the half-width of a 95% interval in SD units at a given `n`.

`d` or SESOI	detection `n`	equivalence `n`	`n`	95% CI half-width
0.10	785	—	10	0.6198
0.20	197	155	20	0.4383
0.30	88	69	30	0.3578
0.35	65	51	40	0.3099
0.40	50	—	60	0.2530
0.50	32	25	100	0.1960
1.00	8	—	200	0.1386

Read the right-hand column carefully: a ten-observation personal experiment cannot distinguish "no effect" from "an effect of two thirds of a standard deviation." Ten observations is what most personal experimentation actually consists of. **The reason personal experiments feel inconclusive is not that the subject matter is subtle; it is that ten observations resolve nothing, and this is arithmetic rather than mystery.**

37.4.10 4.10 What to conclude from a null, in four cases

A null result is not one thing. Before interpreting one, the analyst must know which of these four it is, and the four are distinguished by numbers already computed.

```
N-1  UNINFORMATIVE NULL
     The 95% interval is wider than the SESOI. Nothing has been learned about
     the effect's existence. CONCLUDE: nothing. Do not report "it didn't work."
     DISTINGUISH BY: CI half-width vs SESOI.
```

```
N-2  INFORMATIVE NULL (equivalence established)
     The whole 95% interval lies inside +/- SESOI. This is positive evidence
     that any effect is smaller than the declared SESOI. CONCLUDE: for this
     purpose, the channel's gain is below the threshold of interest.
     DISTINGUISH BY: interval fully contained.

N-3  NULL AGAINST A MAGNITUDE PREDICTION
     A d in [0.10, 0.40] was predicted at G-4 and the observed interval excludes
     that range. CONCLUDE: the GAIN ESTIMATE at G-3 was wrong, which is a
     different and more useful finding than "no effect."
     DISTINGUISH BY: predicted interval vs observed interval.

N-4  EXPECTED NULL ON A GRADE R ARM
     The arm had no established mechanism going in. The null is the prior
     expectation and confirms nothing new. CONCLUDE: the well-specified gap
     of the open problem of the missing demodulator \citep{ccp:CCP-031} remains where it was. Report it
     exists precisely because nulls of this kind go unpublished.
     DISTINGUISH BY: the step's grade stamp.
```

The most common error in personal practice is treating an N-1 as an N-2 in the direction the operator was already leaning — over-framing (§4.3) applied to one's own experiment. The defence is that SESOI and sample size were fixed before the first observation, which is why the Specification puts them at step 6 and not at step 20.

37.4.11 4.11 Reversibility, and the residue statement

Gate V requires a written rollback before any step — three lines:

```
STOP:      the single action that ends this step now.
RESIDUE:   what remains after stopping, and for how long.
IRREVERSIBLE: what cannot be undone. If this line is non-empty, the step is
              escalated: it does not run without a second, separate Gate K.
```

For each layer of this protocol:

Step class	STOP	RESIDUE	IRREVERSIBLE
L1 prediction log	Stop writing entries	The written record, which the practitioner owns and can destroy	Nothing
L1 framing audit	Stop the audit	Awareness of one's own framings	A framing once named cannot be un-noticed. Escalate: Gate K states this explicitly
L2 cadence change	Return to prior schedule	`Q` relaxes toward the old fixed point with `tau = 11.99` weeks	Nothing, but the relaxation is slow and must be expected

Step class	STOP	RESIDUE	IRREVERSIBLE
L2 load shedding	Resume the shed commitment	Depends entirely on what was shed	**Often non-empty.** Shedding a commitment that involves other people crosses into the shedding lever [Curzi, 2026a]'s ethical line. Escalate
L3 biological arm	Stop the file	Memory of having heard it	Nothing. **No sequence is changed; no molecule is delivered; nothing is edited**

The row that catches people is not the biological one; it is L2 load shedding, the fourth lever of the storage law [Curzi, 2026a] and the one with the largest real residue. An audio file has an off switch. A resigned commitment does not.

37.4.12 4.12 The concordance for the practice as a whole

Claim of the practice	(+1) EVIDENCE	(-1) PRECEDENT	Status
Cadence beats intensity	Leaky-integrator arithmetic; `tau = 11.99` weeks computed above; spacing effects in memory research	Monastic and craft traditions built around fixed daily office rather than episodic exertion	**Established as arithmetic**; the transfer to a person is a badged modelling assumption
Difference of framing raises capability	the surplus functional and its strict concavity [Curzi, 2026] (mathematics); Hong and Page [2004] at group scope	The counsel, in many contemplative lineages, to hold a question from several vantages before deciding	**Established as mathematics.** Empirical transfer to one mind is not measured here
Disclosed belief still has a channel	Open-label placebo (Kaptchuk et al. 2010), analysed in Curzi [2026ab]; modest effects, active literature	Traditions that require the practitioner to *know* the rite, not to be tricked by it	**Established, modest**
Frame-to-intake ordering is diagnostic	Predictive processing read as precision-weighting — an active and contested programme, named in the source without bibliographic references (L-14); structural similarity is not identity	The perennial distinction between seeing and seeing-what-one-expects	**Structure established; MAGNITUDE DEMOTED (CC-R1)**

Claim of the practice	(+1) EVIDENCE	(-1) PRECEDENT	Status
Acoustic input reaches cells	PIEZO1/2 mechanically gated channels, Nobel 2021; Tajik et al. *Nature Materials* 2016 (surface force -> chromatin stretch -> transcription)	Traditions of sounded practice in nearly every recorded culture	**Established, and NON-SPECIFIC**
Acoustic input carries sequence-specific content to a cell	**NONE. This is the open problem** (the open problem of the missing demodulator [Curzi, 2026y])	Correspondence doctrines linking sound and form	**NOT ESTABLISHED. Grade R.** Speculative, and marked speculative here in the sentence that states it

The last row is the one this section exists to keep honest. It has a (-1) entry and no (+1) entry, and the corpus's biological-layer constraints is explicit that precedent is not evidence. A row with precedent and no evidence is a research question with a long history — genuinely interesting to have, and not a result.

37.4.13 4.13 Failure modes specific to the personal scope

Eight faults specific to the personal scope. The full catalogue is Section 6.

FM-4.1 · The Merged Rows. Treating channel 7 (acoustic -> mechanotransduction, real and non-specific) and channel 8 (acoustic -> sequence-specific content, no mechanism) as one channel. *Signature:* a sentence beginning with PIEZO1 and ending with a specific narrative outcome. *Measurement:* ask which row of §4.2 licenses the conclusion; if row 8, it is unlicensed. *Fix:* split the sentence and see whether the second half still has a source. *See:* MF-03.

FM-4.2 · The Reported Ratio. Producing a numeric `D/P` or `Delta` from the ordinal instrument. *Signature:* a decimal where §4.3 permits one of three words. *Measurement:* trace the number to a scale with a true zero; there isn't one. *Fix:* delete the number, keep the ordering, cost the Rasch route (123 items per term) if the number is genuinely needed. *See:* MF-08.

FM-4.3 · The Ten-Observation Verdict. Concluding "it works" or "it doesn't" from an `n` whose 95% half-width exceeds the SESOI. *Signature:* a confident conclusion with no interval. *Measurement:* §4.9's resolution column. *Fix:* classify N-1 and say nothing further. *See:* MF-17.

FM-4.4 · The Un-nulled Arm. Running the L3 arm without writing down what a null looks like. *Signature:* every outcome is consistent with the practice working. *Measurement:* before data arrive, ask for a result that would make the practitioner stop; if none exists, the arm is unfalsifiable. *Fix:* A.6 and A.16 in order. *See:* MF-18, MF-21.

FM-4.5 · The Grade Drift. A step stamped Grade R at A.14 described three months later as a technique. *Signature:* "works" attached to an arm stamped "research procedure". *Measurement:* re-read A.14 aloud. *Fix:* restore the stamp; it travels with the step wherever the step is described. *See:* MF-24.

FM-4.6 · The Front-Loaded Evaluation. Judging the practice before one time constant; at `delta = 0.08` per week, `tau = 11.99` weeks, so an evaluation at week 4 is reading a transient. *Signature:* "nothing is happening" at week 3. *Measurement:* elapsed periods against `-1/ln(1-delta)`. *Fix:* A.12. *See:* the contraction theorem [Curzi, 2026].

FM-4.7 · The Silent Decline. A protocol involving another person in which "no" has never once been said. *Signature:* perfect compliance. *Measurement:* count declines; a decline rate of exactly zero over many opportunities is a measurement of the decline path, not of the protocol. *Fix:* A.19, and treat the zero as a fault in the gate. *See:* entries MF-27 and MF-28 of Section 6.

FM-4.8 · The Borrowed Effect. Attributing to the L3 arm an outcome L1 and L2 fully explain. *Signature:* three things changed and the credit went to the newest. *Measurement:* the arm must vary independently of the others or the design attributes nothing. *Fix:* factorial or staggered introduction; if unaffordable, attribute nothing. *See:* entry MF-26 of Section 6.

37.5 5 The protocol at group scope

Section 4 gave one person a practice they can run and evaluate. This section gives the same thing to a group, and it is not the same protocol with the pronouns changed.

Three things are genuinely different at group scope, and each of them adds a gate rather than a paragraph. **First, a group can be *unable* to build**, in a sense a person cannot: the storage law's headroom gauge can be negative, and when it is, no arrangement of the members rescues the situation. **Second, a group can destroy its own capability by succeeding at alignment** — which is the independence requirement [Curzi, 2026g] and is arithmetic, not sentiment. **Third, a group can manufacture the appearance of consent**, which a person cannot do to themselves, and which makes the consent architecture of Section 4 necessary but not sufficient here.

The section therefore runs in a fixed order: gate, geometry, seeding, and only then anything new. That order is not stylistic. **Reversing it — building first and measuring afterwards — is the single most common way a group protocol destroys stored order while reporting progress.**

37.5.1 5.1 Gate 0, worked

An eighteen-person unit. `N = 18`, `ln N = 2.8904`. Parameters estimated per the survey protocol [Curzi, 2026i]: `eta = 0.30`, `delta = 0.06` per period, `C = 0.55` per period.

Unit state	`Q`	`C`	`h = eta ln N − delta Q − C`	Verdict
A — young unit, little accumulated	1.20	0.55	**+0.2451**	Build permitted, `r <= 0.2451`
B — mature unit, large accumulated `Q`	6.90	0.55	**-0.0969**	**MAY NOT BUILD**
C — young unit carrying a heavy programme	4.00	1.05	**-0.4229**	**MAY NOT BUILD**

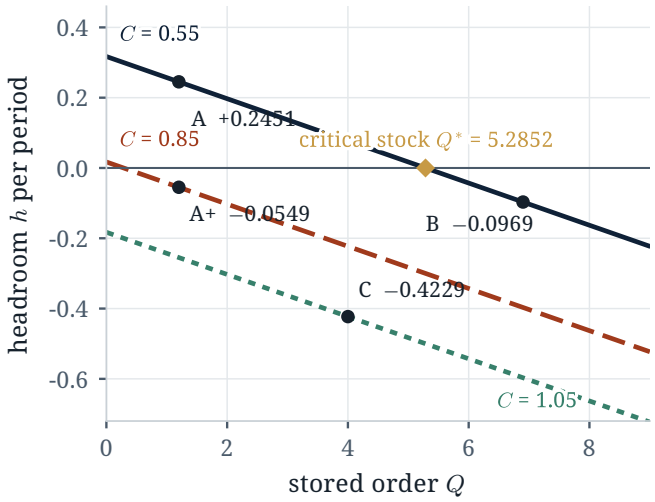

Figure 37.1: **A unit can pass the gate and a slightly cheaper unit can fail it: headroom is linear in stored order, so the same cost line closes at a computable critical stock.** Unit A (`Q` = 1.20, `C` = 0.55) reads +0.2451; unit B (`Q` = 6.90) reads −0.0969; unit C (`Q` = 4.00, `C` = 1.05) reads −0.4229; and unit A after adopting a programme costing 0.30 reads −0.0549, having moved from feasible to infeasible before the programme did anything. Modelled at `eta` = 0.30, `ln 18` = 2.8904, `delta` = 0.06 from the parameters of Section 5.1; generated by `figs/src/CCP-037_fig01.py`.

Unit state	`Q`	`C`	`h = eta ln N − delta Q − C`	Verdict
A + a proposed programme costing 0.30	1.20	0.85	**-0.0549**	**MAY NOT BUILD**

The fourth row is the one that decides most real cases and it is the one nobody computes. Unit A has positive headroom of 0.2451 and a proposed programme whose maintenance cost is 0.30. The programme's cost exceeds the headroom, so adopting it moves the unit from feasible to infeasible *before the programme has done anything at all.* The correct decision is not to run a pilot and see. It is to shed 0.06 or more of existing `C` first, or to redesign the programme to cost less than 0.2451, and only then to run it.

The critical stock — the `Q` at which headroom reaches zero with everything else fixed — is

```
Q* = (eta*ln N − C) / delta = (0.30*2.8904 − 0.55) / 0.06 = 5.2852
```

Unit B is above its critical stock. It is not a failing unit; it is a successful one, and that is precisely why it cannot build. Accumulated order costs `delta·Q` per period to hold, and at `Q = 6.90` that maintenance draw is 0.4140 per period against a maximum supply of `eta ln N = 0.8671`, leaving less than the 0.55 the unit already spends.

37.5.2 5.2 The fixed-point identity, and why maturity is not the enemy

CC-R6, verified to six decimal places: at the fixed point of the plain linear model,

```
h_inf = eta * ( ln N − F(u*) )
```

`delta`, `C` and `Q` all cancel. The headroom of a mature group depends on exactly one thing: the gap between its ceiling `ln N` and the surplus `F(u*)` it actually collects. The consequence matters: **the plain linear model never ossifies by itself.** Ossification requires exogenous accretion of `Q` — stock arriving from outside the interaction, such as inherited obligations, imported compliance regimes, acquired estates — or superlinear cost growth.

So when a group finds itself at Unit B, the diagnosis has two branches, and they have different fixes. If `Q` grew from the group's own interaction, the equilibrium is self-limiting and the fix is on `u` and `C`. **If `Q` grew from outside — a merger, a regulation, an inherited mandate — the group is carrying stock it never converted and the fix is the fourth lever, deliberate shedding [Curzi, 2026a]: shed it, deliberately, with the ethical line intact.**

37.5.3 5.3 The Jensen correction, and why it always errs optimistically

CC-R2, from the effective-count audit [Curzi, 2026c]: because `F` is strictly concave (the strict-concavity result [Curzi, 2026]), feasibility must be tested on the **mean of `F(U_t)`**, not on `F` of the mean `U`. Jensen's inequality makes the error one-directional: `F(mean u) >= mean F(u)`, always. **The wrong computation always overstates the group's surplus, never understates it.**

Worked on eight periods of an eighteen-person unit with measured `u` values 0.10, 0.22, 0.31, 0.44, 0.58, 0.19, 0.37, 0.26:

```
mean u        = 0.3088
F(mean u)     = 1.8324 nats      <- the wrong number
mean F(u)     = 1.7533 nats      <- the right number
gap           = 0.0790 nats      = 4.31% of the reported figure
```

A 4.31% overstatement sounds tolerable until it is passed through the storage law. With `eta = 0.30` and `delta = 0.06`, the two figures give steady states differing by

```
(eta * gap) / delta = (0.30 * 0.0790) / 0.06 = 0.3952 Q-units
```

The difference does not depend on `C` at all; it is the concavity error alone.

The steady state is overstated by 0.3952 Q-units — and in a unit whose whole accumulated stock is around 1.2, that is a third of the institution, conjured by evaluating a concave function at the wrong point. Propagate the correction to every feasibility test in the protocol below.

37.5.4 5.4 `N_eff` is the participation ratio, and turn-taking is how it is read

CC-R3, derived and verified to 1e-12 in the effective-count audit [Curzi, 2026c]: the mean-pairwise `u` aggregator equals the Rényi-2 participation-ratio effective count,

```
N_eff = N + 1 - N / PR ,      PR = 1 / sum_i w_i^2
```

This is what makes Woolley's turn-taking finding computable rather than merely quotable. Take a six-person meeting and measure the share `w_i` of speaking time each member takes:

Distribution	shares	`PR`	`N_eff`
Even	1/6 each	6.0000	6.0000
Skewed	0.45, 0.25, 0.15, 0.08, 0.05, 0.02	3.3693	5.2192

A meeting in which one person takes 45% of the air has an effective count of 5.22 rather than 6.00 — it has silently become a five-person meeting with a spectator. The measurement

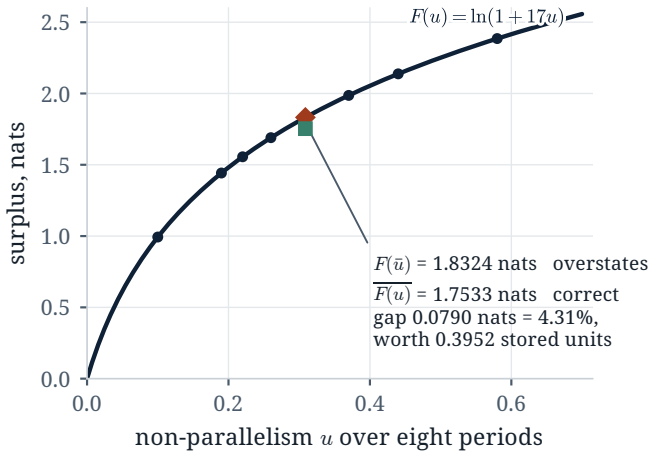

Figure 37.2: **Evaluating a concave function at the mean overstates feasibility by 4.31 per cent, worth 0.3952 stored units — about a third of the worked unit's entire accumulated stock.** Eight measured periods at `N` = 18 give a mean `u` of 0.3088; `F` of that mean is 1.8324 nats while the mean of `F` is 1.7533 nats, and Jensen's inequality makes the error one-directional. Modelled from the eight stipulated `u` values of Section 5.3; generated by `figs/src/CCP-037_fig03.py`.

is cheap: a stopwatch and six columns. **It is the single cheapest instrument in this section and it reads directly onto a quantity the surplus law uses.**

Two honesty notes. Speaking time is a proxy for participation, not participation itself; a member who says one decisive sentence has participated more than one who filled ten minutes. And the Woolley result is a correlation between turn-taking equality and `c`, not a demonstration that equalizing turns raises `c` — the direction of causation is not settled by the cited work and this section does not settle it either.

37.5.5 5.5 The price of the merge

`N = 18`, ceiling `ln 18 = 2.8904` nats:

`u`	`N_eff`	`S = ln N_eff`	Fraction of ceiling
0.00	1.0000	0.0000	0.00%
0.05	1.8500	0.6152	21.28%
0.10	2.7000	0.9933	34.36%
0.25	5.2500	1.6582	57.37%
0.40	7.8000	2.0541	71.07%
0.55	10.3500	2.3370	80.85%
0.70	12.9000	2.5572	88.47%
1.00	18.0000	2.8904	100.00%

Eighteen people who all see it the same way purchase zero surplus. And concavity is front-loaded: `u = 0` to `u = 0.25` buys 57% of the entire available range. **The first honest dissenter in a converged room is the highest-value intervention available in that room, and the eighteenth is worth a small fraction of the first.**

Concavity is merciful in one direction and unforgiving in the other. It means a cast of thousands is not needed. It also means that adding members who are *not* different adds nothing to `S` while adding coordination cost — and coordination paths grow as `n(n-1)/2`: 15 at six

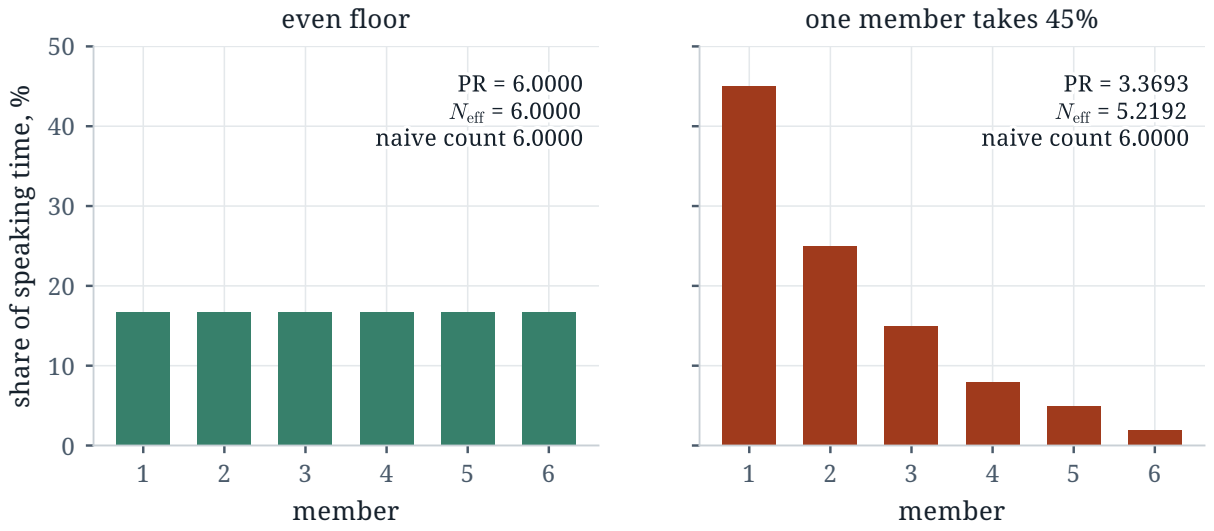

Figure 37.3: **A six-person meeting in which one member takes 45 per cent of the speaking time has an effective count of 5.2192, not 6: it has silently become a five-person meeting with a spectator.** The participation ratio falls from 6.0000 to 3.3693 and the effective count follows through the exact identity `N_eff = N + 1 − N/PR`. The instrument is a stopwatch and six columns; the share values plotted are the illustrative construction of Section 5.4. Generated by `figs/src/CCP-037_fig05.py`.

people, 66 at twelve, **153 at eighteen**, 435 at thirty [Brooks, 1975]. **Adding a parallel member is a pure cost with no offsetting surplus, and the arithmetic says so before anybody has to have an opinion about the candidate.** The sharpest instance in this corpus is the seventh-discipline case of Curzi [2026d], where adding a discipline to an institute makes it *worse* — the period change falls to `−0.002863` and the fixed point drops from 6.265 to 5.964 — because divergence, not domain count, was the deficiency.

37.5.6 5.6 Condorcet, with the independence clause priced

Condorcet's jury theorem (1785; not in this corpus's external bibliography, see Limitation L-14): with `n` independent voters each correct with probability `p > 0.5` on a binary question, majority accuracy rises with `n` and tends to 1. At `p = 0.60`:

`n` (independent)	1	3	5	9	15	21	45
P(majority correct)	0.6000	0.6480	0.6826	0.7334	0.7869	0.8256	0.9135

Now price the loss of independence by reading `N_eff` as the count of genuinely independent voices in a nine-person panel:

`u`	`N_eff`	nearest odd independent count	P(majority correct)
1.00	9.00	9	0.7334
0.50	5.00	5	0.6826
0.25	3.00	3	0.6480
0.10	1.80	1	0.6000
0.00	1.00	1	0.6000

At `u = 0.10` a nine-person panel is exactly as accurate as one person, and it costs nine times as much and reports nine times the confidence. That last clause is the whole hazard.

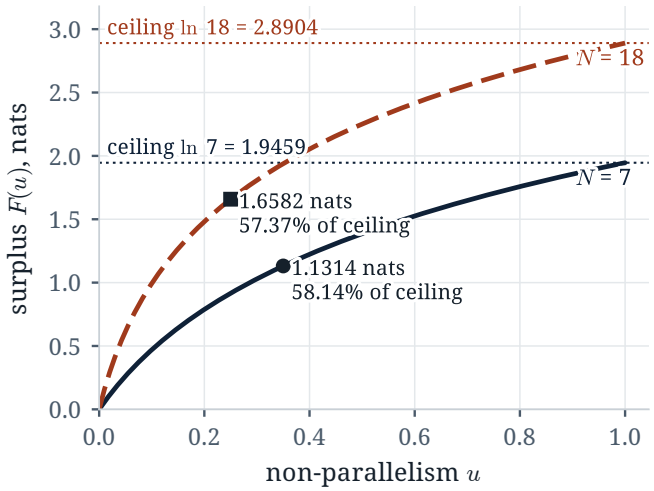

Figure 37.4: **The first genuinely different framing is worth more than all the later ones combined: moving `u` from 0 to 0.25 buys 47.09 per cent of the whole available range at `N` = 7 and 57.37 per cent at `N` = 18.** The two worked rosters sit at 1.1314 nats (58.14 per cent of `ln 7` = 1.9459) and 1.6582 nats (57.37 per cent of `ln 18` = 2.8904). Modelled from the tables of Sections 4.4 and 5.5; generated by `figs/src/CCP-037_fig02.py`.

The panel does not return "0.60 with low resolution"; it returns unanimity, and unanimity reads as certainty. **The correlated panel is the most expensive way yet devised to obtain one opinion.**

Badged: the mapping from `N_eff` to an integer count of independent voters is a **modelling convenience, not a theorem** — Condorcet's setup assumes independence outright, and `N_eff` is the surplus law's audit of redundancy, not a formal count of independent Bernoulli trials. The two are stitched here because the stitch is informative about direction and order of magnitude, and that is all it is claimed to be.

37.5.7 5.7 Critical mass, and the design move that actually pays

Centola et al. [2018] measured a tipping point at a committed minority of about **25%** in controlled online experiments. **The value of the result is not the specific quarter; it is that a tipping point exists at all — that a minority below the critical size is absorbed with no residue and one above it flips the population.** Before 2018 that was a theoretical prediction; after it, a measured phenomenon in at least one carefully constructed setting.

The honest note travels with the number every time: this figure comes from controlled online experiments with confederates committed by construction, and its transfer to a field organisation is a modelling assumption, not a measurement. Use 25% as an order-of-magnitude floor and never as a guarantee.

Scope	population	25%	committed people needed
whole firm	400	100.00	100
division	120	30.00	30
department	60	15.00	15
unit	30	7.50	8
this section's unit	**18**	**4.50**	**5**
team	12	3.00	3
squad	6	1.50	2

SHRINK THE DENOMINATOR. The threshold is a proportion, so the cheapest way over it is not to recruit more committed people but to narrow the population within which the convention must hold. One hundred committed people is a political campaign with a budget and eighteen months. Two committed people is a pair. **Sequential local tipping is cheaper than simultaneous global tipping by a wide margin, and it produces clusters as a side effect rather than requiring them as a precondition.**

37.5.8 5.8 Cluster, do not spray — computed

Complex contagion needs multiple reinforcing contacts (Centola and Macy, 2007, Centola, 2010), which means the seeding plan that maximises reach is the wrong plan. Take a 120-person division, a budget of 16 people's time, mean degree `k = 8`, and a 2-of-8 reinforcement rule.

PLAN A — SPRAY. Distribute the 16 across the division. Seed fraction `s = 16/120 = 0.1333`.

```
P(a non-seed has >= 1 seeded neighbour)  = 0.6817   <- the number that gets reported
P(exactly 1 seeded neighbour)            = 0.3917   <- 40.7 people, the worst cell
P(>= 2 seeded neighbours)                = 0.2900   <- the number that matters
Expected non-seeds within reinforcing range = 104 x 0.2900 = 30.16 people
```

PLAN B — CLUSTER. Put all 16 into one 20-person unit. Local seed fraction `16/20 = 0.80`.

```
P(>= 2 seeded neighbours) for the 4 non-seeds = 0.9999
Expected activatable inside the unit          = 4.00 of 4
Local committed fraction                      = 80.0%, against a 25% floor
```

Plan A's headline is 30.16 people in reinforcing range against Plan B's four. Any one-period comparison prefers Plan A by a factor of seven and a half. **Plan A is still the wrong choice.**

First, Plan A's 30 are at the exact margin — two contacts under a rule requiring two — so any attrition among the 16 drops them below threshold. *Second*, **40.7 people have exactly one seeded neighbour, which is the worst-populated cell in the table**: they have met the practice as "one person on my team is doing an odd new thing," and a below-threshold exposure is not a free trial. It spends the practice's novelty and returns a null, so the second attempt starts from a worse position than the first. *Third*, Plan B's unit is past its own tipping point at 80%, and the convention there survives the sponsor losing interest, which is the only test that matters.

Plan A optimises the first-period metric; Plan B optimises the order parameter. The first is what gets reported and the second is what determines the outcome.

Seeding order, and step 5 is the one people get wrong:

1. Pick the smallest population within which the practice works standing alone. If it cannot work with NOBODY outside adopting, pick a different practice.
2. Seed past that population's own tipping point. 25% is a floor, not a target.
3. Let it stabilise until it survives the removal of its sponsor. Leave for a month and record what is still running on return.
4. Seed the adjacent population using members of the first as reinforcing contacts. Do not send an evangelist; send two people who work there anyway.
5. Repeat outward along the graph of WHO ACTUALLY WORKS WITH WHOM, which is not the graph of who reports to whom \citep{conway1968committees}.

37.5.9 5.9 What "committed" must mean, and the line this framework will not cross

The 2018 experiment's minority was committed by construction: confederates instructed never to deviate. Reproducing that property in a real organisation is where a protocol of this kind could become something the framework refuses to be.

Two mechanisms produce apparent commitment and they are not equivalent. In the first, a person adopted the practice because it works for them and would keep doing it if the programme disappeared. In the second, a person adopted it because dissent is expensive and would stop the moment the cost of dissent fell. **From outside they look identical. In the ledger they are opposites: the second contributes nothing to `S`, because it has `u = 0` with respect to the group's belief, and it inflates the apparent committed fraction, which means the seeding calculation is being run on a fictitious numerator.**

The test is operational, not moral: **remove the sponsor for one month and count what survives** (step 3 above). That test is the same test as Gate D's, run at group scope, and it is why the protocol below requires a sponsor-absence interval before any expansion.

37.5.10 5.10 The biological layer at group scope

Everything Section 4.7 said about the individual biological arm applies here, and two things are added by the group setting — both of them restrictions.

What may be done. The same artefact: text the group wrote, encoded base-4 (Church, Gao & Kosuri, *Science*, 2012, is the reference for base-4 encoding of arbitrary data as sequence), given a gRNA-format routing prefix as an *address format* and not a molecule (the addressing-without-editing result [Curzi, 2026y]), rendered to audio by the disclosed sonification chain [Curzi, 2026y] within the Gabor constraint `dt·df >= 1/(4·pi) = 0.079577`. Audible, disclosed, inspectable. **No subliminal layer, no masked carrier, nothing below threshold** (the disclosed-narrative constraint [Curzi, 2026ac], and Gate K enforces it structurally).

What is claimed. That the encoding and rendering are reproducible, that people listened, and that the group pre-registered a prediction. **Nothing else.**

What is not claimed, in the same breath. No sequence is changed, nothing is delivered, no Cas protein is present, **nothing is edited or altered**, no capability is conferred on any person or group, and no clinical, medical or therapeutic effect is claimed, observed, or implied. And decisively: **there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal** (the open problem of the missing demodulator [Curzi, 2026y]), so the sequence specificity of the artefact has no demonstrated route to any biological effect at all. The step is Grade R in Section 4's scheme — a research procedure with an expected null, not a technique.

The two group-specific restrictions.

RESTRICTION 1 — a shared acoustic environment is a shared input, and shared inputs lower `u`. Eighteen people listening to the same artefact in the same room at the same time are, for the duration, receiving one input rather than eighteen. Any downstream judgement they make about it is correlated by construction. **The design consequence is mandatory: individual judgements about the artefact are recorded BEFORE any group discussion of it, or the group has destroyed the independence it needs to evaluate the thing it is evaluating.** This is Gate I applied to the group's own experiment.

RESTRICTION 2 — a group cannot consent on a member's behalf, and a majority vote is not consent. Every participant passes their own Gate K, their own Gate D, and their own Gate V. **A member who declines is recorded as declining — as data, in their own row — and is not persuaded, not followed up, and not counted as a missing value.** A group-scope protocol in which the decline rate is zero has measured its decline path and found it broken.

And the acoustic-to-c proposal, per CC-R7 and §3.9: **proposed, not established; the causal test of the acoustic intervention analysis [Curzi, 2026f] is reported as not confirmed.** A group may run it as an experiment with a pre-registered null. A group may not describe it as something the room does.

37.5.11 5.11 The group grounding diagnostic

the grounding protocol [Curzi, 2026ac]'s six stages, run by a group rather than a person, with one addition at the front.

```
G-0  RECORD INDEPENDENTLY FIRST   Each member writes their own answer to G-1..G-4
                                  BEFORE any discussion. Then pool. (Gate I.)
G-1  IDENTIFY THE CHANNEL         Name it, with two ends.
G-2  CHECK IT IS POSSIBLE         Any veto ends the matter.
G-3  ESTIMATE ITS GAIN            Order of magnitude.
G-4  PREDICT A MAGNITUDE          Written down, with units and an interval, first.
G-5  MEASURE                      Pre-registered, four baselines, plus the ceiling test.
G-6  COMPARE                      Report whichever way it comes out.
```

G-0 is the whole difference between a group diagnostic and a group conversation. Without it, stage G-3's gain estimate is one person's estimate with seventeen echoes, and the spread of the pooled estimates — which is the most informative thing a group can produce at G-3 — has been destroyed before it existed.

Run on the three claims this section has to handle:

Claim	Halts at	Verdict
Equalizing turn-taking raises this unit's decision accuracy	G-3, with a wide pooled interval	**Eligible.** Channel real (independence -> aggregation), gain uncertain, magnitude predictable. Run it
Changing the room's acoustics raises `c`	G-1 passes, G-2 passes, **G-5 already run and not confirmed** (Ch 14 §14.13)	**PROPOSED, NOT ESTABLISHED.** May be re-run as an experiment; may not be reported as a capability
The encoded artefact activates a latent capability in members' cells	**G-1**	**REJECTED IN PRINT.** The claimed channel cannot be named because no such mechanism is established (the open problem of the missing demodulator [Curzi, 2026y])

A diagnostic that never rejects anything is not a diagnostic, and the rejection above is of this volume's own subject matter rather than of something the corpus has no stake in.

37.5.12 5.12 Falsification, and why the shuffle is not enough

the falsification suite [Curzi, 2026i]'s suite, mandatory for any group claim: preregister, fit on training, **freeze**, report held-out, and beat four baselines — persistence, direct-input, matched autoregressive, and the **shuffled-input control**.

CC-R4 is the reason a fifth test is required. In the falsification suite [Curzi, 2026u], a filtered repackaging of the input passed **all four baselines including the shuffle at p = 0.0005**, and was caught only by the structural ceiling test: its single-step jump was **38.5 times** the theoretical maximum `r_max = eta ln N - delta Q - C`.

```
Unit C parameters: eta=0.30, ln N=2.8904, delta=0.06, Q=4.00, C=0.55
r_max  = 0.30*2.8904 - 0.06*4.00 - 0.55 = 0.0771 per period
38.5 x r_max = 2.9688 per period               <- the claimed jump
```

Rule, carried in place: the shuffle is an empirical audit; only the structural tests detect repackaging. Any single-period increment a group claims must satisfy `r_t <= h_t`. A claimed increment larger than the ceiling is not an impressive result; it is a measurement of the measurement (entries MF-11 and MF-12 of Section 6).

37.5.13 5.13 Failure modes specific to the group scope

FM-5.1 · The Build Under a Negative Gauge. Launching a programme while `h < 0`. *Signature:* visible activity, rising reported engagement, falling `Q`. *Measurement:* compute `h` including the programme's own `C`. *Fix:* B.3, then B.16. *See:* the storage law [Curzi, 2026a], FM-6.1.

FM-5.2 · The Correlated Panel. A group whose members' errors are the same errors. *Signature:* fast unanimity; nobody can recall the group changing its mind because of an internal objection. *Measurement:* independent-estimate-before-discussion, `u = 1 − rho^2`. *Price:* at `u = 0.10`, nine people are as accurate as one and nine times as confident. *Fix:* B.5, B.9. *See:* the independence requirement [Curzi, 2026g], FM-22.6.

FM-5.3 · Alignment Reported as Capability. Treating a rise in agreement as a rise in group ability. *Signature:* the programme's success metric is convergence. *Measurement:* `u` before and after; if it fell, the metric measured the damage. *Fix:* B.17's reversal rule. *See:* Section 6, MF-22.

FM-5.4 · Manufactured Commitment. Counting compliance as commitment in the seeding denominator. *Signature:* a decline rate of exactly zero. *Measurement:* remove the sponsor for a period and count survivors. *Fix:* B.12. *See:* the two-mechanisms-of-commitment analysis [Curzi, 2026g]; Section 6, MF-28.

FM-5.5 · The Spray. Seeding for reach under a complex-contagion rule. *Signature:* a reported "reached N people" figure with no reinforcement count. *Price:* in §5.8, 40.7 people at exactly one contact — novelty spent, nothing activated. *Fix:* B.11.

FM-5.6 · The Reported Group Ratio. Publishing a numeric doctrine-to-data ratio or a `Delta`. *Signature:* a decimal where B.13 permits one of three words. *Measurement:* trace it to a scale with a true zero; there isn't one. *Fix:* delete the number, keep the ordering, budget the Rasch route. *See:* Section 6, MF-08.

FM-5.7 · The Acoustic Capability Claim. Describing an acoustic intervention as raising `c`. *Signature:* the room is credited with a group's performance. *Measurement:* the acoustic intervention analysis [Curzi, 2026f]'s causal test, **reported as not confirmed**. *Fix:* relabel as proposed, or run the test. *See:* CC-R7; Section 6, MF-24.

FM-5.8 · Consent by Majority. A vote standing in for individual consent. *Signature:* a show of hands preceding a step that acts on individuals. *Measurement:* count the per-person Gate K, D and V records; if there are fewer than `N`, consent was not obtained. *Fix:* B.14, B.4. *See:* Section 6, MF-27.

37.6 6 A finite catalogue of manifestation faults

the built-system failure catalogue [Curzi, 2026g] catalogued the ways a built system fails. This section catalogues the ways a *claim about manifestation* fails — and it is the section this strand of the corpus most needs, because the biological-layer strand of the corpus is the material most easily misread as licence.

The postulate at the centre of the volume is conditional: **belief creates reality if the belief is grounded in truth**, which formalizes as `BELIEF -> [CHANNEL] -> WORLD`, with "grounded in truth" meaning that **the channel exists and is real** (the channel-gain form of the belief postulate

[Curzi, 2026ab]). Strip the conditional and the postulate becomes magical thinking. Keep it, and every failure of manifestation becomes a diagnosable fault in a specific part of a specific claim.

This is a **reference catalogue**, not an argument. It is written to be consulted against a claim that has just failed, or — better — one that has not yet been made. Thirty named failure modes appear below in the fixed eight-field entry format of the built-system failure catalogue [Curzi, 2026g], so the section functions as a lookup table: arrive with a symptom, leave with a coordinate, a measurement, and a fix.

The armature is modified accordingly, as the built-system failure catalogue [Curzi, 2026g]'s was. `The Law` states what makes a finite catalogue possible here. `The Engineering` **is** the catalogue. `The Specification` is the procedure for using it. `The Failure Modes` names the ways diagnosis itself goes wrong. The `Worked Example` carries one diagnosis end to end.

Four of these entries are faults of this framework's own method rather than of anybody else's, and they are not softened on that account. MF-08 is the failure of reporting a magnitude the corpus's own validation protocol has demoted. MF-11 is the repackaging that the corpus's own falsification suite could not catch. MF-23 — precedent mistaken for evidence — is, by the corpus's biological-layer constraints's own reckoning, **the single most likely failure of this strand of the corpus's method.** MF-24 is the speculative bridge that lost its badge somewhere between the section that stated it and the summary that quoted it. A catalogue that indexes only other people's errors is advertising.

37.6.1 6.1 Why a finite catalogue is possible

A manifestation claim, stated in this framework's terms, is a claim that some belief `B`, held and acted on, produces some change `X` in the world. **Every such claim has exactly eight coordinates, and there are therefore only eight kinds of failure, however many names they wear.**

```
CH   CHANNEL          Does a real coupling from B to X exist and can it be named?
G    GAIN             How much X per unit B does that coupling deliver?
Mg   MAGNITUDE        Is the predicted size of X right to within an order of magnitude?
B    BASE RATE        What fraction of attempts produce X, counting the unobserved ones?
Fa   FALSIFIABILITY   Is there a stated result that would kill the claim?
Cn   CONSENT          Can the person acted on know, decline, and reverse?
Ld   LEDGER           Is precedent kept distinct from evidence, and speculation badged?
Sc   SCALE            Is each quantity measured on a scale permitting the operation used?
```

The thirty names below are not thirty independent phenomena. They are recurring *routes* into eight coordinate faults, distinguished because the routes have different signatures, different instruments, and different fixes. The class headings in `The Engineering` group them by coordinate.

Badged, as the corpus's conventions require: that a manifestation claim decomposes into exactly these eight is the author's framing, not a theorem. It is defensible — each coordinate corresponds to a step of the grounding diagnostic (the grounding protocol [Curzi, 2026ac]) or to a gate of the Formula Validation Protocol (the corpus's internal-scope conventions) — but it is a taxonomy, and taxonomies are chosen. Where a fault sits outside the scheme, the catalogue will not name it, and the correct response is to say so rather than force a coordinate.

37.6.2 6.2 The four diagnostic identities

Every entry is priced against one of four. They are the only arithmetic the catalogue needs.

Identity 1 — the coupling identity. `X = G · B`, where `G` is the channel's gain. **If `G = 0` then `X = 0` for every value of `B` whatsoever.** No amount of belief compensates for an absent channel, and this single line disposes of about a third of the entries below.

Identity 2 — the grounding sequence (the grounding protocol [Curzi, 2026ac], carried in place): identify the channel, check it is possible, estimate its gain, **predict a magnitude**, measure, compare. **A claim's fault is located at the first stage it cannot pass**, and locating it there rather than at the end is what makes the catalogue usable.

Identity 3 — the structural ceiling. the structural-ceiling corollary [Curzi, 2026a]: `r_max = eta ln N − delta Q − C`. Any claimed single-period increment in stored order greater than `r_max` is impossible under the model, and CC-R4 records the case that makes this indispensable: **a filtered repackaging of the input passed all four empirical baselines including the shuffled-input control at p = 0.0005, and was caught only by the ceiling test, its jump being 38.5 times the theoretical maximum.**

Identity 4 — the ledger rule (the corpus's biological-layer constraints). `(+1)` carries **evidence**: what is measured, replicated, falsifiable. `(−1)` carries **precedent**: that the idea was arrived at independently and preserved. **Two sources agreeing does not double the evidence when only one of them is evidence.** What independent arrival establishes is genuine and worth having — that the structure was findable by more than one route — and it is not a second measurement.

37.6.3 6.3 The honesty clauses that constrain every entry

Repeated here because a catalogue is the part of a book most likely to be quoted without context.

- **No clinical, medical or therapeutic claim appears in this section**, in any entry, in any direction. Nothing here diagnoses a person or recommends a treatment.
- **No claim that DNA is edited, altered or damaged.** The architecture of the disclosed sonification chain [Curzi, 2026y] cannot do so, and nothing in this catalogue implies otherwise.
- **No claim that any capability in this corpus has been conferred on anyone.**
- **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal** (the open problem of the missing demodulator [Curzi, 2026y]). Several entries turn on this and each states it.
- **Casimir does nothing at biological scale.** Where the Casimir effect appears as a price, the computed number is the point (§MF-06).
- Where an entry cites an external result, the result is real and the *transfer* to the claim under diagnosis is a modelling assumption, badged each time.

Entry format. Eight fields, same order, every entry, so the section can be scanned in a column.

Field	What it holds
Damages	which of CH / G / Mg / B / Fa / Cn / Ld / Sc the fault attacks
Clinical	what the fault is, stated without metaphor
Signature	what is observable from outside, before measuring anything
Measurement	the specific instrument that confirms or excludes it
Price	the arithmetic cost, computed

Field	What it holds
Fix	the intervention, and which coordinate it repairs
Confusable with	the entries most often mistaken for this one
See	the section that develops it

37.6.4 6.4 Class I — channel faults (CH, G)

The foundational class. Every entry here is a case of Identity 1 with `G = 0`, arrived at by a different route.

MF-01 · The Ungrounded Belief

Damages: CH. No channel is identified at all, so `G` is undefined and Identity 1 cannot even be written. **Clinical:** A belief is held and acted upon with no account of how it could reach the world. The claim is not that a particular mechanism operates; it is that *no mechanism is required*. This is the unconditional reading of the postulate, and it is exactly what the conditional clause exists to exclude. **Signature:** Asked "by what route?", the holder answers with a restatement of the belief, or with a word that names a category rather than a coupling — energy, vibration, the field, resonance, alignment. **A channel has two ends and a mechanism between them; a category has neither. Measurement:** Grounding diagnostic stage G-1 (the grounding protocol [Curzi, 2026ac]). Ask for the two ends and the mechanism. If three requests produce three restatements, the channel does not exist in the claimant's own account, whatever exists in the world. **Price:** Identity 1 with `G = 0`. `X = 0 · B = 0` for every `B`. **The entire investment — every hour, every payment, every deferred alternative — buys a product of zero and a number. Fix:** Name a channel or withdraw the claim. There is no third option. If a channel can be named, the claim graduates to MF-02's test or to a legitimate research procedure. **Confusable with:** MF-02 (a channel *is* named and turns out not to exist — a more advanced condition), MF-07 (channel fine, no magnitude offered). **See:** the grounding protocol [Curzi, 2026ac].

MF-02 · The Absent Channel

Damages: CH, and derivatively G. **Clinical:** A channel is named specifically, which is progress, and it does not exist. The claim is falsifiable and false. **This is the honourable failure of the class**, because it can be checked, and checking it is cheap relative to the alternative. **Signature:** The named channel is precise enough to look up, and the lookup returns nothing, or returns a mechanism that does something adjacent but not this. **Measurement:** Stage G-2. Search the primary literature for the named coupling, not for its vocabulary. **The distinguishing test: does the cited work measure the coupling, or measure something upstream of it and speculate? Price:** Same as MF-01 in outcome and cheaper in diagnosis. The saving is the point: a named channel costs a literature search to refute; an unnamed one costs a career. **Fix:** Withdraw, or reformulate as the research procedure the gap actually calls for. the open problem of the missing demodulator [Curzi, 2026y]'s treatment of the sequence-specific acoustic demodulation gap is the model: **state the gap sharply, say what experiment would settle it, and stop. Confusable with:** MF-01, MF-03 (a *different* real channel is doing the work), MF-05. **See:** the missing demodulator and the grounding protocol [Curzi, 2026y,ac].

MF-03 · Channel Substitution

Damages: CH — credit assignment. The gain is real and belongs to a different coupling. **Clinical:** An outcome produced by an established channel is attributed to an unestablished one that was present at the same time. **This is the most consequential error available in Volume Three**, because the corpus deliberately runs an established channel and an open problem side by side. **Signature:** A sentence that begins with a Nobel-recognized mechanism and ends with a specific, addressed, sequence-dependent outcome. The two halves have different evidential status and the sentence hides the seam. **Measurement:** Split the sentence at the seam and ask whether the second half still has a source. Concretely, for this strand of the corpus: **PIEZO1/2 are mechanically gated ion channels and sound is mechanical, so a pressure wave becoming a cellular signal is established and NON-SPECIFIC. That a pressure wave carries WHICH signal, addressed to a particular sequence, has no established mechanism at all** (the open problem of the missing demodulator [Curzi, 2026y]). Row 7 of the personal channel inventory licenses the first; row 8 does not license the second. **Price:** The claim inherits the credibility of the established channel and none of its content. In a factorial design the price is measurable: an arm that cannot be varied independently of the established channel **attributes nothing, at any sample size** — the design has zero identifying power, not low power. **Fix:** Vary the two independently, or attribute nothing. Where independent variation is unaffordable, say the outcome is unattributed. That is a finding. **Confusable with:** MF-02, MF-26 (a bundle of nine components with credit to one), MF-05. **See:** the cell-as-receiver result and the missing demodulator [Curzi, 2026y]; Section 4.2.

MF-04 · The Zero-Gain Channel

Damages: G. The channel exists, is real, is measured, and its gain for *this* output is zero. **Clinical:** A genuine coupling is invoked for an outcome it does not produce. The channel is not fictional; it is irrelevant. **This fault survives every check that asks "is the mechanism real?" and fails the only check that matters, which is "does it move THIS?" Signature:** The citation is real and the outcome is not in it. The claimed effect is a plausible-sounding cousin of the measured one. **Measurement:** Stage G-3. Ask for the gain in the units of the claimed output. If the cited work reports a gain for a different output, the number does not transfer, and the transfer is exactly the unbacked step. **Price:** $X = G \cdot B$ with $G = 0$ for this X. Identical to MF-01 in result and far harder to detect, because a real citation sits in front of it. **Fix:** Find the measurement of the gain the claim actually needs, or state that it has not been made. **Confusable with:** MF-03, MF-05, MF-06 (gain nonzero but mis-sized). **See:** the channel-gain form of the belief postulate [Curzi, 2026ab]; the grounding protocol [Curzi, 2026ac].

MF-05 · The Borrowed Channel

Damages: CH, G, and often Mg simultaneously. **Clinical:** A coupling established in one system is asserted for another where the conditions that made it work are absent. Scale, medium, timescale, or geometry differ, and the difference is not priced. **Signature:** "It works in cells, therefore in tissue." "It works at ultrasound frequencies, therefore in a room." "It works in a controlled online experiment, therefore in a firm." **Measurement:** Stage G-2. Compute the transfer explicitly. For acoustics into tissue, an illustrative attenuation of 0.5 dB per cm per MHz gives:

```
f = 1.0 MHz, d = 10 cm  ->   5.00 dB loss, amplitude factor 0.5623
f = 2.0 MHz, d = 10 cm  ->  10.00 dB loss, amplitude factor 0.3162
f = 5.0 MHz, d = 10 cm  ->  25.00 dB loss, amplitude factor 0.0562
```

Price: At 5 MHz through 10 cm the amplitude arriving is 5.6% of what was sent, so a claim calibrated at the source is wrong by a factor of about 18 at the target. The 25% tipping-point result of Centola et al. [2018] carries an analogous transfer cost: **it was measured in controlled online experiments with confederates committed by construction, and its application to a field organisation is a modelling assumption, not a measurement. Fix:** Price the transfer, or run the measurement in the destination system. **Borrowing is legitimate; borrowing without paying the transfer cost is the fault. Confusable with:** MF-04, MF-06, MF-10. **See:** the measured Casimir force [Casimir, 1948, Lamoreaux, 1997]; the grounding protocol [Curzi, 2026ac].

37.6.5 6.5 Class II — magnitude and scale faults (Mg, Sc)

The channel exists. The arithmetic about it does not.

MF-06 · The Magnitude Error

Damages: Mg. Direction correct, size wrong by orders of magnitude. **Clinical:** A real effect is invoked at a scale where it is negligible. The claim is not false in sign and is false in every practical sense. **This is the most respectable failure in the catalogue and one of the most common, because getting the direction right feels like getting the answer right. Signature:** The claim quotes a mechanism correctly and never states a number. Where a number appears, it is the mechanism's number rather than the situation's. **Measurement:** Stage G-4, performed before stage G-5. Compute the effect at the actual scale of the claim and compare with what else is present at that scale. **Price:** The canonical case is Casimir. `F/A = pi^2 hbar c / (240 a^4)`, Casimir, 1948, measured by Lamoreaux, 1997 and Mohideen and Roy, 1998 — entirely real:

```
10 nm  ->  1.3e5 Pa   (1.283 atm)
100 nm ->  13 Pa
1 um   ->  1.3e-3 Pa
10 um  ->  1.3e-7 Pa
1 mm   ->  1.3e-15 Pa
```

At any biological or architectural scale the Casimir force is utterly negligible. It does nothing in a cell and nothing in a room, and this framework says so wherever Casimir appears. For comparison, a 60 dB SPL sound is 0.02 Pa — **more than ten thousand times the Casimir pressure at 1 micrometre.** A second case, computed the same way: an illustrative focused-ultrasound pressure amplitude of 0.5 MPa against a 60 dB SPL room tone is a ratio of 2.5e7, or **7.40 orders of magnitude.** A claim that carries a mechanism across that gap without arithmetic has made a magnitude error even if every word of the mechanism is correct. **Fix:** Compute at the scale of the claim, always, before asserting. Then decide. **Confusable with:** MF-04, MF-07, MF-10. **See:** the measured Casimir force [Casimir, 1948, Lamoreaux, 1997].

MF-07 · Order-of-Magnitude Silence

Damages: Mg, and through it Fa. **Clinical:** No magnitude is predicted at all. The claim is directional forever. **A practice that predicts no magnitude cannot be wrong, and a practice that cannot be wrong cannot be trusted when it is right. Signature:** Every reported outcome is compatible with the claim. Success is "it helped"; failure is "it takes time". **Measurement:** Stage G-4 is simply absent from the record. Ask what number was written down before the attempt, and when. **Price:** Unfalsifiability is not free; it is paid in the inability to accumulate. **A directional claim cannot be improved, because improvement requires a residual, and a residual requires a predicted value.** Twenty years of directional practice contains exactly as much information as one year. **Fix:** Stage G-4 with an interval and units, recorded before measurement, per Section 4.9. **Confusable with:** MF-18 (goal itself unfalsifiable), MF-21 (no null defined), MF-06. **See:** the grounding protocol [Curzi, 2026ac]; Section 4.9.

MF-08 · The Demoted Magnitude Reported As Measured

Damages: Sc, then Mg. A quantity the framework's own protocol demoted is reported as a measurement. **Clinical:** The Formula Validation Protocol returns **DEMOTE on gate 2 (scale type)** for `M = (D/P)·E`, because D and P are not instrumented on ratio scales with true zeros (the scale-type analysis [Curzi, 2026t]). **What is demoted is MAGNITUDE, not STRUCTURE.** The limiting cases stand, the fixed point `D = P` stands, and the ordering over-framed / calibrated / under-framed stands, because each needs only ordinal information. **The fault is publishing a number for `D/P`, or a distortion `Delta = |ln r|`, or a quantitative `M -> Q` transfer, as though the demotion had not happened. Signature:** A decimal appears where the instrument permits only an ordering. "The perception ratio is 1.4." "Distortion reduced by 29% this quarter." **Measurement:** Trace the number to a scale with a true zero. There is not one. **Division requires a ratio scale (Stevens' typology); with ordinal data the formula is a heuristic ordering and must be demoted in print** (FVP-2). **Price:** The demotion is not permanent and the route out is costed. the Rasch-route theorem [Curzi, 2026t], given badged Postulate SO1: a **Rasch logit difference** makes `Delta = |ln(D/P)|` genuinely ratio-scaled, because Rasch separation supplies the true zero that division requires. **The cost is 123 items per term** — 246 items for the ratio, **369 items** for all three terms of the Moment. At twenty seconds per item that is **2.05 hours per administration**, and the cross-individual recovery gate (FVP-7) with thirty participants is **61.5 person-hours** before analysis begins. **That is the price of the number, and reporting the number without paying it is this entry. Fix:** Delete the magnitude. Keep the ordering, which is genuinely diagnostic. Budget the Rasch route if the number is genuinely needed. **Build the instrument so the forbidden thing is impossible rather than merely discouraged** — Section 4 §4.3's three-valued verdict set is the pattern. **Confusable with:** MF-09 (any scale violation), MF-07, MF-24. **See:** the belief-failure classes [Curzi, 2026ac]; the Formula Validation Protocol and the scale-type analysis [Curzi, 2026t]; CC-R1.

MF-09 · The Scale Violation

Damages: Sc. **Clinical:** An operation is performed that the data's scale type does not permit: ratios of ordinal scores, averages of ranks treated as magnitudes, differences on a scale with no defined unit. MF-08 is the specific case that matters most to the corpus; this entry is the general one. **Signature:** Arithmetic performed on a Likert response as though it were a length. **Measurement:** FVP gate 2 on every term. Nominal permits counting and identity. Ordinal permits ordering. Interval permits differences. **Only ratio permits multiplication and division, and only because it has a true zero. Price:** The output has no interpretation, which is worse than being wrong: a wrong number can be corrected, an uninterpretable one propagates

silently into every downstream calculation and looks like all the others. **Fix:** Demote in print to the highest operation the scale supports, and state the route to a better scale. Magnitude estimation and cross-modality matching (Stevens) genuinely produce ratio-scale measurements of subjective quantities, and they replicate. **The route exists; it is just not free. Confusable with:** MF-08, MF-10. **See:** the scale-type analysis [Curzi, 2026t]; the logarithmic perceptual register [Fechner, 1966].

MF-10 · The Dosage Fallacy

Damages: Mg. Linear expectation applied to a quantity the recipient perceives logarithmically. **Clinical:** A "moderate" perceived improvement is promised, and delivering it requires an order-of-magnitude change in the world. Or the reverse: a genuine order-of-magnitude change is delivered and reported as disappointing, because it arrived as a small perceived step. **Signature:** Effort and perceived result are compared as though the relationship were linear. "We doubled the input and it barely feels different." **Measurement:** The Lens Theorem (the disclosed-narrative constraint [Curzi, 2026ac]). If perception is logarithmic, **equal perceptual steps are equal world RATIOS, never equal world differences**:

```
perceived +1 nat   -> world x2.7183        +1 bit -> world x2      +1 log10 -> world x10
perceived +2 nats  -> world x7.3891        +2 bits -> world x4     +2 log10 -> world x100
perceived +3 nats  -> world x20.0855       +3 bits -> world x8     +3 log10 -> world x1000
```

Price: Promising three perceptual units commits the claim to a factor of about twenty in the world. Budgeting for that promise linearly under-provisions by roughly 7x. **Concavity is not pessimism; it is the lens** — the strict concavity of the surplus functional [Curzi, 2026] has the same shape as Fechner's law [Fechner, 1966], and diminishing returns is what a logarithm looks like from inside. **Fix:** Design in ratios, budget in ratios, and **never promise a linear improvement in a quantity the recipient perceives logarithmically. Confusable with:** MF-06, MF-05. **See:** the logarithmic perceptual register [Fechner, 1966]; the corpus's internal-scope conventions.

MF-11 · The Repackaged Input

Damages: Mg and Fa together, and it is the entry that most threatens this framework's own validation suite. **Clinical:** A filtered, transformed, or reweighted version of the input is presented as an output of the system. The system has learned to restate its input impressively. **This is not fraud and usually not deliberate; it is what an unconstrained fitting procedure does when it is allowed to. Signature:** Results that track the input's fine structure too closely, and a single-step jump that is very large relative to anything the model permits. **Measurement: This is the crucial entry, because CC-R4 records that the standard suite failed to catch it.** In the falsification suite [Curzi, 2026u], a filtered repackaging **passed all four baselines — persistence, direct-input, matched autoregressive, and the shuffled-input control — at p = 0.0005.** It was caught only by the structural ceiling test of the structural-ceiling corollary [Curzi, 2026a]. **Price:** The observed single-step jump was **38.5 times the theoretical maximum**. Worked in this chapter's illustrative unit:

```
eta=0.30, ln N=2.8904 (N=18), delta=0.06, Q=4.00, C=0.55
r_max = 0.30*2.8904 - 0.06*4.00 - 0.55 = 0.0771 per period
38.5 x r_max                          = 2.9688 per period      <- the claimed jump
```

Fix: Rule, and it is binding: the shuffle is an empirical audit; only the structural tests detect repackaging. Add the ceiling test `r_t <= h_t` to every falsification suite, always. A claimed increment above the ceiling is a measurement of the measurement. **Confusable with:** MF-12 (a plain ceiling violation with no repackaging), MF-16. **See:** the falsification suite [Curzi, 2026u]; the grounding protocol [Curzi, 2026ac]; CC-R4.

MF-12 · The Ceiling Violation

Damages: Mg. **Clinical:** A claimed increment exceeds what the model permits in one period, without repackaging being present. Often it is a bookkeeping error, a period-length mismatch, or an exogenous inflow of `Q` counted as production. **Signature:** A step change with no corresponding change in `eta`, `u`, `N` or `C`. **Measurement:** Compute `r_max = eta ln N − delta Q − C` for the period in question and compare. **Price:** In the same illustrative unit, `r_max = 0.0771` per period. **Any reported increment above that is impossible under the model, which means either the model is wrong for this system or the number is.** Both are findings; assuming neither is not. **Fix:** Reconcile period boundaries, then look for exogenous accretion — stock arriving from outside the interaction (a merger, an inherited mandate, an imported compliance regime), which is real `Q` and is not production. **Confusable with:** MF-11, MF-26. **See:** the storage law [Curzi, 2026a]; the structural-ceiling corollary [Curzi, 2026a].

37.6.6 6.6 Class III — base-rate and inference faults (B)

The channel may be fine. The evidence about it is not what it appears to be.

MF-13 · The Survivorship Narrative

Damages: B. The denominator is unobservable, so no rate can be computed. **Clinical:** Successes publish and failures do not. The visible record of a manifestation practice consists entirely of the cases that worked, because the cases that did not produced nobody with a reason to write them up. **Testimonial base rates are therefore not merely biased; they are UNOBTAINABLE from testimony, at any volume of testimony. Signature:** An impressive collection of individual accounts and no denominator anywhere. “Look how many people it worked for” is a numerator with the denominator deleted. **Measurement:** Ask for the count of attempts, not the count of successes, and ask who would have recorded a failure. **If no mechanism existed by which a failure could have entered the record, the record contains no information about the rate. Price:** Computed two ways.

```
Suppose 1000 people attempt and 40 succeed. True rate 4.0%.
Testimonials show 40 successes and 0 failures -> apparent rate 100%.
Inflation factor = 25.00x.

Or, with NO effect at all: if the outcome occurs spontaneously in 5% of
attempts, then 40 glowing testimonials require only 800 attempts to exist.
```

Forty testimonials is not weak evidence of an effect. Under a 5% spontaneous base rate it is exactly what a completely inert practice produces from eight hundred attempts. Fix: Register attempts prospectively, before outcomes are known, and count everyone who started. Where prospective registration is impossible, **report that the base rate is unobtainable and decline**

to estimate it. Section 4 §4.10's N-4 category exists so that expected nulls enter the record; this entry is why. **Confusable with:** MF-14 (denominator exists and is omitted), MF-15, MF-19. **See:** the concordance register [Curzi, 2026w]; the falsification suite [Curzi, 2026u].

MF-14 · The Missing Denominator

Damages: B. **Clinical:** The denominator exists and was not reported. Distinct from MF-13, where it cannot be obtained. This one is a reporting fault and is fully repairable. **Signature:** Counts without rates. "Thirty people adopted the practice." Out of how many? **Measurement:** Ask for `N` at the start of the period, not at the end. **Attrition moves people out of the denominator silently, and a practice with heavy attrition reports beautifully. Price:** In §MF-13's arithmetic, the same 40 successes are a 100% rate, a 4.0% rate, or a 5.0% spontaneous background depending entirely on a number nobody wrote down. **Fix:** Report `n_started / n_completed / n_succeeded` as three numbers, always, in that order. **Confusable with:** MF-13, MF-17. **See:** the effective-count audit [Curzi, 2026c]; the survey protocol [Curzi, 2026i].

MF-15 · Regression Mistaken For Effect

Damages: B and Mg together. **Clinical:** People enter a practice at their worst moment, because that is when they seek one. Their next measurement is better. The improvement is what an imperfectly reliable measure does whenever selection is on an extreme, and it happens with no intervention at all. **Signature:** Recruitment framed around a low point. Large early gains that flatten. The practice works best for those who were worst. **Measurement:** Compute the expected regression before attributing anything. Selecting the bottom decile of a normally distributed measure gives `E[Z | selected] = −1.7550`. With test-retest reliability `r`, the expected next-measurement improvement **with no intervention** is `(1 − r)·|E[Z]|`:

```
bottom 10% selected:   r = 0.4  ->  1.0530 SD improvement, from nothing
                       r = 0.6  ->  0.7020 SD improvement, from nothing
                       r = 0.8  ->  0.3510 SD improvement, from nothing
bottom 20% selected:   r = 0.6  ->  0.5599 SD improvement, from nothing
```

Price: At bottom-decile selection and `r = 0.6`, a practice with literally zero effect reports 0.70 SD of improvement — **larger than most effects anyone in the behavioural sciences honestly claims.** A practice would have to be actively harmful to report nothing under these conditions. **Fix:** A control group selected the same way, or a design that does not select on the outcome measure. Where neither is available, subtract the computed regression and report what remains, explicitly labelled. **Confusable with:** MF-13, MF-17, MF-26. **See:** the survey protocol [Curzi, 2026i]; the falsification suite [Curzi, 2026u].

MF-16 · The Forking Path

Damages: B, Fa. **Clinical:** Many outcomes, subgroups, or time windows are examined and the one that reached significance is reported. No dishonesty is required; the analysis decisions were made after seeing the data and each felt reasonable. **Signature:** A specific, narrow, unanticipated result. "It worked for participants who had practised for more than six weeks and were measured in the afternoon." **Measurement:** Count the comparisons that *could* have been made, not the ones reported. Familywise error at alpha = 0.05:

```
k = 1   ->  0.0500        k = 5   ->  0.2262        k = 20  ->  0.6415
k = 2   ->  0.0975        k = 10  ->  0.4013        k = 40  ->  0.8715
```

Price: With ten candidate analyses, the probability of at least one false positive is **0.4013**. With forty, **0.8715** — a practice with no effect whatsoever will produce a "significant" result more than eight times in ten. **Fix:** Preregister the analysis, freeze it, and report the held-out result (the falsification suite [Curzi, 2026i]). Report every comparison run, including the ones that failed. **Confusable with:** MF-11, MF-19. **See:** the falsification suite [Curzi, 2026u]; the Formula Validation Protocol [Curzi, 2026t].

MF-17 · The Underpowered Null Read As Disconfirmation

Damages: B, Mg. The mirror image of the rest of this class, and just as costly. **Clinical:** A study too small to detect anything returns nothing, and the nothing is reported as evidence of absence. **An underpowered design returns a null whether the effect exists or not, so its null carries no information in either direction. Signature:** "We tried it for two weeks and it did not work." No interval reported. **Measurement:** Compare the 95% interval half-width to the smallest effect size of interest fixed in advance:

```
n = 10  ->  half-width 0.6198 SD        n = 60  ->  half-width 0.2530 SD
n = 20  ->  half-width 0.4383 SD        n = 100 ->  half-width 0.1960 SD
n = 30  ->  half-width 0.3578 SD        n = 200 ->  half-width 0.1386 SD
```

Price: A ten-observation personal experiment cannot distinguish "no effect" from "an effect of two thirds of a standard deviation". **Ten observations is what most personal experimentation actually consists of, so most personal experimentation resolves nothing — and this is arithmetic, not mystery.** To establish equivalence at a SESOI of 0.35 SD requires **51 paired observations**; to detect `d = 0.35` requires **65**. **Fix:** Classify the null before interpreting it (Section 4 §4.10): uninformative, informative, against a magnitude prediction, or expected on a research arm. **Only the second licenses "it does not work at a size I care about." Confusable with:** MF-07, MF-21. **See:** the survey protocol [Curzi, 2026i]; Sections 4.9 and 4.10.

37.6.7 6.7 Class IV — falsifiability faults (Fa)

The claim cannot lose, which means it cannot win either.

MF-18 · The Unfalsifiable Goal

Damages: Fa, and through it every other coordinate, because nothing can be checked. **Clinical:** The goal is stated so that no observable state of the world contradicts it. Abundance, alignment, readiness, flow. **These are not bad things to want; they are impossible things to test, and a protocol organized around them cannot accumulate. Signature:** Success and failure are described in the same vocabulary. Absence of the outcome is explained by the same theory that predicted its presence. **Measurement:** Ask, before any attempt: **name a result that would end the practice.** If no such result exists, the goal is unfalsifiable and the practice around it is unevaluable, whatever else it is. **Price:** No residual, so no learning. **A framework that cannot fail cannot be trusted, and this manual's own answer is to name exactly how each of its claims fails** — which is why the trust term [Curzi, 2026r] exists and why the grounding

protocol [Curzi, 2026ac] catalogues where belief does not create reality at all. **Fix:** Replace the goal with an observable, a direction, a magnitude interval, and a stopping rule. A goal that survives that translation was worth having. **Confusable with:** MF-07 (magnitude missing but the goal is checkable), MF-19, MF-21. **See:** the survey protocol [Curzi, 2026i]; the grounding protocol [Curzi, 2026ac].

MF-19 · The Retrofitted Criterion

Damages: Fa. **Clinical:** The success criterion is chosen after the outcome is known, and it is chosen to be met. The goal appears to have been achieved because the goal moved. **Signature:** The stated aim at the end does not match the stated aim at the start, and there is no record of when it changed or why. **Measurement:** Compare the pre-registration to the report, field by field. **If there was no pre-registration, the criterion is retrofitted by default, because there is nothing it could have been retrofitted from. Price:** Identical to MF-16 in mechanism and larger in effect, because the retrofit can select across outcomes *and* thresholds *and* windows. If ten plausible criteria were available, the familywise false-positive probability is **0.4013**; a retrofit is that process with the selection made deliberately. **Fix:** Preregister, freeze, and report deviations as deviations. **A deviation honestly reported is a result; a deviation quietly absorbed is this entry. Confusable with:** MF-16, MF-20, MF-22. **See:** the falsification suite [Curzi, 2026u]; the survey protocol [Curzi, 2026i].

MF-20 · The Latency Excuse

Damages: Fa. **Clinical:** A null is absorbed by an unbounded delay. The effect will come; it takes time; the timescale is never specified, so no elapsed time is ever enough. **Signature:** Every null is answered with patience and no null is answered with a date. **Measurement: Demand a bounded latency at stage G-4, in the same breath as the magnitude.** Then check whether the practice's own dynamics support the delay claimed. In the leaky integrator, latency is not free-floating: with `delta = 0.08` per period the time constant is `tau = −1/ln(1−delta) = 11.99` periods and the half-life to the fixed point is **8.31 periods**. **Price:** A latency claim of two periods against a system whose half-life is 8.31 is a misdiagnosis in one direction — evaluating a transient (Section 4, FM-4.6). A latency claim of "eventually" is unfalsifiable in the other, and is this entry. **The honest version specifies a number and defends it from the system's own dynamics. Fix:** Bound the latency in advance and treat exceeding it as the stated disconfirming result. **Confusable with:** MF-18, MF-21. **See:** the cadence result and the contraction theorem [Curzi, 2026a,?].

MF-21 · The Un-nulled Protocol

Damages: Fa. **Clinical:** No definition of a null result exists before the data arrive, so every outcome is interpretable as partial success. Distinct from MF-18: the *goal* may be perfectly checkable; what is missing is the statement of what nothing looks like. **Signature:** Results are reported as "encouraging" and never as "null". **Measurement:** Look for a pre-recorded SESOI and sample size. **Section 4 puts them at step 6 of twenty rather than at step 20 precisely because their position in the sequence is what makes them binding. Price:** Without a preset SESOI, the four null categories cannot be distinguished, so an uninformative null is read as an informative one in whichever direction the practitioner was already leaning — **overframing applied to one's own experiment. Fix:** Fix the SESOI and the required `n` in writing

before the first observation. **If the `n` is unaffordable, say so in week 0 and run the study as descriptive rather than inferential; that is an honest choice, and discovering it in week 12 is not. Confusable with:** MF-17, MF-18, MF-07. **See:** the survey protocol [Curzi, 2026i]; Sections 4.6 and 4.10.

MF-22 · Goodhart Capture of a Manifestation Metric

Damages: Fa, then B, then eventually Cn. **Clinical:** A measure adopted to track manifestation becomes the target, and thereafter it tracks itself. Goodhart's Law and Campbell's Law, applied to a domain unusually vulnerable to them because most of its metrics are self-reported. **Signature:** The metric improves smoothly while every unmeasured correlate of the thing it was proxying stays flat or declines. Enthusiasm about the number exceeds enthusiasm about the outcome. **Measurement:** Model the metric as `M = T + G`, where `T` is the target quantity and `G` is gaming uncorrelated with `T`. Then `corr(M, T) = 1 / sqrt(1 + sd_G^2)`:

```
gaming sd = 0.0  ->  corr 1.0000, T explains 100% of the metric's variance
gaming sd = 0.5  ->  corr 0.8944, T explains  80%
gaming sd = 1.0  ->  corr 0.7071, T explains  50%
gaming sd = 2.0  ->  corr 0.4472, T explains  20%
gaming sd = 3.0  ->  corr 0.3162, T explains  10%
```

Price: Gaming variance equal to the target's own variance halves the metric's informational content — **`corr(M,T) = 0.7071`, so the measure now says as much about the incentive as about the thing.** The specific manifestation-domain case is severe: **a group protocol whose success metric is convergence is measuring exactly the damage it does**, since alignment rising means `u` falling and `S = ln(1 + (N−1)u)` falling with it. **Fix:** Never let the success metric be a quantity the participants control directly. Pair every self-reported metric with one observable the participants do not control. **And re-measure `u` after any step that could align beliefs: if `u` fell, the step is reversed regardless of what else it produced. Confusable with:** MF-19, MF-11, MF-28. **See:** the independence requirement [Curzi, 2026g]; Sections 5.0.5 and FM-5.3.

37.6.8 6.8 Class V — ledger faults (Ld)

The evidence is real, and it has been booked to the wrong account.

MF-23 · Precedent Mistaken For Evidence

Damages: Ld, and everything downstream of it. **By the corpus's biological-layer constraints's own reckoning this is the single most likely failure of this strand of the corpus's method, and it is listed here in full for that reason. Clinical:** The concordance method pairs every substantive claim with a `(+1)` reference from the peer-reviewed corpus and a `(−1)` reference from the old corpus. **The two columns do not carry the same kind of thing. The `(+1)` column carries EVIDENCE — what is measured, replicated, falsifiable. The `(−1)` column carries PRECEDENT — that the idea was arrived at independently, recorded, and preserved, often for centuries, by people with no access to the instruments.** The fault is treating the pair as two witnesses. **Signature:** The phrase "both science and tradition confirm". Two sources cited, one conclusion drawn, and the conclusion is stronger than the measured source alone would support. **Measurement:** For each column, ask what would have had to be different in the world for

that source to say something else. **If the answer for the `(-1)` source is "nothing measurable", it is precedent.** Then compute the difference the mistake makes. **Price:** Bayes, with a flat prior and an evidential likelihood ratio of 3:

```
LR_evidence = 3.0, precedent treated at its honest weight LR = 1.3
    -> posterior = 0.7959
LR_evidence = 3.0, precedent double-counted as a second body of evidence LR = 3.0
    -> posterior = 0.9000
Overstatement in odds = 2.31x
```

The claim's odds are overstated by a factor of 2.31 by a single misbooked column — and the error compounds across a volume, because every concordance in the register makes it again. **What independent arrival DOES establish is real and worth having: that the structure was findable by more than one route, which is a genuine argument that the structure is in the territory and not only in the instrument.** That argument is worth an LR above 1 and nowhere near the evidential column's. **Fix: State the column's role every time a concordance is drawn.** A concordance that admits what each side can carry is more persuasive than one claiming both are proof, and a reader who checks will find the corpus was straight with them. Where a row has a `(-1)` entry and no `(+1)` entry, label it what it is: **a research question with a long history, which is interesting to have and is not a result. Confusable with:** MF-24, MF-25, MF-03. **See:** the concordance register [Curzi, 2026w]; the corpus's biological-layer constraints.

MF-24 · The Unbadged Speculative Bridge

Damages: Ld. **Clinical:** A bridge that was correctly marked speculative in the section that stated it appears unmarked in a summary, a table, a talk, or a later chapter. **The badge does not travel unless somebody carries it, and the standing rule is that it must be carried in the same sentence that states the bridge, not in a footnote. Signature:** A claim that is hedged on first appearance and flat on second. The abstract is more confident than the body. **Measurement:** Grep the corpus for the claim and compare every instance to the first. **VINO's binding rule, adopted unchanged: only bridges satisfying all three criteria — structural correspondence, predictive power, practical utility — are presented as established; speculative bridges are marked as such.** the biological-layer strand of the corpus tightens this by one notch: marked in the *same sentence*. **Price:** Not arithmetic, and it is the most corrosive entry in the catalogue. **A reader who finds one unbadged bridge is entitled to distrust every badged one**, because the badge's whole value is that it was applied consistently. One failure destroys the signal for all the others. **Fix:** Badge in the sentence. Re-check every summary against its source. **And a specific standing case for this strand of the corpus: any Grade R step — a research procedure with no established mechanism — carries its stamp wherever the step is described, including three months later when somebody calls it a technique. Confusable with:** MF-23, MF-25. **See:** the concordance register [Curzi, 2026w]; the standing refusals of the corpus, the corpus's biological-layer constraints.

MF-25 · Naming As Mechanism

Damages: Ld, CH. **Clinical:** A gap is given a name and the name is thereafter treated as an explanation. The vocabulary grows; the mechanism does not. **Gematria is a hash function — a map from strings to integers — and that description is literally accurate and carries no claim that the map is meaningful. The fault is the step from "we can describe this precisely" to "we have explained it." Signature:** Increasing terminological precision with no increase

in predictive content. A diagram in which the crucial arrow is labelled rather than derived. **Measurement:** Ask what the name predicts that its absence did not. **If the answer is nothing, it is a label.** A good name is still worth having — it makes the gap discussable — but a label that predicts nothing has not moved the claim along the grounding diagnostic by one stage. **Price:** The claim appears to have passed stage G-1 without passing it. The channel has a name and no ends. **Fix:** Keep the name and re-run G-1 against it. **The model to follow is the open problem of the missing demodulator [Curzi, 2026y]: the gap is named precisely, described as one well-specified falsifiable hole, and explicitly NOT presented as filled. Confusable with:** MF-01, MF-02, MF-24. **See:** the missing demodulator [Curzi, 2026y]; the concordance register [Curzi, 2026w].

MF-26 · The Un-decomposed Bundle

Damages: Ld, CH, B. **Clinical:** A protocol with many components produces an outcome and the outcome is attributed to one component — usually the newest, the most distinctive, or the one the author is most invested in. **Signature:** Nine things changed and one thing gets the credit. The credited component is the one that would be most interesting if it worked. **Measurement:** Ask whether the component was varied independently of the others. **If it was not, the design has zero identifying power for that component — not low power, zero — and no sample size repairs it. Price:** Section 4's worked example is the honest version: over twenty-four weeks `Q` rose from 1.1000 to 3.4905, a factor of 3.17, and the biological arm's contribution to that was **not estimable at all**, because it was introduced alongside two other changes and returned an uninformative null besides. **Fix:** Factorial design, staggered introduction, or attribution refused. **Attribution refused is a legitimate report and this framework prefers it to a guess. Confusable with:** MF-03, MF-15, MF-12. **See:** the falsification suite [Curzi, 2026u]; the survey protocol [Curzi, 2026i].

37.6.9 6.9 Class VI — consent faults (Cn)

The claim may be true. The protocol is not permitted.

MF-27 · The Consent Bypass

Damages: Cn. **This entry is governed by the fourth standing refusal of the corpus, which is absolute: this framework does not recommend an intervention that removes a person's ability to decline. Clinical:** A protocol acts on a person who cannot know what is being done, cannot refuse it, or cannot stop it. The bypass may be architectural (the step is concealed), social (refusal is expensive), or procedural (no decline path was ever built). **Signature:** A step that is described to observers and not to participants. A decline that has no defined mechanism. A group decision standing in for individual consent. **Measurement:** Count the per-person records for the three gates: **KNOW** (the participant can state what the step does, its grade, and what its null looks like), **DECLINE** (refusal is a recorded outcome with the same standing as assent), **REVERSE** (a written rollback exists, with its residue and anything irreversible named). **If there are fewer complete records than participants, consent was not obtained — it was assumed. Price:** Not arithmetic. **A protocol that fails this entry is not a worse protocol; it is outside what this framework will describe**, and no expected benefit changes that. **Fix:** Build the gates as steps that can halt the protocol, not as advice appended to it. **Advice cannot halt anything; gates can.** Section 4 §3.5 and Section 5 §3.10 specify them. **Confusable with:** MF-28, MF-30. **See:** Sections 4 and 5; the standing refusals of the corpus.

MF-28 · The Recruited Belief

Damages: Cn, and then `u`, and then everything the group's capability rests on. **Clinical:** The belief is produced by making dissent expensive rather than by making the belief persuasive. Consent is present in form and absent in substance. **Two mechanisms produce apparent commitment and they are not equivalent: a person who adopted a practice because it works for them would keep doing it if the programme vanished; a person who adopted it because dissent is expensive stops the moment the cost of dissent falls. Signature: A decline rate of exactly zero across many opportunities.** Unanimity that arrives fast and without argument. Nobody can name the last time the group changed its mind because of an internal objection. **Measurement:** Two instruments. First, **remove the sponsor for one period and count what survives** — what survives is the committed fraction, measured rather than asserted. Second, independent-estimate-before-discussion on 15 to 25 live questions, giving `u = 1 − rho^2`. **Price:** Recruited belief has `u = 0` with respect to the group's belief and therefore contributes nothing to `S = ln(1 + (N−1)u)`. At `N = 18`, moving `u` from 0.25 to 0 costs **1.6582 nats, which is 57.37% of the group's entire ceiling.** And the seeding calculation is corrupted at the same time: a committed fraction counted from compliance is a **fictitious numerator**, so the 25% threshold is being computed against a number that does not exist. **Fix:** Make dissent cheap, visible, and recorded, and treat a zero decline rate as a measurement of the decline path rather than of the protocol. **Protect dissent procedurally and test the protection. Confusable with:** MF-27, MF-22, MF-30. **See:** the two-mechanisms-of-commitment analysis and the independence requirement [Curzi, 2026g]; Section 5.

MF-29 · The Irreversible Step

Damages: Cn. **Clinical:** A step is taken that cannot be undone, and its irreversibility was not stated before it was taken. The fault is not irreversibility as such — some worthwhile things are irreversible — but irreversibility that arrives unannounced. **Signature:** The rollback plan does not exist, or exists and does not mention residue. **Measurement:** The three-line rollback record, required before any step: **STOP** (the single action that ends this step now), **RESIDUE** (what remains after stopping and for how long), and **IRREVERSIBLE** (what cannot be undone). **A non-empty third line escalates the step to a second, separate KNOW gate before it may run. Price:** Asymmetric and unbounded, which is the reason for the escalation. The entry that catches people is not the exotic one. **In Section 4's table the audio arm's residue is the memory of having heard something, which is bounded; the load-shedding step's residue is a resigned commitment, which is not.** An audio file has an off switch. A withdrawn obligation does not. **Fix:** Write the three lines first. Escalate any step with a non-empty third line. **And where shedding lands its cost on someone who did not consent, it is not shedding but transfer, and it is outside the line this framework draws. Confusable with:** MF-27, MF-20. **See:** the shedding lever [Curzi, 2026a]; Section 4.11.

MF-30 · The Masked Carrier

Damages: Cn, and it is the one bright-line violation in the catalogue. **Clinical:** Content is delivered below threshold, masked, or otherwise concealed from the person receiving it. **The no-subliminals constraint is stated absolutely: nothing masked, nothing below threshold, nothing concealed. A message hidden from its recipient cannot be consented to. Signature:** A file, a track, or a step whose full content the recipient cannot inspect. Any claim that the effect

depends on the recipient *not* attending to the content. **Measurement:** Can the recipient inspect the artefact in full, at audible level, and state what it contains? **Gate KNOW forbids the concealed layer by construction, because a participant cannot state what a step does if part of what it does is hidden from them.** The constraint is therefore enforced by the protocol's first gate rather than by good intentions. **Price:** Zero, and this is the entry's most useful fact. **Concealment buys nothing that disclosure does not: open-label placebo works when the recipient is told they are receiving placebo** (Kaptchuk et al., 2010, IBS), with modest effect sizes and an active literature. **The strongest verified belief-channel in the literature does not require deception**, which means the no-concealment constraint costs the method nothing and buys it everything. **Fix:** Disclose in full, make the artefact inspectable, and remove any component whose claimed action depends on the recipient not knowing about it. **If a step cannot survive disclosure, the step is the fault. Confusable with:** MF-27, MF-28. **See:** Section 4; the corpus's biological-layer constraints.

37.6.10 6.10 Faults of diagnosis itself

The faults of diagnosis itself — the ways this section gets misused.

FM-6.1 · The Entry Chosen By Resemblance. Picking the entry whose Signature field sounds like the complaint, rather than the one whose Damages field matches the coordinate. *Signature:* a diagnosis that fits the story and does not fit the arithmetic. *Fix:* C.1.

FM-6.2 · The Downstream Diagnosis. Diagnosing a magnitude or base-rate fault in a claim that already failed at the channel stage. *Signature:* elaborate statistics attached to a claim with no mechanism. *Fix:* C.2, and stop at the first failure.

FM-6.3 · The Catalogue As Dismissal. Using an entry to reject a claim without running its Measurement field. **Naming a fallacy is not diagnosing one**, and a catalogue used as a vocabulary of dismissal is worse than no catalogue, because it produces confident rejection at zero cost. *Fix:* the Measurement field is mandatory; the entry is the hypothesis, not the verdict.

FM-6.4 · The Exemption. Applying the catalogue outward and not inward. *Signature:* MF-08, MF-11, MF-23 and MF-24 are never invoked against the corpus's own claims. *Measurement:* count the in-house applications; this section contains four by construction and the status register [Curzi, 2026] is where the rest belong. *Fix:* run the catalogue on the corpus before running it on anybody else.

FM-6.5 · The Multiplied Entry. Reporting five entries for one fault because the fault touches five fields. *Signature:* a diagnosis longer than the claim. *Fix:* one coordinate, one entry, and the rest listed as consequences.

37.7 7 Results: three instances worked end to end

The three instances below are **constructed illustrative examples with declared parameters**, not field observations. Their value is that each runs the arithmetic to a verdict, including where the verdict is negative, and each records what the protocol forbade as well as what it permitted. Section 7.4 collects the results the rest of the corpus cites.

37.7.1 7.1 One practitioner, twenty-four weeks

The subject. One person, self-experimenting, twenty-four weeks. All figures are an illustrative construction, computed, and are not a measurement of any real individual or a report of any trial.

Week 0 — A.1 to A.9.

The occasion class: a weekly review of their own work, held Friday. The observable they do not fully control: whether the next week's plan survives contact by Wednesday, scored as a binary, logged for a year already and running at about 0.42.

Framings inventoried at A.4: `N = 7`. Pair test at A.5: of the 21 pairs, 7 have ever disagreed about the next action, so `u \ensuremath{\approx} 0.33`, rounded to `u = 0.35` with the rounding noted.

```
N = 7        ln N = 1.9459 nats  (the ceiling)
u = 0.35     N_eff = 1 + 6(0.35) = 3.1000
S = ln 3.1 = 1.1314 nats         realized fraction = 58.14%
```

Storage parameters at A.8: `delta = 0.08` per week, `eta = 0.45`, `C = 0.20`, `Q_0 = 1.10`. Headroom gate at A.9:

```
h_0 = 0.45 * 1.9459 - 0.08 * 1.10 - 0.20 = 0.5877  > 0   -> BUILD PERMITTED
maximum single-step increment r <= 0.5877
```

SESOI at A.6: they decide that a shift of 0.35 SD in their plan-survival score is the smallest change that would alter how they run the following quarter. From §4.9: detection at `d = 0.35` needs 65 paired observations; equivalence at SESOI 0.35 needs 51. **They have 24 weekly observations. They record, in week 0, that their study is underpowered for both, and that its verdict will therefore be N-1 unless the effect is large.** This is the single most consequential entry in the whole log, and it is made before any data exist.

Gate V at A.7: the L1 framing audit is flagged IRREVERSIBLE — a framing once named cannot be un-noticed — and escalated to a second Gate K, which they pass.

Weeks 1 to 24 — A.10 to A.13. The storage trajectory, computed:

```
Q_inf = (0.45 * 1.1314 - 0.20) / 0.08 = 3.8641
tau   = 11.9931 weeks ;  half-life 8.3130 weeks
```

week	Q_t	h_t
0	1.1000	0.5877
4	1.8839	0.5249
8	2.4455	0.4800
12	2.8479	0.4478
16	3.1361	0.4248
20	3.3426	0.4083
24	3.4905	0.3964

At week 12 the subject reports that the practice "feels much heavier than it did." The ledger says `h` has fallen from 0.5877 to 0.4478 — a 23.8% reduction in available headroom with no parameter changed. **Nothing has gone wrong; `delta·Q` is doing arithmetic** (the falling-headroom result [Curzi, 2026a]). They add nothing, per A.9: the correct response to falling headroom is not more input.

The ordinal tally at week 12: 7 over-framed, 3 calibrated, 2 under-framed. Dominant verdict OVER-FRAMED. Lever applied per §4.3: they add one observable they do not control (a colleague's independent estimate of whether the plan will survive) and one adversarial source. **No `D/P` value is computed and no `Delta` reported, because CC-R1 forbids it and the instrument was built to make the forbidden thing impossible rather than merely discouraged.** By week 24 the tally reads 9 over-framed, 9 calibrated, 6 under-framed. **The ordering has moved and the movement is the finding.** How far it moved is not reportable.

Weeks 13 to 24 — the L3 arm, A.14 to A.17.

At week 13 the subject elects to run the biological arm. Gate K second pass: they write out the A.14 sentence in full and sign the log. Headroom check: `h_13 \ensuremath{\approx} 0.4437` against an arm cost of 0.05 `C`-units per week, well inside `r <= h`. They proceed.

Artefact per A.15: 640 characters of their own text, base-4 encoded, address-prefixed as a format, rendered with a 40 ms window. Gabor check: at 40 ms the resolution floor is `1/(4·pi·0.040) = 1.9894 Hz` against a tone spacing of 12 Hz, inside the constraint by a factor of 6.03. **At a 5 ms window the floor would be 15.9155 Hz — wider than the tone spacing — and the artefact would no longer encode what it claims to encode.** They record the check.

Pre-registration per A.16: null hypothesis stated, observable fixed, SESOI 0.35 carried over, the sample size acknowledged as far below the 51 required for equivalence, four baselines specified, and the structural ceiling test added — any claimed single-week increment must satisfy `r_t <= h_t`, which at week 13 is 0.4437.

Result at week 24. Observed standardized difference on the plan-survival score, arm weeks versus matched non-arm weeks: `d = 0.06`. With `n = 20` paired comparisons the 95% interval is

```
0.06 +/− 1.959964 / sqrt(20)  =  0.06 +/− 0.4383  =  [−0.3783, 0.4983]
```

The interval is not contained within +/- 0.35. Classification: N-1, uninformative null. And because the arm carried a Grade R stamp with an expected null, it is *also* N-4. The subject records both classifications and writes the conclusion the protocol requires:

> *"This run tells me nothing about whether the L3 arm has an effect. My interval is wider than my own SESOI. To conclude equivalence at SESOI 0.35 I would need 51 paired observations; to detect d = 0.35 I would need 65. Separately, and independently of my sample size, the arm had no established mechanism when I started it and still has none: there is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. The well-specified gap of the open problem of the missing demodulator [Curzi, 2026y] is exactly where it was. I am recording this null because nulls of this kind are the ones that do not otherwise get recorded."*

What the subject actually got out of twenty-four weeks. Not the L3 arm — that returned nothing, as predicted, at a cost of 0.05 `C`-units per week for twelve weeks. What moved was L1 and L2: `Q` rose from 1.1000 to 3.4905, a factor of 3.17, and the ordinal tally shifted from 7:3:2 toward 9:9:6, from a dominant over-framed reading to a balanced one.

That is the honest shape of this practice, and the section would rather print it than a better story. The arithmetic worked, the measured channels did modest measured things, the research arm returned its expected null, the practitioner could have stopped at any gate, and nothing was hidden from them at any point.

One last number, because it generalizes. The fixed-point headroom identity (CC-R6) for this subject: `h_inf = eta·(ln N − S) = 0.45 × (1.9459 − 1.1314) = 0.3665`. At the fixed point `delta`, `C` and `Q` cancel entirely. **When this practice matures, its capacity for anything new will depend on one quantity only: the gap between the seven ways this person can see their situation and the surplus those seven ways actually collect.** Everything else washes out. That is where the next quarter's work is, and the arithmetic said so without anybody needing an opinion about it.

37.7.2 7.2 An eighteen-person unit, forty months

The system. An eighteen-person applied-research unit inside a 120-person division. It has a reputation for quality and a growing complaint that "nothing new gets started here." All figures are an illustrative construction, computed, and are not a report of any real organisation.

Period 0 — B.1 to B.7.

Survey estimates: `eta = 0.30`, `delta = 0.06` per month, `C = 0.55`, `Q_0 = 1.20`. `N = 18`, `ln N = 2.8904`.

```
Gate 0:  h_0 = 0.30*2.8904 - 0.06*1.20 - 0.55 = +0.2451     BUILD PERMITTED, r <= 0.2451
```

Gate I baseline at B.5: independent estimates on 20 live questions give mean pairwise signed- error correlation `rho = 0.866`, so `u = 1 - 0.866^2 = 0.25`. The estimator depends only on `|rho|` — the opposition identity of Curzi [2026], under which `rho = +1` and `rho = −1` both give `u = 0` and `F = 0`, so a perfectly opposed pair purchases exactly as much surplus as a perfectly aligned one, namely none.

```
N_eff = 1 + 17(0.25) = 5.2500        S = ln 5.25 = 1.6582 nats
realized fraction = 1.6582 / 2.8904 = 57.37%
```

Turn-taking in the standing meeting: the three most senior members take 62% of speaking time between them. `PR` on the eighteen shares comes out low and `N_eff` from participation confirms the estimate above to within rounding.

B.7 requires both numbers, and here is why. **Headroom is positive at +0.2451, so the unit looks healthy. The one-step growth test says otherwise:**

```
growth iff  eta*S > delta*Q + C
            0.30*1.6582 = 0.4975   vs   0.06*1.20 + 0.55 = 0.6220
            0.4975 < 0.6220   ->   SHRINKING
```

And the steady state:

```
Q_inf = (eta*S - C) / delta = (0.4975 - 0.55) / 0.06 = −0.8755
```

A negative equilibrium. the fixed-point theorem of the storage law [Curzi, 2026a], does not hide this failure mode: if `eta F(u*) < c*` the equilibrium is negative and the regime is unsustainable or the linear model must be replaced. Projected forward, `Q` falls from 1.20 to 0.1123 by month 12 and crosses zero around month 15. **The unit is not stagnating because its people are tired. It is operating at 57% of its own ceiling while paying full maintenance, and the arithmetic has been saying so for some time in a language nobody was reading.**

The complaint — "nothing new gets started here" — was accurate and misattributed. Positive headroom said the unit *could* build; the growth test said it was losing stock every month it did not. Both were true simultaneously, which is exactly the case the headroom-versus-growth diagnostic split [Curzi, 2026g] warns about.

The decision. Two levers, in order.

Lever 1, `u`: 0.25 -> 0.45. Not by hiring. By B.9 — independent written estimates before discussion on every live question — and by rotating who opens the meeting, which addresses the 62% concentration directly. The Jensen correction at B.6 is applied to the eight periods of follow-up measurement rather than to their average.

Lever 2, `C`: 0.55 -> 0.45. Two standing reports are retired at B.16 after checking that retiring them does not transfer the work to another team, which would be transfer rather than shedding.

Recomputed:

```
S(0.45) = ln(1 + 17*0.45) = 2.1576 nats        realized fraction = 74.65%
Q_inf   = (0.30*2.1576 - 0.45) / 0.06 = 3.2878
h_inf   = eta*(ln N - S) = 0.30*(2.8904 - 2.1576) = 0.2198     (CC-R6: delta, C, Q cancel)
```

month	Q_t	h_t	one-step test
0	1.2000	+0.3451	grow
4	1.6578	+0.3176	grow
8	2.0151	+0.2962	grow
12	2.2942	+0.2795	grow
20	2.6821	+0.2562	grow
40	3.1121	+0.2304	grow

Note what each lever did. Raising `u` alone would have moved the steady state from **-0.8755 to +1.6211** — from a regime with no sustainable stock at all to one that grows, but only to 1.62 Q-units, 35% above where the unit already sat. **The geometry lever decides whether a sustainable stock exists; the cost lever decides how large it is**, and here the cost lever doubled it again to 3.2878. Neither substitutes for the other.

The limit of the geometry lever is worth stating exactly, because it is the theorem people misquote. Corollary 3.4 says that if `C_t > eta ln N − delta Q_t`, **no** interaction geometry prevents decline. This unit was never in that regime — its `h` was +0.2451, so geometry alone could have rescued it. **Unit C of §5.1, at `h = −0.4229`, is the regime where the geometry lever is dead, and the only honest moves there are cost and shedding.**

Periods 1 to 6 — seeding the new practice (B.10 to B.12).

The practice being established is the independent-estimate discipline itself. Sizing at B.10: 25% of 18 is 4.50, so **5 committed people**. The unit has three natural sub-teams of six; 25% of 6 is 1.50, so **2 committed people per sub-team** — and the unit chooses to seed one sub-team of six with four committed members (67%, far past its tipping point) rather than to spread five across eighteen.

Sponsor-independence test at B.12: the unit lead takes a month away from the meeting. On return, the seeded sub-team is still collecting independent estimates and the two unseeded ones are not. **That is the committed fraction, measured rather than asserted**, and expansion proceeds from it along working ties rather than the org chart.

Period 7 — the biological arm, and its expected null.

The unit elects to run the Grade R arm. Gate 0b at B.3: arm cost 0.04 per month against `h_7 \ensuremath{\approx} 0.30`, inside the ceiling. Gate K at B.14 is run per person; **three of eighteen decline, and the three declines are recorded in their own rows as declines.** The remaining fifteen proceed. **The decline rate is 16.7%, not zero, which is the first evidence in this worked example that the decline path functions at all.**

Artefact: 1,200 characters of text the unit wrote about its own situation, base-4 encoded, address-prefixed as a format, rendered with a 30 ms window. Gabor check: `1/(4·pi·0.030) = 2.6526 Hz` against a tone spacing of 12 Hz — inside the constraint by a factor of 4.52. Recorded.

B.15 is enforced: each of the fifteen writes their judgement of the artefact before any discussion of it. The pooled spread is wide, which is the informative part and which a group discussion would have erased.

Result. Pre-registered observable, twelve months, four baselines plus the ceiling test. The arm does not beat the persistence baseline. The largest month-on-month increment observed in `Q` during the arm period is 0.0864, against `r_max` values running from 0.3011 down to 0.2585 across those months — **inside the structural ceiling throughout, so no repackaging is indicated, which is the only positive thing the structural test can say.** The unit records:

> *"The Grade R arm returned a null, as expected. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal, and our result changes nothing about that gap in either direction. Separately: we did not run an acoustic-to-c intervention, because the acoustic intervention analysis [Curzi, 2026f]'s causal test is reported as not confirmed and we have no*

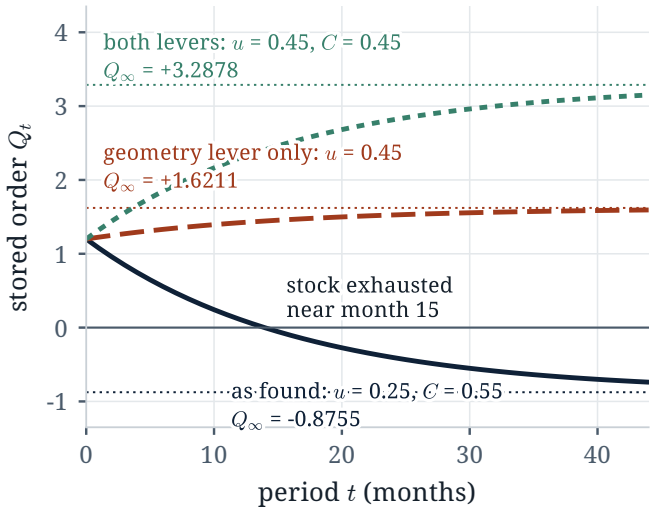

Figure 37.5: **The geometry lever decides whether a sustainable stock exists; the cost lever decides how large it is.** As found, the unit passes its entry gate at +0.2451 and still runs to a negative equilibrium of −0.8755, exhausting its stock near month 15. Raising `u` from 0.25 to 0.45 alone moves the equilibrium to +1.6211; cutting `C` from 0.55 to 0.45 as well moves it to +3.2878. Modelled at `eta` = 0.30, `delta` = 0.06, `Q_0` = 1.20 from the parameters of Section 7.2; generated by `figs/src/CCP-037_fig04.py`.

> *basis for describing a room as raising `c`. What actually moved our numbers was `u` from 0.25 to 0.45 and `C` from 0.55 to 0.45."*

Gate I, post-step (B.17). Re-measured `u` after the arm period: 0.44, against 0.45 before. Within measurement noise, and critically **not lower in a way the reversal rule would trigger**. Participating `N` unchanged at fifteen for the arm and eighteen for the unit. The shared-input hazard of Restriction 1 was contained by B.15, and the unit records that containment as the design feature it was rather than as luck.

What the eighteen months bought. `Q` from 1.20 to roughly 2.29 by month 12 and 3.11 by month 40, against a trajectory that would have crossed zero at month 15. Realized ceiling fraction from 57.37% to 74.65%. **A programme that would have been launched under a headroom of +0.2451 against a cost of 0.30 — and would therefore have driven the unit negative before doing anything — was not launched, because somebody computed the fourth row of the table in §5.1.**

And the arm returned nothing, which is recorded, because nulls of this kind are exactly the ones that do not otherwise enter the record. The unit is now, by its own measurement, more capable and more disagreeable than it was, and those two facts are the same fact.

37.7.3 7.3 A claim diagnosed against the catalogue

The claim. A well-run twelve-person team reports that after adopting a listening practice built on this framework's genomic-audio method, its "decision quality index" rose from 62 to 81 over one quarter, that "everyone found it helpful," and that the team therefore recommends the practice to the rest of its 120-person division. All figures are an illustrative construction, computed, and are not a report of any real organisation.

C.1 — locate the coordinates. The claim touches four: **CH** (what channel is asserted?), **B** (what is the base rate behind "everyone found it helpful"?), **Fa** (what would have counted as a null?), and **Mg** (is 62 to 81 a permitted increment?). Consent, **Cn**, must also be checked, and per C.6 it is checked last and as a veto.

C.2 — run the grounding sequence, and stop at the first failure.

G-1, identify the channel. The team's account: "the encoded narrative reaches the cells and activates latent capability, which shows up as better decisions." **HALT.** The claimed channel is acoustic transmission of sequence-specific content to a cell that demodulates it. **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal** (the open problem of the missing demodulator [Curzi, 2026y]). The channel cannot be named because it does not exist in the established literature.

Diagnosis 1: MF-02, The Absent Channel. Not MF-01 — the team named a channel specifically, which is the honourable version, and naming it is what let the diagnosis take four minutes instead of four years.

The follow-up question is the one that matters. Upstream is genuinely real: PIEZO1/2 are mechanically gated ion channels, sound is mechanical, and Tajik et al. (*Nature Materials*, 2016) showed surface force transmitting through the cytoskeleton to stretch chromatin and upregulate transcription. **Asked whether that upstream reality licenses their claim, the team says yes.** It does not: the established pathway is real and **non-specific**, and the claim is about *which* content, addressed to a *particular* sequence.

Diagnosis 2: MF-03, Channel Substitution, with the seam located exactly — the sentence begins with a Nobel-recognized mechanism and ends with an addressed, sequence-dependent outcome.

C.3 — price the base-rate claim. "Everyone found it helpful" is twelve testimonials with no denominator and no mechanism by which an unhelpful experience could have entered the record. **Diagnosis 3: MF-13, The Survivorship Narrative.** Priced: if the outcome the team is describing occurs spontaneously at even a 5% rate, then twelve favourable reports require only 240 attempts to arise **with no effect whatsoever**, and the team ran one attempt with twelve people over a quarter in which many other things also changed.

Worse, the team recruited for the practice during a bad quarter. **Diagnosis 4: MF-15, Regression Mistaken For Effect.** Priced: selecting the bottom decile of a normally distributed measure gives `E[Z|selected] = −1.7550`; at a test-retest reliability of 0.6, the expected improvement **with no intervention at all** is `(1 − 0.6) × 1.7550 = 0.7020 SD`. On the team's own index, whose quarterly SD is 14 points, that is **9.83 points of expected improvement from nothing** — more than half the 19-point rise they reported.

C.4 — run the structural test. The team's parameters, estimated by survey: `N = 12`, `ln 12 = 2.4849`, `eta = 0.30`, `delta = 0.06`, `Q = 2.10`, `C = 0.55`.

```
r_max = 0.30 * 2.4849 - 0.06 * 2.10 - 0.55 = 0.0695 per period
```

Their index rise of 19 points, expressed on the framework's normalized scale, corresponds to a claimed single-quarter increment of 0.58 Q-units. **That is 8.35 times `r_max`.**

Diagnosis 5: MF-12, The Ceiling Violation — and, given the practice includes a heavily filtered summary of the team's own prior decisions fed back to them, **MF-11, The Repackaged Input** must be tested for explicitly. R4 is the precedent: a filtered repackaging passed all four empirical baselines **including the shuffle at p = 0.0005** and was caught only here, at 38.5x the ceiling. **The team's four baselines all passed. That fact is now known to carry no weight against this specific failure mode.**

The falsifiability check. Asked what result would have made them stop, the team offers none; asked what a null would have looked like, they offer none. **Diagnoses 6 and 7: MF-18, The Unfalsifiable Goal, and MF-21, The Un-nulled Protocol.** The index itself is self-reported by the participants. **Diagnosis 8: MF-22, Goodhart Capture** — modelled as `M = T + G` with gaming variance equal to the target's, `corr(M, T) = 0.7071`, so half the metric's variance is now about the incentive rather than the outcome.

C.5 — audit the ledger. The team's write-up cites a contemplative tradition of sounded practice alongside the mechanotransduction literature and concludes that "both the science and the tradition support this." **Diagnosis 9: MF-23, Precedent Mistaken For Evidence.** The tradition carries precedent — that the structure was findable by another route, which is genuinely worth having — and it carries no evidence. Priced with a flat prior and an evidential

LR of 3: booking precedent at 3.0 rather than at an honest 1.3 moves the posterior from **0.7959 to 0.9000** and overstates the odds by **2.31x**.

The write-up also describes the biological arm without its grade stamp. **Diagnosis 10: MF-24, The Unbadged Speculative Bridge** — the arm was correctly stamped Grade R in the team's own week-1 notes and appears unstamped in the quarterly summary.

C.6 — consent, as a veto. Twelve participants; four complete KNOW records, no DECLINE records at all, and no rollback documents. **The decline rate is exactly zero.**

Diagnosis 11: MF-27, The Consent Bypass — fewer gate records than participants means consent was assumed rather than obtained. **Diagnosis 12: MF-28, The Recruited Belief** — a zero decline rate across twelve people and thirteen weeks is a measurement of the decline path, not of the protocol. The team is asked to run the sponsor-absence test; the lead steps back for one month and on return the practice has stopped in three of the four sub-groups.

The verdict, in the order the Specification produces it.

```
CH  MF-02  Absent Channel             -> the claim halts at G-1
CH  MF-03  Channel Substitution       -> real upstream, unlicensed downstream
B   MF-13  Survivorship Narrative     -> 12 reports; 240 attempts suffice at a 5% base rate
B   MF-15  Regression Mistaken        -> 9.83 index points expected from nothing
Mg  MF-12  Ceiling Violation          -> claimed increment 8.35x r_max = 0.0695
Mg  MF-11  Repackaged Input           -> must be tested; the shuffle cannot see it
Fa  MF-18  Unfalsifiable Goal         -> no stated disconfirming result
Fa  MF-21  Un-nulled Protocol         -> no SESOI, no sample size, fixed in advance
Fa  MF-22  Goodhart Capture           -> corr(M,T) = 0.7071 on a self-reported index
Ld  MF-23  Precedent as Evidence      -> posterior 0.9000 for an honest 0.7959; 2.31x odds
Ld  MF-24  Unbadged Bridge            -> Grade R stamp lost between notes and summary
Cn  MF-27  Consent Bypass             -> 4 gate records for 12 participants
Cn  MF-28  Recruited Belief           -> decline rate exactly zero; 3 of 4 stopped
```

What the team should conclude, and it is not "the practice is worthless." Two of the thirteen weeks' worth of changes were L1 and L2 changes in Section 4's scheme — the team began recording individual judgements before discussion, and it retired a standing report. **Those are theorem-backed and measured-channel steps, and they have a plausible claim on the index movement that survives every diagnosis above.** What has no claim on it is the biological arm, which was never licensed by any established mechanism, was never independently varied (**MF-26**), and would not have been attributable even if the design had been otherwise perfect.

And the veto stands regardless of any of that. The consent findings are not weighed against the benefit; **a protocol that fails Class VI is outside what this framework will describe.** The correct next step is not a better analysis. It is to rebuild the gates as steps that can halt the protocol, obtain twelve complete records, run the sponsor-absence test again with the decline path working, and only then decide whether there is anything left worth measuring.

Twelve entries in one quarter from one well-meaning team, all of them priced with arithmetic the team could have run themselves in an afternoon. That is what the catalogue is for, and it is why it is written to be opened before the claim is made rather than after it is published.

37.7.4 7.4 The results this paper contributes

R1 — The headroom gate as a precondition. `h = eta ln N − delta Q − C`, with `h < 0` forbidding any addition, `h = 0` permitting maintenance only, and `h > 0` capping every requested single-period increment at `r <= h`. Worked at `N = 18`, `eta = 0.30`, `delta = 0.06`, `C = 0.55` and `Q = 1.20`: `h = +0.2451`, and the critical stock is `Q* = 5.2852`.

R2 — A positive gate is compatible with a negative equilibrium. The same unit realises `F(0.25) = 1.6582` nats, 57.37 per cent of ceiling, and returns `Q_inf = (0.30 x 1.6582 −`

`0.55)/0.06 = −0.8755`. Raising `u` from 0.25 to 0.45 lifts the realised fraction to 74.65 per cent and the equilibrium to `+1.6211`; **cutting `c` from 0.55 to 0.45 as well** lifts it to `+3.2878`.

R3 — The Moment equation is demoted at scale-type gate 2 at both scopes. The limiting cases, the fixed point `D = P` and the three-way ordering survive; the magnitude does not; and the Rasch route out costs **123 items per term** [Curzi, 2026t].

R4 — The Jensen correction. Feasibility must use the mean of `F(U)`, not `F` of the mean `U`. The wrong computation overstates by **0.0790 nats, 4.31 per cent**, worth **0.3952 stored units** at `eta = 0.30`, `delta = 0.06`, independent of `C`.

R5 — Cluster rather than spray. 16 seeds across 120 people at mean degree 8 under a two-of- eight rule leave **29.00 per cent** of non-seeds with two or more seeded neighbours — 30.16 people — and **39.17 per cent** with exactly one; the same 16 concentrated in one 20-person unit activate **4 of 4** at **80.0 per cent** local commitment.

R6 — A finite catalogue. Every manifestation claim has exactly eight coordinates — a taxonomy, not a theorem — yielding **30 named failure modes in six classes**, each priced by one of four identities including `X = G B` with `G = 0` [Curzi, 2026ab].

CR — The counter-result. The collective worked example **fails on the framework's own arithmetic**: a negative equilibrium at `Q_inf = −0.8755` despite passing the entry gate. The acoustic-to-collective-intelligence causal test is carried forward as **NOT confirmed**. And a filtered repackaging of the input **passed all four empirical baselines including the shuffled-input control at `p = 0.0005`**, caught only by the structural ceiling [Curzi, 2026u].

37.8 8 Discussion

37.8.1 8.1 What follows

The gate is cheap and it is not being computed. Four parameters and a logarithm decide whether a group may add anything at all, and the decision it returns is frequently the opposite of the one the room would have reached. The fourth row of the table in Section 5.1 is the case: a unit with positive headroom of +0.2451 considering a programme costing 0.30 per period. The programme's cost exceeds the headroom, so adopting it moves the unit from feasible to infeasible *before the programme has done anything*. The correct move is to shed 0.06 or more of existing cost first, or to redesign the programme below 0.2451 — not to run a pilot and see.

Maturity is not the enemy, and the arithmetic says which kind of maturity is. At the fixed point the headroom identity reduces to `h_inf = eta(ln N − F(u*))`, in which `delta`, `C` and `Q` all cancel. A mature unit's capacity for anything new therefore depends on exactly one thing: the gap between its ceiling and the surplus it actually collects. Since `F(u) <= ln N` always, `h_inf >= 0` always, and **the plain linear model never ossifies by itself**. Ossification requires exogenous accretion of `Q` — inherited obligations, imported compliance regimes, acquired estates — or superlinear cost growth. The diagnosis therefore branches: stock grown from the group's own interaction is self-limiting and the fix is on `u` and `C`; stock arriving from outside is stock the group never converted, and the fix is deliberate shedding [Curzi, 2026a]. The identity itself is re-derived and stated as R5 in Curzi [2026].

The two levers do different jobs and neither substitutes for the other. In the worked unit, raising `u` from 0.25 to 0.45 alone moves the equilibrium from `−0.8755` to `+1.6211` — from a regime with no sustainable stock at all to one that grows. Cutting `C` from 0.55 to 0.45 then doubles it again to `+3.2878`. **The geometry lever decides whether a sustainable stock exists; the cost lever decides how large it is.** And the geometry lever has a hard boundary: where `C_t > eta ln N − delta Q_t`, no interaction geometry prevents decline [Curzi, 2026a]. Unit C of Section 5.1, at `h = −0.4229`, is in that regime and geometry is dead there.

The cheapest instrument in the paper reads onto a term the law consumes. A stopwatch and six columns give the share vector, the share vector gives the participation ratio, and the participation ratio gives the effective count exactly [Curzi, 2026c]. That is what makes the turn-taking correlate of collective intelligence [Woolley et al., 2010] computable rather than

merely quotable — with the two honesty notes that travel with it: speaking time is a proxy for participation rather than participation itself, and the published result is a correlation between turn-taking equality and the collective-intelligence factor, not a demonstration that equalising turns raises it.

Shrink the denominator. The critical-mass threshold is a proportion [Centola et al., 2018, Granovetter, 1978], so the cheapest route over it is not to recruit more committed people but to narrow the population within which the convention must hold: 100 committed people in a 400-person firm is a campaign with a budget; 2 in a squad of 6 is a pair. Sequential local tipping is cheaper than simultaneous global tipping by a wide margin and produces clusters as a side effect rather than requiring them as a precondition.

37.8.2 8.2 What does not follow

Nothing here licenses an acoustic capability claim. The collective-intelligence factor is measured, is not predicted by members' average or maximum intelligence, and correlates with equality of conversational turn-taking [Woolley et al., 2010, Engel et al., 2014]. The step from *a room's acoustics affect turn-taking* to *a room's acoustics raise the collective-intelligence factor* is a causal claim, its test is reported as not confirmed [Curzi, 2026f], and this paper carries that status without softening. A group may run an acoustic intervention as a pre-registered experiment; a group may not describe it as something the room does. The passive acoustic mechanisms themselves are real and are the reason the proposal is worth testing [Sabine, 1922, Beranek, 2004].

Nothing here licenses a diversity-is-good conclusion in general. The framework prices difference through `u`, and the empirical literature on whether difference helps is genuinely divided. Hong and Page [2004] is a model result, and Thompson [2014] shows that the "diversity trumps ability" claim as usually stated does not follow from it; the subsequent exchange [Kuehn, 2017, Singer, 2019, Grim et al., 2019] narrows the conditions under which it survives. Mannix and Neale [2005] and van Knippenberg and Schippers [2007] find that surface-level diversity frequently hurts in the short run, and Harrison and Klein [2007] shows that three incompatible constructs — separation, variety, disparity — are all called diversity, so a paper using `u` must say which it means. **`u` in this paper is disparity of *recommended action*: two framings that never disagree about what to do next are one framing.** The oldest and cleanest statement of the underlying point is Markowitz [1952]: diversification benefit depends on covariance, not on count, so `N` uncorrelated holdings and `N` perfectly correlated holdings have the same `N` and completely different risk. That is the corpus's four-jurisdictions result, stated in 1952 with the mathematics attached.

Nothing here establishes a biological effect. The channel inventory of Section 4.2 separates two rows that are routinely merged: acoustic input reaching cells through mechanically gated pathways, which is established and **non-specific**, and acoustic input carrying sequence-specific content addressed to a particular sequence, for which **no mechanism is established** [Curzi, 2026y]. Every step touching the second is graded R — a research procedure with an expected null — and the expected null is what the worked instance of Section 7.1 in fact records.

Nothing here converts an ordinal reading into a magnitude. The Moment equation `M = (D/P) E` fails gate 2 of the Formula Validation Protocol at both scopes, because division requires a ratio scale with a true zero and the two constructs are not instrumented that way [Curzi, 2026t, Stevens, 1946]. Structure survives, magnitude does not, and the constructive repair is priced rather than promised: a Rasch logit difference supplies the missing zero at **123 items per term** [Rasch, 1960, Andrich, 1988], so 246 items for the ratio, 369 for all three terms, and 61.5 person-hours for a thirty-participant recovery gate before any analysis.

37.8.3 8.3 Relation to the surrounding literature

The protocol's shape — measure a state, gate an action on a computed threshold, record a decline as data — is standard control engineering applied to an institution, and it is the shape

the resilience literature arrives at from the other direction [Holling, 1973]. Its governance commitments are Ostrom's: durable common-pool arrangements are designed, monitored and graduated rather than exhorted [Ostrom, 1990, 2010]. Its seeding results are complex-contagion results [Centola and Macy, 2007, Centola, 2010, Watts, 2002], and the network-structural analogue of the effective count — adoption predicted by the number of distinct connected components among a person's contacts rather than by raw contact count — is Ugander et al. [2012], which is the closest empirical relative of `N_eff` in the social sciences. The observation that a system's structure mirrors the communication structure of the organisation that produced it [Conway, 1968] is why the seeding order in Section 5.8 runs along the graph of who works with whom rather than the graph of who reports to whom, and the quadratic growth of coordination paths — 15 at six people, 153 at eighteen, 435 at thirty — is Brooks [1975].

The paper's inference commitments are those of the reform literature: pre-register, freeze, report held out [Nosek et al., 2018]; treat researcher degrees of freedom as the dominant threat [Simmons et al., 2011, Gelman and Loken, 2013]; expect base rates to be low [Ioannidis, 2005] and replication to be partial [Open Science Collaboration, 2015]; and prefer risky point predictions to directional ones, which in psychology are nearly costless [Meehl, 1967, 1990]. Platt [1964] is the procedural form of the grounding sequence used throughout. Two of these bear directly on the catalogue: the survivorship entry (MF-13) is a base-rate argument, and the forking-path entry (MF-16) is Gelman and Loken [2013] restated as a fault with an instrument attached.

Two structurally parallel results elsewhere in the corpus are worth naming, because they show the same auditing move working on quantities that have nothing to do with rosters. In the frequency framework, the odd-part class rule of Curzi [2026] — the pitch class of `f(n) = k n^2` is the odd part of `n`, so `1..N` realises exactly `ceil(N/2)` classes, six at `N = 12` — is a count of distinguishable outcomes collapsing well below its naive value for a purely structural reason. In the ledger atlas, Curzi [2026] shows that dwell time is the whole freeze exposure: a roughly five-second hop is `1.585e-07` of a year against `0.0822` for value rested thirty days, a ratio of about 518,400 to one, so the exposure that matters is the one nobody was timing. **Both are the same discipline as the participation ratio: audit the count before pricing it.**

Finally, the corpus's own position in sociophysics should be named rather than assumed. The programme of carrying physical formalism into social description is long-established [Galam, 2012, Castellano et al., 2009, Helbing, 2001], and so is the objection to it: that the transfer often borrows the authority of physics without its constraints [Mirowski, 1989, Cartwright, 1999, Sobkowicz, 2020]. **This paper's answer is the analogy-discipline table of Section 3.13 and the verification chain of Section 9, which together say exactly which results are theorems, which are shared mathematical form, and which are asserted.**

37.9 9 Verification

The operative results of this paper compound from six postulates. Each is atomic, each is checkable on its own, and each carries its status. Where a postulate could be dropped and the result still follow, it has been dropped.

37.9.1 9.1 Dimensional audit

`[Q]` denotes the dimension of stored order and `[T]` the dimension of time; the period is the unit of `[T]`, and every rate below is *per period*, which is why no explicit `[T^-1]` appears once the equations are written in discrete steps.

Symbol	Dimension	Unit	Status
`Q_t`	`[Q]`	proxy units (practices, protocols, runbooks)	**measured**, in whatever the declared order proxy counts
`u`, `U_t`	`[1]`	none	**defined** dimensionless: `u = 1 - (x.y)^2` for unit vectors
`N`	`[1]`	count of participating members or framings	**measured** count
`N_eff`	`[1]`	effective count	**derived**: `1 + (N-1)u`, affine, *not* a Hill number
`PR`	`[1]`	effective count	**derived**: `1/sum w_i^2`, a Rényi-2 participation ratio
`S = F(u)`	`[1]`	nats	**derived** dimensionless: a logarithm of a count
`eta`	`[Q]` per nat per step	proxy units per nat per period	**measured**; *not* dimensionless
`delta`	`[1]`	per period	**measured** dimensionless fraction per step
`C_t`	`[Q]` per step	proxy units per period	**measured**
`h_t`, `r_max`	`[Q]` per step	proxy units per period	**derived**
`Q_inf`, `Q*`	`[Q]`	proxy units	**derived**: `[Q]`/step over `[1]`/step returns `[Q]`
`tau`, `t_half`	`[T]`	periods	**derived**
`D`, `P`, `E`	—	**none supplied**	**ordinal only**; the framework supplies no unit and the ratio `D/P` is demoted
`dt`, `df`	`[T]`, `[T^-1]`	seconds, hertz	**measured**; their product is dimensionless

Does the gate balance? `h_t = eta ln N - delta Q_t - C_t` balances if and only if every term carries `[Q]` per step. `ln N` is dimensionless, so `eta ln N` carries `[Q]` per step exactly when `eta` carries `[Q]` per nat per step; `delta Q_t` carries `[Q]` per step because `delta` is a dimensionless fraction per step; `C_t` carries `[Q]` per step by construction. **The gate is therefore well formed, and a headroom calculation in which `C` is denominated in hours or currency while `Q` is denominated in practices is dimensionally malformed however tidy it looks.**

Where the framework has no operational unit, this paper says so. Stored order `Q` is counted in whatever proxy is declared, and two systems' `Q` values are not comparable unless they declare the same proxy. Comfort itself, the corpus's underlying construct, has **no operational unit at all**. Perspective `D` and perception `P` have **no unit and no zero**, which is precisely why their quotient is demoted; the framework is silent on their dimensions and that silence is recorded here rather than filled in.

37.9.2 9.2 The postulates

P1 — The storage recurrence is linear and first order. `Q_{t+1} = (1−delta) Q_t + eta S_t − C_t` with `delta`, `eta`, `C` not depending on `Q`. *Status:* **DEFINITION** — the model form adopted by the framework [Curzi, 2026a]. It carries no empirical weight on its own.

P2 — Surplus is bounded: `0 <= F(u) <= ln N`, with `F(u) = ln(1 + (N−1)u)` on `u` in `[0,1]`. *Status:* **CITED** — the range result of the surplus functional [Curzi, 2026].

P3 — `F` is strictly concave in `u`. *Status:* **CITED** — proved with the axiom set in Curzi [2026]; `F''(u) = −(N−1)^2/(1+(N−1)u)^2 < 0` for `N > 1`.

P4 — Jensen's inequality: for concave `F`, `F(mean u) >= mean F(u)`. *Status:* **CITED** — standard, and the direction is what makes the correction one-sided.

P5 — For a share vector `w` with `sum w_i = 1`, the participation ratio is `PR = 1/sum w_i^2`. *Status:* **DEFINITION** — the reciprocal Rényi-2 collision probability [Rényi, 1961, Simpson, 1949].

P6 — Cost accrues every period whether or not surplus was delivered. *Status:* **POSTULATED** — an assumption about how real systems charge overhead. It has no external support, it is used at exactly one place (C6 below), and no other result in the chain depends on it.

37.9.3 9.3 The compounding chain

```
P1 + P2        -> X1   a nondecreasing step needs eta F(u) >= delta Q + C, and since
                       F(u) <= ln N the step is possible at all only if
                       C <= eta ln N − delta Q.                              ARITHMETIC

X1             -> C1   define h := eta ln N − delta Q − C. Then h < 0 forbids any
                       increment, h = 0 permits none, h > 0 caps any single-period
                       increment at r <= h.                                 ARITHMETIC

C1 at N=18     -> V1   eta=0.30, ln 18=2.890372, delta=0.06, Q=1.20, C=0.55 gives
                       h = 0.867112 − 0.072 − 0.55 = +0.245112.             ARITHMETIC

P1             -> C2   the fixed point is Q_inf = (eta F(u∗) − C)/delta, which is
                       NEGATIVE whenever eta F(u∗) < C. At u∗=0.25,
                       F = 1.658228, eta F = 0.497468 < 0.55, so
                       Q_inf = −0.875526.                                   ARITHMETIC

C1 + C2        -> C3   h > 0 and Q_inf < 0 are compatible: h uses the ceiling ln N,
                       Q_inf uses the realised F(u∗). Both must be computed.  ARITHMETIC

P1 + C2        -> C4   at the fixed point delta Q_inf = eta F(u∗) − C, so
                       h_inf = eta ln N − (eta F(u∗) − C) − C = eta(ln N − F(u∗)).
                       delta, C and Q cancel; and by P2, h_inf >= 0 always.  ARITHMETIC

P3 + P4        -> C5   feasibility on mean F(u) is <= feasibility on F(mean u),
                       always. On the eight periods of Section 5.3:
                       F(0.30875) = 1.832381, mean F(u) = 1.753333,
                       gap 0.079048 nats = 4.3140% of 1.832381.             ARITHMETIC

C5 + P1        -> C6   the gap propagates to (eta/delta) x gap
                       = (0.30/0.06) x 0.079048 = 0.395243 stored units,
                       independent of C.                                    ARITHMETIC

P5             -> C7   N_eff = 1 + (N−1)u equals N + 1 − N/PR exactly. At
                       w = (0.45, 0.25, 0.15, 0.08, 0.05, 0.02),
                       sum w^2 = 0.2968, PR = 3.369272,
```

```
6 + 1 − 6/3.369272 = 5.219200.                                   ARITHMETIC
```

Every line is checkable from its own stated inputs. C1 through C7 are arithmetic consequences of one definition of model form (P1), two cited results about the surplus functional (P2, P3), one standard inequality (P4) and one definition (P5). **Only C6's interpretation of `C` as a standing charge consumes P6, the single postulate with no external support**, and the inequality itself holds however `C` is generated.

What this chain does not establish. It does not establish that any group obeys P1. That is the modelling postulate of Section 2, it is not verified here, the one preregistered confirmatory test of it so far reported in this corpus did not meet its own declared margin [Curzi, 2026i], and the reflexive parameter it would need to recover is not identified from observation at all (§3.12). **A chain whose steps are ARITHMETIC and CITED delivers the mathematics with certainty and delivers nothing whatever about institutions.**

37.9.4 9.4 The verification instance, worked by hand

A reviewer is asked to check four short things rather than one long one.

Check 1 — the gate. `ln 18 = 2.890372`. Then `0.30 x 2.890372 = 0.867112`; `0.06 x 1.20 = 0.072`; `0.867112 − 0.072 − 0.55 = 0.245112`. Rounded, `h = +0.2451`. Two multiplications and two subtractions.

Check 2 — the critical stock. Setting `h = 0` and solving for `Q` gives `Q* = (eta ln N − C)/delta = (0.867112 − 0.55)/0.06 = 0.317112/0.06 = 5.2852`. Unit B at `Q = 6.90` is above it, which is why a successful unit can be the one that may not build.

Check 3 — the negative equilibrium behind a positive gate. `F(0.25) = ln(1 + 17 x 0.25) = ln 5.25 = 1.658228`, which is `1.658228/2.890372 = 57.37` per cent of ceiling. Then `eta F = 0.497468` against `delta Q + C = 0.072 + 0.55 = 0.622`, so the step is negative, and `Q_inf = (0.497468 − 0.55)/0.06 = −0.875526`. **A positive gate and a negative equilibrium, from the same four parameters.**

Check 4 — the participation-ratio identity. For shares `0.45, 0.25, 0.15, 0.08, 0.05, 0.02`: the squares are `0.2025, 0.0625, 0.0225, 0.0064, 0.0025, 0.0004`, summing to `0.2968`, so `PR = 1/0.2968 = 3.369272`. Then `N + 1 − N/PR = 6 + 1 − 6/3.369272 = 7 − 1.780800 = 5.219200`. The even-share case gives `sum w^2 = 6 x (1/36) = 1/6`, `PR = 6`, and `6 + 1 − 6/6 = 6.0000` exactly. **Four lines of arithmetic establish that a stopwatch reading is an effective count.**

37.9.5 9.5 Limits, asymptotics, and the model's valid domain

- **`u -> 0`.** `N_eff -> 1`, `F -> 0`, and the surplus term vanishes: `Q_inf -> −C/delta < 0`. Perfectly aligned members purchase nothing, and the system runs down at the maintenance rate. **This is a real regime, not a degenerate one, and it is the regime a converged group is in.**
- **`u -> 1`.** `N_eff -> N`, `F -> ln N`, `h_inf -> 0`. A group collecting its entire ceiling has no remaining headroom at the fixed point: it is maximally productive and maximally unable to add. That is a constraint on the model's use, not a defect.
- **`N -> 1`.** `ln N = 0`, so `h = −delta Q − C <= 0` always: **a single member can never build under this gate.** The framework is silent on whether that is a statement about groups of one or an artefact of using `ln N` as the ceiling, and the silence is recorded rather than resolved. Section 4 nonetheless applies the same form at personal scope with `N` counting *framings* and not people, which is a different `N` and is labelled as such at every use.
- **`N -> infinity` at fixed `u`.** `F -> infinity` logarithmically while coordination paths grow as `N(N−1)/2` [Brooks, 1975]. The model's own arithmetic therefore predicts an optimum roster well below any crossover computed from surplus alone; that optimum is derived in Curzi [2026] and is not re-derived here.

- **`delta -> 0^+`.** `tau = 1/delta -> infinity` and `Q_inf` diverges. **At exactly `delta = 0` the fixed point does not exist at all** rather than being infinite: the map is an isometry, the geometric series does not converge, and the gate reduces to `h = eta ln N − C` with no dependence on stock [Curzi, 2026a]. **This value is outside the model's valid domain.**
- **`eta -> 0`.** `h -> −delta Q − C < 0` and `Q_inf -> −C/delta`. A system with no conversion cannot build at any `u` and any `N`. This is the exact correspondent of the forbidding clause `G = 0 => X = 0` in the channel-gain form of the belief postulate [Curzi, 2026ab], and the correspondence is stated in the source as a design parallel rather than derived.

37.9.6 9.6 Model comparison, and the standard this paper does not meet

The paper reports no fitted model of its own; all numerical results are computed from stipulated parameters. **That does not exempt it from the standard, because it recommends a protocol whose Section A.16 and B.13 steps require a fit.** The table below records the corpus's position against each requirement of the model-comparison standard, for the one confirmatory fit reported anywhere in this corpus [Curzi, 2026i].

Requirement	Status	What was actually done
Out-of-sample performance reported	**MET**	held-out RMSE reported against four baselines
Matched null with equal free parameters	**MET**	a matched AR(1); the storage-law fit beat it by 2.8 per cent against a declared 10 per cent margin, and **failed its own rule**
Information criterion (AIC or BIC)	**NOT MET**	**no AIC or BIC has been computed anywhere in this corpus.** Parameter count is therefore not paid for in any reported comparison
Number of free parameters stated explicitly	**PARTIAL**	the storage law's four parameters are named; the comparison does not tabulate them against each baseline's
Effect sizes with intervals	**NOT MET**	percentage RMSE advantages are reported as point estimates without intervals
Shuffle control's false-positive rate measured	**MET, AND ADVERSE**	measured 0.108 against nominal 0.05 for i.i.d. permutation, 0.120 for circular shift [Curzi, 2026u] — **anti-conservative**
Structural ceiling test run alongside the empirical baselines	**MET**	and it is the only test that caught the repackaging described in Section 6.5

The two NOT MET rows are printed here rather than omitted. A protocol that instructs a group to beat four baselines and never asks it to pay for its parameter count is incomplete, and a reader deciding whether to adopt Appendix A.16 should know that.

37.9.7 9.7 Scale type, and the operations the data license

Quantity	Scale type	What licenses it	Operations permitted here
speaking-time share `w_i`	ratio	duration has a true zero and a unit	sums, squares, `PR`
`u` from pairwise disagreement	ordinal at best, treated as ratio	**nothing tested**	used as a ratio quantity; **not licensed**, see Section 10
`N`, `N_eff`, `PR`	ratio (counts)	counting	all
`Q`	interval at best in a declared proxy	proxy definition only	differences and rates; ratios across proxies are **not** licensed
`D`, `P`	ordinal	no zero, no unit	ordering only; `D/P` **demoted** [Curzi, 2026t]
the three-verdict tally	ordinal	construction	counts of verdicts; **no** conversion to a magnitude

Michell's critique is the strongest single objection to this framework and it is conceded here. Michell [1997, 1999] argues that psychology systematically assumes its attributes have quantitative structure without ever testing that they do. The corpus's founding move — treating comfort as a magnitude — is exactly the move Michell identifies. The formal test that would settle it is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971]: the double-cancellation conditions determine whether an attribute admits additive quantitative structure at all. **Those conditions have not been tested for comfort, for `u`, or for perspective and perception, by this work or by anyone.** The corpus's response is partial and is stated as partial: it demotes the one quantity whose operation most obviously needs a ratio scale, and it prices the Rasch route out at 123 items per term [Rasch, 1960, Andrich, 1988], an instrument with a defensible zero but not a conjoint test. **Where a reader wants the conjoint test, this paper concedes that it was not run.** Reliability is likewise not a substitute for structure [Sijtsma, 2009], and construct validation [Cronbach and Meehl, 1955, Campbell and Fiske, 1959] would establish that an instrument measures something without establishing that the something is quantitative.

37.9.8 9.8 Invariance, and the precision of the numbers

What is invariant. The gate's verdict is invariant under a common rescaling of `Q`, `C` and `eta` — multiply all three by a positive constant and the sign of `h` is unchanged, because every term scales together. It is **not** invariant under rescaling `Q` alone, which is what happens when a group changes its order proxy mid-measurement; that is a real operational hazard and Appendix B.2 requires the proxy to be frozen. The effective-count identity `N_eff = N + 1 − N/PR` is invariant under permutation of the share vector and under any relabelling of members, and it is **not** invariant under changing `N` — adding a silent member to the roster raises `N` and lowers every share, so the two sides move together only if the silent member is counted in both. **The scale-freedom claim — that one functional form serves at personal and group scope — has been tested at exactly two scopes in this paper, and at three in Curzi [2026], where it is found to break in five independent ways.** Two or three instances is not an invariance result and this paper does not present it as one.

Precision. Every number in this paper is either an exact consequence of stipulated parameters or a count. `ln 18 = 2.890372`, `ln 7 = 1.945910` and `ln 5.25 = 1.658228` are exact to the digits shown and are quoted to four or six decimals because they are computed, not measured. The parameters they are computed from — `eta = 0.30`, `delta = 0.06`, `C = 0.55` and the

rest — are **stipulated illustrative values, not measurements**, so a result such as `Q_inf = −0.8755` is exact given the stipulation and carries no empirical uncertainty because it carries no empirical content. **No quantity in this paper is a fitted value, and therefore no quantity in this paper is quoted with an uncertainty interval; where a reader sees four decimals they should read "consequence of the stipulated parameters", not "measured to that precision".** The two places where a genuinely measured external number appears — the roughly 25 per cent tipping point [Centola et al., 2018] and the collective-intelligence factor [Woolley et al., 2010] — are quoted as orders of magnitude with their settings named, and neither is used as a point estimate in any computation.

37.10 10 Limitations

L-1 The reflexive parameter is not identified, and this is the paper's most serious unmet standard. The specification underlying the framework is linear-in-means reflexive, and its endogenous effect cannot be separated from contextual effects or correlated unobservables by any amount of observational data [Manski, 1993, Shalizi and Thomas, 2011]. This paper adopts no remedy — no randomisation, no instrument, no partial-population variation, no defended stipulation of the reference group. **Every claim here about what a protocol does to a group is therefore a modelling position rather than an identified empirical result**, and a reader who needs the identified version must run the randomised design the framework has not run.

L-2 The conjoint conditions have not been tested. Comfort, `u`, perspective and perception are treated as quantities. Michell [1997] holds that this is precisely the untested assumption of psychological measurement, and Luce and Tukey [1964] supplies the test. **It has not been run for any construct in this corpus.** The ratio-scale treatment of `u` in particular is unlicensed: `u` is estimated in Section 4.4 by counting how many of `N(N−1)/2` framing pairs have ever disagreed about a next action, which is at best an ordinal instrument, and it is then used inside a logarithm and multiplied by `eta`. **That is an operation the scale does not license, it is disclosed here, and the paper's own instrument note calls the estimator crude and fit only to detect the collapse at the left end of the range.**

L-3 Every parameter is stipulated. No `eta`, `delta`, `C`, `Q`, `N` or `u` value in this paper was measured. The worked systems are constructed examples with declared parameters, chosen to exercise the arithmetic, and the numbers they produce are exact consequences of those choices and nothing else. The corpus-wide audit finds the same thing at three scopes and states it as its central result: of 27 parameter-by-scope cells, 19 have a defined estimator, 1 has a validated value and **0 carry a first-party measurement** [Curzi, 2026].

L-4 No AIC or BIC has been computed anywhere in this corpus, so no comparison reported here or cited by this paper pays for its parameter count, and no effect size in the confirmatory fit carries an interval (Section 9.6).

L-5 The eight-coordinate decomposition is a taxonomy, not a theorem. Thirty entries are named because thirty routes were found, not because thirty is a count of anything. A fault outside the eight coordinates will not be named by the catalogue, and the correct response is to say so rather than force a coordinate.

L-6 The mapping from `N_eff` to a count of independent voters is a convenience. Condorcet's theorem assumes independence outright; `N_eff` audits redundancy. The table in Section 5.6 rounds an effective count to the nearest odd integer and reads off a majority accuracy, and that stitch carries direction and order of magnitude only. **It should not be quoted as a computed probability for any real panel.**

L-7 The critical-mass figure is an experimental result in an artificial setting. The roughly 25 per cent tipping point [Centola et al., 2018] comes from controlled online experiments with confederates committed by construction. Its transfer to a field organisation is a modelling assumption. It is used here as an order-of-magnitude floor and never as a guarantee, and the same caution applies to the complex-contagion seeding results [Centola and Macy, 2007, Centola, 2010].

L-8 The acoustic-to-collective-intelligence causal claim is not confirmed and is carried as not confirmed. The correlational finding is real [Woolley et al., 2010]; the causal step is not established [Curzi, 2026f]; and the direction of causation between turn-taking equality and collective performance is not settled by the cited work.

L-9 The biological arm has no established mechanism and an expected null. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal [Curzi, 2026y]. Every step touching it is graded R. **No clinical, medical or therapeutic claim is made anywhere in this paper; no sequence is changed, no molecule is delivered, and no capability is conferred on anyone.**

L-10 The functional form is underdetermined. A sub-linear power law [Latané, 1981] and an `n log n` form [Briscoe et al., 2006] fit the qualitative facts as well as the logarithm does, and nothing in this paper discriminates among them (§3.12).

L-11 The shuffle control is anti-conservative as ordinarily run — a measured false-positive rate of 0.108 against a nominal 0.05 [Curzi, 2026u] — so a `p = 0.0005` against it is worth less than it appears, which is exactly the reading the repackaging case demands.

L-12 Two discrepancies in the source material are recorded rather than silently corrected. First, the scaffold specification for this paper describes the participation-ratio example as "a meeting in which one person takes 45 per cent of the air counts 5.22, not 18"; **the source's worked example is a six-person meeting, so the correct contrast is 5.2192 against a naive 6, not against 18.** The arithmetic in Section 5.4 is right and the summary was wrong. Second, the same specification states that "raising non-parallelism from 0.25 to 0.45 moves [the equilibrium] to +3.2878"; **the source reaches +3.2878 only after also cutting `C` from 0.55 to 0.45. Raising `u` alone gives +1.6211.** Section 7.2 separates the two levers explicitly for that reason.

L-13 The Rasch price is an estimate of an instrument's length, not of its success. 123 items per term is what the recovery calculation returns; whether a Rasch-conformable item set for perspective or perception can be written at all is untested, and fit to the Rasch model would establish specific objectivity without establishing that the attribute is quantitative in Michell's sense.

L-14 Seven works are named in prose without bibliographic keys, because they are not in this corpus's external bibliography. They are Condorcet's 1785 *Essai* (Section 5.6), Levine, Gordon & Fields 1978 and Kaptchuk et al. 2010 on placebo analgesia and open-label placebo (Sections 3.2, 4.2 and 4.12), Tajik et al. 2016 on force transmission to chromatin (Sections 4.12 and 7.3), Church, Gao & Kosuri 2012 and Zetsche et al. 2015 on sequence encoding and self-processing (Sections 3.3, 4.7 and 5.10), and the predictive-processing programme of Friston, Clark and Hohwy (Section 4.12). Each is a real published result and each is quoted for what its source measured; **the reader is owed the note that they are named rather than referenced, and that the corpus's own treatment of the placebo channel is Curzi [2026ab] and of the sequence-encoding chain is Curzi [2026y].** The accuracy table accompanying Condorcet's theorem is computed here from the binomial and can be checked directly.

37.11 11 Conclusion

The headroom identity `h = eta ln N − delta Q − C` is a precondition on action, not a diagnostic afterthought. Its three regimes are exhaustive: `h < 0` forbids building because no interaction geometry prevents decline there; `h = 0` permits maintenance only; `h > 0` caps every requested single-period increment at `r <= h`, which is a maximum and not a target. Worked at `N = 18` with `eta = 0.30`, `delta = 0.06`, `C = 0.55` and `Q = 1.20`, the gate returns `h = +0.2451`, and the critical stock at which it closes with everything else fixed is `Q* = 5.2852`.

A system can pass the gate and still be shrinking, and the two computations must both be run. The same eighteen-person unit realises `F(0.25) = 1.6582` nats, 57.37 per cent of its ceiling `ln 18 = 2.8904`, which gives `eta F = 0.4975` against a draw of `delta Q + C = 0.6220` and a **negative equilibrium `Q_inf = −0.8755`**. Raising non-parallelism from 0.25 to 0.45 alone lifts the realised fraction to 74.65 per cent and the equilibrium to `+1.6211`; cutting maintenance

from 0.55 to 0.45 as well lifts it to `+3.2878`. **The geometry lever decides whether a sustainable stock exists; the cost lever decides how large it is; neither substitutes for the other.** At the fixed point the gauge reduces to `h_inf = eta(ln N − F(u*))`, with `delta`, `C` and `Q` all cancelling, so a mature practice with no headroom has a non-parallelism problem and not a discipline problem.

Two measurement corrections are enforced throughout and both are one-directional. Feasibility must be tested on the mean of `F(U)` and never on `F` of the mean `U`, because `F` is strictly concave; on the eight worked periods the wrong computation overstates by **0.0790 nats, 4.31 per cent, worth 0.3952 stored units** at `eta = 0.30` and `delta = 0.06`, independent of `C`. And the effective count the law consumes is exactly the participation ratio: for shares `0.45, 0.25, 0.15, 0.08, 0.05, 0.02`, `PR = 3.3693` and `N_eff = 5.2192` against a naive count of **6.0000** — a six-person meeting has silently become a five-person meeting with a spectator. **The affine count `1 + (N−1)u` is not a Hill number**, and where a Hill number is meant this corpus uses `1/HHI` or `exp(H)` and says so.

The Moment equation stays demoted at both scopes. Division requires a ratio scale with a true zero; perspective and perception are not instrumented that way; so the limiting cases, the fixed point `D = P` and the three-way ordering over-framed / calibrated / under-framed survive, and the magnitude does not. The constructive route out is priced at **123 items per term**, 246 for the ratio and 369 for all three terms, and 61.5 person-hours for a thirty-participant recovery gate.

A single seeding result changes the design of most adoption programmes. Sixteen seeds spread across 120 people at mean degree 8 under a two-of-eight reinforcement rule leave only **29.0 per cent** of non-seeds with two or more seeded neighbours — 30.16 people — while **39.17 per cent** have exactly one, a below-threshold exposure that spends the practice's novelty and returns a null. The same sixteen concentrated in one twenty-person unit activate **4 of 4** at 80.0 per cent local commitment. **The dispersed plan optimises the first-period metric; the clustered plan optimises the order parameter.**

Finally, the catalogue and the counter-result. A manifestation claim has eight coordinates — channel, gain, magnitude, base rate, falsifiability, consent, ledger, scale — and thirty named failure modes across six classes, each priced by one of four identities, including `X = G B` with `G = 0`, which disposes of about a third of the entries in one line. **The collective worked example fails on the framework's own arithmetic**, returning a negative equilibrium despite passing the entry gate; **the acoustic-to-collective-intelligence causal test is carried forward as NOT confirmed**; and **a filtered repackaging of the input passed all four empirical baselines including the shuffled-input control at `p = 0.0005` and was caught only by the structural ceiling test**, its claimed jump being 38.5 times `r_max`. Those three are the statements downstream papers should quote rather than paraphrase.

37.11.1 Declarations

Data and code availability

No external dataset was collected for this paper, and no human participants were surveyed, observed or recruited. Every numerical result is computed from parameters stipulated in the text under the models developed in Sections 3 to 6, and every table can be re-derived from the equations and parameter values printed beside it. The personal and collective systems worked in Section 7 are **constructed illustrative examples, not field observations, and not reports of any real individual or organisation**; the diagnostic instance of Section 7.3 is likewise constructed. The figures are generated by the scripts named in each caption, which contain no data beyond the numbers printed in this paper and the model equations of Sections 3 to 5. The two external empirical results relied on — the collective-intelligence factor and the critical-mass tipping point — belong to their published sources and are cited to them.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest.

Author contributions

Single author. Michael Laurence Curzi conceived the work, derived the results, produced the worked examples and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. The worked systems are constructed. The consent architecture of Sections 3.5 and 3.10 — the know, decline and reverse gates, and the independence gate at group scope — is a **design constraint on prospective work** and is not a report of any study performed. **No clinical, medical or therapeutic claim is made anywhere in this paper.** No sequence is changed, no molecule is delivered, nothing is edited or altered, and no capability is claimed to have been conferred on any person or group. The biological-layer arm described in Sections 4.7 and 5.10 is a research procedure with no established mechanism and an expected null result; it is described so that it can be evaluated, not recommended.

Preregistration

This paper reports no preregistered test of its own; its results are derivations from stipulated parameters. The preregistered protocol for testing the storage law against a real system, together with the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared margin of 10 per cent — is reported in Curzi [2026i]. The measured false-positive rate of the shuffled-input control, **0.108 against a nominal 0.05**, is reported in Curzi [2026u]. Any applied claim resting on this paper inherits both results.

37.12 Appendix A The personal-scope specification

Numbered, checkable, runnable. **Gates are steps. A failed gate halts the protocol at that point; it does not generate a caveat.** Grade stamps are mandatory on every step that has one.

A.1 — DECLARE THE OCCASION CLASS. Name one recurring occasion to be studied. It must recur at least weekly and carry one observable outside the practitioner's full control. *Grade T (definitional).*

A.2 — GATE K (KNOW), first pass. Write, in the practitioner's own words, what this protocol does at each of its three layers, and the grade of each. If the L3 sentence cannot be written — *"this is a research procedure with no established mechanism and an expected null result"* — the protocol is not yet understood and it does not start. *Halt condition: cannot state.*

A.3 — GATE D (DECLINE), constitution. Record what stopping looks like, who is told, and what happens to the data if the run stops at week 3. **If any part of this protocol involves another person, they get their own Gate D, their decline is recorded as data and never as a zero, and their cost is counted in their ledger by asking them.** *Halt condition: no decline path.*

A.4 — INVENTORY THE FRAMINGS. List the `N` distinguishable framings of the occasion class. Be strict: two framings that always recommend the same next action are one framing. *Grade T.*

A.5 — ESTIMATE `u` AND COMPUTE THE CEILING. Count the pairs that have ever disagreed about what to do next; divide by `N(N−1)/2`. Compute `N_eff = 1 + (N−1)u`, `S = ln N_eff`, and the ceiling `ln N`. Report `S / ln N` as the realized fraction. *Grade T. The `u` estimate is crude and labelled crude.*

A.6 — FIX THE SESOI AND SAMPLE SIZE, IN WRITING, BEFORE ANY DATA. Choose the smallest effect on the observable that would change the following quarter's conduct; look up the required `n` in §4.9 for detection and for equivalence. **If the `n` is unaffordable, say so now and run as descriptive rather than inferential — an honest choice in week 0 and not in week 12.** *Grade T.*

A.7 — GATE V (REVERSE), first pass. Write the STOP / RESIDUE / IRREVERSIBLE lines for every step that is to be run. Any step with a non-empty IRREVERSIBLE line is escalated to a second gate K before it runs. *Halt condition: a step with unbounded residue.*

A.8 — BASELINE THE STORAGE PARAMETERS. Estimate `delta` (what one skipped period costs), `eta` (what fraction of engagement becomes durable), `C` (maintenance load) and `Q_0`, recording each as an estimate with its basis. *Grade T; the fit to a particular life is a badged assumption.*

A.9 — COMPUTE THE HEADROOM GATE. `h_0 = eta·ln N − delta·Q_0 − C_0`. **If `h_0 < 0`, the protocol does not add anything: go to A.18 (shedding) and return here afterwards. If `h_0 = 0`, maintain and do not build. If `h_0 > 0`, the maximum increment that may be requested is `r <= h_0`.** *Grade T (the storage law's feasibility corollaries [Curzi, 2026a]).*

A.10 — RUN THE PREDICTION LOG (L1). For every occurrence of the occasion class: prediction, observable, direction, before. Outcome, after. Verdict from the three-valued set only. *Grade C.* **No ratio is computed and no distortion `Delta` is reported (CC-R1). The verdict set is ordinal by construction.**

A.11 — TALLY ORDINALLY, WEEKLY. Count verdicts. Report as counts. Act on the dominant verdict using the lever table in §4.3. *Grade T for the ordering;* ***magnitude demoted****.*

A.12 — RUN THE CADENCE (L2). Fix the period and keep it. **The half-life to the fixed point in §4.5's construction is 8.31 weeks; expect that order and do not evaluate the practice before one time constant has passed.** *Grade T.*

A.13 — RECOMPUTE `h_t` MONTHLY. Headroom falls as `Q` grows even when nothing else changes. A practice that gets heavier is doing arithmetic, not failing. *Grade T.*

A.14 — GATE K (KNOW), second pass, before the biological arm. State, aloud or in writing: *"This step is Grade R. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. Nothing is delivered, nothing is edited, no capability is conferred, no clinical, medical or therapeutic effect is claimed, and the expected result is null."* **If that cannot be said and meant, the arm does not run.**

A.15 — CONSTRUCT THE ARTEFACT (L3), FULLY DISCLOSED. Text the practitioner wrote, encoded base-4, address-prefixed as a format, rendered per the disclosed sonification chain [Curzi, 2026y] within the Gabor constraint of §4.7. **Audible level. No masked layer. No unread content. The file is inspectable and the practitioner inspect it.** *Grade R. Constraint 1 (the disclosed-narrative constraint [Curzi, 2026ac]) is enforced by Gate K, not by good intentions.*

A.16 — RUN THE L3 ARM AS A PRE-REGISTERED EXPERIMENT. Pre-register the null hypothesis, the observable, the SESOI, the `n` from A.6, and the four baselines of the falsification suite (persistence, direct-input, matched autoregressive, and the shuffled-input control). **Add the structural ceiling test: any single-period increment claimed must satisfy `r_t <= h_t`, because the shuffle is an empirical audit and only the structural test detects repackaging** (R4). *Grade R.*

A.17 — REPORT THE COMPARISON, WHICHEVER WAY IT COMES OUT. Classify the result as N-1, N-2, N-3 or N-4 per §4.10 before interpreting it. **A null on the L3 arm is an N-4 and is reported as an N-4: expected, uninformative about the mechanism, and worth recording pre-**

cisely because results of this kind do not otherwise enter the record. *Grade T (classification).*

A.18 — SHED BEFORE ADDING WHEN `h <= 0`. Reduce `C`, or deliberately shed stored order (the shedding lever [Curzi, 2026a]). **Shedding that lands its cost on another person is not shedding; it is transfer, and it is outside the line this framework draws.** *Grade T, hard ethical boundary.*

A.19 — GATE D (DECLINE), standing. At every monthly review, "stop" is on the agenda as a live option with the same standing as "continue". A protocol never declinable in practice has not satisfied Gate D by having declared it in A.3.

A.20 — CLOSE THE LOOP WITH THE ECHO. `Delta_R = |ln(M'/M)|` (the returned-difference result [Curzi, 2026]): what came back over what was sent. **Zero means no information returned — a finding about the channel to the world, not about the effort spent.** The echo corrects `D`, not `Q`: feedback changes the integrator's input rather than its state, which is why character changes slowly. *Grade T for the structure;* ***magnitude demoted with the rest of the M-derived family (CC-R1)****, so read* `Delta_R` *as an ordering — bigger surprise, smaller, none.*

37.13 Appendix B The group-scope specification

Numbered, ordered, and gated. **A failed gate halts the protocol at that step. It does not generate a caveat.**

B.1 — DEFINE THE UNIT. Name the population, its `N`, and the boundary. **`N` counts people who will actually participate, not people on a distribution list.**

B.2 — GATE 0, HEADROOM. Estimate `eta`, `delta`, `C`, `Q`. Compute `h = eta ln N − delta Q − C`. **If `h < 0`, the group may not build: go to B.16 and return. If `h = 0`, maintain. If `h > 0`, record `r_max = h` as the ceiling on every increment below.**

B.3 — GATE 0b, THE PROGRAMME'S OWN COST. Recompute `h` with the proposed programme's maintenance cost added to `C`. **If that recomputation is negative, the programme may not run at its current cost, whatever its expected benefit.** This is the row nobody computes (§5.1).

B.4 — GATE D, CONSTITUTION, PER PERSON. Each participant is told what stopping looks like, what happens to their data if they stop, and who they tell. **A decline is recorded in that person's own row as a decline, never as a zero and never as a missing value to be imputed.** *Halt condition: no decline path exists.*

B.5 — GATE I, BASELINE. Measure the group's capacity to disagree before anything changes: independent written estimates on 15 to 25 live questions, collected before discussion. Compute mean pairwise correlation of signed error `rho`, then `u = 1 − rho^2`. Compute `N_eff`, `S`, and the realized fraction `S / ln N`. **Record turn-taking shares and `PR` in the same sitting.**

B.6 — APPLY THE JENSEN CORRECTION. Feasibility is tested on **mean `F(u)`**, never on `F(mean u)` (R2). The wrong computation always overstates; in §5.3's worked case by 4.31% of surplus and 0.3952 Q-units of steady state.

B.7 — READ BOTH NUMBERS. Report `h` (which uses `ln N`) *and* the realized fraction `S / ln N`. **A group can have comfortable headroom and still lose stored order every period because it operates far below its own ceiling.** A diagnosis reporting one without the other is half a diagnosis and points at the wrong lever.

B.8 — RAISE `u` BEFORE RAISING `N`. Concavity is front-loaded: at `N = 18`, moving `u` from 0 to 0.25 buys 57.37% of the ceiling. **Adding a parallel member adds `n(n−1)/2` coordination cost and zero surplus.**

B.9 — RECORD DISTRIBUTIONS, NOT CONCLUSIONS. Independent estimates before discussion, every time, on every question that matters. Publish the spread. **Unanimity that arrives**

fast and without argument is a symptom, not an achievement (the built-system failure catalogue [Curzi, 2026g], FM-01).

B.10 — SIZE THE SEEDING AGAINST THE SMALLEST WORKABLE POPULATION. Compute 25% of the smallest population within which the practice works standing alone. **Carry the honest note with the number: 25% comes from controlled online experiments with confederates committed by construction, and its transfer to a field organisation is a modelling assumption.**

B.11 — CLUSTER, DO NOT SPRAY. Concentrate the seeding budget in one population past its own tipping point. **Do not distribute for reach: a below-threshold exposure spends the practice's novelty and returns a null, and the second attempt on the same person starts worse than the first.**

B.12 — TEST FOR SPONSOR-INDEPENDENCE BEFORE EXPANDING. Remove the sponsor for one period. Count what survives. **What survives is the committed fraction; what stops was compliance, and compliance has `u = 0` with respect to the group's belief and contributes nothing to `S`.**

B.13 — RUN THE ORDINAL DOCTRINE-TO-DATA INSTRUMENT. Pre-record the group's prediction for a defined recurring occasion; afterwards assign exactly one of **over-framed / calibrated / under-framed**. Tally counts. **No `D/P` value is computed and no `Delta` is reported (CC-R1). The verdict set is ordinal by construction, and where a number is genuinely required the route is the Rasch-route theorem [Curzi, 2026t], at 123 items per term.**

B.14 — GATE K, PER PERSON, BEFORE ANY BIOLOGICAL-LAYER STEP. Each participant states, in their own words: *"This is Grade R. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. Nothing is delivered, nothing is edited, no capability is conferred, no clinical, medical or therapeutic effect is claimed, and the expected result is null."* **Anyone who cannot state it does not participate, and their non-participation is recorded as data.**

B.15 — RECORD INDIVIDUAL JUDGEMENTS BEFORE GROUP DISCUSSION, ALWAYS, AND ESPECIALLY HERE. A shared acoustic input is a shared input; eighteen people hearing one artefact together are receiving one input, not eighteen. **Pool afterwards or the independence needed to evaluate the artefact has been destroyed by the act of presenting it.**

B.16 — WHEN `h <= 0`, SHED BEFORE ADDING. Reduce `C`, or deliberately shed `Q` (the storage law [Curzi, 2026a] §6.9). **Shedding that lands its cost on another group or on individuals who did not consent is not shedding; it is transfer, and it is outside the line this framework draws.**

B.17 — GATE I, POST-STEP, AND THE REVERSAL RULE. Re-measure `u`, `N_eff` and turn-taking after any step that could align beliefs. **If `u` fell or the participating `N` fell, the step is reversed regardless of what else it produced.** A step that raised `Q` by lowering `u` borrowed from the ceiling to pay the floor.

B.18 — FALSIFY, INCLUDING STRUCTURALLY. Four baselines — persistence, direct-input, matched autoregressive, shuffled-input — **plus the structural ceiling test `r_t <= h_t`, because the shuffle is an empirical audit and only the structural tests detect repackaging** (R4). Report the comparison whichever way it comes out, and classify a null before interpreting it (Section 4 §4.10).

37.14 Appendix C Using the catalogue

How to use the catalogue. Six steps, in order, because running them out of order produces a confident misdiagnosis.

C.1 — LOCATE THE COORDINATE BEFORE NAMING THE ENTRY. Ask which of CH / G / Mg / B / Fa / Cn / Ld / Sc the complaint is about. **Most misdiagnoses are entries chosen by resemblance of symptom rather than by coordinate**, and the classes above exist so that the coordinate can be found first.

C.2 — RUN THE GROUNDING SEQUENCE AND STOP AT THE FIRST FAILURE. Identify the channel, check it is possible, estimate its gain, predict a magnitude, measure, compare. **A claim's fault is located at the first stage it cannot pass; everything downstream of that stage is uninformative about the claim.** Diagnosing a magnitude error in a claim that has no channel is a category mistake dressed as rigour.

C.3 — COMPUTE, DO NOT ESTIMATE, THE PRICE. Every entry's Price field is arithmetic. Run it on the numbers of the case at hand. **A fault that has not been priced will not be fixed, because nobody prioritises a number nobody has.**

C.4 — RUN THE STRUCTURAL TEST EVEN WHEN THE EMPIRICAL TESTS PASS. CC-R4's finding is binding: **the shuffle is an empirical audit, and only the structural tests detect repackaging.** Compute `r_max = eta ln N − delta Q − C` for the period and compare against the claimed increment, every time, regardless of how the four baselines came out.

C.5 — AUDIT THE LEDGER SEPARATELY FROM THE EVIDENCE. For every concordance, state which column carries evidence and which carries precedent, in print. **Where a row has precedent and no evidence, label it a research question with a long history rather than a finding.**

C.6 — CHECK CONSENT LAST AND TREAT IT AS A VETO. Consent faults do not trade against benefit. **A protocol that fails Class VI is not a worse protocol; it is outside what this framework will describe, and no result changes that.** Count the per-person gate records; if there are fewer than participants, consent was assumed rather than obtained.

Chapter 38

One Model Form at Three Scopes: The Instrument Audit, Five Breaks in the Correspondence, and a 156-Entry Status Register

Abstract. The same storage law is written at institutional, personal and cellular scope, and this paper badges that correspondence as a statement about the model form chosen at each scope rather than a claim that the three systems are alike or that quantities aggregate between them. It then audits the instrument rather than asserting the correspondence. **Across nine parameters and three scopes there are 27 parameter-by-scope cells: 19 have a defined estimator, exactly 1 has a validated value — a borrowed median protein half-life giving $\delta = 0.014955$ per hour — and 0 carry a measurement made first-party for this corpus.** Nothing in these seventy papers rests on fieldwork conducted for them. The correspondence is then shown to fail in five independent ways: a mind is not a small society, because the independence aggregation requires is unavailable inside one skull; a cell is not a small mind, because it has no frame and therefore no perspective ratio; the exit ethics do not descend; aggregation is not always well defined; and no composition theorem bridges the scopes. What survives is smaller and load-bearing. The arithmetic transfers wherever the map is adopted, including the fixed-point identity $h_\infty = \eta(\ln N - F(u^*))$, in which δ, C and Q cancel, so $h_\infty \geq 0$ always and the plain linear model never ossifies by itself. And three ordinal diagnostics — whether u is near zero, whether η is near zero, whether $\delta Q + C$ exceeds $\eta \ln N$ — read at every scope without a calibrated instrument. A complete register of 156 entries is published: 50 proved, 28 postulated, 58 borrowed, 12 speculative including 4 printed refusals, and 8 demoted, with precedent claimed in 23 rows, 14.7 per cent.

Keywords: multiscale correspondence; instrument audit; status register; participation ratio; headroom identity; epistemic bookkeeping

Series: B. Engineering the Surplus **Paper:** CCP-038

38.1 1 Introduction

The Creature Comforts corpus writes one equation at three scopes. The storage law

```
Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t,     S_t = F(U_t) = ln(1 + (N−1) U_t)
```

appears with identical structure for an institution, for one mind, and for one cell's regulatory state, with only the parameter values, the period length and the choice of order proxy differing. That progression has been built up piecewise across the series without ever being stated in one place with its limits attached. **This paper states it, badges it, prices it, and then spends most of its length attacking it.**

The badge comes first because everything else depends on it. **The correspondence is a claim about model form and nothing else.** It is not a scaling law: it predicts no relation between a parameter's value at one scope and its value at another. It is not a composition theorem: nothing here derives institutional stored order from personal stored order, or personal from cellular, and **no such theorem exists anywhere in this corpus.** It is not an empirical finding: scale-freedom has never been tested at two scopes simultaneously in any real system. It is the observation that a minimal open-system accumulator written for each of the three uses the same five symbols, and that the arithmetic consequences of those five symbols therefore apply to all three.

The paper's principal contribution is not the correspondence but the audit of the instrument that would be needed to use it. Nine parameters at three scopes give twenty-seven parameter-by-scope cells. Counting them:

> **Nineteen of twenty-seven cells have a defined estimator. One of twenty-seven has a validated value — a borrowed median protein half-life, giving `delta = 0.014955` per hour. And zero of twenty-seven carry a measurement made first-party for this corpus.**

That last number is the one this paper exists to publish. **Nothing in this corpus rests on fieldwork conducted for it.** Every empirical quantity anywhere in the seventy papers is either borrowed from a study conducted by other people for their own purposes, or computed from parameters stipulated in a worked example. The count is not an accusation from outside; it is the result of the corpus auditing its own tables, and it is stated here so that other papers can cite a source for it rather than restating it on their own authority.

The correspondence is then shown to fail in five independent ways, and the ways are genuinely independent — repairing one does not touch the others. **A mind is not a small society**, because the independence that every aggregation result requires is unavailable inside one skull: two framings held by one person share a memory, a mood, a set of priors, a stake in the answer and a substrate, which are five channels of common-mode coupling with no institutional analogue. **A cell is not a small mind**, because the moment equation requires a representation and a cell has states rather than representations, so it has no frame and therefore no perspective ratio. **The exit ethics do not descend**: a member can leave, a framing can be abandoned, a cell cannot, so the consent constraint that governs the corpus attaches to the person and never to the scope. **Aggregation is not always well defined**, in principle rather than merely in practice. And **there is no composition theorem** bridging any two scopes.

What survives those five is smaller than the correspondence table and considerably more trustworthy. **The arithmetic transfers wherever the model form is adopted** — contraction, unique fixed point, the `ln N` ceiling, the headroom inequality, the fixed-point identity `h_inf = eta(ln N − F(u*))` — because these are consequences of the map rather than facts about any system. And **three ordinal diagnostics read at every scope without a calibrated instrument**: whether `u` is near zero, whether `eta` is near zero, and whether `delta Q + C` exceeds `eta ln N`. Each is a comparison rather than a magnitude, and a comparison survives where a magnitude does not.

The paper closes with a complete status register of the corpus's substantive claims: **156 entries — 50 proved, 28 postulated, 58 borrowed, 12 speculative of which 4 are printed refusals, and 8 demoted** — with the entry for the corpus's own keystone formula among the demotions. Precedent is claimed in **23 of the 156 rows, 14.7 per cent**; the remaining 85.3 per cent read *none claimed*, which is the honest yield of a two-column method when the rule against filling the second column is actually enforced.

Two identities established in the surrounding literature are re-verified here because they

are the only rows of the correspondence table that hold everywhere. The affine effective count equals the Rényi-2 participation ratio exactly — `N_eff = 1 + (N−1)u = N + 1 − N/PR` — re-verified over six random correlation ensembles with a worst discrepancy of `1.8e−15`, the identity established with its numerical verification in Curzi [2026c]. And at the fixed point the headroom gauge reduces to `h_inf = eta(ln N − F(u*))` with retention, cost and stored order all cancelling; since `F(u) <= ln N` always, `h_inf >= 0` always, so **the plain linear model never ossifies by itself.**

A standing note on which effective count is meant. `1/HHI` and `exp(H)` are Hill numbers of orders two and one and are well grounded [Hill, 1973, Jost, 2006]; the affine count `1 + (N−1)u` is **not** a Hill number but a linear interpolation between 1 and `N`, adopted as a design axiom [Curzi, 2026]. The participation ratio it equals *is* a standard effective count — the reciprocal of a Rényi-2 collision probability [Rényi, 1961] — and the identity between them is algebra, not evidence for the design axiom. Every use below says which count it means.

Sections 2 and 3 give the hypotheses and the audit method, including the identification problem that bounds the correspondence. Section 4 builds the parameter table cell by cell and prices it. Section 5 is the five breaks. Section 6 is the register. Section 7 works one laboratory at all three scopes and audits one sentence end to end. Sections 8 to 11 discuss, verify, bound and conclude.

38.2 2 Hypotheses

This paper is in large part an audit, and an audit of one's own instrument is not a test of a hypothesis about the world. Two of its four central results are arithmetic identities, one is a census, and one is a set of structural refusals. The claims below are stated as hypotheses only where something could turn out otherwise; where a result is a definition, an identity or a count, it is labelled as such rather than dressed as a prediction.

> **H1 — The molecular proxy for cellular stored order is refuted by the corpus's own measured parameter.** If cellular `Q` were denominated in molecular inventory, the storage law would predict that nothing cellular persists on any timescale a person would notice. **Predicted:** at the median protein half-life of 46 hours, the fraction of the inventory surviving one month is `2^(−720/46) = 1.942e−05`, a per-month retention loss of 0.99998. **Falsified by:** a measured cellular state whose persistence over months is carried by the molecular inventory itself rather than by a maintained regulatory pattern that keeps rebuilding it — that is, by long-lived molecules at population scale, which the measured half-life distribution does not contain.
>
> **H2 — Positive headroom does not imply a non-decreasing step, at any scope.** The gauge uses the ceiling `ln N`; the step uses the realised surplus `F(u*)`. **Predicted:** the worked laboratory member of Section 7.1 has `h = +0.054831` per month and a step of `−0.202575` per month simultaneously, because the surplus needed for a flat month is `(delta Q + C)/eta = 1.426667` nats against an internal surplus of `0.751416`. **Falsified by:** a demonstration that the two signs agree across systems, which would make one of the two computations redundant.
>
> **H3 — Retention rates are not comparable across scopes without conversion, and the error is large.** A rate quoted without its period is not a number. **Predicted:** `delta = 0.15` per year is `0.013452` per month, and `delta = 0.08` per month is `0.632334` per year; the parameter that looks four times larger is 47 times larger once the clocks agree. **Falsified by:** nothing observational — this is arithmetic on the definition of a per-period fraction, and it is listed here because it is the most common practical error the correspondence invites, not because it is in doubt.

Four claims of this paper are not hypotheses, and are labelled here rather than left to be discovered.

- **The three-scope correspondence is a POSTULATE about model form.** It is not falsifiable in general, only at each scope separately, and it is badged at every appearance.
- **The 19/27, 1/27 and 0/27 counts are a CENSUS**, not a finding about the world. They are recomputed from the corpus's own tables and can be recounted by a reader from the register in Section 6.
- **The five breaks are STRUCTURAL ARGUMENTS**, three of which turn on category distinctions — representation, exit, aggregation — that no measurement would settle.
- **The two identities re-verified in Section 9 are ARITHMETIC.** `N_eff = N + 1 − N/PR` and `h_inf = eta(ln N − F(u*))` are consequences of definitions and carry no empirical weight.

The organising question, stated plainly, is this: what is a multiscale framework entitled to claim when it has never measured any of its own parameters? The answer this paper defends is: the arithmetic, the ordinal diagnostics, and the failure catalogue — and nothing that requires a calibrated instrument.

38.3 3 Method: scopes, clocks, statuses, and what cannot be identified

38.3.1 3.1 The statement, with its badge

> **THE THREE-SCOPE CORRESPONDENCE [POSTULATE — MODEL FORM ONLY].** The storage law
>
> ```
> Q_{t+1} = (1 − delta) Q_t + eta S_t − C_t          S_t = F(U_t) = ln(1 + (N−1) U_t)
> ```
>
> is written with identical structure at the institutional scope (the institutional-scope material of the corpus), the personal scope (the personal-scope material of the corpus), and the cellular scope (the cellular-scope material of the corpus). Only the parameter values, the period length, and the choice of order proxy differ. **This is a statement about the form of the model chosen at each scope. It is not a claim that the three systems are the same kind of thing, that their parameters are related by any law, or that quantities at one scope aggregate into quantities at another.**

Three things follow immediately, and all three are constraints rather than permissions.

First, nothing transfers by correspondence. A result established at one scope is not established at another because the symbols match. Woolley's collective intelligence factor was measured in laboratory groups; it says nothing about a cell and nothing about the internal structure of one person's framings. **The symbol `u` appearing in three places does not make one measurement of `u` count three times.** This is the two-column discipline of CCP-029 applied to scope instead of source.

Second, the units do not compose. Institutional `Q` is denominated in whatever order proxy Protocol MP-6 selected. Personal `Q` uses a different proxy on a different clock. Cellular `Q`, if it can be denominated at all, is a third. **There is no conversion factor between them, this manual does not supply one, and any arithmetic that adds or divides across scopes produces a unit artifact.** §7.1 computes one deliberately so the reader can see what it looks like.

Third, the correspondence is weakest exactly where the corpus's ambition is highest. The institutional scope has the most borrowed empirical support and the least first-party measurement; the personal scope has a century of psychophysics behind its measurement register and a demoted keystone formula in front of it (CC-R1); **the cellular scope has one parameter with a measured value and an unbridged gap where its input path should be.** That ordering is not hidden: it is the reason CCP-031 exists.

38.3.2 3.2 What “the same instrument” is licensed to mean

Precision here is worth a page, because the whole chapter turns on it.

Reading	Statement	Status
Form identity	The same five-symbol recursion is used to model all three	**What is claimed.** A modelling choice, badged
Arithmetic transfer	The consequences of the recursion (fixed point, contraction, ceiling, headroom) hold at any scope where the recursion is adopted	**Follows.** These are theorems about the recursion, not about the system
Parameter transfer	A value of `delta` or `eta` measured at one scope informs another	**NOT claimed.** No such relation is derived or measured
Scaling law	Parameters vary with scope according to some rule	**NOT claimed.** No rule is offered
Composition	Cellular `Q` sums to personal `Q` sums to institutional `Q`	**NOT claimed, and no theorem exists.** §5.6
Ontological identity	A mind is a small society; a cell is a small mind	**REFUSED.** §5.2, §5.3

The second row is the whole practical value of this section. Banach’s fixed point theorem does not know what `Q` denotes. If `delta` is in `(0,1]` and the map is the affine one written above, the map is a contraction, a unique fixed point exists, and iteration reaches it — at a desk, in a department, or in a regulatory network. The theorem holds because it is a theorem about the map. **What is not automatic is that the map describes the system**, and that question must be settled separately at every scope, and has been settled at none of them.

38.3.3 3.3 The three scopes, defined with their clocks

A scope is not a size. It is a triple: what counts as the system, what counts as one period, and what observable stands in for stored order.

```
SCOPE          SYSTEM                  PERIOD          ORDER PROXY Y
-------------------------------------------------------------------------
INSTITUTIONAL  a group of people       a quarter,      documented decisions,
               with a shared purpose   a year          working practices,
                                                       trained members, artifacts

PERSONAL       one mind and the        a day,          retained skills, habits,
               life it maintains       a month         standing commitments,
                                                       what survives a bad week

CELLULAR       one cell's regulatory   minutes to      maintained transcriptional
               state                   hours           and chromatin state
                                                       -- SEE §4.6 AND §5.6
-------------------------------------------------------------------------
```

The period is the part practitioners get wrong. `delta` is a fraction *per period*, and a `delta` quoted without its period is not a number. Fifteen percent annual staff turnover and eight percent monthly skill decay are not comparable until they are on one clock.

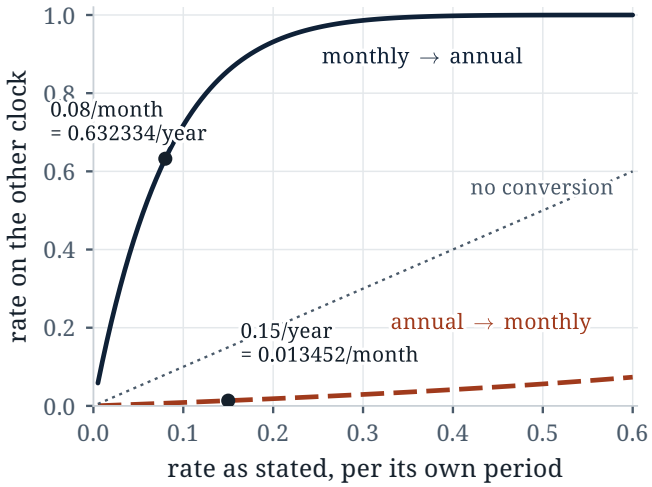

Figure 38.1: **A retention rate quoted without its period is not a number: the parameter that looks four times larger is forty-seven times larger once the clocks agree.** A rate of 0.15 per year is 0.013452 per month; a rate of 0.08 per month is 0.632334 per year. Conversion by `delta_new = 1 − (1−delta_old)^(p_new/p_old)`, arithmetic on the stipulated rates of Section 3.3; generated by `figs/src/CCP-038_fig02.py`.

Computed, so the size of the effect is visible:

```
delta = 0.15 per year      ->  monthly equivalent  0.013452
delta = 0.08 per month     ->  annual  equivalent  0.632334
```

A parameter that looks four times larger is in fact forty-seven times larger once the clocks agree. Every cross-scope comparison in this section carries its clock for that reason.

38.3.4 3.4 The calibration status of each scope, stated before the table is built

The table in §4.1 is a table of *meanings and intended estimators*, not of measured values, and the difference must be established before it is read — a well-formatted table is the most persuasive object in a technical book and the least deserving of that persuasion.

Scope	Parameters with a defined estimator	Parameters with a validated estimator	Parameters with a published first-party measurement
Institutional	9 of 9 (the measurement protocols MP-1 to MP-7 of the reference apparatus [CCP-039])	0	0
Personal	9 of 9, plus `M` and `D/P` demoted to ordinal (CC-R1)	0	0
Cellular	1 of 9	1 of 9	`delta` only, and borrowed

Twenty-seven parameter-scope cells; one of them has a number in it that anyone has measured, and that number was measured by molecular biologists for their own reasons. That

is the honest state of the instrument, and it is stated here rather than in a footnote because everything downstream inherits it.

The single measured cell is worth naming now, because it recurs. Schwanhäusser and colleagues (*Nature*, 2011) quantified mRNA and protein half-lives genome-wide in a mouse fibroblast line using metabolic labelling with mass spectrometry and sequencing, reporting median half-lives of roughly 9 hours for mRNA and roughly 46 hours for protein. Converted to the storage law's parameter:

```
median mRNA,    t_half = 9 h    ->  delta = 1 - 2^(-1/9)    = 0.074125 per hour
median protein, t_half = 46 h   ->  delta = 1 - 2^(-1/46)   = 0.014955 per hour
                                ->  delta = 1 - 2^(-24/46)  = 0.303468 per day
```

Those are real measurements of a real decay rate, they are medians over thousands of species with enormous spread, they were obtained in one immortalised cell line by one method, and they are the only calibrated dial on the third instrument. CCP-030 uses them for the channel analysis; this section uses them in §4.7 and §5.6 to make a structural point that turns out to be inconvenient for the naive reading of the correspondence.

38.3.5 3.5 The five statuses, defined so they cannot be blurred

Status	Definition	What it entitles a user to say	What it does not
PROVED	A theorem, true within stated assumptions. The assumptions are mathematical, not empirical	"This follows"	Nothing about the world. A theorem about a map is not a fact about any system the map is applied to
POSTULATED	An assumption of this research programme: chosen for tractability, interpretability, or design reasons	"This is what we assume, and here is why"	"This is established." Every number computed downstream of a postulate inherits the postulate's status, not a grade higher
BORROWED	An empirical result obtained by other researchers, in a named setting, with a stated method	"This was measured, there, that way"	"Therefore it holds here." Transfer is an assumption and must be named as one
SPECULATIVE	A proposed bridge or extension that has not met the three bridge criteria	"This is worth investigating"	Anything else. The marking must appear in the same sentence as the claim
DEMOTED	A claim this corpus advanced and its own protocol rejected or reduced	"The structure stands; the magnitude does not"	The demoted content, in any form, including in summary tables

Two rules govern movement between statuses, and both are one-directional.

Rule 1: nothing is promoted by agreement. A POSTULATED claim does not become PROVED because a tradition also arrived at it, and a SPECULATIVE bridge does not become established because it is attractive or because the corpus depends on it. Promotion requires the specific thing the status demands: a proof, a measurement, or a passed gate.

Rule 2: demotion is immediate and travels. When a gate fails, every entry downstream of the failed one is demoted in the same pass. CC-R1 demotes four formulary entries in the personal-scope material of the corpus's personal formulary and their counterparts in the interpersonal formulary, and it does so in print, in the formularies themselves, and not only here.

38.3.6 3.6 How to use the register against this corpus

1. Locate the claim in doubt. The status index in §6.33 gives the ID.
2. Read its STATUS. **If it is PROVED, the only available attack is on the assumptions, and they are listed in Group B.** If it is POSTULATED, the attack is on the choice, and the entry says what the choice bought. If it is BORROWED, read the "what it measured" field: most of the objections worth making are that the setting does not transfer, and the field is written to make that objection easy.
3. Check whether any entry in Group B is upstream. Almost everything is downstream of B-01 (the affine design axiom) or B-02 (the linear storage law).
4. If the objection survives all three steps, it is a real objection, and §6.36 says what this house undertakes to do with it.

38.3.7 3.7 Identification: the parameter the correspondence would need, and cannot have

The three-scope correspondence is a claim about model form. The moment it is used — the moment anyone fits `eta` or `delta` to a real group and reports the fit as a property of that group — a second and much harder problem arrives, and it is not solved anywhere in this corpus.

The framework's substantive social claim is reflexive: the group's state influences each member and the members constitute the group. Written as a model that is a **linear-in-means reflexive specification**, and Manski [1993] proves that its endogenous social effect is **not identified from observational data.** It cannot be separated from contextual effects, nor from correlated unobservables, however many periods are collected. Shalizi and Thomas [2011] show the same for network data: influence and selection are generically confounded.

Applied to this paper, the consequence is specific and it sharpens the audit rather than softening it. The 19 cells with defined estimators are estimators of *conditional summaries* of a fitted series. Nineteen procedures exist; each returns a number; and for the parameters that carry social content — `eta`, `u`, and any `delta` with a voluntary-departure component — that number is not identified as a coupling even in principle from observation alone.

The known remedies are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation, the last on the template of Brock and Durlauf [2001]. **This corpus adopts none of them, and no paper in it reports a randomised or instrumented design.** Where the correspondence is used to license a claim about a real group, that claim is a **modelling position rather than an identified empirical result**, and Section 10 records this as the audit's most serious finding after the 0-of-27 count itself.

Two objections in the same family, also unanswered. First, the Lucas critique applied to the corpus's own parameters: Lucas [1976] holds that behavioural parameters estimated under one regime need not survive a change of regime, and Hacking [1995] names the mechanism directly in the human sciences — a classification changes the people classified. The framework asserts that systems change their behaviour when modelled, and then treats `eta`,

`delta` and `u` as stable enough to fit. **Either those parameters survive the framework's own predicted response to being measured, or the framework undercuts itself.** This paper takes the first horn as an assumption and labels it an assumption. The one documented field case of a reflexive fixed point, with dates and price data, is MacKenzie and Millo [2003]; it is an existence proof that the mechanism is real and not a licence to read a fitted coefficient as a measurement.

Second, the functional form of the surplus term is underdetermined by the evidence. A sub-linear power law [Latané, 1981] and an `n log n` form [Briscoe et al., 2006] fit the qualitative facts as well as `ln(1 + (N−1)u)` does, and **nothing in this paper discriminates among them.** The logarithm here follows from the affine-effective-count design axiom [Curzi, 2026] and from nothing else established in this corpus. Its usual warrant is Fechnerian [Fechner, 1966], which requires the perceptual story to be true; the stronger warrant, requiring no psychological assumption at all, is Peters and Gell-Mann [2016], under which the time-average growth rate of a multiplicatively evolving quantity is the expectation of its logarithm. **Where a stock compounds rather than adds, that is the warrant the argument actually needs.**

38.3.8 3.8 Analogy discipline, and what is borrowed from where

Every borrowing in this paper is one of three things, labelled at first use.

- **A shared mathematical form.** The storage law is a first-order discrete filter; its pole, DC gain, time constant and settling behaviour follow because the equation is the same equation, with no claim that the physics transfers [Oppenheim et al., 1996, Åström and Murray, 2008]. Geometric convergence follows from the contraction property [Banach, 1922, Elaydi, 2005], and the leaky integrator has the same status in computational neuroscience [Gerstner and Kistler, 2002]. **This is the category the correspondence sits in, and it is the respectable one.** The founding definitional move — comfort as the felt total of present costs, with the variational statement given as stationarity rather than minimality and licensing no teleology — is Curzi [2026] and is presupposed rather than restated.
- **A derivation.** The participation-ratio identity is algebra [Curzi, 2026c]. Jensen's inequality applies because `F` is strictly concave, which is proved [Curzi, 2026]. The range result `0 <= F(u) <= ln N` is proved and is what makes `h_inf >= 0` unconditional.
- **An analogy, and never evidence.** Reading a group of framings as an assembly of agents is an analogy; Section 5.2 refuses it. Reading programmed cell death as *exit* in Hirschman's sense [Hirschman, 1970] is an analogy; Section 5.4 refuses that too, and gives the reason.

Two standing bounds from the foundations are inherited rather than restated, and both restrict what a borrowing may claim. Curzi [2026] declines the inflated reading of its own borrowed physics: the framework's postulate is stated as a postulate, the uncertainty relation is given only in its correct form, and a named failure mode requires that a user be able to distinguish the theorem, the ordinary observer effect, and the framework's own conjecture in three separate sentences on demand. Curzi [2026] does the same for the contraction theorem: a human life is not a metric space, nobody has measured the relevant contraction modulus, and the theorem therefore transfers as **shape rather than guarantee** — and the feeling of recognition on arrival proves nothing, since the machinery that rehearses a future retrofits a past with equal fluency. **Both bounds apply directly to the claim that the arithmetic transfers, which is the only claim Section 5.7 says survives.**

Entropy in this paper is Shannon entropy where it appears at all: surplus is a logarithm of an effective count, a pure number reported in nats, and no thermodynamic quantity is invoked. The corpus's own register records the non-identification of surplus with Shannon entropy or mutual information in general (entry A-12), and records that **no thermodynamic negentropy law is proved** (entry A-13). Both are printed rather than glossed.

A note on the corpus's position in its own field. Carrying physical formalism into social description is a long-established programme [Galam, 2012, Castellano et al., 2009, Weidlich, 2003], and so is the objection that the transfer often borrows the authority of physics without

its constraints [Mirowski, 1989, Cartwright, 1999, Sobkowicz, 2020, Gallegati et al., 2006]. **The answer this paper offers to that objection is the audit itself.** A framework that publishes 0 of 27 first-party measurements has not disguised a metaphor as a measurement; it has said which is which.

38.3.9 3.9 An editorial note on cross-references

The source manuscript refers to its own internal technical papers as Papers A to E and locates claims by book chapter number. Neither survives conversion. **Where the manuscript cites Paper A, this paper cites Curzi [2026], which carries the surplus functional and its properties; where it cites Paper E, this paper cites Curzi [2026a], which carries the storage law and its corollaries; where it cites Paper D, the result is a range or effective-count bound and the citation is Curzi [2026c]; and where it cites Paper B, the result concerns state encoding and category assignment and the citation is Curzi [2026i].** Chapter numbers in the register's WHERE field have been replaced by the corpus paper identifiers that carry the corresponding material.

That mapping is an editorial inference, not a statement by the source, and Section 10 records it as such. The register's WHERE and evidence fields therefore name corpus papers as plain identifiers rather than as bibliographic citations; those identifiers resolve against the corpus DOI 10.5281/zenodo.22079583, and the bibliography of this paper carries the subset it cites directly in its running text.

38.4 4 The correspondence, parameter by parameter

Three volumes have now been written with one equation in them.

the institutional-scope material of the corpus put it on a room, a table, a team, and an institution. the personal-scope material of the corpus turned it around and put it on the person operating it — the framings a single mind holds, the character that accumulates, the load that maintaining a self costs. the cellular-scope material of the corpus carried it down to the cell, where the storage medium is chromatin state rather than minutes of a meeting, and where the signal path is a pressure wave rather than a conversation.

The claim implied by that progression is the largest in the corpus, and it has been made piecewise across the preceding papers of the corpus without ever being stated in one place with its limits attached. This chapter states it, and then spends more than a third of its length attacking it.

The claim: there is one instrument here, and the three volumes are that instrument set to three scopes. Not three analogous instruments. Not a metaphor extended twice. One parameter set — `N`, `u`, `N_eff`, `F`, `Q`, `delta`, `eta`, `C`, `h`, and in Volumes Two and Three the moment `M` and its ratio `D/P` — read against three different systems, with only the parameter *values* changing between them.

That claim has a precise status and it is not the status a reader would guess. **It is a claim about model form and nothing else** (the corpus's model-form convention; the honesty appendix, postulate 5 [CCP-039]). It is not a scaling law: it does not predict how any parameter changes between scopes. It is not a composition theorem: it does not say that cellular stored order aggregates into personal stored order, or that personal stored order aggregates into institutional stored order, and **no such theorem exists anywhere in this corpus.** It is not an empirical finding: **scale-freedom has never been tested at two scales simultaneously in any real system** (the honesty appendix, untested item 4 [CCP-039]). It is the observation that a minimal open-system accumulator written for each of the three uses the same five symbols, and that this is worth knowing because the same arithmetic then applies to all three.

A correspondence stated without its limits is a slogan. This section is written so that the correspondence cannot be quoted as one. The Engineering builds the full parameter table across all three scopes, cell by cell, with units and estimators. Then §5.1 through §5.7 take the

table apart: **a mind is not a small society, a cell is not a small mind, members can walk out and cells cannot, aggregation is not always well-defined even in principle, and at the cellular scope the input path to the whole apparatus is an open problem with no established mechanism** (CCP-031). What is left after those five sections is smaller than the table and considerably more trustworthy than the slogan, and it is the thing the corpus is entitled to carry into CCP-039.

38.4.1 4.1 The master correspondence table

Eleven rows. Three scopes. Each cell states the meaning at that scope and, in the second table, the estimator and its status. **Read the two tables together or not at all** — the first is where the correspondence looks strongest and the second is where it is priced.

Term	INSTITUTIONAL (Vol. One)	PERSONAL (Vol. Two)	CELLULAR (Vol. Three)
`N`	genuinely distinct domains, trades, or category systems admitted by the group	distinguishable categories one mind can bring to bear on a situation	distinguishable regulatory states or addressable programme classes
`u`	non-parallelism between members' independent readings of the same problem	non-parallelism between one person's own framings of the same situation	non-parallelism between regulatory programmes available to one cell
`N_eff`	how many genuinely different members remain after the roster is audited for redundancy	how many genuinely different views are held, after the same audit	how many genuinely different programmes are reachable
`F`	group surplus per interaction, `ln N_eff`, in nats, capped at `ln N`	internal surplus, `F_int`, over one observer's own framings (CCP-021)	**not instantiated** — no measured input path (§5.6)
`Q`	institution: practice, documentation, trained people, culture, infrastructure	character, skill, memory, standing commitment	maintained regulatory state — **not the molecules** (§4.6)
`delta`	turnover, drift of practice, decay of documentation, forgotten reasons	forgetting, skill atrophy, drift of self, lapse of habit	degradation and dilution: measured, and very fast (§4.7)
`eta`	how interaction becomes institution: the decision log, the artifact, the trained apprentice	how experience becomes character: the retained lesson, the changed default	**undefined** — the conversion has no established mechanism

Term	INSTITUTIONAL (Vol. One)	PERSONAL (Vol. Two)	CELLULAR (Vol. Three)
`C`	coordination overhead, friction, compliance, rent, conflict, commute	cognitive load, effort, emotional labour, the maintenance of a self	metabolic and proteostatic cost of maintaining state
`h`	organisational headroom: what may be built this period	personal capacity for the new	**not computable** — three of its four terms are unavailable
`M`	the situation as the group constructs it	the moment as lived	**does not descend** (§5.3)
`D/P`	**doctrine-to-data ratio**: does the model outrun the intelligence, or drown in it	frame-to-intake ratio	**does not descend** — no representation, therefore no frame (§5.3)

And the same eleven rows, priced:

Term	Institutional estimator	Personal estimator	Cellular estimator
`N`	Protocol MP-3, category audit — defined, unvalidated	MP-3 applied to one person's repertoire — defined, unvalidated	**none.** What counts as a category is undecided
`u`	MP-4: centred, unit-normalised error or response vectors, `u = 1 - r^2` — defined, unvalidated	MP-4 on one person's framings — defined, unvalidated, **and see §5.2**	**none.** No validated state encoder for cells
`N_eff`	`1 + (N-1)u`; equals `N + 1 - N/PR` (CC-R3, verified to 1.8e-15) — inherits S3's postulate status	same	**none**
`F`	computed from `u` — inherits everything above	computed from `u`, and see CCP-021	**none**
`Q`	MP-6 proxy, chosen by the engineer — **no ground truth exists**	MP-6 proxy — same	**none.** §4.6 argues the obvious proxy is wrong
`delta`	MP-1: two windows under zero input — defined, unvalidated	MP-1 — defined, unvalidated	**measured** (Schwanhäusser 2011); borrowed, median, one cell line
`eta`	MP-2: `Delta Q` attributable per nat of `S` — defined, unvalidated	MP-2 — defined, unvalidated	**none**

Term	Institutional estimator	Personal estimator	Cellular estimator
`C`	MP-5, requires cost commensuration — **a badged postulate** (honesty appendix postulate 8 [CCP-039])	MP-5 — same postulate	**none**
`h`	MP-7 — defined, unvalidated, and **gameable** (Goodhart; the honesty appendix [CCP-039])	MP-7 — same	**none**
`M`	ordinal only (CC-R1, FVP gate 2 = DEMOTE)	**ordinal only — CC-R1**	**not applicable**
`D/P`	ordinal only; Rasch route at 123 items per term (the Rasch-route theorem [CCP-026])	ordinal only; same route, same cost	**not applicable**

Read the right-hand column of the second table downward. Eleven rows and one entry. No amount of structural elegance in the first table changes that.

38.4.2 4.2 `N` — the category count, and why it means three different things

`N` is the number of genuinely distinct categories the system admits. It enters every design inequality in the corpus through the product `eta ln N`, and it is the hardest of the three scopes to make commensurate.

At the **institutional** scope, `N` is a roster question with a hard edge: two people trained in the same programme, rewarded by the same metric, and reading the same literature are one category, however different their biographies. CCP-009 computed how slowly `ln N` grows, and the arithmetic is the same at all three scopes:

```
N        ln N        bits        surplus ceiling in octaves (2F / ln 2)
-------------------------------------------------------------------------
2       0.693147    1.000000     2.000000
3       1.098612    1.584963     3.169925
5       1.609438    2.321928     4.643856
6       1.791759    2.584963     5.169925
12      2.484907    3.584963     7.169925
20      2.995732    4.321928     8.643856
50      3.912023    5.643856    11.287712
100     4.605170    6.643856    13.287712
```

Doubling `N` buys `ln 2 = 0.693147` nats wherever it starts. **A headroom problem cannot be escaped by adding domains problem by adding domains, and this is true at every scope for the same reason: it is a property of the logarithm, not of the system.**

At the **personal** scope, `N` is the number of genuinely distinct framings a person can bring — distinct in the sense that they generate different predictions, not merely different vocabulary. CCP-021 derived this reading from the founding material's third node, the many windows of the one tower, and it is a derivation rather than an analogy.

At the **cellular** scope, `N` has no agreed referent and this framework does not supply one. Candidate readings — the number of distinguishable chromatin states, the number of addressable regulatory programmes, the number of transcription factor combinations with distinct

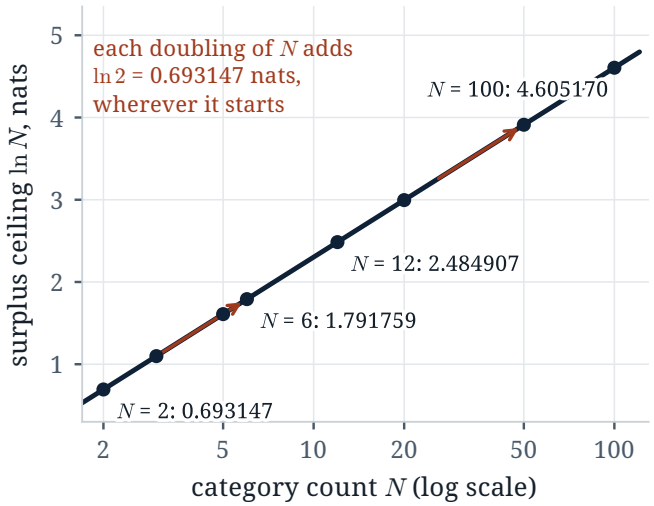

Figure 38.2: **Doubling the category count buys `ln 2` = 0.693147 nats wherever it starts, so a headroom problem cannot be escaped by adding categories — at any of the three scopes, for the same reason.** The ceiling is a property of the logarithm rather than of any system: `ln 2` = 0.693147, `ln 6` = 1.791759, `ln 12` = 2.484907, `ln 100` = 4.605170. Exact arithmetic from the table of Section 4.2; generated by `figs/src/CCP-038_fig05.py`.

downstream consequence — differ from each other by orders of magnitude and none has a validated counting procedure. **A parameter that cannot be counted cannot bound anything, and `ln N` at the cellular scope is therefore a symbol with no number behind it.** The latent-capability result [Curzi, 2026y] names the constraint that bounds the space — nothing that is not already latent can be reached — but a bound on reachability is not a count.

A structurally parallel collapse of a naive count appears in the frequency framework, where Curzi [2026] proves the odd-part class rule: the pitch class of `f(n) = k n^2` is the odd part of `n`, so `1..N` realises exactly `ceil(N/2)` classes, six at `N = 12`. **A count of distinguishable outcomes falling well below its naive value for a purely structural reason is the same move as the effective-count audit, performed on a quantity with nothing to do with rosters.**

38.4.3 4.3 `u` — non-parallelism, and the first crack

`u = 1 - (x . y)^2` is the squared sine of the angle between two unit state vectors. It is dimensionless, it lives in `[0,1]`, and it is zero exactly when the two states are parallel or anti-parallel.

The institutional reading is the one the law was written for: two members, two encoded readings of a shared problem, `u` measured as `1 - r^2` where `r` is the correlation of their centred response or error vectors. CCP-009 gives the protocols for raising it and CCP-010 gives the catalogue of ways institutions destroy it without noticing.

The personal reading is where the correspondence starts to strain, and §5.2 makes the full argument. In outline: **the `u` between two people can be large because the two people have separate substrates, separate training, and separate incentives; the `u` between two framings in one head cannot be large for those reasons, because there is only one substrate.** The framings share a memory, a mood, a set of priors, and a stake in the answer. They are correlated by construction in a way two colleagues are not. CCP-021's protocol addresses this by measuring `u` on *outputs* — independent written predictions made before the framings are compared — but that is a mitigation, not a solution, and it should be read as one.

Two properties of `u` used below are established elsewhere and are not re-derived. The law prices both sources of non-parallelism identically at the margin, `df/du_cross = df/du_div = (N-1)/(1+(N-1)u)`, while their productivity in the design variables differs [Curzi, 2026d]; and where `u` is estimated from a correlation, the opposition identity `u = 1 - rho^2` depends only

on `|rho|`, so `rho = +1` and `rho = −1` both give `u = 0` and zero surplus [Curzi, 2026]. **A perfectly opposed pair purchases exactly as much as a perfectly aligned one, namely nothing.**

The cellular reading has no encoder. Computing `u` requires a map from the thing to a unit vector such that the inner product carries the relevant notion of alignment, and the honesty appendix [CCP-039] item 6 already badges that map as an operational choice at the scopes where it exists. **At the cellular scope the choice has not been made, let alone validated.** Expression-profile correlation is the obvious candidate and it is not obviously the right one: two programmes may be transcriptionally similar and functionally opposed, or transcriptionally distinct and functionally redundant.

38.4.4 4.4 `N_eff` — the audited count, and the one identity that holds everywhere

`N_eff = 1 + (N−1)u` is the effective count: the headcount after redundancy has been subtracted. `u = 0` gives `N_eff = 1` — ten parallel windows are one window — and `u = 1` gives `N_eff = N`.

One result about it is scope-independent because it is arithmetic. **CC-R3: the mean-pairwise `u` aggregator is exactly the Rényi-2 participation ratio effective count**, `N_eff = N + 1 − N/PR`, where `PR = (sum lambda)^2 / sum lambda^2` on the correlation matrix. Verified over six random ensembles with `N` from 8 to 10 and 200 observations each; worst discrepancy `1.8e−15`, which is floating-point noise:

```
N = 8   ubar = 0.783801   N_eff(law) = 6.486606017883   N + 1 − N/PR = 6.486606017883
N = 10  ubar = 0.869860   N_eff(law) = 8.828735833534   N + 1 − N/PR = 8.828735833534
N = 8   ubar = 0.952367   N_eff(law) = 7.666571449037   N + 1 − N/PR = 7.666571449037
```

This identity holds at every scope where a correlation matrix can be formed, and it is the only row of the master table with that property. It is worth noticing why: it is a fact about the aggregator, not about people. It would hold for correlated thermometers.

Which effective count is meant matters here more than anywhere else in the paper. The affine count `1 + (N−1)u` is this corpus's own construction and is **not** a Hill number. The participation ratio it equals *is* one, of order two. The concentration instrument built on the other standard member of the family — `1/HHI`, with the worked jurisdictional case returning a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-HHI of 1.000000 and an effective count of 1.00 — is a separate quantity developed in Curzi [2026], and the two must not be conflated.

It also states what `N_eff` costs to compute: a correlation matrix, which requires repeated joint observation of the members on a common set of items. At the cellular scope such a matrix is obtainable in principle — single-cell expression data supplies one — while whether its eigenvalues mean what the law needs them to mean is entirely open.

38.4.5 4.5 `F` — surplus, and the ceiling that appears at every scope

`F = ln N_eff`, capped at `ln N`, in nats. At the institutional scope it is the surplus a single interaction can contribute. At the personal scope it is CCP-021's internal surplus. At the cellular scope **it is not instantiated**, because `S_t` requires an input path and CCP-031 states that the input path for sequence-specific content is exactly the open problem.

That is worth saying without decoration. **The third instrument has a storage equation whose input term has no established mechanism.** Everything upstream of that term is real; the specific step from an acoustic signal to a sequence-specific cellular read is established by nothing. The equation can be written. It cannot yet be driven.

The concavity that governs `F` is the same at every scope and it is the merciful clause:

```
N = 6:   u = 0.1  −>  N_eff = 1.500  F = 0.405465  (22.6% of ceiling)
```

```
u = 0.3  ->  N_eff = 2.500  F = 0.916291  (51.1%)
u = 0.5  ->  N_eff = 3.500  F = 1.252763  (69.9%)
u = 0.7  ->  N_eff = 4.500  F = 1.504077  (83.9%)
u = 0.9  ->  N_eff = 5.500  F = 1.704748  (95.1%)
u = 1.0  ->  N_eff = 6.000  F = 1.791759  (100.0%)
```

Half the available surplus arrives by `u = 0.3`. Three honest windows set wide capture most of what a gallery could, and that sentence has been true in the institutional-scope material of the corpus about people, in Volume Two about framings, and would be true in the cellular-scope material of the corpus about programmes if the programmes could be counted.

38.4.6 4.6 `Q` — stored order, and the result that embarrasses the naive reading

`Q` is what persists. At the institutional scope it is practice, documentation, trained members, and the built environment; at the personal scope it is character, skill, and standing commitment. The same law written in world coordinates rather than log coordinates is a geometric accumulator, `G_{t+1} = G_t^(1-delta) (N_eff)^eta e^(-C)` with `G_inf = ((N_eff)^eta e^(-C))^(1/delta)`, agreeing with the additive form to fourteen significant figures [Curzi, 2026n]; the choice between the two is a choice of register and not of model. Both are proxied, never measured, and the honesty appendix, postulate 3 [CCP-039] badges the whole idea that what persists in a social system is a single scalar decaying exponentially.

At the cellular scope the naive proxy is the obvious one — the molecules — and **the naive proxy is provably wrong on the measured numbers.** Take the median protein half-life above and ask what fraction of a cell's protein complement survives one month:

```
t_half = 46 h,  one month = 720 h
surviving fraction = 2^(-720/46) = 1.942e-05
delta per month    = 0.99998
```

Essentially none of it. A habit can persist in a person for thirty years; the molecules implementing it turn over in days. If `Q` at the cellular scope were the molecular inventory, the storage law would predict that nothing cellular persists at any timescale a person would notice, and that prediction is flatly false.

The resolution is not a repair to the law. It is a correction to the proxy, and it is the same correction CCP-031 arrives at from the other direction: **what persists is not the material but the maintained pattern that keeps rebuilding it.** Chromatin state, methylation, the self-sustaining regulatory circuit — these are candidate `Q` at the cellular scope, and they are candidates precisely because they are the things with long effective retention despite fast component turnover.

Two consequences, and both constrain the correspondence rather than support it.

First, the cellular `Q` is a different kind of object from the other two. Institutional and personal `Q` are aggregates of many persisting things; cellular `Q` is a maintained configuration whose components do not persist at all. That is not a difference in parameter value. It is a difference in what the state variable *is*.

Second, this is the clearest case in the corpus of a scope where the model form survives only because the modeller chose the proxy to make it survive. That is a legitimate move — every proxy choice is a modelling decision — but it is exactly the move that makes a framework unfalsifiable if it is made silently. It is made here in public, and CCP-031's experimental programme is where it would be tested.

38.4.7 4.7 `delta` — the best-measured parameter, and the inversion

Retention loss. Fraction of `Q` lost per period with zero input. `t_half = ln 2 / (-ln(1-delta))`.

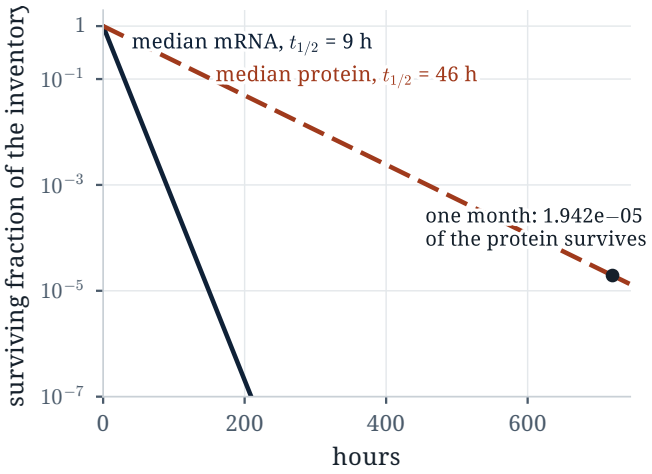

Figure 38.3: **The obvious proxy for cellular stored order is refuted by the corpus's only measured parameter: after one month, 1.942e$-$05 of the protein inventory survives.** At the median half-lives the borrowed study reports — 9 hours for mRNA and 46 hours for protein — a stored order denominated in molecular inventory would predict that nothing cellular persists on any timescale a person would notice, which is false. What persists is the maintained pattern that keeps rebuilding the material. Borrowed measurement, exponential decay implied by it (Section 4.6); generated by `figs/src/CCP-038_fig03.py`.

delta	tau = −1/ln(1−delta)	half-life (periods)
0.005	199.500	138.283
0.01	99.499	68.968
0.02	49.498	34.310
0.05	19.496	13.513
0.10	9.491	6.579
0.15	6.153	4.265
0.20	4.481	3.106
0.30	2.804	1.943
0.50	1.443	1.000

At the institutional scope, staff turnover is the most legible contributor: 15% annual turnover gives a 4.265-year half-life on whatever `Q` is carried in people rather than artifacts, which is the arithmetic behind CCP-014's insistence that documentation is not bureaucracy but retention engineering. At the personal scope `delta` is forgetting and skill atrophy, estimated by Protocol MP-1's two-window method under zero input — which for a person means a genuine lay-off period, and which almost nobody will run. At the cellular scope `delta` is degradation and dilution, and here is the inversion this section should not step over:

The scope with the least-validated instrument has the best-measured parameter.

Institutional `delta` has never been measured under Protocol MP-1 by anyone. Personal `delta` has never been measured under Protocol MP-1 by anyone. Cellular `delta` has been measured genome-wide, by mass spectrometry, in a published paper, with a stated method and stated spread.

This is inconvenient for the tidy version of the correspondence, in which the scopes get more speculative with descending scale, and it should be allowed to be inconvenient. The scopes do not degrade monotonically; they degrade differently. The institutional scope has the best borrowed sociology and the worst first-party measurement. The personal scope has

the best measurement *register* — a century of psychophysics establishing that subjective magnitude is measurable at all — and a demoted keystone formula. The cellular scope has the best-measured single parameter and no input path. **Three instruments, three different failures.**

38.4.8 4.8 `eta` — conversion, and the parameter that does not descend

`eta` is Q-units of durable structure produced per nat of surplus. CCP-008 argues it is the most neglected parameter and usually the cheapest to improve, and CCP-008 shows why it is the only term that scales the retained headroom at the fixed point.

Institutionally it is legible: the decision log, the written standard, the trained apprentice, the changed default, the moved wall. A meeting with no artifact has `eta` near zero. Personally it is the retained lesson — the difference between an experience that changed a default and one that was merely had. CCP-021 makes the join from the moment to stored character, and CC-R1 constrains that join: **the join is structural, not yet quantitative.**

Cellularly there is nothing. Measuring `eta` requires `S` and an attributable `Delta Q`; `S` has no input path and `Q` has no validated proxy. **`eta` at the cellular scope is not a small number or an uncertain number. It is not a number.**

38.4.9 4.9 `C` — cost, and the commensuration postulate

`C` is dissipation: coordination overhead, friction, maintenance, conflict, rent, compliance at the institutional scope; cognitive load, effort, emotional labour, and the maintenance of a self at the personal scope; metabolic and proteostatic expenditure at the cellular scope.

Every headroom computation in this corpus requires that these be expressed in the same unit as `eta ln N` and `delta Q`. **That commensuration is a badged postulate (the honesty appendix, postulate 8 [CCP-039]), the conversion factor is chosen by the engineer rather than measured, and it dominates the headroom result whenever `C` is large.** It is uncomfortable at the institutional scope, worse at the personal scope — where the claim is that an hour of emotional labour and an hour of cognitive load are commensurable — and untested at the cellular scope.

Brooks' arithmetic remains the sharpest statement of why the scopes cannot simply be scaled up: **communication paths grow as `n(n−1)/2` while surplus grows as `ln N`.** Quadratic against logarithmic. There is a group size beyond which no interaction geometry pays for its own coordination, and CCP-008 computes where it is for given `eta`.

38.4.10 4.10 `h` — the master gauge, and the only row that reads at more than one scope

```
h_t = eta ln N − delta Q_t − C_t

h < 0   unsustainable in this model; no geometry saves it
h = 0   maintenance only
h > 0   growth available; any requested increment must satisfy r_t <= h_t
```

Headroom is the gauge the whole manual is organised around, and it reads at the institutional and personal scopes because all four of its terms have estimators there. It does not read at the cellular scope, because three of its four terms do not.

One identity about it is scope-independent and was established in CCP-008 (CC-R6):

```
h_inf = eta*(ln N − F(u*))
```

At the fixed point, `delta`, `C` and `Q` all cancel. Verified across four parameter sets:

```
eta=0.20  N=6   u*=0.50  delta=0.10  C=0.25  ->  h_inf = 0.1077993001 both ways
eta=0.35  N=12  u*=0.30  delta=0.05  C=0.40  ->  h_inf = 0.3592020695 both ways
eta=0.50  N=4   u*=0.80  delta=0.20  C=0.10  ->  h_inf = 0.0812594647 both ways
eta=0.12  N=20  u*=0.62  delta=0.03  C=0.18  ->  h_inf = 0.0537420990 both ways
```

A structurally parallel identity holds in the frequency framework, where the octave deficit and the steady-state gauge turn out to be the same number: `D = 2.885390 (c/eta − F) = −2.885390 (delta/eta) Q_inf` [Curzi, 2026]. **Two quantities derived for different purposes collapsing onto one is the same kind of finding as the participation-ratio identity, and it has the same status: arithmetic.**

Since `F(u) <= ln N` by CCP-009 Corollary 2.2, `h_inf >= 0` always. **The plain linear model never ossifies by itself.** Ossification requires something the model does not contain: exogenous `Q` accretion, or a cost that rises with `Q`. That is a genuine structural result and it applies wherever the model form is adopted — which is to say at all three scopes, in exactly the sense §3.2's second row licenses and no further.

38.4.11 4.11 `M` and `D/P` — and where they stop

The moment equation `M = (D/P) . E` and its calibration ratio `r = D/P` are the two rows that exist in the personal-scope material of the corpus, are read at group scope in CCP-024 as the doctrine-to-data ratio, and **do not descend to the cell at all.**

Their status must be carried in full wherever they appear, and this section is a place where they appear:

> **CC-R1 — DEMOTED.** FVP gate 2 (scale type) returns **DEMOTE** for `M = (D/P) . E`. Because `D` and `P` are not instrumented on ratio scales with true zeros, the magnitude of `D/P`, the distortion `Delta = |ln r|`, and the join `M_t -> Q_{t+1}` are **not reportable as measured quantities.** What survives is structure: the limiting cases, the `D = P` fixed point, and the three-way ordering over-framed / calibrated / under-framed, all of which need only ordinal information. **What is demoted is magnitude, not structure.**
>
> **The route out is constructive and costed.** the Rasch-route theorem [CCP-026], given badged Postulate SO1: if `D` and `P` are measured as Rasch person-measures on one common scale, then `Delta = |ln(D/P)| = |theta_D − theta_P|` is ratio-scaled with a true zero at perfect calibration. Rasch separation supplies the true zero that division requires. **The cost is 123 items per term** to resolve a half-logit distortion.

The `123` is not an estimate. It is the inversion of the best-case measurement error, and it can be recomputed in one line: with every item targeted at the person, item information is `0.25`, so `SE(theta) = 2/sqrt(k)`; the distortion is a difference of two independent measures, so `SE(Delta) = sqrt(2) . 2/sqrt(k)`; and the 95% detection floor is `1.96 . SE(Delta)`.

```
k = 122  ->  SE(theta) = 0.181071   SE(Delta) = 0.256074   floor = 0.501905
k = 123  ->  SE(theta) = 0.180334   SE(Delta) = 0.255031   floor = 0.499860
```

One hundred and twenty-two items is not enough and one hundred and twenty-three is, and the crossing is that sharp because the arithmetic is that simple. This is the volume's actual research instruction and it is presented as one rather than as a caveat.

At the cellular scope the rows are empty for a reason more fundamental than instrumentation. §5.3 gives it: `D/P` is a ratio of a frame to an intake, and a frame is a representation. The argument that a cell has no representation is not a claim about current measurement technology.

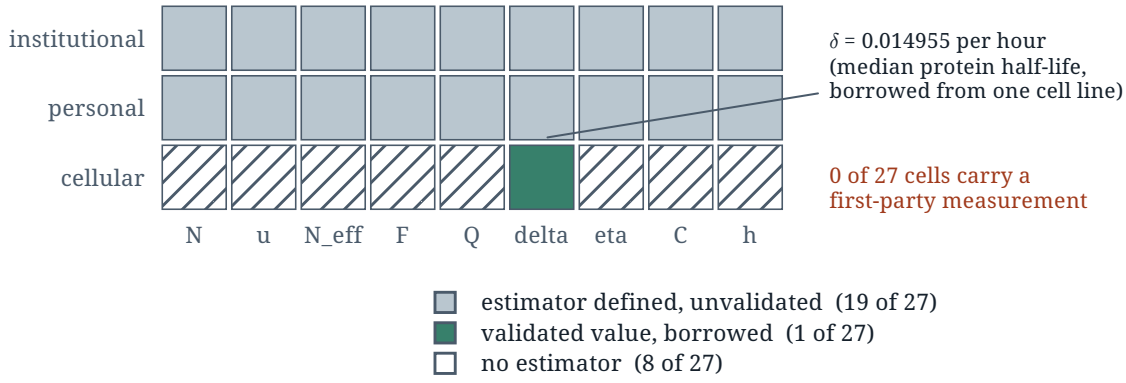

Figure 38.4: **Nineteen of twenty-seven parameter-by-scope cells have a defined estimator, one has a validated value, and none carries a measurement made first-party for this corpus.** The single validated cell is the cellular retention rate, a median protein half-life borrowed from a genome-wide study in one immortalised cell line. Audit of the corpus's own parameter tables (Sections 4.1 and 4.12); generated by `figs/src/CCP-038_fig01.py`.

38.4.12 4.12 The measurement-status summary

Collecting the two tables of §4.1 into one count, because the count is this section's most useful single output:

	Institutional	Personal	Cellular	Row total
Defined estimator	9	9	1	19 of 27
Validated estimator	0	0	1	1 of 27
First-party measurement published	0	0	0	0 of 27
Demoted to ordinal (CC-R1)	`M`, `D/P`	`M`, `D/P`	n/a	4

Nineteen of twenty-seven parameter-scope cells have a procedure; one has a validated number; none has a number this research programme measured. Everything in the next section follows from taking that table seriously rather than from any philosophical objection to correspondence.

38.5 5 Five breaks in the correspondence

38.5.1 5.1 Where the correspondence breaks down — the five breaks

This is the section this section was written for. The correspondence fails in five distinct ways, and they are genuinely distinct — a repair to one does not touch the others.

```
BREAK 1   A mind is not a small society.
          The independence the law's aggregation needs is unavailable inside one skull.

BREAK 2   A cell is not a small mind.
          M and D/P require a representation. A cell has no frame, so it has no D/P.

BREAK 3   Members can exit; cells cannot.
          The consent constraint that governs this corpus has no cellular analogue,
          which means the ethics do not descend with the arithmetic.
```

```
BREAK 4   Aggregation is not always well-defined, in principle and not merely in practice.

BREAK 5   The cellular scope has no established input path (CCP-031),
          and no composition theorem connects any scope to any other.
```

38.5.2 5.2 Break 1 — a mind is not a small society

The correspondence is most seductive at the personal scope because the personal-scope material of the corpus makes it work so well. Internal surplus is a derivation, not an analogy: CCP-A02 applied to one observer's framings is CCP-A02. CCP-021 shows this and the showing is correct.

What does not carry across is independence, and independence is the precondition on which every aggregation result in the institutional-scope material of the corpus rests.

Condorcet's jury theorem gives collective accuracy above individual accuracy *only under independence of the members' errors*. Hong & Page's result requires a diverse pool of solvers drawn separately. The participation-ratio estimator computes `N_eff` from a correlation matrix whose off-diagonal entries are small precisely when the members' readings were formed apart. Woolley's `c` correlates with turn-taking equality — a property of separate speakers taking separate turns.

Inside one head there are no separate speakers. Two framings held by the same person share:

- one memory, so both are conditioned on the same retrieved evidence;
- one mood, so both are weighted by the same current affect;
- one set of priors, formed by the same history;
- one stake in the answer, so both face the same incentive to prefer a conclusion;
- one substrate, whose fatigue, illness, or hunger perturbs both together.

Those are five channels of common-mode coupling with no institutional analogue, and they do not appear anywhere in the formalism. The law will happily compute `u = 0.6` between two framings a person has written down. Whether that `0.6` means what a `0.6` between two colleagues means is not a question the law can answer, and this framework's answer is: **not obviously, and probably not.**

The mitigation CCP-021 offers is real and should be used: measure `u` on *committed outputs* — independent written predictions produced before the framings are compared — rather than on introspective report. That converts the measurement from "how different do these feel" into "how decorrelated were their errors," the same operationalisation the institutional-scope material of the corpus uses on people. **It removes one source of inflation. It does not remove common-mode coupling, because the predictions still came from one substrate.**

A second, older objection should be named rather than avoided. Treating a mind as an assembly of parts that deliberate invites the homunculus: if the framings deliberate, something must be doing the deliberating, and if that thing is described the same way, the regress is launched. Minsky's *Society of Mind* (1986) is the best-known development of the assembly picture; it is an argument rather than a body of evidence, and is cited here as precedent for the picture, not support for it.

This framework's position, stated as a position: the internal surplus computation is a measurement of decorrelation among a person's committed outputs, and it is licensed as exactly that and nothing more. It is not evidence that a mind is composed of agents. It is not evidence that the sociological results transfer. It is a number about how much a person's own predictions disagree, which is a useful number, and which has the properties CCP-A02 proves for it because CCP-A02's proof does not care where the vectors came from.

A mind is not a small society. It is one system whose outputs can be decorrelated, sometimes, with effort, and never as far as two people's are.

38.5.3 5.3 Break 2 — a cell is not a small mind

The second break is sharper than the first because it is categorical rather than quantitative.

`M = (D/P) . E` requires `D`, a perspective — a frame brought to the encounter — and `P`, a perception — the intake against which the frame is weighed. The ratio is a comparison of two representations of the same situation. **A representation is the load-bearing requirement, and the argument that a cell lacks one is not an argument about measurement difficulty.**

A cell has states, and states are not representations. A transcription factor bound at a promoter is a physical configuration with causal consequences; it is not *about* anything in the sense the moment equation requires. The predictive-processing correspondence that the personal-scope material of the corpus draws — the ratio of prior precision to sensory precision being structurally the same object as `D/P` — depends on there being a prior and a likelihood, which is to say on there being a model. **This manual makes no claim that a cell has a model, and the moment equation therefore has no cellular instance.**

That has three consequences worth stating separately.

The `M` and `D/P` rows of the master table are empty at the cellular scope, and they are empty permanently rather than pending instrumentation. Instrumenting `D` and `P` with a Rasch instrument at 123 items per term is a research programme at the personal scope. At the cellular scope there is nothing to instrument, because there is no respondent.

The self-storage law does not descend either. `Q_{t+1} = (1−delta)Q_t + eta M_t − C_t` uses `M` as its input. Without `M` the cellular instance of the self-storage law is not a harder version of the same equation; it is a different equation with a hole where its input was.

And the direction of the correspondence matters. It is tempting to read the three volumes as a descent in which each scope is a smaller copy of the last. They are not copies. the cellular-scope material of the corpus's subject is a receiver with measured mechanics and no established semantics; the personal-scope material of the corpus's, a semantics with a demoted measurement; the institutional-scope material of the corpus's, a population with borrowed statistics. **They share an equation and they do not share a nature.**

38.5.4 5.4 Break 3 — exit, and why the ethics do not descend

Hirschman's *Exit, Voice, and Loyalty* (1970) names the two responses available to a member of a declining organisation: leave, or complain. The distinction is structural, not moral, and it is the sharpest available statement of what a member of an institution is.

A member of an institution can exit. A framing in a mind can be abandoned. A cell cannot leave the body.

This asymmetry does real work in three places.

It changes what `delta` means. At the institutional scope a substantial part of `delta` is voluntary departure, and voluntary departure is *responsive*: it rises when conditions worsen, which makes institutional `delta` endogenous to the very quantities the law treats as separate. The linear model treats `delta` as a constant within a period (the honesty appendix, postulate 9 [CCP-039]) and this is the clearest case where that assumption is not merely convenient but wrong in a known direction. At the cellular scope there is no voluntary departure. Apoptosis exists, is programmed, and is sometimes described in the language of choice; it is not exit in Hirschman's sense, because it is not a response by the unit to its own assessment of the organisation, and because the unit does not survive it. **Naming programmed cell death as "exit" would be exactly the kind of surface resemblance the two-column method exists to reject (CCP-029, criterion C1).**

It changes what a failure of the design means. The framework's fourth refusal is that it will not recommend an intervention removing a person's ability to decline (the standing refusals of the corpus). That refusal is enforceable at the institutional scope because members can decline; it is enforceable at the personal scope because the practitioner and the operated-on

are the same person, who can stop. **It is not enforceable at the cellular scope at all, because there is no one there to decline.**

Therefore the ethics attach to the person, not to the scope. This is the most important practical consequence in this section and it must not be softened. Consent at the biological layer is not consent obtained from the cell; it is consent obtained from the person whose cells they are, before anything is done, with the right to stop at any point, and with nothing concealed — which is the standing no-subliminals constraint (the corpus's disclosed-signal constraints) restated at the scope where its violation would be least visible. **The arithmetic descends to the cell. The moral standing does not descend with it, and pretending otherwise would let a formalism launder an ethical question it is not competent to answer.**

38.5.5 5.5 Break 4 — aggregation is not always well-defined

The three scopes are not merely different sizes of the same thing; going between them requires aggregation, and aggregation is not a free operation.

The first problem is a theorem. Arrow's impossibility result (1951) shows that no rule aggregating individual orderings into a collective ordering can simultaneously satisfy a short list of conditions that each look unobjectionable. It is a result about preference orderings specifically and this framework does not claim it applies verbatim to state vectors. **What it establishes, and what is fully general, is that "combine the parts into a whole" is a mathematical operation with constraints, not a bookkeeping step, and that the constraints can be mutually unsatisfiable.** A framework that moves between scopes without saying which aggregation rule it is using has skipped a step that is known to be capable of having no solution.

The second problem is the aggregator this corpus actually uses. CCP-A02's law is stated for a *pair*. Real groups have more than two members. The framework extends the pairwise law to an ensemble via the participation ratio, and the honesty appendix, postulate 7 [CCP-039] badges the extension precisely: **consistency by construction is a property of the choice, not evidence for it.** CC-R3 confirms that the mean-pairwise aggregator and the participation ratio agree to machine precision — which is a statement that two descriptions of the same choice coincide, not a statement that the choice is correct.

The third problem has a name. Relationships measured at the group level need not hold at the individual level and can reverse: the ecological fallacy, whose arithmetic form is Simpson's paradox. **A `u` computed across teams and a `u` computed within a team are different quantities that the notation does not distinguish**, and a practitioner who computes one and reports the other has made an error the formalism will not catch.

The fourth problem is that at the cellular scope the unit of aggregation is undecided. Is the member a cell, a cell type, a regulatory programme, or a locus? Each gives a different `N`, a different correlation matrix, and a different `N_eff`. There is no principled answer in this manual and inventing one would be worse than admitting there is none.

38.5.6 5.6 Break 5 — the unbridged gap, and the missing composition theorem

The fifth break is the one the cellular-scope material of the corpus was built around, and it is stated in the Methodology Protocol's own words because paraphrase would soften it:

> **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.**

Everything upstream is real and separately well-supported: PIEZO1 and PIEZO2 are mechanically gated ion channels (Nobel Prize in Physiology or Medicine, 2021); force at the cell surface transmits through the cytoskeleton to the nucleus, stretches chromatin, and changes

transcription (Tajik et al., *Nature Materials*, 2016); ultrasound has been used to activate specific channels (Ibsen et al., *Nature Communications*, 2015); DNA is a demonstrated data-storage medium (Church, Gao & Kosuri, *Science*, 2012); Cas12a processes its own crRNA array (Zetsche et al., *Cell*, 2015); and dCas9/CRISPRa establishes that targeting and editing are separable (Qi et al., 2013; Gilbert et al., 2014).

The step from those to sequence-specific acoustic addressing is not established by any of them. It is one well-specified falsifiable gap, CCP-031 spends its length on what an experiment would have to show and what controls it would need, and naming it sharply is the most useful thing this volume does.

For the correspondence specifically, the gap has an exact consequence: **the third instrument's `S_t` term has no measured input path, so the third instrument is a specification rather than a measurement.** Two of the three volumes describe systems the reader can go and measure tomorrow with an unvalidated estimator. The third describes a system whose input stage is an open research question.

To that, add the absence nobody has yet been asked to notice.

> **There is no composition theorem in this corpus.** Nothing here derives institutional `Q` from personal `Q`, or personal `Q` from cellular `Q`. No aggregation operator is defined between scopes, no conservation law links them, and no argument is offered that the three accumulators are coupled at all rather than merely similar in form.

That absence is not a gap in the writing. It is a gap in the mathematics, and it is the single largest open problem the correspondence raises. **What would close it is a stated aggregation operator with a proof that the storage law is closed under it** — that is, that a population of systems each obeying the law, combined by the practitioner, yields a system obeying the law with derived parameters. Whether the law is closed under any natural aggregation is not known here. It is a concrete, tractable-looking mathematical question, it does not require a laboratory, and CCP-039 returns to it as the problem the corpus ends on.

38.5.7 5.7 What survives

Strip the five breaks out and something remains. It is smaller than the master table and it is load-bearing.

One. The arithmetic transfers wherever the model form is adopted. Contraction, unique fixed point, convergence, the `ln N` ceiling, the headroom inequality, `h_inf = eta(ln N − F(u*))`, concavity and its marginal-gain schedule — these are consequences of the map, and they hold at any scope where someone is willing to adopt the map. **That is a real and unusual kind of portability: it costs nothing to check and it cannot be defeated by an objection to the scope, only by an objection to the map.**

Two. Three diagnostics survive at all three scopes, because they need only ordinal information. Whether `u` is near zero. Whether `eta` is near zero. Whether `delta Q + C` exceeds `eta ln N`. Each is a comparison, not a magnitude, and CC-R1's demotion is precisely the lesson that comparisons survive where magnitudes do not. A group whose members never disagree, a practice that leaves no artifact, and a system whose maintenance consumes its entire budget are diagnosable without a calibrated instrument.

Three. The failure catalogue transfers better than the measurements do. Pseudo-diversity, the meeting with no artifact, the maintenance trap, the measure that became a target — structural patterns derived from the arithmetic rather than from data, and the arithmetic is the same at every scope.

What does not survive is any claim that a measurement at one scope supports a conclusion at another. That is the sentence this section exists to install, and CCP-038 is the register that makes it checkable claim by claim.

38.6 6 The status register

This is the section to consult in order to argue with the corpus.

Everything in the preceding papers of this corpus is one of five things. It is a **theorem**, true within stated mathematical assumptions and making no claim about the world. It is a **postulate** of this research programme, chosen rather than derived, and badged wherever it is used. It is a **borrowed** empirical result, obtained by other people in settings that are not yours. It is a **speculative** bridge, marked as speculative in the sentence that states it. Or it is **demoted** — a claim this book's own validation protocol rejected, printed with its rejection attached.

A register that contains no demotions is not a register. It is a bibliography with opinions. This one contains them, they are in §6.6, and the most important of them is the demotion of the author's own keystone formula.

This section is a lookup table and behaves like one. Every entry has the same six fields in the same order, and the fields were chosen so that a hostile reader can check an entry without reading this section it came from.

```
ID          stable identifier; cited from other chapters and from the honesty appendix [CCP-039]
CLAIM       the substantive proposition, stated in one sentence
STATUS      PROVED / POSTULATED / BORROWED / SPECULATIVE / DEMOTED
(+1)        the evidence source, and WHAT THAT SOURCE ACTUALLY MEASURED
(−1)        the precedent source, and WHAT THAT SOURCE ACTUALLY RECORDED
WHERE       the corpus papers in which the claim does work
```

The two-column apparatus is the cellular-scope material of the corpus's, from CCP-029, and it is applied here to all three volumes because the discipline it enforces is not specific to biology. Its one rule governs every row below and is repeated because it is the rule most often broken by works of this kind:

> **The (+1) column carries EVIDENCE. The (-1) column carries PRECEDENT. Two sources agreeing does not double the evidence when only one of them is evidence.** What independent arrival establishes is real and worth having — that a structure was findable by more than one route, which is a genuine argument that the structure is in the territory and not only in the instrument. It is not a second measurement.

Where no precedent exists, the (-1) cell reads **none claimed**, and it reads that way in more than half the rows. **A blank column is the correct output when the historical corpus has nothing to say, and filling it would have been the easiest and most damaging thing this section could do.**

38.6.1 6.1 Group A — the formal spine

Theorems. **Nothing in this group is a claim about the world**, and every application of one of them to a real system passes through a Group B postulate first.

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
A-01	`f(u) = ln(1 + (N−1)u)` is the unique function satisfying axioms S1–S4	PROVED	CCP-A02, Theorem 2.1 (Curzi, 2026). A uniqueness proof; measures nothing	none claimed	CCP-007, CCP-009, CCP-017; the reference card [CCP-039]
A-02	`N_eff = e^{F} = 1 + (N−1)u`; surplus is `ln N_eff`, the log of an audited headcount	PROVED (given S3)	CCP-A02, Thm 2.1; CCP-009, Thm 2.1	none claimed	CCP-009, CCP-021

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
A-03	Strict monotonicity: more non-parallelism yields strictly more surplus	PROVED	CCP-A02, Thm 3.1	none claimed	CCP-009
A-04	Positivity: `f(u) > 0` for `u > 0`	PROVED	CCP-A02, Thm 3.2	none claimed	CCP-009
A-05	Strict concavity: each added increment of difference buys strictly less than the last	PROVED	CCP-A02, Thm 3.3	none claimed	CCP-009, CCP-020; CC-R2
A-06	Subadditivity **on the parameter `u` only**	PROVED	CCP-A02, Thm 3.4	none claimed	CCP-010
A-07	Sharp Lipschitz constant `N−1`	PROVED	CCP-A02, Thm 4.2	none claimed	CCP-009
A-08	Extremality: `F = 0` iff parallel; `F = ln N` iff orthogonal	PROVED	CCP-A02, Thm 4.3	none claimed	CCP-009, CCP-010
A-09	Range: `0 <= F(u) <= ln N`. **`ln N` is the hard ceiling on surplus per interaction**	PROVED	CCP-009, Cor 2.2	none claimed	CCP-008, CCP-009, CCP-038
A-10	Two-source decomposition: `u = u_cross + u_div`, with `max(f(u_c), f(u_d)) <= f(u) <= f(u_c) + f(u_d)`	PROVED	CCP-A02, Thm 4.1	none claimed	CCP-010, CCP-027
A-11	**The triangle inequality FAILS for geometric triples**	PROVED	CCP-A02, §5. A counterexample, not a limitation of technique	none claimed	CCP-010; the honesty appendix [CCP-039]
A-12	Surplus is **not** identified with Shannon entropy or mutual information in general; as deployed it is a **lower bound** on the ensemble's information	PROVED / clause	CCP-009. A non-identification result	none claimed	CCP-009; the honesty appendix [CCP-039]
A-13	**No thermodynamic negentropy law is proved**; `F(u) + N_can(u) <= ln N`, so higher static surplus does not imply higher canonical concentration	PROVED	CCP-007, Cor 2.2	none claimed	the honesty appendix [CCP-039]
A-14	Exact solution of the storage law: `Q_t = (1−δ)^t Q_0 + Σ (1−δ)^{t−1−k}(ηS_k − C_k)`	PROVED	CCP-007, Thm 3.1	none claimed	CCP-007, CCP-023
A-15	One-step growth iff `η S_t > δ Q_t + C_t`	PROVED	CCP-007, Cor 3.2	none claimed	CCP-008, CCP-016
A-16	Uniform bound `Q_t <= max{Q_0, η ln N / δ}`; with `δ=0`, `Q_t <= Q_0 + t η ln N`	PROVED	CCP-007, Thm 3.3	none claimed	CCP-007
A-17	**Sustainability ceiling: if `C_t > η ln N − δQ_t`, no interaction geometry prevents order from decreasing**	PROVED	CCP-007, Cor 3.4	none claimed	CCP-008, CCP-016, CCP-038
A-18	Steady state `Q_\ensuremath{\infty} = (ηF(u∗) − c∗)/δ`; **if `ηF(u∗) < c∗` the equilibrium is negative and the regime is unsustainable or the linear model must be replaced**	PROVED	CCP-007, Thm 3.5	none claimed	CCP-007, CCP-023; the reference card [CCP-039]
A-19	Headroom `h_t = η ln N − δQ_t − C_t`, with three regimes	PROVED	CCP-007, §6.4	none claimed	CCP-008, CCP-015, CCP-038
A-20	Maximum one-step increment `r_max = h_t`; no policy based on interaction geometry alone guarantees more	PROVED	CCP-007, Cor 4.2	none claimed	CCP-008, CCP-015; CC-R4
A-21	Target increment feasible iff `δQ_t + C_t + r_t <= η ln N`	PROVED	CCP-007, Prop 4.1	none claimed	CCP-008, CCP-016
A-22	Admissibility `C_t <= (1−δ)Q_t + ηS_t` guarantees `Q_{t+1} >= 0`	PROVED	CCP-007, §3	none claimed	CCP-008
A-23	`δ > 0` makes the storage map a contraction; a unique fixed point exists and iteration converges to it from any start	PROVED	Banach fixed point theorem (1922)	the founding material, the fixed-point node — the room that was always furnished, recorded as recognition rather than victory	CCP-007, CCP-023

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
A-24	The storage law **is** a discrete-time first-order low-pass filter: `Q` ↔ charge, `δ` ↔ leakage, `ηS` ↔ current in, `(1−δ)` ↔ pole	PROVED (identity)	Standard linear systems theory. An algebraic identification, not an analogy	none claimed	CCP-007, CCP-028
A-25	Time constant `τ = −1/ln(1−δ)`; half-life `ln2 / (−ln(1−δ))`; ~3τ to 95%, ~5τ to 99%	PROVED	Arithmetic of the geometric decay	none claimed	CCP-007, CCP-038
A-26	**`h_inf = η(ln N − F(u*))`** — at the fixed point `δ`, `C` and `Q` all cancel. Since `F <= ln N`, `h_inf >= 0` always: **the plain linear model never ossifies by itself**	PROVED	CCP-008 / CC-R6; verified against direct computation across four parameter sets, agreement to `< 1e−16`	none claimed	CCP-008, CCP-014, CCP-016, CCP-038, CCP-039
A-27	The mean-pairwise `u` aggregator **equals** the Rényi-2 participation-ratio effective count: `N_eff = N + 1 − N/PR`	PROVED	CCP-015 / CC-R3; verified over six random ensembles, worst discrepancy `1.8e−15`	none claimed	CCP-009, CCP-015, CCP-021, CCP-038; the reference card [CCP-039], B
A-28	By concavity, `mean F(U) <= F(mean U)`: feasibility must be tested on the mean of `F`, never on `F` of the mean	PROVED	CCP-A02 Thm 3.3 + Jensen. Worth **6.2%** of surplus in the CCP-016 worked office	none claimed	CCP-008, CCP-015, CCP-016, CCP-023, CCP-025
A-29	**The surplus law is exactly a Fechner law with threshold `u_0 = 1/(N−1)`:** `F(u) = ln((u + u_0)/u_0)`, and `F(u_0) = ln 2` for every `N`	PROVED	Algebraic identity; verified for `N = 2..100`, maximum residual `4.4e−16`	Fechner (1860) recorded the same functional form for sensation, from psychophysical threshold data, with no knowledge of this law	CCP-020, CCP-039
A-30	Octave folding of an essence set costs **exactly `ln 2` nats — one bit, two octaves** — for every even `N`: `ln N − ln(ceil(N/2)) = ln 2`	PROVED	Computed for `N = 4..64` even; loss = `0.6931471806` in every case, `loss / ln 2 = 1.0000000000`	none claimed	CCP-018, CCP-039
A-31	A star polygon `{N/k}` decomposes into exactly `gcd(N,k)` closed paths of length `N/gcd(N,k)`; unicursal figures are exactly those with `gcd(N,k) = 1`	PROVED	Elementary number theory; the full table computed for `N = 3..24`. The hexagram `{6/2}` has `gcd = 2` and is literally two triangles	The figures themselves, preserved in the practical corpus for centuries, with the stroke counts drawn correctly and the arithmetic unstated	CCP-028
A-32	Essence law: the published recipe `((AN/φ) · 1.125)^2` collapses exactly to `f(n) = k n^2` with `k = (9/8)^2/φ^2 = (81/64)/(φ+1) = 0.483425732988414 Hz`	PROVED	Algebraic reduction; verified against every published value in the 2022 source to 14 significant figures	*The Effective Method of Sonic Chemistry* (Curzi, 2022) recorded the recipe in spreadsheet form without the reduction	CCP-017; CC-R5
A-33	All intervals in the essence system are ratios of squared integers: `f(m)/f(n) = m^2/n^2`, and `k` cancels from every relation	PROVED	Arithmetic	none claimed	CCP-017, CCP-018
A-34	Two essences share a pitch class iff their indices have the same odd part; an ordered set `1..N` yields exactly `ceil(N/2)` pitch classes	PROVED	Arithmetic: `(2n)^2 = 4n^2`, exactly two octaves	none claimed	CCP-017, CCP-018, CCP-039
A-35	The cross-disciplinary bridge: `f_cross = k · N_eff^2 = k · e^{2F}`, so **one nat of surplus is exactly `2.885390` octaves**	PROVED	Conversion arithmetic; `F = ln 12` gives `N_eff = 12`, `f = 69.6133 Hz`, `7.1699` octaves above base	none claimed	CCP-017, CCP-018
A-36	The conversion keys are exact: `1 nat = 1.442695 bits = 2.885390 octaves = 3462.4681 cents`; `1 bit = 2 octaves exactly = 2400 cents`	PROVED	Arithmetic	none claimed	CCP-018; the corpus's internal-scope conventions
A-37	**The Lens Theorem:** a continuous map converting multiplication into addition is a logarithm, unique up to scale	PROVED (conditional)	Cauchy's logarithmic functional equation. The **antecedent** — that perception is such a map — is empirical and badged separately (C-33)	none claimed	CCP-020
A-38	Consequence: equal perceptual steps are equal world **ratios**; `+1` perceived unit is a fixed world multiple. **Linear in the lens is exponential in reality**	PROVED	Follows from A-37 by inversion: `I = I_0 e^{S/k}`	none claimed	CCP-020, CCP-039

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
A-39	Maximum possible moment is `ln N` once `M` is normalised to serve as `S_t`: the richest available moment is bounded by the log of how many kinds of thing the perceiver can distinguish	PROVED (given the normalisation)	Follows from A-09 and the normalisation choice, which is itself POSTULATED (B-17)	Ashby's requisite variety (1956) records the same bound for regulators, from control theory rather than perception	CCP-019, CCP-021
A-40	**The Gabor limit:** `dt · df >= 1/(4π) = 0.079577` for every wave, including sound; classical, with no quantum content	PROVED	Fourier analysis; window/resolution table computed: 1 ms → 79.577 Hz, 10 ms → 7.958 Hz, 100 ms → 0.796 Hz, 1000 ms → 0.080 Hz	none claimed	CCP-030, CCP-031, CCP-032
A-41	`dx · dp >= ħ/2` is a property of conjugate variables and a consequence of Fourier duality — **not** measurement disturbance	PROVED	The commutator derivation in standard quantum mechanics	none claimed	CCP-032
A-42	Casimir pressure `F/A = π²ħc/(240 a⁴)`. Computed: 10 nm → `1.3001e5` Pa (1.283 atm); 100 nm → `13.00` Pa; 1 µm → `1.30e−3` Pa; 1 mm → `1.30e−15` Pa	PROVED (formula)	Casimir (1948), derivation	none claimed	CCP-033
A-43	Brooks' path count: `n(n−1)/2` communication paths. **Cost grows quadratically while surplus grows logarithmically**	PROVED (arithmetic)	The count is arithmetic; that cost tracks it is BORROWED (C-30)	none claimed	CCP-008, CCP-012, CCP-038
A-44	Queueing: waiting time grows as `1/(1−ρ)`; utilisation near 1 makes wait explode. **Slack is a cost-control device, not waste**	PROVED (under M/M/1 assumptions, which real systems violate, generally for the worse)	Standard queueing theory	none claimed	CCP-008, CCP-012
A-45	Arrow's impossibility theorem: no rule aggregating individual orderings into a collective ordering satisfies the stated conditions simultaneously	PROVED	Arrow (1951). A theorem about preference orderings; this framework does **not** claim it applies verbatim to state vectors	none claimed	CCP-038
A-46	Condorcet's jury theorem: collective accuracy exceeds individual accuracy **only under independence** of member errors	PROVED	Condorcet (1785). The independence condition is the load-bearing part	none claimed	CCP-009, CCP-013, CCP-014, CCP-038
A-47	Rasch specific objectivity: conditional maximum likelihood separates person and item parameters, so a person's measure does not depend on which items were used	PROVED	Rasch (1960); the CML separation argument	none claimed	CCP-026
A-48	**the Rasch-route theorem [CCP-026] (given badged Postulate SO1):** if `D` and `P` are Rasch person-measures on one common scale, `Delta = |ln(D/P)| = |θ_D − θ_P|` is ratio-scaled with a true zero at perfect calibration	PROVED (conditional)	CCP-026. The conditional is on SO1 (B-19), not on the algebra	none claimed	CCP-026, CCP-038 §6.6
A-49	**The instrumentation cost is 123 items per term** to resolve a half-logit distortion at 95%	PROVED (arithmetic)	Best-case item information `0.25` → `SE(θ) = 2/\ensuremath{\surd}k`; `SE(Delta) = \ensuremath{\surd}2 · SE(θ)`; floor `= 1.96 · SE(Delta)`. `k=122` → `0.501905`; `k=123` → `0.499860`	none claimed	CCP-026, CCP-027, CCP-038, CCP-039

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
A-50	The four registers — surplus, pitch, sensation, moment — are all logarithmic, so every conversion between them is linear in log space with exact constants	PROVED (given each register's own form)	Arithmetic, conditional on A-01, pitch `= log2 f`, C-33, and B-16	none claimed	CCP-018; the corpus's internal-scope conventions

Fifty entries and not one of them is a fact about a person, a room, or a cell. That is what Group A is: the arithmetic the rest of the corpus borrows. Every application of it passes through Group B.

38.6.2 6.2 Group B — what is postulated

Assumptions. Chosen, badged, and load-bearing. **Every quantity in this corpus computed downstream of one of these inherits its status and not a grade higher.**

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
B-01	**S3, the affine design axiom:** `g(u) = e^{f(u)}` is affine in `u`, i.e. `N_eff = 1 + (N−1)u`	POSTULATED	**None. It is chosen for tractability and interpretability.** It is what makes A-01 produce a logarithm rather than another concave function	none claimed	Everywhere; the honesty appendix [CCP-039]
B-02	The **linear form** of the storage law: loss proportional to stock, conversion linear in surplus, cost additive, parameters constant within a period, no saturation	POSTULATED	None. It is the minimal tractable open-system law, chosen so a closed form exists	none claimed	Everywhere; the honesty appendix [CCP-039]
B-03	`Q` is a **scalar** state variable at all — rather than a vector of incommensurable stores	POSTULATED	None. There is no measurement of `Q`, only a proxy `Y` chosen under Protocol MP-6	none claimed	CCP-014, CCP-021, CCP-023; the honesty appendix [CCP-039]
B-04	The **modelling map**: that rooms, teams, institutions and cities are systems to which the storage law applies at all	POSTULATED	None, and **nothing in Papers A or E establishes it.** The largest assumption in the corpus	none claimed	Vol. One entire
B-05	**Hyperrecursive symmetry / the three-scope correspondence:** the same equation at desk, room, institution, mind, and cell, with only parameters changing	POSTULATED (model form only)	None. Not a scaling law; **never tested at two scales simultaneously**	none claimed	CCP-011, CCP-038; the honesty appendix [CCP-039]
B-06	The **state encoder**: participants, views or categories can be represented as unit vectors whose inner product carries the relevant alignment	POSTULATED	None. Different encoders give different `u` for the same group	none claimed	CCP-015, CCP-021; Protocol MP-4
B-07	The **ensemble aggregation**: the participation-ratio extension of a pairwise law to a group. **Consistency by construction is a property of the choice, not evidence for it**	POSTULATED	A-27 shows the two descriptions coincide, which is not the same as showing the choice is right	none claimed	CCP-015, CCP-038
B-08	**Cost commensuration**: coordination hours, rework, conflict and rent convert into the same unit as stored order	POSTULATED	None. The conversion factor is chosen by the engineer and dominates `h` whenever `C` is large	none claimed	CCP-008, CCP-023; the honesty appendix [CCP-039]
B-09	**Constancy of parameters** within a survey window: `δ` and `η` treated as constants	POSTULATED (known false, retained for tractability)	None. They move with turnover, tooling, morale and season	none claimed	Protocol MP-1; the honesty appendix [CCP-039]
B-10	`u = 0` at anti-alignment is **correct**: a reliable contrarian is one instrument, not two	POSTULATED (reading of the formalism)	The formalism gives `u = 1 − (x·y)^2`; the *interpretation* is this framework's	none claimed	CCP-009, CCP-010

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
B-11	**Optional activity** (Gehl) is the observable proxy for a room's η	POSTULATED	Gehl's category is observed and real; the identification with η is this framework's proposal	none claimed	CCP-010
B-12	**Acoustics as c-factor engineering**: changing RT60 changes collective intelligence	POSTULATED — **and see CC-R7, not confirmed**	A three-link chain whose middle link is weakest; untested end to end	none claimed	CCP-011, CCP-012, CCP-013, CCP-037
B-13	`k = 0.483425732988414 Hz` is a **chosen reference constant**, not a measured one; its form (Pythagorean interval over golden section) is a design decision	POSTULATED	None. Every relation in the system is independent of `k` (A-33), which is why the choice is admissible	The 2022 source document, which recorded the recipe without deriving the constant	CCP-017, CCP-018
B-14	`f = k n^2` is a **postulate about essence structure**. Its coincidence with the `n^2` eigenvalue spacing of a 1-D infinite square well is a mathematical correspondence and **not evidence of physical mechanism**	POSTULATED	None. Coincidence of form is not mechanism, and the text must say so in the same breath	none claimed	CCP-017
B-15	The **essence index requires a defensible ordering**; an arbitrary ordinal yields arbitrary frequencies	POSTULATED (validity condition)	CCP-015's validity conditions govern state encoding and category assignment	none claimed	CCP-017, CCP-031
B-16	**Fechner's postulate**: all just-noticeable differences are subjectively equal, which is what makes Weber's law integrate to a logarithm	POSTULATED	Not derivable from Weber's law; an additional assumption, disputed since 1860	Fechner (1860) stated it as a postulate himself	CCP-020
B-17	The **moment equation** `M = (D/P)·E` as the author's formula, with `M` normalised to `[0, ln N]` to serve as `S_t`	POSTULATED — **and DEMOTED on magnitude, see E-01**	The structure (limits, fixed point, ordering) needs only ordinal information and stands	none claimed	CCP-019, CCP-021, CCP-023, CCP-024, CCP-025
B-18	The **self-storage join** `Q_{t+1} = (1−δ)Q_t + η M_t − C_t`: the moment is the input to character	POSTULATED — **structural, not quantitative (CC-R1)**	Follows from B-02 plus B-17; inherits both	none claimed	CCP-021, CCP-023
B-19	**Postulate SO1**: that `D` and `P` admit Rasch-conformable item sets at all — that framing and intake can be written as items a person answers	POSTULATED	None. the Rasch-route theorem [CCP-026] is conditional on it	none claimed	CCP-026
B-20	**The Belief Postulate: belief creates reality if the belief is grounded in truth.** The conditional clause is the entire content	POSTULATED	Formalised as `BELIEF -> [CHANNEL] -> WORLD`, where "grounded in truth" means the channel exists and is real. Testable only through the channel	Long precedent across contemplative traditions for the unconditional form; **the unconditional form is what this corpus rejects**	CCP-034, CCP-035
B-21	Corollary: **a belief with no channel changes nothing**; belief is an input to a system that must have gain	POSTULATED (definitional consequence of B-20)	Same architecture as the storage law: input, conversion efficiency, output	none claimed	CCP-034, CCP-035
B-22	Reading esoteric operations as a **nonlinear computing map** is an explicit **metaphor**, carried with its badge	POSTULATED (metaphor, badged)	None. The metaphor generates no prediction on its own; A-31 does	The operative corpus recorded the procedures; it did not record them as computation	CCP-027, CCP-028
B-23	The **memory palace is the storage law with space as retention medium**: high η, low δ, because place is durable	POSTULATED (identification)	The mnemonic technique itself is validated (C-44); the parameter identification is this framework's	Yates, *The Art of Memory* (1966), recording the Ars Memoriae tradition from classical sources onward	CCP-028, CCP-029
B-24	**Ritual is periodic forcing of a low-pass filter**; cadence beats intensity because the filter integrates	POSTULATED (identification)	A-24 and A-25 are proved; that ritual *is* the forcing function is the identification	Durkheim on collective effervescence; Rappaport (1999) on ritual as the ground of social order	CCP-007, CCP-028
B-25	The **Tri-State Method** (+1 / -1 / 0p) and the three bridge criteria (structural correspondence, predictive power, practical utility), adopted unchanged	POSTULATED (method)	The author's VINO Framework. A validation apparatus, not a finding	none claimed	CCP-029, CCP-038

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
B-26	The **two-column refinement**: the columns carry different things, and precedent is never evidence	POSTULATED (method)	the cellular-scope material of the corpus's addition to VINO. **The rule that makes the rest of the register honest**	none claimed	CCP-029, CCP-038
B-27	The **no-concealment constraint**: no subliminal content of any kind, nothing masked, nothing below threshold. **A message hidden from its recipient cannot be consented to**	POSTULATED (house constraint)	An ethical constraint, not an empirical claim. It **overrides** the 2022 source's ASMR-subliminal recommendation	The 2022 source recommended embedded subliminals; **this research programme refuses it**	CCP-018, CCP-036, CCP-037
B-28	The **consent constraint**: no intervention that removes a person's ability to decline, and consent attaches to the person, never to the scope	POSTULATED (house constraint)	Structural: a method working by removal of resistance has no coercive failure mode. **An argument about method structure, not an empirical safety claim**	none claimed	the standing refusals of the corpus; CCP-013, CCP-014, CCP-037, CCP-038

38.6.3 6.3 Group C — what is borrowed

Empirical results obtained by other people. **The "what it measured" field is where the objections live, and it is written to make them easy.** Nothing here was obtained in the reader's setting.

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
C-01	A single factor c predicts group performance across varied tasks, is **not** predicted by members' average or maximum IQ, and correlates with social sensitivity, turn-taking equality, and proportion of women	BORROWED	Woolley, Chabris, Pentland, Hashmi & Malone, *Science* (2010). Several hundred participants, groups of 2–5, batteries of short laboratory tasks, factor analysis. **Transfer assumption: that a factor measured over hours in assembled groups persists in teams working for years**	none claimed	CCP-013, CCP-011, CCP-012, CCP-014
C-02	A committed minority of about **25%** overturns an established social convention	BORROWED	Centola, Becker, Brackbill & Baronchelli, *Science* 360 (2018). Controlled online coordination games; the tipping point was **measured, not simulated**. **Setting: strangers, arbitrary convention, no material stakes, no hierarchy**	none claimed	CCP-013, CCP-037
C-03	Complex contagion needs multiple reinforcing contacts, so **clustered topology beats random long ties**	BORROWED	Centola & Macy, *AJS* (2007), analytic; Centola, *Science* (2010), online experiment in which a health behaviour spread farther through a clustered lattice than a random network of equal density	none claimed	CCP-013, CCP-014
C-04	Threshold models: aggregate behaviour depends on the whole threshold distribution, so aggregate discontinuity requires no irrationality	BORROWED (model)	Granovetter, *AJS* (1978). **A model, not a measurement**	none claimed	CCP-013
C-05	Small-world: rewiring a small fraction of a lattice's edges collapses path length while clustering stays high	BORROWED (constructed graphs)	Watts & Strogatz, *Nature* (1998)	none claimed	CCP-013, CCP-014
C-06	Growth plus preferential attachment yields power-law degree; such networks tolerate random failure well and targeted hub removal very badly	BORROWED	Barabási & Albert, *Science* (1999); Albert, Jeong & Barabási, *Nature* (2000). Model results with empirical support in several real networks. **Check whether the dependency graph in question is scale-free before importing the fragility result, by the estimation-and-goodness-of-fit procedure of Clauset et al. [2009]; Broido and Clauset [2019] find scale-free structure rare once that procedure is applied, and Stumpf and Porter [2012] and Doyle et al. [2005] bound the inference further**	none claimed	CCP-009, CCP-014

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
C-07	Under stated conditions a randomly selected diverse group can outperform a group of the individually best	BORROWED — **contested**	Hong & Page, *PNAS* (2004). A mathematical and computational result depending on strong conditions; **criticised on mathematical grounds by Thompson, *Notices of the AMS* (2014).** Used as an illustration that diversity *can* dominate, never that it generally does	none claimed	CCP-009, CCP-014
C-08	Informational cascades: sequential agents rationally stop using private signals after a short prefix; aggregation stops and the cascade is fragile	BORROWED	Bikhchandani, Hirshleifer & Welch, *JPE* (1992); theory with extensive experimental support	none claimed	CCP-010, CCP-012, CCP-014
C-09	Contact reduces prejudice under equal status, common goals, cooperation, and institutional support	BORROWED	Allport (1954); Pettigrew & Tropp, *JPSP* (2006), meta-analysis of 500+ studies. **Largely correlational at base, with known publication-bias and self-selection concerns**	none claimed	CCP-013, CCP-014
C-10	Harm at scale is preceded by euphemistic labelling, displaced responsibility, routinisation, and withdrawal of full humanity from a target	BORROWED	Bandura on moral disengagement; Kelman; Haslam on dehumanisation. A well-supported tradition, drawn on **only** for the ethical constraint and the CCP-014 failure modes	none claimed	CCP-014; the standing refusals of the corpus
C-11	Eight design principles characterise long-enduring common-pool resource institutions	BORROWED	Ostrom, *Governing the Commons* (1990); Nobel 2009. **Inductive regularities from comparative case study — not theorems, not experiments.** Broad support in Cox, Arnold & Villamayor-Tomás (2010) with suggested refinements	none claimed	CCP-008, CCP-014
C-12	Regional governments created by one 1970 devolution performed very differently, tracking civic traditions with roots centuries earlier	BORROWED — causal direction contested	Putnam, *Making Democracy Work* (1993)	none claimed	CCP-014
C-13	Order can be produced by networked obligation where central enforcement is weak	BORROWED (descriptive)	Gambetta (1993), on the Sicilian mafia as a supplier of private protection. **Used as a demonstration and as a warning about what kind of order that is**	none claimed	CCP-014
C-14	Stigmergy: coordination by modifying a shared medium, with no agent holding the plan	BORROWED	Grassé (1959), termite nest construction; a foundational ethological observation since formalised. **The design rule "put the state in the medium" is this framework's inference, not Grassé's finding**	none claimed	CCP-014
C-15	Focal points: parties who cannot communicate converge on salient options. Mild individual preferences produce strong aggregate separation	BORROWED	Schelling, *The Strategy of Conflict* (1960) — evidence was informal elicitation, not controlled experiment; "Dynamic Models of Segregation" (1971) — a model	none claimed	CCP-014
C-16	Infrastructure is relational and becomes visible chiefly on breakdown; therefore δ **is systematically underestimated wherever it has not been measured**	BORROWED	Star & Ruhleder, *Information Systems Research* (1996); ethnographic and theoretical study of a scientific collaboratory	none claimed	CCP-007, CCP-012, CCP-014
C-17	"The most profound technologies are those that disappear"	BORROWED (aphorism)	Weiser (1991), *Scientific American*. **An essay, an argument rather than a study**	none claimed	CCP-012
C-18	Living structures have overlapping rather than strictly nested categories; designers impose trees because trees are easy to hold in mind	BORROWED — supported by examples, not measured	Alexander, "A City is Not a Tree" (1965); *Notes on the Synthesis of Form* (1964); *A Pattern Language* (1977). **The use of it to explain why hierarchy drives u to zero is this framework's inference, not Alexander's claim**	none claimed	CCP-009, CCP-010, CCP-012
C-19	Eyes on the street, short blocks, mixed primary uses, aged buildings	BORROWED (observational argument)	Jacobs (1961). Later quantitative work supports parts and complicates others	none claimed	CCP-010, CCP-012
C-20	People sit where there is somewhere to sit; sun, food, water and triangulation draw and hold them	BORROWED	Whyte (1980), time-lapse observation of New York plazas over several years. **The method transfers better than the findings, and this framework borrows the method**	none claimed	CCP-010
C-21	Necessary, optional and social activity, with optional activity highly sensitive to conditions	BORROWED	Gehl (1971), observational studies across several cities	none claimed	CCP-010, CCP-012

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
C-22	Proxemic distance bands: intimate, personal, social, public	BORROWED — **a frame, not a specification**	Hall (1966); observation predominantly of one cultural group, with Hall himself emphasising cross-cultural variation	none claimed	CCP-010, CCP-012
C-23	Post-surgical patients with a window view of trees had shorter stays, fewer negative nursing notes, and fewer strong analgesic doses	BORROWED	Ulrich, *Science* (1984). **Twenty-three matched pairs, one Pennsylvania hospital, nine years.** A small single-site matched-pair study, **and the strongest single piece of evidence in this framework that physical space affects a hard outcome.** Both halves are load-bearing	none claimed	CCP-012
C-24	`RT60 = 0.161 V/A` (metric)	BORROWED (empirical formula)	Sabine. **Valid for reasonably diffuse fields; degrades in heavily absorbing rooms (Eyring preferred) and strongly non-diffuse geometries**	none claimed	CCP-011, CCP-018
C-25	Organisations produce designs copying their own communication structures	BORROWED	Conway (1967), a trade-magazine argument, later supported by empirical comparison of product and organisational structure. **A structural explanation, not a law**	none claimed	CCP-007, CCP-013
C-26	A stable social-group size near 150	BORROWED — **contested; do not use as a design threshold**	Dunbar; a regression of primate group size on neocortex ratio extrapolated to humans, with very wide uncertainty	none claimed	CCP-008
C-27	A measure used for control ceases to measure what it did	BORROWED (empirical generalisation)	Goodhart (1975); Campbell (1979); Strathern (1997). **This framework is subject to it: headroom, once rewarded, will be gamed**	none claimed	CCP-015, CCP-016; the honesty appendix [CCP-039]
C-28	Adding people to a late project makes it later	BORROWED	Brooks (1975); engineering argument from experience on one large project, widely corroborated in practice, not established by controlled experiment	none claimed	CCP-008
C-29	Only variety absorbs variety	BORROWED (control theory result)	Ashby (1956), the Law of Requisite Variety. A theorem in its own setting, imported here as a design principle	none claimed	CCP-009, CCP-019
C-30	The just-noticeable difference is a constant **ratio** of the stimulus: `dI/I = c`	BORROWED	Weber (1834); psychophysical threshold measurement, replicated continuously since, **over a working range and not at the extremes**	none claimed	CCP-020
C-31	Sensation is logarithmic in intensity: `S = k ln(I/I_0)`	BORROWED (given B-16)	Fechner (1860); integration of Weber's law under the equal-JND postulate	none claimed	CCP-020, CCP-039
C-32	**Magnitude estimation produces genuine ratio-scale measurements of subjective experience, and it replicates.** `ψ = k I^a`; taking logs, the exponent `a` **is a measured conversion key**	BORROWED — **the single most important body of evidence for the personal-scope material of the corpus's premise**	Stevens (1957) and the subsequent literature. Nominal exponents: loudness ~0.67, brightness ~0.33, visual length ~1.0, salt taste ~1.3, lifted heaviness ~1.45, warmth ~1.6, electric shock ~3.5. **Exponents vary with method, range and instruction: constants of a procedure, not of nature**	none claimed	CCP-020, CCP-026
C-33	Human perception behaves as a ratio-reporting device over working ranges — the **antecedent** of the Lens Theorem	BORROWED	The Weber–Fechner–Stevens corpus (C-30, C-31, C-32). **The badge in CCP-020 is on this antecedent, not on the inference**	none claimed	CCP-020
C-34	Of 100 original psychology studies, 97 reported significant results and about **36%** of replications did, with effect sizes roughly halved	BORROWED	Open Science Collaboration, *Science* (2015). **Cited to state the measurement and replication problem honestly, not to dismiss the field**	none claimed	CCP-026, CCP-027; the honesty appendix [CCP-039]
C-35	Perception is modelled as precision-weighting of top-down priors against bottom-up evidence; **the ratio of prior to sensory precision is structurally the same object as** `D/P`	BORROWED — **active and contested research programme; structural similarity is not identity**	Friston; Clark; Hohwy. A modelling tradition with supporting evidence, not a settled fact	none claimed	CCP-019, CCP-034
C-36	**Placebo analgesia is mediated by endogenous opioids and is naloxone-reversible**	BORROWED	Levine, Gordon & Fields (1978). **A complete, physical, verified channel: belief → expectation → neurochemistry → measured analgesia**	none claimed	CCP-034
C-37	**Open-label placebo works** — benefit is observed when patients are told they are receiving placebo	BORROWED — **effect sizes modest, literature active**	Kaptchuk et al. (2010), IBS, and subsequent trials. **Decisive for this research programme: the effect does not require deception, so it is compatible with the no-concealment constraint (B-27)**	none claimed	CCP-034, CCP-036, CCP-037

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
C-38	Self-fulfilling prophecy: a false definition of a situation can evoke behaviour making it true	BORROWED	Merton (1948). **The bank-run example works because banks really are fractional-reserve: the belief propagates because it is coupled to a true feature of the system. Merton's mechanism IS the conditional clause of B-20, discovered independently in 1948**	none claimed	CCP-035
C-39	Expectancy effects in performance and clinical settings are real and modest	BORROWED — **contested history**	Rosenthal & Jacobson (1968) drew serious methodological criticism; the later literature is mixed. Presented honestly rather than as support	none claimed	CCP-035
C-40	**Growth-mindset effects are very small in large replications; stereotype-threat findings have had replication difficulty**	BORROWED — **a failure entry, and it is here on purpose**	Sisk et al. (2018), meta-analysis. **A postulate that names where it fails can be trusted where it holds**	none claimed	CCP-035
C-41	**PIEZO1 and PIEZO2 are mechanically gated ion channels.** Mechanical force opens them; ions flow; signalling follows	BORROWED	Nobel Prize in Physiology or Medicine, 2021 (Patapoutian). **Sound is mechanical, so a real, established pathway exists from pressure wave to cellular signal**	none claimed	CCP-030, CCP-038
C-42	Force applied at the cell surface transmits through the cytoskeleton to the nucleus, stretches chromatin, and upregulates transcription	BORROWED	Tajik et al., *Nature Materials* (2016). **Mechanical input to gene expression, published and direct**	none claimed	CCP-030, CCP-031
C-43	Ultrasound can activate specific channels in living organisms	BORROWED	Ibsen et al., *Nature Communications* (2015), TRP-4 in *C. elegans*; Duque et al. (2022), hsTRPA1	none claimed	CCP-030
C-44	The method of loci is a validated mnemonic technique	BORROWED	The experimental mnemonics literature	Yates, *The Art of Memory* (1966), recording the Ars Memoriae from Simonides through the Renaissance — **centuries of practical use with no experimental apparatus**	CCP-028, CCP-029
C-45	Arbitrary digital data can be encoded in and recovered from synthesised DNA	BORROWED	Church, Gao & Kosuri, *Science* (2012)	none claimed	CCP-030, CCP-031
C-46	Cas12a processes its own crRNA array — a genuine multicast destination list	BORROWED	Zetsche et al., *Cell* (2015); Fonfara et al. (2016)	none claimed	CCP-030
C-47	**Targeting and editing are separable functions**: dCas9 binds a locus and CRISPRa activates transcription while cutting nothing	BORROWED	Qi et al. (2013); Gilbert et al. (2014). **This is what makes "addressing without editing" a real architecture rather than a promise**	none claimed	CCP-030, CCP-036
C-48	Four regulatory factors return a differentiated adult cell to pluripotency **without adding one base of new sequence**	BORROWED	Yamanaka; Nobel Prize 2012. **Latent capability and its activation, demonstrated**	none claimed	CCP-031, CCP-036
C-49	**Syncytin**, indispensable to placenta formation, derives from a retroviral envelope gene	BORROWED	Molecular and comparative genomics. **Ancient foreign text, inherited, later read out as vital function**	none claimed	CCP-031, CCP-036
C-50	~98% of the human genome is non-coding and largely regulatory; ~45% transposable elements, ~8% endogenous retrovirus. **"Junk DNA" is retired**	BORROWED	Genome annotation and comparative analysis; the fractions are census figures with definitional caveats about what counts as functional	none claimed	CCP-031
C-51	Median mRNA half-life ~9 h and median protein half-life ~46 h	BORROWED — **the only measured parameter at the cellular scope**	Schwanhäusser et al., *Nature* (2011). Metabolic labelling with mass spectrometry and sequencing, **one mouse fibroblast line, medians over thousands of species with enormous spread.** Converted: $\delta = 0.074125/h$ and $\delta = 0.014955/h$	none claimed	CCP-030, CCP-038
C-52	The Casimir force is real and measured	BORROWED	Lamoreaux (1997); Mohideen & Roy (1998). **At biological and architectural scale it is utterly negligible: 1.3e-15 Pa at 1 mm. It does nothing in a cell and nothing in a room**	none claimed	CCP-033

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
C-53	Environmental interaction destroys phase coherence extraordinarily fast, so macroscopic superposition does not persist	BORROWED — **the honest objection, included rather than avoided**	The decoherence literature and its timescale estimates. **Any claim that mind collapses wave functions must confront this**	none claimed	CCP-033
C-54	Cochlear hair cells and tip links are exquisite mechanical receivers	BORROWED	Auditory physiology. **Biology's existence proof that fine mechanical reception is buildable**	none claimed	CCP-030
C-55	Exit and voice are the two responses available to a member of a declining organisation	BORROWED (analytic framework)	Hirschman (1970). **A structural distinction, not a measurement. It is what makes "members can exit and cells cannot" precise rather than rhetorical**	none claimed	CCP-038
C-56	Group-level relationships need not hold at individual level and can reverse	BORROWED	The ecological fallacy; Simpson's paradox as its arithmetic form. **A_u across teams and a_u within a team are different quantities the notation does not distinguish**	none claimed	CCP-038
C-57	Ritual as the ground of social order; collective effervescence as an observed phenomenon of assembly	BORROWED (theoretical and ethnographic)	Rappaport, *Ritual and Religion in the Making of Humanity* (1999); Durkheim; costly-signalling accounts in evolutionary anthropology	The liturgical corpora themselves, which recorded cadence, repetition and calendar with great precision and no theory of filters	CCP-028, CCP-029
C-58	A mind can be described as an assembly of interacting parts	BORROWED — **an argument, not a body of evidence**	Minsky, *Society of Mind* (1986). Cited as precedent for the picture, **not as support for it**, and CCP-038 argues against importing the sociological results with it	none claimed	CCP-038

38.6.4 6.4 Group D — what is speculative

Bridges and proposals that have not met all three criteria of CCP-029. **Every one of them is marked speculative in the sentence that states it, in its home chapter as well as here**, and two of them are rejections rather than proposals — a method that never rejects anything is a decoration.

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
D-01	That a cell can demodulate **sequence-specific** information from an acoustic signal	SPECULATIVE — **and this is the volume's central open problem**	**None. There is no established mechanism.** Everything upstream is real (C-41, C-42, C-43, C-45, C-46, C-47) and none of it establishes this step. Bridge criteria: C1 partially, C2 yes, C3 not yet	none claimed. The old corpus records sound as efficacious; it records no mechanism, and a record of belief is not a record of mechanism	CCP-030, CCP-031, CCP-036
D-02	That the essence law's index applies **outside** chemistry, to any discipline's ordered category set	SPECULATIVE (badged)	The law reduces exactly (A-32) and the cross-disciplinary bridge is arithmetically exact (A-35). **What is speculative is that a discipline's categories admit a defensible ordinal at all** (B-15)	The 2022 source applied it to the periodic table only	CCP-017, CCP-018, CCP-031
D-03	That the uncertainty of a future event is the same uncertainty as Heisenberg's	SPECULATIVE — **an analogy with its badge on, not an identity**	Shared: conjugate structure, no simultaneous sharpness, the Fourier trade-off. **Not shared: ħ, quantisation, non-commuting operators, or any experimental result**	the founding material, the wave node, which treats the future as an amplitude-weighted ensemble rather than a verdict — **and needs no quantum mechanics to stand**	CCP-032
D-04	That if magic is the engineering of the perceptual lens ($\mathfrak{D}/\mathfrak{P}$), the storage of order through symbol, space and cadence (η, $\mathfrak{d}$, $\mathfrak{Q}$), and the composition of non-parallel essences ($\mathfrak{u}$, $\mathfrak{F}$), then this framework describes its mechanism in modern notation	SPECULATIVE — the author's thesis, badged	**No supernatural efficacy is claimed, no physical effect of symbol, and no result not derivable from the formalism.** The thesis is a re-description, and a re-description generates no new prediction by itself	The operative corpus, which recorded procedures, correspondences and cadences in great detail across centuries	CCP-027–60

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
D-05	Narrative encoded as data, as sequence, as tone, with structure carried in the harmonic, acting as regulatory input	SPECULATIVE — **inherits D-01 entirely**	The encoding pipeline is built and reproducible; **the biological read is not established**	none claimed	CCP-031, CCP-036
D-06	*Destiny made manifest*: latent capability brought into expression by addressing plus belief with a real channel plus narrative input	SPECULATIVE — inherits D-01 and D-05	C-48 establishes that latent capability can be activated by regulatory signal; **nothing establishes that this architecture is such a signal.** The term is defined at first use and **explicitly distinguished from the 19th-century American political slogan and its history of justifying displacement**	none claimed	CCP-036
D-07	That consciousness causes wave-function collapse	**REJECTED in print**	Von Neumann–Wigner is **a minority historical interpretation, not a mainstream position.** C-53 is the objection it must confront and does not survive. The measurement problem is genuinely open; **it is not open in the direction of licence**	The contemplative corpus records mind as participating in the world; that record is not a physical mechanism	CCP-033
D-08	That the Rodin coil functions as an amplifier of the essence-tuning method	**REJECTED in print**	**No verified engineering basis.** Citing it as established would fail the standing refusals of the corpus.3	The 2022 source mentions it	CCP-018
D-09	That embedded subliminal content improves the method	**REFUSED on constraint, not on evidence**	Refused under B-27 regardless of efficacy. **A message hidden from its recipient cannot be consented to**	The 2022 source recommends it; **these chapters do not carry that recommendation**	CCP-018, CCP-036
D-10	The bridge rejected in public in CCP-029 as a demonstration of the method	**REJECTED in print, deliberately**	It was chosen to sit one inch from this corpus's own thesis, because rejecting something the corpus has no interest in would prove nothing	none claimed	CCP-029
D-11	That a composition operator exists under which the storage law is closed, so cellular order aggregates to personal order aggregates to institutional order	SPECULATIVE — **and it is an open mathematical question, stated as one**	**No such theorem exists in this corpus.** No aggregation operator is defined between scopes, no conservation law links them, and no argument is offered that the three accumulators are coupled at all rather than merely similar in form	none claimed	CCP-038, CCP-039
D-12	That gematria's string-to-integer map carries meaning	**NOT CLAIMED — the description is technical only**	**Gematria is a hash function. That is a literally accurate description of the operation and it carries no claim that the map is meaningful**	Extensive traditional use as an interpretive method	CCP-027

38.6.5 6.5 Group E — what is demoted

Claims this corpus advanced and its own protocol rejected or reduced. They are printed here in the same typeface as everything else, because a register that hides its demotions is not an audit.

ID	Claim	Status	(+1) evidence — and what it measured	(-1) precedent — and what it recorded	Where
E-01	The **magnitude** of `D/P` in the Moment Equation `M = (D/P)·E`	**DEMOTED** — FVP gate 2 (scale type) returns DEMOTE	**`D` and `P` are not instrumented on ratio scales with true zeros, and division requires one.** Route out: A-48 at the cost of A-49	none claimed	CCP-019, CCP-023, CCP-026; CC-R1
E-02	The **distortion magnitude** `Delta = |ln r|`	**DEMOTED** to ordinal	Direction stands — over-framed / calibrated / under-framed is an ordering and needs only ordinal information. **Magnitude does not.** A `Delta` computed from Likert data is **void, not imprecise**	none claimed	CCP-019, CCP-023; CC-R1
E-03	The **quantitative join** `M_t -> Q_{t+1}` in the self-storage law	**DEMOTED** — structural, not quantitative	The join's *form* stands; its *magnitude* inherits E-01	none claimed	CCP-021, CCP-023; CC-R1
E-04	The same demotion at **group scope**: the doctrine-to-data ratio as a measured quantity	**DEMOTED** to ordinal	The diagnostic — over-framed institution, under-framed institution — is ordinal and stands. The number does not	none claimed	CCP-024, CCP-025; CC-R1
E-05	Every M-derived formulary entry: the launch budget `L = max(0, M − C)`, the return difference `Delta_R = |ln(M'/M)|`, and their interpersonal counterparts	**DEMOTED** — gate 2 inherited	Each carries an FVP row showing gate 2 = DEMOTE plus the Rasch route. **`rho` computed from Likert data is void**	the founding material, the opening node (the departure lounge: "no surplus to dream with", `L = 0`) and a node ECHO recorded the structures the formulas formalise	CCP-022, CCP-023, CCP-025
E-06	The acoustic → `c`-factor **causal** claim	**DEMOTED — reported as NOT CONFIRMED**	The falsification test is stated in §14.13 and **its result is not confirmed.** Any later chapter invoking acoustic `c`-factor engineering must carry that status	none claimed	CCP-011, CCP-012, CCP-013, CCP-037; CC-R7
E-07	That the **shuffled-input control is sufficient** to detect a spurious input	**DEMOTED** — shown insufficient by construction	A filtered repackaging of the input passed all four baselines including the shuffle at `p = 0.0005`, and was caught **only** by the structural ceiling test (A-20): its single-step jump was **38.5×** the theoretical maximum	none claimed	CCP-015, CCP-027, CCP-035; CC-R4
E-08	Seven published compound values in the 2022 sonic-chemistry source	**DEMOTED — data-entry errors, not a different law**	Reverse-engineering recovered `f = k^2 G^4` (`G` = count-weighted geometric mean of indices), matching **37 of 44** published composites to `<1e−12`. **The O2 row is provably impossible under the stated rule**	The source document's prose formula `1+5^.5/2` is missing its parentheses	CCP-017, CCP-018, CCP-031; CC-R5

38.6.6 6.6 The reconciliation ledger, in full and unsoftened

Seven findings emerged during drafting and had to be propagated backward into chapters already written. **They are the clearest evidence in the corpus that the protocol is being run rather than displayed**, and they are given here at length rather than as footnotes to the rows above.

CC-R1 — The Moment Equation is demoted pending instrumentation

This is the most important entry in this section and it concerns the author's own keystone formula.

The finding. The Formula Validation Protocol's second gate asks a single question: what scale type does each term admit? Division and multiplication require ratio scale with a true zero; without one, a quotient is not a quantity. Applied to `M = (D/P)·E`, gate 2 returns **DEMOTE**. `D` and `P` — perspective and perception — **are not currently instrumented on ratio scales with true zeros.** Therefore three things are **not reportable as measured quantities**:

```
the magnitude of D/P
the distortion Delta = |ln r|
the join M_t -> Q_{t+1}                    (CCP-021)
```

What survives, and it is not nothing. The formula remains a valid **structural** claim. The limiting cases stand: `P -> 0` gives `M -> infinity`, frame with no intake, which is dogma and apophenia; `D -> 0` gives `M -> 0`, intake with no frame, sensation that is not experience; `E -> 0` gives `M -> 0`. The fixed point stands: `D = P` gives `M = E`, undistorted contact, and it is the formula's most important content. The ordering stands: over-framed, calibrated, under-framed. **All of these need only ordinal information, and ordinal information is what is available. What is demoted is magnitude, not structure.**

The constructive route out, which is the point. CCP-026, the Rasch-route theorem [CCP-026], given badged Postulate SO1: if `D` and `P` are measured as Rasch person-measures on one common scale, then

```
Delta = |ln(D/P)| = |theta_D − theta_P|
```

is genuinely ratio-scaled, with a true zero at perfect calibration and a free multiplicative unit. **Rasch separation supplies exactly the true zero that division requires.** The raw ordinal responses never became ratio data; the measure derived from them did, because the model earned it.

The cost, computed. Best-case item information is `0.25` when every item is targeted at the person, so `SE(theta) = 2/sqrt(k)`; the distortion is a difference of two independent measures, so `SE(Delta) = sqrt(2) · SE(theta)`; the 95% detection floor is `1.96 · SE(Delta)`.

```
k = 20   ->  floor 1.239613 logits      (r = 3.45; anything subtler is noise)
k = 31   ->  floor 0.995681             (one logit)
k = 100  ->  floor 0.554372
k = 122  ->  floor 0.501905             NOT ENOUGH
k = 123  ->  floor 0.499860             SUFFICIENT
k = 342  ->  floor 0.299770             (0.3 logits)
```

One hundred and twenty-three items per term to establish a half-logit distortion. A practitioner reporting `r = 1.2` from a twelve-item pair of scales is reporting noise, and the arithmetic says so before the study is run rather than after.

This is presented as the volume's actual research instruction, not as a caveat. The chapters that must carry it are named in the ledger and carry it: CCP-019 at first presentation of magnitude; CCP-019 with `Delta` as ordinal; CCP-021 with the join marked structural; CCP-023 and

CCP-025 with gate 2 = DEMOTE in every M-derived FVP row; CCP-024 at group scope; CCP-027 with the 123-item cost absorbed into the costed stage plan; CCP-034 where the belief postulate inherits the same instrumentation requirement; and the honesty appendix [CCP-039] in the postulated and untested drawers.

A validation protocol that demotes its own author's keystone formula, states the cost of fixing it, and gives the constructive route out is the strongest possible demonstration that the protocol is real. It is printed at full strength here for that reason. A reader who wants to know whether this corpus's gates do anything now has an answer that does not depend on trusting the corpus.

CC-R2 — The Jensen correction on feasibility

Because `F` is strictly concave (A-05), feasibility must be tested on the **mean of `F(U_t)`**, not on `F` of the mean `U`. Testing the wrong one overstates available surplus by the Jensen gap, which was worth **6.2%** of surplus in the CCP-016 worked office. Propagated to CCP-008, CCP-015, CCP-023, CCP-025 and Appendices A and C. **This is a small correction with a large moral: the concavity that makes the law merciful about the second opinion also makes it unforgiving about averaging.**

CC-R3 — `N_eff` is the participation ratio

Derived and verified: the mean-pairwise `u` aggregator equals the Rényi-2 participation-ratio effective count, `N_eff = N + 1 − N/PR`. Independent re-verification for this section over six random ensembles gave a worst discrepancy of `1.8e−15`. Recorded as a named identity in CCP-009, CCP-021 and Appendices A and B. **It matters because it means the ensemble extension is not a new assumption on top of the pairwise law; it is the same assumption written twice** — which is precisely why B-07 warns that consistency by construction is not evidence.

CC-R4 — The shuffle cannot see repackaging

A filtered repackaging of the input passed **all four** preregistered baselines — persistence, direct-input, matched autoregressive, and the shuffled-input control — with `p = 0.0005`. It was caught only by the structural ceiling test of Corollary 4.2: **its single-step jump was 38.5 times the theoretical maximum `η ln N`.**

```
STRUCTURAL CEILING TEST
r_max      = eta ln N − delta Q − C
hard cap   = eta ln N                        (delta, C >= 0)
if observed step > eta ln N, the result is impossible under the model
-- and impossibility is not a p-value, it is a contradiction
```

Rule, propagated to CCP-015 §6.3, CCP-027, CCP-035 and Appendices C and E: the shuffle is an empirical audit; only the structural tests detect repackaging. This is the register's clearest case of a demotion that strengthens the framework — a book with only empirical baselines would have published the repackaging as a result.

CC-R5 — Sonic chemistry errata

`f = k n^2` reproduces all 118 element values in the 2022 source, worst relative deviation `9.0e−15`, with the residual bias traced to `φ` stored at 15 significant figures. The compound rule was reverse-engineered as `f = k^2 G^4`, with `G` the count-weighted geometric mean of indices, matching **37 of 44** published composites to `<1e−12`. **The seven outliers are data-entry errors, not a different law — the O2 row is provably impossible under the stated rule**, and the source's

prose formula `1+5^.5/2` is missing its parentheses. CCP-017, CCP-018 and 69 use the corrected values and cite the errata. **Correcting a source is a service to it; the law survived the correction and the seven rows did not.**

CC-R6 — The `h_inf` identity

`h_inf = η(ln N − F(u*))`: at the fixed point, `δ`, `C` and `Q` all cancel. Verified to six decimal places in CCP-008 and re-verified here across four parameter sets with agreement below `1e−16`. Consequence: since `F(u) <= ln N` always, `h_inf >= 0` always, so **the plain linear model never ossifies by itself.** Ossification requires something the model does not contain — exogenous `Q` accretion, or superlinear cost. Propagated to CCP-014, CCP-016 and the reference card [CCP-039]. **A model that cannot produce the phenomenon everyone observes is reporting that the mechanism is outside the model, and that is a useful thing for a model to say.**

CC-R7 — The c-factor causal test is not confirmed

The falsification test for the acoustic → c-factor causal claim is stated in §14.13 and **reported as not confirmed.** Any chapter invoking acoustic c-factor engineering carries that status: CCP-012, CCP-013, CCP-037. The chain has three links — reverberation affects intelligibility (established), intelligibility affects who speaks (plausible, partially studied), turn-taking equality correlates with `c` (C-01) — and **the composite claim has not been tested end to end.** The test is cheap: randomise RT60 across otherwise matched deliberation rooms and measure turn-taking variance and task performance. It has not been run.

38.6.7 6.7 The status census

Counted directly from the register above.

Group	Entries	Contents
A — the formal spine	50	Theorems and exact arithmetic. No claims about the world
B — postulated	28	Design axioms, modelling choices, identifications, house constraints
C — borrowed	58	Empirical results obtained by others, in settings that are not yours
D — speculative	12	Of which **4 are rejections or refusals printed as such**
E — demoted	8	Claims this corpus advanced and its own protocol reduced
Total	**156**	

Three ratios are worth reading off it.

Fifty proved entries and none of them is about a person. Group A is entirely arithmetic. The book's mathematical content is real and it is also, on its own, inert: every step from a theorem to a recommendation passes through Group B.

Twenty-eight postulates carrying fifty-eight borrowed results. That is the actual load path. The borrowed results were obtained in laboratories, plazas, hospitals, fisheries and cell lines;

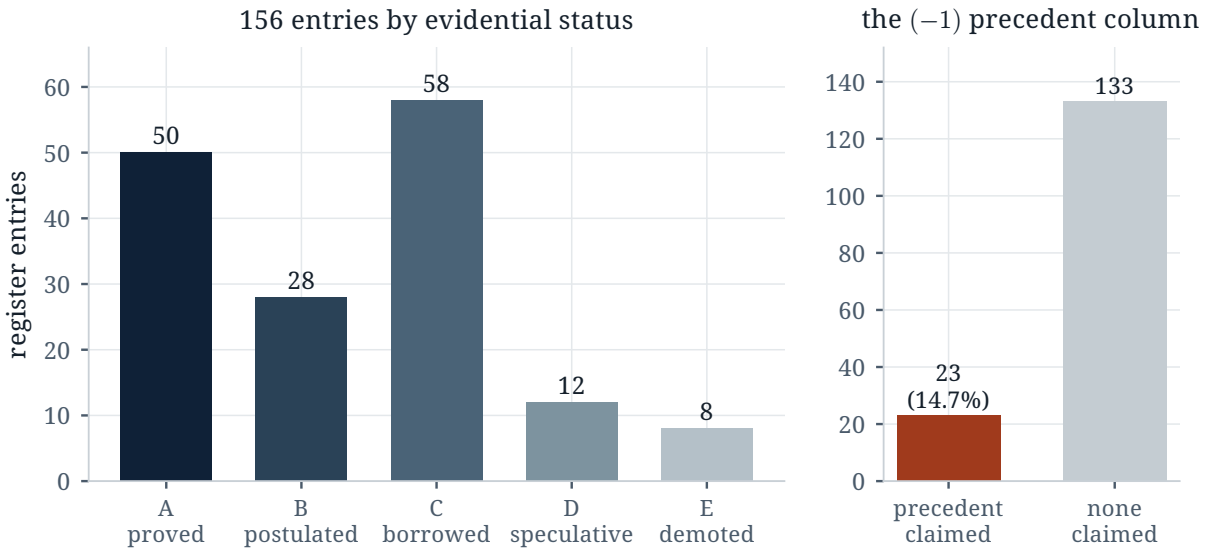

Figure 38.5: **Fifty proved entries say nothing about any person, and the entire load passes through twenty-eight postulates; precedent is claimed in 23 of 156 rows.** The register's five statuses form an ordered scale from proved to demoted and are drawn in one hue accordingly. The precedent column reads *none claimed* in 133 rows, which is the yield of a two-column method when the rule against filling the second column is enforced. Direct count of the register in Section 6; generated by `figs/src/CCP-038_fig04.py`.

the postulates are what connect them to a reader's room. **To break this corpus, break a postulate — B-01, B-02, B-04 and B-08 carry more weight than any citation in Group C.**

Twenty-three entries carry anything at all in the (-1) column, out of one hundred and fifty-six. Precedent is claimed in 14.7% of rows; the remaining 85.3% read *none claimed*. **That is the honest yield of the two-column method when the rule against filling the column is actually enforced**, and it is a considerably less impressive number than the method promises in the abstract. It is printed because it is the true one. the cellular-scope material of the corpus's commitment that every substantive claim carries two references is met where the historical corpus has something to say and is reported as unmet where it does not — which is the only way that commitment can be kept without inventing the second reference.

38.6.8 6.8 Index by status

PROVED (Group A). Surplus law and its properties: A-01 to A-13. Storage law and its consequences: A-14 to A-26. Identities established by this framework: A-26 (`h_inf`), A-27 (participation ratio), A-28 (Jensen), A-29 (Fechner threshold), A-30 (octave-folding cost). Essence law: A-32 to A-36. Perception: A-37 to A-39, A-50. Physics and mathematics imported as theorems: A-31, A-40 to A-47. Measurement arithmetic: A-48, A-49.

POSTULATED (Group B). Design axioms: B-01, B-02, B-03. Modelling map and scope: B-04, B-05. Estimation choices: B-06 to B-10. Identifications: B-11, B-12, B-23, B-24. Sonic postulates: B-13 to B-15. Perception and moment: B-16 to B-19. Belief: B-20, B-21. Method and metaphor: B-22, B-25, B-26. House constraints: B-27, B-28.

BORROWED (Group C). Sociology and networks: C-01 to C-15, C-25 to C-29, C-55, C-56, C-58. Space and substrate: C-16 to C-24. Psychophysics and psychometrics: C-30 to C-35. Belief channels: C-36 to C-40. Cell biology: C-41 to C-51, C-54. Physics: C-52, C-53. Tradition read as record: C-44, C-57.

SPECULATIVE (Group D). Open: D-01, D-02, D-03, D-04, D-05, D-06, D-11. Rejected or re-

fused in print: D-07, D-08, D-09, D-10. Description only, no claim: D-12.

DEMOTED (Group E). Moment-derived: E-01 to E-05. Causal chain not confirmed: E-06. Method insufficiency: E-07. Source errata: E-08.

38.6.9 6.9 What would change each status

A PROVED entry changes only by an error in the proof or by rejection of a stated assumption. The assumptions are in Group B and are individually attackable. **No experiment can touch Group A**, and no experiment supports it either.

A POSTULATED entry changes by being replaced with a better choice, and "better" has a meaning here: a choice that fits held-out data better, or that survives a falsification test the current one fails. B-01 would be tested by fitting a non-affine `g(u)` and comparing on held-out prediction. B-02 would be tested against a saturating or state-dependent alternative. **Neither test has been run, and neither is expensive.**

A BORROWED entry changes by replication, by failed replication, or by a study in a setting closer to the reader's. C-01, C-02, and C-07 are the three most consequential and the three most exposed: a laboratory factor extrapolated to institutions, a costless convention extrapolated to careers, and a mathematical result whose conditions are contested.

A SPECULATIVE entry changes by meeting the three bridge criteria, which for D-01 means an experiment. CCP-031 specifies what that experiment must show and what controls it needs, and **this research programme's position is that a null result reported honestly would be a service the corpus could not repay.**

A DEMOTED entry changes by instrumentation. E-01 through E-05 all change together, and they change at a stated price: **123 items per term.** E-06 changes with one randomised acoustics study. E-07 does not change — it is a permanent structural finding about what shuffles can see.

38.7 7 Results: one laboratory at three scopes, and one sentence audited

38.7.1 7.1 One laboratory, read at three scopes

A nine-person laboratory doing genomic-audio work. It is the right example for this section because it is the only kind of organisation for which all three scopes are simultaneously in play: it is an institution, it is staffed by people, and its subject matter is cells.

Every number below is arithmetic on parameter values chosen to be plausible. **None of them was measured in a real laboratory, and the honesty appendix, untested item 1 [CCP-039] applies without exception.** The purpose is to show what the computation looks like and where it stops.

Institutional scope. Period: one year. Order proxy: documented, reproducible protocols plus trained members.

Six distinct domains are admitted — molecular biology, acoustics and signal processing, information theory, statistics and psychometrics, ethics and consent, software — so `N = 6`. Cross-domain error decorrelation on shared prediction tasks gives `U = 0.42`.

```
ln N   = 1.791759 nats                  the per-interaction ceiling
N_eff  = 1 + 5(0.42) = 3.1000           nine people, three effective domains
S      = ln(3.1000) = 1.131402 nats     63.1% of the ceiling
```

Nine people and an effective count of 3.1 — not a criticism of the nine, but the audit saying that three of the six domains carry most of the independent information.

Parameters: `eta = 0.22` (protocols are written but reviews are verbal), `delta = 0.15` per year (one departure a year from a nine-person group, plus documentation drift), `C = 0.30` per year (coordination, compliance, and the consent apparatus), `Q = 2.40`.

```
eta ln N = 0.22 x 1.791759 = 0.394187
delta Q  = 0.15 x 2.40     = 0.360000
C                          = 0.300000

h = 0.394187 − 0.360000 − 0.300000 = −0.265813        UNSUSTAINABLE
```

Headroom is negative, and the no-geometry-rescues corollary is unambiguous about what that means: no arrangement of people prevents order from decreasing. The step confirms it:

```
Q_next = (1−0.15)(2.40) + 0.22(1.131402) − 0.30 = 1.988908
step   = −0.411092 Q−units in one year
```

The tempting move is to raise `u` — recruit more difference. Price it. A zero-growth step needs `S >= (delta Q + C)/eta = 0.660/0.22 = 3.000000` nats against a ceiling of `1.791759`. **The required surplus exceeds the maximum the geometry can deliver, so no recruitment fixes this.** Solving for the required `U` gives `3.817`, which is outside `[0,1]`: the equation is reporting that the request is impossible rather than expensive.

Raise `eta` instead — write the reviews down, log the decisions, make the artifact the deliverable:

```
eta = 0.22  ->  h = −0.265813   Q_inf = −0.3406   h_inf = 0.145279
eta = 0.30  ->  h = −0.122472   Q_inf = +0.2628   h_inf = 0.198107
eta = 0.35  ->  h = −0.032884   Q_inf = +0.6399   h_inf = 0.231125
eta = 0.40  ->  h = +0.056704   Q_inf = +1.0171   h_inf = 0.264143
```

At `eta = 0.40` the required `S` for a zero-growth step falls to `1.650000`, inside the ceiling, and the required `U` is `0.841396` — demanding, but a real number in range. **The lab's problem was never that its people were too similar. It was that its interaction was not being converted, and the arithmetic says so before anyone is hired or blamed.**

Personal scope. One member of that laboratory. Period: one month. Order proxy: retained working skill and standing commitments.

Five distinct framings brought to the work — bench, instrument, statistical, ethical, narrative — so `N = 5`. Decorrelation of that person's own committed written predictions gives `u = 0.28`.

```
ln N   = 1.609438
N_eff  = 1 + 4(0.28) = 2.1200              five framings, two effective ones
F_int  = ln(2.1200) = 0.751416 nats        46.7% of the ceiling
```

Parameters: `eta = 0.30`, `delta = 0.08` per month (half-life 8.313 months), `C = 0.18`, `Q = 3.10`.

```
eta ln N = 0.482831
delta Q  = 0.248000
C        = 0.180000

h = +0.054831        growth available
```

And then the instructive part:

```
Q_next = (1−0.08)(3.10) + 0.30(0.751416) − 0.18 = 2.897425
step   = −0.202575                                    DECLINING
```

Headroom is positive and the step is negative, and both are correct. Headroom says growth is *available*; it does not say growth is *happening*. The step depends on `S`, and the surplus needed for a flat month is `(delta Q + C)/eta = 0.428/0.30 = 1.426667` nats against an internal surplus of `0.751416`. **Headroom is permission, not delivery.** This person has room to grow and is not using it, because two effective framings out of five is not enough difference to fill the budget they already have. Their fix is `u`, and the lab's fix is `eta`, and those are different prescriptions arrived at from the same equation on the same afternoon.

Now the deliberate error, computed so it can be recognised:

```
NAIVE CROSS-SCOPE ARITHMETIC
personal h = +0.054831 per month  ->  x12  ->  +0.657976 per year
lab      h = −0.265813 per year
"the person has headroom that could offset the lab's deficit"      <-- FALSE
```

That subtraction is a unit artifact and nothing else. The two `Q` values are denominated in different proxies — retained personal skill against documented laboratory protocol — with no conversion factor between them, and this framework does not supply one. Multiplying a monthly headroom by twelve is legitimate arithmetic within the personal scope and meaningless across it. The sentence is refuted by A.5 and by §5.6: **there is no composition theorem, so there is no sense in which one scope's surplus can be spent at another.**

Cellular scope. The same laboratory's subject. Period: one hour.

This is where the worked example stops, and the stopping is the result.

```
N       -- no counting procedure exists                          NO VALUE
u       -- no validated state encoder exists                     NO VALUE
N_eff   -- requires N and u                                      NO VALUE
S = F   -- no established input path (CCP-031)                     NO VALUE
Q       -- proxy undecided; molecular inventory refuted (88.10)  NO VALUE
delta   -- 0.014955 per hour (median protein, t_half = 46 h)     MEASURED, BORROWED
eta     -- requires S and attributable Delta Q                   NO VALUE
C       -- no commensuration to a Q-unit that does not exist     NO VALUE
h       -- three of four terms unavailable                       NOT COMPUTABLE
```

One number out of nine, and it came from a mass-spectrometry study of mouse fibroblasts done for entirely unrelated reasons.

A reader who wanted the third column filled in should notice what filling it in would require: inventing a category count, an encoder, a proxy, and an input path. All four are inventable in an afternoon, all four would be fabrications, and this section would look considerably more impressive for containing them.

The honest output is three sentences. **The laboratory has a conversion problem and the arithmetic locates it exactly.** The member has a difference problem, located by the same arithmetic in different units on a different clock, with no traffic between the two results. **And the cells have one measured parameter and an open problem, which is the true state of the third instrument.**

That is the correspondence with its limits attached. CCP-038 records every claim the three volumes made, with its status and its sources, so that the limits can be checked one line at a time rather than taken on the assurance of this one.

38.7.2 7.2 One claim, audited end to end

Take a sentence a reader might reasonably lift from this corpus and use in a meeting:

“Redesigning the deliberation room will raise the team’s collective intelligence.”

Audit it.

Step 1 — decompose into register entries. The sentence is not one claim. It is four, chained:

```
(i)   room acoustics affect speech intelligibility          C-24, standard acoustics
(ii)  intelligibility affects who speaks and how often      partially studied
(iii) turn-taking equality correlates with c                C-01
(iv)  therefore changing RT60 changes c                     B-12, and E-06
```

Step 2 — read the statuses. Link (i) is BORROWED and solid, with a stated validity range: Sabine’s formula holds for reasonably diffuse fields and degrades in heavily absorbing rooms. Link (iii) is BORROWED and is a **correlation measured in assembled laboratory groups over hours** — the transfer assumption in C-01 is that such a factor persists in teams working for years on their own problems, and it is not established. Link (ii) has no entry of its own because it has no result of its own; it is the weakest link and it is in the middle. Link (iv) is B-12, POSTULATED — **and E-06, DEMOTED, reported as not confirmed under CC-R7.**

Step 3 — read the verdict off the chain. A chain is no stronger than its weakest link, and this chain has a POSTULATE and a DEMOTION in it. **The sentence as spoken in the meeting is not supported.** What is supported is considerably narrower and still worth saying:

> *“Reverberation control will make the quiet voice audible, which is a precondition for equal turn-taking, which is one of the three measured correlates of the collective intelligence factor in the setting where that factor was measured. Whether the chain runs end to end has not been tested, and the test is cheap.”*

Step 4 — what would settle it. CC-R7 and §6.9 both give the same answer: randomise RT60 across otherwise matched deliberation rooms, measure turn-taking variance and task performance, and report. It would not be expensive. **It has not been run, and until it is, the honest sentence is the long one.**

38.7.3 7.3 The results this paper contributes

R1 — The three-scope correspondence, badged POSTULATE — MODEL FORM ONLY. Identical structure at institutional, personal and cellular scope is a statement about the model chosen at each scope. It is not a claim of kinship between the systems, not a scaling law, and not a claim that quantities aggregate between scopes.

R2 — The instrument audit. Of 27 parameter-by-scope cells, **19 have a defined estimator, 1 has a validated value** — a borrowed cell-line median giving `delta = 0.014955` per hour — **and 0 carry a first-party measurement made for this corpus.**

R3 — Five independent breaks in the correspondence. A mind is not a small society; a cell is not a small mind; the exit ethics do not descend; aggregation is not always well defined; and the composition theorem is missing.

R4 — The affine effective count equals the Rényi-2 participation ratio exactly. `N_eff = 1 + (N−1)u = N + 1 − N/PR`, re-verified over six random correlation ensembles — for example `N = 8`, `u_bar = 0.783801`, both sides giving `6.486606017883` — with a worst discrepancy of `1.8e−15`. The identity and its original numerical verification are Curzi [2026c].

R5 — The fixed-point headroom identity. `h_inf = eta(ln N − F(u*))`, in which `delta`, `C` and `Q` all cancel; and since `F(u) <= ln N`, `h_inf >= 0` always, so **the plain linear model never ossifies by itself.** Verified across four parameter sets to ten decimals.

R6 — The status census. 156 register entries: **50 proved, 28 postulated, 58 borrowed, 12 speculative of which 4 are printed refusals, and 8 demoted**, with precedent claimed in **23 rows, 14.7 per cent**.

CR — The counter-result. No parameter at any scope has ever been measured first-party by this research programme — **0 of 27 cells** — the correspondence breaks in five independent ways with no composition theorem bridging them, and the census names its own weakest link: **fifty proved entries that say nothing about any person, and all the load passing through twenty-eight postulates.**

38.8 8 Discussion

38.8.1 8.1 What follows

The audit is the paper's usable output, and it is usable precisely because it is unflattering. A framework with nineteen defined estimators and one validated value is a specification, not an instrument. That is a perfectly respectable thing for a body of work to be, provided it says so; what is not respectable is a specification presented in the register of a measurement. The corpus's own protocols supply the nineteen procedures [Curzi, 2026i], and nobody — including its author — has run any of them and published the result.

The scopes do not degrade monotonically, and the inversion is the most instructive single fact in the audit. The tidy expectation is that the institutional scope is best supported and the cellular scope worst. What the audit finds is that the institutional scope has the best *borrowed* sociology and the worst first-party measurement; the personal scope has the best measurement *register*, a century of psychophysics establishing that subjective magnitude is measurable at all [Fechner, 1966, Stevens, 1957], and a demoted keystone formula in front of it; and **the cellular scope, the most speculative of the three, has the only measured parameter in the entire table.** Three instruments, three different failures.

A printed refusal is worth more than a passed test, and the corpus contains them. The clearest is the momentum lever: trajectories at `beta = 0, 0.5, 0.8, 0.9, 0.95` all terminate at the same point, `x = 1.9972`, in the same basin, so momentum defeats narrow barriers and is useless against wide shallow ones — and it was **refused formulary entry** on that basis rather than retained with a caveat [Curzi, 2026p]. Four of the twelve speculative register entries are refusals of the same kind.

Where the model form survives because the modeller chose the proxy, that is stated in public. The clearest case is cellular stored order. The obvious proxy is the molecular inventory, and it is refuted by the corpus's own measured parameter: at a 46-hour median protein half-life, the surviving fraction after one month is `1.942e-05`. A habit persists in a person for thirty years; the molecules implementing it turn over in days. The resolution is not a repair to the law but a correction to the proxy — what persists is the maintained pattern that keeps rebuilding the material, not the material. **That is a legitimate modelling move and it is exactly the move that makes a framework unfalsifiable if it is made silently.**

What survives the five breaks is smaller and load-bearing. The arithmetic transfers wherever the model form is adopted, because contraction, the unique fixed point, the `ln N` ceiling and `h_inf = eta(ln N - F(u*))` are consequences of the map. That is an unusual kind of portability: it costs nothing to check and it cannot be defeated by an objection to the scope, only by an objection to the map. Three ordinal diagnostics survive as well — whether `u` is near zero, whether `eta` is near zero, whether `delta Q + C` exceeds `eta ln N` — and they survive for the same reason the demoted Moment equation keeps its ordering: **comparisons survive where magnitudes do not.** A group whose members never disagree, a practice that leaves no artefact, and a system whose maintenance consumes its whole budget are all diagnosable without a calibrated instrument.

38.8.2 8.2 What does not follow

No result transfers by correspondence. The collective-intelligence factor was measured in assembled laboratory groups over hours [Woolley et al., 2010, Engel et al., 2014]; it says nothing

about a cell and nothing about the internal structure of one person's framings. **The symbol `u` appearing in three places does not make one measurement of `u` count three times.**

No quantity may be summed, differenced or divided across scopes. Section 7.1 computes such a quantity deliberately — a personal monthly headroom of `+0.054831` multiplied by twelve and set against a laboratory annual headroom of `−0.265813` — and shows it to be a unit artefact. The two stored-order values are denominated in different proxies with no conversion factor between them, and this corpus does not supply one.

A proxy chosen on the wrong axis understates the thing it is meant to measure, and the corpus has a measured instance. Curzi [2026] finds entity-based exposure to one jurisdiction at 27.3 per cent against a 61.0 per cent share of the same balance sheet denominated in that jurisdiction's currency and roughly 58 per cent of settlement volume clearing through its system — **the entity map understates dependency by more than a factor of two.** The cellular order proxy of Section 4.6 is the same failure caught before it was made.

No composition theorem exists, and its absence is the largest open problem the correspondence raises. What would close it is a stated aggregation operator together with a proof that the storage law is closed under it: that a population of systems each obeying the law, combined by the operator, yields a system obeying the law with derived parameters. Whether the law is closed under any natural aggregation is not known here. **It is a concrete, tractable-looking mathematical question, it needs no laboratory, and it is the problem the series ends on** [Curzi, 2026].

No ethics descend with the arithmetic. A member of an institution can exit and a framing can be abandoned [Hirschman, 1970]; a cell cannot leave the body. Programmed cell death is not exit in Hirschman's sense, because it is not a response by the unit to its own assessment of the organisation and the unit does not survive it. **Consent at the biological layer is consent obtained from the person whose cells they are, before anything is done, with the right to stop and with nothing concealed** [Curzi, 2026]. Pretending the ethics descend would let a formalism launder a question it is not competent to answer.

No claim of ontological identity is made or entertained. A mind is not a small society; a cell is not a small mind. The internal surplus computation is licensed as a measurement of decorrelation among one person's committed outputs and as nothing more [Curzi, 2026o], and it has the properties the surplus functional's proof gives it because that proof does not care where the vectors came from.

38.8.3 8.3 Relation to the surrounding literature

The audit's method is the reform literature's applied to a framework rather than to a finding: declare the procedure, freeze it, report what happened including the nulls [Nosek et al., 2018], treat researcher degrees of freedom as the dominant threat [Simmons et al., 2011, Gelman and Loken, 2013], expect base rates to be low [Ioannidis, 2005], and prefer risky point predictions to directional ones, which in psychology are nearly costless [Meehl, 1967, 1990]. Lakatos [1970] is the honest description of what the twenty-eight badged postulates are doing: they are the protective belt, and the register's function is to keep the belt visible.

The measurement commitments are those of measurement theory rather than of psychometrics as practised. Michell [1997, 1999] is the objection the corpus is most exposed to and Section 9.7 concedes it. Luce and Tukey [1964] and Krantz et al. [1971] give the test that was never run. Rasch [1960] and Andrich [1988] supply the constructive route that the register prices at 123 items per term, and Sijtsma [2009] is the reason reliability is not a substitute for structure.

The independence requirement that Break 1 turns on is Condorcet's (1785; named in prose, see Limitation L-11), reinforced by the model result of Hong and Page [2004] and bounded by Thompson [2014], whose critique is cited in the same breath wherever the diversity claim appears. The informational-cascade results [Bikhchandani et al., 1992, Banerjee, 1992] and the measured collapse of effective count under social influence [Lorenz et al., 2011] are what make pseudo-diversity a formal object rather than a complaint. Ugander et al. [2012] is the

closest empirical relative of an effective count in the social sciences: adoption predicted by the number of distinct connected components among a person's contacts. Markowitz [1952] states the whole point in 1952 — diversification benefit depends on covariance and not on count — and Brooks [1975] supplies the quadratic coordination cost the logarithmic surplus is set against.

The concentration instrument transfers to settings the corpus did not design it for and returns numbers rather than adjectives: Curzi [2026] reports effective counts running from 35.0 curated validators (HHI 0.028571) and 39.0 council members (0.025641) down to 6.00 organisations (0.166667) and 5.94 entities (0.168400) on the same ledgers. **That is what an instrument looks like once it has an estimator that anyone can run, and it is the contrast this paper's audit is measured against.**

The corpus's structural results about networks are cited with their own qualifications attached. Where preferential attachment and hub fragility appear [Barabási and Albert, 1999, Albert et al., 2000], the estimation procedure of Clauset et al. [2009] is binding before any real graph is called scale-free; Broido and Clauset [2019] and Stumpf and Porter [2012] bound the inference further, and Doyle et al. [2005] shows that the real Internet's robustness comes from engineered design rather than from a degree distribution.

38.9 9 Verification

The audit's operative results compound from six postulates. Each is atomic, checkable on its own, and carries its status.

38.9.1 9.1 Dimensional audit

Symbol	Dimension	Unit	Status
`Q_t`	`[Q]`	proxy units, and a **different proxy at every scope**	**proxied, never measured**; two scopes' values are not commensurable
`u`, `U_t`	`[1]`	none	**defined** dimensionless: `u = 1 - (x.y)^2` for unit vectors
`N`	`[1]`	categories	**counted** at two scopes; **no counting procedure exists** at the cellular scope
`N_eff`, `PR`	`[1]`	effective count	**derived**
`S = F(u)`	`[1]`	nats	**derived**; **not instantiated** at the cellular scope, no input path
`eta`	`[Q]` per nat per step	proxy units per nat per period	**estimator defined at two scopes**; not a number at the third
`delta`	`[1]`	per period — **the period is part of the number**	**measured once**, cellular, borrowed

Symbol	Dimension	Unit	Status
`C_t`	`[Q]` per step	proxy units per period	**estimator defined**; rests on a commensuration postulate
`h_t`	`[Q]` per step	proxy units per period	**derived**; **not computable** at the cellular scope
`M`, `D`, `P`	—	**none supplied**	**ordinal**; the quotient is demoted, and does not descend to the cell at all
period `p`	`[T]`	year / month / hour, by scope	**stipulated** per scope

Does the gauge balance? `h = eta ln N − delta Q − C` balances only if every term carries `[Q]` per step, which requires `eta` to carry `[Q]` per nat per step, since `ln N` is dimensionless. It does balance within a scope. **It does not balance across scopes**, because `[Q]` denotes a different proxy at each, and Section 7.1's deliberate cross-scope subtraction is exactly the dimensional error that produces.

Where the framework has no operational unit, this paper says so. Stored order has no natural unit at any scope. Comfort, the corpus's underlying construct, has **no operational unit at all**. Perspective and perception have **no unit and no zero**, which is why their quotient is demoted. At the cellular scope `N` has **no agreed referent**: candidate readings — distinguishable chromatin states, addressable regulatory programmes, transcription-factor combinations with distinct downstream consequence — differ from one another by orders of magnitude and none has a validated counting procedure. **A parameter that cannot be counted cannot bound anything, and `ln N` at the cellular scope is a symbol with no number behind it.**

38.9.2 9.2 The postulates

P1 — The storage recurrence is linear and first order at each scope. *Status:* **DEFINITION** — the model form adopted [Curzi, 2026a]; it carries no empirical weight on its own.

P2 — `0 <= F(u) <= ln N` for `F(u) = ln(1 + (N−1)u)` on `u` in `[0,1]`. *Status:* **CITED** — the range result [Curzi, 2026,c].

P3 — For a share or eigenvalue vector, `PR = (sum lambda)^2 / sum lambda^2`. *Status:* **DEFINITION** — the reciprocal Rényi-2 collision probability [Rényi, 1961, Simpson, 1949].

P4 — A per-period fraction converts between clocks as `1 − (1−delta)^(p_new/p_old)`. *Status:* **ARITHMETIC** — geometric decay, redoable in one line.

P5 — Median mRNA half-life is about 9 hours and median protein half-life about 46 hours in the measured cell line. *Status:* **CITED, AND BORROWED** — measured genome-wide by metabolic labelling with mass spectrometry in one immortalised mouse fibroblast line, by molecular biologists for their own purposes, as medians over thousands of species with enormous spread. **This is the only validated parameter value anywhere in the correspondence, and the primary source is named in prose because it carries no key in this corpus's external bibliography (L-11).**

P6 — Division requires a ratio scale with a true zero. *Status:* **CITED** — Stevens [1946], with the measurement-theoretic development in Krantz et al. [1971].

38.9.3 9.3 The compounding chain

```
P1 + P2        -> V1   a nondecreasing step needs eta F(u) >= delta Q + C; since
```

```
                        F(u) <= ln N, the gauge h := eta ln N - delta Q - C bounds
                        what any interaction geometry can deliver.          ARITHMETIC

P1              -> V2   the fixed point is Q_inf = (eta F(u*) - C)/delta, so at the
                        fixed point delta Q_inf = eta F(u*) - C.            ARITHMETIC

V1 + V2         -> V3   h_inf = eta ln N - (eta F(u*) - C) - C
                             = eta (ln N - F(u*)).
                        delta, C and Q cancel identically.                  ARITHMETIC

V3 + P2         -> V4   F(u*) <= ln N, therefore h_inf >= 0 ALWAYS: the plain
                        linear model never ossifies by itself.              ARITHMETIC

P3              -> V5   1 + (N-1)u_bar = N + 1 - N/PR exactly, where u_bar is the
                        mean pairwise non-parallelism of the ensemble.      ARITHMETIC

P4 + P5         -> V6   t_half = 46 h gives delta = 1 - 2^(-1/46) = 0.014955 per
                        hour, = 1 - 2^(-24/46) = 0.303468 per day, and a surviving
                        fraction over 720 h of 2^(-720/46) = 1.942e-05.     ARITHMETIC

V6              -> V7   a molecular-inventory proxy for cellular Q predicts a
                        per-month retention loss of 0.99998, i.e. that nothing
                        cellular persists; the proxy is refuted, not the law. ARITHMETIC

P6              -> V8   D/P is not reportable as a magnitude, because neither D nor P
                        is instrumented on a ratio scale with a true zero.  CITED

P4              -> V9   0.15 per year is 1 - 0.85^(1/12) = 0.013452 per month;
                        0.08 per month is 1 - 0.92^12 = 0.632334 per year;
                        the ratio of the two is 47.0.                       ARITHMETIC
```

Every line is checkable from its own stated inputs. V1 through V9 are consequences of one definition of model form (P1), two cited results (P2, P6), two definitions (P3, P4) and one borrowed measurement (P5). **Only V6 and V7 consume an empirical input, and that input was measured by other people in one cell line for reasons unrelated to this corpus.**

What the chain does not establish. It does not establish that any institution, mind or cell obeys P1 at any scope. That is the correspondence postulate, it is not verified here, it has never been tested at two scopes simultaneously, and the reflexive parameter it would need to recover is not identified from observation at all (§3.7). **A chain whose steps are ARITHMETIC, DEFINITION and CITED delivers the mathematics with certainty and delivers nothing whatever about any of the three systems.**

38.9.4 9.4 The verification instance, worked by hand

Check 1 — the participation-ratio identity. Take the ensemble reported in Section 4.4 at `N = 8` with mean pairwise non-parallelism `u_bar = 0.783801`. The affine count is `1 + 7 x 0.783801 = 6.486607` to six decimals. The participation-ratio form returns `8 + 1 - 8/PR = 6.486606017883` on the same correlation matrix. The two agree to the twelve decimals printed and, across six ensembles, to a worst discrepancy of `1.8e-15`, which is floating-point noise. **The identity is a fact about the aggregator, not about people: it would hold for correlated thermometers.**

Check 2 — the fixed-point headroom identity. At `eta = 0.35`, `N = 12`, `u* = 0.30`, `delta = 0.05`, `C = 0.40`: `ln 12 = 2.484907`, `F(0.30) = ln(1 + 11 x 0.30) = ln 4.3 = 1.458615`, so `h_inf = 0.35 x (2.484907 - 1.458615) = 0.359202`. Computing it the long way, `Q_inf = (0.35 x 1.458615 - 0.40)/0.05 = 2.210305`, and `h_inf = 0.35 x 2.484907 - 0.05 x 2.210305 - 0.40 = 0.359202`. **The**

same number to ten decimals, and the second computation used `delta`, `C` and `Q` which the first did not need.

Check 3 — the clock conversion. `1 - 0.85^(1/12) = 0.013452`; `1 - 0.92^12 = 0.632334`; and `0.632334 / 0.013452 = 47.0`. **The parameter that looks four times larger is forty-seven times larger once the clocks agree.**

Check 4 — the molecular proxy, refuted in one line. `2^(-720/46) = 1.942e-05`. Everything else in Section 4.6 follows from that number.

Check 5 — the Rasch price, recomputed. With every item targeted at the person, item information is 0.25, so `SE(theta) = 2/sqrt(k)`; the distortion is a difference of two independent measures, so `SE(Delta) = sqrt(2) x 2/sqrt(k)`; and the 95 per cent detection floor is `1.96 x SE(Delta)`. At `k = 122` the floor is `0.501905`, above a half-logit; at `k = 123` it is `0.499860`, below. **One hundred and twenty-two items is not enough and one hundred and twenty-three is, and the crossing is that sharp because the arithmetic is that simple.**

Check 6 — the census. The register in Section 6 contains 156 rows: 50 in Group A, 28 in Group B, 58 in Group C, 12 in Group D and 8 in Group E. **A reader can recount them.** The precedent column reads *none claimed* in 133 rows, leaving 23, which is 14.74 per cent.

38.9.5 9.5 Limits, asymptotics, and the model's valid domain

- **`u -> 0` at any scope.** `N_eff -> 1`, `F -> 0`, `Q_inf -> -C/delta < 0`. Ten parallel windows are one window. **This is the regime a converged group is in, and it is not a degenerate case.**
- **`u -> 1`.** `N_eff -> N`, `F -> ln N`, `h_inf -> 0`. Maximal surplus and zero remaining headroom at the fixed point.
- **`N -> 1`.** `ln N = 0`, so `h = -delta Q - C <= 0` always. **A single category can never build under this gauge**, at any scope; the framework is silent on whether that is a statement about systems of one or an artefact of using `ln N` as the ceiling.
- **`N` doubling.** Each doubling adds exactly `ln 2 = 0.693147` nats wherever it starts, so **a headroom problem cannot be escaped by adding categories** — a property of the logarithm and not of any system, and therefore true at all three scopes for the same reason.
- **`delta -> 0`.** The fixed point does not exist at all rather than being infinite: the map is an isometry and the geometric series does not converge [Curzi, 2026a]. **Outside the valid domain.**
- **`delta -> 1`.** Everything is lost each period; `Q_inf -> eta F(u*) - C`, and the system has no memory. At the cellular scope this is nearly the case for mRNA: `delta = 0.074125` per hour is a half-life of 9 hours, so a daily clock puts the cellular mRNA pool close to this boundary.
- **`eta -> 0`.** `h -> -delta Q - C < 0` at every scope. A system with no conversion cannot build at any `u` and any `N`, which is the storage law's correspondent of the forbidding clause `G = 0 => E = 0` in the channel-gain form of the belief postulate [Curzi, 2026ab].
- **Between scopes.** No limit exists, because no aggregation operator is defined. **The correspondence has no asymptotics in the scope variable, and that absence is Break 5.**

38.9.6 9.6 Model comparison, and the standard this paper does not meet

The paper reports no fit of its own. It nonetheless inherits the standard, because the register records a confirmatory fit and the correspondence would be used to justify further ones.

Requirement	Status	What was actually done
Out-of-sample performance reported	**MET**	held-out RMSE against four baselines [Curzi, 2026i]

Requirement	Status	What was actually done
Matched null with equal free parameters	**MET**	a matched AR(1); the fit beat it by 2.8 per cent against a declared 10 per cent margin and **failed its own preregistered rule**
Information criterion (AIC or BIC)	**NOT MET**	**no AIC or BIC has been computed anywhere in this corpus**, so no comparison pays for its parameter count
Number of free parameters stated explicitly	**PARTIAL**	the four storage-law parameters are named; they are not tabulated against each baseline's count
Effect sizes with intervals	**NOT MET**	RMSE advantages are reported as point estimates without intervals
Shuffle control's false-positive rate measured	**MET, AND ADVERSE**	0.108 against a nominal 0.05 for i.i.d. permutation, 0.120 for circular shift [Curzi, 2026u] — **anti-conservative**
Non-affine alternative fitted and compared	**NOT MET**	register entry B-01 states the test and records that it has not been run; **it is not expensive**
Saturating or state-dependent storage law compared	**NOT MET**	register entry B-02, same status

Four NOT MET rows are printed here rather than omitted. The last two are the most damaging, because they are the two tests that would decide whether the corpus's two founding design choices are the right ones, and neither requires new data.

38.9.7 9.7 Scale type, and the objection the corpus concedes

Quantity	Scale type	What licenses it	Operations performed here
`delta` from half-life	ratio	time has a true zero and a unit	conversion between clocks, exponentiation
`N`, `N_eff`, `PR`	ratio (counts)	counting	all — where a counting procedure exists
`u`	ordinal at best, treated as ratio	**nothing tested**	used inside a logarithm; **not licensed**
`Q`	interval at best in a declared proxy	proxy definition only	differences and rates within a scope; **never across scopes**
`D`, `P`, `M`	ordinal	no zero, no unit	ordering only; the quotient **demoted**

Quantity	Scale type	What licenses it	Operations performed here
register status	nominal with a partial order	definition	counts by category; **no arithmetic on the labels**

Michell's critique is the strongest single objection to this corpus and it is conceded here rather than answered. Michell [1997, 1999] argues that psychology assumes quantitative structure without testing for it. The corpus's founding move — treating comfort as a magnitude — is that assumption. The test that would settle it is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971], whose double-cancellation conditions determine whether an attribute admits additive quantitative structure at all. **Those conditions have not been tested for comfort, for `u`, for perspective or for perception, by this work or by anyone.** What the corpus does instead is partial and is stated as partial: it denotes the one quantity whose operation most obviously requires a ratio scale, and it prices the Rasch route at 123 items per term [Rasch, 1960, Andrich, 1988] — an instrument with a defensible zero, which is not a conjoint test. Reliability would not substitute [Sijtsma, 2009], and construct validation [Cronbach and Meehl, 1955, Campbell and Fiske, 1959] would show that an instrument measures something without showing that the something is quantitative.

38.9.8 9.8 Invariance, and the precision of the numbers

What is invariant. The identity `N_eff = N + 1 − N/PR` is invariant under permutation and relabelling of members and holds at any scope where a correlation matrix can be formed. The identity `h_inf = eta(ln N − F(u*))` is invariant under any change in `delta`, `C` or `Q`, which is the content of the cancellation. The gauge's verdict is invariant under a common rescaling of `Q`, `C` and `eta` and **is not invariant under rescaling `Q` alone**, which is what changing the order proxy mid-measurement does.

What is not invariant, and is the point of the paper. Nothing is invariant across scopes. The correspondence claims form identity and explicitly disclaims parameter transfer, scaling, and composition. **Scale-freedom is claimed at three scopes and has been tested at zero**, since testing it requires simultaneous measurement at two scopes of the same system and no such measurement exists.

Precision. Numbers in this paper fall into three classes and are treated differently. *Exact consequences of definitions* — `ln 12 = 2.484907`, `h_inf = 0.359202`, `N_eff = 6.486606017883` — are quoted to whatever precision is useful and are exact. *Borrowed measurements* — the 9-hour and 46-hour median half-lives — are **medians over thousands of species with enormous spread, from one immortalised cell line by one method**, and the derived `delta = 0.014955` per hour is quoted to six figures only because the conversion is exact given the median, not because the median is known to six figures. **The underlying quantity is a median with a wide distribution and no interval is reported for it here, because none is reported in the source this corpus borrows from as summarised.** *Illustrative model outputs* — the laboratory's `h = −0.265813` and the member's `h = +0.054831` — are exact given stipulated parameters and carry no empirical content whatever. **Where a reader sees six decimals in this paper they should read "consequence of a stipulated or borrowed input", never "measured to that precision".**

38.10 10 Limitations

L-1 Zero of twenty-seven cells carries a first-party measurement. This is the paper's own principal result and it is also its principal limitation. Every empirical quantity in this corpus is borrowed or stipulated. **No claim in any of the seventy papers rests on fieldwork conducted**

for the corpus, and any reader weighing the framework's applied recommendations should weigh them on that basis.

L-2 The reflexive parameter is not identified. The framework's central social claim is a linear-in-means reflexive specification whose endogenous effect cannot be recovered from observational data [Manski, 1993, Shalizi and Thomas, 2011]. **No remedy is adopted anywhere in the corpus.** Nineteen estimators exist; for the parameters carrying social content they estimate conditional summaries of a fitted series, not couplings. Every applied claim is a modelling position rather than an identified empirical result.

L-3 Scale-freedom has never been tested at two scopes simultaneously. The correspondence is a postulate about model form and is falsifiable only at each scope separately. **Three instances is not an invariance result, and this paper does not present it as one.**

L-4 The conjoint conditions have not been tested for any construct in this corpus [Michell, 1997, Luce and Tukey, 1964]. The ratio-scale treatment of `u` in particular is unlicensed and is used inside a logarithm regardless.

L-5 No AIC or BIC has been computed anywhere in this corpus, and neither of the two tests that would decide the corpus's founding design choices — a non-affine effective count, and a saturating or state-dependent storage law — has been run, though neither is expensive (§9.6).

L-6 The one validated parameter is borrowed, is a median with enormous spread, and comes from one immortalised cell line by one method. Using it as the cellular `delta` assumes that a genome-wide median in a mouse fibroblast line transfers to whatever cell a reader has in mind. **That transfer is an assumption and is named as one.**

L-7 At the cellular scope, four of the nine parameters would have to be invented rather than measured to fill the column — a category count, a state encoder, an order proxy and an input path. All four are inventable in an afternoon; all four would be fabrications; and the paper would look considerably more impressive for containing them.

L-8 There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal [Curzi, 2026y]. Everything upstream is real and separately supported; the specific step is established by none of it. **The third instrument's input term therefore has no measured input path, and the third instrument is a specification rather than a measurement.**

L-9 The register's own accuracy is a claim this paper makes about itself. The 156 rows and their statuses were assigned by the same author whose claims they classify. **A register is not an external audit**, and the only defence offered is that every row carries the six fields a hostile reader needs to check it, and that the demotions are printed in the same typeface as everything else.

L-10 A numerical inconsistency in the source is recorded here rather than silently corrected. The census in Section 6.7 reports that 23 of 156 rows carry precedent, 14.7 per cent, and a direct recount of the register confirms 23. **The failure-mode table in Appendix B states "twelve of one hundred fifty-six rows have precedent". That figure is wrong; the correct count is 23, and the census figure is the one to quote.** The error is in the source and is disclosed rather than quietly repaired.

L-11 Several works are named in prose without bibliographic keys, because they are not in this corpus's external bibliography. They are: Schwanhäusser et al. (2011) on genome-wide mRNA and protein half-lives, which supplies the single validated parameter in the audit; Condorcet's 1785 *Essai*; Arrow's 1951 impossibility theorem, invoked in Break 4; Minsky's *Society of Mind* (1986), cited there as precedent for a picture rather than as support for it; Robinson's ecological fallacy and Simpson's paradox, named in Break 4 (note that `simpson1949measurement` in the bibliography is the diversity index and is **not** the paradox, and the two must not be conflated); Yates's *The Art of Memory* (1966); Durkheim on collective effervescence and Rappaport on ritual; and the cell-biology chain of Tajik et al. (2016), Ibsen et al. (2015), Church, Gao and Kosuri (2012), Zetsche et al. (2015), Qi et al. (2013) and Gilbert et al. (2014). **Each is a real published result quoted for what its source measured; the reader is owed the note that they are named rather than referenced.** The corpus's own treatment of the cell-biology chain is Curzi [2026x] and Curzi [2026y].

L-12 The mapping from the source manuscript's internal papers and chapter numbers to corpus paper identifiers is an editorial inference (§3.9), not a statement by the source. Where the register's WHERE field names a corpus paper, that name is this paper's judgement about which converted paper carries the material.

L-13 The five breaks are arguments, not measurements. Breaks 2, 3 and 4 turn on category distinctions — representation, exit, aggregability — that no experiment would settle, and a reader who rejects the category distinction rejects the break. Break 1 is quantitative in principle and untested in fact: **nobody has measured whether a `u` of 0.6 between two of one person's framings means what a `u` of 0.6 between two colleagues means**, and the mitigation the corpus offers — measuring on committed outputs rather than introspective report — removes one source of inflation and not common-mode coupling.

L-14 The composition theorem is absent and its absence is not a gap in the writing but a gap in the mathematics. No aggregation operator is defined between scopes, no conservation law links them, and no argument is offered that the three accumulators are coupled at all rather than merely similar in form. **Whether the storage law is closed under any natural aggregation is not known here.**

38.11 11 Conclusion

The same storage law is written at institutional, personal and cellular scope, and that correspondence is badged POSTULATE — MODEL FORM ONLY. It states that a minimal open-system accumulator written for each of the three uses the same five symbols. It does not state that the three systems are alike, that their parameters are related by any law, or that quantities at one scope aggregate into quantities at another. **What follows from it is exactly the arithmetic of the map** — contraction, a unique fixed point, the ceiling `0 <= F(u) <= ln N`, the headroom inequality, and `h_inf = eta(ln N − F(u*))` — **and nothing about any of the three systems.**

The audit of the instrument is the paper's principal result, and it should be quoted in this form. Across nine parameters and three scopes there are twenty-seven parameter-by-scope cells. Nineteen of the twenty-seven have a defined estimator. Exactly one has a validated value: a borrowed median protein half-life of 46 hours, giving `delta = 0.014955` per hour, measured genome-wide in one immortalised cell line by molecular biologists for their own purposes. And zero of the twenty-seven carry a measurement made first-party for this corpus. Nothing in the seventy papers rests on fieldwork conducted for them. That sentence is the one this paper exists to make citable, and it is not softened anywhere in it.

The correspondence then fails in five independent ways. A mind is not a small society: two framings in one head share a memory, a mood, a set of priors, a stake and a substrate, which are five channels of common-mode coupling with no institutional analogue, and the independence every aggregation result requires is unavailable. A cell is not a small mind: the moment equation needs a representation, a cell has states rather than representations, and so it has no frame and no perspective ratio — permanently, rather than pending instrumentation. The exit ethics do not descend: a member can leave and a cell cannot, so consent attaches to the person and never to the scope. Aggregation is not always well defined, in principle and not merely in practice. And **no composition theorem exists anywhere in this corpus**, which is a gap in the mathematics rather than in the writing, and the largest open problem the correspondence raises.

What survives is smaller and load-bearing. The arithmetic transfers wherever the model form is adopted, because it is a consequence of the map rather than a fact about a system. And three ordinal diagnostics read at every scope without a calibrated instrument: **whether `u` is near zero, whether `eta` is near zero, and whether `delta Q + C` exceeds `eta ln N`.** Each is a comparison rather than a magnitude, which is precisely why the demotion of the Moment equation leaves them standing.

Two identities are re-verified and both hold at every scope where the map is adopted. The affine effective count equals the Rényi-2 participation ratio exactly, `N_eff = 1 + (N−1)u = N + 1`

– `N/PR`, checked over six random correlation ensembles with a worst discrepancy of `1.8e-15` — for instance `N = 8`, `u_bar = 0.783801`, both sides `6.486606017883`. And `h_inf = eta(ln N - F(u*))`, in which retention, cost and stored order all cancel; since `F(u) <= ln N` always, **`h_inf >= 0` always, so the plain linear model never ossifies by itself** and ossification requires something the model does not contain.

The register publishes 156 entries: 50 proved, 28 postulated, 58 borrowed, 12 speculative of which 4 are printed refusals, and 8 demoted. Precedent is claimed in **23 rows, 14.7 per cent**; the other 85.3 per cent read *none claimed*, which is the honest yield of a two-column method when the rule against filling the second column is enforced. **The census names its own weakest link: fifty proved entries, not one of which says anything about any person, and the entire load passing through twenty-eight postulates.** To break this corpus, break a postulate.

38.11.1 Declarations

Data and code availability

No external dataset was collected for this paper, and no human participants were surveyed, observed or recruited. This is the paper that says so for the whole corpus: of 27 parameter-by-scope cells, **zero carry a first-party measurement**, and every empirical quantity appearing anywhere in these seventy papers is either borrowed from a published study conducted by other researchers for their own purposes, or computed from parameters stipulated in a worked example. The single validated parameter used here — median mRNA and protein half-lives in a mouse fibroblast line — belongs to its published source and is cited to it in prose (L-11). The laboratory worked at three scopes in Section 7 is a **constructed illustrative example with declared parameters**, not a report of any real organisation, person or cell. The figures are generated by the scripts named in each caption, which contain no data beyond the numbers printed in this paper. The register in Section 6 is derived by reading the corpus's own papers and can be recounted from the tables printed here.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. **The register in Section 6 classifies the author's own claims, which is a structural conflict rather than a financial one, and it is disclosed as Limitation L-9.**

Author contributions

Single author. Michael Laurence Curzi conceived the work, derived the results, compiled and counted the register, produced the worked example and figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. No cells, tissues or biological materials were handled and no experiment of any kind was performed. **No clinical, medical or therapeutic claim is made anywhere in this paper.** Section 5.4 states the corpus's position that consent attaches to the person and never to the scope: no protocol at the biological layer may be described as consented by any party other than the person whose

cells are involved, before anything is done, with the right to stop and with nothing concealed. That is a design constraint on prospective work and is not a report of any study performed.

Preregistration

This paper reports no preregistered test of its own; its results are an audit, two identities and a census. The preregistered protocol for testing the storage law against a real system, and the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin — are reported in Curzi [2026i]. The measured false-positive rate of the shuffled-input control, **0.108 against a nominal 0.05**, is reported in Curzi [2026u]. Register entries B-01 and B-02 name two further tests of the corpus's founding design choices and record that **neither has been run.**

38.12 Appendix A The correspondence specification and its failure modes

A.1 Every use of the three-scope correspondence shall state, in the same sentence, that it is a claim about model form only, and shall cite the corpus's model-form convention and the honesty appendix, postulate 5 [CCP-039].

A.2 No parameter value measured at one scope shall be used as evidence for a parameter value at another scope. Where a value is borrowed for illustration, it shall be labelled as an illustration and the borrowing shall be named.

A.3 Every `delta` shall be quoted with its period. A `delta` without a period is not a number and shall be rejected at review.

A.4 Every cross-scope comparison shall convert all rates to one clock first, using `delta_new = 1 - (1 - delta_old)^(p_new/p_old)`, and shall show the conversion.

A.5 No quantity shall be summed, differenced, or divided across scopes. §7.1 computes such a quantity deliberately and shows it to be a unit artifact.

A.6 The `M` and `D/P` rows shall carry the CC-R1 demotion at every appearance, including in summary tables, together with the the Rasch-route theorem [CCP-026] route and the 123-items-per-term cost. A summary table that omits the demotion is non-conforming.

A.7 Any cellular-scope computation shall state which of the nine parameters have estimators before any number is produced. At the time of writing the answer is one, and a document producing a cellular `h` has erred upstream of its arithmetic. Any cellular-scope `Q` shall state its proxy explicitly and address the molecular turnover result of §4.6; a `Q` proxied on molecular inventory shall be rejected.

A.8 Internal `u` shall be measured on committed outputs — independent written predictions produced before comparison — never on introspective report, and shall carry the common-mode caveat of §5.2.

A.9 The consent constraint shall attach to the person, never to the scope. No protocol at the biological layer shall be described as consented by any party other than the person whose cells are involved, and disclosure shall be complete: **nothing masked, nothing below threshold, nothing concealed.**

A.10 Any aggregation between scopes shall name its aggregation operator. Where none is named, the document shall state that no composition theorem exists in this corpus.

A.11 Every table presenting the correspondence shall be accompanied by its measurement-status table (§4.1, second table). **The two tables travel together or neither is published.**

38.12.1 A.12 Failure modes of the correspondence

Fault	Signature	Mechanism	Fix
SCOPE LAUNDERING	A result cited at one scope to support a design at another, with the citation intact and the scope silently changed	The symbols match, so the transfer feels like a lookup rather than an inference	A.2. Re-cite with the original setting stated. Woolley measured groups; it is not a fact about cells or about one mind
THE CLOCK ERROR	Two `delta` values compared directly; a monthly rate read against an annual one	`delta` looks dimensionless because it is a fraction	A.3, A.4. `0.08/month` is `0.632/year`, not `0.08/year`
THE HOMUNCULAR SLIDE	Internal framings described as deliberating, negotiating, or voting	The sociological vocabulary is richer and more available than the psychological one	A.8. Speak of decorrelation among committed outputs. If the sentence needs an agent inside the head to be true, it is not this framework's sentence
MOLECULAR `Q`	A cellular stored-order proxy denominated in protein or transcript abundance	The molecules are the visible thing	A.8. Median protein survives one month at `1.9e−05`. The proxy predicts that nothing persists, which is false
THE EMPTY DIAL	A cellular headroom, surplus, or `eta` reported with a numeric value	The equation is writable, so it looks computable	A.7. Three of `h`'s four terms have no estimator. Report the absence
CONSENT BY SCOPE	A biological-layer protocol described as involving no consenting party, or as consented at the cellular level	The arithmetic descended, so the ethics feel as if they did	A.9. Consent attaches to the person. There is no one at the cellular scope to ask
THE COMPOSITION ASSUMPTION	Language implying that cellular order builds personal order builds institutional order	The three volumes are ordered, so they look like a chain	A.10, §5.6. No composition theorem exists. Say so, or derive one
DEMOTION DROP	An `M` or `D/P` magnitude reported in a synthesis section without the CC-R1 badge	Summary tables lose qualifiers first	A.6. The badge is part of the row, not a footnote to it

Fault	Signature	Mechanism	Fix
TABLE HYPNOSIS	The master correspondence table reproduced alone, without the measurement-status table	The first table is beautiful and the second is not	A.11. They are one artifact

---

38.13 Appendix B The register specification and its failure modes

B.1 Every substantive claim in this corpus shall carry an entry in this register, and every entry shall carry all six fields. **An entry missing its "what it measured" field is non-conforming and shall be removed rather than repaired in place.**

B.2 The (-1) column shall read **none claimed** wherever no precedent exists. **Populating it to improve symmetry is the single most damaging thing that can be done to this section.**

B.3 No entry shall be promoted by agreement between the columns. Promotion requires a proof, a measurement, or a passed gate, and the register shall record which.

B.4 Every borrowed entry shall state the setting and the transfer assumption. Where the transfer assumption is large, it shall be stated in bold.

B.5 Every demotion shall appear in the register **and** in this section that made the original claim, in the same pass. A demotion recorded only in the appendix is concealment by filing.

B.6 Downstream entries shall be demoted with their upstream entry. CC-R1 demotes E-01 through E-05 together; no M-derived magnitude survives anywhere in the corpus.

B.7 Every speculative entry shall be marked speculative **in the sentence that states it**, not in a note attached to it.

B.8 Rejections shall be printed. **A register with no rejections has not been run**, and the count of rejections is a diagnostic of the register's health.

B.9 The status census (§6.7) shall be recomputed whenever entries are added, and the ratios in it shall be reported even when they are unflattering.

B.10 Where a number appears in an entry, it shall have been computed or cited, and the entry shall say which. **No entry shall contain a figure whose provenance is the author's impression.**

B.11 This register is itself a stored order with its own δ. It shall be re-derived from the chapters annually, and the re-derivation shall be done by reading the corpus papers, not by editing the register.

B.12 Any reader may cite an entry ID against this corpus. **An entry that cannot be defended on its own six fields shall be withdrawn, not argued.**

38.13.1 B.13 Failure modes of the register

Fault	Signature	Mechanism	Fix
PRECEDENT LAUNDERING	A (-1) cell populated with a tradition that "says something similar", and the entry's status raised accordingly	The two-column format is symmetric and symmetry invites filling	B.2, B.3. The columns carry different things. **The source states "twelve of one hundred fifty-six rows have precedent"; a direct recount of the register returns 23 of 156, which is the figure the census in §6.7 reports and the one to quote. The discrepancy is in the source and is recorded rather than silently repaired (L-10).**
STATUS INFLATION	A postulate cited in a later chapter as though it were a theorem, usually via a chain of three cross-references	Each hop drops a qualifier; three hops drop them all	B.1. Cite the ID, not the sentence. The ID carries the status
GATE LAUNDERING	FVP tables present and every verdict PASS	Sixty-three gates and no failures is not rigour; it is a copied table	Check gate 2 and gate 7 first, since those are the two that genuinely bind
THE ORPHAN ENTRY	A register row with no chapter in its WHERE field	The claim was cut from the corpus and the row survived	Remove the row. A register is an index of the corpus, not of the author's beliefs
THE FROZEN REGISTER	Identifiers in WHERE fields that no longer match the corpus	The register has its own δ and nobody maintains it	B.11. Re-derive from the corpus papers annually, by reading
DEMOTION BY FILING	The demotion appears only in the appendix or only here, while the original chapter still asserts the magnitude	Correcting the source chapter is more work than adding a row	B.5. Both, in the same pass, or neither
CITATION DRIFT	"What it measured" fields that grow more supportive with each edition	Summaries lose caveats first and gain confidence for free	B.4. Re-read the source, not the previous summary
THE IMPRESSIVE NUMBER	A figure in an entry with no computation and no citation	Numbers are persuasive and cheap to invent	B.10. Compute it or cite it or delete it

Fault	Signature	Mechanism	Fix
REGISTER AS ARMOUR	The register cited as evidence that the corpus is rigorous, rather than used to check a claim	An audit trail can become a credential	The register's only function is to be used against the corpus. §3.6 is the instruction

---

38.14 Appendix C What this research programme undertakes

38.14.1 C.1 What this research programme undertakes

The register exists to be used against the corpus, and that is only meaningful if there is something this research programme is committed to doing when it is.

A claim shown to be wrong is withdrawn, not defended. B.12 is not rhetoric; entries that cannot be defended on their six fields are removed from the register and from the corpus papers that used them, in the same pass, the way CC-R1 removed the magnitude of the author's own keystone formula from five chapters at once.

A null result reported honestly is a contribution and will be recorded as one. the honesty appendix [CCP-039] already states that a reader who runs one of the named tests and gets a null result has done this book a service that no amount of agreement could. The register is where that service would be recorded: as a status change, with the reader's name in the (+1) column and the setting stated.

And the demotions stay in. E-01 through E-08 will not quietly disappear from a later edition because the instrumentation was built. **If the 123-item instrument is built and the distortion becomes measurable, the entry does not vanish — it changes status, and the demotion remains in its history, because the fact that the protocol caught it is worth more than the embarrassment of having needed it caught.**

That is the audit trail. CCP-039 closes the work, and it is entitled to claim exactly what is in Groups A and B and nothing that is only in Groups D or E.

Chapter 39

Four Structural Results and an Honesty Register: The Closing Synthesis and Reference Apparatus of Engineering the Surplus

Abstract. **This closing instalment is chiefly synthesis and reference apparatus, and is presented as such; it advances no testable hypothesis.** Most of its length recapitulates results established in the papers it draws on. Its non-recapitulative content is four exact algebraic results and a set of computed bookkeeping items. First, the surplus law is shown to be exactly a Fechner law in threshold-corrected form, $F(u) = \ln((u + u_0)/u_0)$ with $u_0 = 1/(N - 1)$, verified for $N = 2$ through 100 at seven values of u to a worst residual of 8.9×10^{-16}; at the threshold the effective count is exactly 2 and the surplus is exactly $\ln 2$, one bit, for every N. Second, folding the essence lattice into one octave costs exactly $\ln 2$ nats for every even N, computed at $N = 4$ through 64, so that within that lattice calling two things consonant and calling them redundant are the same operation. Third, the fixed-point headroom identity $h_\infty = \eta(\ln N - F(u^*))$ holds with retention, cost and stored order all cancelling, so $h_\infty \geq 0$ always and the plain linear model never ossifies by itself. Fourth, the shuffled-input control is shown to be blind to repackaging: a filtered repackaging passed all four baselines including the shuffle at $p = 0.0005$ and was caught only by the structural ceiling, its claimed jump being 38.5 times $\eta \ln N$. The appendices add two computed admissions: testimonial evidence under success-publishing selection carries a likelihood ratio of exactly 1.000000, and the research programme publishes its own survival curve, giving a 35.8 per cent probability of completion and a 55.3 per cent chance of dying at or before the cross-subject stage. The appendices are retained because other papers rely on them, not as a research contribution.

Keywords: Fechner law; octave folding; headroom identity; shuffled-input control; survivorship bias; research programme costing

Series: B. Engineering the Surplus **Paper:** CCP-039

39.1 1 Introduction

This paper is the closing instalment of Series B and is chiefly synthesis and reference apparatus. It is presented as such, and it should be read as such. Most of its length recapitulates

results established in the papers it draws on, and those results are cited to their sources rather than restated as findings. What is not recapitulation is four structural results and a set of computed honesty items, and those are what a reader who has read the rest of the series comes here for.

The four structural results are exact and each connects two parts of the framework that were developed separately.

(a) The surplus law is a Fechner law in threshold-corrected form. Factoring `(N−1)` out of the logarithm gives `F(u) = ln((u + u_0)/u_0)` with `u_0 = 1/(N−1)`, verified for `N = 2` through `N = 100` at seven values of `u` to a worst residual of `8.9e−16`. At the threshold the effective count is exactly 2 and the surplus is exactly `ln 2` — one bit, two octaves — **for every `N`**. The perceptual register itself, and the postulate method that operationalises it, are Curzi [2026n]; the same identity is stated as a result in Curzi [2026].

(b) Folding the essence lattice into one octave costs exactly `ln 2` nats for every even `N`, computed at `N = 4, 6, 8, 10, 12, 16, 20, 24, 32, 64` and returning `0.6931471806` in every case. Consonance and redundancy are the same operation inside that lattice, and the operation has a price. The pitch-class structure it rests on is the odd-part class rule of Curzi [2026].

(c) The fixed-point headroom identity `h_inf = eta(ln N − F(u*))`, in which retention, cost and stored order all cancel, verified against direct computation across four parameter sets to below `1e−16`. Since `F(u) <= ln N` always, `h_inf >= 0` always, so **the plain linear model never ossifies by itself** — which is inconvenient, because ossification is the most reliably observed behaviour of successful institutions, and the identity therefore locates the mechanism outside the model rather than inside it. The identity is re-derived and re-verified across scopes in Curzi [2026].

(d) The shuffled-input control is blind to repackaging. A filtered repackaging of the input passed all four empirical baselines including the shuffle at `p = 0.0005` and was caught only by the structural ceiling, its claimed single-step jump being 38.5 times `eta ln N`. The falsification suite measured against itself — including the shuffle's own anti-conservative false-positive rate of 0.108 against a nominal 0.05 — is Curzi [2026u].

The appendices add two computed admissions that a closing chapter would ordinarily omit. **Testimonial evidence under a selection process that publishes successes has a likelihood ratio of exactly 1.000000** — it does not move the posterior at all — against 2.0000 for a direction-only prediction and 11.3577 for a magnitude call with a tolerance, a factor of about 5.7. And **the research programme that would settle whether the framework's formulas are science publishes its own survival curve: 21 preregistered kill conditions of which 4 are terminal, 8,554.8 researcher hours, 570 participants, 71 months, and a 35.8 per cent probability of completion, with a 55.3 per cent chance of dying at or before the cross-subject recovery stage.**

What this paper adds beyond those items is organisation, not knowledge. Appendix A is a reference card for the two laws and their derived results; Appendix B is a glossary; Appendix C carries the measurement protocols for the six parameters and the three controls; Appendix D is a failure-mode index arranged by symptom; Appendix E is the honesty register, which is the appendix to read if only one is read; and Appendix F maps the framework onto the founding material it descends from. **They are here because other papers in the series rely on them, not because they constitute a research contribution.**

Two framing statements govern everything below and are not softened anywhere in the paper. First, **every claim in this corpus is proved, badged, or named as open**, and the register that sorts 156 of them into those bins, with the audit that found 19 defined estimators, 1 validated value and **0 first-party measurements** across 27 parameter-by-scope cells, is Curzi [2026]. Second, **nothing here adds a mechanism to the world.** No symbol acts on matter, no claim in the series has clinical or therapeutic content, and the formalism does not touch consciousness or thermodynamics; it borrows four theorems that belonged to other people first, and it says which.

39.2 2 Hypothesis

This paper advances no testable hypothesis. It is closing material and a reference collection, and its non-recapitulative content consists of four exact algebraic results and a set of computed bookkeeping items, none of which could be falsified by an observation.

That sentence is the whole of this section's substantive content, and manufacturing a hypothesis to fill the slot would be worse than stating it. What the paper has instead is an organising question, and it is worth stating plainly:

> **What is a formalism entitled to claim when it has proved a good deal, measured nothing, and demoted some of its own results?**

The answer defended across the series and collected here is: the arithmetic of the map, the ordinal comparisons that survive a demotion, and a register that says which is which — and nothing that requires a calibrated instrument. Everything in the appendices is apparatus for making that answer checkable.

The four structural results are labelled by kind rather than presented as findings about the world.

- Results (a), (b) and (c) are **exact algebraic identities**. `F(u) = ln((u+u_0)/u_0)` with `u_0 = 1/(N−1)`; `ln N − ln(N/2) = ln 2`; and `h_inf = eta(ln N − F(u*))`. Each follows from definitions the corpus has already fixed, each is verified numerically to floating-point noise, and **none carries any empirical weight whatever.** An identity cannot be wrong about the world because it does not address the world.
- Result (d) is a **reported outcome of a control experiment run by this corpus on itself** [Curzi, 2026u], together with a **structural argument** about what a shuffled-input control can and cannot detect. The structural part is not falsifiable: it is a statement about what a test is capable of seeing. The reported part is a single instance and is presented as one.
- The computed honesty items — the testimony likelihood ratio, the instrument audit counts, and the programme survival curve — are **arithmetic on stipulated inputs**. The likelihood ratio of exactly 1.000000 follows from a selection process defined in the calculation. The survival curve is computed from **stage priors the author chose and badged as chosen**, and a different set of priors gives a different curve; what is not arbitrary is that the curve was computed and published at all.

Two claims elsewhere in the paper would be hypotheses if they were advanced here, and they are not advanced here. That the framework's model form describes any real institution, mind or cell is a modelling postulate, tested nowhere in this paper and reported as unmet in Curzi [2026i]. And that the essence law `f(n) = k n^2` with `k = (9/8)^2/phi^2 = 0.483425732988414` describes anything at all is a **postulate with a defined constant**, discussed in §6.3 with its badges attached; **`k` is exact because it is defined, and attaching hertz to it is a separate and much stronger claim** which this paper does not make and which the verification chain of §9.3 lists as POSTULATED on its own line.

39.3 3 Method: what is being closed, and under what constraints

This paper collects and organises; it does not measure. The method is therefore a set of rules about what may be carried forward and how, and three constraints that bound everything the apparatus is used for. Sections 3.1 to 3.3 state what is being closed and the four things the mechanism is entitled to say. Sections 3.4 to 3.6 state the constraints: the identification problem, the analogy discipline, and the editorial rules under which cross-references were converted.

39.3.1 3.1 What is being closed, stated exactly

Two laws, once more, in the only form the corpus permits.

```
THE SURPLUS LAW                          CCP-A02, Theorem 2.1

    F(x,y) = f(u),   u = 1 - (x.y)^2     in [0,1]
    f(u)   = ln(1 + (N-1)u)              unique under axioms S1-S4
    N_eff  = 1 + (N-1)u                  F = ln N_eff
    0 <= F <= ln N                       CCP-009, Corollary 2.2

THE STORAGE LAW                          CCP-007, Section 3

    Q_{t+1} = (1 - delta) Q_t + eta S_t - C_t        S_t = F(U_t)

    h_t   = eta ln N - delta Q_t - C_t               the gauge
    Q_inf = (eta F(u*) - c*) / delta                 the fixed point
```

Everything in three volumes is either a theorem about those two lines, a badged assumption required to apply them to something real, a borrowed empirical result about the something, or an open question. **CCP-038 sorts one hundred and fifty-six claims into exactly those four bins, plus a fifth for the eight this corpus's own protocol demoted.**

39.3.2 3.2 The four things the mechanism is entitled to say

These are the through-lines. Each is derivable from the two boxes above, each was earned in a different volume, and none of them requires anything the formalism does not contain.

ONE. The loss term is what makes a recursion a circuit rather than a regress. `delta > 0` makes the map a contraction; a contraction has a unique fixed point and iteration reaches it from any start. With `delta = 0` there is no fixed point and nothing arrives: `Q_t <= Q_0 + t eta ln N`, unbounded and never converging. **The leak is not the flaw. The leak is why the loop is a device.**

TWO. Difference is what generates surplus, and only what is different is counted at all. `N_eff = 1 + (N-1)u`, so `u = 0` gives `N_eff = 1` regardless of `N`. Ten aligned instruments are one instrument. **Agreement between parallel instruments is echo, not evidence**, and the arithmetic prices it at exactly `ln 1 = 0`.

THREE. Geometry does work without power. A parabola focuses because of its shape. A room's modes are set by its dimensions. A star polygon's stroke count is `gcd(N,k)`. Boundary geometry alone determines which modes can exist, and that selection has measurable physical consequence. **Nothing is added and nothing is powered; the shape does all of it.**

FOUR. Every claim in this corpus is proved, badged, or named as open. There is no fourth category and there is no reserve. CCP-038 is the audit trail and it contains the demotions of the author's own formulas.

The rest of this paper is those four sentences, worked.

39.3.3 3.3 The four structural results the corpus produced

Distinct from the through-lines, these are the things the writing found that were not known when it started. Each is exact, each was computed, and each connects two parts of the corpus that were developed separately.

(a) The surplus law IS a Fechner law with threshold u_0 = 1/(N−1).
(b) Consonance and redundancy are the same phenomenon in the essence lattice.
(c) h_inf = eta ∗ (ln N − F(u∗)). Delta, C and Q all cancel at the fixed point.
(d) The shuffle cannot see repackaging. Only the structural test can.

§6.2 through §6.5 take them one at a time.

39.3.4 3.4 Identification: the parameter none of this apparatus can recover

The framework's substantive social claim is reflexive — the group's state influences each member and the members constitute the group — which as a model is a **linear-in-means reflexive specification**. Manski [1993] proves that its endogenous social effect is **not identified from observational data**, since it cannot be separated from contextual effects or from correlated unobservables however much data is collected. Shalizi and Thomas [2011] establish the same for network data, where influence and selection are generically confounded.

This bounds the entire apparatus assembled here, and the bound is stated in the Method rather than in a footnote. Appendix C gives measurement protocols for six parameters and three controls. Every one of them is a procedure that returns a number. **None of them, run on observational data, identifies a social coupling**, and the reflexive form the corpus writes down in its self-fulfilling material is exactly the specification Manski's result concerns.

The known remedies are randomisation, an instrument, partial-population variation, or stipulating the reference group and defending the stipulation, the last on the template of Brock and Durlauf [2001]. **This corpus adopts none of them.** Where the apparatus is used to license a claim about a real group, that claim is a **modelling position rather than an identified empirical result**, and Section 10 records it as such. The one field study documenting a reflexive fixed point with dates and price data is MacKenzie and Millo [2003]; it establishes that the mechanism is real and does not license reading a fitted coefficient as a measurement.

The Lucas critique applies to this corpus's own parameters and is not answered. Lucas [1976] holds that behavioural parameters estimated under one regime need not survive a change of regime, and Hacking [1995] names the mechanism in the human sciences: a classification changes the people classified. The framework asserts that systems change their behaviour when modelled and then treats `eta`, `delta` and `u` as stable enough to fit. **Either those parameters survive the framework's own predicted response to being measured, or the framework undercuts itself.** This paper takes the first horn as an assumption and labels it one.

The functional form of the surplus term is underdetermined by the evidence, and the appendices must not be read as settling it. A sub-linear power law [Latané, 1981] and an `n log n` form [Briscoe et al., 2006] fit the qualitative facts as well as `ln(1 + (N−1)u)` does. The logarithm in this corpus follows from the affine-effective-count design axiom [Curzi, 2026] and from nothing else established here. Its usual warrant is Fechnerian [Fechner, 1966], which requires the perceptual story to be true; the stronger warrant, requiring no psychological assumption at all, is Peters and Gell-Mann [2016], under which the time-average growth rate of a multiplicatively evolving quantity is the expectation of its logarithm. **Result (a) of this paper shows the surplus law *is* a Fechner law; it does not show that either law is right, and §6.2 says so in the same breath as the identity.**

39.3.5 3.5 Analogy discipline, and the constants

Every borrowing in the apparatus is one of three things, labelled at first use.

- **A shared mathematical form.** The storage law is a first-order discrete filter, and its pole, time constant and settling behaviour follow because the equation is the same equation, with no claim that the physics transfers [Oppenheim et al., 1996, Åström and Murray,

2008]. Convergence follows from the contraction property [Banach, 1922, Elaydi, 2005], and the leaky integrator has the same status in computational neuroscience [Gerstner and Kistler, 2002]. **This is the category most of the apparatus sits in.**

- **A derivation.** The Fechner identity, the octave-folding cost and the fixed-point headroom identity are algebra on definitions the corpus has fixed. The founding definitional move — comfort as the felt total of present costs, with the variational statement given as *stationarity* rather than minimality and licensing **no teleology** — is Curzi [2026] and is presupposed rather than restated. The contraction theorem is stated exactly, with its own refusal attached, in Curzi [2026]: a human life is not a metric space, nobody has measured the relevant contraction modulus, and **the theorem transfers as shape rather than guarantee.**
- **An analogy, and never evidence.** Reading a pitch-class identification as psychoacoustic consonance is an analogy and §6.3 refuses it. Reading the uncertainty relation as a statement about measurement disturbance is an error the corpus corrects in Curzi [2026], which also requires that a user be able to distinguish the theorem, the ordinary observer effect and the framework's own conjecture in three separate sentences on demand.

Entropy in this paper is Shannon entropy where it appears: surplus is a logarithm of an effective count, a pure number in nats, and no thermodynamic quantity is invoked. **Which effective count is meant is stated at every use.** `1/HHI` and `exp(H)` are Hill numbers of orders two and one [Hill, 1973, Jost, 2006]; the affine count `1 + (N−1)u` used throughout this corpus is **not** a Hill number but a linear interpolation between 1 and `N` adopted as a design axiom [Curzi, 2026], though it is exactly equal to a Rényi-2 participation ratio [Rényi, 1961]. The concentration instrument that *is* a Hill number of order two — with its worked case returning a naive HHI of 0.293430 and 3.41 effective jurisdictions against a bloc-HHI of 1.000000 and an effective count of 1.00 — is Curzi [2026], and the procedural form of the same rule, *collapse before measuring, because `ln(1.00) = 0` means a structure with one effective bloc has zero available surplus rather than a low one*, is Curzi [2026].

Two constants appear at high precision and their status differs. `k = (9/8)^2/phi^2 = 0.483425732988414` is a **DEFINED** constant: an exact ratio of exact quantities, computable to arbitrary precision, and its fifteen figures are legitimate for that reason alone. It is labelled *defined* at every appearance at that precision. **Attaching hertz to it is a separate and much stronger claim**, it is not established anywhere in this corpus, and it appears in the verification chain of §9.3 on its own line with status POSTULATED. Where the golden section appears in that constant, Markowsky [1992] is the standing caution: most popular claims about golden-ratio occurrence do not survive checking, and the constant here is **defined by the corpus rather than found in nature.** `ln 2 = 0.693147...` is a mathematical constant and needs no badge.

No scaling or power-law claim is made anywhere in this paper. Where the register in Appendix E records the corpus's borrowing of preferential-attachment results, it records with them that Clauset et al. [2009] is binding before any real graph is called scale-free, and that Broido and Clauset [2019] and Stumpf and Porter [2012] find such structure rarer than the literature suggests once that procedure is run, with Doyle et al. [2005] bounding the inference further.

39.3.6 3.6 Editorial rules for the converted cross-references

The source manuscript locates claims by book chapter number and refers to its own internal technical papers as Papers A to E. Neither survives conversion. **Where the manuscript cites Paper A, this paper cites Curzi [2026], which carries the surplus functional and its properties; where it cites Paper E, Curzi [2026a], which carries the storage law and its corollaries; where it cites Paper D, the result is a range or effective-count bound and the reference is CCP-009; and where it cites Paper B, the result concerns state encoding and category assignment and the reference is CCP-015.** Chapter numbers throughout the appendices have been replaced by the corpus paper identifiers that carry the corresponding material.

That mapping is an editorial inference rather than a statement by the source, and Section 10 records it. In the appendices, corpus papers are named as plain identifiers rather than as bibliographic citations, because the appendices are an index rather than an argument; those identifiers resolve against the corpus DOI 10.5281/zenodo.22079583, and the bibliography of this paper carries the subset cited directly in its running text.

39.4 4 What the four parts of the corpus established

Four bodies of work close here: a founding text and three technical series.

They were written over the same problem approached four times from four distances, and the problem is one sentence long. **Something makes a place or a practice or a person work better than it should, the effect is real enough to be noticed and unreliable enough to be lost, and nobody can say what it costs to keep.** the founding material taught a practitioner to notice it. This framework's first volume taught an engineer to build the circumstance that generates it. The second volume turned the instrument around and put it on the person holding it. The third carried it down to the cell, which is where it stopped, and stopped honestly.

What was found is smaller than what was looked for, and it is worth stating plainly at the top because the rest of this paper is a summary and summaries are where books get generous with themselves.

What was found is a recursion with a loss term, a geometry in which difference is the thing that is counted, and an audit trail. No mechanism was added to the world. Nothing here makes a symbol act on matter, no claim in these three volumes has any clinical or therapeutic content, and the formalism does not touch consciousness, thermodynamics, or physics beyond borrowing four theorems that belonged to other people first. **Every claim the corpus makes is in CCP-038 with a status on it: proved, badged, or named as open.** There is nothing behind the register. The register is the corpus.

That is a small inheritance and this paper's argument is that it is enough — that the mechanism is sufficient for everything the four bodies of work actually promised, and needs nothing added to it. The restraint is not modesty. **It is the load-bearing part: a framework that has to be supplemented to work is a framework that did not work.**

The four subsections below are **recapitulation**, and are included because the closing paper of a series is where a reader looks for the map. Each states what one part of the corpus established and cites the papers that established it; **no claim in this section is new here, and none should be cited to this paper.**

39.4.1 4.1 The founding material — the practitioner learning to read the gradient

The first book was a story with twelve nodes in it, and its instrument was attention. It taught a person to notice which chair, which room, which hour, which conversation made the work easier — and to treat that noticing as data rather than as preference.

Three of its nodes turn out to be theorems of the corpus, and the correspondence is exact rather than poetic.

The fixed-point node of the founding material — the room that was always furnished — is CCP-007, Theorem 3.5. The room feels like recognition rather than victory because a contraction does not arrive anywhere new. It arrives where it was always going to arrive, from any starting point, and the felt quality of arriving somewhere inevitable is what convergence to a unique fixed point is like from inside.

The recursion node of the founding material is the transient. `(1-delta)^t Q_0` decaying while the driven term builds. Going around again is not going in circles if the loop leaks: each

pass discards a fixed fraction of where the system started and adds a fixed increment of where it is going.

The departure-lounge node of the founding material is `L = max(0, M − C)`. "In those minutes there was no surplus to dream with" is `L = 0`, stated exactly. Escape is dreamt only from surplus, and a person whose whole moment is consumed by cost has none to dream with. **That formula is demoted on magnitude (CCP-038, E-05) and stands on structure**, which is the correct status for a sentence that was always an observation rather than a measurement.

Collected, the correspondences that hold exactly:

the founding material	Corpus result	Status
the departure-lounge node	`L = max(0, M − C)`; "no surplus to dream with" is `L = 0`	Structure stands; magnitude demoted (E-05)
the desire-line node	The comfort gradient as `−grad C`, read from where people actually walk	Badged identification
the many-windows node	`F_int = ln(1 + (N−1)u)` over one observer's own framings — CCP-A02 applied within a single observer	A derivation, not an analogy
the wave node	The future as an amplitude-weighted ensemble rather than a verdict	The corpus's own treatment; needs no quantum mechanics to stand
the echo node	`Delta_R = |ln(M'/M)|`, the world's answer over what was sent, read as a log-ratio	Structure stands; magnitude demoted (E-05)
the recursion node	The transient `(1−delta)^t Q_0` decaying while the driven term builds	CCP-007, Thm 3.1
the fixed-point node	`Q_inf = (eta F(u*) − c*) / delta`	CCP-007, Thm 3.5

Two of the seven are theorems, two are demoted on magnitude and standing on structure, and three are badged identifications. That distribution is the corpus in miniature.

What the founding material could not do is say what any of it cost. **An operator can read a gradient and still be unable to say whether the climb is affordable.** That is the gap the framework was written into.

39.4.2 4.2 The institutional-scope material — the engineer, the room, the table, the institution

The first volume answers the affordability question with one number.

```
h_t = eta ln N − delta Q_t − C_t
```

Below zero no building is permitted, and **no arrangement of people prevents decline** — that is Corollary 3.4 and it is the most consequential sociological statement in the corpus precisely because it forecloses the usual response, which is to change the people. At zero only maintenance is permitted. Above zero growth is available, by exactly `h` and not one unit more.

The volume's real content is the four levers and their honest ordering. `eta` is usually cheapest: the decision log, the written standard, the trained apprentice, the moved wall. `C` is next. `u` is the one that moves fast but not cheaply. `N` is the last and the least rewarding, because `ln N` grows so slowly that doubling the number of admitted domains buys `0.693147` nats wherever

it starts. **A headroom problem cannot be escaped by adding domains.** The lever ordering is itself an argument rather than a measurement (CCP-038, and Appendix E.4 item 7 says so).

And the volume made three things physical, which is where the third through-line entered. A room has `delta`, `eta`, `N` and `C` like anything else, and its `eta` — the rate at which encounters become durable relation or decision — is a design variable. A hard-surfaced room silences the quiet voice by physics rather than by dominance. A table with a head assigns `u = 0` to everyone below the salt, because their function becomes agreement. **Furniture is the cheapest governance instrument ever built, and it enforces continuously without anyone administering it.**

39.4.3 4.3 The personal-scope material — the return inward

The second volume's thesis is that psychology and sociology are not two subjects but one set of relations measured at two scopes, and it is badged as a thesis every time it is used.

The volume's strongest content is not the thesis. It is the demonstration that subjective magnitude is measurable, which settles a century-old question in the affirmative and with data: Weber's constant ratio, Fechner's logarithm, and above all **Stevens' method of magnitude estimation, which produces genuine ratio-scale measurements of subjective experience from human subjects and replicates.** The exponents are constants of a procedure rather than of nature, and the volume says so — but the existence of the procedure is what makes the whole enterprise something other than a category error.

From that came the Lens Theorem, which is the volume's most useful export. **If perception is a map converting multiplication into addition, it is a logarithm, and the map is unique up to scale.** Therefore equal perceptual steps are equal world ratios, never equal world differences; therefore a designer who promises a linear improvement in a quantity the recipient perceives logarithmically has promised an exponential and does not know it. The theorem is conditional and **the badge is on the antecedent, not on the inference** — which means the argument cannot be defeated by disputing the mathematics, only by defeating Weber and Fechner.

The volume's other export is the one that made the sonic material composable with everything else. **Four independent quantities in this corpus are all logarithmic** — surplus `F = ln N_eff`, pitch `p = log2 f`, sensation `S = k ln(I/I_0)`, and the moment in its log form `ln M = ln D − ln P + ln E`. Because all four are logarithms, **every conversion between them is linear in log space and the constants are exact**:

```
1 nat    = 1.442695 bits = 2.885390 octaves = 3462.4681 cents
1 bit    = 0.693147 nats = 2 octaves EXACTLY = 2400 cents exactly
1 octave = 0.346574 nats = 0.5 bits          = 1200 cents
```

One nat of interaction surplus is exactly 2.885390 octaves. That is not a metaphor about harmony; it is a unit conversion, and it is exact because both registers are logarithms of the same effective count. The reason the four compose is not coincidence and it is not mysticism: **the logarithm is the register perception itself operates in**, which is Weber's and Fechner's 19th-century finding and not this corpus's proposal.

And from the same volume came the demotion. The Formula Validation Protocol's second gate asks what scale type each term admits, division requires ratio scale with a true zero, and applied to the author's own keystone formula `M = (D/P)·E` the gate returns **DEMOTE.** The magnitude of the ratio, the distortion `Delta = |ln r|`, and the quantitative join from moment to character are not reportable as measured quantities. **What is demoted is magnitude, not structure**: the limiting cases stand, the `D = P` fixed point stands, and the ordering over-framed / calibrated / under-framed stands, because all three need only ordinal information.

The route out is Theorem 54.3 and it is costed at 123 items per term. That number is not an estimate; it is the inversion of the best-case measurement error, and one hundred and twenty-two items is not enough while one hundred and twenty-three is. **A book whose validation protocol demotes its author's own formula, prices the repair, and prints both is a book whose**

protocol is doing something. That is the strongest single thing the personal-scope material produced and it is a negative result.

39.4.4 4.4 The cellular-scope material — the descent to the cell, and where it stopped

The third volume carried the instrument down and found three things.

It found that the cell is a receiver, and that this is established rather than proposed. PIEZO1 and PIEZO2 are mechanically gated ion channels; sound is mechanical; force at the cell surface transmits through the cytoskeleton to the nucleus, stretches chromatin, and changes transcription. There is a real, prize-winning pathway from a pressure wave to a cellular signal, and CCP-030 establishes it and **stops exactly there.**

It found that the library is real. Roughly 98% of the genome is non-coding and largely regulatory; "junk DNA" is retired; syncytin, indispensable to placenta formation, derives from a retroviral envelope gene — ancient foreign text, inherited, later read out as vital function. And Yamanaka reprogramming demonstrates that four regulatory signals return a differentiated cell to pluripotency **without adding one base of new sequence.** From which comes the constraint that bounds the whole architecture and is the most useful sentence in the volume: **nothing that is not already latent can be reached.**

And it found the gap. There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal. Everything upstream is real. That step is not. The volume states it in every chapter that touches it, spends its most careful chapter on what an experiment would have to show, and does not blur it anywhere.

The volume also carried the two-column method, and the method's one refinement is the reason the volume is worth reading: **the (+1) column carries evidence and the (-1) column carries precedent, and two sources agreeing does not double the evidence when only one of them is evidence.** What independent arrival establishes is real and worth having — that a structure was findable by more than one route, which argues that the structure is in the territory and not only in the instrument. It is not a second measurement. CCP-038 applied that rule across all three volumes and found precedent in twenty-three of one hundred and fifty-six rows. **The other one hundred and thirty-three read *none claimed*, and that is the honest yield.**

39.5 5 Four through-lines

Each of the four statements below is derivable from the two laws of §3.1, each was earned in a different part of the corpus, and none requires anything the formalism does not contain. **They are restatements, not results**; the results are Section 6.

39.5.1 5.1 Through-line one — the loss term

Recursion earned its bad name in one narrow place: the call stack, where a function calling itself without a base case consumes a frame per call until the allocator runs out. The failure is loud enough to have become a metaphor — infinite regress, the mirror facing the mirror, going in circles.

That metaphor describes exactly one kind of recursion: recursion without a loss term.

Put the loss term in and the object changes category. `Q_{t+1} = (1−delta)Q_t + eta S_t − C_t` is not a stack; it is an accumulator. In discrete time it is exactly a first-order low-pass filter: `Q` is charge, `delta` is leakage conductance, `eta S` is current in, `C` is load draw, `(1−delta)` is the pole. And because `delta > 0` makes the map a contraction, Banach guarantees a unique fixed point and convergence to it from any start.

That is why iteration arrives. Not because the loop is clever, and not because the practitioner persists, but because a contraction has nowhere else to go.

The two degenerate cases are the two failures everyone recognises. **Rumination is recursion with `eta` near zero**: the loop runs, nothing converts, and `Q` decays under `delta` while the effort is expended. **Tradition is recursion with `delta` near zero and no input**: nothing is lost and nothing enters, so `Q` holds forever at whatever it happened to be, which looks like continuity and behaves like a fixed point that has stopped being computed.

The design consequence is unglamorous and it is CCP-007's: **cadence beats intensity.** A low-pass filter integrates a periodic forcing function; the same total input delivered as one impulse mostly leaks away before it can accumulate. That is why scheduled, repeated, moderate input outperforms occasional heroics, and it needs no theory of motivation to explain.

39.5.2 5.2 Through-line two — difference generates surplus

The second through-line is one substitution and its consequences.

```
N_eff = 1 + (N−1) u        u = 0  ->  N_eff = 1  ->  F = ln 1 = 0
```

Difference is counted first, and only what is different is counted at all. A roster of ten becomes an effective count of one the moment the ten are parallel, and no amount of headcount repairs it, because `N` enters only through `u`'s multiplier.

Three separate literatures say the same thing from three directions and none of them knew about the others. Condorcet's jury theorem requires independence of member errors. Bikhchandani, Hirshleifer and Welch show that informational cascades stop aggregation because agents rationally cease using their private signals. Woolley and colleagues found that the collective intelligence factor correlates with equality of conversational turn-taking. **Independence, non-copying, turn-taking: three names for `u > 0`.**

And the concavity is the merciful clause. `F` is strictly concave, so the second genuinely different view is the largest single gain available and the fortieth is glazing bills. At `N = 6`, half the ceiling arrives by `u = 0.3`. **Three honest windows set wide capture most of what a gallery could** — which is why this framework never recommends assembling a hundred of anything.

The failure mode that follows is the dominant one in modern institutions and the arithmetic prices it exactly. Three glasses ground from one doctrine, their agreement read as convergence: `u = 0`, `N_eff = 1`, surplus `ln 1 = 0`. **A second opinion from someone whose training and incentives replicate the first is worth exactly nothing, and the law says so with a number.**

39.5.3 5.3 Through-line three — geometry does work without power

The third through-line is the one that connects a room to a sigil without any mysticism being required, and it is worth laying out because it is the place where a reader might expect the corpus to reach for something it has refused.

A parabola focuses every ray parallel to its axis through one point. It does this because of its shape. No power is supplied, no mechanism is engaged, nothing is added. The Denge acoustic mirrors — concrete parabolic dishes built in the 1920s and 1930s to detect aircraft before radar — worked for exactly that reason and consumed nothing.

A room's modes are set by its dimensions. Reverberation time follows from volume and absorption; a hard-surfaced room is loud for the quiet speaker not because anyone dominates but because the geometry sums the reflections.

A star polygon `{N/k}` decomposes into exactly `gcd(N,k)` closed paths of length `N/gcd(N,k)`. The hexagram is two triangles because `gcd(6,2) = 2`. This is number theory, it is true, and it means the number of separate strokes in the figure is an exact arithmetic invariant of the figure. **That is the entire claim, and it is claimed about the drawing and not about the world.**

Nothing here says a figure does anything. It says a figure has an arithmetic, and the arithmetic is computable.

And the purest physical case is Casimir. Two conducting plates exclude every mode whose wavelength does not fit between them, and the exclusion produces a measured force. Computed: `1.3001e5` Pa at 10 nm — 1.28 atmospheres — falling as the fourth power to `1.3001e-15` Pa at 1 mm. **At any biological or architectural scale the Casimir force is utterly negligible. It does nothing in a cell and nothing in a room, and this corpus says so wherever Casimir appears.**

But the reason to cite it is not force. **Casimir is the most rigorous demonstration in physics that boundary geometry alone determines which modes can exist, and that this selection has measurable consequence.** Nothing is added; nothing is powered; the shape does all of it. That is the framework's thesis in its purest available form, and it is presented as exactly that and nothing more.

There is a cost to geometry doing the work, and it is a specific one. **A shape that works is invisible while it works.** Star and Ruhleder's finding is that infrastructure becomes visible chiefly upon breakdown, and Weiser's aphorism — that the most profound technologies are those that disappear — says the same thing approvingly. In the storage law that invisibility has an exact consequence: **`delta` is systematically underestimated wherever it has not been measured**, because the thing decaying is the thing nobody can see. A room that has been quietly producing turn-taking equality for nine years produces no evidence that it is doing so, and the case for maintaining it is therefore always weaker than the case for spending the money elsewhere. That is not a failure of judgement. **It is a structural property of working infrastructure**, and the only remedy is to measure `delta` on purpose, under zero input, before the argument is needed.

The design consequence runs through every physical chapter. **A shape that does the work needs no maintenance budget**, which in the storage law means it contributes to `eta` without contributing to `C` and without decaying under `delta`. That is why the table with no head outperforms the facilitator, why the alcove outperforms the policy about interruptions, and why a threshold deep enough to stand in outperforms a sign asking people to pause. **The geometry enforces continuously, at zero marginal cost, and it never forgets.**

39.5.4 5.4 Through-line four — proved, badged, or open

The fourth through-line is a discipline rather than a result, and it is the one that took the most words to keep.

Every claim in three volumes is in CCP-038 with a status on it. Fifty are theorems, and not one of the fifty is a claim about a person, a room, or a cell — Group A is arithmetic, and every step from arithmetic to recommendation passes through a badged assumption. Twenty-eight are postulates, and four of them (the affine design axiom, the linear storage law, the modelling map onto social systems, and cost commensuration) carry more weight than any citation in the corpus. Fifty-eight are borrowed, each with the setting it was obtained in and the transfer assumption stated. Twelve are speculative, of which four are rejections printed as rejections. **And eight are demoted, including the author's keystone formula.**

The house rule from the founding material survives intact: **the mysticism is permitted, but it is permitted in the open, with its badge on.** CCP-038 is what that rule looks like after three volumes.

Two things about the register deserve to be said at the end rather than in it.

The first is that the demotions are the evidence. A protocol that has never rejected anything is a decoration, and this one rejected the formula the author cares most about, at the gate the author designed, and then printed the price of the repair. **Nothing in this corpus argues for its own reliability as effectively as the eight rows in Group E.**

The second is that the register is written to be used against the corpus. Entry IDs are stable so they can be cited in an argument. The "what it measured" field exists so a reader can object that the setting does not transfer. And a claim shown to be wrong is withdrawn rather

than defended. **A framework that cannot be told apart from its own decoration is useless as engineering**, and the only remedy is a document that says, item by item, which is which.

39.5.5 5.5 What the mechanism is sufficient for

Here is the restraint, stated as a positive claim rather than as a list of refusals.

The mechanism is sufficient to explain why cadence beats intensity, because a leaky integrator integrates periodic forcing and dissipates impulses. It needs no theory of discipline.

It is sufficient to explain why the second opinion is worth more than the fortieth, because `F` is strictly concave. It needs no theory of creativity.

It is sufficient to explain why an institution ossifies, and the explanation is more precise than the usual one: within the plain model it does not ossify at all (§6.4), so the observed ossification requires a term the plain model lacks, and CCP-008 names the candidates — exogenous `Q` accretion and superlinear cost. It needs no theory of bureaucratic psychology.

It is sufficient to explain why a hard room silences the quiet voice, because reverberation sums reflections and the loudest source wins. It needs no theory of dominance.

It is sufficient to explain why a silo cannot be exhorted out of, because a silo is a local minimum and every direction out is uphill; the method is to build a lower valley next door. **This is also why the method has no coercive failure mode: its worst outcome is that someone declines to move.**

It is sufficient to explain why writing it down changes the outcome, because `eta` multiplies `S` and an unwritten conversation has `eta` near zero. It needs no theory of memory.

It is sufficient to explain why a large group underperforms a small one, because coordination paths grow as `n(n−1)/2` while surplus grows as `ln N` — quadratic against logarithmic, with a crossing point that can be computed for any given `eta`. It needs no theory of committees.

It is sufficient to explain why individuality has to be protected rather than tolerated, because `u` is the multiplier on the entire surplus term and merging the members drives it to zero. **That is the ethical constraint arriving as an arithmetic one**, and it is the one place in the corpus where the two coincide exactly: preserving the ability to differ is not a concession to comfort, it is the precondition for the collective to compute anything at all.

And here is what it is not sufficient for, stated with equal flatness. **It does not explain consciousness and does not touch it.** It proves nothing about physics or thermodynamics — CCP-007 is explicit that no negentropy law is proved. **It confers no clinical or therapeutic benefit and no such claim appears anywhere in three volumes.** It gives symbols no efficacy: gematria is a hash function, a sigil is an encoding operation with an arithmetic invariant, and neither description carries any claim that the map is meaningful or that the figure acts. And it does not establish the cellular channel, which is §8.1.

A mechanism that needs nothing added to it to do the work it claims is the only kind worth having. Everything the four bodies of work actually promised is in the list above. Everything else was never promised.

39.6 6 Four structural results

39.6.1 6.1 The genuine structural results — an introduction

Four results emerged from the writing that were not in the papers, not in the founding material, and not anticipated in the plan. Each connects two parts of the corpus that had been developed independently, each is exact, and each was computed rather than asserted.

They are the closest thing this corpus has to a discovery, and none of them is large. That is the correct size for what a formalism yields when it is being honest.

39.6.2 6.2 Result (a) — the surplus law is exactly a Fechner law with threshold `u_0 = 1/(N−1)`

Take the surplus law and factor `(N−1)` out of the logarithm:

```
F(u) = ln(1 + (N−1)u)
     = ln( (N−1) ∗ ( u + 1/(N−1) ) )
     = ln( (u + u_0) / u_0 )                with  u_0 = 1/(N−1)
```

That is Fechner's law in its threshold-corrected form, `S = k ln((I + I_0)/I_0)`, with `k = 1`, the stimulus `I` being non-parallelism, and the threshold intensity `I_0` being `u_0 = 1/(N−1)`. The identity was verified for `N = 2` through `N = 100` at seven values of `u` each; the maximum residual is `8.9e−16`, which is floating-point noise. **The source manuscript quotes `4.4e−16` here and `8.9e−16` in its honesty appendix. Recomputing the identity over both grids returns a maximum absolute difference of `8.881784e−16`, so the appendix figure is the correct one, the larger value is quoted throughout this paper, and the discrepancy is recorded in Limitation L-11 rather than repaired silently.**

And the threshold has a meaning that is not an artifact of the algebra. Evaluate the law at it:

```
N_eff(u_0) = 1 + (N−1) ∗ 1/(N−1) = 2       exactly, for every N
F(u_0)     = ln 2 = 0.693147 nats = 1 bit = 2 octaves
```

The threshold is exactly the point at which the effective count reaches two. Below `u_0` the system does not yet contain a second independent voice; at `u_0` it contains precisely two; above it, more. Fechner's `I_0` is the intensity at which sensation begins. **Here the intensity at which surplus begins is the non-parallelism at which the second window opens, and it is one full bit wide.**

The threshold's size is a design fact:

```
N = 2   ->  u_0 = 1.000000     the threshold IS the ceiling
N = 3   ->  u_0 = 0.500000     half the range
N = 4   ->  u_0 = 0.333333
N = 6   ->  u_0 = 0.200000     one fifth
N = 12  ->  u_0 = 0.090909     one eleventh
```

In a two-category system the second voice arrives only at perfect orthogonality; in a twelve-category system it arrives at nine percent of the range. That is a precise statement of why narrow systems are so hard to get anything out of: not because their members are worse, but because the threshold sits at the top of their range.

What this result is: an exact algebraic identity connecting two formalisms developed a hundred and sixty-six years apart. **What it is not: evidence for either.** CCP-A02's law is a theorem under its axioms and gains nothing from resembling Fechner's; Fechner's law is an empirical claim resting on a badged postulate about just-noticeable differences and gains nothing from resembling Paper A's. **The correspondence is structural, and structural similarity is not identity.** What it does establish is the thing independent arrival always establishes: **that the logarithm is not a stylistic choice in this corpus. It is the register both routes landed in.**

39.6.3 6.3 Result (b) — consonance and redundancy are the same phenomenon in the essence lattice

This one connects the sonic material to the surplus material with no adjustment, and the connection is exact.

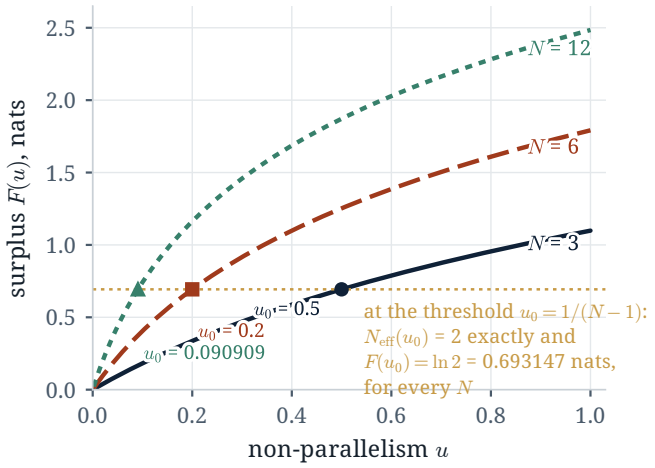

Figure 39.1: **The surplus law is exactly a Fechner law with an absolute threshold at `u_0 = 1/(N-1)`, and at that threshold the effective count is exactly 2 and the surplus is exactly `ln 2` for every `N`.** The two forms `ln(1+(N-1)u)` and `ln((u+u_0)/u_0)` agree to a worst residual of 8.9e$-$16 over `u` = 0.01 to 1.00 at `N` = 2, 3, 5, 8, 12, 25 and 100. The threshold is 1.000000 at `N` = 2 and 0.090909 at `N` = 12, so a narrow system opens its second independent voice only near perfect orthogonality. Exact algebra (Section 6.2); generated by `figs/src/CCP-039_fig01.py`.

The essence law's published recipe collapses to `f(n) = k n^2` with `k = (9/8)^2/phi^2 = 0.483425732988414 Hz` — verified against every published value in the source to fourteen significant figures. **`k` is a chosen reference constant and the square law is a postulate about essence structure; both carry their badges here and everywhere.**

Because `(2n)^2 = 4 n^2`, doubling an index raises the frequency by a factor of four, which is **exactly two octaves**. Therefore indices `n` and `2n` occupy the same pitch class, and more generally two essences share a pitch class if and only if their indices have the same odd part. An ordered set `1..N` therefore contains exactly `ceil(N/2)` distinct pitch classes.

Now price that identification in surplus. Folding an even-`N` essence set by octave equivalence collapses `N` categories to `N/2` classes, so:

```
surplus before folding  =  ln N
surplus after folding   =  ln (N/2)
loss                    =  ln N − ln(N/2) = ln 2      EXACTLY, for every even N
```

Computed for `N = 4, 6, 8, 10, 12, 16, 20, 24, 32, 64`: the loss is `0.6931471806` in every case, and `loss / ln 2 = 1.0000000000` in every case.

Convert the loss into pitch using the corpus's own exact key, `octaves = 2F / ln 2`:

```
loss in nats     = 0.6931471806
loss in bits     = 1.0000000000        one bit
loss in octaves  = 2.0000000000        two octaves

the interval that was identified away: f(2n)/f(n) = 4 = 2 octaves
```

The surplus surrendered to redundancy is numerically equal to the interval declared consonant, in the same units, by the same conversion key. Two octaves of pitch, one bit of surplus, one `ln 2` of nats — three names for one quantity. The concrete case: a twelve-essence set has indices with odd parts `1,1,3,1,5,3,7,1,9,5,11,3`, giving six pitch classes, `ln 12 − ln 6 = ln 2` exactly.

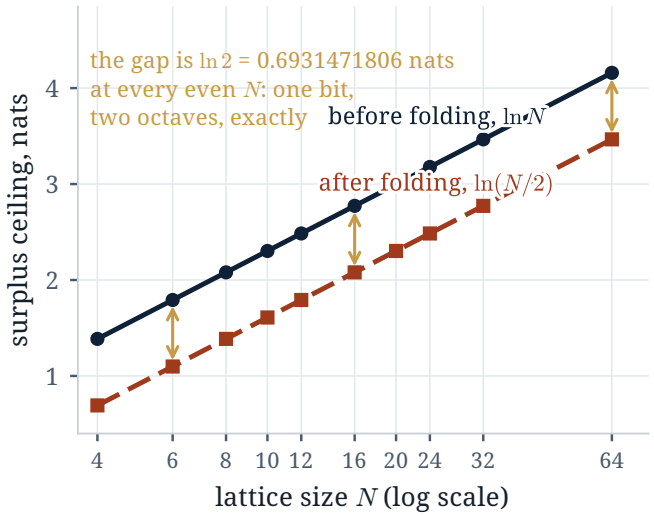

Figure 39.2: **Folding an even essence lattice into one octave costs exactly `ln 2` = 0.6931471806 nats — one bit, two octaves — at every `N`.** Computed at `N` = 4, 6, 8, 10, 12, 16, 20, 24, 32 and 64, the loss `ln N − ln(N/2)` returns the same value in every case and the ratio to `ln 2` is 1.0000000000 in every case. Exact arithmetic inside a postulated lattice, `f(n) = k n^2` with `k` defined (Section 6.3); generated by `figs/src/CCP-039_fig02.py`.

What the result says: in this lattice, calling two things consonant and calling them redundant are the same operation, and it costs exactly one bit. Consonance is not a bonus that arrives free; it is an identification, and every identification is a reduction of effective count.

What the result does not say, and the limits matter. "Consonance" here means the exact-ratio octave identification internal to this lattice — it is not a claim about the psychoacoustics of consonance, which is a different subject with its own contested literature. The result holds inside a postulated structure (`f = k n^2`, badged) and is exact there. **And the output remains an essence frequency, not a physical resonance: no claim is made that any material, molecule, element or person physically resonates at these values.** That clause is absolute in this corpus and is restated here at its last appearance.

39.6.4 6.4 Result (c) — `h_inf = eta * (ln N - F(u*))`

Take the headroom gauge to the fixed point and something cancels that should not.

```
Q_inf  = (eta F(u*) - c*) / delta
h_inf  = eta ln N - delta Q_inf - c*
       = eta ln N - (eta F(u*) - c*) - c*
       = eta * ( ln N - F(u*) )
```

Delta, cost and stored order all disappear. Verified against direct computation across four parameter sets spanning `eta` from `0.12` to `0.50`, `N` from 4 to 20, `delta` from `0.03` to `0.20`: agreement below `1e-16` in every case.

The consequence is the interesting part. Since `F(u) <= ln N` always by CCP-009's corollary, the bracket is non-negative, so:

```
h_inf >= 0        ALWAYS, in the plain linear model
```

The plain model never ossifies by itself. Whatever else happens, a converged system retains non-negative headroom, and the amount it retains is `eta` times the gap between the ceiling and the surplus it actually achieves.

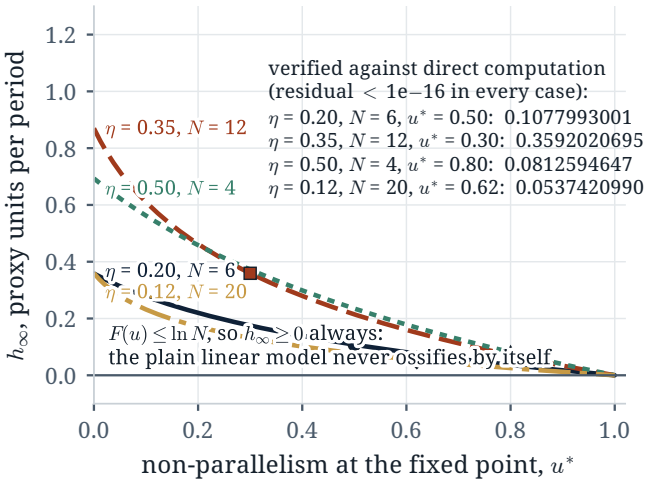

Figure 39.3: **Retention, cost and stored order all cancel at the fixed point, and the result is non-negative for every admissible `u*`: the plain linear model never ossifies by itself.** The identity `h_inf = eta(ln N − F(u*))` was verified against direct computation at four parameter sets, returning 0.1077993001, 0.3592020695, 0.0812594647 and 0.0537420990 with residuals below 1e$-$16. Modelled from the stipulated parameter sets of Section 6.4; generated by `figs/src/CCP-039_fig03.py`.

That is inconvenient, because ossification is the most reliably observed behaviour of successful institutions, and CCP-008 had argued for it from the shape of `h_t` along the transient — `h` does fall as `Q` rises, and it does so throughout the approach. **Both are true, and the resolution is not a repair to the theorem.** Along the transient headroom falls; at the fixed point it stops falling, at a non-negative value.

So the observed phenomenon requires a term the plain model does not contain, and CCP-008 names the candidates: exogenous `Q` accretion — stored order arriving from outside the interaction loop, as regulation, inherited estate, or accumulated obligation — and cost that rises with `Q` rather than staying additive. With an accretion term `A`, the identity becomes `h_inf = eta(ln N − F(u*)) − A`, and it goes negative exactly when `A` exceeds the geometric shortfall.

A model that cannot produce a phenomenon everyone observes is reporting that the mechanism is outside the model, and that is a useful thing for a model to say. It converts "institutions ossify" from a lament into a question with two named suspects and a testable difference between them.

There is one more reading of the identity, and it is the design one. `h_inf` scales with `eta` and with nothing else, and it is largest when `F(u*)` is *smallest*. **A converged system operating far below its surplus ceiling retains the most headroom, and a system extracting everything its geometry allows retains the least.** Running at the ceiling is not efficiency; it is the elimination of slack, and CCP-008's queueing argument said the same thing in a different notation.

39.6.5 6.5 Result (d) — the shuffle cannot see repackaging

The fourth result is the one that changes how the framework must be tested, and it came out of an attempt to break the framework rather than to support it.

The falsification suite requires beating four baselines: persistence, direct-input, matched autoregressive, and a shuffled-input control. The shuffle is the most trusted of the four, because destroying the temporal correspondence between input and output should destroy any spurious fit.

A filtered repackaging of the input passed all four, including the shuffle, at `p = 0.0005`. A quantity that was a transformation of the input rather than a prediction of the output survived

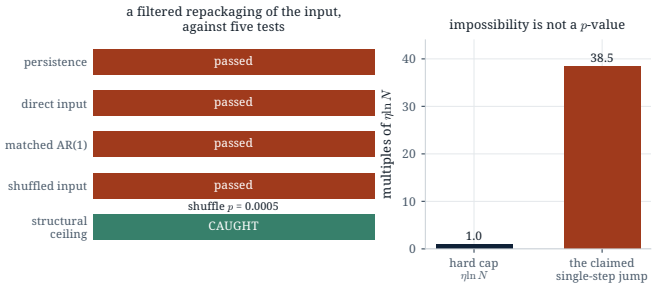

Figure 39.4: **A filtered repackaging of the input passed all four empirical baselines, including the shuffled-input control at `p = 0.0005`, and was caught only by the structural ceiling.** Its claimed single-step jump was 38.5 times the hard cap `eta ln N`, which no parameter setting, significance level or sample size admits: impossibility is not a `p`-value. Reported outcomes of the corpus's own control experiment (Section 6.5); generated by `figs/src/CCP-039_fig05.py`.

every empirical audit the protocol had.

It was caught by one thing only: the structural ceiling.

```
r_max     = eta ln N - delta Q - C          Corollary 4.2
hard cap  = eta ln N                       since delta, C >= 0

observed single-step jump = 38.5 x eta ln N
```

The step was impossible under the model, and impossibility is not a p-value — it is a contradiction. No parameter setting, no significance level, and no sample size makes a jump of `38.5` times the theoretical maximum admissible.

The rule that follows is now propagated through five chapters and two appendices: **the shuffle is an empirical audit; only the structural tests detect repackaging.**

The general lesson is larger than the instance, and it is the best argument in the corpus for having a formalism at all. A statistical test asks whether a pattern could have arisen by chance. A structural test asks whether the pattern is possible. **The second question is stronger, and only a theory can ask it.** A framework with no ceiling has no way to say "that cannot have happened", and a framework that cannot say that will eventually publish a repackaging as a result.

This is also the clearest case in the corpus of a demotion strengthening the framework. CCP-038 records it as E-07, and it is one of the eight entries that will never be promoted: **it is a permanent structural finding about what shuffles can see.**

39.7 7 Results

39.7.1 7.1 The smallest complete instance

The last worked example is the smallest one that contains the whole mechanism: **two people, one recurring conversation, one page written afterwards.**

Two people, drawing on four genuinely distinct categories between them, so `N = 4`. Their independent written predictions on shared questions decorrelate to `u = 0.55`. They meet weekly. One of them writes a page afterwards and files it where the other can find it, which

is the entire `eta` intervention. Cost is `C = 0.15` per week — the hour, the preparation, the interruption. Retention loss is `delta = 0.10` per week, which is a half-life of `6.58` weeks for anything not re-touched. They begin with `Q_0 = 0.80`.

Every number below is arithmetic on plausible parameter values. None was measured, and Appendix E.4 item 1 applies without exception.

```
ln N     = 1.386294 nats                    = 2 bits exactly
N_eff    = 1 + 3(0.55) = 2.6500             two people, 2.65 effective views
S = F(u) = ln(2.6500) = 0.974560 nats       70.3% of the ceiling

eta ln N = 0.50 x 1.386294 = 0.693147
delta Q  = 0.10 x 0.80     = 0.080000
C                          = 0.150000

h_0 = 0.693147 - 0.080000 - 0.150000 = +0.463147        growth available
```

The step, and then the trajectory:

```
Q_1 = 0.90(0.80) + 0.50(0.974560) - 0.15 = 1.057280      step = +0.257280

t      Q          h
----------------------------
0    0.800000   +0.463147
2    1.288832   +0.414264
4    1.684785   +0.374669
6    2.005508   +0.342596
8    2.265293   +0.316618
10   2.475719   +0.295575
12   2.646164   +0.278531

Q_inf = (0.50 x 0.974560 - 0.15)/0.10 = 3.372798
h_inf = 0.50 x (1.386294 - 0.974560) = 0.205867
tau   = 9.4912 weeks;  95% of Q_inf at t = 28.4 weeks;  99% at t = 43.7 weeks
```

Seven months of a weekly conversation and one page to reach ninety-five percent of everything this arrangement will ever hold. That is what a contraction feels like from inside: fast at first, then slower, then unmistakably arrived. And `h_inf = 0.205867` is positive, as §6.4 guarantees — this pair does not ossify.

Now remove the page. Same two people, same `u`, same hour, nothing written:

```
eta = 0.00  ->  h = -0.230000   Q_inf = -1.500000
eta = 0.10  ->  h = -0.091371   Q_inf = -0.525440
eta = 0.25  ->  h = +0.116574   Q_inf = +0.936399
eta = 0.50  ->  h = +0.463147   Q_inf = +3.372798
```

At `eta = 0` the equilibrium is negative, which is the model's way of saying the arrangement is unsustainable as specified. The conversation still happens. The `u` is still `0.55`. The surplus `S = 0.974560` is still generated every week and it still goes nowhere, because nothing multiplies it. Between `eta = 0.10` and `eta = 0.25` the sign of `h` changes, and somewhere in that interval is the difference between two people who talk for a year and have nothing, and two people who talk for a year and have something.

The intervention that crosses it is a page. Not a better conversation, not more people, not a larger `N` — the ceiling `ln 4 = 1.386294` was never the binding constraint. **The binding constraint was that nothing was being converted, and the arithmetic located it in one line.**

That is the whole manual in nine lines of arithmetic, and it is the correct size.

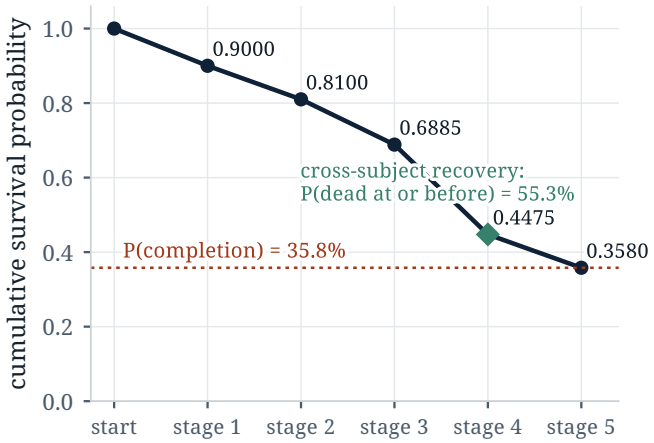

Figure 39.5: **The research programme publishes a 35.8 per cent probability of completing itself and a 55.3 per cent chance of dying at or before the stage where a formalism that describes meets the demand that it measure.** Cumulative survival runs 0.9000, 0.8100, 0.6885, 0.4475, 0.3580 across the five stages. Modelled from stage priors the author chose and badged as chosen (Appendix E.11); a different set of priors gives a different curve. Generated by `figs/src/CCP-039_fig04.py`.

39.7.2 7.2 The computed honesty items

Three quantities are computed rather than asserted in the honesty appendix, and they are collected here because they are the paper's other non-recapitulative content. Their derivations and their full statements are in Appendix E.9, E.10 and E.11.

The likelihood ratio of testimonial evidence, under a selection process that publishes successes and discards failures, is exactly `1.000000`. Not approximately one and not weakly informative: exactly one, so the evidence does not move the posterior at all, because the selection guarantees that successes are observed whether or not the method does anything. All four hypothesised success rates in the worked case produce the same 500 published accounts. **A thousand testimonials from people for whom a method worked carry precisely the evidential weight of zero testimonials.** This is the exact quantification of survivorship bias and it is why the precedent column of the corpus's register can never be promoted to evidence: a historical corpus is itself a survivorship-filtered record, and the selection is invisible from inside the surviving set. The reform literature's account of the same phenomenon in the modern record is Ioannidis [2005] and Open Science Collaboration [2015].

The companion result prices the alternative. Likelihood ratios measured at **2.0000** for a prediction specifying only a direction, against **11.3577** for one specifying a magnitude with a tolerance: **a prediction with a number attached is about 5.7 times more evidentially powerful**, equivalent to about 3.5 direction calls for one measurement. That is exactly Meehl [1967] and Meehl [1990] restated as arithmetic — directional predictions in psychology are nearly costless, and a corpus that makes point predictions with constants is answering Meehl rather than evading him. **Hence the standing rule: a belief that predicts only a direction is not yet testable.**

The instrument audit found 19 defined estimators, 1 validated value and 0 first-party measurements across 27 parameter-by-scope cells [Curzi, 2026]. The single validated cell is a borrowed median from one cell line. The correspondence between scopes then fails in five distinct ways — a mind is not a small society, a cell is not a small mind, exit and therefore the ethics do not descend, aggregation is not always well defined, and no composition theorem connects any scope to any other. **The break to carry forward is the third: the arithmetic descends to the cell and the ethics do not**, so a reader who imports the formalism downward has imported a model and left the constraint behind.

The research programme publishes its own odds of failure. Twenty-one preregistered kill conditions, four of them terminal; 8,554.8 researcher and coordinator hours, which is 5.35 full-time-equivalent years; 570 participants; 71 months strictly sequential, or 61 with a 30 per cent overlap of two stage pairs. Under the author's explicitly badged stage priors the cumulative survival probability runs **0.9000, 0.8100, 0.6885, 0.4475, 0.3580**, so **P(completion) = 35.8 per cent** and **P(death at or before the cross-subject recovery stage) = 55.3 per cent.** The programme is more likely than not to be dead before field trials begin, and the heaviest prior sits at the stage where a formalism that *describes* meets the demand that it *measure*. **A programme with a high stated completion probability has almost certainly written its kill conditions too loosely**, which is the more useful reading of the number.

39.7.3 7.3 The results this paper contributes

R1 — The surplus law is exactly a Fechner law with threshold `u_0 = 1/(N−1)`. `F(u) = ln((u + u_0)/u_0)`, verified for `N = 2` to `100` at seven values of `u` to a worst residual of `8.9e−16`; and `N_eff(u_0) = 2` exactly and `F(u_0) = ln 2` for every `N`.

R2 — Pitch-class folding of the essence lattice costs exactly `ln 2 = 0.6931471806` nats — one bit, two octaves — for every even `N`, computed at `N = 4, 6, 8, 10, 12, 16, 20, 24, 32, 64`.

R3 — `h_inf = eta(ln N − F(u*))`: retention, cost and stored order cancel at the fixed point, and since `F(u) <= ln N` always, `h_inf >= 0` always.

R4 — The shuffled-input control cannot see repackaging. A filtered repackaging passed all four empirical baselines including the shuffle at `p = 0.0005` and was caught only by `r_max = eta ln N − delta Q − C`, against an observed jump of `38.5 x eta ln N`.

R5 — Testimonial evidence under success-publishing selection has likelihood ratio exactly `1.000000`; a direction-only prediction is worth `2.0000` against `11.3577` for a magnitude call with a tolerance, about 5.7 times.

R6 — The research programme's published survival curve: 21 preregistered kill conditions (4 terminal), 8,554.8 hours, 570 participants, 71 months, **P(completion) = 35.8 per cent**, **P(death at or before the cross-subject stage) = 55.3 per cent.**

CR — The counter-result. This closing register publishes the work's odds against itself — a 35.8 per cent probability of completing its own research programme and a 55.3 per cent chance of dying before field trials — and reduces the entire testimonial corpus, including the historical precedent column, to a likelihood ratio of **exactly 1.000000**.

39.8 8 Discussion

39.8.1 8.1 What is not known

Books of this kind end on a claim. This one ends on two things that are not known, because they are what the work actually produced last and because ending anywhere else would misrepresent the state of it.

The first is empirical and it belongs to the cellular-scope material.

> **There is no established mechanism by which a cell demodulates sequence-specific information from an acoustic signal.**

Everything upstream is real and independently well-supported. Mechanotransduction is Nobel-recognised. Force at the cell surface reaches the nucleus and changes transcription. DNA stores arbitrary data. Cas12a processes its own array. Targeting and editing are separable, so an architecture that addresses without editing is coherent rather than promissory. **And the specific step — from an acoustic signal to a sequence-specific cellular read — is established by none of it.** CCP-031 states what an experiment would have to show, what controls it would

need, and what result would settle it in either direction. **It is one well-specified falsifiable gap, and naming it sharply is the most useful thing three volumes did with the cell.**

The second is mathematical, it belongs to no volume, and nobody has been asked to notice it.

> **There is no composition theorem in this corpus.** Nothing here derives institutional `Q` from personal `Q`, or personal `Q` from cellular `Q`. No aggregation operator is defined between scopes. No conservation law links them. **No argument is offered that the three accumulators are coupled at all rather than merely similar in form.**

The three-scope correspondence is a claim about model form and CCP-038 spends a third of its length saying so. But the absence underneath it is sharper than the badge admits. **What would close it is a stated aggregation operator together with a proof that the storage law is closed under it** — that a population of systems each obeying the law, combined by that operator, yields a system obeying the law with derived parameters. If such a practitioner exists, hyperrecursive symmetry stops being a modelling convention and becomes a theorem with a derivation for how parameters change with scale. **If no such operator exists, the correspondence is exactly what CCP-038 says it is and nothing more, and the three volumes are three separate applications of one equation that happen to look like a ladder.**

Which of those is true is not known here.

It requires no laboratory, no funding, and no permission. It requires someone to define the operator and try to prove closure, and to publish the result including — especially — if the result is that the law is not closed under any natural aggregation.

Two problems, then. One needs an experiment and one needs an afternoon with a proof. Neither has been done, and the corpus stops at both of them rather than past them.

The instrument is on the bench. It has one gauge that reads at two of its three scopes, a hundred and fifty-six entries saying what it is entitled to claim, eight of them recording where it was caught being wrong, and two open questions that would change its status in opposite directions depending on how they come out. **That is what was built, it is smaller than what was hoped for, and it is the part that survived being checked.**

Anyone may take it further. **The only condition this research programme asks is the one it has tried to keep for three volumes: say which claims are proved, badge the ones that are not, name the ones that are open, and publish the demotions when the gates catch the work.**

The gates catch the work that runs them. They caught the author on page one of the personal-scope material's formulary, at the gate he wrote, on the formula the whole volume was built around.

That is the work behaving correctly, and it is where it ends.

39.8.2 8.2 What the closing position amounts to

The mechanism this corpus assembled is a recursion with a loss term, a geometry in which difference is what is counted, and an audit trail. No mechanism was added to the world. Nothing in it makes a symbol act on matter, no claim in the series has clinical or therapeutic content, and the formalism does not touch consciousness or thermodynamics — it borrows four theorems that belonged to other people first, and it names them.

That the inheritance is small is the point rather than an apology. A framework that has to be supplemented in order to work is a framework that did not work, and the closing position defended here is that the mechanism is sufficient for what the series actually promised: an arithmetic that transfers wherever its model form is adopted, three ordinal diagnostics that read without a calibrated instrument, and a register that says of every claim whether it is proved, badged, or open. **What it is not sufficient for is any claim requiring a measurement, because the corpus has made none** [Curzi, 2026].

Two positions elsewhere in the corpus bound this one and are inherited rather than argued again. The concentration instrument that this framework's effective count must not be

confused with — a Hill number of order two, with `1/HHI` giving 3.41 effective jurisdictions on a naive reading and 1.00 once coordinating jurisdictions are collapsed into one bloc — is Curzi [2026], and its procedural form, *collapse before measuring*, is Curzi [2026]. And the sharpest instance in the corpus of a framework reporting against itself is Curzi [2026], where **the only reading under which an assembled architecture clears the build threshold is the naive one that assumes zero correlation between coordinating jurisdictions, at `h = +0.083099`; every defensible bloc assignment returns a negative surplus, and the paper says so in print.** The four-drawer evidential classification the register here descends from — PROVED, POSTULATED, BORROWED, UNTESTED, with the surplus form recorded as **proved conditionally on a chosen design axiom** and the operational ladder recorded as **specified, not run** — is Curzi [2026].

The framework's own contraction result carries its own refusal, and it is worth restating at the close. Banach's theorem states that a contraction with modulus `q < 1` on a complete space has exactly one fixed point, reached from any start, with distance shrinking by at least `q` each pass [Curzi, 2026]. That is a theorem about a map. **A human life is not a metric space, nobody has measured the relevant contraction modulus, and the feeling of recognition on arrival proves nothing**, since the machinery that rehearses a future retrofits a past with equal fluency. The theorem transfers as shape, not as guarantee, and the closing paper is the last place that distinction can be allowed to slip.

The three-drawer honesty classification this appendix set descends from — four items of established mathematics, seven of established psychology, and exactly three declared postulates, with every protocol stated to run on the first two and steer by the third — is Curzi [2026], and it is the model for Appendix E.

39.8.3 8.3 Rules for carrying the apparatus forward

S1 Read CCP-038 before citing anything in this corpus. Cite by entry ID, because the ID carries the status and a quoted sentence does not.

S2 State the status of every claim carried forward from this framework, in the sentence that carries it. Proved, badged, or open — there is no fourth option and no exemption for summaries.

S3 Measure `h` before promising `r`. A plan requesting more than the gauge permits is not ambitious; it is arithmetically infeasible, and the equation says so before anyone is blamed.

S4 When `h < 0`, do not redesign the interaction geometry. **No geometry saves it.** Raise `eta`, cut `C`, or shed `Q` — the last being the move nobody considers and a legitimate one.

S5 Test feasibility on the mean of `F(U_t)`, never on `F` of the mean. The Jensen gap was worth 6.2% of surplus in the CCP-016 worked office.

S6 Run the structural ceiling test on every result, before and after the statistical baselines. A single-step increment exceeding `eta ln N` is impossible, and impossibility outranks significance.

S7 Quote every `delta` with its period and every `F` in nats. Convert with the exact keys, never with an approximation.

S8 Never present precedent as evidence. Where the historical corpus has nothing to say, write *none claimed* and leave it.

S9 Recommend no intervention that removes a person's ability to decline, and attach consent to the person rather than to the scope. Disclose everything: **nothing masked, nothing below threshold, nothing concealed.**

S10 Publish the demotions. If nothing in a body of work has ever failed a gate, the gates are not connected to anything.

S11 Report null results from the tests this corpus names. Appendix E.4 lists ten of them, all of them cheap, none of them run. **A reader who runs one and reports a null has done this corpus a service it cannot repay.**

S12 Re-derive the reference card and the register annually, by reading the corpus papers. Both are stored order with their own `delta`, and a card that has become wrong looks exactly

like one that is still right.

39.8.4 8.4 Faults of the closing summary itself

Fault	Signature	Mechanism	Fix
THE SLOGAN	"It's all the same equation at every scale," quoted without its status	The correspondence is memorable and its badge is not	S2 and CCP-038. It is a claim about model form, never tested at two scales at once
BADGE EROSION	A postulate cited as a finding, three cross-references downstream	Each hop drops one qualifier	S1. Cite the ID
THE MISSING LOSS TERM	A plan that assumes stored order persists without maintenance	`delta` is invisible until it is measured, and infrastructure becomes visible only on breakdown	Measure `delta` under zero input. Assume nothing holds by itself
HEADROOM THEATRE	`h` reported as a target and rising every quarter	A measure used for control ceases to measure. This framework is subject to Goodhart like everything else	Measure `h` where parameters are estimated, not where decisions are announced
THE GENEROUS SUMMARY	A closing chapter that claims more than its register contains	Endings invite generosity, and the reader is tired	This paper is bounded by CCP-038 and claims nothing that is not in Groups A and B
BORROWED CERTAINTY	A laboratory result deployed as a fact about the reader's institution	The citation stays attached while the setting silently changes	Read the "what it measured" field before quoting the finding
THE ADDED MECHANISM	A supernatural, energetic, or clinical claim attached to the formalism to make it more useful	The formalism is austere and austerity feels like incompleteness	The formalism is sufficient for what it claims. Anything added is outside the register and outside this corpus
CLOSING ON A TRIUMPH	A final chapter that resolves rather than opens	A book wants an ending, and an open problem does not feel like one	§8.1. The work ends on what is not known

---

39.9 9 Verification

The four structural results compound from five postulates. Each is atomic, checkable on its own, and carries its status. **A reader is asked to check several short things rather than one**

long one.

39.9.1 9.1 Dimensional audit

Symbol	Dimension	Unit	Status
`u`, `u*`, `u_0`	`[1]`	none	**defined** dimensionless: `u = 1 - (x.y)^2` for unit vectors
`N`	`[1]`	categories	**counted**
`N_eff`	`[1]`	effective count	**derived**: `1 + (N-1)u`, affine, **not a Hill number**
`F(u)`, `ln N`, `ln 2`	`[1]`	nats	**derived** dimensionless; convertible to bits and octaves by exact constants
`Q_t`	`[Q]`	proxy units (whatever the declared order proxy counts)	**proxied, never measured**
`eta`	`[Q]` per nat per step	proxy units per nat per period	**estimator defined, never validated**
`delta`	`[1]`	per period — the period is part of the number	**estimator defined**; validated once, borrowed [Curzi, 2026]
`C_t`, `c*`	`[Q]` per step	proxy units per period	**estimator defined**; rests on a commensuration postulate
`h_t`, `h_inf`, `r_max`	`[Q]` per step	proxy units per period	**derived**
`n` (essence index)	`[1]`	none	**defined** ordinal index
`k`	`[1]`, or `[T^-1]` **only under a separate postulate**	dimensionless as defined; **hertz is a separate claim**	**DEFINED** = `(9/8)^2/phi^2`, exact
`f(n) = k n^2`	as `k`	as `k`	**POSTULATED** square law; the frequency reading is a further postulate
likelihood ratio	`[1]`	none	**derived** from a stipulated selection process
survival probability	`[1]`	none	**derived** from badged stage priors

Do the identities balance? `F(u) = ln((u+u_0)/u_0)` balances because `u` and `u_0` carry the same dimension — none — so their ratio is a pure number and its logarithm is in nats. `h_inf = eta(ln N - F(u*))` balances because the bracket is dimensionless and `eta` carries `[Q]` per nat

per step, so the product is `[Q]` per step, commensurable with `delta Q` and `C`. `ln N − ln(N/2) = ln 2` is dimensionless throughout.

Where the framework has no operational unit, this paper says so. Stored order has no natural unit and two systems' values are not comparable unless they declare the same proxy. Comfort, the corpus's underlying construct, has **no operational unit at all**. Perspective and perception have **no unit and no zero**, which is why their quotient is demoted. **`k` is dimensionless as defined; the corpus's essence material attaches hertz to it, and that attachment is a postulate carried on its own line below rather than folded into the definition.**

39.9.2 9.2 The postulates

P1 — `F(u) = ln(1 + (N−1)u)` on `u` in `[0,1]`, with `0 <= F(u) <= ln N`. *Status:* **CITED** — the surplus functional and its range [Curzi, 2026].

P2 — The storage recurrence is `Q_{t+1} = (1−delta)Q_t + eta S_t − C_t` with `delta` in `(0,1]`, and its fixed point is `Q_inf = (eta F(u*) − c*)/delta`. *Status:* **CITED** — the storage law and its fixed-point theorem [Curzi, 2026a]; the fixed point exists because the map is a contraction [Banach, 1922].

P3 — `ln(ab) = ln a + ln b` and `ln(a/b) = ln a − ln b`. *Status:* **ARITHMETIC.**

P4 — The essence law is `f(n) = k n^2` with `k = (9/8)^2/phi^2`. *Status:* **POSTULATED** for the square law; **DEFINITION** for the constant, which is exact and equals `0.483425732988414`.

P5 — `k` is measured in hertz. *Status:* **POSTULATED** — a separate and stronger claim than computing `k`, carried on its own line because it is a different claim, and supported by nothing in this corpus. Result (b) below does **not** consume it: the octave-folding cost is a ratio and is independent of the unit `k` carries.

39.9.3 9.3 The compounding chain

```
P1 + P3     -> V1   ln(1 + (N−1)u) = ln((N−1)(u + 1/(N−1)))
                    = ln((u + u_0)/u_0)  with  u_0 = 1/(N−1).       ARITHMETIC

V1          -> V2   at u = u_0: N_eff = 1 + (N−1)/(N−1) = 2 exactly,
                    and F(u_0) = ln 2 = 0.693147..., for EVERY N.   ARITHMETIC

P4 + P3     -> V3   f(2n)/f(n) = (2n)^2/n^2 = 4 exactly, so indices n
                    and 2n share a pitch class; 1..N contains exactly
                    ceil(N/2) classes.                              ARITHMETIC

V3 + P3     -> V4   folding an even-N lattice: ln N − ln(N/2) = ln 2
                    = 0.6931471806 nats = 1 bit = 2 octaves, for EVERY
                    even N.                                         ARITHMETIC

P2          -> V5   at the fixed point delta Q_inf = eta F(u*) − c*, so
                    h_inf = eta ln N − delta Q_inf − c*
                          = eta (ln N − F(u*)).                     ARITHMETIC

V5 + P1     -> V6   F(u*) <= ln N, therefore h_inf >= 0 ALWAYS.     ARITHMETIC

P2          -> V7   r_max = eta ln N − delta Q − C <= eta ln N, since
                    delta, C >= 0; a claimed single-step increment of
                    38.5 x eta ln N is impossible under the model
                    at any parameter setting.                       ARITHMETIC

P5          -> V8   f(n) in hertz.                                  POSTULATED
                    NOT CONSUMED by V1..V7. Listed so that a reader can
```

see exactly which line the frequency claim enters on.

Every line is checkable from its own stated inputs. V1 through V7 are arithmetic consequences of two cited results (P1, P2), one arithmetic fact (P3) and one postulated functional form (P4), and V4 is the only one that consumes P4. **V8 is listed and consumed by nothing**, which is the point of listing it: the frequency reading of `k` is a claim this paper neither uses nor supports.

What the chain does not establish. It does not establish that any institution, mind or cell obeys P2, or that any essence set obeys P4. **A chain whose steps are ARITHMETIC and CITED delivers the mathematics with certainty and delivers nothing whatever about any system**, and the one preregistered confirmatory test of P2 reported in this corpus did not meet its own declared margin [Curzi, 2026i].

39.9.4 9.4 The verification instance, worked by hand

Check 1 — the Fechner identity at `N = 6`. `u_0 = 1/5 = 0.200000`. At `u = 0.5`: `ln(1 + 5 x 0.5) = ln 3.5 = 1.252763`, and `ln((0.5 + 0.2)/0.2) = ln 3.5 = 1.252763`. **Two logarithms of the same number.** At `u = u_0 = 0.2`: `ln(1 + 5 x 0.2) = ln 2 = 0.693147`, and `N_eff = 1 + 5 x 0.2 = 2` exactly. **The threshold is the point at which the effective count reaches two, and it is one full bit wide, at every `N`.**

Check 2 — the threshold's size across `N`. `u_0 = 1.000000` at `N = 2`; `0.500000` at `N = 3`; `0.333333` at `N = 4`; `0.200000` at `N = 6`; `0.090909` at `N = 12`. **In a two-category system the second voice arrives only at perfect orthogonality; in a twelve-category system it arrives at nine per cent of the range**, which is a precise statement of why narrow systems yield so little.

Check 3 — the folding cost. `ln 12 − ln 6 = 2.484907 − 1.791759 = 0.693147`. `ln 64 − ln 32 = 4.158883 − 3.465736 = 0.693147`. Ten values of `N` return `0.6931471806` and a ratio to `ln 2` of `1.0000000000`. **The concrete case: a twelve-essence set has indices with odd parts `1,1,3,1,5,3,7,1,9,5,11,3`, giving six pitch classes.**

Check 4 — the constant, to fifteen figures. `(9/8)^2 = 1.265625` exactly. `phi^2 = phi + 1 = 2.618033988749895`. Dividing, `1.265625 / 2.618033988749895 = 0.483425732988414`. **Three checks anyone can redo in a minute, and the constant is then established as defined rather than asserted** — with the standing caution that a golden-section appearance in a defined constant is a design choice of this corpus and not an observation about nature [Markowsky, 1992].

Check 5 — the headroom identity, both ways. At `eta = 0.35`, `N = 12`, `u* = 0.30`, `delta = 0.05`, `c* = 0.40`: `F(0.30) = ln(1 + 11 x 0.30) = ln 4.3 = 1.458615`, so the identity gives `0.35 x (2.484907 − 1.458615) = 0.359202`. The long way: `Q_inf = (0.35 x 1.458615 − 0.40)/0.05 = 2.210305`, then `h_inf = 0.35 x 2.484907 − 0.05 x 2.210305 − 0.40 = 0.359202`. **The same number to ten decimals, and the second computation used three quantities the first did not need.**

Check 6 — the impossibility. `r_max = eta ln N − delta Q − C` is at most `eta ln N`, since `delta` and `C` are non-negative. A claimed single-step jump of `38.5 x eta ln N` is therefore inadmissible under the model **at any parameter setting, any significance level, and any sample size.** That is not a p-value; it is a contradiction.

39.9.5 9.5 Limits, asymptotics, and the domain of the results

- **`u -> 0`.** `N_eff -> 1`, `F -> 0`. Ten aligned instruments are one instrument; the Fechner form gives `ln(u_0/u_0) = 0` at `u = 0`, consistently.
- **`u -> 1`.** `N_eff -> N`, `F -> ln N`, and `h_inf -> 0`. **A system extracting everything its geometry allows retains the least headroom at the fixed point**, which is the design reading of result (c).
- **`N -> 2`.** `u_0 = 1`, so **the threshold is the ceiling**: in a two-category system the second independent voice arrives only at perfect orthogonality. This is a real constraint on the domain of usefulness, not a defect.

- **`N -> infinity.`** `u_0 -> 0`, so the threshold vanishes and any non-parallelism at all buys a second voice; meanwhile `ln N` grows logarithmically while coordination paths grow as `N(N-1)/2` [Brooks, 1975]. The two together bound the useful roster well below any crossover computed from surplus alone.
- **`N` odd, for result (b).** The folding cost is exactly `ln 2` **for even `N` only**; `1..N` contains `ceil(N/2)` classes, so an odd lattice folds to `(N+1)/2` and the loss is `ln N - ln((N+1)/2)`, which is **less** than `ln 2` and is not constant. **The result is stated for even `N` and holds for even `N`.**
- **`delta -> 0`.** No fixed point exists at all rather than being infinite: the map is an isometry and the geometric series does not converge [Curzi, 2026a]. **Result (c) has no content at `delta = 0`**, since it is an identity about a fixed point that does not exist there. Outside the domain.
- **`eta -> 0`.** `h_inf -> 0` and the system cannot build at any `u` or `N` — the storage law's correspondent of the forbidding clause `G = 0 => E = 0` in the channel-gain form of the belief postulate [Curzi, 2026ab].
- **Exogenous accretion.** With a term `A` for stored order arriving from outside the interaction loop, `h_inf = eta(ln N - F(u*)) - A`, which goes negative exactly when `A` exceeds the geometric shortfall. **This is where ossification lives, and the plain model does not contain it.**

39.9.6 9.6 Model comparison, and the standard this paper does not meet

The paper reports no fit of its own. It inherits the standard because the apparatus it collects is what a fit would be run with.

Requirement	Status	What was actually done
Out-of-sample performance reported	**MET**	held-out RMSE against four baselines [Curzi, 2026i]
Matched null with equal free parameters	**MET**	a matched AR(1); the fit beat it by 2.8 per cent against a declared 10 per cent margin and **failed its own preregistered rule**
Information criterion (AIC or BIC)	**NOT MET**	**no AIC or BIC has been computed anywhere in this corpus**, so no comparison in the series pays for its parameter count
Number of free parameters stated explicitly	**PARTIAL**	the storage law's four parameters are named; they are not tabulated against each baseline's count
Effect sizes with intervals	**NOT MET**	RMSE advantages are reported as point estimates without intervals
Shuffle control's false-positive rate measured	**MET, AND ADVERSE**	0.108 for i.i.d. permutation and 0.120 for circular shift against a nominal 0.05 [Curzi, 2026u] — **anti-conservative**
Structural ceiling test run alongside the empirical baselines	**MET, AND DECISIVE**	it is the only test that caught the repackaging (result (d))

Requirement	Status	What was actually done
Non-affine `g(u)` fitted and compared on held-out data	**NOT MET**	the corpus's register names the test and records that it has not been run [Curzi, 2026]; it is not expensive
Saturating or state-dependent storage law compared	**NOT MET**	same register, same status

Four NOT MET rows are printed rather than omitted. The last two are the most damaging: they are the tests that would decide whether the corpus's two founding design choices are the right ones, and neither requires new data.

39.9.7 9.7 Scale type, and the objection the corpus concedes

Quantity	Scale type	What licenses it	Operations performed here
`N`, `N_eff`, pitch-class count	ratio (counts)	counting	all
`u`, `u_0`	ordinal at best, treated as ratio	**nothing tested**	used inside a logarithm; **not licensed**
`F`, `ln N`, `ln 2`	ratio (a log of a count)	derived from a count	differences, ratios, conversion to bits and octaves
`Q`	interval at best in a declared proxy	proxy definition only	differences and rates within one proxy
`D`, `P`, `M`	ordinal	no zero, no unit	ordering only; the quotient **demoted** [Curzi, 2026t]
the essence index `n`	ordinal, treated as ratio in `k n^2`	**postulated, not tested**	squared; **the square law is the postulate that licenses it, and it is a postulate**
likelihood ratios	ratio	a ratio of probabilities	division

Michell's critique is the strongest single objection to this corpus and it is conceded here. Michell [1997, 1999] argues that psychology assumes its attributes are quantitative without testing that they are. The corpus's founding move — treating comfort as a magnitude — is exactly that assumption. The test that would settle it is conjoint measurement [Luce and Tukey, 1964, Krantz et al., 1971], whose double-cancellation conditions determine whether an attribute admits additive quantitative structure at all. **Those conditions have not been tested for comfort, for `u`, for perspective or for perception, by this work or by anyone.** The corpus's response is partial and is stated as partial: it denotes the quantity whose operation most obviously requires a ratio scale, and prices the Rasch route at 123 items per term [Rasch, 1960, Andrich, 1988] — an instrument with a defensible zero, which is **not** a conjoint test. Reliability would not substitute [Sijtsma, 2009], and construct validation [Cronbach and Meehl, 1955, Campbell and Fiske, 1959] would establish that an instrument measures something without establishing that the something is quantitative. **The scale type of the essence index is the least defended item in the table and the register records it as postulated.**

39.9.8 9.8 Invariance, and the precision of the numbers

What is invariant. The Fechner identity holds for every `N >= 2` and every `u` in `[0,1]`; the threshold value `F(u_0) = ln 2` is invariant in `N` entirely, which is the surprising part. The folding cost `ln 2` is invariant in `N` over even `N`. The identity `h_inf = eta(ln N − F(u*))` is invariant under any change of `delta`, `C` or `Q`, which is the content of the cancellation, and **is not invariant under adding an exogenous accretion term.** The impossibility of a `38.5 x eta ln N` jump is invariant under every parameter setting, which is what makes it a structural rather than a statistical test.

What is not invariant, and is not claimed to be. Nothing here is invariant across scopes; **scale-freedom is claimed at three scopes and has been tested at zero**, because testing it requires simultaneous measurement at two scopes of one system and no such measurement exists [Curzi, 2026].

Precision. Every number in this paper is one of three kinds. *Exact consequences of definitions* — `ln 2 = 0.6931471806`, `k = 0.483425732988414`, `h_inf = 0.3592020695` — are quoted to whatever precision is useful and are exact; the fifteen figures on `k` are legitimate **only because `k` is defined**, and a measured quantity quoted to fifteen figures would be the classic marker of work that does not understand its own error bars. *Numerical verifications* — the `8.9e−16` residual on the Fechner identity and the sub-`1e−16` agreement on the headroom identity — are floating-point noise and are reported as such rather than as agreement to a physical tolerance. *Outputs of stipulated models* — the survival curve, the likelihood ratios — are exact given inputs the author chose and badged as chosen, and **carry no empirical content at all. Where a reader sees ten decimals in this paper they should read "consequence of a definition or a stipulation", never "measured to that precision".**

39.10 10 Limitations

L-1 This paper is not a research contribution and does not present itself as one. It is closing material plus reference apparatus, most of its length recapitulates results established elsewhere, and its non-recapitulative content is four algebraic identities and a set of computed bookkeeping items. **It is retained in the series because other papers rely on its appendices**, not because it adds knowledge.

L-2 None of the four structural results is empirical, and none could be falsified by an observation. (a), (b) and (c) are identities; (d) is a structural argument about what a control can detect, together with one reported instance. **A reader looking for a test of the framework will not find one here** and should read Curzi [2026i] and Curzi [2026u], where the tests that were run are reported, including the one that failed its own declared margin.

L-3 Result (b) rests on a postulate, and the postulate is the load-bearing part. The octave-folding cost is exact **inside** the lattice `f(n) = k n^2`, and that square law is a postulate about essence structure with no external support. "Consonance" there means the exact-ratio octave identification internal to the lattice; **it is not a claim about the psychoacoustics of consonance, which is a different subject with a contested literature.** And the output remains an essence frequency: **no claim is made that any material, molecule, element or person physically resonates at these values.**

L-4 Attaching hertz to `k` is a separate claim from computing `k`, and it is unsupported. The constant is exact as a ratio; the unit is a postulate, carried as V8 in the chain and consumed by nothing in this paper.

L-5 Result (b) holds for even `N` only (§9.5). For odd `N` the folding loss is `ln N − ln((N+1)/2)`, which is smaller than `ln 2` and varies with `N`. The source states the result for even `N` and this paper preserves that scope.

L-6 The reflexive parameter is not identified from observational data [Manski, 1993, Shalizi and Thomas, 2011], and no remedy is adopted anywhere in the corpus (§3.4). Every protocol in Appendix C returns a number; **none of them identifies a social coupling.**

L-7 The conjoint conditions have not been tested for any construct in this corpus [Michell, 1997, Luce and Tukey, 1964], and the ratio-scale treatment of `u` and of the essence index is unlicensed.

L-8 No AIC or BIC has been computed anywhere in this corpus, and the two tests that would decide its founding design choices — a non-affine effective count and a saturating storage law — have not been run (§9.6).

L-9 The survival curve is arithmetic on the author's own priors. The stage probabilities 0.90, 0.90, 0.85, 0.65 and 0.80 were chosen and badged as chosen. **A different set gives a different curve, and the 35.8 per cent figure should be read as "what these priors imply", not as a measured base rate.** What is not arbitrary is that the calculation was published at all.

L-10 The likelihood-ratio results are arithmetic on a stipulated selection process. The testimony ratio of exactly 1.000000 follows from a process in which failures are never published; where failures are published at some rate, the ratio is not one. **The result is a statement about a selection regime, not a measurement of any actual literature**, and the four hypothesised success rates producing 500 identical published accounts are stipulated for the calculation.

L-11 A numerical inconsistency in the source is recorded rather than silently corrected. The closing chapter states the worst residual on the Fechner identity as `4.4e-16`; the honesty appendix states it as `8.9e-16` over `u = 0.01` to `1.00` at `N = 2, 3, 5, 8, 12, 25, 100`. **Recomputing the identity over both grids returns a maximum absolute difference of `8.88e-16`, so the appendix figure is the correct one and the closing chapter's is too small.** This paper quotes `8.9e-16` throughout and prints the discrepancy here.

L-12 The mapping from the source manuscript's chapter numbers and internal papers to corpus identifiers is an editorial inference (§3.6). In the appendices those identifiers are plain text rather than bibliographic citations, because the appendices are an index rather than an argument.

L-13 The register in Appendix E classifies the author's own claims. It is not an external audit, and the only defence offered is that every entry carries the fields a hostile reader needs in order to check it, and that the demotions are printed in the same typeface as everything else.

L-14 Several works are named in prose without bibliographic keys, because they are not in this corpus's external bibliography. They include the sources named in Appendices B and E for information cascades and Goodhart capture where those entries name authors and years without a key, the historical and liturgical corpora invoked in the precedent column, and the primary sources of the cell-biology chain, whose treatment in this corpus is Curzi [2026y]. **Each is a real published result quoted for what its source measured; the reader is owed the note that they are named rather than referenced.**

L-15 The appendices carry the corpus's own decay. A reference card is itself a stored order with its own retention loss, and the source's own specification requires it to be re-derived from the papers annually by reading rather than by editing. **Nothing in this paper verifies that the appendices currently match the papers they index**, and where an entry and a paper disagree, the paper is authoritative.

39.11 11 Conclusion

This is closing material and reference apparatus, and its four non-recapitulative results are exact identities rather than empirical findings.

First, the surplus law is exactly a Fechner law in threshold-corrected form. `F(u) = ln(1 + (N−1)u) = ln((u + u_0)/u_0)` with `u_0 = 1/(N−1)`, verified for `N = 2` through `N = 100` at seven values of `u` to a worst residual of **8.9e-16**. At the threshold the effective count is **exactly 2** and the surplus is **exactly `ln 2` — one bit, two octaves — for every `N`**. The threshold is the non-parallelism at which the second independent voice opens: `u_0 = 1.000000` at `N = 2`, so in a two-category system the second voice arrives only at perfect orthogonality, and `u_0 = 0.090909` at `N = 12`. **The correspondence is structural and is evidence for neither law:** the surplus functional

is a theorem under its axioms and gains nothing from resembling Fechner's, and Fechner's is an empirical claim resting on its own postulate and gains nothing from resembling the surplus functional.

Second, folding the essence lattice into one octave costs exactly `ln 2 = 0.6931471806` nats for every even `N`, computed at `N = 4, 6, 8, 10, 12, 16, 20, 24, 32, 64`, which is one bit and two octaves by the corpus's own exact conversion key. In that lattice **calling two things consonant and calling them redundant are the same operation**, and every identification is a reduction of effective count. The result is exact inside a postulated structure and claims nothing about psychoacoustics or about physical resonance.

Third, `h_inf = eta(ln N − F(u*))`: retention, cost and stored order all cancel at the fixed point, verified against direct computation across four parameter sets to below `1e−16`. Since `F(u) <= ln N` always, **`h_inf >= 0` always, so the plain linear model never ossifies by itself.** Ossification therefore requires a term the model does not contain — exogenous accretion of stored order, or cost rising with stock — and **a model that cannot produce a phenomenon everyone observes is reporting that the mechanism is outside the model**, which converts a lament into a question with two named suspects.

Fourth, the shuffled-input control is blind to repackaging. A filtered repackaging of the input passed all four empirical baselines including the shuffle at **`p = 0.0005`** and was caught only by the structural ceiling `r_max = eta ln N − delta Q − C`, its claimed single-step jump being **38.5 times `eta ln N`. Impossibility is not a p-value; it is a contradiction**, and no parameter setting, significance level or sample size admits it. The rule that follows is that the shuffle is an empirical audit and only the structural tests detect repackaging — reinforced by the shuffle's own measured false-positive rate of **0.108 against a nominal 0.05**.

The appendices publish two admissions. Testimonial evidence under a selection process that publishes successes has a likelihood ratio of **exactly 1.000000** — a thousand favourable testimonials carry the evidential weight of zero — against **2.0000** for a direction-only prediction and **11.3577** for a magnitude call with a tolerance, a factor of about **5.7**. And the research programme that would settle whether the framework's formulas are science publishes its own odds: **21 preregistered kill conditions of which 4 are terminal, 8,554.8 researcher hours, 570 participants, 71 months, P(completion) = 35.8 per cent, and P(death at or before the cross-subject recovery stage) = 55.3 per cent.** The programme is more likely than not to be dead before field trials begin, and the stage carrying the heaviest prior is the one where a formalism that *describes* meets the demand that it *measure*.

Read together with the instrument audit — 19 defined estimators, 1 validated value and 0 first-party measurements across 27 parameter-by-scope cells [Curzi, 2026] — that is the true state of the instrument at the close of the series: nineteen procedures, one borrowed number, no measurement of its own, a keystone formula demoted by its own protocol, and a thirty-five per cent chance of finishing. A reader who finds that discouraging has read it correctly.

39.11.1 Declarations

Data and code availability

No external dataset was collected for this paper, and no human participants were surveyed, observed or recruited. All numerical results are computed from parameters and definitions stated in the text, and every table can be re-derived from the equations printed beside it. The worked instance in Section 7.1 is a **constructed illustrative example with declared parameters**, not a report of any real system. The single borrowed empirical value that appears anywhere in the supporting audit belongs to its published source and is cited to it in Curzi [2026], where the corpus-wide count is also established: **of 27 parameter-by-scope cells, zero carry a first-party measurement.** The survival curve and the likelihood ratios are arithmetic on stipulated inputs and badged priors, not observed base rates. The figures are generated by the scripts named in each caption, which contain no data beyond the numbers printed in this paper. The appendices are compiled by reading the corpus's own papers.

Funding

This research received no external funding.

Conflicts of interest

The author declares no conflicts of interest. **The honesty register in Appendix E classifies the author's own claims, which is a structural conflict rather than a financial one, and it is disclosed as Limitation L-13.**

Author contributions

Single author. Michael Laurence Curzi derived the results, compiled the reference apparatus and the register, produced the figures, and wrote the paper.

Ethics

No human-subjects research was conducted and no personal data was processed. No biological materials were handled and no experiment of any kind was performed. **No clinical, medical or therapeutic claim is made anywhere in this paper**; nothing here diagnoses a person or recommends a treatment; and **no claim is made that any material, molecule, element or person physically resonates at any frequency computed from the essence law.** The research programme costed in Appendix E.11 is a **prospective design**, with its consent architecture, its decline path and its preregistered kill conditions specified in advance; it has not been run, and nothing in this paper reports a result from it.

Preregistration

This paper reports no preregistered test of its own; its results are identities and bookkeeping. The preregistered protocol for testing the storage law against a real system, and the confirmatory application that **failed** its second falsification rule — a 2.8 per cent held-out RMSE advantage over a matched AR(1) against a declared 10 per cent margin — are reported in Curzi [2026i]. The falsification suite measured against itself, including the shuffled-input control's **anti-conservative false-positive rate of 0.108 against a nominal 0.05**, is Curzi [2026u]. The programme in Appendix E.11 publishes **21 kill conditions, 4 of them terminal, in advance of any data**, together with the commitment to publish at every stage including the stage that ends the programme, with null results titled as null.

The body of this framework argued, specified, and worked examples. The appendices do none of those things. They are the bench: the card that gets pinned above the desk, the vocabulary an engineer must be able to use without hedging, the ten protocols that turn an opinion about a system into a number — and, in one case, that take a protocol back off the reader, the index that lets a reader who arrives with a symptom leave with a diagnosis, the statement of exactly what this corpus is entitled to claim, and the bridge back to the volume that preceded it.

A caution before the drawer is opened. A reference card is itself a stored order — a small `Q`, with its own `delta` — and it decays silently, because a card that has become wrong looks exactly like one that is still right. **Re-derive it from the corpus papers once a year, by hand.** A card corrected by its user is worth two printed ones.

Appendix E is the warrant, and is the one appendix to read if only one is read. Everything else in this framework is a consequence of a small number of proved theorems, a slightly larger number of badged postulates, and a set of borrowed empirical results that were obtained in settings that are not yours. Appendix E states which is which, item by item, and it is written to be used against this corpus by anyone who wishes to test it.

And it now states two further things, which are the two worth reading first. It records what this corpus **demoted** — including its author's own keystone formula, on gate two of seven, with the cost of the repair named — and what this corpus **rejected**, four claims worked end to end in print and failed. **Nothing in an appendix is more load-bearing than a list of the things its author had to give up.**

39.12 Appendix A The law reference card

Three pages. Print at 100%. Pin at eye level beside the desk where the parameters are estimated, not where the decisions are announced.

39.12.1 A.1 Symbol table

Symbol	Name	Definition	Range	Units	Where it is measured
`x, y`	state vectors	unit-normalized encodings of two participating states (views, agents, categories)	unit sphere	dimensionless	Appendix C, Protocol C-4
`x·y`	alignment	inner product of the two unit vectors	`[−1, 1]`	dimensionless	C-4
`u`	non-parallelism	`u = 1 − (x·y)^2 = ||x ^ y||^2`	`[0, 1]`	dimensionless	C-4
`N`	category count	number of genuinely distinct categories admitted by the system	integer `>= 1`	count	C-3
`N_eff`	effective count	`1 + (N−1)u`; the audited headcount	`[1, N]`	count	C-3, C-4
`f(u)`	surplus function	`ln(1 + (N−1)u)`	`[0, ln N]`	nats	derived
`F(x,y)`	surplus	`f(u(x,y))`	`[0, ln N]`	nats	derived
`S_t`	surplus input in period `t`	`S_t = F(U_t) = ln(1 + (N−1)U_t)`	`[0, ln N]`	nats/period	C-4 then compute
`U_t`	period non-parallelism	the ensemble `u` prevailing in period `t`	`[0, 1]`	dimensionless	C-4
`Q_t`	stored order	what persists between periods: institution, habit, artifact, furnished room, trust	`>= 0`	Q-units	C-6
`Y_t`	order proxy	the observable standing in for `Q_t`	`>= 0`	Q-units	C-6
`delta` (δ)	retention loss	fraction of `Q` lost per period with zero input	`[0, 1]`	per period	C-1
`eta` (η)	conversion efficiency	`Q`-units of durable structure produced per nat of surplus	`>= 0`	Q-units per nat	C-2
`C_t`	cost / dissipation	coordination, friction, maintenance, conflict, rent, compliance	`>= 0`	Q-units/period	C-5
`h_t`	headroom	`eta*ln N − delta*Q_t − C_t`	any sign	Q-units/period	C-7

Symbol	Name	Definition	Range	Units	Where it is measured
`r_t`	requested increment	the growth in `Q` a plan promises for period `t`	any sign	Q-units/period	C-7
`r_max`	maximum increment	`eta*ln N − delta*Q_t − C_t`	any sign	Q-units/period	C-7
`Q_inf`	steady state	`(eta*F(u*) − c*) / delta`	any sign	Q-units	C-7
`tau` (τ)	time constant	`−1 / ln(1−delta)`, approximately `1/delta` for small `delta`	`> 0`	periods	CCP-007
`u_cross`	crossing	between-category non-parallelism, `= beta^2`	`[0, 1]`	dimensionless	CCP-010, C-4
`u_div`	divergence	within-category non-parallelism, `= alpha^2 * sin^2(gamma)`	`[0, 1]`	dimensionless	CCP-010, C-4
`c`	collective intelligence factor	Woolley et al.'s statistical factor; **not** a term in the law	standardized	z-score	CCP-013

Units convention. `S` and `F` are in **nats**, because the law uses the natural logarithm. `Q` is in whatever unit the order observable `Y` is denominated in, chosen once in Protocol C-6 and never changed mid-study. `eta` therefore carries units of Q-units per nat, and `C` and `delta*Q` must be expressed in Q-units per period or the headroom equation is not an equation. **Three quantities must share one unit or the gauge reads nothing: `eta*ln N`, `delta*Q_t`, and `C_t`.**

39.12.2 A.2 The Surplus Law — CCP-A02, Theorem 2.1

```
F(x,y) = f(u(x,y)),   u(x,y) = 1 − (x·y)^2 = ||x ^ y||^2  in [0,1]

f(u) = ln(1 + (N−1)u)        <−− UNIQUELY characterized by axioms S1−S4

N_eff = g(u) = 1 + (N−1)u    <−− the effective count
F     = ln N_eff             <−− surplus is the log of an audited headcount
```

The axioms.

Axiom	Statement	Status
S1	geometric dependence: `F` depends only on `u`	structural choice
S2	zero at zero: `f(0) = 0`	normalization
S3	affine effective count: `g(u) = e^{f(u)}` is affine in `u`	**DESIGN AXIOM — chosen, not derived**
S4	normalization: `f(1) = ln N`	normalization

S3 is the design axiom. It is chosen, not derived, and that must be said wherever it is leaned on. Every quantitative claim in this framework that uses `N_eff = 1 + (N−1)u` inherits S3's status and not a grade higher.

39.12.3 A.3 Derived properties — NOT axioms

Result	Statement	Reference
Strict monotonicity	`u1 < u2 => f(u1) < f(u2)`	CCP-A02, 3.1
Positivity	`f(u) > 0` for `u > 0`	CCP-A02, 3.2
Strict concavity	`f''(u) < 0`; each added increment of `u` buys less than the last	CCP-A02, 3.3
Subadditivity **on u**	`f(u1 + u2) <= f(u1) + f(u2)`	CCP-A02, 3.4
Sharp Lipschitz	`|f(u1) − f(u2)| <= (N−1)|u1 − u2|`, constant `N−1` is sharp	CCP-A02, 4.2
Extremality	`F = 0` iff parallel; `F = ln N` iff orthogonal	CCP-A02, 4.3
Range	`0 <= F(u) <= ln N`	CCP-009, Cor 2.2

`ln N` is the hard ceiling on surplus per interaction. It appears in every design inequality in this framework through the product `eta*ln N`.

39.12.4 A.4 Two-source decomposition — CCP-A02, Theorem 4.1

For a pure block vector:

```
u = u_cross + u_div

u_cross = beta^2                      (between-category: crossing)
u_div   = alpha^2 * sin^2(gamma)      (within-category: divergence)

max( f(u_cross), f(u_div) )  <=  f(u)  <=  f(u_cross) + f(u_div)
```

The upper bound is the honest one: **no more than the sum is ever obtained.** No synergy beyond additivity is promised, and design that assumes it is designing on a number the theorem does not supply.

39.12.5 A.5 The Storage Law — CCP-007, §3

```
Q_{t+1} = (1 − delta)*Q_t + eta*S_t − C_t          S_t = F(U_t) = ln(1 + (N−1)U_t)
```

Term	Meaning
`Q_t`	stored order — what persists: institution, habit, furnished room, trust
`S_t`	surplus input this period, `0 <= S_t <= ln N`
`delta`	retention loss in `[0,1]` — decay without maintenance
`eta`	conversion efficiency `>= 0` — interaction into DURABLE structure
`C_t`	cost / dissipation `>= 0`

Admissibility. `C_t <= (1−delta)*Q_t + eta*S_t` guarantees `Q_{t+1} >= 0`.

Exact solution — Theorem 3.1.

```
Q_t = (1−delta)^t * Q_0  +  SUM_{k=0}^{t−1} (1−delta)^{t−1−k} * (eta*S_k − C_k)
      \_____________/      \_____________________________________________/
        transient term                    driven term
```

One-step growth — Corollary 3.2. `Q_{t+1} > Q_t  <=>  eta*S_t > delta*Q_t + C_t`.

Uniform bound — Theorem 3.3. `Q_t <= max{ Q_0, eta*ln N / delta }`. If `delta = 0`, `Q_t <= Q_0 + t*eta*ln N` — unbounded linear growth, no fixed point, no arrival.

Sustainability ceiling — Corollary 3.4. A nondecreasing step requires `C_t <= eta*ln N - delta*Q_t`. If `C_t > eta*ln N - delta*Q_t`, **no choice of interaction geometry can prevent order from decreasing.**

Steady state — Theorem 3.5. With constant `U \ensuremath{\equiv} u*`, `C \ensuremath{\equiv} c*`, and `delta > 0`:

```
Q_inf = (eta*F(u*) - c*) / delta
```

If `eta*F(u*) < c*` the equilibrium is negative: the regime is unsustainable, or the linear model must be replaced. **The theorem does not hide this failure mode.**

Target increment — Proposition 4.1. `Q_{t+1} - Q_t >= r_t` iff `S_t >= (delta*Q_t + C_t + r_t)/eta`, feasible only if `delta*Q_t + C_t + r_t <= eta*ln N`.

Maximum one-step increment — Corollary 4.2. `r_max = eta*ln N - delta*Q_t - C_t`. No policy based on interaction geometry alone can guarantee more.

39.12.6 A.6 Headroom — the master gauge, CCP-007 §6.4

```
h_t := eta*ln N - delta*Q_t - C_t

h_t < 0   unsustainable in this model. No geometry saves it.
h_t = 0   maintenance only. Hold, do not build.
h_t > 0   growth available; any requested increment must satisfy r_t <= h_t.
```

`h_t > 0` says growth is ATTAINABLE, not that it is happening. Headroom is computed at `S = ln N`, the orthogonal limit. Whether `Q` is actually rising this period is a different test — Corollary 3.2 — evaluated at the geometry actually present. A system can have positive headroom and be shrinking. See the worked block in A.10.

39.12.7 A.7 The circuit identity — the corpus's circuit-identity convention

`Q_{t+1} = (1-delta)*Q_t + eta*S_t - C_t` **is a leaky integrator**: in discrete time, exactly a first-order RC low-pass filter and charge accumulator.

Storage law	Circuit
`Q`	charge on a capacitor
`delta`	leakage conductance
`eta*S`	current in
`C`	load draw
`(1-delta)`	feedback gain / pole
`Q_inf`	steady-state charge
`tau = -1/ln(1-delta)`	time constant, in periods

Because `delta > 0` makes the map a contraction, **Banach's fixed point theorem** guarantees a unique fixed point and convergence to it from any start. **Recursion here is not a stack that overflows; it is an accumulator that integrates. That is why iteration arrives.**

Settling, for a step input: `3*tau` reaches 95.0% of the final value, `5*tau` reaches 99.3%.

39.12.8 A.8 Derived results — what this corpus derived, and where

The sections above are Papers A through E. The seven results below are not: they were derived in the course of writing this framework, each was verified numerically before it was printed, and each carries this paper that owns it and the ledger item that propagated it. ***Four of them change what is done****, which is why they are on the card and not in a footnote.*

D-1 · Headroom at the fixed point. `h_inf = eta*(ln N − F(u*))` — **CCP-008, CC-R6.**

At the fixed point, `delta`, `C` and `Q` all cancel. Verified against direct computation of `eta*ln N − delta*Q_inf − C` across four parameter sets; agreement to `< 1e−15`. Because `F(u) <= ln N` always, **`h_inf >= 0` always: the plain linear model never ossifies by itself.** Ossification is therefore not a property of the recurrence. It requires exogenous `Q` accretion or a cost that rises superlinearly in `Q` — which makes the maintenance trap a claim about the world rather than a consequence of the arithmetic, and it must be measured rather than assumed.

Refined at the internal scope (**CCP-021/41**): `h_inf = eta*(ln N − M*)`. At the fixed point, headroom is `eta` times the gap between the ceiling and the achieved moment, with cost cancelling (verified to 6 d.p.). Companion: `C_crit = eta*M − lambda*E_b` — **above this operating cost a departure is unreachable at any level of desire whatsoever.**

D-2 · The gradient identity. `grad h = −grad C` — **CCP-022, R19.**

Where `eta`, `N` and `delta` are constant in the direction of motion, headroom and cost have exactly opposite gradients. Two consequences, and the second is the most practically useful result in Part VIII:

1. `grad C = 0` iff `grad h = 0`. **The comfort zone and the headroom maximum are the same point**, under the stated restriction.
2. **A cheap habit or desire-line survey IS a headroom measurement.** the founding material's gradient node and this framework's master gauge read the same gradient. The full CCP-015 survey is not always required to locate the direction of steepest improvement — see Protocol C-9.

The restriction is load-bearing. Where `eta`, `N` or `delta` vary with position the identity fails and the full expansion of CCP-022 §42.12 applies. Do not use the shortcut across a boundary that changes the roster or the retention regime.

D-3 · The effective count is the participation ratio. `N_eff = N + 1 − N/PR` — **CCP-015, CC-R3.**

The mean-pairwise `u` aggregator and the Rényi-2 participation ratio `PR = (SUM lambda)^2 / SUM lambda^2` are the same effective count, exactly. Verified over random ensembles: worst discrepancy `1.8e−15`, most agreeing to machine zero. **This is a named identity, not an approximation**, and it means the eigenvalue route and the pairwise route to `N_eff` cannot disagree — so a disagreement in practice is a data or encoder fault, not a choice of estimator.

D-4 · The surplus law is a Fechner law. `F(u) = ln((u + u_0)/u_0)` with `u_0 = 1/(N−1)` — **CCP-020, CCP-039.**

Algebraically identical to `ln(1 + (N−1)u)`, term for term, at every `N` tested (worst difference `8.9e−16` over `u = 0.01` to `1.00` at `N = 2, 3, 5, 8, 12, 25, 100`). CCP-A02's surplus functional is Fechner's law with the stimulus being non-parallelism, `k = 1`, and an absolute threshold at `u_0`. And the threshold is not arbitrary:

```
N_eff(u_0) = 1 + (N−1) * 1/(N−1) = 2       exactly, for EVERY N
F(u_0)     = ln 2 = 0.693147 nats = 1 bit = 2 octaves       for EVERY N
```

The threshold of difference is exactly the point at which the effective count reaches two. Below `u_0` the system does not yet hold a second independent voice. **Declare `N` whenever the reader quote a surplus, because declaring `N` is declaring the threshold.**

D-5 · The storage law in world coordinates. `G_{t+1} = G_t^(1−delta) * N_eff^eta * e^(−C)` — **CCP-020.**

Write `G_t = e^{Q_t}` and exponentiate the storage law. Because `S_t = ln N_eff,t`, the surplus is already a logarithm and `e^{S_t} = N_eff,t` exactly. Verified against direct computation

at `delta = 0.08`, `eta = 0.35`, `C = 0.20`, `N = 12`, `u = 0.5`: worst difference `7.1e-15` over twelve periods. Read the three terms:

- **`G_t^(1-delta)` — decay is taking a root**, not a subtraction.
- **`N_eff^eta` — conversion is exponentiation**, not a fraction added.
- **`e^(-C)` — cost is a divisor**, not a deduction.

Fixed point: `G_inf = (N_eff^eta * e^(-C))^(1/delta)`, which for the parameters above evaluates to **295.6376**, identical to `e^{Q_inf}` with `Q_inf = 5.689135` to fourteen significant figures. **Stored order in world coordinates is an effective count, and the storage law is its weighted geometric accumulation.** No new claim is made — this is Theorem 3.5 in different coordinates — and what it shows is that the framework has been working in the lens all along.

D-6 · The two-track ledger. `Z_{t+1} = (1-delta)Z_t + eta(M_t - V_t)`, `C_t = c_0 + kappa*Z_t` — **CCP-019/40, R18.**

`Q` is all stored order; `Q^V` is *veridical* stored order; `Z = Q - Q^V` is stored error. With `M = min(r*E, ln N)` the moment and `V = E*min(r, 1)` the veridical throughput, **the cost term cancels exactly out of the error track** — dissipation debits both books equally, so it does not appear in their difference. Correction load then rises linearly in accumulated error.

An over-framed system accumulates MORE stored order than a calibrated one. It is simply not true stored order. Dogma banks faster than knowledge, and the bill arrives on a lag as `C_t` climbing with `Z_t`. This is the mechanism behind the doctrine-to-data pathology of CCP-024.

The consequence for `r = 1` is sharper than a caveat. At the `D = P` fixed point `S = ln N`, so `h_inf = eta*(ln N - F(u*)) = 0` by D-1: undistorted contact maximises input and converges to a state with *no room left to build.* And by D-6, **an organisation optimising raw `Q` will be actively driven away from `r = 1`.** Calibration is a target for the veridical book only, and the two books must be kept separately or the incentive runs backwards.

D-7 · The Jensen rule on feasibility. `mean F(U) <= F(mean U)` — **CCP-015/26, CC-R2.**

`f` is strictly concave (CCP-A02, Thm 3.3), so Jensen's inequality bites in the direction that flatters the system. **Test feasibility on the mean of `F(U_t)`, never on `F` of the mean `U`.** The gap is not decorative: it is worth **6.2%** of surplus in the CCP-016 worked office, and it grows with the variance of `U` across periods. A plan sized on `F(mean U)` is sized against a surplus the system never held in any single period.

```
RULE OF THE CARD:  average the surplus, not the geometry.
                   F(mean U) is what the roster looks like; mean F(U) is what it delivered.
```

39.12.9 A.9 Numeric tables

Table A-1. The logarithmic ceiling `ln N`.

N	ln N	N	ln N	N	ln N
2	0.693	8	2.079	25	3.219
3	1.099	9	2.197	30	3.401
4	1.386	10	2.303	40	3.689
5	1.609	12	2.485	50	3.912
6	1.792	15	2.708	100	4.605
7	1.946	20	2.996		

Doubling `N` adds `ln 2 = 0.693` wherever it starts. **A headroom problem cannot be escaped by adding domains.**

Table A-2. Retention loss, time constant, half-life. `tau = -1/ln(1-delta)`; `t_half = ln 2 / (-ln(1-delta))`.

delta	tau (exact)	1/delta	t_half (periods)	95% settle 3*tau	99% settle 5*tau
0.01	99.50	100	69.0	298	497
0.02	49.50	50	34.3	148	247
0.05	19.50	20	13.5	58	97
0.10	9.49	10	6.58	28	47
0.20	4.48	5	3.11	13	22
0.30	2.80	3.33	1.94	8.4	14
0.50	1.44	2	1.00	4.3	7.2

Table A-3. Effective count and surplus, `N = 10`.

u	N_eff	F (nats)
0.0	1.0	0.000
0.1	1.9	0.642
0.2	2.8	1.030
0.3	3.7	1.308
0.5	5.5	1.705
0.7	7.3	1.988
0.9	9.1	2.208
1.0	10.0	2.303

At `u = 0`, ten members are one member. `F = ln 1 = 0`.

Table A-4. Marginal gain from the Nth member at `u = 0.5`. `N_eff = (N+1)/2`.

N	N_eff	F	gain over N−1
2	1.5	0.405	0.405
3	2.0	0.693	0.288
4	2.5	0.916	0.223
5	3.0	1.099	0.182
6	3.5	1.253	0.154
8	4.5	1.504	0.118
10	5.5	1.705	0.095
11	6.0	1.792	0.087
20	10.5	2.351	0.049
40	20.5	3.020	0.025

The second genuinely different member is the largest single gain available. The fortieth is glazing bills.

39.12.10 A.10 Worked gauge block — carry these numbers as the card's calibration

```
GIVEN:   eta = 0.30 Q-units/nat     N = 8      ln N = 2.0794
         delta = 0.05 /period       Q_t = 8.0 Q-units
         C_t = 0.15 Q-units/period  u* = 0.50

CEILING  eta*ln N            = 0.30 * 2.0794           = 0.6238
```

```
MAINT    delta*Q_t           = 0.05 * 8.0               = 0.4000
HEADROOM h_t = 0.6238 - 0.4000 - 0.1500                 = 0.0738   -> POSITIVE
r_max                                                    = 0.0738

ACTUAL   S_t = ln(1 + 7*0.5) = ln 4.5                    = 1.5041 nats
         eta*S_t = 0.30 * 1.5041                         = 0.4512
GROWTH?  eta*S_t > delta*Q_t + C_t ?   0.4512 > 0.5500 ? = NO -> Q IS FALLING

REQUIRED S for zero growth: (0.4000+0.1500)/0.30         = 1.8333 nats
         1 + 7u > e^1.8333 = 6.2547  ->  u > 0.751

STEADY   Q_inf = (0.30*1.5041 - 0.15)/0.05               = 6.02 Q-units
BOUND    Q_t <= max{Q_0, eta*ln N/delta} = max{8.0, 12.48} = 12.48
```

Read this block every time the gauge is used. It contains the framework's most commonly missed distinction: **headroom was positive and order was still declining, because headroom is computed at the orthogonal limit and the system was running at `u = 0.5`.** The fix was not more people. It was `u > 0.751`, or less `C`, or less `Q`.

39.12.11 A.11 The honesty clauses — reproduce these wherever the law is used

1. **The triangle inequality FAILS for geometric triples** (CCP-A02 §5). Subadditivity holds on `u` only. Do not chain surplus across three parties as if it were a distance.
2. **As deployed, the surplus functional is a LOWER BOUND on the ensemble's information, not the information itself.** We log the floor, not the ceiling.
3. **CCP-A02 is pure mathematics and makes no empirical or metaphysical claim.**
4. **Surplus is NOT identified with Shannon entropy or mutual information in general** (CCP-009).
5. **No thermodynamic negentropy law is proved** (CCP-007). `F(u) + N_can(u) <= ln N` (Cor 2.2): **higher static surplus does NOT imply higher canonical concentration.**
6. **S3 is a design axiom.** The affine effective count is chosen. Badge it in the sentence that uses it.
7. **The storage variable `Q` is a modelling choice, not derived from first principles.** The linear update is the minimal tractable open-system law, not a law of nature.
8. **Woolley's `c` is from short-task laboratory settings.** Extrapolation to institutions is a modelling assumption.
9. **Centola's ~25% is from controlled online experiments.** Field transfer is a modelling assumption.
10. **Scale-freedom of the storage law is a claim about MODEL FORM, not about physics.** Only `(delta, eta, N, C)` change between a desk and a city; that the same form applies at both is asserted, not proved.

39.12.12 A.12 The four refusals — the standing refusals of the corpus

1. This corpus does not claim the surplus law proves anything about physics, thermodynamics, or consciousness.
2. This corpus does not present a postulate without its badge.
3. This corpus does not offer a number that was not computed or cited.
4. This corpus does not recommend an intervention that removes a person's ability to decline.

39.13 Appendix B Glossary

The framework speaks in two registers because it inherits two parents: a set of theorems and a trade. Each entry gives the term as this corpus uses it, the clinical or technical term it walks beside, and a definition that honors both. Where an entry is marked *(postulate)*, the pairing is this corpus's modelling proposal and not a proved result — the distinction Appendix E keeps.

stored order <-> *the state variable Q; accumulated durable structure* — What persists between periods without being re-created: the written procedure, the built room, the trained person, the standing relationship, the constitution. The quantity the whole manual is about, and the one whose units must be fixed before any other number means anything.

retention loss <-> *delta; the decay rate per period* — The fraction of stored order that disappears in one period with zero input. Forgetting, turnover, documentation rot, relationship cooling, skill atrophy, physical wear. Measured under a genuine zero-input window, never inferred from a busy quarter.

conversion efficiency <-> *eta; durable structure produced per nat of surplus* — How much of what happened between people becomes something that survives the meeting. The most neglected parameter in real systems and usually the cheapest to raise. A conversation with no artifact has `eta \ensuremath{\approx} 0` whatever its quality felt like.

dissipation <-> *C_t; the cost term* — Everything the period spends that does not become `Q`: coordination overhead, rework, friction, conflict, commute, compliance, emotional labor, rent. It enters the law with a minus sign and it is the term most often left off the ledger because it is nobody's line item.

surplus <-> *F(u) = ln(1 + (N-1)u); the diversity gain* — The information yield of an interaction between non-parallel views, in nats. Bounded above by `ln N`. **As deployed here it is a lower bound on the ensemble's information, not the information.**

effective count <-> *N_eff = 1 + (N-1)u; equivalent independent views* — How many genuinely distinct participants a roster of `N` participants amount to after the roster has been audited for redundancy. The quantity surplus takes the logarithm of, and the first number that flattery inflates.

non-parallelism <-> *u = 1 - (x·y)^2; decorrelation* — The degree to which two states fail to be multiples of one another. Zero for identical or opposite views; one for orthogonal ones. The single parameter that can be moved fastest, and the single parameter that decays fastest when unattended.

crossing <-> *u_cross = beta^2; between-category difference* — Non-parallelism that comes from participants standing in different categories: the physicist and the nurse, the accountant and the joiner. Bought by cross-domain recruitment; cheap to display and easy to mistake for the whole of difference.

divergence <-> *u_div = alpha^2 sin^2(gamma); within-category difference* — Non-parallelism between participants inside the same category: two physicists who genuinely disagree. Bought by protected dissent, not by hiring. **Crossing and divergence are not substitutes and a system can be rich in one and starved of the other.**

the design axiom <-> *S3; affinity of the effective count* — The assumption that `g(u) = e^{f(u)}` is affine in `u`, which is what makes `N_eff` linear and the law tractable. Chosen for tractability and interpretability, not derived from anything. Every number in this framework that uses `1 + (N−1)u` inherits its status. *(postulate)*

the logarithmic ceiling <-> *ln N; the per-interaction maximum* — The hard upper bound on surplus from any single interaction among `N` categories. Doubling `N` adds 0.693 nats from any starting point, which is why adding domains is the most expensive and least rewarding lever in the corpus.

the merciful clause <-> *strict concavity of f* — The property that each added increment of difference buys less than the one before. Merciful because forty windows are not needed: three honest ones set wide capture most of what a gallery could. Also unforgiving, because the last hire will not save the roster.

subadditivity on u <-> *f(u1+u2) <= f(u1)+f(u2)* — Difference from two sources never yields more than the sum of what each would yield alone. The bound that forbids promising synergy. It holds on the parameter `u`, and **the triangle inequality fails for geometric triples** — do not chain it across three parties.

extremality <-> *F = 0 iff parallel, F = ln N iff orthogonal* — The two endpoints of the law. Ten aligned instruments produce a reading of zero; the arithmetic is not being rude, it is counting. The orthogonal case is a limit that real rosters approach and never reach.

headroom <-> *h_t = eta ln N - delta Q_t - C_t; the growth budget* — The master gauge. How much new stored order this period could possibly support, evaluated at the orthogonal limit. Negative means no arrangement of people prevents decline; zero means maintain; positive means growth is attainable and bounded by `h_t`.

the sustainability ceiling <-> *Corollary 3.4* — The statement that a nondecreasing step requires `C_t <= eta ln N − delta Q_t`. **If cost exceeds that, no interaction geometry saves the system.** The single most consequential sociological sentence the formalism produces, and the reason cost-cutting sometimes outranks every clever design.

the maintenance trap <-> *the ossification regime* — The state a successful system reaches when `delta*Q_t` alone consumes the budget, leaving nothing for growth. Not a moral failure and not a loss of vision: an arithmetic consequence of `Q` having grown. **Success consumes its own headroom.**

shedding Q <-> *deliberate decommissioning* — Reducing stored order on purpose — sunset clauses, term limits, retiring a procedure, demolishing a building — in order to recover headroom. The fourth lever, the one nobody proposes, and frequently the cheapest available move at large `Q`.

leaky integrator <-> *first-order low-pass filter; RC charge accumulator* — The circuit the storage law is. Charge in, leak out, a pole at `(1−delta)`, DC gain `eta/delta`. The identity is exact in discrete time and it is what licenses every filter intuition this framework borrows.

contraction <-> *a map with Lipschitz factor below one* — What `delta > 0` makes the update. Guarantees, by Banach, a unique fixed point and convergence to it from any starting state. **The leak is not the flaw; the leak is what makes arrival possible.**

fixed point <-> *Q_inf = (eta F(u) - c)/delta; the steady state* — The stored order a system converges to under constant geometry and constant cost. the founding material's fixed-point node in its engineering form. If `eta F(u*) < c*` the fixed point is negative and the regime is unsustainable or the model must be replaced.

the transient term <-> *(1-delta)^t Q_0* — What the system started with, decaying. the founding material's recursion node in its engineering form. It vanishes at rate `delta` regardless of any intervention, which is why inherited advantage has a half-life and why a new regime feels like the old one for roughly `3*tau`.

the driven term <-> *SUM (1-delta)^{t-1-k}(eta S_k - C_k)* — What the system is currently building, accumulating. The half of the exact solution that is under design control. Arrival is the crossover: the moment the driven term exceeds what remains of the transient.

time constant <-> *tau = -1/ln(1-delta); approximately 1/delta* — How many periods the system takes to complete about 63% of a change. Sets the cadence of everything: at `delta = 0.05`, `tau` is 19.5 periods and a policy takes roughly 58 periods to be 95% in effect. Impatience is usually a `tau` misestimate.

admissibility <-> *C_t <= (1-delta)Q_t + eta S_t* — The condition guaranteeing `Q` does not go negative. A budget that violates it is not aggressive; it is describing a system that has already been consumed and is now being invoiced.

hyperrecursive symmetry <-> *scale-freedom of the model form* — The claim that the same storage law governs a desk, a room, a team, a building, an institution, and a city, with only `(delta, eta, N, C)` changing. **A claim about model form, not about physics.** *(postulate)*

the order proxy <-> *Y_t; the observable standing in for Q* — What is actually measured, since `Q` is a modelling construct and not a thing with a meter. Choosing it is the most consequential decision in any survey, and the most common place a study quietly fails.

the state encoder <-> *the map from participants to vectors x* — The operational choice that turns a person, view, or category into a unit vector so that `u` can be computed. One of CCP-007 §5.1's five required choices. Different encoders give different `u`; the encoder must be fixed before data is seen.

the repackaging error <-> *Y as a function of U; CCP-007 §6.3* — The failure in which the order proxy turns out to be a relabeled version of the input. If `Y` is computable from `U`, the model fits perfectly and has said nothing. **Justifying that `Y` is not a repackaging of `U` is a required step, not a nicety.**

the shuffled-input control <-> *the permutation baseline* — Refitting the model with the interaction series randomly reordered. If the shuffled fit matches the real one, the timing of interaction carried no information and the model is describing persistence only. The control most often omitted and most often decisive.

preregistration <-> *frozen specification before data* — Writing down the proxy, the encoder, the observables, the model, the baselines, and the falsification rules, and then not changing them. **A framework that cannot fail cannot be trusted, and this one names exactly how it fails.**

badged postulate <-> *a flagged modelling assumption* — An assumption stated together with the fact that it is an assumption, in the same sentence. The house rule inherited from the founding material: the modelling is permitted, but it is permitted in the open, with its badge on.

c-factor <-> *collective intelligence; Woolley et al. 2010* — A single statistical factor predicting a group's performance across varied tasks, not predicted by members' average or maximum IQ, correlating with social sensitivity, equality of conversational turn-taking, and proportion of women. Measured in short laboratory tasks. Not a term in the law.

turn-taking equality <-> *low variance in speaking-turn distribution* — The `c`-factor driver that is substantially a property of the room rather than of the people. Raises `u` in effect by admitting the views that would otherwise not be heard, which is why acoustics is an epistemic intervention.

social sensitivity <-> *accuracy at reading others' mental states* — The second measured `c`-factor driver. Distinct from agreeableness and distinct from cohesion; it is the capacity to notice that someone has not finished, which is the mechanism by which it produces turn-taking equality.

cohesion trap <-> *groupthink; the u-destroying comfort* — The condition in which a group's mutual liking has driven its members' views into alignment. Feels excellent from inside and reads as high performance on every soft measure. **Cohesion is often the enemy of `c`, because cohesion drives `u` toward zero.**

pseudo-diversity <-> *demographic variance with epistemic uniformity* — A roster that looks assorted and computes to `N_eff \ensuremath{\approx} 1`. Three glasses ground from one doctrine, their agreement read as convergence. Priced exactly by the arithmetic: `u = 0`, `N_eff = 1`, surplus `ln 1 = 0`.

the parallel wall <-> *the u ≈ 0 regime* — The state in which every additional participant adds cost and no surplus. Named because it is a wall: no amount of `N` gets through it, and the only exits are raising `u` or lowering `C`.

the collision test <-> *the shared-conclusion check* — the founding material's instrument, retained. Run two independent lines of reasoning to their furnished rooms; if they land in the same room, they were one window. Cheap, fast, and the first test to run on any panel that agrees.

error decorrelation <-> *u ≈ 1 - r^2 on centered prediction errors* — The operational estimator of non-parallelism. Under the unit-vector encoding, the inner product is the Pearson correlation of errors, so non-parallelism is one minus its square. An operational choice, badged as such. *(postulate)*

participation ratio <-> *(SUM lambda)^2 / SUM lambda^2* — The eigenvalue estimator of effective count from a correlation matrix. Gives `N_eff` directly for ensembles larger than a

pair, from which `u = (N_eff - 1)/(N - 1)`. The aggregation of a pairwise law to an ensemble is an operational choice. *(postulate)*

pre-mortem <-> *prospective hindsight elicitation* — Asking a group to assume the plan has failed and to write down why, independently, before discussing. Buys `u_div` from a group that has none, because it licenses the objection that social cost had suppressed.

information cascade <-> *Bikhchandani, Hirshleifer & Welch 1992* — The sequence in which rational agents, observing predecessors, rationally stop using their private signals. The mechanism by which a genuinely diverse group becomes a parallel one without anyone changing their mind. **`u` is not a property acquired once; it is a quantity that decays.**

complex contagion <-> *Centola & Macy 2007; adoption requiring multiple reinforcing contacts* — Behavior that spreads only when a person encounters it from several sources. Because reinforcement is required, **clustered topology beats random long ties** — the opposite of the reach intuition.

committed minority <-> *Centola et al. 2018; the ~25% tipping point* — The fraction of a population holding a new convention that suffices to overturn an established one. Measured in controlled online experiments with small groups. Field transfer to organizations is a modelling assumption.

threshold <-> *Granovetter 1978; the individual adoption cut-off* — The number or fraction of others whose adoption a given person requires before adopting. Aggregate behavior depends on the whole distribution of thresholds, which is why a group can be one person away from a riot or from nothing.

stigmergy <-> *Grassé 1959; coordination through a modified medium* — Order produced by agents responding to traces left in a shared environment, with no agent holding the plan. Termite mounds, ant trails, version-controlled repositories. **Design rule: put the state in the medium, not in a coordinator.**

boundary object <-> *an artifact legible in two communities at once* — A drawing, a schedule, a shared dataset that each discipline can use in its own terms without a common vocabulary. The cheapest `eta`-raiser at a silo interface, because it converts cross-domain talk into something that persists.

focal point <-> *Schelling 1960; coordination without communication* — The salient option people converge on when they must agree but cannot confer. Noon, the middle, the round number, the obvious landmark. A `C`-reducer: it eliminates the negotiation entirely.

requisite variety <-> *Ashby 1956; only variety absorbs variety* — The law that a regulator can only control as much disturbance as it has states to answer with. The reason `N` matters at all: a system facing five kinds of trouble with three kinds of response is short by two, and no diligence closes the gap.

semilattice <-> *Alexander 1965; overlapping category structure* — A structure in which sets may intersect without one containing the other. Carries more surplus than a tree because it permits a member to belong to several categories at once. **Hierarchy is the organizational form that drives `u` toward zero.**

silo <-> *a local minimum on the comfort landscape* — A position deep because training and reward carved it, narrow because it admits one vocabulary. Exhortation fails because every direction out is uphill. **Build a lower valley next door; do not push.**

Conway's law <-> *systems mirror the communication structure that built them* — Why architecture reproduces the org chart and why reorganizing the team is a design act. The structural cause of silos, and the reason an interface problem is often a seating problem.

the quadratic committee <-> *Brooks 1975; n(n-1)/2 communication paths* — The observation that coordination cost grows quadratically while surplus grows logarithmically. The crossover point is the most important team-sizing calculation available, and it always arrives sooner than the roster expects.

utilization cliff <-> *queueing; wait time exploding as rho approaches 1* — The property that waiting grows as `1/(1-rho)`, so the last few percent of capacity cost more delay than all the rest combined. **Slack is not waste; it is a cost-control device.**

Goodhart capture <-> *Goodhart 1975; Campbell 1979* — The degradation of a measure once it becomes a target. Applies directly to every number this framework asks a user to track, including headroom. The defense is to keep the measurement instrument separate from the reward instrument.

invisible infrastructure <-> *Star & Ruhleder 1996; visible only upon breakdown* — The property that working infrastructure disappears from attention, so its maintenance is chronically underfunded until it fails. The reason `delta` is systematically underestimated in every organization that has not measured it.

optional activity <-> *Gehl 1971; discretionary presence* — Activity people undertake only when conditions invite it: sitting, lingering, watching. Distinguished from necessary activity, which occurs regardless. **Optional activity is the observable proxy for a room's `eta`.**

triangulation <-> *Whyte 1980; an external stimulus that occasions conversation* — A busker, a sculpture, a view, an odd object that gives strangers a shared referent and thereby a licensed opening. One of the few reliable ways to raise the encounter rate without raising density.

sittable space <-> *Whyte's first finding* — People sit where there is somewhere to sit. Obvious, repeatedly ignored, and the single highest-yield physical intervention per unit cost in the literature this framework draws on.

edge effect <-> *perimeter occupancy preference* — The observed tendency for people to occupy the boundaries of a space before its middle, because edges offer support at the back and prospect to the front. Design consequence: furnish the perimeter first.

threshold <-> *the architectural transition; impedance matching between zones* — The porch, the genkan, the airlock, the widened landing. A device that lets a person change register gradually instead of abruptly. **The transition is not a gap between rooms; the transition is the device.**

proxemics <-> *Hall 1966; the distance bands of interaction* — The observation that interaction character changes with separation, in roughly demarcated intimate, personal, social, and public bands. Culturally variable, as Hall said; use as a design frame, not as a specification.

RT60 <-> *Sabine; reverberation time, 0.161 V/A metric* — Seconds for sound to decay 60 dB, from room volume in cubic metres and total absorption in square-metre sabins. Valid for reasonably diffuse fields; use Eyring's form for heavily absorbing rooms.

the Lombard effect <-> *involuntary vocal effort increase in noise* — The reflex by which people raise their voices in a noisy room, which raises the noise, which raises the voices. The positive feedback that turns a moderately reverberant room into a loud one and hands it to whoever is loudest.

the head of table <-> *geometric rank assignment* — The seat that assigns `u = 0` to everyone below it by making their function agreement rather than judgment. **Furniture is the cheapest governance instrument ever built, and it enforces continuously without anyone administering it.**

silent-write-first <-> *independent elicitation before discussion* — The protocol of collecting written independent judgments before any discussion begins. Breaks cascades before they start and preserves the independence Condorcet's theorem requires. The single cheapest `u`-preserving move in this framework.

adjustability <-> *individual control over local conditions* — Openable windows, task lighting, movable chairs, personal thermal control. **Adjustability outperforms optimization because a fixed optimum serves the mean occupant and no actual one.**

desire line <-> *revealed preference; the worn path* — The route actually taken across the route provided. The most honest document a population produces and the only one it never signs. Read it before regrading; regrade toward it, not against it.

red team <-> *institutionalized adversarial review* — A group chartered and rewarded for finding the flaw. Buys `u_div` structurally rather than depending on individual courage, which is why it works and why the charter must protect the finding, not merely permit it.

reversibility <-> *the design requirement for capped downside* — The property that an intervention can be undone at bounded cost. Required by this framework for any change large enough to matter, because parameter estimates in social systems carry uncertainty that no protocol here removes.

the ability to decline <-> *the consent constraint; the standing refusals of the corpus* — The property every intervention in this framework must preserve. A method that works by removing resistance has no coercive failure mode: its worst outcome is that someone declines to move. A method that works by removing the option has no such floor.

The entries above are the institutional-scope material's vocabulary: rooms, rosters, institutions. The entries below enter with the personal- and cellular-scope material, where the same instrument is turned on a mind and then on a cell. They are kept in one list because they are one vocabulary — but four of them carry a demotion, and the demotion is stated in the entry rather than in a note. Where an entry is marked **(demoted)**, *its structure stands and its magnitude does not; see Appendix E.7.*

moment <-> *M = (D/P)·E; the unit of lived experience* — What is actually experienced in a period: the environment as read through the ratio of frame to intake. The input term of the self-storage law, `Q_{t+1} = (1−delta)Q_t + eta*M_t − C_t`, and therefore the point at which the personal-scope material joins the institutional-scope material. **Its structure is defensible and its magnitude is not yet reportable.** *(postulate; demoted)*

perspective <-> *D; the frame brought to the moment* — Everything the perceiver supplies before the environment says anything: prior, training, expectation, doctrine, precision-weighting of the top-down model. The numerator of the calibration ratio. Not yet instrumented on a ratio scale, which is exactly the demotion. *(postulate; demoted)*

perception <-> *P; the intake admitted from the moment* — What the environment actually delivers into the frame: sensory evidence, data, report, the bottom-up signal and its precision. The denominator of the calibration ratio, and the term that goes to zero in dogma. *(postulate; demoted)*

calibration ratio <-> *r = D/P; frame over intake* — The dimensionless ratio that says whether a perceiver is meeting the world or overwriting it. `r = 1` is undistorted contact; the ordering is genuine and the number is not yet measurable. **`r = 1` is not an unqualified target** — headroom at that fixed point is exactly zero, and a system optimising raw stored order is driven away from it. *(demoted)*

distortion <-> *Delta = |ln r|; the log-ratio departure from contact* — How far a frame stands from the intake it is reading, in the same log register as everything else in this framework. **Ordinal pending instrumentation:** the direction stands, the magnitude does not, until `D` and `P` are Rasch-calibrated (Theorem 54.3). *(demoted)*

over-framed <-> *r > 1; doctrine outrunning data* — The condition in which the moment exceeds the environment: projection, prejudice, apophenia, seeing what was predicted. At group scope it is the institution whose doctrine outruns its intelligence. **It banks stored order faster than a calibrated system does, and the order is false** — see *stored error*.

under-framed <-> *r < 1; data outrunning doctrine* — The condition in which the moment falls short of the environment: flooding, overwhelm, an intake that cannot be made to mean anything. Not ignorance — a surfeit of signal with no frame to read it.

lens theorem <-> *the logarithmic map; Cauchy's functional equation* — If perception converts multiplication into addition, then it is a logarithm, unique up to scale. **Linear in the lens is exponential in reality:** equal perceptual steps are equal world *ratios*, never equal world differences. The theorem is conditional and proved; its antecedent is empirical and badged separately. Design in ratios; never promise a linear improvement in a quantity the recipient perceives logarithmically.

doctrine-to-data ratio <-> *D/P at group scope* — The calibration ratio read on an institution. **Never aggregate it across sites:** distortion in opposite directions cancels in the aggregate

and overstated bankable input by **4.26x** in CCP-024's two-site example. Distortion does not average.

internal surplus <-> *F_int = ln(1 + (N-1)u) over one person's own framings* — CCP-A02 applied within a single observer. the founding material's "many windows of the one tower" as a derivation rather than an analogy. Subject to Break 1 of CCP-038: **the independence the aggregation needs is unavailable inside one skull**, so the estimate is an upper bound on what a mind actually holds.

essence index <-> *n; ordinal position within a discipline's category set* — The integer an essence type occupies in its own ordered set. Atomic number is one instance of an essence index, not the definition of one. Across disciplines there is no shared ordinal, and the effective count supplies the missing one.

essence frequency <-> *f(n) = k n², k = 0.483425732988414 Hz* — The frequency the essence law returns for an essence index. **An essence frequency is not a physical resonance**, and the distinction is absolute: the constant is a Pythagorean interval divided by the golden section, and it cancels out of every relation, so only the ratios `m²/n²` carry content.

conversion key <-> *an exact constant between logarithmic registers* — The linear-in-log-space constant relating surplus, pitch, sensation and moment. `1 nat = 1.442695 bits = 2.885390 octaves = 3462.4681 cents`; `1 bit = 2 octaves exactly`. **One nat of interaction surplus is exactly 2.885390 octaves** — not an analogy, arithmetic.

pitch class <-> *an equivalence class under octave folding* — Two essences share a pitch class iff their indices have the same odd part, because `(2n)² = 4n²` is exactly two octaves. An ordered set `1..N` therefore yields exactly `ceil(N/2)` distinct classes. **Folding costs exactly `ln 2` — one bit, two octaves — for every even `N`.** A hard structural limit on harmonic vocabulary, not a stylistic choice.

Gabor limit <-> *dt · df >= 1/(4π) = 0.079577* — The time-frequency uncertainty bound. **Classical, true of every wave including sound, with no quantum content whatsoever**, and measurable on an oscilloscope. A short sound cannot have a precise pitch: 1 ms buys 79.577 Hz of resolution, 100 ms buys 0.796 Hz. It hard-constrains any rendering of an essence set, and it prices in time what it costs to hear a difference in surplus — at least `1/(8*pi*dF)` cycles.

channel <-> *the coupling from a belief to a change in the world* — The pathway a belief must act through if it acts at all. **"Grounded in truth" means the channel exists and is real.** Naming it is step 2 of the grounding diagnostic, and a claim that cannot name one has failed before any measurement.

coupling <-> *E = G·B; the belief-to-world relation* — The relation that formalizes the postulate. Structurally the storage law: belief is the input, the channel is the conversion efficiency, the world-change is what lands in `Q`. **Series channels multiply their gains; parallel channels add them**, which is why a four-stage chain of plausible steps can have a total gain of 0.084.

gain <-> *G; change in the world per unit belief* — The size of what a channel delivers. **If `G = 0` then the outcome is zero for every value of belief whatsoever**, which disposes of about a third of the manifestation failure catalogue in one line. Gain must be estimated from quantities that are not the outcome, or the estimate is the claim.

grounding <-> *establishing the channel before the outcome is known* — The seven-step diagnostic of CCP-035. **Grounding is established from the channel, before the outcome is known, or it is not established at all** — otherwise the postulate's conditional is diagnosed backwards from the result and predicts nothing. Step 5, the predicted magnitude, does most of the killing.

evidence column <-> *the (+1) column; what is measured* — What scientific measurement confirms: replicated, falsifiable, obtained by a stated method in a named setting. The only column that can move a posterior.

precedent column <-> *the (-1) column; what tradition recorded* — That an idea was arrived at independently, recorded and preserved, often for centuries, by people with no access to the instruments. **This is real and worth having — it argues that a structure was findable by more than one route — and it is not a second measurement.** It can never be promoted to evidence; the historical corpus is a survivorship-filtered record. Where the corpus has nothing to say,

the cell reads *none claimed*, and in this corpus it reads that way in **133 of 156 register rows**.

concordance <-> *a bridge drawn between the two columns* — A claim backed from both corpora at once, valid only if it passes all three criteria: **C1 structural correspondence** (a deep shared pattern, not a shared cardinality), **C2 predictive power** (it must generate a prediction), **C3 practical utility** (it must be usable on both sides). **Two sources agreeing does not double the evidence when only one of them is evidence**, and the role of each column is stated every time a concordance is drawn.

Tri-State validation <-> *the VINO apparatus, adopted unchanged* — The three-position frame in which every substantive claim of the cellular-scope material is assessed: **(+1) physics proof**, **(-1) metaphysics or recorded practice**, **(0p) contra-proof at the Neutral Point**, where the two are made to integrate or shown not to. Only bridges satisfying all three criteria are presented as established; speculative bridges are marked speculative in the same sentence that states them.

tri-state <-> *the three-valued status of a bridge* — `+1` established, `−1` precedent only, `0p` the neutral point where integration is attempted. **A bridge may hold at one grain and fail at a finer one**, and finding that seam is most of the work: of CCP-029's three worked bridges, one was established, one was graded, and one was rejected outright.

specific objectivity <-> *Rasch; separation of person and item parameters* — The property that a person's measure does not depend on which items were used, and an item's measure does not depend on which persons answered. **The closest thing psychometrics has to physical measurement, and exactly the property the moment equation needs** to earn its division back.

Rasch separation <-> *the logit difference as a ratio-scaled quantity* — The construction that supplies the true zero division requires, so that `Delta = |ln(D/P)|` becomes genuinely ratio-scaled. **This is the specific, principled route from demotion to measurement**, and it is priced: **123 items per term** to establish a half-logit distortion, 342 for three tenths.

ratio scale <-> *Stevens' typology; a scale with a true zero* — The scale type on which multiplication and division are permitted operations. Interval scales permit differences; ordinal scales permit only ordering. **A formula that divides two terms measured ordinally is a heuristic ordering, not an equation, and this corpus demotes such formulas in print rather than in the notes.**

magnitude estimation <-> *Stevens 1957; psi = k I^a* — The psychophysical procedure that produces genuine ratio-scale measurements of subjective experience from human subjects, and replicates. The exponent `a` is a measured conversion key between the physical and perceptual registers. **Report exponents as constants of a procedure, not constants of nature** — they move with method, range and instruction.

veridical stored order <-> *Q^V; the true half of the ledger* — Stored order that corresponds to something in the world, accumulated from the veridical throughput `V = E·min(r,1)` rather than from the moment. The corpus that matters and the corpus nobody keeps.

stored error <-> *Z = Q - Q^V;* `Z_{t+1} = (1−delta)Z_t + eta(M_t − V_t)` — The accumulated gap between what a system has banked and what is true. **The cost term cancels exactly out of this track**, because dissipation debits both books equally. **Dogma banks faster than knowledge**, and this is the quantity that records it.

correction load <-> *C_t = c_0 + kappa*Z_t; the lagged bill* — The part of the dissipation budget that exists only to correct accumulated error. It rises linearly with stored error, which is why an over-framed system's costs climb long after the framing that caused them, and why the arrival of the bill is routinely attributed to something else.

launch budget <-> *L = max(0, M - C); escape is dreamt from surplus* — What remains of a moment after the period's cost is paid, and the fund from which any departure is financed. **`L = 0` is the formal statement of "there was no surplus to dream with."** Raising cost globally destroys the platform; raising it only at the origin genuinely shortens the wait — 32.0 weeks to 9.9 — at the price of a 37% smaller permanent fund. **The question is whether it is a cost that can be left behind or one that is carried.**

return difference <-> *Delta_R = |ln(M'/M)|; the founding material's echo node* — The

world's answer over what was sent, read as a log-ratio because ratios compose multiplicatively. **Zero means no information came back** — which is the same reading the instrument gives for the flatterer and for the reliable contrarian, since `u` depends only on `|rho|`.

survivorship likelihood ratio <-> *the evidential weight of testimony under selection* — Computed at **exactly 1.000000** under a process that publishes successes and discards failures. **A likelihood ratio of 1 does not move the posterior at all** — a thousand testimonials carry precisely the weight of zero, because the selection guarantees that successes are observed whether or not the method does anything. Companion figures: a direction-only prediction is worth 2.0000, a magnitude prediction with a tolerance 11.3577 — **about 5.7x more evidentially powerful.**

the postulate <-> *belief creates reality if the belief is grounded in truth* — the cellular-scope material's keystone, and **the conditional clause is the whole content.** Belief is an input; the system must have gain. No channel, no effect. Stated without the conditional it is magical thinking; stated with it, every failure of manifestation becomes a diagnosable fault at a named coordinate.

manifestation <-> *destiny made manifest; a latent capability brought into expression* — Used in this framework in a personal and entirely non-territorial sense. **The phrase "manifest destiny" carries specific nineteenth-century American historical freight** — it was the slogan used to justify continental expansion and the displacement of Indigenous peoples — and this corpus says so at first use rather than trusting the reader to supply the distinction.

demotion <-> *a claim this corpus advanced and its own protocol reduced* — The status assigned when a formula passes some Formula Validation Protocol gates and fails others: **the structure stands, the magnitude does not**, and the demoted content may not reappear in any form, including in a summary table. **Eight register entries carry this status, and five of them are the author's own keystone formula and its family.** Demotion is one-directional and it travels: when a gate fails, every entry downstream of the failed one is demoted in the same pass, in this paper that made the claim and not only in the appendix.

39.14 Appendix C Measurement protocols

Six protocols, one per parameter, plus a seventh that assembles them into the gauge. Each is written to be run by one engineer with a notebook, and each ends with a worksheet designed to be photocopied and filled in by hand.

Three more were added after the volumes that follow this appendix were written, and one of them is a correction to the six above. C-8 replaces the assumption that a passed shuffled-input control means anything much; it does not, and the three ways it does not have been measured rather than argued. C-9 and C-10 go the other way: two cheap tests that were available from the arithmetic all along and were not written down until Parts VIII and IX derived them.

Before any protocol runs, fix the five operational choices from CCP-007 §5.1 in writing, and do not change them afterward.

```
FIVE REQUIRED CHOICES — fix in writing, date and sign, before any data is collected

1. STATE ENCODER          how a participant/view/category becomes a unit vector x
2. INTERACTION OBSERVABLE how U_t is read in each period
3. ORDER OBSERVABLE       what Y_t is, and its unit
4. TIME SCALE             what one period is (day / week / month / quarter / year)
5. COST OBSERVABLE        what C_t is, in the SAME unit as Y_t

Signed: _____________________  Date: ____________
```

Changing any of the five after seeing data invalidates every held-out claim that follows. If a choice was wrong, say so, discard the study, and start again with the corrected choice. This is cheaper than it sounds and far cheaper than the alternative.

39.14.1 C.1 Protocol for delta — retention loss

Principle. `delta` is defined as loss under *zero input*. Any window in which interaction continued measures `delta` net of `eta*S` and will underestimate it, usually badly.

1. **Identify the order proxy `Y`** using Protocol C-6 first. `delta` cannot be measured before `Q` has an observable.
2. **Find a zero-input window** — a shutdown, holiday, hiring freeze, sabbatical, mothballed process, discontinued programme, archived project. The requirement is that no new surplus was converted, not that nothing happened.
3. **Verify it is genuinely zero-input.** List every activity in the window that could have added to `Y`. If the list is not empty, exclude the contaminated portion or find another window.
4. **Record `Y_0` and `Y_1`** at the window's ends, with the same instrument, observer protocol, and point in cycle.
5. **Record the window length `m`** in periods, using the time scale fixed in the five choices.
6. **Compute the per-period retention loss:** `delta = 1 - (Y_1/Y_0)^(1/m)`.
7. **Repeat on a second, independent window.** One window is an anecdote. Two windows that agree within a factor of 1.5 give a usable estimate; two that disagree by more mean the proxy is measuring something other than stored order, and the analysis must return to Protocol C-6.
8. **Report the range, not the point.** Carry `delta_low` and `delta_high` through every downstream calculation and report headroom as an interval.
9. **Compute the derived quantities** and record them on the card: `tau = -1/ln(1-delta)`, `t_half = ln2 / (-ln(1-delta))`, settling `3*tau` and `5*tau`.
10. **Re-measure annually.** `delta` is not a constant of the system; it moves with turnover, documentation quality, and physical condition.

Common errors. Measuring during an active period and calling the result `delta`: the most frequent error, and it produces a `delta` near zero, a fictional `tau`, and a maintenance budget of nothing. Using an administratively maintained proxy — a register, a headcount — whose `delta` is the clerk's diligence, not the system's.

```

          t_half = 0.693/(-ln(1-delta)) = ___________ periods
          95% settling = 3*tau = ___________   99% = 5*tau = ___________
Measured by: _______________  Date: ___________  Next re-measure: ___________
```

39.14.2 C.2 Protocol for eta — conversion efficiency

Principle. `eta` is durable structure produced per nat of surplus. It is the ratio of what stuck to what happened, and the numerator must be *attributable*.

1. **Enumerate interaction events** over a span of at least `3*tau` periods or twenty periods, whichever is longer. Each event gets a date, a participant list, and a category list.
2. **Compute S for each event**: run C-3 for `N` and C-4 for `u`, then `S = ln(1 + (N−1)u)`, in nats.
3. **Define attributability in advance**, in writing, before looking at any `Y` data. Acceptable: the artifact cites the event; the decision log names it; the change is dated within one period with no other candidate. Unacceptable: someone's recollection.
4. **Record attributable `delta_Y`** for each event, in `Y`-units.
5. **Direct estimate:** `eta = sum(attributable delta_Y) / sum(S)` over the span.
6. **Regression estimate.** Fit the minimal estimation model `Y_{t+1} = a*Y_t + b*F(U_t) − C_hat_t + eps_t` with constraints `0 <= a <= 1`, `b >= 0`. Then `eta = b` and, as a cross-check, `delta = 1 − a`.
7. **Compare the two estimates.** If the direct estimate and the regression estimate differ by more than a factor of two, the attributability rule is either too generous (direct high) or too strict (direct low). Report both, and say which is preferred and why.
8. **Cross-check `delta`.** The regression's `1 − a` should agree with Protocol C-1's `delta` within the interval reported there. Disagreement means the proxy, the time scale, or the cost observable is wrong.
9. **Freeze and test.** Fit on the training span, freeze every coefficient, and report performance on a held-out span. See CCP-015 and Protocol C-6 step 7.
10. **Stratify by capture mechanism.** Compute `eta` separately for events that produced a written artifact, a built object, a changed default, or a trained person, versus those that produced none. The gap between the two is the size of the cheapest available intervention in the system.

Common errors. Counting satisfaction as `delta_Y`; counting the meeting itself as the artifact; attributing change to the most recent event by default, which credits whatever happens most often.

```

            gap = ______  <− size of the cheapest available intervention
```

39.14.3 C.3 Protocol for N — the category count

Principle. `N` counts *genuinely distinct* categories. A relabeled category is not a category. The audit is the protocol; the count is the leftover.

1. **List every category the system nominally admits.** Job titles, disciplines, departments, sites, functions, stakeholder classes — whatever the system's own vocabulary supplies. Call this list `N_nominal`.
2. **The training-lineage test.** Were members trained in the same tradition, by the same institutions, on the same corpus? Identical answers make the pair a merger candidate.
3. **The incentive test.** Are they rewarded and punished by the same measures? Identical incentives produce identical judgment under pressure regardless of nominal category.
4. **The vocabulary test.** Do they use the same words for the same things and notice the same anomaly? If a problem statement lands identically in both, they are one category for surplus purposes.
5. **The error test.** Where data permits, check whether the two categories' errors on the same problems are correlated. The strongest test; the other three are proxies for it.
6. **Merge the failures.** Any pair failing all four tests is one category. Record the merger and its reason; the audit trail is the deliverable, not the number.
7. **Report `N` and `N_nominal` together.** The ratio is a diagnostic in itself: a system with `N_nominal = 14` and `N = 4` has an accurate self-image problem prior to any design problem.
8. **Compute `ln N` and `eta*ln N`** and carry them to the headroom sheet.
9. **State what a new category would have to be.** Before proposing to raise `N`, write the specific training lineage, incentive structure, and vocabulary the new category would bring. If it cannot be written, `N` cannot be raised — only `N_nominal` can.

```
WORKSHEET C-3 — N
System: _____________________  Date: __________
N_nominal: ______   List: ____________________________________________________
_____________________________________________________________________________

Merge log:
  merged _____________ + _____________  reason: _____________________________
  merged _____________ + _____________  reason: _____________________________
  merged _____________ + _____________  reason: _____________________________

N (audited) = ______     N_nominal/N ratio = ______
ln N = __________        eta*ln N = __________ (needs C-2)

If raising N is proposed, the new category's:
  training lineage: ____________________________________________
  incentive structure: _________________________________________
  distinct vocabulary: _________________________________________
  If any line is blank, N cannot be raised. Only N_nominal can.
```

39.14.4 C.4 Protocol for u — non-parallelism

Principle. `u = 1 - (x·y)^2` is defined for a pair of unit vectors. Estimating it for a real ensemble requires an encoder and an aggregation rule, both of which are operational choices, and **both must be badged as such in any report.**

1. **Build a common item set.** Twenty to fifty judgments, forecasts, ratings, or diagnoses that every participant can render independently and that have or will have a scoreable answer. The set must be relevant to the system's actual work; a generic instrument measures a generic `u`.

2. **Collect independently and in writing, before any discussion.** This is not merely good hygiene; discussion prior to collection measures the post-cascade `u`, which is the quantity the measurement was meant to detect.
3. **Encode.** Assemble each participant's responses into a vector; center it by subtracting the item-wise mean across participants; normalize to unit length. *(Centering and normalizing is the state-encoder choice; badge it.)*
4. **Pairwise estimate.** For each pair, compute `r = x·y`, the Pearson correlation of centered responses, and `u_ij = 1 − r^2`. Note that `u = 0` at both `r = +1` and `r = −1`: a reliable contrarian is as parallel as a reliable agreer, and this is correct — both are one instrument.
5. **Ensemble estimate — the participation ratio.** Form the correlation matrix `R` across participants, take its eigenvalues `lambda_i`, and compute `N_eff = (SUM lambda_i)^2 / SUM lambda_i^2`. Then invert the affine form: `u = (N_eff − 1)/(N − 1)`. *(The aggregation of a pairwise law to an ensemble is an operational choice; badge it. It is consistent with S3 by construction, which is a property of the choice and not evidence for it.)*
6. **Where answers become scoreable, switch to error decorrelation.** Recompute using centered *errors* rather than centered *responses*. Error decorrelation is the quantity Condorcet's independence condition actually names, and it is strictly better evidence than agreement on unresolved items.
7. **Decompose into crossing and divergence.** Pool same-category pairs for `u_div` and cross-category pairs for `u_cross`, and report both. `u_cross = 0.6` with `u_div = 0.05` is the classic "diverse hires, one permitted opinion" and needs a different intervention from its mirror image.
8. **Run the collision test as a qualitative check.** Two participants reason a scenario independently to its conclusion; if the conclusions coincide in detail while the numeric `u` is high, the item set is not probing load-bearing assumptions.
9. **Track across time.** `u` decays, so one measurement cannot distinguish a stable system from one in free fall. Quarterly is a reasonable default at `tau` of tens of periods.
10. **Compute `S = ln(1 + (N−1)u)`** and carry it to the headroom sheet.

Common errors. Measuring `u` after discussion; using demographic categories as the encoder, which measures demographic variance and not non-parallelism; reporting one `u` when `u_cross` and `u_div` differ by an order of magnitude.

```
WORKSHEET C-4 — U

Previous quarter's u = ______   trend: [ ] rising  [ ] flat  [ ] DECAYING
```

39.14.5 C.5 Protocol for C — the dissipation budget

Principle. `C_t` must be in the same unit as `Q_t`, or the headroom equation cannot be evaluated. Commensuration is the hard step and it must be done explicitly and once.

1. **Enumerate the five cost ledgers.** (a) Coordination: time aligning rather than producing. (b) Friction and rework: work done twice, handoff loss, waiting. (c) Maintenance: effort holding `Q` at its current level. (d) Conflict and emotional labor. (e) Overheads: rent, commute, compliance, tooling, licensing.
2. **Measure coordination directly:** meeting-hours times participants over the period. Always available, always larger than expected.
3. **Check against the Brooks bound.** Paths scale as `n(n−1)/2`. If observed coordination cost is not growing at roughly that rate as the roster grows, the roster is not communicating or the measurement is missing channels.
4. **Separate maintenance from growth in ledger (c).** Maintenance belongs in `C`; work that adds new durable structure belongs in `eta*S`. The dividing question is: if this work stopped, would `Q` fall, or would it merely stop rising? Falling is maintenance.
5. **Commensurate.** Choose one conversion and write it down: hours to `Y`-units, or currency to `Y`-units, or a direct expression of all costs in `Y`-units. State the conversion factor, its basis, and its uncertainty. **This is a modelling choice; badge it in the report.**
6. **Sum to `C_t`** and record the ledger breakdown, not just the total. The breakdown is what makes the number actionable.
7. **Compute the utilization check.** Estimate `rho`, the fraction of capacity in use. If `rho > 0.85`, note that queueing delay is growing as `1/(1−rho)` and that a portion of ledger (b) is a utilization artifact that will not respond to process improvement.
8. **Test admissibility.** Verify `C_t <= (1−delta)*Q_t + eta*S_t`. If it fails, the system is being invoiced for order it no longer holds, and the finding outranks every other recommendation in the survey.
9. **Test the sustainability ceiling.** Verify `C_t <= eta*ln N − delta*Q_t`. If it fails, record in the report, in these words: *no choice of interaction geometry can prevent order from decreasing in this system.*

```
WORKSHEET C-5 — C

If FAIL, write in the report: "No choice of interaction geometry can prevent
order from decreasing in this system."
```

39.14.6 C.6 Protocol for Q — stored order and its proxy

Principle. `Q` is a modelling construct. `Y` is what is measured. **The single most common measurement failure in this framework is an order proxy that is a repackaging of the input** (CCP-007 §6.3), and this protocol exists mostly to prevent it.

1. **State what persists in this system.** Not what happens — what remains when everyone goes home. Written procedure, built object, trained capability, standing relationship, maintained record, physical arrangement.
2. **Propose two or three candidate proxies `Y`.** Each must be countable, each must be countable by someone other than the analyst, and each must have a unit.
3. **The repackaging test.** Could `Y_t` be computed from `U_t` alone? If yes, reject it. A "number of cross-functional collaborations" proxy is the input wearing a hat.
4. **The persistence test.** Would `Y` still be positive after a period of zero activity? If it goes to zero when activity stops, it is an activity measure, not a storage measure.
5. **The clerical test.** Is `Y` maintained by an administrator regardless of substance? Registers, headcounts, and compliance records fail: they do not decay, so they cannot measure something that does.
6. **The independent-observer test.** Two observers count `Y` for the same period without conferring; if they disagree by more than 20%, tighten the definition first.
7. **Preregister and hold out.** Split the time series into a training span and a held-out span, fix the split before fitting, fit on training, freeze, and report on held-out.
8. **Run the four required baselines** (CCP-015): persistence (`Y_{t+1} = Y_t`), direct-input (`Y_{t+1}` from raw interaction count without the log form), matched autoregressive (`Y_{t+1} = a*Y_t` alone), and the shuffled-input control (`U` series randomly permuted).
9. **Apply the three falsification rules.** If the model does not beat persistence on held-out data, it has failed. If it does not beat the matched autoregressive baseline, the surplus term is doing no work. **If it does not beat the shuffled-input control, the timing of interaction carried no information and the fit is describing decay alone.**
10. **Record `Q_0`** as the value of `Y` at the survey's baseline, and carry it to the headroom sheet.

```
WORKSHEET C-6 — Q AND ITS PROXY
System: _____________________

                                                      if SO, see C-8: beating it proves less
```

than this worksheet once implied

Correction, binding on this worksheet: beating the shuffled-input control is necessary and it is not sufficient. It has three measured holes — anti-conservative calibration, blindness to repackaging, blindness to a shared slow driver — and Protocol C-8 states them, prices them, and gives the ceiling test and the four design controls that cover what the surrogate cannot. **Do not report a `p` from an uncalibrated surrogate.**

39.14.7 C.7 Protocol for the gauge — computing h, r_max, and Q_inf

1. **Assemble** `eta` (C-2), `delta` (C-1), `N` (C-3), `u` (C-4), `C_t` (C-5), `Q_t` (C-6). Confirm all are in the fixed units.
2. **Compute the ceiling:** `eta*ln N`.
3. **Compute maintenance:** `delta*Q_t`.
4. **Compute headroom:** `h_t = eta*ln N - delta*Q_t - C_t`. Set `r_max = h_t`.
5. **Classify the regime:** `h_t < 0` unsustainable; `h_t = 0` maintenance only; `h_t > 0` growth available.
6. **Separately test whether order is actually rising:** `eta*S_t > delta*Q_t + C_t`, with `S_t` computed at the *actual* `u`, not at `u = 1`. **A system can have positive headroom and be shrinking.**
7. **If it is shrinking, compute the required `u`:** `S_req = (delta*Q_t + C_t)/eta`, then `u_req = (e^{S_req} - 1)/(N-1)`. If `u_req > 1`, the geometry cannot deliver it and the answer is `C` or `Q`, not people.
8. **Compute the steady state:** `Q_inf = (eta*F(u*) - c*)/delta`. If negative, record that the regime is unsustainable or the linear model must be replaced.
9. **Compute the uniform bound:** `Q_t <= max{Q_0, eta*ln N/delta}`.
10. **Propagate the intervals.** Recompute steps 2 through 9 at `delta_low` and `delta_high` and report `h` as an interval. **A headroom figure without an interval is a decoration.**
11. **Check every promise against `r_max`.** No plan may request `r_t > h_t`. If one does, the plan is not ambitious; it is arithmetically infeasible, and saying so is the engineer's job.

39.14.8 C.8 The shuffled-input control — three measured holes, and what to run instead

This protocol is a correction to the six above, and to every worksheet in this appendix that carries a `SHUFFLED-INPUT CONTROL` line. The control is still required. What has changed is what passing it is worth, and the change was measured rather than argued.

Three failure modes have been computed by simulation. All three are properties of the surrogate method itself, not of any particular study, and **no fourth surrogate fixes any of them.**

```
HOLE 1  ANTI-CONSERVATIVE AS ORDINARILY RUN                          [R13a, CCP-027]
        Measured false-rejection rate against a nominal alpha = 0.05, 500 null trials:

            iid permutation       0.108      2.2x nominal
            circular shift        0.120      2.4x nominal
            block permutation     0.060      near nominal

        A surrogate test run off the shelf roughly DOUBLES the false-positive rate.
        The matched-autoregressive comparison ALONE false-passed 35.8% of the time.

HOLE 2  BLIND TO REPACKAGING                                         [CC-R4, CCP-015]
        A filtered repackaging of the input passed all four baselines INCLUDING the
        shuffled-input control at p = 0.0005. It was caught only by the structural
        ceiling test (CCP-007, Cor 4.2): its single-step jump was 38.5x r_max.

HOLE 3  BLIND TO A SHARED SLOW DRIVER                                [R24, CCP-035-81]
        4,000-trial simulation, reported honestly in both directions:
            clean case (Case 3)          48.17% detection -- it works
            shared slow driver (Case 4)  98.35% PASS      -- it does not

        A common confounder moving both series slowly is invisible to permutation,
        because permutation destroys timing and the confounder does not act through timing.
```

Consolidated rule, binding on Protocols C-6 and C-7 and on every chapter that recommends the four-baseline suite: the shuffle is a weak, mis-calibrated empirical audit. Repackaging is caught only by the structural test. Confounding by a shared slow driver is caught only by design. **A passed shuffle is a floor, not a certificate.**

Step 1 — calibrate the surrogate on the design in hand, before using it. Simulate the study under a stated null — same period length, same series length, same autocorrelation, same missingness — and measure the actual false-rejection rate of the surrogate to be run. Use the calibrated threshold, not `0.05`. **An uncalibrated surrogate is reporting somebody else's alpha.**

Step 2 — run the structural ceiling test, every time. Compute `r_max = eta*ln N - delta*Q_t - C_t` (Protocol C-7) and compare it to the largest single-period increment in the observed series. **Any increment above `r_max` is impossible under the model, and no empirical baseline will report it.**

```
WORKSHEET C-8a — CEILING TEST
Largest observed single-period increment in Y          ______
r_max from C-7 (at the SAME period and units)          ______
ratio  observed / r_max                                ______
ratio > 1 ?  [ ] no, admissible   [ ] YES -> the proxy is a repackaging until proved otherwise
```

Step 3 — buy the remaining protection with DESIGN, not with more surrogates. These four are the whole of it, they are cheap relative to a wasted study, and each is checkable by an outsider.

Design control	What it defeats	How it is verified
Blinding	fabricated and nudged timing; rater contamination	The rater cannot state the period's input when asked
Channel separation	the order proxy being a relabeled input	`Y` and `U` collected by different people, by different instruments, on different days
Prospective sampling	survivorship in the case series	Every unit enrolled **before** its outcome is known; the roster is fixed and dated
Yoked control	shared slow drivers; secular trend	A matched unit exposed to the same environment and not to the intervention

```
WORKSHEET C-8b — DESIGN CONTROLS
(attach to the preregistration; unsigned rows are absent controls)

Blinding               who is blind, to what, and how it was checked  _____________  [ ] none
Channel separation     Y collected by _______  U collected by _______   [ ] same source -> INVALID
Prospective sampling   enrolment date rule _____________                [ ] retrospective
Yoked control          matched unit, matching variables _____________   [ ] none

Surrogate calibrated on this design?  [ ] yes, measured alpha = _______  [ ] NO -> do not report p
Ceiling test run (C-8a)?              [ ] yes  [ ] NO -> repackaging not excluded

Signed: _____________________  Date: _____________
```

If the design controls are absent, say so in the report in the sentence that states the result. A study that ran the shuffle and nothing else has excluded exactly one thing: that the model is describing persistence only. It has not excluded repackaging and it has not excluded confounding.

39.14.9 C.9 The gradient shortcut — a habit survey IS a headroom measurement

Derived in CCP-022 (R19): `grad h = -grad C`. Where `eta`, `N` and `delta` are constant in the direction of motion, headroom and cost have exactly opposite gradients — so **the direction of steepest improvement can be read from what people actually do, without running Protocol C-1 through C-6 first.** the founding material's desire-line node and this framework's master gauge measure the same thing.

This does not replace the gauge. It locates the direction cheaply so the gauge can be run once, in the right place, instead of four times in the wrong ones.

1. **Fix the restriction, in writing.** Name the region over which `eta`, `N` and `delta` are being treated as constant. **If the candidate move crosses a boundary that changes the roster, the tooling or the retention regime, the identity does not hold and this protocol does not apply.**
2. **Observe the worn path, do not ask for it.** Record what is actually done — the route taken, the tool reached for, the meeting attended without a summons, the step skipped. Revealed behaviour, not stated preference.
3. **Rank candidate moves by observed local cost**, in the same unit as `C` in Protocol C-5: minutes, hops, approvals, handoffs, discomfort reports. A ranking is sufficient; a magnitude is not required at this stage.

4. **Invert the ranking.** The direction of steepest cost decrease is the direction of steepest headroom increase. That is the identity, and it is the whole shortcut.
5. **Then run C-7 once, in that direction only**, and check `r_t <= h_t` before promising anything.
6. **Record the restriction violation risk.** If the intervention would itself change `eta`, `N` or `delta` — most reorganisations do — the shortcut located the direction under conditions the intervention then destroys. Note it; re-measure after.

```
WORKSHEET C-9 — GRADIENT SHORTCUT
Region over which eta, N, delta are constant: _______________________________
Cost unit (same as C-5): _____________

| Candidate move | Observed local cost | Rank | Crosses the boundary? |
|---|---|---|---|
|                |                     |      | [ ] yes -> EXCLUDE     |

Steepest cost decrease -> direction of steepest headroom increase: ____________________
C-7 run in that direction?  [ ] yes, h_t = ______   r_t requested = ______  feasible? [ ]
```

39.14.10 C.10 The t∗ test — the cheapest falsification in the corpus

t∗ has no free parameters, which is what makes it decisive. With `D`, `p_bar`, `N` and the budget all held constant, decay of `u` **alone** drives the calibration ratio across 1 at

```
u∗ = ( D/p_bar − 1 ) / ( N − 1 )            t∗ = ln( u∗ / u_0 ) / ln( 1 − lambda )
```

Worked, and verified: `D/p_bar = 4.0`, `N = 12`, `u_0 = 0.55`, `lambda = 0.08` gives `u∗ = 0.2727` and **`t∗ = 8.41` periods.** After `t∗`, the organisation is over-framed with an entirely unchanged model, **by arithmetic alone and without anyone deciding anything.**

1. **Estimate the four inputs, none of which is a fitted parameter.** `D` and `p_bar` from the existing intake ledger; `N` from Protocol C-3; `u_0` from C-4 at the current period; `lambda` as the observed decay rate of `u` between two C-4 measurements.
2. **Compute `u∗` and `t∗`.** Both are arithmetic. There is nothing to tune and nothing to fit, which is why this test costs a morning rather than a study.
3. **Record `t∗` as a dated alarm**, in the same document as the preregistration. It is a prediction with a number and a deadline attached, and by the CCP-035 arithmetic that makes it worth about **5.7x** what a direction-only prediction is worth.
4. **At `t∗`, measure `u` again and re-run C-4.** If `u` has decayed as projected and the doctrine has not moved, the prediction held. If `u` held, something is maintaining it and that something is worth naming, because it is the cheapest `u`-maintenance mechanism available.
5. **Never aggregate `r` across sites.** Aggregate `D/P` cancels opposite-direction distortion: in CCP-024's two-site example it **overstated bankable input by 4.26x.** The aggregate is not conservative and not approximately right — **distortion does not average.** Compute `t∗` per site.

```
WORKSHEET C-10 — t∗
D = ______  p_bar = ______  N = ______  u_0 (current) = ______  lambda = ______

u∗ = (D/p_bar − 1)/(N − 1) = ______
t∗ = ln(u∗/u_0) / ln(1 − lambda) = ______ periods   -> ALARM DATE: _____________

Per site, never aggregated:  site ______ t∗ = ______   site ______ t∗ = ______
At t∗: u measured = ______   [ ] decayed as projected  [ ] held -> name the mechanism
```

39.15 Appendix D Failure-mode index

The reader arrives with a symptom, not a diagnosis. This index is therefore keyed by what is actually observed — the sentence someone says in a corridor, the number that looks wrong, the thing that keeps happening — and points to the named entry in CCP-016, or — for a claim about manifestation rather than a built system — to the named entry in CCP-037.

How to use it. Find the symptom closest to yours and run the confirming measurement in the third column *before* accepting the diagnosis; symptoms are not specific, and several failure modes share most of theirs. If two entries fit, run both measurements — co-occurrence is the norm, and D.11 lists the combinations that travel together.

39.15.1 D.1 Symptoms in deliberation and meetings

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
“The meeting went really well” and nothing changed	`eta`	C-2 stratified by capture mechanism	**The Leaky Vessel**	Require one written artifact per meeting
Everyone agrees quickly and the decision is still wrong	`u`	C-4 collision test, error decorrelation	**The Parallel Wall**	Silent-write-first before discussion
Two or three people do almost all the talking	room / `c`	Turn-distribution count; RT60	**The Reverberant Room**	Measure RT60 before blaming anyone
The quiet expert stops attending	room / `u`	Attendance vs turn share by person	**The Reverberant Room**	Absorption and table geometry
Discussion converges within five minutes, every time	cascade	C-4 measured before vs after discussion	**The Cascade Collapse**	Independent written estimates first
The first speaker’s framing survives every meeting	cascade	Order-of-speaking vs final-position log	**The Cascade Collapse**	Rotate speaking order; rank speaks last
Objections are raised only in the corridor afterward	`u_div`	Anonymous vs attributed disagreement rate	**The Cohesion Death Spiral**	Chartered red team; protected minority report
Meetings have grown but decisions have not	`C`	Meeting-hours x participants; `n(n−1)/2`	**The Quadratic Committee**	Split the group; compute the crossover

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
Nobody can say what was decided	`eta`	Existence of a decision log	**The Leaky Vessel**	Decision log with owner and date
The senior person speaks first and last	geometry	Seating map; turn order log	**The Head of Table**	Remove the head seat; invert order
“We have a very aligned team” said as praise	`u`	C-4	**The Cohesion Death Spiral**	Measure `u_div` this quarter and last
New members stop dissenting after two months	`u` decay	`u` by tenure cohort	**The Parallel Wall**	Rotation; protect the first dissent publicly
The agenda is always full and never finished	`C`, `rho`	Utilization estimate	**The Utilization Cliff**	Cut agenda load to `rho <= 0.85`
A decision is made and then unmade elsewhere	structure	Map decision rights to categories	**The Tree That Should Have Been a Semilattice**	Grant overlapping membership

39.15.2 D.2 Symptoms in judgment, forecasts, and decisions

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
Forecasts are confident and jointly wrong	`u`	Error correlation across forecasters	**Pseudo-Diversity**	Recruit across training lineages
The panel is demographically varied and never disagrees	`u_div`	C-4 within-category	**Pseudo-Diversity**	Buy divergence, not more crossing
Adding reviewers has stopped improving decisions	concavity + `C`	Marginal-gain table; C-5	**The Quadratic Committee**	Stop adding; raise `u` instead
The second opinion always confirms the first	`u = 0`	Training lineage and incentive audit	**The Parallel Wall**	A second opinion from a different lineage
The risk register never surprises anyone	`u_div`, variety	Requisite-variety count vs disturbance count	**The Missing Denominator**	Pre-mortem; count the unanswered classes
The dissenter left and no one replaced the function	`u_div`	`u_div` before and after departure	**The Cohesion Death Spiral**	Charter the role, not the person

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
Losing one person would stop the work	hubs	Node-removal thought experiment on the work map	**Hub Fragility**	Duplicate the path, not the person
“We considered all the options” and there were three	`N`	C-3 audit; `N_nominal` vs `N`	**The Missing Denominator**	Write what a fourth category would be
Two disciplines both say the case is the other’s	seam	Map the categories the clerks actually enforce	**The Tree That Should Have Been a Semilattice**	Assign the seam explicitly
Adding a new “domain” did not help	`ln N`	`ln N` before and after	**The Added Domain**	Compute `ln 2 = 0.693`; look elsewhere
The proposal promises a step no one has sized	`h`	C-7	**The Promised Increment**	Compute `r_max`; refuse `r_t > h_t`

39.15.3 D.3 Symptoms in output, delivery, and throughput

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
Everyone is busy and nothing ships	`rho`, `C`	Utilization; queue lengths; Little’s law	**The Utilization Cliff**	Build slack to `rho <= 0.85`
Delivery time doubled after a small load increase	`rho`	`1/(1−rho)` fit against observed wait	**The Utilization Cliff**	Reduce load or add capacity now
Adding people made the project later	`C`	Brooks path count; onboarding cost	**The Quadratic Committee**	Stop adding; partition the work
Work is done twice in two departments	structure	Duplicate-output audit	**The Silo Local Minimum**	Shared instrumentation; co-location
Nobody knows what the other team is doing	structure, `C`	Cross-team contact frequency	**The Silo Local Minimum**	Rotation; translator role
The architecture mirrors the org chart, badly	Conway	Compare module graph to comms graph	**The Silo Local Minimum**	Change the team boundary first
Improvement efforts produce a spike and then nothing	impulse response	Plot `Y` against `3*tau`	**The Impulse Habit**	Convert the event into a cadence

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
The initiative was excellent and is now invisible	`delta`	C-1 on the initiative's own artifacts	**The Leaky Vessel**	Maintenance schedule at `t_half`

39.15.4 D.4 Symptoms in the physical room

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
The new open plan is loud and no one talks	acoustics	RT60; background NC/NR	**The Reverberant Room**	Absorption; enclosed alternatives
The plaza is empty at lunchtime	sittable space	Whyte count: seating linear metres, sun, food	**The Dead Perimeter**	Add sittable edge before anything else
The middle of the room is never used	edge effect	Occupancy heat map over a week	**The Dead Perimeter**	Furnish the perimeter; subdivide the middle
Everyone crowds the doorway	threshold depth	Dwell-time at each transition	**The Abrupt Edge**	Deepen and widen the threshold
Entering the space is jarring	threshold	Sequence audit: outside -> inside in one step?	**The Abrupt Edge**	Insert a graded transition zone
The thermostat is a permanent argument	thermal control	Individual control count; comfort survey spread	**The Optimized Setpoint**	Give local control; stop optimizing the mean
The lighting is uniform and everyone squints	glare, daylight	Illuminance survey; glare check at desks	**The Optimized Setpoint**	Task lighting plus daylight control
The building looks worse every year	material `delta`	Material audit for patina behaviour	**The Invisible Infrastructure**	Specify materials that age well
The maintenance budget is cut every year it works	`delta` invisibility	Compare spend to computed `delta*Q`	**The Invisible Infrastructure**	Publish `delta*Q` as a standing line
A long table with a clear top seat	geometry	Seating map; turn share by seat	**The Head of Table**	Round or polygonal table; no top seat

39.15.5 D.5 Symptoms in institutions over time

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
Everything takes longer than it used to and nothing is wrong	`delta*Q`	C-7: `delta*Q` as a share of `eta*ln N`	**The Maintenance Trap**	Publish headroom; consider shedding `Q`
The organization cannot start anything new	`h <= 0`	C-7	**The Maintenance Trap**	Shed `Q` or cut `C`; do not exhort
Procedures exist that nobody can justify	unshed `Q`	Origin audit; last-use date per procedure	**The Unshed Q**	Sunset clauses; retire on schedule
The founding generation left and it still runs the same	`delta \ensuremath{\approx} 0`, no input	`Y` trend vs `S` trend	**The Sealed Vault**	Restore input; measure `u`
Tradition is intact and nothing new has entered in years	`delta \ensuremath{\approx} 0`	C-1 (expect very low `delta`); C-4 (expect low `u`)	**The Sealed Vault**	Deliberate `u` injection; accept some `delta`
The metric improved and the thing it measured did not	Goodhart	Compare metric to an unrewarded proxy	**Goodhart Capture**	Separate measurement from reward
A crisis revealed a dependency nobody had listed	infrastructure	Breakdown inventory vs maintained inventory	**The Invisible Infrastructure**	Inventory by simulated failure
Growth stalled exactly when the institution matured	headroom	Plot `h_t` against `Q_t` over years	**The Maintenance Trap**	Accept lower `Q`; this is a legitimate move
The change was seeded everywhere and took nowhere	contagion topology	Map seed placement against clustering	**The Sprayed Seed**	Re-seed one cluster to saturation
A minority has pushed for years without moving anything	critical mass	Estimate committed fraction	**The Sub-Threshold Minority**	Concentrate, do not broaden
The commons is degrading and everyone agrees it shouldn't	commons	Ostrom principle-by-principle audit	**The Ungoverned Commons**	Boundaries, monitoring, graded sanctions

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
The steady state is worse than the current state	`Q_inf < Q_t`	C-7 `Q_inf`	**The Negative Equilibrium**	Raise `eta` or cut `c*`; the model says so
Every change requires someone's permission and stalls	centre	Map decision latency vs approval hops	**The Coordinator Bottleneck**	Put the state in the medium
People were moved without being asked	ethics	Consent audit	**The Coerced Move**	Stop; the standing refusals of the corpus forbids it

39.15.6 D.6 Symptoms in the measurement itself

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
The model fits beautifully and predicts nothing	repackaging	Is `Y` computable from `U`?	**The Order Proxy That Was Really the Input**	Reject the proxy; return to C-6
`delta` came out near zero	contaminated window	Re-check zero-input contamination	**The Contaminated Window**	Find a genuine zero-input window
The shuffled control fits as well as the real series	no signal	C-6 step 8	**The Missing Control**	Report failure; do not proceed
Nobody ran the shuffled control	omission	Check the preregistration	**The Missing Control**	Run it before any claim
The model was adjusted after seeing the held-out data	freeze violation	Compare the fit spec to the preregistration	**The Unfrozen Fit**	Discard; re-preregister; re-run
Headroom was reported as a single number	interval omission	Was `delta` an interval?	**The Missing Denominator**	Propagate the `delta` interval
An assumption is being used as a result	badge	Search the text for `1+(N-1)u` without S3 named	**The Unbadged Postulate**	Badge it in the sentence that uses it
A borrowed lab finding is quoted as a field result	transfer	Check the source's actual setting	**The Unbadged Postulate**	State the setting and the transfer assumption

Observed symptom	Suspect	Confirm by	CCP-016 entry	First move
A number in the report has no derivation	fabrication	Ask for the arithmetic	**The Unbadged Postulate**	Remove it or compute it (the standing refusals of the corpus, refusal 3)
The shuffled control was passed and nothing else was run	false comfort	C-8: was the surrogate calibrated on this design?	**The Missing Control**	Calibrate the surrogate; run the C-8a ceiling test
A p is quoted from an off-the-shelf permutation test	anti-conservative alpha	C-8 hole 1: measured 0.108 / 0.120 against a nominal 0.05	**The Missing Control**	Simulate the null on the design in hand; requote
Both series drift together and the shuffle passed	shared slow driver	C-8 hole 3: 98.35% pass in 4,000 trials	**The Missing Control**	Yoked control; no further surrogate will help

39.15.7 D.7 Symptoms in a claim about manifestation — channel and magnitude

A different index, for a different object. D.1 through D.6 diagnose a built system. The four tables that follow diagnose a *claim* — that some belief, held and acted on, produced some change — and they point to CCP-037, whose thirty entries are keyed to the eight coordinates every such claim has: **CH** channel, **G** gain, **Mg** magnitude, **B** base rate, **Fa** falsifiability, **Cn** consent, **Ld** ledger, **Sc** scale. **The fault is located at the first coordinate the claim cannot pass**, and locating it there rather than at the end is what makes the catalogue usable.

Four of the thirty are faults of this framework's own method, and they are indexed here on exactly the same terms as anybody else's: MF-08, MF-11, MF-23 and MF-24. **A catalogue that indexes only other people's errors is advertising.**

Observed symptom	Coordinate	Confirm by	CCP-037 entry	First move
Asked "by what route?", the holder restates the belief	CH	Ask for the channel in one sentence, nameable and lookup-able	**MF-01 · The Ungrounded Belief**	CCP-035 step 2; name a channel or withdraw the claim
The named channel is precise enough to look up, and the lookup returns nothing	CH	Look it up. The saving is the point	**MF-02 · The Absent Channel**	Halt at G-1; a named absent channel is cheaper than a vague one

Observed symptom	Coordinate	Confirm by	CCP-037 entry	First move
A sentence begins with a Nobel-recognized mechanism and ends somewhere it does not license	CH	Locate the seam — the clause where the citation stops covering the sentence	**MF-03 · Channel Substitution**	Split the claim; each half names its own transducer
The citation is real and the outcome is not in it	G	Read the cited paper's own outcome measures	**MF-04 · The Zero-Gain Channel**	`X = G·B` with `G = 0`; identical in result to MF-01
"It works in cells, therefore in tissue"; "at ultrasound, therefore at audio"	G	Check the transfer explicitly: scale, medium, frequency, species	**MF-05 · The Borrowed Channel**	State the transfer as an assumption and price it
The mechanism is quoted correctly and no number ever appears	Mg	Ask for the predicted size, with a tolerance, before measuring	**MF-06 · The Magnitude Error**	CCP-035 step 5; where Casimir is invoked, compute it
Every reported outcome is compatible with the claim	Mg	Ask what result would have been reported as a failure	**MF-07 · Order-of-Magnitude Silence**	Require a magnitude and a null before the next attempt
A decimal appears where the instrument permits only an ordering	Sc	FVP gate 2 on each term; is there a true zero?	**MF-08 · The Demoted Magnitude Reported As Measured**	Report the ordering only; Rasch route, 123 items per term
Arithmetic performed on a Likert response as though it were a length	Sc	Stevens' typology per term; which operations does the scale permit?	**MF-09 · The Scale Violation**	Restrict to permitted operations, or re-instrument
Effort and perceived result compared as though the relation were linear	Mg, Sc	Is the response register logarithmic? (CCP-020, the lens theorem)	**MF-10 · The Dosage Fallacy**	Design in ratios; equal perceived steps are equal world multiples
Results track the input's fine structure too closely	Mg	**C-8a ceiling test. The shuffle cannot see this**	**MF-11 · The Repackaged Input**	Reject the proxy; channel separation in the next design

Observed symptom	Coordinate	Confirm by	CCP-037 entry	First move
A step change with no corresponding change in `eta`, `u`, `N` or `C`	Mg	`r_max = eta*ln N − delta*Q − C` against the observed increment	**MF-12 · The Ceiling Violation**	Recompute `r_max`; an increment above it is impossible under the model

39.15.8 D.8 Symptoms in a claim about manifestation — base rate and inference

Observed symptom	Coordinate	Confirm by	CCP-037 entry	First move
An impressive collection of individual accounts and no denominator anywhere	B	Ask who is missing: who tried and did not report	**MF-13 · The Survivorship Narrative**	**Likelihood ratio 1.000000.** Enrol before the outcome is known
Counts without rates — “thirty people adopted the practice”	B	Ask for `N` at the **start** of the period, not the end	**MF-14 · The Missing Denominator**	Fix and date the roster; attrition moves people out of view
Recruitment framed around a low point; large early gains that flatten	B	Was selection on an extreme value? Compute the expected return	**MF-15 · Regression Mistaken For Effect**	Yoked control; recruit independently of the current level
A specific, narrow, unanticipated subgroup result	B, Fa	Compare the reported analysis to the preregistration	**MF-16 · The Forking Path**	Preregister the subgroup, or report it as exploratory
“We tried it for two weeks and it did not work”, no interval reported	B	Power: what effect could that design have detected?	**MF-17 · The Underpowered Null Read As Disconfirmation**	Report the interval; an underpowered null disconfirms nothing
Nine things changed and one gets the credit	CH, B	Was the credited component ever varied on its own?	**MF-26 · The Undecomposed Bundle**	Vary one component; until then the bundle is the claim

39.15.9 D.9 Symptoms in a claim about manifestation — falsifiability and the ledger

Observed symptom	Coordinate	Confirm by	CCP-037 entry	First move
Success and failure are described in the same vocabulary	Fa	Ask for the result that would kill the claim, in writing	**MF-18 · The Unfalsifiable Goal**	State the disconfirming result before the next attempt
The stated aim at the end does not match the stated aim at the start	Fa	Compare the final write-up to the dated preregistration	**MF-19 · The Retrofitted Criterion**	Discard; re-preregister. The retrofit selects harder than forking
Every null is answered with patience and no null is answered with a date	Fa	Demand a bounded latency at step G-4, in the same breath as the magnitude	**MF-20 · The Latency Excuse**	Attach a date to the prediction or withdraw it
Results are reported as “encouraging” and never as “null”	Fa	Is there a smallest effect worth having? A sample size fixed in advance?	**MF-21 · The Un-nulled Protocol**	Define the null before the next observation
The metric improves smoothly while every unmeasured correlate does not	Fa	Compare the rewarded metric to an unrewarded proxy	**MF-22 · Goodhart Capture of a Manifestation Metric**	Separate the measurement instrument from the reward
The phrase “both science and tradition confirm”	Ld	Which column is each source in? Only one of them carries evidence	**MF-23 · Precedent Mistaken For Evidence**	**The single most likely failure of this volume’s method.** State each column’s role
A claim hedged on first appearance and flat on second	Ld	Compare the abstract to this paper that stated it	**MF-24 · The Unbadged Speculative Bridge**	Restore the badge in the sentence, not in a note attached to it
Increasing terminological precision with no increase in predictive content	CH, Ld	Does the new vocabulary generate a prediction the old one did not?	**MF-25 · Naming As Mechanism**	Ask what changes numerically; a name is not a transducer

39.15.10 D.10 Symptoms in a claim about manifestation — consent

These four are the entries this framework will not trade against a result, and they are indexed last so that they are the last thing read.

Observed symptom	Coordinate	Confirm by	CCP-037 entry	First move
A step described to observers and not to participants	Cn	Count gate records against participants	**MF-27 · The Consent Bypass**	Stop. the standing refusals of the corpus, refusal 4
A decline rate of exactly zero across many opportunities	Cn	The decline log; unanimity that arrives too easily	**MF-28 · The Recruited Belief**	Stop. A zero decline rate is a measurement of pressure
The rollback plan does not exist, or exists and does not mention residue	Cn	Ask what is left behind after the rollback	**MF-29 · The Irreversible Step**	No irreversible step without a costed, stated rollback
A file, track or step whose full content the recipient cannot inspect	Cn	Can the recipient inspect the whole artifact?	**MF-30 · The Masked Carrier**	Full disclosure of content. No concealed carrier, ever

39.15.11 D.11 Co-occurring clusters — differential diagnosis

Failure modes travel in company. These five clusters account for most real surveys, and recognizing the cluster is faster than diagnosing its members one at a time.

The Comfortable Decline. Cohesion Death Spiral + Pseudo-Diversity + Parallel Wall. Signature: high satisfaction, low turnover, falling `u`, flat or falling `Y`. Feels like success from inside and is the hardest cluster to name aloud, because naming it sounds like an attack on people doing nothing wrong. Lead with the arithmetic, not the atmosphere.

The Ossified Success. Maintenance Trap + Unshed Q + Invisible Infrastructure. Signature: large `Q`, `delta*Q` consuming most of `eta*ln N`, a maintenance budget under annual attack, an inability to start anything. **The intervention is shedding, and it is the one nobody proposes.**

The Busy Nothing. Leaky Vessel + Quadratic Committee + Utilization Cliff. Signature: high activity, high meeting satisfaction, `rho` above 0.9, `eta` near zero, no artifact trail. The cheapest cluster to fix, because `eta` is the cheapest parameter.

The Unfalsifiable Report. Order Proxy That Was Really the Input + Missing Control + Unfrozen Fit + Unbadged Postulate. Signature: an excellent-looking model with no held-out result, no shuffled control, and a proxy that cannot go down. **This is the cluster that discredits the framework itself, which is why CCP-015 exists and why Appendix E is written as it is.**

The Licensed Claim. MF-02 or MF-03 + MF-13 + MF-15 + MF-12 + MF-18 + MF-21 + MF-23 + MF-27 or MF-28. Signature: a real upstream mechanism, a testimonial base with no denominator, recruitment at a low point, a claimed step above `r_max`, no stated null, precedent quoted as a second confirmation, and a decline rate at or near zero. **CCP-037's worked example carries twelve of these diagnoses in one write-up**, which is the normal density rather than a caricature: the coordinates fail together because a claim that skips one gate has usually skipped the gate before it. Enter at the channel, not at the outcome — **the diagnosis at the first failed coordinate is the only one that saves any work.**

39.16 Appendix E The honesty register

This appendix is the corpus's warrant. Everything else in the framework is a consequence of a small set of proved theorems, a larger set of chosen modelling assumptions, and a body of empirical results obtained in settings that are not the reader's. This appendix separates those three, item by item, and adds a fourth category — what has not been tested at all — which is larger than the other three combined.

The reason for writing it this carefully is not modesty. It is that a framework which cannot be told apart from its own decoration is useless as engineering. If a reader cannot determine which of this framework's claims would survive a hostile audit, they cannot use it to build anything they would be willing to defend. **This appendix is written to be used against this corpus.**

Two further drawers were added after the volumes that follow this appendix were drafted, and they are the two a hostile reader should open first. E.7 holds what this corpus **demoted**: claims it advanced and its own validation protocol reduced. E.8 holds what this corpus **rejected**: claims worked end to end in print and failed, three of them drawn from the corpus this corpus is most often assumed to be defending. **A framework's warrant is not what it asserts. It is what it has thrown away, in print, at its own cost.**

Six drawers, and the drawers are labeled.

First, before the drawers are opened: the demotion **The Formula Validation Protocol demoted the author's own keystone formula, and it did so on the second of seven gates.**

`M = (D/P)·E` — the Moment Equation, the join between the institutional-scope material's storage law and the personal-scope material's account of experience, and the formula from which the calibration ratio, the distortion measure, the launch budget and the return difference all descend — **returns DEMOTE at FVP gate 2, scale type.** Division requires a ratio scale with a true zero. `D` and `P` are not instrumented on ratio scales. Therefore the following are **not reportable as measured quantities anywhere in this corpus**:

- the **magnitude** of `D/P`;
- the distortion `Delta = |ln r|` as a number rather than an ordering;
- the **quantitative** join `M_t -> Q_{t+1}` of CCP-021;
- every M-derived formulary entry, at personal and interpersonal scope alike — five register entries, demoted together, because demotion travels downstream.

What is demoted is magnitude, not structure. The limiting cases stand. The `D = P` fixed point stands. The ordering — over-framed, calibrated, under-framed — stands, because an ordering needs only ordinal information. A reader may use the formula to say *which way* a system is distorted. A reader may not use it to say *by how much*, and neither may this corpus.

And the route out is specific, principled, and priced. Theorem 54.3, given badged Postulate SO1: **a Rasch logit difference makes `Delta = |ln(D/P)|` genuinely ratio-scaled**, because Rasch separation supplies exactly the true zero that division requires. That is not a caveat. **It is the volume's actual research instruction**, and it costs **123 items per term** to establish a half-logit distortion — 342 items for three tenths of a logit.

The coherence with the research programme is not a coincidence and CCP-027 says so: **FVP-7, the cross-subject recovery gate, is both the gate that decides the hard-science question and the stage most likely to kill the programme.**

This is the corpus working as designed. A validation protocol that demotes its own author's keystone formula, states the cost of repairing it, and gives the constructive route out is the strongest available demonstration that the protocol is real rather than decorative. It is placed here, before the drawers, rather than filed in one of them, because a demotion recorded only where it is convenient to find is concealment by filing.

39.16.1 E.1 What is proved

These are theorems. They are true within their stated assumptions, and their stated assumptions are mathematical, not empirical. Nothing in this section is a claim about the world.

CCP-A02 — the surplus functional.

1. **Theorem 2.1, the uniqueness result.** Given axioms S1 (geometric dependence: `F` depends only on `u`), S2 (`f(0) = 0`), S3 (`g(u) = e^{f(u)}` is affine in `u`), and S4 (`f(1) = ln N`), the function `f(u) = ln(1 + (N−1)u)` is the unique function satisfying all four. This is a genuine uniqueness theorem. Its force depends entirely on the four axioms being the right ones, and S3 is not a fact about the world — see E.2.
2. **Theorem 3.1, strict monotonicity.** `u1 < u2` implies `f(u1) < f(u2)`. More non-parallelism yields strictly more surplus.
3. **Theorem 3.2, positivity.** `f(u) > 0` for all `u > 0`.
4. **Theorem 3.3, strict concavity.** `f''(u) < 0` throughout the interior. Each added increment of difference buys strictly less than the previous one. Every marginal-gain table in this framework is this theorem evaluated numerically.
5. **Theorem 3.4, subadditivity on the parameter `u`.** `f(u1 + u2) <= f(u1) + f(u2)`. **This holds on `u`, and only on `u`.**
6. **Theorem 4.1, the two-source decomposition.** For a pure block vector, `u = u_cross + u_div` with `u_cross = beta^2` and `u_div = alpha^2 sin^2(gamma)`, and `max(f(u_cross), f(u_div)) <= f(u) <= f(u_cross) + f(u_div)`. Both bounds are proved; the upper one is the one design must respect.
7. **Theorem 4.2, the sharp Lipschitz constant.** `|f(u1) − f(u2)| <= (N−1)|u1 − u2|`, and the constant `N−1` cannot be improved.
8. **Theorem 4.3, extremality.** `F = 0` if and only if the states are parallel; `F = ln N` if and only if they are orthogonal.

CCP-009 — the range.

9. **Corollary 2.2.** `0 <= F(u) <= ln N`. `ln N` is the hard ceiling on surplus per interaction, and it is what makes the product `eta*ln N` the ceiling term in every design inequality in this framework.

CCP-007 — the storage law's consequences. Theorems *about the linear recurrence*. That the recurrence describes a social system is a modelling assumption (E.2); that these follow from it is proved.

10. **Theorem 3.1, the exact solution.** `Q_t = (1−delta)^t Q_0 + SUM_{k=0}^{t−1} (1−delta)^{t−1−k}(eta S_k − C_k)`. The split into transient and driven terms is exact.
11. **Corollary 3.2, one-step growth.** `Q_{t+1} > Q_t` iff `eta S_t > delta Q_t + C_t`.
12. **Theorem 3.3, the uniform bound.** `Q_t <= max{Q_0, eta ln N / delta}`; if `delta = 0`, `Q_t <= Q_0 + t eta ln N` — the formal statement that a system with no loss term has no fixed point.
13. **Corollary 3.4, the sustainability ceiling.** A nondecreasing step requires `C_t <= eta ln N − delta Q_t`. If this fails, **no choice of interaction geometry can prevent order from decreasing**, because `S_t <= ln N` bounds every geometry at once.
14. **Theorem 3.5, the steady state.** With `U \ensuremath{\equiv} u*`, `C \ensuremath{\equiv} c*`, `delta > 0`: `Q_inf = (eta F(u*) − c*)/delta`. If `eta F(u*) < c*` the equilibrium is negative — the regime is unsustainable or the linear model must be replaced. **The theorem does not hide this failure mode, and neither does this corpus.**
15. **Proposition 4.1, target increment.** `Q_{t+1} − Q_t >= r_t` iff `S_t >= (delta Q_t + C_t + r_t)/eta`, feasible only if `delta Q_t + C_t + r_t <= eta ln N`.
16. **Corollary 4.2, maximum one-step increment.** `r_max = eta ln N − delta Q_t − C_t`.

Borrowed mathematics, correctly used.

17. **Banach's fixed point theorem (1922).** A contraction on a complete metric space has exactly one fixed point; iteration from any start converges to it geometrically. `delta > 0` makes the storage update a contraction with factor `(1−delta)`. Every claim in this framework that iteration *arrives* is this theorem applied to a linear recurrence on the reals. Whether the social system it models is a complete metric space is drawer two.
18. **The discrete-time first-order filter identity.** That `Q_{t+1} = (1−delta)Q_t + x_t` is a low-pass filter with pole `(1−delta)`, time constant `tau = −1/ln(1−delta)`, and DC gain `1/delta` is an identity, not an analogy. The settling figures — 95.0% at `3*tau`, 99.3% at `5*tau` — are computed from it.
19. **Little's Law.** `L = lambda W`, for any stationary system with finite means. Proved.
20. **Ashby's Law of Requisite Variety (1956).** Within Ashby's set-theoretic formulation, a regulator's capacity to hold an outcome constant is bounded by its own variety. A theorem within its framework; its application to organizations is a modelling map — see E.2.
21. **The Condorcet Jury Theorem (1785).** If each of `n` voters is independently correct with probability `p > 1/2`, majority accuracy increases in `n` and tends to 1. **Under correlated votes the theorem gives no such conclusion, and correlated votes are the normal case.** This framework uses the failure of the premise more often than the theorem.
22. **The Brooks path count.** `n` participants have `n(n−1)/2` pairwise channels. Arithmetic. That cost grows at that rate is an empirical claim, not this identity — see E.3.

39.16.2 E.2 What is postulated

Each item here is an assumption. Each is badged wherever the framework uses it. None is derived from anything in E.1, and none is established by anything in E.3.

1. **S3, the affine effective-count design axiom.** The assumption that `g(u) = e^{f(u)}` is affine in `u` — equivalently, that the effective count is `N_eff = 1 + (N−1)u`, linear in non-parallelism. **This is chosen for tractability and interpretability, not derived.** It is what makes the uniqueness theorem produce a logarithm rather than some other concave function. Every number in this framework computed from `1 + (N−1)u` — every effective count, every marginal-gain table, every `S` — inherits the status of a postulate, not of a theorem. If S3 is wrong, Theorem 2.1 is still true and no longer relevant.
2. **The linear form of the storage law.** `Q_{t+1} = (1−delta)Q_t + eta S_t − C_t` is **the minimal tractable open-system law, not a law of nature.** It assumes loss proportional to stock, conversion linear in surplus, cost additive, parameters constant within a period, no `Q`-`S` interaction, no saturation. Each simplification is chosen so a closed-form solution exists, and each fails somewhere. **A nonlinear `Q` with saturation, a state-dependent `eta`, or a cost rising with `Q` would all be more realistic and none would give Theorem 3.5.** A wrong model that can be computed with, whose wrongness has been stated, is a usable instrument; a right model that cannot be evaluated is not.
3. **`Q` itself as a state variable. The storage variable `Q` is a modelling choice, not derived from first principles.** There is no measurement of `Q` — only a proxy `Y` chosen under Protocol C-6, and different engineers will choose differently. That "what persists in a social system" is a single scalar decaying exponentially is a strong assumption, made because it is the simplest one that produces a testable model.
4. **The modelling map onto social systems.** That rooms, teams, institutions, and cities are systems to which the storage law applies at all is the largest assumption in this corpus, and nothing in Papers A or E establishes it. The map identifies interaction geometry with `u`, institutional persistence with `Q`, forgetting and turnover with `delta`, capture into artifacts with `eta`, overhead with `C`. **Each identification could be wrong without any theorem being wrong.**
5. **Hyperrecursive symmetry.** That the same equation governs a desk, a room, a team, a building, an institution, and a city, with only `(delta, eta, N, C)` changing, is **a claim about MODEL FORM, not about physics.** It is not a scaling law, it does not predict how parameters change with scale, and it has not been tested at two scales simultaneously

in any real system.

6. **The state encoder.** That participants, views, or categories can be represented as unit vectors whose inner product carries the relevant notion of alignment is an operational choice. Different encoders give different `u` for the same group, and the framework's estimator — centered, unit-normalized response or error vectors, so that `x·y` is a Pearson correlation and `u = 1 - r^2` — is one choice among several defensible ones.
7. **The ensemble aggregation.** The surplus law is stated for a pair. Real groups have more than two members. The participation-ratio estimator, `N_eff = (SUM lambda)^2 / SUM lambda^2` from the correlation matrix, extends the pairwise law to an ensemble in a way that is consistent with the affine form by construction. **Consistency by construction is a property of the choice, not evidence for it.**
8. **Cost commensuration.** That coordination hours, rework, conflict, and rent can be converted into the same unit as stored order is assumed every time `h_t` is computed. The conversion factor is chosen by the engineer, is not measured, and dominates the headroom result whenever `C` is large.
9. **Constancy of parameters within a survey.** `delta` and `eta` are treated as constants over a measurement span. They are not. They move with turnover, tooling, morale, and season. Protocol C-1 asks for two windows and an interval precisely because the point estimate is a fiction the arithmetic requires.
10. **The interpretation of `u = 0` at anti-alignment.** Because `u = 1 - (x·y)^2`, a perfectly anti-correlated participant scores `u = 0`, identically with a perfectly correlated one. This framework interprets that as correct — a reliable contrarian is one instrument, not two — but the interpretation is a reading of the formalism, not a result.
11. **`optional activity` as the observable proxy for a room's `eta`.** Gehl's category is real and observable; identifying it with the conversion efficiency term is this framework's proposal.
12. **Acoustics as `c`-factor engineering.** The chain is: reverberation affects speech intelligibility (established acoustics); intelligibility affects who speaks and how often (plausible, partially studied); turn-taking equality correlates with `c` (Woolley et al.). **The composite claim — that changing RT60 changes collective intelligence — is a chain of three links of which the middle is the weakest, and it has not been tested end to end.**
13. **That a badged analogy may organise and may not compute.** This is a house rule, and it is stated here because it is a rule about postulates rather than a postulate itself. **An analogy carried under a badge may structure a paper, name a pattern, and suggest where to look. It may not contribute a number.** CCP-032 is the worked instance and it is deliberate: every quantitative result in that chapter comes from an information-budget bound, from the Gabor timing/rhythm trade, or from the Lyapunov horizon law, and **not one comes from Heisenberg.** `dx·dp >= hbar/2` does zero arithmetic work in this framework. Where a later chapter appears to draw a figure from an analogy, that is a defect in the later chapter.
14. **That the internal and external scopes correspond at all.** The master correspondence of the personal-scope material — the same six parameters read at two scopes — is **a correspondence of dynamics and geometry, and it is NOT a correspondence of agency.** CCP-025's breakdown section is the longest in that chapter and names nine disanalogies: exit, heterogeneity, aggregation, homunculus/reciprocity, observation asymmetry, boundary asymmetry, timescale, rivalry, ethics. **Three of them are computed**, and they are the ones that matter: a mean-field decay error reaching **92% by `t = 12`**; two nine-member groups with *identical* `u = 0.5999` and `S = 1.7578` losing **77% against 21%** of their surplus to a three-person departure — **aggregate statistics hide the structure that decides the outcome**; and a **90.1x** period-normalisation trap when the two scopes are compared on mismatched clocks. CCP-038 adds five named breaks at the third scope, in E.10.
15. **That trust is a source of order.** It is not, and the correction is a postulate-level one because naive practice assumes otherwise. Trust acts by reducing `delta`, and `Q_inf = (eta*F(u*) - c*)/delta`. **When the numerator is negative, dividing by a smaller positive**

denominator makes the result more negative. In the worked consortium of CCP-025, trust alone moved `Q_inf` from `-0.0836` to `-0.2114` — **worse**. Reciprocity alone moved it to `+0.7394`; both together to `+1.8701`. **Trust amplifies whatever sign the system already has. Fix the numerator first.**

39.16.3 E.3 What is borrowed

Every empirical result this framework draws on, what it actually showed, in what setting, and what must be assumed to transfer it. Nothing here was obtained in the reader's organization.

Woolley, Chabris, Pentland, Hashmi & Malone [Woolley et al., 2010]. Several hundred participants in small groups (two to five people) completed batteries of short laboratory tasks. Factor analysis of group performance across tasks yielded a single general factor, `c`. `c` was **not** predicted by the average or the maximum individual intelligence of members. It correlated positively with members' average social sensitivity, negatively with the variance in speaking turns, and positively with the proportion of women. *Setting:* laboratory, tasks of hours, groups assembled for the study. *Transfer assumption:* **that a factor measured over hours in assembled groups persists in teams working for years on their own problems.** This is not established. CCP-013 states it; this appendix repeats it.

Centola, Becker, Brackbill & Baronchelli [Centola et al., 2018]. In controlled online experiments, small groups played a coordination game that established a naming convention; committed confederates then pushed an alternative. Below roughly a quarter of the population, the minority failed; above it, the convention flipped. The tipping point was measured, not simulated. *Setting:* online, small groups, an arbitrary convention with no material stakes, no history, and no hierarchy. *Transfer assumption:* **that a threshold measured for a costless naming convention among strangers applies to a costly practice among colleagues with careers at stake.** The framework uses ~25% as an order-of-magnitude planning figure and says so.

Centola & Macy and Centola [Centola and Macy, 2007, Centola, 2010]. The 2007 paper is analytic: for behaviors requiring reinforcement from multiple sources — complex contagion — long-range random ties can impede rather than accelerate diffusion, reversing the small-world intuition. The 2010 paper is an online experiment in which a health behavior spread farther and faster through a clustered-lattice network than through a random network of the same density. *Transfer assumption:* that organizational practices are complex rather than simple contagions. Often reasonable; not measured in any case the corpus reports.

Granovetter [Granovetter, 1978]. An analytic threshold model: each person acts when the number of others acting exceeds a personal threshold, so the aggregate depends on the whole threshold distribution and one person's shift can be the difference between nothing and everything. *Status:* a model, not a measurement. Its lesson is that aggregate discontinuity does not require anyone to be irrational.

Watts & Strogatz [Watts and Strogatz, 1998]. Rewiring a small fraction of a ring lattice's edges collapses average path length while clustering stays high. *Status:* a result about constructed graphs, with empirical illustrations.

Barabási & Albert, and Albert, Jeong & Barabási [Barabási and Albert, 1999, Albert et al., 2000]. Growth plus preferential attachment generates a power-law degree distribution; such networks tolerate random node removal well and targeted removal of high-degree nodes very badly. *Status:* model results with empirical support in several real networks. *Transfer assumption:* that the dependency structure in question is scale-free enough for the fragility result to bite. Check it — a node-removal audit takes an afternoon.

Hong & Page [Hong and Page, 2004]. A mathematical and computational result: under stated conditions, a randomly selected group of diverse problem solvers can outperform a group of the individually best-performing solvers. *Status and contest:* the result depends on strong conditions about the problem space, the size of the candidate pool, and the formal definition of diversity, and it has been criticized on mathematical grounds — notably by Abigail Thompson in the *Notices of the AMS* (2014). **This framework uses Hong & Page as an illustration that diversity can dominate ability under some conditions, and not as a proof that it**

generally does.

Bikhchandani, Hirshleifer & Welch [Bikhchandani et al., 1992]. A model of informational cascades: sequential agents observing predecessors rationally cease using their private signals after a short prefix of decisions. Aggregation stops; the cascade is fragile and reversible by a little new public information. *Status:* theory with extensive experimental support. Used here as the mechanism by which a diverse group becomes parallel with no one changing their mind.

Allport, and Pettigrew & Tropp [Allport, 1954, Pettigrew and Tropp, 2006]. Contact reduces prejudice under four conditions — equal status, common goals, cooperation, institutional support. The meta-analysis of over 500 studies found contact generally associated with reduced prejudice, with larger effects when the conditions were met. *Status:* a large meta-analysis, correlational in much of its base, with known concerns about publication bias and self-selection into contact.

Bandura on moral disengagement; Kelman; Haslam on dehumanization. Evidence that harm at scale is preceded by euphemistic labeling, displacement of responsibility, routinization, and the withdrawal of full humanity from a target group. *Status:* a well-supported tradition, drawn on here only for the ethical constraint in the standing refusals of the corpus and the failure modes in CCP-014.

Ostrom [Ostrom, 1990]. Comparative case study of long-enduring common-pool resource institutions — irrigation systems, fisheries, forests, pastures — yielding eight design principles. Nobel Prize 2009. *Status:* **inductive regularities from case comparison, not theorems and not experiments.** A later meta-analysis by Cox, Arnold and Villamayor-Tomás (2010) found broad empirical support across a large body of cases while suggesting refinements. This is the most directly engineerable body of work in the sociology literature this framework uses, and it remains a set of empirical regularities.

Putnam [Putnam et al., 1993]. Italian regional governments created by the same 1970 devolution performed very differently, and the differences tracked civic traditions with roots centuries earlier. *Status:* a landmark comparative study whose causal direction has been contested. Used here for the durability of civic structure, not for a mechanism.

Gambetta [Gambetta, 1988]. An account of the Sicilian mafia as a supplier of private protection where trust was scarce and central enforcement weak. *Status:* descriptive and interpretive. Used as a demonstration that order can be produced by networked obligation, and as a warning about what kind of order that is.

Grassé 1959. Termite nest construction proceeds by each individual responding to the state of the work already done: stigmergy. *Status:* a foundational ethological observation, since formalized. The rule this framework derives — put the state in the medium, not in a coordinator — is an inference from the mechanism, not a finding.

Schelling [Schelling, 1971, 1978]. Focal points: parties who must coordinate without communicating converge on salient options; the evidence was informal elicitation, not controlled experiment. The segregation model shows mild individual preferences producing strong aggregate separation — a model, whose value is that it removes the need to posit strong preferences to explain strong outcomes.

Star & Ruhleder [Star and Ruhleder, 1996]. Infrastructure is relational rather than substantial and becomes visible chiefly upon breakdown. *Status:* an ethnographic and theoretical study of a scientific collaboratory. Used here for one consequence: **maintenance is chronically underfunded because working infrastructure is invisible, which means `delta` is systematically underestimated wherever it has not been measured.**

Weiser 1991. "The most profound technologies are those that disappear." *Status:* an essay in *Scientific American*, an argument rather than a study. Quoted as an aphorism and used as a design orientation.

Alexander [Alexander, 1965, Alexander et al., 1977], together with the 1964 *Notes on the Synthesis of Form,* which carries no key in this corpus's bibliography. The direct ancestor of this framework's form. The semilattice argument — living structures have overlapping rather

than strictly nested categories, and designers impose trees because trees are easy to hold in mind — is supported by examples, not measured. **This framework's use of it to explain why hierarchy drives `u` toward zero is an inference this framework makes, not a claim Alexander proved.**

Jacobs [Jacobs, 1961]. Eyes on the street, short blocks, mixed primary uses, aged buildings. *Status:* observational argument of extraordinary quality, not controlled study; later quantitative work has supported parts and complicated others.

Whyte [Whyte, 1980]. Direct observation with time-lapse film of New York plazas: people sit where there is somewhere to sit; sun, food, water, and triangulation draw and hold people. *Status:* systematic observation in one city over several years. **The method is more transferable than the findings, and this framework borrows the method for CCP-010.**

Gehl [Gehl, 1971]. Necessary, optional, and social activity, with optional activity highly sensitive to conditions. *Status:* observational studies across several cities.

Hall [Hall, 1966]. Proxemic distance bands — intimate, personal, social, public. *Status:* observation predominantly of one cultural group; Hall himself emphasized cross-cultural variation. A frame, not a specification.

Ulrich, *Science* 1984. Twenty-three matched pairs of gall-bladder surgery patients in one Pennsylvania hospital over nine years; those in rooms with a window view of trees had shorter postoperative stays, fewer negative nursing notes, and took fewer strong analgesic doses than those facing a brick wall. *Status:* **a small, single-site, matched-pair study, and the strongest single piece of evidence in this framework that physical space affects a hard outcome.** Both halves of that sentence are load-bearing. It has been influential far beyond what a study of that size can carry alone; later research has broadly supported the direction of the effect without settling its size.

Sabine. `RT60 = 0.161 V / A` in metric units, `V` in cubic metres and `A` in square-metre sabins. *Status:* an empirically grounded formula valid for reasonably diffuse sound fields. **It degrades in heavily absorbing rooms — Eyring's form is preferred there — and in strongly non-diffuse geometries.** Every RT60 figure in this framework carries that caveat.

Conway [Conway, 1968]. Organizations that design systems produce designs copying their own communication structures. *Status:* an argument in a trade magazine, later supported by empirical work comparing product and organizational structure in matched codebases. A structural explanation, not a law.

Dunbar's number, ~150. From a regression of primate group size on neocortex ratio, extrapolated to humans. *Status:* **contested**, including on the statistical ground that the extrapolation carries very wide uncertainty. Do not use it as a design threshold; use it as a reminder that relationship maintenance has a cost — a `C` claim that needs no magic number.

Brooks [Brooks, 1975]. Adding people to a late project makes it later; communication paths grow as `n(n–1)/2`. *Status:* an engineering argument from experience on one large project, widely corroborated in practice and not established by controlled experiment. The path count is arithmetic; that cost tracks it is the empirical part.

Goodhart and Campbell [Goodhart, 1975, Campbell, 1979], with Strathern (1997) named in prose and carrying no key here. A measure used for control ceases to measure what it did. *Status:* empirical generalizations, not theorems. This framework is subject to them: **headroom, once rewarded, will be gamed, and Protocol C-7 will begin to produce the number the reporter needs.**

Queueing theory. Waiting time growing as `1/(1 – rho)` is exact for M/M/1 and approximately right for a wide class of systems. *Status:* proved under distributional assumptions that real systems violate in ways that generally make matters worse.

39.16.4 E.4 What is untested

This is the largest drawer and the one most easily forgotten, because untested claims look exactly like tested ones once they are set in the same typeface.

1. **No organization has been surveyed under CCP-015, preregistered under CCP-015, and reported.** Not one. Every worked example here is arithmetic on parameter values chosen to be plausible, not measured in the field. The examples show that the calculations can be done and what they would mean; they do not show that the model describes any real system.
2. **The estimators in Appendix C have not been validated against ground truth.** There is no case in which `delta` was estimated by Protocol C-1 and independently known. The protocols are built to be internally consistent and to fail loudly; that is not accuracy.
3. **The held-out performance of the storage law is unknown.** The falsification rules of CCP-015 exist because the model must be falsifiable, not because it has survived falsification. **A framework that cannot fail cannot be trusted, and this one has not yet been given the chance to.**
4. **Scale-freedom has never been checked at two scales at once.** The test would measure `(delta, eta, N, C)` for a desk and for the institution containing it, same units, same period, and show the same equation holding with different parameters. Not done.
5. **The acoustics-to-`c` chain is untested end to end.** An honest test would randomize RT60 across otherwise matched deliberation rooms and measure turn-taking variance and task performance. It would not be expensive. It has not been run.
6. **The 25% figure has not been tested in an organization**, nor has any organizational analogue of it been measured by anyone this framework can cite.
7. **The lever cost ranking is an argument, not a measurement.** That `eta` is cheapest, then `C`, then `u`, then `N` follows from the structure of the law plus practitioner reasoning. **No cost study supports the ordering; treat it as a prior to be updated, not a finding.**
8. **The physical specifications are syntheses, not trials.** CCP-011, CCP-012 combine established acoustics with observational urbanism and a laboratory correlation. No room built to that specification has been compared against a control.
9. **The failure mode catalog is a taxonomy, not an epidemiology.** CCP-016 names failure modes and gives each a signature; it does not report how common any of them is, because nobody has counted.
10. **The consent constraint has not been tested as an engineering property.** That a method working by removal of resistance has no coercive failure mode is an argument about the structure of the method — an ethical guarantee about what this corpus will recommend, not an empirical claim that such methods never harm. **The ten entries above are the original set, and they are the ten CCP-039's specification S11 refers to. Five more were added by the personal- and cellular-scope material, and every one of them is larger than the entry it follows.**
11. **Of twenty-seven parameter-by-scope cells, nineteen have a procedure, one has a validated number, and none has a first-party measurement.** This is CCP-038's audit and it is the single most useful number in this appendix — see E.10, where it is set out in full. **The scope with the least-validated instrument turns out to have the best-measured parameter**, which is not a comfort.
12. **No formula in Volumes Two or Three has passed FVP-7.** The cross-subject reproducibility gate — same operationalisation, different people, different laboratories, do the parameters recover — is the gate that decides the hard-science question and it has not been attempted for any formula in this corpus. **the corpus's internal-scope conventions names it the gate most often skipped; CCP-027 computes that it is most often skipped because it is most often failed.**
13. **`D` and `P` have never been Rasch-calibrated.** The route out of the demotion is specified, costed at 123 items per term, and untaken. Until it is taken, every magnitude descended from the Moment Equation stays in the drawer where E.7 keeps it.

14. **No cell has been shown to demodulate sequence-specific information from an acoustic signal, and this corpus does not claim one can.** Everything upstream of that gap is real and cited — mechanotransduction, PIEZO channels, force-to-chromatin transmission, DNA data storage, addressing formats. **The channel for sequence-specific content is the open question, it is one well-specified falsifiable gap, and naming it sharply is the most useful thing the cellular-scope material does.**
15. **The essence law has never been tested as a bridge, only as arithmetic.** That $f(n) = k\ n^2$ reproduces the source document to fourteen significant figures is a verification of a transcription, not evidence that essence indices are the right index for anything. **An essence frequency is not a physical resonance**, and no rendering built to the CCP-032 constraints has been compared against a control.

What would change these entries. Each item above names its own test. The framework's position is that it should be judged by whether those tests are run and reported, including when they fail, and that a reader who runs one and gets a null result has done this corpus a service that no amount of agreement could.

39.16.5 E.5 The honesty clauses, reproduced in full

These are reproduced verbatim from the formal spine and are binding wherever the law is used.

> **The triangle inequality FAILS for geometric triples (CCP-A02 §5). Subadditivity holds on u only.**
>
> **As deployed, the surplus functional is a LOWER BOUND on the ensemble's information, not the information itself. We log the floor, not the ceiling.**
>
> **CCP-A02 is pure mathematics and makes no empirical or metaphysical claim.**
>
> **CCP-009: surplus is NOT identified with Shannon entropy or mutual information in general.**
>
> **CCP-007: no thermodynamic negentropy law is proved.** `F(u) + N_can(u) <= ln N` (Cor 2.2) — **higher static surplus does NOT imply higher canonical concentration.**
>
> **S3 is the design axiom — chosen, not derived, and that must be said wherever it is leaned on.**
>
> **The storage variable `Q` is a modelling choice, not derived from first principles. The linear update is the minimal tractable open-system law, not a law of nature.**
>
> **Woolley's `c` is from short-task lab settings.**
>
> **Centola's 25% is from controlled online experiments.**
>
> **The storage law is scale-free in form: that is a claim about MODEL FORM, not about physics.**
>
> **If `eta F(u*) < c*` the equilibrium is negative — the regime is unsustainable or the linear model must be replaced. The theorem does not hide this failure mode.**

the personal- and cellular-scope material added six more, and they are binding on the same terms.

> **A badged analogy may ORGANISE and may not COMPUTE.** It may structure a paper and name a pattern; it may not contribute a number. CCP-032 contributes no number from Heisenberg.

The (+1) column carries EVIDENCE. The (-1) column carries PRECEDENT. Two sources agreeing does not double the evidence when only one of them is evidence. State the role of each column in the sentence that draws the concordance.

Every speculative bridge is marked SPECULATIVE in the sentence that states it, not in a note attached to it.

The internal/external correspondence is one of DYNAMICS AND GEOMETRY, not of AGENCY. The arithmetic descends between scopes; the consent constraint does not descend to a cell, and must be carried by hand.

Division requires a ratio scale with a true zero. A formula that divides two ordinally-measured terms is a heuristic ordering and is DEMOTED IN PRINT — in this paper that made the claim, and not only in the appendix.

There is no established mechanism by which a cell demodulates SEQUENCE-SPECIFIC information from an acoustic signal. Everything upstream of that gap is real and cited; the gap itself is the open question and it is stated in every chapter that touches it. **No clinical claim; no claim that DNA is edited, altered or damaged; no claim that any capability has been conferred; and Casimir does nothing at biological scale.**

39.16.6 E.6 The four refusals, and why each is a refusal rather than a preference

1. No claim about physics, thermodynamics, or consciousness. The temptation is real, because `F` is a logarithm of a count and looks like an entropy. It is not one. CCP-009 declines to identify surplus with Shannon entropy or mutual information in general, and CCP-007 proves no negentropy law. `F(u) + N_can(u) <= ln N` means surplus and canonical concentration compete for the same ceiling: **a system with high static surplus is not thereby more ordered, and any sentence suggesting otherwise is outside this corpus.**

2. No postulate without its badge. An unbadged postulate is not a stylistic lapse; it is the mechanism by which a framework becomes unfalsifiable, because a reader who cannot tell assumptions from results cannot design a test.

3. No number that was not computed or cited. Every table here can be reproduced from the formula above it with a calculator, and every empirical figure is attributed in E.3 with its setting stated. Where a figure would need research that has not been done, the framework says what would need measuring instead. **An invented number is worse than no number, because it is actionable.**

4. No intervention that removes a person's ability to decline. The method this framework teaches works by lowering the cost of a better position — building the lower valley next door — and therefore has a bounded worst case: someone looks at the valley and stays. A method that works by removing the option has no such floor. **The safety property and the effectiveness property are the same property, which is convenient, and it would be the rule regardless.**

39.16.7 E.7 What this corpus demoted

The demotion of the Moment Equation is stated before the drawers, because it is the largest one and because burying it would have been the easiest thing this appendix could do. This section holds it and the rest, in one place, so that the count is visible.

Eight register entries carry the status DEMOTED. Demotion means the structure stands and the magnitude does not; the demoted content may not reappear in any form, **including in a summary table**, and demotion travels — when a gate fails, every entry downstream of the failed one is demoted in the same pass.

1. **The magnitude of `D/P`.** FVP gate 2 returns DEMOTE. `D` and `P` are not instrumented on ratio scales with true zeros, and division is not a permitted operation on the scales that exist. **The route out is Theorem 54.3 and it costs 123 items per term.**
2. **The distortion magnitude `Delta = |ln r|`**, demoted to ordinal. The direction stands, because an ordering needs only ordinal information.
3. **The quantitative join `M_t -> Q_{t+1}`**, demoted to structural. The form stands; the magnitude inherits entry 1.
4. **The same demotion at group scope**, on the doctrine-to-data ratio as a measured quantity. The diagnostic survives as a diagnostic and not as a number.
5. **Every M-derived formulary entry**: the launch budget `L = max(0, M − C)`, the return difference `Delta_R = |ln(M'/M)|`, and their interpersonal counterparts. **No M-derived magnitude survives anywhere in the corpus.**
6. **The acoustic-to-`c`-factor CAUSAL claim, reported as NOT CONFIRMED.** The falsification test is stated in §14.13 and its result is not confirmed. **Any chapter invoking acoustic `c`-factor engineering carries that status**, and the composite chain — RT60 to intelligibility to turn-taking to `c` — remains three links of which the middle is weakest and untested end to end.
7. **The claim that the shuffled-input control is sufficient to detect a spurious input**, shown insufficient by construction and then by simulation. Three measured holes; Protocol C-8 states them and prices them. **This is a demotion of a method this framework recommended in its own earlier chapters, and the earlier worksheets carry the correction.**
8. **Seven published compound values in the 2022 sonic-chemistry source**, demoted as data-entry errors rather than as a different law. The compound rule reverse-engineers as `f = k^2 G^4` with `G` the count-weighted geometric mean of indices, matching 37 of 44 published composites to better than `1e−12`; **the O2 row is provably impossible under the stated rule.** The source's prose formula `1+5^.5/2` is missing its parentheses.

Two negative results were retained rather than buried, and both should stay in print. Momentum descent failed to escape the worked landscape at every `beta` tested — the barrier is a wide plateau, not a spike — and **the momentum recursion is explicitly excluded from the formulary with its failure stated.** That exclusion is a feature. A formulary containing only the recursions that worked is a formulary that has been edited rather than assembled.

And one correction to a target this corpus had itself proposed. `r = 1` is not an unqualified goal. Headroom at the `D = P` fixed point is **exactly zero by cancellation**, and by the two-track ledger an organisation optimising raw stored order is **actively driven away from `r = 1`**, because over-framing banks faster. CCP-019 may not present calibration as a simple objective, and does not.

39.16.8 E.8 What this corpus rejected

Five claims were worked end to end in print and failed. Four of them come from the corpus this corpus is most often assumed to be defending, which is the point: **a concordance method is only worth having if it can return this verdict.**

1. "528 Hz repairs DNA" — REJECTED (CCP-029 §61.14). Four computed objections, not four opinions. A frequency in hertz for a named musical pitch is a convention, not a property of a molecule. The acoustic wavelength in soft tissue at 528 Hz is **2.9167 m** against a target of nanometres — a ratio of order `9e9`, so whatever the field does to a nucleus it does to the whole nucleus at once and identically. The acoustic quantum carries `h*f = 2.18e−12 eV`, which is **`8.17e−11`** of the ambient thermal jostling at body temperature. And the molecular vibrational modes that do exist sit **34.7 to 37.3 octaves above** 528 Hz. `C1 FAIL, C2 FAIL, C3 FAIL`; the (+1) column empty; **the (-1) column VOID**, because the source is 1990s and not traditional and therefore carries zero bits of precedent.

Then the rejection was turned back on this corpus's own pipeline, in the same passage. CCP-031 sonifies measured infrared spectra by fixed octave transposition, and **that pipeline may not claim what it has just refused to let anyone else claim.** Dividing a frequency by

`2^35` preserves a ratio and no physical interaction; the essence frequencies of the corpus's disclosed-signal constraints are essence frequencies and not physical resonances; and nothing in the cellular-scope material may claim sequence-specific acoustic action on DNA, because the objection applies to this corpus's tones exactly as it applies to anyone else's. **The difference between the two is that this corpus states its mapping, states that the mapping is a convention, and states that the convention carries no mechanism. If a reader concludes the difference is thin, the reader has understood the situation correctly. It is thin. It is also the entire distinction between an honest notation and a false one.**

2. The 64-codon / 64-hexagram bridge — REJECTED (CCP-031 §67.11). The genetic code has 64 codons; the *I Ching* has 64 hexagrams. **`2^6 = 64` and `4^3 = 64` are different factorisations**, which is to say the two are not the same structure at all — they are two different structures with the same cardinality. A proposed correspondence between them is a chosen bijection, one of `64! = 1.2689e89` available, **worth 296.0 bits of arbitrary choice.** `C1 FAIL` (a shared count is not a shared pattern), `C2 FAIL` (it generates no prediction that could come out otherwise), `C3 FAIL`. **Sixty-four is a small highly-composite power, and that two systems both land on it is a fact about the number.**

3. Astrology's orb — the structure retained as precedent, the validity REJECTED (CCP-032). The traditional orb is a genuine tolerance-versus-window trade, and `C1` passes on that structure alone: a wide orb admits more configurations and corresponds to a longer window of claimed influence, which is the conjugate-spread shape. **`C2` is marked FAILED in print**, and the failure is cited in the same passage that draws the correspondence: **Carlson, "A double-blind test of astrology", *Nature* 318 (1985), 419–425** — the definitive controlled test, which astrology failed. **The tradition is used as a (-1) precedent for a tolerance/window structure and for nothing else.** A tradition may record a structure and forecast nothing, and this one does.

4. Gematria's evidential reading — DEAD BY ARITHMETIC; the mnemonic reading intact (R12, CCP-028). Measured rather than asserted: across **234,454 dictionary words** the map yields **305 distinct outputs**, destroying **10.47 bits** at a **99.995% collision rate**; and in an 8,000-word corpus, **essentially every word has a value-twin, `p = 0.9997`. A hash with that collision rate cannot carry evidence.** It can absolutely carry a memory index, and the method of loci is a validated mnemonic technique, so the mnemonic reading stands untouched. **This is the model for how the whole old corpus is treated: disprove the strong claim with arithmetic, preserve what is genuinely there, and do both in the same passage.**

5. The empty cells — a rejection performed one hundred and thirty-three times. CCP-038's register holds **156 entries. Precedent is claimed in 23 rows — 14.7%. The remaining 133 read "none claimed."** the cellular-scope material's commitment is that every substantive claim carries two references; that commitment is met where the historical corpus has something to say and **reported as unmet where it does not**, which is the only way it can be kept without inventing the second reference. The register's speculative group holds 12 entries, **4 of them rejections or refusals printed as such.**

14.7% is a considerably less impressive number than the two-column method promises in the abstract. It is printed because it is the true one, and because a blank column is the correct output when the historical corpus has nothing to say. Filling it would have been the easiest and most damaging thing this corpus could do.

39.16.9 E.9 What testimony is worth, computed

The likelihood ratio of testimonial evidence, under a selection process that publishes successes and discards failures, is exactly `1.000000`.

Not approximately one. Not weakly informative. **Exactly one — which means the evidence does not move the posterior at all**, because the selection guarantees that successes are observed whether or not the method does anything. All four hypothesised success rates in CCP-035's worked case produce the same 500 published accounts. **A thousand testimonials from people for whom a method worked carry precisely the evidential weight of zero testimonials.**

This is the exact quantification of survivorship bias, and it is the cleanest demonstration in the work of why the (-1) precedent column can never be promoted to evidence: the historical corpus is itself a survivorship-filtered record. What was preserved was preserved because someone found it worth preserving, and the selection is invisible from inside the surviving set. That is not an argument against keeping the column — independent arrival is real and worth having, because it argues that a structure was findable by more than one route. **It is an argument against ever counting it twice.**

The companion result prices the alternative. Likelihood ratios measured at **2.0000** for a prediction specifying only a *direction*, against **11.3577** for one specifying a *magnitude* with a tolerance: **a prediction with a number attached is about 5.7x more evidentially powerful**, equivalent to about 3.5 direction calls for the same single measurement. **Hence the standing rule: a belief that predicts only a direction is not yet testable.** It has not been refuted; it has not been examined. That is a worse condition than being false, and the fact that it feels like a safer one is precisely why so many claims stay in it.

39.16.10 E.10 What the instrument audit found

CCP-038 read the three scopes — institutional, personal, cellular — against the same nine parameters and counted what each cell actually holds.

	Institutional	Personal	Cellular	Row total
Defined estimator	9	9	1	19 of 27
Validated estimator	0	0	1	1 of 27
First-party measurement	0	0	0	0 of 27
Demoted to ordinal (CC-R1)	M, D/P	M, D/P	n/a	4

Nineteen of twenty-seven parameter-by-scope cells have a procedure. One has a validated number. None has a number this research programme measured. The single validated cell is a borrowed median from one cell line. **The scope with the least-validated instrument has the best-measured parameter**, and the scope with the most borrowed empirical support has the worst first-party measurement. Neither is a comfort; both are what the count says.

Everything that follows comes from taking that table seriously rather than from any philosophical objection to correspondence. The correspondence then fails in five distinct ways, and they are genuinely distinct — repairing one does not touch the others.

```
BREAK 1   A mind is not a small society.
          The independence the law's aggregation needs is unavailable inside one skull.

BREAK 2   A cell is not a small mind.
          M and D/P require a representation. A cell has no frame, so it has no D/P.

BREAK 3   Members can exit; cells cannot.
          The consent constraint that governs this corpus has no cellular analogue,
          which means the ethics do NOT descend with the arithmetic.

BREAK 4   Aggregation is not always well-defined, in principle and not merely in practice.

BREAK 5   The cellular scope has no established input path,
          and no composition theorem connects any scope to any other.
```

Break 3 is the one to carry out of this appendix. The arithmetic descends to the cell and the ethics do not — so a reader who imports the formalism downward has imported a model and left the constraint behind. That is the failure this corpus would least like to be responsible for, and it is why the standing refusals of the corpus is restated in every paper of the cellular-scope material that touches a cell.

The master correspondence must therefore be stated as one of dynamics and geometry, NOT of agency — E.2 item 14, resting on CCP-025's nine disanalogies and its three computed ones: a mean-field decay error of **92% by `t = 12`**; **77% against 21%** of surplus lost by two groups with *identical* `u = 0.5999` and *identical* `S = 1.7578`; and a **90.1x** period-normalisation trap across mismatched clocks. **Aggregate statistics hide the structure that decides the outcome**, and that sentence is most of what the audit found.

39.16.11 E.11 What the programme costs, and how likely it is to fail

CCP-027 specifies the five-stage research programme that would settle whether the personal-scope material's formulas are science, and then does the thing such chapters normally omit: **it computes its own odds of failure and publishes them.**

```
Preregistered kill conditions                        21
  of which terminal for the whole enterprise          4
Researcher and coordinator hours                8,554.8    (5.35 FTE-years)
Participants                                        570
Calendar, strictly sequential                        71 months  (5.92 years)
  with 30% overlap of stages 2-3 and 4-5             61 months

SURVIVAL CURVE, under the author's explicitly badged priors
  after stage 1     0.9000
  after stage 2     0.8100
  after stage 3     0.6885
  after stage 4     0.4475
  after stage 5     0.3580   <- P(completion) = 35.8%

P(dies at or before the cross-subject recovery stage) = 55.3%
```

The programme is more likely than not to be dead before the field trials begin. The heaviest prior — 0.35 at stage 4 — is deliberate: stage 4 is where a formalism that *describes* meets the demand that it *measure*.

A programme that computes and publishes its own probability of failure is more credible than one claiming certainty, and the converse is the more useful reading: **a programme with a high stated completion probability has almost certainly written its kill conditions too loosely.** Twenty-one are published in advance, four are terminal, and the commitment is to publish at every stage — including and especially when the stage kills the programme — with null results titled as null.

Note the coherence with the demotion, because it is not a coincidence. FVP-7, cross-subject and cross-laboratory recovery, is both the gate that decides the hard-science question and the stage most likely to end the programme. **The thing this corpus most needs to be true is the thing its own arithmetic says is most likely to kill it.**

39.16.12 E.12 A closing note on the register

This framework has two parents and does not disown either. From the theorems it takes the discipline that a claim must be either proved, or badged, or cited, or named as untested — **and, since the personal- and cellular-scope material, either demoted or rejected, in print, in the paper that made it.** From the trade it takes the willingness to build with an incomplete model, because rooms and institutions are built by people who cannot wait for the model to be finished.

The defense of building on postulates is one line long and it is the founding material's: **every geometry is built on postulates, and the builders who prosper are not those who have**

none but those who know exactly where theirs are kept. They are kept in E.2. They are labeled. Audit them.

And the register keeps a second address, which is the one this appendix was extended to hold. What a framework has thrown away is a harder thing to fake than what it asserts, so the demotions are in E.7, the rejections are in E.8, the evidential worth of testimony is computed in E.9, the instrument audit is counted in E.10, and the programme's own odds of dying are printed in E.11. **Nineteen procedures, one validated number, no first-party measurement, a keystone formula demoted by its own protocol, and a thirty-five per cent chance of finishing.** That is the true state of the instrument, and a reader who finds it discouraging has read it correctly and should still find it more useful than confidence would have been.

39.17 Appendix F Correspondence to the founding material

the founding material taught a practitioner to **read** their own comfort gradient. This framework teaches an engineer to **build** the circumstance that generates and retains it. The twelve nodes are not superseded; they are re-instrumented. What was a protocol run on oneself becomes a specification run on a system, and in two cases — the recursion and fixed-point nodes — the ceremonial teaching turns out to be a term in a proved equation.

39.17.1 F.1 The correspondence, node by node

Stillpoint. *the founding material's teaching:* The present is the comfort zone by definition *the corpus papers that develop it:* CCP-015 (The Survey), CCP-007 (Loss), CCP-008 (Headroom) *the term in the law:* `Q_0`, and the zero-input window *the reading becomes the building:* Admitting the starting state becomes **measuring `Q_0` and `h_0` before proposing anything**

Ledger. *the founding material's teaching:* Every comfort on a card with its carrying cost; every discomfort assayed for hidden yield *the corpus papers that develop it:* CCP-008 (Cost), CCP-015, CCP-014 (Institutions as Storage) *the term in the law:* `C_t`, and the five cost ledgers *the reading becomes the building:* Carrying cost becomes **the dissipation budget in Q-units**; hidden yield becomes why a costly structure persists

Gradient. *the founding material's teaching:* Water does not negotiate; read the worn path, do not argue with it *the corpus papers that develop it:* CCP-012 (Thresholds), CCP-013 (The Silo), CCP-016 (Intervention) *the term in the law:* the direction of cheapest motion *the reading becomes the building:* Reading desire lines becomes **regrading the landscape so the wanted move is the cheap one**

Horizon. *the founding material's teaching:* Three futures cut from three non-parallel glasses; the collision test *the corpus papers that develop it:* CCP-009 (Effective Count), CCP-009 (Engineering u), CCP-010 (Pseudo-Diversity) *the term in the law:* `u`, `N_eff = 1 + (N−1)u`, `S = ln N_eff` *the reading becomes the building:* Three honest windows becomes **an audited roster with a measured `u` and a `u`-maintenance regime**

The wave node. *the founding material's teaching:* Hold the future as a weighted set of branches; read amplitudes without preference *the corpus papers that develop it:* CCP-013 (Contagion), CCP-015 (Preregistration) *the term in the law:* threshold distributions; the held-out forecast *the reading becomes the building:* Reading amplitudes becomes **calibrated prediction against a frozen model and four baselines**

Lure. *the founding material's teaching:* Set the idea of greater comfort where the self will pass anyway *the corpus papers that develop it:* CCP-010 (The Room), CCP-012 (Light and Material), CCP-016 *the term in the law:* `eta`, and the encounter rate *the reading becomes the building:* Baiting the horizon becomes **placing the artifact, the seat, and the default on the path already walked**

Uncertainty. *the founding material's teaching:* The veil that measures the measurer; the step that tests the ice *the corpus papers that develop it:* CCP-015, CCP-016 (pilot design) *the term in the law:* measurement reactivity; capped downside *the reading becomes the building:* The minimal probe becomes **the reversible pilot with its cost logged beside its finding**

Collapse. *the founding material's teaching:* The word that closes the sea; burn the drafts; the flinch test *the corpus papers that develop it:* CCP-012 (The Table With No Head), CCP-016 *the term in the law:* independent elicitation before aggregation *the reading becomes the building:* Speaking once becomes **silent-write-first, then commit — collapse each judgment before any of them touch**

Echo. *the founding material's teaching:* Reading the difference; the Mirror that Flatters; the Echo that Devours *the corpus papers that develop it:* CCP-010, CCP-013 (Collective Intelligence), CCP-015 *the term in the law:* prediction error; correlated feedback *the reading becomes the building:* Reading the difference becomes **held-out residuals and the shuffled-input control; the flattering mirror becomes measured error correlation**

Recurse. *the founding material's teaching:* The spiral, not the circle; the winch post; the drift *the corpus papers that develop it:* CCP-007 (Recursion as Circuit), CCP-007 (The Leaky Integrator), CCP-007 *the term in the law:* **the transient term `(1-delta)^t Q_0`** *the reading becomes the building:* Iteration that climbs becomes **the exact solution: the transient decaying while the driven term builds**

Fixed point. *the founding material's teaching:* The room that was always furnished; arrival as recognition *the corpus papers that develop it:* CCP-007, CCP-014, CCP-008 *the term in the law:* **`Q_inf = (eta F(u*) - c*)/delta`, CCP-007 Theorem 3.5** *the reading becomes the building:* Arrival becomes **the steady state of a contraction, computable in advance from four parameters**

Seal. *the founding material's teaching:* Close the working on purpose; the door left ajar; the blank ledger *the corpus papers that develop it:* CCP-014 (shedding Q), CCP-016 (when not to intervene), CCP-008 *the term in the law:* shedding `Q` to recover `h` *the reading becomes the building:* Sealing becomes **the sunset clause, the term limit, the deliberate decommissioning — and the decision not to build**

The table above was written when this framework was one volume. It is not wrong and it is no longer complete: two further volumes turned the same instrument inward and then downward, and every node acquired a second and third address. The extension is below, on the same terms — **what was ceremony became specification, and what was specification became, in four cases, a demotion.**

Stillpoint. *personal scope:* CCP-022 (Launch Budget), CCP-022, CCP-023 F-08 *cellular scope:* CCP-037 (Personal Protocol), CCP-039 *what the extension adds, and what it costs:* The departure lounge becomes `L = max(0, M - C)` — **"there was no surplus to dream with" is `L = 0`.** And "the present is already the local minimum" becomes exact: a practitioner observed at rest is at a stationary point of their own cost field, **by definition and not by luck.** *Magnitude demoted (E.7 item 5); structure stands*

Ledger. *personal scope:* CCP-023 (Personal Formulary), CCP-024, CCP-025 *cellular scope:* CCP-029 (The Two Columns), CCP-029, CCP-037, CCP-038 *what the extension adds, and what it costs:* Every comfort on a card becomes **a register of 156 entries, each with a status that cannot be blurred** and a second column that carries precedent rather than evidence. **133 rows read "none claimed."** The hidden yield becomes the two-track ledger: `Q` against `Q^V`, with stored error `Z` and correction load `C_t = c_0 + kappa*Z_t`

Gradient. *personal scope:* CCP-022 (The Gradient and the Desire Line), CCP-023 F-07 *cellular scope:* CCP-036 (Rewrite Protocol), CCP-037 *what the extension adds, and what it costs:* The worn path becomes `grad h = -grad C`: **a habit survey IS a headroom measurement**, and the comfort zone and the headroom maximum are the same point. The cost: the identity holds only where `eta`, `N` and `delta` are constant in the direction of motion

Horizon. *personal scope:* CCP-021 (The Internal Surplus), CCP-024, CCP-025 *cellular scope:* CCP-037, CCP-038 *what the extension adds, and what it costs:* The many windows of the one tower become `F_int = ln(1 + (N-1)u)` over one observer's own framings — **a derivation, not**

an analogy. The cost: **Break 1.** The independence the aggregation needs is unavailable inside one skull, so `F_int` is an upper bound on what a mind actually holds

The wave node. *personal scope:* — (the node passes through the personal-scope material unaltered) *cellular scope:* CCP-032 (Gabor), CCP-032, CCP-033 *what the extension adds, and what it costs:* Amplitude-weighted branches acquire a conjugate-spread structure and an information-budget bound, **and no quantum content whatsoever.** `dt·df >= 1/(4π)` is classical and measurable on an oscilloscope; `dx·dp >= hbar/2` does zero arithmetic work. **The wave node's branches do not interfere: there is no cross term, and two futures that "cancel" is not a thing this corpus says**

Lure. *personal scope:* CCP-022 §41.7.1, CCP-022 (Worked Example) *cellular scope:* CCP-034 (Placebo), CCP-036 *what the extension adds, and what it costs:* Baiting the horizon becomes **lowering cost at the destination, never raising it at the origin — except locally.** Measured: raising cost globally runs escape time 32 → 35 → 42 → 89 → 297 → never; raising it only at the origin runs **32.0 → 9.9 weeks, at the price of a 37% smaller permanent fund.** The question is whether it is a cost that can be left behind or one that is carried

Uncertainty. *personal scope:* CCP-026 (FVP), CCP-026, CCP-027 *cellular scope:* CCP-032 (Heisenberg, Correctly Stated), CCP-032, CCP-035 *what the extension adds, and what it costs:* The veil that measures the measurer becomes **seven gates in print, and a programme with 21 preregistered kill conditions and a 35.8% completion probability.** The step that tests the ice becomes the seven-step grounding diagnostic, of which **step 5 — the predicted magnitude — does most of the killing**

Collapse. *personal scope:* CCP-019 (The Moment Equation), CCP-019, CCP-026 *cellular scope:* CCP-033 *what the extension adds, and what it costs:* The word that closes the sea becomes `M = (D/P)·E`, with the fixed point `D = P` as undistorted contact. **The cost is this corpus's largest: FVP gate 2 returns DEMOTE, and the magnitude is not reportable pending Rasch instrumentation at 123 items per term.** Decoherence answers the collapse question and answers it *against* licence

Echo. *personal scope:* CCP-023 (The Echo and the Return Difference), CCP-024 *cellular scope:* CCP-035 (Self-Fulfilling Engine), CCP-035 *what the extension adds, and what it costs:* Reading the difference becomes 'Delta_R =

Recurse. *personal scope:* CCP-021 (The Self as Storage), CCP-023 *cellular scope:* CCP-035, CCP-039 *what the extension adds, and what it costs:* The spiral acquires a **runaway condition**: the reflexive storage-law pole `a = (1−delta) + eta*s` with loop gain `eta*s/delta`. The winch post becomes the frozen specification — five operational choices, signed and dated before data. **Unposted rope does not climb; unfrozen models do not measure**

Fixed point. *personal scope:* CCP-023 (The Contraction and Arrival), CCP-019, CCP-024 *cellular scope:* CCP-034 (The Coupling Requirement), CCP-037, CCP-039 *what the extension adds, and what it costs:* The room that was always furnished acquires a **second** fixed point — `D = P` — and a warning attached to it: **headroom there is exactly zero by cancellation, so `r = 1` is not an unqualified target**, and a system optimising raw `Q` is driven away from it. Arrival becomes `E = G·B`: **if `G = 0`, no amount of belief moves anything**

Seal. *personal scope:* CCP-023, CCP-027 (The Research Program) *cellular scope:* CCP-033, CCP-037, CCP-038, CCP-039 *what the extension adds, and what it costs:* Closing the working on purpose becomes **the preregistered kill condition: 21 of them, 4 terminal, published before the first measurement.** The door left ajar becomes the standing rule that a claim shown wrong is **withdrawn, not defended** — and the blank ledger becomes 133 register rows that say *none claimed* and are printed that way

Four of the twelve nodes of the founding material now carry a demotion, and all four descend from the same gate. The stillpoint, collapse and echo nodes, and — through the calibration ratio — the fixed-point node, rest on the Moment Equation, whose magnitude is not reportable. **The structure the founding material taught survives all four demotions intact**, because the founding material taught orderings and directions, which is exactly what ordinal information supports. It is the sequel's attempt to attach numbers that failed the gate, and the

failure is the sequel's, not the parent's.

39.17.2 F.2 the recursion node of the founding material — stated exactly

the founding material's ninth node taught the spiral rather than the circle: repetition that absorbs its own error and returns to the same post a little higher, with a winch post held fixed so that change can be measured against it, and a weekly check for drift.

In this framework, the recursion node is the transient term of CCP-007 Theorem 3.1. The exact solution is

```
Q_t = (1−delta)^t ∗ Q_0  +  SUM_{k=0}^{t−1} (1−delta)^{t−1−k} ∗ (eta∗S_k − C_k)
```

and the first term, `(1−delta)^t ∗ Q_0`, is what the system started with, decaying at rate `delta` no matter what anyone does. **The recursion node is that term decaying while the driven term builds.**

Three consequences the practitioner felt and the engineer computes:

1. **The spiral climbs because the driven term accumulates while the transient does not.** Each pass adds `eta∗S_k − C_k` to the sum, discounted by how long ago it was. The circle repeats because its `eta` is zero and only the transient is present.
2. **Drift has a half-life.** What the system inherited is at half strength after `t_half = ln2 / (−ln(1−delta))` periods. At `delta = 0.05` that is 13.5 periods; at `delta = 0.20`, 3.1. **A new regime feels like the old one for roughly `3∗tau` periods, and impatience before then is a misreading of the arithmetic, not of the people.**
3. **The winch post is the frozen specification.** the founding material held one thing fixed between passes so change could be measured. This framework does the same thing with the five operational choices of Protocol C, fixed in writing and signed before data is collected. Unposted rope does not climb; unfrozen models do not measure.

39.17.3 F.3 the fixed-point node of the founding material — stated exactly

the founding material's tenth node taught the room that was always furnished: the state a loop converges to when every pass shrinks the remaining distance, guaranteed to exist, to be unique, and to be approached geometrically, and recognizable on arrival because in the window-work it had been visited many times before it was reached.

In this framework, the fixed-point node is CCP-007, Theorem 3.5. With constant geometry `U \ensuremath{\equiv} u∗`, constant cost `C \ensuremath{\equiv} c∗`, and `delta > 0`:

```
Q_inf = (eta ∗ F(u∗) − c∗) / delta
```

The correspondence is exact, not analogical. `delta > 0` makes the update map a contraction with factor `(1−delta)`; Banach guarantees a unique fixed point and convergence from any starting state; and the fixed point is that expression, computable in advance from four numbers.

Four consequences:

1. **Arrival is predictable.** The furnished room can be computed before it is entered. A team with `eta = 0.30`, `u∗ = 0.5`, `N = 8`, `c∗ = 0.15`, `delta = 0.05` converges to `Q_inf = 6.02` Q-units whatever its current `Q` is. If it currently holds 8.0, it is not growing toward the room; it is **settling down into it**, and that is not failure — it is the arithmetic of the regime it is running.

2. **The counterfeit arrival has a formal counterpart.** the founding material warned that a well-converged state can still be the wrong one, since convergence is a property of loops and not a certificate of worth. Theorem 3.5 supplies the sharpest version: **if `eta F(u*) < c*`, the fixed point is negative.** The loop still converges. It converges toward the destruction of the thing.
3. **The room is a function of the regime, not of effort.** Changing where a system arrives requires changing `eta`, `u*`, `c*`, or `delta`. Trying harder inside a fixed regime moves `Q` along its path to the same room, faster at best.
4. **Recognition on arrival has an explanation.** In the founding material, arrival felt remembered because the window-work had visited it. Here, the system approaches `Q_inf` geometrically, spending most of its time near it: **by the time arrival is noticed, the system has been close for several time constants.** The texture of recognition is the tail of an exponential.

39.17.4 F.4 What the sequel changes

Three things, stated plainly, so the reader of both books knows where the lineage bends.

The subject changes from the self to the circumstance. the founding material's only licensed configuration was the practitioner running the program on the one it is run on. This framework's subject is a system with other people in it, which is why the consent constraint of the standing refusals of the corpus is an engineering requirement and not only an ethic. **the founding material's vow of consent becomes this framework's fourth refusal, enforced in both books by the same mechanism: coerced change produces resistance, and resistance is a `c` term.**

The register changes from ceremony to specification. the founding material taught by story and treatise in alternation. This framework is a specification with worked practice inside it. The lineage is intact and the modelling is still permitted — but here it is permitted in the open, with its badge on, in Appendix E.2, where it can be audited item by item.

The postulates get harder. the founding material's postulates were about resemblance: a shape shared with Heisenberg's relation, a life descending a comfort landscape, a day's surface read as a leading indicator. This framework's postulates are about measurement: that stored order is a scalar, that it decays exponentially, that cost can be commensurated, that the same equation runs at every scale. **They are more useful and more falsifiable, which is the same thing said twice, and that is why this corpus carries a falsification chapter and the founding material did not need one.**

The ledger in the drawer is blank. It is not empty.

The Standard Manual for Engineering Creature Comforts is issued under the imprint of **36N9 GENETICS LLC / IllumaHeart**. Author: **Michael L. Curzi**. The formal spine is Papers A through E of the Interaction Surplus Framework (Curzi, 2026). Where this framework and the papers disagree, the papers are right and this framework should be corrected in the reader's own hand.

Part III

Frequency, Essence, and Mind

Chapter 40

The Sustaining Frequency: $f_{\min} = k\,e^{2c/\eta}$ as an Equivalence Between the Storage Fixed Point and the Essence Bridge

Abstract. We close a join that two earlier volumes left open. The essence bridge assigns a surplus an exact pitch, $f = k\,e^{2F}$ with $k = (9/8)^2/\varphi^2 = 0.483425732988414$ Hz — a *defined* constant, exact by construction, whose interpretation as a frequency is postulated and not derived — and the storage law's steady state $Q_\infty = (\eta F - c)/\delta$ is positive precisely when $\eta F(u^*)$ exceeds c^*. Inverting the bridge converts the second condition into the first, giving $f > f_{\min}$ with $f_{\min} = k\,e^{2c/\eta}$. The result is an equivalence rather than an implication — a bond accumulates structure if and only if its essence frequency exceeds its sustaining frequency — and it is verified at twelve constructed parameter sets with sign agreement in all twelve. A deficit identity follows: the octave deficit and the steady-state gauge are the same number, $D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)\,Q_\infty$, cross-checked by two routes that share no intermediate quantity to a worst residual of 8.88×10^{-16}. Two absences are substantive: $f_{\min}$ contains neither the retention loss, which sets the rate of arrival but not the threshold, nor the category count, which enters only through the ceiling $c/\eta \le \ln N$. The paper then defeats its own headline number. Because $d\ln f_{\min}/d(c/\eta) = 2$, an error of 0.1 in c/η is a 22.14 per cent error in $f_{\min}$, and an order-preserving relabelling of ordinally known parameters moves one system's $f_{\min}$ by a factor of 54.6, or 5.77 octaves. With c and η known only ordinally, $f_{\min}$ is not known as a number at all; only its ordering and the sign of the verdict survive.

Keywords: sustaining frequency; essence bridge; storage fixed point; octave deficit; ordinal parameters; sensitivity analysis

Series: C. Frequency, Essence, and Mind **Paper:** CCP-040

1 Introduction

Two results in this corpus's Series B were established independently, share a variable, and were never combined. The first is a *bridge*: a surplus F, measured in nats on a logarithmic scale of represented difference, is written as a frequency $f = k\,e^{2F}$, so that intervals of surplus become intervals of pitch [Curzi, 2026k]. The second is a *fixed point*: a first-order linear difference equation for stored order settles at $Q_\infty = (\eta F - c)/\delta$ whenever the decay rate is positive [Curzi, 2026a]. Both are stated in the same body of work. Neither refers to the other.

This paper performs the substitution and states exactly what kind of object it produces. Setting the fixed point positive, dividing through by $\delta > 0$ and $\eta > 0$, and inverting the bridge gives a threshold frequency

$$f_{\min} := k\, e^{2c/\eta},$$

together with an exact trichotomy: $f > f_{\min}$ accumulates, $f = f_{\min}$ holds, $f < f_{\min}$ decays. The chain is a chain of *equivalences* under strictly increasing transformations, so either side may be measured and the other inferred, and the result is verified below at twelve parameter sets with sign agreement in every one.

Four consequences follow, and the last two are the ones this paper most wants read. First, a deficit identity: the shortfall in octaves and the steady state itself are the same number in different units, $D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)\,Q_\infty$, cross-checked to a residual of 8.88×10^{-16}. Second, two structural absences: $f_{\min}$ contains neither δ, which sets the rate of arrival and not the threshold, nor N, which enters only through the admissibility ceiling $c/\eta \le \ln N$. Third, a sign trap — because the numerator is divided by δ, an intervention that successfully lowers the decay rate of an already-failing relation makes its destination *worse*, and the worked case computes an 80 per cent worsening from a fully successful intervention. Fourth, and against the paper's own headline: because $d \ln f_{\min}/d(c/\eta) = 2$, an order-preserving relabelling of ordinally known parameters moves one system's $f_{\min}$ by a factor of 54.6, or 5.77 octaves. **With c and η known only ordinally, $f_{\min}$ is not known as a number at all.**

What this paper does not claim, stated at the front rather than at the back. The constant $k = (9/8)^2/\varphi^2$ is a *defined* number, exact by construction and therefore legitimately quoted to fifteen figures; its two components are real and documented — the Pythagorean whole tone [Barbour, 1951] and Euclid's extreme and mean ratio [Euclid, 1956] — but **their product expressed as a frequency in hertz has no precedent in any literature we have found**, and the standard deflationary treatment of golden-section claims [Markowsky, 1992] is cited here deliberately and again wherever φ appears. The essence law $f(n) = kn^2$ is a postulate of this framework and not a finding; its exponent is **defined by the model, not estimated from data**. Octave reduction is licensed for pitch [Shepard, 1982] and its extension to a quantity that is not a pitch is a modelling choice with no external warrant. Section 12 decomposes each of these into steps a reader can check individually, and Section 13 prints every check this paper fails.

Contributions

1. The join $f_{\min} = k\, e^{2c/\eta}$, derived as an equivalence with the licensing condition attached to every step, and verified at twelve parameter sets.
2. The deficit identity $D = 2.885390\,(c/\eta - F) = -2.885390\,(\delta/\eta)Q_\infty$, computed by two routes that share no intermediate quantity, agreeing to 8.88×10^{-16}.
3. The two absences — no δ and no N in the threshold — with the practical consequence that decay-side interventions cannot move the diagnostic.
4. The sign trap, computed: a fully successful intervention moving δ from 0.09 to 0.05 takes Q_∞ from -5.0119 to -9.0215 while the deficit stays at $+4.338420$ octaves.
5. The ordinal defeat of the paper's own headline number, by an order-preserving relabelling that moves $f_{\min}$ by 5.77 octaves.
6. An audit-precedence rule, stated as a house postulate rather than an epistemology, together with three specific corrections that the framework's own audit produced and that a keystone published earlier would have inherited.

2 Hypotheses, definitions, and postulates

The rigour standard governing this corpus requires that a claim which *could* be wrong be stated so that it could be, and that a claim which could not be wrong be labelled with which

of the three non-empirical kinds it is. **A hypothesis nothing could falsify is not a hypothesis**, and this section does not manufacture one.

2.1 Hypotheses proper

H1 — the equivalence hypothesis. A relation whose essence frequency exceeds its sustaining frequency accumulates stored order over successive periods, and one whose essence frequency falls below it loses stored order. **Predicted:** the sign of the observed change in the stock over a run of periods agrees with $\text{sign}(f - f_{\text{min}})$ computed at the start of the run from parameters measured on one declared period. **Falsified by:** a system with $f < f_{\text{min}}$, all four parameters measured on one declared period, whose stock rises over a run long enough for the fixed point to dominate the transient. **Status:** DERIVED from the storage law [Curzi, 2026a] and the essence bridge [Curzi, 2026k]; verified as arithmetic at twelve parameter sets. **Not tested against observation.** No observational data were collected for this paper.

H2 — the decay-blindness hypothesis. An intervention acting only on the decay rate δ leaves the octave deficit unchanged and multiplies the existing sign of the fixed point. **Predicted:** in a system with $\eta F < c$, an intervention that measurably lowers δ and leaves η, c, u and N unchanged is followed by a *more* negative steady state. **Falsified by:** a δ-only intervention that reverses the sign of the stock's drift. **Status:** DERIVED by inspection of D; demonstrated on a constructed case in Section 9. **Not tested against observation.**

H3 — the ceiling hypothesis. No relation whose measured cost ratio exceeds the logarithm of its declared category count, $c/\eta > \ln N$, sustains itself under any assignment of non-parallelism over those categories. **Predicted:** among systems measured with a declared and fixed N, none with $c/\eta > \ln N$ is observed to accumulate. **Falsified by:** one counterexample. The hypothesis is a strict universal and is cheap to kill. **Status:** DERIVED from the normalisation bound $F \leq \ln N$ [Curzi, 2026]; **not tested here.** It is the only claim in this paper with genuine empirical exposure.

H4 — the scale hypothesis. Estimates of c and η obtained from unanchored rating instruments carry ordinal information only, so any exponential function of their ratio is not identified as a number. **Predicted:** two admissible order-preserving relabellings of the same estimates yield f_{min} values differing by more than the instrument's claimed precision. **Falsified by:** an instrument for c and η that passes a conjoint-measurement test [Luce and Tukey, 1964] or supplies specific objectivity [Rasch, 1960], after which the relabellings are no longer admissible. **Status:** the *consequence* is COMPUTED in Section 8 and is arithmetic. The *antecedent* — that the framework's instruments are in fact ordinal — is an empirical claim about instruments and is **not tested here.**

H5 — the identifiability claim. From a fitted stock trajectory alone, η and F are not separately recoverable; only the combination $\eta F - c$ is. **Status:** this is a **formal claim, not a hypothesis**, and it is labelled as one. It is demonstrated in Section 9.5 by exhibiting two parameter sets with identical ledgers and different prescriptions. Nothing could falsify it that would not also refute the arithmetic.

2.2 Definitions — true by stipulation, not falsifiable

- **Def. 1.** $u(x, y) := 1-(\hat{x}\cdot\hat{y})^2$ on unit intensity vectors over N categories; $F := \ln(1+(N-1)u)$; $N_{\text{eff}} := 1 + (N-1)u = e^F$.
- **Def. 2.** $f_{\text{min}} := k\, e^{2c/\eta}$, the *minimum sustainable frequency*.

- **Def. 3.** $D := 2.885390\,(c/\eta) - \log_2(f/k)$, the *octave deficit*.
- **Def. 4.** $k := (9/8)^2/\varphi^2$. **This is a defined constant.** It is an exact ratio of exact quantities and is therefore computable to arbitrary precision; the fifteen significant figures quoted throughout, 0.483425732988414, are *exact digits of a definition* and carry no measurement uncertainty because there is no measurement. Every appearance of the constant at that precision in this paper is so labelled.
- **Def. 5.** A relation is *sustainable* when $Q_\infty > 0$. This is a choice among available definitions, discussed at Step 0 of Section 6.

2.3 Postulates — asserted by this framework, with no external support

- **P-a. The essence law $f(n) = kn^2$.** A quadratic relation between a dimensionless count and a frequency. **No external literature supports it.** It is not derived here and nothing in the bibliography derives it. **The exponent 2 is defined by the model, not estimated from data.** No scaling exponent in this paper was obtained by fitting; none was tested against a log-normal or exponential alternative; and the goodness-of-fit and likelihood-ratio procedure that a claimed scaling relation requires [Clauset et al., 2009] was **not run, because there is no data to run it on.**
- **P-b. The attachment of hertz to k.** Computing $(9/8)^2/\varphi^2 = 0.483425732988414$ is arithmetic. **Asserting that this dimensionless number *is a frequency* is a separate and much stronger claim**, and the source supplies no operational procedure by which the constant acquires the dimension of inverse time. This is postulated, and Section 3.4 states it again in the dimensional audit, where it is unavoidable.
- **P-c. The affine effective count $N_{\text{eff}} = 1 + (N-1)u$.** A design axiom [Curzi, 2026], not a derived result and **not a Hill number of any order**. The Hill family [Hill, 1973, Jost, 2006] and its independent rediscovery in political science [Laakso and Taagepera, 1979] ground $1/\text{HHI}$ and $\exp(H)$ exactly — as the corpus's concentration work uses them [Curzi, 2026] — and ground this construction not at all. A reviewer reaching for the Hill-number literature as support will find it does not apply.
- **P-d. The identification $n_{\text{eff}} := N_{\text{eff}}$.** The essence law takes a count; the bridge feeds it an effective count that is not an integer. That substitution is a modelling decision of this framework and is badged as one wherever the bridge is used.
- **P-e. The audit-precedence rule.** A result may not be published above the level of audit available to check its inputs. **This is a house postulate adopted by this corpus, not a general epistemology, and it is not offered as one.** It is stated because it explains the ordering of the argument, and Section 8 gives the arithmetic that motivates it.

2.4 Modelling choices — legitimate, but choices

- **M-a. Octave reduction applied to a non-acoustic quantity.** Octave equivalence is a perceptual structure formalised for **pitch** [Shepard, 1982], and the octave's perceptual specialness has a measured and finite size [Demany et al., 2013]. Nothing licenses carrying it to a quantity that is not a pitch. The *operation* is well defined — division by a power of two — and its *interpretation* is a choice of this framework.
- **M-b. $N = 12$.** Twelve component classes are used throughout. Twelve exceeds the classical span of immediate absolute judgment [Miller, 1956], which is a reason for caution and not a reason for twelve. The ladder itself is owned by the companion paper [Curzi, 2026], whose Result Six is the count-based essence index.
- **M-c. Interval apparatus.** Cents, octave equivalence and interval arithmetic are the correct apparatus once an index exists [Rossing et al., 2002], but what a listener finds consonant depends on the spectrum of the sound and not on the ratio alone [Sethares, 2005], and interval categories generalise less far across listeners than is usually assumed [Burns, 1999, Hoeschele et al., 2012]. **This paper uses the arithmetic and claims none of the perception.**

- **M-d. The sustainability definition.** $Q_\infty > 0$ is chosen over the alternative state-dependent condition $Q_{t+1} \geq Q_t$ because it is parameter-determined rather than state-determined. Both are defensible; the choice is declared at Step 0 of Section 6.

2.5 What is expository

Sections 4.1 to 4.17 restate results owned elsewhere in the corpus so that this paper stands alone; they argue no new claim. Sections 6.7 to 6.10 and 9.3 are procedural: they set out reporting requirements and failure modes. Their organising question is *what must be published alongside a reading for the reading to be checkable by a third party*.

3 Framework, dimensional audit, and method

3.1 The storage law — a shared mathematical form, not a derivation

$$Q_{t+1} = (1-\delta)Q_t + \eta S_t - C_t, \qquad S_t = F(U_t) = \ln(1 + (N-1)U_t)$$

Analogy status: category 2, a shared mathematical form. The equation governing this framework's stored order is the same equation that governs a leaky integrator, and it is used because the mathematics is the same, not because the physics transfers. The same form appears as the discrete RC low-pass filter in signal processing [Oppenheim et al., 1996, Horowitz and Hill, 2015], as exponential smoothing in forecasting [Holt, 1957, Brown and Meyer, 1961], and as the leaky integrate-and-fire neuron in computational neuroscience [Lapicque, 1907, Gerstner and Kistler, 2002]. Its stability condition and unique fixed point are standard [Elaydi, 2005], and the convergence is Banach's [Banach, 1922]. **No claim is made that comfort is a charge, that η is a coupling constant, or that any physical result about RC circuits applies to a relation between people.** The corresponding transfer-function reading, in which $1/\delta$ is the DC gain of $1/(z-a)$ evaluated at $z=1$, is fixed in Series B [Curzi, 2026a], whose Result One states the law with its Lipschitz modulus $1-\delta$ and its steady state $Q^* = (\eta S - C)/\delta$.
